atmosphere packages. Serial loin chops were taken posterior to the 10th rib and displayed for 1, 8, and 15 d post-fabrication. A sample of longissimus muscle anterior to the 10th rib was collected from each pig; samples were pooled by pen forming 36 homogenous samples. Samples were ground, packaged, and displayed for 0, 6, and 12 d post-fabrication. NSVE had no effect on carcass characteristics or meat quality when compared to synthetic E. Increasing dietary NSVE decreased TBARS ($P < 0.01$) for loin chops and for ground pork. High levels of vitamin E did not appear to prevent discoloration of loin chops. Lower levels of NSVE might be used in pig diets with the same benefit of higher doses of synthetic vitamin E.

295 Comparison of dose and durations of ractopamine on late finishing pig carcass characteristics and meat quality. L. W. Kutzler*¹, S. F. Holmer¹, D. D. Boler¹, S. N. Carr², M. J. Ritter², C. W. Parks², F. K. McKeith¹, and J. Killefer¹, ¹*University of Illinois, Urbana*, ²*Elanco Animal Health, Greenfield, IN*.

The study objective was to compare various doses and durations of ractopamine hydrochloride (RAC; Paylean®, ELANCO Animal Health, Greenfield, IN) on pig carcass weight, cutability, and meat quality. Late finishing pigs with an average starting weight of 93 kg were allotted to 12 treatments, 35 d prior to market. Treatments consisted of two control diets: negative control diet (NEG; 13.1 % CP, 0.64 TID Lys), positive control diet (POS; 17.8 % CP, 0.94 TID Lys); two RAC diets 5 ppm (4.5 g/ton) or 7.4 ppm (6.75 g/ton) with pigs on RAC for 7, 14, 21, 28, or 35 d prior to market. Durations intended for RAC were fed at NEG until incorporation of RAC when CP was increased to 17.77 % to comply with label requirements. At harvest, five pigs closest to pen average (240 pigs total) were selected for carcass, cutability and meat quality measurements. Eleven orthogonal contrasts were used to compare treatments with significance at $P \leq 0.05$. Overall, carcass trait contrasts between 5 ppm and 7.4 ppm were not significant. Carcass weight for RAC was 5.56 kg greater than NEG, $P = 0.0002$. Increasing linear duration effects on carcass weight were significant for 5 ppm and 7.4 ppm, $P = 0.0002$ and $P = 0.003$ respectively. Percent lean for RAC was 1.00 greater than NEG, $P = 0.004$. An increasing linear duration effect on percent lean was significant for 5 ppm, $P = 0.02$. Carcass cut yield for RAC was 1.24 % greater than NEG, $P = 0.001$. An increasing linear duration effect on carcass cut yield was significant for 5 ppm, $P = 0.03$. Subjective marbling score for RAC was 0.49 less than NEG, $P = 0.001$. Linear duration effects on marbling score were not significant for 5 ppm or 7.4 ppm. Subjective color values were not significantly different, nor were shear force aging curves significantly different from NEG. Overall, RAC at both levels of 5 ppm and 7.4 ppm had greater responses in carcass weight and cutability than NEG, and had minimal affect on meat quality.

Key Words: Ractopamine, Cutability, Meat Quality

296 Comparison of growth performance, carcass characteristics, and meat quality of barrows, immunocastrated pigs and entire males. C. Pauly² and G. Bee*¹, ¹*Agroscope Liebefeld-Posieux Research Station ALP, Posieux, Switzerland*, ²*Swiss College of Agriculture, Zollikofen, Switzerland*.

In Switzerland, castration of piglets without anesthesia will be banned in 2009. Two alternatives, which allow avoiding surgical castration

under anesthesia are immunocastration or entire male production. Thus, the study's objective was to compare the growth performance, carcass characteristics, and meat quality as well as to evaluate by a trained sensory panel the incidence of boar taint in the LM of barrows (B), immunocastrated pigs (IP), and entire males (EM). At weaning 36 Swiss Large White pigs were blocked by BW into 12 blocks and assigned to B, IP, and EM. All pigs were group-penned from weaning to 107 kg BW and had ad libitum access to standard diets. The 2 IMPROVAC® injections were applied to the IP at an average BW of 22.2 and 74.3 kg, respectively. Because ADG did not differ among the experimental groups (IP: 0.92; EM: 0.88; B: 0.93 kg/d; $P > 0.05$) but EM and IP consumed less feed than B (IP: 191; EM: 185; B: 202 kg; $P < 0.05$), IP and EM were more efficient than B (G:F: IP: 0.42; EM: 0.43; B: 0.39 g/g; $P < 0.01$). However, carcass leanness was greatest ($P < 0.05$) in EM (57.5%) followed by IP (56.3%) and B (54.5%). As expected the level (expressed per g lipid of the backfat) of androstenone was higher ($P < 0.01$) in EM (1.2 µg) than IP and B (0.2 µg) whereas skatole level was higher ($P < 0.05$) in both the EM (0.31 µg) and IP (0.08 µg) than the B (0.05 µg). On a scale from 1 (weak) to 9 (strong), sensory scores for boar odor and flavor were lower ($P < 0.01$) in the LM of B and IP than EM, whereas juiciness and tenderness scores did not ($P > 0.05$) differ. Initial and ultimate pH, color, percentage drip, thaw and cooking loss did not differ among the experimental groups ($P > 0.05$), whereas shear force values were higher ($P < 0.01$) in the LM of B and EM compared to IP (3.7, 3.8, and 3.5 kg, respectively). Although carcasses of EM were leaner, the similar feed efficiency and especially the lower sensory scores for boar odor and flavor in the LM of IP, confirm that immunocastration might be the best alternative to avoid castration under anesthesia.

Key Words: Boar Production, Immunocastration, Sensory Quality

297 Effect of gender and slaughter weight on meat quality and weight loss of hams during ripening in Iberian pigs reared under intensive production systems. M. P. Serrano¹, D. G. Valencia¹, R. Lázaro¹, D. Menoyo¹, A. Fuentetaja², and G. G. Mateos^{*1}, ¹Universidad Politécnica de Madrid, Spain, ²Copese, Segovia, Spain.

Iberian (IB) pigs, a native breed of Spain, have been traditionally reared under free range conditions, fed on grass and acorns, and slaughtered at heavy weights (160 to 180 kg body weight, BW). Currently, to meet the increasing demand for IB products, 80% of IB pigs are reared indoors, fed on concentrates, and slaughtered at 140–150 kg BW. Originally, males (CM) and females (CF) were castrated, but intact females (IF) might also be used. An increase in slaughter weight (SW) increases intramuscular fat which benefits the production of high quality cured products. However, excessive BW results in overly fat pigs which penalizes the acceptability of the end products. A total of 96 IB dam × Duroc sire pigs were used to study the influence of gender (coded CM, CF, IF) and SW (145 and 156 kg BW) on meat quality, fatty acid (FA) profile of backfat (BF), and ham weight losses during ripening. There were four pens of four pigs each per treatment. Meat samples were taken from the Longissimus dorsi at the level of the last rib and BF samples were taken at the tail insertion. Ripening of hams lasted for 719 d (19 d for salting, 63 d for postsalting, 28 d for drying, and 609 d for cellar phase). Meat quality (except chroma value), FA profile of BF, and ham weight losses during ripening were not affected by gender or by SW. Chroma (c*) was higher in meat from CF than in meat from CM with meat from IF being intermediate (15.5 vs. 14.9 vs. 13.6; $P \leq 0.05$). We conclude that based on meat quality and weight losses during the drying process, intact females are a good alternative to castrated females to produce high quality Iberian cured products. Also, Iberian pigs can be slaughtered at either 145 or 156 kg body weight without any loss in meat quality or in ham weight losses during ripening.

Key Words: Iberian Pigs, Gender, Slaughter Weight

Nonruminant Nutrition: Past and Future of Nonruminant Nutrition

298 ASAS Centennial Presentation: Landmark studies in swine nutrition during the past century. G. L. Cromwell*, *University of Kentucky, Lexington.*

During this centennial year of the American Society of Animal Science (ASAS), it is of interest to look back over the history of our Society and, in particular, to the many contributions made by researchers in the area of swine nutrition. A great number of basic and applied research studies involving the nutrition of weanling, growing, and finishing pigs, and gestating and lactating sows have been conducted by swine nutritionists during the past 100 years. Most of these studies were conducted at universities by scientists or graduate students under their leadership. Others were conducted by nutritionists in the feed and pharmaceutical industries as well as government scientists at ARS/USDA sites. Important contributions also were made by animal scientists beyond our borders. Many of the important findings have been reported in the *Journal of Animal Science* during its 66 years of existence. Before the first issue of the *Journal* was published in 1942, some of the earlier studies were reported in the Proceedings of the Annual Meeting of the Society of Animal Production, the forerunner of ASAS. These research studies have progressively led to a better understanding of the utilization of energy, protein, amino acids, carbohydrates, fats, minerals, and vitamins by pigs and have helped to quantify the nutrient requirements of pigs for various stages of growth, for sows during gestation and lactation, and to a limited extent, for boars. Determining the nutritional value of a wide array of feedstuffs, evaluating feeding strategies, and assessing the value of growth promoting and carcass enhancing agents have been important research contributions as well. To identify the particular studies that were among the most instrumental in contributing to our present knowledge of swine nutrition is, to say the least, a daunting assignment. To aid in this task, a survey of swine nutritionists was conducted in which they were asked to identify and rank the 10 most significant findings in swine nutrition during the past 100 years. The results of that survey will be presented.

299 ASAS Centennial Presentation: Nonruminant nutrition - A proud past but uncertain future. R. A. Easter*, *University of Illinois, Urbana.*

Nonruminant nutrition is a sterling example of multidisciplinary scholarship requiring practitioners to integrate knowledge from fields as diverse as animal biology, ingredient composition, housing environments, experimental design and analysis, animal feeding behavior, meat quality and production system management. For the past 100 years academic and industry research programs have steadily advanced the science leading to improved animal well-being, increased production efficiency and more nutritious products for human consumption. University programs have provided a reliable supply of graduates well-prepared for careers in industry, government and academia. Global consumer demand for food products derived from nonruminant species is projected to expand at roughly three percent per annum for the foreseeable future. At same time, the market for companion animal feeds is reliably linked to growth in economies in many developing countries. Yet the future of nonruminant nutrition cannot be assumed. Across the developed world public support for educational programs in applied agriculture, especially in animal agriculture, is declining and student interest continues to diminish. Increasingly, the direction of academic research is a function of state and national funding priorities. Applied nonruminant nutrition research, which has been the mainstay of graduate student preparation, is rarely identified as a priority. The situation is not hopeless. The need for high-quality research and education in nonruminant nutrition is very real. The challenge is for industry and academic leaders to jointly develop an implementable strategy for the future.

Symposium: Physiology and Endocrinology: Emerging Concepts on Dietary Components that Influence the Physiology and Endocrinology of Domestic Farm Animals

300 Reproductive consequences of nutritionally-induced changes in the pH of the bovine reproductive tract. G. A. Perry*, *South Dakota State University, Brookings.*

During some production situations cattle are fed excess protein. However, increased protein intake during early pregnancy has been associated with decreased fertility and increased embryonic mortality. Increased protein intake elevated blood urea nitrogen and decreased uterine pH, during the luteal phase, but did not influence pH of other bodily fluids. Ionic composition of both oviduct and uterine fluids is derived from ions from the blood and ions secreted from oviduct and uterine epithelium. The oviductal and uterine microenvironment plays a central role in pregnancy success. At the initiation of estrus uterine pH declines to that of semen (≈ 6.8); pH at this time likely plays a role in sperm survival. Uterine pH can influence sperm motility and longevity and has been associated with pregnancy success following fixed-time AI. This decrease in pH at the initiation of estrus appears to be estradiol dependent since elevated concentrations of estradiol prior to ovulation, even when estrus was not induced, decreased uterine pH. Intake of excess protein (UIP or DIP) did not influence uterine pH at estrus; however, it decreased uterine pH during the luteal phase. Following the pH nadir during estrus, pH increased prior to ovulation and remained neutral (≈ 7.0) during the luteal phase. During early embryonic development, the embryo is dependent on nutrients provided by oviduct and uterine fluids for growth and survival. Alterations in pH during these early stages of embryonic development when the embryo's ability to regulate pH is limited can likely influence distribution of mitochondria as well as membrane permeability and severely inhibit embryo development. When embryos that were not able to regulate pH (blocking of NA^+/H^+ antiporter or $\text{HCO}_3^-/\text{Cl}^-$ exchanger) were exposed to acidic or alkaline conditions, embryonic development to the blastocyst stage was significantly reduced. In summary, excess dietary protein can influence uterine pH during early embryo development, and changes in pH during early pregnancy, a time when the embryo can not adjust pH, can greatly reduce pregnancy success.

Key Words: Uterine pH, Pregnancy Success

301 Performance, metabolism and immunity in domestic animals fed diets contaminated with *Fusarium* mycotoxins. T. K. Smith*, *University of Guelph, Guelph, ON, Canada.*

A series of experiments was conducted with gestating and lactating sows, mature horses and lactating dairy cows to determine the effect of feed-borne *Fusarium* mycotoxins on performance, metabolism and immunity. Blends of naturally-contaminated corn and wheat were found to contain deoxynivalenol (DON, vomitoxin) as the major contaminant. In all experiments, animals were fed: (1) control diet (2) diet containing contaminated grains or (3) contaminated grains + 0.2% polymeric glucomannan mycotoxin adsorbent (GMA, Mycosorb, Alltech Inc., Nicholasville, KY). Sows were fed experimental diets for 21 days before farrowing and for 21 days post-farrowing. Horses were fed the experimental diets for 21 days. Dairy cows were fed test rations for 56 days. The feeding of diets containing contaminated grains significantly reduced sow weight gain during gestation and this was partially prevented by the feeding of GMA. The feeding of contaminated grains significantly

increased the incidence of stillborn piglets, however, this was prevented by the feeding of GMA. The feeding of diets containing contaminated grains in the lactation period resulted in significantly reduced feed intake and greater weight loss compared to controls. Horses fed contaminated diets significantly reduced feed intake and had elevated blood activity of gamma-glutamyltransferase compared to controls. The feeding of GMA prevented these effects. There was no effect of diet on milk production, feed intake, milk somatic cell counts or milk composition when fed to dairy cows. The feeding of contaminated feedstuffs, however, significantly reduced serum concentrations of IgA and also resulted in a significant elevation of serum urea concentrations. The feeding of GMA prevented these effects. It was concluded that mature pigs, horses and dairy cows are all adversely affected by feed-borne *Fusarium* mycotoxins and that contaminated feeds should be fed only with caution and with an appropriate mycotoxin adsorbent.

302 Effectiveness of supplemental antioxidants for enhancing reproductive function in cattle. P. J. Hansen*, *University of Florida, Gainesville.*

Production of reactive oxygen species (ROS) is an inherent feature of oxygen metabolism. About 1-2% of the oxygen consumed by cells is incompletely reduced to water. The ROS formed as a result can damage plasma membranes, proteins, and DNA. An increase in oxygen consumption, for example during lactation, hyperthermia or following exercise, results in increased ROS production. The major source of ROS is the mitochondrion but specific enzymes such as myeloperoxidase and cyclooxygenase also cause generation of ROS. Reproductive responses to supplementation are likely to depend upon the magnitude of ROS generation, the efficacy of the supplement for altering redox status and the availability of antioxidants in the control diet. One period in which supplemental antioxidants can affect reproduction is the periparturient period. At this time, dry matter intake is reduced, antioxidants are secreted into the colostrum, and ROS generation from leukocytes is high because of the need for placental expulsion, clearance of lochia from the postpartum uterus, and immunological adjustments to lactation. Administration of vitamin E and selenium alone or in combination can reduce incidence of retained placenta and uterine infectious disease. Similar effects have been reported for administration of β -carotene. Fertility responses to vitamin E and selenium have been mixed; there is some evidence for greater responses for second service than for first service. Another condition that may increase ROS generation is heat stress. One study found increased ROS metabolites in erythrocytes in cows during summer as compared to winter. Feeding supplemental β -carotene increased the proportion of cows pregnant by 120 d postpartum in the summer but not the winter. However, administration of other antioxidants in the summer, including vitamin E or vitamin E and selenium, did not affect fertility. Future research into effectiveness of antioxidant supplementation in cattle is likely to involve nutraceutical molecules that may be more effective in affecting tissue redox status than antioxidant supplements that are commonly used today.

303 Phytase: Not just for environmental protection-novel roles in system physiology. X. G. Lei*¹ and J. M. Porres², ¹*Cornell University, Ithaca, NY*, ²*University of Granada, Granada, Spain*.

Phytase is a phosphohydrolytic enzyme that initiates the stepwise removal of phosphate from *myo*-inositol hexakisphosphate or phytate. The heightened environmental awareness of phosphorus pollution originating from animal manure during the past two decades has led to an exciting era of phytase research and a widespread application of the enzyme in animal feeding. It is well-documented that supplemental phytase improves bioavailability of phytate-phosphorus to swine and poultry by 20-45%. This improvement results in up to 50% reduction in manure phosphorus excretion by animals and prevents nearly 22,000 tons of manure phosphorus from entering the environment annually in the USA from marketing pigs alone. However, potentials of phytase are far beyond just environmental protection. This presentation will review

past research on the unique roles of phytase in system physiology, and explore novel application of the enzyme in improving animal and human health. Alleviation of iron-deficient anemia by phytase depicts its roles in the circulatory system. Releasing the phytate-chelated zinc enables phytase to modulate growth and immune function. While hydrolysis of phytate into various forms of inositol phosphates may produce bioactive signal transducers, it could also alter the susceptibility of digestive system to oxidative stress. Impacts of phytase on the skeleton system have been focused on its benefits to bone strength and mineral content in animals fed low-phosphorus diets. In fact, dietary phytase affects bone metabolism-related hormones, and still can improve bone property and function even in animals fed a high-phosphorus diet. These intriguing actions of phytase underscore its broad and complex roles in physiology.

Key Words: Anemia, Immune, Phytase

Production, Management and the Environment: Nutrient Management and the Environment

304 Development of methane conversion factors for US cattle using mechanistic models. E. Kebreab*¹, K. A. Johnson², S. L. Archibeque³, D. Pape⁴, and T. Wirth⁵, ¹University of Manitoba, Winnipeg, Manitoba, Canada, ²Washington State University, Pullman, ³Colorado State University, Ft. Collins, ⁴ICF International, Washington, DC, ⁵Environmental Protection Agency, Washington, DC.

Methane is one of the greenhouse gases emitted from livestock and up to 23 times more potent than carbon dioxide in its ability to trap heat in the atmosphere. In most countries, national estimates of enteric methane emissions are based on models developed by the Intergovernmental Panel for Climate Change (IPCC). For countries for which livestock emissions are important, the IPCC recommends a more complex approach which incorporates country-specific information and use of sophisticated models that consider diet composition in detail. Therefore, the objectives of this study were to (1) evaluate models for their prediction ability using measurements made on individual cattle and (2) develop methane conversion factors (Y_m) for US cattle. The mechanistic models chosen were MOLLY, a whole-animal model developed at the University of California, Davis and COWPOLL, a largely rumen model for lactating dairy cows developed in Europe. Diet details from experiments conducted in the US were used as inputs to the models. Mean square prediction error (MSPE) was used to evaluate the models statistically. In dairy cattle, COWPOLL had the lowest root MSPE (12.5% of mean) but in feedlot, MOLLY had the lowest root MSPE (11.2% of mean). Both models had little mean bias or deviation from line of unity and over 90% of errors were random. The models were then used to estimate Y_m from cattle fed different diets in various states across the US. The average Y_m in dairy cows was 5.63% of gross energy (range 3.78 to 7.43%) compared to 6.5% ± 1% recommended by IPCC. In feedlot cattle, the average Y_m was 3.88% (range 3.36 to 4.56%) compared to 3% ± 1% recommended by IPCC. The models were able to pick up differences in diet composition such as fat supplementation or amount and source of starch inclusion. Due to significant effect of diet on Y_m, it is recommended that national inventories with large animal populations use diet specific Y_m values estimated by mechanistic models to calculate methane emissions from cattle.

Key Words: Methane, Ruminant, Modeling

305 Characteristics and use of separated manure solids following anaerobic digestion for dairy freestall bedding in three Iowa dairy herds. L. L. Timms*, Iowa State University, Ames.

Study objectives were to evaluate the characteristics of separated manure solids and impact on herd performance in 3 dairy herds. All herds had mattresses in freestalls and used separated manure solid following anaerobic digestion from herd 1. Samples were collected on a biweekly basis for 1 year and included 1) raw manure 2) manure effluent post anaerobic digestion but prior to separation; 3) fresh separated manure solids; 4) piled separated solids; and 5) separated solids bedding samples from freestalls. Samples were analyzed for dry matter content and environmental mastitis pathogens. Bulk tank milk samples were taken for bacterial analysis and both creamery and DHI data was available. Dry matter content of fresh separated solids was 28-41% (avg. 34%) with piled solids running ~2-5% higher DM. DM% of solids in stalls averaged 65-75% during summer-fall, and 50-60% during winter. Total gram negatives and alpha streps., and coliforms post digestion and in

stalls were 100,000 and 100, and 1-10 million/g and 1 million, 100,000, and 1000 for herds 1-3, respectfully. Herd 1 averages 250-350,000 and has declined slightly since solids use. Herd 2 averages 200-300,000 and has maintained that average. Herd 3 averages 100-200,000 SCC, and had maintained that average. All herds had no Strep. ag. and some evidence of Staph. aureus (contagious). Herds 1 and 2 had very high levels of environmental streps., coagulase negative staphs., and some high Coli counts (> 200) indicating issues with milking preparation and teat cleanliness prior to unit attachment. This combined with some Staph. aureus may be the reason for higher SCC in these dairies. Herd 3 showed very good bulk tank results for environmental and skin bacteria indicating excellent premilking sanitation and a major reason for lower SCC. This data shows that composted manure solids can provide a comfortable, effective, economical bedding source if a consistent product is generated and managed properly, and stall, alley, and milking management areas are optimized.

Key Words: Separated Manure Solids, Anaerobic Digestion, Animal Performance

306 Aerobic composting or anaerobic stockpiling of beef feedlot manure. M. K. Luebbe*, G. E. Erickson, T. J. Klopfenstein, and J. R. Benton, University of Nebraska, Lincoln.

Two manure management and storage methods, manure stockpiled anaerobically or composted aerobically for 111 d, were evaluated for nutrient recovery. In July, manure from 11 open pens was scraped, sampled, and weighed before constructing three anaerobic stockpiles and four aerobic windrows. Windrows were turned on d 14, 35, 61, and 90 while stockpiles were not disturbed. Manure core samples and temperature were collected on d 0, 36, 62, and 111. Nutrient recoveries were calculated using total ash as an internal marker. Ammonium N was measured on samples as-is and after drying for 24 h in a 100°C oven. Dry matter and OM recovery was not different (P>0.70) on d 111. Total N concentration was greater (P<0.01) on d 111 for stockpiled manure than compost (6.0 and 5.0 g/kg DM, respectively). Total N recovery was greater (P<0.01) for stockpiled manure than compost on d 111 (75.8 and 65.6%, respectively). Organic N (% of total N) was greater (P<0.01) for compost than stockpiled manure on d 36, 62, and 111. Ammonium N (% of total N) for fresh samples was greater (P<0.01) for stockpiled manure than compost on d 36, 62, and 111. Nitrate N was greater (P<0.01) for compost than stockpiled manure on d 62 and 111. Total N recoveries calculated using oven dried samples tended to be greater (P=0.10) for stockpiled manure than compost on d 111 (70.5 and 65.0%, respectively). Recovery of P₂O₅ was not different (P=0.81) for composted and stockpiled manure at d 111 (97.0 and 95.8%, respectively). Concentration of P₂O₅ was similar (P=0.40) for stockpiled manure and compost on d 111 (9.0 and 8.7 g/kg DM, respectively). The N:P ratio was greater (P=0.01) for stockpiled manure than compost on d 111 (1.54 and 1.32, respectively). When manure samples were dried down completely to simulate hot, dry conditions during field application, the amount of ammonia N lost from stockpiled manure was not great enough to offset the total N recovery advantage of this method. When evaluated on a nutrient basis, stockpiled manure has greater value as a fertilizer compared with composted manure.

Key Words: Nitrogen, Cattle, Compost

307 Effect of dietary protein level and degradability and energy density on ammonia losses from manure in dairy cows. M. Agle¹, A. N. Hristov*¹, S. Zaman¹, C. Schneider¹, P. Ndegwa², and V. K. Vaddella², ¹University of Idaho, Moscow, ²Washington State University, Pullman.

Two trials with lactating dairy cows were conducted to investigate the effect of dietary CP level and degradability (Trial 1) and dietary energy density (Trial 2) on ammonia losses from manure. Experiments were replicated Latin square design with 2-wk adaptation periods. Three diets were tested in Trial 1 and 2 diets in Trial 2. Concentrations of CP, RDP, and RUP (NRC, 2001) in Trial 1 diets were (% DM basis): 17.6, 12.2, and 5.4 (HighCP); 15.2, 9.8, and 5.4 (LowCP); and 14.4, 8.3, and 6.1 (ExtraLowCP). RDP supply exceeded requirements in HighCP, was adequate in LowCP, and was deficient in ExtraLowCP. In all diets, metabolizable protein intake met the requirements of the cows. Dietary NE_L concentration was similar between diets (1.54 to 1.57 Mcal/kg DM). Diets in Trial 2 had similar CP (and RDP/RUP) concentration (17.8-17.9% DM), but differed in NE_L density: 1.65 (LowEnergy; 50% forage) vs. 1.83 (HighEnergy; 30% forage) Mcal/kg DM. In both trials, diets were offered at ad libitum intake. Average DMI and milk yield in Trial 1 were 24.2 and 30.8 kg/d (respectively) and were not affected ($P = 0.153$ and 0.453) by diet. In Trial 2, average DMI and milk yield were 26.0 and 33.4 kg/d and did not differ between diets ($P = 0.502$ and 0.191). At the end of each experimental period, fresh urine and feces were collected from the cows and stored frozen at -80°C. After thawing, reconstituted manure (1 part by weight urine and 1.7 parts feces) was analyzed for ammonia emitting potential *in vitro*. In Trial 1, two weeks cumulative ammonia losses were reduced ($P = 0.001$) with LowCP and ExtraLowCP compared with HighCP (1.7, 1.4, and 2.3 g N, respectively). Diet had no effect ($P = 0.207$) on ammonia losses in Trial 2 (2.0 and 2.3 g N; LowEnergy and HighEnergy, respectively). This study demonstrated that manipulation of dietary CP/RDP, but not energy, can significantly reduce ammonia losses from dairy manure.

Key Words: Dietary Protein, Ammonia Losses from Manure, Dairy Cow

308 Simulating effects of grass management on methane emission in lactating cows. A. Bannink*¹, M. C. J. Smits¹, J. A. N. Mills², E. Kebreab³, J. L. Ellis⁴, J. France⁴, and J. Dijkstra⁵, ¹Animal Sciences Group, Wageningen University Research Centre, Lelystad, The Netherlands, ²University of Reading, Reading, United Kingdom, ³University of Manitoba, Winnipeg, Canada, ⁴University of Guelph, Guelph, Canada, ⁵Wageningen University, Wageningen, The Netherlands.

The type and rate of degradation of carbohydrates in the rumen affect methane production. Because experimental data for grass based diets are essentially lacking, the objective was to simulate the effect of grass characteristics on methane emission from enteric fermentation. A dynamic model of rumen and hindgut fermentation processes (Mills et al., JAS 79:1584-1597) was used. Stoichiometry of yield of volatile fatty acids from different types of carbohydrates and protein was updated based on a recent analysis of *in vivo* data from lactating cows. Methane yield was calculated from predicted hydrogen balance. Various types of ryegrass products were evaluated: fresh grass (G) and grass silage (GS), high (HF) and low (LF) N fertilization level, and early (EC) and late (LC) cutting. Simulations were performed with various levels of DM intake (DMI), and low (10%) or high (60%) level of concentrate on a DM basis. The results demonstrated a strong impact of DMI, proportion

of concentrate and type of grass consumed on methane emission rate and milk yield (FCM). At constant DMI of 17 kg/d, methane loss per kg FCM increased with a reduced N fertilization level (LF vs. HF) and delayed cutting (LC vs. EC). Lowest emissions were predicted for HF fresh grass and HFEC silage. The higher concentrate level decreased losses with LFEC but not with HFEC. Increasing DMI level strongly reduced methane loss per kg FCM.

Table 1. Simulated methane yield from ryegrass diets

% concentrate	10	10	10	10	10	10	60	60	60
DMI kg/d	17	17	17	17	17	17	17	17	23
Grass type	GS	GS	G	GS	GS	G	GS	GS	GS
Management	HFEC	HFLC	HF	LFEC	LFCL	LC	HFEC	HFLC	HFEC
Methane

309 Application of computer models in evaluating alternatives to reduce excess nutrients on a beef farm. M. J. Baker*¹, D. G. Fox¹, and L. O. Tedeschi², ¹Cornell University, Ithaca, NY, ²Texas A&M University, College Station.

A two part study was conducted to evaluate the use of the Cornell Net Carbohydrate and Protein System (CNCPS) and the Cornell Value Discovery System (CVDS) in predicting animal performance and in designing a cropping and feeding system that minimizes land applied nutrients while optimizing profitability on a Holstein steer feeding operation. Study 1 utilized farm records to compare several cropping and feeding strategies to baseline data. Replacing alfalfa silage with corn silage (strategy 1) or grass haycrop silage (strategy 2) was predicted to reduce excess nitrogen (N) due to increased utilization by the crop and reducing imported N due to N fixation by alfalfa. However soil erosion control and soil fertility maintenance required that alfalfa be part of the crop plan. Over 19 months (Study 2), complete data was collected on animal (n=450), environment, feed and manure nutrients for four groups of Holstein steers. The average arrival and harvest weight was 149 kg and 597 kg, respectively. Cattle were managed in three weight phases: light, middle and heavy and marketed at thirteen months. Using observed DMI, the CNCPS was able to predict animal ADG within 0.20 kg, 0.07 kg and 0.06 kg for the light, medium and heavy groups, respectively. The CVDS accurately predicted the DM required for the observed gain (predicted DM required was 101% of actual DM fed). Correlations between dietary and manure N, phosphorous (P) and potassium (K) were variable, possibly due to sampling procedure and the interaction of temperature and manure ammonia volatilization. Compared to a dairy, purchased feed was less resulting in lower imported N, P and K. Nutrient efficiency was also low due to the small amount of product that leaves the farm as meat compared to milk. Increasing nutrient efficiency will be difficult because there is little excess dietary N and the increases in product for export will be small. We conclude computer models can be used to aid farmers in designing feeding systems that optimize nutrient utilization.

Key Words: Nutrient Modeling, Holstein Steer

310 Challenges in using flux chambers to measure ammonia and VOC flux from simulated feedlot pen surfaces and retention ponds. N. A. Cole*¹, R. W. Todd¹, D. B. Parker², M. B. Rhoades², and E. Caraway², ¹USDA-ARS-CPRL, Bushland, TX, ²West Texas A&M University, Canyon, TX.

Few methodologies currently available to estimate ammonia and volatile organic compound (VOC) emissions from livestock operations have been adequately validated for accuracy. Flow-through flux chambers and wind tunnels are sometimes used; however, ammonia and VOC flux from pen or pond surfaces are affected by atmospheric turbulence, atmospheric concentration, and temperature, all of which are altered by a chamber. Two lab-scale studies were conducted to determine the effects of flux chamber air exchange rate (0 to 4 turnovers/minute) on ammonia flux from a simulated retention pond or feedlot pen surface. Buffered ammonium sulfate solutions (pH = 7.6, 8.6, and 9.6) were used as a surrogate ammonia source to simulate a feedlot retention pond. Similar buffer solutions were added to a cellulose media to simulate a feedlot pen surface. With both simulated surfaces, ammonia flux increased with increasing air turnover rate. Flux rates at 4 turnovers/minute were approximately 2x flux rates at 0.5 turnovers/minute and 50% of flux rates from "unaffected" containers placed outside the flux chambers. In a third lab experiment, VOC flux was measured from fresh cattle feces and retention pond effluent using a wind tunnel with air flow rates ranging from 0.5 to 9.7 meters/second (approximately 1 to 32 turnovers/minute). In general, VOC flux doubled for each 2-fold increase in air flow rate. Previous chamber studies have noted a large spatial variability in ammonia flux from pen and lagoon surfaces with CV ranging from 23 to 192%. Based on 11 chamber studies, the number of ammonia flux estimates required to be 95% confident that the estimated mean is within 20% of the true mean (determined as $CV^2/100$) ranges from 5 to 369; with a mean of approximately 75. These findings suggest that flux chambers will not give accurate estimates of ammonia or VOC flux from pen or lagoon surfaces and that large numbers of samples may be required when using chambers for treatment comparisons.

Key Words: Ammonia, VOC, Flux Chamber

311 Odorant production and persistence of generic *E. coli* in manure slurries from cattle fed 0, 20, 40, and 60% wet distillers grains with solubles (WDGS). V. H. Varel*¹, J. E. Wells¹, E. D. Berry¹, M. J. Spiels¹, D. N. Miller², C. L. Ferrell¹, S. D. Shackelford¹, and M. Koochmaria¹, ¹USDA-ARS, US Meat Animal Research Center, Clay Center, NE, ²USDA-ARS, Agroecosystem Management Unit, Lincoln, NE.

Ethanol production from corn removes starch and concentrates the remaining nutrients including CP and minerals. When WDGS are fed to cattle in place of corn, CP and minerals exceed dietary needs. This may increase N emission, P run-off, and odor production. Crossbred steers (n = 160; 434 kg) were assigned in a completely randomized block design to 9 × 9 m pens with concrete floor (10 animals/pen; 4 pens/trt). Steers were fed a finishing diet that contained either 0, 20, 40, or 60% WDGS on a DM basis, and provided 13.4, 14.6, 18.7 or 22.8% CP, respectively. One kg of manure slurry (14 to 23% DM) was

randomly collected across each pen (Aug. 20, Sept. 24, and Oct. 22). Samples were analyzed immediately for odorants, DM, pH, ammonia, L-lactate, and level of generic *E. coli*. After incubation of the samples at 22°C for 2, 4, 7, 10, 14, 21, and 28 d, samples were analyzed for the above parameters plus methane production. Ammonia, reduced sulfur, indole, phenol, isovalerate, isobutyrate and acetate increased ($P < 0.01$) with increasing amounts of WDGS in the diet. Other odorants, skatole, caproate, valerate, butyrate, and propionate were greater ($P < 0.01$) in manure slurries from cattle fed either 20 or 40% WDGS, compared to 0% WDGS. L-lactate was greater ($P < 0.01$) in slurries from cattle fed 0% WDGS (447 $\mu\text{mol/g DM}$) compared to the other treatment slurries (14-15 $\mu\text{mol/g DM}$). L-lactate lowered slurry pH (6.3, 7.1, 7.6, and 8.2, respectively, for 0, 20, 40, and 60% WDGS) which inhibited microbial fermentation, generic *E. coli* persistence, and methane production. Because of the favorable pH in the 40 and 60% WDGS slurries, most of the odorant compounds were rapidly converted to methane during a 28 d static incubation. These data indicate feeding WDGS can increase odorants in manure slurries and extend the persistence of generic *E. coli*.

Key Words: Distillers Grains, Feedlot Cattle, Manure Odor

312 Quantification of nutrient excretion and volatile fatty acid production from a swine wean-finish facility. D. M. Sholly*, D. T. Kelly, A. L. Sutton, B. T. Richert, and J. S. Radcliffe, *Purdue University, West Lafayette, IN.*

A total of 1,920 pigs were used in a 2 × 2 factorial, wean-finish experiment to determine the effects of diet (control, CTL vs. low nutrient excretion, LNE) and manure pit management (6 mo. deep-pit, DP vs. monthly pull plug, PP) on nutrient excretion and VFA production. Pigs were housed in a 12-room environmental building where quantitative manure collection in 24 pits (2/room) was available. Each room housed 30 barrows and 30 gilts (3 pens each), which were split-sex and phased to meet or exceed the nutrient requirements of pigs (NRC, 1998) at different stages of growth. The CTL and LNE diets were corn-SBM based and had equal Lys:calorie. The LNE diets had reduced CP and P, increased synthetic amino acids, phytase, non-sulfur TM premix and added fat. Regardless of manure storage, manure generation was reduced by 0.39 L/pig/d when pigs were fed the LNE diet vs. the CTL diet (4.05 vs. 4.44 L/pig/d, $P < 0.008$). Excretion of total N, P, and K was reduced ($P < 0.001$) by 27.5, 42.5, and 20.4%, respectively, from LNE fed pigs. Pigs fed the LNE diet also had a 25.5, 23.8, 32.3, 18.5, 35.8, and 26.7% reduction ($P < 0.05$) in acetate, iso-butyrate, butyrate, iso-valerate, valerate, and total VFA production, respectively, compared to CTL fed pigs. Ammonium N production was reduced (16.5 vs. 18.4 g/pig/d, $P < 0.002$) with PP manure strategy compared to DP strategy. The PP strategy also reduced total VFA production by 20.5% (26.0 vs. 32.7 mM/pig/d, $P < 0.001$) compared to DP strategy. There was no interaction ($P > 0.05$) of diet and storage for nutrient or VFA production. In summary, implementing LNE diet formulation or using a monthly pull plug strategy can significantly decrease nutrient excretion and VFA production.

313 Supplements for replacement beef heifers grazing dry summer California foothills annual range. R. D. Sainz^{*1}, L. F. B. Carvalho^{1,2}, L. R. A. Sodré^{1,3}, G. D. Cruz¹, D. M. Myers¹, J. W. Oltjen¹, and M. Arana⁴, ¹University of California, Davis, ²Federal Rural University of Pernambuco, Recife, PE, Brazil, ³University of São Paulo, Pirassununga, SP, Brazil, ⁴A. L. Gilbert Company, Oakdale, CA.

California beef producers depend upon foothill rangelands forage, but due to the Mediterranean climate there are marked seasonal variations in forage availability and quality. Low forage quality during summer requires costly feed supplementation to maintain adequate performance. A previous study showed benefits from use of a high protein supplement for replacement heifers in the summer (Monteiro et al., 2007, J. Anim. Sci. 85 (Suppl. 1):257). This study evaluated two low-cost supplements for 60 weaned Angus-Hereford heifers grazing dry summer range: a dry high protein/energy/mineral mix (UCD-DR; 58% CP) and a home-made low-moisture molasses-based tub supplement (UCD-TUB; 48% CP). Heifers (222 ± 2.2 kg BW) were stratified by BW and allocated randomly to six groups of 10: two supplement types, with three replicates (pastures) each. Heifers were allowed free-choice access to both supplements (using self-feeders for UCD-DR) at all times. Supplement intakes and daily costs averaged 441 and 425 g/d (± 29, P = 0.55) and \$0.229 and \$0.173 (± 0.015, P = 0.01) for the UCD-DR and UCD-TUB groups, respectively. Heifers' ADG were 434 and 284 g/d (± 7.5, P = 0.07) for the UCD-DR and UCD-TUB groups, respectively. Supplementation with high protein, plus energy and minerals for heifers grazing dry summer range maintained ADG as expected. The dry mix tended to produce greater ADG, despite being consumed at a similar rate to the molasses-based tubs. On the other hand, the cost of the tub supplement (\$369/ton) was lower than the dry mix (\$471/ton), and the labor requirement was lower for the tubs as well. Producers can maintain performance and reduce costs of production on California annual range by formulating and mixing their own feed supplements.

314 Feed intake, gain and feed efficiency of Suffolk ram lambs from a flock emphasizing performance traits. M. E. Benson^{*2}, A. B. Culham¹, and G. M. Hill¹, ¹Michigan State University, East Lansing, ²Washington State University, Pullman.

There is little data available on the feed intake and conversion of feed to gain associated with sheep selected for and attaining high levels of growth performance. This study was conducted to identify animal variation in daily feed intake (DFI), average daily gain (ADG), feed conversion ratio (FCR) and feeding behavior. Thirty Suffolk ram lambs born from January 27 to March 6, 2007 were used in this 42-44 d growing study. Rams were creep fed from birth, weaned at approximately 60 d of age (DOA), and fed a corn, soybean meal based diet from weaning throughout the test period. The diet was offered ad libitum and met or exceeded all NRC (1985) requirements for early weaned lambs with rapid growth potential. An Osborne FIRE electronic feed intake monitoring system was used to measure individual feed intakes and lamb weights, and to record intake behavior. Each ram was fitted with a RFID eartag transponder and was randomly allocated to a pen,

each with one electronic feeder resulting in 7 or 8 rams/feeder. Over the growth period, rams gained an average of 23.7 kg resulting in ADG of .55 ± 0.02 kg/d. ADG ranged from .13 to .77 kg/d. Rams consumed an average of 1.9 ± 1.0 kg of feed/d. Rams that grew faster consumed more feed. ADG and DFI were positively related with an r² of .66, P < .0001. Very efficient feed conversion rates (FCR) were attained by rams with an average FCR of 3.6 ± .20. FCR was negatively and most highly correlated with ADG (r² = -.44, P = .02) which resulted in the cost of gain being most economical in some of the fastest gaining rams. The r² of FCR with DFI was .33; P = .08. Rams visited the feeders an average of 16.1 (± 8.0) times/d and spent 55.6 (± 4.1) minutes /d in the feeders. Rams were identified in this study that had similar rates of high ADG yet widely different feed conversion ratios. This variation within a flock selected for high growth rates indicates the potential to improve growth performance and nutrient utilization simultaneously.

Key Words: Sheep, Growth, Feed Conversion

315 Variation in total mixed rations on farms utilizing feed management software. B. House^{*}, L. Holden, and G. Varga, Pennsylvania State University, University Park.

Providing a consistent and adequate supply of nutrients is an important factor in optimizing health and production of dairy cattle. The total mixed ration feeding system is widely utilized as a tool to provide a consistent supply of nutrients; however nutrient variability is still a concern. The objective of this study was to quantify nutrient variation as it compares to balanced rations on five Pennsylvania dairies. Herd size averaged 650 (327) cows with an average production of 33.1 (.98) kg/d. Twelve weekly samples were taken from May through July 2007 for twelve different rations. Samples were analyzed for DM, CP, ADF, NDF, and some minerals. The sampled rations were checked for mixing accuracy using feed management software. Using paired t-tests, the mean composition of formulated rations were compared with actual ration analyses. Across all herds, analyzed rations differed significantly (P < .01) from formulated rations with less CP, and more ADF and NDF. Analysis within herds showed a difference (P < .05) in DM% between formulation and analysis in three farms. The average nutrient coefficient of variation ranged from 5 to 10%. Using the average variation and average sample analysis, resulting average variation expected in rations were calculated. Variation in ration composition between actual analyses and formulation is due to several different sources. Values for CP, ADF, and NDF differed for analyzed compared to formulated rations in herds using feeding management software.

Table 1. Nutrient deviations and variation for 12 rations across five herds

Across All Rations (%)	DM	CP	ADF	NDF	P
Avg. Formulation –					
Avg. Analysis	-0.52	1.14	-2.97	-3.58	-0.006
P-value	0.0521	<.0001	<.0001	<.0001	0.2369
Std. Dev. of Difference	3.03	1.00	2.18	2.77	0.026
n	130	130	130	111	29

Coefficient of Variation within a Ration

316 Residual feed intake of pre- and post-pubertal heifers of diverse breed types. A. N. Loyd*, A. W. Lewis, R. D. Randel, and C. R. Long, *Texas AgriLife Research, Overton, TX.*

With the rising costs of feedstuffs, reducing feed expenses is important for livestock producers. Residual feed intake (RFI) is a measure of feed efficiency developed to identify animals which may require less feed to achieve the same performance as their cohorts. This retrospective analysis of RFI used data collected during 1973 and 1974 from the McGregor location of the Texas Agricultural Experiment Station. Heifers were obtained from a large crossbreeding program involving a five-breed diallel of Angus, Brahman, Hereford, Holstein and Jersey. Breed groups were Dairy (D; n = 16) comprised of Holstein, Jersey, and their crosses, English (E; n = 16) comprised of Angus, Hereford, and their crosses, D x E crosses (n = 19), D x Brahman (B) crosses (n = 12), E x B crosses (n = 9), and B (n = 5). At approximately six months of age, pre-pubertal heifers (n = 77) were individually penned and received ad libitum access to a balanced ration. Feed intake and body weight data collected 84 days prior to puberty and 90 days post-puberty were utilized for this study. The ration was changed at puberty to provide a lower energy density. Considering all females as cohorts, RFI was calculated for each heifer for each period. A moderate, positive correlation ($r = 0.48$; $P < 0.0001$) was found between pre-pubertal and post-pubertal RFI. A difference in RFI among breed types was also detected ($P = 0.11$ for pre-pubertal and $P < 0.0001$ for post-pubertal). This implies that RFI may not be an accurate method to compare feed efficiency of individuals of diverse breed types. When RFI was covaried with the breed type specific NEm, differences in RFI among breed groups, both pre- and post-pubertal, were no longer significant ($P > 0.05$). This implies that a portion of the variation in RFI is accounted for by NEm, thus supporting the argument that RFI may not be a good method to compare cattle of diverse breed types. It is possible that RFI determined during the post-weaning period is only a moderate predictor of variation in RFI during the post-pubertal period.

Key Words: Cattle, Residual Feed Intake, Puberty

317 Effect of feeding method and temperament on measures of feed efficiency and age at puberty in Brahman bulls. N. D. Ramirez*¹, D. A. Neuendorff³, A. W. Lewis³, S. T. Willard⁴, R. C. Vann⁷, S. Bowers⁴, T. H. Welsh, Jr.⁵, T. D. A. Forbes⁶, R. L. Stanko^{1,2}, and R. D. Randel³, ¹Texas A&M University, Kingsville, ²Texas AgriLife Research Station, Beeville, TX, ³Texas AgriLife Research and Extension Center, Overton, TX, ⁴Mississippi State University, Starkville, ⁵Texas

A&M University, College Station, ⁶Texas A&M University Agricultural Research and Extension Center, Uvalde, TX, ⁷MAFES-Mississippi State University, Raymond.

The objective of this study was to determine the effect of feeding method, limited (LF) or ad libitum (AL), and temperament on measures of efficiency in spring-born Brahman bulls. Bulls (n=32) were randomly allocated to either be LF or AL fed for 70 d (P1). Following a 7-d rest, treatments were exchanged in a cross-over design and bulls were fed an additional 70 d (P2). Bulls were blocked by BW and assigned to pens (n=11, 2 to 5 bulls/pen). Pen score (PS) and exit velocity (EV: m/s) were used to qualify temperament. Mean (\pm SEM) age and BW at the beginning of the trial were 343 ± 4 d and 327 ± 8 kg. Bulls were individually fed twice daily a 12% CP (NEm=0.291 Mcal/kg and NEg=0.272 Mcal/kg) pelleted ration. Bull BW was recorded and amounts fed were adjusted daily during AL and weekly during LF. RFI was calculated as the residual from the linear regression of DMI on mid-test BW^{0.75} and ADG. Feeding method did not effect ($P > 0.1$) RFI, ADG, DMI, and feed efficiency (FE; G:F, g of ADG/kg of DM). However, feeding period influenced ($P < 0.06$) ADG (1.06 ± 0.04 and 0.95 ± 0.04 kg/d) and DMI (8.4 ± 0.2 and 9.4 ± 0.4 kg). Order of feeding treatment influenced ($P = 0.06$) FE. Overall, RFI was correlated ($P < 0.001$) with FE in LF (-0.56) and AL (-0.65) bulls, and PUB was correlated ($P < 0.05$) with DMI (-0.37) in LF bulls only. Mean (\pm SEM) RFI and ADG in LF and AL were -0.52 ± 0.3 and 0.54 ± 0.8 , and 1.00 ± 0.04 and 1.01 ± 0.04 kg/d, respectively. Treatment influenced RFI in P1, but not in P2, LF (RFI=-0.62 \pm 0.42) were more efficient ($P < 0.01$) than AL (RFI=0.66 \pm 0.1) bulls. In P1, RFI was correlated ($P < 0.05$) with FE (-0.56) in LF but not AL bulls; ADG was correlated ($P < 0.05$) with DMI (0.71), and EV was correlated ($P < 0.05$) with PS (0.56) in LF but not AL bulls. In P2, RFI was correlated ($P < 0.01$) with FE in LF (-0.65) and AL (-0.74) bulls. These data suggest that there may be a relationship between method of feeding and measures of feed efficiency and thus selection for efficiency (low RFI). Limit feeding spring-born Brahman bulls may be more appropriate than AL feeding to establish accurate measures of efficiency.

Key Words: Residual Feed Intake, Reproduction, Brahman Bulls

318 Effect of reflective insulation on calves in polyethylene hutches. B. H. Carter*, T. H. Friend, J. H. Matis, J. E. Sawyer, and M. A. Tomaszewski, *Texas A&M University, College Station.*

Radiant heat load on calf hutches may add to heat stress by increasing interior hutch temperature. A summer trial was conducted on a Texas Panhandle dairy to determine if covering polyethylene hutches with reflective insulation would reduce heat load on individually housed Holstein-Friesian calves. Twenty of 38 hutches were covered with a 2.5 x 2.2 m sheet of reflective aluminum and polyethylene double bubble film insulation (8 mm thick) over the top and two sides of hutches. Interior hutch temperature was recorded for 72 h at 10-min intervals. Body (ear canal) temperature (BT) was measured for two 72-h periods at 10-min intervals when calves averaged 35 and 56 d of age. Respiration rate was recorded by observation at 2-h intervals for 48 h of each period. Results for the two periods were pooled. Effects of ambient thermal heat index (THI) on the rate of body and hutch temperature change were modeled for each calf and hutch using linear regression. The slopes for body and hutch temperature were compared for insulation effect using 2-sample t-tests. Estimated mean respiration rate, calf

BT and interior hutch temperature were calculated for each calf at high (> 72) and moderate (< 72) THI. Effects of insulation on respiration rate, BT and hutch temperature were tested at high and moderate THI using 2-sample t-tests. Calf BT was similar ($P=0.16$) among insulation treatments at high THI, but was higher ($P=0.05$) for calves in insulated hutches at moderate THI. Insulation had minimal effect on the rate of BT change ($P=0.11$). Respiration rates were lower ($P=0.04$) for calves in insulated hutches at high THI, and tended to be lower at moderate THI ($P=0.17$). Covering hutches reduced ($P<0.01$) interior temperatures by $1.4 \pm 0.14^\circ\text{C}$ at high THI but increased ($P<0.01$) interior temperatures by $0.58 \pm 0.09^\circ\text{C}$ at moderate THI. The rate of temperature change for insulated hutches was lower than control hutches ($P<0.01$). Covering polyethylene hutches with reflective insulation moderated temperature and its change within hutches, reduced respiration rate of calves, and may benefit calves by retaining heat in cooler temperatures.

Key Words: Dairy, Hutch, Reflective

319 Changes in newborn calf and colostrum management on U.S. dairy operations 1991-2007. J. E. Lombard*, C. A. Kopral, B. A. Wagner, and G. W. Hill, *USDA:APHIS:VS:Centers for Epidemiology and Animal Health, Fort Collins, CO.*

The National Animal Health Monitoring System has conducted 4 studies evaluating the dairy industry – 1991, 1996, 2002 and 2007. One objective of this study was to evaluate changes in newborn calf and colostrum management over this time period. States were selected in each of the study years to represent at least 75% of dairy operations and dairy cows with responses statistically weighted to make inferences back to the population from which the sample was selected. The percentage of operations where newborn calves were separated from their dam immediately after birth increased from 28.0% in 1991 to 55.9% in 2007. For operations that hand-fed colostrum, the percentage of operations that evaluated the quality of colostrum has increased from 5.2% in 2002 to 13.0% in 2007 and its use increased as herd size increased. The practice of pooling colostrum has decreased from 27.0% in 2002 to 21.0% in 2007. More operations are storing colostrum in a refrigerator in 2007 (11.1%) compared to 7.8% in 2002; however, most operations that hand-fed colostrum, did so without storing it. Colostrum was primarily hand-fed from a bucket or bottle from 1991 to 2007. There have been no changes in the percentage of operations by the method of delivering the first feeding of colostrum. Approximately one-third of operations allowed calves to obtain colostrum at first nursing. The percent of operations by quantity of colostrum fed during the first 24 hours has not changed since 1991 with about 30% providing 4 or more quarts. Two or less quarts were normally fed on approximately one-quarter of operations from 1991–2007. Although more operations are removing calves from their dams immediately after birth, the quantity of colostrum administered on dairy operations hasn't changed since 1991. The importance of feeding 4 quarts of high quality colostrum to every calf is an opportunity for continued producer education.

Key Words: Colostrum, Calves

320 Relationship between temperament and chute exit velocity of Senepol calves after weaning. R. W. Godfrey* and R. C. Ketring, *University of the Virgin Islands, Agricultural Experiment Station, Kingshill, VI.*

The objective of this study was to evaluate the relationship between temperament and growth in weaned Senepol calves. Bull ($n=22$) and heifer ($n=31$) calves were evaluated at weaning (211 ± 3 d of age), 90 d post-weaning (302 ± 2 d of age) and as yearlings (374 ± 3 d of age) using chute score (CS) and exit velocity (EV) as indicators of temperament. Calves were weighed at each evaluation and scrotal circumference (SC) was measured for bulls as yearlings. The CS was determined on a 1 to 5 scale with 1 being calm and 5 being extremely agitated and EV, reported in m/sec, was measured as the animals exited the chute using an electric timing system. None of the calves received a CS greater than 4 at any time. At weaning there was no difference ($P>0.10$) in CS between bulls and heifers (1.6 ± 0.2 vs. 1.9 ± 0.1 , respectively). At 90 d and as yearlings heifers had higher ($P<0.002$) CS than bulls (2.4 ± 0.1 and 2.5 ± 0.2 vs. 1.7 ± 0.2 and 1.7 ± 0.2 , respectively). The CS increased ($P<0.004$) over time in heifers but not in bulls. Heifers had greater ($P<0.0001$) EV than bulls at weaning, 90 d and as yearlings (3.2 ± 0.1 , 3.2 ± 0.1 and 2.9 ± 0.2 vs. 2.7 ± 0.2 , 2.6 ± 0.2 and 2.4 ± 0.2 m/sec, respectively). The EV did not change over time in either bulls or heifers ($P>0.10$). In bulls with a CS of 3 ADG from weaning to 90 d was greater ($P<0.04$) than ADG from weaning to yearling. There was no difference ($P>0.10$) in ADG from weaning to 90 d and weaning to yearling in bulls with a CS of 1 or 2. In heifers there was no difference ($P>0.10$) in ADG during any time period among any of the CS groups. Overall CS and EV had a moderate correlation ($P<0.001$, $r=0.424$). The CS and EV had a moderate correlation at weaning ($P<0.0001$, $r=0.518$), 90 d ($P<0.005$, $r=0.383$) and at yearling ($P<0.005$, $r=0.446$). Weight and EV were correlated at 90 d ($P<0.001$, $r=-0.434$) but not at any other time and CS was not correlated with weight at any time ($P>0.10$). These results show that the temperament of Senepol calves does not change over time after weaning and heifers are more temperamental than bulls.

Key Words: Temperament, Cattle, Behavior

321 The effect of severe winter weather on net energy required for maintenance by yearling steers. P. T. Grubb*, J. J. Wagner, and T. L. Engle, *Colorado State University, Fort Collins.*

Severe winter storms in southeast Colorado resulted in 38 cm snow accumulation over Christmas weekend in 2006 and an additional 96 cm snow accumulation over New Years weekend in 2007. This snow was accompanied by strong winds which caused excessive drifting. Economic losses suffered by the cattle feeding industry were severe and several research trials were lost at SECRC. Enough data from one of the studies were salvaged to provide an interesting look into the effect of severe winter weather on net energy requirements for maintenance. A set of 214 steers were weighed on December 26, 2006 and average weight (minus four percent pencil shrink) was $558 \text{ kg} \pm 21.7$. Over the following 58 day period there was a 7.0% death loss and average daily gain was $-0.13 \text{ kg} \pm 0.21$ for these steers. Average steer weight (minus four percent pencil shrink) was $550 \text{ kg} \pm 18.7$ on February 22, 2007. During the worst days of the storms, pen feed delivery records were not maintained. However, for accounting purposes, records of total feed delivered to each lot of cattle at SECRC were maintained. This allowed for calculations of net energy required for maintenance based on overall performance and total feed delivered. Total DM delivered to these steers was 53,436.7 kg and average NEM concentration in the diet was 2.263 mcal/kg DM. Daily dry matter intake averaged 9.67 kg/hd/d. Net energy equations published by the National Research Council (1996) were used to calculate average empty body weight (EBW, 497.7 kg), empty body

gain (EBG, -0.00686 kg/d), and retained energy (RE, -0.038 mcal/d). The negative RE value showed that the steers were not recovering enough energy from the diet to meet maintenance requirements. Net energy required for maintenance was 21.927 mcal/hd/d or 0.208 mcal per kg EBW^{0.75}. Statistical analyses of these results were not possible due to the inability to recover pen dry matter intake estimates. However, these data indicate that NEm required during and in the aftermath of a major winter weather event may be 2.7 fold higher than NEm required (0.077*EBW^{0.75}) under thermal neutral conditions.

Key Words: Net Energy for Maintenance, Cold Stress, Retained Energy

322 Hoop buildings vs. conventional feedlots for steers: Effects on growth and performance. P. Lammers*¹, A. Johnson¹, S. Lonergan¹, J. Harmon¹, R. Baker¹, S. Shouse², W. Busby², and M. Honeyman¹, ¹Iowa State University, Ames, ²Iowa State University Extension, Ames.

As the cattle feeding industry focuses on environmental management, there is increasing interest in facilities that minimize runoff such as deep-bedded hoop barns. The objective of this study was to compare the performance of yearling steers between housing treatments: pens inside a deep-bedded hoop barn with a partial concrete floor (HP) vs. pens in a conventional, outside feedlot with shelter (FD). Results are from 2

complete yr. Each yr, 2 groups of yearling steers were fed. Summer/fall groups were put on test in August and marketed in November. Winter/spring groups were put on test in December and marketed in April/May. Steers (422 kg) were randomly allotted to 3 pens within each housing treatment with approximately 40 hd per pen (HP = 4.65 m²/steer; FD = 14.7m²/steer). A description of the hoop barn is reported in Hoop Barns for Beef Cattle 2004, MidWest Plan Service AED-50. All steers were fed a complete and balanced ration and had ad libitum water access from 1 drinker/pen. Cattle in HP received corn stalks for bedding year-round (2-3 kg/d) and FD cattle were supplied bedding only during the winter/spring season (0.5-1 kg/d). Cattle weights and feed disappearance were recorded and used to calculate performance. Carcass data were recorded at the time of harvest (608 kg). Gain-to-feed (kg gain/kg feed) was more for steers in FD than HP (0.15 vs 0.14; *P* = 0.04). There were also trends for FD cattle to have greater ADG (1.90 vs 1.83 kg/d; *P* = 0.05) and larger total gains on test (190.4 vs 182.2 kg; *P* = 0.06). Housing did not affect ADFI, hot carcass wt, marbling, or carcass grade. Summer/fall steers were heavier, had greater ADG and G:F, and produced larger carcasses than winter/spring steers. There were no differences in marbling score or carcass grade between the 2 seasonal periods. There were no housing × season interactions for any measure examined. The difference in G:F and trend for lower ADG for steers fed in hoop barns warrants additional study. Overall the cattle performed similarly with similar carcass data for both housing systems.

Key Words: Deep-Bedded Hoop Barns, Feedlot Beef Cattle

Ruminant Nutrition: Fats and Fatty Acids

323 Effect of supplemental fat source on immunity of periparturient Holstein cows. B. C. do Amaral*, C.R. Staples, O. de F. Zacaroni, S. A. Sennikov, L. Badinga, F. Silvestre, J. D. Arthington, and W. W. Thatcher, *University of Florida, Gainesville*.

The study objective was to evaluate if dietary supplemental polyunsaturated fatty acids, enriched in omega-6 or omega-3 fatty acids, can regulate and improve the immunosuppressive state that is typical of periparturient Holsteins heifers (n=16) and cows (n=29). Treatments were: 1) Control (CO, no fat supplement), 2) Ca salts of fatty acids made from safflower oil (Omega-6, 63% C18:2), and 3) Ca salts of fatty acids made from palm oil and fish oil (Omega-3, 11% eicosapentaenoic acid plus docosahexaenoic acid, StrataG™). Supplemental fats (Virtus Nutrition, Corcoran, CA) were fed at 1.5% of dietary DM during pre and postpartum periods. Blood samples were taken thrice weekly for 7 wk for determination of acute phase proteins. Phagocytotic and oxidative burst activities of neutrophils were measured using flow cytometry in whole blood samples taken at -18, 0, 7, and 40 DIM. Multiparous cows fed Omega-6 had greater concentrations of fibrinogen (259 vs 206 mg/dl) compared to Omega-3-fed cows, but values were not different for primiparous cows (226 vs. 254 mg/dl; treatment by parity interaction $P < 0.05$). Heifers fed omega-3 had reduced concentrations of ceruloplasmin compared to omega-6-fed heifers (10.5 vs. 11.9 mg/dl) but values were not different for cows (11.4 vs. 11.1 mg/dl; treatment by parity interaction; $P < 0.05$). Multiparous cows fed fat supplements had greater (59.8 $\mu\text{g/ml}$) concentrations of acid soluble protein in plasma during the first 3 wk postpartum compared to CO cows (42.9 $\mu\text{g/ml}$), but this was reversed for primiparous cows (51.7 vs. 45.0 mg/dl; treatment by parity by DIM interaction; $P = 0.06$). Concentrations of WBC (8796 vs 11,492 WBC/ μl ; $P = 0.06$) and neutrophils (2463 vs 3495 per μl ; $P < 0.01$) were lower for omega-3 fed cows compared to cows fed CO or omega-6. Based on median fluorescence intensity, the average neutrophil from omega-3-fed cows phagocytised less *E. Coli* than those from CO or omega-6-fed cows. Omega-3 attenuated immune responses compared to Omega-6-fed animals.

Key Words: Fat, Immunity, Dairy

324 Effect of supplemental fat source on production, metabolism, and milk composition of periparturient Holstein cows. B. C. do Amaral*, C. R. Staples, O. F. Zacaroni, S. A. Sennikov, L. Badinga, and W. W. Thatcher, *University of Florida, Gainesville*.

Objective was to evaluate two sources of supplemental lipid enriched in omega-6 or omega-3 fatty acids for influence on production, metabolism and milk composition of periparturient Holsteins heifers (n=16) and cows (n=29). Treatments were the following: 1) Control (no fat supplement), 2) Ca salts of fatty acids made from safflower oil (Omega-6, 63% C18:2), and 3) Ca salts of fatty acids made from palm oil and fish oil (Omega-3, 11% eicosapentaenoic acid plus docosahexaenoic acid, StrataG™). Supplemental fats (Virtus Nutrition, Corcoran, CA) were fed at 1.5% of dietary DM. Blood was taken daily for 10 DIM for PGFM analysis and thrice weekly thereafter until 49 DIM for measures of plasma metabolites. Milk yield was recorded twice daily and weekly samples were taken for milk composition. Milk samples from wk 5, 6, and 7 were pooled for fatty acid analysis. Orthogonal contrasts were 1 vs. 2+3, and 2 vs. 3. The mean DMI postpartum (13.4, 13.7, and 13.5

kg/d; SE = 0.6) and postpartum (18.0, 18.7, and 16.9 kg/d; SE = 0.8), mean milk yield (32.8, 34.4, and 31.2 kg/d; SE=1.4), mean milk protein concentration (3.0, 2.9, and 2.9%; SE=0.1), mean BW (603, 593 and 593 kg; SE = 18), mean BCS (3.12, 3.26, and 3.15; SE = 0.10), plasma glucose (68.8, 69.5, and 69.5 mg/dl; SE=1.8), plasma NEFA (459, 391, and 433 $\mu\text{Eq/l}$; SE=38), and plasma BHBA (5.7, 5.7, and 5.9 mg/dl; SE=0.5) for treatments 1, 2, and 3, respectively were not different among treatment groups. Heifers fed Omega-3 had greater plasma concentration of PGFM at 6 DIM compared to Omega-6-fed heifers (treatment by parity by DIM interaction; $P < 0.05$). Concentration of milk fat from cows fed omega-6 (3.52 %) or omega-3 (3.21%) was lower than that from control cows (3.76%). Cows fed fats had greater milk concentrations of CLA isomers and C18:1 trans-10, and Omega-3-fed cows had greater concentrations of these FA compared to Omega-6-fed cows. Fat supplementation changed the fatty acid profile of milk without changing milk yield or plasma metabolites.

Key Words: Fat, Milk, Fatty Acid

325 Effects of supplemental flaxseed or corn on site and extent of digestion in beef heifers grazing summer rangelands in the northern Great Plains. E. J. Scholljegerdes* and S. L. Kronberg, *USDA-ARS, Northern Great Plains Research Laboratory, Mandan, ND*.

Six Angus heifers (367 \pm 8.0 kg) fitted with ruminal and duodenal cannulas were used in a split-plot designed experiment to determine the effects of ground flaxseed or corn and advancing season on site and extent of digestion when beef heifers grazed summer range in the northern Great Plains. Starting on June 9, 2006 heifers were rotationally grazed on three 12 ha native pastures and were randomly allotted to one of three treatments being: no supplement (CON); a cracked corn-soybean meal supplement fed at 0.35% of BW once daily (CRN); or a ground flaxseed supplement fed at 0.2% of BW once daily (FLX). Supplements were formulated to be isonitrogenous and isocaloric on a TDN basis. There were three experimental periods that were 28 days in length with 18 d for diet adaptation and 10 d for intensive sampling. Provision of supplement did not affect ($P = 0.22$) masticate IVOMD, however, between supplemented treatments, cattle fed FLX tended ($P = 0.08$) to select a lower quality masticate than CRN. Forage OM intake was not affected ($P = 0.12$) by supplementation nor was there a difference ($P = 0.49$) between CRN and FLX. A quadratic ($P = 0.001$) response was observed for forage OM intake as the grazing season advanced. Duodenal and fecal OM flow was not different ($P = 0.39$) across treatments. Therefore, true ruminal and total tract OM digestibility (% of intake) did not differ ($P = 0.37$ to 0.56) between CON and supplemented treatments and total tract digestibility was greater ($P = 0.01$) for CRN than FLX. Total duodenal N flow did not differ ($P = 0.16$) across treatments but responded quadratically ($P = 0.03$) with advancing season. True ruminal N digestibility was not affected by supplementation ($P = 0.16$ to 0.26). Likewise, ruminal NDF digestibility also did not differ ($P = 0.26$) with supplementation and CRN was not different ($P = 0.22$) from FLX. Total ruminal VFA decreased with supplementation ($P = 0.04$) and ruminal molar proportion of acetate was greater ($P = 0.02$) for FLX than CRN. Therefore, ground flaxseed appears to be a suitable energy supplement for cattle grazing summer rangelands.

Key Words: Digestibility, Flaxseed, Grazing

326 The influence of single essences on conjugated linoleic acid and vaccenic acid content in cows milk. S. La Terra^{*1}, M. Manenti¹, F. La Terra¹, M. Caccamo¹, G. Azzaro¹, S. Carpino¹, and G. Licitra^{1,2}, ¹CoRFiLaC, Regione Siciliana, Ragusa, Italy, ²D.A.C.P.A., Catania University, Catania, Italy.

Milk from cows fed fresh green forage, especially those grazing grass, had a much higher unsaturated: saturated FA proportion, with more poly-unsaturated FA and more Conjugated Linoleic Acid (CLA). Rumenic acid, in particular, was higher in milk from silage-fed cows. *Anthemis arvensis*, *Calendula arvensis*, *Sinapis arvensis*, *Chrysanthemum coronarium* and Geraniaceae species were evaluated individually for their capacity to influence the content of CLA in milk. The plant species were collected at flowering age, and part of the forage was dried to produce hay. A single dose of both, fresh and dried forage was fed individually, ad libitum to two Holstein cows of similar lactation and milk production. The cows were adapted to a TMR ration, and TMR was given to the cows at the middle and at the end of the experiment as controls. A minimum time of seven days among treatments was maintained. Animals were held off feed for five hours before offering treatments. Feed intake was recorded by weighing provided forage or TMR and refusal. Milk was sampled the day before and the day of the treatment during the evening milking before and after treatment feeding, respectively. Generally, more hay was ingested compared to fresh forage. CLA level increased after treatment feeding with *Calendula arvensis* from 13.55 to 18.65 (nmol/mg fat), *Chrysanthemum coronarium* from 8.7 to 11.2 (nmol/mg fat), and *Anthemis arvensis* from 6.1 to 9.45 (nmol/mg fat). Vaccenic acid followed the same trend of CLA 38.19-43.3 (nmol/mg fat) in *Calendula arvensis*; 26.83-29.73 (nmol/mg fat) in *Chrysanthemum coronarium*; and 25.93-28.93 (nmol/mg fat) in *Anthemis arvensis*. Our data also shows that concentration of the total CLA and the Vaccenic acid do not have variations with *Sinapis arvensis* and Geraniaceae species. These differences may be due to fresh forage composition or the lesser amounts fed. We also found higher levels of Vaccenic acids and Rumenic acid in milk from fresh forage compared to milk from hay.

Key Words: Essence, CLA, Vaccenic Acid

327 Dietary coconut oil and animal fat blend decrease lactational performance of Holstein cows fed a high starch diet. M. Hollmann* and D. K. Beede, Michigan State University, East Lansing.

Medium-chain fatty acids in coconut oil (CO) are known to suppress methane generation in the rumen. However, little is known about the impact of CO on lactational performance. Our objectives were to evaluate the supplementation of dietary lipids in a high-starch diet fed to mid-lactation Holstein cows and to compare the incremental replacement of an animal fat blend (AFB) with CO. Thirty-two multiparous cows were adapted for 4 wk to a basal diet (CONTROL) with 60% concentrate: 28% corn silage: 12% alfalfa silage and hay, dry basis. CONTROL was formulated to contain: 16.5% CP (10.1% RDP and 6.4% RUP), 27.4% NDF (67% of NDF from forage), 3.0% fat, and 36.8% starch, dry basis. During the last week of adaptation, covariates of performance were measured daily (Table 1). Cows were blocked by covariate MY and assigned to one of four iso-nitrogenous diets (n = 8 per trt): CONTROL; 5% AFB; 2.5% AFB:2.5% CO; or, 5% CO, dry basis. When fat was substituted for dry ground corn, corn gluten meal was added to maintain N content of all diets. Measurements of cow performance and milk composition monitored during wk 3 of feeding treatment diets are presented in Table 1. However, DMI and MY dropped 39% and 24%,

respectively, within 3 d with 5% CO and those cows were removed from the trial on d 6; their data were excluded from statistical analysis. Fat supplementation reduced DMI, MY and milk component yields and depressed milk fat and lactose concentrations. Replacing AFB partially with CO additionally lowered milk fat content and yield.

Table 1.

	Covariate	Diets		Contrasts (<i>P</i> <)		
		Control	AFB	AFB-CO	Control vs. AFB, AFB-CO	AFB vs. AFB-CO

Key Words: Coconut Oil, Milk Fat Depression, Feed Intake

328 Effect of supplementation with sunflower oil (SO) or seeds (SS) combined or not with fish oil (FO) on milk production in grazing dairy cows. G. A. Gagliostro^{*1}, D. A. Garciarena¹, F. Luparia¹, A. Ferlay², and Y. Chilliard², ¹Instituto Nacional de Tecnología Agropecuaria, INTA, Balcarce, Buenos Aires, Argentina, ²Institut National de la Recherche Agronomique, Saint Genès Champanelle, France.

After a covariate period (2 wk) without lipid supplement sixty four Holstein cows were assigned to four treatments (16 cows/treatment) during 5 experimental weeks. During each milking cracked corn grain (1.3 kg DM/cow) and a mineral-vitamin premix were consumed. Between the morning and the afternoon milkings cows grazed a pasture (*Avena sativa* L) at an herbage allowance of 11 kg DM/cow/day. Pasture DM intake was estimated by group within treatments and averaged 6.28, 5.51, 5.10 and 5.44 kg/cow/day in SS, SS-FO, SO, and SO-FO. After the p.m. milking, cows received four TMR diets: 1) SS = 74.7% corn silage (CS); 25.3% SS, 2) SO = 76.7% CS, 12.3% sunflower meal (SM), 11% SO; 3) SS-FO = 72.4% CS, 24.5% SS, 3.1 % FO and 4) SO-FO = 74.3% CS, 11.9% SM, 10.6% SO, 3.2% FO. SS were roughly ground before mixing. Intake of TMR was estimated by group resulting in 7.52, 7.33, 3.45 and 4.63 kg DM/cow/d for SS, SO, SS-FO and SO-FO respectively. FO represented 0.91 and 1.14% of total DMI in SS-FO and SO-FO. Cows were weighed at the start (wk -2) and the end (wk 5) of the trial and the subcutaneous fat depth (SFD) between the 12th and 13th ribs was also measured (scanner). Data were analyzed as a completely randomized design with repeated measures adjusted by covariable. Significant interactions between sources of vegetable oil

(SS or SO) and FO were not detected. No differences in milk yield (15.4 kg/d) were detected ($P>0.10$). Milk fat content (29.95 vs 28.05 g/kg, $P<0.01$), 4%FCM (13.22 vs 12.52 kg/d, $P<0.04$) and milk fat yield (0.47 vs 0.43 kg/d, $P<0.01$) were higher in SO than in SS diets. Feeding FO decreased ($P<0.01$) milk fat content (25.5 vs 32.5 g/kg), 4%FCM (11.9 vs 13.8 kg/d), milk fat yield (0.39 vs 0.50 kg/d), milk protein content (36.0 vs 37.2 g/kg) and yield (0.54 vs 0.57 kg/d) and lactose content (48.0 vs 49.35 g/kg). Cows lost BW only when FO was included in the diet (-0.203 vs +0.138 kg/d, $P<0.01$). Changes in SFD were not detected ($P>0.29$). Effects of FO are more important on milk production and composition than those of C18:2n-6 source.

Key Words: Milk Yield, Sunflower Oil, Fish Oil

329 Effects of particle size of calcium salts of fatty acids on rates of biohydrogenation and disappearance of essential fatty acids in sacco. E. Block^{*1}, E. Evans², C. J. Sniffen³, and N. Clark⁴, ¹Church & Dwight Co Inc, Princeton, NJ, ²Technical Advisory Services Inc, Bowmanville, ON, Canada, ³Fencrest LLC, Holderness, NH, ⁴Atlantic Dairy and Forage Institute, Fredericton Junction, NB, Canada.

Calcium (Ca) salts of fatty acids (FA) can be produced to contain varying quantities of unsaturated fatty acids, yet remain in the solid form. The Ca salt must dissociate into free Ca and FA before biohydrogenation (BH) takes place, thus impacting the rate of BH. Estimates of rate of dissociation and BH are widely varied in the literature. The purpose of this research was to assess the relative effects of particle size on net BH. A sample of the commercial product MEGALAC-R[®] (Church & Dwight Co., Inc., Princeton, NJ) was obtained from a local feed mill. A portion was ground to pass through a 1 mm screen. Samples (5 g) of intact and ground MEGALAC-R were placed in 10 cm X 15 cm Ninex bags and quadruplicate samples were incubated in the rumens of two rumen cannulated lactating dairy cows for 1, 6, 12 and 18h. FA recovery was determined for the samples. Regression of total of each FA recovered vs. incubation time was used to compute rate functions. A paired T test was used to compare intact and ground rates. Rates of increase in saturated fatty acids and rates of decline in unsaturated fatty acids were higher ($P<0.05$) with the ground Ca salt sample (Table 1). Additionally, these rates varied for the individual fatty acids in the samples. Calculated passage rates for unsaturated fatty acids averaged 53.0% higher with intact samples. This trial demonstrates that particle size of Ca salts of FA is an important factor for reducing BH and improving unsaturated fatty acid supply past the rumen.

Table 1. Rates of change of Fatty Acids, %/h

Fatty acid	Intact rate	Ground rate	Intact R ²	Ground R ²
C16:0	+0.872	+1.779	0.786	0.813
C18:0	+1.230	+3.775	0.839	0.961

330 Calcium status influences the periparturient cow's ability to consume and utilize high levels of supplemental ruminal inert fat and is potentially mediated by insulin. L. M. Norat-Collazo*, A. Lukose, P. G. Smith, L. O. Ely, and M. A. Froetschel, *The University of Georgia, Athens.*

The mechanism for calcium status to influence the transition cow to utilize greater supplemental fat postpartum was investigated using a factorial designed experiment (2 X 2) with 12 multiparous Holstein cows. Cows were fed 2 weeks prepartum diets containing either 0 (+DCAD) or 9.3 % (-DCAD) of an anionic salt product (Biochlor[®]) to provide a cation-anion difference of 138 VS -143 meq/kg DM. Postpartum diets contained either 0 (LF) or 5.3 % (HF) of rumen inert fat (Megalac-R[®]). Daily intake and milk were measured for 12 weeks postpartum. At hourly intervals intake and diurnal circulating concentrations of hormones and metabolites (insulin, glucose, blood urea nitrogen (BUN), non-esterified fatty acids (NEFA), and plasma calcium) were measured during a 24 h period within week 1, 4 and 8 postpartum. Digestibility and energy balance were measured on week 6 and 12 postpartum. Cows fed HF diets consumed 9.8-16.3% less DM as compared to LF. Cows fed -DCAD had 13.8 to 15.2% lower DMI week 1-2 and increased DMI 7.8 to 10.7 % from week 7-11 postpartum. Cows fed +DCAD and HF produced 18% less milk week 1-9; whereas, cows fed -DCAD and HF produced 28.6% more milk during week 8-12 as compared to controls. Insulin decreased in -DCAD fed cows whereas it was increased in cows fed HF. Insulin sensitivity appears to increase with prepartum -DCAD and decrease with HF. Feeding -DCAD did not counteract effects of fat supplementation on circulating insulin concentrations. Insulin was more related to meal feeding than other blood parameters measured. Insulin taken at h intervals during meal feeding was negatively correlated with meal size and this relationship increased as smaller meal size data was removed from the data set. Endocrine and metabolic parameters were influenced by dietary treatments indicating that differences in productivity and intake were related to greater insulin responsiveness, dietary fat utilization, and adipose tissue mobilization of cows in early lactation.

331 Fat from corn germ compared with corn distillers grains and corn oil in dairy cow diets. M. M. Abdelqader*, A. R. Hippen, D. J. Schingoethe, and K. F. Kalscheur, *South Dakota State University, Brookings.*

The objective of this study was to determine the effect of feeding fat from corn germ compared with fat from distillers grains and corn oil on milk production and composition of dairy cows. Eight multiparous and eight primiparous lactating Holstein cows were used in a replicated 4 x 4 Latin square with 4-wk periods. Dietary treatments were a control (CON) diet containing 2.5% of ruminally inert lipid (Energy Booster 100[®]; Milk Specialties Co., Dundee, IL), 14% corn germ (CG), 30% distillers grains (DDGS), and 2.5% corn oil (CO). All diets were formulated to be isonitrogenous (18.0% CP, DM basis) and isolipidic (6.0% EE, DM basis). Dry matter intake was increased by feeding CG compared with CON; however, no difference in DMI was observed among CG, DDGS, and CO. Treatments had no effect on milk yield or energy-corrected milk. Feeding CG had no effect on milk fat percentage when compared with CON; however, DDGS tended to decrease ($P = 0.10$) milk fat percent-

age, and CO decreased ($P < 0.01$) milk fat percentage when compared with CG. Both DDGS and CO decreased ($P < 0.01$) concentrations of de novo synthesized fatty acids and increased ($P < 0.01$) the concentrations of preformed fatty acids in milk when compared with CON. Feeding DDGS and CO increased the concentration of vaccenic and conjugates of linoleic acid in milk fat. In conclusion, feeding dried distillers grains at 30% of DM decreased milk fat compared with a control diet, though fat from corn germ appeared to have minimal impact on milk fat when compared with dried distillers grains and corn oil.

332 Duodenal flow and intestinal disappearance of fatty acids in lambs fed canola, brown mustard, or camelina seeds. P. L. Price*, V. Nayigihugu, C. M. Murrieta, D. C. Rule, J. M. Krall, and B. W. Hess, *University of Wyoming, Laramie.*

Four black-face wether lambs (77.5 ± 4.2 kg BW) fitted with ruminal, duodenal, and ileal canulae were used to compare site and extent of fatty acid digestion of diets with canola, brown mustard, or *Camelina sativa* seeds. Experimental design was a 4×4 Latin square and experimental diets consisted of 18% ground (2.54 cm) bromegrass hay, 65.2% cracked corn, 15% soybean meal, and 1.8% limestone (as-fed basis, Control) with oil seeds replacing enough of the soybean meal to provide 3% added fatty acid from each of the whole oil seeds. Urea was added to produce isonitrogenous diets. A 7-d adaptation period was followed by 2 d of duodenal and ileal sampling. Duodenal flow of 18:0 was greater ($P = 0.001$) for lambs fed canola and brown mustard than lambs fed the Control and camelina diets. Duodenal flow of 18:1 *c*9 was greater ($P < 0.001$) for lambs fed canola than lambs fed Control with lambs fed brown mustard and camelina being intermediate. Duodenal flow and apparent small intestinal disappearance (g/d) of 18:1^t11, 18:3^c9^c12^c15,

and 22:1^c11 were greatest ($P \leq 0.003$) in lambs fed camelina. Intestinal disappearance (% entering the duodenum) of 18:1^c9 ranked ($P = 0.001$) canola < brown mustard < camelina = Control. Lambs fed Control and camelina had a greater ($P < 0.001$) percentage of total fatty acids digested in the small intestine than lambs fed canola; lambs fed brown mustard were intermediate. Although lambs fed canola or brown mustard had greater ($P = 0.007$) amounts of 18:0 disappearing from the small intestine, a lesser ($P = 0.001$) percentage of 18:0 disappeared from the small intestine of lambs fed brown mustard or canola. We conclude that the likelihood of enhancing unsaturated fatty acid content of food products derived from lamb is greatest for diets containing camelina seeds. Furthermore, total energy available from fatty acids digested in the small intestine would not be comparable among the various oil seeds.

Key Words: Lambs, Fat Supplementation, Oil Seeds

333 Effect of a dietary antioxidant AGRADO® Plus on production performance of early lactation dairy cows. G. R. Bowman*¹, M. Vazquez-Anon¹, and J. Nocek², ¹Novus International, Inc., St. Charles, MO, ²Spruce Haven Research, Union Springs, NY.

The objective of this study was to evaluate the effect of feeding a dietary antioxidant (AOX, AGRADO® Plus) on milk production and milk constituents during early lactation. Thirty multiparous lactating Holstein cows (30 days postpartum) housed in a tie stall facility were randomly assigned to one of the two treatments. Cows were balanced for DIM, milk yield at 30 days postpartum, and body condition score. All cows received the same basal diet throughout the 12 week study; however, cows assigned to AOX treatment received 250 mg/kg DM of the dietary antioxidant. Cows receiving the AOX significantly ($P = 0.01$) increased DMI by 2.3% over control (22.7 vs 22.2 ± 0.15) and tended to increase milk yield ($P < 0.10$). Both 3.5% fat corrected milk and energy corrected milk increased with AOX supplementation by 5.5% ($P < 0.01$; 44.8 vs 42.5 ± 0.4) and 4.8% ($P < 0.01$; 43.7 vs 41.7 ± 0.4), respectively. Milk fat percent was 3.3% for cows receiving the control diet and increased to 3.5% for AOX supplementation. No significant changes were observed in milk protein yield and percentage. Although mammary health was excellent throughout the study there was a decline in somatic cell count (SCC; 220,780 control and 129,480 AOX, $\pm 28,260$) when the dietary antioxidant was fed ($P = 0.02$). No changes were observed in blood plasma concentration for the antioxidant enzymes superoxide dismutase and glutathione peroxidase or total antioxidant status between cows supplemented with and without AOX. The dietary antioxidant, AGRADO® Plus, increased feed intake, FCM, fat yield, fat percent, and tended to increase milk yield. This study also indicated that AOX may have a positive influence on the immune system as indicated by the decline in SCC.

Key Words: Antioxidant, Milk, Fat

Ruminant Nutrition: Rumen Fermentation and Microbiology

334 Chemotaxis toward glucose and xylose by mixed ruminal protozoa and dose-responsive insulin recovery from wortmannin inhibition by entodiniomorphid cultures. H. L. Diaz*¹, J. L. Firkins¹, M. A. Lyons¹, and J. R. Knapp², ¹The Ohio State University, Columbus, ²Fox Hollow Consulting, LLC, Columbus, OH.

Isotrichid (IS) protozoa migrate toward sugars after feeding and then sink ventrally. We hypothesized that entodiniomorphids (EN) also sense glucose and xylose (end-products of glucanases and xylanases). Two blood capillary tubes (75 mm) were not filled (positive control, POS) or filled with 0 (negative control, NEG), 1, 10, 100, or 1000 mM of glucose or xylose in saline and then placed in 3 replicate beakers with 20 mL of rumen fluid from a dairy cow withheld feed for 12 h or repeated 3 h after feeding. IS counts in the tubes peaked for 1000 mM glucose when feed was withheld but 100 mM after feeding (interaction $P < 0.01$). There was no interaction ($P > 0.20$) for EN. IS were 3 fold more chemotactic toward xylose than glucose, with the reverse for EN. Combining 2 studies for the fed cow, tubes contained 2.1, 6.5, 25.5, 140.2, 65.7, and 22.1 IS counts for NEG, 1, 10, 100, and 1000 mM glucose, and POS, respectively ($140.2 > 65.7 > \text{rest}$, $P < 0.06$); and for EN, 7.0, 12.0, 23.1, 6.4, 33.1, and 115.8 ($115.8 > 33.1 > 23.1 > \text{rest}$, $P < 0.09$). IS depleted the sugar gradient or physically blocked the tube entrance from EN for 100 mM. Chemotaxis and phagocytosis by higher eukaryotic cells is mediated by phosphatidylinositol-3-kinase, a component in insulin signaling inhibited by wortmannin (WORT). Cryopreserved *Entodinium caudatum* (Ento) and *Epidinium caudatum* (Epi) were incubated with 0.2 or 2.0 μM WORT 30 min prior to stimulation by insulin. Counts at 24 h (proportion of 0-h counts) for Ento were 1.54, 1.30, 1.12, 1.54, 1.91, 0.94, 0.87, 1.18, and 1.00 for control; 0.2 μM WORT + 0, 0.1, 0.5, and 2.5 μM insulin; and 2.0 μM WORT + 0, 0.1, 0.5, and 2.5 μM insulin. Normalized Epi counts were 1.32, 0.92, 1.22, 1.19, 1.16, 0.84, 0.91, 1.19, and 0.97. Insulin linearly ($P < 0.08$; corrected for unequal spaces) rescued Ento from 0.2 μM WORT, with no effect at 2.0 μM . Insulin recovery for Epi was $P > 0.15$ for 0.2 μM but $P < 0.05$ quadratic for 2.0 μM WORT. These data justify future research to coordinate chemotaxis with nutrient sensing signals that stimulate rumen protozoal growth rate.

Key Words: Rumen Protozoa, Chemotaxis, Glucose

335 Influence of disodium fumarate on ruminal fermentation and microbial growth in sheep fed high-forage diets. Y. W. Zhou*, J. X. Liu, and L. Zhou, Zhejiang University, Hangzhou, P.R. China.

The present study was conducted to examine the effects of disodium fumarate (DF) addition on fermentation and microbial populations in the rumen of sheep fed high-forage diets. In Experiment 1, six Hu sheep fitted with ruminal cannulae were randomly allocated to a 2 × 2 cross design involving two dietary treatments: added with 0 or 20g DF daily. Animals were maintained in individual pens with basal diet (concentration/forage=30:70) and free access to water. Each period lasted for 15d. Rumen samples were taken for determination of fermentation parameters, and microbial populations in fluid and solid samples were analyzed using real-time PCR method. Ruminal pH decreased sharply in the DF group compared with the control ($P < 0.05$). Total volatile fatty acid ($P < 0.001$) and acetate ($p < 0.05$) were increased significantly, but butyrate decreased ($P < 0.01$) by adding DF. Addition of DF tended

to decrease ammonia N production ($P = 0.081$). The populations of methanogens, protozoa, fungi and *R. flavefaciens* decreased ($P < 0.001$) in fluid samples by DF addition, whereas *R. albus* populations increased both in fluid ($P = 0.011$) and solid ($P < 0.001$) samples. Experiment 2 was conducted to observe the dynamics of DF addition on rumen fermentation and bacterial growth. Three cannulated sheep were fed continuously for 42 d on a diet (concentration/forage=30:70) added with 20g/d DF. Rumen samples were collected every 7 d after the first 14d for adaptation. No apparent effects were observed ($P > 0.05$) of DF on pH, acetate and butyrate. Addition of DF produced dynamic changes in propionate ($P = 0.043$), ammonia N ($P = 0.0006$), and growth of fluid-and-solid-associated microorganisms. The populations of methanogens and *R. flavefaciens* decreased ($P < 0.0001$) linearly in fluid samples, but the *R. albus* populations increased in both fluid and solid samples ($P < 0.0001$). These results demonstrated the ability of DF addition to improve *in vivo* rumen fermentation by increasing total VFA production, and to influence bacterial populations of the rumen in sheep under high-forage diets in a positive way by increasing *R. albus* and decreasing methanogens.

Key Words: Disodium Fumarate, Ruminal Metabolism, Microbial Populations

336 Extract from *Larrea tridentata* reduces growth of rumen bacteria. J. Browne-Silva, S. L. Lodge-Ivey*, J. Petersen, R. Reyna-Islas, and M. B. Horvath, New Mexico State University, Las Cruces.

Larrea tridentata plant extract (CBPE) has antioxidant and antimicrobial properties. The use antimicrobials for growth promotion in livestock has been criticized and resulted in an interest in the use of natural plant extracts as rumen modifiers. The effect of the consumption of CBPE on rumen bacteria and fermentation has not been documented. An *in vitro* experiment was conducted to evaluate the effect of CBPE on growth of pure cultures of rumen bacteria and microbes found in whole rumen fluid from a cow. Varying levels of CBPE were dissolved in ethanol and added to pure culture incubations at 0, 5, 10, 50, and 100 $\mu\text{g}/\text{mL}$. Similarly, CBPE was added to growth medium with microbes from whole rumen fluid at 0, 10, 20, 30, 40, 50, 60, 70, 80, 100, 150, 200, 250, 300, 400, 500 $\mu\text{g}/\text{mL}$. Growth was monitored by optical density (OD) at 600 nm. Independent of species, additions of (0 vs 100 $\mu\text{g}/\text{mL}$) to pure cultures of rumen bacteria caused a 35 fold decrease in OD (0.71 vs 0.02; $P < 0.001$). Addition of 10 $\mu\text{g}/\text{mL}$ CBPE caused a 62% decrease in OD compared with 0; $\mu\text{g}/\text{mL}$. Ethanol control was similar (0.57 vs 0.71) to 5 $\mu\text{g}/\text{mL}$ CBPE (0.51; $P > 0.10$). Growth of *Butyrivibrio fibrisolvens* H17E, *Prevotella ruminicola* GA33, and *Ruminococcus albus* 8 was most affected by CBPE compared to *P. ruminicola* 118B, *R. flavefaciens* FD1, and *Streptococcus bovis* JB1 (0.01, 0.20, 0.10 vs 0.59, 0.58, 0.65, respectively). Growth of microbes in whole rumen fluid was not affected until 100 $\mu\text{g}/\text{mL}$ of CBPE was added to the growth medium ($P > 0.05$). There was a 133% reduction in OD between 0 vs 100 $\mu\text{g}/\text{mL}$ CBPE (0.60 vs 0.08) and a 50% reduction when comparing 50 vs 100 $\mu\text{g}/\text{mL}$ CBPE ($P < 0.001$). Addition of CBPE greater than 100 $\mu\text{g}/\text{mL}$ did not result ($P > 0.05$) in a decrease in OD. These data suggest that CBPE is toxic to rumen bacteria. Level of toxicity is dependent upon species and mixture of bacteria present. The bioconversion of CBPE by rumen bacteria is currently under investigation.

Key Words: Rumen Bacteria, Antibiotics, Plant Extract

337 Effects of a combination of feed additives on methane production, diet digestibility and animal performance in lactating dairy cows. S. M. van Zijderveld^{*1,2}, B. C. J. Fonken^{1,2}, J. R. Newbold³, W. B. Fokkink³, J. Dijkstra², W. J. J. Gerrits², and H. B. Perdok¹, ¹Provimi B.V., Rotterdam, the Netherlands, ²Animal Nutrition Group, Wageningen University, Wageningen, the Netherlands, ³Provimi Research and Innovation Centre, Brussels, Belgium.

An experiment was conducted to study the effects of a mixture of lauric acid (C12:0), myristic acid (C14:0), linseed oil and calcium fumarate on methane production, diet digestibility and milk production. Inclusion rates of the additives were 0.4, 1.2, 1.5 and 0.7% of DM, respectively. The basal diet comprised (DM basis) 37.1% grass silage, 37.1% corn silage, 1.7% wheat straw and 42.0% concentrate. The experiment was designed as a randomized block design and conducted using 20 lactating Holstein-Friesian dairy cows (FPCM production 32.8 ± 4.9 kg/d, 176 ± 76 DIM at the start of the experiment). Cows were assigned to either the control treatment (CON) or the treatment receiving the additives (ADD) for treatment periods of 22 days. In the ADD ration, rumen-inert fat from palm oil was substituted for lauric acid, myristic acid and linseed oil to maintain diets isolipidic. Cows were housed in 2 identical, open-circuit, indirect climate respiration chambers (2 cows per chamber) during experimental observations in the third week. As a consequence of restricted feeding, DMI did not differ between treatments (16.7 and 16.5 kg DM/day for CON and ADD, respectively). Apparent digestibility of OM, N, starch and sugar were unaffected, apparent fat digestibility was higher for ADD (65.6 vs 75.6%, P= 0.01). Daily milk yield did not differ between treatments (27.8 vs. 27.2 kg/day, P=0.70). Milk fat concentration tended to be lower (P = 0.06) in ADD (41.0 g/kg) than in CON (46.3 g/kg). FPCM production was lower for ADD as a result of the lower fat content for this treatment (29.4 vs 27.4 kg/d, P= 0.02). MUN levels were significantly lower for ADD (10.3 vs. 8.0 mg/dl, P=0.02), possibly reflecting a defaunating effect of the additives, with a consequentially lower rumen ammonia production. Methane production was lower for ADD relative to CON (362 vs. 326 g methane/cow/day, P = 0.02).

Key Words: Methane, Digestibility, Dairy Cows

338 Ruminal parameters of cattle drenched with a placebo or live cultures of *Megasphaera elsdenii* strain CH4. M. R. McDaniel^{*1}, J. J. Higgins¹, J. M. Heidenreich¹, M. K. Shelor¹, G. L. Parsons¹, P. H. Henning², and J. S. Drouillard¹, ¹Kansas State University, Manhattan, ²KK Animal Nutrition, Centurion, South Africa.

A metabolism study was conducted to evaluate ruminal parameters in cattle intraruminally dosed with 0, 1x10¹⁰, 1x10¹¹, or 1x10¹² CFU of *Megasphaera elsdenii* strain CH4 following an abrupt change from an all-forage diet to a 66% concentrate diet. Angus steers (n=20; average BW=253 kg) fitted with ruminal fistulas were blocked by BW and assigned randomly to treatments. Cattle were allowed free access to alfalfa hay and water, which were removed for 12 h prior to administering treatments. *Megasphaera* treatments were dosed via the rumen cannula as a liquid suspension containing 10⁹ viable cells/mL of *M. elsdenii* strain CH4. The placebo consisted of 100 mL of autoclaved culture. On the morning of the diet change, cattle were administered their treatments and then allowed free access to a diet consisting of 34% alfalfa hay and 66% concentrate. Ruminal pH and concentrations of lactate and VFAs were monitored following introduction of the concentrate diet. Ruminal lactate concentrations increased in response to

the diet change (P<0.05), but concentrations were lower for cattle that received *M. elsdenii* compared to the placebo group (P<0.05). Compared to the placebo group, cattle administered *M. elsdenii* maintained higher ruminal pH 24 h after feeding the concentrate diet (P<0.05). Dosing cattle with *M. elsdenii* before introduction of a concentrate diet may reduce the risk of acidosis by preventing accumulation of lactic acid and avoiding severe depressions in ruminal pH.

Table 1. Ruminal VFA, lactate, and pH of cattle intraruminally dosed with 0, 1x10¹⁰, 1x10¹¹, or 1x10¹² CFU of *M. elsdenii* strain CH4.

	Colony forming units of <i>M. elsdenii</i> strain CH4								
	0		1x10 ¹⁰		1x10 ¹¹		1x10 ¹²

Key Words: *Megasphaera elsdenii*, Lactate, VFA

339 Quantitative detection of bacterial genomes following intraruminal dosing of cattle with *Megasphaera elsdenii* strain CH4. M. R. McDaniel^{*1}, J. J. Higgins¹, J. M. Heidenreich¹, M. K. Shelor¹, G. L. Parsons¹, P. H. Henning², and J. S. Drouillard¹, ¹Kansas State University, Manhattan, ²KK Animal Nutrition, Centurion, South Africa.

Angus steers (n=20; average BW=253 kg) fitted with ruminal fistulas were used to quantify changes in bacterial populations following intraruminal dosing with *Megasphaera elsdenii* strain CH4. Treatments consisted of inoculation with a placebo (100 mL of autoclaved culture) or 1x10¹⁰, 1x10¹¹, or 1x10¹² CFU of *M. elsdenii* strain CH4. Cattle were blocked by initial BW, assigned randomly to treatments, placed into individual pens, and allowed *ad libitum* access to alfalfa hay, salt, and water for a 3-wk adaptation period. Treatments were administered via the ruminal cannula following 12 h of feed and water deprivation. Immediately after dosing, steers were given *ad libitum* access to a diet consisting of 34% roughage and 66% concentrate. Ruminal samples were collected at 0, 2, 4, 6, 8, and 24 h after feeding for quantitative rt-PCR detection of native and introduced strains of *M. elsdenii*, as well as total bacterial genomes. Capacity for metabolism of lactic acid was evaluated by inoculating 0.2 mL of strained ruminal fluid into anaerobic culture tubes containing 15 mL of semi-defined lactate media. Tubes were incubated at 39C, and turbidity changes were determined by measuring absorbance at 2-h intervals for 12 h. Total number of bacterial genomes 24 h after inoculation was unaffected by intraruminal dosing of *M. elsdenii* strain CH4 (P>0.05). Populations of total *M. elsdenii* and *M. elsdenii* strain CH4 increased to 3.6 x 10⁸ and 2.4 x 10⁸ genomes/mL, respectively, by 24 h after inoculation (P<0.05). Turbidity of cultures containing lactate media increased in response to *M. elsdenii* administration (P<0.05), suggesting a greater capacity for lactate utilization

in inoculated cattle compared to the placebo group. Inoculating cattle with *M. elsdenii* is effective in bolstering populations of ruminal lactate utilizers, and may be useful in preventing ruminal lactate accumulation in grain-fed cattle.

Key Words: *Megasphaera elsdenii*, Lactate, Acidosis

340 Bacterial population shifts in the rumen of lactating dairy cows within and across feeding cycles. D. G. Welkie¹, D. M. Stevenson², and P. J. Weimer^{*1,2}, ¹University of Wisconsin, Madison, ²USDA-ARS, Madison, WI.

While species composition of the ruminal microflora is thought to change during the feeding cycle due to variations in feed intake and ruminal environmental conditions, no studies have systematically characterized these purported population shifts. We used PCR amplification and automated ribosomal intergenic spacer analysis (ARISA) of bacterial DNA from bulk liquid and solid samples to profile changes in bacterial community composition (BCC) in 2 rumen-cannulated lactating cows over 4 successive 12-h feeding cycles. Cows were fed a TMR based on corn silage, alfalfa haylage, dry corn, and soybean meal. Ruminal samples were collected 2, 4, 6, 9, and 12 h post-feeding within each cycle. Cows did not differ in ruminal pH patterns and displayed only slight differences in VFA profiles, but displayed considerable differences in BCC. On average, samples contained 119 phylotypes (unique PCR amplicon lengths), of which 82 exceeded 1% of the peak height of the most abundant amplicon on capillary electrophoresis. Mean number of phylotypes did not differ ($P>0.05$) by sample type (solid or liquid), cycle number, or sampling time across cycles. Of 257 total phylotypes detected, only 19 were unique to a one cow. Between cows, 29 phylotypes were detected only in the liquid phase, and 24 of these were common to both cows. By contrast, only 5 phylotypes were detected only in the solid phase, 2 of which were common to both cows. Principal component analysis revealed that bacterial population shifts within and across cycles were much greater in liquid samples than in solid samples. Bacterial populations generally returned to near their pre-feed compositions by the end of each cycle, suggesting that feeding resets BCC.

Key Words: Bacteria, Rumen

341 Effect of lauric acid and coconut oil on ruminal fermentation, digestion, ammonia losses from manure, and milk fatty acid composition in dairy cows. A. N. Hristov^{*1}, M. Vander Pol¹, M. Agle¹, S. Zaman¹, C. Schneider¹, P. Ndegwa², V. K. Vaddella², K. Shingfield³, and K. Johnson², ¹University of Idaho, Moscow, ²Washington State University, Pullman, ³MTT Agrifood Research Finland, Jokioinen.

Six multiparous Holstein cows were used in a replicated 3 × 3 Latin square design trial to investigate the effect of lauric acid (LA) or coconut oil (CO) on ruminal fermentation, nutrient digestibility, and ammonia losses from manure in dairy cows. Treatments consisted of intra-ruminal doses of 240 g/d stearic acid (SA; control), 240 g LA, and 530 g CO administered once daily, before feeding. Between periods, cows were inoculated with ruminal contents from donor cows and allowed a 7-d recovery period. Treatment did not affect ($P = 0.56$ to 0.82) DMI (26.4

kg/d), milk yield (30.2 kg/d), or milk composition. Ruminal pH was slightly increased ($P = 0.04$) by CO compared with the other treatments and ruminal ammonia concentration was decreased ($P = 0.03$) by LA and CO compared with SA (7.9, 7.9, and 10.1 mM, respectively). Protozoal counts were decreased ($P < 0.01$) by LA and CO relative to SA (26.1, 20.0, and 75.4×10^4 , respectively). Methane production rate in the rumen was lowered ($P = 0.05$) by CO compared with LA and SA (2.5, 7.1, and 6.4 g/h, respectively). Total tract apparent digestibility of DM, OM, N, and NDF was not affected ($P = 0.37$ to 0.66) by treatment. Compared with SA, cumulative (15 d) *in vitro* ammonia losses from manure were reduced ($P < 0.01$) by LA, but not by CO ($P = 0.35$). Milk fat 12:0 concentration was increased ($P < 0.001$), while 16:0, 18:0, and total cis 18:1 content was decreased ($P < 0.01$) by LA and CO compared with SA. CO also enhanced ($P < 0.001$) milk 14:0 concentration relative to SA and LA. Treatments had no effect ($P = 0.15$) on milk fat CLA content. Current data confirmed the antiprotozoal activity of LA and CO in the rumen, which was accompanied by decreased ammonia concentration, and for CO reduced methane production. Addition of LA and CO in the rumen significantly altered milk fatty acid composition.

Key Words: Lauric Acid, Coconut Oil, Dairy Cow

342 Effect of esterified linolenic acid addition on methanogenesis, fermentation and microbes in the rumen of sheep fed diets with different forage to concentrate ratios. C. M. Zhang^{*}, J. X. Liu, Z. P. Yuan, X. W. Yi, W. T. Li, and Y. Q. Guo, Zhejiang University, Hangzhou, P.R. China.

This study was conducted to investigate the effect of esterified linolenic acid (ELA) addition on methane production, fermentation characteristics and ruminal microbes in the rumen of sheep fed diets with different forage to concentrate ratio (F/C). The experimental design was a 4 × 4 Latin square with 2 × 2 factorial arrangement of treatments. Four groups of sheep were fed a forage-rich diet without (F/C=70:30, DM basis) or with ELA (F/C=70:25, 5% ELA), a concentrate-rich diet without (F/C=30:70) or with ELA (F/C=25:70, 5% ELA). Methane emission was reduced by addition of ELA markedly. A significant interaction was observed among the basal diet, ELA addition and methane production. Diet type had minor effect on total volatile fatty acids, while ELA addition decreased total volatile fatty acid significantly ($P < 0.05$). Inclusion of ELA decreased molar proportion of acetate and butyrate, and increased molar proportion of propionate in concentrate-rich diet ($P < 0.05$), but had little effect on the fermentation pattern in forage-rich diet ($P > 0.05$). Methanogen and protozoa populations were decreased markedly by ELA addition, but not affected by F/C or their interaction. Growth of fungi was inhibited by the reducing F/C ratio, but little affected by ELA addition and their interaction. Addition of ELA promoted the growth of *R. flavefaciens* and *R. albus* markedly, but had little effect on *F. succinogen* numbers. Reducing F/C ratio decreased *R. albus* population markedly, but had minor effect on growth of *R. flavefaciens* and *F. succinogen*. There were no interactions between F/C and ELA addition on all the determined microbes. It is inferred that interactions of fat with the basal diet have to be taken into consideration to develop effective feeding strategies against ruminal methanogenesis.

Key Words: Esterified Linolenic Acid, Methanogenesis, Rumen Microbes

343 Summary of the effect on ruminal fermentation of Protein Edge® supplementation in continuous culture experiments. C. S. Mooney*, H. M. Dann, C. S. Ballard, K. W. Cotanch, and R. J. Grant, *William H. Miner Agricultural Research Institute, Chazy, NY.*

The objective of this analysis was to determine the effect of feeding bacteria and fungal fermentation extracts, Protein Edge® (PE; Agri-formulations, Inc., Waddington, NY), on *in vitro* fermentation across six continuous culture experiments conducted at Rumen Fermentation Profiling Laboratory (West Virginia University, Morgantown, WV). The six experiments varied in liquid dilution rate (12.0, 12.0, 12.0, 12.0, 13.0, and 8.6%/h), solids dilution rate (3.6, 3.6, 3.6, 3.6, 4.6, and 3.3%/h), measured dietary crude protein (14.6, 14.3, 14.4, 16.5, 18.4, and 14.0%), and measured dietary neutral detergent fiber (35.1, 40.3, 36.8, 38.1, 32.1, and 39.5%), respectively. Within each experiment, treatments were a basal diet (control) and a basal diet supplemented with PE (equivalent to 14.2 to 42.5 g/animal/d) with the number of replicates being ≥3 per treatment. The dataset was analyzed with Analyze Model function of JMP® using fixed effect of experiment, fixed effect of treatment, and experiment by treatment interaction. Supplementation with PE did not affect ($P > 0.14$) digestibility of carbohydrate fractions, chemical composition of the microbial mass exiting the fermenter, or molar proportion and daily production of most volatile fatty acids. However, PE supplementation increased crude protein digestibility (81.7 vs. 74.3%; $P < 0.01$) when compared to control. Overall, PE supplementation affected N metabolism by decreasing bypass N in effluent (0.5 vs. 0.7 g/d; $P < 0.01$) while increasing microbial N (MN) in effluent (1.9 vs. 1.7 g/d; $P < 0.01$) indicating greater capture or retention of N within the microbial mass. Supplementation with PE increased ($P < 0.01$) MN production efficiency (g MN/kg substrate) +10% per kg dry matter, +13% per kg organic matter, and +14% per kg carbohydrate. Across experiments, PE altered N metabolism leading to greater microbial N production efficiency in a continuous culture system. Based on this result, adjustment of microbial efficiency constants within ration balancing programs may be warranted.

Key Words: Nitrogen Efficiency, Continuous Culture, Feed Additive

344 Effect of controlled *in vitro* pH on fermentative activity of ruminal contents from finishing cattle adapted to supplemental dried distiller's grains. S. Uwituzo*, J. M. Heidenreich, T. G. Nagaraja, J. J. Higgins, and J. S. Drouillard, *Kansas State University, Manhattan.*

Ruminal pH typically is lower in cattle fed flaked grain diets compared to cattle fed rolled grain diets; leading us to hypothesize that low ruminal pH may restrict digestion of dried distiller's grains with solubles (DDG) in flaked grain diets. A study was conducted to investigate effects of pH on *in vitro* fermentative activity of ruminal contents from cattle adapted to a finishing diet containing 25% (DM basis) DDG. The study was a randomized complete block design with a 3×4 factorial treatment arrangement. Factors were pH (5, 5.5, or 6) and incubation time (6, 12, 24, and 48 h). A 50:50 mixture of DDG and dry-rolled corn was used as substrate. Fermentations consisting of a 2:1 mixture of McDougall's buffer and ruminal fluid were adjusted to target pH using citric acid. Fermentations were duplicated on each of 3 d (6 observations/treatment). Concentrations of VFA and *in vitro* disappearance of DM (IVDMD) were measured. There was an interaction ($P < 0.01$) between pH and incubation time with respect to concentrations of acetate, propionate, valerate, total VFA, and A:P ratio. VFA concentrations were higher for pH 5.5 and 6 fermentations after 6 and 12 h, but were higher for pH 5 fermentations after 24 and 48 h. IVDMD increased with increasing pH (Lin, $P < 0.01$; Quad, $P < 0.01$) and incubation time. These results may help to explain decreases in cattle performance and diet digestibility when distiller's grains are substituted for steam-flaked grains.

Table 1. *In vitro* fermentation of a 50:50 dry rolled corn:DDG substrate by ruminal contents from cattle adapted to DDG

Item	Incubation time, h				Contrasts P-Values ^a			
	6	12	24	48	1	2	3	4
Total VFA, mM					0.55	0.01	<0.01	0.35
pH 5	49	103	167	170				
pH 5.5	91	115	154	158				
pH 6	93	123	152	136				
IVDMD,%					<0.01	<0.01	0.23	<0.01
pH 5	34	38	48	54				
pH 5.5	37	46	48	59				
pH 6	56	58	61	67				

^aContrasts are 1 = effect of pH; 2 = effect of incubation time; 3 = time \times pH interaction; and 4 = pH 5 vs average of pH 5.5 & 6

Small Ruminant: Goats and Sheep

345 ASAS Centennial Presentation: Impact of animal science research on U.S. goat production and predictions for the future. T. Sahlu*¹, L. J. Dawson^{1,2}, T. A. Gipson¹, S. P. Hart¹, R. C. Merkel¹, R. Puchala¹, Z. Wang¹, S. Zeng¹, and A. L. Goetsch¹, ¹American Institute for Goat Research, Langston University, Langston, OK, ²Oklahoma State University, Stillwater.

Goat research in the U.S. has increased but at a rate less than that in production. Research on goat meat includes nutritional quality, packaging, color, sensory characteristics, and preharvest management. Goat skins have value for leather, yet quality of goat leather has not been extensively studied. Research in the production, quality, antibiotic residues, and sensory characteristics of goat milk and its products has aided development of the U.S. dairy goat industry. Limited progress has been made in genetic improvement of milk or meat production. There is need to explore applications of genomics and proteomics and improve consistency in texture and functionality of goat cheeses. New goat meat and milk products are needed to increase demand and meet the diverse tastes of the American public. Despite research progress in control of mohair and cashmere growth, erratic prices and sale of raw materials have contributed to further declines in U.S. production. Innovative and cooperative ventures are needed for profit sharing up to the consumer level. Internal parasites pose the greatest challenge to goat production in humid areas largely because of anthelmintic resistance. Study of alternative controls is needed, including immunity enhancement via nutrition, vaccination, pasture management such as co-grazing with cattle, and genetic resistance. Similarly, the importance of health management is increasing related in part to a lack of effective vaccines for many diseases. Nutrition research should address requirements for vitamins and minerals, efficiencies of protein utilization, adjusting energy requirements for nutritional plane, acclimatization, and grazing conditions, feed intake prediction, and management practices for rapid-growth 'feedlot' production systems. Moreover, efficient technology transfer methods are needed to disseminate current knowledge and that gained in future research.

Key Words: Goats, Research

346 Effects of kidding season on performance of meat goat does in Kentucky. K. M. Andries* and E. Sherrow, *Kentucky State University, Frankfort.*

Price for meat goats are showing a seasonal trend with prices generally starting to rise in late fall and winter and peaking in spring with the lowest prices seen during late summer. Because of this many goat producers in Kentucky are moving their kidding season to late fall or winter with little information on the impact this may have on herd performance. A study was designed to evaluate doe performance using two kidding seasons. The objectives of this study were to evaluate doe performance by comparing total birth, 60 day and 90 day kid weight, doe productivity ratio, conception rate, and kid survival to weaning in two alternative kidding seasons. One hundred and twenty commercial meat type does were randomly assigned to either a fall (late October, November, and December) or spring (late March, April, and May) kidding season. Data collected during the first two years included birth weight, birth type, sex, 60 day weight, and 90 day weaning weight on the kids. Sixty day weight was adjusted for age and 90 day weights were

adjusted for sex, age, and age of dam. Doe weight and body condition score were taken at weaning (90 days) and the productivity ratio was calculated by dividing the total weight of kids at 90 days by the doe weight taken at weaning. Kidding season had a significant ($p < .01$) effect on doe weight, total weight at 60 days, conception rate, and number of kids born per doe. Season also had a slightly significant effect on total birth weight ($p = 0.0487$). Doe weight and total birth weight were higher in fall than spring, however total 60 day weight, conception rate, and number of kids born per doe were higher for spring kidding groups. Interaction between year and kidding season was significant ($p < .01$) for productivity ratio, number born, number at 60 days, and number at 90 days ($p = .022$). This indicates that kidding season does not have a strong influence on kid weight per doe. However, differences in conception rate and kids born per doe may decrease profitability of fall and early winter kidding programs.

Key Words: Meat Goats, Season of Birth, Efficiency

347 Use of electronic rumen boluses for the identification of different goat breeds in the U.S. S. Carné*¹, T. A. Gipson², M. Rovai^{1,2}, R. C. Merkel², and G. Caja¹, ¹Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain, ²E. (Kika) de la Garza American Institute for Goat Research, Langston University, Langston, OK.

With the aim of assessing the influence of breed on electronic bolus retention, 295 goats from 4 breeds were identified with 3 bolus types containing 32 mm HDX transponders. Ruminant pH was used as an indicator to evaluate feeding conditions. Bolus features were: **B1** (75 g, 68.2 × 21.0 mm, n = 100), **B2** (82 g, 69.1 × 21.2 mm, n = 100) and **B3** (20 g, 56.4 × 11.2 mm, n = 95). Distribution of boluses by breed and bolus type (B1, B2, B3) was: Alpine (25, 24, 25), Boer-cross (26, 24, 23), Angora (25, 26, 24) and Spanish (25, 25, 23). Goats were also identified with a standard flag-button plastic ear tag (4.6 g, 51 × 41 mm). Boluses were administered with a balling gun adapted to each bolus type. Time required for bolus administration was recorded as well as any incident observed. An ISO handheld reader was used to read the boluses. Retention rate (read/applied × 100) of boluses and ear tags was recorded at d 1, 7, 30, 60 and 120. Ruminant pH was measured with a portable pH meter, in random samples of 5 goats from each breed and feeding conditions, after bolus administration and at wk 1, 2, 3 and 4. Ruminant fluid was obtained at 2 h after feeding by using an oro-ruminal probe. Time required for bolus administration varied according to bolus type (B1, 24 ± 2 s; B2, 27 ± 2 s; B3, 14 ± 2 s; $P < 0.05$) and goat breed (Alpine, 34 ± 3 s; Boer-cross, 16 ± 1 s; Angora, 17 ± 2 s; Spanish, 19 ± 2 s; $P < 0.05$). No health or behavior disturbances were observed. Ruminant pH differed according to breed and feeding conditions (lactating Alpine, 6.50 ± 0.07; yearling Alpine, 6.73 ± 0.08; Boer-cross, 6.62 ± 0.04; Angora, 6.34 ± 0.06; Spanish, 6.32 ± 0.08; $P < 0.001$) but showed no influence on bolus retention. Only 1 goat regurgitated a B3 bolus when inverted on an operating table during laparoscopy surgery. At 120 d, bolus retention was greater than ear tag retention (99.7 vs. 97.6%; $P = 0.07$). In conclusion, medium-term bolus retention was not affected by breed and feeding conditions, and remained over the ICAR requirements for official livestock identification (>98%). Long-term bolus and ear tag retention is under study.

348 Comparison of pneumatic, needle-free vaccination to needle vaccination for sheep. M. R. Mousel^{*1}, T. D. Leeds¹, S. N. White², and L. M. Herrmann-Hoesing², ¹USDA-ARS U.S. Sheep Experiment Station, Dubois, ID, ²USDA-ARS Animal Disease Research Unit, Pullman, WA.

Administering vaccines using needle-free injection technology as opposed to traditional needles would likely reduce the lateral spread of infectious diseases in sheep flocks. In addition, needle-free technology could reduce the damage to carcasses caused by needle injections (i.e., lesions and broken needle fragments). Therefore, the objectives of this study were to determine whether a pneumatic, needle-free injector could inject s.c. and induce similar antibody responses as traditional needle vaccinations. To determine optimal pressure for s.c. vaccine delivery, 2 8-mo-old wethers received injections of Chinese ink in isotonic, sterile saline at pressures from 207 to 414 kPa in increments of 69 kPa. To evaluate antibody responses, 100 8-mo-old wethers were vaccinated at d 0 with ovalbumin, in an aluminum hydroxide adjuvant and isotonic, sterile saline, using either a needle-free injector or traditional needles. The wethers received a secondary injection of ovalbumin at d 28 using the same type of administration as d 0. Serum samples were collected before vaccination on d 0 and 28, as well as on d 14 and 42. An ELISA was used to determine serum anti ovalbumin antibody titers on d 0, 14, 28, and 42. An optimum pressure of 207 to 276 kPa was determined to deliver a safe and effective s.c. injection using the needle-free method. Serum anti ovalbumin titers at d 14, 28, and 42 were not different ($P > 0.12$) between traditional needle vaccination and pneumatic, needle-free injector. This indicates that needle-free vaccination and traditional needle vaccination produced an equivalent antibody response. Injecting 7 to 9 sheep with the needle-free method (mean 60.6 s) was faster ($P < 0.01$) than changing needles for every animal (mean 155.3 s). In addition, the needle-free injector will reduce biohazard waste, eliminate the possibility of accidental needle sticks for livestock handlers, and will likely reduce iatrogenic infection of sheep.

349 Expected rank correlations for varying degrees of ultrasound accuracy. T. D. Leeds^{*1}, C. A. Moffet¹, D. R. Notter², and G. S. Lewis¹, ¹USDA, ARS, U.S. Sheep Experiment Station, Dubois, ID, ²Virginia Polytechnic Institute and State University, Blacksburg.

Live-animal ultrasound backfat thickness (BF) and loin muscle area (LMA) data must be accurate to correctly rank animals. The Beef Improvement Federation and National Swine Improvement Federation have established accuracy criteria for their respective species, but no such criteria have been established for sheep. We used Monte Carlo simulation to derive expected rank correlations for varying degrees of ultrasound accuracy (i.e., SE of prediction; SEP) for BF and LMA in cattle, pigs, and sheep. Normally-distributed carcass BF and LMA data were simulated ($n = 100 \text{ records} \cdot \text{trait}^{-1} \cdot \text{species}^{-1}$) using species-specific mean and SD estimates for each of 10,000 replications. Estimates used for cattle, pigs, and sheep, respectively, were: BF mean = 1.14, 1.74, and 0.571 cm; BF SD = 0.510, 0.500, and 0.225 cm; LMA mean = 80.6, 43.3, and 16.7 cm²; LMA SD = 9.10, 5.64, and 2.67 cm². For each replication, unbiased ultrasound data were generated as carcass data + variate ($N(0, \sigma = \text{SEP})$) for a range of ultrasound accuracy. Spearman rank correlations between the carcass and ultrasound data were

calculated for each replication. Means and SD of the rank correlation estimates were calculated across all replications within each degree of ultrasound accuracy. Means and SD of the rank correlations were described as a function of SEP using polynomial regression. As expected, rank correlations decreased, and SD of rank correlations increased, as SEP increased. The maximum SEP to achieve an expected rank correlation of 0.85 (arbitrary) between carcass and ultrasound measures for cattle, pigs, and sheep, respectively, were: BF = 0.290, 0.285, and 0.125 cm; LMA = 5.24, 3.25, and 1.53 cm². At these SEP, the SD of rank correlation estimates for all traits within all species was approximately 0.031. The SEP values reported here are based on an arbitrary rank correlation value, and are dependent upon trait variation within populations. However, this report describes an objective approach for establishing ultrasound accuracy criteria in sheep.

Key Words: Sheep, Ultrasound, Accuracy

350 Backfat thickness, LM area, and LM depth effects on carcass yield, composition, and value in sheep. T. D. Leeds^{*1}, M. R. Mousel¹, D. R. Notter², H. N. Zerby³, C. A. Moffet¹, and G. S. Lewis¹, ¹USDA, ARS, U.S. Sheep Experiment Station, Dubois, ID, ²Virginia Polytechnic Institute and State University, Blacksburg, ³The Ohio State University, Columbus.

Backfat thickness, LM area, and LM depth were measured on 172 wethers to determine relationships between these measures and carcass yield, composition, and value. Wethers were F₁ progeny from the mating of 4 terminal sire breeds to Rambouillet ewes and were finished on a concentrate diet to a mean BW of 62.9 kg (SD = 9.5 kg). Before transport to harvest, LM area, LM depth, and backfat thickness were measured from transverse ultrasound images taken between the 12th and 13th ribs. After harvest, these measures were taken on the carcasses. The SE of prediction, a measure of ultrasound accuracy, for the technician were 0.140 cm, 1.55 cm², and 0.263 cm for backfat thickness, LM area, and LM depth, respectively. Carcasses were fabricated into subprimal items, and weights were recorded. Carcass yield, composition, and value were described using linear models that included fixed effects of BW (or carcass weight), breed of sire, backfat thickness, and LM area (or LM depth). At a standardized BW and backfat thickness, wethers with larger LM area and LM depth yielded larger and more valuable carcasses, and these relationships were detectable with ultrasound. For each SD increase in carcass LM area, dressing percentage increased 1.57 percentage points, gross carcass value increased US\$5.12, and boxed carcass value increased US\$6.84 ($P < 0.001$). For each SD increase in ultrasound LM area, dressing percentage increased 0.95 percentage points, gross carcass value increased US\$3.15, and boxed carcass value increased US\$3.86 ($P < 0.001$). The response in boxed carcass value attributed to disproportionate increases in high-value subprimal item weights was small. Responses in dressing percentage and carcass value were significant ($P < 0.01$) for ultrasound and carcass LM depth, but were smaller in magnitude when compared with LM area. These data indicate biological and economical incentives for increasing LM area in wethers, and live-animal ultrasound can provide reliable estimates of carcass measures. These results are applicable to terminal sire breeders and producers who market sheep using carcass-merit pricing systems.

Key Words: Sheep, Ultrasound, Carcass yield

351 Phenotypic correlations among growth and carcass traits of Polypay and White Dorper × Polypay crossbred lambs. D. K. Aaron*, D. G. Ely, E. Fink, B. T. Burden, M. M. Simpson, and A. K. Lunsford, *University of Kentucky, Lexington*.

Wether lambs from two genetic types, Polypay (PP; n = 32) and White Dorper (WD) x PP crosses (WDX: 1/2 WD x 1/2 PP, n = 36; 3/4 WD x 1/4 PP, n = 34; 7/8 WD x 1/8 PP, n = 18; 15/16 WD x 1/16 PP, n = 12), were used to estimate phenotypic correlations among growth and carcass traits. Wethers were weaned at an average of 70 d of age and 26 kg, were managed postweaning on pasture and supplemented with grain at 2 to 3% BW, and were harvested at an average of 208 d of age and 55 kg. Partial correlations among growth and carcass traits, pooled within model fixed effects, were obtained separately for PP and WDX using multivariate procedures. Homogeneity of genetic type correlations were tested using Chi-square criteria. In general, correlations were homogenous between PP and WDX; thus, data were combined and pooled within genetic type correlations calculated. When heterogeneous correlations ($P < 0.05$)

were observed, they involved associations with live and carcass weights. Overall, weaning weight was positively correlated ($P < 0.05$) with final weight (0.48), hot carcass weight (0.40), leg (0.40), rack (0.20), and shoulder (0.20) weights but was negatively correlated with postweaning ADG (-0.50) and harvest age (-0.30). Postweaning ADG was positively associated with final weight (0.22; $P < 0.05$) but negatively associated with harvest age (-0.45; $P < 0.05$). Dressing percentage was positively correlated ($P < 0.05$) with hot carcass weight (0.57), rib fat (0.36), body wall thickness (0.37), yield grade (0.36) and leg, rack, and shoulder weights (0.36, 0.21, and 0.43). Positive correlations ($P < 0.05$) between longissimus muscle area and harvest weight, body wall thickness, and wholesale cut weights indicated moderate to strong relationships. Generally, correlations indicated weak to moderately strong relationships among all growth and carcass traits. Where heterogeneous correlations existed between PP and WDX, they indicated stronger associations among traits measured on WDX lambs.

Swine Species

352 Multi-breed comparison of body composition in swine using dual energy X-ray absorptiometry (DXA) and magnetic resonance imaging (MRI) under special consideration of Cerdo Iberico. A. M. Scholz*, S. Schneider, and P. V. Kremer, *Ludwig Maximilians University Munich, Oberschleissheim, Bavaria, Germany.*

Swine breeders try to meet different consumer demands worldwide. Therefore in this study, totally 77 pigs were studied by dual energy X-ray absorptiometry and magnetic resonance imaging at an average age of the breeding groups between 144 and 160 days. The pigs originated from different extensive or conventional breeds or crossbreeds: Cerdo Iberico (Ib; n=5); Duroc (Du) x Ib (DuIb, n=15); German Landrace + German Large White = White Sow Lines (WSL; n=8), Hampshire (Ha) + Pietrain (Pi) x Ha + Pi x PiHa (Pi_Ha; n=6); Pi x Du + Pi x PiDu (Pi_Du; n=24); and Pi or PiDu x WSL (n=19). A whole body scan was performed by dual energy X-ray absorptiometry with a GE Lunar DPX IQ in order to measure the amount and percentage of fat tissue, lean tissue and bone mineral, while a Siemens Magnetom Open with a large body coil was used for magnetic resonance imaging in the thorax region between 13th and 14th vertebrae in order to measure longissimus muscle and above fat areas of both body sides. A mixed model procedure using SAS 8.2 was used to analyze the data. As expected, the extensive breed Ib followed by DuIb crossbreeds shows the highest body fat content combined with the smallest loin eye areas and a lower body weight at an average age of 154 days. The least amount of fat and largest muscles deposit pigs with pure Ha or Pi x Ha origin. The (white) sow lines and their terminal crossbreeds or crossbreeds with Pi x Du origin show an intermediate body composition. The highest body weights reached DuIb and Pi_Du combined with a completely diverse body composition (DuIb = fat; Pi_Du = lean). DuIb has the significantly highest DXA bone mineral density. Therefore, with exception of Cerdo Iberico itself, DuIb seems to be strongly suited for outdoor swine farming not alone in Spain.

Table 1. DXA and MRI results

Breeding Group	DXA Fat %	DXA BMD g/cm ²	MRI Loin cm ²	MRI Fat cm ²	Body Weight kg
Ib	27.2±1.6 ^a	1.00±.02 ^{ad}	46 ±5 ^a	38 ±3 ^a	47 ±4

353 Performance and carcass characteristics of pigs destined for natural label or commodity pork markets. A. F. Harper*¹, M. J. Estienne¹, T. D. Pringle², and K. A. Alberti¹, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²University of Georgia, Athens.

Weanling pigs (n = 72) were used to assess diet and sire effects on pork produced for natural label or commodity markets. Natural label

diets contained no antimicrobial additives or animal slaughter by-products. Commodity diets contained antimicrobial additives (27 ppm carbadox followed by 33 ppm bacitracin methylene disalicylate) and animal slaughter by-products. Pigs were produced by AI of Yorkshire x Landrace sows using semen from a Berkshire boar or a terminal-line Hampshire boar. Treatments were: natural diets fed to Berkshire-sired pigs, natural diets fed to Hampshire-sired pigs, commodity diets fed to Berkshire-sired pigs and commodity diets fed to Hampshire-sired pigs. There were 6 replicate pens of 3 pigs each per treatment. Feed and water were available ad libitum. Two pigs per pen from 5 replications were selected on d 132 for harvest and carcass evaluation. During the nursery period (d 0 – 34), pigs fed the natural diet had lower ADG (431 vs. 458 ± 9 g, P = 0.06) than those fed the commodity diet; sire effects during the nursery period were not significant (P > 0.16). Thereafter there were no effects of diet or sire on performance during the growing-finishing period (d 35 – 132) or over the entire trial (P > 0.26). Carcass evaluation showed no fat or muscling differences due to diet (P > 0.15), but pigs sired by the Berkshire boar had greater tenth rib back fat thickness (27.2 vs. 21.7 ± 1.4 mm, P = 0.03) and smaller loin muscle area (41.2 vs. 54.5 ± 1.7 square cm, P = 0.001) than pigs sired by the Hampshire boar. Pigs fed the natural diet had greater loin shear force (3.04 vs. 2.56 ± 0.05 kg force, P = 0.05) than those fed the commodity diet. For pigs sired by the Berkshire boar, loin pH was greater (5.57 vs. 5.46 ± 0.03, P = 0.05) and Minolta a* (redness) value was lower (9.8 vs. 11.5 ± 0.4, P = 0.02) than in pigs sired by the Hampshire boar. No other differences in objective pork quality measures were observed (P > 0.37). For the 132 d trial pig performance was similar across feeding programs and sires. Pigs sired by the Berkshire boar produced more subcutaneous fat and less muscling, but differences in pork quality were minor.

Key Words: Pig, Diet, Sire

354 Effect of gender and slaughter age of heavy pigs on production of high quality dry-cured hams. M. A. Latorre*¹, L. Ariño², and B. Blanco³, ¹Centro de Investigación y Tecnología Agroalimentaria de Aragón, Zaragoza, Spain, ²Integraciones Porcinas S.L., Teruel, Spain, ³Jamones y Embutidos Alto Mijares S.L., Teruel, Spain.

High quality dry-cured hams under the protection and designation of “Teruel hams” trademark are produced from heavy pigs in a specific area of Spain. Two aspects are required to consider finally a carcass suitable for Teruel ham; carcass weight and fat depth at Gluteus medius (GM) level should be at least 84 kg and 18 mm, respectively. A total of 120 (Landrace x Large White) x Duroc pigs, with an average age of 176 d, were used to study the effect of gender and slaughter age on growth performance and carcass quality of pigs destined to Teruel ham. There were three treatments; barrows slaughtered at 196 d of age (B; 130.8 kg BW), gilts slaughtered at 203 d of age (G1; 130.2 kg BW), and gilts slaughtered at 210 d of age (G2; 134.3 kg BW). Each treatment was replicated four times (ten pigs penned together). Animals fed commercial wheat, barley, and soybean meal diet, containing 2,360 kcal NE/kg and 0.68% total lysine. B ate more feed (P < 0.001), grew faster (P < 0.05), and showed worse feed conversion ratio (P < 0.01) than G1 or G2. No effect of treatment on carcass weight, and therefore on proportion of carcasses with 84 kg of minimum weight, was detected (P > 0.05). However, B had more fat at GM than G1, with G2 in an intermediate position (P < 0.05). In consequence, B and G2 showed similar percent-

age of carcasses with at least 18 mm of GM fat depth and both higher than G1 ($P < 0.001$). The weight of trimmed ham was not affected by treatment ($P > 0.05$), but the trimmed ham yield was lower in B or in G2 than in G1 ($P < 0.01$). At the end of the trial, B and G2 showed similar final percentage of suitable carcasses for Teruel ham, and both higher than G1 ($P < 0.001$). It is concluded that the production of suitable Teruel ham is optimum for barrows at 130 kg BW. However, an increase in slaughter age by two weeks in gilts, with regard to barrows, improves the production and the homogeneity of Teruel ham.

Key Words: Slaughter Age, Dry-Cured Ham, Pigs

355 Genetic opportunities for pork production without castration. J. W. M. Merks*, K. A. Engelsma, S. Bloemhof, and E. F. Knol, *IPG, Institute for Pig Genetics B.V., Beuningen, The Netherlands.*

Quality of food in terms of health and taste has high priority in our society and consumers do not accept off-flavor meat. Therefore, in most countries, male pigs are castrated shortly after birth to prevent the production of meat with the so called 'boar taint'. However, castration is a surgical intervention which is of growing concern in the society and becoming an animal welfare issue. In addition pork production with entire males is 5-12% more efficient than pork production with male castrates.

The main responsible compounds for boar taint are androstenone and skatole but these substances do not explain the perception of boar taint in taste panels completely. More compounds have recently been discussed in this respect, such as indole, and other steroids of the Δ -16-steroids group.

The genetic aspects of the 3 main boar taint components, androstenone, skatole and indole were investigated in purebred animals of a commercial sire line; more than 1300 fat samples from the neck were collected of pigs with an average live weight at slaughter of 125 kg and analyzed for these 3 compounds. Average values (minimum and maximum) were for androstenone; 1.59 $\mu\text{g/g}$ (0.01 - 10.15), for skatole 0.075 $\mu\text{g/g}$ (0.01 - 0.93) and for indole 0.05 $\mu\text{g/g}$ (0.01 - 0.68).

Heritabilities for the boar taint compounds ranged between 0.25 and 0.75, among others depending on estimated before or after log transformation or as a 0/1 trait with threshold values close to what is generally seen as accepted. The genetic correlations with production traits were close to zero or favorable like with backfat and lean meat%. For female reproduction traits only androstenone showed clearly negative genetic correlations with litter mortality (-0.59), interval weaning- 2nd insemination (-0.44), and with age at first insemination (-0.24). Genetic correlations with the male reproduction traits (volume, motility, longevity of semen) were also close to zero. These results clearly indicate the genetic opportunities to lower concentrations of the main compounds of boar taint, which on long term may enable production of entire male pigs without the problems of boar taint.

Key Words: Castration, Boar Taint, Selection

356 Lignocellulose as dietary fiber source in swine nutrition. A. Kroismayr*^{4,2}, J. Leibetseder¹, C. Plitzner², K. Neufeld³, and P. Affentranger⁴, ¹University of Veterinary Medicine, Vienna, Austria, ²University of Natural Resources and Applied Life Sciences, Vienna, Austria, ³Animal Nutrition Research Center, Austria, ⁴Agromed Austria, Kramsbrunn, Austria/EU, ⁵UFA AG, Switzerland.

Lignocellulose from fresh wood containing fermentable and non-fermentable fiber components is used in animal nutrition as fiber source because of its positive impact on digestion and for prevention of diarrhea. Fermentable and non-fermentable fiber components have different modes of action in the GI tract and seem to influence digestive process positively due to symbiotic activity.

In the presented piglet study, carried out by UFA AG, Switzerland, a combination of fermentable and non-fermentable lignocellulose components was investigated. For the 35 days lasting experiment 228 weaning piglets were split into 2 groups. Control group received a standard weaning diet including organic acids and feed enzymes. Treatment group received the control diet plus 1.5 % of the investigated lignocellulose product. The treatment effects were evaluated by analysis of variance (ANOVA). Means were compared with Bonferroni - Holmes test ($p < 0.05$).

Results show positive influence of lignocellulose on performance of piglets. Daily weight gain was significantly higher in the treated group (364 g per day) compared to the control group (342 g per day). Feed conversion rate was not influenced by the lignocellulose product (1.54 treatment vs. 1.57 control). In conclusion the combination of fermentable and non-fermentable lignocellulose components led to increased performance of piglets in this trial.

357 Effects of crystalline amino acids and sodium bicarbonate on physiological pH in swine. K. L. Dorton, L. N. Edwards*, T. E. Engle, R. M. Enns, and D. B. Anderson, *Colorado State University, Fort Collins.*

This experiment was conducted to determine the effects of dietary inclusion of crystalline amino acids and NaHCO_3 on urine and blood parameters indicative of physiological pH in swine. The experiment was a crossover design study divided into 6 periods consisting of the following: P1) 4 d acclimation phase; P2) 6 d baseline phase; P3) 4 d treatment; P4) 4 d treatment crossover; P5) 2 d sodium bicarbonate (NaHCO_3) addition; and P6: 2 d NaHCO_3 crossover. Barrows ($n = 8$) were stratified by urine pH collected during P2 and by initial body weight. During P3 and P4, treatments consisted of: 1) soybean meal (high protein diet; HP) or 2) crystalline amino acids (low protein diet; CAA). During P5 and P6, treatments consisted of the above diets with and without the addition of NaHCO_3 . Diets were formulated to meet or exceed NRC (1996) requirements for energy, protein, vitamins, and minerals. During P3 and P4, barrows that received HP had a greater stored urine pH (Mean \pm SEM, HP: 7.81 ± 0.08 , CAA: 7.66 ± 0.08 ; $P = 0.02$), blood pH (HP: 7.37 ± 0.008 , CAA: 7.32 ± 0.008 ; $P < 0.01$), blood urea nitrogen (BUN; HP: 10.24 ± 0.63 , CAA: 6.94 ± 0.63 ; $P < 0.01$), and ionized Ca (iCa; HP: 1.48 ± 0.02 , CAA: 1.43 ± 0.02 ; $P = 0.02$), and lower partial pressure carbon dioxide (HP: 55.61 ± 2.44 , CAA: 65.74 ± 2.44 , $P = 0.01$) and sodium concentration (HP: 141.33 ± 0.08 , CAA: 142.08 ± 0.08 , $P < 0.01$) than barrows that received CAA. During P5 and P6, barrows that were supplemented with NaHCO_3 had a greater stored urine pH ($P < 0.01$), base excess ($P < 0.01$), bicarbonate concentration ($P = 0.04$) and total carbon dioxide ($P = 0.05$) and tended to have a greater blood pH ($P = 0.08$). Sodium bicarbonate supplementation also resulted in lower BUN ($P = 0.03$), iCa ($P = 0.01$), potassium concentration (P

= 0.02), chloride concentration ($P = 0.02$), and glucose concentration ($P = 0.02$). These results indicate that the CAA diets were acidogenic and that the addition of 2.5% NaHCO_3 reversed this acidogenesis by affecting physiological indicators of pH.

Key Words: Acid Base Balance, Acidogenic, Dietary Electrolyte Balance

358 Effects of inclusion of fermentable carbohydrates on L-tryptophan metabolism by porcine fecal microbiota studied *in vitro*. C. Y. Li*, J. X. Liu, Y. Z. Wang, Y. M. Wu, and J. K. Wang, *Ministry of Education Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, P.R. China.*

Sugar beet pulp (SBP), rye grass hay (RYE), alfalfa hay (ALF) and fructooligosaccharides (FOS) were used to investigate their effects on the metabolism of L-tryptophan to skatole and indole by a mixed bacterial population from the large intestines of pigs. Microbial suspensions were anaerobically incubated at 38°C, and indole compounds, pH value and volatile fatty acids were analyzed after 24 h fermentation. Effects of carbohydrate sources on the microbial diversity were analyzed using denaturing gradient gel electrophoresis (DGGE) of PCR amplicons of 16S rDNA, cloning and sequencing. Skatole contents and its relative rate of production were significantly decreased by SBP or FOS addition, but increased by addition of RYE or ALF. Rate of tryptophan degradation was reduced by ALF addition remarkably. Total and individual volatile fatty acids were significantly higher in all carbohydrate-added groups than in the none-added. Additions of SBP, RYE, ALF and FOS in pig fecal slurries with L-tryptophan markedly decreased the culture medium pH values. The DGGE profiles showed differences between cultures with different carbohydrate substrates. Fermentation with SBP showed a higher bacterial diversity than with others, with three distinct bands appeared. Sequences of the corresponding 16S rRNA of two bands were related to *Eubacterium rectale* (94%) and *Clostridium sp.* (96%), respectively. Three bands were present only in SBP, RYE and ALF samples. Two of them represented 93 and 98% similarity to *Lachnospira pectinoschiza* and *Clostridium disporicum* DSM 5521, respectively. These results suggest that the reduced contents of skatole observed in the presence of SBP and FOS may be caused by decreased tryptophan degradation to indolic compounds and by shifted microbial metabolism of tryptophan toward indole production at the expense of skatole, resultant from the changed microbial ecosystem and pH value. The bacteria *Clostridium disporicum* DSM 5521 may play a role in the production of skatole.

Key Words: Carbohydrate Sources, Pig Fecal Bacteria, Skatole

359 The impacts of vaccination and feeding a gel nutritional supplement on nursery pig performance. L. Layman*¹, W. Holt¹, L. Karriker¹, K. Stalder¹, B. de Rodas², D. Brown², and A. Johnson¹, ¹Iowa State University, Ames, ²Land O'Lakes Purina Feed, Gray Summit, MO.

An experiment involving 192 weanling pigs (4.2 kg BW) was conducted to determine if feeding a nutritional gel supplement when vaccinated improved pig performance. Pigs were sorted by size and sex and penned in groups of four (12 pens/treatment) in an off-site nursery. Dietary

treatments were applied to pens in a 2x2 factorial arrangement with one factor being with and without vaccination and another factor with and without the nutritional gel supplementation. Pigs in the vaccinated groups received a commercial single dose of *Mycoplasma hyopneumoniae* killed bacterin (2 cc vaccine/pig) on day 10 post-weaning and pigs on the gel group received the nutritional supplementation in a gel form (UltraCare®Gel) on d 9 to 11. All pigs were fed common Phase 1 (d 0 to 7), 2 (d 7 to 14), 3 (d 14 to 28) and 4 (d 28 to 42) diets. Pigs provided the gel weighed more ($P = 0.048$) than non gel pigs on d 14. Pigs not vaccinated tended ($P = 0.08$) to weigh more on d 14 when compared to vaccinated pigs. From d 7 to 14, pigs receiving the nutritional supplementation in the gel form had greater ($P = 0.048$) ADG than pigs not receiving gel and vaccinated pigs had lower ($P = 0.09$) ADG than non-vaccinated pigs. Pigs provided the gel had superior ($P < 0.01$) ADFI during d 9 to 11 when compared to pigs not receiving the gel. Pigs not vaccinated had improved ($P < 0.01$) ADFI on d 10 and d 7 to 14 when compared to vaccinated counterparts. Feed to gain (F/G) from d 7 to 14 was greater ($P = 0.004$) for pigs receiving the nutritional supplementation in a gel form versus those that did not. There were no ($P = 0.98$) vaccination effects for Feed: gain. During the overall 42-d experiment, no ($P > 0.05$) differences were observed in ADG, ADFI or F/G between vaccinated and non-vaccinated pigs or between pigs fed the nutritional supplementation in a gel form and non-gel fed pigs. In conclusion, using a gel-based product at vaccination time for nursery pigs offers some short term performance benefits.

Key Words: Gel, Pigs, Vaccination

360 Integrating benefits of organic apple and pork production: Evaluation of Plum curculio larva survival with ingestion and passage through the pigs' digestive tract. D. W. Rozeboom*, D. L. Epstein, J. M. B. Moore, and M. E. Whalon, *Michigan State University, East Lansing.*

The ability of the Plum curculio larvae to survive passage through the pigs' digestive tract was tested by feeding known numbers of live larvae and examining total fecal collections in a 5-day feeding study. Plum curculio, *Conotrachelus nemuphar*, is a pest management challenge faced by upper Midwest organic fruit growers. The overarching project goal was to develop a system that integrates swine grazing for control of the Plum curculio insect, while enhancing profit potential through sales of organic apples and pork. This experiment was conducted to understand the effectiveness of grazing pigs in consuming and killing the Plum curculio larvae residing in dropped apples on the orchard floor. Six barrows weighing 28.7 to 33.1 kg, were individually-housed in a 1.2 x 1.8 m pens equipped with low-pressure nipple drinkers. Flooring was perforated plastic to allow urine to pass uncollected through to concrete flooring and drains about 30 cm below. Fencing was solid plastic in order to prevent neighboring pigs from interfering with the collection of feces which was done using bags directly attached on the skin surrounding the anus. Each morning, pigs received 9 to 15 live Plum curculio larvae which had been gently mixed into 110 g of apple pulp. After consumption of the pulp-larvae mixture, pigs were given 340 g of a corn-soybean meal based diet. Two other meals of similar amounts of pulp and dry feed were provided in the afternoon and evening. Fecal bags were changed 3 times daily and feces were gently washed using flowing water, a soft spatula, and grain screens. A total of 264 Plum curculio larvae were fed in 26 meals which were followed by complete 24-h fecal collections. In 3 instances fecal bags had been detached prior to staff arrival and feces lost. No live Plum curculio larvae were found in any of the complete

fecal collections. The remains or carcass of one dead larva was found in the feces of one pig on d 2. This experiment demonstrated that ingestion by pigs was lethal to *Plum curculio* larvae.

Key Words: Pig, *Plum Curculio*, Organic

361 Effects of environment on non-ambulatory, injured and fatigued pigs and losses during transport and lairage at a commercial abattoir. R. Fitzgerald^{*1}, K. Stalder¹, N. Matthews², C. Schultz-Kaster², and A. Johnson¹, ¹*Iowa State University, Ames*, ²*Farmland Foods, Milan, MO*.

The objective of this retrospective study was to quantify the effects of harvest week, weather, and transport conditions that influence the frequency of non-ambulatory, injured and fatigued pigs and mortalities during transport and lairage. A total of 1,923,441 pigs were harvested at a commercial abattoir. Relative humidity, temperature, wind speed, and dew point were collected for trailer loads (n = 11,553) from of pigs May 2005 to April 2006. A temperature-humidity index was cal-

culated (NOAA,1976) and was used as a model covariate along with load time per pig, trailer density, and pig rest time. Week, pull nested within farm, split or normal load type, load crew, driver, trailer, wind direction, and wind speed were used as fixed effects in the model for the analysis of total defects (defects = fatigued + injured + dead pigs per trailer load) percentage per load using generalized linear models (GLIMMIX, SAS Inst. Inc.). The ILINK function was used to convert logarithmically-transformed trait means to their original units of measure. The frequency of fatigued, injured, and dead pigs occurred at 5.46 (n = 10510), 0.55 (n = 1061), and 2.32 (n = 4459) per thousand pigs transported, and 60.03% of the loads resulted in at least one defect. Pigs transported to the abattoir during summer months (June – August) resulted in fewer defects (P<0.001) than pigs transported during winter months (December – February) due to a higher incidence of fatigued and dead pigs. Contrarily, injured pigs increased in frequency during July through October. Percentage of defects increased (P<0.0001) with trailer density. The results of this study demonstrate that multiple factors influence and could be modified to reduce the percentage of defects per load of finishing pigs.

362 ASAS Centennial Presentation: Animal science teaching: A century of excellence. D. S. Buchanan*¹ and L. C. Martin², ¹North Dakota State University, Fargo, ²The Ohio State University, Columbus.

Teaching has been central to the life of many members of ASAS since the organization's inception one hundred years ago. A high proportion of the scientists who publish research in the Journal of Animal Science or who present the results of research at the annual meetings also hold a teaching appointment. Virtually all members of ASAS are the product of animal science teaching programs and ASAS has, and continues to, play a central role in graduate student education. While ASAS recognizes an outstanding teacher with an award each year, those individuals recognized represent but a small sampling of the numerous excellent teachers who populate academic departments associated with ASAS. Teaching programs and symposia have been an area of growth at the annual meeting of ASAS during the last few decades as members gather to learn from one another about the latest techniques and innovations. Opportunities for enhancement of teaching programs abound and the student population continues to become more diverse in background, interests and career goals. Individual members of ASAS have been, and continue to be, interested in developing the next generations of animal scientists and leaders in the various industries we serve. Methods of delivery are expanding rapidly. This presentation will explore ways ASAS can build on its rich history and expand its contributions to the teaching of animal science and to the availability and delivery of information pertaining to all types of managed animals.

Key Words: Teaching, Animal Science, Students

363 How current students differ and what impact this has on learning in the classroom. L. C. Martin*, *The Ohio State University, Columbus.*

Effective teaching depends upon being able to connect with students. Because learning is contextual, a better understanding of student interests, values and perceptions serves to provide a stronger foundation for effective teaching within the discipline. Millennials (those born between 1982 and 2002) represent the second largest generation in history (second only to the baby boomers) and have unique characteristics that differentiate them from previous generations. Because they have different needs and expectations, educators have found it challenging to engage this new generation of learners. The millennial generation is the most diverse in history (only about 60% white), a growing number of students are delaying enrollment in college and fewer young men are choosing to pursue higher education. Millennials communicate via social networks, instant messaging, text messaging and occasional emails, read magazines rather than newspapers, watch less television, learn by trial and error, and are more consumer driven in their view of higher education. Multitasking is a way of life; they prefer to keep a flexible schedule and expect institutions to provide more educational choices, greater flexibility, and increased personalization and customization. They become frustrated by delays, seek immediate answers to their questions and resent what they perceive to be "busy work." These unique characteristics have challenged the effectiveness of traditional classroom teaching and are

forcing institutions to consider a new learning paradigm. As animal sciences programs prepare for the future, it will become increasingly more important to consider the unique characteristics of this millennial generation in course and curriculum development, classroom teaching, co-curricular engagement, and student development.

Key Words: Millennials, Teaching, Learning

364 Changes that have occurred in animal science teaching. J. A. Sterle*¹ and J. J. Parrish², ¹Texas A&M University, College Station, ²University of Wisconsin, Madison.

A centennial is a time to reflect on the journey that has taken us to the present point. It is a time to celebrate accomplishments, recall fond memories, and anticipate the future. The committees planning the centennial meeting of the American Society of Animal Science were charged with the task of selecting a "classic" paper and re-presenting it. While this approach works well for the committees representing disciplines (animal breeding, physiology, etc.), the Undergraduate and Graduate Teaching committee decided on a different approach. Finding it nearly impossible to select only one outstanding educator throughout Animal Science departments nationwide, the committee decided to create a video of multiple outstanding teachers. By capturing these individuals and their teaching philosophies on tape, this precious bit of history could be preserved. Short video segments were recorded at the home institutions of faculty members who were well-known for excellence in teaching. The segments were edited and produced into a short video segment for inclusion of the centennial celebration.

Key Words: Teaching, Centennial, History

365 The use of multimedia in the classroom. H. Khatib*, *University of Wisconsin, Madison.*

The use of multimedia in classroom is not new. It has been used for the last several decades in the form of overhead projectors, slide shows, filmstrips, among other tools. However, with the introduction of the computer and other electronic devices, multimedia is now being used in a number of ways including PowerPoint, digital videos, case studies, newsgroups, mailing lists, YouTube and more. Multimedia is motivating for most learners in that they enjoy working with it and the combination of pictures, text, audio and video provides a stimulating environment for students. I extensively utilize PowerPoint and elements of multimedia including videos, YouTube films, web sites, and other visual aids to make connections between genetics and real life. For example, in a lecture about African trypanosomiasis, a short video telling a story of an African woman affected with sleeping sickness was presented. In a different lecture about host pathogen interaction, a cartoon of Tom & Jerry was presented as an example of how pathogens escape the immune system of the host. In a lecture about the applications of DNA, I used music as an example. Music was composed algorithmically from the raw genetic data and protein sequences and is available as free downloads on the internet. Materials from web-sites about musical DNA were

presented. In a lecture about transgenics in animals, PowerPoint slides on transgenic plants were presented. Inspired by the presentation, the students were asked to draw figures on the power of genetic engineering in animals. Additional examples and feedback of the students will be further discussed. My conclusions are that the use of multimedia in classroom leads teachers to think about their students, classes, and lessons in new ways and that it moves instructors from the role of classroom authority into the role of learning coach or facilitator.

Key Words: Multimedia, Genetics, Undergraduate

366 The use of podcasts in the classroom. J. J. Parrish*, *University of Wisconsin, Madison.*

Podcasts are a method to deliver video, images and/or sound via the web. The effect of podcasts on student learning was investigated in an undergraduate reproduction course; 2-50 minute lectures and a 2 hour lab each week. The course is required for both Animal and Dairy Science majors. In year 1 (students=52), lectures were delivered in a traditional classroom setting using powerpoint slides. In year 2 (students=61), the instructor was gone due to sabbatical leave. Labs were given by a TA the same as in year 1. The lectures however were recorded via the commercial software, Profcast. The software allows recording of a powerpoint presentation's slides, complete with audio synchronized to each slide. The resulting file is posted to the web, can be downloaded and replayed in iTunes, a free digital media player application. Students could either take the course in year 2 or wait an additional year if they did not want to take a podcast only delivered lecture. It was unlikely that any pre-selection of students occurred. There was an improvement in exam scores of 10% in year 2 ($p < 0.05$) with a doubling of essay question scores. The same exams were given in year 1 and 2 and also in years 0 and -1. In years -1, 0, and 1, there were no differences in exam scores ($p > 0.05$). Exams in this class are not returned to students but they have access to on-line practice questions that were available in both year 1 and 2. Despite the improvement in learning, there was a trend toward less satisfaction on course evaluations. While many students liked the podcast format, some expressed an inability to ask questions as a problem. Improvement in learning outcomes may be due to allowing students to listen to the lecture at a time when they are better able to retain information. Normally, this class is offered from 8:50 – 9:40 AM and lecture attendance is around 80%. Students indicated they listened to podcasts in the afternoon or evening. Podcasts provide a method to deliver lectures or other course material where students select the viewing time. Podcast are particularly well suited for distance education and

increased student access but may require additional opportunities for student teacher interaction.

Key Words: Podcast, Web

367 Teaching and learning with an instructional web site. M. A. Wattiaux*, *University of Wisconsin, Madison.*

Web postings are now commonplace, but pedagogical use of websites remains a challenge. In the last four years, we have adopted a teaching strategy based on in-class discussions of pre-assigned web-postings (<http://dairynutrient.wisc.edu>) and used course evaluations to study students' perception of the class website. The eight classes presented here were taught from the fall (F) of 2005 to the spring (S) of 2007 and included: College Classroom: Teaching in Science and Engineering (F 06, n=14), Environmental Management of Livestock Operations (F 05-06, n=24), Ruminant Nutrition (S 05-06, n=43), Dairy Cattle Husbandry Practicum (S 07, n=18), and Agriculture in Emerging Economies: Dairying in Mexico (F 05-06, n=18). Respondents included 33 graduate and 84 undergraduate students ranging from freshmen to seniors. Scores were on a 1-to-10 Likert-type scale (1 = "not at all" and 10 = "a great deal"). For each of following statements, mean score (a measure of agreement: high score = high agreement) and mean standard deviation (a measure of consensus: high standard deviation = low consensus) were respectively: "I learned a lot", 8.0, 1.7; "The electronic material combined with in-class discussion was good", 8.7, 1.0; "The website was useful", 8.3, 1.9; "The website should be further developed for future classes", 7.0, 2.1; and "Additional class time for lecturing would be helpful", 5.3, 2.4. Students agreed with discussion of pre-assigned material as an alternative to lecture. However, they were divided on the value of additional class time in lecture. For some students the absence of lecture was a welcome departure from tradition. Others may have grown accustomed to lecture or felt less comfortable with an open-ended classroom environment. Scores for further reliance on the website in the future ranged from 4.2 to 8.2. Some students opined that the site "contained all the information that was really needed" or that it had to be maintained as-is because of the good "combination" with in-class material. Creating coherence between the out-of-class web-related components and the in-class components of these courses was a challenge that depended on learning objectives and perceived educational needs of each cohort.

Nonruminant Nutrition: Feed Additives I

368 Effects of mannan oligosaccharide and mannan rich fraction of *Saccharomyces cerevisiae* on production of cytokines by alveolar macrophages. M. T. Che*, R. W. Johnson, K. W. Kelley, and J. E. Pettigrew, *University of Illinois, Urbana*.

The study, consisting of 3 in vitro assays, was conducted to evaluate 1) inflammatory activity of alveolar macrophages (AM Φ) from pigs fed diets supplemented with mannan oligosaccharide (MOS); 2) cytokine production by AM Φ stimulated in vitro with MOS, mannan rich fraction (MRF) of *Saccharomyces cerevisiae* cell wall, Lipopolysaccharide (LPS), and Poly I:C (PLIC). In assay 1, pigs fed diets with 0%, 0.2%, and 0.4% MOS for 2 weeks post-weaning were slaughtered (1 pig/pen, 6 replicate pens) for collection of AM Φ which were stimulated in vitro with LPS or PLIC. In assays 2 & 3, replicates were donor pigs. In assay 2, AM Φ collected from 4 pigs were stimulated with 7 treatment doses of MOS, MRF, LPS, or PLIC. In assay 3a, AM Φ from 6 pigs were stimulated with MOS, LPS, PLIC, MOS plus LPS, and MOS plus PLIC. Assay 3b was identical to 3a but used MRF instead of MOS. AM Φ were cultured for 24 h, washed 3 times, and then stimulated for 24 h prior to collection of supernatants for measurement of pro-inflammatory (TNF- α) and anti-inflammatory (IL-10) cytokines by ELISA. In vitro LPS-stimulated AM Φ from pigs fed 0.2% or 0.4% MOS diets produced less TNF- α ($P < 0.01$) and more IL-10 ($P = 0.051$) than 0% MOS diet. However, no treatment effects on both cytokines were seen when AM Φ were stimulated with PLIC. TNF- α level peaked at stimulating concentrations of 500 $\mu\text{g/mL}$ MOS, 2500 $\mu\text{g/mL}$ MRF, 1 $\mu\text{g/mL}$ LPS, and 50 $\mu\text{g/mL}$ PLIC. Both MOS and MRF suppressed TNF- α response of LPS-stimulated AM Φ ($P < 0.01$), whereas TNF- α production by PLIC-stimulated AM Φ was decreased only by the presence of MRF ($P < 0.01$). IL-10 production by AM Φ stimulated with MOS or MRF was not affected by the presence of LPS or PLIC. In general, feeding MOS to weaned pigs for 2 weeks or in vitro stimulation of MOS reduced TNF- α production of LPS-stimulated AM Φ .

Key Words: MOS, Weaned Pigs, Cytokine Production

369 Effects of dietary yeast culture supplementation to gestation and lactation diets on performance of sows and litters. S. W. Kim*¹, M. Brandhem², B. Newton³, D. Cook³, and I. K. Yoon⁴, ¹*North Carolina State University, Raleigh*, ²*Hitch Pork Producers, Guymon, OK*, ³*Akey, Lewisburg, OH*, ⁴*Diamond V Mills, Cedar Rapids, IA*.

Four hundred ninety one sows at a commercial operation (Hitch Pork Producers, Guymon, OK) were used to determine dietary effects of yeast culture supplementation (XPC, Diamond V XPCTM Yeast Culture, Diamond V Mills, Cedar Rapids, IA) on litter performance. Sows were grouped by parity (primiparous vs. multiparous). Sows within a group were then allotted to 3 treatments consisting of: CON (no added yeast culture), YC5 (5 and 15 g/d XPC during gestation and lactation, respectively), and YC12 (12 and 15 g/d XPC during gestation and lactation, respectively). Sows were housed individually and fed their assigned gestation and lactation diets from d 35 of gestation to d 21 of lactation. Sows were fed 2.0-kg/d during gestation and *ad libitum* during lactation. Voluntary feed intake was measured daily during lactation. At farrowing, total numbers of pigs born and those born alive were measured. Litter weights were measured at birth and weaning on d 21 of lactation. Litter weight gain of multiparous sows in YC5 (47.4 kg) was 7.5% greater ($P <$

0.05) than CON (44.1 kg) but did not differ from sows in YC12 (45.0 kg). Litter weight gain of primiparous sows did not differ among treatment groups. Number of days from weaning to successful breeding of YC5 (5.75 d) and YC12 (6.80 d) was smaller ($P < 0.05$) than CON (8.74 d) for all sows. Voluntary feed intake of primiparous sows did not differ between CON (6.8 kg) and YC5 (6.6 kg); however, sows in YC12 (6.3 kg) had a smaller ($P < 0.05$) voluntary feed intake than CON. Production efficiency (litter weight gain per lactation feed intake of sow) of YC12 (3.19) was greater ($P < 0.05$) than CON (2.98) considering all sows and that of YC5 (3.09) was greater ($P < 0.05$) than CON (2.84) considering multiparous sows only. This study indicates that dietary yeast culture supplementation benefits productivity of multiparous sows by improving litter weight gain and reducing days from weaning to successful breeding. Improvement in litter weight gain may possibly be due to increasing milk nutrient output, which remains to be investigated.

Key Words: Litter Weight Gain, Sow, Yeast Culture

370 In vitro efficacy of yeast cell walls to bind pathogenic bacteria and to influence performance of broiler chickens. A. Ganner*, S. Nitsch, and G. Schatzmayr, *BioMin Research Center, Tulln, Lower Austria, Austria*.

Yeast cell wall products have been proposed to improve livestock health leading to increased performance. Amongst others this effect can be associated with the ability to bind enteropathogenic bacteria.

Aim of this study was to investigate different yeast cell wall products for their ability to bind *Salmonella*, *E. coli*-, *Campylobacter* and *Clostridium* strains. The products were examined with a quantitative microplate-based assay by measuring the optical density as growth parameter of adhering bacteria. 8 out of 10 *S. typhimurium* and *S. enteritidis* strains adhered to cell wall product MOS1 with an amount of up to 105 CFU/ml. 5 different *E. coli* strains (F4; O108 K; O139 K82; O149 K91; O141 K85ac) were tested for their ability to bind to MOS1. 4 of these strains showed an average binding capability (around 102 CFU/ml) whereas 105 *E. coli* F4 cells bound per ml. *C. jejuni* and *C. perfringens* did not bind to MOS1.

A feeding trial with broiler was conducted to evaluate the efficacy of MOS1 in comparison with commercially available MOS products (MOS2 and MOS3) on performance and health status in a 35 days study. 800 one day old mixed sexed broiler were distributed to 4 experimental groups with 8 replicates: control group A, group B (MOS1, 2kg/T), group C (MOS2, 2kg/T) and group D (MOS3, 2kg/T). In the course of the trial a positive influence could be observed by the addition of MOS1 and MOS2. Live weight (1649g MOS1, 1634g MOS2) and daily weight gain (46.07 g MOS1, 45.64 g MOS2) were improved and showed statistical differences ($P < 0.05$) compared to group A (1502g live weight, 41.84 g dwg) and MOS3 (1456 g live weight, 40.65 g dwg). Feed consumption was increased and feed conversion improved when compared to the control. Mortality rate was higher in group A ($> 6\%$), compared to the groups B, C, D (3,4 and 4,5%). Our results are in agreement with the literature that MOS is able to bind enteropathogenic bacteria, such as *E. coli* and *Salmonella*. This might have been one reason for the increase in performance in the broiler feeding trial.

Key Words: Yeast, *E. coli*, Broiler Performance

371 Effect of enzymatically hydrolyzed yeast supplementation on performance and in protecting broilers against a mild coccidiosis challenge. S. Jalukar^{*1}, J. Oppy¹, and S. Davis², ¹*Varied Industries Corporation, Mason City, IA*, ²*Colorado Quality Research Inc., Wellington, CO*.

This study evaluated the effect of enzymatically hydrolyzed yeast and yeast culture manufactured as a combined supplement called Celmanax[®] on broilers with a mild coccidiosis challenge with *Eimeria*. Celmanax[®] contains complex sugars like galactosamine, mannose and mannan oligosaccharide (MOS). Zero days old Cobb 500 chicks were assigned in 8 replications to 12 treatments with 10 birds/pen. The treatments included 1) Control non treated (NT), challenged 2) Celmanax[®] 2 kg/MT (Cel 2), challenged 3) Celmanax[®] 4 kg/MT (Cel 4), challenged 4) Control, NT non challenged (NC) 5) Cel 2 6) Cel 4 7) Salinomycin (Sal) 50 g/MT 8) Sal 50 g/MT, challenged. Chicks were on the treatment diets from day 0-21. The birds were infected at 15 days of age with 31,000 *E. tenella* (ET) oocysts/bird or with ~37,500 *E. acervulina* (EA) oocysts and ~25,000 *E. maxima* (EM) oocysts/bird. Treatments were assigned to brooding cages using a complete randomized block design. Efficacy

was evaluated by measuring body weight, feed intake and adjusted feed conversion (AFC), and intestinal lesion scores.

The non challenged treatments with Cel 2 and 4 performed well and had numerically improved weight gain (0.32 and 0.31 kg respectively) than the NT, NC control (0.3 kg). The 15-21 day data indicates that the Celmanax[®] treatments challenged with EA and EM did not prevent a significant impact on weight gain and AFC as the salinomycin. The lesion score data indicates that the EM and EA challenge was controlled significantly with Sal treatment (p=0.001) but not by Cel 2 and 4 treatments. The Sal, Cel 2 and Cel 4 treatments significantly decreased the ET lesion scores (0.93, 1.0 and 1.18 respectively p=0.001) compared to the un-treated *Eimeria* control (1.73). Both Cel 2 and Sal improved weight gain (0.306 and 0.31 kg respectively) but only Cel 2 improved AFC (1.389) in chicks challenged with ET compared to NT NC chicks (0.3 kg and 1.393). Overall, Celmanax[®] appeared to have performance improving properties when fed to non-challenged broilers, and showed significant efficacy against *E. tenella* but not against *E. maxima* and *E. acervulina* challenge.

Key Words: Coccidiosis, Poultry

Physiology and Endocrinology: Effects of Environment and Handling on Performance

372 Effects of female holding temperature and post-ovulatory oocyte ageing on egg survival in Pilot Peak Lahontan cutthroat trout, *Oncorhynchus clarki henshawi*. J. P. Bigelow*^{1,3}, M. M. Peacock², W. M. Rauw², and L. Gomez-Raya², ¹U.S. Fish and Wildlife Service, Gardnerville, NV, ²University of Nevada, Reno.

Twenty, 3-year-old females were held at 12.4 °C, and 20 females at 7.2°C from December 18 through the time of ovulation and hand spawning at the hatchery. Females were partially spawned one, four, and seven d post ovulation. Eggs were fertilized with milt from 3-year-old males held in 12.4°C water (one male per female) and then incubated at 12.4°C. All egg batches were enumerated by hand at the eyed-stage of development when dead eggs were removed. Normal appearing fry reaching the yolk sac resorption stage of development were counted 41 d post fertilization. Percent survival was calculated against the total number of eggs for each batch. Mean egg survival was 168% higher for females held at 7.2°C rather than 12.4°C when eggs were collected within one day of ovulation. The effect of water temperature on egg survival was highly significant ($P<0.001$) indicating that reproduction might be reduced in rivers and lakes affected by global warming. Two females in the 12.4°C group exhibited egg survivals higher than the mean survival in the 7.2°C group, suggesting a possible role for individual genetic variability in temperature tolerance. There was no significant effect of oocyte ageing up to one week post ovulation at either temperature. Relative fecundity was lower in the 12.4°C group, and was positively correlated to egg survival in that treatment, suggesting impeded ovulation at the higher temperature. Female length and weight were negatively correlated to egg survival at 12.4°C, indicating reduced heat tolerance for larger fish. These results have implications for management of the captive broodstock, and for reproductive temperature requirements of broodstock progeny spawning in the wild, especially in light of expected global temperature increases.

Key Words: Lahontan Trout, Reproduction, Temperature Tolerance

373 Differential effects of heat stress and reduced nutrient intake on production and metabolism in young growing beef cattle. M. D. O'Brien*, J. B. Wheelock, S. R. Sanders, G. C. Duff, R. P. Rhoads, and L. H. Baumgard, *University of Arizona, Tucson.*

To differentiate between heat stress (HS) and decreased DMI on physiological and metabolic indices in growing beef cattle, we conducted an experiment where a thermal-neutral control group ($n=6$) was pair-fed (PF) to match nutrient intake with heat-stressed Holstein bull calves ($n=6$). Bulls (4-5 mo, 110-160 kg) housed in climate-controlled chambers were fed an 86% concentrate, 14% protein diet and subjected to two experimental periods: 1) thermal-neutral (TN; 18-20°C) and ad libitum intake for 9 d and 2) HS (cyclical daily temps ranging from 29.4 to 40.0°C) and ad libitum intake or PF (TN conditions) for 9 d. During each period, blood was collected daily and all bulls received an iv insulin challenge on d 7 and a glucose tolerance test (GTT) on d 8. Rectal temperatures and respiration rates increased ($P<0.01$) during HS (39.02 to 40.57°C and 42 to 126 breaths/min). HS reduced (12%) DMI and by design, PF bulls had similar nutrient intake reductions. During period 1, body weight gain averaged 1.25 kg/d and both HS and PF reduced ($P<0.01$) ADG similarly (-0.09 kg/d). Compared to PF, HS decreased ($P<0.05$) basal circulating glucose levels (5%) and tended ($P<0.07$) to increase plasma insulin levels (0.60 vs 0.46 ng/mL), but neither

HS nor PF altered plasma NEFA concentrations (95 μ Eq/L). Although there were no treatment differences, both HS and PF increased ($P<0.05$) PUN levels (75%) compared to period 1. In contrast to TN ad libitum conditions, both HS and PF had increased (16%) glucose disposal, but compared to PF, HS had a larger (67%; $P<0.05$) insulin response to the GTT. Neither treatment altered the glucose response to an insulin challenge (area under the curve or fractional rate of glucose clearance). Independent of reduced nutrient intake, HS alters post-absorptive carbohydrate (basal and stimulated) metabolism, characterized primarily by increased insulin levels and insulin response to a GTT. However, HS-induced reduction in feed intake appears to fully explain reduced body weight gain in young Holstein bull calves.

Key Words: Heat Stress, Beef, Insulin

374 The influence of bovine temperament on rectal temperature and stress hormones in response to transportation. N. C. Burdick*¹, J. A. Carroll², R. D. Randel³, R. C. Vann⁴, S. T. Willard⁵, L. C. Caldwell¹, J. W. Dailey², L. E. Hulbert², and T. H. Welsh, Jr.¹, ¹AgriLife Research, Texas A&M System, College Station, TX, ²USDA-ARS Livestock Issues Research Unit, Lubbock, TX, ³AgriLife Research, Texas A&M System, Overton, TX, ⁴Mississippi State University, Raymond, ⁵Mississippi State University, Mississippi State.

This study was designed to determine the influence of bovine temperament on rectal temperature (RT), cortisol (CS) and epinephrine (EPI) secretion in response to transportation. Brahman bulls (10 months of age) were selected from the spring 2007 calf crop based on temperament score which was an average of exit velocity (EV; objective measure) and pen score (PS; subjective behavior score). The bulls with the lowest (C; $n=5$; 0.75 m/s EV and 1 PS), intermediate (I; $n=8$; 1.59 m/s EV and 2.25 PS), and highest (T; $n=4$; 3.59 m/s EV and 5 PS) scores were used for this study. Prior to transportation (departure) blood was collected and serum and plasma harvested. Bulls were also fitted with RT devices that recorded at 1-min intervals. Bulls were then loaded on a trailer and transported 770 km. Upon arrival similar blood samples were collected. Serum CS and plasma EPI concentrations were determined by RIA and EIA, respectively. RT data were summed into 10-min intervals prior to statistical analysis. Data were analyzed by ANOVA using Statview (SAS) and Pearson's correlation coefficients calculated. At departure there was no effect of temperament on CS concentrations ($P>0.05$). Concentrations of EPI were lower in C (110.21 \pm 20.52 pg/mL) and I (133.46 \pm 27.91 pg/mL) when compared to T bulls (359.85 \pm 112.50 pg/mL $P=0.01$). There was no difference due to temperament between departure and arrival concentrations of CS or EPI ($P>0.05$). During transport, RT peaked within 20 min (max RT) before decreasing to baseline values ($P<0.01$). C bulls (39.35 \pm 0.01°C) had lower RT when compared with I (39.61 \pm 0.02°C) and T bull (39.63 \pm 0.02°C; $P=0.06$). Moderate-to-high positive correlations were detected among: max RT and EV ($r=0.62$; $P<0.01$); EV and departure EPI ($r=0.64$; $P<0.01$); EV and arrival EPI ($r=0.58$; $P=0.01$); and EV and arrival CS ($r=0.55$; $P<0.01$). There was a tendency for a positive correlation between max RT and departure EPI ($r=0.46$; $P=0.06$). In conclusion, max RT was reached within 20 min of onset of transportation. Temperament and adrenal function were predictive of RT changes due to transportation.

Key Words: Bovine Temperament, Transportation, Rectal Temperature

375 Effects of acclimation on performance, physiologic responses, and puberty attainment of Brahman-crossbred heifers. R. F. Cooke*^{1,2}, B. R. Austin², J. V. Yelich², and J. D. Arthington¹, ¹University of Florida - IFAS, Range Cattle Research and Education Center, Ona, ²University of Florida - IFAS, Animal Sciences, Gainesville.

The objective of this study was to evaluate the effects of acclimation on growth, plasma concentrations of progesterone (P4) and cortisol, and puberty attainment of Brahman-crossbred heifers. Over 2 consecutive years, 80 heifers were initially evaluated for puberty status via trans-rectal ultrasonography (d 0 and 10) and for temperament by measurements of chute score, pen score, and exit velocity (d 10) within 30 d after weaning. On d 10, heifers were stratified by puberty status, temperament and BW, and randomly assigned to control or acclimation treatment. Heifers were maintained in bahiagrass (*Paspalum notatum*) pastures and received a blend of soybean hulls and cottonseed meal at a daily rate of 2.7 kg of DM per heifer throughout the experimental period (d 0 to 130). The acclimation process (d 11 to 40) consisted of bringing heifers to the cowpens 3 times weekly, where heifers were exposed to common handling practices and returned to pastures within 2 h. Heifer puberty status, evaluated via plasma P4 concentrations and trans-rectal ultrasonography, and BW were assessed on d 40 and 50, d 80 and 90, and d 120 and 130. Blood samples were also collected prior to (d 10) and at the end of the acclimation process (d 40) for determination of plasma P4 and cortisol concentrations. Heifer temperament was assessed again on d 40 of the study. No treatment x year interaction was detected. Acclimated heifers had decreased ($P < 0.05$) BW gain compared to control heifers (0.50 vs. 0.58 kg/d, respectively). Attainment of puberty, however, was increased ($P < 0.01$) for acclimated heifers. A treatment x day interaction was detected ($P < 0.05$) for plasma cortisol and P4 (within prepubertal heifers only) concentrations because heifers from both treatments had similar concentrations on d 10, but acclimated heifers had decreased concentrations of these hormones compared to control heifers on d 40 (3.6 vs. 5.2 ng/mL of cortisol, respectively; 0.50 vs. 0.91 ng/mL of P4, respectively). Results from this study indicated that although acclimation decreased BW gain, it enhanced the attainment of puberty of Brahman-crossbred heifers.

Key Words: Brahman-Crossbred Heifers, Acclimation, Puberty

376 Effects of acclimation on performance, physiologic responses, and pregnancy rates of Brahman-crossbred cows. R. F. Cooke*^{1,2}, D. B. Araujo^{1,2}, G. C. Lamb³, and J. D. Arthington¹, ¹University of Florida - IFAS, Range Cattle Research and Education Center, Ona, ²University of Florida - IFAS, Animal Sciences, Gainesville, ³University of Florida - IFAS, North Florida Research and Education Center, Marianna.

The objective of this study was to evaluate the effects of acclimation on performance, plasma concentrations of hormones and metabolites, and pregnancy rates of Brahman-crossbred cows. Approximately 30 d after weaning (August), 238 Brahman x British and 164 Braford cows were stratified, within breed, by temperament (measurements of chute score, pen score, and exit velocity), BW and BCS, and randomly allocated to 14 groups (Braford = 8; Brahman x British = 6). Groups were randomly assigned to control or acclimation treatment. Cows were maintained in bahiagrass (*Paspalum notatum*) pastures and received a blend of cane molasses and urea at a daily rate of 1.8 kg of DM per cow beginning in December. Cows were acclimated from August to February, and the acclimation process consisted of visiting groups twice weekly and hand-offering approximately 50 g of range cubes per cow. On February, cow temperament, BW and BCS was again assessed and cows were exposed to mature bulls for 90 d. Blood samples were collected at the beginning of the acclimation period and also breeding season for determination of cortisol, IGF-I, ceruloplasmin, and haptoglobin concentrations. Pregnancy was determined via trans-rectal ultrasonography 70 d after the end of breeding season. Within Braford cows, a treatment effect was detected ($P < 0.01$) for pregnancy rates because acclimated cows conceived earlier and at greater number compared to control cows. When data were combined between treatments and breeds, the probability of pregnancy increased linearly ($P < 0.05$) as temperament score and concentrations of ceruloplasmin, haptoglobin, and cortisol (Braford cows only) obtained at the beginning of the breeding season decreased. Probability of pregnancy was affected quadratically ($P < 0.05$) by BCS and IGF-I concentrations also assessed at the beginning of the breeding season. In conclusion, acclimation increased pregnancy rates of mature Braford cows, whereas measurements and physiologic responses associated with temperament and energy status appear to influence the probability of cows to conceive and maintain pregnancy during the breeding season.

Key Words: Brahman-Crossbred Cows, Acclimation, Pregnancy

Animal Behavior and Well-Being: Livestock: Swine and Sheep

377 ASAS Centennial Presentation: Animal behavior as a discipline within the American Society of Animal Science: One hundred years of change and promise. W. R. Stricklin*, *University of Maryland, College Park.*

Animal science emerged as a discipline from a tradition of using animals for human needs. One hundred years ago, the majority of Americans lived on farms in close association with animals. Animal husbandry programs emphasized good stockmanship which assumed students had a general knowledge of animal behavior. Today, 2% of Americans live on farms and husbandry systems differ greatly from earlier ones. Thus, the need for animal scientists to teach animal behavior is increasingly recognized. Within ASAS behavior research grew slowly and was influenced by other disciplines. The psychology-based American discipline of Behaviorism began 100 years ago but continues to have influence. Behaviorism contended that only what animals do (behavior) can be measured, and concepts such as motivation, feelings, pain, etc. were dismissed on the basis of parsimony. Concurrently, the European-based discipline of Ethology viewed behavior as genetically adaptive. American animal scientists Jay L. Lush et al. researched genetic aspects of behavior, but this work lessened as Animal Breeding faded. Ethology clashed with Behaviorism's view that behavior arises strictly from development and learning. The Ethologists' contention that suffering results when genetically-based behavioral drives are thwarted was included in the 1965 British Brambell report, a document that continues to influence animal welfare discussions. More recent USA public concern for welfare resulted in federal research funding. However, because the funds were labeled "animal well-being," behavior was typically researched only as a dependent variable. Consequently, the arguably sorely needed, stand-alone research-based subdiscipline of Applied Behavior within American animal sciences is yet to be attained.

Key Words: Applied Behavior, Animal Welfare, Animal Science

378 The effect of the autosort system on swine well-being. A. E. DeDecker*, J. M. Suchomel, and J. L. Salak-Johnson, *University of Illinois, Urbana.*

Limited data exist on the impact that autosort, a behavior-based production system, has on pig well-being. The objectives of this study were to evaluate a) how different autosort floor layouts affect wean-to-finish pig behavior and physiology (Exp1) and more specifically b) how different food court layouts affect pig well-being (Exp2). At weaning, pigs were randomly assigned to a water court (WC; 20% floor space, n = 633), food court (FC; 40% floor space, n = 617), fast lane (FL; 12.5% floor space per zone, n = 630) autosort layout, or conventional large pen (CV; control, n = 609). Physiological measures were evaluated via blood samples pre- and post-transportation. Live behavioral observations were registered during a 3-wk training period and at loading. Scan sampling was used to determine the total number of pigs performing specific behaviors at a given time. Data were analyzed using Proc GLM and MIXED with repeated measures and Chi-Square (SAS). In Exp1, cortisol levels were higher among CV pigs than among autosort pigs pre-transportation (P<0.001). Levels of IGF-1 were higher in the FC than all other treatments pre-transportation, while there was a differ-

ence pre- to post- transportation in the FC (P<0.04). White blood cell counts and neutrophil-to-lymphocyte ratio were greater (P ≤ 0.06) in CV pigs pre- and post- transportation than in certain autosort layouts. Floor layout influenced percent monocytes and eosinophils pre- and post- transportation (P ≤ 0.05). Number of pigs engaged in and time spent eating or drinking, as well as training and loading behaviors, were significantly affected by treatment (P ≤ 0.05). In Exp2, preliminary data indicate that pigs in a FC layout are less difficult and require less time to load than pigs from large and small CV pens (P<0.05). Number of rears and prod use were greater in pigs from small CV pens than all other treatments (P<0.05). During training, behaviors were different among treatments (P<0.05). Floor layout influenced white blood cell counts pre- and post-transportation. These data indicate that autosort layouts can affect ease of loading, various behaviors, and physiological measures throughout wean-to-finish.

Key Words: Autosort, Cortisol, Pig

379 The motivation of dominant and subordinate gestating sows for an enriched group pen. M. R. Pittman*¹, A. K. Johnson², J. P. Garner¹, R. D. Kirkden¹, B. T. Richert¹, and E. A. Pajor¹, ¹*Purdue University, West Lafayette, IN*, ²*Iowa State University, Ames.*

The swine industry is under pressure to consider alternatives to gestation stalls, including enriched group housing. The importance of these alternatives from the sows' perspective is unknown. The aim of this study was to compare the motivation of dominant (D) and subordinate (S) gestating sows for access to a group pen with feeding stalls and the following enrichments, a rubber mat, cotton cords, compost and straw. Groups of 3 Landrace x Yorkshire sows (42) were mixed post-breeding and test sows (D, n=7; S, n=7) were identified. Sows were trained to press an operant panel to gain access to the enriched group pen in which they spent 23 h. The fixed ratio schedule (the number of times that the sow was required to press) was increased daily. The highest schedule reached was the measure of motivational strength. The behavior of the sows was also recorded throughout the experiment. Data were analyzed with ANOVA using GLM and post-hoc Tukey tests. Upon entering the pen, sows, regardless of social status, spent 43.8 ± 3.64% of observations using the enrichments (rope 0.06 ± 0.02%, compost 21.4 ± 3.09%, and straw 22.3 ± 3.61%). The highest schedule pressed was not significantly different for D vs. S sows (41 ± 11.77 vs. 53 ± 11.74; P>0.10). However, previous work has shown that this level of pressing is roughly equivalent to the motivation of a sow working to gain access to a food reward after consuming 50% of her ad lib (4 kg) intake suggesting access to the enriched pen was important to sows. There were no statistical differences between D and S sows in drinking, straw use or compost use (all comparisons, P>0.10). D sows showed higher aggression compared to M sows (P<0.10) and S sows (P<0.05), while M vs. S sows was not significantly different (P>0.10). Locomotion was lower in D sows compared to S sows (P<0.10). In conclusion, D and S sows are equally motivated to gain access to an enriched group pen and behaved similarly within the space, spending almost half of their time in enrichment directed behavior.

Key Words: Gestating Sows, Motivation, Enriched Housing

380 Behavioral changes in young pigs infected with *Salmonella*. J. Higginson*¹, J. T. Gray², and S. T. Millman³, ¹University of Guelph, Guelph, ON, Canada, ²Des Moines University, Des Moines, IA, ³Iowa State University, Ames.

The objectives of this study were to determine if aggression, cleanliness, and exploratory behavior were altered when group-housed swine are infected with *Salmonella*. Twelve groups of 5 Landrace/Yorkshire weaned pigs (n=60 pigs) were housed in separate biosecure rooms. One pig per group was randomly selected as the seeder animal and given 10⁷-10⁸ CFU of *Salmonella typhimurium* orally on Day 0. All pigs were individually marked for identification and observers were blind to treatments. Fresh lesion scores and cleanliness scores were recorded daily on Day -1 through Day +6. Latency to approach a novel object was used as a measure of exploratory behavior, and was performed using 4 different objects on Days -1, +1, +3 and +6 with order of presentation balanced between groups. Preliminary analysis was performed using t-tests, comparing seeder animals to the mean of the undosed penmates. Infected pigs did not differ from their penmates for lesion scores (mean + S.E. was 0.25 ± 0.06 and 0.20 ± 0.04 for seeder and penmates respectively, P=0.54). Lesion scores did not differ relative to days. Similarly, seeder pigs did not differ from penmates for cleanliness scores (mean + S.E. 1.54 ± 0.19 and 1.60 ± 0.09 for seeders and penmates respectively, P=0.79). However, seeder pigs were significantly cleaner than penmates on Day +2 (1.03 ± 0.16 versus 1.54 ± 0.19, P<0.05). All pigs approached the novel object significantly faster on subsequent days (P<0.05), but there was no significant difference between seeders and non-seeders for this behavior. In conclusion, there was little evidence to support differences in behavior of animals infected with *Salmonella* relative to their healthy penmates for cleanliness, lesions scores or exploratory motivation.

Key Words: Sickness Behavior, Swine, *Salmonella*

381 The social behavior carried out by unacquainted sows on mixing may predict the likelihood of escalation into aggression. J. N. Marchant-Forde*¹, J. P. Garner², E. L. Schenck¹, A. K. Johnson³, and D. C. Lay Jr.¹, ¹USDA-ARS, West Lafayette, IN, ²Purdue University, West Lafayette, IN, ³Iowa State University, Ames.

Aggression is a major well-being challenge when housing sows in groups. Aggression can increase injuries and stress, whilst detrimentally affecting productivity and cost of production. The aim of this project was to determine the behavioral sequences associated with fight and non-fight interactions when two unacquainted sows are mixed. Twelve unacquainted multiparous sows were mixed in pairs immediately after weaning. Body weight, parity, litter of origin, and body length were measured 1 d prior to mixing. All sows were paired based on body weight and parity. Each pair was placed in a 6 m² pen, with 1.2m high solid walls to eliminate outside influences on behavior, for 1 hr during which behavior was video-recorded in real time. All social interactions were extracted from the video data by one experienced observer, using an ethogram containing 10 behaviors to describe each interaction. A new interaction was defined as ≥5 sec of non-contact from the end of the previous interaction. Aggressive interactions were defined as a bite to the body. To identify behaviors predictive of aggression, the first 20 behaviors in an observation, and the last 20 immediately preceding the first act of aggression were collated, to form non-aggressive and aggressive behavioral profiles respectively. Behavioral data were analyzed using a split-plot GLM, blocked by observation. Profiles

differed between the start of the observation and prior to the first fight (F_{9,95} = 4.89; P<0.0001). Bonferroni post hoc planned comparisons showed that 'nose-to-nose contact' decreased immediately before a fight (P=0.0001; alpha = 0.005), and 'no reaction to social behavior' was greater (P=0.0060; alpha = 0.005). In conclusion, nose-to-nose contact reduces the chance of aggression in sows, while a failure to respond to social behaviors increases it.

Key Words: Pigs, Aggression, Mixing

382 The effects of ractopamine, gender, and social rank on aggression and peripheral monoamine levels in finishing pigs. R. Poletto*^{1,2}, J. P. Garner¹, H. W. Cheng², B. T. Richert¹, and J. N. Marchant-Forde², ¹Purdue University, West Lafayette, IN, ²USDA-ARS-LBRU, West Lafayette, IN.

The aim of this study was to evaluate effects of a "step-up" ractopamine (RAC) feeding program on home pen aggression and peripheral levels of tryptophan (Trp), serotonin (5HT), dopamine (DA), norepinephrine (NE) and epinephrine (EP) in finishing pigs. Thirty-two pigs (16 barrows and 16 gilts) were assigned as either control (CTL) or RAC treatment (pen=4/gender). Treated animals were fed RAC at 5 ppm for 2 wk, then 10 ppm for additional 2 wk. The dominant and subordinate pigs in each pen were determined at assignment by the proportion of encounters won or lost over 36 h. Behavior in the home pen was continuously recorded once a wk (0800 h to 1100 h) for 5 wk to determine number of bites (B), head knocks (HK) and pursuits (P). Blood was collected from each animal once a wk for 5 wk, starting prior to dietary treatment and levels of Trp, 5HT, DA, NE and EP were measured using HPLC. A 2×2×2 factorial analysis was computed with repeated measures mixed models using individuals as units. Gilts showed more B (1.7±0.2 vs. 0.9±0.2, P<0.05) per interaction compared to barrows. Compared to baseline, RAC-fed gilts increased B while others decreased (P<0.05). CTL barrows showed the lowest number of HK (0.4±0.1), with others showing similar counts (0.7±0.1, treatment×gender, P<0.05). Pursuits increased greatly from baseline in RAC-fed gilts, but decreased for others (treatment ×gender, P<0.01). Overall, gilts showed more total actions per aggressive interaction than barrows (2.5±0.2 vs. 1.5±0.2, P<0.01) and RAC-fed gilts had an increase in the total number actions performed (P<0.01). RAC-fed gilts had lower 5HT compared to RAC-fed barrows (treatment×gender, P=0.08) and overall, Trp and 5HT levels increased up to d11 then plateaued (day, P<0.01). Dominant RAC pigs had highest concentrations of NE (P<0.05), and dominant barrows had higher EP levels than subordinate ones (P<0.05), but EP concentrations were similar in gilts regardless of social status. Gilts, especially RAC-fed gilts, showed more aggressive behavior which may be linked to lower 5HT availability, leading to increased production costs and impairment of welfare.

Key Words: Swine, Ractopamine, Aggression

383 Preference for foods by lambs conditioned with rumen distension and contraction. J. J. Villalba* and F. D. Provenza, Department of Wildland Resources, Utah State University, Logan.

Bloat is a major nonpathogenic cause of death and illness in livestock characterized by an accumulation of fermentation gas within the rumen which increases intraruminal pressure. We determined whether sheep

could associate ingestion of specific foods with the consequences of increased intraruminal pressure and its subsidence. In Experiment 1, 6 fistulated lambs (39 ± 2 Kg) were offered ground alfalfa, a familiar food, for 30 min after a rubber balloon was or was not inserted into the rumen of each animal. When present, the balloon was either not distended or distended with air to a volume of 1.8, 2.5 or 4.5 L. Food intake did not differ when the balloon was absent from the rumen or when it was present but not distended ($P > 0.05$). However, distension affected food intake ($P < 0.001$), which decreased linearly with an increase in distension ($r^2 = 0.7$). In Experiment 2, the 6 fistulated lambs were offered a novel food, Group 1 ($n = 3$) wheat bran and Group 2 ($n = 3$) beet pulp, after which a balloon in the rumen of each lamb was distended to a volume of 2.5 L for 30 min. The foods were then switched (Group 1: beet pulp; Group 2: wheat bran) and the balloons were deflated, relieving the intraruminal pressure. Lambs were then offered choices between the 2 novel foods and between the novel foods and alfalfa. All lambs strongly avoided the food ingested before the onset of ruminal distension, but preferred the novel food ingested when distension subsided ($P < 0.001$). A Control group of lambs that experienced the same conditioning protocol but without changes in ruminal pressure neither preferred nor avoided the novel foods ($P > 0.05$). Thus, sheep learned about the negative effects of increased intraruminal pressure and the positive effects of recovery from intraruminal pressure. These associations are likely to be critical in learning avoidances of bloat-inducing plants and preferences for plants and supplements that relieve the incidence of bloat.

Key Words: Bloat, Foraging, Sheep

384 Feeding behavior and rumen pH of lactating dairy sheep fed diets with different starch, NDF, and peNDF content. G. Molle¹, F. Boe², V. Giovanetti¹, M. Decandia¹, E. Zerbini³, and A. Cannas², ¹AGRIS Sardegna, Dipartimento Ricerca nelle Produzioni Animali, Olmedo, Italy, ²Dipartimento di Scienze Zootecniche, University of Sassari, Italy, ³Cargill Animal Nutrition, Spessa, Italy.

There is little information on the combined effects of dietary NDF, physical effective NDF (peNDF), and starch on feeding behavior and

rumen function in lactating dairy sheep. To address this gap, 40 Sarda ewes in mid-lactation were individually fed ad libitum 8 complete pelleted diets (5 ewes per diet), which differed in NDF and starch content and source. Based on their main ingredient, diets were denominated: corn meal (CM), wheat middlings (WM), corn flaked (CF), barley meal (BM), corn cobs (CC), beet pulp (BP), alfalfa (AA) and soybean hulls (SH). For each diet, peNDF was measured by dry sieving. Two hours after the morning feeding, rumen liquid was sampled with a stomach tube and its pH was measured. Sheep feeding behavior was observed for 24 h. Eating (ET), ruminating (RT), total chewing (CT = ET + RT) and idling times (IT) were measured by scan sampling each sheep every 2.5 min. Group average data were analysed using correlation and regression models.

Extreme peNDF were in diets CC and AA (25 to 27% DM) and WM and CF (6 to 9% DM), respectively. The RT was associated with peNDF intake ($r = 0.76$, $P = 0.03$), while it was not related to total NDF intake ($r = 0.54$, $P = 0.17$). In addition, the feeding behavior was strongly influenced by NDF particles larger than 2.36 mm ($r = 0.96$, $P < 0.001$, and $r = 0.93$, $P < 0.001$, for RT and CT, respectively) but not by those between 1.18 mm and 2.36 mm ($P > 0.1$ for both RT and CT), suggesting that the threshold of 1.18 mm used to define the peNDF might not be appropriate for sheep fed pelleted diets with small particle size.

Rumen pH was mostly influenced by the intake of starch ($r = -0.63$, $P = 0.09$) and NDF ($r = 0.69$, $P = 0.06$), while it was poorly associated with peNDF intake ($r = 0.53$, $P = 0.17$) and not associated at all with RT ($r = 0.13$, $P > 0.1$) or CT ($r = 0.1$, $P > 0.1$). This suggests that when sheep are fed diets characterized by small particle size, rumen pH is mainly influenced by NDF and starch intake rather than by peNDF content or RT.

Key Words: Feeding Behavior, peNDF, Rumen pH

Animal Health V

385 Advances in respiratory disease research. G. D. Snowden*, *National Center for Foreign Animal and Zoonotic Disease Defense, College Station, TX.*

Respiratory disease complex is the most costly livestock disease in the USA. Recent scientific advances in metaphylactic and therapeutic treatments, pathogenic mechanisms, immunological responses, inherent host resistance, management and preconditioning treatments, and several other areas to reduce the prevalence and economic impact of respiratory diseases have been reported. Innovative nutritional approaches for animals newly introduced to a feedlot suggest changes to vitamin and mineral content, and nutrient concentrations of initial diets to reduce respiratory disease morbidity. The effect of fear and stress in livestock on their immune system is being clarified. Research is also expanding our understanding of the pulmonary innate immune system regulating antimicrobial peptide/protein expression of the respiratory tract which may lead to novel prophylactic and therapeutic modalities to minimize mortality and morbidity. The method of infection by microbial pathogens is beginning to be understood as the role of pro-inflammatory chemokines and cytokines that recruit neutrophils, macrophages, and lymphocytes to the respiratory tract is elucidated. New vaccines administered by the mucosal route are being developed from research that manipulated the genome of various bacteria and viruses to identify the role of different proteins in the pathogenesis. Genetic selection to reduce respiratory disease may become more plausible as genetic factors influencing susceptibility to respiratory diseases are identified in many livestock species. A few quantitative trait loci associated with respiratory disease resistance have also been recently identified. Although complete control of respiratory disease may not be likely in the near future, new technologies and information will likely reduce the prevalence of respiratory disease in livestock.

Key Words: Immune Response, Shipping Fever, Livestock

386 An evaluation of tulathromycin treatment at post-weaning movement on the incidence of respiratory disease and on growth in commercial dairy calves. A. Stanton*¹, S. J. LeBlanc¹, R. T. Dingwell¹, D. Kelton¹, S. T. Millman¹, J. Wormuth¹, and K. E. Leslie¹, ¹*University of Guelph, Guelph, ON, Canada*, ²*CY Heifer Farm, Elba, NY.*

Bovine respiratory disease (BRD) is common following weaning and movement of calves from individual to group housing. The objective was to evaluate the effects of tulathromycin administered at the time of grouping post-weaning on the incidence of respiratory disease and on growth in dairy calves. The study was conducted at a custom heifer raising facility in New York State. 1,367 weaned dairy calves were randomly assigned to receive either tulathromycin (TUL) or oxytetracycline (TET), once SC at the time of movement. Weights and heights were measured on all calves at arrival at the farm (2-7 days of age), at enrolment (~56 days of age), and ~6 weeks post-enrolment (~97 days of age). All disease events were recorded by trained barn staff. The incidence of BRD was 8% and 13% in the TUL and TET groups, respectively. Controlling for source farm and enrolment cohort, calves treated with TET were 1.9 times more likely to be treated for BRD within 60 days post-enrollment than calves treated with TUL ($P < 0.001$).

Independent of experimental treatment, calves with non-specific fever in the 2 weeks before enrollment were 2.7 times more likely to have BRD than calves without fever ($P < 0.05$). In calves ($n = 1,207$) that were not diagnosed with non-specific fever by farm staff between birth and 5 weeks of age, animals treated with TUL had an ADG 0.11 kg/d greater than TET calves ($P < 0.001$). Accounting for treatment group, calves that had non-specific fever within 2 weeks before enrollment had a decrease in ADG of 0.11 kg/d ($P < 0.01$). Among calves diagnosed with non-specific fever between birth and 5 weeks of age ($n = 160$), treatment TUL or TET did not have a significant effect on ADG. Separate from the effect of experimental treatment, diagnosis of BRD within 60 days post-enrollment decreased ADG by 0.2 kg/d. Treatment did not affect mortality.

In this population of calves at risk of respiratory disease in the post-weaning period, treatment with TUL resulted in a lower incidence of BRD and increased weight gain than treatment with TET.

Key Words: Tulathromycin, Weaned Dairy Calves, Respiratory Disease

387 An evaluation of a Brix refractometer for measurement of colostrum quality and success of passive transfer. V. Biemann*, J. Garner, C. Throop, N. Perkins, and K. Leslie, *University of Guelph, Guelph, ON, Canada.*

New techniques to evaluate colostrum and passive transfer in dairy cattle are needed. These methods must be simple, rapid, accurate, inexpensive, and adaptable to farm conditions. The Brix refractometer was evaluated in colostrum samples from 231 Holstein cows from 3 dairy herds from May to August 2007. In addition, serum samples were collected from a subset of the newborn calves from these cows within 1 to 4 days of age. The immunoglobulin concentration of the colostrum samples was measured by a radial immunodiffusion (RID) assay. The correlation coefficient between the RID and the Brix scores for the 222 colostrum samples was $R^2 = 0.32$. Using a Brix score of 18%, the sensitivity and specificity for identifying colostrums samples with inadequate IgG concentrations (50g/L) was 34% and 94%, respectively. By these results, use of the Brix refractometer to identify and discard colostrum of inferior quality for first feeding in dairy calves would result in a large number of false negative colostrums being eliminated. Factors affecting these test characteristics were evaluated. Unlike the Colostrometer™, no significant difference was found between Brix scores taken at 3 different colostrum temperatures (5, 20 and 38°C). Interestingly, no substantial difference in colostrum quality was observed between primiparous and multiparous animals in this study. A total of 202 calf serum samples were evaluated using the Brix refractometer and a standard digital refractometer to measure serum total solids (TS). A correlation coefficient of 0.77 was determined between the Brix and digital refractometer results. These data indicate considerable utility of the Brix instrument for assessment of passive transfer in dairy calves. There is a need for further evaluation and refinement of the Brix refractometer for use as a tool for assessment of colostrum quality. Yet, having one instrument for both evaluations would make it a very useful farm management tool.

Key Words: Refractometer, Colostrum, Calves

388 Comparison of Brix (sugar) refractometer and colostrometer for evaluation of colostrum quality in dairy cows. P. Dinsmore^{*1} and A. Skidmore², ¹Colorado State University, Fort Collins, ²Schering-Plough Animal Health, Alexander, NY.

Measurement of colostrum Ig is an important on-farm procedure to ensure adequate transfer of Ig to the newborn calf. A colostrometer, which measures the specific gravity (SG) of colostrum, is currently available but not widely used. It has disadvantages: 1) colostrum SG is more strongly associated with protein than Ig, and 2) SG is affected by colostrum temperature. A Brix sugar refractometer (Brix) has been useful in estimating equine colostrum quality. It is simple and rapid to use. The study objective was to evaluate the Brix for measuring dairy cow colostrum quality and to compare it to the colostrometer. First-milking colostrum was obtained from 117 cows on a large Colorado dairy. Colostrometer measurements were made by farm personnel. Brix measurements were made in triplicate on fresh samples and were performed by the senior author. A subset of samples (17) was tested at 3°C, 20°C, and 38°C. The samples were submitted for radial immunodiffusion (RID) measurement of IgG, as well as fat and protein determination. No temperature effect was found, and the triplicate Brix measurements were statistically identical for a given sample. When reading the Brix values, a wide band of color transition was found in 25% of samples and was found to be strongly associated with fat level in the sample. The multiple linear regression model with the highest R² (0.623) included Brix value and lactation group. The correlation between colostrometer and RID was 0.36. At the minimum colostrum IgG concentration of 50mg/ml indicating adequate colostrum quality, the Brix value was 23 and 20 for lactation 1 and lactation 2+ cows, respectively. Using these cutoff values and RID=50 mg/ml as the gold standard, the specificity of the colostrometer, Brix for lactation 1, and Brix for lactation 2+ were 0.25, 0.56, and 0.37, respectively. Compared to the colostrometer, the Brix refractometer values were more highly correlated with colostrum IgG values, was simpler to use, and was unaffected by temperature of the colostrum.

Key Words: Colostrum, IgG, Refractometer

389 Thermal imaging of the bovine muzzle and the correlation to rectal temperature. S. M. Behrends*, T. B. Schmidt, P. Ryan, S. Willard, M. McGee, C. Welch, C. Trejo, J. O. Buntyn, and C. Huston, Mississippi State University, Mississippi State.

Crossbred calves (n=133) weighing an average of 228.82 ± 22.15 kg were evaluated upon arrival at a 10,000-head capacity backgrounding facility to evaluate an easily obtainable measurement taken at arrival as a prognostic tool for sorting incoming cattle. Standard protocol upon arrival was individual ID (ear tag), antiemetic application and vaccinations for respiratory disease (modified live vaccine) and clostridial pathogens. In addition to arrival protocol, heifers were weighed, rectal temperature determined, and a thermal image (FLIR ThermaCAM EX320) was captured. Thermal images were collected at a standard distance of 76.2 cm from the restraining chute. To determine the correlation between rectal temperature and thermal images; the image of Planum Nasolabiale Area (PNA) of the muzzle was highlighted and then bisected by one vertical line, one horizontal line, and two diagonal lines into quadrants that intersected at the geometric center of the PNA. Muzzle temperature was positively correlated with rectal temperature taken at the time of processing (P<0.01). The most highly correlated area on the muzzle was the convergence of lines in the geometric center

of the PNA (r=0.50; P<0.01) and the least correlated measure was the diagonal line bisecting the PNA (r=0.34; P<0.01). Factor 1 from principle component analysis (PCA) had high loadings for quadrants bisected by the vertical line (0.99 and 0.97; PCA). Thermal temperature measures of the bovine muzzle appear to hold promising correlations to rectal temperature and with further investigation possibly provide a tool for early detection of stress and susceptible cattle.

Key Words: Body Temperature, Cattle, Muzzle

390 Sorting heifers with high risk of bovine respiratory disease based on arrival serum haptoglobin concentration. B. P. Holland*, L. O. Burciaga-Robles, D. L. Step, and C. R. Krehbiel, Oklahoma State University, Stillwater.

Heifers (n=337; initial BW=241±17 kg) were assembled at a western Kentucky order buyer facility and shipped in two groups 957 km to Stillwater, OK. Upon arrival blood was collected and serum analyzed for haptoglobin (Hp) concentration. Heifers were sorted into 3 groups according to arrival Hp concentration. Groups were LOW (<1 µg/100 mL), MED (1 to 3 µg/100 mL), and HIGH (>3 µg/100 mL). Within 36 h after arrival, calves were penned according to groups and fed for a 63-d receiving/growing period. Body weight and blood for Hp analysis were collected on d 7, 14, 21, 42, and 63. Blood for Hp analysis was also collected at the time of antimicrobial treatment for bovine respiratory disease (BRD). Haptoglobin concentrations on arrival were 0.79, 1.93, and 7.60 µg/100 mL for LOW, MED, and HIGH, respectively (P<0.01). On d 7, Hp tended (P=0.08) to be greater for HIGH than LOW and MED. Similarly, Hp tended (P=0.09) to be least for LOW, intermediate for MED, and greatest for HIGH on d 21. Arrival BW was greater for LOW and HIGH than MED (P<0.01). However, BW did not differ throughout the remainder of the trial (P>0.27). Average daily gain was least (P=0.01) for HIGH from d 1 to 7, but no other differences (P>0.19) in ADG were observed. Overall DMI was not different (P=0.89) among treatments, but was greater (P=0.02) for LOW (6.26 kg/d) and MED (5.74 kg/d) than HIGH (5.18 kg/d) from d 1 to 21. Overall morbidity due to BRD was greater (P=0.01) for MED and HIGH (66.9 and 76.2%, respectively) than for LOW (50.8%). The number of heifers requiring three treatments was also greater (P=0.01) for MED and HIGH (28.2 and 28.5%, respectively) than for LOW (9.78%). However, heifers considered chronically ill was greatest (P=0.03) for MED (18.3%), intermediate for HIGH (9.6%), and least for LOW (5.2%). Total mortality and case fatality rate did not differ (P>0.68) among groups. Average daily gain and DMI early in the growing period, as well as overall morbidity, were affected by arrival Hp concentration. Arrival Hp concentration may be a beneficial tool for making management decisions for calves with high risk of BRD.

Key Words: Acute Phase Protein, Bovine Respiratory Disease, Calves

391 Effects of on-arrival vs. delayed clostridial or modified-live respiratory vaccinations on health, performance, bovine viral diarrhea titers, and physiological measures in high-risk, newly received beef calves. J. T. Richeson^{*1}, E. B. Kegley¹, M. S. Gadberry², P. A. Beck³, J. G. Powell¹, and C. Jones⁴, ¹University of Arkansas, Fayetteville, ²University of Arkansas, Little Rock, ³University of Arkansas, Hope, ⁴Boehringer-Ingelheim Vetmedica, Inc., St. Joseph, MO.

Stress commonly associated with weaning, marketing, and shipment of feeder cattle can compromise immune function, and vaccine administration during immunosuppression may reduce vaccine efficacy and calf growth. Four treatments were compared in a 2 × 2 factorial arrangement to evaluate the effect of on-arrival (d 0) vs. delayed (d 14) administration of 7-way clostridial (Alpha[®] 7, Boehringer-Ingelheim Vetmedica, Inc. [BIVI]; CLOS) and modified live viral respiratory (Express[®] 5, BIVI; RESP) vaccines. Crossbred calves (n = 263) were weighed (238 ± 1.2 kg), stratified by gender, and assigned randomly to vaccination treatment: 1) arrival CLOS, arrival RESP (ACAR), 2) arrival CLOS, delayed RESP (ACDR), 3) delayed CLOS, arrival RESP (DCAR), and 4) delayed CLOS, delayed RESP (DCDR). Gain did not differ ($P = 0.74$) averaging 0.98, 0.93, 0.95, and 0.91 kg/d for ACAR, ACDR, DCAR and DCDR, respectively for the entire 56-d trial. Vaccination timing did not affect morbidity ($P = 0.49$); however, there tended to be CLOS ($P = 0.07$) and RESP timing effects ($P = 0.09$) on d to initial bovine respiratory disease (BRD) treatment episode. Average d to initial BRD treatment were less for ACAR (6 ± 0.8 d) compared to DCDR (8 ± 0.8 d; $P = 0.01$). Serum cortisol concentrations were greater ($P \leq 0.01$) on d 0 than 14 or 28 but no treatment × day interaction ($P = 0.21$) was observed. RESP timing affected ($P = 0.001$) serum BVD titer levels, with greater ($P < 0.01$) levels in calves administered RESP vaccine on arrival. Delaying CLOS or RESP vaccination did not affect gain or morbidity in high risk, newly received stocker calves. Calves administered RESP vaccine on d 0 developed antibody titers to BVD earlier than delayed RESP treatments.

Key Words: Receiving Cattle, Vaccination, BRD

392 Effect of length of time between maternal separation and shipping on post-weaning performance of beef calves weaned during the fall. J. W. Bolte^{*1}, K. C. Olson¹, J. R. Jaeger¹, T. B. Schmidt², D. U. Thomson¹, B. J. White¹, R. L. Larson¹, A. Sproul¹, L. A. Pachenco¹, and M. D. Thomas¹, ¹Kansas State University, Manhattan, ²Mississippi State University, Starkville.

Ranch-of-origin weaning periods of between 30 and 60 d are recommended for preconditioning beef calves. Our objective was to test the validity of this recommendation for calves aged 160 to 220 d and weaned during the fall. Angus × calves (n=433) were stratified by age and assigned randomly to 1 of 5 weaning dates that corresponded to the length of time between separation from the dam and shipment to an auction market: 60, 45, 30, 15, or 0 days. Calves were vaccinated against common diseases 14 d before weaning and again on the day of weaning. On a common shipping date (d 0; November 7), calves were transported 3 h to an auction market and held for 12 h. Calves were then transported 1 h to a feedlot. All calves were fed common pre- and post-shipment diets ad libitum. Calf ADG during the 60 d preceding shipping tended to increase linearly ($P=0.09$) with longer weaning periods. Incidence of undifferentiated fever during the 14 d after maternal separation was greater ($P<0.01$) for calves weaned 60 d than those weaned 45, 30, or 15 d. Calf BW at shipping tended to increase linearly ($P=0.06$) with successively longer weaning periods. Calf BW 30 and 60 d after shipping

increased linearly ($P<0.01$) with successively longer weaning periods; however, ADG was similar ($P>0.6$) between treatments from d 1 to 30 and d 31 to 60 after feedlot arrival. Incidence of undifferentiated fever during the 60 d after shipping was greater ($P<0.01$) for calves weaned 0 d than those weaned 60, 45, 30, or 15 d. Under the conditions of our study, successively longer ranch-of-origin weaning periods improved calf ADG prior to shipping but did not affect ADG during the 60 d following feedlot arrival. Treatments retained their relative ranks in body size from shipping to the end of the study. Weaning management influenced when calves were most likely to become ill.

Key Words: Preconditioning, Weaning, Beef Calves

393 Effects of *Mannheimia haemolytica* challenge on blood gas, oxygen consumption and net splanchnic flux of volatile fatty acids in fed or fasted steers. L. O. Burciaga-Robles^{*}, C. R. Krehbiel, D. L. Step, J. W. Dillwith, R. Madden, M. Montelongo, A. W. Confer, J. N. Gilliam, B. P. Holland, and C. L. Goad, Oklahoma State University, Stillwater.

This experiment evaluated arterial blood gas concentration, net splanchnic flux of VFA and O₂ consumption during a bovine respiratory disease (BRD) challenge. Twenty-two steers (BW = 320±24 kg) with chronic catheters to measure blood flow and net flux across the portal-drained viscera (PDV) and liver were used. Arterial, portal, and hepatic blood samples were collected at 1.5-h intervals on d 0, 1, 2, and 3. Treatments (2×2 factorial arrangement) were: 1) ad libitum feeding and not challenged (FED/CON); 2) ad libitum feeding and challenged (d 0) with *M. haemolytica* via a tracheal tube (FED/CH); 3) 72-h fasting and not challenged (FAST/CON); 4) 72-h fasting and challenged (FAST/CH). All data were analyzed using repeated measures and first-order autoregressive correlation structure. FED or FAST did not affect blood gas variables, whereas CON steers had lower blood pH (7.45 vs 7.47; $P=0.01$), BeB (3.38 vs 4.25 mmol/L; $P=0.01$), base excess of extra cellular fluid (2.45 vs 3.51 mmol/L; $P=0.01$) and greater hematocrit (27.1 vs 24.5%; $P=0.03$) and O₂ concentration (2.69 vs 2.52 mM; $P=0.007$) compared with CH animals. FED steers had greater PDV (-190 vs -129 mmol/h; $P=0.03$), TST (-438 vs -269 mmol/h; $P=0.01$), and tended ($P=0.07$) to have lower (-194 vs -206 mmol/h) liver O₂ consumption than FAST steers. FED animals had greater (1.20 vs 0.79 mM; $P<0.001$) arterial acetate concentration compared with FAST; arterial propionate, butyrate, isobutyrate, isovalerate and valerate concentrations were not affected. FED steers had increased portal flux of propionate (67.3 vs 33.7 mmol/h; $P=0.022$), and hepatic removal of propionate (-61.6 vs -25 mmol/h; $P=0.001$), isobutyrate (-4.18 vs -1.43; $P<0.001$) and isovalerate (-7.46 vs -2.55 mmol/h; $P=0.006$). Our data confirms that BRD alters arterial blood gas profile, but generally did not affect O₂ consumption or VFA flux across splanchnic tissues. Fasting decreases O₂ consumption; however, energy demands by splanchnic tissues may not be altered during an acute challenge with BRD.

Key Words: Bovine Respiratory Disease, Net Flux, Oxygen Consumption

Symposium: ARPAS Symposium: Livestock Pharmaceuticals: The Past, The Present, The ...

394 Fifty years of pharmaceutical technology and its impact on the livestock we produce. R. L. Preston*, *Professor Emeritus, Bellingham, WA.*

Technology, including pharmaceutical technology, has contributed to improved animal efficiency and health over the past 50 years and will continue to do so in the future. Technology is utilized by the livestock industry because it improves efficiency and health thereby reducing the cost of production that in turn, reduces the cost of food for the consumer and helps to sustain the economic production of animals. However, there are well-funded anti-technology forces at work to limit the application of technology in beef, food animal and agricultural production in general. The mainstream media smothers consumers with confusing information that often transforms their ignorance into fear. This impacts their willingness to believe what they read and hear, and can result in misguided choices. All land-based industries are affected by these misguided choices, by legislation and by regulations that threaten their economic sustainability. This presentation details the impact of past and current technology on the efficiency of livestock production and demonstrates the potential impact that anti-technology forces could have not only on livestock production but also on this country's food production in the future. Technology must play a continuing role in agriculture. Although scientific research will continue, the eventual acceptance of technology will depend on getting consumers to better understand and value the role of scientific research in assuring them of a sufficient and affordable supply of safe, high-quality, nutritious food.

395 How are we making bacteria more resistant to antibiotics? Darwinian impacts. T. R. Callaway*¹, J. L. Rychlik², T. S. Edrington¹, R. C. Anderson¹, and D. J. Nisbet¹, ¹ARS, *Food and Feed Safety Research Unit, College Station, TX*, ²Rychlik and Associates, *Hillsboro, OR.*

This presentation will address the Darwinian selection of genes of antibiotic resistance in food animals. Darwin's concept of survival of the fittest is as critical when applied to bacteria as it is to animals. Bacteria live in a highly competitive environment that is similar to the microbiological world with its selective pressures. Neo-Darwinism views genes as selfish and as the ultimate unit of natural selection rather than the host organism. Bacteria carrying antibiotic resistance genes are merely vehicles for ensuring the reproduction and dissemination of these genes. Antibiotic resistance genes can be shared horizontally amongst bacteria of the same or different species through conjugation, transduction and transformation. Mobile genetic elements (DNA fragments, transposons, phage and plasmids) are wild cards in the evolution of bacteria and can introduce or combine new genes or groups of genes to bacteria, especially antibiotic resistance genes. The horizontal and vertical movement of these genes is critical to the further dissemination of the genes by ensuring the survival of the bacterial hosts. Addition of selective pressure via feeding antibiotics helps to select for new antibiotic resistance and provides an environmental niche opening for resistant strains to fill and proliferate. Strategies for using new or medically-important antibiotics must be developed and implemented that do not enhance Darwinian and neo-Darwinian selection for antibiotic resistance genes and their host organisms. The antibiotic resistance gene is as critical as the bacteria itself as related to the dissemination of antibiotic resistance throughout the food animal population.

Key Words: Darwinian Selection, Antibiotic Resistance, Genetic Transfer

396 Antibiotic resistance gene transfer in the intestinal tract – possible implications for agriculture? A. Slayers*, *University of Illinois, Urbana.*

Every day, many bacteria pass through the human intestinal tract. Many of these bacteria come from the food supply and may thus have become resistant to antibiotics if the farm where they originated uses antibiotics routinely. Since most of these bacteria do not cause disease, it may seem irrelevant to be concerned about whether or not they are resistant to antibiotics. They could become a human health problem, however, if they are able to pass their resistance genes to bacteria that normally reside in the colon, because members of the resident colonic microflora are common causes of post-surgical infections. To assess the likelihood of horizontal resistance gene transfer in the colon, we have determined whether the same resistance gene is found in bacteria from different species or genera. Our findings and those of others suggest that transfer of resistance genes across species and genus lines occurs fairly readily in the human colon.

Key Words: Antibiotic Resistance

397 Does ionophore resistance risk human health? J. B. Russell*, *ARS/USDA, Ithaca, NY.*

Since World War II livestock in the United States have been fed sub-therapeutic doses of antibiotics as "growth promotants." The mechanism of this action is still not entirely clear, but it appears that antibiotics by altering the natural gut flora inhibit bacteria that are detrimental to the host. This routine use of antibiotic in animal feed has led to concern and debate. With the general increase in antibiotic resistance, their effectiveness use to combat disease has diminished, and many common pathogenic bacteria to carry multiple antibiotic resistances. In January 2006, the European Union banned the use of all antibiotics as animal growth promotants, and this ban includes a special class of antibiotics called ionophores. Ionophores are fed to beef cattle and more recently dairy cattle, but their mode of action that is distinctly different from other commonly used antibiotics. Ionophores dissipate ion gradients across the cell membranes of sensitive bacteria. Ruminant bacteria that produce hydrogen, a precursor of methane or deaminate amino acids are inhibited, and these effects increase energy and amino acid availability to the animal. However, many ruminal bacteria are resistant to ionophores even if ionophores are not fed, and this resistance is due to the outside surface of their cells (glycocalyx). Adaptation experiments indicated that ionophore resistance did not confer an increased resistance to other classes of antibiotics, and there is no evidence suggesting that ionophore resistance can be spread from one bacterium to another. Because only some animals can be safely fed ionophores, and ionophores have never been used for human therapy, ionophore resistance is not apt to pose a significant threat to human health.

Symposium: ASAS Graduate Student Symposium: Academia, Industry, Government, or None of the Above: Graduation is Coming, What Next?

398 Applying for an academic position. T. Etherton*, *Penn State University, University Park.*

Graduate students with an interest in pursuing an academic position in higher education are confronted with many challenges, as well as exciting opportunities. Getting positioned to be a strong candidate for a tenure-track faculty position begins with having the requisite abilities needed for success. These include “high intellect”, strong work ethic, great written and oral communication skills, being mentally tough, and understanding and putting the greater good of the team ahead of self-interests. In many beginning faculty positions, especially those that involve a basic science research component, a post-doctoral fellowship is a requirement. It is critically important that it be done in a strong program. This is not only a key period in a young career to learn new research techniques but also to grow one’s “brand name”. It is an expectation that several high-quality papers be published (in a timely manner) from the thesis and post-doctoral fellow experience.

With respect to the application process, there are a number of important considerations. A surprising number of letters of applications and resumes are not well written or organized. This is trouble. When you get the “big” interview prepare. It can be a pressure-packed situation. Not only is there is the seminar to prepare (and it has to be great) but you need to do a lot of homework. Learn about the faculty/staff and programs - be prepared for the “exit interview” with the Chair/Head. You might be asked about salary expectations, be ready. You will undoubtedly get questions for which you do not know the answer. Don’t guess. And, be precise. I have sat through more than a few exit interviews, and listened to a lot of talk but not much effective communication. If you get a job offer then you should get guidance about the salary and startup package- how the process works. Remember this is your point of greatest leverage. Be professional, seek a second visit to look at the program to better determine what your needs are for the startup package. When you sign the letter of offer you will have entered the “academy”. Enjoy the experience. It is a fabulous job filled with opportunity to do the greater good.

399 How a career in animal science can help save endangered wildlife species. J. L. Brown*, *National Zoological Park, Conservation and Research Center, Front Royal, VA.*

This presentation highlights how techniques I learned as an Animal Sciences graduate student are being used to study and preserve endangered species. Wildlife populations all over the world are disappearing at an alarming rate, mostly due to destructive human activities. Reversing this trend will require protecting animals and their habitat. For many, it also will involve managing captive populations as hedges against extinction in the wild. Decades of experience have shown that successful animal management relies on a thorough knowledge of species biology through studies of nutrition, genetics, reproduction, behavior, immunology and health. While we are careful to maintain that “a cheetah is not a cow”, there are many aspects of domestic animal science that can be applied

to wildlife species. This especially is true for the reproductive sciences where much of our basic physiology knowledge and ability to develop assisted reproductive techniques (e.g., AI and IVF) stem from studies using domestic animals as research models. My area of expertise, endocrinology, has benefited tremendously by techniques developed for livestock. One major challenge is that, with rare exception, most wild animals are intractable. Thus, our laboratory has developed non-invasive approaches to monitoring hormones excreted in urine, feces and saliva. Many of the assays I used to study dairy cattle have proven applicable to a variety of endangered species. As assisted reproductive techniques become increasingly important for managing zoo species, endocrine tools are key to developing appropriate hormonal therapies. The ability to assess endocrine status of animals managed by different husbandry strategies also has profound implications for enhancing our limited understanding of how social and environmental cues modulate reproductive fitness and success. Thus, an Animal Sciences background can well prepare an individual for a career in wildlife research. Given that almost nothing is known about >90% of extant species, there is more than enough work to go around.

400 Careers in government. R. D. Green*, *Pfizer Animal Genetics, Sutton, NE.*

The landscape for animal science careers has evolved substantially over the past decade and is likely to continue changing for the foreseeable future. With increasing regulatory demands related to animal agriculture, and a decrease in the number and general scope of animal science programs in academia, a higher proportion of those with graduate training in the animal sciences are finding their professional home in one of the several government agencies tied to animal agriculture. The principal federal agencies employing animal scientists are USDA’s Agricultural Research Service (ARS); Animal and Plant Health Inspection Service (APHIS); Food Safety Inspection Service (FSIS); and Agricultural Marketing Service (AMS); as well as the Food and Drug Administration (FDA) and to some degree the National Institutes of Health (NIH). Increasingly, these agencies are finding it more difficult to identify suitable candidates for positions who are well trained in the most up-to-date science (e.g. molecular biology, genomics, proteomics, synthetic biology, etc.) while also being conversant in and sufficiently knowledgeable of production animal agriculture and husbandry. As a result of this trend coupled with the need to better educate potential employees regarding the culture and nature of government service, more agency post-doctoral fellowship opportunities are being offered as a means of transitioning from graduate school to career civil service. Government careers bring the opportunity to be at the “front lines” of solving problems for animal agriculture and the public good with perhaps the most telling job satisfaction statistic being the very high percentage of civil service animal scientists spending their full careers in the government ranks.

401 Graduate student career opportunities in the animal science industry. J. F. Stika*, *Certified Angus Beef LLC, Wooster, OH.*

Globalization, consolidation, technological advancement, and a more vocal consumer have each contributed to dramatic changes within animal agriculture during the past decade. Concurrent with these changes has been an increase in the breadth of employment opportunities available to graduate students. Agriculture in the 21st Century is becoming more precision based, technology driven, and more focused on providing solutions to customer issues. Demand for technical service, research, and development positions has increased. Both masters and doctoral graduates are being sought for these positions as companies emphasize hiring more science-oriented, technical savvy specialists to replace or compliment bachelor level sales-oriented positions. As the complexity of our industry has increased, so has the expectation companies place on new graduates entering the workforce. While discipline specific technical expertise is the basis for many new positions in animal agriculture, the business environment requires that graduate students move beyond a specific discipline and into the realm of systems thinking and multi-disciplinary problem solving. Two types of graduate training programs are still needed. One focusing the student toward a career in basic research while another focuses on applied science. However, becoming an exceptional candidate for employment takes extra effort. Those most valued in the industry must be able to successfully merge biological, financial, public policy, and marketing awareness with an appreciation for the value of time and efficiency. Necessary skills beyond technical expertise include time management, effective communication, relationship building, goal setting and prioritizing, organization, and independent thinking. The opportunities for graduates of animal, dairy, and poultry science programs will continue to diversify as the issues facing animal agriculture become more challenging and the solutions more technical with broader implications across the entire industry.

402 Opportunities for graduate students in American Society of Animal Science. A. E. Radunz*, *The Ohio State University, Columbus.*

The American Society of Animal Science (ASAS) has a strong commitment to graduate students and providing opportunities for involvement in the organization. Several opportunities are available including serving on the board of directors and society committees and participating in graduate student activities. The ASAS membership annually elects one graduate student to the board of directors for a two-year term. Graduate student directors represent graduate students in the organization, develop networking contacts, and learn how ASAS operates. In 2007, the first graduate student symposium was incorporated in the national meeting program and a committee comprised of graduate students and professionals was appointed to organize this symposium. The organization encourages graduate students to serve on committees within the organization and students can be nominated for a committee by an ASAS member. Furthermore, graduate students presenting research at the meeting can apply for travel scholarships. Networking opportunities are offered to graduate students at the meetings including the graduate student mixer and job placement center, which is organized by graduate students. Involvement in the society can reap many rewards such as networking contacts, career opportunities, and knowledge of the society. More information on these opportunities can be found on the graduate student website at <http://www.asas.org/gradinfo/index.asp>.

Breeding and Genetics: Applications of Genomic Analysis

403 Validation of multiple marker DNA profiles for carcass merit across multiple populations of beef cattle. J. D. Nkrumah* and B. W. Woodward, *Merial Limited, Duluth, GA.*

Genomic information can be employed in the management and selection of beef cattle to increase profitability and genetic progress. Advances in livestock genomics have resulted in the detection of numerous polymorphisms that putatively show associations with a range of economically relevant traits in beef cattle. The goal of DNA marker validation work is to re-evaluate and potentially confirm the proposed effects of genetic markers reported by the research community, usually in an experimental population, by utilizing information from commercial herds that are unrelated to the original herd(s) in which the initial discovery was made. Genetic markers discovered to date generally have small effects, which may not be economically relevant unless used in combination. Most reported associations are also based on markers that do not cause the phenotypic variation but are linked to, and therefore serve as surrogates for yet to be detected causal mutations. The significance and the sign of marker effect estimates, or which genotype combination is favorable may vary from population to population. To ensure broad applicability across the industry, DNA marker effects need to be tested across multiple populations and evaluated for the value in profile. Not all markers will provide statistically significant associations across all populations evaluated, but a profile could continue to remain instructive for determining differences among animals in as many herds and breeds as possible. As an example, we have created DNA profiles using a set of markers for beef carcass marbling score (effect = 96.0; $P = 10^{-12}$) and percent choice (effect = 43%; $P = 10^{-06}$), as well as multiple marker panels for carcass rib eye area (effect = 13.0 cm²; $P = 10^{-20}$), yield grade (effect = 1.20; $P = 10^{-27}$), and carcass backfat thickness (5.8 mm; $P = 10^{-18}$) based on assessments in multiple commercial populations with more than 6,000 steers and heifers. We have subsequently confirmed these profile associations using EPDs for similar traits and genotypes from a repository of about 2,000 beef bulls representing the major beef breeds used in North America.

Key Words: Beef Cattle, Carcass Merit, SNP Profile Validation

404 Genetic prediction of beef tenderness using a multi-marker SNP panel. S. P Miller*¹, M. J. Kelly¹, and D. J. Nkrumah², ¹*University of Guelph, Guelph, ON, Canada,* ²*Merial Limited, Duluth, GA.*

Beef tenderness is the most important quality attribute contributing to the consumer acceptance of beef. However improvement of beef tenderness has not been included in traditional beef breeding programs due to cost and difficulty of measuring this trait. The standard measurement used to assess tenderness of beef is the shear force, which is the force required to shear a standardized cooked meat sample. Recently commercial DNA tests have been developed that explain some of the variation in shear force. We have used the Merial/Igenity large SNP panel to screen for associations between SNP and beef tenderness in a multi-breed beef population that were assessed for shear force (n=648). This population consisted of progeny of mainly crossbred dams mated to terminal sires. The predominant breeds were Angus, Simmental, Limousin, Charolais

and Piedmontese. The effect of each marker was fit individually in a mixed model that included breed proportion, contemporary group and a polygenic effect. Markers that were significant in the single marker regressions were used to develop a multiple marker panel. Each of the markers that remained in the panel was explaining a significant proportion of the variation in shearforce ($P < 0.05$) and the marker effects ranged from 0.14kg to 0.49kg. The multi-marker panel explained 12% of the phenotypic variance. Given that the heritability of tenderness from this dataset is approximately 20% the current panel explains a large proportion of the genetic variance within this population. Selecting animals based on this panel will shift the mean tenderness from 4.92kg to 4.59kg which is slightly lower to that achieved selecting the best bulls based on their across breed expected progeny difference (4.47kg). These results indicate the growing power of SNP panels to explain significant genetic differences for beef tenderness and their practical application in the beef industries efforts to improve consumer demand.

Key Words: Beef, Tenderness, Genomics

405 Multiple marker DNA profiles for production, fertility, and functional traits in Holstein cattle. J. D. Nkrumah and B. W. Woodward*, *Merial Limited, Duluth, GA.*

Genetic marker-assisted selection is expected to significantly accelerate the rate of genetic progress through increased accuracy of selection, reduction of generation interval, and increasing selection differentials. A number of polymorphisms with moderate to large effects on economically relevant dairy traits have been reported, including the K232A polymorphism in the DGAT1 gene, the F279Y polymorphism in the growth hormone receptor (BGHR) gene, and the Y581S polymorphism in the ATP-binding cassette sub-family G2 (ABCG2) gene. Other polymorphisms have been reported to show small but economically significant associations on important traits in beef and dairy cattle, but most of these have not received further consideration in terms of validation and application in marker-assisted selection. In the present study, we have assembled a repository of over 2,000 dairy AI sires with high reliabilities for production, functional, and conformation traits, and attempted the validation of the effects of several markers on these traits in Holstein cattle. Current multiple marker association analyses using daughter yield deviations for milk, fat, and protein explain differences of about 700 kg ($P < 10^{-11}$), 30 kg ($P < 10^{-19}$), and 17 kg ($P < 10^{-12}$), respectively, among animals with extreme genotype combinations. We have also developed multiple marker panels using daughter deviations that explain up to 5.0 mo differences in dairy productive life ($P < 10^{-05}$), 2.5 percentage points in daughter pregnancy rates ($P < 10^{-04}$), and 1.8 genetic standard deviations in dairy form ($P < 10^{-15}$). These results show that significant increases in the predicted merit for dairy cattle can be obtained by evaluating models that allow the simultaneous computation of the effects of markers of small or moderate to large effects that are each independently associated with specific traits of economic importance.

406 Application of a Bayesian approach to identify candidate markers for marker assisted selection in pigs. M. A. Cleveland* and N. Deeb, *Genus plc, Hendersonville, TN.*

Genome-wide approaches to estimate genetic effects have proliferated due to increased availability and affordability of markers. These methods assume marker density is high and animals can be genotyped for all markers, which may not be feasible. This study investigated the ability of a Bayesian approach that fits all marker effects simultaneously to correctly identify markers in linkage disequilibrium (LD) with quantitative trait loci (QTL), at varying marker densities. A single chromosome of 200 cM containing five QTL was simulated, where effects were 0.2, 0.4, 0.6, 0.8 and 1.0 phenotypic standard deviations. Single nucleotide polymorphisms (SNPs) were assigned to the chromosome, based on gene drops from a small founder population, in five simulations where average SNP spacing was targeted at 0.1, 0.5, 1.0, 2.0 and 10.0 cM, respectively. Phenotypes were simulated for 2,600 animals selected from several generations of a closed population of pigs. The data were analyzed using single marker regression and a Bayesian multiple marker approach. The single marker regressions yielded many significant effects. The results from the Bayesian analysis showed clear signals at markers adjacent to the QTL, where most other markers had effect estimates at or near zero. In some cases there were multiple peaks near QTL where the effect was distributed between flanking markers. The decrease in marker density did not reduce the ability to identify markers adjacent to QTL, even at large distances where LD would be reduced. The Bayesian approach was also applied to a commercial dataset of 1,066 pigs with genotypes for 180 targeted SNPs across the genome. The analysis identified six markers with non-zero effects on a mortality trait. Results from these analyses indicated the Bayesian approach was suitable for identifying markers of moderate to large size for inclusion in marker-assisted genetic evaluation systems. This strategy can be used to identify marker associations when density is not optimal, in situations where genome-wide evaluation is not yet feasible.

Key Words: Pigs, Genome-Wide Association, Bayesian Analysis

407 Genomic selection of purebreds using data from admixed populations. A. Toosi*¹, R. Fernando¹, J. C. M. Dekkers¹, and R. L. Quaas², ¹*Iowa State University, Ames*, ²*Cornell University, Ithaca, NY.*

Genomic selection involves using marker genotype and phenotype data in a training population to estimate effects of all markers. These estimates are then used to predict the breeding value (BV) of selection candidates given their marker genotypes. In livestock, genomic selection has been investigated by computer simulation of purebred populations. Traits of interest are, however, often measured in crossbreds with uncertain breed composition. If such crossbreds are used as the training population without proper accounting of breed composition, estimates of marker effects may be biased due to population admixture. On the other hand, if the available markers are in high linkage disequilibrium with the trait loci (QTL), it may not be necessary to explicitly account for breed composition. To investigate this idea, a single chromosome of size 1.5 Morgans was simulated with 5000 evenly dispersed loci, of which 250 loci were assigned as QTL. After 1000 generations of random mating in a base population of effective size 500, two sub populations of effective

size 100 were isolated and random mating was continued for another 50 generations to create two breeds (A and B). These breeds were used to generate an F1, F2, and an admixed population. These populations and breed A were used as the training data set, with a total of 1000 individuals with phenotype for a trait controlled by 100 segregating QTL and heritability of 0.30. A Bayesian method (Bayes-B) was used to estimate the effects of 2000 segregating markers. Using these estimates and genotypes of selection candidates, the BVs of breed A animals eight generations away from the training population were estimated. The accuracy of the prediction was quantified by the correlation between the marker based predicted BV and the true BV. The accuracy was highest (0.85) when breed A was used as the training population. When the crossbreds were used as the training population, the accuracy ranged from 0.75 to 0.79. This demonstrates that, under the simulated conditions, purebreds can be accurately selected for crossbred performance using high-density marker data, without pedigree or breed information.

408 A marker-assisted assessment of genotype by environment interaction: SNP-mortality association in broilers in two hygiene environments. N. Long¹, D. Gianola¹, G. J. M. Rosa*¹, K. A. Weigel¹, and S. Avendaño², ¹*University of Wisconsin, Madison*, ²*Aviagen Ltd., Newbridge, UK.*

An interplay between genetic and environmental factors, genotype by environment interaction ($G \times E$), determines phenotypes of complex traits, and implies that some genetic effects may be relevant only in certain environments. $G \times E$ was investigated here by detecting hygiene environment-specific SNP subsets associated with broiler chicken mortality at both early and late ages, followed by an examination of consistency between SNP subsets selected from different hygiene (low and high) environments. The trait was mean progeny mortality rate in 253 sire families, calculated after adjusting records for non-genetic and non-hygiene related environmental effects affecting mortality at the individual bird level. Over 5,000 whole genome SNPs were narrowed down via a machine learning (filter-wrapper) feature selection procedure applied to mortality rates in each of the low and high hygiene environments. For both early and late mortality, it was found that the SNP subsets selected were not consistent across hygiene environments, in terms of either across-environment predictive ability or extent of linkage disequilibrium (LD) between the subsets. Reduction in mortality predictive ability due to $G \times E$ was assessed by the ratio of two PRESS (predicted residual sum of squares) statistics, one associated with using SNPs selected from the same hygiene environment, and the other one associated with the SNP subset from a different environment. The reduction was 30% and 20% for early and late mortality, respectively. In addition, an extremely low level or absence of LD between SNP subsets selected under low and high hygiene also indicated $G \times E$. These findings suggest that there may not be a universally best SNP subset for predicting mortality, and that interactions between genomes and environmental factors need to be considered when attempting to associate genetic variants with complex traits.

Key Words: Genotype by Environment Interaction, SNP-Mortality Association, Hygiene Environments

409 Linkage disequilibrium and persistence of phase in Holstein Friesian, Jersey and Angus cattle. A. P. W. De Roos^{*1}, B. J. Hayes², R. J. Spelman³, and M. E. Goddard^{2,4}, ¹CRV, Arnhem, The Netherlands, ²Animal Genetics and Genomics, Primary Industries Research Victoria, Attwood, Australia, ³Livestock Improvement Corporation, Hamilton, New Zealand, ⁴University of Melbourne, Melbourne, Australia.

Genomic selection across multiple populations is complicated because linkage disequilibrium (LD) between markers and QTL may differ across populations. The objectives of this study were to compare the extent of LD and the persistence of LD phase across multiple cattle populations. LD measures r and r^2 were calculated for syntenic marker pairs using genome-wide single nucleotide polymorphisms (SNP) that were genotyped in Dutch and Australian Holstein Friesian (HF) bulls, Australian Angus cattle, and New Zealand Friesian and Jersey cows. Average r^2 was around 0.35, 0.25, 0.22, 0.14, and 0.06 at marker distance 10, 20, 40, 100 and 1000 kb, respectively, which indicates that genome-wide association studies or genomic selection within cattle breeds would require ~50,000 SNP. The correlation of r values between populations for the same marker pairs was close to 1 for pairs of very close markers (<10 kb) and decreased with increasing marker distance and the extent of divergence between the populations. The correlation of r values between Dutch and Australian HF, was still above 0.80 for marker distances of more than 1 Mb. Between Australian HF and New Zealand Friesian, or between New Zealand Friesian and New Zealand Jersey this correlation dropped below 0.80 for marker distances above ~50 kb, whereas between Australian Angus and New Zealand Jersey, the correlation dropped below 0.80 when the markers were more than 5 kb apart. To find markers in that are in LD with QTL across diverged breeds, such as HF, Jersey, and Angus, would require ~300,000 markers.

Key Words: Linkage Disequilibrium, Genetic Markers, Cattle

410 Estimated linkage disequilibrium in a multi-breed beef herd based on the Illumina BovineSNP50 BeadChip. M. J. Kelly^{*1}, M. Sargolzaei¹, Z. Wang², D. Kolbehdari², P. Stothard², F. Schenkel¹, S. S. Moore², and S. P. Miller¹, ¹University of Guelph, Guelph, ON, Canada, ²University of Alberta, Edmonton, AB, Canada.

Genomic breeding values may enable the beef industry to select genetically superior cattle for traits that are expensive or impossible to measure in conventional breeding programs. However, to estimate genomic breeding values with sufficient accuracy or fine mapping QTLs, a high degree of linkage disequilibrium (LD) between markers and the QTL is required. The average amount of LD between markers (SNPs) and QTLs across the bovine genome was assessed using the Illumina BovineSNP50 BeadChip within a multi-breed beef herd. A preliminary experiment comprised 374 multi-breed beef cattle (predominantly progeny of cross-bred cows mated to purebred terminal sires). Breeds represented included mostly Angus, Simmental, Limousin, Charolais and Piedmontese. Animals were genotyped for 56,947 SNPs. After exclusion of SNPs from the analysis when minor allele frequency was below 10% which included monomorphic SNPs (21%), due to a high proportion of uncalled genotypes (~0.1%), deviation from Hardy-Weinberg equilibrium (0.2%), located on chromosome X (1.6%), or unlocated (15%), 35,317 SNPs remained. The average distance between adjacent SNPs, once these edits were made, was 58 kb. Therefore, on average, the maximum distance between SNPs and QTLs should be half this (29 kb). The average r^2 based on 3428 marker pairs between markers 30 to 35 kb apart was calculated to be 0.21 (SD=0.26), this is somewhat lower

than that found in purebred populations. An approximation of the power to detect QTLs with this level of LD was examined (at $p < 0.01$). A QTL had to explain at least 8.5% of the phenotypic variance in order to be detected with a statistical power greater than 90% with a sample size of 1000. To detect smaller effects (2.5% of phenotypic variance) would require larger sample sizes (~3500) or higher levels of LD ($r^2 \sim 0.7$). Thus subsequent work will focus on genotyping a larger population and fine mapping regions of interest.

Key Words: Beef, Genomics, Linkage Disequilibrium

411 Linkage disequilibria of the SLA region loci with malignant melanoma in Sinclair swine. L. Gomez-Raya^{*1}, M. Miller¹, C. S. Ho², V. Kirchoff¹, D. M. Smith², W. M. Rauw¹, D. Thain¹, A. Rink¹, and C. W. Beattie³, ¹University of Nevada, Reno, ²University of Michigan, Ann Arbor, ³University of Illinois, Chicago.

The experimental design consisted of a boar mated to 11 sows to produce 70 offspring. A total of 20 DNA-markers within the Swine Leukocyte Antigen (SLA) region were typed (SW1856, SLAM62, SLA-1, SLA-3, SLA-2, SLAM037, SLAM055, SLAMA14, SLAMA13, SLAM046, SLAMS045, SLAMS044, SLAM043, SLAMA18, SLAM095, DRB, DQB, SLAMS092, SLAM047, SW0102). Linkage disequilibrium at each pair of loci was estimated by inferring the haplotypes contributed by the dams for all informative offspring. Linkage disequilibrium between each pair of loci was estimated using the normalized D' of Lewontin but allowing for more than two alleles. Strong linkage disequilibria were estimated for each pair of DNA-markers between SW1856 and DQB (ranging from 0.95 to 1). Testing of linkage disequilibrium within the boar family was performed while searching for 1) susceptibility to SSCM (at least one tumor during the first six weeks of life), and 2) number of tumors at birth (TB), at 6 weeks post-partum (T6), and the difference in tumor number between birth and six weeks (T6-B). Loci affecting melanoma susceptibility were not detected. However, we detected a QTL affecting T6-B in this region (P-value of 0.0028 in the permutation test). We tested for population-wide linkage disequilibrium for the number of tumors using the allele inherited from the dam. Our results showed that alleles are statistically associated with T6 and T6-B (up to 2.1 tumors at $P < 0.05$). However, the strong linkage disequilibria of loci in this region may limit finer mapping of a QTL.

Key Words: Swine, Malignant Melanoma, Swine Leukocyte Antigen

412 QTL with dominance effect affecting residual feed intake on BTA6. G. C. Márquez^{*1}, R. M. Enns¹, M. D. Grosz², and M. D. MacNeil³, ¹Colorado State University, Fort Collins, ²Monsanto Co., St. Louis, MO, ³USDA, Agricultural Research Service, Miles City, MT.

Residual feed intake (RFI) is a measure of feed efficiency and therefore an economically relevant trait. A genome-wide scan for quantitative trait loci (QTL) affecting RFI in beef cattle was conducted. Approximately equally spaced microsatellite markers ($n = 229$) spanned the 29 bovine autosomes. Two half-sib families of backcross progeny were produced by mating two F1 Line 1 Hereford (L1) \times composite gene combination (CGC) bulls to L1 and CGC cows. Progeny of the first sire were born in 1996 ($n=155$) and of the second sire were born in 1997 ($n=120$). Phenotypic data on feed intake and weight gain was collected in 1997

and 1998 for the two calf crops. Due to serial harvest for collection of carcass data, time on feed varied from 82 to 167 days. RFI was calculated as the residual after fitting the regression of daily feed intake on average daily gain, average weight, sex, and year of birth. Genotypes and phenotypes were collected from 218 animals. The backcross progenies from L1 and CGC females were analyzed separately using composite interval mapping. In the backcross to L1 cows, evidence for a QTL affecting RFI was found on BTA6 with a LOD score of 3.2 at 58 cM. Substitution of the L1 allele for the CGC allele reduced RFI by 0.9 kg/d. This QTL was absent in the backcross to CGC cows. Presence of an allele substitution effect in one backcross, but not the other, is consistent with the dominance model of inheritance. Thus, these results indicate a putative QTL with dominance effect on RFI located at approximately 58 cM on BTA6.

Key Words: Beef Cattle, Quantitative Trait Loci, Residual Feed Intake

413 Confirmation of quantitative trait loci for carcass and meat quality traits on pig chromosome 6 in a Duroc x Pietrain resource population. I. S. Choi*, R. O. Bates, N. E. Raney, D. B. Edwards, M. E. Doumit, and C. W. Ernst, *Michigan State University, East Lansing.*

We have previously reported quantitative trait loci (QTL) affecting carcass composition and pork quality on pig chromosome 6 (SSC6) in the Michigan State University Duroc x Pietrain F₂ resource population. The objective of the present study was to confirm these QTL by

incorporation of marker genotype data for an additional 452 F₂ pigs into the QTL analysis, thus improving the QTL detection power by nearly doubling the number of informative meioses. A total of 962 F₂ pigs were genotyped for the SSC6 markers S0087, SW122, SW1881 and SW322. Other SSC6 markers genotyped for the original genome scan (510 F₂ pigs) included S0099, SW2406, SW2525, S0220 and SW2419. Data were analyzed with line cross least squares regression interval mapping methods using sex and litter as fixed effects and carcass weight or harvest age as covariates. Carcass composition phenotypes included primal cut weights, skeletal characteristics, backfat thickness, muscle pH and carcass temperature. Meat quality data collected on boneless *longissimus* muscle chops included marbling, firmness, drip loss, and objective and subjective color. QTL significant at the 1% chromosome-wise level were found for first rib, tenth rib, last rib and last lumbar vertebra backfat, and for hot carcass weight, carcass length, loin muscle area, ham weight, loin weight and belly weight. QTL significant at the 5% chromosome-wise level were found for 24 h carcass temperature, Boston shoulder weight and marbling score. These results confirmed previously identified QTL and included four new QTL (carcass weight, first rib backfat, Boston shoulder weight and belly weight). In addition, F-ratios and LOD scores were increased for all traits except marbling score. However, three previously identified QTL failed to reach the 5% chromosome-wise level of significance (subjective color score, CIE a* and spareribs weight). The incorporation of additional F₂ animal genotypes into the QTL analysis helped to improve the power and precision of QTL detection and our results confirm QTL for carcass composition and pork quality on SSC6 in the MSU resource population.

Key Words: Pig, QTL, Carcass Composition

Symposium: Companion Animals: Perceptions and Implications of Companion Animals in Research and Teaching - Domestically and Globally

414 ASAS Centennial Presentation: Evolution of companion animals - A perception shift. L. P. Case*^{1,2}, ¹University of Illinois, Urbana, ²AutumnGold Consulting, Mahomet, IL.

We are a nation of dog and cat lovers. Never before in our history have we spent more time, money, and emotional energy on a group of animals that are kept solely for companionship. Pet food sales are a multi-billion dollar industry and pet owners are spending more than 11 billion dollars each year on veterinary care. This devotion is further illustrated by the exponential growth of the pet supply industry, including increasing numbers of pet “super-stores”, play-parks, training centers, and doggie day care centers. During the 1980’s, recognition of the “human-animal bond” led to serious study of the roles that pets play in our lives. These studies have shown that pets provide significant benefits to our emotional, physical and social well being. Unlike any other non-human species, dogs and cats have become fully integrated into our lives and our hearts. It is ironic then, that at a time when we recognize and appreciate our bonds with animal companions, dark elements of this relationship are equally pervasive. Animal shelters in the United States kill between 3 and 4 million dogs and cats annually. Dog fighting, although outlawed, has reached epidemic proportions in some areas of the country. Colonies of feral cats are so prevalent that organizations are devoted completely to their advocacy. Episodes of animal cruelty and neglect are reported with alarming frequency in the media; so frequently that discussions of the connection between animal cruelty and human violence have become daily parlance. How then did we come to have such paradoxical perceptions and treatment of our animal companions? Facts and myths about our pets’ ancestries and the cultural changes that led to domestication will be presented. Motivations for and results of selective breeding practices that created pets with wildly differing appearances and temperaments are discussed. A review of our working relationships with dogs and cats and the evolution of those relationships into bonds of companionship provides an understanding of pets today and a basis for continuing the evolution of our relationship with our two “best friends”.

Key Words: Companion Animals, Domestication, Human-Animal Bond

415 Past-present perceptions and research in companion animals – A domestic viewpoint. G. Czarnecki-Maulden*, Nestle Purina Research Center, St. Louis, MO.

The objective of this presentation is to review the evolution of research in companion animals in the United States over the past fifty years and how it relates to the perception of pets, trends in human nutrition and progression of the pet food industry. Nielsen reports on market data, pet food labels and literature reviews for specific time periods were evaluated. Much of the early canine and feline nutrition research focused on defining nutrient functions. Often this research focused on the use of dogs and cats as models for humans. This lack of research on dogs and cats was reflected in the type of pet foods on the market. Fifty years ago, most pet foods were “one size fits all”. As dogs and cats became more valued members of the human family, interest in companion animal nutrition blossomed. Increasingly, research has focused on functional ingredients and improving quality of life and longevity. Research areas

often parallel those in human nutrition. New non-invasive methodologies have allowed the study of body systems and metabolic pathways previously unattainable. Along with the changing focus of companion animal nutrition research came a shift in where the research is conducted. Industry scientists published few studies 30-50 years ago and there were only a handful of companion animal nutritionists in academia or industry. Now most pet food companies have several nutritionists. As a result, pet foods have become increasingly specialized and nutritionally focused.

Key Words: Nutrition, Dog, Cat

416 Past-present perceptions and research in companion animals – An international viewpoint. P. Nguyen*¹, L. Prola², R. C. Nap³, P. P. Mussa², and J. Nery¹, ¹National Veterinary School of Nantes, Nantes, France, ²Veterinary School of Turin, Turin, Italy, ³Uppertunity Consultants, Utrecht, The Netherlands.

In Europe animal experiments are subdued to the European convention ETS 123 and the EU directive 86/609 both adopted in 1986. The directive provides a minimum framework for housing and care of research animals. It also aims to promote the 3Rs. States may adopt more stringent regulation, and animal rights organizations (AROs; with different levels of “activism”: from those who aim to promote animal interests or influence public attitudes towards animals, to those who recommend strong-arm methods, to free research animals, and to carry out economical sabotage) have played a role in influencing the public opinion and politicians towards animal welfare and the use of animals in research. Sweden adopted an Animal Welfare Act. In the Netherlands the Party for the Animals has 2 seats in parliament. In Italy to get an authorization for dog research may need having each animal adopted by a family. Bull fighting is authorized here while displaying lobster on ice is fined there...

In EU, dogs and cats represent only $\pm 0.23\%$ (28000 in 2005) of total research animals. This use has been decreasing over the last 15 years. Some countries do not use any dog or cat while 3 account for 65% of dogs used in EU and 2 for 60% of cats. The EU directive is under revision and it could be influenced by a lobby engaged on banning research on primates. No doubt that pet animals are on the second line.

Using pets to study their physiology and diseases can still make scientific sense but using them to study human diseases or experimenting on healthy animals and deliberately making them sick has become unacceptable. Some AROs reject any animal experiment, even food testing, due to the use of “cruel and unethical” methods with the only objective of marketing edge. Some even publish lists of brands recommended or to boycott. More than direct effect on public opinion, this can strongly influence research definition and funding. Pet research has been reduced by improved access to information. Invasive protocols have been strongly restricted. Funding is driven by citation indexes, evidence of need, and optimal ratio between research benefit and disagreement for research animals.

Key Words: Companion Animals, Animal Research, Europe

417 Evolution of regulatory issues in companion animals. S. L. Traylor*, *Alltech, Inc., Nicholasville, KY.*

The evolution of food for companion animals is relatively short compared with the domestication of companion animals. Until commercial pet food grew in popularity, dogs ate whatever was available in their environment. This might have included meat scraps, raw milk, or eggs. In 1860, James Spratt developed the first processed dog biscuit and more than likely, sparked interest in regulatory and consumer related issues. During the early years, a small number of companies marketed pet food; however, they were not without their problems. Demand for these products was not high and the consumer often found the contents green with mold or rancid. Interestingly, it was about fifty years later that the first Federal Food Law was promulgated. The Pure Food and Drug Act of 1906 bill was rewritten in 1938, as amended, this is today's law and provides protection for man and animal. In parallel with Federal Law, the Association of American Feed Control Officials was formed and they quickly became the regulatory authority at the state level for labeling compliance. Although modern pet food formulations have become more complicated, the labels of the Depression Era have not changed much from those of today. Most regulatory authorities speculate that the information on the label is not likely to change significantly. However, at the date of submission, there are whole host of "safety" bills that have been introduced in Congress. These bills aim to provide the FDA, USDA and other agencies with new food safety authorities and responsibilities. One bill that was signed into law, the Food and Drug Administration Amendments Act (FDAAA), requires the FDA to promulgate rules in two years that will create ingredient standards, process control requirements, updated labeling and additional nutritional information for pet foods. The era of voluntary regulatory compliance is dated and the regulatory environment for the animal and pet food industry will require additional resources to implement the new feed safety regulations that are inevitable.

Key Words: Companion Animal, Regulatory, Feed Safety

418 Trends in pet food safety. R. Johnson*, *Private Pet Food Consultant.*

In the spring of 2007, the North American pet food industry experienced the most dramatic product recall in its history. Due to the number of pet food brands involved and intense media coverage, Congressional inquiries were generated as to the manner in which the safety of pet foods could be compromised. The basis for this massive recall was investigated by Federal and State agencies which determined that adulterated vegetable protein products coming from China contained melamine. Public and media attention to this recall exceeded anything that the Federal Drug Administration (FDA) had ever experienced. The result of these Congressional Hearings was a mandate for the implementation of a comprehensive feed safety program. The FDA has been directed by Congress, under the Federal Drug Administration Amendment Act (FDAAA), to develop a Food/Feed Safety Program. The FDAAA will create a reportable food registry for FDA regulated products. Within two years the FDA is to enact ingredient standards/definitions, processing standards, and a reportable food registry. The FDA and the American Association of Feed Control Officials (AAFCO) signed a Memorandum of Agreement to work together in development of the goals of FDAAA. In December 2007, the FDA signed a Memorandum of Understanding with China to exchange, investigate, and pursue feed safety issues. Congressional House Bills for 2008 are seeking required CGMP/

HACCP process control regulations for all foods and feed within two years. They would also increase civil monetary penalties and establish private rights of litigation. Items that can be expected for pet food safety will be the establishment of CGMP, where risk warrants; authorized increase in FDA inspections, based upon risk; FDA authorization of accredited third party inspections; expanded research and diagnostic laboratory activities related to improved food safety; modernization of computer systems for Federal Departments and Agencies for exchange of information on importers and shipments; authorization by the FDA for establishment of overseas inspection of high risk imports; and the utilization of third party inspectors.

Key Words: Pet Food, Food Safety, FDA

419 Alternatives to live animal models in companion animals: Research location shift. G. Kuhlman* and M. A. Tetrick, *Procter & Gamble Pet Care Research & Development, Lewisburg, OH.*

There are multiple options to consider for alternatives to current live companion animal testing methodologies. These options include refining the research environment, reducing the number of animals used or replacing the animal model. This presentation will focus on the refinement of the research setting as well as the shift from research environments into privately owned companion animals in the home. These refinements provide greater access to the five freedoms and are steps along the continuum to replacement alternative methods.

In considering housing refinements for felines, automated urine and fecal collection systems have been developed. These systems allow for social housing and interactions among groups of cats while still allowing individual feeding and individual identified collection of fecal and urine samples. Additionally, careful adaptation and acclimation of cats to research procedures such as blood sampling have been developed that allow for minimal restraint and greatly reduce stress for the cats and reduce the risk of injury for veterinary personnel. Similarly for dogs, implementation of paired housing allows conspecific species interaction but requires careful oversight and management as well as refinement of research procedures to be successful.

Shifting the location of dogs and cats participating in research studies to the home and veterinary clinic has been successfully accomplished. Clinical research in collaboration with veterinarians allows enrolling dogs or cats with preexisting clinical conditions to evaluate dietary interventions e.g. renal failure, diabetes, osteoarthritis, etc. Methods such as split plate preference studies typically run in the research setting can be adapted to be conducted by the pet owner in the home. While there are limitations that come with this location shift it also affords flexibility to recruit specific breeds, age groups, and health conditions and provides the ability to expand or contract capacity reducing overhead when not engaged in research. Application of these refinements has the potential to enhance welfare and facilitate research.

Key Words: Alternative Methods, Canine, Feline

420 Alternative systems for evaluating digestion in companion animals. D. L. Harmon* and M. R. C. de Godoy, *University of Kentucky, Lexington.*

To enable accurate diet formulation the ability to predict the behavior of individual feed ingredients is needed. This requires knowledge of

digestion and absorption of nutrients contained in these ingredients which is usually obtained in animal feeding studies. It is not possible to evaluate every ingredient source in animal studies, thus assays for comparing ingredients are widely used to estimate ingredient quality. This is particularly true in regards to amino acid and mineral bioavailability. Models that have been directly compared with the dog and cat include the cecectomized rooster, protein efficiency ratio in chicks, the blue fox, the mink and the rat. The rooster assay had very high correlations ($r = 0.87$ to 0.92) for individual amino acid digestibilities with values obtained in the dog indicating that it was a useful means of predicting nutrient availability in the dog. In vitro systems for determining digestibility have also been developed. These range from complex, multi-compartment, computer controlled systems to enzyme-test tube assays. Their application to pet foods has been limited; however, high correlations with in vivo digestion have been reported. One problem described when evaluating commercial pet foods is the narrow range of results obtained, thus making the development of an accurate prediction model difficult. Fermentation systems have been used based on fecal inoculum from both dogs and cats; however, the application has been limited to characterization of dietary fiber or other ingredient sources. Their application to complete diets is limited.

Key Words: Fermentation, In vitro, Digestion

421 Computer modeling: An alternative to live companion animal testing. R. M. Yamka* and N. Z. Frantz, *Hill's Pet Nutrition, Inc., Topeka, KS.*

In recent years, the pet food industry has been striving to refine, reduce and replace animal testing through alternative methods. Methods of alternative testing can include both in vitro and/or computer modeling. The aim of this review is to gain a fundamental understanding in how computer models are typically developed and the types of models available to the pet food industry today. The models discussed in this review will include urine pH, digestibility, metabolizable energy, stool quality and body composition. Since most of the models available today utilize the nutrient composition of the foods for prediction, this review will discuss how the incorporation of some of these models into food formulation can result in the reduction of time and costs associated with getting foods to market.

Key Words: Dog, Cat, Computer Modeling

422 ASAS Centennial Presentation: The future of teaching and research in companion animal biology in departments of animal sciences. J. McNamara*, *Washington State University, Pullman.*

Departments of Animal Sciences must be relevant to a society in which a small number of people can raise all the animal products needed. While involvement in animal agriculture has declined, lowering enrollments in many Departments, several of these adapted by seeking out and welcoming students from a diverse background. This is not a new trend, as research and teaching about pets dates to the 1940's. The adaptation was spotty and not without some 'discussion'. The future is now, and in most states, the undergraduate curriculum depends on having a number of students interested only in companion animals. A benefit is that we can often recruit 'new blood' into agriculture, and students have gone and will go on to excellent careers in agriculture. We have a new challenge: how to maintain and expand the efforts in both teaching and research. Departments wishing to expand in teaching have examples of successful courses and curricula from other departments that they can use. Some departments have, and others should, expand their teaching across their university to teach about pets to a wider audience than their own majors. In research, a small number of faculty have been able to establish extramurally funded projects on pets. Horses are included in this effort, and several departments have excellent equine programs. But it will be difficult for more than a handful of departments to have a serious research effort in dogs, cats, birds, fish or exotic animals. Departments will have to make a concerted effort to invest in such endeavors, joint ventures with other Universities and Colleges of Veterinary Medicine (or Medicine) will probably be required. Funding sources for traditional efforts in nutrition, reproduction, physiology, etc. are small and inconsistent; however, with the progress of the canine, and now feline, genome project, there should be opportunities from federal funding sources aimed at using animal models for human health. In addition, efforts in animal behavior and welfare can be expanded, perhaps with some funding from private foundations or animal-supportive organizations.

Key Words: Companion Animals, Research, Teaching

Symposium: Dairy Foods: Changes and Challenges of Probiotics in Dairy Products

423 Probiotics: From Metchnikoff to bioactives. N. P. Shah*, Victoria University, Melbourne, Victoria, Australia.

Nobel Laureate Ilya Metchnikoff suggested that human body was slowly poisoned by toxins present in the body produced by pathogens in the intestine and body's resistance steadily weakened by proliferation of enteric pathogens, all of which were successfully prevented by the consumption of fermented milk. Probiotics are live microorganisms which when administered in adequate amounts confer a health benefit on the host. Traditionally probiotics have been incorporated in yoghurt; however, a number of carriers for probiotic have been examined recently including mayonnaise, and spreads, in addition to other products of dairy origin i.e. cheese or cheese-based dips. It has been estimated that there are approximately 70 probiotic-containing products marketed in the world. Probiotic organisms are also available commercially in milk, sour milk, fruit juices, ice cream, single shots and oat-based products. Lunbest, Olifus, Bogarde, and Progurt are some of the commercial products. Probiotic products are very popular in Japan as reflected in more than 53 different types of probiotic containing products on the market. Commercial cultures used in these applications include mainly strains of *Lactobacillus* spp., *Bifidobacterium* spp. and *L. casei*. Since Metchnikoff's era, a number of health benefits has been contributed to products containing probiotic organisms. The strains *L. rhamnosus* GG (Valio), *Saccharomyces cerevisiae* Boulardii (Biocodex), *L. casei* Shirota (Yakult), and *B. animalis* Bb-12 (Chr. Hansen) are certainly the most investigated probiotic cultures with the established human health efficacy data against management of lactose malabsorption, rotaviral diarrhoea, antibiotic-associated diarrhoea, and *Clostridium difficile* diarrhoea. The functionality of dairy proteins may also be enhanced via liberation of bioactive peptides through proteolysis. Among bioactive peptides, angiotensin I-converting enzyme (ACE) inhibitors have been extensively studied due to their hypotensive role. Accordingly, several commercial products with highly proteolytic strains of *L. helveticus* have been developed and marketed to possess hypotensive activity including Calpis®, and Evolus®.

Key Words: Probiotics, ACE-I Peptides, Proteolytic System

424 Probiotics in natural cheese. B. Dias* and N. Mix, Kraft Foods Inc, Glenview, IL.

Significant increase in consumer awareness of probiotic cultures has boosted these cultures to becoming one of the top consumer trends in foods delivering health benefits. While probiotics have traditionally been found in yogurts, natural cheese has proven to be a good carrier for these cultures. Furthermore, studies have suggested that consuming probiotics in a cheese matrix is favorable for the viability of probiotics through the digestive tract. This has led to the marketing of several varieties of cheese containing added probiotic cultures. Natural cheeses are comprised of a complex microbial ecosystem which is in a constant state of flux as the cheese ages. Changes, including the addition of probiotic microorganisms, have the potential to significantly impact the chemical and microbiological properties of cheese. Hence, careful selection of strains is necessary to minimize alterations to the flavor and texture of cheese.

This presentation will review and discuss recent developments in relation to the production of probiotic cheese, the advantages and disadvantages

of cheese as a carrier, the stability of probiotic cultures in cheese, and the impact of processing on the viability of probiotics in natural cheese.

Key Words: Cheese, Probiotic

425 Development of yoghurt and specialty milks containing probiotics. C. P. Champagne*, Agriculture and Agri-food Canada, St. Hyacinthe, QC, Canada.

Yoghurt and fermented milks have been the most widely used food matrixes for the development of probiotic-containing functional foods. In this review-type presentation, the potential for innovation in this field will be examined. As opposed to starter cultures which are often prepared at the dairy plant, in yoghurt manufacture, probiotics are generally inoculated with direct-to-the-vat (DV) cultures. They are found in frozen or freeze-dried form. Examples will be given as to the effect the method of storage of the DV probiotic concentrate, its method of preparation (thawing or rehydration procedures) and the moment of addition in the yoghurt process on the viability of the probiotics in the product. Probiotic bacteria generally do not grow well in milk and are adversely affected by starters and storage conditions. Examples will be given on how strain selection, ingredients selection (flavours, enzymes, fruits or vegetables, prebiotics), strain microencapsulation and packaging can be used to innovate and develop new products while addressing these stability problems. Unfermented milks are now seen on the market. Data will be presented on the effect of strain viability of probiotics in such products is affected by strain and some technological processes (degassing, strain encapsulation). Fluid milk could be of great interest in promoting the survival of probiotics to the gastric environment, and some thoughts on the effect of the food matrix on probiotic functionality will be offered.

Key Words: Lactobacillus, Bifidobacterium, Functional Foods

426 Recent trends in the microencapsulation and delivery of probiotics in dairy foods. K. Kailaspathy*, University of Western Sydney, Hawkesbury, NSW, Australia.

Micro encapsulation has become the recent tool used for protecting and delivering bio-actives in the development of bio-functional foods. Probiotic foods are by far the largest functional food market. They provide several health benefits including immuno stimulation. Viability, physiological and metabolic activity of probiotic bacteria in a food product at the point of sale are important consideration for their efficacy, as they have to survive during shelf life of a food, transit through high acidic and alkaline conditions in the gastro-intestinal tract. It is essential that products sold with any health claims meet the recommended criterion of a minimum of 1 million CFU/g of probiotic bacteria at the expiry date and the minimum therapeutic dose per day is suggested to be 100 million cells. The reported health benefits of probiotic bacteria are: enhancement of immunity against intestinal infections, immune enhancement, prevention of diarrhoeal diseases, prevention of colon cancer, prevention of hypercholesterolemia, improvement in lactose utilization, prevention of upper gastro-intestinal tract diseases and stabilisation of the gut

mucosal barrier. Various studies have shown that probiotic organisms survive poorly in foods like yoghurt and fermented milks with cell numbers being much lower than the recommended levels at the expiry date. Therefore there is a need to protect the probiotic bacteria against adverse processing and storage conditions as well as during transit in the gastro-intestinal tract. Micro encapsulation is an inclusion technique for entrapping live cells such as probiotic bacteria, into a polymeric (gelled) matrix that may be coated by one or more semi-permeable polymers, by virtue of which the encapsulated substance become more stable than the free one. The aim of our investigation was to study the survival of micro encapsulated bacteria in fermented dairy products and their release in the gut and immune-stimulating effects; stability and release.

Key Words: Microencapsulation, Probiotics, Controlled Release

427 Identification of probiotic features in *Lactobacillus acidophilus* affected by dairy delivery. M. A. Azcarate-Peril*, R. Tallon, and T. R. Klaenhammer, *North Carolina State University, Raleigh.*

Historians generally agree that yogurt and other fermented milk products were born by accident when Neolithic people living in Central Asia, where the climate was appropriate, noticed that milk, which they carried in pouches made out of sheep's stomachs, had curdled. Today,

fermented milk products are often associated with good health and extended life, and some members of the lactic acid bacteria group are recognized as probiotics. In fact, *Lactobacillus acidophilus*, a member of this group, is commonly added to yogurt to promote health benefits. Approximately, 80% of the yogurt in the United States contains added *L. acidophilus*.

This study examined how growth or delivery in milk systems impacts the expression of traits that are important for probiotic activity, fermentative properties, and survival in a dairy environment or the human gastrointestinal tract. We employed microarray hybridization experiments to first, monitor gene expression of *L. acidophilus* cells propagated in milk during early, mid and late logarithmic phase, and stationary phase. Second, we characterized gene expression after exposure to specific milk components: casein, alpha-lactalbumin, beta-lactoglobulin, glycomacropeptide, and milkfat globule membrane fractions. Additionally, we investigated how mutations in genes differentially expressed during growth in milk affect acidification activity, survival under storage conditions, and adhesion to mucin and Caco-2 tissue culture cells. Whole genome transcriptional studies provided us with an overview of how probiotic organisms survive and function in both the dairy environment and the gastrointestinal tract. From this point on, a functional genomics approach is instrumental to elucidate the role of genes induced or repressed in the presence of compounds of interest, and how we can reprogram bacterial genetic systems to benefit the host.

Key Words: Probiotics, Gene Expression, Milk and Dairy Products

Symposium: Extension Education: From 40 Acres and a Mule to Today: Historical Perspective of Extension Programming

428 ASAS Centennial Presentation: History of extension. J. Paterson*, *Montana State University, Bozeman, MT.*

When President Wilson signed the Smith-Lever Act on May 8, 1914, he called it one of the most significant and far-reaching measures for the education of adults ever adopted by the government. Its purpose was to aid in diffusing among the people, useful and practical information on subjects related to agriculture and home economics. Even though most farm people at the turn of the 20th century were literate, many were not comfortable with the printed word and by tradition distrusted book farming. Seaman Knapp has often been referred to as the father of the Extension Service. Then 70 years old, Knapp had been a farmer, professor, and president of Iowa Agriculture College. He believed that the only way to change cotton-farming practices related to the boll weevil was to conduct research on the farmers own land. Starting in the 1980s, the Extension System shifted from a focus on audience to a focus on issues. A more recent Extension mission statement was to enable people to improve their lives and communities through learning partnerships that put knowledge to work. Why the changes? When Cooperative Extension was started in 1914, about 30% of US workers were employed in farming compared to today where approximately one percent of the hired workforce is in farming. Starting in the 1990s, Extension was charged to develop and implement a system based on issue-oriented goals which were: 1) an agricultural production system that is highly competitive in the global economy; 2) a safe, secure food and fiber system; 3) a healthy, well-nourished population; 4) a greater harmony between agriculture and the environment and 5) enhanced economic opportunity and quality of life. Today land use, obesity prevention, responsible use of pesticides, urban revitalization, non-agriculture commerce, and specific attention to the needs of underserved audiences are among the expanded Extension programs. Recently, some observers believe that the Extension Service has experienced mission creep and should return to a focus on agriculture while others argue that the Extension Service is a captive of agriculture interests and should serve a broader national purpose.

Key Words: Extension, History of CES, Cooperative extension

429 ASAS Centennial Presentation: Evolution of delivery methods. M. Hutjens*, *University of Illinois, Urbana, IL.*

One of extension's mission is to interpret and deliver research data and results to clientele. Early methods included on-farm demonstrations and field days to stakeholders. The traditional methods included face-to-face discussions and local meetings as travel was limited and on-farm validation important. As technology and transportation improved, delivery methods become more varied including local, regional, and national meetings using flip charts, overheads, slides (glass to plastic), and power points. The use of mass media including dairy magazines, local newspaper, mass media, radio, and television continue to be effective sources of information. Another method focused non-traditional on clientele with programs specifically for veterinarian (such AABP), dairy sanitarians, feed consultants, and A.I personnel. As extension funding becomes more limiting, more delivery systems are sponsored

and funded by industry groups (feed, seed, and A.I. organizations are examples) with extension educators presenting part of the program. Newer clientele groups include Hispanic program in Spanish and international conferences that are translated. The arrival of the Internet has expanded the methods to reach clientele including e-mail, webinars, on-line classes, and face-to-face discussions on-line. In the seminars, two new approaches will be discussed including the University of Illinois Dairy Certificate program (<http://online.ansci.uiuc.edu/>) and pod casts (<http://web.extension.uiuc.edu/podcasts/dairy/>). The dairy certificate program on the Internet was initiated in 1998 with the five classes (nutrition, reproduction, management, milk secretion, and principles of dairy science). Over 350 students have enrolled in classes with three certificates awarded while other students enroll for information and new knowledge, career enhancement, completion of a graduate advanced degree, and continuing education requirements.

Key Words: Extension, Internet, Delivery

430 ASAS Centennial Presentation: From 40 acres and a mule to today: Historical perspective of extension programming: Horse-Quest. E. A. Greene*, *University of Vermont, Burlington.*

eXtension (pronounced e-extension) is a web-based educational tool created by extension specialists, agents, and educators for the purpose of providing a complementary resource for use by extension personnel and clientele. This national extension initiative provides information divided by content areas (e.g. Horses, Dairy, Beef, Financial Planning, etc.). "Community of Practices" (CoP), made up of extension experts in each specific area of interest, develop the peer reviewed content for the site. The HorseQuest CoP, which has content contributed by more than 40 experts at over 30 institutions, was the first CoP to publicly launch their content in September 2006. The website (www.extension.org/horses) provides clientele a variety of methods and learning opportunities related to the care, management, and training of horses. Areas on the site include: Interactive Learning Lessons, Web Chats, Frequently Asked Questions, Basic Information, and News. Content is delivered through text, photos, videos, podcasts, flash applications, and interactive chats. The HorseQuest CoP has led the way in providing unique educational opportunities to reach their clientele. Through self guided Learning Lessons, horse enthusiasts can move at their own pace, or alternatively, research the topics through the "best of the best" articles available on the site. The "Ask the Expert" mechanism allows for individual questions to be addressed. Our experts also facilitate quarterly live chats on highly requested topics (e.g. Horse Care on Small Acreage, Feed Supplements, Exercise Physiology, etc.). Site usage statistics were evaluated by month from September 2006 through January 2008 using simple linear regression. Unique visitor traffic ($R^2 = .847$), Number of Visits ($R^2 = .836$), Pages Visited ($R^2 = .758$), and Page Hits ($R^2 = .753$) all significantly increased over time ($p < .001$). Finally, with eXtension site's recent conversion to Web 2.0 format, site users will be able to provide additional feedback through improved evaluation and ranking systems.

Key Words: Horse, eXtension, Internet

431 ASAS Centennial Presentation: DAIReXNET - Method of delivering extension programming for the dairy industry which transcends traditional methods of information delivery and state/regional borders. D. M. Amaral-Phillips* and L. McClanahan, *University of Kentucky, Lexington*.

DAIReXNET was launched in October 2007 at the World Dairy Expo in Madison, WI. This national, extension-driven web resource was developed using the latest in Web 2.0 technologies as a part of the eXtension effort and is designed to meet the educational and decision-making needs of dairy producers, allied industry partners, extension educators and consumers. Through collaboration amongst dairy professionals, relevant, cutting-edge information and learning opportunities are provided which are science-based and peer-reviewed in a format accessible 24/7. Informational resources include (1) **answers** to frequently asked questions, (2) **access** to information by top experts in their fields of expertise, (3) access to cutting-edge **content** currently in 13 subject areas, (4) **searchable** state and regional **newsletters**, (5) **consumer links** about the dairy industry and its products, and (6) news and lists of dairy events. Currently, resources are provided in the areas of business management and farm labor, calf and heifer management, facilities, food safety, genetics, health and diseases, mastitis and milking management, milk marketing, nutrient management, nutrition of milking and dry cows, organic dairy production, and reproduction. Several of these materials are available in Spanish for Spanish-speaking farm workers. Plans for 2008 are to continue to expand these resource areas and include pilot areas in the form of learning modules, hold webinar meetings for dairy producers and allied industry on cutting-edge, timely topics, and hold a webinar training session for county extension educators across the US. Leadership for this project is provided by 10 dairy extension professionals from across the United States. Additionally, our subject areas are led by 13 dairy experts from across the country. To date, 211 dairy professionals representing 35 universities and allied industries and the top 25 states for milk production have contributed to DAIReXNET. DAIReXNET can be accessed through the following web address: <http://www.extension.org/dairy+cattle>.

Key Words: Dairy, DAIReXNET, Extension programming

432 ASAS Centennial Presentation: Beef Cattle Clearinghouse: An eXtension Website. R. Rasby*¹, G. Selk², L. Anderson³, R. Weaber⁴, T. Marston⁵, C. Wright⁶, J. Paterson⁷, C. Mathis⁸, G. Lardy⁹, J. Whittier¹⁰, D. Strohhenn¹¹, T. McCollum¹², S. Paisley¹³, C. Lane¹⁴, D. Hamernik¹⁵, ¹*University of Nebraska, Lincoln*, ²*Oklahoma State University, Stillwater*, ³*University of Kentucky, Lexington*, ⁴*University of Missouri, Columbia*, ⁵*Kansas State University, Manhattan*, ⁶*South Dakota State University, Brookings*, ⁷*Montana State University, Bozeman*, ⁸*New Mexico State University, Las Cruces*, ⁹*North Dakota State University, Fargo*, ¹⁰*Colorado State University, Fort Collins*, ¹¹*Iowa State University, Ames*, ¹²*Texas A&M University, Amarillo*, ¹³*University of Wyoming, Laramie*, ¹⁴*University of Tennessee, Knoxville*, ¹⁵*USDA-CSREES, Washington, DC*.

A core Community of Practice (CoP) from Land Grant Universities organized to design a national website who's target audiences are producers, extension educators, and clientele with beef cattle interest. The goal of the CoP is to provide on-demand access to unbiased, research-based

information via the internet. This national effort allows for expertise to engage with clientele using the Beef Cattle Clearinghouse website. Beef cattle production systems vary tremendously across the United States due to the wide variety of resources available. Therefore, input into the Beef Cattle Clearinghouse website from a large number of faculty members from universities throughout the United States is imperative for the success of this educational effort. The Beef Cattle Clearinghouse website is database driven. All the material entered into the website is stored in a database that visitors can access via the online search engine. The website functionalities will consist of Cattle Questions (Frequently Asked Questions and Answers), Beef Pros (Ask the Expert), Beef Trains (Learning Modules) and Beef Tips (Timely Topics). Currently, there are 650 Cattle Questions and 200 Beef Tips in the data base. Our goal is to expand the CoP membership nationally to make the content more inclusive and to better serve the wide variety of clientele who access information through the Beef Cattle Clearinghouse eXtension website (<http://www.extension.org/beef+cattle>).

Key Words: Beef cattle, eXtension, Website

433 ASAS Centennial Presentation: Pork Information Gateway in eXtension. D. J. Meisinger*, *US Pork Center of Excellence, Iowa State University, Ames*.

Extension has always been about outreach. The goal is to interpret and convey research information and best management practices to users. The US Pork Center of Excellence (USPCE) is dedicated to this same goal through traditional means and using new technologies. This public/private partnership has a mission to add value to the pork industry by facilitating research and learning for U.S. pork producers through national collaboration. Indeed, the Pork Information Gateway (PIG) was initiated to serve pork producers with the latest information all in one place and to bring it to them with electronic technology. This web based interactive system is multi-disciplinary, multi-functional, and national in scope and utilizes all the best knowledge and interpretive abilities of extension specialists across the country. The goal was to utilize peer reviewed fact sheets, a question and answer format, and reference publications in a library format and add a glossary, images, and upcoming events to reach producers with all their needs. When the opportunity arose to link with eXtension to be part of a much bigger program, PIG became the community of practice for swine in eXtension. Most recently, a PIG Opportunities portal was added which provides students information on careers in the pork industry, a listing of swine science courses available, and a listing of internships which can be applied for throughout the country. Work is underway to add a weather and markets portal to encourage daily visits by pork producers. The current bank of knowledge on PIG is comprised of 232 peer reviewed fact sheets, over 2000 frequently asked questions and answers, and over 1500 reference documents including manuals, speeches, and swine day reports. The user friendly search function has been updated to provide users with the ability to find their answers immediately. A newly added feature allows partners to obtain impact reports which show the use of PIG in their state or by their co-branded site. This feature will be especially popular among extension specialists to demonstrate the use of their information in their states.

434 Effect of limiting hay access time on dry matter intake by beef cows. C. J. Fleenor*, R. P. Lemenager, M. C. Claeys, and S. L. Lake, *Purdue University, West Lafayette, IN.*

Sixty-three two and three year old mid-gestation Angus cross cows (BW=596.7 kg; BCS=5.15) were randomly assigned by BW, BCS and age to three treatments, with three replications per treatment, to determine the effects of limiting access time and forage quality on hay DMI. Treatments were limited access time (1, 2 or 4 h) to different qualities of hay per 24 h period. Daily, cows were fed large round bales (LRB) of low quality hay (50.65% TDN, CP 8.9%, 64.35% NDF) in rectangular hay feeders that provided adequate bunk space/cow; and were supplemented with soybean hulls and a vitamin-mineral mix to meet NRC requirements for maintenance. Average DMI/d for the 1, 2 and 4 h access times was 3.19, 5.18 and 7.31 ($P < 0.001$) kg and 0.53, 0.90 and 1.23 ($P < 0.001$) % of BW, respectively. To determine the effect of forage quality on DMI, small square bales differing in quality were fed one d/wk in lieu of LRB (9 estimates/hay quality/access time). High quality grass hay (HQ; 58.0% TDN, 15.4% CP, 51.28% NDF) was fed during wk 1-3, low quality grass hay (LQ; 44% TDN, 11.37% CP, 60.0% NDF) was fed during wk 4-6 and a mixed grass-legume hay (MX; 61.0% TDN, 14.81% CP, 52.08% NDF) was fed during wk 7-9. Average DMI was 7.32, 6.43 and 6.90 ($P < 0.05$) kg/d; 1.23, 1.07 and 1.16 ($P < 0.01$) % of BW/d; and 3.36, 2.96 and 3.27 ($P = 0.04$) kg consumption rate/hour for the HQ, LQ and MX hays, respectively. Estimated DMI/d was calculated from NDF as 2.34, 2.00 and 2.30% of BW and 13.96, 11.93 and 13.75 ($P < 0.001$) kg. Average DMI for 1, 2 and 4 h access time was, respectively, 3.72, 6.57 and 10.36 ($P < 0.001$) kg/d; 0.62, 1.10 and 1.74 ($P < 0.001$) % BW/d; and 3.72, 3.29 and 2.59 ($P < 0.01$) kg consumption rate/hour. Estimated DM savings compared to calculated ad libitum daily consumption was 71.9, 50.2 and 21.5% for the 1, 2 and 4 h access times. These data can be used by producers that need to extend limited forage supplies and provide a basis for creating diets using nutrient dense feeds that meet cow requirements.

Key Words: Cows, Hay Intake, Limited Access Time

435 Effect of ruminal fill on foraging behavior, intake rate, and plasma ghrelin, serum insulin and glucose levels of cattle grazing a vegetative micro-sward. P. Gregorini*¹, K. J. Soder¹, and R. S. Kensinger², ¹USDA-ARS Pasture Systems and Watershed Management Research Unit, University Park, PA, ²Pennsylvania State University, University Park.

The impact of ruminal fill (RF) on foraging behavior, intake rate and levels of circulating ghrelin, insulin and glucose was measured with four rumen-cannulated lactating dairy cows foraging micro-swards of vegetative orchardgrass. The treatments compared were removal of 1.00 (RF0), 0.66 (RF33), 0.33 (RF66) or 0 (RF100) of total ruminal content. Treatments were randomly applied in a 4 x 4 Latin-square design. Cows were evacuated and re-filled according to treatment at 1200 (treatment setting), then offered the micro-swards at 0200. Micro-swards were weighed before and after foraging sessions. Foraging sessions were time unlimited, but cows were allowed to take a maximum of 15 bites.

Herbage was analyzed by canopy strata for chemical composition, toughness and module of elasticity. Eating time, intake rate, total jaw movements, and bite parameters (mass, depth, area and rate) data were collected. Plasma was analyzed for ghrelin and serum for insulin and glucose. Short-term intake rate, bite mass and bite area decreased ($P < 0.05$) while bite depth increased as RF increased. The RF did not affect ($P > 0.05$) biting rate or total jaw movements. Increasing RF resulted in lower ($P < 0.05$) mean levels of circulating ghrelin, with no changes ($P > 0.05$) in mean levels of insulin and glucose. However, increasing RF decreased ($P < 0.05$) the incremental change in ghrelin, insulin and glucose levels from the time of treatment setting until the foraging sessions. Little was known regarding bite dimensions and instantaneous herbage intake rate adjustment as a function of RF, or if short-term temporal variations of RF reflect changes in the underlying endocrine physiology. The present study elucidates some of the underlying endocrine physiology under short-term temporal variations of RF and its effect on foraging behaviour.

Key Words: Appetite Regulating Hormones, Foraging Behavior, Ruminal Fill

436 Microclimate effects on temporal/spatial distribution of beef cows in cool-season grass pastures. D. Bear*, J. Russell, and M. Haan, *Iowa State University, Ames.*

Pastures on five southern Iowa cow/calf farms were used to evaluate the effects of microclimatic conditions on cattle grazing in cool-season grass pastures with streams and/or ponds. Pastures ranged from 14 to 129 ha and contained varying proportions of cool season grasses, legumes, sedge, weeds, brush, and bare ground. The percentage of shade ranged from 22 to 73% within pastures. Cows were Angus and Angus-cross on four of the farms, and Mexican Corriente on the remaining farm. In spring, summer, and fall of 2007, 2 to 3 cows per farm were fitted with Global Positioning System (GPS) collars to record position at 10 min intervals for periods of 5 to 14 d. Ambient temperature, black globe temperature, dew point, wind speed and wind direction were collected with HOBO data loggers at 10 min intervals over the grazing season on each farm. Streams, ponds, and fence lines were referenced on a geospatial map and used to establish zones in the pastures. Designated zones were: in the stream or pond, and <15.2, <30.5, <61.0, and >61.0 m from the stream or pond. Thirty-four data sets were obtained throughout the grazing season to determine cattle position. Mean proportions of observations when cattle were in the streams or ponds in summer (1.9%) did not differ from fall (1.3%), but were greater ($P < 0.10$) than spring (0.9%). Cattle distribution amongst other zones did not differ between seasons. Mean proportions of time cattle spent in any of the designated zones differed ($P < 0.05$) among farms. The proportion of time cattle were in and within 15.2 m of a stream or pond increased with increasing ambient temperature ($^{\circ}\text{C}$; $y = 3.8837 + -0.1249x + 0.0181x^2$, $r^2=0.37$) and black globe temperature ($^{\circ}\text{C}$; $y = 3.3538 + 0.0303x + 0.0068x^2$, $r^2=0.28$). The proportion of time cattle are in or near to surface water resources increases with increasing temperatures, but remains less than 24.0% at temperatures up to 37 $^{\circ}\text{C}$.

Key Words: Beef Cattle, Grazing, Temporal/Spatial Distribution

437 Grazing management and microclimatic effects on cattle distribution patterns in riparian pastures. M. Haan, J. Russell*, D. Bear, and D. Morrical, *Iowa State University, Ames.*

Cattle grazing in riparian areas may contribute to sediment and nutrient loading of surface waters. The objectives of the current study were to determine the impacts of grazing management and microclimate on cattle distribution patterns relative to a pasture stream. Six 12-ha cool-season grass pastures, each bisected by a 195-m stream segment, were assigned to one of three treatments using a randomized complete block design with two replicates: continuous stocking with unrestricted stream access (CSU), continuous stocking with stream access restricted to a stabilized crossing (CSR), and rotational stocking with stream access in a riparian paddock (RS). Pasture was considered the experimental unit. In 2005, 2006, and 2007 each pasture was stocked from mid-May through mid-October with 15 Angus cows, initial BW (mean±SE) 614±72, 577±53, and 621±56 kg, respectively. Cattle distribution patterns were monitored by visual observation and GPS collars monthly. Over three grazing seasons, cattle were in or within 34 m of the stream an average of 6 and 16% of the time, respectively, in CSU pastures, based on visual observations. Based on GPS collars, cattle were in or within 34 m of the stream an average of 1.2 and 10.6%, respectively, in CSU pastures. Based on visual observation and GPS collars the proportion of time cattle in CSR and RS pastures were present in and within 34 m of the stream were less ($P<0.05$) than CSU pastures. The presence of off-stream water decreased ($P<0.05$) the proportion of time cattle spent in the stream during the 2006 grazing season but not in 2005 or 2007. At greater ambient temperatures ($Y=112.9-4.4X+0.04X^2$, $r^2=0.85$) and heat load index ($Y=12.2-0.96X+0.02X^2$, $r^2=0.80$), the proportion of time cattle were within 34 m of the stream increased. Observed cattle distribution patterns were highly related ($r^2=0.99$) with defecation distribution patterns. The use of RS, CSR, and the presence of off-stream water may be effective management practices for altering cattle distribution patterns and reduce nutrient and pathogen loading of pasture streams.

Key Words: GPS, Water Quality, Heat Load Index

438 Morphological composition of marandu palisadegrass pasture managed under different herbage allowance grazed by dairy cattle in rotational stocking system. A. C. R. Ruggieri*, E. R. Januskiewicz¹, D. R. Casagrande^{1,3}, R. A. Reis^{1,2}, and M. A. Magalhães^{1,2}, ¹São Paulo State University, Jaboticabal, São Paulo, Brazil, ²Conselho Nacional de desenvolvimento Científico e Tecnológico, Brasília, DF, Brazil, ³Fundação de Amparo a Pesquisa do Estado de São Paulo, São Paulo, Brazil.

This study evaluated the effect of herbage allowance (HA) on sward morphological characteristics in a palisadegrass (*Brachiaria brizantha* cv. Marandu) pasture grazed by dairy cattle (BW= 450kg) in a rotational stocking system. The experiment was conducted at UNESP in Sao Paulo State, Brazil, from November 2005 to April 2006. Four HA (4, 7, 10 and 13% of BW) treatments were allocated in a complete randomized block design with three replications. Stocking density was calculated based on paddock occupation for eight hours in one day followed by 21 days rest. Hand-plucked samples and sward height of the paddock were collected and measurements were performed during the morning and afternoon of five grazing cycles. There was a tendency ($P=0.1507$) for animals to select the leaf fraction in the morning and stems in the afternoon for 4, 7 and 10% HA. The opposite was observed at 13% HA with greater ($P<0.05$) intake of stems in the morning and leaves the

afternoon. At 13%HA, sward height was taller ($P<0.01$) than that on other HA and had longer stem elongation. Thus when the grazing started the intake of stems may have increased. However, in the fifth cycle, there was a tendency ($P=0.25$) for more intake of stems in the morning on all HA. This may be associated with the transition from summer/winter growing conditions. In the afternoon the intake of leaves was greater. The greater intake of stems in the morning exposed leaves in the lower pasture strata, facilitating increased leaf intake. Among the HA studied the 7% HA presented highest leaf: stem ratio during the experimental period.

Key Words: *Brachiaria brizantha*, Pasture, Intake

439 Evaluation of forage sampling method and chemical composition of diet selection by cattle grazing subtropical forages during the summer. A. Hughes* and M. Hersom, *University of Florida, Gainesville.*

As with many tropical grasses, the nutritive value of bahiagrass (*Paspalum notatum*) has been reported to be relatively low, and the data that does exist consists of hand-harvested samples, which does not account for the ability of cattle to selectively graze pasture. The objective of this study was to characterize the chemical composition of forage selected by cattle and compare that to forage collected by hand sampling during the summer. Forage and masticate samples were collected monthly from pastures with estimated high and low forage availabilities (FA). Samples were collected at four locations from May 2007 to August 2007 and were analyzed to determine DM yield, height-adjusted DM yield, IVOMD, NDF, ADF, and selection index. Forage height was measured using a rising-disk meter to estimate forage quantity within the pasture. Forage samples were collected by hand-clipping the herbage to a height of 3.5 cm and dried at 55°C for 48 h. Masticate samples were collected using eight ruminally cannulated steers (2 steers/location) and then lyophilized. Mean DM yield across all 4 locations exhibited a FA x month interaction ($P<0.001$). Height-adjusted DM yield differed between months ($P<0.001$) and between FA ($P=0.05$). Concentration of IVOMD was greater ($P<0.001$) in masticate compared to hand-samples. Also, IVOMD concentration demonstrated a month x type interaction ($P=0.005$). Selection indices indicate that steers were able to select diets from May to August that were 20, 8, 19 and 28% greater in IVOMD concentrations than hand-samples. The ability to select for greater IVOMD differed ($P=0.05$) among months but not between FA ($P=0.06$). Concentrations of NDF and ADF differed among months ($P<0.05$) being lowest in May (67 and 32%) and increasing in August (73 and 42%). Concentrations of NDF and ADF were 3% less ($P<0.02$) for masticate samples compared to hand samples, indicating that steers were selecting a diet that was lower in cell wall concentrations. During the growing season, cattle will selectively graze bahiagrass forage that is greater in IVOMD and lower in NDF and ADF than what is estimated by hand-sampling.

Key Words: Forage, Grazing, Selection

440 Productivity and *in vitro* gas production of leaves and stems of Pennisetum purpureum cv Cuba CT-115 in Northern Mexico. E. Gutiérrez-Ornelas*, A. Cerrillo-Soto², A. S. Juárez-Reyes², H. Bernal-Barragán¹, H. Morales-Treviño¹, R. S. Herrera³, and R. Mejías³, ¹Facultad de Agronomía Universidad Autónoma de Nuevo León, Car-

retera Zuazua-Marín km 17. Marín N. L. México. CP 66700,²Facultad de Medicina Veterinaria y Zootecnia Universidad Juárez del Estado de Durango, Carretera al Mezquital Km 11, Durango, México, ³Instituto de Ciencia Animal, San José de Las Lajas, Habana Cuba.

Pennisetum purpureum cv Cuba CT-115 (CT115) is a tropical tall grass introduced to subtropical regions in northern Mexico. The objective of this study was to evaluate DM production, in vitro gas production and chemical characteristics of leaves, stems and whole plant samples. Four plots (5 × 10 m) of CT115 were established with no fertilization in non-irrigated clay soil in February 2006. Productivity was assessed by harvesting by hand three random samples (5 m² each) at 30 cm height in two growing seasons (autumn 2006 and summer 2007). Forty plants were selected during the autumn of 2006 to establish the relationship between number of stems and DM production. Sub-samples from both years were separated into leaves and stems. Forage components above 1 m height from summer growing season were used for in vitro gas production and chemical analyses. Triplicate samples (200 mg DM each) were incubated in 100 ml calibrated glass syringes and gas production was registered at 3, 6, 9, 12, 24, 48, 72, and 96 h. Data were

fitted to the equation: $p=a+b(1-e^{-ct})$, where **p** represents gas volume (ml) at time **t**; **a** the intercept; **a+b** the potential gas production and, **c** is the constant rate. In vitro gas parameters were analyzed by ANOVA for a completely randomized design with 3 × 2 factorial arrangement of treatments (plant components and years). Dry matter production was 8.5 and 15.7 ton/ha during 2006 and 2007, respectively. In 2006, DM production increased linearly ($P<0.05$; $r^2=0.87$) with number of stems per plant. Rate of gas production was higher ($P<0.05$) for stems (5.6% h⁻¹) than leaves (3.8% h⁻¹) and whole plant (4.0% h⁻¹), with no year or interaction effect ($P>0.05$). The other in vitro gas parameters were not affected ($P>0.05$, **a** = -0.45 ml; **a+b** = 50.2 ml) by treatments. Leaf:stem ratio for the 2007 forage samples was 2.7, CP and NDF contents were respectively 8.0% and 74.2% for leaves, and 9.4% and 72.4% for stems. CT-115 is a good forage for livestock in northern Mexico; its leaves and stems had similar chemical composition but the higher constant rate of *in vitro* gas production for stems may imply better nutritive value of this plant component.

Key Words: *Pennisetum purpureum*, In Vitro Gas Production, Tropical Grass

Horse Species II

441 ASAS Centennial Presentation: Historical review and future outlook of equine nutrition. H. Hintz*, *Cornell University, Ithaca, NY.*

Although horses were still very important for farming in 1908 research on equine nutrition was not of high priority at most US agricultural colleges and experiment stations. The decline of the use of horses on farms, in the transportation industry and for hauling freight that started in the second decade of the twentieth century reinforced the low priority given to equine nutrition research. Nevertheless several members of the animal science community such as S. Brody (energy metabolism), P.B. Pearson (vitamin nutrition), W. D. Dawson (growth of foals) and A. L. Harvey (protein nutrition) provided valuable data in the 1930s and 1940s. In the 1960s the increased use of horses for recreation and the rapid growth of the horse population in the US stimulated interest in equine nutrition. University of Kentucky, Texas A&M, University of Florida and Cornell University started equine nutrition programs in the late 1960s. Many other universities developed equine nutrition programs in subsequent years. At the 2007 meeting of the Equine Science Society (ESS), papers related to equine nutrition were presented from 26 US universities and institutions. Most of the members of ESS are also members of ASAS. The improved knowledge of horse nutrition and hence better diets has been credited as a major factor in the improved health and increased longevity of horses. The horse industry continues to thrive and opportunities for valuable equine nutrition are endless. Examples include further studies on the microbiology of gut to help combat diseases such as founder, colic and metabolic syndrome, evaluation of nutraceuticals and other supplements, more defined studies on trace mineral requirements and metabolism, amelioration of the long existing problem of limited numbers of horses per treatment perhaps by developing regional cooperative studies or other more creative ideas. The relationship of nutrition and diseases in horses should be studied by teams consisting of researchers from several disciplines. There is much to be done.

Key Words: Horse, Nutrition, History

442 Glycemic and insulinemic responses differ in the morning versus the afternoon. L. M. Williamson¹, W. B. Staniar^{*2}, and R. J. Geor¹, ¹*Virginia Polytechnic Institute and State University, Blacksburg,* ²*Pennsylvania State University, State College.*

Glycemic and insulinemic responses influence equine health through change to metabolism. The objective of this study was to quantify the morning and afternoon glycemic and insulinemic responses to a meal. A post ANOVA multiple comparison procedure was used to examine potential differences, considered significant at a $P < 0.05$. On the 4 study days, blood plasma samples were taken from 8 Thoroughbred mares via a jugular vein catheter at 0, 15, 45, 75, 105, 135, 165, 225, 285, 345, 405, 435, 465, 495, 525, 585, 645, 705, and 765 minutes. A grain meal of 1.5 kg was fed immediately following the 15 (AM (0800)) and 405 (PM (1400)) min samples. Glucose (mg/dl) and insulin (mIU/L) were measured with a glucose oxidase and chemiluminescent assay, respectively. Dependent variables were peak values for glucose and insulin, area under the curve for glucose and insulin, and the time to peak, which represents the time from feeding the meal to when glucose or insulin reached peak values. There was no detectable difference in the starch intake of the AM diets 323 ± 133 g in comparison to the PM

330 ± 127 g, or the time taken to eat in the AM 22 ± 23 min versus that in the PM 24 ± 21 min. Baseline (mean of samples 0 and 15) glucose and insulin were 94 ± 5.3 mg/dl and 6.1 ± 2.9 mIU/L, respectively. The AM peak values for glucose and insulin (143 ± 17 mg/dl, 57 ± 31 mIU/L) were higher than the PM peak values (123 ± 8.6 mg/dl, 37 ± 20 mIU/L). No difference was detected in the time to peak values for AM versus PM for glucose (127 ± 49 , 118 ± 51 min) and insulin (137.4 ± 55.7 , 118.9 ± 43.5 min). The glucose and insulin area under the curve in the AM (8103 ± 2860 min*mg*dl⁻¹, 8468 ± 5050 min*mIU*L⁻¹) were higher than the PM values (4170 ± 1744 min*mg*dl⁻¹, 4358 ± 2091 min*mIU*L⁻¹). The horse shows a higher glycemic and insulinemic response to meal in the morning when compared to a similar afternoon meal. The specific mechanism may relate to circadian patterns of other metabolic regulatory hormones like melatonin or may simply be due to the fact that glucose and insulin values have only just returned to baseline when the afternoon meal is fed. Time of day is a factor when evaluating glycemic and insulinemic response.

Key Words: Glycemic, Equine

443 Effect of different ingredients or ingredient combinations on glycemic and insulinemic responses in horses. J. L. Shelton^{*1}, B. D. Nielsen², and C. I. O'Connor-Robison², ¹*Cargill Animal Nutrition, Minnetonka, MN,* ²*Michigan State University, East Lansing.*

The objective of this study was to determine the effect of different ingredients and ingredient combinations on glycemic and insulinemic responses in horses. A 12x12 Latin square design was used with mature Arabian horses (average age of 16 yr). Horses were maintained entirely on a roughage diet and subjected to a glycemic response test once weekly. The 12 treatments were: dextrose, EnergX (food grade identity preserved corn co-product), cracked corn, pelleted corn, steam pelleted corn, whole oats, steam rolled oats, steam crimped barley, COB (steam pelleted corn, steam rolled oats, steam crimped barley at a ratio of 1:1:1), COB+4% molasses, COB+8% molasses, EnergX+2% soy oil. The control treatment consisted of an oral dextrose drench given at the rate of 0.5 g dextrose/kg of BW. All remaining treatments were fed to provide 1 kcal DE/kg of BW. Once a week for 12 weeks, horses were jugular-catheterized after a 12-h fasting period. A fasting blood sample was taken 30 min later. Thirty min later, another baseline blood sample was taken and horses were fed their respective treatment. Blood samples were taken at 30, 60, 90, 120, 150, 180, 210 and 240 min after treatment. Samples were analyzed for glucose and insulin concentrations. Glucose and insulin area under the curve (AUC) were analyzed using the mixed model of SAS. When the individual ingredients were fed to horses, there were differences in glucose and insulin AUC ($P < 0.05$). For glucose AUC, EnergX had the lowest and steam processed corn had the highest. For insulin AUC, EnergX had the lowest and whole oats had the highest. As corn was further processed, differences between the corn treatments existed for glucose and insulin AUC ($P < 0.05$). Adding molasses to the COB product had a minimal effect on glycemic or insulinemic responses. These data indicate that glycemic and insulinemic responses can be affected by feeding different ingredients to the horse. Also, nutrients other than starch and sugar can play a role in reducing glycemic index in feeds for horses.

Key Words: Horse, Glycemic Response, Insulin

444 Glycemic response to meal length in equines. J. R. Bland^{*1}, E. L. Wagner¹, and W. H. McElhenney², ¹*Auburn University, Auburn, AL*, ²*Tuskegee University, Tuskegee, AL*.

Cereal grains are an ideal feedstuff for horses with high energy demands because of their high soluble carbohydrate content. However, consumption of a single meal high in soluble carbohydrates causes an immediate increase in blood glucose. This increase could be problematic for horses with certain health conditions such as insulin resistance or laminitis. Because some horses require additional energy for growth, performance, pregnancy or lactation, it becomes difficult to completely cut cereal grains out of their diet. Therefore, new feeding management strategies are needed to attenuate the blood glucose response to a soluble carbohydrate-rich meal. The objective of this study was to examine the relationship between time to consume a concentrate meal and the glycemic response to that meal as measured by peak plasma glucose, glucose area under the curve, time to peak plasma glucose, and insulin response. Eight mature horses were used in an experiment consisting of eight 7-d periods where treatment combinations were arranged in a 2x4 factorial. Horses were offered approximately 4 Mcal of oats or sweet feed twice daily starting at 0600 and 1800 hrs. Horses were offered their respective concentrate in 1, 2, 3 or 4 equal portions at 15 minute intervals, thereby restricting rate of intake of the concentrate. Blood was collected via jugular catheters at the evening feeding on d 7 of each period, with a baseline sample collected 30 min prior to feeding (1750 hrs), then every 30 min post-feeding until 2400 hrs. Plasma glucose and insulin concentrations were determined, and resulting data were analyzed by the GLM procedure in SAS. Time to peak plasma insulin was longer for horses consuming oats ($P < 0.05$), but there were no other significant differences for concentrate type, portions or treatment interactions for glucose and insulin. A period effect ($P < 0.05$) was noted for peak plasma glucose and time to peak plasma glucose. There was a trend toward a period effect ($P < 0.10$) for glucose area under the curve, but no period effects were observed for measures of insulin. Glucose and insulin responses to a concentrate meal were not altered by time to consume the meal in the present study.

Key Words: Glycemic Response, Meal Length, Horse

445 Aquacid alters markers of bone metabolism in yearling Arabians. B. D. Nielsen^{*}, R. E. Cate, C. I. O'Connor-Robison, and D. S. Rosenstein, *Michigan State University, East Lansing*.

The purpose of this study was to test whether a calcified seaweed mineral supplement (Aquacid), high in Ca and Mg, but low in P, can alter markers of bone metabolism and mineralization of the equine third metacarpus (MCIII). Prior to treatment assignment, 14 yearlings (four geldings and ten fillies) had dorsal-palmar and lateral-medial radiographs taken of their left MCIII. Radiographs were analyzed using a digital densitometer to determine the radiographic bone aluminum equivalence (RBAE) of each cortex as an estimate of mineral content. Blood samples were also taken at this time. Horses were stratified according to RBAE and gender, and then pair-matched and assigned to two treatment groups, which were housed in separate pastures. Horses were group-fed, with each horse receiving an average of 1.6 kg of oats divided into two equal feedings of 0.8 kg oats per feeding. Each group was supplemented with a mineral supplement in addition to their daily ration. The treated group (Aq) received 75 g Aquacid/horse/d mixed in with their oats. The 75 g

Aquacid provided an additional 15 g of Ca and a negligible amount of P (0.07 g). The control group (Co) received 39.5 g of limestone mixed in with their oats to provide a similar dose of Ca (15 g) and a negligible amount of P (0.008 g). Horses remained on the study for 112 d with blood samples being taken every 28 d. At d 56 and 112, another set of radiographs was taken for determination of changes in RBAE. Blood samples were analyzed for osteocalcin (OC: a marker of bone formation) and serum crosslaps (CTX-1: a marker of bone resorption) to help detect any alterations in bone metabolism. Using d 0 values as a covariate for bone markers, there was a trend ($P = 0.07$) for OC concentrations to be greater in the Aq horses than in Co. Likewise, CTX1 concentrations were greater ($P < 0.0001$) in Aq horses than in Co. There were no differences in RBAE values. These findings suggest Aquacid, while not altering bone mass, increases bone turnover and may aid in repairing damaged bone and preventing injuries.

Key Words: Horse, Bone, Calcium

446 Inflammation and vitamin E intake in horses during a CCI/CCI*** three-day event.** C. A. Williams^{*1}, E. D. Lamprecht¹, and A. O. Burk², ¹*Rutgers, The State University of New Jersey, New Brunswick*, ²*University of Maryland, College Park*.

The objective was to compare the vitamin E content in the total diet of horses competing in a three-day event to systemic inflammatory measures throughout competition. Competitors in the 2007 Jersey Fresh CCI**/CCI*** three-day event ($n = 35$) gave informed consent to participate in the study. A detailed nutritional management survey was completed by the investigators and all grain, hay and bran rations were weighed, plus pre-competition pasture intake was estimated. Calculations for daily intake of vitamin E at competition used manufacturer or NRC (2007) values, and recommended daily intakes used NRC (2007) equations. Blood samples, BW and body condition scores were taken before the competition (PRE), 20 to 30 min after cross country (XC), and 18 to 24 h of recovery (POST). Blood samples were evaluated for plasma nitric oxide (NO), tumor necrosis factor- α (TNF), creatine kinase (CK) and aspartate aminotransferase (AST). Data were analyzed using a mixed model ANOVA with repeated measures in SAS. Average intake of vitamin E from hay, grain and supplements was 1587.5 ± 230 IU/d (123.5 ± 22 IU/kg feed/d); the recommended intake was 1065.3 ± 16 IU/d (80.7 ± 0.5 IU/kg feed/d). There was a significant difference between sample times for NO ($P = 0.013$), TNF ($P = 0.013$) CK ($P < 0.0001$), and AST ($P = 0.0007$). Nitric oxide and TNF decreased ($P < 0.01$) between PRE and POST, yet was not different between XC and POST. However, CK increased between PRE and XC ($P < 0.0001$), but remained similar to XC at POST. Where AST decreased from PRE to XC ($P = 0.032$), and was higher than both PRE ($P = 0.059$) and XC ($P = 0.0002$) at POST. There was a correlation with BW and NO ($r = -0.32$, $P = 0.002$), and BW and TNF ($r = -0.41$, $P < 0.0001$). Vitamin E intake also correlated with NO ($r = -0.21$, $P = 0.04$) and TNF ($r = -0.31$, $P = 0.002$). However, there were no correlations with pasture intake and the blood chemistry measures. These results indicate that pro-inflammatory measures decrease, while muscle enzymes increased, in horses undergoing intense exercise during competition. These equine athletes are also consuming vitamin E in excess of current recommendations, which may have an impact on systemic inflammatory markers.

Key Words: Antioxidant, Equine, Exercise

447 Effect of high fat diets and fat source on immune function in yearling horses. K. R. Vineyard*, L. K. Warren, and J. Kivipelto, *University of Florida, Gainesville.*

Recent research suggests omega-3 (n-3) and omega-6 (n-6) fatty acids (FA) may affect immune function differently in humans. To determine if the fat source used in a high fat diet affects immune function in horses, 24 Quarter Horse and Thoroughbred yearlings were randomly assigned to one of three treatments for 42 d: a fish oil (1/3) and olive oil (2/3) blend (FISH, n=8), corn oil (CORN, n=8), and no supplemental fat (NON, n=8). All horses had free-choice access to bahiagrass pasture, and a grain mix top-dressed with 6% FISH or CORN to create a 10% fat concentrate was fed at 1.25% BW/d. NON grain mix was fed at a rate of 1.37% BW/d to make diets isocaloric. FISH contained 8.6 g linoleic acid (LA), 5.1 g eicosapentaenoic acid (EPA) and 2.4 g docosahexaenoic acid (DHA)/ 100 g fat, supplying 7.2 g n-3/100 kg BW/d. CORN contained 57.7 g LA/ 100 g fat, supplying 43.1 g n-6/100 kg BW/d. Blood samples were obtained at 0 and 42 d for determination of plasma and red blood cell membrane (RBC) FA composition, lymphocyte proliferation (LP), PGE₂ production by peripheral blood mononuclear cells (PBMC), and neutrophil phagocytic and oxidative burst activity. Horses were administered a tetanus booster on d 21, and titers were analyzed at d 42. Data were analyzed using the MIXED procedure of SAS, and contrasts were utilized to compare NON vs. fat-added treatments. Treatment did not affect weight gain, which averaged 0.7±0.1 kg/d. Horses fed FISH had higher (P<0.05) plasma and RBC EPA, DHA, and total n-3 and lower (P<0.05) plasma and RBC LA and total n-6 than CORN and NON. Plasma and RBC LA was higher (P<0.05) and arachidonic acid was lower (P<0.05) in horses fed CORN than NON. LP and neutrophil function were not affected by treatment. PGE₂ production was lower for FISH and CORN than NON (P<0.05). Using baseline titers as a covariate, horses fed fat-added diets had higher tetanus titers at d 42 than NON (P<0.05). Results indicate that fat source in a 10% total fat concentrate affects the FA profile of plasma and cell membranes, and fat supplementation may affect immune function. However, the immune response does not appear to differ between horses fed sources rich in n-6 or n-3 FA when fed at a rate to provide 12% of daily DE from fat.

Key Words: Omega-3, Omega-6, Immunity

448 Seasonal effects of diet on the omega-6 and omega-3 fatty acid composition of plasma and red blood cells in grazing horses. L. K. Warren* and J. Kivipelto, *University of Florida, Gainesville.*

Although low in total fat, research suggests forage may serve as a significant source of dietary α -linolenic acid. However, the fatty acid (FA) composition of pasture forage has been shown to be affected by season, which could alter the FA profile of cell membranes in grazing horses. To characterize the effect of season and diet on the FA composition of plasma and red blood cells (RBC), monthly blood samples were obtained for 24-mo from 5 mature geldings. Horses were maintained on an 8.1-ha, mixed-cultivar bahiagrass pasture. Pasture samples were collected at 1-mo intervals from areas on or near where there was recent evidence of grazing. Horses also had free-choice access to Coastal bermudagrass hay from Dec-Feb. The effect of season on plasma, RBC and forage FA composition were determined by the MIXED procedure of SAS (v 9.1), where spring=mean of Mar, Apr, May; summer=mean of Jun, Jul, Aug; fall=mean of Sept, Oct, Nov; and winter=mean of Dec, Jan, Feb. C18:2 was lowest in winter plasma (P<0.05) and tended to be lower in winter RBC (P<0.1). C20:4 was lower in winter and spring plasma (P<0.01) and tended to be lower in fall RBC (P<0.1). Plasma C18:3 was lowest in winter and spring (P<0.01) and C20:5 was lowest in spring (P<0.01). RBC C18:3 and C20:5 peaked in fall (P<0.01) and were lowest in spring (P<0.01). C22:5 and C22:6 were not affected by season in plasma, but were lowest in spring RBC (P<0.05). Total n-6 FA were higher in summer and fall in plasma (P<0.05) and tended to be higher in summer and fall in RBC (P<0.1). Total n-3 FA peaked in fall and were lowest in spring in plasma (P<0.01) and RBC (P<0.01). Pasture C18:2 was lower in winter (P<0.05) and C18:3 was higher in spring and winter. Hay C18:2 was higher (P<0.01) and C18:3 was lower (P<0.01) than pasture in all seasons, which altered FA intake during the winter. Collectively, these results indicate that plasma and RBC C18:2 and C18:3 composition mimic seasonal dietary intake in grazing horses. Longer-chain n-6 and n-3 FA in plasma and RBC appear to be dependent on the relative availability of C18:2 and C18:3 in the diet.

Lactation Biology I

449 The acute response to milk removal and the long-term response to frequent milking treatment involve distinct mechanisms.

E. H. Wall*, J. P. Bond, and T. B. McFadden, *University of Vermont, Burlington.*

Frequent milking during early lactation of dairy cows elicits a persistent increase in milk yield. We hypothesized that this response would be associated with increased mammary growth and altered expression of genes involved in the insulin-like growth factor (IGF) axis. Four multiparous cows were assigned at parturition to unilateral frequent milking (UFM; twice daily milking of the left udder half (2×; 0230 and 1430 h), four-times daily milking of the right udder half (4×; 0230, 0530, 1430 and 1730 h)). Mammary biopsies were obtained from both udder halves at 5 days in milk (DIM) at 0530 h (immediately after 4× glands were milked). Incorporation of [³H]-thymidine into DNA, mammary cell apoptosis, and expression of IGF-1, IGF-1 receptor, and IGF binding protein (IGFBP)-1 mRNA were not affected by UFM (P 's > 0.20), whereas expression of IGFBP-3 was lower in 4× glands (P ≤ 0.06). Using Affymetrix GeneChip® Bovine Genome Arrays, we identified 84 genes that were differentially expressed in 2X vs. 4X glands (P < 0.05). Because biopsies were obtained when glands were at different intervals since the previous milking, our results included both the acute mammary response to milk removal and the long-term response to UFM treatment. A second experiment was designed to distinguish the mechanisms involved in each of these responses. Mammary biopsies were obtained from UFM cows (n = 5) at 0500 h, when udder halves were at the same interval since the previous milking. Mammary cell apoptosis and expression of the genes listed above were not affected by UFM (P 's > 0.20). We identified an intersection of 13 genes that were differentially expressed in both experiments, consistent with their involvement in the persistent milk yield response. In contrast, the remaining 71 genes appear to be involved in the acute mammary response to milk removal. We conclude that frequent milking does not alter mammary growth or genes of the IGF axis at 5 DIM. Moreover, the acute mammary response to milk removal and the long-term response to frequent milking appear to involve separate mechanisms.

Key Words: Frequent Milking, Gene Expression

450 The effects of increased milking frequency during early lactation on metabolism and mammary cell proliferation in Holstein cows.

F. Soberon*¹, J. L. Lukas¹, M. E. Van Amburgh¹, A. V. Capuco², and T. R. Overton¹, ¹Cornell University, Ithaca, NY, ²Bovine Functional Genomics Laboratory, USDA-ARS, Beltsville, MD.

Primiparous (n =30) and multiparous (n =30) cows were assigned randomly at calving to one of 2 treatments to evaluate metabolic and mammary cell responses to increased milking frequency (IMF). Controls were milked twice daily (2X) for 119 d and the IMF group was milked four times daily (4X) from d 2 until d 21 postpartum and 2× from d 22 until d 119. Early lactation IMF did not affect overall milk yield (42.0 vs. 40.6 kg/d; P > 0.10). An interaction of treatment by week (P < 0.01) indicated that IMF cows yielded 4.8 kg/d more milk than controls during wk 2 and 3 but yields were comparable thereafter. Although there was no interaction of treatment and parity (P = 0.31), a trend (P = 0.08) for an interaction of treatment, parity, and week suggested that overall responses were larger in primiparous cows. When cows subjected to

mammary biopsies were excluded, an overall interaction of treatment by parity existed (P < 0.01) such that milk yield was increased throughout the study period by IMF (40.1 vs. 34.2 kg/d) in primiparous but not multiparous cows (47.1 vs. 50.1 kg/d). Plasma nonesterified fatty acids were elevated in multiparous (679 vs. 468 μ Eq/L) but not primiparous (583 vs. 562 μ Eq/L) cows subjected to IMF (treatment by parity, P < 0.05). Plasma β -hydroxybutyrate was not affected by IMF. Mammary tissue was biopsied from a subset of cows (n =8 per parity group and treatment) at calving, 21 d postpartum, and 75 d postpartum and used for immunohistochemical localization of Ki-67. A treatment by day interaction (P = 0.03) indicated that IMF cows had fewer labeled epithelial cells than controls at d 21 (0.31 vs. 0.82%) but more labeled epithelial cells at d 75 (1.37 vs. 0.65%). Overall, results suggest that metabolic health may influence the milk yield response of cows to early lactation IMF. Further analysis of mammary cellular dynamics is needed to determine specific mechanisms for milk yield responses to early lactation IMF.

Key Words: Milking Frequency, Mammary Gland

451 Effects of serotonin receptor antagonists on milk protein gene expression in primary bovine mammary epithelial cells.

L. Hernandez*^{1,2}, J. Collier¹, L. Baumgard¹, N. Horseman², and R. Collier¹, ¹University of Arizona, Tucson, ²University of Cincinnati, Cincinnati.

Serotonin (5-HT) is proposed to be a feedback inhibitor of lactation (FIL) in the bovine specifically, decreasing α -lactalbumin and β -casein mRNA expression in primary bovine mammary epithelial cells (BMEC) and milk yield in lactating dairy cows. However, there are 7 5-HT receptor subtypes currently identified and it is critical to determine which one(s) is present in bovine mammary tissue. Therefore, we investigated effects of selective 5-HT receptor antagonists on milk protein mRNA expression in BMEC. Cells were cultured in collagen gels, proliferated for 7 d in a serum-free (SF) medium containing IGF-I, EGF, and insulin and then treated with a SF lactogenic medium containing IGF-1, hydrocortisone and PRL with gel release for 48 h. Treatments included 0.1, 1.0 and 10 μ M of the 5-HT receptor antagonists; SB-224289 (1b antagonist), ritanserin (2a antagonist), SB-204741 (2b antagonist), and pimoziide (7 antagonist), and 0.0001, 0.01 and 1.0 μ M of SB-204070 (4 antagonist). Lactogenic medium with gel release alone served as control (CTRL). Exogenous SB-224289, at a dose of 1.0 μ M and all doses of ritanserin up-regulated α -lactalbumin mRNA expression (P < 0.05) relative to the CTRL. The 1.0 μ M of ritanserin had the greatest effect on α -lactalbumin mRNA expression, causing a 16-fold increase relative to the CTRL (P < 0.001). All other treatments did not affect α -lactalbumin mRNA expression (P > 0.05). The 0.1 μ M doses of SB-224289, SB-204070 and pimoziide increased β -casein mRNA expression (P < 0.05) relative to the CTRL. The 1.0 μ M dose of ritanserin increased β -casein mRNA expression relative to the CTRL (P < 0.05). Antagonism of the 5-HT1b and 5-HT2a receptors increased α -lactalbumin mRNA expression. Furthermore, antagonism of the 5-HT1b, 5-HT4 and 5-HT7 increased β -casein mRNA levels. These results indicate there are multiple 5-HT receptor subtypes present in bovine mammary epithelial tissue and further support the involvement of the serotonergic system as a FIL in the bovine.

Key Words: Serotonin, FIL, Serotonin Receptors

452 Effect of experimental tight junction opening on milk production. H. Ben Chedly^{*1}, M. Boutinaud¹, P. Lacasse³, R. Bounhamous², and P.-G. Marnet^{2,1}, ¹INRA, UMR 1080 Production du Lait, Saint Gilles, France, ²Agrocampus Rennes, Rennes, France, ³AAFC-Dairy and Swine R&D Centre, Sherbrooke, QC, Canada.

In situations where milk yield is decreasing rapidly, an opening of tight junctions between mammary epithelial cells (MEC) is often observed. The goal of this experiment was to determine if an experimental induction of tight junction opening by chelation of milk calcium by EGTA or citrate affects milk production, MEC activity and MEC apoptosis. Three hours after milking, 4 dairy goats received a 250 mL intra-mammary infusion of EGTA (115 mM) in the right gland and an equal volume of physiologic saline in the left gland. Similarly, 4 other goats received a 32 mL infusion of citrate (50 mM) in the right gland and lactose (300 mM) in the left gland. The procedure was repeated for 4 consecutive milkings. Mammary biopsies were performed before the milking following the 4th infusion. EGTA infusion induced a decrease in milk free calcium concentration (55%; $P < 0.01$) associated with an increase in milk serum albumin concentration (6 fold; $P < 0.01$), milk Na/K ratio ($P = 0.02$) and blood lactose ($P = 0.02$) indicating the opening of tight junctions. In contrast, the increase in milk serum albumin concentration caused by lactose infusion was larger than for citrate, ($P = 0.02$) suggesting that lactose caused tight junction opening. Tight junction opening in EGTA and lactose treated udder was associated to a decrease in milk yield (respectively 30%; $P = 0.03$ and 25%; $P = 0.01$). Gene expression of proteins involved in milk synthesis or cell apoptosis were quantified by qRT-PCR. Induction of tight junction opening was associated with lower α -lactalbumin ($P = 0.08$ and $P = 0.03$) and higher pro-apoptotic protein Bax ($P = 0.10$ and $P = 0.02$) mRNA levels for EGTA and lactose infusions, respectively. Higher TUNEL labeling were observed in EGTA ($P = 0.10$) and lactose ($P = 0.02$) infused glands which confirmed cell death induction. In conclusion, the lower MEC activity and higher MEC apoptosis were involved in the milk yield decrease consecutive of tight junction opening.

Key Words: Tight Junction, Mammary Gland, Apoptosis

453 Suppression of bovine α S1-casein gene expression during involution of the mammary gland is associated with increased DNA methylation at a STAT5-binding site in the α S1-casein promoter. K. Singh^{*1}, K. Swanson¹, C. Couldrey¹, H.-M. Seyfert², and K. Stelwagen¹, ¹AgResearch Ltd, Ruakura Research Centre, Hamilton, New Zealand, ²Research Institute for the Biology of Farm Animals (FBN), Dummerstorf, Germany.

Milk protein gene expression in the mammary gland is regulated in a tissue-specific and temporal manner. During lactation, the transcription factor STAT5 is activated in response to prolactin and stimulates expression of milk protein genes by binding to target sequences on the promoters. At the onset of mammary involution there is a rapid decline in milk protein gene expression. DNA methylation is an epigenetic event which results in the silencing of gene expression. The DNA methylation at a functional STAT5-binding site in the promoter of the bovine α S1-casein gene is associated with the shutdown of casein synthesis during acute mastitis. To elucidate the silencing mechanism of α S1-casein during bovine mammary gland involution, the DNA methylation

status across the promoter was examined in alveolar tissue obtained from non-pregnant cows in mid-lactation slaughtered at 0, 6, 12, 18, 24, 36, 72 and 192h ($n = 6$ per group) after the last milking. Quantitative real time RT-PCR analysis showed α S1-casein mRNA levels were down-regulated 6.6-fold ($P < 0.01$) by 24 h post milking, relative to 6 h and expression continued to decrease ($P < 0.001$) until 192 h after the last milking. A quantitative MassARRAY methylation analysis (www.sequenom.com) showed 2 of the 3 CpG sites at the STAT5-binding site approximately -10kbp upstream of the α S1-casein-encoding gene, had increased methylation levels. One site was increased ($P < 0.05$) from 21% to 44% at 36 h post milking compared to 18 h. The other site was increased ($P < 0.05$) from 34% to 60% by 192 h post milking compared to 18 h post milking. Results suggest that alterations in methylation status at CpG sites at the functional STAT5 binding site in the far upstream promoter are associated with the silencing of the α S1-casein gene during involution.

Key Words: DNA Methylation, Bovine α S1-Casein, Mammary Involution

454 Extending lactation in pasture-based dairy cows: Effect of genetic strain and diet on hormones and metabolites. J. Kay^{*}, P. Aspin, C. Phyn, J. Roche, D. Clark, and E. Kolver, DairyNZ, Hamilton, New Zealand.

The effect of genetic strain and diet on plasma hormone and metabolites was investigated in pasture-based dairy cows milked continuously for up to 670 d. Fifty-six genetically divergent New Zealand (NZ) and North American (NA) Holstein-Friesians (HF) grazed pasture and were offered 0, 3, or 6 kg concentrate DM/cow/d for 604 ± 8 DIM. Weekly blood samples collected from individual cows during wk 1-10 and wk 47-63 (extended lactation) were analyzed for NEFA, BHBA, insulin, glucose, leptin, growth hormone (GH) and IGF-I. Data were averaged for each period and analyzed by REML with genetic strain, diet and interactions as fixed effects and cow as random effect. In the first 10-wks postpartum there was no strain effects on BHBA, leptin, insulin or glucose, however NA HF had greater ($P < 0.05$) NEFA and GH and lower ($P < 0.05$) IGF-I compared with NZ HF. Plasma NEFA and GH were also greater ($P < 0.05$) in NA HF during the extended lactation period, but IGF-I was not affected by strain, and BHBA and glucose were greater ($P < 0.05$) in NZ HF. During the extended lactation period, leptin was greater ($P < 0.01$) and insulin tended to be greater ($P = 0.07$) in NZ HF. A strain by diet interaction ($P < 0.01$) revealed that this effect was due to a greater leptin and insulin content in NZ HF fed the highest concentrate level than either of the other 5 treatments that did not differ from each other. Supplementation during the first 10-wk postpartum linearly increased ($P < 0.01$) glucose and decreased GH, but did not alter BHBA, NEFA, leptin, insulin or IGF-I. During the extended lactation period, NEFA and IGF-I were unaltered and glucose and GH followed the same pattern with diet. However, BHBA increased linearly ($P < 0.01$) with increasing supplementation. These data are consistent with the previously reported greater milk production and BCS loss in NA HF compared to NZ HF and indicate potential strain differences in recoupling of the somatotrophic axis and energy partitioning. These results have implications for breeding and diet management during an extended lactation.

Key Words: Extended Lactation, Genetic Strain, Pasture-Based

455 Effect of the prolactin-release inhibitor Quinagolide on dairy cows. P. Lacasse^{*1}, V. Lollivier², R. M. Bruckmaier³, Y. R. Boisclair⁴, G. W. Wagner⁵, and M. Boutinaud², ¹*Dairy and Swine R&D centre, Sherbrooke, QC, Canada*, ²*INRA, Agrocampus Rennes, St-Gilles, France*, ³*University of Bern, Switzerland*, ⁴*Cornell University, Ithaca, NY*, ⁵*University of Western Ontario, London, ON, Canada*.

In most mammals, prolactin (PRL) is essential to maintain lactation. Nevertheless, short term suppression of PRL by bromocriptine has produced inconsistent effects on milk yield in cows and goats. To assess the effect of long term inhibition of PRL release in lactating dairy cows, five Holstein cows in early lactation received daily i.m. injection of 1 mg of Quinagolide for 9 weeks. Four control cows received the vehicle (water). During the last week of treatment, one half-gland was milked once (1X) and the other twice a day (2X). Blood samples were harvested at milking on wks -1, 1, 4 and 8 and mammary biopsies were taken at wks -1, 4 and 8. Daily injections of Quinagolide reduced milking-induced PRL release ($P<0.05$) but not basal PRL. Quinagolide induced a faster decline in milk production ($P<0.05$). During week 9, the inhibition of milk production by Quinagolide was maintained in half-gland milked 2X ($P<0.05$) but not in half-gland milked 1X. Milk production was significantly correlated with the quantity of PRL released at milking ($P<0.01$) but not with its basal level. Quinagolide did not affect the release of oxytocin at milking. The concentration of IGF-1 was not affected by treatment or correlated with milk production. Serum concentration of leptin and of the calcitropic hormone stanniocalcin were not affected by the treatment. Levels of κ -casein ($P<0.05$) and α -lactalbumin ($P=0.06$) mRNA determined by qRT-PCR were lower in mammary biopsies of Quinagolide-treated cows at wk 4. Western blotting and immunohistological determination of tissue harvested at wk 8 have shown that the protein PCNA was less abundant ($P<0.05$) and present in a lower number of cells ($P<0.05$) in Quinagolide-treated animals, suggesting a reduction in cell proliferation. In conclusion, chronic administration of the prolactin-release inhibitor Quinagolide reduces milk production in dairy cows.

Key Words: Leptin, Stanniocalcin, Persistency

456 Effect of estradiol cypionate injected at dry-off on lactose concentrations in bovine plasma. M. S. Gulay^{*1}, M. J. Hayen², H. H. Head², and K. C. Bachman², ¹*Mehmet Akif Ersoy University, Burdur, Turkey*, ²*University of Florida, Gainesville*.

Elevation of lactose in plasma of dairy cows because of mammary cell tight junction leakage serves as an indicator of the onset of mammary tissue involution. Therefore, objective of this study was to determine the effect of supplemental estradiol cypionate (ECP) at dry-off on concentrations of plasma lactose in Holstein cows. Thirty-two Holstein cows were assigned to four dry-off treatment groups ($n=8$ /group; 30 d dry, 30 d dry +ECP, 60 d dry, and 60 d dry +ECP). Single injections of ECP (15 mg) in cottonseed oil or equal quantities of cottonseed oil carrier were administered intramuscularly at dry-off to equal numbers of cows given 30 or 60 d dry periods. Blood samples were collected from the coccygeal vein 24 h prior to dry-off, at dry-off, and throughout the subsequent 48 h (12, 8, 4, 4, 4, 4, 4 and 8 h intervals) to monitor plasma lactose. Actual

dry period lengths for cows in 30d, 30d+ECP, 60d, and 60d+ECP were 26.8, 29.1, 54.2, and 59.1 d, respectively. No differences in mean milk yields at dry off for the four groups were observed (30d=16.1 \pm 4.3, 30d+ECP=14.3 \pm 4.3, 60d=14.0 \pm 4.2, 60d+ECP=14.4 \pm 4.4 kg/d; $P=0.47$). Similarly, no significant effect of ECP on overall concentrations of plasma lactose was detected (30d=282.7 \pm 52.1, 30d+ECP=189.5 \pm 48.9, 60d=191.0 \pm 51.6 and 60d+ECP=196.6 \pm 52.9 μ M; $P=0.62$). Lactose concentrations increased and were greatest in blood plasma at 20 h after the injection and final milk removal. At 40 h, concentrations approached those observed prior to dry-off. Plasma lactose concentrations at 20 h were positively correlated with milk yield at dry-off ($R^2=0.52$). The temporal profiles of lactose in blood plasma were similar across all treatments and indicated that supplementing 15 mg ECP at dry-off did not alter markedly the course of tight junction leakage that occurs in mammary epithelial tissue when milk removal is discontinued at dry-off.

Key Words: Dry Period, Estrogen, Plasma Lactose

457 Heat stress abatement for dry cows: Does cooling improve transition into lactation? B. C. do Amaral^{*1}, J. Hayen¹, E. E. Connor², S. Tao¹, and G. E. Dahl¹, ¹*University of Florida, Gainesville*, ²*USDA-ARS, Beltsville, MD*.

Environmental factors, especially temperature and photoperiod, influence health and productivity of dairy cows during lactation, possibly via similar physiological effects. For example, heat stress is a critical component of lowered milk yield during summer. Long days improve yield during lactation, while short days improve health and subsequent performance in dry cows. The objective of the study was to evaluate the effects of heat stress prepartum under controlled photoperiod on lactation performance and hepatic metabolic gene expression of periparturient Holstein cows ($n=16$). Cows were dried off 46 d before expected calving date and assigned to treatments by mature equivalent milk production. The treatments were: 1) Heat stress (HT) and 2) Cooling (CL). Both treatments had a photoperiod of (14L:10D). Rectal temperature was measured 2x daily during the dry period. After calving, cows were housed in a free stall barn with cooling, and milk yield was recorded daily up to 42 DIM. Daily DMI was measured from -35 to 42 d relative to calving. Liver biopsies were collected at dry off, -20, +2, and +20 d relative to calving for cows on HT ($n=5$) and CL ($n=4$) to measure mRNA expression of *prolactin receptor (PRL-R)*, *suppressors of cytokine signaling (SOCS1, 2, and 3)*, *CAV1*, *IGFII*, *IGFBP5*, a key transcription factor in lipid biosynthesis (*SREBP1-c*), and enzymes of lipid metabolism (*FASN*, *ACACA*, *ACADVL*, *LCAT*, *CPT1A*, and *ACOX*) by real-time qPCR. HT cows had greater afternoon rectal temperatures (39.2 vs. 38.8°C) and decreased DMI prepartum (12.0 vs. 14.1 kg/d) and milk yield postpartum (25.4 vs. 33.3 kg/d) compared with CL cows. Relative to CL cows, hepatic mRNA expression of *SOCS2* and *IGFBP5* was down-regulated in HT cows. Expression of *ACADVL* was up-regulated in CL cows at d +2 but down-regulated at d +20 relative to HT cows. These results suggest that heat stress abatement in the dry period improves subsequent lactation, possibly through *SOCS-2* and its regulation of hepatic lipid metabolism.

Meat Science and Muscle Biology: Beef Quality

458 National Market Cow and Bull Beef Quality Audit-2007: A survey of producer-related defects. J. D. W. Nicholson¹, R. J. Maddock², R. J. Delmore³, T. E. Lawrence⁴, W. R. Henning⁵, T. D. Pringle⁶, D. D. Johnson⁷, J. C. Paschal¹, R. J. Gill¹, J. J. Cleere¹, B. B. Carpenter¹, R. V. Machen¹, J. P. Banta¹, J. W. Savell¹, D. S. Hale^{*1}, and D. B. Griffin¹, ¹Texas A&M University, College Station, ²North Dakota State University, Fargo, ³California Poly Technical University, San Luis Obispo, ⁴West Texas A&M University, Canyon, ⁵Pennsylvania State University, University Park, ⁶University of Georgia, Athens, ⁷University of Florida, Gainesville.

Packing plants (n = 23) were audited for producer-related defects found in cull cows and bulls. Interviews, live animal and carcass evaluations, and subprimal evaluations were conducted during audits at each plant. Similar audits were conducted in 1994 and 1999. A drastic reduction in downer (non-ambulatory) incidence was found between 1999 and 2007. Fewer cattle had horns, brands, and mud/manure contamination on hides than in 1999. Predominant hide color for beef cows was black (44%). Fewer cattle displayed evidence of bovine ocular neoplasia than in 1994 and 1999. The frequency of injection site knots on live cattle was less in the round and more in the shoulder region than in 1999. Dairy cows were more frequently lame in 2007 than 1999, while beef cows were less lame. Carcass bruising was less evident during the 2007 audit than in previous audits. An increase in liver, tripe, heart, head, and tongue condemnation was found in 2007 than in 1999. Carcasses weighed more in 2007 (305 kg) than in 1999 (246 kg), as well as had less fat. The overall maturity score for cow and bull carcasses was D⁵⁴. The average fat color score was more yellow for beef cows (3.14) than dairy cows (2.42). The majority of all cattle (64%) were able to be traced back to their original owner. End-user audits revealed a higher incidence of injection site lesions in dairy rounds (48%) than in beef rounds (12%).

459 Expression of myosin heavy chain mRNA in skeletal muscle of zilpaterol-HCl fed steers. R. J. Rathmann^{*1}, T. J. Baxa², J. T. Vasconcelos¹, M. L. Galyean¹, B. J. Johnson², and M. F. Miller¹, ¹Texas Tech University, Lubbock, ²Kansas State University, Manhattan.

The objective of this experiment was to determine whether zilpaterol-HCl (ZH) influences protein turnover through the alteration of skeletal muscle gene expression. A 4 x 4 factorial arrangement of treatments in a completely random design was used with the feeding of ZH (8.33 mg/kg, DM basis) to 560 crossbred beef feedlot steers (112 pens; 7 pens/treatment) for durations of 0, 20, 30, and 40 d before slaughter with a 3-d withdrawal. The ZH duration treatments were applied to 4 slaughter groups (136, 157, 177 and 198 d on feed). Feedlot performance, carcass measurements, and the mRNA abundance of β -adrenergic receptors (β -AR), calpastatin (CAL), myosin heavy chain (MHC) isoform 2a, and insulin-like growth factor I (IGF-I) were determined. Within 10 min postmortem, samples were collected from the semimembranosus muscle for RNA isolation from 4 randomly selected steers from each treatment within the 157, 177, and 198 d slaughter groups. No ZH duration x slaughter group interactions were detected ($P > 0.10$) for feedlot or carcass data. Feeding ZH increased ADG, G:F, HCW, dressing percent, and LM area ($P < 0.01$); and decreased fat at the 12th rib, YG, marbling score ($P < 0.01$), and KPH ($P = 0.03$). Feeding ZH did not alter β 1-AR, β 2-AR, CAL, or IGF-I mRNA abundance ($P > 0.10$). There was ZH

duration x slaughter group interaction ($P < 0.01$) for the expression of MHC-2a, in which feeding ZH decreased MHC-2a mRNA abundance for every ZH duration within the 177 and 198 d slaughter groups ($P < 0.02$), but not for the 157 d group ($P > 0.10$). There was a tendency for a linear decrease in CAL mRNA abundance as ZH duration increased ($P = 0.07$), and there was a linear increase in β 2-AR ($P = 0.03$) and CAL ($P < 0.01$) mRNA abundance as days on feed increased. Collectively, the data indicate that ZH may influence net protein turnover by decreasing MHC-2a mRNA expression; however, further research is needed to confirm these results.

Key Words: Myosin, Skeletal Muscle, Zilpaterol

460 Zilpaterol-HCl feeding reduces myosin heavy chain mRNA abundance in skeletal muscle of finishing steers. T. J. Baxa^{*1}, J. P. Hutcheson², M. F. Miller³, W. T. Nichols², M. N. Streeter², D. A. Yates², and B. J. Johnson¹, ¹Kansas State University, Manhattan, ²Intervet Inc., Millsboro, DE, ³Texas Tech University, Lubbock.

This experiment investigated the effects of zilpaterol-HCl with and without the steroidal implant Revalor-S (Rev-S) on feedlot performance and mRNA expression of β -adrenergic receptors (β -AR), insulin-like growth factor I (IGF-I), and myosin heavy chain (MHC) isoforms 1, 2a, and 2x. A total of 2279 (426.2 kg) feedlot steers were administered Rev-S (0 vs. 120 mg trenbolone acetate and 24 mg estradiol) on day 0, and fed zilpaterol (0 vs. 8.3 mg/kg on a dry matter basis) during the last 30 days with a 3 day withdrawal. Treatments were randomly assigned to 24 pens. At slaughter, semimembranosus muscle tissue was excised for RNA isolation from four carcasses per pen. Zilpaterol administration increased ($P < 0.01$) ADG, G:F, HCW, and LM area; decreased ($P < 0.01$) 12th rib fat depth, and marbling; and improved ($P < 0.01$) yield grade. There was no effect ($P > 0.10$) for zilpaterol feeding on the expression of β 1-AR mRNA concentrations; however there was a tendency ($P = 0.09$) for Rev-S administration to decrease β 1-AR mRNA levels. All treatments had no effect ($P > 0.10$) on β 2-AR mRNA. Administration of Rev-S decreased ($P = 0.03$) β 3-AR mRNA, and zilpaterol feeding had a tendency ($P = 0.07$) to decrease β 3-AR mRNA. There was no effect ($P > 0.10$) on the expression of IGF-I mRNA for all treatments. For MHC-1 mRNA, there was a tendency ($P = 0.09$) for zilpaterol by implant interaction, with zilpaterol decreasing ($P = 0.03$) MHC-1 mRNA levels. We also observed a zilpaterol by Rev-S interaction ($P = 0.05$) for MHC-2x abundance. Zilpaterol administration decreased ($P = 0.01$) MHC-2a, and numerically decreased MHC-2x. These data indicate the combined use of zilpaterol and Rev-S additively contributes to total lean tissue accumulation in finishing feedlot steers. In addition, zilpaterol feeding reduced the abundance of myosin heavy chain mRNA in skeletal muscle which could be a consequence of altered protein synthesis and degradation.

Key Words: β -Adrenergic Receptors, Skeletal Muscle, Zilpaterol

461 Effects of ractopamine hydrochloride and zilpaterol hydrochloride fed to beef steers for the final 33 days of the finishing period on growth performance, carcass traits and Warner Bratzler shear force. W. J. Platter¹, R. A. Gomez¹, W. T. Choat^{*1}, S. M. Scramlin²,

and F. K. McKeith², ¹Elanco Animal Health, Greenfield, IN, ²University of Illinois, Urbana.

This study was conducted to evaluate the effects of ractopamine hydrochloride, (Optaflexx[®]) [RAC] and zilpaterol hydrochloride, (Zilmax[®]) [ZH] on performance, carcass characteristics and Warner Bratzler shear force (WBSF). Three hundred beef steers (516 ± 8 kg) were blocked by re-implant (Component TES[®] plus Tylan[®]) BW, breed make-up and condition score and randomly assigned to one of three treatments (10 steers per pen; 10 pens per treatment). Treatments were; control [C], RAC (200 mg RAC•hd⁻¹•day⁻¹ for 33 days), and ZH (7.5 ppm, ~75 mg•hd⁻¹•day⁻¹ ZH for 30 days plus a 3 day withdrawal). Both RAC and ZH improved (P < 0.05) daily gain (ADG), feed efficiency (FE), final BW and carcass wt (HCW) compared with C. Compared to RAC, ZH had (P < 0.05) lower ADG, feed intakes and final BW along with greater (P < 0.05) HCW and dressing percentages. RAC had no effect on carcass quality or yield in this experiment. However, ZH decreased (P < 0.05) backfat and KPH fat, increased (P < 0.05) ribeye area and improved (P < 0.05) yield grade when compared with C. Marbling score was not different between treatments. RAC steaks had higher (P < 0.05) WBSF values than C after 7 days of aging and did not differ from C after 14 days of aging. ZH steaks were tougher (P < 0.05) than C and RAC steaks even after 21 days of aging. This study indicates that both RAC and ZH are effective at improving feedlot performance during the final 33 days of the finishing period. Feeding ZH significantly increased WBSF, even with extended aging periods.

Table 1. Least squares means

462 Sensory attributes of beef from steers finished with corn or high-tannin sorghum. R. E. Larrain^{*1,2}, D. M. Schaefer¹, and J. D. Reed¹, ¹University of Wisconsin, Madison, ²Pontificia Universidad Católica de Chile, Santiago, RM, Chile.

The objective of this study was to test if finishing steers with diets containing high-tannin sorghum (HTS) affects sensory attributes of beef. Steers (n = 31) were randomly allocated to 3 diets containing: 132 g/kg supplement, 100 g/kg corn silage and 768 g/kg grain. Grains were corn (control), HTS and a 1:1 mix of both. Animals were individually penned and harvested in 2 groups after 102 and 123 d. Strip loins were removed from each carcass 48 h post-mortem. Samples were aged in vacuum packages at 2°C for 14 d. Steaks (2.54 cm thick) were cooked in

an electric broiler to an internal temperature of 71°C. A seven-member trained panel evaluated samples from all animals. Loins were evaluated for juiciness, tenderness, beef flavor intensity, grass-fed beef flavor intensity, off-flavor intensity and degree of cooking-doneness. A continuous 15 cm line scale with anchors at both sides was used. The model used for analysis was a completely randomized design with diet as variable, harvest group and panelist as blocks and degree of cooking-doneness as covariate. There was no difference among treatments in juiciness and intensity of beef flavor, grass-fed beef flavor and off flavors (Table 1). Main effect of diet in tenderness tended to be significant but none of the treatments was different from the control (Table 1). We concluded that replacement of corn by HTS in finishing diets for steers did not affect beef sensory attributes when evaluated by a trained panel.

Table 1. Trained-panel sensory attributes of beef from steers finished with corn (C) or high-tannin sorghum (HTS)

	C	HTS	1:1 mix C:HTS	P diet effect
Juiciness	7.27 ± 0.24	6.57 ± 0.24	7.12 ± 0.22	0.094
Tenderness	7.84 ± 0.25	7.22 ± 0.26	8.06 ± 0.24	0.055
Beef flavor intensity	8.37 ± 0.19	8.07 ± 0.19	7.99 ± 0.18	0.307
Grass-fed beef flavor intensity	2.86 ± 0.17	3.00 ± 0.17	2.78 ± 0.16	0.646
Off flavor intensity	1.88 ± 0.17	1.78 ± 0.17	1.63 ± 0.16	0.548

463 Development of a natural beef production and marketing program for Holstein bull calves. M. J. Baker^{*1}, D. G. Fox¹, W. R. Henning², L. O. Tedeschi³, and D. J. Ketchen¹, ¹Cornell University, Ithaca, NY, ²Pennsylvania State University, University Park, ³Texas A&M University, College Station.

The effects of diet and sex condition on feedlot performance, carcass quality, and taste panel acceptability were evaluated for Holstein bulls (n=36), implanted steers (n=36), and non-implanted steers (n=36). During Phase 1 (84 d), cattle were fed a high grain (HG) or high forage (HF) diets, and then fed a common high grain diet (Phase 2) until they reached the USDA low Choice quality grade. During Phase 1, bulls and implanted steers were not different (P > 0.05) in ADG, DMI, or F:G. The HG cattle gained faster, consumed more DM, and were more efficient than HF (P < 0.01). During Phase 2 there was no difference (P > 0.01) between bulls and implanted steers in days on feed (DOF), ADG, or DMI. For steers, implants decreased DOF (P < 0.05) and increased (P < 0.01) ADG and DMI. There was no difference (P > 0.05) in F:G due to sex or implant. Cattle that had previously been on the HF diet had a higher ADG (P < 0.05), but were not different (P > 0.05) in all other performance traits. Over the entire feeding period there was no difference (P > 0.05) between bulls and implanted steers in ADG, DMI, or F:G. In steers, implants increased ADG and DMI (P > 0.05). Compared to implanted steers, bulls tended to have less backfat (P = 0.05) and marbling (P = 0.06) but were similar in ribeye area (REA; P = 0.15), and had numerically lower yield grades, darker lean and lower USDA quality grade. No differences were found in carcass traits due to previous diet, other than HG increased REA. The consumer taste panel favored bull beef over that from implanted steers in juiciness

and tenderness but found both sources of beef to be equally acceptable. Juiciness and tenderness were improved in HF treatment ($P > 0.05$). We conclude that young Holstein bulls grow and convert feed to weight gain as efficiently as implanted steers and produce beef that is of equal or better eating quality.

Key Words: Holstein Beef, Implants, Natural Market

464 Fatty acid composition of beef finished on various forage species or concentrates. S. K. Duckett^{*1}, J. P. S. Neel², J. P. Fontenot³, W. Clapham², and W. S. Swecker, Jr.³, ¹Clemson University, Clemson, SC, ²USDA-ARS, Beaver, WV, ³Virginia Tech University, Blacksburg.

Angus-crossbred steers ($n = 128$) were used to determine the effects of forage species grazed in the last 41 d or high concentrate finishing on the fatty acid composition of beef. Steers grazed mixed pastures (bluegrass/white clover) for 93 d and then grazed alfalfa (AL; $n = 36$), pearl millet (PM; $n = 24$), or mixed (MP; $n = 36$) pastures for the final 44 d of finishing. Due to drought conditions in year 3, steers did not graze PM pastures. Steers were also finished on traditional high concentrate diets (C; $n = 32$) for 134 d. Total lipid content of LM was 60% lower ($P < 0.01$) for forage-finished than C with no differences among forage species. Saturated fatty acid percentage was higher ($P < 0.05$) for AL, PM, and MP than C due to greater ($P < 0.05$) concentrations of stearic acid. Monounsaturated fatty acid (MUFA) percentage was higher ($P < 0.05$) for C than all forage-finished treatments. MUFA was also higher ($P < 0.05$) in PM than AL. Omega-6 fatty acid concentration was higher ($P < 0.05$) for AL than PM and C with MP intermediate. Linolenic acid and total omega-3 fatty acid concentrations were higher ($P < 0.05$) for AL than MP and PM, which were also greater ($P < 0.05$) than C. The ratio of omega-6 to omega-3 fatty acids was lower ($P < 0.05$), hence more desirable from a human health standpoint, for forage-finished (1.3) than C (6.1). Trans-11 vaccenic acid (TVA) concentration was greater ($P < 0.05$) for forage-finished than C; whereas, trans-10 octadecenoic acid concentration was greater ($P < 0.05$) for C than forage-finished. The cis-9 trans-11 isomer of conjugated linoleic acid (CLA) concentration was greater ($P < 0.05$) for PM than AL and MP. CLA percentages were higher ($P < 0.05$) for all forage species compared to C. Forage species grazed during the final 44 d of finishing altered the concentrations of CLA, MUFA, omega-6 and omega-3 fatty acids. Forage finished beef

was leaner and contained greater concentrations of CLA, TVA, and omega-3 fatty acids than concentrate finished.

Key Words: Beef, Forages, Fatty Acids

465 Effect of finishing steers on different forages or high concentrate diet on rib composition, color, and palatability. S. K. Duckett^{*1}, J. P. S. Neel², J. P. Fontenot³, W. Clapham², and W. S. Swecker, Jr.³, ¹Clemson University, Clemson, SC, ²USDA-ARS, Beaver, WV, ³Virginia Tech University, Blacksburg.

Angus-crossbred steers ($n = 128$) were used to determine the effects of forage species grazed in the last 41 d or high concentrate finishing on rib composition, color, and palatability of beef. Steers grazed mixed pastures (bluegrass/white clover) for 93 d and then grazed alfalfa (AL; $n = 36$), pearl millet (PM; $n = 24$), or mixed (MP; $n = 36$) pastures for the final 44 d of finishing. Due to drought conditions in year 3, steers did not graze PM pastures. Steers were also finished on traditional high concentrate diets (C; $n = 32$) for 134 d. Hot carcass weight (HCW) was on average 97 kg heavier ($P < 0.01$) for C than MP, AL, and PM for the three year period. Percentage total fat was 45% greater ($P < 0.05$) and percent fat-free lean was 27% lower for C than forage-finished in the 9-10-11th rib section. No differences were detected in lean, fat and bone composition among forage species. Lightness (L^*) of LM was higher ($P < 0.01$) for C than AL, MP and PM. Lightness values were also higher ($P < 0.05$) for AL than MP. Redness (a^*) of LM was higher ($P < 0.05$) for C than MP and PM in year 1 and higher ($P < 0.05$) than all forage-finished treatments in year 2. In year 3, redness of LM did not differ ($P > 0.05$) among treatments. Yellowness (b^*) of s.c. fat was higher ($P < 0.01$) for AL, MP, and PM than C in all three years. Ultimate LM pH was lower ($P < 0.05$) for C than PM, MP, or AL. Warner-Bratzler shear force did not differ ($P = 0.90$) among finishing treatments and averaged 2.6 kg. Descriptive flavor panel evaluation found that C had higher ($P < 0.05$) beef flavor identification and less ($P < 0.05$) off-notes than AL or MP. Steaks from MP had higher ($P < 0.05$) organ meat (livery) flavor than AL, C, or MP. Finishing steers on forages versus concentrates to an equal animal age endpoint lowered carcass weight and fat content with no change in tenderness. Forage species utilized during the final 44 d of finishing did not alter rib composition or tenderness and had only minor influences on color and palatability.

Symposium: Nonruminant Nutrition: Oxidative Stress and the Use of Antioxidants for Nonruminant Animals

466 Oxidative stress during the lifecycle of animals. W. P. Weiss* and D. C. Mahan, *The Ohio State University, Wooster and Columbus.*

Reactive oxygen species (ROS) are chemical compounds that contain oxygen and are highly reactive because they have, or can be easily converted to compounds that have, unpaired electrons. Common ROS in biological systems include superoxide, hydroxyl radical, hydrogen peroxide, and fatty acid peroxides. ROS are produced via normal oxidative metabolism and certain ROS are absolutely essential for cell signaling and other functions. However, because of their reactive properties, concentrations of ROS must be controlled, and sophisticated antioxidant systems have been developed to keep ROS in check. Oxidative stress occurs when the antioxidant system is overwhelmed by the production of ROS which can lead to increased prevalence of infectious disease via impaired immune cell function, longer term health disorders such as atherosclerosis, and perhaps various sudden death syndromes. For example mortality of weanling pigs was greatly reduced when they were injected with Se and/or vitamin E (two important components of antioxidant systems). Oxidative stress commonly occurs during an infection or other challenge to the immune system. Indeed, the massive production of ROS is essential to kill invading bacteria and trigger various immune responses. These ROS can also cause tissue damage and prolong the disease state; therefore, antioxidants are extremely important to certain types of immune cells. Oxidative stress is also associated with partition. The concentrations of serum antioxidants (e.g., ascorbic acid, glutathione peroxidase, Se, and vitamin E) in sows decline starting 80 d post coitum. Numerous studies have shown that serum concentrations of several antioxidants decrease markedly during the peripartum period and in some animals changes in antioxidant status has been associated with the immunosuppression that occurs during that period. Profitable swine and poultry production requires rapid production of lean tissue, larger litter sizes, and greater milk production and egg production. These requirements place increasing demands on the metabolic system of these animals which can lead to increased oxidative stress unless antioxidant systems are enhanced most likely via nutrition.

Key Words: Reactive Oxygen Species, Oxidative Stress

467 Roles in animals of the antioxidant micronutrients vitamin E, vitamin C, and selenium. R. F. Burk*, *Vanderbilt University, Nashville, TN.*

Three essential micronutrients have major antioxidant properties in animals: vitamin E is a lipid soluble free radical scavenger that protects membranes; vitamin C is a reducing substance in the aqueous phase; and selenium forms the active sites of the glutathione peroxidases and the thioredoxin reductases. These micronutrients interact with one another at a molecular level. Radical scavenging by vitamin E converts it to a free radical form, which is converted back to the active vitamin E by reaction with vitamin C at the membrane-aqueous interface. The resulting vitamin C free radical is converted back to the active vitamin C by the selenoenzyme thioredoxin reductase at the expense of NADPH. Nutritional deficiencies of each micronutrient occur and have been characterized.

Severe vitamin C deficiency causes scurvy in most susceptible species, but the manifestations of severe vitamin E and selenium deficiencies vary from species to species. We have carried out studies in guinea pigs to assess the effects of mild deficiencies in two of these micronutrients that occur simultaneously. Combined mild deficiencies of vitamin E and selenium, each of which was too mild to affect the animal, caused massive skeletal muscle necrosis that was fatal. It was associated with mitochondrial abnormalities in the muscle. Combined mild deficiencies of vitamin E and vitamin C caused infarcts in the spinal cord and brainstem leading to death. These results demonstrate that combined mild deficiencies of antioxidant micronutrients can have serious effects on animal health and indicate the need to ensure adequate intake of all three antioxidant micronutrients. Supported by NIH ES02497.

Key Words: Oxidative Stress, Antioxidant Micronutrients, Central Nervous System Injury

468 Bioavailability of natural and synthetic vitamin E in sows and their progeny. C. Lauridsen*, *University of Aarhus, Tjele, Denmark.*

Two of the critical stages for dietary vitamin E as a nutrient for growth and health status in pigs are immediately after birth and after weaning. Supplemental vitamin E is usually added to animal feed in the form of all-rac- α -tocopheryl acetate, which is an equimolar mixture of all eight possible stereoisomers of which only the RRR stereoisomer possesses the natural configuration. Relatively little information is available in pigs concerning vitamin E delivery to the fetus during gestation or to the suckling progeny from milk. In addition, little is known regarding the effect of supplementing vitamin E to sow diets on the subsequent effect on the vitamin E status of the progeny after weaning. By feeding sows capsules with labelled vitamin E forms it was found (Lauridsen et al., 2002) that swine discriminate between RRR- and all-rac- α -tocopherol with a preference for RRR- α -tocopherol; thus, the official bioequivalence factor of 1.36:1 RRR- to all-rac- α -tocopherol is underestimated. The increased bioavailability the RRR- α -tocopherol resulted in a 2:1 ratio of the natural and synthetic vitamin E forms in milk and in the suckling progeny. In a subsequent experiment it was shown (Lauridsen & Jensen, 2005) that increasing dietary all-rac- α -tocopheryl acetate (70, 150, and 250 IU/kg) during lactation increased the concentration of α -tocopherol in milk and plasma of sows, and in tissues of the pigs at weaning (day 28 after birth). However, after weaning (from day 35 to 49 of age) a decrease in α -tocopherol concentration in most tissues was seen irrespective provision of a dietary level of all-rac- α -tocopheryl acetate at 70 IU/kg feed. In recent studies different nutritional strategies have been investigated to overcome the decrease in vitamin E status following weaning, e.g. by investigating different forms of natural and synthetic vitamin E (Lauridsen & Jensen, 2006), and vitamin C supplement (Lauridsen & Jensen, 2005).

469 Synthetic antioxidant applications in nonruminants. R. J. Harrell*, J. Andrews, V. Robinson, M. Vazquez-Anon, and S. Carter, *Novus International Inc., St Charles, MO.*

Synthetic antioxidants are used to preserve feed quality by preventing the oxidation of lipids, which can lead to improved animal performance. Oxidation begins in feed and feed ingredients and can have a negative impact on the gastrointestinal tract and performance of animals fed oxidized fats. In the presence of oxygen and a catalyst, such as trace minerals, unsaturated fatty acids are oxidized forming free radicals. Generally, synthetic antioxidants control oxidation of lipids by acting as free radical scavengers. Examples include tert-butylhydroquinone, ethoxyquin, butylated hydroxytoluene, and butylated hydroxyanisole. Oxidation occurs in body tissues as a normal process and tissues have a complement of antioxidant compounds and enzymes to prevent oxidative damage including superoxide dismutase, catalase, glutathione, and vitamins E and C. Poor quality feed ingredients, disease, environmental conditions, and level of production can lead to oxidative stress. Oxi-

dativ stress occurs when the endogenous antioxidant capacity of the animal is not enough to control free radical formation. Accumulation of free radicals in the body would lead to tissue damage and reduced performance. A prime target for oxidative stress is the gastrointestinal tract and liver where studies have shown that feeding oxidized fat not only reduces the feed energy value, but also increases epithelial cell turnover, reduced immune function and hepatic function. Synthetic antioxidants are very effective at stabilizing dietary fat sources at the site of oxidation and the choice is dependent on the fat source. Certain antioxidants are more effective against animal based fats, whereas other antioxidants are more effective in preventing oxidation of vegetable oils. Synthetic antioxidants can partially ameliorate the negative effects of feeding oxidized fats by preventing further oxidation through control of peroxides leading to reduced damage to intestinal structure and function, preserving tissue antioxidant activity to reduce oxidative stress and improve performance.

470 Fibroblast growth factor 2-induced expression of interferon-tau is mediated by protein kinase C in bovine trophectoderm. Q. Yang*, S. E. Johnson, and A. D. Ealy, *University of Florida, Gainesville.*

Interferon-tau (IFNT) serves as the maternal recognition of pregnancy signal in cattle and sheep. Pre- and peri-attachment conceptus production of IFNT is controlled in part by members of the fibroblast growth factor (FGF) family. FGF2 supplementation stimulates IFNT mRNA and protein concentrations in bovine blastocysts and trophectoderm. The objective of this work was to identify the intracellular signaling modules invoked by FGF2 in bovine trophectoderm cells (CT1). CT1 cells were treated for 2 h with chemical inhibitors for either protein kinase C (PKC) isoforms (0.5 μ M Calphostin), extracellular signal-regulated kinases (ERK)1/2 (50 μ M PD98059), p38 mitogen-activated protein kinase (MAPK) (25 μ M SB203580) or vehicle-only prior to FGF2 supplementation for 24 h. After cell lysis and RNA extraction, quantitative RT-PCR revealed a 10.70 ± 1.93 fold increase ($P=0.001$) in IFNT mRNA abundance in response to FGF2. Suppression of ERK1/2 or p38 activity did not alter the FGF2 response. However, exposure to the pan-PKC inhibitor limited ($P=0.01$) the ability of FGF2 to increase in IFNT mRNA abundance (2.42 ± 1.13 fold induction above control). Media supplementation with 100 nM phorbol 12-myristate 13-acetate (PMA), a PKC activator, mimicked the FGF2 response in CT1 cells. Selectivity of the PKC response was examined in the presence of chemical antagonists to PKC- $\alpha/\beta/\gamma$ (5 μ M Gö6976) or PKC- δ/θ (5 μ M rottlerin). Treatment of CT1 cells with Gö6976 did not affect FGF2- or PMA-mediated increases in IFNT mRNA abundance. By contrast, inhibition of PKC- δ/θ attenuated ($P<0.01$) the PMA and FGF2 responses. Thus, PKC- δ or - θ likely is required for FGF2-mediated IFNT expression. Further studies are forthcoming to confirm this and other roles for PKC- δ/θ during bovine conceptus development. Project supported by National Research Initiative Competitive Grant #2003-35203-13345 and 2003-35203-15382 from the USDA Cooperative State Research, Education, and Extension Service.

471 Expression of fibroblast growth factors and their receptors during pre- and peri-attachment development in bovine conceptuses. F. N. T. Cooke* and A. D. Ealy, *The University of Florida, Gainesville.*

For pregnancy to continue beyond the length of a normal estrous cycle, the bovine conceptus must secrete copious quantities of interferon-tau (IFNT) to interrupt the luteolytic process and maintain pregnancy. This laboratory discovered that fibroblast growth factor 2 (FGF2) increases IFNT production in cultured bovine trophectoderm and blastocysts. Several genes encode FGFs and some of these FGFs possess receptor subtype binding affinities similar to FGF2. To better understand the functional roles of FGFs during bovine conceptus development, studies were completed to: 1) identify the FGF receptor (FGFR) subtypes expressed by pre- and peri-attachment bovine conceptuses, and 2) identify conceptus-derived FGFs that may interact with these receptors. RT-PCR was completed using total RNA extracted from in vitro-derived bovine

blastocysts and in vivo-derived elongated conceptuses (3 pools/stage) and primers specific for bovine FGFR1, 2, 3 or 4. Sequencing of the amplified products revealed expression of receptor subtypes FGFR1IIIc, 2IIIb, 3IIIc, and 4 at both stages of development. Since FGFR2IIIb is crucial for trophectoderm development in other species, expression of ligands that act through this receptor subtype was explored. Transcripts for FGF1, 2, and 10 but not FGF7 were detected in elongated bovine conceptuses. In blastocysts, FGF1 and 2 mRNA abundance was low and FGF10 transcripts were not amplified. FGF7 transcript abundance was not analyzed at the blastocysts stage. In summary, at least four FGFRs reside in pre- and peri-attachment bovine conceptuses. Moreover, conceptuses express at least three candidate FGFs during elongation, the time of peak IFNT expression. Further studies are required to examine how some or all of these ligands interact with their receptors to regulate IFNT expression and conceptus development in cattle and other ruminants. Project supported by National Research Initiative Competitive Grant #2003-35203-13345 and 2003-35203-15382 from the USDA Cooperative State Research, Education, and Extension Service.

Key Words: Embryo, Pregnancy, Placenta

472 Reduced angiogenic factor expression in cotyledonary (COT) arteries of overnourished, obese ewes at midgestation. Y. Ma*¹, M. J. Zhu¹, P. W. Nathanielsz^{1,2}, and S. P. Ford¹, ¹*University of Wyoming, Laramie,* ²*University of Texas, San Antonio.*

In the sheep, maternal:fetal exchange takes place in placentomes, which are comprised of maternal caruncular and fetal COT tissues. We have demonstrated previously that COT vascularity in obese ewes was decreased ~50% by 75 d gestational age (dGA). This study investigated the role of selected angiogenic factors in reducing COT vascularity in pregnant obese ewes. Multiparous ewes carrying twin fetuses were assigned to a control (C, 100% of NRC recommendations; n = 10) or obesogenic (OB, 150% of NRC; n = 10) diet from 60 d before conception to 75 dGA, at which time COT arteries were collected from 5 ewes/group and snap frozen on liquid nitrogen. The remaining ewes in each group were maintained on their respective diets and allowed to lamb. At 75 dGA, OB ewes and their fetuses were ~50% and ~25% heavier, respectively, than C ewes and fetuses. Lambs from both dietary groups exhibited similar birth weights. COT artery mRNA levels of vascular endothelial growth factor (VEGF) and its receptors FLT-1 and KDR, angiopoietin-1 (ANG-1) and -2 (ANG-2), and their receptor Tie-2, basic fibroblast growth factor (FGF-2), and placenta growth factor (PLGF) were quantified via Real-time PCR. VEGF, ANG-1, ANG-2, FGF-2 and PLGF mRNA level were reduced ($P<0.05$) 2 fold or more in COT arteries of OB vs. C ewes, while no treatment differences were observed in FLT-1, KDR, or Tie-2 expression. COT arterial protein levels of VEGF, PLGF and FGF-2 were then quantified by Western-blot, and were reduced ($P<0.05$) 41%, 32% and 50%, respectively in OB ewes when compared to C ewes. This decrease in COT artery angiogenic factor expression in OB ewes would be expected to decrease vascularity and thus nutrient delivery to the fetus, slowing fetal growth, and reducing lamb birth weight. NIH INBRE 1P20RR16474.

Key Words: Angiogenic Factors, COT Vascularity, Obese Ewe

473 Increased circulating progesterone (P₄) levels during the estrous cycle in offspring of nutrient restricted ewes. L. A. George*¹, P. W. Nathanielsz^{1,2}, and S. P. Ford¹, ¹University of Wyoming, Laramie, ²University of Texas, San Antonio.

We have reported that fetuses of ewes nutrient restricted from 28-78 d of gestation (dGA) exhibited increased oxidative base lesions within DNA of day 78 fetal oogonia compared to controls (Murdoch et al., 2003, *Reprod. Biol. Endocrinol.* 1:6). Such lesions in fetal oogonia could affect oocyte/follicular/corpora lutea (CL) function later in life. P₄ secretion by the CL is vital for initiation and maintenance of cyclicity and pregnancy. This study examined the impact of maternal nutrient restriction during early gestation on P₄ secretion during an estrous cycle of female offspring. Dams were fed either a nutrient restricted (NR: 50% NRC recommendations) or control (C: 100% NRC) diet from 28 to 78 dGA and then both groups were fed 100% of requirements to lambing. Female lambs from NR and C dams were commingled in a single group and fed 100% NRC from weaning through testing. During October and November, yearlings born from NR (n=7) and C (n=7) dams were monitored daily for estrus and blood sampled every three days from standing estrus (d 0) to the subsequent estrus. This procedure was repeated at 3 yrs of age. NR and C ewes were of similar BW both at 1 (62.4 ± 3.1 kg) and 3 (75.8 ± 2.6 kg) yrs of age. Estrous cycle lengths were similar across treatment groups (19.1 ± 0.2 d). P₄ area under the curve was 20% higher in NR vs. C offspring at 1 yr of age (P = 0.05), and 23% higher at 3 yrs of age (P = 0.08). Maternal diet-induced increases in systemic P₄ in female offspring of NR vs. C ewes could indicate differences in either CL P₄ secretion, incidence of multiple ovulations and/or P₄ clearance. Regardless of mechanism, these data provide evidence for the persistent in utero programming of progesterone levels in offspring induced by differences in early gestational maternal nutrition.

Key Words: Fetal Programming, Estrous Cycle, Progesterone

474 Increased macrophage migration inhibitory factor (MIF) in the pancreas of fetuses gestated by overnourished, obese ewes. L. Zhang*¹, M. J. Zhu¹, P. W. Nathanielsz^{1,2}, and S. P. Ford¹, ¹University of Wyoming, Laramie, ²University of Texas Health Sciences Center, San Antonio, TX.

MIF is an integral component of the stress response and has been shown to be released by the pituitary, macrophage, and the T-lymphocyte in response to inflammation, infection and stress. More recently MIF was identified as a glucose-dependent pancreatic beta cell product, which increases insulin secretion in an autocrine fashion, and thus may play an important role in carbohydrate metabolism (Waeber et al. 1997. *Proc. Natl. Acad. Sci.* 94:4782-4787). In a recently developed sheep model of maternal obesity, we have reported that blood glucose and insulin concentrations were markedly elevated at midgestation in fetuses from obese mothers. This study investigated the potential role of MIF in the regulation of fetal pancreatic insulin secretion in our obese model. Multiparous ewes carrying twin fetuses were assigned to a control (C, 100% of NRC recommendations; n=5) or obesogenic (OB, 150% of NRC; n=5) diet from 60 d before conception to 75 days of gestation (dGA), at which time fetal pancreatic tissue were collected and snap frozen on liquid nitrogen or fixed in paraformaldehyde and paraffin embedded. At 75 dGA, OB ewes and their fetuses were ~50% and ~25% heavier

(P<0.05), respectively, than C ewes and fetuses. Fetal pancreatic tissue sections were incubated with guinea pig anti-porcine insulin or rabbit anti-MIF antibodies at 4° C overnight, then with fluorescent labeled 2° antibodies: Rhodamine labeled goat anti-guinea pig or AlexaFluor 488 labeled goat anti-rabbit for 60 min at 22° C. By evaluating immunostaining of both insulin positive cells and MIF positive cells, we determined that MIF is largely expressed within the cytoplasm of insulin positive beta cells. The protein level of MIF in pancreatic tissue was quantified via Western blot using a specific polyclonal antibody to MIF. The pancreatic MIF protein level was increased (P<0.05) in fetuses of OB ewes compared with fetuses from C ewes. The increased pancreatic MIF expression in fetuses from OB ewes would be expected to potentiate insulin release and thus glucose uptake by fetal body tissues. NIH INBRE 1P20RR16474.

475 Effects of soy-derived phytoestrogen and estradiol exposure on reproductive development in male neonatal pigs. K. Necaie*¹, K. Moulton¹, D. Christiansen¹, K. Walters¹, M. Crenshaw¹, C. Scanes², and P. Ryan¹, ¹Mississippi State University, Starkville, ²University of Wisconsin, Milwaukee.

While dietary phytoestrogens are known to mimic estrogenic effects on adult mammalian reproductive systems, there is little information on the effects of these compounds on fetal or neonatal reproductive development. The objective of this study was to evaluate the effects of soy-derived isoflavones on normal reproductive development in neonatal pigs. Yorkshire-Landrace crossbred sows (100 d gestation) were randomly assigned to a lactating diet (2.3 kg/sow/d) supplemented with either Novasoy 70, an isoflavone extract, (NOV, n=8) or without (CON, n=8). Mean BW for CON and NOV sows was 275.8 ± 7.0 kg and 278.8 ± 13 kg, respectively. Feed was top-dressed 2 x d with the NOV from d 100 of gestation to farrowing. Male neonatal pigs (NPs) were weighed on post natal day (PND) six then randomly assigned to one of four treatments (n=10 to 12/treatment): 1) control (vehicle), 2) estradiol (50 µg/kg BW/d) as a positive control, 3) low genistein dose (3 mg/kg BW/d) and 4) high genistein dose (9 mg/kg BW/d). NPs were dosed by oral gavage 2 x d for 7 d commencing on PND 7. Doses were adjusted daily according to BW change. On PND 14, NPs were euthanized and the testes, epididymi and seminal vesicles were recovered, grossly examined, and wet tissue weights recorded. Wet tissue weights were analyzed using GLM mixed model procedures. At PND 14 body weights did not differ (P > 0.05) between assigned NP treatments. Novasoy treatment of sows had no effect on testes, epididymal or seminal vesicles weights. However, estradiol treatment of NP increased seminal vesicle wet weight as a % of BW (P=0.075), but there was no observed effects of estradiol or either genistein treatments on NP testes and epididymal weights. While no detrimental effects of estrogen exposure were observed in testes or epididymis, changes in seminal vesicle tissue weights demonstrates that oral exposure to estradiol but not genistein may alter reproductive development in male neonatal pigs. Thus, the neonatal pig may provide a useful model for assessing effects of dietary phytoestrogens on reproductive development in infants on soy-based formulas.

476 Meta-analysis of progesterone supplementation during early pregnancy in cattle. G. E. Mann*, *University of Nottingham, Sutton Bonington Campus, Loughborough, UK.*

Progesterone is a critical hormone during early pregnancy in the cow. As a result a number of studies have investigated the effects of progesterone supplementation on pregnancy rate. An earlier meta-analysis of some of these studies revealed an overall improvement in pregnancy rate and marked effects of factors such as time of treatment (Mann and Lamming, 1999, *Reproduction in Domestic Animals* 34, 269-274). In this study an updated meta-analysis was carried out on 30 studies involving a total of 5262 control cows and 4726 progesterone treated cows. Treatment was by a variety of routes including intravaginal insert, subcutaneous implant and im injection. Data was analyzed by Chi square test with Yates correction. While the results of individual studies showed wide variations (range of 28.5% decrease to 34.4% increase), progesterone treatment did result in an overall increase ($P < 0.05$) in pregnancy rate of 2.4%. Treatment following natural or synchronized estrus resulted in an overall increase ($P < 0.001$) of 4.9% while treatment following synchronized ovulation did not result in any increase. In cows treated following unsynchronized ovulation, very early (d 0 to 2) or late (after d 10) initiation of treatment had no significant effect on pregnancy rate, while initiation of treatment between d 3 to 9 resulted in an overall 8.5% increase ($P < 0.001$) in pregnancy rate. This analysis demonstrates that progesterone supplementation is of no benefit following synchronized ovulation. However, if ovulation has not been synchronized, treatment results in improvements in pregnancy rate that are highly dependant on time of treatment.

Key Words: Cow, Progesterone, Pregnancy

477 Effect of endocannabinoid (EC) agonists on cow corpus luteum (CL) function in vitro. C. W. Weems^{*1}, Y. S. Weems¹, A. W. Lewis², D. A. Neuendorf², and R. D. Randel², ¹*University of Hawaii, Honolulu*, ²*Texas A&M University, Overton.*

Thirty to 40 % of pregnancies are lost during the first 3rd of pregnancy due to inadequate progesterone (P4) secretion. Loss of CL P4 secretion during the estrous cycle is via uterine secretion of PGF2 α . Cow CL secretion of PGE and PGF2 α , which are derived from arachidonic acid (AA) in phospholipids, increased linearly with time in culture with the PGE:PGF2 α ratio being 1:1. PGE1 or PGE2 are luteotropic and antiluteolytic in vitro and in vivo (C Weems et al. *The Vet J* 171:206, 2006; Y Weems et al. *Prostaglandins* 55:28, 55:359, 1988). EC are also derived from phospholipids and are associated with infertility, which could be via negative effects on implantation or CL function (Wang et al. *J Clin Invest* 116:2122, 2006; *Endo Rev* 27:427, 2006). The objective was to elucidate effects of EC1 or EC2 receptor agonists, antagonists or a fatty acid amide hydrolase (FAAH) inhibitor of EC catabolism on cow CL P4, PGE and PGF2 α secretion. Day-15 CL slices were weighed, randomized to treatments (100 ng/mL; n = 8) within cow, and incubated at 39.5 C in M199 1 hr without treatment and 4 and 8 hr with treatments. Treatments were: Vehicle (VEH), PGE1, PGF2 α , AM 251 (EC1 antagonist), AM 630 (EC2 antagonist), ACPA (EC2 agonist), IMMA (EC2 agonist), MAFP (inhibits FAAH catabolism of EC), MAFP+ACPA or MAFP+IMMA. Media collected at 4 and 8 h were analyzed for P4, PGE and PGF2 α by RIA. Data were analyzed by a 2X10 Factorial Design for ANOVA. P4 was increased by PGE1 ($P < 0.05$) and reduced ($P < 0.05$) by PGF2 α , ACPA, IMMA, MAFP, MAFP+ACPA, and MAFP+IMMA. PGE and

PGF2 α increased ($P < 0.05$) with time in VEH controls. PGE1 increased PGE and PGF2 α increased PGF2 α at 4 and 8 h ($P < 0.05$). ACPA, IMMA, MAFP, MAFP+ACPA and MAFP+IMMA lowered ($P < 0.05$) PGE secretion at 4 and 8 h and by AM251, AM 630 and PGF2 α at 8 h. AM 251, AM 630, MAFP+IMMA, ACPA, IMMA or MAFP+ACPA decreased ($P < 0.05$) PGF2 α at 4 and 8 h and by PGE1 at 8 h. Overall EC negatively affect cow CL function, The CL may be one site for EC decreased fertility.

Key Words: Cow, Corpus Luteum, Endocannabinoids

478 Peripheral concentrations of insulin are negativity correlated with cytochrome P450 3A activity and mRNA expression in dairy cows. C. O. Lemley*, L. R. Tager, K. M. Krause, and M. E. Wilson, *West Virginia University, Morgantown.*

Current dairy cow pregnancy rates to first service are very low, dramatically decreasing the potential profits to the industry. Dairy cow pregnancy rates have been improved with progesterone supplementation. Low peripheral concentrations of progesterone may be due to deficiencies in luteal secretion and/or excessive hepatic catabolism via cytochrome P450 enzymes. The objectives of the current experiment were to determine any association between plasma insulin concentrations and hepatic cytochrome P450 activity and/or mRNA expression. Six lactating Holstein dairy cows (123 \pm 38 DIM) were fed one of three diets (14 d experimental period) utilizing a Latin rectangle design. Diets were formulated to be isocaloric and isonitrogenous, while causing differential insulin secretion (2% propylene glycol diet, 15.1% corn starch diet or a high fiber diet). Energy balance and DMI on d 10-14 were similar among cows fed the three different diets. On d 12 a jugular blood sample was collected prior to the morning feeding at 0 hr, and then at 1, 2, 3, 4, 5, 6, 8, and 10 hr post-feeding for determination of insulin concentrations. On d 14 a liver biopsy was collected 3 hr post-feeding and used for determining cytochrome P450 2C and 3A activity and mRNA expression. Insulin response for each cow over the 10 hr blood sampling period was used to generate area under the curve (AUC) values. A correlation analysis revealed a significant negative correlation between cytochrome P450 3A activity and insulin AUC ($r = -0.49$, $P < 0.05$), as well as cytochrome P450 3A mRNA expression and insulin AUC ($r = -0.50$, $P < 0.05$). However, neither cytochrome P450 2C activity nor mRNA expression were correlated with insulin AUC. In conclusion we have demonstrated a significant negative correlation between cytochrome P450 3A activity and mRNA expression with insulin AUC, supporting the notion that feedstuffs that stimulate insulin secretion may be useful in decreasing excessive progesterone catabolism.

Key Words: Insulin, Cytochrome P450, Progesterone Catabolism

479 Biostimulatory effect of bulls alters characteristics of cortisol concentration patterns before resumption of ovulatory activity in postpartum, anovular, suckled beef cows. S. A. Tauck*, J. R. Olsen, J. R. C. Wilkinson, and J. G. Berardinelli, *Montana State University, Bozeman.*

The objective was to determine if bulls alter temporal patterns of cortisol concentrations in postpartum, suckled beef cows before resumption of ovulatory activity (ROA). The null hypotheses were that interval to

ROA and characteristics of cortisol patterns do not differ between cows exposed or not exposed to bulls. At 72 ± 3.5 d (\pm SE) postpartum, anovular cows were assigned randomly to be exposed (BE; n=8) or not exposed (NE; n=5) to bulls for 33 d in separate pen areas. Day 0 was designated as the start of bull exposure and BE cows had been exposed to bulls for 6 d before the initiation of the intensive sampling period. Blood samples were collected daily via an indwelling jugular catheter from each cow at 15-min intervals between 1000 to 1400 h over a 10-d interval (d 7 to 16) for assay of cortisol. Interval from d 0 to ROA, mean cortisol, and pulse frequency, amplitude, and duration, and inter-pulse interval were analyzed by ANOVA. Interval to ROA was shorter ($P < 0.05$) for BE (11.4 d) than NE (21 d) cows. Mean cortisol and characteristics of cortisol patterns did not differ ($P > 0.10$) between BE and NE cows from D 7 to 16. However, characteristics of cortisol patterns in BE cows differed ($P < 0.05$) before and after ROA. Five BE cows and only one NE cow began to cycle before or during the sampling period. Before the initiation of cycling activity cortisol pulse frequency was lower ($P < 0.05$) in BE cows than NE cows. Mean cortisol and cortisol pulse duration were correlated positively ($P < 0.05$) with interval to ROA in BE cows, while only mean cortisol was correlated positively ($P < 0.05$) with interval to ROA in NE cows. In conclusion, bull exposure decreased cortisol pulse frequency and lengthened cortisol pulse duration before ROA. The results indicate that changes in characteristics of cortisol concentrations precede the biostimulatory effect of bulls to induce resumption of ovulatory activity in postpartum, anovular, suckled beef cows.

Key Words: Bull Biostimulation, Cortisol, Postpartum

480 Effects of oro-nasal administration of androstadienone on characteristics of cortisol concentrations in postpartum, suckled beef cows. J. R. C. Wilkinson*, S. A. Tauck, J. R. Olsen, and J. G. Berardinelli, *Montana State University, Bozeman.*

The objective was to determine if oro-nasal administration of androstadienone changes characteristics of cortisol concentration patterns in postpartum, anovulatory beef cows. The hypotheses were that characteristics of cortisol concentration patterns do not change before, during, or after exposure to androstadienone in anovular cows. To test these hypotheses, three primiparous, crossbred cows were fitted with indwelling jugular catheters 2 d before the start of the experiment (92 ± 5.9 d after calving). Treatments were: oro-nasal administration of 0.9% saline on day 1 (S1); androstadienone (Andro; 10 mg/mL 0.9% saline) on day 2 (Andro); and 0.9% saline on day 3 (S2) for 4 h over 3 consecutive days. Oro-nasal exposure consisted of three vigorous sprays: one in each nostril and one on the top of the nose, given each h over a 4-h period each d. Samples were collected at 15-min intervals for 4 h from 1000 to 1400 h each day. Characteristics of cortisol patterns (mean, baseline, pulse frequency, amplitude, and duration) were analyzed by ANOVA. Mean, baseline, and pulse amplitude in cows did not differ ($P > 0.10$) among treatments. Pulse frequency was greater ($P < 0.05$) in cows during the S1 (1 pulse/h) and S2 (1 pulse/h) treatments than in cows during the Andro treatment (0.5 pulses/h). Pulse duration did not differ ($P > 0.10$) among cows treated with S1 and S2 or S2 and Andro. However, pulse duration was longer ($P < 0.05$) when cows were given Andro (75 min) than when given S1 (46.8 min). Androstadienone, administered oro-nasally to postpartum cows did not alter mean, baseline, and pulse amplitude of cortisol. However, androstadienone exposure appeared to decrease pulse frequency and increase the duration of pulses of cortisol. These preliminary results indicate that androstadienone may be a putative pheromone involved with the biostimulatory effect of bulls on resumption of ovulatory activity in postpartum, suckled beef cows.

Key Words: Bull Biostimulation, Postpartum, Pheromone

Production, Management and the Environment: Disease, Management and Environment

481 Milking procedures and prevalence of contagious mastitis pathogens on U. S. dairy operations. J. E. Lombard^{1*}, C. A. Kopral¹, T. Van Slyke², F. Welcome², and Y. Schukken², ¹USDA:APHIS:VS:Centers for Epidemiology and Animal Health, Fort Collins, CO, ²Quality Milk Production Services, Ithaca, NY.

The National Animal Health Monitoring System's Dairy 2007 study collected milking procedures and other management practice data from 582 operations in 17 of the top dairy states. In addition, a single bulk tank milk sample was collected from 534 operations to estimate the prevalence of the contagious mastitis pathogens - *Staphylococcus aureus*, *Streptococcus agalactiae* and *Mycoplasma*. Milk was cultured according to NMC protocols. After adjusting for the study design, an estimated 43.3% of U.S. dairy operations were infected with *S. aureus*, while *S. agalactiae* and *Mycoplasma* prevalences were 2.7 and 3.2%, respectively. Only *Mycoplasma* had herd size differences where prevalence increased as herd size increased ($P=0.005$). The presence of *S. aureus* was positively associated with use of a backflush system, milking mastitis cows in a separate string and culturing milk from fresh cows and high SCC cows ($p<0.05$). Operations infected with *S. agalactiae* were more likely to have purchased cattle in 2006, applied a nonlabeled predip using a cup, or had a BTSCC greater than 400,000 ($p<0.05$). The use of a labeled predip using a sprayer, a postdip or a backflush system were associated with decreased odds of being infected with *S. agalactiae* ($p<0.05$). Operations who had cultured *Mycoplasma* in the 12 months prior to the interview, applied a labeled predip using a sprayer, provided vitamin ADE or selenium supplementation, purchased cattle, had a BTSCC greater than 400,000 or had concurrent infection with *S. aureus* were at increased odds of being infected with *Mycoplasma* ($P<0.05$). Operations that used a water hose with disinfectant, or applied labeled predip using a cup or single use towels were less likely to be infected with *Mycoplasma* ($P<0.05$). Although some of the associations found in this analysis are likely effects of infection, rather than causes, not purchasing cattle and following recommended milking procedures appears to decrease the prevalence of contagious mastitis pathogens and improve milk quality.

Key Words: Mastitis, Milk Quality, Pathogens

482 Reliability of a standardized environmental sampling protocol to quantify *Mycobacterium avium* ssp. *paratuberculosis* in free-stall dairies. S. S. Aly^{1*}, R. J. Anderson², I. A. Gardner¹, R. H. Whitlock³, T. Fyock³, J. M. Adaska⁴, and J. Jiang¹, ¹University of California, Davis, ²California Department of Food and Agriculture, Animal Health Branch, Sacramento, CA, ³University of Pennsylvania, Kennett Square, ⁴California Animal Health and Food Safety Laboratory, Tulare Branch, Tulare, CA.

Mycobacterium avium ssp. *paratuberculosis* (MAP) is the cause of Johne's disease in dairy cattle and can be detected in fecal slurry in pens housing infected cows. The extent to which environmental samples are comparable across collectors and time affects the reliability of a sampling protocol. High reliability is important if such samples are to be used as part of a diagnostic strategy to detect MAP super-shedder cows and monitor temporal changes in environmental MAP load. The objective of this longitudinal study was to quantify MAP in environmental samples collected using a standardized sampling protocol from free-stall pens

using culture on Herrold's egg yolk medium (HEYM) and quantitative real-time PCR (qrt-PCR), and estimate the variability in results due to dairy, pen, collector and time.

A standardized sampling protocol was used to collect environmental samples from unflushed cross-over alleys in 31 cow pens in 4 California free-stall dairies (803, 1024, 1300 and 3577 cows). Samples were collected simultaneously by two veterinarians on each of days 1, 3 and 5 after scraping alley surfaces while keeping pen populations stable. Results were analyzed using variance components models and variability due to dairy, pen, collector and time were estimated and used to compute intraclass correlation coefficients (ICC). Among-pen variation was the largest source of sample variation. The ICC for similarity in samples collected by different collectors from the same location on the same day was 80% for qrt-PCR and 82% for HEYM. The ICC for samples collected by the same collector from the same location on different days was 82% for qrt-PCR and 65% for HEYM.

Environmental sampling of free-stall pens using a standardized sampling protocol can be reliable and yield comparable results with minimal variation due to collector or time. As part of a diagnostic plan, environmental samples can be used to identify pen populations with high MAP loads that are likely to include super-shedders thus reduce testing costs compared to whole herd tests and encourage more owners to enroll in Johne's disease control programs.

Key Words: Johne's, Environmental Sampling Reliability

483 Prevalence of bovine viral diarrhoea virus in bulk tank milk and associations with herd characteristics on U.S. dairy operations. J. E. Lombard^{1*}, E. J. Dubovi², and C. A. Kopral¹, ¹USDA:APHIS:VS:Centers for Epidemiology and Animal Health, Fort Collins, CO, ²Cornell University, Ithaca, NY.

Bulk tank milk was collected and tested for BVD antigen during the National Animal Health Monitoring System's Dairy 2007 study. Information regarding BVD-related management practices and dairy cow health and productivity was also collected. One objective of the study was to estimate the prevalence of persistent infection with BVD and associated herd level factors. Samples were collected from 527 operations during the months of March through August 2007. After adjusting for study design and incorporating weighting procedures, 1.7% of dairy operations had PCR evidence of BVD infection. BVD virus was detected in bulk tank milk on 1.0% of operations with less than 500 cows and 12.9% of operations with 500 or more cows. A larger percentage of operations in the West (7.8%) were BVD-infected compared to the East (1.1%). The mean number of cows represented in the bulk tank samples were 125 for noninfected and 677 for infected operations. Vaccination for both heifers and cows was more commonly performed on infected compared to noninfected operations. Operations that brought in new additions during 2006 were more likely to have BVD virus in their bulk tank than operations that did not purchase cattle. Infertility problems, defined as percent of cows >150 days open, were higher for infected operations compared to noninfected (18.2% of cows versus 14.3%). Although there were no differences in the percentage of removals, noninfected operations sold a higher percentage of removal as dairy replacements compared to infected operations (6.2% and 1.9%, respectively). Rolling herd average milk production was higher for infected operations (10,201 kg) compared to noninfected operations (9,254

kg). Results suggest that large operations and those that purchase new additions are more likely to have animals with persistent BVD infection compared to small closed herds.

Key Words: BVD, Bulk Milk, Prevalence

484 Prevalence of *Mycobacterium avium* subspecies *paratuberculosis* and associations with herd characteristics on U.S. dairy operations. J. E. Lombard*¹, R. T. Capel², B. A. Wagner¹, J. B. Payeur², and C. P. Fossler¹, ¹USDA:APHIS:VS:Centers for Epidemiology and Animal Health, Fort Collins, CO, ²USDA:APHIS:VS:National Veterinary Services Laboratories, Ames, IA.

During the National Animal Health Monitoring System's Dairy 2007 study, in addition to information collected on management practices and health, 6 environmental samples were collected from 524 operations for culture of *Mycobacterium avium* subspecies *paratuberculosis*, the causative agent of Johne's disease. One objective of the study was to estimate the prevalence of *M. paratuberculosis* and associated herd level factors. Samples were collected during the months of March through August 2007. Samples were cultured on Herrolds egg yolk in both tubes and flasks and confirmed as positive with PCR. After adjusting for study design and incorporating weighting procedures, 45.8% of samples were positive and 68.1% of operations had at least one sample that was culture positive for *M. paratuberculosis*. The largest percentage of samples that tested positive were from flush water (64.6%) and lagoons (61.2%) while the lowest percent positive were from gutter cleaners (32.1%). The herd-level prevalence of *M. paratuberculosis* increased as herd size increased with 95.0% of large operations (500 or more cows) being infected. No regional or month of collection differences were observed at the operation level. Operations that brought in herd additions during 2006 were at increased risk of being infected. The overall percentages of removals or deaths were not different between infected and noninfected operations. However, differences were observed in the percentage of cows removed for poor production (8.8% for noninfected operations compared with 14.8% for infected operations). In addition, noninfected operations had a higher percentage of removals sold as replacements (12.5%) compared with infected operations (4.5%). There were no significant differences in RHA milk production. The prevalence of *M. paratuberculosis*-infected dairy operations in the U.S is higher than previously reported.

Key Words: Paratuberculosis, Prevalence, Johne's Disease

485 Puncture force resistance of hoof horn from New Zealand (NZ) Friesian and Jersey cross NZ Friesian dairy. L. A. Lethbridge, J. K. Margerison*, G. W. Reynolds, R. Laven, and C. S. Brennan, Massey University.

The aim was to assess the resistance to puncture of the hoof horn from differing claws and regions of claws in prepartum New Zealand (NZ) Friesian and Jersey cross NZ Friesian dairy breeds. At 14 weeks of age all four hooves from 9 (5 Jersey × NZ Friesian (JXNZF); 4 NZ Friesian (NZF)) male dairy cattle had their hooves held and the distal Imm surface of the sole horn removed. All 8 claws were scored for the

presence of lesions and hoof samples were collected from the weight bearing regions 1 to 5 (according to the International foot map (IFM) and tested for puncture force (PF) using a texture analyser. PF of regions 1 and 2, corresponding to the white line, was consistently significantly lower compared with regions 4 and 5, which correspond with the sole, for both NZF and JXNZF (NZF: 1; 0.62^c, 2; 0.57^c, 3; 0.74^b, 4; 0.80^{ab}, 5; 0.86^a (SEM 0.013) P<0.001; JXNZF: 1; 0.76^b, 2; 0.64^c, 3; 0.86^{ab}, 4; 0.94^a, 5; 0.93^a (SEM: 0.019) P<0.001). Horn PF of JXNZF was consistently higher for both sole and white line regions compared with Friesian (IFM 1: NZFR; 0.67^b, JXNZF; 0.85^a (SEM 0.021) P< 0.001; IFM 2: NZFR; 0.60^b, JXNZF; 0.70^a (SEM 0.022) P< 0.001; IFM 3: NZF; 0.73^b, JXNZF 0.85^a (SEM 0.023) P< 0.001; IFM 4: NZF 0.78^b, JXNZF 0.91^a (SEM 0.020) P<0.001; IFM 5: NZF; 0.84^b, JXNZF; 0.90^a (SEM 0.021) P< 0.001). In conclusion hoof taken from Jersey cross Friesian cattle required a significantly higher maximum force to puncture than that from Friesian cattle, making claws less susceptible to puncture and wear. PF for white line tissue (1 and 2) was significantly lower than that from the sole (4 and 5) in both breed types.

486 Incidence of peripartum health related problems in Argentine dairy herds. C. Corbellini¹, F. Busso¹, F. Bargo², B. Suarez², J. Grigera*², M. Podetti², and G. Tuñon³, ¹INTA, Argentina, ²ELANCO, Argentina, ³AACREA, Argentina.

Claves is a program conducted by INTA, AACREA and ELANCO to monitor the incidence of peripartum health problems. A data set of 15165 multiparous and 7607 primiparous dairy cows was used to determine body condition score (BCS=1 to 5 scale) and to calculate the incidence of health problems in the first 90 DIM. BCS was measured at dry off, prepartum, calving and postpartum (46 DIM). Case definition incidences (cases/100 animals) of assisted parturition (API), retained placenta (RPI), clinical hypocalcaemia (HCI), metritis (MI), clinical mastitis (CMI), lameness (LI), sub-clinical ketosis (SCKI= milk BHBA concentration ≥ than 2 mg/100 ml, Ketotest®) and death rates (DR) were standardized and calculated. Incidences were compared between primiparous and multiparous cows using Chi-square test (PROC FREQ of SAS) and t Student test was used for BCS (PROC TTEST). Multiparous cows were dried off with BCS=3.2. At prepartum, BCS was similar for multiparous (3.3) and primiparous cows (3.3), but at calving and postpartum it was lower (P<0.01) for multiparous cows (3.2 and 2.8) than for primiparous cows (3.4 and 2.9), respectively. At 55 DIM, multiparous and primiparous cows reached milk production peak (27.6 and 24.2 kg/d), with a BCS decrease of 0.4 and 0.5 points, respectively. RPI, HCI, CMI and DR were greater (P<0.01) in multiparous (8.1, 5.9, 25.6, 5.6) than in primiparous cows (4.3, 0.8, 13.7, 3.0), while API and LI were greater (P<0.01) in primiparous (28.2, 13.9) than in multiparous cows (13.1, 11.1). There were no differences between MI and SCKI for multiparous (4.3, 4.5) and primiparous cows (2.5, 2.4), respectively. SCKI ranged from 2 to 24 %, with a higher incidence in multiparous cows (BCS ≥ 3.8) or when BCS reduction at 46 DIM was ≥ 1. The mayor causes of death were traumatic calving, hypocalcaemia, endotoxic and mastitis and mostly occurred in the first week of lactation (44 and 34.1% for multiparous and primiparous cows, respectively).

Key Words: Peripartum, Health Problems, Incidence

487 Relationships between production measurements and sow longevity in a university research herd. M. S. Hicks* and W. F. Owsley, *Auburn University, Auburn, AL.*

Sow production data were collected by the Auburn University Swine Nutrition Unit from 1996-2003 to determine the relationship of performance measurements (weaning, breeding and farrowing dates, lactation feed intake, number born alive (NBA), number weaned, litter birth weight, litter weaning weight), indicators of sow longevity (sow weight pre-farrowing, sow backfat pre-farrowing, sow weight at weaning, sow backfat at weaning, lactation weight change and backfat change) and longevity (parity). The data were analyzed using the GLM procedure of SAS. Maximum R^2 for sow weight loss and backfat loss was calculated using the STEPWISE procedure, MAXR option, of SAS. Parity had an effect on both number born alive and number weaned ($P < .05$) but not litter weaning weight. As parity increased, number born and weaned also increased. Parity also affected lactation weight change ($P < .05$), measured as kg per parity or percent weight change. Weight change decreased with increased parity, as total kg and percentage of pre-farrowing weight.

The same was found for changes in backfat measured in mm change ($P < .05$), but not when measured as a percentage of pre-farrowing backfat. Sow weight loss and backfat loss decreased as feed intake increased ($P < .05$). Weight loss increased as the number of pigs weaned per litter increased ($P < .05$). Lactational fat loss increased as the litter weaning weight increased ($P < .05$). For lactation weight loss, a maximum R^2 was reached with a 6 variable model including pre-farrowing weight and fat, parity, intake, weaning weight and number weaned ($R^2 = .3308$, $P < .05$). For lactation fat loss, a maximum R^2 was reached with a 7 variable model including pre-farrowing weight and fat, parity, intake, number born alive, weaning weight and number weaned ($R^2 = .3245$, $P < .05$). Using this study and the available literature, the variables of lactation feed intake, number born alive, number weaned, litter weaning weight, sow weight pre-farrowing, sow backfat pre-farrowing and parity should account for approximately 30 percent of the variation in longevity, and should in part help understand what is required to keep a female productive longer.

Key Words: Sow Productivity, Performance, Longevity

Symposium: Ruminant Nutrition: Glycerin as a Feed for Ruminants

488 Glycerin as a feed ingredient, official definition(s) and approvals. R. S. Sellers*, *American Feed Industry Association, Arlington, VA.*

Glycerin is generally recognized as safe (GRAS) animal food ingredient as provided for in Title 21, Code of Federal Regulations, Section 582.1320. The glycerin defined in this regulation is refined glycerin and has historically been from the soap making industry. Crude glycerin from biodiesel production can contain contaminants, of which, methanol is the most common one of concern. The U.S. Food and Drug Administration (FDA) has issued an industry letter stating that glycerin from biodiesel should meet the U.S. Pharmacopeia (U.S.P.) standards for glycerin, which includes a limit of 150 mg/kg of methanol, and FDA would consider such glycerin with higher methanol limits as unsafe for feeding to animals, unless it were otherwise demonstrated to be safe. The government of the Federal Republic of Germany has stated that levels of 5,000 mg/kg of methanol in glycerin are safe for animal food. An industry coalition is collecting data and meeting with FDA to determine what information is needed to demonstrate crude glycerin safety for use in animal food with levels higher than 150 mg/kg.

489 Ruminal and physiological metabolism of glycerin. C. R. Krehbiel*, *Oklahoma State University, Stillwater.*

Glycerin, or glycerol ($\text{HOCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$), is a 3 carbon compound that forms the backbone of triacylglycerols and phospholipids in animals and plants. The demand for biodiesel from fats and oils has increased the availability of glycerol as a potential feed ingredient for ruminants. Three fates of glycerol in the rumen have been estimated, and include passage (13%), fermentation (44%) and absorption (43%). Early reports on glycerol suggested rapid fermentation to propionate by ruminal bacteria. In vitro fermentation studies suggested that species of *Selenomonas* were the major fermenters of glycerol, with the main products being propionate, lactate, succinate and acetate. However, other end products from glycerol fermentation have been reported. The most consistent response from both in vitro and in vivo experiments appears to be a slight increase in proportion of propionate and a greater increase in butyrate. When butyrate has increased, a concomitant increase in β -hydroxybutyrate concentrations in plasma has been observed. Differences most likely result from varied experimental conditions, but might suggest changes or interactions among microbial species. It has also been suggested that microorganisms adapt to glycerol feeding, as rates of disappearance increase with increased days of feeding glycerol. The fate of absorbed glycerol across the ruminal epithelium would most likely be conversion to glucose in the liver. Glycerol kinase converts glycerol and ATP to glycerol-3-phosphate and ADP at the triose phosphate level, directing glycerol towards gluconeogenesis. Net portal appearance of glycerol has been shown to account for only 10% and liver removal 8% of an intraruminal glycerol dose. Arterial concentration of glycerol increased, whereas glucose concentration was not affected. Others have observed that concentrations of blood glucose increased when dairy cows were intraruminally dosed with glycerol. Rates of glycerol absorption across the ruminal epithelium relative to the amount that is fermented may determine the gluconeogenicity of glycerol in ruminant animals. Metabolic fates of glycerol associated with glycerol fermentation in the rumen and metabolism in liver will be discussed.

490 Glycerin as a feed for ruminants: Using glycerin in high-concentrate diets. J. S. Drouillard*, *Kansas State University, Manhattan.*

The availability of glycerin as a feedstock for cattle and other livestock species is increasing due to rapid expansion of the biodiesel industry. Glycerin is a viscous, sweet liquid, is effective in controlling dust, and can aid in preventing segregation of diet components in a total mixed diet. Published literature pertaining to utilization of glycerin in concentrate-fed animals is scarce, but studies currently are underway at several U.S. institutions. German researchers reported that glycerol can readily replace up to 10% of readily fermentable starches, but its energetic value when fed in conjunction with a starch-based diet (60% concentrate) was approximately 85% of its value when fed with a forage-based diet. Feeding glycerol has been reported to shift VFA production in favor of propionate at the expense of acetate both in vitro and in vivo. Since propionate production typically is greater for concentrate fed animals, there may be less opportunity to improve energetic efficiency when glycerol is combined with concentrates compared to feeding with forages. Crude glycerin has been reported to decrease DMI when included at 10% of diets that contain combinations of dry-rolled corn and grain co-products, but ADG increased, resulting in efficiency improvements of 16 to 23% compared to diets without glycerin. Efficiency improvements were greatest when diets contained more starch, which is in contrast to observations of German researchers. In flaked-corn diets, feeding glycerin has been reported to have a quadratic effect on efficiency ($P < 0.05$), with the greatest improvements associated with low levels of feeding. Efficiency changes were 11, 10, 8, 3, and -3% for diets containing 2, 4, 8, 12, and 16% glycerin, respectively. Adding glycerin to flaked corn diets yielded a linear increase in longissimus muscle area ($P < 0.05$) and linear decreases in subcutaneous fat and marbling deposition ($P < 0.05$). Crude glycerin is promising as a feed for finishing cattle, though much remains to be learned about optimal levels of feeding and implications for carcass quality, composition, and sensory attributes.

491 Using glycerin as a supplement for forage-fed ruminants. B. W. Hess*¹, S. L. Lake², and S. A. Gunter³, ¹University of Wyoming, Laramie, ²Purdue University, West Lafayette, IN, ³University of Arkansas, Hope.

The utility of crude glycerin as a feed additive for forage-fed ruminants depends largely on how well the animals are able to utilize the glycerol and other dietary components when crude glycerin is added to the diet. Several studies have demonstrated that ruminal fermentation of pure glycerol results in the production of VFA, with propionate and butyrate being most prominent. No effect of up to 1% pure glycerol on the growth, adhesion, and cellulolytic activity of 2 rumen cellulolytic bacterial species has been observed in a pure culture in vitro system. However, growth and cellulolytic activity of the 2 bacterial species were greatly inhibited at a concentration of 5% pure glycerol. It has been reported that pure glycerol can comprise 13.3% of the diet without affecting diet digestibility when the in vitro system was inoculated with ruminal microorganisms, and OM fermentation increased if microbes were adapted to glycerol. With the exception of annual cool-season grasses, our in vitro experiments indicate that up to 15% crude glycerin may be

added to various feedstuffs without affecting DM or fiber digestibility. Although lag time for NDF disappearance tended to decrease linearly ($P = 0.07$) as crude glycerin increased to 30% of the in vitro substrate, rate and extent of DM, N, and NDF disappearance were largely unaffected by inclusion of crude glycerin in the substrate. Other researchers observed either no effect or a positive effect on nutrient digestibility with up to 20% crude glycerin in diets containing a low-starch concentrate. Preliminary results from a study with prepuberal beef heifers indicate that ADG is comparable between diets with 25% crude glycerin and a soybean hull-based supplement. Furthermore, substituting wheat grain with crude glycerin of different purities to provide glycerin at about 9% of the dietary DM did not influence nutrient disappearance from the total tract of steers. Thus, crude glycerin is a viable feed additive for ruminants consuming roughage-based diets.

Key Words: Glycerol Supplementation, Forage Diets, Ruminants

492 Use of glycerin in dairy diets. S. S. Donkin*, *Purdue University, West Lafayette, IN.*

Glycerin, also known as glycerol, is a colorless, odorless, hygroscopic, and sweet-tasting viscous liquid. It is a sugar alcohol with high solubility index in water and has a wide range of applications in the food, pharmaceutical, and cosmetic industries. The use of glycerin in diets for dairy cattle is not novel; however, this interest has been renewed

due to the increased availability and favorable pricing of glycerin as a consequence of recent growth in the biofuels industry. Experimental evidence supports the use of glycerin as a transition cow therapy but feeding rates are low, ranging from 5 to 8 % of the diet DM. There is a paucity of research that examines the use of glycerin as a macro-ingredient in rations for lactating dairy cows. Most reports indicate a lack of effect of addition of glycerin to the diet when it replaces corn or corn starch. Recent feeding experiments with lactating dairy cows indicate replacing corn with glycerin to a level of 15% of the ration DM does not adversely effect milk production or composition. Glycerin fed to dairy cattle is fermented to volatile fatty acids (VFA) in the rumen and early reports indicated that glycerin is almost entirely fermented to propionate. In vitro data indicates glycerin fermentation increases the production of propionate and butyrate at the expense of acetate. Rumen microbes appear to adapt to glycerin feeding and consequently, cows fed glycerin also require an adaptation period to glycerin inclusion. Debate exists regarding the fate of glycerin in the rumen and although most reports suggest that glycerin is largely fermented in the rumen, the extent of rumen digestion may depend on level of inclusion in the diet. Data are lacking regarding the rates of rumen fermentation of glycerin at intake levels for high producing dairy cattle. Although recent data indicates that glycerin can be included in diets fed to dairy cattle at macro ingredient levels data which would permit a full appreciation of the feeding value of glycerin and the resulting impact on cow health and productivity, is lacking.

Small Ruminant: Sheep

493 ASAS Centennial Presentation: Impacts of animal science research on U.S. sheep production and predictions for the future. C. J. Lupton*, *Texas AgriLife Research, San Angelo, TX.*

A 100 yr ago, there were over 48 million sheep in the U.S. In 1910, they were valued at \$4/hd with 43% of income from sale of sheep, lambs, and meat and 57% from wool. Great fluctuations in this ratio over the years have challenged breeder and researcher alike. By 2007, sheep numbers had declined to 6.2 million with the average sheep shearing 3.4 kg of wool (< 10% of income), 0.2 kg more than in 1909 but 0.5 kg less than fleeces in the mid 1950s. Sheep operations have declined by more than 170,000 in the past 40 yr. A cursory examination of this information might lead one to conclude that animal science research has made little impact on sheep production in the U.S. On the contrary, lamb crops in the new millennium (range = 109 to 115%) are greater than those recorded in the 1920s (85 to 89%) and dressed lamb weights increased from 18 to 32 kg from 1940 to present. In the past century, researchers conducted thousands of investigations with progress reported in new, existing and cross breed evaluations, quantitative and molecular genetics, selection, nutrition, fiber, meat, hides, milk, growth, physiology, reproduction, endocrinology, management, behavior, the environment, disease, pharmacology, toxicology, and range, pasture, and forage utilization such that a vast amount of new information was accrued. Our understanding of sheep has benefited also from research conducted on other species, and vice versa. Many factors that have contributed to decline in the sheep industry are not easily influenced by academic research (e.g., low per capita consumption of lamb meat, predation, reluctance to adopt new technology, cost and availability of labor with sheep-related skills, and fewer young people pursuing careers in agriculture). The size of the U.S. sheep industry is expected to remain stable with possible slow growth in the foreseeable future. To remain profitable, producers will take advantage of new (or previously unused) technology, the public's desire for things natural, domestic niche and international fiber markets, and the sheep's ability to control noxious weeds and thrive in sub-optimal ecosystems.

Key Words: Impact, Research, Sheep

494 Impact of grazing systems on management of gastrointestinal nematodes in weaned lambs in Arkansas. J. M. Burke*¹, J. E. Miller², and T. H. Terrill³, ¹USDA, ARS, Booneville, AR, ²Louisiana State University, Baton Rouge, ³Fort Valley State University, Fort Valley, GA.

Gastrointestinal nematode (GIN) control for 'natural' or organic lamb production is needed, especially where *Haemonchus contortus* is prevalent. Objective was to determine the impact of grazing systems on GIN infection of weaned lambs. Naturally infected Katahdin lambs (120 d of age) were randomly assigned to graze 1) continuous bermudagrass (CB; n = 14), 2) rotationally grazed bermudagrass, moved every 3.5 d and returned to original plot 35 d later (RB; n = 14), 3) continuous tall fescue (TF; n = 7), or 4) continuous sericea lespedeza (SL; n = 19). In late summer, all lambs were supplemented with 500 g corn/SBM because of declining body condition. Fecal egg counts (FEC) and packed cell

volume (PCV) were determined weekly and BW monthly. Individuals were dewormed with 0.5 g copper oxide wire particles when FAMACHA score increased to ≥ 3 . FEC peaked on first d of grazing (D 0) and was lowest in SL lambs by D 28 (grazing system \times day, $P < 0.001$). TF lambs became the most anemic by D 21 (grazing system \times day, $P < 0.001$). Between 0 and 3 dewormings/lamb were necessary and there tended to be fewer SL lambs and more TF and CB lambs dewormed by D 105 (CB, 1.69; RB, 1.27; TF, 1.66; SL, 0.85 ± 0.26 ; $P < 0.10$). Worm free tracer lambs were introduced to CB (n = 6) and RB (n = 8) plots following the last rotation to determine worm burdens after 20 d grazing. Abomasal worm burden was greater in RB than CB tracer lambs ($P < 0.05$), but intestinal worm numbers were similar. Greater number of abomasal worms may occur because RB lambs required less deworming than CB lambs leading to more eggs on the RB plots. TF lambs gained no BW while grazing TF and BW never reached that of other lambs (grazing system \times day, $P < 0.001$). BW of SL lambs was lower on D 28 than CB and RB lambs. In summary, the TF grazing system was unacceptable for GIN control or weight gain. The SL grazing system was best for GIN control, but did not persist during drought. Weight gains were similar between CB and RB groups of lambs, but CB lambs required more deworming. This research was funded by CSREES, IOP Grant #2005-51300-02392.

Key Words: Gastrointestinal Nematodes, Grazing Systems, Lambs

495 Nutrient digestibility of straw-based diets by sheep. C. Anderson Alexander-Huerta, A. S. Juárez-Reyes*, M. Murillo-Ortiz, R. Montoya-Escalante, G. Nevárez-Carrasco, and M. A. Cerrillo-Soto, *Universidad Juárez del Estado de Durango, Durango, Dgo. México.*

A study was conducted to estimate the effect of oat and bean straw-based diets on nutrient digestibility in sheep. Five criollo sheep (45 ± 4.5 kg BW) fitted with ruminal and duodenal cannulae were fed the experimental diets consisting of 70% oat straw (T1); 40% oat straw (T2), 70% bean straw (T3); 40% bean straw (T4); and a control with 20% oat straw and 20% bean straw (T5). Other ingredients were alfalfa hay, ground corn and cotton seed meal. Diets were isonitrogenous (11% CP). Each period of the trial consisted of a 14-day adjustment and a 5-day collection phases. Mordanted fiber was used as internal marker, it was dosed through the rumen cannula, whereas purines were utilized for estimation of microbial efficiency. Data were analyzed using PROC GLM for a 5 \times 5 Latin Square experimental design. Intakes of OM were similar ($P > 0.05$) across diets. However, sheep fed T3 consumed higher amounts ($P < 0.05$) of NDF and ADF. Apparent OM ruminal digestion was different across diets ($P < 0.05$). Sheep fed T2 registered higher OM rumen digestibilities. Feeding T3 and T5 to sheep, however, resulted in lower OM digestibilities. No differences ($P > 0.05$) in apparent ruminal NDF and ADF digestibilities were registered. Total tract digestibilities of OM, NDF or ADF were not affected by diets. Similarly, no effect was observed in N intakes. Nonetheless, differences were registered in microbial efficiency. Sheep fed T5 registered the highest efficiencies. Data evidenced the potential of diets based on bean and oat straw when other sources of food are scarce.

496 WITHDRAWN

497 Ability of ewes to rebreed while lactating in spring. K. M. Jordan*, J. W. Knight, and D. R. Notter, *Virginia Polytechnic Institute and State University, Blacksburg.*

These studies were conducted to investigate the ability of a sheep population genetically selected since 1988 to lamb in fall and containing 50% Dorset, 25% Rambouillet, and 25% Finnsheep breeding to breed while lactating during anestrus. Raddled rams were introduced to lactating ewes, and percentages of ewes marked, diagnosed pregnant by ultrasonography, and lambing were recorded. In April 2006, January-lambing ewes of the selected line were compared to St. Croix ewes, a hair sheep breed often considered to be lowly seasonal. Rams were introduced at an average of 61 d (range 46-79 d) postpartum. By 21 and 42 d after ram introduction, more ewes in the selected population than St. Croix ewes were marked by rams (42 vs 0% and 71 vs 35%, respectively, $P < 0.05$). However, the overall percentage of ewes exposed to rams for 42 d that subsequently lambled (41%) did not differ between breeds even though ewes in the selected line had been marked earlier and in greater numbers than St. Croix ewes. Thus, significant fetal loss appears to have occurred in ewes in the selected line. A second study in May 2007 used ewes that lambled in March and averaged 43 d (range 33-52 d) postpartum to study fetal loss in 35 ewes in the selected line that were bred while lactating during what is generally believed to be the deepest part of anestrus. Of the 18 ewes that were marked, 13 were diagnosed pregnant 120 d after ram introduction. Ten ewes maintained their pregnancy through September but only seven produced lambs of normal birth weight while three produced underweight, premature lambs that did not survive. Therefore, even though more than 51% of ewes were marked, only 20% of ewes gave birth to viable lambs. These studies indicate that ewes in the selected line are able to become pregnant while lactating during anestrus, but are often unable to carry the lambs to term. Although the selected ewes appear to be well suited to accelerated lambing systems involving 7 to 8-mo lambing intervals,

reduction of lambing intervals to 6 to 7-mo appears to have detrimental effects on fetal survival.

Key Words: Sheep, Fertility, Season

498 Lactational and reproductive effects of melatonin in lactating dairy ewes mated during spring. G. Caja*, A. A. K. Salama, S. Carné, E. Albanell, X. Such, and R. Casals, *Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

A total of 110 dairy ewes of 2 breeds differing in milk yield and milk composition (Manchega, $n = 57$; Lacaune, $n = 53$) were used to evaluate the lactational and reproductive effects of using s.c. implants of 18 mg melatonin (Melovine, Ceva Salud Animal, Barcelona, Spain) for improving fertility at ram mating during lactation in spring. Ewes were switched from a seasonal lambing system (December) to an out-of-season lambing system (September) to obtain greater lamb and milk market prices under Spanish conditions. Lambs were weaned from their mothers in January (35 d of age), and the ewes were machine milked thereafter (wk 5 to 30 of lactation). At spring (April 21) lactating ewes were assigned to 4 balanced groups according to breed to which the experimental treatments were randomly applied: Control (untreated; $n = 55$) and MEL (melatonin implanted 42 d before mating; $n = 55$). Intensive management and feeding (ad libitum forage and 0.4 to 0.8 kg concentrate according to requirements) was maintained throughout lactation and ewes improved BCS during matting. Rams of each breed were also treated with 3 implants of MEL at d 60 before mating and were joined to ewes (1 ram/12 to 15 ewes) for 90 d (June 2 to August 31). Milking was maintained throughout the matting period and ewes were dried off during July. Milk yield was recorded weekly and sampling for milk composition was done fortnightly. Results showed no effects of MEL on milk yield ($P > 0.05$) and milk fat and protein contents ($P > 0.05$) for both breeds. Both MEL and control ewes showed good ability for out-of-season breeding during milking, and lambing was concentrated in 21 and 25 d, respectively. On average, fertility ($P < 0.05$) and prolificacy ($P = 0.12$) increased as a result of the MEL treatment (Table 1). Lamb birth weight (3.72 kg BW, on average) and mortality rate (4.2%, on average) did not vary. In conclusion, use of melatonin in dairy ewes was effective to improve reproductive performance in out-of-season conditions, without effects on milk yield and milk composition.

499 Effect of protein degradability on milk production of dairy ewes. C. M. Mikolayunas*, L. E. Armentano, and D. L. Thomas, *University of Wisconsin, Madison*.

To study the effect of protein degradability on milk yield and milk urea N (MUN) concentration in dairy ewes, three diets were formulated of similar energy density but varying dietary concentrations of rumen-degradable protein (RDP) and rumen-undegradable protein (RUP): 12% RDP and 6% RUP (12-6), 14% RDP and 4% RUP (14-4), 12% RDP and 4% RUP (12-4) (% of dry matter). Eighteen multiparous dairy ewes in mid-lactation were assigned to 2 blocks of 9 ewes each according to milk yield and randomly assigned within block to 6 pens of 3 ewes each. Dietary treatments sequences were balanced for carryover in two 3×3 Latin Squares and applied to pens for 2 wk. Milk yield was measured during the final 8 milkings (4 d) and milk composition (% fat, % protein and MUN) was determined on compiled samples (morning and evening milking) from the final 2 d of each period. Pen dry matter intake was measured on the final 4 d of each period. Pen data were analyzed using the PROC MIXED model of SAS. The model included square, treatment, period \times square and treatment \times square, and the random effect was pen (square). There was an interaction ($P < 0.01$) of block by diet for dry matter intake and milk, fat, and protein yield. Across both squares, milk yield was greater ($P < 0.01$) for the 12-6 treatment compared to the 14-4 and 12-4 treatments (2.02 vs. 1.79 and 1.79 kg/d, respectively). Milk fat yield was greater ($P < 0.05$) for the 12-6 treatment compared to the 14-4 and 12-4 treatments (122.1 vs. 110.7 and 108.0 g/d, respectively), and milk protein yield was greater ($P < 0.05$) for the 12-6 treatment compared to the 14-4 and 12-4 treatments (94.9 vs. 85.6 and 85.0 g/d, respectively). Milk urea N concentration was greater ($P < 0.05$) for the 12-6 and 14-4 treatments compared to the 12-4 treatment (26.33 and 27.39 vs. 23.43 mg/dL, respectively). There was no effect of dietary treatment on dry matter intake. The results indicate a positive effect of RUP on milk yield. Higher dietary crude protein concentration resulted in higher milk urea excretion, regardless of protein degradability.

Key Words: Dairy Sheep, Protein Degradability, Milk Urea Nitrogen

500 Implementing electronic identification for milk recording in dairy sheep. A. Ait-Saidi, A. A. K. Salama, S. Carné*, and G. Caja, *Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain*.

Dairy ewes ($n = 48$) were used to compare manual (**M**) vs. semi-automated (**SA**) systems for identification (**ID**) and milk recording (MEC Project AGL-2007-64541). Ewes were grouped according to milking frequency (once daily, 0.98 ± 0.05 L/d; twice daily, 1.45 ± 0.06 L/d). The M system used visual ID, on-paper data recording, and manual data uploading to a computer. The SA system used e-ID (20 g ceramic boluses, containing 32 mm HDX transponders) by a hand-held reader and manual data recording by reader keyboard (milk yield and observations), and data was automatically uploaded to a computer by Blue-tooth connection. Data were collected for groups of 2×12 ewes for 10 test-days of each system and milking frequency over a period of 70 d. Time data was converted to a decimal scale. Dynamic reading efficiency measured at the milking parlor entrance (speed, 1 ewe/s) using a stationary transceiver with a frame antenna was 100%. Milk recording time varied according to milking frequency and milk recording system, being greater in M (0.49 to 0.56 min/ewe; $P < 0.001$) than in SA (0.40 to 0.47 min/ewe; $P < 0.001$), and correlated with ewe milk yield during the experiment ($R^2=0.62$). Average data transfer time per batch of 24 ewes was greater for M (0.13 ± 0.01 min/ewe) than SA (0.03 ± 0.01 min/ewe). Total milk recording time was greater in M (0.62 to 0.70 min/ewe; $P < 0.001$) than in SA (0.43 to 0.50 min/ewe; $P < 0.001$). Time for transferring data to the computer of groups of 24 ewes, was 3.27 ± 0.09 and 0.78 ± 0.03 min for M and SA, respectively. Increase for the next additional 24 ewes in SA was only 0.19 ± 0.01 min. Data errors were only found for the M system (3.6%). Differences in labor time between M and SA increased with number of ewes processed on the same test-day (4.6 to 218.6 min for 24 to 1,008 ewes, respectively) and reduction in milk recording cost ranged from \$US 1.0 to 49.3 (0.8 to 36.5 Euros), being able to pay for the extra costs of e-ID. In conclusion, both labor cost and data errors showed the benefits of using electronic identification for milk recording in sheep, the benefit being greater with complete (am and pm) milk recording and in larger flocks.

Key Words: Transponder, Milk Recording, Dairy Sheep

Teaching/Undergraduate and Graduate Education: Teaching in the Animal Sciences

501 The Academic Roadmap: A web-based tool for improving student recruitment, retention and success in the agricultural sciences. K. H. Petersson*, D. Grossman-Garber, C. English, T. P. Husband, D. P. Murray, and A. I. Veeger, *University of Rhode Island, Kingston.*

Today's students are frequently unaware of the diversity of career trajectories and opportunities available to them in the field of agriculture. The scientific challenges that will be faced in the coming decades are daunting, making it imperative that talented young minds are attracted into the field of agriculture. The Academic Roadmap (AR) is a web-based tool developed at the University of Rhode Island to improve student recruitment, retention, and overall student success in higher education in general and agricultural-related fields in particular. The AR is a 'one-stop' portal to an academic discipline, its associated course(s) of study, and related career tracks. In a sense, it is a 'user-friendly' way for students to access information on careers and relevant majors from one source. The AR contains general information on the field, as well as detailed information on curriculum, learning outcomes, experiential learning opportunities, careers, and graduate programs for each academic discipline. Each of these sections of the AR is linked, showing the student how courses taken relate to learning outcomes which then relate to career options down the road. Also contained in the AR are 'hot topics' in the field so students can learn about the real-world applications of their studies and on-going research efforts. Past and present student biographies and links to virtual labs and field trips bring the site to life. Currently AR's have been developed for four disciplines, one of which is Animal & Veterinary Science. Efforts are currently underway to personalize the roadmaps for students through a 'My Academic Roadmap' module that is linked to the university's student records database. Student response to the AR, obtained through an online survey, was overwhelmingly positive. Ninety-eight percent of students surveyed (n=328) found the website to be valuable/very valuable. The long-term goal of this project is to disseminate the completed AR to land-grant institutions nationwide via a multi-state, integrated USDA project to help improve training and retention of students in agricultural-related fields.

502 Capstone experiences in animal and poultry sciences: Opportunity and challenge. C. M. Wood*, W. E. Beal, E. A. Dunnington, D. E. Eversole, H. Jiang, A. P. McElroy, R. K. Splan, and M. L. Wahlberg, *Virginia Tech, Blacksburg.*

The Department of Animal and Poultry Sciences (APSC) at Virginia Tech recently revised the undergraduate curriculum using a holistic and comprehensive process. The most significant new requirement is a two-credit capstone experience that every student must complete within 45 credits (three terms) of graduation. Specific learning objectives include: 1) employing critical thinking skills to acquire, analyze, interpret, and integrate information from a variety of sources; 2) solving problems in authentic or realistic situations in the animal sciences; 3) planning and completing a project pertaining to each student's discipline and field; 4) demonstrating verbal, visual, and written communication skills;

5) contributing to a team effort; 6) assessing and describing potential contributions to society; and 7) effectively competing for career and/or post-baccalaureate opportunities. By its nature, each capstone experience will be unique to the student who designs it in consultation with his/her advisor. To aid students in that process, a new sophomore-level seminar course was developed that includes drafting a capstone experience proposal. The capstone proposal must clearly outline how the learning objectives listed above will be achieved and how student attainment of the objectives will be assessed. Proposals must be submitted to a faculty committee for approval no later than the term prior to undertaking the capstone experience. Potential capstone experiences in the animal sciences could include, but are not limited to, Study Abroad, Field Studies, Internships, Undergraduate Research, Independent Studies, and formal coursework at the senior or masters level. With more than 450 APSC majors, the challenges presented by this new requirement are many but are outweighed by the tremendous opportunities.

Key Words: Undergraduate Education, Experiential Learning, Capstone Experience

503 The Graduate Experience Program. J. A. Atkins*¹, D. L. McNamara², and G. W. Jesse¹, ¹*University of Missouri, Columbia*, ²*University of Wisconsin, Platteville.*

The objective of the Graduate Experience Program is to offer undergraduates insight into graduate education and career opportunities within animal science. This is a one credit problems course that is taught and organized by graduate students. The class meets every other week to discuss topics concerning graduate school aimed at helping students decide whether graduate education is the right decision for them. These topics include exercises in developing career goals and what degree they need to meet those goals, applying to graduate schools, writing résumés, graduate education expectations and philosophies, reading and discussing scientific articles, and presenting research at professional meetings. Each undergraduate student has a primary graduate student mentor who meets with them individually and ensures the undergraduate's scientific interests are being met. During these meetings, undergraduates gain first-hand experience with collecting samples, performing lab work, attending seminars, participating in journal clubs, attending scientific meetings, and many other activities important in graduate training. Undergraduate students are required to meet with at least two other graduate students in the department in order to experience a broad range of research opportunities within the division. At the end of the semester the undergraduates present their experiences from this course, and report on three graduate programs, professional schools, or job postings that appeal to them and what steps they need to take in order to be good candidates. Graduate students involved in the course learn to be effective mentors by attending to the needs of the undergraduate students and developing the course material taught which improves their scholarship of teaching. To date, 22 undergraduate students have enrolled in the graduate experience program and more than 30 graduate students have been actively involved in mentoring and teaching this class.

Key Words: Undergraduate and Graduate, Teaching, Mentoring

504 A holistic approach to undergraduate curriculum review and revision in animal and poultry sciences: Process and results. C. M. Wood*, W. E. Beal, E. A. Dunnington, D. E. Eversole, A. P. McElroy, and R. K. Splan, *Virginia Tech, Blacksburg*.

With more than 450 majors and nine degree combinations, the undergraduate program in the Department of Animal and Poultry Sciences (APSC) at Virginia Tech is large and complex. The department recently conducted a holistic review of the undergraduate curriculum that involved all faculty in APSC and collaboration with colleagues in other departments. This effort resulted in a complete revision that yielded 29 new and updated courses, a new option, and two revised minors. Changes included dropping public speaking and adding statistics; an increased emphasis on life skills, guidance in curriculum choices and career planning through a series of courses in the freshman, sophomore and senior years; dropping one senior production course from the requirements, and adding animal handling laboratories, an animal products course and a capstone experience requirement. The Production-Business Option was strengthened with the addition of an advanced livestock enterprise analysis course, and an additional companion animal course was added to the elective list, along with several other courses. The review and revision effort was led by the department's Undergraduate Education Committee (UEC). Eight discipline and species committees, chaired by UEC members, reviewed the entire curriculum from their particular perspectives. Departmental outcomes assessment information, demographic trends of APSC students, university requirements, and peer department programs were studied to project the needs of students entering college in the next five to ten years and to formulate draft recommendations. Two faculty workshops yielded a framework that was 95% complete, and course proposal writing groups were formed. A complete set of recommendations was subsequently submitted to university governance. Implementation of the revised curriculum began in Fall 2007 and will be phased in over the next two years as those freshmen proceed through their undergraduate careers.

Key Words: Undergraduate Education, Curriculum Revision, Capstone Experience

505 The challenges and opportunities of teaching a virtual introduction to animal science course. M. Latour*, *Purdue University, West Lafayette, IN*.

In 2000, a virtual version of introduction to animal sciences was created and over the past eight years, the course has reached more than 350 students in over 20 countries and has paved the way for significant funding into the university to support ongoing programs. Like the on-campus course it is designed to teach the fundamentals of animal agriculture but through a series of course modules (n=20). Through the eight year period, studies have been conducted using these students to examine the following: a) impact of virtual teaching assistants vs. the professor and b) the acceptance of course modules and what makes some more appealing to students. Our studies show that online teaching assistances are significantly ($P \leq 0.005$) preferred vs. the professor in the online course, but the reverse if true on campus; that is, on campus students significantly ($P \leq 0.003$) choose to communicate the professor vs. the on campus teaching assistance. In the online course, students ranked one module significantly lower ($P \leq 0.03$) when compared to the other 19 modules with two modules being intermediate to both. The nature of the low ranking module was somewhat expected, but the other two modules that were intermediate to the top ranking and low rankings,

were found to be significantly ($P \leq 0.01$) beneficial to the students and incorporated some face-to-face interaction. In addition to these studies, there are many different challenges imposed on the professor teaching to an audience covering the world; that is, the instructor must be sensitive to natural disasters, military and homeland security, foreign governments, aiming the course to hit specified objectives, internet challenges, and ability to work with students to secure creditable information regardless of learning resources. Hence, the purpose of this work is to show the importance of virtual teaching assistants, course module development and the challenges an instructor might face in teaching students across the world. Lastly demonstrate how funding through distance learning courses can significantly impact ongoing programs.

506 Engaging students with service learning within an animal science curriculum at Texas Tech University: A ten year perspective. H. Brady*, *Texas Tech University, Lubbock*.

The pedagogy of active and service learning can be effectively used in any discipline within higher education to increase student engagement and retention. In this presentation, the evolution of a service learning curriculum in the Department of Animal and Food Sciences will be discussed with an emphasis on practical applications and suggestions for other disciplines/ courses. An overview of Animal Science 3309, Principles of Hippotherapy, offered since 1998, will be discussed including evolution of the class, development of a service program, and active involvement of the class. This class has developed from working with 4 disabled children and borrowed horses to now being an integral part of a full time Premier Accredited Program serving over 60 riders per week. Hippotherapy is the use of the horse and its movement to augment therapy goals and improve the quality of life in individuals with cognitive and physical disabilities. Students become actively engaged as they are assigned to the same children each week and actively plot their progress through lab reports and reflections. Group projects used in the course will be covered, including the development of creative teaching lessons which are taught to the children by the students. This program was chosen as one of 13 Exemplary Courses in the National Case Study for Learner-Centered Approaches in Agriculture, Food and Natural Resources. As part of this presentation, video clips will demonstrate the class in action, the students teaching the sessions to riders with disabilities and, and interviews of participants. Over these years, data have been collected and we have published that in addition to dramatic improvements in the riders, we have seen significant changes in the Texas Tech undergraduate students who take this course. It was determined that students who have taken the course had a greater understanding of disabilities and of the hardships that families of children with disabilities face. In conclusion, the active engagement of students by a service learning curriculum is a powerful tool for use in higher education.

Key Words: Service Learning, Hippotherapy

507 Use of eID to monitor classroom attendance. L. D. Luqué* and D. A. Nichols, *Kansas State University, Manhattan*.

Kansas State University (KSU) offers an introductory animal science course to give students, primarily freshman, of all backgrounds an

overview of the animal production industry. The objective of this study was to develop a model to effectively and efficiently record attendance. Records will then be used to manage attendance, encourage attendance, and identify students with poor attendance in a large class. To accomplish these objectives, KSU created a program using Microsoft Excel. The program records student attendance by day and provides an output of total attendance, identifying those students with poor classroom attendance. This study was conducted over 18 wks during the fall 2007 semester at KSU. Unique Destron full duplex button tags (eID) were assigned to electronically identify students and record attendance. Students were asked to pass their eIDs past an Allflex stick reader (Allflex USA, Inc.) as they entered the classroom. Total attendance was recorded and summarized prior to the start of each class. Two sections of the course were offered: Tuesday and Thursday at 8:05AM (A; n = 118), and Monday, Wednesday, and Friday at 11:30AM (B; n = 171). Results showed a correlation between student attendance and course grade ($P < 0.0001$; n = 287; r = 0.59). Students with a higher classroom attendance had a higher final grade. When comparing student gender (male, female), year in school (freshman, sophomore, junior, senior), section (A, B), and declared major (animal science (ASI), non-animal science (NON)) to percent of classroom attendance, student gender and declared major were important factors. Females had a higher percentage of attendance compared to males ($P < 0.05$) and ASI majors tended to have a higher percentage of attendance compared to NON majors ($P = 0.10$). To conclude, this model of using eID to monitor classroom attendance is an efficient, easy, and quick means of recording attendance.

Key Words: Classroom Attendance, Electronic Identification

508 'A Postcard Home' provides opportunity for first-year students to gain writing experience. J. M. Mapes*, G. M. Hill, M. W. Orth, and J. E. Link, *Michigan State University, East Lansing.*

A misconception of writing is that it should be learned outside of science courses. However, writing assignments are valuable tools to engage students in course concepts and are critical for developing writing skills. A short writing assignment, entitled 'A Postcard Home', was adapted from an assignment created by Dr. William Beal, professor at Virginia Polytechnic Institute and State University. Students in the Introductory Animal Agriculture course were given a specially designed postcard and instructed to write a letter home to someone that they considered as a family member or supporter. In their letter, students described an experience from class and what they learned. They addressed the postcards, which were then mailed by the instructor. Objectives were to engage students in course material, provide an opportunity to develop writing skills, and involve family in students' education. Students could earn up to 10 points, and were evaluated on four criteria: spelling, grammar, sentence structure, and ability to follow directions. Within each criterion individual errors were valued at 0.5 points. If the same error was made multiple times, such as misspelling the same word, half a point was deducted for the first instance only, so as not to discourage students in their writing. Spelling and punctuation errors were the most common. For evaluation purposes, grades were based on a 4.0 scale, with divisions at 9, 8, 7, 6, and 5 points. Out of 142 students, 64% had a 4.0, 19% had a 3.0, 12% had a 2.0, 2% had a 1.0, and 1% had a 0.0. Overall, students performed well, with over 50% of the class scoring 9 points or more. Students seemed to enjoy the assignment; many included humorous explanations of what they were learning in class. Connecting to class material through personal experience engages students in what they are learning. Short writing assignments provide students the opportunity to develop or improve writing skills, while minimizing the amount of work for instructors. Writing is a critical skill in the sciences and should be fostered in all levels of coursework.

Key Words: Writing, Education, Animal Science

POSTER PRESENTATIONS

Animal Behavior and Well-Being: Methodology

TH1 Functional test of the hypothalamic-pituitary-adrenal axis of sows which perform various abnormal behaviors. D. C. Lay Jr.*, *Livestock Behavior Research Unit, Agricultural Research Service - USDA, West Lafayette IN.*

The objective of this study was to assess the function of the hypothalamic-pituitary-adrenal (HPA) axis of sows which perform differing abnormal behaviors to determine if regulation of their HPA axis had been altered. When dexamethasone is injected i.v., in normal individuals plasma cortisol is suppressed. Individuals with an altered regulation of their HPA are resistant to this suppression. Sows (n = 27) were housed in traditional gestation stalls and fed once daily in the morning. Behavioral data were collected weekly on 3 separate days (-7, 0, 7 d): 7 d prior to treatment, on the day of treatment, and 7 d after treatment. At 0830, 1 h after sows were fed, behavioral assessments were conducted to determine the incidence and type of stereotypic behavior that each sow performed. On d 0, a 10 mL blood sample was collected from all sows at approximately 2000 h. Immediately following blood collection, all sows received 2 mg of dexamethasone administered i.v. The following morning, 12 h later, a second blood sample was collected from each sow. Dexamethasone suppressed plasma cortisol in 23 sows who exhibited base concentrations of 38.8 ± 3.2 ng/mL which were decreased to 9.0 ± 0.9 ng/mL by 12 h later. Four sows proved to be resistant to the dexamethasone. These sows exhibited base concentrations of 40.7 ± 11.1 ng/mL which increased to 53.7 ± 9.5 ng/mL by 12 h later. Fourteen sows performed oral stereotypic behaviors during more than 50 % of the observations. These sows tended to ($P < 0.08$) have greater base cortisol concentrations and they also had greater ($P < 0.04$) post-dexamethasone plasma cortisol than sows performing stereotypic behavior during less than 50 % of the observations. These data indicate that sows which perform oral stereotypic behavior may have altered regulation of their hypothalamic-pituitary-adrenal axis.

Key Words: Stress, Swine, Hypothalamic-Pituitary-Adrenal Axis

TH2 Validation of a water HOBO and the Noldus Observer for drinking behavior in the nursery pig. A. M. Meiszberg*¹, A. K. Johnson¹, J. W. Dailey², J. A. Carroll², L. J. Sadler¹, J. R. Garvey¹, and N. Krebs³, ¹*Animal Science, Iowa State University, Ames*, ²*USDA-ARS, Livestock Issues Research Unit, Lubbock, TX*, ³*Pork Industry Institute, Texas Tech University, Lubbock.*

Collecting accurate behavioral events for extended periods can be time consuming. If a device could accurately record duration and frequency for a behavioral event, this would provide a useful research tool. The objectives of this study were to determine the accuracy of an automatic water meter compared to a human observer for drinking duration (s) and the frequency of visits to the waterer by nursery pigs. Eleven PIC USA gilts (22 ± 2 d of age; 6.5 ± 1.4 kg BW) were used to compare 2 methods; Observer software (OBS) and water meter Hobos (WMHOB) affixed to the water line. For our study, the WMHOB was defined as the control for drinking duration and visits. All gilts were housed individually in stainless steel pens and had ad libitum access to a corn-based diet and one water nipple. Drinking behavior was collected on d 0, 7, and 14 of the trial using one color camera positioned over 4 attached pens that recorded onto a RECO-204 DVR for 24 h at 1 fps. Drinking was defined as head over the water nipple. Behavioral measures were collected continuously from DVD by 2 experienced observers. Data were transformed prior to statistical analysis, and the duration and frequency were analyzed using the general linear model (GLM) and regression procedures in SAS. The GLM model included the method of observation and pig nested within method for the error term. The method of observation affected ($P = 0.001$) the duration (13.88 ± 1.43 s for WMHOB vs. 22.58 ± 1.46 s for OBS) and visits ($P = 0.005$) for drinking behavior (4.94 ± 0.33 visits for WMHOB vs. 3.48 ± 0.33 visits for OBS). For duration and frequency of visits to the drinker, R^2 was 0.563 and 0.687 respectively. In conclusion, the relationship between methods was weak. Also, OBS method underestimated the number of visits and overestimated the total duration of drinking for the nursery pig compared to the WMHOB.

Key Words: Drinking, Pig, Water

TH3 Temporary glycosuria alters molasses consumption in Holstein calves. C. S. Wilcox^{*1}, M. M. Schutz¹, S. S. Donkin¹, and S. D. Eicher², ¹*Purdue University, West Lafayette, IN*, ²*USDA- ARS, West Lafayette, IN*.

Cognitive activities and stress increase hippocampal glucose demand. Elevated circulating cortisol improves glucose conservation and neogenesis. Chronic activation of the adrenal cortex causes adrenal fatigue and lowers cortisol production causing hypoglycemia. In chronic stress rat models, sucrose intake is altered. This study was conducted, as a preliminary study of stress in dairy calves, to determine the effect of phlorizin-induced glucose demand on molasses consumption. Phlorizin temporarily blocks renal absorption of glucose from the urine causing glycosuria. This increases the demand for glucose in order to maintain normal physiologic blood glucose concentrations. To ensure preruminant status, all calves were maintained on milk replacer (fed at 10% of body weight) and given free access to water. In a completely randomized design with 2 treatments, 3-wk-old calves ($n = 6/\text{treatment}$) received 0.365g of phlorizin by s.c. injection (3 ml) or 3 ml of s.c. of saline. During a 7-d adjustment period and 24 h after treatment, all calves were allowed free access to molasses. Hourly urinary output, urinary glucose concentration, and molasses consumption were measured. Data were analyzed using GLM procedure in SAS. Mean molasses consumption for 24 h after treatment was 0.72g (± 0.07) for the control group and 1.42g (± 0.01) for the phlorizin-treated group ($P = 0.02$). Urinary output for the 8-h test period was 1.13 kg (± 0.06) for the control group and 1.67 kg (± 0.08) for the phlorizin-treated calves ($P = 0.026$). Mean urinary glucose peaked at 60 mg/dL 4 h after treatment for calves given phlorizin while the concentration for the control group fluctuated between 0 and 5 mg/dL ($P = 0.001$). Phlorizin treatment significantly increased urinary excretion, urinary glucose concentration and molasses consumption in 3-wk-old Holstein calves. Results of our study showed that alterations in glucose metabolism, specifically increased urinary glucose losses, and increased voluntary sucrose intake. Additional investigations are needed to confirm the relationship of stress with voluntary sucrose intake and to extend the utility of this feeding behavior response as an experimental model.

Key Words: Dairy Calf, Glucose, Phlorizin

TH4 Effect of alternative models for increasing stocking density on the lying behavior, hygiene, and short-term productivity of lactating Holstein dairy cattle. P. D. Krawczel^{*1,2}, C. S. Mooney¹, H. M. Dann¹, M. P. Carter¹, R. E. Butzler¹, C. S. Ballard¹, and R. J. Grant¹, ¹*William H. Miner Agricultural Research Institute, Chazy, NY*, ²*Department of Animal Science, The University of Vermont, Burlington*.

Spatial requirements of dairy cows may be assessed using several experimental models that attempt to simulate on-farm conditions. The objective of this study was to determine the differences in lying behavior, hygiene, and milk production of Holstein dairy cows when housed at a stocking density of 100 (1 cow per stall and headlock) or 142% imposed by either 1) the denial of access to freestalls and headlocks, 2) the denial of freestalls, headlocks, and 26.6 m² of alley space to simulate adding cows to the pen, or 3) adding 14 cows to increase group size. Cows ($n = 136$) were assigned to 1 of 4 pens in a 4-row freestall barn and treatments were allocated using a 4 \times 4 Latin square with 14-d periods. Lying time (h) and number of bouts per d for 12 focal cows per pen were determined using dataloggers recording at 1-min intervals during the final 5 d of each period. Hygiene of focal cows was assessed from the difference in the scores observed after the legs and udder were cleaned on d 2 of each period and those observed on d 14. Milk yield and dry matter intake were established from the pen mean over the final 4 d of each period. Milk composition was evaluated from samples collected during all milkings on d 12 of each period. Data were analyzed using MIXED procedure of SAS. Lying time was greater (13.0 h/d; $P < 0.002$) for 100% stocking density than 142% stocking density treatments, which did not differ (11.8 h/d; $P > 0.10$). Lying bouts (12.3 per d) did not differ among treatments ($P > 0.10$). The changes in udder (0.6) and leg (1.3) hygiene score per period were not affected by treatment ($P > 0.10$). Milk fat (3.6%), true protein (3.19), somatic cell score (4.5), milk yield (43.8 kg/d), and dry matter intake (24.6 kg/d) did not differ ($P > 0.10$) by treatment. The three stocking density models evaluated in this short-term study appear to be equally valid based on the lack of response in lying behavior and lactation performance. Additionally, all 3 models resulted in 1.2 h/d less lying time than the 100% stocking density control.

TH5 Hard water preservative effect of Birjand Quanats to reduce lead acetate toxicity on *Capoeta fusca*. A. Omid^{*} and H. Farhangfar, *Birjand University, Birjand, Iran.*

This study was conducted in order to determine the acute toxicity of lead acetate on *Capoeta fusca*. For this purpose 580 fishes with mean length of $12/28 \pm 0/14$ and mean weight of $16/64 \pm 0/52$ were divided into 15 control and treatment groups of fishes. The fishes kept in 20 L aquariums and the procedure designed in static condition according to Organization Economic Cooperation and Development (OECD) method. Mortality rate was recorded in 96 h and lead acetate LC50 was calculated by standard statistical method. LC50 of 10/992, 10/594, 9/338 and 7/575 ppm were determined at 24, 48, 72 and 96 hours post exposing respectively. Also minimum and maximum lethal concentrations of lead were determined as 4 and 12/5 ppm and MAC was 0/7575. Lead acetate in soft water (Hardness 10 mg/L) was highly toxic for fish but in hard water (Hardness: 310 mg/L) had a little toxicity. High trend of lead for interaction with minerals such as calcium and carbonates is the major reason of this phenomenon. Lead toxicity is decreased with increase of water hardness and this is the cause of fish tolerance against some heavy metals pollution in natural environment.

Key Words: *Capoeta fusca*, Water Hardness, Lead Acetate

TH6 Less common complication of traumatic reticulitis in cattle: Abscess on left thoracic wall. A. Omid^{*}, *Birjand University, Birjand, Iran.*

Little accurate information is available on the prevalence or incidence of thoracic abscess as a complication of traumatic reticulitis. During two years among 75 cases confirmed suffering from traumatic reticulitis five cows with thoracic abscesses were examined clinically, radiography and ultrasonographically. There was a wide range of clinical signs include anorexia, abdominal pain, recurrent tympany and/or weight loss. All of the cases had a big abscess in back portion of left humerus on thoracic wall. In every case, the diagnosis was confirmed by centesis and aspiration of the abscess. In all cows, radiographic findings revealed a metal foreign body in the reticulum penetrating it. Ultrasonography revealed a large reticular abscess with a well developed capsule appeared as echogenic deposits that sometimes accompanied by hypoechogenic fluid. Abscesses had an echogenic capsule with a hypoechogenic center. The abscess was elongated toward left thoracic wall and appeared in posterior portion of left humerus. In one case, the tip of wire was detected on abscess surface but in others the skin was intact. The abscess was incised and drained from body surface and reticulum during a rumenotomy. All the cows after abscess drainage and treatment with antibiotics recovered their health. Clinical findings, laboratory testing, ultrasonography and radiography when combined each other, could have a large practical application in diagnosis and treatment of traumatic reticulitis complications. Foreign bodies should be considered in the differential diagnosis of localised swelling on thoracic wall. Ultrasound was a useful diagnostic tool, to help retrieve a fluid sample for culture and sensitivity, monitor the progression of the lesion and to guide surgical debridement

Key Words: Traumatic Reticulitis, Abscess, Cow

TH7 Comparison of attachment to feed ingredients of whole *E. coli* K88 cells and purified F4/K88 fimbriae. P. M. Becker¹, S. Galetti², J. Van der Meulen¹, A. Bannink^{*1}, and H. C. A. Widjaja¹, ¹*Wageningen University Research Centre, Lelystad, The Netherlands,* ²*University of Milan, Milan, Italy.*

F4(K88) fimbriae-producing ETEC are an important cause of diarrhea in young pigs. Alternative adhesion matrices that interfere with the attachment of *E. coli* K88 to pig intestinal receptors are promising antidotes. In this study, live *E. coli* K88 cells (O149 F4(K88)ac, K91, LT, STb) were compared with purified F4(K88ac) fimbriae in terms of their binding capacity for feed-related plant materials. For determination of whole cell attachment, microtitration plates were coated with suspensions of powdered plant materials in PBS buffer, employing BSA as blocking reagent and reference. *E. coli* K88 cells were allowed to adhere to the coating at RT for 30 min. Then, the wells were washed to remove non-adherent bacteria. After addition of Minca-IsoVitaleX medium, plates were incubated in the reading chamber of a photometer at 37°C. The OD was automatically read at 650 nm in 15 min intervals. The test principle was based on an inverse relationship between adhering cell numbers and detection times of growth. For determination of F4 fimbrial binding, microtitration plates were coated with 0.1 µg fimbriae/well. Suspensions of powdered plant materials were pipetted into the wells and plant materials were allowed to bind to F4 fimbriae during incubation at room temperature for 1 h. Then, the plates were washed to remove non-binding material. F4-fimbriae that were not masked by bound plant material were quantified by means of HRP-conjugated Mab AC5 antibodies. For three plant materials, namely tempeh (fermented soybeans), pumpkin fruit, and tomato fruit, the high binding affinity of whole *E. coli* K88 cells was supported by the results obtained with purified F4 fimbriae. In other cases, such as for a yeast cell-wall preparation, sunflower meal, and sesame seed meal, additional factors to F4 on the cell surface of *E. coli* K88 might have contributed to the binding of intact cells.

Key Words: Anti-Adhesion, *E. coli* K88, Plant Materials

TH8 Effects of spray-dried porcine plasma on nasal associated lymphoid tissue in a lung inflammation model in mice. A. Pérez-Bosque^{1,2}, M. Maijó¹, L. Miró¹, J. Polo², L. Russell³, J. Campbell³, E. Weaver³, J. Crenshaw³, and M. Moretó^{*1}, ¹*Universitat de Barcelona, Barcelona, Spain,* ²*APC Europe, Granollers, Barcelona, Spain,* ³*APC Inc., Ankeny, IA.*

Spray-dried porcine plasma (SDPP) is a complex mixture of proteins and other biologically important compounds that is used as a dietary supplement for farm animals. Dietary supplementation with animal plasma can ameliorate the inflammatory response in an experimental model of intestinal inflammation induced by *S. aureus* enterotoxin B. Since the common mucosal immune system connects the inductive sites (Peyer's patches and Nasal Associated Lymphoid Tissue; NALT) with the effector sites (lamina propria of the intestinal and respiratory tracts) we have now studied the effect of dietary plasma proteins on pulmonary inflammation. C57BL/6 Hsd mice were fed diets supplemented with 8% SDPP (SDPP group), 1.5% IgC (porcine immunoglobulin concentrate; IgC group) or milk proteins (Control group) from day 19 (weaning) until day 33. On day 32, mice were given an intranasal dose of 500 µg LPS/kg

b.w. (groups LPS, LPS-SDPP and LPS-IgC), or PBS (groups Control, SDPP and IgC), and killed 24h later. The percentages of subpopulations of lymphocytes and polymorphonuclear cells (PMN) in bronchoalveolar lavage fluid (BALF) and in lung tissue were measured. In BALF, LPS administration increased 27-fold the number of leucocytes. LPS also modified the profile of the cells in BALF (In Control group, 3% were lymphocytes and 97% PMN; in LPS group they were 40% and 60%, respectively; $P < 0.001$). Diets supplemented with either SDPP or IgC did not modify the LPS response, but SDPP reduced the LPS-induced activation of monocytes ($P < 0.05$). In lung tissue, LPS increased the percentage of neutrophils and monocytes, resulting in a 50% increase in infiltrated granulocytes ($P < 0.05$). The supplemented diets did not modify the LPS effects. However, both SDPP and IgC diets reduced the percentage of resident neutrophils and monocytes ($P < 0.05$) as well as the degree of activation of lung neutrophils ($P < 0.05$). These results indicate that plasma protein supplementation reduces innate immune cells from NALT without affecting the pulmonary immune response to LPS, although the degree of activation of infiltrated monocytes may be reduced by SDPP.

Key Words: Acute Lung Inflammation, Plasma Protein Supplements

TH9 Endophyte infected fescue seed causes vasoconstriction in horses as measured by Doppler ultrasonography. E. S. Moore*, A. G. Parks, L. M. Lawrence, and K. J. McDowell, *University of Kentucky, Lexington.*

Pregnant mares grazing endophyte infected (E+) tall fescue frequently incur problems in late pregnancy such as extended gestation, thickened placenta, dystocia,agalactia, and potentially death of the foal and/or mare. This experiment was designed to test the hypothesis that consumption of E+ tall fescue seed by horses causes vasoconstriction that can be measured by Doppler and real-time ultrasonography. Eleven horses were randomly assigned to receive either E+ whole fescue seed (E+W; n=3), E+ ground fescue seed (E+G, n=4), or E- ground fescue seed (E-G; n=4). The experiment was divided into two periods (P). P1 was an adjustment period during which a sweet feed ration and alfalfa cubes were fed, and varied from 7-14 days as horses established a consistent feed intake. P2 was a 15-day treatment period during which fescue seed was mixed into the feed rations. Seed was mixed with the daily grain ration in twice/day feedings, in increasing amounts such that each day horses received seed at 0.16% body weight (BW) on days 4-9 (averaging 327 ppb ergovaline and 227 ppb ergovalinine) and 0.22% BW on days 10-15 (averaging 416 ppb ergovaline and 288 ppb ergovalinine). The medial palmar artery of the left foreleg of each horse was scanned using real-time B-mode, color Doppler and Doppler spectral traces on 3 or 4 days during P1, and on 4 days during P2 (days 3, 8, 10 and 15 relative to seed being offered). Five replicate scans were taken on each horse on each day and 14 measurements were taken during each scan. The sonograms were performed by the same 2 people throughout and sonographers were blinded to treatment. When P2 was compared to P1, animals fed E+G fescue seed had reduced ($p < 0.05$) cross sectional vessel diameter (long axis, short axis and mean diameter), circumference and area, whether examined within individual animals or across animals by treatment group. Consumption of E+G fescue seed caused vasoconstriction which could be measured by Doppler ultrasonography.

Key Words: Horse, Fescue, Doppler Ultrasonography

TH10 Survey of *Clostridium perfringens* Type A prevalence and genotypes in calves and *in vitro* development of Omni-Bos CB™, a calf specific, *Bacillus*-based direct fed microbial. C. Wehnes*, V. Patskevich, K. Mertz, and T. G. Rehberger, *Agtech Products, Inc., Waukesha, WI.*

Clostridium perfringens Type A has been associated with diarrhea (scours) in calves; however, there is a lack of data characterizing *C. perfringens* genotypes in calves. Therapies and prophylaxes are available for *C. perfringens* A; however, these products typically were either not designed specifically for reducing *C. perfringens* or were designed against only a few toxinotypes of *C. perfringens*. Therefore, a survey of *C. perfringens* in calves was performed with the objectives of assessing *C. perfringens* prevalence and genotypes. Genotyping results were utilized to develop a *Bacillus*-based direct fed microbial (DFM) which inhibited a broad range of *C. perfringens* genotypes. From March 2005 to January 2006, 705 fecal swabs and 108 gastrointestinal tract samples were collected from scouring calves in California, Iowa, Ohio, Pennsylvania, Washington, and Wisconsin. Randomly Amplified Polymorphic DNA Polymerase Chain Reaction and BioNumerics software (Applied Maths Inc. Austin, TX) were utilized to create genetic fingerprints and to assess *C. perfringens* genotypic diversity respectively. *C. perfringens* were detected in 239 of 813 samples (29%) and 917 *C. perfringens* colonies were isolated. All isolates were *C. perfringens* A. The results of the *C. perfringens* genotypic survey indicate that there were 149 genotypes at 75% similarity using the Dice similarity coefficient with the unweighted pair group method using arithmetic averages. Representatives of all 149 genotypes were utilized in an inhibition assay to determine percent inhibition of *C. perfringens* by the filtrates of six *Bacillus* strains. A multistrain product (Omni-Bos CB™) was formulated using three *Bacillus* strains. BS1 inhibited 88%, BS3 inhibited 85%, and BS8 inhibited 82% of the *C. perfringens*; together these strains inhibited 89%. Future research should focus on testing the effects of this novel DFM *in vivo* as well as comparing inhibition of *C. perfringens* by the therapies and prophylaxes available for use in calves with this DFM.

Key Words: Probiotic, RAPD PCR, Microbiota

TH11 The effects of feeding tall fescue seed on daily feed intakes of horses. A. G. Parks* and L. M. Lawrence, *University of Kentucky, Lexington.*

Twelve horses (3 mature geldings, 6 mature, non-pregnant mares, and 3 two-year-old fillies) were studied in a randomized complete block design. Each horse's daily feed intake was monitored through an adaptation period and a 14-d treatment period. Horses were maintained throughout the adaptation and treatment periods on a diet of alfalfa cubes (fed ad libitum) and sweet feed (0.4% BW daily, as fed). During the adaptation period, horses were offered increasing amounts of alfalfa cubes daily until the amount of cubes offered exceeded the amount of cubes consumed. The length of the adaptation period varied (7-14 d) depending on the length of time required to establish a consistent cube intake for all horses in the group. After the adaptation period, horses were randomly assigned to one of three treatments: endophyte-free ground tall fescue (TF) seed (E-G), endophyte-infected ground TF seed (E+G), or endophyte-infected whole TF seed (E+W). Seed was topdressed on the sweet feed in increasing amounts during d 0-4. Horses were then offered seed at 0.16% body weight on d 4-9 and at 0.22% BW on d 10-14. For d 4-9, E+ diets averaged 327 ppb ergovaline and 227 ppb ergovalinine. Ergovaline and ergovalinine concentrations in the E+ diets on d 10-14

averaged 416 ppb and 288 ppb, respectively. Two horses in the E+G group refused portions of the sweet feed and seed mixture on several days, suggesting a palatability issue with this treatment. However, inclusion of E- or E+ seed in the diet did not affect mean daily alfalfa cube intakes for the final three days of the study compared to the final three days of the adaptation period for E-G horses (10.3 ± 1.1 kg vs. 10.8 ± 0.8 kg, $P = 0.371$), E+W horses (10.9 ± 0.4 kg vs. 11.0 ± 0.2 kg, $P = 0.681$), or E+G horses (10.3 ± 0.6 kg vs. 10.2 ± 0.5 kg, $P = 0.882$). While tall fescue seed consumption did not appear to affect daily feed intake, all observations were made in the fall when environmental temperatures were mild. Further studies should be conducted in hot weather.

Key Words: Fescue Toxicosis, Horses, Intake

TH12 Hemodynamics in the caudal artery of beef heifers fed different ergot alkaloid concentrations. G. E. Aiken^{*1}, J. R. Strickland¹, M. L. Looper², and F. N. Schrick³, ¹USDA-ARS-Forage-Animal Production Research Unit, Lexington, KY, ²USDA-ARS-Dale Bumpers Small Farms Research Center, Booneville, AR, ³University of Tennessee, Knoxville.

Doppler ultrasonography was used to compare hemodynamics in the caudal artery of heifers fed diets with either endophyte (*Neotyphodium coenophialum*) infected (E+; $1.14 \mu\text{g}$ ergovaline/g DM), endophyte free (E-; $0 \mu\text{g}$ ergovaline/g DM), or a mixture of E+ and E- (E+E-; $0.38 \mu\text{g}$ ergovaline/g DM) tall fescue seed in a base ration of chopped alfalfa hay plus concentrate. Eighteen endophyte-naïve, Angus x Brangus heifers were stratified by BW into individual pens and fed the E- diet for a 7-d adjustment period. A 9-d experimental period followed with the 3 diets. Doppler ultrasound measurements (caudal artery area, heart rate, and flow rate) and blood samples for determination of serum prolactin were collected during the adjustment period (d 4, 5, and 7) to determine baseline measures, and during the experimental period at 3, 27, 51, 75, 100, 171, and 195 h from initial feeding of the diets. Statistical analyses compared proportionate differences between baseline and responses during the experimental period. Prolactin concentrations for the E- diet during the experimental period were similar to baseline concentrations, and Doppler measures were sporadic. Prolactin concentrations for the E+ and E+E- diets were less ($P < 0.05$) by 27 h and 51 h, respectively, and remained decreased until 195 h after initial feeding. Caudal artery area for the E+ diet was less ($P < 0.01$) between 27 and 171, and caudal artery area for the E+E- diet was less ($P < 0.01$) between 51 and 99 h. Reductions in heart rate with the E+ diet were only detected ($P < 0.05$) at 27, 99, and 171 h; no changes in heart rate were observed the E+E- diet. Blood flow rates for E+ and E+E- diets declined after 51 h, but increased to the baseline by 99 h for the E+E- diet and by 171 h for the E+ diet. Results indicated that reductions in blood flow rate through the caudal artery occur by 51 h after consumption of either low or high ergot alkaloid concentrations, even though vasoconstriction and heart rate responses were more sensitive to the higher alkaloid concentration. Doppler ultrasonography is a method to potentially establish threshold toxicity levels for the ergot alkaloids.

Key Words: Bovine, Fescue Toxicosis, Ergot Alkaloids

TH13 Analysis of locomotion scores with altered periparturient management. S. Eicher^{*1}, M. M. Schutz², J. Townsend², K. Daniels², S. Donkin², and A. Parkhurst³, ¹USDA-ARS, West Lafayette, IN, ²Purdue University, West Lafayette, IN, ³University of Nebraska, Lincoln.

The objective of this study was to evaluate locomotion scoring as a predictor of lameness in heifers and multiparous cows subjected to periparturient management change. Heifers were either milked 3 wk prior to expected calving or not milked until after calving. The multiparous cows were fed hyper alimentation, hypo alimentation, or control diets beginning on d -15 prior to expected calving until calving. Locomotion scores and lameness incidence were collapsed into pre- and post-calving scores for comparison because of infrequent incidence of lameness. The greatest factor tending ($P = 0.10$) to predict lameness was parity. Although speed was greater ($P < 0.05$) for control heifers, it did not predict lameness. However, persistence of lameness was correlated ($P < 0.05$) with speed following calving. Overfed cows had greater ($P = 0.001$) back arch scores than other treatments, suggesting that they may be experiencing pain associated with walking; but it was not a significant factor in predicting lameness. Odds Ratio analysis supported the ANOVA analysis. Discriminant analysis of 13 treatment-lameness categories indicated that hyper alimentation cows had greater incidence of lameness than the others. Control heifers were again found to have fewer incidence of lameness than control cows. The first canonical function, essentially a weighted average of all 5 treatments, correlated most strongly with back arch ($r = 0.914$, $P = 0.0285$) and speed ($r = 0.735$, $P = 0.001$). The second canonical discriminant function was primarily the difference between speed ($r = 0.507$, $P = 0.001$) and back arch ($r = 0.370$, $P = 0.007$). The third canonical discriminant function represented extremes of the significant correlations; head bob ($r = 0.835$, $P = 0.001$) and foot rotation ($r = 0.287$, $P = 0.039$). Prepartum milking did not affect lameness in heifers and feeding routine of cows only mildly affected incidence of lameness. Results accentuate the complexity of lameness and reinforce that it develops with time.

Key Words: Dairy Cattle, Lameness, Locomotion Score

TH14 Experimental haemonchosis in resistant and susceptible Creole kids. J. C. Bambou^{*}, E. González-García, C. de la Chevrotière, R. Arquet, N. Vachiéry, and N. Mandonet, INRA UR143 Unité de Recherches Zootechniques (URZ), Centre Antilles Guyane, Domain Duclos, 97170 Petit Bourg, Guadeloupe (French West Indies).

This study was developed to characterize the peripheral immune response during haemonchosis in goats by comparing genetically resistant and susceptible animals. We analysed the changes of circulating lymphocytes populations after experimental infection with *Haemonchus contortus* in sixteen nematode resistant ($n = 8$) and susceptible ($n = 8$) Creole kids (BW = 18.23 ± 4.56 kg) which were kept under confinement receiving an *ad libitum* diet based on a mix of tropical hay. Kinetics of faecal eggs count (FEC), packed cell volume (PCV), eosinophilia, as well as body weight (BW) changes, were weekly monitored. Flow cytometry was used to follow changes in peripheral blood mononuclear cell (PBMC) populations at early stage, 0, 3 and 35 days post-infection (d.p.i.). Data of FEC, PCV, eosinophilia and BW were analyzed by non-orthogonal contrast of SAS, while relative proportion of T lymphocyte (LT) sub-populations was compared across time by using GLIMMIX

(SAS, 2000). Main significant differences in eosinophils counts were detectable from the beginning until 7 d.p.i., afterwards, no differences were found. At the beginning, PCV values were lower in susceptible animals compared to resistant but at physiological level (31.5 and 28.9 respectively, $P=0.051$). These differences became higher from 21 d.p.i. onwards. Interestingly, from 21 to 35 d.p.i. FEC in resistant animals were significantly lower than in susceptible. Thus, at the end of the infection susceptible animals showed a FEC 11 folds higher than resistant ($P=0.031$). However, no evolution across time and no difference between resistant and susceptible kids were evidenced in circulating LTCD8+ and LTCD4+ sub-populations. Surprisingly, a significant decrease in CD4+ sub-populations was evidenced throughout the experiment in both groups, probably due to a mucosal localization of activated cells. The analysis of the local immune response in the abomasal mucosa could help to verify this hypothesis.

Key Words: Gastrointestinal Parasitism, *Haemonchus contortus*, Creole Goats

TH15 JDIP – Phase II. K. E. Olson*, *KEO Consulting, Schaumburg, IL.*

The Johne's Disease Integrated Program (JDIP) is a comprehensive consortium of academic, agency and industry researchers focused on

developing real-world solutions that will help producers deal more effectively with Johne's disease and mitigate potential losses. Currently in the third year of the original project, it is the first Coordinated Agricultural Project (CAP) proposal to receive approval for a second round of funding by the USDA-CSREES-NRI. Phase 2 funding will allow findings from the initial round of funding to be used to expand understanding of the transmission of the disease as well as potential new diagnostics, therapeutics and management tools that will allow producers to deal more effectively with the disease. Proposals approved for year four funding in the JDIP Core areas 1) Epidemiology and Biostatistics; 2) Diagnostics and Strain Differentiation; 3) Genomics, Antibodies and Proteomics and 4) Animal Models and Facilities as well as the Project areas of: 1) Epidemiology and Transmission; 2) Diagnostics and Strain Differentiation; 3) Map Biology and Pathogenesis; 4) Map Immunology and Vaccine Development and 5) Extension and Communication will be highlighted. Additional funding, made available by USDA APHIS VS, will fund projects over the next three years that are focused on identifying and validating potential Johne's vaccine candidates with the greatest likelihood of success in the field. An overview of work in this area will be included.

Key Words: Johne's, MAP, JDIP

Contemporary and Emerging Issues

TH16 Best practices for the conduct of animal studies to evaluate crops genetically modified for input and output traits. G. L. Cromwell*, G. F. Hartnell, A. J. Lewis, G. R. Dana, D. H. Baker, M. R. Bedford, K. C. Klasing, F. N. Owens, J. Wiseman, L. K. Kurtyka, and M. J. Levine, *International Life Sciences Institute and Federation of Animal Science Societies, Washington, DC and Savoy, IL.*

The International Life Sciences Institute (ILSI) in collaboration with the Federation of Animal Science Societies (FASS) appointed two task forces consisting of scientists with expertise in animal nutrition, animal health, feed chemistry, food science, statistics, and other relevant disciplines to develop two documents that would assist researchers in the evaluation of crops genetically modified (GM) for input and output traits. The rationale was to provide a platform for the scientific evaluation of crops containing input traits (e.g., herbicide tolerance, insect protection; composition of crops unchanged) and output traits (composition of crops intentionally changed) when fed to food-producing animals and to promote international harmonization of experimental methods. Both documents provide best practices on how to produce, handle, store, and process GM crops containing the genetically enhanced trait(s), sample and analyze the harvested and processed crop, and analyze and interpret the results. In addition, the input document describes experiments for assessing cereal grains, oilseeds, and forages for lactating and growing ruminants, swine, and poultry. The output document also provides information on the types of studies to consider in evaluating specific GM traits, such as modification of protein, amino acids, lipids, carbohydrates, minerals, vitamins, antioxidants, enzymes, and antinutrients in specific crops when fed to target animal species; and how to design and conduct livestock, poultry, and aquaculture studies including proper comparator selection, animal-product processing effects, and sensory evaluation of the end-product. The input and output documents were subjected to peer review by 38 domestic and international experts and were published by ILSI in 2003 and 2007, respectively.

Key Words: Genetically Modified Traits

TH17 Animal biotechnology: The movie. A. L. Van Eenennaam* and W. E. Pohlmeier, *University of California, Davis.*

The public experience with animal biotechnology often starts and ends with Dolly the sheep, the first mammal ever cloned from an adult cell. The hype that surrounded Dolly rapidly became entangled with the debate over human cloning, and the ensuing discussion failed to elaborate on, or even differentiate between, the broad range of technologies encompassed by the ill-defined term “animal biotechnology”. In the absence of information, animal biotechnologies tend to evoke a negative reaction. To address this knowledge deficit and the fact that few general audience educational resources about this topic have been developed by publicly-funded animal scientists, a 30-minute educational movie entitled **Animal Biotechnology** was produced. The movie begins with a brief historical description of the development of various animal biotechnologies and places the most controversial of these technologies, cloning and genetic engineering, within that framework. Both biomedical and agricultural applications of animal biotechnology are discussed, in addition to some of the science-based and ethical concerns that are engendered by certain applications. Excerpts from interviews with leading academic and industry scientists conducted at the UC Davis Transgenic Animal Conference in 2007 scientists in the field are interspersed throughout the movie. The script and visuals underwent anonymous scientific peer-review prior to release. The target audience for the movie includes college and high school students and interested members of the general public. To make the movie widely available to the general public, it will be posted on YouTube, the UC Davis Animal Biotechnology website, and DVD copies will be made available to educators and other interested parties at scientific and educational meetings. Funding for this project was provided by USDA NRI Grant 2005-01655.

Key Words: Biotechnology, Cloning, Education

Dairy Foods: Dairy Products and Processing I

TH18 Stability of a long life drinking yoghurt. M. M. Macchione and W. H. Viotto*, *State University of Campinas, Campinas, SP, Brazil.*

Heat treatment of yoghurt after fermentation may extend its shelf-life, but proteins may become instable because of the heating in low pH. This work studied the effect of 2 different post-fermentation heat treatments (72°C/15s and 110°C/15s) and 2 storage temperatures (5–7°C and 25–30°C) on the physicochemical and microbiological properties of drinking yoghurt stabilized by pectin. Skim milk with 12% sugar was heated at 80°C/30min and 2% EPS producing starter culture (mix of *Streptococcus thermophilus* and *Lactobacillus bulgaricus*: Yo-Mix™ 601 Lyo from Danisco™ Brazil) was added at 45°C, until reaching pH 4.0. Pectin (0.45% of Grindsted™ Pectin AMD 382, from Danisco™ Brazil) was added with 2% sugar and the yoghurt was treated in a tubular heat-exchanger followed by aseptic homogenization. The product stability was evaluated during 95 days, by following analyses: pH and titratable acidity; sedimentation and syneresis (by centrifugation); apparent viscosity (Brookfield rheometer), standard plate count (PCA), lactic acid bacteria (MRS) and yeasts and moulds (PDA plus antibiotics). Heat treatment intensities and storage conditions did not affect the products stability, and no physical changes occurred during all the storage time. The only parameter affected was the viscosity, which was lower for the most intensive treatment (25cp x 35cp) and increased under refrigerated conditions (3–5cp) for both treatments. There were no changes in acidity (1.1% lactic acid), pH (3.9), sedimentation (2–3%) and syneresis (none) due to the type of heat treatments and storage temperature and time. All the heat treatments resulted in stable products, with no microbiological growth during the 95 days of storage. Maximum standard plate count was 25 CFU/ml and no detectable amounts of yeasts and moulds were found.

Key Words: Drinking Yoghurt, Long Life, Stability

TH19 Thirty-four percent whey (WPC) and serum protein (SPC) concentrate and 65% serum protein (SP) reduced micellar casein: production and composition. J. Zulewska*¹, D. M. Barbano², M. W. Newbold², M. A. Drake³, E. A. Foegeding³, and C. Moraru², ¹*University of Warmia and Mazury, Olsztyn, Poland*, ²*Cornell University, Ithaca, NY*, ³*North Carolina State University, Raleigh.*

Raw whole milk (ca. 1200 kg) was split into two portions. One portion was pasteurized and made into Cheddar cheese and whey and the other was cold separated into skim milk (SM) and cream. The SM was pasteurized and microfiltered (MF) at 50°C with a 0.1 micron ceramic uniform transmembrane pressure system to produce a 65% SP reduced micellar casein concentrate (MCC) and MF permeate. The separated whey and MF permeate were ultrafiltered (UF) to produce liquid 34% WPC and SPC. This was replicated 3 times. No difference in UF flux when processing whey or MF permeate from skim milk using a spiral wound 10 kDa polyethersulfone membrane was detected after 60 min of processing, 15.7 vs. 14.6 kg/m²/h. The liquid WPC was opaque while the SPC was clear and the pH of the liquid WPC was lower than the WPC, 6.44 vs. 6.74. Half of the MCC, WPC, and SPC was spray dried, moisture 3.8, 3.0, and 4.1%, respectively and the other half was freeze dried, moisture 3.3, 2.5 and 3.1%, respectively. The protein content of

WPC and SPC powders (total nitrogen × 6.38) were 34.5 and 35.3% on a dry basis, respectively. Spray dried WPC contained more fat on a dry basis than SPC, 1.94 vs. 0.25%, and this may cause flavor or flavor stability differences. The WPC contained more glycomacropeptide than SPC (4.1 vs. 0% of protein) and this may cause differences in functionality. The WPC and SPC contained phosphorus, calcium, magnesium, potassium, sulfur, and sodium at the following percentages on a dry basis: 0.63 and 0.56, 0.57 and 0.44, 0.12 and 0.11, 1.91 and 1.88, 0.52 and 0.57, and 0.45 and 0.43, respectively. WPC contained significantly higher content of calcium and phosphorus than SPC, which may influence functionality. No differences in L, a, b color values were detected for the spray dried WPC and SPC at 90.25 and 90.05, -0.42 and -0.50, and 6.40 and 5.90, respectively. The spray dried 65% SP reduced MCC contained 2.3% fat and 57.9% protein on a dry basis.

Key Words: Whey and Serum Protein Concentrate, Production, Composition

TH20 Comparison of sensory and functional properties of 34% serum (SPC) and 34% whey protein concentrates (WPC). J. P. Evans*¹, P. J. Luck¹, E. A. Foegeding¹, J. Zulewska³, D. M. Barbano², and M. A. Drake¹, ¹*North Carolina State University, Raleigh*, ²*Cornell University, Ithaca, NY*, ³*University of Warmia and Mazury, Olsztyn, Poland.*

Serum proteins (SP) are primarily α -lactalbumin and β -lactoglobulin removed directly from skim milk while these same proteins for WPC manufacture are typically harvested from whey after cheese making. Since SP are not exposed to the cheese make-process, enzymatic and/or chemical reactions that can lead to off-flavors, or a reduction in functionality, are reduced. Research today has not compared flavor and functionality of SPC and traditional WPC. SPC and WPC (34%) were manufactured in triplicate from the same lot of milk. At each replication, liquid SPC and WPC were collected and spray-dried (SD) and freeze-dried (FD). Solubility, heat stability, gelation and foaming properties were measured. A trained sensory panel documented the sensory profiles of liquid retentate and rehydrated spray or freeze-dried powders. Volatile components were extracted by solid phase micro-extraction (SPME) followed by gas chromatography-mass spectrometry. Both SPC and WPC were characterized by low intensities of sweet aromatic and cardboard flavors, but these intensities were lower in SPC compared to WPC. Diacetyl flavor was absent in SPC. SD increased flavor intensities compared to FD, but the types of flavors documented were not different. Volatile compound results were consistent with sensory results. All SPC treatments were more soluble and had generally lower turbidity than their corresponding WPC treatment. In addition, all SPC treatments exhibited greater foaming properties than corresponding WPC treatments. No stable foams were generated from liquid or freeze-dried WPC treatments, and spray-dried WPC produced foams low in yield stress, overrun and stability. SPC treatments were also more heat stable and produced stronger gels than similar WPC treatments. These results indicate that 34% SPC has distinct differences in functional and flavor characteristics from WPC.

TH21 The effect of crosslinked β -cyclodextrin treatment on the rheological and sensory properties of ice cream. H. J. Ha* and H. S. Kwak, *Sejong University, Seoul, Korea.*

This study was designed to examine the effect of crosslinked β -cyclodextrin (β -CD) treatment on cholesterol removal, and the rheological and sensory properties of ice cream when stored at 4, -12, -18 and -28°C. Cholesterol-reduced milk and cream were made by crosslinked β -CD. Ice cream mixes were formulated with 15% milk fat, 8% nonfat milk solids, 1.3% sugar and 0.3% stabilizer. Then it was pasteurized at 65°C for 30 min, homogenized in a single-stage homogenizer at 10.4 MPa and cooled to 4°C before tests were performed. The cholesterol removal reached 90.3% when crosslinked β -CD was treated. Ice crystal size was greater in the control at 4 and -28°C storage temperature, however, it was smaller at -12 and -18°C storage temperature. The viscosity of the cholesterol-reduced ice cream was significantly lower at all temperatures than that in the control. In addition, the viscosities in both groups were significantly higher at -18°C storage temperature compared with other temperatures. The meltdown stability appeared to be lowered with the crosslinked β -CD treatment in all storage temperatures. Most of color values were different between the control and the cholesterol-reduced ice cream. The L-value was increased in the melted state than in the frozen state in all temperatures, whereas a-value was decreased. Appearance of the cholesterol-reduced ice cream was similar to the control, however, it was decreased at -28°C storage temperature. In addition, the overall acceptability was lower in both groups at -28°C storage temperature. The present study indicated that the crosslinked β -CD treatment showed the lower viscosity and meltdown stability, however, sensory characteristics were not significantly lowered compared with the control.

Key Words: Ice Cream, Viscosity, Meltdown Stability

TH22 Rapid determination of emulsifier and stabilizer concentration in ice cream. S. L. Cropper*, N. A. Kocaoglu-Vurma, L. E. Rodriguez-Saona, and W. J. Harper, *The Ohio State University, Columbus.*

Ice cream is a complex foam structure consisting of fat, sweeteners, flavorings and air incorporated during the freezing process. Emulsifiers and stabilizers are used to help stabilize the air within the fat matrix producing a better quality product. Fourier Transform Infrared Spectroscopy (FTIR) has shown to be a rapid and effective method for analyzing and determining ingredient concentrations in ice cream.

The objective for this research was to generate a multivariate calibration model using infrared spectroscopy to quantify stabilizer and emulsifier concentrations in ice cream.

Ice creams were made with 10% fat, 11% milk solids non-fat, 18% sugar and varying concentrations of mono and diglycerides (MDG) and carboxy methyl cellulose (CMC) ranging from 0.0-0.15 % for MDG and 0.0 to 0.20 % for CMC. All ingredients were blended and the mix was homogenized, pasteurized, and aged at 4°C for two days. Following aging, the mixes were frozen using a scraped surface heat exchanger at -4°C and then stored at -40°C. Each ice cream was thawed and 0.5 μ L was placed directly onto the ZnSe-ATR crystal, vacuum dried to produce a thin film, and the spectra, which was collected in the mid-IR region (4000-700 cm⁻¹), was analyzed using partial least squares regression (PLSR) analysis.

Multivariate models (PLSR) for emulsifier (MDG) and stabilizer (CMC) were developed from infrared spectra (770-1800 and 2800-3005 cm⁻¹),

resulting in a correlation coefficient of validation (r_{Val}) \geq 0.92 and a standard error of validation (SEV) of 0.01% for estimation of emulsifier and stabilizer levels.

Infrared spectroscopy can estimate MDG and CMC in the ice cream individually and in combination within the complete ice cream matrix. This method provides an efficient way to analyze emulsifier and stabilizer concentrations in ice cream and offers a faster means of quantification of ingredients. Infrared spectroscopy can be used to better understand the combined roles of emulsifiers and stabilizers in the ice cream system. Overall, this technique allows for easier monitoring of ice cream quality during processing and will enable the manufacturer to minimize production cost while ensuring the highest quality.

Key Words: FTIR, Ice Cream

TH23 Addition of rice extract improves the quality characteristics and consumer acceptability of banana flavored yogurt. T. Bor*, D. Song, C. W. Seo, and S. A. Ibrahim, *North Carolina A&T State University, Greensboro.*

Manufacturing dairy products with consistent and desirable textures continue to be a concern to the industry. Different approaches have been studied recently to improve texture ranging from using different process techniques to different ingredients. Rice possesses some unique properties that may be of interest to the dairy industry. Rice is rich in oligosaccharides, hydrocolloids compounds that could be used to improve the texture of dairy products. The objective of this study was to evaluate the effects of rice extract on the quality characteristics and consumer acceptability of banana flavored yogurt. Rice flour (10% wt/vol) was cooked with tap water for 45 min and stored at 4 C for 2 days to allow for gel formation. Plain yogurt was purchased from a local store and mixed with rice extract at 5% (wt/wt, rice extract/ yogurt). Sliced fresh banana (2% wt/wt) was then mixed with the yogurt mix. The finished product was stored in the refrigerator for 12 h before conducting the sensory evaluation. A consumer panel recruited from the university campus (n= 90) rated the acceptability and sensory characteristics of the products. In addition, pH values, apparent viscosity, color and water holding capacity of the yogurt samples were recorded. Results showed that panelists gave high acceptability scores for yogurt with rice flour samples in term of texture, appearance and overall acceptability. The addition of rice flour did not change the pH value of the yogurt. The viscosity, color and water holding capacity measurements were slightly changed with the addition of rice flour. These findings suggest that rice extract can be added to improve the quality characteristics and consumer acceptability of banana flavored yogurt. Moreover, since rice and banana flavored products are popular among ethnic groups including Asians and Hispanics, the use of this food combination of has promising market potential.

Key Words: Yogurt, Rice

TH24 Functional properties of 65% serum protein reduced micellar casein concentrates obtained by microfiltration. C. M. Belicium¹, J. Zulewska², M. Newbold¹, C. I. Moraru*¹, and D. M. Barbano¹, ¹*Cornel University, Ithaca, NY*, ²*University of Warmia and Mazury, Olsztyn, Poland.*

The objective of this work was to characterize the functional properties of micellar casein concentrates (MCC) obtained by microfiltration

(MF). 65% serum protein (SP) reduced MCC was obtained by MF of skim milk in a uniform transmembrane pressure system equipped with a 0.1 micron ceramic membrane. The MF retentate (MCC) was both spray dried (3.8% m.c.) and freeze dried (3.3% m.c.). The spray dried 65% SP reduced MCC contained 57.9% protein (d.b.) and 2.3% fat. Solubility, emulsification and foaming properties of the MCC powders were determined. The rheological properties of the MCC liquid retentate and of reconstituted MCC powders were also measured. The powder solubility was the property mostly affected by the drying method. The sediment for freeze dried MCC ranged between 0.25±0.00 mL and 1.58±0.14 mL among 3 replicates, and for spray dried MCC between 5.83±0.58 mL and 8.67±0.29 mL. The foam expansion was higher for spray dried (212.9%) as compared to freeze dried MCC (151.1%); foam stability was poor for all samples. No significant differences in emulsification properties between spray and freeze dried MCC were observed, with emulsification stability values of 69.73±2.17% and 65.98±1.09%, respectively. Low amplitude rheological measurements of reconstituted MCC of 7.5% to 15% concentration showed slightly higher values of the storage modulus (G') for spray dried as compared to freeze dried MCC. The fresh retentates had lower G' and G'' than the reconstituted samples, at the same concentration, due to denaturation of residual SP in the dried samples. No significant differences in apparent viscosity, yield stress and flow index were observed between different batches or drying methods. Viscosity and yield stress increased with concentration. At the same concentration, fresh retentates were more viscous than reconstituted samples, due to the denaturation of SP in the MCC powders. Flow indices decreased with increasing concentration, indicating a tendency towards shear thinning behavior of the concentrated MCC. Fresh retentates had a flow behavior closer to Newtonian than reconstituted MCC, due to the native state of proteins.

Key Words: Micellar Casein, Functionality

TH25 Surface hydrophobicity of co-extruded and milled corn starch with whey protein concentrate as a function of pH. S. L. Amaya-Llano*^{1,2}, E. Castano-Tostado², F. Martinez-Bustos¹, and L. Ozimek³, ¹*Ciencia de Materiales, CINVESTAV Queretaro, Queretaro, Mexico*, ²*PROPAC, Universidad Autonoma de Queretaro, Queretaro, Queretaro, Mexico*, ³*University of Alberta, Edmonton, AB, Canada*.

The aim of this work was to study the effect of co-extrusion over blends of corn starch and WPC measuring surface hydrophobicity. Surface hydrophobicity (SH) was used to define the potential interaction between starch and protein at varied technological parameters of extrusion such as temperature, moisture and hydrogen ion concentration. The extrusion factors were: barrel temperature (70-180°C), feed moisture (18-30%), pH (3-8), different proportions of corn starch (75-95%), and whey protein concentrate (WPC, 80% protein concentration) (25-5%). The extrusion process was carried out using a single screw extruder, designed and manufactured by Cinvestav-IPN, Mexico. The screw compression ratio was 1:1 with a 5.0-mm die-nozzle. The co-extruded product was milled to particle size below 250 µm. This milled product can be used as a new food ingredient as source of protein, as stabilizer or emulsifier. In order to define suitable food applications of the new ingredient, functional properties must be determined. Surface hydrophobicity is a good indicator of the ingredient hydrophobic sides available for interaction in food systems. Also, the SH was used in this study to probe interaction between corn starch and WPC during extrusion process. Results showed

that SH is affected by processing parameters of extrusion and it can be used to monitor the interaction between proteins and carbohydrates.

Key Words: Surface Hydrophobicity, Extrusion, Whey Protein Concentrate

TH26 Effect of ultrasound treatment on microbial load in milk. S. Gokavi, T. Silk, and M. Guo*, *University of Vermont, Burlington*.

Non-thermal technologies such as ultrasound are emerging as promising alternatives to heat treatment for food processing. Ultrasound is defined as sound waves with a frequency greater than 20 kHz that are able to travel through gas, liquid and solid materials with proven bactericidal effects, especially when combined with mild heat treatments. The objective of the present study was to determine the effect of ultrasound treatment on standard plate count levels (SPC) present in raw milk and non-pathogenic *Escherichia coli* and *Listeria innocua* inoculated in ultra-high temperature (UHT) milk. An ultrasonic processor (VCF 1500HV, Sonics & Materials, Inc., CT) consisting of a continuous flow cell and a 10" titanium alloy probe (Frequency 20 kHz, 100% power level, 650 W acoustic power, 132 W/cm² acoustic intensity) with a 370 ml sample processing chamber was used. Samples were subjected to two treatments: batch and continuous flow (420 ml/min) at two temperatures 25±2° and 55±2°C with treatment times of 6, 12, 18 and 24 min. Both batch and continuous treatment at 25±2°C for 24 min yielded a 3-log reduction of SPC, a 3-log reduction of *E. coli* and 1 to 2-log reduction of *L. innocua*. Ultrasound treatment with mild heat (55±2°C) was effective at reducing SPC in raw milk. Reductions were also noted in *E. coli* and *L. innocua* levels inoculated in UHT milk. Batch ultrasound treatment combined with mild heat for 24 min yielded a 5-log reduction of SPC, a 4-log reduction of *E. coli* and 3-log reduction of *L. innocua*. Continuous flow ultrasound treatment combined with mild heat for 24 min resulted in a 6-log reduction of SPC, a 6-log reduction in *E. coli* and *L. innocua*. Inactivation regressions were second-order polynomials, showing an initial period of rapid inactivation, eventually tailing off. Results indicate that ultrasound technology is a promising processing alternative for the reduction of microbial load in milk and other liquid foods.

Key Words: Milk, Ultrasound Treatment, Microbial Load

TH27 Effects of high pressure homogenization on milk. C. A. Boeneke*, A. Pastorek, and K. J. Aryana, *Louisiana State University Agricultural Center, Baton Rouge*.

Homogenization is a process of forcing milk through tiny orifices. The resulting pressure causes the fat globules to become smaller limiting their separation in the emulsion. Although effective, some separation of the fat can still occur over time. As demand for dairy products with longer shelf lives i.e., products processed using Ultra High Temperature and Ultra Temperature pasteurization grows, separation of the fat is a concern. In this experiment, milk was standardized to 2% and 3.25% fat before homogenization at 50, 125, and 200 MPa using an APV 2000 two stage homogenizer (APV Systems Albertslund, Denmark) to determine effects of increased homogenization pressure on the finished product. Milk was collected and stored at 7 °C for 3 weeks. Milks were analyzed for fat content, rate of creaming, viscosity and color. Milk was evaluated for flavor, body/texture, and appearance/color at the end of 1, 2, and 3

weeks of storage by a 5 member trained panel. Trained panelists were unable to detect differences in flavor, appearance/color, or mouth-feel over a three week period. Homogenization was affected by pressure, inlet temperature, and fat content of the milk. No creaming was observed over a two week storage period. Changing milk inlet temperature and homogenization pressures influenced results.

Key Words: Milk, High Pressure Homogenization

TH28 Classification of cream butter by infrared spectroscopy and multivariate analysis. S. Herringshaw*, N. Kocaoglu-Vurma, and L. Rodriguez-Saona, *The Ohio State University, Columbus.*

Food authenticity has become a focal point attracting the attention of producers, consumers, and policy makers. Major authenticity issues concern the true labeling of food whereby substitution of high value raw materials with cheaper materials is common practice. Factors such as milk sources and production methods result in a wide range of butter types, some of which command a premium price. There is a need for rapid and reliable analytical tools for determination of authenticity since traditional methods often involve time-consuming and laborious processes. Our objective was to evaluate the application of infrared spectroscopy combined with pattern recognition techniques to discriminate among butter samples in relation to quality and authenticity. Butter produced by different manufacturers from different production lots were purchased from a local market (Columbus, OH). Samples were filtered at 65°C and the collected fat samples were directly applied onto a temperature-controlled single bounce ZnSe crystal for attenuated total reflectance measurements. The ZnSe crystal was heated at 65°C and spectra analyzed using soft independent modeling of class analogy (SIMCA), a multivariate classification technique. This simple protocol generated unique mid-infrared signature profiles that permitted the chemically-based classification of butter samples based on manufacturer. By using the spectral region from 1200-900 cm⁻¹, multivariate (SIMCA) modeling showed well-separated clusters that discriminated among butter samples, due to -HC=CH- trans bending out of plane vibration modes (968 cm⁻¹) presumably attributed to conjugated fatty acids. Infrared spectroscopy combined with multivariate analysis provides a simple and efficient tool for classification of butter with minimal sample preparation. This rapid protocol can provide both the industry and regulatory agencies with markers by which butter can be classified and whereby uniform quality can be established thus providing a tool for determining butter authenticity.

Key Words: Butter, Authenticity, Infrared Spectroscopy

TH29 Effect of various antioxidants on the characteristics of plain yogurt. B. Brignac¹ and K. Aryana*², ¹*Louisiana State University, Baton Rouge*, ²*Louisiana State University Agricultural Center, Baton Rouge.*

Free radicals have a significant influence on ageing and age-related conditions. Optimal intake of antioxidant nutrients may contribute to enhanced quality of life and may delay / slow the onset of ageing. The objective was to study the effect of vitamin C, vitamin E, beta carotene and a combination of these three antioxidants on the characteristics of plain yogurt. The antioxidants Vitamin C, vitamin E and beta carotene

and a combination of Vitamin C + vitamin E + beta carotene were incorporated at 100% of their respective recommended dietary allowance of 60 mg, 10 mg and 3 mg and 60 + 10 + 3 mgs respectively in an 8 oz cup of yogurt. Product manufacture was replicated three times. Flavor scores for yogurts with vit E and yogurts with beta carotene were high and not significantly ($p < 0.05$) different from each other. Flavor scores for yogurts with vit E were significantly ($p < 0.05$) higher than the control. Yogurts with vit C + vit E + beta carotene had flavor scores that were not different from control but were significantly ($p < 0.05$) lower than yogurts with vit E and beta carotene. Control yogurts and yogurts with vit C and yogurts with vit E had significantly ($p < 0.05$) high appearance scores which were not significantly ($p < 0.05$) different from each other but were significantly ($p < 0.05$) higher than yogurts with vit C + vit E + beta carotene. Yogurts with vit C + vit E + beta carotene had the lowest appearance scores. Yogurt with vit E had higher body and texture scores compared to the control while yogurts with vit C has lower scores compared to the control. The remaining yogurts had body and texture scores not significantly ($p < 0.05$) different compared to the control. Yogurts with vit C + vit E + beta carotene had the highest a* values compared to the remaining yogurts which were not significantly ($p < 0.05$) different from each other. Compared to control there were no significant ($p < 0.05$) differences in pH, apparent viscosity, lactobacilli counts, L* and b* values of yogurts with antioxidants. Use of antioxidants influenced some characteristics of plain yogurt.

Key Words: Yogurt, Antioxidant, Quality

TH30 Effect of stabilizer and emulsifier concentrations on particle size and melting rate of ice cream. S. L. Cropper*, N. A. Kocaoglu-Vurma, and W. J. Harper, *The Ohio State University, Columbus.*

Stabilizers and emulsifiers are used in ice cream to improve texture and maintain structure. Emulsifiers help to minimize the coalescence of fat and destabilize the fat globule in the matrix. Stabilizers are commonly utilized for their ability to bind water in ice cream, but also have been found to play a part in enhancing fat aggregation. Determining how particle size and melting rate is influenced by stabilizer and emulsifier concentration is beneficial to see what the maximum quantities of these ingredients are required to provide the best texture.

The objective for this research was to determine the influence of varying emulsifier and stabilizer concentrations on particle size and melt rate of ice cream.

Ice cream mixes were prepared with 10% fat, 11% milk solids non-fat, 18% sugar and varying concentrations of mono and diglycerides (MDG) and carboxy methyl cellulose (CMC) ranging from 0.0-0.15 % for MDG and 0.0 to 0.20 % for CMC. All ingredients were blended and the mix was homogenized, pasteurized, and aged at 4°C for two days. After aging, the mixes were frozen using a scraped surface heat exchanger to -4°C and then stored at -40°C. Each type of ice cream was evaluated for particle size, d [4, 3] (volume-surface weight diameter), using a particle size analyzer and the melting rate by a melt test, which determined sample weight loss at ambient temperatures over time.

Particle size analysis showed, for samples containing MDG only, d [4, 3] values to be significantly higher at concentrations $\geq 0.09\%$. The d [4, 3] values for samples containing 0.05% and 0.10% CMC were significantly higher than the control when CMC concentrations were varied at set MDG concentrations of 0.075% or 0.15%. The melting rates were not significantly different at any of the tested concentrations.

The results show that the effect of stabilizers and emulsifiers on particle

size is concentration dependent. Using the proper amounts of stabilizers and emulsifiers in ice cream is important in order to produce a higher quality product that is more desirable to consumers.

Key Words: Melt Test, Particle Size, Ice Cream

TH31 Fluctuation on composition and insoluble aggregates in a WPC manufacturing line: Implications for quality and function. M. Costa^{2,1}, M. Gigante², P. Tong¹, and R. Jimenez-Flores*¹, ¹California Polytechnic State University, San Luis Obispo, ²UNICAMP, Campinas-Sao Paulo, Brazil.

In response to quality demands of users and producers of whey protein powders, we have investigated the basic influence that composition has upon processing of liquid whey into WPC in a commercial plant. Several researchers indicate either the formation of 'aggregates' or the difference in particle size in the whey concentrates, as the main causative agents of quality and functionality variation. However, very few studies have thoroughly analyzed the fundamental origin or causes for the variability of whey powders in a systematic and holistic way. This work is an initial step to gather base-line information on the range of variability in particle size and composition of the liquid whey protein concentrate (LWPC) and the resulting powder (WPC80) in a commercial plant. Our study was carried out for a period of 8 weeks in a plant that process in excess of 10 million pounds of milk per day. Due to security and sanitation aspects, employees of the plant did the sampling. Upon receipt each sample was divided and 15ml of the LWPC sample were frozen for later composition analyses (protein, fat, lactose, ash, total solids). For each set of sample, we prepared 5% protein solutions with the WPC and LWPC, which were stirred for 1 hour and analyzed in the same (LWPC) or in the following day (WPC). Particle size and Solubility were measured for each sample. All samples were analyzed for total composition. The results indicate that while protein concentrations are maintained within a narrow range, lactose and residual fat have the highest ranges of variation. During our study the liquid concentrate had an average of 20.22 (± 0.97) % protein, while lactose was 1.06 (± 0.58) and residual fat 1.35 (± 0.19); for the WPC protein was 78.78 (± 0.72), lactose 7.94 (± 1.12) and residual fat 5.66 (± 0.53). Particle size analysis resulted in Volume %: liquid concentrate solutions had no particle larger than 20 μ m (the LWPC were stored in a cooler until be analyzed; results could varied when heated), while the WPC solutions in average had around 27% of the particles in the over 20 μ m range, so mean and mode parameters had higher values in the WPC solutions. Our analysis of the proteins by SDS-PAGE indicates that the aggregates have a very complex composition that is not correlated with only insoluble b-LG. Our results seem to point towards differences in minerals and residual fat, as primary causative agents of particle size fluctuations in WPC manufacture. As for processing, Ca, pH and temperature along processing are major aggregate-inducing factors.

Key Words: Whey Protein Concentrate, Protein, Insoluble Aggregates

TH32 Influence of pulsed electric field processing on protease activity of *Lactobacillus acidophilus* LA-K in skim milk. O. Cueva¹ and K. Aryana*², ¹Louisiana State University, Baton Rouge, ²Louisiana State University Agricultural Center, Baton Rouge.

The objective was to study the effect of square waveform bipolar pulse widths on protease activity of *Lactobacillus acidophilus* LA-K. Freshly thawed *Lactobacillus acidophilus* LA-K was suspended at 1% wt/v in 0.1% wt/v peptone and was treated in an OSU-4 pilot plant pulsed electric field (PEF) processor. The processing conditions that remained constant were field strength of 25 Kv/cm, pulse period of 10000 us, delay time of 20 μ s and processing temperature of 21°C. The treatments were square waveform bipolar pulse widths of 0, 3, 6 and 9 μ s. Immediately after passing through the PEF processor the *Lactobacillus acidophilus* LA-K cell suspension was used to inoculate skim milk followed by incubation at 40°C. After 0, 12 and 24 h of incubation, protease activity in control and all treatments was evaluated by the *o*-phthalaldehyde (OPA) assay followed by absorbance measurements using a spectrophotometer set at 340 nm. The pulse width x incubation time interaction effect was significant ($P < 0.0001$). The maximum absorbance values were recorded for samples treated for 6 μ s and incubated for 24 hours (mean \pm SD) (0.45 ± 0.003) followed by 9 μ s for 24 h (0.43 ± 0.004), followed by 3 μ s for 24 h (0.35 ± 0.002) followed by the control (0.35 ± 0.006 absorbance units). A different trend was seen for the samples incubated for 12 h. Samples treated for 9 μ s showed maximum absorbance values (0.32 ± 0.006) followed by 6 μ s (0.25 ± 0.003) followed by 3 μ s (0.240 ± 0.000) followed by the control (0.213 ± 0.000 absorbance units). For a 24 h incubation, samples processed at 6 μ s pulse width gave the maximum protease activity, while for a 12 h incubation, samples processed at 9 μ s pulse width showed maximum protease activity.

Key Words: Pulse Width, Non Thermal, Processing

TH33 Production of native whey from whole milk. I. Jarto*¹, J. A. Lucey¹, D. Zhu¹, and K. E. Smith², ¹University of Wisconsin, Madison, ²Wisconsin Center for Dairy Research, Madison, WI.

The objective of the study was to investigate the viability of using whole milk (WM) as a starting material to produce native whey protein by spiral-wound microfiltration (MF). A single commercial scale 0.3 μ m polyvinylidene fluoride spiral-wound element was used. Pasteurized skim milk (SM) or pasteurized non-homogenized WM with an initial volume of 230 kg was microfiltered at either 4 or 13°C with inlet and outlet pressures of 120-135 kPa and 42-75 kPa, respectively. The milk was microfiltered to a volume concentration factor (VCF) of 3 with an hour of batch recirculation at VCF of 1, 2, and 3. Operating conditions and flux were recorded over time. Permeate and retentate samples were collected for compositional analysis. A Malvern Mastersizer was utilized to evaluate the fat globule size distribution before and after MF processing. MF performance was evaluated as a function of permeate flux rate and whey protein transmission over VCF of 1 to 3. At 4°C, lower MF flux was observed for WM compared to SM, particularly at higher VCF (probably due to increased viscosity of WM). During MF at 4°C, the average ratios of WM permeate flux to SM permeate flux at VCF 1, 2, and 3 were 0.98, 0.87, and 0.31, respectively. However, at 13°C the flux in WM was more comparable to SM, with average ratios of WM permeate flux to SM permeate flux at VCF 1, 2, and 3 of 1.00, 0.98, and 0.74, respectively. Fat globule size distribution was not altered by the MF processing in any trial. During MF at 4°C, the whey protein concentration in permeates at VCF 1, 2, and 3 were 0.09%, 0.13%, and 0.23% for SM and 0.09%, 0.16%, and 0.35% for WM, respectively. During MF at 13°C, the whey protein concentration in permeates at VCF 1, 2, and 3 were 0.06%, 0.12%, and 0.21% for SM and 0.05%, 0.11%, and 0.25% for WM, respectively. Our study concluded that native whey proteins can be separated successfully at low temperatures from WM

using spiral-wound MF membranes at rates comparable with the whey protein permeation rate in SM.

Key Words: Whole Milk, Microfiltration, Native Whey Protein

TH34 Flavor assessments of heated sweet cream butter. E. L. Harvey*, A. M. Renaud, and S. A. Rankin, *University of Wisconsin, Madison*.

Butter contains numerous compounds capable of reacting during the course of extended heat treatment such as baking or frying. The objective of this work was to determine the effect of heat treatment on the volatile character of unsalted sweet cream butter using instrumental and sensory methods. This work reports the qualitative presence of volatile compounds generated by extended heat treatment of butter. Pasteurized (87.2°C, 19s) 37% milkfat cream was churned to invert the emulsion. After draining the buttermilk, the fresh butter was analyzed for the presence of volatile compounds using GC/MS with SPME (DVD/

Carboxen/PDMS fiber). The butter was placed in a glass vial with Teflon-lined closure and rapidly heated to by immersion in a mineral oil bath. The heated samples were analyzed using GC/MS and SPME as above, and the results were compared with those of the fresh butter. The fresh sample contained numerous volatiles including short chain free fatty acids (butanoic acid, hexanoic acid, octanoic acid, nonanoic acid, and decanoic acid). Aldehydes and ketones were also found including hexanal, nonanal, 2-heptanone, and nonanone. The lactones δ -hexanolactone, δ -octalactone, and δ -decalactone, and one sulfur compound dimethyl sulfone occurred in both samples. The heated samples contained increases in the number of volatile compounds including lipid oxidation and Maillard reaction products. Partially trained descriptive panel assessments demonstrated relationships between heating and several sensory descriptors. This work provides a rapid method for the assessment of heated butter volatiles as well as describing the influence of thermal treatment on sensory character. Applications of this work may be used by processors to optimize flavor contributions resulting from heat treatment of butter.

Key Words: Heated Butter, Solid-Phase Microextraction, Sensory Analysis

Forages and Pastures III

TH35 Grazing management effects on physical and nutritional characteristics of pastures. M. Haan, J. Russell*, and D. Morrical, *Iowa State University, Ames.*

Cattle grazing in riparian areas may contribute to sediment and nutrient loading of surface waters. A study was conducted to evaluate the effects of cattle grazing on physical characteristics and the nutrient composition of cool-season grass pastures. Six 12-ha cool-season grass pastures, each bisected by a 195-m stream segment, were assigned to one of three treatments: continuous stocking with unrestricted stream access (CSU), continuous stocking with stream access restricted to a stabilized crossing (CSR), and rotational stocking with stream access in a riparian paddock (RS). In 2005, 2006, and 2007 each pasture was stocked from mid-May through mid-October with 15 Angus cows, initial BW (mean±SE) 614±72, 577±53, and 621±56 kg, respectively. Forage sward height and mass, and the proportions of bare and manure-covered ground were measured monthly from open and congregation sites on the stream banks and at distances of 0 to 34 m, 34 to 68 m, and greater than 68 m from the stream bank. Forage samples were analyzed for IVDMD, CP, and phosphorus (P). Occurrence of bare and fecal-covered ground were greater ($P<0.05$) in congregation than open areas of pastures across all grazing treatments during most months. Forage mass on stream banks did not differ between grazing treatments, but was lesser ($P<0.05$) within the 34 m zone of CSU pastures than in CSR pastures. Sward height was inversely related to forage mass. Proportion of bare ground on stream banks did not differ between grazing treatments. Proportions of bare ground within 34 m of the stream in CSU pastures were greater ($P<0.05$) than the CSR or RS pastures in late summer of 2005 and 2006. Fecal cover was greater ($P<0.05$) on the banks and within 34 m of the stream in CSU pastures than CSR pastures in most months. Crude protein and P concentration and IVDMD of forage did not differ between treatments. Forage characteristics and ground cover in the riparian area of a rotationally stocked pasture were similar to an ungrazed riparian buffer indicating that improved grazing management practices may be able to reduce negative impacts of cattle on surface water quality while still allowing use of riparian areas for cattle production.

Key Words: Water Quality, Forage Quality

TH36 Grazing management effects on selected stream bank characteristics and erosion. M. Haan¹, J. Russell*¹, and J. Kovar², ¹*Iowa State University, Ames*, ²*USDA-ARS, Ames, IA.*

Cattle grazing in riparian areas may contribute to sediment and nutrient loading of surface waters. A study was conducted to establish the effects of cattle grazing on stream bank erosion. Six 12-ha cool-season grass pastures, each bisected by a 195-m stream segment, were assigned to one of three treatments: continuous stocking with unrestricted stream access (CSU), continuous stocking with stream access restricted to a stabilized crossing (CSR), and rotational stocking with stream access in a riparian paddock (RS). In 2005, 2006, and 2007 each pasture was stocked from mid-May through mid-October with 15 Angus cows, initial BW (mean±SE) 614±72, 577±53, and 621±56 kg, respectively. Stream bank erosion susceptibility score (0 = low susceptibility, 60 = high susceptibility) and stream channel morphology (based on image analysis at 10 transects per pasture) were determined pre-, mid-, and post-grazing in all years. Stream bank erosion was measured at ten transects per pasture using erosion pins. Exposed pin length was measured monthly

during the grazing season, and one month post-grazing in all years. At one location per pasture, bank erosion was also measured with ground-based LiDAR (Light Detection and Ranging) pre- and post-grazing in 2006 and 2007. Stream banks in CSU pastures had a greater ($P<0.05$) erosion susceptibility score than did CSR or RS pastures. Stream cross-sectional area decreased at a rate of 13.0 cm² per day, with no difference ($P>0.05$) between grazing treatments. Annual net erosion, as determined by erosion pins, averaged -5.3 (erosion), 0.1 (deposition), and -6.6 (erosion) cm in 2005, 2006, and 2007, respectively, and did not differ ($P>0.05$) between treatments in any year. Over the entire study period (May, 2005 through December, 2007) the rate of net soil erosion from stream banks averaged -0.01 cm of soil per day and did not differ ($P>0.05$) between treatments. Similar to erosion pins, no differences ($P>0.05$) in soil erosion between treatments when measured by LiDAR. Grazing management had little effect on stream bank erosion during three years of the study.

Key Words: Water Quality

TH37 Ingestive behavior of dairy cattle during the different grazing down process of palisadegrass subjected to rotational stocking. A. C. Ruggieri*¹, E. R. Januskiewicz¹, D. R. Casagrande^{1,2}, A. G. Pascoa¹, R. A. Reis^{1,3}, and M. J. R. Paranhos da Costa^{1,3}, ¹*São Paulo State University, Jaboticabal, São Paulo, Brazil*, ²*Fundação de Amparo a Pesquisa do Estado de São Paulo, São Paulo, Brazil*, ³*Conselho Nacional de Desenvolvimento Científico Tecnológico, Brasília, Distrito Federal, Brazil.*

This study aimed evaluate the effect of different herbage allowance (HA) in a rotational stocking on animal behavior and the relationship between time of grazing and sward height and patterns of herbage ingestion of dairy cattle on palisadegrass (*Brachiaria brizantha* cv. Marandu). The experiment was carried out at UNESP in São Paulo State, Brazil, from November 2005 to April 2006. Treatments were four HA (4, 7, 10 and 13% of LW) allocated in a complete randomized block design with three replications. Measurements were performed in five grazing cycles and the stocking density was calculated aiming at a paddocks occupation of the eight hours in one day, and 21 days of resting period. The response variables analyzed were: vertical height of the plants in each feeding station, animal behavior and patterns of animal movement and search for herbage. The method of analysis was the focal behavior. The bite rates were different due to differences on HA. The bite rate was highest at the third grazing cycle due to the increase in the sward height. On the second grazing cycle the animals concentrated the grazing in the stratum above 15 cm in the 4 and 10% HA. In the 13% HA the animals grazed a highest layer of plants, due to great available herbage mass. In the forth grazing cycle the grazing stratum increased with the increment of the sward height. In highest heights, the animals reduced the grazing time. In all the HA the animals grazed stratum superior to 15 cm above the soil. In the fifth cycle, with 4% of HA the animals concentrated the grazing in the stratum height above 20 cm and above 10 cm in the 7% and 13% HA. When the herbage mass is abundant, the competition among the animals is smaller providing a selective grazing. In superior sward heights the animals dedicate less time in the grazing activities as a consequence of the highest herbage mass.

Key Words: Animal Behavior, Herbage Allowance, Sward Structure

TH38 Behavior of steers grazing novel endophyte tall fescues in southern Arkansas. B. Stewart*¹, P. Beck¹, D. Singh², and S. Gunter¹, ¹University of Arkansas, Hope, AR, ²Barenbrug USA, Tangent, OR.

Calves grazing Kentucky-31 (KY-31) tall fescue often exhibit signs of fescue toxicosis caused by ergot alkaloids produced by fungal endophytes. These fungal ergot alkaloids enable the tall fescue to be highly persistent in harsh conditions. Performance of calves grazing Endophyte-free (EF) tall fescue is improved but plant persistence is reduced. Novel endophyte (NE) tall fescues combine the advantages of plant persistence with the increased animal performance of fescues not containing the endophytes. Eleven 0.81-ha pastures (Una silty clay loam) were sprayed with 4.7 L glyphosate/ha and no-till seeded with EF (Barcel, Barenbrug USA, Tangent, OR), NE (Jessup AR542, Pennington Seed, Madison, GA; and BAR FA BE 9301A, Barenbrug USA), and KY-31 tall fescues in the fall of 2005. Calves (n=33, BW= 227 ± 6.7 kg, n=3/ pasture) were used to evaluate animal grazing behavior once/hour from daylight to dark on one day per month. Due to a treatment x time x month interaction ($P < 0.01$), data were separated by month and reanalyzed. In January and March grazing was affected ($P < 0.01$) by time of day across treatments. Calves were observed grazing for 94.5% of the observations prior to 11:30 and 84.9% of the observations thereafter in January. In March calves were observed grazing for 87.2% of the observations prior to 11:30 and for 77.8% of the observations between 11:30 and 16:30. Calves grazed for 96% of the observations after 16:30 with the exception of 17:30 where there was a tendency ($P = 0.09$) for KY-31 calves to graze less than the others (72 vs. 97%). In 2007 calves were removed from EF (lack of forage) and KY-31 (heat stress). In May 2006, there was a treatment x time interaction ($P = 0.08$). At 6:30, KY-31 tended ($P = 0.09$) to graze less (75 vs. 100%) than the EF and NE calves. Calves in EF pastures grazed more ($P < 0.01$) than the others (100 vs. 89%) at 8:30. At 9:30, 100% of all calves were cooling. At 11:30, NE grazed less ($P < 0.01$) than the others (54 vs. 100%). At 16:30, EF grazed more ($P < 0.01$) than the others (100 vs. 52%). The results of this experiment indicate that calves on NE pastures grazed more frequently during the heat of the day and stayed on pasture longer into the summer when compared to KY-31 and EF fescue.

Key Words: Tall Fescue, Grazing, Behavior

TH39 Giving beef calves a choice of pasture-type influences behavior and weight gain. H. T. Boland*¹, G. Scaglia², and W. S. Swecker, Jr.³, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²Iberia Research Station, LSU Agricultural Center, Jeanerette, LA, ³Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.

A 38-d backgrounding study was conducted to determine the response of spring born Angus cross-bred steer calves (n=54, initial BW=228±1 kg) when grazing endophyte-free tall fescue (*Festuca arundinacea* Shreb.) or alfalfa (*Medicago sativa* L.) as single monocultures or paddocks of 50% fescue and 50% alfalfa (by area) as adjacent monocultures (F: A). Fescue and alfalfa paddocks were rotationally stocked at a rate of 3.1 steers/ha while F: A stocking rate was 4.5 steers/ha. Calves were fitted with pedometers that recorded percentage of time spent standing, lying, or active (walking), and the number of steps taken per day. The experiment was a randomized complete block design and the MIXED procedure was used to analyze the data with block as a random effect, paddock as the experimental unit, and day as the repeated measure.

Alfalfa paddocks were of higher CP ($P < 0.0001$) than tall fescue paddocks (24 vs 12 %, respectively). Alfalfa paddocks also had lower ($P < 0.0001$) NDF (36%) and ADF (24%) than tall fescue paddocks (62 and 33%, respectively). Calves grazing alfalfa were more ($P = 0.03$) active (5.0%) than F: A calves (4.1%) while those grazing tall fescue did not differ in activity level from other treatments (4.8%). Similarly, calves grazing alfalfa took more ($P = 0.02$) steps/d (3072) than F: A calves (2411), with calves grazing tall fescue taking an intermediate number of steps/d (2927). Calves grazing tall fescue spent less ($P = 0.003$) time standing and more ($P = 0.003$) time lying (48.0 and 47.3%, respectively) than calves grazing alfalfa (49.2 and 45.8%, respectively) or the F: A calves (50.7 and 45.2%, respectively). Calves grazing alfalfa had lower ($P < 0.02$) ADG (0.57 kg) than calves grazing tall fescue (0.79 kg) or F: A (0.83 kg). Providing calves with a choice of forages improved their performance over grazing alfalfa alone. Calves could be maintained at a higher stocking rate with numerically greater ADG when given a choice of forages compared to tall fescue alone.

Key Words: Grazing Behavior, Adjacent Monocultures, Pedometers

TH40 Tall fescue based forage systems supplemented with winter annuals for stocker cattle. B. T. Campbell*¹, A. E. Fisher¹, G. E. Bates¹, J. C. Riggins², F. N. Schrick¹, and J. C. Waller¹, ¹University of Tennessee, Knoxville, ²University of Tennessee, Springfield.

A four year study (2004-2007) was conducted at Highland Rim Research and Education Center near Springfield, TN to compare tall fescue (*Lolium arundinaceum* Schreb.) forage systems in which rye (*Secale cereale* L.)/ryegrass (*Lolium multiflorum* Lam.) was used to supply additional high quality forage to stocker cattle. Twelve 1.2-ha pastures were assigned to two cool-season forages and two forage systems with three replicate pastures each. Cool-season forage treatments were: (1) endophyte-infected (*Neotyphodium coenophialum*) Ky-31 tall fescue and (2) Jessup MaxQ™ tall fescue. The two forage systems were: (1) stockpiled tall fescue, supplemental feed (a blend of byproduct feeds formulated to provide energy and protein equivalent to tall fescue hay) during winter, spring growth tall fescue and (2) stockpiled tall fescue, rye/ryegrass during winter when available, spring growth tall fescue and rye/ryegrass. Forage systems containing rye/ryegrass were established by drilling 38 kg of rye and 6.8 kg ryegrass in a prepared seedbed in 0.4 ha of the allotted 1.2 ha pasture area. All pastures were clipped in late spring to assure vegetative growth. In late-November, four weaned beef steers were randomly allotted to each pasture based on age, weight, and breed and remained on pastures until mid to late June. Steers grazed rye/ryegrass when it reached average height of 20 cm and were removed at an average height of 8 to 10 cm. Forage heights before and after grazing of rye/ryegrass and the number of days grazing were recorded. When forage was unavailable or insufficient, cattle were fed a byproduct-based supplement. Animal weights were collected on two consecutive days at the beginning and end of the trial. Data collected at 14-d intervals included: steer weight, forage availability by clipping strips (2 per 0.4-ha pasture), and blood serum for prolactin. Data were analyzed using the MIXED procedure of SAS and differences determined at $P < 0.05$. Steers grazing Jessup MaxQ™ pastures gained more ($P < 0.05$) weight and had higher ($P < 0.05$) serum prolactin levels than those grazing Ky-31 regardless of presence of rye/ryegrass.

Key Words: Tall Fescue, Beef Cattle, Stockers

TH41 Efficacy of EndoFighter™ for steers grazing endophyte-infected tall fescue pastures during summer. R. Norman^{*1}, C. D. Lane, Jr.¹, S. S. Block², A. E. Fisher¹, B. T. Campbell¹, F. N. Schrick¹, and J. C. Waller¹, ¹University of Tennessee, Knoxville, ²ADM Animal Nutrition Research, Decatur, IL.

An 84-d grazing trial was conducted (Jun 14-Sep 7) near Spring Hill, TN to determine the efficacy of EndoFighter™, an ADM Alliance Nutrition, Inc. product designed to be fed to cattle grazing or fed endophyte-infected fescue. Jesup tall fescue pastures grazed in this trial were >90% infested with *Neotyphodium coenophialum* (E+). Sixty weaned crossbred steers (267 kg) were used in a completely randomized design and randomly allotted to pastures with four animals per 1.2-ha paddocks and five replications per treatment. Treatments were ADM Alliance Nutrition, Inc. mineral products: 1) Mastergain® mineral = Control; 2) EndoFighter™ mineral; and 3) Prototype mineral. Steers had free choice access to E+ grass, water and shade. Steers were weighed on d 0, 1, 21, 42, 63, 83, and 84. Initial and final weights were an average of the two beginning and ending weights, respectively. Data collected were initial, d 21, d 42, d 63, and final weights, and ADG (period 1 = d 1 to 21; period 2 = d 22 to 42; period 3 = d 43 to 63; period 4 = d 64 to 84; total = d 1 to 84). Blood serum was collected at d 0, 21, 42, 63, and 84 for prolactin analysis. Mineral consumption and animal grazing behavior were determined at 14-d intervals. Data were analyzed using the MIXED procedure of SAS and differences determined at $P < 0.05$. For all variables except behavior, contrasts were performed to compare Control to mineral supplements containing EndoFighter™ or Prototype. This trial was conducted during extreme heat (d 1-42 had $30 \text{ d} \geq 32^\circ \text{C}$; d 43-84 had $31 \text{ d} \geq 35^\circ \text{C}$ with $19 \text{ d} \geq 39^\circ \text{C}$) and drought conditions, thus forage was limited during the last 42 d of the trial and E+ hay was provided. Total ADG (kg) and average daily mineral consumption (g) were: 0.50, 134; 0.54, 147; 0.44, 116; for Control, EndoFighter™ and Prototype, respectively. Serum prolactin was not different ($P > .05$) among treatments for the entire trial. However, serum prolactin levels for EndoFighter™ were higher ($P < 0.05$) than Control at d 21 (26.0 vs. 10.1 ppb, respectively) and d 42 (58.9 vs. 30.8 ppb, respectively).

Key Words: Beef Heifers, Tall Fescue, EndoFighter™

TH42 Two year study on finishing beef cattle performance and forage characteristics of ryegrass (*Lolium perenne*), rye (*Secale cereale*) and oats (*Avena sativa*). A. C. Pereira^{*}, E. J. Bungenstab, J. C. Lin, B. Gamble, S. P. Schmidt, C. R. Kerth, and R. B. Muntiferung, Auburn University, Auburn, AL.

A 2-yr grazing trial was conducted with ryegrass (RG; *Lolium perenne*), rye (R; *Secale cereale*) and oats (O; *Avena sativa*) as winter pasture for forage-finished beef. Replicate 1.42-ha paddocks (2 per forage) were established and stocked initially with 3 Angus × Continental crossbred steers per paddock (374 ± 5.5 kg initial BW in year 1 and 410 ± 7.0 kg in year 2). All steers had free-choice access to salt-mineral mix and water. Grazing was initiated on Jan 19 (84 d grazing season in year 1) and on Nov 27 (145 d grazing season in year 2) when average forage DM availability reached 1000 kg/ha. Forage mass and nutrient composition were determined by clipping 0.25-m² quadrats (n=8 per paddock) prior to the beginning of grazing and every 2 wk during the trial. Stocking rates were adjusted using put-and-take steers to maintain forage in the vegetative stage. Evaluation of animal performance was discontinued when steers reached 530 kg. Average daily gain differed ($P < 0.05$) between years, but there was no animal × year interaction. In year 1, seasonal-

mean ADG (1.81 ± 0.03 kg/d) did not differ among treatments. In year 2, RG produced higher ($P < 0.05$) ADG (1.18 ± 0.06 kg/d) than did R (0.94 ± 0.06 kg/d), but ADG did not differ between RG and O (1.03 ± 0.06 kg/d). There was no year effect or year × treatment interaction for forage concentrations of CP and NDF. Rye contained more CP ($19.8 \pm 0.8\%$) than did RG ($17.4 \pm 0.8\%$), but %CP did not differ between R and O ($17.9 \pm 0.8\%$). Ryegrass had lower ($P < 0.05$) concentration of NDF ($40.0 \pm 1.4\%$) than did O ($46.3 \pm 1.4\%$) and R ($45.1 \pm 1.4\%$). Total gain/ha differed ($P < 0.05$) between years, but there was no year × treatment interaction. Year 1 had lower ($P < 0.05$) gain/ha (371 ± 17.0 kg) than did year 2 (556 ± 17.0 kg/ha). There were no differences in total gain/ha among forage sources in either year, however RG was superior than R but did not differ from O in year 2 in supporting ADG.

Key Words: Grazing, Finishing, Pasture

TH43 Effect of forage species during finishing on growth rate, final weight and carcass parameters from pasture finished cattle. J. P. S. Neel^{*1}, J. P. Fontenot², W. M. Clapham¹, S. K. Duckett³, E. E. D. Felton⁴, and W. S. Swecker, Jr.², ¹USDA-ARS-AFRC, Beaver, WV, ²Virginia Polytechnic Institute and State University, Blacksburg, ³Clemson University, Clemson, SC, ⁴West Virginia University, Morgantown.

In 2005 and 2006, Angus-crossbred steers (n = 72; 431 ± 40 kg initial BW) were used to compare growth rate, final weight and carcass parameters from pasture-finished cattle grazing cool-season mixed (MP), alfalfa (AL), or pearl millet (PM) pastures during the final 44 d of finishing. Mixed pasture consisted primarily of bluegrass (*Poa pratensis* L.), orchardgrass (*Dactylis glomerata* L.), fescue (*Festuca* L.) and white clover (*Trifolium repens* L.). Steers were harvested on the same dates, across treatments, at a commercial meat plant. Forage species did not influence final weight (FW), marbling score (MS), quality grade (QG), rib fat (RF), kidney, pelvic and heart fat (KPH) or yield grade (YG). Forage species influenced ($P < 0.05$) ribeye area (REA) with PM being greater ($P < 0.05$) than MP and AL. There was a trend ($P = 0.06$) for forage species to impact carcass weight (CW) with PM tending ($P < 0.06$) to be greater than MP and AL. Year influenced REA and KPH with REA being greater ($P < 0.05$) in 2006 and KPH being greater ($P < 0.05$) in 2005. The interaction between finishing treatment and year was significant ($P < 0.05$) for finishing period ADG (ADG) and dressing percentage (DP). Year did not influence ADG for MP or PM while ADG was greater ($P < 0.001$) in 2005 than 2006 for AL. Pearl millet produced greater ($P < 0.05$) ADG than MP. In 2005, AL had equivalent ADG to PM but lower ($P < 0.05$) ADG than PM and MP in 2006. Year influenced ($P < 0.05$) DP in AL and PM, being greater in 2006 than 2005. Dressing percentage was greater ($P < 0.05$) for AL and PM than MP in 2006. Pearl millet and MP produced consistent ADG across years. Animal performance was improved with PM versus MP during both years and was greater than AL in 2006.

Key Words: Finishing, Pasture, Forage

TH44 Performance and carcass characteristics of the supplemented or not beef heifers grazing palisade grass (*Brachiaria brizantha*) on the rainy season. D. R. Casagrande^{1,2}, R. A. Reis^{*1,3}, A. C. Ruggieri¹, T. T. Berchielli^{1,3}, M. H. Moretti^{1,2}, J. F. de Mattos^{1,2}, and M. A. A. Balsalobre⁴, ¹São Paulo State University, Jaboticabal, São

Paulo, Brazil, ²Fundação de Amparo Pesquisa do Estado de São Paulo, São Paulo, São Paulo, Brazil, ³Conselho Nacional de Desenvolvimento Científico e Tecnológico, Brasília, Distrito Federal, Brazil, ⁴Bellman Nutrição Animal, Mirassol, São Paulo, Brazil.

This research evaluated performance (kg/d and kg/ha) and carcass characteristics of beef heifers (initial BW = 200 kg; 1/4 Saint Gertrudis × 1/4 Nelore × 1/2 Braunvieh) grazing palisade grass pastures from December 2006 to April 2007. Treatments were the factorial arrangement of three forage allowances (FA; 2.0, 2.5, 3.0 kg DM/kg BW) and two levels of supplementation (none, C; 0.3%BW/d, PS), distributed in a randomized complete block design with two replications. The PS ingredients were: cotton seed meal, citrus pulp, urea, Megalac[®], and mineral (26.0% CP, 81.0%TDN). Six tester heifers were stocked continuously in each experimental unit (1.0 ha). Desired FA was maintained using put-and-take heifers (BW = 230 kg). Average daily gain was 0.49 and 0.66 kg/d for C and PS (P<0.05), respectively; response to PS was greater (P<0.05) at the end of experimental period. Supplementation increased (P<0.05) gain per unit of land from 523 to 627 kg/ha. Forage allowance did not affect (P>0.05) ADG (0.48, 0.53, 0.60 kg/d for 2.0, 2.5, and 3.0 kg DM/kg LW, respectively). Gain per unit of land increased (P<0.05) from 502 to 647 kg/ha as FA increased from 2.0 to 3.0 kg DM/kg LW. Heifers supplemented with PS had larger (P<0.05) *longissimus dorsi* muscle area but fat thickness over the loin and rump were not affected. We conclude that supplementation increased ADG, gain per unit of land, and *longissimus dorsi* muscle area of beef heifers grazing palisade grass pastures in different forage allowances.

Key Words: Forage Allowance, Supplementation, Tropical Grass

TH45 Productivity, utilization and nutritive quality of dallisgrass (*Paspalum dilatatum*) as influenced by stocking density under continuous or rotational grazing. E. J. Bungenstab*, A. C. Pereira, J. C. Lin, J. L. Holliman, and R. B. Muntifering, Auburn University, Auburn, AL.

Information on dallisgrass (*Paspalum dilatatum*) under intensive grazing is limited. Therefore, we conducted a trial in which replicate 0.40-ha paddocks in a dallisgrass pasture were continuously grazed (CG), or replicate 0.40-ha paddocks were subdivided into either two 0.20-ha, three 0.13-ha or four 0.10-ha cells and rotationally grazed (RG). Within RG treatments, 0.20-, 0.13- and 0.10-ha cells were grazed for 7 d followed by 7, 14 or 21 d rest, respectively. Three Angus × Continental crossbred steers (initial BW, 354 ± 6 kg) were assigned randomly to each paddock initially, and cattle were weighed at 28-d intervals. Post-grazing residual forage DM and pre-grazing forage DM availability and quality were measured weekly in RG cells, concurrently with measurement of forage DM availability and quality in CG paddocks. One steer was removed from each paddock after 28 d because of persistent drought. Data were analyzed by the GLM/Least Squares Means procedure of SAS. Over the 84-d trial, total liveweight gain from the 0.10-ha cells (143 kg/ha) was greater (P = 0.08) than from 0.13-ha cells (63 kg/ha), but was not different from 0.20-ha cells (111 kg/ha) or CG paddocks (108 kg/ha). Similarly, ADG was greater (P = 0.08) for RG steers from 0.10-ha (1.03 kg/d) than 0.13-ha (0.45 kg/d) cells, but was not different between steers from 0.20-ha cells (0.80 kg/d) or CG paddocks (0.78 kg/d). Mean forage concentration of CP was greater (P = 0.09) for 0.10-ha and 0.13-ha than 0.20-ha cells and CG paddocks. Forage concentration of NDF was lower (P = 0.03) for 0.13-ha cells than CG paddocks, and ADF concentration was lower (P = 0.07) for CG paddocks, 0.10-ha and 0.13-ha cells than

0.20-ha cells. Mean forage DM availability was greater (P = 0.03) for the 0.20-ha, 0.13-ha and 0.10-ha cells (2819, 2587 and 2462 kg/ha, respectively) than CG paddocks (1793 kg/ha), and mean residual forage DM following grazing in the RG cells (2,172 kg DM/ha) was not different from the CG paddocks. Results indicate that intensive RG management of dallisgrass has potential for increasing forage productivity while maintaining nutritive quality compared with CG.

Key Words: Dallisgrass, Rotational Grazing, Stocking Density

TH46 Supplementation with different levels and sources of energy for steers on *Panicum maximum* Jacq cv Tanzânia pasture: forage availability, morphological composition and nutritive value. M. C. Ar. Santana*¹, V. P. B. Euclides², and A. B. Mancio³, ¹Universidade Estadual Paulista, Jaboticabal, São Paulo, Brazil, ²Empresa Brasileira de Pesquisa Agropecuária - Embrapa, Campo Grande, Mato Grosso do Sul, Brazil, ³Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.

Tropical forages are the primary base of the bovine production system and supplementation strategies contribute to improved utilization. This experiment was carried out to evaluate the forage mass, morphological composition, and nutritional value of *Panicum maximum* Jacq. cv Tanzânia, and the influence of supplementation with different levels and energy sources on animal performance. The experiment was conducted from July 22 to October 21, 2005, on guineagrass pasture fertilized with two levels of N (150 and 300 kg of N/ha/yr). Forty-eight crossbred steers, average age = 12 mo, were used in a completely randomized design of a 2×3 factorial treatment arrangement (2 N levels and 3 supplements), with four replications. The supplements were: a) mineral salt, and supplementation at 1% of LW with the following supplements, b) 41.1% corn, 49.5% soybean meal, 2.5% calcium carbonate, 0.6% mineral salt, 6% NaCl and 0.06% of rumensin; c) 24.3% soybean meal, 24.3% soybean hulls, 48% soybean seed, 2.5% calcium carbonate, 0.6% of mineral salt, 6% NaCl and 0.06% of rumensin. There were no treatment interactions (P>.63) for forage variables of that were evaluated. The supplements did not influence the morphological composition (P>.43), mass (P>.45) or nutritional value (P>.06) of the forage. The steers supplemented with 1% LW performed better (P<.01) than those supplemented with mineral salt. However there was no effect (P>.14) of energy source, being on average, 500, 960 and 1,000 g/steer/d for supplement a, b and c, respectively. The fertilizer N level influenced the CP (P<.05), in vitro organic matter digestibility (P<.05) and mass (P<.02) of forage which were higher for the highest level of fertilization. In spite of variation in its composition and available forage, the guineagrass pasture was able to maintain, throughout the dry season, a reasonable nutritional value.

Table 1. Least square means for forage mass (FM), crude protein (CP), in vitro organic matter digestibility (IOMD) of guineagrass fertilized with 150 (N150) and 300 (N300) kg/ha.

	N150	N300	Pr>F
FM (kg/ha of DM)	2320 (190)	3017 (222)	0.02
CP (%)	7.1 b (0.27)	9.0 a (0.32)	0.05
IOMD (%)	51.0 b (1.13)	57.4 a (1.35)	0.05

Means followed by different letters in the same row are different by Tukey's Test (P<0.05). Values between parentheses represent the standard means error.

Key Words: Levels of Nitrogen, Feed Supplementation, Forage Mass

TH47 Monensin and *Saccharomyces cerevisiae* as additive for beef heifers grazing *Brachiaria brizantha* cv. Marandu. L. M. Abaker Bertipaglia^{1,3}, G. M. Peruca de Melo¹, A. Prates e Oliveira^{1,3}, R. Andrade Reis^{*1,2}, T. T. Berchielli^{1,2}, A. S. Ferraudo^{1,2}, E. Braga Malheiros^{1,2}, and L. Abaker Bertipaglia¹, ¹São Paulo State University, Jaboticabal, São Paulo, Brazil, ²Conselho Nacional de Desenvolvimento e Tecnológico, Brasília, Distrito Federal, Brazil, ³Coordenação de Aperfeiçoamento de Pessoal de Nível Superior, Brasília, Distrito Federal, Brazil, ⁴Fundação de Amparo à Pesquisa do Estado de São Paulo, São Paulo, São Paulo, Brazil.

This trial was conducted to evaluate protein supplementation with additives on performance of heifers (Santa Gertrudez, Brahman, Nelore) maintained in palisade grass pasture. The experiment was performed during the transition from rainy to dry season (P1-March to June) and in the dry period (P2-July to September). The supplements were: mineral (M); protein supplement (PS); PS plus monensin (PSM, 137mg/kgDM); PS plus yeast (PSY, 43×10⁶CF/kgDM); and PS plus monensin and yeast (PSMY). Supplementation levels were 0.4% BW in P1, and 0.5% BW in P2. Forage quantity and quality were evaluated in addition to total DM, intake and total animal weight gain (TWG). The data were analyzed as a randomized block design with repeated measures. Pasture total herbage mass, green dry matter mass, and leaf proportion decreased after June (beginning of P2). Forage quality (cell wall, N and in vitro organic matter digestibility) in extrusa samples changed little during the periods. During P1, SPM heifers had the lowest forage intake (1.8%BW); the other treatments averaged 2.0%BW. However, in P2 all supplement groups had lower forage intake (average 1.5%BW) than M (2.0%BW). The additives PSM, PSY and PSMY increased supplement intake (0.5%BW) compared to PS (0.4%BW). Protein supplementation increased TWG (37.1 and 47.0kg/period, P1 and P2), compared to the animals of the M supplementation (24.0 vs 22.7 kg/period, P1 and P2). The PSM group gained more TWG (40.7kg) than PSY (30.9kg) in P1; however in P2 the additives did not affect the TWG. Animal performance was associated with forage green DM mass, green and died proportions. Extrusa sampling methodology was not a good approach to evaluate the supplementation effects in this trial.

Key Words: Intake, Supplementation, Tropical Grass

TH48 Effects of rumen degradable protein supplementation on forage intake and digestibility of early weaned beef calves consuming stargrass hay and receiving soybean hull supplementation. T. Saraiva¹, J. M. B. Vendramini^{*1}, L. E. Sollenberger², U. Inyang¹, R. Farias¹, and J. D. Arthington¹, ¹University of Florida, Ona, ²University of Florida, Gainesville.

The objective of this study was to evaluate the effects of different levels of rumen degradable protein supplementation, on forage intake and digestibility of early weaned calves consuming stargrass (*Cynodon nlemfuensis*) hay and receiving 0.85% BW soybean hulls supplementation. The experiment was conducted at the Range Cattle Research and Education Center, Ona, FL from 4 June 2007 to 7 July 2007. Calves were weaned on 6 Jan 2007 at an average age of 84 d. They grazed annual ryegrass (*Lolium multiflorum*) pastures and were moved to a stargrass pasture on 5 May 2007. The treatments were three levels of rumen degradable protein supplementation, soybean meal (SBM, 35% RUP 65% RDP), a 50:50 mixture of SBM-soyplus[®] (modified expeller soybean meal, 60% RUP 40% RDP), or soyplus[®], supplemented at

0.15% BW. Three early weaned steers (160±18 kg BW) were used. The statistical design was a latin square 3 x 3, 3 treatments and 3 periods (10 d adaptation, and 7 d data collection). Ground stargrass hay (11% CP, 51% IVOMD) was offered daily and adjusted to allow 10% refusals. Daily offered forage and refusals were weighed, and subsampled for DM determination. Total feces production was collected, placed in aluminum pans, and dried at 60°C for diet apparent digestibility determination. There was no difference (P>0.10) in forage DM and total DM intake among treatments. Forage DM and total DM intake were 2.2±0.1 and 2.9±0.1 % BW respectively. In addition, there was no effect of different levels on rumen degradable protein supplementation on diet apparent digestibility, 57.5±2.5 %. In conclusion, it is unlikely that rumen degradable protein supplementation at the levels tested in this study will improve performance of early weaned calves that are being fed soybean hulls while grazing warm-season grasses pastures during the summer in Florida.

Key Words: Early Weaned Calves, Forage Intake, Stargrass

TH49 Effect of urea inclusion and cooking time on intake of blocks containing greasy cottonseed meal by beef cows. T. A. Wickersham^{*1}, F. M. Rouquette², J. E. Sawyer¹, and R. O. Dittmar, III¹, ¹Texas A&M University, College Station, ²Texas AgriLife Research, Overton, TX.

One hundred pregnant, spring-calving beef cows (body condition score (BCS) = 5.2 and BW = 574 kg) were used to evaluate intake of cooked molasses protein supplements. Cows were stratified by BCS and BW, and randomly assigned to 1 of 12 dormant Tifton 85 bermudagrass pastures from October 1 through November 2. Pastures were randomly assigned to receive a block type (3 pastures per block type). All blocks contained 25% greasy cottonseed meal (a byproduct of the biodiesel industry, 30% CP), but differed in urea content and length of cooking. Blocks contained 0 (N) or 20 equivalents of CP from urea (U) and were cooked for a standard time to achieve regular hardness (R) or for an extended time to increase hardness (H) in a 2 × 2 factorial arrangement to yield NR, NH, UR, and UH. Blocks were weighed and hardness measured with a penetrometer 3 times weekly to determine intake and block hardness. Cow BW and BCS were recorded on d 0 and d 33. Cow data were analyzed as a completely random design with pasture as the experimental unit. Block hardness and disappearance were evaluated as repeated measures with pasture as the subject. Block hardness was influenced by the interaction between urea inclusion and cook time (P = 0.01). Blocks without urea were hardest regardless of cook time (NR = 8.3, NH = 8.1 kg/cm²); including urea softened blocks, but increasing cook time increased hardness (UR = 4.57, UH = 5.34 kg/cm², SE = 0.16). A cook × urea × day interaction existed (P = 0.03) for block intake, driven by greater intake (P < 0.03) of UR than all other block types from d 7 to 19. Block intake was influenced by the interaction between urea inclusion and cook time (P = 0.01). Urea inclusion increased intake, but longer cook time reduced intake of urea containing blocks by 44% (P < 0.01) while longer cook time resulted in only numerical reductions in intake of N blocks (1.06, 0.59, 0.46, 0.35 ± 0.05 kg/d; UR, UH, NR, NH, respectively). Block type did not result in significant BCS changes; however, including urea tended (P = 0.07) to increase BCS change (U = 0.22, N = -0.28). Similarly, BW change was not affected by treatment (P > 0.21), but increased for all treatments during the study.

Key Words: Protein, Supplement, Self-Fed

TH50 Effects of three levels of rumen degradable protein supplementation on performance of early weaned calves grazing stargrass and receiving soybean hulls. T. Saraiva¹, J. M. B. Vendramini^{*1}, L. E. Sollenberger², U. Inyang¹, R. Farias¹, and J. D. Arthington¹, ¹University of Florida, Ona, ²University of Florida, Gainesville.

Warm-season grasses have reduced concentrations of CP fraction A, rapidly degradable in the rumen, and rumen degradable protein may be a limiting factor on performance of early weaned beef calves grazing warm season grasses. The objective of this study was to evaluate the effects of different levels of rumen degradable protein supplementation on performance of early weaned calves grazing stargrass (*Cynodon nlemfuensis*) pastures and receiving 0.85% BW of soybean hulls. Calves were weaned on 6 Jan. 2007 at an average age of 84 d. They grazed annual ryegrass (*Lolium multiflorum*) pastures until 5 May 2007, when they were moved to experimental pastures where they remained until 22 Aug. 2007. The treatments were three levels of rumen degradable protein supplementation, soybean meal (SBM, 35% RUP 65% RDP), a 50:50 mixture of SBM-soyplus[®](modified expeller soybean meal, 60% RUP 40% RDP), or soyplus[®], supplemented at 0.15% BW, and distributed in a randomized incomplete block design. Treatments SBMSP and SP were replicated three times and SBM two times. The experimental units were 0.51-ha pastures, each divided into two paddocks for rotational stocking (14-d grazing and 14-d rest period). Four calves were assigned to each pasture. Every 28 d, calves were weighed and average daily gain calculated. Herbage mass was measured every 14 d using the disk plate meter methodology. Hand plucked samples were collected every 14 days and were analyzed for CP and IVOMD. There was no difference ($P \geq 0.10$) in forage CP (11%), IVOMD (56%), herbage mass (1880 kg/ha), and herbage accumulation (99 kg/ha/d) among treatments. Calves average daily gain did not differ among treatments (0.56 kg/d). The levels of rumen degradable protein treatments tested in this study did not improve performance of early weaned calves grazing stargrass and receiving soybean hulls. It is likely that soybean hulls supplementation supplied the RDP required by early weaned calves grazing stargrass and affected the response of the rumen degradable protein treatments.

Key Words: Early Weaned Calves, Stargrass, Rumen Degradable Protein

TH51 Comparing mathematical models to estimate *in vitro* gas production kinetic parameters of the forage consumed by grazing cattle. M. Murillo-Ortiz, M. A. Cerrillo-Soto*, E. Herrera-Torres, O. Reyes-Estrada, A. Juárez-Reyes, G. Nevárez-Carrasco, and E. Ávila-Rodríguez, *Universidad Juárez del Estado de Durango, Durango, Dgo. México.*

The goodness-of-fit test of three mathematical models: Mitscherlich (M1), McDonald (M2) and Orskov and McDonald (M3) to describe the kinetic parameters of *in vitro* gas production from forage selected by grazing cattle was evaluated. Extrusa samples from four steers were incubated in 100 ml calibrated glass syringes. Gas production measures overtime were fitted to the models. The residual mean square (RMS) and the mean square of predicted error (SMPE) were used as selection criteria. The NLIN procedure NLIN (SAS, 2003) was utilized to estimate the kinetic parameters and to evaluate the goodness-of-fit of the models. The parameters and the statistical criteria were then analyzed in a completely randomized design. Means were compared using Tukey's test. The gas produced from the soluble fraction **a** (ml/500 mgDM) was different among models ($P < 0.05$). Values ranged from

-12.2 with M3 to 0.709 with M1. The highest value ($P < 0.01$) for the gas produced from the insoluble but slowly degradable **b** (ml/500mgDM), was recorded with M1 (97.4 ml/500mgDM) and the lowest with M3 (60.5 ml/500mgDM). The potential gas production **a+b** was similar in M2 (100.5ML/500mgDM) and ($P > 0.05$) M1 (98.1ml/500mgDM); however, both values were higher ($P < 0.05$) than those obtained with M3 (48.3ml/500mgDM). The constant rate of gas production **kd** was highest ($P < 0.05$) with M1 (7.2 % h^{-1}) and the lowest with M3 (3.4 % h^{-1}). Regarding to the statistical criteria to evaluate the goodness-of-fit test of the models, both the RMS and the SMPE were different ($P < 0.05$) among models. M1 had the best goodness-of-fit with values of 7.5 for RMS and 20.3 for SMPE which were lower to those registered with M2 (RMS=15.0; SMPE=58.1) and with M3 (RMS=40.3; SMPE= 112.5). It is concluded that M1 had the best statistical performance to describe the kinetic parameters of *in vitro* gas production.

Table 1. Statistical criteria for fitting of the models to evaluate *in vitro* gas production kinetics

Models	Parameters					
	a	b	a+b	kd	I	lag
M1	0.70 ^c	97.4 ^a	98.1 ^a	7 ^a	2.74	
M2	4.75 ^b	95.3 ^a	100.5 ^a	4 ^b		4.3
M3	-12.2 ^a	60.5 ^b	48.3 ^b	3 ^c		
Means	5.8	84.4	82.3	4.6		
SD	1.8	2.6	3.3	0.01		
			Selection criteria			
Models	RMS	SMPE				
M1	7.6 ^c	20.3 ^c				
M2	15.0 ^b	58.1 ^b				
M3	40.3 ^a	112.5 ^a				
SD	0.27	0.91				

Means within columns with different superscript differ ($P < 0.05$); RMS=residual mean square; SMPE=square mean of predicted error; I and lag=lag phase (h); a, b (ml/500mgDM); kd (% h^{-1})

TH52 Comparison of techniques for estimation of forage dry matter intake by cattle grazing grass pastures. M. Undi*, K. H. Ominski, C. Wilson, and K. M. Wittenberg, *University of Manitoba, Winnipeg, Manitoba, Canada.*

Four techniques were compared for their ability to estimate forage DMI of grazing animals. In the Cage technique, the difference between forage clipped from 0.25m² quadrats inside and outside grazing cages after 12 to 20 days of grazing represented forage consumed by grazing animals. The second technique used n-alkane controlled release capsules to measure DMI of individual animals (n-alkane marker technique). The other two techniques were prediction equations; one utilized BW and ADG to estimate DMI (Minson equation) and the other related dietary net energy concentration and BW to DMI (Net Energy equation). The four methodologies were applied to a three-year study evaluating liquid hog manure on the productivity of grass pastures. The study utilized steers of a relatively uniform body size on six continuously-grazed grass pastures. When individual animal intakes were compared, the Net Energy equation estimated lower ($P < 0.05$) DMI than the Minson equation, with the n-alkane marker technique being intermediate. Dry matter intake (mean±SD, kg d⁻¹) was 5.3±0.76, 7.3±0.53, and 6.5±2.58 for the Net Energy equation, Minson equation, and n-alkane marker

technique, respectively. Dry matter intake estimated by the Cage technique averaged $17.5 \pm 11.61 \text{ kg d}^{-1}$ and was higher ($P < 0.05$) than estimates from the other techniques. Dry matter intake estimates from different techniques were ranked ($P < 0.05$): Cage technique > Minson equation > n-alkane marker technique > Net Energy equation. The DMI estimates generated by the Cage technique had the largest coefficient of variation, with extreme values representing a DMI range from 0.3 to 15.2% BW. The strongest correlation ($r = 0.48$; $P = 0.0001$) in DMI estimates was between the Net Energy and Minson equations due to the inclusion of BW as a component in both equations. The n-alkane marker technique and prediction equations produced repeatable DMI estimates. These results suggest that prediction equations can be useful for rapid DMI estimation and that the n-alkane marker technique may be more suitable when a wide range of pasture conditions are expected over the course of the evaluation period.

TH53 An alternative method to assess 24h ruminal *in vitro* neutral detergent fiber digestibility. J. P. Goesser*, P. C. Hoffman, and D. K. Combs, *University of Wisconsin, Madison*.

Run to run variance due to the inconsistent nature of rumen fluid inoculum confounds comparisons of forage *in vitro* NDF digestibility (NDFD) analyzed in different repetitions or laboratories. Our objective was to determine if priming rumen fluid and allowing it to produce a standard amount of gas before inoculating samples improved assay repeatability. In two experiments, we compared run to run variance of NDFD estimates between two modified Goering and Van Soest (1970) *in vitro* assays. In both assays, dried, ground (1mm) alfalfa samples (0.5 g) sealed in Ankom F57 bags were placed in 125 ml Erlenmeyer flasks and incubated with Van Soest *in vitro* media and 10 ml of rumen fluid. In experiment 1, rumen fluid was collected from a cannulated cow fed a high forage diet and prepared one of two ways; rumen fluid was either used immediately after it was collected and strained through cheese cloth (GVA), or strained fluid was combined with buffer, reducing solution and 12.5mg cellulose/ml rumen fluid and allowed to produce 0.3ml gas/ml rumen fluid prior to inoculation (RPA). The assay was repeated 5 times, with 13 samples per method. In experiment 2, inoculum was prepared one of three ways; RPA, GVA except rumen fluid was collected and pooled from two cows (GVP), or RPA with fluid pooled from 2 cows. The *in vitro* assays were repeated 5 times with 8 samples per method. NDF was analyzed using Ankom²⁰⁰ forage fiber analyzer and 24h NDFD was determined as: $\text{NDFD (\% of NDF)} = 100 \times [(\text{NDF}_{0\text{h}} - \text{NDF}_{\text{residue}}) / (\text{NDF}_{0\text{h}})]$. Data for each experiment were analyzed using a mixed model procedure and repetition sum of squares for each technique were determined and compared with an F-test to assess technique repeatability. In both experiments rumen fluid priming significantly reduced rep sums of squares, 51.2 v. 503 and 23.3 v. 164, compared to the respective GVA or GVB. However priming significantly decreased NDFD values, 22.5 v. 24.8 and 23.9 v. 26.6%, compared to GVA and GVB, respectively. Priming rumen fluid with cellulose improved ivNDFD assay precision, but depressed ivNDFD.

Key Words: In Vitro, NDF Digestion, Methods

TH54 Improvement of the rumen fluid priming method for measuring *in vitro* NDF digestibility. J. P. Goesser*, P. C. Hoffman, and D. K. Combs, *University of Wisconsin, Madison*.

Recently we developed an alternate method to assess 24h *in vitro* NDF digestibility (ivNDFD) based on priming rumen fluid inoculum. Priming rumen fluid inoculum with cellulose improved ivNDFD assay repeatability but depressed ivNDFD means. Our objective in this study was to determine if priming with a mixture of carbohydrate and urea would affect ivNDFD mean and variance. Three modified Goering and Van Soest (1970) ivNDFD assays were evaluated over 24, 28, 48, 54, and 72h using dried, ground (1mm) alfalfa or wheat straw (0.5g) sealed in Ankom F57 forage fiber bags. Bags were placed in 125ml Erlenmeyer flasks and incubated with Van Soest media and 10 ml of rumen fluid. Rumen fluid was collected prior to feeding from two cannulated cows fed a high forage diet and was prepared in one of three ways; pooled rumen fluid was strained and used immediately to inoculate flasks (GV); strained, pooled fluid was combined with buffer, reducing solution and 0.125mg primer/ml rumen fluid and allowed to produce 0.3ml gas/ml rumen fluid prior to sample inoculation (CG); CG method without the primer mixture (UN). The assay was repeated 5 times, with 5 time points and 2 subsamples/time point/method. Neutral detergent fiber was analyzed using an Ankom²⁰⁰ forage fiber analyzer and NDFD was determined as: $\text{NDFD (\% of NDF)} = 100 \times [(\text{NDF}_{0\text{h}} - \text{NDF}_{\text{residue}}) / (\text{NDF}_{0\text{h}})]$. Results were analyzed using a mixed model procedure, and data were subset by method to obtain repetition sum of squares, which were compared with an F-test to assess method repeatability. The ivNDFD rate (%/h), extent (% NDF), and lag time (h) did not differ between the methods (6.47, 47.4, 10.6 and 4.67, 45.2, 12.3) for alfalfa and straw respectively. Rep sums of squares was reduced with CG compared to GV (19 v. 228, $P < 0.018$), however mean NDFD estimates were similar (35.51 v. 35.94). These results suggest the modified ivNDFD method using rumen fluid primed with a mixture of carbohydrate and urea reduced run to run error and resulted in similar estimates of NDFD as the modified Goering and Van Soest method.

Key Words: In Vitro, NDF Digestion, Methods

TH55 Comparison of means and run to run variation of *in vitro* NDFD between two labs using different *in vitro* NDFD methods. J. P. Goesser*, L. M. Bauman, P. C. Hoffman, and D. K. Combs, *University of Wisconsin, Madison*.

This study compared the results and precision of a modified *in vitro* NDFD assay (CG), run in our research lab, to a modified Goering and Van Soest (1970) ivNDFD assay (COM) run at the UW-Marshfield Soils & Forage Laboratory (Marshfield, WI). Nine dried, ground (1mm) forage samples were evaluated in duplicate in three repetitions for 24, 30, and 48h ivNDFD by both laboratories, using a coded design where neither laboratory technician could identify the samples. The method in our research lab was: forage samples (0.5g) sealed in Ankom F57 forage fiber bags, were placed in 125ml Erlenmeyer flasks and incubated with Van Soest media and 10ml of rumen fluid. Rumen fluid inoculum was collected prior to feeding from two cannulated cows fed a high forage diet and was combined with buffer, reducing solution and 0.125mg priming mixture/ml rumen fluid and allowed to produce

0.3ml gas/ml rumen fluid prior to inoculation. The primer consisted of a mixture of carbohydrate and NPN substrates. NDF was analyzed using an Ankom²⁰⁰ forage fiber analyzer. The procedure at Marshfield was: forage samples (0.5g) were weighed into 125ml Erlenmeyer flasks and incubated with Van Soest media and 10ml of rumen fluid. Rumen fluid was from a cannulated cow fed a high forage diet. Samples were inoculated immediately after collecting rumen fluid. Feed and residual NDF was analyzed using the Van Soest method (<http://uwlab.dyndns.org/marshfield/>). In both labs, NDFD was determined as: $\text{NDFD (\% of NDF)} = 100 \times [(\text{NDF}_{0\text{h}} - \text{NDF}_{\text{residue}}) / (\text{NDF}_{0\text{h}})]$. Results were analyzed using a linear mixed model procedure, and repetition sum of squares were compared with an F-test to assess method repeatability. The rep sums of squares did not differ, but ivNDFD standard errors for CG and COM were 0.823 and 1.41, respectively. A rep by time interaction ($P < 0.001$) was evident for COM, which was not significant for CG. These data suggest the CG method, run in our lab, was more precise than the COM procedure run in a commercial setting across 24, 30 and 48h time points.

Key Words: In Vitro, NDF Digestion, Methods

TH56 Amount of sample NDF affects estimates of in vitro NDF digestibility. J. P. Goeser*, P. C. Hoffman, and D. K. Combs, *University of Wisconsin, Madison*.

The amount of forage sample dry matter is known to affect estimates of *in vitro* NDF digestibility (ivNDFD). The objective of this study was to determine if the amount of sample NDF also affects estimates of ivNDFD. *In vitro* NDFD of six forages (bm3 whole-plant corn and stover, normal whole-plant corn and stover, alfalfa silage, and wheat straw) were compared. Each forage was dried, ground (1mm), and weighed into Ankom F57 forage fiber bags to achieve 0.125, 0.25, or 0.5 g of NDF per sample bag. Sample dry matter weights ranged from approximately 0.15 to 1.5 g per bag. Samples were digested in duplicate using a modified ivNDFD assay for 0, 24, 30, or 48 h. Rumen fluid inoculum was collected and pooled from two cannulated donor cows. Inoculum was mixed with buffer, reducing solution and primed with a mixture of carbohydrates and nitrogen, and allowed to produce 0.3 ml gas/ml of rumen fluid mix prior to inoculating feed samples. NDF digestibility was calculated as: $\text{NDFD (\% of NDF)} = 100 \times [(\text{NDF}_{0\text{h}} - \text{NDF}_{\text{residue}}) / (\text{NDF}_{0\text{h}})]$ and data were modeled using SAS Proc Mixed. The model included fixed effects of NDF level, forage, time, and all interactions. Forage, time and NDF level all significantly ($P < 0.0001$) affected ivNDFD. As amount of sample NDF increased from 0.125 g to 0.5 g, ivNDFD decreased from an average of 39.78 to 28.03% of NDF across the three time points. Interactions were significant for NDF level and feed, feed and time, NDF level and feed and time, and tended to interact ($P < 0.059$) for NDF level and time. In conclusion, as the amount

of sample NDF increased, estimates of ivNDFD decreased for each forage. *In vitro* NDFD estimates were also affected by forage and time. These results suggest that differences in NDF digestibility due to factors such as forage maturity could be partially confounded by differences in the amount of sample NDF if forages are weighed into the *in vitro* systems by dry matter weight, rather than amount of sample NDF.

Key Words: NDF, In Vitro, NDF Digestion

TH57 Measures of acid detergent lignin recovery and evaluations of the 2.4 time lignin factor for estimating indigestible NDF. E. Raffrenato*, M. E. Van Amburgh, and P. J. Van Soest, *Cornell University, Ithaca, NY*.

The Cornell Net Carbohydrate and Protein System uses 2.4 times acid detergent lignin (ADL) in a ration with NDF to estimate indigestible NDF (iNDF) in forages (Chandler et al. 1980). Previous tests for nutritional uniformity indicated an average recovery of 86%. However, sintered glass filters with a 40 μm aperture might not achieve complete recovery of fine particles (Uden, 2006). The objectives of our study were to evaluate ADL recovery and to assess the ratio between ADL and iNDF after improved recovery of ADL in order to estimate iNDF. Thirty forage samples of various species and ADL content were analyzed for ADL content in Gooch crucibles of porosity of 40 μm , with or without glass microfiber filters (1.5 μm ; Whatman[®], 934-AH). The same samples were also fermented *in situ* for 16 d using bags of PPT monofilament fabric with porosity of 15 μm and an open area of 8.5% (Ankom Technology). The bags were inserted into a PVC tube and in the rumen of two fistulated dry cows. The same samples were also fermented for 16 d in the same bags in a Daisy Ankom System. Medium and rumen fluid were renewed every 4 d. All bags were analyzed for NDF after 16 d. Ratios between ADL and NDF, for estimation of iNDF, were back calculated with the iNDF obtained after the fermentations. Recovery of ADL varied among samples, but was generally higher using the filter paper. ADL recoveries were between 1 and 75% higher using the filter paper with higher recoveries for the lower ADL forages (corn silages and vegetative grasses). Long fermentations were consistent within specie for both *in-situ* and *in-vitro* procedures. The 2.4 factor was not constant and was impacted by the increased ADL recoveries. The observed ratio was higher in forages higher in ADL and NDF (2.4 to 4.2). Further, the observed ratio was lower in most corn silages and grasses and ranged from 1.4 to 2.5. The data suggest re-evaluation of the lignin procedure to improve recovery of lignin particles and the development of forage family and specie-specific equations for the estimation of the iNDF value.

TH58 Supplementation of arginine plus conjugated linoleic acid decreases the fat/lean mass ratio in rats. J. Nall*¹, G. Wu¹, K. H. Kim², S. B. Smith¹, and L. A. Ford¹, ¹Texas A&M University, College Station, ²National Institute of Animal Science, Suwon, Korea.

This experiment tested the hypothesis that the combination of dietary conjugated linoleic (CLA) plus arginine will decrease fat accumulation and increase muscle mass. Twenty-four male Sprague Dawley rats were assigned to treatments in a 2 × 2 factorial design with 6 rats per treatment group (control: 2.55% alanine + 1.5% canola oil; arginine: 1.25% arginine-HCl + 1.5% canola oil; conjugated linoleic acid (CLA; mixed isomers): 2.55% alanine + 1.5% CLA; arginine + CLA: 1.25% arginine + 1.5% CLA). There was no significant difference in food intake over the 5-wk treatment period. Both arginine and CLA increased final body weights ($P < 0.04$). Abdominal fat mass ($P = 0.08$) and the abdominal fat:lean body mass ratio ($P = 0.04$) were decreased by CLA but were unaffected by arginine. Epididymal fat pad weight was not affected by arginine or CLA ($P > 0.55$). CLA tended ($P < 0.07$) to decrease the plasma oleic/stearic acid ratio, primarily by increasing stearic acid, consistent with a depression ($P = 0.0001$) in the concentration of oleic acid in liver in CLA-supplemented rats. Conversion of ¹⁴C-labeled glucose and palmitic acid to total lipids and CO₂ in epididymal adipose tissue *in vitro* was unaffected by CLA. However, arginine decreased ($P = 0.02$) palmitic acid incorporation into total lipids in epididymal adipose tissue. Also, there was a significant arginine × CLA interaction for glucose incorporation into lipid in epididymal adipose tissue ($P = 0.02$). Arginine stimulated lipid synthesis from glucose in the absence of CLA, but had no effect in the presence of CLA. In liver, arginine increased the rate of conversion of glucose to CO₂ ($P = 0.06$). The combination of arginine plus CLA depressed the concentrations of plasma arginine and lysine ($P = 0.05$ and 0.04 , respectively). The data indicate that the combination of arginine plus CLA decreases the fat/lean mass ratio, which may be due to effects on the metabolism of both liver and adipose tissue. (Funded in part by the National Institute of Animal Science, Rural Development Administration, Korea.)

TH59 Developmental regulation of delta-like protein 1 (DLK1) expression during chicken muscle development and regeneration. J. Shin*, D. Bae, J. A. Deilius, S. G. Velleman, S. Lim, J. D. Latshaw, M. P. Wick, and K. Lee, *The Ohio State University, Columbus.*

DLK1 has been known to be responsible for muscle hypertrophy of calipye sheep and diseases associated with muscle development as shown in human uniparental disomy (UPD) chromosome 14 and mouse UPD12. However, no study to date has shown the expression pattern of DLK1 during muscle development regarding its role in specific developmental stages. Therefore, we investigated the temporal expression and localization of DLK1 during specific stages of chicken muscle development. Chicken DLK1 (gDLK1) mRNA was significantly induced by 2-fold at day 1 after cell differentiation and thereafter gradually decreased in primary chicken myoblast cultures ($p < 0.05$). During mouse C₂C₁₂ cell differentiation, DLK1 protein, absent at D0, was expressed as early as D2 and reached maximal amounts at D4 when the myotubes were actively formed. DLK1 protein expression was decreased at D6 when the length and thickness of myotubes increased. During the muscle repair process

in chickens, gDLK1 mRNA expression was dramatically induced by 4-fold at day 7 after injury ($p < 0.05$), recapitulating the expression pattern observed in normal muscle development. Although gDLK1 gene expression decreased after hatching in both meat- (broiler) and egg-type (layer) chickens, broiler chicken muscle had 3-fold greater expression of gDLK1 compared to layers ($p < 0.01$). The temporal expression of DLK1 and localization of its protein in differentiated myoblasts and early myotube suggest its important role in these developmental processes. These findings provide a new insight into the role of DLK1 in muscle development, regeneration, and associated muscle diseases and support the DLK1 gene as a selection marker for superior muscling in food animals.

TH60 Serum amyloid A protein mediates the regulation of docosahexaenoic acid on the expression of porcine genes related to lipid metabolism. S. T. Ding*, C. H. Chen, and H. J. Mersmann, *Natioanl Taiwan University, Taipei, Taiwan, ROC.*

Serum amyloid A protein (SAA) is an apolipoprotein that may replace apolipoprotein A1 (apoA1). Porcine hepatic SAA mRNA is increased by dietary docosahexaenoic acid (DHA) treatment. The purpose of this study was to investigate the role of SAA protein in regulating gene expression related to lipid metabolism in pigs. We demonstrated that 100 μM DHA treatment significantly increased SAA and apoA1 mRNA expression in porcine hepatic cell culture ($P < 0.05$). Therefore, we produced porcine SAA recombinant protein and found that addition of 40 nM SAA to porcine preadipocytes in culture stimulated interleukin-6 (IL-6) mRNA expression ($P < 0.05$), similar to the biological function of SAA in human. We also found peroxisome proliferator-activated receptor γ (PPARγ) and PPARα mRNA were decreased (40% and 60%, respectively) in differentiated adipocytes after treatment with 2 μM SAA. In addition, the SAA treatment caused an increase in inflammatory cytokine gene expression (IL-6 and tumor necrosis factor α), and glycerol release ($P < 0.05$), indicating increased lipolysis. Because the expression of perilipin, a lipid droplet-protective protein, was reduced by the SAA treatment, we hypothesized that SAA increased lipolysis by decreasing the expression of perilipin, which would then allow an increase in hormone sensitive lipase activity. In conclusion, we demonstrated that the DHA-induced SAA gene expression decreased PPAR expression to consequently down-regulate the expression of several genes involved in lipid metabolism. Accordingly, SAA may play a role in mediating the function of dietary DHA on lipid metabolism and could be a factor regulating obesity.

Key Words: Porcine Adipocyte, Perilipin, Serum Amyloid A Protein

TH61 Exocrine pancreatic insufficiency arrests growth of young pigs even after the parenteral or enteral feeding of an elemental diet. S. Rengman*¹, O. Fedkiv¹, J. Botermans², J. Svendsen², B. R. Weström¹, and S. G. Pierzynowski¹, ¹Lund University, Lund, Sweden, ²Swedish University of Agricultural Sciences, Alnarp, Sweden.

Weaned pigs fed a commercial feed maintain normal growth while pigs with induced exocrine pancreatic insufficiency (EPI) show an arrested growth during the same conditions. Supplementation with a pancreatic enzyme preparation to the feed is known to normalise the growth of young EPI-pigs. Our aim was to further evaluate the importance of the exocrine pancreas of the growth in weaned pigs.

To induce EPI, the main pancreatic duct was ligated close to the duodenal papilla and then cut between the ligatures. Two weeks later the pigs were fitted with gastric fistulas and jugular vein catheters after which the pigs were given 10 days of recovery.

Conventional pigs were fed a commercial pig feed for young pigs, n=5, elemental diet (ED) intragastrically (ig), n=3 or intravenously (iv), n=3 during 6 days. Pigs with EPI were fed a commercial pig feed, n=6, ED ig, n=6, ED iv, n=6 or a fat-enriched diet (with or without pancreatic enzyme supplementation) during 6 days. The pigs received 0.504 MJ/kg/day of the commercial pig feed or the ED while 0.641 MJ/kg/day of the fat-enriched diet. Weekly weight gain was compared among the groups.

The three groups of pigs that were fed pig feed, ED ig or ED iv, all showed a normal increase in bwt, 14%/week, similar to ordinary production pigs. The recorded weight change in EPI-pigs that were fed pig feed, ED ig or ED iv spanned from -6 to 3% bwt/week. The significant difference in growth between conventional pigs and EPI-pigs was $p \leq 0.001$ for pig feed and ED iv and $p \leq 0.01$ for ED ig. The group that were fed a fat-enriched diet supplemented with pancreatic enzymes, showed a normalised growth, compared to the group receiving fat-enriched diet without pancreatic enzymes $p \leq 0.001$.

Conventional pigs maintain a normal growth independently of diet (pig feed or ED) and administration routes (enteral or parenteral) while the EPI-pigs showed an impaired growth or even lost weight when receiving the same treatments. A proper digestion and absorption of nutrients is not enough to maintain normal growth in weaned pigs with EPI.

Key Words: Pancreas, Growth, Pig

TH62 Indispensability of exocrine pancreatic function for the growth of young weaner pigs. O. Fedkiv*, S. Rengman, B. R. Weström, and S. G. Pierzynowski, *Lund University, Lund, Sweden.*

Data regarding the role of exocrine pancreatic enzymes for the growth of pigs of different ages is inconsistent. Thus, the aim of the study was to highlight the role of exocrine pancreas secretion for growth and performance of pigs in different age. The experiments were performed on 24 crossbred pigs. In order to develop exocrine pancreatic insufficiency (EPI), the pancreatic duct was ligated in 6 pigs at the age of 6 weeks (weaners, 10.5 ± 1.3 kg) and in 6 pigs at the age of 15 weeks (growers, 43 ± 5 kg). Parallel studies were performed on control pigs at age 8 weeks (13.2 ± 0.7 kg) and 15 weeks (37 ± 4 kg), respectively. The pigs were fed *ad libitum* during one hour, twice a day (in the morning and in the evening) with a commercial feed (Växtill 320, Lantmännen, Sweden). Weekly recordings of food consumption and growth were performed before, during and after supplementation with a pancreatic enzyme preparation (Creon® Minimicrospheres™, SolvayPharma GmbH, Hanover, Germany) starting 4 weeks after pancreatic duct ligation (PDL). PDL in weaners caused growth arrest while it had a little effect on the growth of growers. The daily weight gain (DWG) and daily feed consumption (DFC) in EPI pigs and corresponding controls one week before, one week during pancreatic enzyme supplementation (PES) and one week after are presented in the table below. Pancreatic

exocrine secretion is indispensable to ensure growth of weaner pigs while not for growers. Feed supplementation with a preparation of pancreatic enzymes improves appetite and ensures lower feed conversion in control and in EPI pigs.

Table 1.

Pigs	DFC before (kg/day)	DWG before (kg/day)	DFC during PES (kg/day)	DWG during PES (kg/day)	DFC after (kg/day)	DWG after (kg/day)
EPI weaners	0.33±0.06 ^a	0±0.1 ^A	0.46±0.07 ^b	0.29±0.04 ^B	0.29±0.06 ^a	0±0.3 ^A
Control weaners	0.85±0.09 ^c	0.67±0.1 ^C	1.1±0.07 ^d	0.83±0.2 ^C	1.3±0.13 ^c	0.67±0.16 ^C
EPI growers	2.2±0.3 ^{f,g,h}	1.1±0.36 ^D	3.2±0.6 ⁱ	1.4±0.26 ^D	3.0±0.86 ^h	0.72±0.25 ^C
Control growers	2.1±0.2 ^f	1.2±0.35 ^D	2.6±0.17 ^{f,g,h,i}	1.4±0.16 ^D	2.8±0.18 ^{g,h,i}	1.3±0.17 ^D

TH63 Effects of maternal low and high protein diets on body composition and skeletal muscle properties of newborn piglets. C. Rehfeldt, C. Kalbe, J. Block, G. Nuernberg, B. Stabenow, D. Loesel*, and C. C. Metzges, *Research Institute for the Biology of Farm Animals, Dummerstorf, Germany.*

To study the impact of maternal low and high protein intake on body composition and cellular properties of skeletal muscle of the offspring, 40 German Landrace gilts were artificially inseminated (age 8 mo, 148 kg) and fed iso-energetic diets (11.6 MJ ME/kg DM) with high (HP, 30%; n=14), low (LP, 6%; n=14) or control protein (CP, 12%; n=12) levels throughout gestation. The resulting median of litter size was 13. All piglets were weighed at birth and 4 of them were taken from each litter for detailed analyses.

Birth weight was lower in LP and HP compared with CP piglets (1.19, 1.22, 1.38 kg, respectively; $P < 0.01$). Preliminary data reveal that LP and HP piglets exhibited a higher percentage of internal organs ($P = 0.08$). The weight of the kidneys was significantly affected by diet ($P = 0.01$) with being increased in HP piglets. Within large litters (>13) HP piglets exhibited a higher percentage of skeletal muscle tissue than LP piglets (44.5 vs 41.6%; $P = 0.05$). Skeletal muscle characteristics were analyzed in *semitendinosus* (ST), *longissimus*, and *biceps femoris* muscles. Weight ($P = 0.09$) and circumference ($P = 0.02$) of ST muscle were affected by diet and tended to be lowered by 11% in LP piglets. On average of all muscles protein/RNA ratio was decreased by 12% in LP ($P < 0.05$), which was more pronounced in piglets of litters >13 showing also numeric decreases in protein concentration and creatine kinase activity ($P = 0.07$; 0.04, respectively, for diet*litter size class). Total DNA content in ST muscle was higher in HP compared with CP ($P = 0.09$; 12%) and LP ($P < 0.05$; 15%). The results suggest that a 50% decrease in protein supply to gilts during pregnancy impairs intrauterine growth and skeletal muscle development, in particular in piglets of large litters. In contrast, a respective increase in nutritional protein stimulates myonuclear proliferation, which may indicate a higher potential for postnatal lean growth. (supported by DFG, KA 1844/1-1, PAK 24).

TH64 Body composition of transgenic pigs expressing the myostatin pro domain. A. D. Mitchell* and R. J. Wall, *USDA-ARS, Animal Bioscience and Biotechnology Laboratory, Beltsville, MD.*

Previous results have shown that male mice expressing a myostatin pro domain construct (MLC-Pro) have increased body weight, more total body lean mass, and lower percentage of total body fat. Founder transgenic (TG) pigs were generated by standard pronuclear microinjection techniques using the same MLC-Pro construct. Subsequently, MLC-pro TG and littermate control pigs were produced by mating a G-2 TG boar with non-TG females. The purpose of this study was to use dual energy X-ray absorptiometry (DXA) to monitor, in vivo, the course of changes in body composition of female control (n = 19) and female MLC-Pro TG (n = 19) pigs between 60 and 120 kg BWT. The female TG pigs expressing the MLC-Pro construct has less total body

lean mass at 60, 100 and 120 kg BWT when compared to littermate controls ($P < 0.05$). Consequently, at the same weights the TG females had a higher ($P < 0.05$) percentage of total body fat (9.0 vs. 11.2, 14.4 vs. 19.3, and 15.3 vs. 20.9%, respectively). There was no difference in total body bone mineral content. When the pigs were restrictively fed at maintenance energy intake for eight weeks starting at either 60 or 100 kg BWT, the change in body composition was similar for TG and control pigs. Likewise, when the pigs restricted at 60 kg were subsequently fed ad libitum to 100 kg, the response was similar for TG and control pigs. These results indicate that TG female pigs expressing the MLC-Pro construct have a higher percentage of total body fat compared littermate controls and that these differences persist during a period of restricted intake.

TH65 Characterization of putative mammary stem cells in intact and ovariectomized prepubertal heifers. N. Korn¹, L. Riggs², R. M. Akers³, and S. Ellis*¹, ¹Clemson University, Clemson, SC, ²Louisiana State University, Baton Rouge, ³Virginia Polytechnic Institute and State University, Blacksburg.

Prepubertal ovariectomy impairs mammary development in heifers through poorly understood mechanisms that may relate to changes in stem cell physiology. A trial was conducted to determine whether ovariectomy alters the frequency or proliferative activity of mammary stem cells, as assessed by localization of retained bromodeoxyuridine (BrdU) label and detection of proliferative cell markers (Ki67) in parenchymal cell populations. At 35d of age, all heifers were injected with BrdU once per day (5mg/kg BW, iv in pH8.5 physiologic saline) for 5d to label putative stem cells. On d40, all animals underwent either an ovariectomy (OVX; n=17) or sham (INT; n=18) operation. Groups of heifers were sacrificed at 15d intervals to provide tissues for histologic analysis of parenchymal cells. At least 5 non-sequential sections per animal were stained for dual detection of Ki67 and BrdU. Statistical comparisons were complicated by heterogeneous variation and confounded effects of treatment (OVX vs. INT) on parenchymal growth. In control animals sacrificed at 40d age (n=2), BrdU- and Ki67-double positive (DP) cells were distributed throughout the basal, embedded, and luminal strata of the epithelium. At d55, there was a marked reduction in BrdU retention and DP cells in INT animals, but distribution of DP cells through the parenchymal strata was unaltered. In samples from d70 to d160 heifers, DP cells were very rarely observed in parenchyma from INT animals, primarily due to reduced BrdU retention. In OVX animals, abundant BrdU labeling was seen at d55 and d70, but very few DP cells were observed, likely because of reduced Ki67 labeling. Between d85 and d160, BrdU retention in OVX animals declined steadily and became almost undetectable at d160. Our data suggests that ovariectomy does not abruptly alter populations of mammary stem cells. Instead, ovariectomy reduces proliferation and may allow for gradual senescence.

TH66 Cloning the promoter region for bovine phosphoenolpyruvate carboxykinase gene and identification of propionate responsive region. S. L. Koser*, M. Thomas, and S. S. Donkin, *Purdue University, West Lafayette, IN.*

Cytosolic phosphoenolpyruvate carboxykinase (PCK1) is a rate-limiting enzyme for gluconeogenesis that is sensitive to nutritional and hormonal status. Bovine genomic sequence data was scanned using BLAST to determine matches to the 5' end of mRNA for bovine PCK1 mRNA. A 1459 bp fragment of bovine PCK1 was cloned by PCR that included 221 nt corresponding to the 5' untranslated region and 1238 nt of the proximal promoter. Segments corresponding to -815, -409, and -251 through +197 of the promoter of the bovine PCK1 gene were ligated to the firefly luciferase reporter gene. Constructs were transfected into rat hepatoma (H4IIE) cells and tested for their ability to drive gene expression. Cotransfection with renilla luciferase reporter served as a transfection control. A promoterless vector and a reporter driven by the SV40 promoter served as negative and positive controls for the experiment. Transfections were established over a 5-h period and cells were exposed to either 2.5 mM propionate, or vehicle for 23 h. Cells were harvested and the abundance of firefly and renilla luciferase were

determined in cell extracts. All bovine PCK1 promoter constructs tested were capable of driving expression of luciferase. Basal expression, as the ratio of firefly to renilla luciferase activity, was enhanced ($P < 0.05$) from 0.28 to 1.09 when the size of the promoter construct was reduced from -815 to -409 but truncation to -251 did not further alter basal expression. Propionate induced ($P < 0.05$) expression of all constructs compared to controls although the response for the -215 construct was muted relative to constructs -815 and -409. When luciferase expression ratios were adjusted for basal activity the -409 promoter construct of PCK1 was most responsive to propionate and further truncation to -251 reduced ($P < 0.05$) this responsiveness (706 vs. 484 \pm 98 as a percent of control). The data indicate response elements for propionate are located within -251 and -815 of the bovine PCK1 promoter. Supported by USDA-CSREES NRI Grant no. 2006-35206-16646.

TH67 Quantification of glucose-6-phosphatase mRNA abundance in liver of transition dairy cows. E. M. Cedeño*, S. L. Koser, and S. S. Donkin, *Purdue University, West Lafayette, IN.*

Glucose-6-Phosphatase (G6Pase) catalyzes the final reaction for both gluconeogenesis and glycogenolysis, hydrolyzing glucose-6-phosphate (G6P) to glucose and inorganic phosphate. The activity of G6Pase appears to be largely controlled on the transcriptional level and predominantly exerted by hormonal cues and reduced feed intake. Therefore we hypothesized that G6Pase would be responsive to the onset of calving in transition dairy cows. Eleven mature Holstein cows were given ad libitum access to feed (1.61 Mcal NE/kg) beginning 28 days prior to expected calving. After calving all cows received a diet containing 1.67 Mcal NE/kg. Liver biopsy samples were obtained on days -28, +1, and +28 relative to calving. Total RNA was extracted, reverse transcribed to cDNA and used in real time PCR analysis for G6Pase and glyceraldehyde-3-phosphate dehydrogenase (GAPDH). Primers spanning exon junctions were selected based on bovine genomic sequence data. Expression of G6Pase was compared among days relative to calving and analysis accounted for the effect of day and cow x day. There was a tendency ($P = 0.08$) for G6Pase mRNA to be elevated at calving. Abundance of G6Pase mRNA relative to GAPDH was 0.8 vs. 1.1 \pm 0.28 for -28 and +1 days relative to calving. G6Pase was elevated ($P < 0.05$; 1.80 \pm .28) at +28 days relative to calving and precalving abundance. The data indicate that increased expression of G6Pase at calving and postcalving in liver is part of the adaptation to increased hepatic glucose release in transition cows.

Key Words: Gluconeogenesis, Liver, Transition Cows

TH68 Plasma and tissue concentrations of glucose, acetate, propionate, lactate, and hydroxybutyrate in calves subjected to conventional and accelerated milk replacer programs. H. A. Weeks*, A. G. Rius, K. M. Daniels, R. M. Akers, C. Umberger, and M. D. Hanigan, *Virginia Polytechnic Institute and State University, Blacksburg.*

The objective of the study was to evaluate the effects of milk replacer (MR) composition and feeding rate on plasma, liver, and muscle glucose,

lactate, acetate, propionate, and hydroxybutyrate concentrations. It was hypothesized that high rates of MR intake would cause delayed initiation of rumination resulting in reduced plasma and tissue acetate concentrations. Plasma and tissue samples previously collected from 24 Holstein heifer calves were used for the analyses. Water and starter (20% CP, 1.43% fat) were offered ad libitum and calves were fed twice daily one of four MR (n=6/treatment). Treatments were: 1) control MR (CON; 20% CP, 20% fat fed at 441 g DM/d), 2) a high protein MR (HPLF; 28% CP, 20% fat) fed at 951 g DM/d, 3) a high protein high fat MR (HPHF; 27% CP, 28% fat) fed at 951 g DM/d, and 4) treatment 3 fed at 1431 g DM/d (HPHF+). All samples were deproteinized, lyophilized to dryness, reconstituted in phosphate buffered D2O containing 0.5 mM DSS as an internal standard, and subjected to nuclear magnetic resonance spectroscopy. Spectra were phase adjusted and baseline corrected before calculation of peak integrals. All peaks were normalized to a constant DSS peak area of 100. Plasma concentrations of acetate (P<0.001) and lactate (P<0.02) increased with age reflecting onset of rumination. Increased nutrient supply from MR resulted in significant increases in plasma glucose (P<0.001) and decreased plasma acetate (P<0.01). Plasma propionate, lactate, and hydroxybutyrate were not affected by treatment. Dietary treatments did not significantly affect metabolite concentrations in liver or muscle. However concentrations of glucose (P<0.001), acetate (P<0.001), propionate (P<0.05), and hydroxybutyrate (P<0.001) were significantly greater in liver than in muscle. It was concluded that increasing nutrient intake from MR delays onset of rumination, but changes in blood concentrations of metabolites were not reflected in tissue concentrations.

Key Words: Calf, Acetate, Glucose

TH69 Effect of β -mannanase enzyme mixture addition to soy-containing milk replacers on growth and health of neonatal calves. M. E. Van Amburgh¹, L. Nabte-Solis¹, E. B. Helmes², D. A. Ross¹, and T. D. Sonnenberg¹, ¹Cornell University, Ithaca, NY, ²ChemGen, Gaithersburg, MD.

The objective of this study was to evaluate the performance of a high protein, soy protein concentrate (SPC) containing milk replacer (MR) fed to pre-ruminant calves with or without β -mannanase-based enzymes prior to and during the weaning phase of growth. Fifty-six Holstein bull calves were purchased and randomly assigned to one of four dietary treatments. Calves were 14 \pm 12 d of age at the initiation of treatments and mean weight at assignment of treatments was 48 \pm 5.33 kg. Milk replacer was provided at 0.28 Mcal GE/kg BW^{0.75} during the first 7 days and then increased to 0.32 Mcal GE/kg BW^{0.75}. The positive control diet consisted of a commercially available MR formulated with all milk ingredients (Excelerate, MSC Specialty Nutrition, Dundee, IL, 28% CP, 15% fat). The remaining treatments received a soy-containing MR that was formulated with 50% of the protein replaced by a SPC (Profine VF, Solae Inc., St. Louis, MO). Two different levels of a feed enzyme product, SZP (ChemGen Corp., Gaithersburg, MD), were added to two of the three SPC-containing MR at the time of mixing to provide the four treatments: all milk MR; two SPC-containing MRs with two levels of the enzyme mixture measured by β -mannanase activity; and the SPC-containing MR with no added enzymes. Calves were fed MR from day 1 to 35, then on day 36 were offered a commercially available starter and weaned by day 56. Milk replacer intake and overall DMI were not different among treatments (P = 0.3) and overall DMI averaged 1.65 \pm 0.08 kg over the 63-day period. The enzyme treatments did not significantly affect DMI. Daily gain of calves among treatments were

not different (P = 0.3) through the study, and averaged 0.90 kg/d. Replacing 50% of the protein in a 28% CP all-milk MR with a low antigen SPC had no significant effect on calf growth or health. The addition of β -mannanase-based enzymes to the SPC containing MR showed a trend (P<0.08) towards increased feed efficiency and ADG of the calves.

Key Words: Calves, Soy Protein Concentrate, Enzymes

TH70 Effects of *Bacillus subtilis* natto on performance and morphological features of ruminal papillae in dairy calves. H. T. Zhang, J. Q. Wang*, D. P. Bu, S. Y. Luan, L. F. Deng, L. Y. Zhou, H. Y. Wei, and K. L. Liu, *Chinese Academy of Agricultural Sciences, Beijing, China.*

Two types of *Bacillus subtilis* natto culture (Na, N1) were added to the milk/starter to evaluate effects of natto culture on the growth of calves and development of ruminal papillae. 24 Holstein bull calves of 7 \pm 1d of age were divided into three groups. Natto was provided in two ways: first, natto cultures were mixed with milk and provided to all the calves. Calves were weaned until the intake of starter was up to 2% of their weight, and four calves were slaughtered randomly after weaning. In the second experiment, natto cultures were fed directly and the calves were slaughtered 8 weeks after weaning. Ruminal epitheliums at the area of ventral rumen sac were obtained. In the first experiment, weaning day of N1 group (49.7 d) shortened significantly when compared with the control group (57 d) (P<0.05). In the second experiments, average daily gain of N1 and Na group enhanced about 16.2% (P=0.09) and 22.1% (P=0.02), respectively. DMI data showed a similar pattern. Calves fed with natto culture enhanced carcass yield with remarkable difference (P=0.01). In respect of rumen papillae, the number and the surface of papillae per cm² mucosa of Na and N1 groups increased remarkably compared with control. Under electron microscope, we found the shape of the papillae of control was leaf-like, narrow stalk, clumping, parakeratotic and dark-brownish color. In contrast, papillae of Na and Ni groups were flattened, tongue-shaped and straw-colored. The shape and size of the ingesta which packed into the surface of papillae were also different. Results from the present study indicated that supplementation of natto culture could promote the development of rumen papillae and the growth of calves.

TH71 Increasing levels of dietary corn oil to grazing steers alters lipogenic gene expression. S. K. Duckett*, S. L. Pratt¹, and E. Pavan², ¹Clemson University, Clemson, SC, ²INTA, Balcarce, Argentina.

Subcutaneous adipose tissues were collected at slaughter from eighteen steers fed increasing levels of dietary corn oil [0 g/kg BW (NONE), 0.75 g/kg BW (MED) and 1.5 g/kg BW (HI)]. Steers rotationally grazed endophyte-free tall fescue pastures for 197 d and were supplemented individually with cottonseed hulls plus dietary corn oil level treatment. Subcutaneous adipose tissues were processed for RNA extraction. Relative gene expression of genes involved in lipogenesis [fatty acid synthase (FASN), acetyl Co-A carboxylase (ACC), lipoprotein lipase (LPL), stearoyl Co-A desaturase (SCD), Spot-14], transcriptional

events [peroxisome proliferators-activated receptors (PPAR γ), CCAAT/enhancer-binding proteins (C/EBP α), sterol regulatory binding proteins (SREBP-1), and STAT-5], and housekeeping (GAPDH and β -actin) was determined by qRT-PCR. At the MED level of oil supplementation, FASN and SCD mRNA expression were up-regulated ($P < 0.05$) by 1.4-fold compared to NONE. In contrast, FASN and SCD mRNA expression were down-regulated ($P < 0.05$) by 0.7- and 0.8-fold for HI versus NONE. LPL mRNA expression was up-regulated ($P < 0.05$) in HI vs. NONE and unchanged ($P > 0.05$) in MED vs. NONE. For the HI oil supplementation level, Spot-14, SREBP-1 and NFY were up-regulated ($P < 0.05$) compared to NONE. Relative expression of other genes (ACC, PPAR γ , C/EBP α , and STAT-5) were unaffected ($P > 0.05$) by dietary treatment. High levels of oil supplementation (8% dietary fatty acids, DM basis) to grazing steers up-regulated gene expression of key enzymes responsible for the uptake of dietary fatty acids (LPL), and down-regulated those involved in de novo fatty acid synthesis (FASN) and conversion of saturated to monounsaturated fatty acids (SCD).

Key Words: Beef, Supplementation, Gene Expression

TH72 Lipogenic gene expression in steers finished on high concentrate diets and pasture with or without energy supplementation. S. K. Duckett*¹, S. L. Pratt¹, and E. Pavan², ¹Clemson University, Clemson, SC, ²INTA, Balcarce, Argentina.

Twenty-eight Angus steers (289 kg) were finished on a high concentrate diet (85% concentrate/15% roughage; C), or endophyte-free tall fescue pastures with either corn grain supplement (0.52% BW; PC), or corn oil plus soybean hull supplement (0.10% BW corn oil plus 0.45% BW soybean hulls; PO), or no supplement (pasture only; P). Subcutaneous adipose tissues were processed for RNA extraction and fatty acid composition by GLC. Relative gene expression of genes involved in lipogenesis [fatty acid synthase (FASN), acetyl Co-A carboxylase (ACC), lipoprotein lipase (LPL), stearoyl Co-A desaturase (SCD), Spot-14], transcriptional events [peroxisome proliferators-activated receptors (PPAR γ), CCAAT/enhancer-binding proteins (C/EBP α), sterol regulatory binding proteins (SREBP-1), and STAT-5], and housekeeping (GAPDH and β -actin) was determined by qRT-PCR. SCD mRNA expression was up-regulated ($P < 0.001$) by 7-, 18- and 46-fold for PO, PC and C, respectively, over P. Monounsaturated fatty acid (MUFA) content (g/100g) was also increased ($P < 0.05$) by 21%, 38%, and 75% for PO, PC, and C, respectively, compared to P. FASN mRNA expression was up-regulated ($P = 0.0036$) by 4.6- and 8.8-fold for PC and C, respectively, compared to P. Palmitic acid, the end product of de novo fatty acid synthesis, was also increased by 24% and 55% for PC and C, respectively, compared to P. Finishing steers on a high concentrate diet (C) down-regulated ($P = 0.005$) STAT5 mRNA by 21-fold compared to pasture only (P). Spot-14 mRNA expression was up-regulated ($P < 0.0001$) by 3-, 2-, and 13-fold for PO, PC, and C, respectively, compared to P. Relative expression of other genes (ACC, LPL, PPAR γ , C/EBP α , and SREBP-1) were unaffected ($P > 0.05$) by dietary treatment. Corn grain fed as a supplement or in a high concentrate diet up-regulated gene expression of key lipogenic enzymes responsible for the conversion of saturated fatty acids to MUFA (SCD) and de novo synthesis of fatty acids (FASN).

Key Words: Beef, Supplementation, Gene Expression

TH73 Melengestrol acetate enhances adipogenic gene expression in an *in vitro* muscle-derived cell transdifferentiation model. K. Y. Chung* and B. J. Johnson, Kansas State University, Manhattan.

We hypothesized that within postnatal skeletal muscle there was a population of muscle cells that have unique characteristics to accumulate lipid droplet. Under appropriate stimuli, these particular cells could be induced down the adipose tissue pathway, to form marbling, rather than muscle. Muscle-derived cells (MDC) were digested from semimembranosus muscle tissue of three 14-month crossbred steers. Isolated MDC were plated on pre-coated matrigel plates. Addition of insulin, oleic acid, and ciglitizone (IOC) for 7 days resulted in morphological differences in MDC compared to control cultures. Multilocular lipid droplets stained with Oil-Red-O were located not only in single MDC but in fused myotubes. Relative PPAR γ mRNA levels in MDC incubated with IOC were increased ($P < 0.05$). However, myogenin mRNA levels in MDC incubated with IOC were repressed ($P < 0.05$) compared to non-treated MDC. Cultures of MDC treated with 10 nM estradiol (E₂) showed low lipid droplet compared with control cultures. However, cultures treated with 10 nM melengestrol acetate (MGA) resulted in cultures with highly distributed lipid droplets not only in single cell but in the myotubes. Relative C/EBP β and PPAR γ mRNA levels from MDC treated with MGA were increased ($P < 0.05$) compared to control cultures. Estradiol treatment had no effect on mRNA levels. The addition of both E₂ and MGA to MDC increased ($P < 0.05$) C/EBP β mRNA level and tended ($P = 0.06$) to increase PPAR γ mRNA level. Relative C/EBP β , PPAR γ , and myogenin mRNA levels were investigated with C2C12, C3H 10T(1/2), and 3T3-L1 cells. Treating cultures with 10 nM MGA increased ($P < 0.05$) C/EBP β level in C2C12 myoblasts and tended ($P = 0.08$) to 3T3-L1 preadipocytes. There was no difference ($P > 0.05$) in relative myogenin mRNA level among control, E₂, and MGA treatments. These data indicate that indeed there are populations of cells present in postnatal skeletal muscle that under the appropriate stimuli in a culture model will differentiate into adipogenic pathway. In addition, the synthetic progestin, MGA appeared to upregulate genes necessary for the adipogenesis in the MDC.

Key Words: Melengestrol Acetate, Transdifferentiation, Muscle-Derived Cell

TH74 More selenium (Se) accumulates in whole blood, red blood cells, and liver of beef heifers when supplemented by an organic vs inorganic source. S. F. Liao*, W. R. Burris, K. R. Brown, J. A. Boling, and J. C. Matthews, University of Kentucky, Lexington.

To determine if source of dietary Se supplement differentially affects Se concentrations of blood constituents and liver tissue in growing cattle, 30 Angus heifers (261 \pm 6 d of age) were fed a corn silage-based diet with no Se supplementation for 75 d. Heifers (BW 393 \pm 9 kg) then were randomly assigned to 3 mineral supplement treatments (n = 10) and individually fed the supplement plus 7.8 kg/d of a basal cracked corn and cottonseed hull-based diet for 105 or 106 d, using a Calan gate system (5 heifers/pen). The basal diet supplied 0.4 mg Se/d per head, whereas the mineral supplements provided no additional Se/d (control), 3 mg inorganic Se/d as sodium selenite (ISe), or 3 mg organic Se/d as Sel-Plex (OSe; Alltech, Inc.). Selenium effects on feed efficiency and Se content of blood and liver samples were analyzed by ANOVA. Treatments did not affect ADG (0.58 to 0.67 kg/d) or feed:gain (14.4 to

12.1). Although plasma Se content was not affected, Se in whole blood, red blood cells and liver of ISe and OSe treatment animals was 18 and 59%, 31 and 62%, and 31 and 81% higher ($P < 0.0001$), respectively, than for controls (Table 1). Moreover, whole blood, red blood cells, and liver tissue of OSe animals contained 35, 24, and 38% more ($P < 0.05$) Se than did ISe, respectively. These data show that more Se accumulates in the measured Se pools (except for plasma) of growing heifers when Se is supplemented in the organic (Sel-Plex) vs inorganic (sodium selenite) form.

Table 1. Effect of dietary selenium (Se) supplementation on tissue Se concentrations

Item	Control	Se supplementation		SEM	P value ¹
		Inorganic Se	Organic Se

TH75 Basal content of sugar transporter mRNA in small intestinal epithelia of beef steers is differentially increased by abomasal vs ruminal infusion of starch hydrolysate. S. F. Liao*, D. L. Harmon, E. S. Vanzant, K. R. McLeod, J. A. Boling, and J. C. Matthews, *University of Kentucky, Lexington.*

Glucose and fructose are absorbed from the small intestinal lumen by SGLT1 and GLUT5, respectively, whereas GLUT2 mediated the transport of glucose and fructose across both basolateral and apical membranes. To test that mRNA content of these transporters in duodenal (D), jejunal (J), and ileal (I) epithelia is differentially altered by ruminal vs abomasal infusion of corn starch hydrolysate (SH; by α -amylase, at 20% of ME intake), 18 ruminally and abomasally catheterized Angus steers (BW \approx 260 kg) were assigned to either water (basal), ruminal SH, or abomasal SH infusion treatments ($n = 6$) and fed an alfalfa-cube based diet at $1.3 \times \text{NE}_m$ requirement. After 14 or 16-d of infusion, steers were killed, small intestinal epithelia harvested, and total RNA extracted. Real-time RT-PCR analysis was conducted to quantify the relative (mRNA:18S rRNA) expression of SGLT1, GLUT5, and GLUT2. Basal expression of SGLT1 and GLUT2 mRNA was greatest ($P \leq 0.10$) by J, whereas J and D expression of GLUT5 mRNA was greater ($P \leq 0.07$) than I. GLUT5 mRNA content was not affected by SH infusion. In contrast, D SGLT1 mRNA content was increased ($P = 0.07$) 64% by ruminal SH infusion and abomasal SH infusion increased ($P \leq 0.05$) I expression of SGLT1 mRNA by 1.3-fold and GLUT2 mRNA by 6.0-fold. These results indicate that increased luminal SH increases the potential for glucose absorption across the I epithelium, increased rumen microbe-derived nutrient supply increases the potential for apical uptake of glucose (GLUT2), whereas fructose uptake potential (GLUT5) was not changed. When viewed with previous findings that SGLT1 activity is insensitive to increased luminal SH, the results also indicate that luminal substrate control of glucose uptake capacity in

cattle is complex. For GLUT2 and GLUT5, the findings in this trial are novel for cattle and suggest that GLUT2 activity may respond to luminal substrate supply.

Key Words: Bovine, SLC2 and SLC5 Gene Expression, Substrate Regulation

TH76 Roles of increased IGF-I expression and the estrogen 17β , androgen and IGF-I receptors in estradiol- 17β and trenbolone acetate- stimulated proliferation of cultured bovine satellite cells. E. Kamanga-Sollo¹, M. E. White¹, M. R. Hathaway¹, K. Y. Chung², B. J. Johnson², and W. R. Dayton*¹, ¹University of Minnesota, St. Paul, ²Kansas State University, Manhattan.

A combined estradiol 17β (E2)/trenbolone acetate (TBA) implant causes a significant increase in muscle IGF-I mRNA and both E2 and TBA stimulate a significant increase in IGF-I mRNA level in bovine satellite cell (BSC) cultures in media containing 10% fetal bovine serum (FBS). Even though treatment of cultured BSC with E2 or TBA in media containing 1% IGF-BP-3-free swine serum results in increased proliferation there is no effect on IGF-I mRNA expression, suggesting that increased IGF-I expression may not be responsible for anabolic steroid enhanced BSC proliferation. To further examine the role of estrogen, androgen and IGF-I receptors and their respective ligands in E2 and TBA-stimulated BSC proliferation, we assessed the effects of specific inhibitors on E2 or TBA-stimulated proliferation of BSC. Both ICI 182 780 (an estrogen receptor blocker) and flutamide (an inhibitor of androgen receptor) suppressed ($p < 0.05$) E2 and TBA-stimulated BSC proliferation, respectively. JB1 (a competitive inhibitor of IGF-I binding to the IGF-I receptor) reduced ($p < 0.05$) both E2 and TBA-stimulated proliferation in BSC cultures. Both the Raf-1/MAPK kinase (MEK)1/2/ERK1/2, and the phosphatidylinositol 3-kinase (PI3K)/Akt pathways play significant roles in the actions of IGF-I on proliferation and differentiation of myogenic cells. PD98059, an inhibitor of the MAPK pathway, and wortmannin, and inhibitor of the PI3K pathway, both suppressed ($p < 0.05$) E2 and TBA-stimulated proliferation of cultured BSC. Our data suggest that IGF-I plays a role in E2 and TBA stimulated proliferation of cultured BSC even in the absence of increased IGF-I expression.

Key Words: Anabolic Steroid, Satellite Cells, IGF-I

TH77 Effects of trenbolone acetate (TBA), Estradiol (E2) and combined TBA/E2 implants on muscle IGF-I and IGF-II mRNA levels in feedlot steers. M. S. Pampusch¹, M. E. White¹, M. R. Hathaway*¹, K. Y. Chung², B. J. Johnson², and W. R. Dayton¹, ¹University of Minnesota, St. Paul, ²Kansas State University, Manhattan.

We have previously shown that a combined TBA/E2 implant significantly increases IGF-I mRNA levels in longissimus dorsi (LD) muscles of feedlot steers by 28 days after implantation. Here we compare the effects of E2 (24 mg), TBA (120 mg) and combined E2 (24 mg)/TBA (120 mg) implants on IGF-I mRNA levels in the LD muscles of steers implanted for 28 days. Five yearling steers per group were implanted with each implant and 5 control steers received no implant. Steers were weighed weekly starting on d0 and muscle biopsy samples were taken from each steer on d0 (prior to implantation) and on d28. RNA was prepared from each sample and real-time RT-PCR was used to determine

the levels of IGF-I and IGF-II mRNA. Total weight gain over the 28 d period of the study was significantly greater ($p < 0.05$, $n = 5$) for steroid-treated steers than for control steers. The IGF-I mRNA levels in LD muscles of control animals were not different on d0 and d28. On d28 of implantation, the IGF-I mRNA level was 60% higher ($p < 0.05$, $n = 5$) in E2/TBA implanted animals than in control steers. Similarly, on d28 the LD muscle IGF-I mRNA level was 70% higher ($p < 0.05$, $n = 5$) in E2 implanted steers than in control animals. In contrast the TBA implant did not significantly increase LD muscle IGF-I mRNA levels after 28 days of implantation. Muscle IGF-II mRNA levels were not affected by any of the implants. These data suggest that E2 is responsible for the increased muscle IGF-I mRNA level observed in steers implanted with a combined E2/TBA implant.

Key Words: IGF-I, Anabolic Steroid, Muscle

TH78 Effects of androgen and estrogen (E2) receptor blockers and E2-conjugated BSA on estrogen and trenbolone acetate-stimulated IGF-I expression in cultured bovine satellite cells. E Kamanga-Sollo¹, M. E. White*¹, M. R. Hathaway¹, K. Y. Chung², B. J. Johnson², and W. R. Dayton¹, ¹University of Minnesota, St. Paul, ²Kansas State University, Manhattan.

Even though combined implants containing androgenic and estrogenic steroids are routinely used to enhance muscle growth in domestic meat producing animals, in particular cattle, there is no consensus concerning the mechanism by which they enhance muscle growth. A combined trenbolone acetate (TBA)/estradiol 17 β (E2) implant has been shown to increase muscle IGF-I mRNA level and satellite cell number in yearling steers. Additionally, TBA or E2 treatment of cultured bovine satellite cells (BSC) resulted in increased IGF-I mRNA expression. The objective of the present study was to further evaluate the mechanisms of TBA and E2 action on BSC. Flutamide, an androgen receptor blocker, suppresses ($p < 0.05$) TBA-stimulated IGF-I expression by cultured BSC indicating TBA functions through the classical androgen receptor. In contrast, ICI 182 780 (ICI), an estrogen receptor blocker, did not suppress E2-stimulated IGF-I expression in BSC cultures. In fact, treatment of cultured BSC with 100 nM ICI in the absence of E2 resulted in a 2-fold increase ($p < 0.05$) in IGF-I mRNA level. BSA-conjugated-E2 (E2-BSA) binds to estrogen receptor (ER)- α and ER- β but is not able to cross the cell membrane. E2-BSA (10, 100, or 300 nM) did not stimulate proliferation of cultured BSC indicating that E2-stimulated proliferation is mediated through classical intracellular ER receptors; however, 100 nM E2-BSA did stimulate ($p < 0.05$) IGF-I mRNA expression. These results raise the possibility that binding of E2 to cell surface receptors, rather than intracellular ER, is responsible for E2-stimulated IGF-I expression in BSC and suggest that the effects of E2 on IGF-I mRNA level in these cells may not be mediated through the classical genomic mechanisms involving ER- α and the AP-1 response element as it is in others tissues examined to date.

Key Words: IGF-I mRNA, Muscle, Receptor Blockers

TH79 Proglucagon and GLP-2 receptor mRNA distribution in the ruminant gastrointestinal tract. C. C. Taylor-Edwards*, D. B. Edwards, M. J. Doig, E. S. Vanzant, K. R. McLeod, J. A. Boling, J. C. Matthews, and D. L. Harmon, University of Kentucky, Lexington.

The role of glucagon-like peptide-2 (GLP-2) in ruminants is relatively unknown, despite its importance in the regulation of gastrointestinal growth in non-ruminants. This experiment investigated the mRNA expression pattern of proglucagon (GCG), the precursor of GLP-2, and the GLP-2 receptor (GLP-2R) in the ruminant digestive tract. Effects of nutrient supply on mRNA expression patterns and measures of gastrointestinal mass were tested using three infusion treatments: water (control) or an additional 20% of ME intake as starch hydrolysate into the rumen or abomasum. Eighteen ruminally and abomasally cannulated Angus steers (260 kg BW) were blocked by weight and randomly assigned to treatment ($n = 6$). Steers were fed an alfalfa-cube diet at $1.3 \times NEM$ requirement. Steers were infused for 19 to 21 d, with the first 7 d of the period used as an adaptation period to infusion in which the amount of starch hydrolysate infused was incrementally increased each day. Steers were killed, gastrointestinal tissues weighed, and epithelial samples obtained from the forestomachs (rumen, omasum, and abomasum) and intestines (duodenum, jejunum, ileum, and colon). After extraction of total RNA from collected epithelia, real-time PCR was used to determine the expression of GCG and GLP-2R mRNA relative to 18S rRNA. Treatment had no effect on empty BW or mass of most gastrointestinal tissues except the small intestine; abomasal starch infusion increased small intestinal weight (% empty BW) by 17% ($P = 0.003$) and 18% ($P = 0.002$) compared with water or ruminal starch infusion, respectively. Expression of GCG mRNA was 5000-fold greater ($P < 0.0001$) in intestines than forestomachs. Likewise, GLP-2R expression was 49-fold greater ($P < 0.0001$) in intestines than forestomachs. Although dietary treatment did not affect expression patterns of GCG and GLP-2R mRNA, these results describe the tissue distribution of mRNA for the GLP-2 precursor and the GLP-2 receptor in ruminants.

Key Words: Glucagon-Like Peptide-2, Ruminant, mRNA Expression

TH80 Effects of overfeeding adolescent ewe lambs on progeny growth. G. J. Eckerle*, R. V. Anthony, and R. K. Peel, Colorado State University, Fort Collins.

Adolescent lambs, impregnated by embryo transfer and fed ad lib throughout gestation, are reported to produce growth restricted offspring. It was our objective to determine if ad lib feeding of periparturient ewes following natural mating at the second observable estrus, impacted birthweight and postnatal growth characteristics of the offspring. Two replicate studies were completed, in which singleton-bearing ewe lambs were fed a complete gestational diet (11.4 MJ metabolic energy/kg DM) at a rate which met NRC gestational age requirements (MN; $n = 8$ year 1, $n = 7$ year 2) or were fed ad lib (15% refusal rate) throughout gestation (HN; $n = 6$ year 1, $n = 7$ year 2). There was no effect ($P \geq 0.10$) of gestational intake on lamb birthweight (year 1: 5.0 ± 0.23 vs. 4.9 ± 0.20 kg; year 2: 5.01 ± 0.42 vs. 5.68 ± 0.40 kg; MN vs. HN respectively), lamb abdominal circumference or crown-rump length. However, during year 2, neonatal death loss was increased in HN pregnancies (0% vs. 57%; MN vs. HN), due to increased ($P \leq 0.01$) dystocia (1.0 ± 0.0 vs. 3.5 ± 0.7 score; 1=no assistance to 5=cesarean section). During year 1, lambs were weaned at 80 days of age and fed ad lib (11.4 MJ metabolic energy/kg DM) until 140 days of age. Neither preweaning (0.32 ± 0.018 vs. 0.33 ± 0.015 kg/d, MN vs. HN) nor overall (0.28 ± 0.009 vs. 0.29 ± 0.010 kg/d; MN vs. HN) growth rate were effected ($P \geq 0.10$) by gestational intake. During year 2, lambs remained with their dams until they were weaned at 60d., and were fed ad lib until reaching the target slaughter weight (59 kg). Similar to year 1, no differences ($P \geq 0.10$) were observed in growth rate, target weight age, or in carcass characteristics (rib eye

area, back fat thickness and percent kidney pelvic and heart fat) collected at slaughter. Collectively, our results indicate that ad lib feeding adolescent ewe lambs, which conceived to natural service, does not impact fetal or postnatal growth rate of the progeny, but may result in increased dystocia rate and neonatal mortality.

Key Words: Peripubertal Lambs, Gestational Overfeeding, Progeny Growth Rates

TH81 Biological efficiency of crossbred beef cattle finished on feedlot and slaughtered with distinct body weights. R. Mello^{*1,3}, M. H. de Faria², A. C. de Queiroz³, F. D. de Resende², D S Henrique³, and F Maldonado², ¹Universidade Federal de Roraima, Boa Vista, RR, Brazil, ²APTA, Colina, SP, Brazil, ³Universidade Federal de Viçosa, Viçosa, MG, Brazil.

The objective in this trial was to assess the bionutritional efficiency of crossbred F1 Red Angus ± Nellore (1/2 RA 1/2 N) and F1 Blond D'Aquitain ± Nellore (1/2 BA 1/2 N) young bulls finished on feedlot and slaughtered with 480, 520 and 560 kg of shrunk body weight (SBW). A completely randomized experimental design in a 2 ± 3 (2 genetic groups ± 3 slaughter weights) factorial arrangement with six replicates was used. Data were analyzed in the SAS[®] software using initial SBW as a covariate. The table below shows the least-square means of ADG, DMI, gain to feed ratio (GFR), biologic multivariate nutritional index (BMNI), Kleiber ratio (KR) and residual feed intake (RFI). There was no difference among the different treatments for ADG. There was not significant effect for GG, SW and interaction on relative DMI (% BW and g/BW^{0.75}). As the slaughter weight rised the absolute DMI (kg/d) increased. The 1/2 BA 1/2 N young bulls slaughtered with 480 kg had lower (P<0.05) feed:gain ratio (5.2) than others (> 6.8), but GFR and KR didn't differ (P>0.05) among treatments. The 1/2 BA 1/2 N young bulls had lower (P<0.05) BMNI and RFI than 1/2 RA 1/2 N young bulls. The lighter young bulls had lower (P<0.05) BMNI in relation to the heavier young bulls. Thus, crossbred F1 Blond D'Aquitain ± Nellore young bulls and lighter animals are more bionutritionally efficient in the finishing phase on feedlot than F1 Red Angus ± Nellore and heavier animals.

Table 1. Least square means

	Genetic Group (GG)		Slaughter Weight (SW)		
	½ RA ½ N	½ BA ½ N	480	520	560

TH82 Estimation of carcass and empty body chemical composition of Nellore and Caracu breeds. S. F. M. Bonilha^{*1}, L. O. Tedeschi², I. U. Packer³, A. G. Razook¹, L. A. Figueiredo¹, R. F. Nardon⁴, and G. F. Alleoni⁴, ¹Instituto de Zootecnia, Agência Paulista de Tecnologia dos Agronegócios, Sertãozinho, SP, Brazil, ²Texas A&M University, College Station, ³Universidade de São Paulo/ESALQ, Piracicaba, SP, Brazil, ⁴Instituto de Zootecnia, Agência Paulista de Tecnologia dos Agronegócios, Nova Odessa, SP, Brazil.

Linear regressions, based on 9-11th rib section chemical composition, were developed to estimate carcass and empty body chemical composition of 56 selected Nellore (NeS), 52 control Nellore (NeC), and 56 selected Caracu (CaS) bulls, with 20 to 24 mo of age at slaughter. Carcass composition was obtained after grinding, homogenizing, sampling, and analyzing edible fraction + bones. Empty body chemical composition was obtained after grinding, homogenizing, sampling, analyzing, and combining blood, hide, head + feet, viscera, and carcass. The percentages of water and ether extract (EE) were determined both on the rib section and on carcasses of group 1 (36 NeS; 36 NeC; and 36 CaS bulls). In group 2 (20 NeS; 16 NeC; and 20 CaS bulls) empty body percentages of water and EE were also determined. Linear regressions were developed between carcass and rib section compositions (for group 1) and between carcass and empty body compositions (for group 2). The interactions between chemical components and genetic groups in the developed equations were not significant (P > 0.05). The 9-11th rib section percentages of water (RW) and EE (RF) precisely predicted (r² > 0.75) the percentage of carcass water (CW): %CW = 29.0806 + 0.4873×%RW, r² = 0.81, SE = 1.06; %CW = 64.8316 - 0.3549×%RF, r² = 0.78, SE = 1.14. The percentages of RW and RF precisely predicted the percentage of carcass fat (CF): %CF = 10.4039 + 0.5179×%RF, r² = 0.86, SE = 1.26; %CF = 61.6067 - 0.6928×%RW, r² = 0.85, SE = 1.33. Linear regressions (r² > 0.75) between percentages of CF and CW and empty body water (BW) were found: %BW = -9.7560 + 1.1637×%CW, r² = 0.88, SE = 1.43; %BW = 73.1673 - 0.8274×%CF, r² = 0.88, SE = 1.41. Linear regressions (r² > 0.75) between percentages of CF and CW and empty body EE (BF) were found: %BF = 0.3667 + 1.0393×%CF, r² = 0.98, SE = 0.65; %BF = 101.3752 - 1.4095×%CW, r² = 0.91, SE = 1.47. Chemical composition of 9-11th rib section precisely estimated carcass percentages of water and EE. Good linear regressions were detected between carcass and empty body chemical composition.

Key Words: 9-11th Rib Section, Ether Extract, Water

Horse Species

TH83 Temporal variables of the Arabian and Morgan Western Pleasure Jog. M. Nicodemus* and A. Luckett, *Mississippi State University, Mississippi State.*

The western pleasure class is one of the most popular rail classes for the Quarter Horse, Paint Horse, Arabian, and Morgan. However, kinematic research defining western pleasure gaits is only available for the stock-type breeds. Therefore, the objectives of this study were to define the jog of the western pleasure Arabian and Morgan and to compare the jog of these two breeds. 7 registered Arabians and 7 registered Morgans showing in a western pleasure class at their respective national competitions were filmed at 60 Hz performing the jog. Carded judges for their respective breeds selected the horses and strides that were used in this study according to breed standards. Frame-by-frame analysis of 5 strides for each horse was performed to determine temporal variables. Means (standard deviations) were determined with duration variables given as a percent of stride duration. Effect of breed type for each variable was tested using a one-way analysis of variance ($P < 0.05$). Both breeds performed a symmetrical, 4-beat stepping gait with a lateral footfall sequence and diagonal couplets (Table). For both breeds, the majority of the stride was spent in the stance phase with the longest period of limb support being diagonal bipedal support (Arabian: $83 \pm 3\%$, Morgan: $77 \pm 3\%$) followed by quadrupedal support (Arabian: $12 \pm 1\%$, Morgan: $16 \pm 1\%$). Analysis of variance indicated no significant difference between breeds for the measured variables. The only distinguishing factor between the two breeds was that only the Arabian demonstrated pairing of the diagonal limbs as the limbs came off the ground. Due to this pairing of the diagonal limbs found only in the Arabian, the Arabian was the only breed that lacked a period of tripodal limb support with two hind limbs. The objective description of these gaits from these measured variables can be applied in the selection and evaluation of the western pleasure Arabian and Morgan.

	Arabian	Morgan
Velocity (m/s)	1.69±0.16	1.92±0.21
Stride Length (m)	1.57±0.19	1.86±0.17
Stride Frequency (strides/s)	1.08±0.08	1.03±0.04
Stride Duration (ms)	921±48	971±42
RF Stance (%)	58±2	60±1
LF Stance (%)	59±1	60±3
RH Stance (%)	56±2	59±2
LH Stance (%)	56±1	59±3
Tripodal-2 Fore (%)	5±4	5±3
Tripodal-2 Hind (%)	0±0	2±1
LF-RH Advanced Placement (%)	3±2	2±1
RF-LH Advanced Placement (%)	2±1	3±1
LF-RH Advanced Lift-Off (%)	0±0	2±1
RF-LH Advanced Lift-Off (%)	0±0	2±2

Key Words: Temporal Variables, Western Pleasure, Jog

TH84 Use of chicken vs. chukar (*Alectoris chukar*) egg yolk as components of freezing media for stallion semen. S. E. Harmon and G. W. Webb*, *Missouri State University, Springfield.*

Recent published reports have indicated a possible increase in post-thaw motility and viability for stallion spermatozoa when the chicken egg yolk

in the freezing media is replaced by that of other avian species (including duck, quail and pigeon). Two experiments were conducted to compare the affects of chicken vs. chukar (*Alectoris chukar*) egg yolk on post thaw motility of stallion spermatozoa. In each experiment, three ejaculates were collected from each of 4 stallions. Immediately post collection aliquots of each ejaculate were diluted 1:1 with INRA 96™ extender (IMV, International), centrifuged to remove the seminal plasma, split into 8 parts and resuspended with one of 8 fast freeze (experiment 1) or 8 slow freeze extenders (experiment 2) to a final concentration of 150×10^6 spermatozoa/ml. Aliquots frozen using the fast freeze method were diluted with extenders which consisted of Lactose-EDTA containing 4% glycerol and either 13, 16, 19, or 22% of either chicken or chukar egg yolk and allowed to equilibrate for 30 min and loaded into 0.5 ml straws. Prior to freezing straws were suspended 8 cm above the liquid nitrogen for 10 min. Aliquots frozen using the slow freeze method were diluted in INRA 96™ supplemented with 4% glycerol and either 2, 4, 6, 8% of either chicken or chukar egg yolk. Aliquots were then placed in a 23° C water bath for equilibration and cooling to 4° C over a 2 h period prior to freezing using the same procedure as (experiment 1). After a minimum of 2 wks storage two straws per ejaculate/treatment combination were thawed and evaluated for motility using CASA (CEROS®; Hamilton Research Inc, Beverly, MA). Post storage percentage of intact acrosomes of these same samples was evaluated following staining with Spermac Stain™ (FertiPro, Beernem, Belgium). Data were analyzed using a GLM procedure with a one-way ANOVA and Tukey's used to test differences between treatments. Within freezing method (fast vs. slow) there was no effect ($P \leq 0.05$) of egg yolk source on post thaw motility or percentage of intact acrosomes and therefore no advantage observed by substitution of chicken with chukar egg yolk as a component of freezing diluents for stallion spermatozoa.

Key Words: Stallion, Semen, Egg Yolk

TH85 Nutrient composition and selection preferences of forages by feral horses: The horses of Shackleford Banks, North Carolina. S. J. Stuska¹, S. E. Pratt^{*2}, H. L. Beveridge², and M. J. Yoder², ¹*Cape Lookout National Seashore, Harkers Island, NC*, ²*North Carolina State University, Raleigh.*

Health of the horses of Shackleford Banks is influenced by the nutritional composition of the plants that are consumed. Over the years, cases of developmental orthopedic disease have been observed in growing horses, which may be due to nutritional imbalances in the diet. However, assessing nutritive status of wild herbivores is challenging; it is difficult to accurately determine what is being consumed. Forage nutrient content analysis coupled with fecal analysis can give an estimate of the nutritive profile for the animal, though it does not determine total daily intake. Horses were observed and representative samples of what they were eating were collected during four seasons over two years. Samples were analyzed for DM, CP, Ca, P and DE (reported as DM). Fresh fecal samples were also collected and pooled during the second year of the study for microhistological analysis to estimate selection and proportions of plant species consumed. Significant differences in seasonal variation in plant consumption and nutritive content was determined with ANOVA. Plant selection and nutrient composition of the plant was significantly different across the seasons. In the fall, sea oats (*Uniola paniculata*) (41.6%), centipede grass (*Eremochloa ophiuroides*) (23.9%)

and smooth cordgrass (*Spartina alterniflora*) (12.5%) made up 78.0% of the horse's diet. In the winter, consumption of sea oats decreased by half, while the variety of plants consumed increased. In the spring, centipede consumption dropped in favor of increased sea oats, cordgrass, and pennywort. In the summer, sea oats (30%), centipede (14.8%) and cordgrass (19.5%) made up 64.3% of the horse's diet with other plants making up the difference. Cordgrass had the highest DE (2.28 ± 0.32 Mcal/kg) and CP ($10.2 \pm 2.1\%$) throughout the year. Sea oats and centipede had lower mean nutrient profiles over the seasons; 1.7 ± 0.05 Mcal/kg DE, $5.31 \pm 0.4\%$ CP and 1.8 ± 0.09 Mcal/kg DE, $5.07 \pm 1.4\%$ CP respectively. Given the average nutrient composition of the forages, high dietary intakes would be required for these horses to meet their nutritional needs. It is possible that nutrient deficiency contributes to growth problems observed in these horses.

Key Words: Feral, Horse, Nutrition

TH86 Estimation of body weight in ponies. G. S. Owen*¹, E. L. Wagner¹, and W. S. Eller², ¹Auburn University, Auburn, AL, ²Louisiana State University, Baton Rouge.

The ability to accurately estimate body weight in horses and ponies is of great benefit in the dosage of medication and anthelmintics, as well as in feeding management practices. An established formula is widely used to estimate the body weight of horses, where estimated weight (lbs), (kg) = (heartgirth² x body length)/(330 in³), (11880 cm³). The objective of this study was to validate the use of a weight estimation formula in ponies, which measure less than or equal to 14.2 hands (147.3 cm) at the withers. Sixty-eight ponies were weighed on a calibrated livestock scale, and measurements of heartgirth, body length and height at the withers were recorded. Mean pony height was 134.4 ± 10.8 cm, with a mean scale weight of 343.7 ± 82.6 kg and a mean body condition score of 5.7 ± 1.0 on a nine-point scale. A paired t-test determined that there was a significant difference ($P < 0.05$) between actual weight (343.7 ± 82.6 kg) and weight estimated by the established formula (310.2 ± 76.4 kg). Linear regression was used to fit the body measurements and weight data to a model based on the established formula. Due to the low n in the model, bootstrap estimation with 5000 replications was used to estimate the parameters. A new coefficient (299 in^3 , 10787 cm^3) was estimated in fitting the model ($R^2 = 0.99$). The estimated denominator was found to be significantly different from the denominator in the previous formula ($P < 0.05$). Inclusion of the new coefficient in the formula appears to reliably estimate the actual body weight in ponies.

Key Words: Pony, Weigh Estimation, Body Measurements

TH87 Basal insulin and glucose concentrations in horses of North Carolina. K. M. Owens*, S. E. Pratt, L. E. Dowler, and M. T. Cloninger, North Carolina State University, Raleigh.

In equines, research suggests an associative role of decreased insulin sensitivity (insulin resistance) in disease states such as laminitis and metabolic syndrome. There are little data available regarding values of insulin sensitivity among large horse populations due, in part, to the difficulty of quantification. Basal glucose and insulin concentrations have been used to estimate glucose and insulin dynamics. The objectives of this study were to determine ranges of basal glucose and insulin

concentrations in horses of North Carolina and to determine how these are related to management and innate factors (diet, age, gender, breed, etc.). Horse owners were solicited through various North Carolina equine publications and websites to identify volunteers. Horses (n = 366) were sampled at their home farms by one of three trained personnel between August and December, 2007. Owners completed a questionnaire with information pertaining to age, breed, medical history and exercise protocols. Also, body weight, feed intake and body condition score (BCS) was assessed by the authors. Blood samples were collected via jugular venipuncture for assessment of serum insulin (INS) and plasma glucose at least 4 hours post-feeding or exercise. The insulin: glucose ratio (I:G) was calculated from this data. Mean (\pm SD) INS and I:G were 13.7 ± 29.4 mIU/L and 3.2 ± 2.6 mIU/L/mM respectively. Both I:G and INS were positively correlated with age (I:G $r = 0.129$, $P = 0.025$; INS $r = 0.118$, $P = 0.040$) and BCS (I:G $r = 0.135$, $P = 0.019$; INS $r = 0.161$, $P = 0.005$). Neither body weight nor concentrate consumption (as % body weight) were related to INS or I:G. There were no significant differences among mares, geldings or stallions. Breeds had significantly different I:G ($P = 0.030$), with pony breeds being significantly higher than breeds such as the Quarter Horse. Pony breeds, older horses and those with high BCS should be carefully managed. Approximately 9% of horses sampled were hyperinsulinemic (defined as INS > 30 mIU/L) regardless of BCS. While not a quantitative measure of insulin sensitivity, hyperinsulinemia may indicate a risk for insulin resistance and associative conditions.

Key Words: Equine, Insulin, Glucose

TH88 Equine identification in the Amish community: An overview of a survey conducted in Pennsylvania. A. Swinker*, K. Vanderman, H. McKernan, A. Graeff, and B. Gill, The Pennsylvania State University, University Park.

Amish are a Christian settlement from Europe that settled in North America in the eighteenth and nineteenth centuries. The Amish relied heavily upon equid for transportation and farm work. Today they reside in 27 states. Pennsylvania's Amish population totals 4,294 households. About 70 percent of the US Amish live in Ohio, Pennsylvania, and Indiana; with Lancaster County, PA being the second largest settlement. Understanding the concerns of the Amish is essential to help NAIS (National Animal Identification System) with equine tracking and identification. The average Pennsylvania Amish household reported owning 5.6 equid. The objectives of this study were; 1) acquire an Amish population to survey, 2) sample the Amish community to measure their concerns and acceptance of NAIS and 3) to acquire questionnaires completed by Amish families. A total of 78 Amish households were asked to participate in the survey. Thirty-two families did participate in the survey. The survey was conducted by an enumerated written questionnaire and asked questions related to equine ownership, animal and premises identification. Surveys were edited for completeness, legibility, accuracy and validity. Data were analyzed, SPSS (SPSS Inc., Chicago, IL) for descriptive and inferential statistics. Sample consisted of 2 women and 30 men, 25 percent reported to be in the horse business. Eighty-seven percent of surveyed respondents refused to participate in the NAIS program, one person was willing to participate and 3 were uncertain. Eighty eight percent of respondents reported hearing about NAIS by word of mouth while 43 percent read about it in newspapers or breed magazines. Of those sampled only one had a premises ID number and four were unsure. Twenty Seven reported they did not have a premise ID number. When asked about their level of concerns the Amish report a high level of concern about recovering

lost or stolen horses. They also considered tracing sources of, spread of and notification of disease a high concern. However, confidentiality of information was rated moderate and an improved identification method for horses was of low concern.

Key Words: Equine, Amish, Identification

TH89 Equine show and event manager survey of resistance to the implementation of national equine identification. A. Swinker*, K. Vanderman, A. Graeff, K. Vines, and B. Gill, *The Pennsylvania State University, University Park*.

The NAIS (National Animal Identification System) is a program to identify and record the movement of animals in the event of a foreign animal disease outbreak. Survey objectives were to collect input from equine event managers concerning the National Animal Identification System and identify its application to the equine industry. A fifteen question on-line survey was developed related to emergency preparations, premises information, equine travel, NAIS opinion, and how NAIS could be incorporated into equine event management. The survey was sent to 250 email addresses reaching 243 equine show managers with representation from all 50 states and Canada. Shows of a variety of sizes were represented, ranging from large sanctioned breed shows to small local events. The survey was open to invited participants only. At the close of the data collection 152 people visited the site and 115 had completed surveys. The return rate was 47.3%. Seven addresses were undeliverable. Data were analyzed using SPSS (SPSS Inc., Chicago, IL) for descriptive and inferential statistics. Twenty-five percent of the surveyed managers reported being in favor of NAIS, 42% were neutral, 14% were unsure while 18% were opposed. Survey results showed a real need to educate equine show managers on the benefits of NAIS. When asked, at your equine event, would microchipping equid for identification be useful 40% reported that it would be useful to verify equine ID and prevent fraud. Thirty-seven percent reported it would prevent/deter theft of equid from the show grounds and 34% reported it would prevent the incorrect equine from being shown. However, 53% reported NAIS will increase paper work at events. Equine show and event managers reported some benefits of utilizing NAIS.

Key Words: Equine, Show, Identification

TH90 United States equine owner's survey on the implementation of national equine identification. K. Vanderman*, A. Swinker, H. McKernan, B. Gill, and R. Radhakrishna, *The Pennsylvania State University, University Park*.

A survey was designed to assess the composition of the equine industry, and identify resistance to and the impact of the National Animal Identification System (NAIS) on equine owners. A six-section, traditional paper survey was developed with questions related to ownership, emergency preparations, premises information, equine travel, NAIS opinion, and demographic characteristics. A mailing list of 10,010 name/addresses of horse owners was created representing 14 major equine groups. A sample (N= 2,783) received surveys randomly with follow up mailings, resulting in a response rate of 50.16%. SPSS (SPSS Inc., Chicago, IL) was used for descriptive and inferential statistics. Pearson's correla-

tion, simple linear regression and multiple regression were used to determine the relationship between select variables. Data showed that 55.5% of equine owners do not have a plan of action for their equid during a disaster and 80% do not practice biosecurity. The majority of owners (62.8%) reported they were not familiar with NAIS, 32.7% were somewhat familiar, and 4.2% were very familiar. Sixteen percent were interested in participating in NAIS, 52% were unsure, while 32% were not interested. Over 73% identify their equine by color/markings, followed by DNA (43.3%), tattoos (30.8%), and hair whorls (21.9). About 3% use microchipping to identify their equid. Approximately 81.4% were familiar with microchipping as a form of identification, and 21.7% own other animals that were microchipped. The majority of respondents were "very concerned" regarding tracing the source of a disease and eliminating its spread (47.5%), being notified about disease outbreaks in their area (57.5%), recovering lost or stolen equid (49.9%), and maintaining confidentiality of information (40.9%). Survey results indicated that equine owners should be educated about the spread of disease, the role of NAIS, and additional benefits of participation such as equine theft recovery. This education would assist the equine industry in its acceptance of NAIS.

Key Words: Equine, Identification, NAIS

TH91 Equine veterinarians and health care professionals survey of resistance to the implementation of national equine identification. N. Dreschel*, K. Vanderman, A. Swinker, E. Jedrzejewski, and J. Werner, *The Pennsylvania State University, University Park*.

The National Animal Identification System (NAIS) is a program to identify and track animals for disease monitoring. A survey was designed to evaluate equine health care professionals' attitudes towards NAIS and the application of NAIS to the equine industry. A twenty-seven question survey related to emergency preparations, premises information, equine travel, NAIS opinion, disease outbreaks, and how NAIS can be utilized in a veterinary clinic measured participants' responses. An online survey was e-mailed to equine veterinarians and health care professionals that were members of AAEP's (American Association of Equine Practitioners) chat group. This group represents veterinarians from all regions of the United States. The survey was available only to these invited participants and was not open to the public. At the close of the survey, 158 people have visited the survey site and 139 surveys were completed. SPSS (SPSS Inc., Chicago, IL) was used for descriptive and inferential statistics. Pearson's correlation, simple linear regression and multiple regression were used to determine the relationship between select variables. Of those who reported, 47% are in favor of NAIS, 4% are opposed, and 50% are neutral or unsure. When asked, "Do you feel that NAIS will be useful in quickly stopping the spread of a foreign animal disease?", 55% reported yes and 45% felt it would not. Equine health care providers rated their familiarity with NAIS as not at all familiar (17%), somewhat familiar (62%), or very familiar (21%). The majority of respondents (75%) do not use microchip numbers as part of their client database, although 53% are currently microchipping animals. Other studies have shown that equine owners receive the majority of their equine care information from their veterinarians. By further informing this group, there is an opportunity to increase awareness and education of NAIS.

Key Words: Equine, Identification, Veterinarians

TH92 Application of forensic science technique to the management of an endangered horse population. E. Bömcke*^{1,2} and N. Gengler^{1,3}, ¹*Gembloux Agricultural University, Gembloux, Belgium*, ²*FRIA, Brussels, Belgium*, ³*FNRS, Brussels, Belgium*.

Implementing conservation strategies needs the knowledge of relationships inside the concerned population. The aim of the study was to find tools to help breeders to manage populations with weak pedigree information. The Skyros pony is an indigenous Greek breed with breed risk status is defined as critical-maintained (Food and Agriculture Organization). Partial pedigree information is available, but its quality is poor as the average number of generation-equivalents is under 0.8 for the first known generation and under 1.4 for the second to the fifth. A method used in human forensic science and called Familial Searching was tested in this study to improve the pedigree. First, 99 living individuals were genotyped at 16 microsatellite loci. For ungenotyped animals, conditional expectation of gene contents was calculated given molecular and pedigree data. In Humans, Familial Searching is used, in addition to matching DNA evidence directly to criminal profiles, to search for people (present in a database) who are related to an individual that left the DNA evidence. This method is based on the calculation of decision statistics (likelihood ratio (LR)) between the genotype of an individual and the genotype of each other analyzed individual, where a higher LR indicates greater probability to be related, a value of zero means no probability to be related. The known pedigree was used as 'local' prior information, i.e. information related to specific pairs of individuals. General knowledge about the studied population (generation interval, sexual maturity, ...) was considered as 'global' prior information. Including prior information reduced the number of comparisons by over 50%. First results showed that the parents were always classified into the 5 highest LR. It also simplified parentage verifications, as it allowed the detection of 90% of false parentage (LR=0). By creating new links in the pedigree through the detection of unregistered parents, the percentage of animals with one or both unknown parents decreased and consequently the number of generation-equivalents increased. Therefore Familial Searching was found to be a useful tool to improve the pedigree of the Skyros breed.

Key Words: Likelihood, Pedigree, Horse

TH93 Sites of active nutrient absorption in the equine gastrointestinal tract. B. E. Aldridge*, T. B. Lescun, and J. S. Radcliffe, *Purdue University, West Lafayette, IN*.

Nine horses were used to investigate active nutrient absorption in the proximal (13.7 m from the ileocecal junction) and distal (9.1 m from the ileocecal junction) jejunum, ileum (5 cm from the ileocecal junction) and mid-right ventral colon using modified Ussing chambers. Immediately following euthanasia, intestinal tissues were collected and mounted in modified Ussing chambers to determine basal short-circuit current (I_{sc}), and to determine the capacity for active glucose, phosphorus, glutamine, and glycyl-sarcosine absorption in each portion of the intestine based on changes in I_{sc} following the addition of 10 mM of each compound to the mucosal buffer. Chambers were osmotically balanced by adding mannitol to the serosal buffer. Finally, carbachol was added to the serosal buffer to test for chloride secretory ability. Basal I_{sc} and active glutamine absorption were not different (P>0.10) between intestinal sections. Active glucose absorption tended (P<0.10) to be higher in the ileum than the proximal jejunum and right ventral colon with the distal jejunum being intermediate. Phosphorus absorption was higher

(P<0.02) in the right ventral colon (18.45 μA/cm²) compared to the proximal (7.9 μA/cm²) and distal jejunum (10.3 μA/cm²) and ileum (7.3 μA/cm²). Greater active absorption (P<0.05) of the di-peptide glycyl-sarcosine was observed in the distal jejunum and right ventral colon compared to the proximal jejunum, with the ileum being intermediate. Secretion of chloride ion, following a serosal carbachol challenge, was greater (P<0.01) in the right ventral colon (19.07 μA/cm²) compared to the proximal (3.97 μA/cm²) and distal jejunum (4.96 μA/cm²) and the ileum (3.04 μA/cm²). Based on the results of this experiment, the importance of each section of the intestine differs depending on the nutrient being evaluated.

Key Words: Nutrient, Absorption, Equine

TH94 Genistein reduces LPS stimulated TNFα release from equine monocytes. A. R. Taylor* and J. A. Clapper, *South Dakota State University, Brookings*.

Endotoxemia is often manifested by an overproduction of circulating proinflammatory cytokines, such as tumor necrosis factor-α (TNF) in response to lipopolysaccharide (LPS). Genistein is a non-steroidal tyrosine kinase inhibitor that has been shown to decrease the release of TNF from circulating monocytes in response to LPS. To further examine if genistein could be used to reduce LPS stimulated TNF release in the horse the following experiment was performed. Blood (180 mLs) was collected by jugular venipuncture from a mature healthy gelding and the isolated leukocyte rich plasma was layered over Histopaque 1077 and centrifuged to obtain an enriched monocyte population. Monocytes were washed twice in sterile PBS, counted, and diluted to 1 x 10⁷ cells/mL in RPMI 1640. Monocytes were then added to polystyrene tubes (4 x 10⁶ cells/tube) and incubated at 37°C in 5% CO₂ for 2 h to allow monocytes to adhere. Non-adherent cells were decanted and monocytes were covered with RPMI 1640 containing 1% FBS and 0, 1 pM, 1 nM, 10 nM, 1 μM and 10 μM genistein and incubated an additional hour at 37°C in 5% CO₂. Media was then replaced with media containing the various concentrations of genistein with and without 100 pg/mL LPS (*E. coli* O55:B5) and incubated for 6 h at 37°C in 5% CO₂ after which the supernatants were collected by centrifugation and frozen at -80°C until assayed for TNF by ELISA. Triplicate tubes were prepared for each genistein-LPS combination. Differences in supernatant concentrations of TNF-α were determined using the Proc Mixed procedure of SAS. Supernatant concentrations of TNF in tubes containing no LPS were not different (P>.05) and were at the detection limit of the assay. Supernatant concentrations of TNF decreased (P<.05) as genistein concentrations increased. Tubes containing 1 and 10 μM genistein produced less (P<.05) TNF than the 1 pM and 1 nM tubes in response to LPS, however, they were not different (P>.05) than LPS alone. These preliminary data suggest that genistein may be beneficial in reducing TNF release in response to LPS in the horse.

Key Words: Equine, Genistein, LPS

TH95 Effect of exercise and superoxide dismutase on systemic antioxidants and nitric oxide in horses. E. D. Lamprecht*, C. A. Bagnell, and C. A. Williams, *Rutgers, The State University of New Jersey, New Brunswick*.

The main objectives were to evaluate effects of exercise and oral superoxide dismutase (SOD) supplementation on systemic antioxidant status and nitric oxide (NO) in horses. Standardbred mares ($n = 12$) were used in this double blind, randomized crossover design. Horses were assigned to a treatment (TRT; 3 g/d of oral SOD powder with 3000 IU) or placebo (CON; 3 g/d cellulose powder) group. Mares were supplemented for 6 wks, completed a 6 wk wash-out period and were crossed over for another 6 wk supplementation. A repeated sprint exercise treadmill test (RSET) was conducted on d 28 (RSET 1,3) and d 42 (RSET 2,4) during each phase. Blood samples were collected before exercise (PRE), at peak effort (PEAK), 30 min, 2h, 4h, 24h, and 36h post exercise (POST). Samples were analyzed for plasma NO, erythrocyte total glutathione (tGSH) and glutathione peroxidase (GPx). Data were analyzed using a mixed model ANOVA with repeated measures in SAS. Results showed main effects for exercise test and sample time. Nitric oxide was higher for RSET 1 and 2 ($P < 0.01$) compared to RSET 3 and 4. A decrease in NO between 30 min POST and 4h POST ($P < 0.01$) was followed by an increase at 36h POST to pre-exercise values ($P < 0.01$). Relative to the other RSET, tGSH was lower ($P = 0.051$) and GPx activity was higher ($P < 0.01$) during RSET 4. Both tGSH ($P < 0.01$) and GPx ($P < 0.01$) were higher at PEAK compared to all other samples. No treatment effect of SOD was detected. Decreased NO levels for RSET 3 and 4 and increased GPx activity during RSET 4 may reflect a physiological adaptation to exercise or a change in reproductive hormone profile due to seasonal variation between trial phases. The NO peak at 36 h POST may indicate a delayed pro-inflammatory response to tissue microdamage. Elevated levels of tGSH and GPx at PEAK may be a compensatory antioxidant response to exercise-induced oxidative stress. Sample analysis for systemic SOD concentration and other markers of inflammation and oxidative stress is currently underway to identify benefits of oral SOD supplementation in horses.

Key Words: Equine, Oxidative Stress, Exercise

TH96 Evaluation of plasma alpha-tocopherol daily within-horse variation. P. D. Siciliano*, L. E. Dowler, and S. E. Pratt, *North Carolina State University, Raleigh.*

Two experiments were conducted to evaluate plasma alpha-tocopherol concentration (TOC) daily within-horse variation (Exp. 1) and to determine the effect of a single meal on plasma TOC (Exp. 2). In Exp. 1 venous jugular blood samples were collected from 4 pregnant (mo 6 to 7 of gestation) mares of light horse breeding (5 to 11 yr of age) between 730 and 830 followed by 8 hourly samples and analyzed for plasma TOC. All horses were fed 5 kg DM of grass hay 18 h prior to sample collection and received no additional feed during the sampling period. Water was always available. Results were analyzed using ANOVA for repeated measures design. Mean (\pm SD) plasma TOC over the sampling period for horses 1, 2, 3, and 4 was 3.75 ± 0.20 , 4.72 ± 0.15 , 4.23 ± 0.11 and 3.99 ± 0.12 $\mu\text{g/ml}$, respectively and was unaffected by time. In Exp. 2 seven horses 4 mares and 3 geldings of light horse breeding (3 to 12 yr of age) were randomly assigned to 1 of 2 treatments followed by reversal of treatments 24 h later: fasted (FST; $n = 7$) or fed (FD; $n = 7$). At 730 FD horses were offered 2.1 kg DM of grain-mix-concentrate (187 IU vitamin E/kg DM) plus 3.3 kg DM mixed grass hay while FST horses received no feed. Neither group received any feed for the period 18 h prior to 730. Venous jugular blood samples were collected at 1030 from all horses and analyzed for plasma TOC. Results were analyzed as a paired t-test using the PAIRED statement of SAS. The mean (\pm SD) within horse paired treatment difference was not significant (0.05

± 0.12 $\mu\text{g/ml}$). The results suggest within horse plasma TOC does not vary significantly over an 8-hr period in fasting horses and is unaffected 3 h following a hay grain meal.

Key Words: Alpha-Tocopherol, Horse, Vitamin E

TH97 Effect of selenium supplementation and dietary energy manipulation on mares and their foals: Foaling parameters and foal physical characteristics. B. J. Karren*¹, J. F. Thorson², C. A. Cavinder¹, C. J. Hammer², and J. A. Coverdale¹, ¹Texas A&M University, College Station, ²North Dakota State University, Fargo.

To investigate maternal plane of nutrition and role of Se yeast on foaling parameters and physical characteristics of foals, 28 Quarter Horse mares were utilized in a randomized complete block design. Mares were blocked by expected foaling date and assigned randomly within block to dietary treatments. Dietary treatments were arranged as a 2x2 factorial with two levels of nutrition, pasture or pasture plus grain (fed at 0.75% BW) and two levels of Se supplementation (0 or 0.3 mg/kg BW) equaling four treatment groups: pasture (P), pasture + grain (PG), pasture + grain + Se (PGS), or pasture + Se (PS). P and PS mares received approximately 100% of calculated NRC DE requirements, while PG and PGS received 120%. Selenium supplementation began 110 d prior to estimated foaling (d 0) and all dietary treatments were terminated at parturition. At parturition foaling parameters: time of water break to birth, time to stand, time to nurse, and time of birth to placenta expulsion were recorded. Colostrum samples were collected and quality estimated via refractometer and colostrometer. Placenta weight, foal birth weight, foal wither and hip height, foal body length, and total length of gestation were recorded. All data were analyzed using PROC GLM of SAS. Time of water break to birth, time to stand, time to nurse, time of birth to placental expulsion, placental weight, foal birth weight, wither and hip height, and body length were not affected ($P > 0.10$) by nutrition or Se supplementation. However, PG and PGS mares had greater BW ($P < 0.03$) prior to foaling, and greater colostrum refractometer values (Brix %) ($P = 0.01$). There was a nutrition x Se interaction ($P = 0.01$) with PGS mares having the shortest gestational length and PS mares having the longest. These data indicate that maternal plane of nutrition but not supplemental Se effects BW and colostrum quality (Brix %) of mares. Additionally, the interaction between nutrition and Se supplementation may affect gestational length. Despite differences in nutrition and Se supplementation there was no difference in foaling parameters or foal physical characteristics.

Key Words: Se, Foaling

TH98 Effect of selenium supplementation and dietary energy manipulation on mares and their foals: Placental dynamics. J. F. Thorson*¹, B. J. Karren², M. L. Bauer¹, C. A. Cavinder², J. A. Coverdale², and C. J. Hammer¹, ¹North Dakota State University, Fargo, ²Texas A&M University, College Station.

To investigate maternal plane of nutrition and role of Se yeast on placental dynamics, 28 quarter horse mares were used in a randomized complete block design. Mares were blocked by expected foaling date and assigned randomly within block to dietary treatments. Dietary treatments were arranged as a 2x2 factorial with two levels of nutri-

tion, pasture or pasture + grain (fed at 0.75% BW) and two levels of Se supplementation (0 or 0.3 mg/kg BW). This resulted in four treatments: pasture (P), pasture + Se (PS), pasture + grain (PG), and pasture + grain + Se (PGS). P and PS mares received approximately 100% of calculated NRC DE requirements, while PG and PGS received 120%. Selenium supplementation began 110 d prior to the estimated foaling (d 0) and all dietary treatments were terminated at parturition. At parturition, placental expulsion time and weight were recorded and two samples collected. Placental samples were placed in cryogenic vials, snap frozen in liquid nitrogen, and stored at -60°C until DNA, RNA and protein analysis. Samples were analyzed for concentrations of DNA and RNA using the diphenylamine and orcinol procedures. Protein in tissue homogenates was determined with Coomassie brilliant blue G, with bovine serum albumin as the standard. Concentration of DNA was used as an index of cell number, with protein:DNA and RNA:DNA ratios used as indices of cellular size and potential activity, respectively. All data were analyzed using a GLM model of SAS. There was no effect ($P \geq 0.20$) of Se or level of nutrition on cell number, potential cellular activity, placenta expulsion time, or placental weight. However, mares supplemented with Se had decreased ($P = 0.02$) placental cell size (32.50 mg protein/mg DNA) compared to mares not supplemented with Se (24.14 mg protein/mg DNA). Results indicate Se supplementation reduced cellular size without deviation in cell number or gross placental weight, while maternal plane of nutrition did not affect any placental parameters measured. Further studies are needed to understand the physiological significance of a reduced placental cellular size.

Key Words: Equine, Placenta, Selenium

TH99 Digestible energy requirements of two and three year old fillies receiving light exercise. J. E. Ringler*, B. D. Cassill, K. C. Watson, S. Hayes, and L. M. Lawrence, *University of Kentucky, Lexington.*

The National Research Council (NRC, 2007) recently published a method for calculating the digestible energy (DE) requirements of

growing horses receiving regular exercise. The method uses equations based on body weight (BW), age, average daily gain (ADG), and activity level. This study compared actual DE intakes of young horses receiving regular exercise to the DE requirements predicted using the NRC (2007) equations. Six fillies (five 2 year olds and one 3 year old, average BW of 450 kg) were individually housed and fed during four experimental periods (P), 35, 36, 25, and 28 d in length, respectively. Alfalfa cubes were offered at 1.4% BW in P1 and 1.5% BW in P2, P3, and P4. The amount of concentrate was adjusted to produce an ADG of approximately 0.2 kg/d. During P1 all fillies received the same concentrate; in P2, P3, and P4 fillies received either the P1 concentrate or one of two other concentrates, which were assigned as part of a different study. All fillies received the same light exercise (averaging 5 mph for 40 min, 5d/wk). Daily DE intakes and predicted DE requirements were averaged by period and horse and compared using paired t-tests. When individual horse data were averaged by period, the actual DE intakes (Mcal/d) were 21.1 (P1), 24.6 (P2), 24.7 (P3), 24.0 (P4), and were not different from the predicted requirements of 22.3, 23.2, 23.8, and 23.9, respectively ($P > 0.128$). When averaged within horse, the actual and predicted DE requirements (Mcal/d) were: Horse 1: 24.7 and 24.2 ($P = 0.544$); Horse 2: 21.8 and 20.6 ($P = 0.511$); Horse 3: 24.1 and 22.5 ($P = 0.405$); Horse 4: 24.1 and 21.7 ($P = 0.102$); Horse 5: 21.7 and 22.2 ($P = 0.509$); and Horse 6: 25.2 and 28.5 ($P = 0.263$), respectively. Predicted values ranged from 90.0 to 113.1% of the actual values. While a small number of horses were used, data from this study suggest the NRC (2007) equations predict the average actual DE requirements of two to three year old horses receiving light exercise, but that differences among individuals exist.

International Animal Agriculture

TH100 A model of personal preparation for the international agricultural teaching and extension program between the United States and China. J. Peng*, *Purdue University, West Lafayette, IN.*

There are prosperous agricultural education collaborations between the U.S. and China as a result of intensifying global economic integration. A globally competent person is one of the many factors that can affect the success of an international agricultural program between the U.S. and China. With growing globalization, the increased demand for qualified persons to fill international agriculture educator positions at colleges and universities prompted the idea of writing this paper. This autoethnographic study mainly draws on an animal agricultural educator's long-term personal life and professional agricultural education experiences in China as well as a six-year (2002-2007) personal life and professional agricultural education experiences in the U.S. This autoethnographic study specifically focuses on an animal agricultural educator's beliefs and practices relate to the U.S.-China culture and agricultural science learning. This autoethnographic study outlines the important personal preparation experiences that relate to the international agriculture teaching and extension program between the U.S. and China. The personal preparation experiences eventually build up the personal competence for the international agricultural teaching and extension program. Among the personal competence, the understanding of other cultures and languages is emphasized as a basic communication skill that is required to work in an international program. Personal motivation is another key competence that is required to work in any international program. Using the real examples of an international agriculture educator, this paper indicates the role as well as the specialization areas of individuals who plan to work in the international agricultural teaching and extension arena. Overall, this paper presents an innovative model of the preparation of an educator in the international agricultural teaching and extension area, with also the hope for the other educators and administrators to evaluate and generate their own 'ideal' personnel qualifications for that area.

Key Words: International, Personal Preparation, Agricultural Teaching and Extension

TH101 Energy and financial analysis of the conversion of a conventional beef cattle production system to an organic beef food-chain in Veracruz, Mexico. P. Fajersson*¹, G. Alvarado¹, G. Benítez¹, I. J. González¹, J. Nieto¹, W. Sangabriel¹, and P. Parada², ¹*Colegio de Postgraduados, Campus Veracruz, Veracruz, Mexico*, ²*Carnes La Rumorosa, Poza Rica, Veracruz, Mexico*.

Energy and financial analyses were conducted for the conversion of a conventional 730 ha pasture based 550 head beef cattle system (CPS) to an organic beef cattle foodchain (OBF), selling beef in 8 states in Mexico, to evaluate its sustainability and profitability over time. Visits to the OBF, interviews with the owner and a questionnaire were used to obtain production costs, quantify inputs and collect data to calculate the energy and financial costs before and after the conversion. In the energy analysis, the inputs used were identified, quantified, each assigned a value and then transformed into energy units (thousands of BTU) and compared, and also used to determine critical points of the foodchain to identify opportunities to improve resource use. A sensibility analysis of 3 future scenarios identified strengths and weaknesses in a dynamic environment. The fixed costs were USD 525,010 over time, but the

variable ones (USD 85,932 in the CPS) were less than in the OBF (USD 67,227). The marginal gain of the fixed costs were USD -448,296 and USD -368,682, respectively, while the difference between return on investment was 21% in the CPS and 63% in the OBF, which represents the real gain from the conversion. Using only the variable costs, the marginal gain was USD 86,407 for the CPS and USD 166,022 for the OBF, in a 1 to 1.92 ratio. The organic certification increases production costs, but guarantees access to value added markets. It is possible for the OBF to achieve the required increase in beef production to remain competitive without deterioration of natural resources in its low input, organic agroforestry system, but the economic gain depends on the value added to the organic beef. The energy flow reflected the utilization of natural resources and the values their direct and indirect use in generating beef for society. In this context, the OBF was more efficient, 0.65 compared to 0.45, and 3.2 times more efficient in producing a kg of beef than the CPS. The conversion increased the system's sustainability and the OBF remained profitable in all future scenarios.

Key Words: Organic Beef, Energy Efficiency, Profitability

TH102 A meta-analysis on effects of supplementing low quality roughages with tree foliages on intake and growth in sheep. A. K. Patra*, *West Bengal University of Animal and Fishery Sciences, Belgachia, Kolkata, India.*

A meta-analysis of data obtained from previous studies was conducted to understand the responses of foliage supplementation on intakes of basal DM (BDMI), total DM (TDMI), and daily gain (ADG). Thirty-four published studies containing 223 treatments and 1127 sheep met criteria for inclusion in the meta-analysis. Major predictive variables considered were percentages of foliages in diet (SPTP), CP in foliages (SCPP), CP in basal roughages (BCPP), CP in diet (CPP) and foliage CP intake (SCPI). TDMI (g/d) increased quadratically ($P < 0.001$) with increasing SCPP, SCPI ($R^2 = 0.66$), BCPP, SPTP ($R^2 = 0.58$) and CPP ($R^2 = 0.73$). The maximal TDMI was 778 g/d at 42% SPTP, 894 g/d at 19.8% CPP, 893 g/d at 148 g/d SCPI and 749 g/d at 26.4% SCPP ($P < 0.001$; $R^2 = 0.58, 0.73, 0.66, \text{ and } 0.37$, respectively). BDMI increased quadratically with increasing SPTP, CPP and BCPP; but decreased quadratically with increasing SCPP ($P < 0.001$; $R^2 = 0.07$). The breakpoint of BDMI was 570 g/d at 6.58% of CPP ($P < 0.001$, $R^2 = 0.28$). Overall, BDMI responded at very low level of SPTP, peaking at 7.6% SPTP with 572 g/d of BDMI ($P < 0.001$, $R^2 = 0.72$). However, when BCPP was less than 3%, the maximal BDMI was 489 g/d at foliage levels of 25.7%. When BCPP was between 3 to 6%, maximal BDMI was at 13% of foliage and the basal forage intake of 597 g/d; However, BDMI decreased linearly with SPTP when BCPP was greater than 6%. Foliage CP content did not influence on BDMI (g/d) when basal diets had CP percentage greater than 4%, but decreased quadratically with increasing SCPP when BCPP was less than 4%. ADG responded positively and quadratically to SCPP, SCPI, STPT, CPP and TDMI (g/d) and the relationships were moderate to high. Maximal ADG was 42 g/d at 43% SPTP, 41 g/d at 9.4% CPP, 42 g/d at 53 g/d SCPI, 35 g/d at 25% SCPP and 46 g/d at 889 g/d TDMI ($P < 0.001$; $R^2 = 0.74, 0.84, 0.74, 0.29 \text{ and } 0.74$, respectively). Results indicate that the interactions of quality and quantity of foliage and quality of basal forage influence the intake of DM and animal performance in sheep.

Lactation Biology

TH103 Identification of internal controls for quantitative PCR in mammary tissue from lactating cows receiving various lipid supplements. A. K. G. Kadegowda^{*1}, M. Bionaz², B. Thering², L. S. Piperova¹, R. A. Erdman¹, and J. J. Loores², ¹University of Maryland, College Park, ²University of Illinois, Urbana.

Dietary lipid supplements affect mammary lipid metabolism through changes in lipogenic gene expression. Quantitative PCR (qPCR) is one of the most sensitive, reliable, and accurate techniques available to date for gene expression analysis. However, variation introduced in qPCR data by analytical/technical errors needs to be accounted for via normalization using appropriate internal control genes (ICG). Objectives were to mine individual bovine mammary microarray data on >13,000 genes across 66 cows from two independent studies to identify the most suitable ICG for normalization of qPCR. In addition to unsupplemented control diets, cows were fed saturated or unsaturated lipids (fish oil, Energy Booster) for 21 d, or were infused with supplements (Butterfat, CLA mixture, long-chain fatty acids) into the abomasum to modify milk fat synthesis and fatty acid profiles. GeneSpring[®] GX identified 49 genes that did not vary in expression across the 66 samples. Subsequent gene network analysis revealed that 22 of those genes were not co-regulated. Among those, COPS7A, CORO1B, DNAJC19, EIF3K, EMD, GOLGA5, MTG1, UXT, MRPL39, GPR175, and MARVELD1 (sample/reference expression ratio = 1 ± 0.1) were selected for qPCR analysis upon verification of goodness of BLAT/BLAST sequence and primer design. Relative expression of B2M, GAPDH, and ACTB, previously used as ICG in bovine mammary, was highly unstable (0.9 ± 0.6) across studies. Gene stability analysis, via geNORM software, uncovered EMD, MARVELD1, MRPL39, GPR175, UXT, and EIF3K as the most stable genes and, thus, suitable as ICG. geNorm also indicated that use of 3 to 5 ICG was most appropriate for calculating a normalization factor. Overall, results showed that the geometrical average of at least three among EMD, MARVELD1, MRPL39, GPR175, UXT, and EIF3K is ideal for normalization of mammary qPCR data in studies involving lipid supplementation of dairy cows.

Key Words: House Keeping Genes, Quantitative PCR, Lipid Supplements

TH104 Gene network analysis in mammary tissue of lactating cows receiving abomasal infusions of butterfat, long-chain fatty acids, or CLA. A. K. G. Kadegowda^{*1}, L. S. Piperova¹, S. L. Rodriguez-Zas², R. E. Everts², H. A. Lewin², R. A. Erdman¹, and J. J. Loores², ¹University of Maryland, College Park, ²University of Illinois, Urbana.

Abomasal infusion of butterfat and long-chain fatty acids (LCFA) induced the most contrasting responses in the concentrations of milk FA with ≤ 16 -carbons (greater with butterfat) and polyunsaturated FA (greater with both) relative to control. To better characterize gene networks associated with lipid synthesis and other cellular processes that might be responsive to dietary lipid, mammary tissue from lactating cows receiving no lipid (control; $n = 6$) or abomasal infusions of 400 g/d butterfat ($n = 4$), 245 g/d LCFA (59% cocoa butter + 36% olive oil + 5% palm oil; $n = 4$), or 100 g/d conjugated linoleic acid (CLA, 10 g of t10c12 CLA; $n = 6$) was used for gene expression analysis. Transcript profiling was conducted with a 13,257 bovine oligonucleotide (70-mers)

array. Annotation was based on similarity searches using BLASTN against human, mouse and bovine RefSeq, human, mouse, and bovine UniGene, and bovine TIGR. Cy3- and Cy5-labelled cDNA from mammary and a reference standard were used for hybridizations. ANOVA ($P \leq 0.01$) identified >300 differentially expressed genes in mammary due to treatments. Relative to control, LCFA infusion resulted in 295 genes and butterfat in 101 genes with changes in expression of 1.5-fold or greater. Gene network analysis identified inflammatory response (54 genes), cell growth/proliferation (104 genes), and cell death (90 genes) as modified families of related genes due to LCFA vs. control. Similar analysis in cows receiving butterfat identified lipid metabolism (14 genes), molecular transport (15 genes), and cell morphology (16 genes) as gene families most affected. Interestingly, signaling pathways most affected by butterfat included acute-phase response and complement system. Overall, results indicate that supply of short and medium chain FA (butterfat) vs. LCFA affect expression of previously-unrecognized cellular gene networks.

Key Words: Lactation, Genomics, Fatty Acids

TH105 Differential expression of lipid transporters and their regulators during the lactation cycle in the bovine mammary gland. O. Mani¹, M. T. Sorensen², K. Sejrsen², R. M. Bruckmaier^{*1}, and C. Albrecht¹, ¹University of Bern, Switzerland, ²University of Aarhus, Denmark.

The transport of lipophilic compounds across mammary gland (MG) epithelial cells determines milk lipid content and composition. ATP-binding cassette (ABC) transporters are known to play a pivotal role in cellular lipid efflux. As only scarce information is available about the transfer of lipids and cholesterol in the MG, we investigated the expression of lipid transporters and their regulators during lactation and dry period (DP) in dairy cows.

Repeated MG biopsies were taken from 10 cows at the end of lactation (d 347), during DP (d 48, 16 ante partum - ap) and subsequent lactation (d 14, 42, 88, 172 post partum - pp). mRNA levels of ABCG2, ABCA1, ABCA7, ABCG1 and NPC1, their regulatory genes LXRA and PPARg, and regulators of sterol synthesis SREBF1 and SREBF2 were determined by real-time RT-PCR.

mRNA levels of ABCG2 were significantly increased pp and throughout lactation as compared to the DP ($P < 0.0001$). ABCA1 and ABCA7 were elevated during the DP ($P = 0.0197$ and < 0.0001 , resp.) as compared to mid and late lactation and downregulated pp ($P = 0.0443$ and 0.0003 , resp.). ABCG1 showed no significant changes between the different functional stages of the MG. The intracellular cholesterol transporter NPC1 as well as LXRA and PPARg were elevated pp ($P = 0.0003$, 0.0271 and 0.0375 , resp.). SREBF1 was increased throughout lactation ($P < 0.0001$) as compared to the DP; a similar but not significant expression pattern was observed for SREBF2.

These results indicate that lipid transporters show differential expression between lactation and DP. This may be due to physiological changes in the MG like immigration of macrophages or accumulation of fat due to loss of liquid in the involuting MG. To test these hypotheses and to elucidate underlying molecular mechanisms cellular localization of candidate transporters in the MG will be investigated.

Key Words: Mammary Gland, Lipid Transporter, Dairy Cow

TH106 Unprotected conjugated linoleic acid (CLA) negatively affects milk production and secretion of milk components in dairy ewes. D. E. de Oliveira*¹, M. P. Soares¹, F. J. Bianchetti¹, R. Fornazier¹, M. R. Fachinello¹, M. Girardi¹, D. Fernandes¹, D. Soster¹, M. A. S. da Gama², M. G. C. D. Peixoto², S. de O. Juchem³, and L. O. Tedeschi⁴, ¹Universidade do Estado de Santa Catarina, Chapecó 89801-070, SC, Brasil, ²Embrapa Gado de Leite, Juiz de Fora, MG, Brasil, ³University of California, Davis, ⁴Texas A&M University, College Station.

Feeding conjugated linoleic acid (CLA) in a rumen-inert form to dairy ewes has been shown to increase milk production, alter milk composition, and increase the CLA content in milk fat. However, few studies utilized unprotected CLA sources. The objective of this study was to evaluate the effects of an unprotected CLA supplement (28% of c-9, t-11 and 28% of t-10, c-12 isomers) on milk yield and composition of dairy ewes. Twenty four lactating Lacaune ewes (40 to 70 DIM) were used in a cross-over design and received two treatments: 1) Control (C) and 2) CLA (30 g/d). The CLA supplement was mixed into the concentrate (1.2 kg/d, as-fed) and fed in two equal meals after morning and afternoon milkings. Ewes were individually fed 2.5 kg/d of corn silage and grazed a pasture of annual ryegrass and white clover. Each experimental period consisted of 21 d: 7 d for adaptation and 14 d for data collection. All ewes were fed the C diet for 7 d before the second collection period to prevent any carry-over effect. Milk production was daily recorded and milk samples were collected at each milking and a daily composite was obtained. Milk samples were analyzed for contents of fat, protein, lactose, and somatic cell count (SCC). Data were analyzed as repeated measurement design using PROC MIXED procedure of SAS, assuming period and ewe within treatment sequence as random effects. The CLA treatment decreased milk fat content (CLA = 3.86, C = 5.62%; P<0.01, SD=0.15), milk yield (CLA = 1.73, C = 1.88 kg/d; P<0.01, SE=0.08) and milk lactose content (CLA = 4.48, C = 4.55%; P<0.01, SD=0.06). Ewes fed CLA had greater milk protein content (CLA = 5.00, C = 4.91%; P<0.01, SE=0.06) and linear SCC score (CLA = 3.93, C = 3.34; P<0.01, SE=0.25). Secretion of all milk components was reduced by CLA. As previously shown in dairy cows (Bell and Kennelly, 2003, JDS 86:1321-1324 and Keating AF et al., Domest. Anim. Endocrinol (2007)), it is possible that relatively large amounts of c-9, t-11 and t-10, c-12 CLA isomers might have reached the abomasum of these ewes and resulting in precocious involution of mammary gland.

Key Words: Conjugated Linoleic Acid, Mammary Gland, Milk Components

TH107 Effects of rumen-protected choline administration on mRNA expressions of selected enzymes involved in mammary lipid metabolism. L. Pinotti*¹, F. D'Ambrosio¹, R. Bruckmaier², C. Albrecht², V. Dell'Orto¹, and A. Baldi¹, ¹University of Milan, Milan, Italy, ²University of Bern, Bern, Switzerland.

Aim of this study was to investigate the effects of rumen-protected choline administration on mRNA expressions of selected enzymes involved in mammary lipid metabolism. Eight pregnant multiparous Saanen goats were assigned to one of two experimental groups: CTR, control group, no choline supplementation; RPC, supplemented with 4 g/day choline chloride in rumen-protected form (Sta-Chol 50%, Ascoc Chimici, Forli, Italy). Treatment was administered individually from day -30 to day 30

relative to kidding. Through the first month of lactation milk yield and composition were measured weekly. On day 28 in milk, from the same animals mammary tissue samples were collected under sterile conditions. Samples were stored at -80°C until RNA extraction. Synthesis of cDNA was performed by reverse transcription-polymerase chain reaction. Glyceraldehyde 3-phosphate dehydrogenase and beta-actin were chosen to confirm a constant gene expression level in the investigated total RNA extractions. Quantitative analysis of PCR products was carried out from cDNA fragments of FAS (Fatty acid synthase), LPL (Lipoprotein Lipase), SREBP-1 (Sterol regulatory binding protein-1), SREBP-2 (Sterol regulatory binding protein-2), and PPAR γ (Peroxisome proliferator-activated receptor gamma). mRNA expression levels have been normalized to GAPDH relative to total RNA and presented as logarithm dualis. Data were analyzed by the general linear model procedure of SAS. Milk yield and milk composition did not differ between groups. Moreover, choline supplementation did not affect the mRNA expressions of the enzymes involved in mammary lipid metabolism. However, present results are based on a limited number of goats, thus possible choline effects at mammary gland levels in lactating dairy goats deserve further investigation.

Key Words: Choline, Mammary Gland, Lipid Enzymes

TH108 Hormonal influence on mammary tissue composition in pre-pubertal Holstein heifers. B. P. Hudson*¹, B. T. Velayudhan¹, S. E. Ellis², and R. M. Akers¹, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²Clemson University, Clemson, SC.

It is known that mammary gland growth and development are hormonally regulated. However, hormonal regulation is poorly understood in pre-pubertal heifers. The purpose of these two studies was to evaluate the effects of exogenous bovine somatotropin (bST) or ovariectomy on mammary tissue composition in pre-pubertal Holstein heifers. In a first experiment, 19 heifers (7 \pm 4 d of age) were randomly assigned to one of two treatments bST (500 mg; n=10) or placebo (0.9% saline; n=9). Animals were administered treatments every three weeks beginning on day 23. All animals were fed milk replacer and calf starter for eight wk and thereafter starter and hay. Mammary parenchyma (PAR) and fat pad (MFP) were harvested for analysis of protein, lipid and DNA at two times (after the second or after the fourth injection). There was a significant increase in total DNA, total protein, DNA/100 kg BW and protein/100 kg BW due to day and a significant treatment by day interaction on DNA and lipid concentration in PAR. In MFP there was a treatment by day interaction for DNA and protein/100 kg BW. In the second study, 36 heifers were randomly assigned to one of two treatments, ovariectomy (OVX; n=18) or sham (INT; n=18). All animals were fed traditional milk replacer and calf starter. Treatments were applied on 40 d of age and mammary samples were harvested either at 55, 70, 85, 100, 130, or 160 d age. Composition of PAR was not affected by ovariectomy (p>0.05), while MFP protein concentration was decreased in OVX (26.6 vs 22.6 \pm 1.2 μ g/mg MFP). Total protein as well as DNA and lipid per 100 kg BW in MFP were significantly affected by age. There was an age by treatment interaction effect on total DNA and lipid in MFP. In conclusion, bST and ovariectomy impacted the composition of MFP but not PAR.

Key Words: Mammary, bST, Ovariectomy

TH109 Feeding genistein to prepubertal gilts stimulates their mammary development. C. Farmer^{*1}, S. Gilani², M.-F. Palin¹, H. Weiler³, M. Vignola⁴, R. K. Choudhary⁵, and A. V. Capuco⁵, ¹*Agriculture and Agri-Food Canada, Dairy and Swine R & D Centre, Sherbrooke, QC, Canada*, ²*Nutrition Research Division, Health Canada, Ottawa, ON, Canada*, ³*McGill University, Ste-Anne-de-Bellevue, QC, Canada*, ⁴*Nutreco Canada Agresearch, St-Romuald, QC, Canada*, ⁵*USDA-ARS, Bovine Functional Genomics Lab, Beltsville, MD, USA*.

The possible role of dietary genistein on mammary development of prepubertal gilts was investigated. Forty-five gilts were fed one of three diets from 90 d of age until slaughter (day 183 ± 1). Diets were: without soya (CTL0, n=15); soya-based commercial (CTLS, n=15); and soya-based commercial with 2.3 g/d of genistein (GEN, n=15). All diets were isonitrogenous and isocaloric. Jugular blood samples were obtained on days 89 and 183 to determine concentrations of genistein, prolactin, estradiol, IGF-I and cross-linked N-telopeptide of type I collagen (NTx, day 183 only). At slaughter, mammary glands were excised, parenchymal and extraparenchymal tissues were dissected and composition of parenchymal tissue was determined. Histochemical analyses of mammary parenchyma were performed and mRNA level of specific genes determined. Dietary genistein increased parenchymal protein ($P < 0.05$) while decreasing dry matter ($P < 0.05$) and tending to lower fat content compared to the CTLS, but not the CTL0, diet. There was more parenchymal DNA (1.26 vs. 0.92 mg/g, $P < 0.05$) in GEN than CTLS gilts. Circulating concentrations of hormones or NTx were not affected by GEN ($P > 0.1$) but concentrations of genistein were greater ($P < 0.0001$) in GEN than CTLS gilts. Percent ER α -positive epithelial cells was lower ($P < 0.05$) in GEN than CTLS gilts whereas BrdU labelling index was unaltered ($P > 0.1$). Transcript levels for ER α , ER β , IGF-I, EGF, EGFR and TGF α were not altered by treatments ($P > 0.1$). Feeding dietary genistein to prepubertal gilts led to hyperplasia of mammary parenchymal tissue.

Key Words: Genistein, Gilts, Mammary Development

TH110 Evidence that prolactin does not drive the milk yield response to frequent milking in early lactation. J. G. Titus^{*1}, H. M. Crawford², E. H. Wall¹, G. E. Dahl², and T. B. McFadden¹, ¹*University of Vermont, Burlington*, ²*University of Illinois, Urbana*.

Frequent milking of dairy cows in early lactation causes an increase in milk yield that persists throughout lactation, however the mechanisms regulating this response are unknown. We hypothesized that prolactin (PRL) released during additional milkings stimulates the increase in milk yield; therefore blockade of PRL secretion in frequently-milked cows should eliminate the milk yield response. Our objectives were to determine effects on milk yield and to gain insight into potential mechanisms of action by measuring mammary cell proliferation and apoptosis as well as expression of genes associated with angiogenesis. Eighteen multiparous Holstein cows were assigned to one of three treatments for the first 21 d of lactation: twice-daily milking (2 \times), four-times daily milking (4 \times), or four times daily milking plus administration of the prolactin inhibitor, bromocriptine (Bromo) at two of the four milkings. Milk weights were recorded daily and blood samples were obtained on d 1, 4, 7, 14 and 21 of lactation for quantifying plasma PRL. Mammary biopsies were taken at 8 ± 3 DIM for determination of [3H]-thymidine incorporation into DNA in vitro, mammary cell apoptosis, and isolation

of total RNA. During treatment, milk yield was lower in the 2 \times group than in the 4 \times or Bromo groups (33.4, 37.3 or 38.0kg/d, $P < 0.001$), but was not different between 4X and Bromo treatments ($P > 0.4$). Mean PRL concentrations were greater in 4 \times cows than in 2 \times or Bromo cows (12.4, 9.2 and 7.0ng/mL, $P < 0.01$), but did not differ between 2X and Bromo cows ($P > 0.1$). Incorporation of [3H]-thymidine was greater in 2X cows relative to both of the 4X groups ($P < 0.01$) whereas mammary cell apoptosis was not affected by treatment ($P \geq 0.9$). Mammary expression of PRL receptor, insulin-like growth factor 2, insulin-like growth factor binding protein 5, and the vascular endothelial growth factor receptors, flt-1 and flk-1 did not differ among treatments ($P > 0.9$), suggesting that angiogenesis was not affected. We conclude that increases in plasma PRL do not drive the milk yield response to frequent milking in early lactation.

Key Words: Frequent Milking, Prolactin, Angiogenesis

TH111 Reduced nursing frequency during prolonged lactation in the mouse decreases milk production and increases mammary expression of tryptophan hydroxylase 1 (TPH1), but does not accelerate mammary gland remodeling. D. L. Hadsell^{*1}, W. Olea¹, D. Torres¹, J. George¹, and R. J. Collier², ¹*Baylor College of Medicine, Houston, TX*, ²*The University of Arizona, Tucson*.

We have observed that lactating mouse dams nursed 4 times per day (4X) maintained lactation, but had lower milk yields by the weigh-suckle-weigh method, than dams nursed ad libitum (AL). Therefore, we hypothesized that decreased nursing frequency would also decrease lactation persistence, increase mammary gland remodeling, and alter the expression of genes linked to milk production (α -lactalbumin), mammary involution (lactoferrin) and mammary secretory cell feedback inhibition (TPH1). To test this hypothesis, milk output, mammary epithelial and adipocyte content, and mammary gland gene expression was measured on days 8, 14, or 28 postpartum in dams (n=5-16/treatment group) that nursed either AL or 4X for up to 3 weeks. Milk yield (1.3±0.1 g) was lower on day 14 in 4X than AL, which had similar yield to day 8 of the pretreatment period (2.4±0.3 g). On days 14 and 28, milk production in both groups was similar, and both were lower than that observed on day 8. Mammary epithelial content in 4X dams, as determined in cytokeratin 8 stained tissue sections, was higher than AL on day 28 (70±2 and 56±2 %). Alveolar luminal area was greater in 4X than AL on both days 14 (4030±201 and 3307±207 μm^2) and 28 (3293±246 and 2010±275 μm^2). Mammary adipocytes in perilipin-stained tissue sections, were larger in AL than 4X on day 28 (374±53 and 134±5 μm^2). Expression of α -lactalbumin and lactoferrin genes was greater on day 28 than day 8 postpartum, but not affected by nursing frequency. Expression of the TPH1 gene was higher in 4X than AL on day 14 (4.2±0.9 and 1.7±.3 fold over day 8), but similar to AL on day 28. These data suggest that reduced nursing frequency decreases milk synthesis through a mechanism involving serotonin biosynthesis, but may also delay the normal mammary gland remodeling that occurs with prolonged lactation. This project was supported by National Research Initiative Competitive Grant no. 2007-35206-17831 from the USDA Cooperative State Research, Education, and Extension Service.

TH112 Evaluation and classification of milking disorders in Swiss dairy cattle. C. J. Belo¹, S. Schlegel², J. Moll³, and R. M. Bruckmaier*¹, ¹University of Bern, Bern, Switzerland, ²Swiss Federal Institute of Technology Zurich, Zurich, Switzerland, ³Swiss Brown Cattle Breeders Federation, Zug and ASR, Bern, Switzerland.

Morphological dysfunction of the udder and the teat as well as pathophysiological reduction of the release of oxytocin perturb or inhibit milk removal. To evaluate the incidence of these disorders and to classify them as anatomical or pathophysiological, questionnaires were sent to 2099 Swiss dairy farms with at least 25 dairy cows representing the major breeds in Switzerland (Brown Swiss: BS, Holstein: HO, Red Holstein x Simmental: SI). A high percentage of the questionnaires were returned (BS: 78%, HO: 73%, SI: 72%). Thus we have obtained information on a total of 67548 cows. Of these cows, 2642 (BS: 5%, HO: 3%, SI: 3%) were reported with poor milkability and 1198 problem cows (BS: 2.5%, HO: 1%; SI 1%) were regularly treated with oxytocin. In addition, 242 of the dairy farms that had reported animals with poor milkability were contacted by phone and asked for more details about the reported disorders and the specific activities performed in case of problem. The farmers reported milk ejection disorders (SI: 76%, HO: 63%, BS: 48%), poor milkability (BS: 34%, HO: 21%, SI: 7%) and external factors such as stray voltage, engine disturbances and other animal diseases (BS: 28%, HO: 16%, SI: 15%). Apart from using oxytocin, the farmers reported careful teat stimulation, massage of vulva and udder, air blown into the vagina or homeopathy. About half the dairy farms have culled the animals because of the problem.

51 cows were selected in 18 farms which had reported a supposed disturbed milk ejection, i.e. an incomplete delivery of the milk based on a lack of oxytocin release. The presence of milk ejection disorder was investigated by recording the milk flow with a mobile unit (LactoCorder). After cessation of spontaneous milk flow, oxytocin was injected iv. and the amount of residual milk was measured. In 18% of the tested cows disturbed milk ejection was not detected, contrary to the assumption of the farmers.

Key Words: Milk Ejection, Inhibition, Cattle

TH113 Prestimulation combined with a short waiting time before cluster attachment affects milk removal in dairy cows. S. Kaskous*¹ and R. M. Bruckmaier², ¹Damascus University, Damascus, Syria, ²University of Bern, Bern, Switzerland.

The suitability of combining manual prestimulation with a short waiting time before cluster attachment and machine milking was investigated. 21 dairy cows in their second to sixth lactation were divided in three lactational stages with seven animals each, early (<100 d), mid (100 to 200 d) and late (>200 d) lactation. In addition, cows were classified based on their estimated degree of udder filling as a ratio between the actual milk yield and the maximum storage capacity. During the experiment, cows were machine milked twice daily at 5 a.m. and 4 p.m. and milk flow curves were recorded. The animals were manually prestimulated for 15, 30 or 45 s, followed by a waiting time of 0, 30, 45 or 60 s, i.e. 12 different treatments were applied for each animal. The treatments were performed in a random sequence for each animal, but remained unchanged for two subsequent milkings (morning and evening). Total

milk yield did not significantly differ between treatments in all stages of lactation and at all degrees of udder filling. Average milk flow (AMF) and peak flow rate (PFR) in early lactation, and similarly in mid lactation (udder filling 60-100%) were highest after a prestimulation of 30 s followed by a waiting time of 30 or 45 s, or after a prestimulation for 45 s without additional waiting time ($p < 0.05$). In late lactation and at low degrees of udder filling (20-40 %), AMF and PFR were highest after a prestimulation of 45 s combined with a waiting time of 30, 45 or 60 s ($p < 0.05$). In conclusion, total milk yield does not differ between prestimulation treatments and additional waiting time as applied in the present study. An optimal course of milk removal is reached after a prestimulation of 30 s, combined with a waiting time of 30 to 45 s in early and mid lactation. In late lactation a prestimulation for 45 s is required, combined with an additional waiting time of 30 to 60 s.

Key Words: Prestimulation, Waiting Time, Milking

TH114 Identification of internal controls for quantitative PCR in swine mammary gland during pregnancy and lactation. S. Tramontana^{1,2}, M. Bionaz*², A. Sharma², D. E. Graugnard², E. A. Cutler², P. Ajmone-Marsan¹, W. L. Hurley², and J. J. Loo², ¹Università Cattolica del Sacro Cuore, Piacenza, Italy, ²University of Illinois, Urbana.

High-throughput microarray analysis is an efficient means of obtaining a genome-wide view of transcript profiles across physiological states. However, quantitative PCR (qPCR) remains the chosen method for high-precision mRNA abundance analysis. Essential for reliability of qPCR data is normalization using internal control genes (ICG). Identification of reliable ICG is now, more than ever before, a fundamental step for accurate gene expression profiling. To identify swine ICG, we mined mammary microarray data on >13,000 genes at -34, -14, 0, 7, 14, 21, and 28 d relative to parturition in 27 cross-bred primiparous gilts. GeneSpring GX analysis revealed *TBK1*, *PCSK2*, *PTBP1*, *API5*, *VAPB*, *QTRT1*, *TRIM41*, *TMEM24*, *PPP2R5B*, and *AP1S1* as the most stable genes (sample/reference = 1 ± 0.2). We also included 9 genes previously identified as ICG in bovine mammary. Co-regulation on these 19 genes was assessed using gene network analysis, which identified *AP1S1*, *API5*, *MTG1*, *VAPB*, *TRIM41*, *MRPL39*, and *RPS15* as having no known co-regulation. *UXT* and *ACTB* were added to this list and mRNA abundance of the 9 genes measured by qPCR. Expression of all ICG chosen decreased ($P < 0.05$) markedly during lactation. Gene stability analysis, via geNorm software, identified *API5*, *VAPB*, and *MRPL39* as the most stable ICG and indicated that the use of 3 ICG was most appropriate for calculating a normalization factor. In a previous study with bovine mammary tissue, decreased mRNA of stably-expressed genes during lactation was apparent, and due to a dilution effect brought about by large increases in expression of highly abundant, metabolism-related genes. To verify this effect, highly-abundant mammary genes such as *CSN1S2*, *SCD*, and *LTF* were evaluated by qPCR. The tested ICG had a negative correlation with these genes, demonstrating the presence of a dilution effect as in bovine mammary tissue. Overall, results underscore the importance of proper validation of internal controls for qPCR and highlight the limitations of using time effects as the criteria for selection of appropriate ICG.

TH115 Serial mammary biopsies in cows do not alter overall milk production. H. Dover*, M. VandeHaar, J. Liesman, O. Patel, L. De Vries, and K. Plaut, *Michigan State University, East Lansing.*

Serial biopsies of the mammary gland are useful in studies of mammary biology; however, many researchers assume the cow's long term milk production might be impaired. The objective of this study was to determine the effect of mammary biopsies during late lactation through the dry period on overall milk production. Six multigravid cows were biopsied approximately 275-290 days in milk (biopsy 1), 7 days after dry off (biopsy 2), 3 weeks (biopsy 3) and 1 week (biopsy 4) before expected calving date. Animals were sedated with xylazine hydrochloride, and the biopsy site was numbed with lidocaine gel before lidocaine injection. A biopsy tool (AgResearch, Hamilton, NZ) powered by a cordless drill was used to obtain approximately 1 g of mammary tissue per biopsy. Immediately after biopsies 1 and 4, a teat cannula was inserted into the biopsied quarter to drain any accumulated blood. For approximately 3 days, cows were hand stripped at each milking until blood clots were no longer observed in the milk. Cows joined the milking herd after biopsy 1 and 4. Analysis of milk yields during the lactation prior to and following the biopsies indicate that milk production in biopsied cows was not different from the herd ($P>0.1$). At 30-60 days in milk, primiparous cows averaged 35 kg/day of milk prior to biopsy and 48 kg/day in the lactation following biopsy; for multiparous cows, milk yield averaged 50 kg/day prior to biopsy and 54 kg/day in the lactation following biopsy. The use of teat cannulae after biopsy appears to improve cow comfort. Results show that serial mammary biopsies do not impair milk production in dairy cows.

TH116 Effect of dry period length on calving related disorders. M. S. Gulay*¹, M. J. Hayen², K. C. Bachman², and H. H. Head², ¹*Mehmet Akif Ersoy University, Faculty of Veterinary Medicine, Department of Physiology, Burdur, Turkey,* ²*University of Florida, Gainesville.*

Objectives were to evaluate effects of dry period (60 vs. 30 d), with or without estradiol cypionate (ECP) injections, on incidence rates of digestive problems and displaced abomasum (DP), retained fetal membranes (RFM), metritis (MET), clinical mastitis (MAS), ketosis (KET), or foot problems (FOOT) during the first 60 d postpartum. One hundred eighty-nine multiparous Holstein cows from two separate trials were combined for analyses. Dry period treatments included 30 d dry+ECP (30DE; n=48), 30 d dry (30D; n=44) and 60 d dry (60D; n=97). Single injections of ECP (7.5 ml; 15 mg; 30DE) or 7.5 ml of cottonseed oil (30D) were supplemented i.m. at final milk removal; 60D group was the control group and received no ECP or cottonseed oil. Across all treatment groups the incidence rates (number of diseased cows divided by the total number of cows) for DP, RFM, MET, MAS, KET, and FOOT were 8.5, 6.4, 12.7, 19.6, 4.2, and 9.5%, respectively. No significant Chi-Square values ($P<0.1$) were detected among the treatment groups. Incidence rates of DP, RFM, MET, MAS, KET, and FOOT for 30DE, 30D and 60D groups were 2.8, 6.5, and 12.4%; 6.8, 4.2, and 7.2%; 9.1, 10.4, and 15.5%; 22.7, 18.8 and 18.6%; 4.6, 4.2 and 4.1%; and 9.1, 6.3, and 11.3%, respectively. The proportions of sick cows in the 3

groups (number of cows having one or more cases of diseases divided by the total number of cows) were 36.4, 35.4, and 48.5%, respectively. When 30DE and 30D groups were combined and compared to the 60D group, a significant difference was detected between short and longer dry period, but only for DP ($P<0.05$). Moreover, proportions of sick cows in the combined 30D dry group also tended to be lower (38.9 vs. 48.5%; $P=0.08$). Odds ratio values suggested that cows given longer dry periods were 1.68 times more likely to get sick during first 60 d after calving. Thus, results indicated that shortening dry period length (30D) with or without supplemental ECP did not negatively affect postpartum calving disorders compared to cows given 60D and improved health status slightly.

Key Words: Dry Period Length, Transition Period, Diseases

TH117 Dietary energy management during pregnancy and its effects on transition health in dairy heifers. M. S. Laubach¹, D. B. Carlson², L. Mabasa², K. S. Cho², A. W. Fowler², and C. S. Park*², ¹*South Dakota State University, Brookings,* ²*North Dakota State University, Fargo.*

The objective of this study was to determine if a gestational one stair-step compensatory nutrition regimen (SSCN) affects metabolic and immune status of dairy heifers during the transition period. The experiment consisted of two sequential trials (20 heifers for trial 1; 10 heifers for trial 2). Holstein heifers (95 d in gestation) averaging 511 kg of body weight were assigned into two groups: control and treatment (SSCN). The control diet [14% crude protein (CP); 2.35 Mcal/kg metabolizable energy (ME)] was intended for a constant gain of 0.45 kg/d throughout the last two trimesters of gestation. The SSCN heifers were fed a restriction diet (18.5% CP; 2.35 Mcal/kg ME) during the second trimester at 70% of the ME intake of control heifers, and a realimentation diet (14% CP; 3.05 Mcal/kg ME) during the third trimester. Blood was collected around parturition on d -14, -11, -9, -7, -5, -4, -3, -2, -1, 0 (within 3 h of calving), 1, 2, 3, 4, 5, 7, 9, 11, and 14 to monitor various metabolites, total white blood cell counts (WBC), and lymphocyte populations [cluster of differentiation 3 (CD3), CD4 and CD8]. In both trials, serum glucose, insulin, triglycerides, and nonesterified fatty acids were not different between groups before or after parturition. SSCN heifers before parturition tended to have higher WBC ($P = 0.06$); however, after parturition there was no difference between groups. The CD8 cells tended to be higher ($P = 0.10$) in the SSCN group compared with the control before parturition and were higher ($P = 0.02$) after parturition; the increase of CD8 cells in SSCN heifers may be related to the enhancement of immune cell production due to increased compensatory energy metabolism from the realimentation diet during the last trimester. SSCN heifers yielded 4% more milk than control heifers (34.8 vs. 36.1 kg/d; $P = 0.18$). These results indicate that SSCN did not affect general metabolic parameters, but moderately improved immune status of transition heifers.

Nonruminant Nutrition: Mineral

TH119 Impact of massive doses of copper or zinc on growth performance and nutrient digestibility of newly weaned piglets.

M. Pelletier-Grenier*¹, A. Giguere², and F. Guay¹, ¹Universite Laval, Quebec, QC, Canada, ²Agriculture and AgriFood Canada, Sherbrooke, QC, Canada.

This study was conducted to evaluate the impact of massive dose of copper (Cu) or zinc (Zn) on the growth performance and digestive capacity of newly weaned piglets. Twenty three castrated male piglets, (7.4 kg) were used for the growth and digestibility studies. The three post-weaning diets were formulated according to NRC and only Zn or Cu was supplemented according dietary treatment: 1) Control diet (C): 25 ppm Cu and 134 ppm Zn; 2) Cu diet: 135 ppm Cu and 123 ppm Zn; 3) Zn diet: 28 ppm Cu and 2,343 ppm Zn. The pigs were individually fed with specific diet for 12 days. Feed intake was daily determined and pig weight was evaluated on d0, 8 and 12. On d8, chromic oxide (0.25%) was added to diets as indigestible marker. The faeces and urine were collected during d9 to 12 to evaluate the digestibility and retention of nitrogen, energy, phosphorus and calcium. Results showed that Cu supplementation improved ($P<0.05$) ADG, ADFI et G:F ($P<0.05$) and Zn supplementation tended to increase ADG and G:F ($P<0.09$) during the overall period of d0 to 12 compared to Control diet. During d8 to 12, Zn and Cu supplementations were increased ADG, ADFI and G:F ($P<0.05$). During collect period, Cu supplementation was increased total absorption and retention of nitrogen, energy and phosphorus ($P<0.05$). Zn supplementation was also increased total absorption and retention of energy ($P<0.05$) and tended to increased absorption and retention of nitrogen and phosphorus ($P<0.09$). However, Zn and Cu supplementations did not have any effect on digestibility and retention:ingestion ratio of nitrogen, energy and phosphorus. For calcium, Zn and Cu supplementation did not have any effect on total absorption and retention but reduced the retention:ingestion ratio ($P<0.05$). These results suggest that the effect of Zn and Cu supplementations on growth performance (ADG, ADFI, G:F) can not be associated to better nutrient digestibility and retention efficiency.

Key Words: Piglet, Zinc, Copper

TH120 Effect of different Ca and P level on early growth of fast-growth lines of Wulong Goose.

B. W. Wang*, M. A. Zhang, X. P. Wu, G. L. Liu, and X. H. Jia, Qingdao Nongye University, Qingdao, Shandong Province, China.

Two hundred and eighty-eight 1-day-old Wulong geese of Fast-growth Lines were selected to be fattened respectively in netting bed, and then divided into eight groups with three replications in each group, twelve geese for each replication. The basal diets were added with different contents of Ca and NPP (non-Phytate Phosphorus) in a completely randomized design involving a 4 × 2 factorial arrangement of treatments. Ca and NPP were added with pure CaCO₃ and NaH₂PO₄. The result suggested that, during the early period (0-4week), the proportion of Ca and NPP had significant influence on its growth ($P<0.05$), the most absolutely increasing was 1168±95.6g in the four weekend when the dietary level of Ca was 0.65% and NPP was 0.30% (the proportion of Ca and NPP was 2.17:1), and the least absolutely increasing was 820±33.3g when the dietary level of Ca was 0.55% and NPP was 0.40% (the proportion of Ca and NPP was 1.38:1), so were the eviscerated weight with giblet ratio (1871±85 and 1473±99) and feed/gain (F/G)

(2.24±0.36 and 1.90±0.41). But the alkaline phosphatase (AKP) activity was not significantly affect by the Ca and NPP level ($P>0.05$). The Wulong geese grew well at the proportion between 1.88:1 and 2.50:1, and grew worst at 1.38:1.

Key Words: Wulong Goose, Ca, NPP

TH121 Effects of dietary *Escherichia coli* phytase supplementation on growth performance, carcass quality and excretion of copper and zinc concentrations in finishing pigs.

S. O. Shin*¹, Y. H. Kim², J. C. Park², H. J. Jung², H. G. Moon², S. Y. Ji², I. C. Kim², S. J. Lee², and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²National Institute of Animal Science, RDA, Cheonan, Chungnam, Korea.

This study was conducted to evaluate the effects of dietary *Escherichia coli* phytase supplementation on growth performance, carcass quality and excretion of copper and zinc concentrations in finishing pigs. The total of seventy two [(Landrace×Yorkshire) × Duroc] pigs (65.43±0.72 kg in average initial body weight) were used in 56 days assay. Dietary treatments included 1) CON (basal diet) 2) P5 (basal diet + phytase 0.05%) and 3) P10 (basal diet + phytase 0.1%). There were three dietary treatments with six replicate pens per treatment and four pigs per pen. During the overall periods, ADFI (Average daily feed intake) was increased ($P<0.05$) in phytase supplementation treatments (2.752 and 2.751 kg) compared to CON treatment (2.566 kg). At the 5th week, dry matter, nitrogen and ash digestibilities were higher ($P<0.05$) in P5 treatment (73.59, 84.12 and 33.71%, respectively) than in CON (66.43, 74.16 and 14.29%, respectively) and P10 treatments (71.19, 80.95 and 26.50%, respectively) and CON treatment (74.16%) showed the lowest ($P<0.05$) effect on nutrition digestibility. However, phosphorus digestibility was higher ($P<0.05$) in both phytase supplementation treatments (66.76 and 63.15%) than in CON treatment (47.58%). The pH of *M. logissimus dorsi* was significantly higher ($P<0.05$) in CON treatment (5.72) than phytase supplementation treatments (5.57 and 5.58). L* value of *M. logissimus dorsi* muscle color was significantly increased ($P<0.05$) in P10 treatment (57.25) compared to CON (54.94) and P5 treatments (54.32). Also, a* value was increased ($P<0.05$) in CON treatment (16.89) compared with phytase supplementation treatments (16.18 and 16.65). However, excretion of copper and zinc concentrations were no difference among the treatments. In conclusion, the results of the experiment was affected by dietary *Escherichia coli* phytase supplementation on ADFI, digestibilities, pH and color of meat in finishing pigs.

Key Words: *Escherichia coli* Phytase, Growth Performance, Excretion of Copper and Zinc Concentrations

TH122 Effects of rare earth supplementation on growth performance, blood immunological parameters, meat quality and fecal odor emission gases in finishing pigs.

S. O. Shin*¹, J. H. Lee¹, H. D. Jang¹, Y. J. Chen¹, J. H. Cho¹, J. D. J. D. Hancock², K. Y. Whang³, and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Kansas State University, Manhattan, ³Korea University, Seoul, Korea.

This study was conducted to evaluate the effects of rare earth supplementation on growth performance, blood immunological parameters,

meat quality and fecal odor emission gases in finishing pigs. The total of sixty four [(Landrace×Yorkshire)×Duroc] pigs (65.42±1.16 kg in average initial body weight) were used in 10 weeks assay. Dietary treatments included 1) NC (antibiotic free diet), 2) PC (NC diet + 6 weeks 44ppm of tylosin/ 4 weeks 22ppm of tylosin) 3) RE1 (NC diet + 100ppm of RE), 4) RE2 (NC diet + 200ppm of RE). There were four dietary treatments with four replicate pens per treatment and four pigs per pen. During the overall periods, there were no significant differences in ADG (Average daily gain), ADFI (Average daily feed intake) and gain/feed ratio among treatments ($P>0.05$). Dry matter and nitrogen digestibility were higher in RE2 treatment than other treatments ($P<0.05$). Also, energy digestibility was higher in RE2 treatment than PC and RE1 treatments ($P<0.05$). At the 6th week WBC (white blood cell) was significantly increased ($P<0.05$) in RE1 treatment than NC and RE2 treatments. L^* value of *M. logissimus dorsi* muscle color was significantly increased ($P<0.05$) in rare earth supplementation treatments compared to NC treatment ($P<0.05$). In fatty acid contents of leans, total MUFA was significantly higher in RE2 treatment than others treatments ($P<0.05$). Also, total UFA was significantly increased in RE2 treatment compared with NC and PC treatments ($P<0.05$). In fatty acid contents of fats, total SFA of rare earth supplementation treatments were lower than in PC treatments ($P<0.05$). UFA:SFA ratio was significantly higher in rare earth supplementation treatments than PC treatment ($P<0.05$). In fecal odor emission, NH_3 was significantly decreased ($P<0.05$) in rare earth supplementation treatments compared to NC and PC treatments. In conclusion, the results of the experiment was affected by rare earth supplementation on digestibilities, meat quality, fatty acid and fecal odor

Key Words: Rare Earth, Growth Performance, Fecal Odor Emission Gases

TH123 The effect of different copper (inorganic and organic) and fat (tallow and glycerol) sources on growth performance, nutrient digestibility, and fecal excretion profile in growing pigs (regional study). Y. Huang^{*1}, J. S. Yoo¹, H. J. Kim¹, Y. J. Chen¹, J. H. Cho¹, Y. K. Han², and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Sungkyunkwan University, Suwon, Korea.

A 2 × 2 trial was conducted to investigate the effect of different copper (inorganic and organic) and fat (tallow and glycerol) sources on growth performance, nutrient digestibility, gas emission, diarrhea appearance, and fecal Cu concentration in growing pigs. The trial used 96 pigs (63 d of age) with an average initial weight of 28.36 ± 1.14 kg. Pigs were assigned to four treatments: 1) basal diet with 134 ppm Cu (Korea recommendation) as CuSO₄ + tallow; 2) basal diet with 134 ppm Cu as CuSO₄ + glycerol; 3) basal diet with 134 ppm Cu as CuMet + tallow; 4) basal diet with 134 ppm Cu as CuMet + glycerol. During the entire experimental period, there were no differences among treatments in the magnitude of improvement for ADG (average daily gain), ADFI (average daily feed intake) and G/F (gain: feed) ratio. Nitrogen (N) digestibility of pigs fed diets with organic copper was improved compared with those of pigs fed diets with inorganic copper ($P<0.05$). The interaction of Cu × fat was observed on both nitrogen ($P<0.05$) and energy ($P<0.01$) digestibilities. Ammonia emission was significantly lower in organic copper added treatments than inorganic copper added treatments ($P<0.05$). Mercaptan and hydrogen sulfide emission were decreased by the addition of glycerol ($P<0.05$). Neither main effects of Cu or fat source nor their interaction was observed on diarrhea appearance during all the experimental period. The copper concentration in feces was significantly lower in organic copper source treatments than

that in inorganic copper source treatments ($P<0.05$). The result of this experiment indicate that substitute organic copper for inorganic copper in diet has less fecal Cu excretion, while it has no effect on the growth performance. The different fat (tallow and glycerol) source have interaction with different copper source on nutrient digestibility. Glycerol supplementation could decrease sulfuric odorous compound concentrations in different source of Cu.

Key Words: Copper, Fat Source, Growing Pig

TH124 The effects of 200 ppb added chromium from chromium propionate on the growth performance and carcass characteristics of finishing pigs. J. R. Bergstrom^{*1}, M. D. Tokach¹, S. S. Dritz¹, J. L. Nelssen¹, R. D. Goodband¹, J. M. DeRouchey¹, J. D. Hahn², and F. R. Valdez², ¹Kansas State University, Manhattan, ²Kemin Industries, Inc., Des Moines, IA.

A total of 1,207 pigs (initial BW = 30.7 kg; PIC, 337×1050) were used in a 103-d experiment to evaluate the effects of 200 ppb Cr from KemTRACE[®] (KemTRACE[®] is a registered trademark of Kemin Industries, Inc.) brand Chromium Propionate (CrPr) on growth performance and carcass characteristics. There were 22 pens per treatment with 25 to 28 pigs per pen evaluating CrPr from d 0 to 84; and 11 pens per treatment evaluating CrPr (0 and 200 ppb) and Paylean[®] (0 and 10 ppm) in a split-plot arrangement from d 84 to 103. Pigs were randomly allotted to a corn-soybean meal-based diet with 3% added choice white grease (control diet) or the control diet with 200 ppb Cr from CrPr. Treatments were fed in three 4-wk phases (d 0 to 28, 28 to 56, and 56 to 84). On d 84, pigs fed the control or Cr treatment were allotted to a fourth dietary phase containing either 0 or 10 ppm Paylean[®]. For the d 0 to 84 period, growth performance of pigs fed the control or 200 ppb CrPr was not different (915 vs 916 g/d ADG). From d 84 to 103 and overall (d 0 to 103), pigs fed diets containing Paylean[®] had increased ($P<0.01$) ADG (1143 vs 969 g/d and 951 vs 926 g/d, respectively) and final weight (128.3 vs 124.5 kg). However, a CrPr × Paylean[®] interaction ($P<0.04$) was observed for d 84 to 103 ADFI and G:F and overall (d 0 to 103) G:F. From d 84 to 103, adding Paylean[®] to the control reduced ADFI (2833 vs 2711 g/d); whereas, adding Paylean[®] to diets containing CrPr increased ADFI (2744 vs 2845 g/d). Added CrPr alone increased G:F from d 84 to 103 (0.35 vs 0.34) and overall (0.393 vs 0.387) compared to the control; whereas, pigs fed both Paylean[®] and CrPr had lower G:F than those fed Paylean[®] alone from d 84 to 103 (0.41 vs 0.42) and overall (0.397 vs 0.403). Neither Paylean[®] or CrPr influenced any of the carcass characteristics measured. Using the high energy diets in this trial, there was no observed response to the dietary inclusion of Cr from CrPr in grow-finish pigs.

Key Words: Chromium, Lysine, Ractopamine HCl

TH125 Evaluation of organic and inorganic trace minerals for pigs. Y. L. Ma^{*}, M. D. Lindemann, G. L. Cromwell, R. B. Cox, and G. Rentfrow, University of Kentucky, Lexington.

Crossbred pigs weaned at 21 ± 3 d (n = 144; BW = 7.4 ± 0.28 kg) were used to assess an organic form of several trace minerals to standard inorganic forms on performance and meat quality when trace minerals were deleted for various times preslaughter. Pigs were allotted to 24

pens (6 pigs/pen) based on gender and BW and fed a diet containing either inorganic ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, ZnO , $\text{FeSO}_4 \cdot \text{H}_2\text{O}$, MnO) or organic (Bioplexes®; Alltech Inc., Nicholasville KY) trace minerals (Cu, Zn, Fe, Mn) at the NRC (1998) requirement for each of 5 phases of BW from 7 to 120 kg (equivalent to 14, 14, 42, 28, 42-d periods, respectively). The pigs were weighed bi-weekly throughout the 140-d experiment. Two pigs were removed from each pen at the end of Phase IV (BW = 82.6 ± 0.80 kg), and again at the end of Phase V (BW = 126.6 ± 3.08 kg) for the determination of carcass measurements and collection of tissue samples (heart, liver, kidney, and spleen). After Phase IV, 3 pens from each treatment were switched to a common diet without trace mineral supplementation in 2-wk intervals. This resulted in 4 groups within each mineral treatment in which trace mineral supplementation was deleted for 0, 2, 4, and 6 wk of Phase V. ADG, ADFI, and G:F were not affected ($P > 0.27$) by the treatments during the first 4 phases (inorganic vs. organic: 773 vs. 778 g/d, 1,680 vs. 1,708 g/d, and 0.461 vs. 0.456, respectively). ADG for all phases was also not affected (inorganic vs. organic: 858 vs. 864 g/d, $P = 0.69$). Tissue weights, carcass shrink, LEA, and 10th rib BF were not affected by the source of mineral or length of mineral deletion ($P > 0.32$). Loin chop 48-hr drip loss was linearly decreased (6.43, 5.79, 6.54, 4.43%, $P = 0.06$) as the duration of mineral deletion was increased. Mineral deletion resulted in a quadratic effect for the Hunter L* color scores (d 0: 54.1, 56.3, 57.4, 55.2, $P < 0.05$; and d 6: 56.6, 57.9, 59.1, 57.3, $P = 0.08$) and the d 6 a* score (10.6, 10.3, 9.9, 10.6, $P = 0.08$). The results failed to show an effect of trace mineral source on growth performance or carcass characteristics; however, some aspects of meat quality were affected by the duration of mineral deletion.

Key Words: Trace Minerals, Pigs

TH126 Iron status evolution of weaned piglets fed different iron sources. P. Schlegel^{*1}, S. Durosoy¹, and M. Dupas², ¹*Pancosma S.A., Geneva, Switzerland*, ²*IDENA, Sautron, France*.

Three hundred eighty four (384) twenty-one day old weaned piglets (Large White*Landrace)*(Large White*Pietrain) were assigned on BW, gender and litter origin to 32 slotted pens. Piglets were fed ad-libitum a basal weaner diet (day 0-21) followed by a basal starter diet (day 21-42). Weaner and starter basal diets were formulated on wheat, barley, soy and contained 11.2 and 10.2 MJ/kg NE, 19.7 and 17.7 g/kg CP, respectively. Basal diets were not iron-supplemented. Dietary treatments were: basal weaner and starter diets supplemented with 100 mg/kg Fe from FeSO_4 or supplemented with 100 mg/kg Fe from crystalline iron glycinate (FeGly, B-TRAXIM® 2C Fe, Pancosma S.A., Switzerland). Prior study, piglets had free access to a commercial creep feed and were injected with 100 mg of iron dextran. Blood samples were collected on two identified piglets (one female, one castrated male) per pen on days 0, 21 and 42 for Hemoglobin (Hb) and hematocrit (Ht) analysis and red blood cell count (RBC). Between day 0 and 21 Hb was measured every second day using Hemocue® kit. Initial Hb, Ht and RBC were similar between treatments. The Hb evolution for the first 21 days was variable over time (day effect: $p < 0.10$). Hb depressions occurred during the first two days and between day 14 and 18 when compared with initial values. The Hb evolution from d0 to 21 was different between dietary treatments ($p < 0.05$) whereas Hb was hardly above 8 g/dl with FeSO_4 and hardly below 8 g/dl with FeGly. There was no source*day interaction ($p > 0.10$). On day 21, piglets fed FeGly had increased Hb levels (+15.5%, $p < 0.05$); increased Ht (+12.3%, $p < 0.001$) and increased RBC (+5.1%, $p < 0.10$) compared to FeSO_4 . On day 42, Hb and Ht were increased ($p < 0.001$)

for FeGly compared to FeSO_4 . Results of this study suggest that Fe from FeGly is more bioavailable than FeSO_4 and reduces therefore the risk in anemia when supplemented to post-weaning piglets.

Key Words: Iron, Bioavailability, Piglet

TH127 Effects of sodium bisulfate on growth performance of weaning pigs. J. Jarrett^{*}, S. Carter, J. Bundy, M. Lachmann, and T. Walraven, *Oklahoma State University, Stillwater*.

Two experiments were conducted to determine growth performance of weaning pigs fed sodium bisulfate (NaHSO_4), as a potential acidifier, at varying levels of inclusion. Pigs were stratified by sex, weight and ancestry and assigned to one of four dietary treatments containing 0, 0.2, 0.4, and 0.8% inclusion of NaHSO_4 . All diets were formulated on a total lysine basis for a typical, 4 phase, nursery-feeding program (1.60, 1.50, 1.35, and 1.20%). NaHSO_4 was added at the expense of sodium chloride. Pigs and feeders were weighed weekly to determine ADG, ADFI, and G:F. In Exp. 1, 200 pigs (5 pens/trt; 10 pigs/pen) were fed a common Phase 1 diet. Pigs were then allotted to one of four treatments for Phases 2 - 4. In Phase 2, there was no difference ($P > 0.10$) in ADG or ADFI among treatments, but G:F tended to improve (linear, $P < 0.07$) with increasing NaHSO_4 . There were no differences ($P > 0.10$) in ADG, ADFI, or G:F for Phases 3 and 4. Overall in Exp. 1, there was no difference ($P > 0.10$) in ADFI; however, ADG ($P < 0.05$) and G:F ($P < 0.06$) improved quadratically as NaHSO_4 levels increased in the diet. In Exp. 2, 240 pigs (6 pens/trt; 10 pigs/pen) were allotted at weaning in the same fashion to the four dietary treatments fed in all four phases. During Phase 1, there was no effect ($P > 0.10$) of NaHSO_4 on ADG, ADFI, or G:F. In Phase 2, NaHSO_4 addition increased (linear, $P < 0.04$) ADG and tended to improve G:F (linear, $P < 0.09$). No differences ($P > 0.10$) were observed in growth performance for Phase 3. During Phase 4, NaHSO_4 increased (linear, $P < 0.02$) ADG and tended to increase G:F (linear, $P < 0.07$). Overall, in Exp. 2, there was no effect ($P > 0.10$) of NaHSO_4 on ADFI or G:F, but increasing inclusion of NaHSO_4 tended to improve ADG (linear, $P < 0.07$). When combining results from both experiments (11 pens/trt) for Phases 2 - 4, ADG tended to increase (linear, $P < 0.06$) and G:F improved (quadratic, $P < 0.03$) for pigs fed NaHSO_4 . These results suggest that feeding NaHSO_4 at 0.4 or 0.8% inclusion may improve growth performance in weaning pigs.

Key Words: Weaning Pigs, Sodium Bisulfate, Growth Performance

TH128 Effects of dietary inorganic sulfate levels on growth performance and markers of intestinal inflammation in growing pigs. T. E. Weber^{*1}, C. Spence², T. R. Whitehead², and B. J. Kerr¹, ¹*USDA-ARS, Ames, IA*, ²*USDA-ARS, Peoria, IL*.

Ethanol co-products may contain moderate amounts of inorganic sulfur. In the intestine, inorganic sulfate is reduced to hydrogen sulfide by sulfate-reducing bacteria. Hydrogen sulfide has been found to alter the inflammatory response in rodent models, but the impact of dietary sulfate on inflammation in pigs has not been reported. In a 35 d experiment, pigs ($n = 64$; 13.3 ± 1.7 kg) were fed diets containing 0, 0.625, 1.25, 2.5, or 5.0% calcium sulfate. Two control diets containing reduced levels of calcium and sulfur were also fed. On d-35, all pigs were weighed and samples of intestinal tissue and mucosa were harvested from pigs fed 0

and 5% calcium sulfate for analysis of cytokine, intracellular adhesion molecule 1 (ICAM1), and suppressor of cytokine signaling 3 (SOCS3) mRNA. The activity of mucosal alkaline phosphatase and sucrase, and the abundance of I κ B α and phosphorylated p22/p44 MAP kinase (MAPK) in intestinal tissue were also determined. Increasing dietary sulfate had no impact on ADG or ADFI, but there was a cubic effect ($P < 0.05$) for G:F as sulfate levels increased. There was no difference in growth performance found in pigs fed reduced calcium or sulfate levels when compared to pigs fed the diet containing added inorganic sulfate. Real-time RT-PCR analysis revealed that feeding 5% inorganic sulfate increased ($P < 0.05$) the relative abundance of ICAM1, tumor necrosis factor α (TNF α), and SOCS3 mRNA and tended ($P < 0.09$) to increase the relative abundance of IL-6 mRNA in ileal tissue compared to pigs fed 0% added inorganic sulfate. In pigs fed diets containing 5% inorganic sulfate there tended ($P < 0.10$) to be a decrease in IL-6 and TNF α mRNA. Pigs fed 5% inorganic sulfate had a reduced ($P < 0.05$) abundance of I κ B α and an increase ($P < 0.05$) in phosphorylated MAPK in ileal tissue, but there was no effect in colon tissue. Addition of 5% inorganic sulfate had no impact on mucosal alkaline phosphatase or sucrase activity. These data suggest that growing pigs can tolerate relatively high levels of dietary inorganic sulfate and that high sulfate levels alter intestinal inflammatory mediators.

Key Words: Pig, Sulfate, Cytokine

TH129 Differential expression of 15 selenoprotein genes in various tissues of pigs. H. Zhao¹, J. C. Zhou¹, X. Xia¹, K. N. Wang¹, J. G. Li¹, Y. Zhao¹, Y. Liu¹, and X. G. Lei^{*1,2}, ¹*Sichuan Agricultural University, Ya'an, China*, ²*Cornell University, Ithaca, NY*.

Although 25 selenoproteins have been identified in mice, there is little information on the sequences and expression of the new selenoproteins in pig tissues. Recently, we have cloned porcine *gpx2*, *sel X*, *sel N*, *sel P*, *sel I5* and *sps2*. This experiment was to determine expression profiles of these 6 genes and another 9 selenoprotein genes (*gpx1*, *gpx3*, *gpx4*, *di1*, *di3*, *sel M*, *sel W*, *sel K*, and *txnr1*) in 7 porcine tissues by quantitative real-time RT-PCR. Weanling male pigs (BW = 10.3 \pm 0.32 kg, n=4) were fed a corn-soybean meal diet containing 0.3 mg Se/kg for 8 wk, and were killed to collect liver, kidney, loin, brain, testis, pituitary, and thyroid for total RNA isolation. Relative mRNA levels of the selected genes were detected using the One-Step SYBR Green Real-Time RT-PCR

(7900HT, Applied Biosystems, Perkin Elmer, Foster City, CA), and normalized with the levels of beta-actin and glyceraldehydes 3-phosphate dehydrogenase. The inter-tissue comparisons were estimated using the Delta-delta method (Applied Biosystem). Results indicate detectable mRNA expression for all the 15 genes in all the 7 assayed tissues. Liver, kidney, and muscle had the highest expression of *gpx1*, *gpx3*, *sel P*, *sel W*, *sel X*, *sps2*, *sel K*, and *txnr1*. Pituitary showed a high expression of *gpx3*, *gpx4*, *di3*, *sel I5*, and *sel N*. In the thyroid, expression of *sel M* was the highest, followed by *sel P* and *sel N*. In the brain, expression of *sel W* ranked the highest, followed by *sel P* and *sel N*. In conclusion, the 15 selenoprotein genes were differentially expressed in a tissue- and protein-specific fashion in growing pigs.

This project was supported in part by the Chang Jiang Scholars Program of the Chinese Ministry of Education (to XGL) and two research grants from the Chinese Natural Science Foundation (to XGL and JCZ).

Key Words: Quantitative Real-time RT-PCR, Selenium, Sus Scrofa

TH130 Intestinal and renal Type II NaPi co-transporter gene expression patterns in growing pigs fed with different levels of dietary calcium. Y. Yin*, S. X. Wang, T.-J. Li, R.-L. Huang, X.-F. Kong, P. Kang, Q. Hu, Z. Liu, and W. Wang, *The Chinese Academy of Sciences, Changsha, Hunan, P.R. China*.

This study was conducted to investigate the effect of different levels of dietary calcium on the patterns of NaPi-II co-transporter mRNA expression in growing pigs. 25 barrow pigs (20.9 \pm 0.95 kg) were fed a diet containing 5 different levels of Ca (0.29, 0.44, 0.60, 0.75, and 0.91%) by using different supplementations of limestone powder. Each trial lasted for 35 days and the pigs were slaughtered on the last day. Jejunum and kidney samples were collected to measure the mRNA expression of NaPi-IIc and NaPi-IIa using real-time PCR. Compared with the calibrator Ca level of 0.60% according to the NRC (1998), pigs fed diets with Ca level of 0.44%, 0.75 % and 0.91% had higher mRNA expression of NaPi-IIc in jejunum (1.49, 13.60 and 7.65) and NaPi-IIa in kidney (2.15, 6.53 and 8.48). Pigs fed with Ca level of 0.29% had lower mRNA expression of NaPi-IIa. These results suggest that the levels of dietary calcium affect mRNA expression of NaPi-II in jejunum and kidney.

Key Words: Pigs, Sodium-Dependent Pi Absorption, Phosphorus

Nonruminant Nutrition: Protein and Amino Acids

TH131 Determination of the order of limiting amino acids in milk-based liquid diets for pigs from 1.5 to 5.5 kg. A. I. Broome¹, R. J. Harrell², J. Odle¹, K. E. Sullivan¹, and J. H. Eisemann^{*1}, ¹North Carolina State University, Raleigh, ²Novus International Incorporated, St. Louis, MO.

This experiment was designed to determine the order of limiting amino acids (AA) beyond lysine (LYS) in a whey-skim milk-caseinate diet to be fed to low birth weight pigs. Initial pig weight was 1.71±0.30 kg (Rep. 1) and 1.62±0.11 kg (Rep. 2). The order was determined using a deletion assay. This was done using a positive control (PC) diet with AA concentrations and ratios to LYS at or above NRC recommendations, a negative control (NC) diet that reduced AA concentrations and ratios to LYS to 60% of the PC diet ratios, a supplemented negative control (Supp. NC) diet with AA supplemented to provide concentrations and ratios to LYS similar to the PC diet, and deletion diets which removed threonine (THR), tryptophan (TRP), sulfur amino acids (SAA), or phenylalanine (PHE) from the Supp. NC diet to levels in the NC diet. All diets contained 4.2 Mcal GE and 20.6 g LYS/kg DM. Diets were fed ad libitum (n=8/diet). Gain, intake, G:F, and PUN concentration were analyzed for effects of diet, replicate, and interaction. The SEM values were 7.33 g/d, 7.72 g DM/d, 0.02, and 0.33 mM, respectively, for diet main effect. Gain for animals fed PC (346 g/d), NC (269 g/d), and Supp NC (315 g/d) diets differed (P<0.05). Gain of pigs on all deletion diets was similar. The SAA deletion diet produced less gain (291 g/d, P<0.05) than Supp. NC diet. Intake was similar in pigs fed PC (306 g DM/d) and NC diets (310 g DM/d) and greater (P<0.05) than for pigs on all other diets. Feed efficiency decreased for pigs fed NC diet (0.87, P<0.05) compared to all other diets. Pigs fed SAA deletion diet had the greatest (P<0.05) PUN concentration (6.96 mM). Pigs fed THR deletion diet (5.70 mM) and PC diet (5.55 mM) had similar concentrations. Based on increased PUN concentration and decreased gain in pigs fed the SAA deletion diet relative to the Supp. NC diet, it is likely that SAA were next limiting. Threonine would likely be next limiting after SAA, also based on increased PUN concentrations.

Key Words: Limiting Amino Acids, Liquid Diets, Pigs

TH132 Use of distillers dried grains with solubles and soybean hulls in nursery pig diets. F.F. Barbosa*, S.S. Dritz, M.D. Tokach, J.M. DeRouchey, R.D. Goodband, and J.L. Nelssen, Kansas State University, Manhattan, Kansas, United States.

Two 21-d experiments with 1,584 pigs in each experiment were conducted to evaluate growth performance of nursery pigs fed different levels of distillers dried grains with soluble (DDGS) or soybean hulls. In each experiment, pigs (10.9 kg in Exp. 1 and 12.4 kg in Exp. 2) were allotted to 72 pens (36 pens of barrows and 36 pens of gilts) with 22 pigs per pen on day 21 after weaning. A pen of barrows and gilts shared a common feeder and, thus, feeder was the experimental unit. In Exp. 1, treatments were a corn-soybean meal based control diet or the same diet with 7.5%, 15%, or 22.5% added DDGS. Increasing DDGS from 0 to 22.5% did not influence ADG (P>0.26; 506, 512, 516, or 515 g/d) or ADFI (P>0.21; 758, 754, 737, or 743 g/d); but linearly (P<0.004) increased G:F (0.67, 0.68, 0.70, and 0.69). The survival rate (99.0 to

99.5%) was not affected (P>0.60) by diet. In Exp. 2, treatments were arranged as a 2 x 2 factorial with either 0 or 15% DDGS and 0 or 4% soybean hulls. Adding DDGS, soybean hulls or the combination of DDGS and soybean hulls to the control diet did not influence (P>0.17) ADG (557, 555, and 542 vs. 555 g/d). There was an interaction (P<0.01) between DDGS and soybean hulls for ADFI and a trend for an interaction (P<0.09) for G:F. Adding DDGS reduced ADFI and increased (P<0.04) G:F to a greater extent when added to the control diet (786 vs 822 g/d; 0.71 vs 0.68) than when added to the diet containing soybean hulls (789 vs 804 g/d; 0.69 vs 0.69). Adding soybean hulls to the control diet did not affect (P>0.17) pig performance. The survival rate (99.5 to 100%) was not affected (P>0.31) by treatments. In summary, 15 to 22.5% DDGS and up to 4% soybean hulls were added to diets for 12 to 24 kg pigs without influencing ADG while increasing levels of DDGS (up to 22.5%) improved feed efficiency in these experiments.

Key Words: Distillers Dried Grains with Solubles, Soybean Hulls, Nursery Pigs

TH133 Amino acid supplementation of hydrolyzed feather meal diets for finisher pigs: I. Growth performance and serum metabolite profile. K. C. Divakala^{*1}, L. I. Chiba¹, R. B. Kamalakar¹, S. P. Rodning¹, E. G. Welles¹, K. A. Cummins¹, J. Swann², F. Cespedes², and R. L. Payne³, ¹Auburn University, Auburn, AL, ²American Proteins, Inc., Hanceville, AL, ³Evonik-Degussa Corp., Kennesaw, GA.

The objective of this study was to determine the possibility of replacing soybean meal (SBM) in pig diets completely with feather meal (FM). Corn-SBM, finisher (F) 1 and 2 positive control diets (PC) were formulated to contain 6.1 and 4.7 g apparent ileal digestible (AID) Lys/kg, respectively, and corn-FM, negative control diets (NC) were formulated to be iso-N to the PC. The NC were supplemented with AA to satisfy all the AID indispensable (Ind) AA requirements based on the 1998 NRC AID AA (NRC; NC + Lys and Trp) and the assumption that the apparent ileal digestibility of all Ind AA in FM is 40% (40-2AA = NC + Lys, Trp, and Thr, but no His and Ile, and 40All = NC + Lys, Trp, Thr, His, and Ile). Forty-five gilts and 45 barrows (57.8 ± 0.8 kg; 3 gilts or 3 barrows/pen) were randomly assigned to 5 F-1 diets. At 81.0 ± 1.4 kg, pigs were offered F-2 diets. Pigs had ad libitum access to feed and water, and blood samples were collected at the end of the study (112.1 ± 1.8 kg). As expected, overall ADFI, AID Lys (representing Ind AA) intake (LysI), ADG, and G:F were greater and G:LysI was lower in pigs fed the PC than those fed the NC (P < 0.001). Overall G:LysI tended to be lower in pigs fed the NRC than those fed the PC (P = 0.083) or 40-2AA and 40All (P = 0.094), and pigs fed the 40All had numerically higher G:F (P = 0.119) and G:LysI (P = 0.160) than those fed the 40-2AA. Pigs fed the PC had more serum albumin and total protein (TP; P < 0.001) but less glucose (P = 0.031) and cholesterol (P < 0.001) than those fed the NC, and TP was higher (P = 0.031) in pigs fed the 40All than those fed the 40-2AA. Diets had no effect on urea N or triglycerides. The results seemed to indicate that pigs fed the FM diet supplemented with the necessary AA can utilize AA for weight gain as efficiently as those fed the corn-SBM diet.

Key Words: Finisher Pigs, Feather Meal, Growth Performance

TH134 Amino acid supplementation of hydrolyzed feather meal diets for finisher pigs: II. Carcass traits, meat quality, and internal organs. K. C. Divakala^{*1}, L. I. Chiba¹, R. B. Kamalakar¹, S. P. Rodning¹, E. G. Welles¹, K. A. Cummins¹, J. Swann², F. Cespedes², and R. L. Payne³, ¹Auburn University, Auburn, AL, ²American Proteins, Inc., Hanceville, AL, ³Evonik-Degussa Corp., Kennesaw, GA.

Forty-five gilts and 45 barrows were used to determine the possibility of replacing soybean meal (SBM) in pig diets completely with feather meal (FM). Pigs (57.8 ± 0.8 kg; 3 gilts or 3 barrows/pen) were randomly assigned to 5 finisher (F) 1 diets. At 81.0 ± 1.4 kg, pigs were offered F-2 diets. Corn-SBM, F-1 and F-2 positive control diets (PC) were formulated to contain 6.1 and 4.7 g apparent ileal digestible (AID) Lys/kg, respectively, and corn-FM, negative control diets (NC) were formulated to be iso-N to the PC. The NC were supplemented with AA to satisfy all the AID indispensable (Ind) AA needs based on the 1998 NRC AID AA (NRC; NC + Lys and Trp) and the assumption that apparent ileal digestibility of all Ind AA in FM is 40% (40-2AA = NC + Lys, Trp, and Thr, but no His and Ile, and 40All = NC + Lys, Trp, Thr, His, and Ile). Pigs had ad libitum access to feed and water, and all pigs were slaughtered at 112.1 ± 1.8 kg. Pigs fed the PC had less average backfat than those fed the NC ($P = 0.016$) or the NRC ($P = 0.020$). The LM was greater ($P < 0.001$) in pigs fed the PC or the 40All than those fed the NC or the 40-2AA, respectively. Pigs fed the PC had greater ($P < 0.01$) % lean, lean gain (LG), and LG:F than those fed the NC, but their LG:F or LG:Lys (representing Ind AA) intake (LysI) was similar to those fed the NRC. The LG:F ($P = 0.030$) and LG:LysI ($P = 0.028$) were lower in pigs fed the NRC than those fed the 40-2AA and the 40All, and LG:LysI tended to be higher ($P = 0.068$) in pigs fed the 40All than those fed the 40-2AA. Pigs fed the 40All had greater ($P < 0.001$) meat color, firmness, and marbling scores than those fed the 40-2AA. Diets had no clear effect on organ weights. The results seemed to indicate that pigs fed the FM diet supplemented with the necessary AA can utilize AA and feed for LG as efficiently as those fed the corn-SBM diet.

Key Words: Finisher Pigs, Feather Meal, Carcass Traits

TH135 Effects of dietary crude protein level on concentrations of fecal volatile fatty acids, and fecal and urinary ammonia and volatile organic compounds in growing pigs. S. B. Cho^{*}, D. W. Kim, O. H. Hwang, C. W. Choi, W. T. Chung, J. H. Lee, I. B. Chung, and B. S. Lee, *National Institute of Animal Science, RDA, Suwon, Republic of Korea.*

Present study aimed to investigate effects of dietary crude protein (CP) level on concentrations of fecal volatile fatty acids (VFA), and fecal and urinary ammonia and volatile organic compounds (VOC) in growing pigs. Twenty boars were allotted to one of four dietary treatments in randomized complete block design with five replicates. Dietary treatments consisted of four corn-soybean based meals containing 10, 12, 14, or 16% CP. Synthetic amino acids of lysine, methionine and threonine were added into the diet to provide similar contents of limiting amino acids among treatments. Pigs were housed individually in metabolic cages to allow collection of feces and urine. Fresh feces and urine samples were collected to analyze concentrations of VFA, ammonia, and VOC. Total VFA concentration from fresh feces for CP 10% diet (12.3g/kg) was higher ($P < 0.05$) than that from the other diets (mean 7.7g/kg). Fecal ammonia concentration for CP 14% diet (6.0g/kg) was lower ($P < 0.05$) than that from the other diets (mean 7.6g/kg). Phenol (10.0mg/kg), p-cresol (408.4mg/kg) and ammonia (2.1g/kg)

concentration in urine under 12% diets decreased ($P < 0.05$) compared with those over CP 14% diets (22.2mg/kg, 883.2mg/kg and 5.4g/kg, respectively). Present results indicate that dietary CP level may regulate odor-producing substances in growing pigs.

Key Words: Crude Protein, Pig, Volatile Organic Compounds

TH136 Feed preferences in nursery pigs fed diets containing varying fractions and qualities of dried distillers' grains with solubles (DDGS). B. S. Seabolt¹, E. van Heugten^{*1}, K. D. Ange-van Heugten¹, and E. Roura², ¹North Carolina State University, Raleigh, ²Lucta SA, Barcelona, Spain.

Three experiments were conducted to evaluate nursery pig preference of diets containing DDGS of different quality and levels of inclusion. Pigs were adjusted to a commercial diet (without DDGS) at weaning for at least 10 d and subsequently housed individually. Each pen contained two identical feeders positioned side by side and preference was measured for two days. In Exp. 1, 60 pigs (11.63 ± 0.27 kg BW) were given a choice between a control diet (0% DDGS) and a diet containing either 0, 10, 20 or 30% DDGS. In Exp. 2, 80 pigs (10.25 ± 0.20 kg BW) were given a choice between a control diet (0% DDGS) and a diet containing either 0% DDGS, 30% good quality DDGS or 30% poor quality DDGS. Quality was determined by odor and color of the DDGS. In Exp. 3, 80 pigs (11.15 ± 0.18 kg BW) were given a choice between a control diet without DDGS and a diet containing either 10% or 20% good quality, or 10% or 20% poor quality DDGS. Feed disappearance was measured for two days in each experiment and preference was calculated as intake of the test diet as a percentage of total feed intake. In Exp. 1, a linear decrease ($P < 0.001$) in preference for DDGS containing diets was observed, where preferences were 58.2%, 34.8%, 26.4%, and 17.2% for the 0%, 10%, 20% and 30% DDGS inclusion, respectively. In Exp. 2, no significant differences in preference were detected between good and poor quality DDGS when fed at 30% of the diet. In Exp. 3, no significant differences in preference between the control diet and 10% good or poor quality DDGS were evident. However, mean intake was greater ($P < 0.05$) for the control diet (439 g/d) compared to the 20% good quality DDGS (144 g/d). Mean intake was also greater ($P = 0.09$) for the control diet (407 g/d) compared to the 20% poor quality DDGS (242 g/d). Nursery pigs prefer a diet without DDGS over a diet containing DDGS even at low inclusion levels. Quality of DDGS as defined in this study had no effect on preference.

Key Words: Dried Distillers Grains with Solubles, Pigs, Preference

TH137 Effect of dietary protein level on serum haptoglobin and pro-inflammatory cytokine concentrations in piglets challenged with *Escherichia coli* K88. F. O. Opapeju^{*1}, R. L. Payne², and C. M. Nyachoti¹, ¹University of Manitoba, Winnipeg, MB, Canada, ²Evonik-Degussa Corporation, Kennesaw, GA.

A 14-d study was conducted to investigate the effect of dietary CP level on serum haptoglobin and pro-inflammatory cytokine concentrations in piglets challenged with enterotoxigenic *Escherichia coli* K88. Forty piglets (average BW = 5.32 ± 0.24 kg), housed in groups of 4 pigs per pen, were randomly allotted to 2 diets (5 pens/diet) immediately after weaning. Diet 1 contained 22.5% CP (high CP diet) and diet 2 contained

17.6% CP (low CP diet) supplemented with amino acids. The two dietary CP levels were achieved by using different combinations of corn, wheat and casein. The diets contained the same amount of ME and standardized ileal digestible Lys, Met + Cys, Thr, Trp, Ile, and Val based on the ideal protein ratio. Pigs were orally challenged with 6 mL of *E. coli* suspension (10^{10} cfu/mL) on d 8 after weaning. Blood samples were collected from 1 pig per pen on 7 d and 24 h before challenge and 8 h, 24 h, 72 h and 7 d post-challenge for determination of serum haptoglobin, TNF- α , IL-8 and IL-1 β concentrations in the serum. Pigs fed the low CP diet had lower ($P < 0.05$) levels of haptoglobin (9 vs. 25 mg/dL), TNF- α (106 vs. 138 pg/mL), IL-8 (52 vs. 119 pg/mL) and IL-1 β (72 vs. 116 pg/mL) at 8 h post-challenge compared with those fed the high CP diet. There were no effects of diet on any of the measured parameters at the other periods of blood collection. The results indicate that a low protein diet supplemented with amino acids fed to pigs immediately after weaning reduced inflammation resulting from an enterotoxigenic *Escherichia coli* challenge.

Key Words: Dietary Protein, Piglets, Pro-Inflammatory Cytokines

TH138 Influence of micronization (fine grinding) of soy bean meal and fullfat soy bean on nutrient digestibility and digestive traits in young pigs. D. G. Valencia, M. P. Serrano, R. Lázaro, M. A. Latorre, and G. G. Mateos*, *Universidad Politécnica de Madrid, Spain.*

A trial was conducted to test the effect of micronization (very fine grinding) of soybean meal (SBM) and fullfat soy bean (FFSB) on coefficient of ileal apparent digestibility (CIAD) of dietary components and digestive traits of piglets. The experimental design was completely randomized with 4 treatments arranged factorially (SBM and FFSB, micronized and ground) and six replicates each (one piglet). Four isonutritive diets (2,490 kcal NE/kg and 1.28% available Lys) were fed from 23 to 45 d of age. The main difference among them was the mean particle size of the soy bean product used (47 and 881 μ m for the SBM and 41 and 778 μ m for the FFSB, micronized and ground, respectively). In all cases the source tested supplied 5.5% of the dietary protein (CP). The CIAD of dietary components, the pH of the gastrointestinal tract (GIT) and the weight of digestive organs and spleen were measured at 45 days of age. Particle size did not affect any trait studied ($P \geq 0.10$). Type of soy bean product had no effect on CIAD of CP or amino acids ($P \geq 0.10$). However, piglets fed the SBM diets had higher CIAD of organic matter (0.765 vs. 0.705) and gross energy (0.761 vs. 0.711) than piglets fed the FFSB diets ($P \leq 0.001$). The pH of the different segments of the GIT was not affected by the soybean product used ($P \geq 0.10$). Pigs fed SBM had heavier pancreas (2.3 vs. 1.9 g/kg body weight; $P \leq 0.05$) and livers (35.9 vs. 32.7 g/kg body weight; $P \leq 0.01$) than pigs fed FFSB. The poor nutrient digestibility of pigs fed FFSB as compared to pigs fed SBM might be related to the conditions applied during processing of the bean. It is concluded that pigs fed soy bean meal had better digestibility of organic matter and gross energy than pigs fed FFSB and that fine grinding of the two soy protein sources does not affect nutrient digestibility.

Key Words: Particle Size, Soy Bean Products, Digestibility in Piglets

TH139 Effects of including field peas in diets fed to weanling pigs. H. H. Stein*¹ and D. N. Peters², ¹*University of Illinois, Urbana,* ²*South Dakota State University, Brookings.*

Two experiments were conducted to measure effects of including field peas in diets fed to weanling pigs. Pigs that were weaned at 20 d and fed a common starter diet for 2 wk post-weaning were used in both experiments. In Exp. 1, 120 pigs were randomly allotted to 5 treatments with 3 or 4 pigs per pen and 7 replicate pens per treatment. The control diet was based on corn (56.8%), soybean meal (16.0%), and extruded full fat soybeans (21.0%). Two additional diets were formulated by including 24.5 or 49.0% raw field peas in the control diet at the expense of corn and soybean meal. The last 2 diets were similar to these diets with the exception that 24.5 or 49.0% extruded field peas were used rather than raw field peas. All diets were provided on an ad libitum basis during 25 d. There were no differences among pigs fed the 5 treatment diets in ADG (574, 559, 548, 598, and 549 g/d), ADFI (1,013, 1,024, 962, 1,003, and 914 g/d) or G:F (0.57, 0.55, 0.58, 0.60, and 0.61 g/g). Experiment 2 used 168 pigs that were randomly allotted to 6 treatments with 4 pigs per pen and 7 replicate pens per treatment. A control diet containing corn (57.1%), soybean meal (27.0%), and dried whey (10.0%) was formulated. Five additional diets were formulated by including, 12, 24, 36, 48, or 60% field peas in this diet at the expense of corn and soybean meal. Pigs were fed experimental diets on an ad libitum basis during 4 wk and results showed that there were no differences in ADG, ADFI, or G:F among treatment groups (Table 1). It is concluded from these experiments that up to 60% raw field peas may be included in diets fed to pigs from 2 weeks post-weaning. Use of extruded field peas does not improve pig performance compared with raw field peas.

Table 1. Increasing concentrations of field peas in diets fed to weanling pigs (Exp. 2)

Peas, %	0	12	24	36	48	60	SEM	P-value, Linear	P-value, Quadratic
Initial BW, kg	8.94	8.92	8.92	8.92	8.95	8.94	0.729	0.99	0.98
ADFI, g	930	933	944	913	884	915	58	0.61	0.97

TH140 Effects of dietary pine cone meal on egg production, egg quality, serum cholesterol and cholesterol content and fatty acid composition of egg yolk in laying hens. S. O. Shin*¹, J. H. Cho¹, Y. J. Chen¹, J. D. Kim², J. H. Lee³, K. W. Park³, and I. H. Kim¹, ¹*Dankook University, Cheonan, Chungnam, Korea,* ²*CJ CheilJedang, Seoul, Korea,* ³*Korea National Arboretum, Pocheon, Gyeonggi, Korea.*

This study was conducted to evaluate the effects of dietary pine cone meal on egg production, egg quality, serum cholesterol, cholesterol content and fatty acid composition of egg yolk in laying hens. The total of 252 (51-wks) Hy-line brown commercial hens were used for 5 weeks. Dietary treatments included 1) T1 (basal diet + 1% cottonwood sawdust), 2) T2 (basal diet + 0.5% cottonwood sawdust + 0.5% pine cone meal) and 3) T3 (basal diet + 1% pine cone meal). During the overall period, there were no differences in egg production, egg weight and egg quality among treatments. Lipids profile (total, HDL, LDL cholesterol and Triglyceride) in serum was not affected by treatments. Egg yolk cholesterol was not different among the treatments. In fatty acid contents of yolk, C18:3 was higher ($P < 0.05$) in T1 treatment (0.33%) than T3 treatment

(0.27%). Total SFA, PUFA, MUFA and UFA/SFA were no differences in experimental period. In conclusion, results of the experiment was affected by dietary supplementation of pine cone meal on C18:3 fatty acid contents of yolk in laying hens, without adversely production.

Key Words: Pine Cone Meal, Serum Cholesterol, Laying Hens

TH141 Effects of dietary pine cone meal on growth performance, serum cholesterol, carcass quality and fatty acid composition and cholesterol content of meat in broiler chickens. S. O. Shin^{*1}, J. H. Cho¹, J. D. Kim², J. H. Lee³, K. W. Park³, and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²CJ CheilJedang, Seoul, Korea, ³Korea National Arboretum, Pocheon, Gyeonggi, Korea.

This study was conducted to evaluate effects of dietary pine cone meal on growth performance, serum cholesterol, carcass quality and fatty acid composition and cholesterol content of meat in broiler chickens. Three treatments were assigned to 480 (2 days) Arbor Acre broiler chicks with eight replications, allocating 20 broiler chicks in each replication. Dietary treatments included 1) CS (1% cottonwood sawdust), 2) PCM0.5 (0.5% cottonwood sawdust + 0.5% pine cone meal) and 3) PCM1.0 (1% pine cone meal). During the overall period there was no difference of growth performance among treatments. Also, cholesterol profile (total, HDL, LDL cholesterol and triglyceride) in serum and carcass characteristic were not affected by treatments. TBARS of leg and breast meat was significantly decreased ($P<0.05$) in PCM1.0 treatment (0.014 and 0.021 mgMA/kg, respectively) compared to CS treatment (0.025 and 0.030 mgMA/kg, respectively). In fatty acid contents of leg meat, C20:0 was significantly higher ($P<0.05$) in PCM0.5 treatment (0.32%) than PCM1.0 treatment (0.25%). Also, C18:3n3 was significantly lower ($P<0.05$) in PCM1.0 treatment (0.02%) than other treatments (0.04% and 0.04%). Cholesterol contents of leg, breast meat and abdomen fat were not affect by treatment. In conclusion, results of the experiment were affected by dietary supplementation of pine cone meal on TBARS of leg and breast meat.

Key Words: Pine Cone Meal, Growth Performance, Broiler

TH142 Effects of dietary level of brewer's grain on growth performance and digestibility in growing pigs. J. S. Yoo^{*1}, J. D. Kim², K. Y. Whang³, H. J. Jung⁴, S. B. Cho⁴, H. B. Seok¹, and I. H. Kim¹, ¹Dankook University, Cheonan, Choongnam, Korea, ²CJ CheilJedang, Seoul, Korea, ³Korea University, Seoul, Korea, ⁴National Institute of Animal Science, Korea.

This study was conducted to investigate the effects of dietary brewer's grain supplementation on growth performance and digestibility in growing pigs. A total of forty-eight pigs (18.1kg, average initial body weight) were used during 42 days. Dietary treatments included: 1) CON (basal diet), 2) BG5 (basal diet + 5% brewer's grain) and 3) BG10 (basal diet + 10% brewer's grain). Each treatment had 8 replicates of 2 pigs per pen in a randomized complete block design. Growth performance was not affected ($P>0.05$) by treatments. However, in nutrient digestibility, DM digestibility was higher ($P<0.05$) in BG5(79.67%) treatment than CON(77.39%) and BG10(78.43%) treatments. Nitrogen digestibility was the highest ($P<0.05$) in BG10(84.35%) treatment and among another(72.67%, 82.63%) treatments, also, BG5(82.63%) treatment

was higher ($P<0.05$) than CON treatment. Energy digestibility was higher ($P<0.05$) in BG5(80.88%) treatment than CON(78.41%) treatment. In conclusion, dietary brewer's grain supplementation had no influence on growth performance whereas improved nutrient digestibility in growing pigs.

Key Words: Brewer's Grain, Growth Performance, Pigs

TH143 Effect of bedding types and different crude protein levels on growth performance, visceral organ weight and blood characteristics in broiler chickens. Y. Huang^{*1}, J. S. Yoo¹, Y. J. Chen¹, J. H. Cho¹, J. D. Kim², J. D. Hancock³, and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²CJ CheilJedang, Seoul, Korea, ³Kansas State University, Manhattan.

The object of this study was to assess whether bedding types could influence the growth performance of broiler chickens fed on high and low crude protein (CP) diets. The broilers were bedded with clean hulls or shavings. For hundred and eighty broiler chickens (Ross) were divided into six treatment groups including: 1) high CP diet with rice hulls, 2) high CP diet with wood shavings, 3) high CP diet with coconut hulls, 4) low CP diet with rice hulls, 5) low CP diet with wood shavings, and 6) low CP diet with coconut hulls. Each treatment included four replicate pens with twenty broilers per pen. Weight gain, feed intake, feed/gain ratio, visceral organ relative weight, RBC, WBC, and lymphocyte levels were evaluated. The Bursa of Fabricius, liver and abdominal fat relative weight, WBC, and lymphocyte levels were not altered consistently by any of the treatments. For the overall period, weight gain and feed intake was higher in the coconut hulls treatment groups as compared with wood shavings treatments ($P<0.05$). Feed intake was also higher in low CP diet than in the high CP diet treatment groups ($P<0.05$). The concentration of RBC in blood was reduced significantly by bedding wood shavings while these levels were increased in rice hulls treatments ($P<0.05$). In conclusion, our results indicate that coconut hulls are suggested as a replacement of rice hulls and wood shavings as a resource for broiler bedding, and reduced CP level increases feed intake, especially in the finisher period.

Key Words: Bedding, Broiler

TH144 Comparative efficacy of import fish meals and fermented (*L. acidophilus* GB-LC2) fish meal on growth performance, protein cells concentrations in serum, nutrient digestibility in weanling pigs. J. H. Cho^{*1}, Y. J. Chen¹, J. S. Yoo¹, I. B. Chung², J. H. Ahn², and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²National Institute of Animal Science, RDA, Korea.

The current study was conducted in an effort to evaluate and compare the effects of feeding imported fish meals and fermented fish meal on growth performance, protein cells concentrations in serum, nutrient digestibility, backfat thickness and lean percent in weaning pigs. One hundred twenty pigs [(Landrace × Yorkshire) × Duroc] barrows (6.70±0.20kg) were used in a 35 - d feeding trial. Dietary treatments included: E1 (5 and 2.5% LT fish meal in phase 1 & 2, respectively), E2 (5 and 2.5% Bio-CP fish meal), LF (5 and 2.5% domestic fish meal) and FLF (5 and 2.5% fermented domestic fish meal). During 35 days after weaning, there were no difference in average daily feed intake and

gain/feed ratio (n=24) among the treatments ($P>0.05$). However, pigs fed the E2 diet had greater ($P<0.05$) average daily gain (n=24) than pigs fed LF diets during entire feeding period. Weekly backfat thickness and lean percent (n=48) were not affected ($P>0.05$) by the experimental diets during the entire 5-wk study period. No differences ($P>0.05$) were observed for concentrations of albumin, creatinine, blood urea nitrogen and total protein in serum (n=48) on 0, 14 and 35 days. On 7 days, creatinine concentrations was highest ($P<0.05$) for pigs fed the LF diet compare to pigs fed the E2 and FLF diets ($P<0.05$). During 35 days after weaning, pigs fed the E2 and FLF diets had a greater nitrogen digestibility (n=48) than pigs fed the LF diet ($P<0.05$). In conclusion, the results of this study indicate that fermented fish meal had similar effects on growth performance and nitrogen digestibility as compared to imported fish meal.

Key Words: Fish Meal, Nitrogen Digestibilities, Weaning Pigs

TH145 Effect of deoiled corn dried distillers grains with solubles, solvent extracted on nursery pig growth performance. J. Y. Jacela^{*1}, L. Brandts², J. M. DeRouchey¹, S. S. Dritz¹, M. D. Tokach¹, R. D. Goodband¹, J. L. Nelssen¹, R. C. Thaler², D. Peters², and D. E. Little³, ¹Kansas State University, Manhattan, ²South Dakota State University, Brookings, ³DairyNet Inc., Brookings, SD.

Deoiled corn dried distillers grains with solubles, solvent extracted (dDGS) is a co-product of ethanol production which is traditional dried distillers grains with solubles with a majority of oil removed. A total of 210 pigs (initial BW 9.9 kg) were used in a 28-day study to evaluate the effect of dDGS on nursery pig performance. From weaning to just prior to start of the trial, all pigs were placed on a common diet until they reached an average of 10 kg BW. Pigs were then blocked based on pen weights and each pen was randomly assigned to 1 of 5 dietary treatments. There were 7 pens per treatment with 6 pigs per pen. The treatments provided 0, 5, 10, 20, and 30% dDGS formulated to contain equivalent dietary ME and standardized ileal digestible (SID) lysine based from a previous study at Kansas State University. Pen weights were obtained on d 0, 14, and 28 and feed intake was recorded on a pen basis. Growth rate ($P>0.52$), feed intake ($P>0.95$), and feed efficiency ($P>0.55$) were similar between treatments regardless of the level of dDGS in the diet. Results from this experiment suggest that dDGS can be included in nursery pig diets of up to inclusion levels of 30% without affecting growth performance.

Table 1.

Item	dDGS, %					SE
	0	5	10	20	30	
Final wt, kg	22.7	22.8	22.2	22.4	22.3	0.6
ADG, g	455	459	452	445	442	19.7
ADFI, g	749	771	760	751	761	8.9
G:F	0.61	0.60	0.59	0.59	0.58	0.03

Key Words: Nursery Pig, Deoiled Corn Dried Distillers Grains, Growth

TH146 Evaluation of distillers dried grains with solubles (DDGS) and Allzyme[®] SSF in grow-finish pigs. J. Pierce* and J. Bannerman, Alltech, Inc., Nicholasville, KY.

An experiment was conducted to evaluate the effects of Allzyme[®]SSF on the growth performance and carcass quality of pigs fed diets containing graded levels of DDGS in grow-finish pigs. A total of 420 pigs (42 pens of 10 pigs/pen) were randomly allotted by weight and sex to six dietary treatments. Diets were corn-soybean meal based with DDGS substituting for corn and soybean meal. The diets were formulated to meet or exceed the NRC 1998 nutrient requirements for each of three growth phases. The six dietary treatments were arranged in a 3x2 factorial structure with 10, 20, or 30% DDGS without or with 200g/tonne of Allzyme[®]SSF, respectively. All pigs were weighed at the onset of the experiment and then 30, 73 and 111 days later. Each pig was tattooed and sent to a commercial slaughter facility in the Midwest. Backfat samples were taken from five randomly chosen carcasses from each pen and analyzed for iodine values (IV) as an indicator of the degree of fat saturation. Means for ADG and F:G for the entire 111 day experiment were 856, 855, 823, 855, 855, 853 g/d and 2.83, 2.83, 2.83, 2.76, 2.89, 2.83 for the six treatments, respectively. As the level of dietary DDGS was increased, ADG was decreased ($P<0.05$), however the addition of Allzyme[®]SSF maintained ADG which resulted in a DDGSxAllzyme[®]SSF interaction ($P<0.09$). Last rib back fat and ham pH were unchanged by treatment, however, loin depth decreased linearly as DDGS was increased in the diet ($P<0.05$). Iodine values increased linearly as DDGS was increased ($P<0.05$) indicating less saturated fat. The increased iodine values that result from feeding 30% DDGS to finishing pigs until slaughter may not currently be an acceptable practice because of reduced pork quality. However, there is a possibility of oil removal for biodiesel and other purposes growing in the future. The addition of Allzyme[®]SSF to diets containing DDGS can reduce cost of gain in growing-finishing swine while maintaining growth performance.

Key Words: Pigs, Distillers Grains, Enzyme

TH147 Comparison of finishing pigs performance when diets containing DL- methionine and cull chickpeas in substitution of soybean meal and corn. J. M. Uriarte*, J. F. Obregón, H. R. Guemez, F. G. Rios, and O. S. Acuña, Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México.

To determinate the effect of substitution of soybean meal and corn for cull chickpeas on growth performance, 48 pigs (BW = 53.63 ± 1.70 kg; Large white x Landrace x Large white x Pietrain) in groups of four were placed in 12 concrete floor pens (2.5 x 2.5 m). In a complete randomized experimental design, pens were fed one of three diets: 1) Diet with 15.2 % CP and 3.35 Mcal ME/kg, containing corn 76.5 %, soybean meal 15.5 %, and premix 4 % (CONT); 2) Diet with 17.1 % CP and 3.35 Mcal ME/kg with corn 42.5 %, cull chickpeas 50 %, soybean meal 3.5 %, and premix 4 % (CHP50) and 3) Diet similar to CHP50 with 0.2 % of methionine added (CHP50M). Pigs were weighed at days 0 and 48 of experiment and feed intake was recorded daily. The average daily gain (ADG) and feed intake/gain ratio were calculated from these data. Body weight at day 48 (95.17, 95.65 and 96.17 kg) was not affected ($P=0.91$) by CONT, CHP50 and CHP50M, respectively. ADG (0.82, 0.92 and 0.90 kg) was not similar ($P=0.04$) between dietary treatments.

Feed intake (2.47, 2.57 and 2.60 kg) was not modified ($P=0.66$) by treatments. Feed/gain ratio (3.04, 2.82, and 2.90) was similar ($P=0.30$) between treatments. It is concluded, that cull chickpeas with 0.2 % added DL-methionine can be used up 50 % in diets for finishing pigs without affecting growth performance.

Key Words: Chickpeas, Growth Performance, Methionine

TH148 Carcass traits of pigs fed with cull chickpeas with added DL-methionine. J. M. Uriarte*, J. F. Obregón, H. R. Guemez, F. G. Rios, O. S. Acuña, and A. R. Cortina, *Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México.*

To determine the effect of substitution of soybean meal and corn for cull chickpeas on carcass traits of the finishing pigs, 48 pigs (BW = 53.63 ± 1.70 kg; LW × Land × LW × Piet) in groups of four were placed in 12 concrete floor pens (2.5 x 2.5 m). In a complete randomized experimental design, pens were fed one of three diets: 1) Diet with 15.2 % CP and 3.35 Mcal ME/kg, containing corn 76.5 %, soybean meal 15.5 %, and premix 4 % (CONT); 2) Diet with 17.1 % CP and 3.35 Mcal ME/kg with corn 42.5 %, cull chickpeas 50 %, soybean meal 3.5 %, and premix 4 % (CHP50) and 3) Diet similar to CHP50 with 0.2 % of methionine to added (CHP50M). Pigs were weighed at days 0 and 48 of experiment. After 48 days nine pigs by treatment were slaughtered and carcass traits measured. Body weight at day 48 (95.17, 95.65 and 96.17 kg) was not affected ($P=0.91$) by CONT, CHP50 and CHP50M, respectively. Hot carcass weight (78.83, 76.13 and 77.45 kg) was similar between treatments ($P=0.66$), and carcass yield (78.43, 75.87 and 77.82 %) was not affected by treatments ($P=0.15$). Backfat (1.87, 1.90 and 1.78 cm) was no affected, rib eye area (35.80, 37.25 and 35.70 cm²) was similar between treatments. It is concluded, that cull chickpeas with 0.2 % added DL-methionine can be used at up 50 % of diets for pigs without affecting carcass traits.

Key Words: Chickpeas, Carcass Traits, Methionine

TH149 Comparison of chromic oxide and acid insoluble ash as digestibility markers in the determination of apparent total tract digestibility in finishing pigs. V. D. Naranjo*, S. Powell, T. D. Bidner, and L. L. Southern, *LSU Agricultural Center, Baton Rouge.*

Two experiments were conducted to compare Cr₂O₃ and acid insoluble ash (AIA) as digestibility markers for determining apparent total tract digestibility of DM (DMD), CP (CPD), and GE (GED) in early and late finishing pigs fed ad libitum. In both experiments, growth performance was determined at the end of the 14-d studies. Fecal samples were collected from each pig by rectal palpation on d 12, 13, and 14 and combined within day, pig, and pen (1 sample per pen) at the end of the collection period. Feed and fecal samples were analyzed for CP, GE, Cr, and AIA concentration. Finishing pigs (Exp. 1, n = 18 barrows, initial BW = 50 ± 2.90 kg; Exp. 2, n = 18 barrows and 18 gilts, initial BW = 85 ± 5.90 kg) were used. In Exp. 1, pigs were randomly assigned to 6 pens and fed a diet containing 1% added AIA (diatomaceous earth, Perma-Guard, Inc.) and 0.5% Cr₂O₃ (3,352 ppm Cr). In Exp. 2, pigs were assigned to 6 pens per diet (3 pens of 3 barrows and 3 pens of 3 gilts) on the basis of BW and sex to 2 diets (Diet 1 = 0.5% Cr₂O₃; Diet 2 = 1% added AIA). The diets were nutritionally adequate and based on corn and soybean meal.

In Exp. 1, the diet analyzed to contain 1.48% AIA and 3,171 ppm Cr. The 1.48% AIA is because both the diatomaceous earth and the Cr₂O₃ contribute to the total AIA in the diet. Pigs had an ADG of 827 g, ADFI of 2,382 g, and G:F of 0.35. No significant differences ($P > 0.10$) were observed in CPD (70.63 vs. 67.72 %), but DMD (85.40 vs. 83.95 %) and GED (82.05 vs. 80.26 %) were greater ($P < 0.10$) with the Cr₂O₃ marker. In Exp. 2, Diet 1 analyzed to contain 3,484 ppm Cr and Diet 2 analyzed to contain 1.0% AIA. Growth performance was not affected by diet ($P > 0.10$). Pigs had an ADG of 611 g, ADFI of 2,820 g, and G:F of 0.22. As in Exp. 1, no significant differences were observed in CPD (52.42 vs. 54.45%), but in contrast to Exp. 1, DMD (72.78 vs. 75.95%) and GED (66.34 vs. 71.19%) were greater ($P < 0.05$) with the AIA marker. These data suggest that Cr₂O₃ and AIA result in similar digestibility values and that CP digestibility is not as susceptible to the specific marker as DM and GE.

TH150 Effects of dried distillers grains and Gromega365™ on sow bratwurst quality. H. White*¹, K. Hesselbrock¹, N. Augspurger², J. Spencer², A. Schinckel¹, and M. Latour¹, ¹Purdue University, West Lafayette, IN, ²JBS United, Sheridan, IN.

Feeding corn dried distillers grains with solubles (DDGS) to sows may impact the fatty acid profile and quality of final products such as bratwurst. The purpose of this study was to determine differences in bratwurst quality made from sows fed one of four dietary treatments: control [CON], control plus DDGS [CDDGS], control plus Gromega 365™ [CG], or DDGS plus Gromega 365™ [DDGSG] based on freshness quality scoring. DDGS was fed at 30% dietary inclusion during gestation and 15% during lactation. Freshness quality of bratwurst was based on a 1-4 scale (1=lowest and 4=highest). DDGSG bratwurst had a significantly ($P < 0.02$) higher overall quality score. Bratwurst fatty acid profiles also differed between treatments. The level of linoleic acid was significantly ($P < 0.0001$) higher in the DDGSG followed by the CDDGS group with both non DDGS treatments being lowest. The highest ($P < 0.0001$) calculated iodine value was observed in the CDDGS (65.6), followed by DDGSG (59.7) and the lowest being the two non DDGS diets (53.1 [CON] and 55.9 [CG]). In summary, there were noted differences in overall bratwurst quality which favored the DDGSG group. Similarly, when comparing the DDGS fed groups (DDGSG vs. CDDGS), the overall iodine value was lower in the DDGSG bratwurst.

Key Words: DDGS, Sows, Bratwurst

TH151 The effects of extrusion and inclusion of dried distillers grains on nitrogen retention in swine. A Dietz*¹, R.L. Atkinson¹, P Walker², and G Apgar¹, ¹Southern Illinois University, Carbondale, ²Illinois State University, Normal.

Eight steered ileal cannulated pigs (PIC L337×C22; 51.2 ± 3.8 kg) were used in a 4 × 4 repeated Latin square design to determine the effect of extrusion and protein source on N retention. Each period consisted of 5 d adjustment, 3 d total fecal and urine collection, followed by 2 d ileal collection, with 1 d rehydration between ileal collections. Semi-purified diets were formulated to supply 0.9% lysine from the following protein sources: 1) 100% non-extruded dried distillers grains +

solubles (DDG;ND); 2) 100% extruded DDG (ED); 3) 70:30% soybean meal:DDG mix non-extruded (NM); 4) 70:30% soybean meal:DDG mix extruded (EM). Protein sources were extruded using a single screw dry extruder. Treatments were balanced to meet AA requirements and fed at 9% metabolic body weight offered twice daily (0700 and 1700 h). Feed, feces and urine were analyzed for DM and N content. Data were analyzed using the MIXED procedures of SAS to compare effects of extrusion and inclusion of DDG. The inclusion of DDG decreased ($P < 0.01$) N intake and extrusion decreased N intake ($P < 0.0001$). As DDG increased in the diet, fecal N increased ($P = 0.01$). Although extrusion had no effect on N in the urine, increasing DDG in the diet decreased N in the urine ($P = 0.03$). However, neither extrusion nor protein source altered total N output ($P > 0.25$) or BV ($P > 0.12$). N digested (g/d) decreased with both extrusion ($P = 0.003$) and inclusion of DDG ($P < 0.0001$). Furthermore, N digestibility, as a % of N intake, decreased ($P = 0.003$) with DDG inclusion, however; digestibility was not effected ($P = 0.31$) by extrusion. N retention was reduced by both extrusion ($P = 0.01$) and inclusion of DDG ($P = 0.09$). Extrusion tended ($P = 0.07$) to decrease net protein utilization, however; protein source had no effect ($P = 0.99$) on utilization. These data suggest that protein source does not effect N utilization; however, extrusion of the diets containing DDG may decrease N retention.

Key Words: Dried Distillers Grains, Nitrogen, Swine

TH152 L-Tryptophan dietary supplementation stimulated an earlier feed intake and reduced the physical activity of early weaned piglets. M. Anguita¹, R. G. Hermes^{*1}, J. Gasa¹, D. Melchior², and J. F. Pérez¹, ¹Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain, ²Ajinomoto Eurolysine S.A.S., Paris, France.

L-Tryptophan (Trp) has been related with different metabolic functions that regulate feed intake, stress recovery and immune response. In the present study we evaluated if L-Tryptophan supplementation above the daily requirements proposed by different feeding systems (18% of the daily lysine-Lys- requirement) may improve the adaptation of piglets after weaning. A total of 30 piglets were selected from ten different sows (three piglets /sow, 6.80 kg \pm 0.372) and allocated into fifteen pens (two piglets/pen). Three dietary treatments were designed based on the Trp to Lys ratio and the feeding manner, and distributed to the different pens (one pig per sow was present in each treatment). Two treatments were administered *ad libitum*, Trp18 (Trp:Lys = 0.18) and Trp22 (Trp:Lys = 0.22), and a third treatment, rTrp22, were restrictively fed to the same intake shown by Trp18 from day four after weaning. Feed intake was daily registered and the posture of the animals (laying or standing) controlled ten times within a day on days 4 to 6 and 9 to 10. No differences ($p = 0.372$) were observed on the accumulated feed intake per animal on day 4 after weaning (314, 437 and 449 g for Trp18, Trp22 and rTrp22, respectively). However, differences were observed on the motivation of piglets to eat early after weaning. Three out of five pens (3/5) on Trp18 showed a feed intake below 50 g/animal 72 h after weaning, while 4 out of 5 on Trp22 showed a higher feed intake, above 90 g/animal 48 h after weaning ($p = 0.046$). Differences ($p \leq 0.001$) were also observed on the behavior of the animals on days 6, 9 and 10, with pigs fed on Trp22 showing a lower number of records (44%) standing up than Trp18 (62%) and rTrp22 (84%). Therefore L-Tryptophan supplementation may improve the adaptation of piglets after weaning by enhancing feed intake.

Key Words: Piglets, L-Tryptophan, Feed Intake

TH153 Lysine restriction and realimentation affected growth, blood metabolites, and myostatin and leptin expressions in weaned pigs. Y. X. Yang¹, J. Guo², Z. Jin¹, S. Y. Yoon¹, J. Y. Choi¹, M. H. Wang², X. S. Piao³, S. J. Ohh¹, B. W. Kim¹, and B. J. Chae^{*1}, ¹College of Animal Life Sciences, Chuncheon, Kangwon-Do, Republic of Korea, ²School of Biotechnology, Chuncheon, Kangwon-Do, Republic of Korea, ³National Key Lab of Animal Nutrition, China Agricultural University, Beijing, P. R. China.

A total of 128 weaned pigs (Landrace \times Yorkshire \times Duroc) were used in a 6-wk study to investigate the effects of lysine restriction and realimentation on performance, digestibility, blood profiles, and gene expressions of leptin and myostatin. Pigs were randomly allotted to four treatments on the basis of their body weights, each treatment comprised of four pens and each pen had 8 pigs. The starter diets fed to pigs during the first two weeks (P1) contained 1.350, 1.080, 0.945 or 0.810% lysine levels. Then common grower 1 and 2 diets were offered for two weeks (P2 and P3 containing 1.150 and 0.950% lysine, respectively) each. During P1, average daily gain (ADG, 391, 335, 306 and 295 g/d) decreased linearly ($P < 0.05$) with the increasing levels of lysine restriction. Final body weight did not differ ($P > 0.05$) among all the treatments. The apparent digestibilities of CP during P1 and P2, GE and CP during P3 were improved linearly ($P < 0.05$) with the decrease in dietary lysine levels. The apparent ileal digestibilities of Lys and Leu increased linearly ($P < 0.05$) with an increase in the degree of lysine restriction. Linear ($P < 0.05$) improvements in plasma triglyceride (29.8 to 40.0 mg/dl) and glucose (95.5 to 114.8 mg/dl) and decreased ($P < 0.05$) blood urea nitrogen (15.6 to 8.55 mg/dl), total protein (6.8 to 5.78 g/dl) and albumin (3.3 to 3.9 g/dl) during P1 were noticed with an increase in the degree of lysine restriction. During P2, pigs fed with lysine restricted starter diets had lower (linear, $P < 0.05$) blood urea nitrogen and total protein, however no differences in the plasma metabolites were noted during P3. The relative abundance of myostatin mRNA in skeletal muscle and leptin mRNA in subcutaneous adipose were lower ($P < 0.05$) in pigs fed lysine-restricted diets. These results indicated that pigs fed a lysine-restricted diet exhibited compensatory growth, while changes in myostatin and leptin mRNA abundance by lysine restriction suggested that lysine played a role in regulating protein and fat metabolism in young pigs.

Key Words: Lysine, Restriction, Pigs

TH154 Impaired translation initiation activation and reduced protein synthesis in weaned piglets fed a low-protein diet supplemented with essential amino acids. Y. Yin^{*1}, D. Deng¹, W. Chua¹, K. Yao¹, T. Li¹, R. Huang¹, Z. Liu¹, and G. Wu², ¹The Chinese Academy of Sciences, Changsha, Hunan, P.R.China, ²Texas A&M University, College Station.

Weanling mammals (including infants) often experience intestinal dysfunction when fed a high-protein diet. Recent work with the piglet (an animal model for studying human infant nutrition) shows that reducing dietary protein intake can improve gut function during weaning but results in inadequate provision of essential amino acids (EAA) for muscle growth. The present study was conducted with weaned pigs to test the hypothesis that supplementing deficient EAA (Lys, Met, Thr, Trp, Leu, Ile, and Val) to a low-protein diet may maintain the activation of translation initiation factors and adequate protein synthesis in tissues. Pigs were weaned at 21 days of age and fed diets containing 20.7, 16.7, or 12.7% crude protein (CP), with the low-CP diets supplemented with

EAA to achieve the levels in the high-CP diet. On d 14 of the trial, tissue protein synthesis was determined by the phenylalanine flooding method. Reducing dietary CP levels decreased protein synthesis in pancreas, liver, kidney, and longissimus muscle. A low-CP diet reduced the phosphorylation of eukaryotic initiation factor (eIF) 4E-binding protein-1 (4E-BP1) in skeletal muscle and liver and increased the formation of an inactive eIF4E 4E-BP1 complex in muscle, while decreasing the phosphorylation of mammalian target of rapamycin (mTOR) and the formation of an active eIF4E eIF4G complex in liver. These results demonstrate for the first time that chronic feeding of a low-CP diet suppresses protein synthesis in animals, in part, by inhibiting mTOR signaling. Additionally, our findings indicate that supplementing deficient EAA to low-protein diets is not effective in restoring protein synthesis or whole-body growth in weanling piglets. We suggest that conditionally essential amino acids (e.g. glutamine and arginine) may be required to maintain the activation of translation initiation factors and optimal protein synthesis in tissues of weanling pigs.

Key Words: mTOR Signaling, Protein Synthesis, Piglets

TH155 Effects of dietary protein level on intramuscular fat content and its fatty acid composition in lean and obese genotype finishing pigs. H.-J. Xu^{1,2}, Y.-L. Liu³, W.-T. Gu¹, Y.-L. Yin^{*1}, X.-F. Kong¹, R.-L. Huang¹, W.-J. Tang¹, and Z.-Q. Liu¹, ¹The Chinese Academy of Sciences, Changsha, Hunan, P.R. China, ²West Anhui University, Luan, Anhui, China, ³Wu Han Polytechnic University, Wuhan Hubei, China.

Effects of dietary protein level on intramuscular fat (IMF) content and fatty acid composition in lean and obese genotype finishing pigs were studied. Twenty two Crossbred (Duroc×Landrace×Large White) barrows and eighteen Ningxiang barrows were equally randomly assigned to two groups and fed diets I (14% CP) and diet II (15% CP), respectively. Longissimus dorsi (LD) and semitendinosus muscle (ST) samples were collected to determine IMF content and fatty acid composition. Ratio of oleic acid (C18:1) and linoleic acid (C18:2) in LD of Crossbred was lower (36.6% vs 47.1%, $p < 0.01$) and higher (19.0% vs 9.4%, $p < 0.01$) than that of Ningxiang, respectively, when diet I was fed. When diet II was fed, the IMF amount of LD in Crossbred was lower (1.49% vs 3.39%, $p < 0.01$) than that in Ningxiang and lower 1.49% vs 2.21%, $p < 0.05$) than that of its own ST; ratio of stearic acid (C18:0), C18:1 and C18:2 in LD of Crossbred was higher (17.0% vs 13.4%, $p < 0.01$), lower (33.4% vs 47.4%, $p < 0.01$) and higher (20.6% vs 10.3%, $p < 0.01$) than that of Ningxiang, respectively while ratio of palmitic acid (C16:0), C18:0, C18:1 and C18:2 in ST of Crossbred was lower (23.5% vs 27.3%, $p < 0.01$), higher (15.3% vs 11.3%, $p < 0.01$), lower (42.2% vs 50.6%, $p < 0.01$) and higher (17.2% vs 9.6%, $p < 0.01$) than that of Ningxiang; ratio of C18:1 in LD of Crossbred was lower (35.0% vs 43.8%, $p < 0.01$) than that of its own ST while ratio of C18:0 and C18:1 in LD of Ningxiang was higher (13.4% vs 11.4%, $P < 0.05$) and lower (47.4% vs 50.6%, $p < 0.05$) than that of its own ST, respectively. These results indicate that different muscle types of different breeds responded differently in IMF content and fatty acid composition to the change in dietary protein level.

Key Words: Fatty Acids, Protein, Genotype

TH156 Dietary protein intakes affects expression of the cationic amino acid transporter-1 gene in the small intestine of finishing pigs. C. Y. Shi^{1,2}, W. Y. Chu², T. J. Li², M. M. Geng², R. L. Huang², S.-Y. Bin¹, and Y.-L. Yin^{*2}, ¹Guangxi Normal University, Guilin, Guangxi, China, ²The Chinese Academy of Sciences, Changsha, Hunan, P. R. China.

This study was conducted to determine the effect of dietary protein intakes on expression of the cationic amino acid transporter-1 (CAT1) gene in the small intestine of finishing pigs. Thirty-six castrated male pigs (Duroc × Landrace × Large White), with an average initial body weight of 55.6 ± 7.0 kg, were randomly allocated to one of the three dietary treatments. The pigs were housed individually in floor pens and fed diets containing three CP levels (13%, 16%, and 19%). After 45 days of feeding, 3 pigs in each treatment were randomly selected to be slaughtered. The duodenum, jejunum and ileum were obtained for the analysis of mRNA levels for CAT1 using real-time RT-PCR. The results indicate that CAT1 mRNA levels in the duodenum, jejunum and ileum fed the 16% CP diets were 1.01 ± 0.14 , 1.55 ± 0.24 and 0.66 ± 0.19 , respectively, CAT1 mRNA levels in the duodenum, jejunum and ileum fed the 19% CP diets were 1.60 ± 0.23 , 1.91 ± 0.38 and 1.11 ± 0.57 , respectively, CAT1 mRNA levels did not differ ($P > 0.05$) between the two groups of pigs fed the 16% and 19% CP diets. However, the CAT1 mRNA levels were 1.95 ± 0.46 and 34.75 ± 7.13 , increased ($P < 0.05$) by 48% and 96%, respectively, in the duodenum and jejunum of pigs fed the 13% CP diet, when compared with pigs fed the 16% CP diet. In contrast, the CAT1 mRNA level in the ileum of pigs fed the 13% CP diet was 0.53 ± 0.26 and was 25% lower ($P < 0.05$) than that in pigs fed the 16% CP diet. These results indicate that dietary protein intakes differentially influence expression of the CAT1 gene in the different segments of the pig small intestine to regulate the absorption of basic amino acids derived from dietary protein.

Key Words: Gene Expression, Finished Pig, Intestine

TH157 Molecular cloning, distribution and expression of the amino acid transporter y+LAT1 gene in tissues of young Tibet pigs. W. T. Gu¹, W. Y. Chu¹, W. C. Wang¹, M. M. Geng¹, T. J. Li¹, Y. L. Yin^{*1}, and G. Y. Wu^{1,2}, ¹The Chinese Academy of Sciences, Changsha, Hunan, P. R. China, ²Texas A&M University, College Station.

The Tibet pig (a Chinese swine breed) has a relatively small body size and provides a useful model for studying mechanisms that regulate animal growth and development. As an initial step of our investigation, we cloned the gene encoding the amino acid transporter y+LAT1 (HGMW-approved gene symbol SLC7A7) from the small intestine of the Tibet pig. This sodium-dependent cationic-amino-acid transporter functions to transport of arginine, lysine, ornithine, and histidine in cells. The Tibet porcine SLC7A7 gene encoded 487 deduced amino acid residues, which show a higher degree of sequence similarity to the human y+LAT1 gene (92%) than to the rat (89%) and opossum (88%) counterparts. The membrane topology analysis indicated that the porcine y+LAT1 protein had 12 putative transmembrane domains. Confocal microscopic examination of porcine y+LAT-GFP-expressing Vero cells revealed the localization of the protein on the plasma membrane. Using the RT-PCR technique, the y+LAT1 mRNA was detected in the brain, kidney, duodenum, jejunum, ileum, liver, and skeletal muscle of Tibet

pigs at both 7 and 21 d of age. Interestingly, the y+LAT1 mRNA was present in the spleen and backfat of Tibet pigs at 21 d of age but absent from these two tissues at 7 d of age. These results indicate age- and tissue-dependent expression of the y+LAT1 gene in Tibet pigs.

Key Words: Amino Acid Transporter, Tibet Pigs, Gene Expression

TH158 Molecular cloning, distribution and expression of the amino acid transporter b0,+ AT mRNAs in young Tibet pigs. W. Y. Chu¹, W. C. Wang¹, W. T. Gu¹, M. M. Gen¹, T. J. Li¹, Y. L. Yin^{*1}, and G. Y. Wu^{1,2}, ¹The Chinese Academy of Sciences, Changsha, Hunan, P. R. China, ²Texas A&M University, College Station.

The amino acid transporter b0,+ AT functions to transport both neutral and basic amino acids by cells. This event is crucial for the absorption of dietary amino acids by the small intestine and the uptake of circulating amino acids by extraintestinal tissues. We used the Tibet pig (a Chinese swine breed), which has a relatively small body size, as a model to study mechanisms that regulate animal growth and development. Particularly, we succeeded in cloning the gene encoding the amino acid transporter b0,+ AT (HGMW-approved gene symbol SLC7A9) in the small intestine of Tibet pigs. The Tibet porcine SLC7A9 gene encoded 487 deduced amino acid residues, showing a higher degree of sequence similarity to the horse b0,+ AT gene (91.2%) than to the monkey (89.5%) and human (89%) counterparts. The membrane topology analysis indicated that the b0,+ AT protein had 12 putative transmembrane domains. Confocal microscopic examination of porcine b0,+ AT-GFP-expressing Vero cells revealed the localization of the protein on the plasma membrane. The RT-PCR analysis showed that the b0,+ AT mRNA was present in the brain, kidney, duodenum, jejunum, ileum, liver, and skeletal muscle of Tibet pigs at 7 and 21 d of age. The b0,+ AT mRNA was also in the spleen and backfat of Tibet pigs at 21 d of age but could not be detected in these two tissues at 7 d of age. These results indicate age- and tissue-dependent expression of the b0,+ AT gene in Tibet pigs.

Key Words: Amino Acid Transporter, Tibet Pigs, Amino Acid Transporter

TH159 Digestibility and metabolism of nitrogen and energy in finishing Ningxiang pigs. W.-J. Tang, X.-F. Kong, Z.-Q. Liu, R.-L. Huang, T.-J. Li, and Y.-L. Yin*, *The Chinese Academy of Sciences, Changsha, Hunan, P. R. China.*

The experiment was conducted to determine the effects of dietary crude protein levels on nutrient digestibility and metabolism of nitrogen and energy. Nine finishing Ningxiang pigs (boar, castration) with an average BW of 65.0 kg ± 2.5 kg were randomly assigned to 3 treatment groups with 3 replications of 1 pig, fed diets with 10.41%, 12.91% or 15.43%

CP, respectively. The experiment lasted 8 days, and all of the fecal and urinary samples were collected on the last three days. Results showed that pigs fed the diet with 12.91% CP level had the highest apparent digestibility of DM and energy, and the CP digestibility decreased with the increasing of dietary CP level ($P < 0.05$). Ingestive nitrogen, fecal nitrogen, urinary nitrogen, and total nitrogen in excretion, absorption and retention of nitrogen, and fecal and urinary energy increased with the increasing of dietary CP level ($P < 0.01$). Utilization and apparent digestibility of nitrogen, ME and ME/GE decreased with the increasing of dietary CP level ($P < 0.05$). These findings suggested that the dietary CP level had a significant effect on the digestibility of energy and crude protein, as well as the deposition and excretion of nitrogen.

Key Words: Protein, Utilization, Pigs

TH160 Ontogenetic development and nutritional regulation of Amino Acid Transporter EAAC1 in intestine of swine. X. Wu¹, C. Y. Xie², Y. L. Yin^{*1}, L. Wang³, W. Y. Chu¹, M. M. Geng¹, T. J. Li¹, R. L. Huang¹, and Y. Q. Hou³, ¹The Chinese Academy of Sciences, Changsha, Hunan, P. R. China, ²Huazhong Agricultural University, Wu Han, China, ³Wuhan Polytechnic University, WuHan, Hubei, China.

EAAC1 is responsible for the uptake of glutamate, a major metabolic fuel of the enterocyte through the Na⁺-dependent transport system X-AG. To evaluate the ontogenetic development and nutritional regulation of EAAC1 gene expression in small intestine, twenty Duroc×Landrace×Yorkshire crossbreed piglets (d 1, 7, 14, 21, and 28 d) were killed during lactation. Three intestinal segments (duodenum, jejunum, and ileum) were collected for total RNA and protein isolation. The abundance of mRNA and protein was evaluated using real time-PCR and western blotting using antibodies for EAAC1, respectively. Abundance of EAAC1 generally declined from d 1 to 14 and subsequently increased to d 21 in the jejunum. Intestinal of pigs 14 d were used for EAAC1 distribution in all segments. The results showed that abundance of EAAC1 mRNA and protein was greater in duodenum, and then jejunum and ileum (1.54:1.35:1.17 and 1.70:1.46:1, $P \leq 0.05$). Then intestinal segments from growing pigs (with average body weight of 55.6±7.0 kg) fed with four experimental diets with different dietary protein (DP) levels (13, 16, 19%, and 16% with 1% arginine) and DE levels (12.6, 14.6, 16.5 MJ/kg and 14.6 MJ/kg with 1% arginine) were studied. In general, both of the EAAC1 mRNA and protein abundance decreased from low to high DP (1.54:0.68:0.67 and 1.70:1.24:0.97), and 1% arginine enhanced EAAC1 expression in duodenum. On the contrary, EAAC1 protein had greater expression in high DE diet, and abundance in pigs with 14.6% DE added 1% arginine were lowest (1.10:1.69:2.13:1, $P \neq 0.05$). In conclusion, gene expression of EAAC1 is not only differentially distributed among intestinal segments, but also differentially regulated by age, and was affected by diet, especially by arginine.

Key Words: Amino Acid Transporter, Intestine, Pigs

Physiology and Endocrinology: Physiology of Heat Stress

TH161 Thermal and nutritional regulation of hepatic gluconeogenic genes in growing beef cattle. M. D. O'Brien*, L. C. Cole, J. B. Wheelock, S. R. Sanders, G. C. Duff, L. H. Baumgard, and R. P. Rhoads, *University of Arizona, Tucson.*

The effect of heat stress (HS) on hepatic expression of key gluconeogenic genes in growing beef cattle was examined and a pair-fed (PF) design was used to differentiate HS effects from those related to reductions in feed intake (FI) typically associated with HS. Holstein bull calves (134 ± 4 kg) were housed in climate-controlled chambers, fed an 86% concentrate, 14% protein diet and subjected to two experimental periods: 1) thermal-neutral (TN; 18-20°C) with ad libitum intake for 9 d and 2) HS (cyclical daily temperatures ranging from 29.4°C to 40.0°C) with ad libitum intake or PF (thermal-neutral conditions) for 9 d. Throughout the study, individual FI was measured on a daily basis whereas rectal temperature (RT) and respiration rate (RR) were measured at four h intervals. Liver biopsies were obtained on d 9 of each period. Hepatic total RNA was isolated, cDNA synthesized and real-time PCR analysis performed. During HS, RT and RR increased (39.0 to 40.6°C and 42 to 126 breaths/min; $P < 0.01$) and DMI decreased by 12%. By design, PF bulls received a similar plane of nutrition. Pyruvate carboxylase (PC) gene expression increased ($P < 0.05$) following HS exposure but remained unchanged during PF. Neither HS nor PF affected expression of the cytosolic phosphoenolpyruvate carboxykinase 1 (PCK) gene. Abundance of peroxisome proliferator-activated receptor- γ coactivator-1 α (PGC-1 α) mRNA, a transcriptional coactivator that acts at the promoter level of gluconeogenic genes such as PC and PCK, was measured. Despite altered PC gene expression, PGC-1 α mRNA abundance was unaffected by HS. Similarly, reduced FI during PF did not alter PGC-1 α gene expression. In summary, modulation of PC gene expression by HS appears to occur via mechanisms which are independent of reduced nutrient intake.

Key Words: Heat Stress, Cattle, Hepatic Gluconeogenesis

TH162 Seasonal differences in gene expression in oocytes from Holstein cows in a subtropical environment as revealed by gene array analysis. P. J. Hansen*¹, M. Salem², A. M. Brad¹, J. Yao², and G. W. Smith³, ¹University of Florida, Gainesville, ²West Virginia University, Morgantown, ³Michigan State University, East Lansing.

In dairy cows, oocyte competence for development after fertilization or electrical activation is reduced during and after heat stress. There is evidence that follicular function can be reduced by heat stress as early as ~30 d before ovulation. The molecular basis for the effect of heat stress on oocyte function is not well understood. Here, gene array analysis was used to identify differences in RNA transcript profiles between oocytes collected in summer and winter. Cumulus-oocyte complexes (COCs) were harvested from ovaries of Holstein cows collected at an abattoir in Florida. Only those with at least 4-5 layers of cumulus cells and evenly granulated oocyte cytoplasm were collected. Oocytes were denuded of cumulus cells and stored at -80°C in pools of ~20. A total of six pools were collected in summer (July-Aug) and six pools in winter (Jan-Feb). RNA was extracted from each pool, subjected to linear amplification and amplified RNA from each pool labeled and hybridized using a two-color, dye swap design to a bovine array consisting of 8,000 unique, 70-mer oligos representing predicted bovine mRNAs. Initial data analysis

revealed 105 and 44 transcripts with greater abundance in summer and winter, respectively ($P < 0.01$) and mapping to distinct gene ontology categories. Further analysis incorporating a false discovery rate of 6 % revealed 7 transcripts displaying greater abundance during summer. Three encode for genes of unknown function. Known genes encoding for transcripts of increased abundance during summer included glutathione S-transferase subunit isoform I, which participates in repair of oxidative stress damage, cyclin D2, which can activate CDK kinases involved in cell proliferation and block inhibition of cell cycle caused by retinoblastoma protein, PRA1 family protein 2, which is involved in protein trafficking, and 17-beta-hydroxysteroid dehydrogenase type 1, which is involved in steroid metabolism. Results are consistent with summer conditions causing an increase in transcripts for proteins that act to stabilize oocyte function during thermal stress. Support: BARD US3986-07

Key Words: Heat Stress, Oocyte, Gene Array

TH163 The effect of heat stress and exogenous bovine somatotropin on expression of genes associated with hepatic gluconeogenesis in lactating dairy cows. J. B. Wheelock*, A. J. LaNoce, M. D. O'Brien, S. R. Sanders, R. J. Collier, L. H. Baumgard, and R. P. Rhoads, *University of Arizona, Tucson.*

Recent evidence indicates heat stress (HS) alters whole-body glucose metabolism independently of HS-induced reductions in feed intake. The majority of bovine whole-body glucose demands are met by hepatic gluconeogenesis however it is unknown whether HS affects liver glucose production. Therefore, study objectives were to examine hepatic expression of key gluconeogenic genes in lactating dairy cows during HS or in thermal neutral pair-fed animals (PF) and administered bovine somatotropin (rbST) in each condition. Multiparous (99 DIM) Holstein cows [n = 10 (HS), n = 12 (PF)] were subjected to three 7 d experimental periods: 1) thermal neutral, ad libitum intake, 2) HS or PF, and 3) HS or PF with rbST (POSILAC[®]) administered on d 1 of period 3. HS temperatures were cyclical, ranging from 29.7 to 39.2°C. Milk yield, DMI, respiration rate (RR) and rectal temperature (RT) were measured daily. Liver biopsies were obtained on d 7 of each period for total RNA isolation, cDNA synthesis and real-time PCR analysis. Heat stress increased RR and RT and reduced DMI by 30%. By design, PF cows received a similar plane of nutrition. During HS and PF, milk yield decreased by 27.5 and 15.3%, respectively and increased following rbST administration (~13%). During PF, pyruvate carboxylase (PC) and cytosolic phosphoenolpyruvate carboxykinase (PCK) gene expression increased (60%, $P < 0.05$) or tended to increase (40%, $P < 0.10$), respectively. In contrast, PC gene expression increased by 45% ($P < 0.05$) but PCK mRNA abundance was unaltered by HS. Similarly, peroxisome proliferator-activated receptor- γ coactivator-1 α (PGC-1 α) mRNA abundance tended to increase ($P < 0.10$) during PF but was unaffected by HS. Administration of rbST did not alter gluconeogenic mRNA abundance despite causing a 2- and 3-fold increase ($P < 0.05$) in insulin-like growth factor-I (IGF-I) gene expression during HS and PF, respectively. In summary, HS leads to a change in hepatic gluconeogenic gene expression that appears independent of reduced feed intake.

Key Words: Heat Stress, Gluconeogenesis, Cattle

TH164 Heat shock modulates adipokines secretion in 3T3-L1 adipocytes. U. Bernabucci*, L. Basirico, P. Morera, N. Lacetera, B. Ronchi, and A. Nardone, *Dipartimento di Produzioni Animali, Viterbo, Italy.*

Several studies have demonstrated that high temperatures are responsible for modifications of lipid/carbohydrate metabolism in farm animals, but mechanisms are not yet clarified. Adipose tissue acts through secretory factors called adipokines (adiponectin and leptin) that are expressed in differentiated adipocytes and are involved in modulation of both lipid and glucose metabolism. To date there is no information concerning the possible relationship between heat stress and adipokines expression. Therefore, the objective of the present study was to investigate the effect of heat shock on adiponectin and leptin secretion in 3T3-L1 adipocytes. Adipocytes were incubated at different temperatures: 37 (control), 39 and 41°C. For each temperature, samples were collected after 0, 2, 4, 8, 16 and 24h of exposure. Adiponectin and leptin secretion were measured in cell culture media using commercial ELISA kits. As molecular markers of cell injury Hsp70.2 gene expression was determined by real time-PCR. Cell viability was determined by XTT assay. Heat shock affected adipokines secretion. Compared with 37°C, secretion of adiponectin increased ($P \leq 0.01$) at 39°C, while at 41°C, the protein was not detectable. Unlike adiponectin, the concentration of leptin increased ($P \leq 0.01$) at 41°C. The Hsp-70.2 gene expression was increased ($P \leq 0.05$) already at 39°C and the higher level ($P \leq 0.01$) was reached at 41°C compared with 37°C. Exposure to different temperatures did not affect cell viability. Results of the present study show that mild heat stress (39°C) caused an increase in adiponectin secretion, while severe heat stress (41°C) caused upregulation of leptin and downregulation of adiponectin. The study provides the first evidence of a direct modulation of heat shock on adiponectin and leptin secretion in 3T3-L1 adipocytes. Changes in leptin and adiponectin induced by severe heat stress might be involved in the alteration of lipid/carbohydrate metabolism occurring in animals exposed to a hot environment.

Key Words: Heat Shock, 3T3-L1, Adipokines

TH165 Effects of elevated ambient temperature on length of gestation and ruminal temperature at parturition of beef cows. E. C. Wright*, M. J. Prado-Cooper, C. L. Bailey, and R. P. Wettemann, *Oklahoma Agricultural Experiment Station, Stillwater, OK.*

Angus x Hereford cows ($n = 27$) were randomly assigned to four groups and AI to calve in mid August (MAug), late August (LAug), mid September (Sept) or mid October (Oct) to evaluate the effects of elevated ambient temperature on length of gestation and ruminal temperature at parturition. Temperature boluses (SmartStock, LLC) were placed in the rumen at 255 d of gestation. Boluses were programmed to transmit temperature every hr. Cows grazed native pasture in Oklahoma and had a body condition score of 6.5 ± 0.4 at calving. Length of gestation in five previous years were shorter (277.7 ± 1.4 d; $P = 0.01$) for cows that calved in August compared with cows that calved in October (281.8 ± 2.3 d). Maximum ambient temperatures during the week before the expected calving date were greater for MAug ($34.1 \pm 2.3^\circ\text{C}$) and LAug ($34.0 \pm 2.7^\circ\text{C}$, $P < 0.001$) compared with Sept ($29.7 \pm 3.5^\circ\text{C}$) and Oct ($28.5 \pm 3.2^\circ\text{C}$). Length of gestation was shorter for cows in MAug (274.7 ± 5.5 d, $P = 0.05$) compared with Oct (278.8 ± 3.1 d), but did not differ from LAug (277.0 ± 2.5 d, $P = 0.29$) and Sept (276.2 ± 3.1 d, $P = 0.50$). Ruminal temperature during the week before calving was not influenced by month of calving ($P = 0.84$) and averaged $38.8 \pm 0.27^\circ\text{C}$ for all months. Concentrations of cortisol in plasma 1 and 2 d before parturition were less for LAug (6.3 ± 5.7 ng/mL) compared with MAug (10.8 ± 5.9 ng/mL, $P = 0.03$) and Oct (12.5 ± 4.7 ng/mL, $P = 0.003$) cows. Exposure of beef cows to elevated ambient temperature results in shorter gestations.

Key Words: Gestation Length, Parturition, Beef Cow

TH166 Egg shape index in fertility and hatchability of Japanese quail. G. Contreras*, A. Silman, C. B. Castro, J. J. Portillo, and A. Estrada, *Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México.*

The objective was to determine the effect of egg shape index on fertility and hatchability of Japanese quail. Quails (7 wk old; 120 females and 40 males) were housed in batteries with five levels and four cages per level. The quails were fed with diets containing 20.5 % of CP and 2.9 Mcal of DE/kg at a rate of 35 g per animal/d and feed was offered twice daily at 0800 and 1600 h. 540 eggs were collected during a nine wk period. Based on a length:width proportion, two groups were formed: ovoid (1.28 at 1.38) and redounded (1.18 at 1.27). The eggs were stored for three d at 8° C before incubation. The eggs were disinfected with formaldehyde gas (2X). 60 eggs (30 ovoid and 30 redounded) were put in a metallic rack with equal divisions and placed in an automatic incubator for 14 d at 37.7° C and 60 % relative humidity. At d 15 eggs were removed and placed in a hatching machine. The weights of chicks were recorded at 24 h. The un-hatched eggs were broken to investigate fertility and embryo development. The data were subjected to analysis of variance and means compared by Tukey test ($\alpha = 0.05$). To quantify and determine the relationship between shape index and external characteristics, Pearson's correlation analysis was used. Shape index did not affect ($P > 0.05$) fertility (95.8 %), hatchability (63.5 %) and hatching (56.67 %). Shape index affected ($P < 0.01$) the egg weight, egg length and egg width. Ovoid eggs were 2.2 % heavier than redounded eggs (14.41 vs. 14.09 g). There were a positive correlation ($P < 0.001$) between shape index and egg weight (0.22) and egg length (0.76), but a negative correlation with egg width (-0.26 and -0.08, ovoid and redounded, respectively). The chicks weight were modified ($P < 0.05$) by egg shape index, whereas the chicks hatched of eggs redounded were 2.64% lighter (9.83 vs. 9.57 g). The difference in birth weight of chicks in this study can be attributed more to the egg weight than shape index. The results indicate that the egg shape index of Japanese quail does not affect the fertility or hatchability during the first nine wk of lay.

Key Words: Shape Index, Japanese Quail, Fertility and Hatchability

TH167 Detection of microRNA in porcine somatic and reproductive tissues. S. L. Pratt*, E. Curry, and H. M. Barton, *Clemson University.*

MicroRNA (miRNA) are present in all mammalian tissues examined to date and are implicated in tissue/cell differentiation, carcinogenesis, and embryonic development. They function by altering the translation efficiency of mRNA. Estimates have been made predicting over 1000 miRNAs are encoded in the mammalian genome, but only 112 porcine miRNA have been identified. Our objective was to verify and/or establish the expression of 6 miRNA in somatic and reproductive tissues including liver, heart, kidney, lung, uterus, oviduct, ovary, corpus luteum and the cumulus oocyte complex (COC). Cycling gilts were sacrificed on d 9 of the estrous cycle (estrus = day 1). Tissues were collected, snap-frozen in liquid nitrogen and stored at -80°C until used for the isolation of miRNA. COC greater than 3 mm were aspirated from ovaries obtained from pre-pubertal gilts at slaughter. Criteria for oocyte selection were a uniform cytoplasm and at least 3 layers of cumulus cells. They were frozen in liquid nitrogen and stored at -80°C. Total cellular RNA

(tcRNA) was isolated from porcine tissues using the mirVana miRNA isolation kit (Ambion, Austin, TX). All tcRNA samples were subjected to end-point RT-PCR using the mirVana qRT-PCR miRNA detection kit and primer sets (Ambion, Austin, TX) and products visualized using non-denaturing slab gel electrophoresis. Visible products were subcloned into the pDrive vector (Qiagen, Valencia, CA) and used to transform competent *E. coli*. The plasmid was then isolated and subjected to dideoxy sequencing at the Clemson University Genomics Institute. PCR product was detected for miR-31 in all tissues examined except for the heart and liver. No product for the miR-124a primer set was detected in any tissue examined. Products were observed in all tissues for primer sets for miR-24, 92, 132, and 212. Our data suggest tissue restricted expression of miR-31 and -124a; however, future studies evaluating hormonal/developmental effects on their expression are required. In addition, studies to elucidate the identity of miRNA expressed in porcine reproductive tissues are required.

TH168 Endocrine regulation of colostrum production in primiparous sows. A. Foisnet¹, C. Farmer², M. Etienne¹, J. Le Dividich¹, and H. Quesnel^{1*}, ¹INRA, Saint Gilles, France, ²Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada.

The aim of this experiment was to investigate hormonal changes potentially involved in colostrogenesis in sows. Colostrum production was estimated in 16 LR × LW sows during 24 h starting at the onset of parturition using piglets' weight gains (Devillers et al., 2004). Jugular blood samples were taken daily from day 105 of gestation until 2 days postpartum and were assayed for prolactin, progesterone (P4), estradiol-17β (E2) and cortisol. Lactose concentrations were measured in colostrum at the onset of parturition then 3, 6 and 24 h later. Colostrum production averaged 3.22 ± 0.34 kg. Four sows had a very low colostrum yield (1.10 ± 0.13 kg), while the others produced between 3.00 and 4.80 kg (3.93 ± 0.16 kg). Colostrum production was not correlated ($P > 0.1$) with litter size or litter weight at birth, nor with plasma E2 or cortisol concentrations at any time before farrowing. Colostrum production was correlated with serum prolactin concentrations during the 2 days before parturition (d-2 and d-1) ($r = 0.60$; $P = 0.014$), plasma P4 concentrations on d-1 and d0 (farrowing) ($r = -0.58$; $P = 0.018$) and with P4:E2 ratio on d-1 and d0 ($r = -0.54$; $P = 0.015$). The low producing sows tended to have lower prolactin concentrations on d-2 and d-1 than the 12 medium-to-high producing sows (12.88 ± 2.76 vs. 20.08 ± 1.62 ng/ml; $P = 0.079$) and higher P4 concentrations on d-1 and d0 (8.54 ± 1.53 vs. 5.56 ± 0.57 ng/ml; $P = 0.053$). A negative correlation between P4 concentrations and colostrum production was also observed in the ewe and was attributed to the inhibitory effect of P4 on lactose synthesis (Banchemo et al., 2006). In the present study, no correlation was found between plasma P4 concentrations and lactose concentrations in colostrum. Results suggest that impaired colostrum production is due to a hormonal imbalance. Devillers et al., 2004. *Anim. Sci.* 78: 305-313; Banchemo et al., 2006. *Reprod. Nutr. Dev.* 46: 447-460.

TH169 Maintenance of pregnancy with Matrix[®] in PGF_{2α}-treated sows. C. E. Ferguson*, M. C. Poole, D. M. Gandy, and F. M. LeMieux, *McNeese State University, Lake Charles, LA.*

This experiment was conducted to evaluate the effectiveness of Matrix[®] in maintaining pregnancy post PGF_{2α} administration in swine. Nine crossbred sows (Yorkshire x Landrace) were maintained on gestation diets, naturally mated with a boar of proven fertility and diagnosed pregnant via ultrasonography at approximately 30 d post-mating. All sows received 15 mg of PGF_{2α} (Lutalyse, Pharmacia[®]) twice at 12 h intervals. Sows were randomly assigned to a control (n = 3) no Matrix[®] or treatment (n = 6) 30 mg of Matrix[®] at time of first PGF_{2α} administration. Treatments were administered for 6 consecutive d at 24 h intervals. Matrix[®] was administered daily via top dressing bread; control sows received bread without Matrix[®]. Ultrasound was used to determine pregnancy status throughout the experiment. Control sows began to abort within 2 to 3 d following first PGF_{2α} administration and the pregnancy was completely terminated (determined by the absence of viable fetuses and fluid within the uterus during ultrasound scanning) by 3 to 4 d post-PGF_{2α}. These females displayed estrus behavior and were mated by a boar following abortion. Sows receiving Matrix[®] remained pregnant for the entire 7 d Matrix[®] feeding period. Treatment sows completed the abortion process by 4 d post last Matrix[®] administration. It was concluded that all sows lacked functional corpora lutea (as result of PGF_{2α} administration) as evidence of all sows aborting in the control and treatment group following cessation of Matrix[®] administration. These results demonstrate that Matrix[®] at a dose of 30 mg per head per d can maintain pregnancy in sows at approximately 30 d of gestation treated with a luteolytic dose of PGF_{2α}. The significance of this finding is the development of a practical method of maintaining pregnancy in sows by top dressing a feedstuff with an exogenous progesterin.

Key Words: Sows, Luteolytic, Progesterin

TH170 Defined pattern of Sertoli cell differentiation in pubertal porcine testes. J. J. Ford* and T. H. Wise, *USDA/ARS/USMARC, Clay Center, NE.*

Number of Sertoli cells is a primary determinant of mature testicular size and sperm production. In boars, formation of the blood/testis barrier occurs by 4 mo of age in commercial breeds and signals the end of Sertoli cell proliferation. Previous studies established that expression of p27Kip1, a cyclin-dependent kinase inhibitor and a marker of Sertoli cell differentiation, was first detected at 70 d of age and by 90 d was apparent in tubules of most boars; however, its pattern of expression did not appear random. To test if Sertoli cell differentiation occurs in a defined pattern, one testis was removed from 25 crossbred boars at 90 d of age. From each testis, 2 aliquots of tissue were taken adjacent to the tunica and 2 other aliquots were sampled near the mediastinum. Tissues were fixed and embedded. Tissue sampled near the tunica was further divided into 2 regions, one < 1.5 mm and the other > 1.5 mm from the tunica. A minimum of 200 tubules from each of the 3 regions/boar was evaluated for tubule diameter and % with Sertoli cell nuclei positive for p27Kip1 assessed by immunohistochemistry. Mean diameter of seminiferous

tubules increased ($P < 0.01$) from 75.9 μm near the tunica to 90.2 μm in the mediastinum, and % of tubules positive for p27Kip1 was greater ($P < 0.001$) near the mediastinum than near the tunica. Tubules within the sub-tunica region were intermediate for both of these traits. Presence of p27Kip1 correlated positively ($P < 0.01$) with mean diameter of tubules within each of the 3 regions. Weight of the second testis at 10 mo of age correlated negatively ($P < 0.03$) with diameter of tubules within the mediastinum at 90 d of age. These findings establish that differentiation of Sertoli cells progresses from the mediastinum toward the tunica thereby implying that proliferation continues for a longer period at the outer region of the seminiferous tubules. Also, 90-d-old boars with testes containing small diameter tubules have a greater compensatory response to unilateral castration than 90-d-old boars with larger diameter seminiferous tubules.

Key Words: Boar, Puberty, Sertoli Cell

TH171 Comparison of domestic and feral pig physiology, immunity and growth. B. L. Davis*^{1,2}, M. A. Sutherland^{1,2}, P. J. Bryer^{1,2}, J. F. Smith^{1,2}, and J. J. McGlone^{1,2}, ¹*Pork Industry Institute, Lubbock, TX*, ²*Texas Tech University, Lubbock.*

Feral pigs in Texas are descended from introduced European wild pigs and escaped domestic pigs that have established wide-ranging populations. Little is known about the physiological, immune and performance differences between feral and domestic pigs. The objective of this project was to: 1) compare physiological, immune and growth measures between domestic and feral pigs, 2) determine the effect of the circadian rhythm on glucocorticoid secretion in feral and domestic pigs and 3) determine if feral pigs are carriers of common domestic swine diseases. Domestic (n=4) and trapped feral (n=4) pigs of approximately 3 wk of age were used for this comparative study. Body weights were recorded and blood samples were collected over time for analysis of cortisol concentrations, hematology values and immune measures. On day 6, blood samples were taken every 6 h over a 24 h period (0600, 1200, 1800, 2400 h). Cortisol concentrations were higher among feral compared with domestic pigs (111.8 vs. 37.2 \pm 13.85 ng/mL, $P < 0.01$) and were greater ($P < 0.01$) in feral compared with domestic pigs at 0600, 1200, 1800 and 2400 h. The percentage of lymphocytes (56.0 vs. 48.8 \pm 1.38 %, $P < 0.05$) and mean cell volume (57.0 vs. 52.5 \pm 0.69 %, $P < 0.005$) were greater among feral compared with domestic pigs. Red blood cell distribution width was lower in feral compared with domestic pigs (18.7 vs. 22.9 \pm 0.42 %, $P < 0.01$). Innate immune measures did not differ ($P > 0.05$) between feral and domestic pigs. Average daily gain was lower in feral compared with domestic pigs (0.1 vs. 0.3 \pm 0.04 kg/d, $P < 0.01$). Feral pigs tested negative for the Pseudorabies virus, but tested positive for Brucella abortus antibodies. Physiological, immune and growth difference were observed between feral and domestic pigs either due to environmental or genetic differences. Feral pigs were carriers of a swine and human pathogen and could be a potential biosecurity risk for commercial pig farms and human populations.

TH172 Identification of fertility markers in seminal plasma proteins of cryopreserved bull semen: A proteomic approach. J. F. Odhiambo*, L. Corum, S. Wolfe, E. E. Felton, and R. A. Dailey, *West Virginia University, Morgantown.*

Secretions from the accessory sex glands are mixed with sperm at ejaculation and contribute a majority of semen volume. However, during cryopreservation, most seminal plasma is replaced with semen extenders, mainly egg yolk or milk proteins. Experiments in rodents and pigs showed that seminal plasma was important for fertility and fetal survival (O et al, 1988). Previously, we observed consistent success of pregnancy after AI with adjunctive seminal plasma. The precise nature of the active constituents remains unknown, but four proteins (Osteopontin, Spermadhesin Z13, BSP 30 kDa and Phospholipase A₂) have been identified as markers of fertility in dairy bulls (Moura et al., 2006). Therefore, the present study used a proteomic analysis of expression patterns of seminal plasma proteins in cryopreserved semen of bulls of known low fertility ($1.8 \leq \text{CFI} \leq 2.9$; CFI: Composite Fertility Index™, Select Sires Inc.) Proteins were separated by 2-dimensional SDS-PAGE followed by staining with Coomassie blue and analysis of polypeptide maps using CQuest software. Proteins were identified by capillary liquid chromatography nanoelectrospray ionization tandem mass spectrometry (CapLC-MS/MS). Low fertility bulls had three expression patterns. Spot volume analysis and peptide identification of the patterns indicated higher expression (55%) of proteins from semen extender between 30 to 60 kDa, a *train* (35%) of spots within 20 to 30 kDa, while the remainder of the spot volume was expressed below 20 kDa. Three spots were identified as: 1) Seminal plasma protein PDC-109 precursor [BSP-A1/A2], MW 15.4 kDa, pI 4.76, 2) Spermadhesin-1 precursor [Acidic seminal fluid protein], MW 15.0 kDa, pI 4.93, and 3) Spermadhesin Z13, MW 13.4 kDa, pI 5.50. Low fertility of dairy bulls has been associated with higher expression of Spermadhesin Z13 isoforms in accessory gland fluid (Moura et al., 2006). Therefore, identification of that protein and its precursor in seminal plasma of low fertility bulls corroborates and strengthens its potential use as a marker of low fertility in bulls.

Key Words: Spermadhesin, BSP-A1/A2, Seminal Plasma

TH173 Effect of sex-sorted sperm dosage on conception rates of Holstein cows and heifers. J. M. DeJarnette*¹, R. L. Nebel¹, C. E. Marshall¹, J. F. Moreno², C. R. McCleary², and R. W. Lenz², ¹*Select Sires, Inc., Plain City, OH*, ²*Sexing Technologies, Inc., Navasota, TX*.

Ejaculates were collected by artificial vagina from 3 Holstein sires and sorted to 90% purity for X-chromosome bearing spermatozoa (range 88 to 93%) using flow cytometry. Sorted sperm were diluted to 2.1, 3.5 or 5.0 x 10⁶ sperm per dose in an egg-yolk (20%), TRIS, glycerol (7%) extender. Collections were repeated until a total of >600 straws per sperm dose per sire were obtained. Each sperm dose was loaded into color-coded 0.25 mL French straws with alternate colors used to define treatments across sires. Within sires, straws were packaged at 9 per cane (3 of each color) and strategically allocated to 75 Holstein herds with

targets for 50% use in heifers and 50% in lactating cows. Straw color was recorded in the on-farm record keeping system at the time of insemination. Data were analyzed separately for cows and heifers. Among heifers, a total of 2,125 useable records were retrieved from 51 herds (238 ± 5.5 services/sperm dose/sire, range: 218 to 263). Conception rates in heifers were influenced by the sire by sperm dosage interaction. Within Sire A, conception rates of heifers were greater for the 5 x 10⁶ (59.5%) than for the 2.1 x 10⁶ (46.4%) sperm dose and intermediate for the 3.5 x 10⁶ sperm dose (52.2%). However across sires, sperm dosage had no effect on heifer conception rates (46.7%, 51.2% and 52.5% for 2.1, 3.5 and 5.0 x 10⁶ sperm dosages, respectively). Among cows, a total of 2,369 services were retrieved from 56 herds (263 ± 8.8 services/sperm dose/sire, range: 233 to 303). Conception rates of cows (29.4%) were not affected by sire or sperm dosage (27.0%, 29.1% and 30.3% for 2.1, 3.5 and 5.0 x 10⁶ sperm dosages, respectively). In conclusion, these data indicate increased sperm dosage may enhance virgin heifer conception rates for some (but not all) sires, whereas neither sire nor sexed-sperm dosage impacted conception rates of lactating cows. Additional studies of sexed-sperm dosage across a larger sampling of bulls are warranted to determine if and how such a practice can be cost effectively implemented for the benefit of the dairy industry.

Key Words: Sexed Semen, Flow Cytometry, Conception Rate

TH174 An update on the commercial application of sex-sorted semen in Holstein heifers. J. M. DeJarnette*, R. L. Nebel, and C. E. Marshall, *Select Sires, Inc., Plain City, OH*.

Insemination and (or) calving data were retrieved from herds that used sex-sorted semen (SS) in Holstein heifers from Jan, 2005 to Jan 2008. The unadjusted conception rate (CR) to SS across 132 herds and all service numbers was 45.2% (n=41,398). Across all herds, 74% of SS was used at 1st service, 18% at 2nd service, and 8% at ≥ 3 service. The unadjusted CR was 47%, 40%, and 34% for service numbers 1, 2 and ≥ 3 , respectively. Among 49 herds reporting ≥ 50 services to both sexed (724 \pm 132) and conventional semen (CS; 961 \pm 110), CR was influenced by herd and the service number x semen type interaction (See table). Among unsuccessful services in these 49 herds, heifers bred to SS were more likely to be re-inseminated in a normal 21 day interval than were CS bred heifers. Among all single births the percentage of female calves born to SS was 89.3% (n=13,515) and increased to 90.1% for validated gestation lengths of 265 to 295 d (n=7,768). Among twin births, a greater percentage ($P < 0.01$) of female-female pairs were observed for SS (74%, n=68) than CS (26%, n=197). Among 27 herds reporting ≥ 50 females calves born to SS (340 \pm 59) and CS (592 \pm 79), the percentage of still births was influenced by herd, age at freshening, month of freshening, and sire of conception but was not influenced by semen source ($P = 0.68$). Due to the known bias in use and preferential treatment of SS vs. CS, these results must be interpreted with caution. However, these data suggest SS averages ~45% CR in Holsteins heifers resulting in ~90% female offspring with no evidence of a negative effect on incidence of still births nor repeat intervals to estrus.

Table 1. Conception rates by service number and distribution of repeat AI intervals in 49 herds reporting ≥ 50 services to both sexed and conventional semen % (n)

	1st Service	2nd Service	≥ 3 rd Service		
Conventional	56.4 (21,864)	53.8 (13,389)	45.4 (11,772)		
Sexed	47.0 (26,465)	43.1 (6,375)	38.1 (2,567)		
Sexed as % of conventional	83.3%	80.1%	83.9%		
Repeat AI interval	<17 d	18-24 d	25-35 d	36-48 d	49-90 d
Conventional (n=17,184)	10.7%	65.4%	9.6%	9.6%	4.7%
Sexed (n=16,413)	7.4%	69.7%	8.8%	9.5%	4.6%

Key Words: Sexed Semen, Flow Cytometry, Conception Rate

TH175 Use of commercially available oocytes and sexed sperm for IVF/ET and AI in dairy cattle. S. Rasmussen*, Z. Brink, K. McSweeney, and G. E. Seidel, *Colorado State University, Fort Collins.*

Assisted reproduction technologies allow options for dairy farmers to improve herd genetics, provide greater biosecurity, and possibly increase profit in other ways. Transfer of embryos (ET) produced with sexed semen, and artificial insemination (AI) with sexed semen are examples. Sexed and non sexed semen from 3 bulls was used for either AI or to produce embryos in vitro. Holstein oocytes, matured in a portable incubator during shipment, were purchased commercially and fertilized 23 h after collection with standard IVF procedures using 1×10^6 sperm/mL. There was no difference in blastocyst rate per oocyte due to bulls: A (11.1%; n = 893), B (13.5%; n = 1531), or C (11.8%; n = 1362); however, sexed sperm resulted in fewer blastocysts (8.1%; n = 3018) than nonsexed sperm (15.4%; n = 768) ($P < 0.01$). Blastocysts were transferred 7.5 d after onset of IVF. Estrous cycles of cows at least 63 d post partum were synchronized as follows: reproductive tracts were scanned using ultrasonography, and cows with a normal-appearing uterus were injected with 100 μ g GnRH i.m. Seven d later cows were scanned again and given 25 mg of PGF₂ α i.m. only if a CL and follicle between 13-19 mm were present; cows not meeting these criteria were not used for this project; 2.5 d later cows received 100 μ g GnRH i.m. Cows were bred 16-18 h later with control ($>10 \times 10^6$ sperm/dose) or sexed semen (2×10^6 sperm/dose), or a fresh embryo was transferred one wk later. Pregnancy status was determined at ≥ 35 of pregnancy by ultrasound. Cows with dead or dying fetuses were considered non pregnant. There was no difference ($P > 0.1$) between sexed (36.9%; 31/84) and nonsexed AI (47.2%; 42/89) pregnancy rates, which were higher than sexed (19.4%; 14/72) or non sexed (23.2%; 16/69) ET pregnancy rates ($P < 0.05$). The pregnancy rate with sexed semen was 78.2% of control semen (mainly due to one bull which was 44.8% of control). Pregnancy rates were unsatisfactory with embryos produced in vitro from shipped oocytes under the conditions of this experiment. Supported by NRI grant no. 2006-55203-17390 from USDA.

Key Words: Sexed Semen, AI, IVF

TH176 Effects of heterospermic insemination on conception rates of lactating dairy cows. J. M. DeJarnette*¹, R. L. Nebel¹, D. Laansma², and C. E. Marshall¹, ¹Select Sires, Inc., Plain City, OH, ²Northstar Cooperative, East Lansing, MI.

This study evaluated the effects of heterospermic insemination on conception rate of Holstein cows. Three Holstein sires with above average conception potential as determined by one or more sire fertility ranking systems were selected for use in this trial. On each of two days, 2 ejaculates were collected by artificial vagina from each sire and evaluated for volume, concentration, and motility before and after pooling within sire. Aliquots were strategically removed from the within sire pools to create an across sire pool containing equal numbers of total sperm from each of the 3 sires (heterospermic). All 4 samples (3 homospermic, 1 heterospermic) were extended to 40×10^6 sperm/mL in an egg-yolk-Citrate-glycerol extender. Samples were loaded into color-coded 0.5 mL French straws (n = 500/sample/collection day; 4000 total), and frozen in liquid nitrogen vapor. Straws were randomly used in 5 herds of lactating Holstein cows during the months of Apr. through Oct., 2007. At the time of AI, straw color and collection date were recorded in the on-farm records management system. Data (n = 3,384) were extracted from electronic downloads and analyzed in least-square means models including the effects of herd, sire, batch within sire, parity, postpartum interval, season and all two-way interactions. Conception rates were influenced ($P < 0.05$) by interactions of herd with parity, season, and postpartum interval. All interactions and main effects of sire and semen batch were not significant ($P > 0.05$). Conception rates for sires A, B, C and the heterospermic mix were 26.8%, 25.3%, 29.3% and 25.4%, respectively (n = 846 ± 15 /sire). In conclusion, heterospermic insemination may provide a means to guard against poor conception rates should a subfertile sire be selected. However these data provide no evidence that the conception rate of a heterospermic mixture will be greater than that obtained from homospermic use of the highest conception bull(s) in the mix.

Key Words: Heterospermic Insemination, Mixed Semen, AI

TH177 Effects of preincubation of sperm at 38.5 or 40°C before insemination on developmental competence of bovine embryos derived from in vitro fertilization. K. E. M. Hendricks* and P. J. Hansen, *University of Florida, Gainesville.*

The ability of the preimplantation embryo to develop depends in part on genetic and non-genetic inheritance from gametes. Here, the hypothesis was tested that aging of ejaculated sperm would affect embryo competence for development. Oocytes were inseminated with frozen/thawed sperm maintained for 4 h at 38.5°C or 40°C. Control oocytes were inseminated with sperm not subjected to 4 h incubation. The percent of cleaved embryos that became blastocysts at d 8 after insemination (BI/CI) was used to assess embryo competence. In Exp. 1 (n = 9 bulls), oocytes were fertilized for 22 h and the resultant embryos cultured in 5% CO₂ in air. The percent of oocytes that became blastocysts (BI/Ooc) and BI/CI was lower for oocytes inseminated with preincubated sperm than for oocytes inseminated with control sperm ($P < 0.01$). There were no differences between oocytes inseminated with sperm at 38.5°C when compared to 40°C. For Exp. 2 (n = 13 bulls), embryos were cultured in 5% O₂. The percent of oocytes that cleaved (66.1 ± 3.2 , $60.2 \pm 3.2\%$, and $74.5 \pm 3.2\%$ for 38.5°C, 40°C and control; $P < 0.05$), BI/Ooc (23.6 ± 2.3 , $14.9 \pm 2.3\%$, and $27.9 \pm 2.3\%$, $P < 0.01$), and BI/CI (32.9 ± 2.9 , $22.2 \pm 2.9\%$, and $37.4 \pm 2.9\%$; $P < 0.05$) was lower for oocytes insemi-

nated with preincubated sperm. Similarly, BI/Ooc ($P < 0.05$) and BI/CI ($P < 0.05$) was lower for oocytes inseminated with sperm at 40°C than for oocytes inseminated with sperm at 38.5°C. A high cleavage rate in a parthenogenesis group ($38.9 \pm 3.2\%$) made interpretation of data difficult because of the possibility that fertilization rate was overestimated. Accordingly, Exp. 3 ($n = 8$ bulls) was carried out with fertilization reduced to 8 h. There were no differences between oocytes inseminated with sperm preincubated at 40°C compared to oocytes inseminated with sperm preincubated at 38.5°C. Results indicate that embryos produced with aged sperm can have reduced competence for development although aging effects were independent of temperature within the range of 38.5-40°C. Support: USDA NRICGP 2007-35203-18070 and BARD US 3986-07.

Key Words: Bovine, Sperm Preincubation, Embryo Developmental Competence

TH178 Paternal influence on the in vitro embryonic development of vitrified oocytes based on estimated relative conception rate. V. M. Anchamparuthy*, A. Dhali, R. E. Pearson, W. M. Lott, and F. C. Gwazdauskas, *Virginia Polytechnic Institute & State University, Blacksburg.*

Variation with in vitro fertilization (IVF) characteristics among bulls was reported, but has not been reported with vitrified oocytes. This study was designed to test the influence of sire based on ERCCR after AI with the frozen thawed semen on the in vitro embryonic developmental competence of 2 classes of vitrified oocytes ($n = 1,968$) derived from follicles of different diameters, small (less than 4 mm) and medium (4 to 10 mm). Follicle size had a significant ($P \leq 0.05$) impact on the developmental rates of embryos from cleavage to the blastocyst stage. The oocytes from medium sized follicles had a 9.9% increase in the cleavage rate compared to oocytes from small follicles. The increase in the blastocyst rate was only 5.9% between the oocytes from small and medium-sized follicles. The sires showed significant ($P \leq 0.05$) effects on embryonic developmental rates. Similarly, sire by follicle size interaction was significant for blastocyst rates and sire by treatment interaction was significant on cleavage and blastocyst rates. There were differences among bulls. Fertilized oocytes ($n = 1,685$) using semen from Bulls I, II, III, and IV showed cleavage rates of 49.3, 55.0, 50.0, and 40.9%, respectively ($P \leq 0.05$). Both morula and blastocyst stages of development were significantly different ($P \leq 0.05$) among bulls. While the developmental rates to morula were 26.4, 29.9, 23.4 and 16.7% for Bull I, II, III, and IV, respectively, and the blastocyst developmental rates were 18.1, 17.9, 10.0, and 10.0%, respectively. Bull I had the highest blastocyst development from vitrified oocytes (10.9%; $P \leq 0.05$) and the corresponding rate for its control oocytes was 25.3%. The blastocyst rates from the vitrified oocytes were 6.0, 2.5, and 1.0%, respectively, for Bull II, III and IV, with the corresponding rates in the control oocytes of 29.9, 17.4, and 18.9%, respectively. Our results show that differences in development exist in source of oocytes and sires used for IVF after vitrification. No correlation exists between post-IVF outcome and field fertility based on ERCCR.

Key Words: Bull, Oocyte, Vitrification

TH179 Effects of dietary fats differing in n-3/n-6 ratio on oocyte quality in dairy cows. M. Zachut*^{1,2}, I. Dekel¹, H. Lehrer¹, A. Arieli², A. Arav¹, and U. Moallem¹, ¹*Agriculture Research Organization, Bet Dagan, Israel*, ²*Faculty of Agriculture, Hebrew University, Rehovot, Israel.*

The objective of the current study was to examine the effects of feeding encapsulated fats containing different n-3/n-6 ratio on oocyte quality in dairy cows. Twenty-four multiparous Israeli-Holstein cows, averaging 114 DIM, were assigned to one of three treatment groups: 1) **Control** ($n = 7$) were fed a lactating cow diet; 2) **E-LNA** ($n = 8$) were supplemented with 1 kg/d of encapsulated fat containing 40% linseed oil which is high in linolenic acid; or 3) **E-LA** ($n = 9$) were supplemented with 1 kg/d of encapsulated fat containing 40% sunflower oil which is high in linoleic acid. Ovum pick-up (**OPU**) and *in vitro* fertilization (**IVF**) sessions ($n = 13$) began 94 d after the commencement of the dietary treatments, and were conducted on 5 cows per treatment twice a week. Plasma FA profile was significantly affected by dietary treatments; the percentages of C18:2, C20:3 and C20:4 in plasma were lower in E-LNA cows than in E-LA or control ($P < 0.004$), whereas the percentage of C18:3 in plasma was more than 5 fold higher in E-LNA cows as compared to E-LA or control cows ($P < 0.0001$). The average number of follicles aspirated during the OPU procedure from each cow at each session was higher in E-LNA cows than in control ($P < 0.01$; 11.4, 13.8 and 11.8 for control, E-LNA and E-LA, respectively), and the number of recovered oocytes per cow was higher in control than in E-LA ($P < 0.05$) but did not differ from the E-LNA. The average number of grade 1 oocytes per cow was lower in E-LA than in both other groups ($P < 0.05$). A total of 388 oocytes were selected for IVF across treatments. The percentage of matured oocytes did not differ among treatments; however the oocytes cleavage rate was higher in E-LNA oocytes than in control ($P < 0.05$; 43.0, 52.3 and 49.5% for control, E-LNA and E-LA, respectively). In conclusion, dietary fat with a high n-3/n-6 ratio (linseed oil) seems to positively affect ovarian follicle numbers and IVF cleavage rate.

Key Words: Linolenic Acid, Oocytes Quality

TH180 Influence of cysteine in conjunction with growth factors during in vitro production of bovine embryos. W. M. Lott*, V. M. Anchamparuthy, M. L. McGilliard, I. K. Mullarky, and F. C. Gwazdauskas, *Virginia Polytechnic Institute & State University, Blacksburg.*

Cysteine (Cys) supplementation to in vitro maturation (IVM) media increases cellular glutathione production, which reduces reactive oxygen species. Similarly, the beneficial effects of growth factors for improving the rate of blastocyst development have been reported, but not in conjunction with Cys. The aim of this study was to determine whether supplementation of Cys during oocyte maturation and growth factors, epidermal growth factor (EGF) and insulin-like growth factor-I (IGF-I), during embryo culture, would improve cleavage and blastocyst rates of in vitro produced bovine embryos. Bovine oocytes from slaughterhouse ovaries were matured in TCM-199, with or without the addition of Cys (0.6 mM) at 0 h (0 h Cys) or 12 h (12 h Cys) of maturation. Matured oocytes were fertilized in BSA. After in vitro fertilization, embryos were allocated to culture treatments using synthetic oviductal fluid medium. Culture treatments included fetal calf serum (FCS, 4%); IGF (100 ng/mL); EGF (10 ng/mL); IGF+EGF (100 ng/mL+10 ng/mL); 0 h Cys with

IGF; EGF; or IGF+EGF; and 12 h Cys with IGF; EGF; or IGF+EGF. Developmental scores were assigned to each embryo on d 2, 4, and 8 of culture. Even though rates for cleavage and blastocyst stage were not different ($P \geq 0.05$) among treatments, significant improvements in the proportion of oocytes undergoing cleavage (12 h Cys IGF+EGF, 75.3%) and blastocyst (0 h Cys IGF, 40.3%) formation were achieved when Cys was added to the maturation media, as compared to control (FCS: cleavage, 61.7% and blastocyst, 34.5%) without supplementation. Similarly a combined effect of IGF+EGF for the cleavage (72.6%) and blastocyst (37.8%) development was obtained. In conclusion, supplementation of Cys during IVM of oocytes, in conjunction with growth factors, excluding IGF-I, during *in vitro* culture, resulted in a similar embryonic development to that of FCS, and could effectively be used as a replacement for FCS.

Key Words: Cysteine, Embryo, Growth Factor

TH181 Simulated microgravity conditions affect preimplantation bovine embryo development *in vitro*. S. Jung*, S. D. Bowers, and S. T. Willard, *Mississippi State University, Mississippi State.*

Alternative *in vitro* embryo culture environments require further investigation to determine whether they may improve, or be deleterious to, embryo development. The objective of this study was to investigate bovine preimplantation embryo development in a simulated (and varied) microgravity environment *in vitro*. A Rotating Cell Culture System (RCCS) bioreactor with a High Aspect Ratio Vessel (HARV) was used to generate a low shear simulated microgravity condition. *In vitro* matured and fertilized bovine oocytes were cultured in mSOF (modified synthetic oviductal fluid supplemented with 8 mg/ml BSA and amino acids) at 39°C and 5% CO₂ in humidified air. On d 2 pi (post insemination), cleaved embryos (2-, 4-, and 8-cell stage embryos n=1524) were equally distributed to one of following culture conditions: Control, 100 µl microdrops of mSOF medium covered by mineral oil in a Petri dish; High Speed, 100 µl microdrops of mSOF medium with mineral oil overlay in HARV rotated at 34 rpm on a horizontal axis; Low Speed, 100 µl drops of mSOF medium with mineral oil overlay in HARV rotated at 3.7 rpm on a horizontal axis. The final developmental rates were assessed on d 9 pi. The experiment was replicated four times and arc-sine transformed data were analyzed by ANOVA and Fisher's PLSD test. The proportions of 2- to 8-cell stage embryos in the High Speed and Low Speed groups (100.0 and 99.6%, respectively) were significantly higher ($P < 0.05$) than 2- to 8-cell stage embryos in the Control group (67.7%) on d 9 pi; with only 1 embryo reaching the morulae stage for the Low Speed group. Thus in the Control group, a greater ($P < 0.05$) proportion of morulae and blastocyst stage (15.8% and 16.5%, respectively) embryos were achieved than in the High (0%) and Low (0% blastocyst and 0.4% morulae) groups. There were no significant differences ($P > 0.05$) in embryo development rates between the High and Low Speed groups with respect to any of the embryo stages noted on d 9 pi. These results indicate that simulated microgravity culture conditions have a negative impact on preimplantation bovine embryo development *in vitro*.

Key Words: Bovine Embryo, *In vitro* Culture, Microgravity

TH182 Insulin-like growth factor-1 reduces the anti-development effects of menadione on development of bovine preimplantation embryos. J. I. Moss* and P. J. Hansen, *University of Florida, Gainesville.*

Insulin-like growth factor-1 (IGF-1) can reduce effects of heat shock on development of preimplantation bovine embryos. The present objective was to determine whether IGF-1 can block other adverse environmental conditions affecting embryonic development. The approach was to evaluate effects of IGF-1 on embryos treated with menadione. This polycyclic aromatic ketone serves as a precursor for vitamin K2 and can inhibit development of mouse embryos (Toxicology 191:77). Bovine embryos were produced *in vitro* and cultured in KSOM-BE2 medium. At d 5 after fertilization, embryos ≥ 16 cells were placed in fresh drops ± 100 ng/ml of recombinant human [Arg3]-IGF-1 (analog with reduced affinity for IGF binding proteins). Menadione was added 1 h after addition of IGF-1 at a final concentration of 0, 1, 2.5 and 5 µM. Embryos were cultured for 24 h, washed, and then cultured in fresh KSOM-BE2 medium until d 8. The experiment was replicated 14 times with 120-204 embryos per treatment. The percent of embryos that became blastocysts at d 8 was affected by the menadione x IGF interaction ($P < 0.001$). Menadione reduced development in a concentration-dependent manner and IGF-1 reduced effects of 1 and 2.5 µM. Percent of embryos becoming blastocysts was $50.1 \pm 2.4\%$, $36.2 \pm 2.9\%$, $5.8 \pm 2.9\%$, and $0 \pm 2.6\%$ for 0, 1, 2.5 and 5 µM in the absence of IGF-1 and $37.0 \pm 2.5\%$, $46.3 \pm 2.5\%$, $13.0 \pm 2.5\%$ and $0 \pm 2.6\%$ in the presence of IGF-1. In conclusion, the anti-developmental action of menadione on development of bovine embryos can be blocked by IGF-1. Research supported by BARD US-3986-07 and USDA NRICGP 2007-35203-18070.

Key Words: Insulin-Like Growth Factor-1, Preimplantation Embryos, Menadione

TH183 Effect of the addition of hyaluronan to bovine embryo culture on *in vitro* survival after cryopreservation and *in vivo* survival following transfer to recipients. L. Bonilla*¹, J. Block^{1,2}, and P. J. Hansen¹, ¹University of Florida, Gainesville, ²EmboGen LLC, Gainesville, FL.

Experiments were conducted to determine whether hyaluronan could: 1) improve survival after cryopreservation, and 2) increase pregnancy rates following transfer to recipients. In experiment 1, embryos (n = 3,564 putative zygotes) were cultured in modified synthetic oviductal fluid (SOF) with 1.0 mM alanyl-glutamine in 5% (v/v) oxygen with either no surfactant, 1 mg/mL polyvinyl alcohol (PVA) or 4 mg/mL bovine serum albumin (BSA) and ± 1 mg/mL hyaluronan. Blastocyst and expanded blastocyst-stage embryos on day 7 were vitrified using open pulled straws (Mol. Reprod. Dev. 1998, 51:53-58). Vitrified embryos were thawed and then cultured for 72 h in modified SOF containing 10% (v/v) fetal bovine serum and 50 µM dithiothreitol. There was no effect of hyaluronan on re-expansion at 24 and 48 h or hatching rate at 72 h. Re-expansion rate at 24 and 48 h and hatching rate at 72 h was reduced ($P < 0.0001$) by BSA (24 h, 72.9 ± 2.6 vs. $22.6 \pm 4.8\%$, 48 h, 77.3 ± 2.7 vs. $20.7 \pm 4.9\%$, 72 h, 72.5 ± 2.7 vs. $21.5 \pm 5.0\%$). For experiment 2, heat-stressed lactating Holsteins were synchronized for timed-embryo transfer using the OvSynch protocol. Embryos produced *in vitro* were

cultured in modified SOF with 4 mg/mL BSA, 100 ng/mL insulin-like growth factor-1, and \pm 1 mg/mL hyaluronan. At day 7 after expected ovulation, a single embryo was transferred to each recipient with a palpable corpus luteum. Pregnancy was diagnosed by rectal palpation at d 35-90 of gestation. There was a treatment x embryo stage interaction ($P < 0.03$). Hyaluronan increased pregnancy rates for recipients that received morula and blastocyst-stage embryos (15/92=16.3% vs. 22/78=28.2%) but had no effect for recipients receiving expanded blastocysts (31/82=37.8% vs. 25/83=30.1%). There was no effect of hyaluronan on in-vitro survival after vitrification, but BSA reduced cryosurvival. Hyaluronan increased pregnancy rate among recipients that received morula and blastocyst-stage embryos, but not for recipients that received expanded blastocysts (USDA 2006-55203-17390).

Key Words: Hyaluronan, Vitrification, Embryo Transfer

TH184 Effect of progesterone concentration during follicular development on fertilization and embryo quality in dairy cows. R. L. A. Cerri^{*1,2}, R. C. Chebel², F. Rivera², C. D. Narciso², R. A. Oliveira², and J. E. P. Santos¹, ¹University of Florida, Gainesville, ²University of California Davis, Tulare.

Objectives were to evaluate the effects of differing progesterone (P4) concentrations on follicular dynamics and embryo quality. Lactating Holstein cows (n = 154), were randomly assigned to 1 of 2 treatments. Cows had their estrous cycle presynchronized and were then submitted to a modified Ovsynch (GnRH + CIDR, 7 d prostaglandin F2a [PG] + CIDR removal, 2 d GnRH, 12 h timed AI) starting on d 7 of the estrous cycle. Cows enrolled in the high P4 (HP) treatment received no further treatments and cows in the low P4 (LP) treatment received additional PG injections on d 2, 2.5 and 3 of the estrous cycle preceding the Ovsynch and on d 0, 2, 2.5 and 3 after the first GnRH of the Ovsynch. Ovaries were evaluated by ultrasonography and blood was sampled for P4 and estradiol (E2) concentrations throughout the study. Uteri were flushed 6 d after AI and recovered embryos/oocytes were evaluated. Concentrations of P4 were greater ($P < 0.01$) for HP cows from d 2 to 7 after first GnRH of Ovsynch (4.3 vs. 1.5 ng/mL); concentrations of E2 at PG (3.0 vs. 3.8 pg/mL) and at the last GnRH (4.6 vs. 5.3 pg/mL) were less ($P < 0.01$) for HP than LP. Proportion of cows in estrus at timed AI was less ($P = 0.01$) for HP than LP (5.3 vs. 38%). The ovulatory follicles of HP cows were smaller ($P < 0.01$) at PG (14.6 vs. 17.2 mm) and GnRH of the Ovsynch (16.9 vs. 19.7 mm), which resulted in smaller ($P = 0.03$) CL diameter 6 d after AI (22.8 vs. 24.3 mm). Double ovulation after the last GnRH of the Ovsynch was less ($P = 0.01$) for HP than LP (4.5 vs. 18.6%). Fertilization rate was similar ($P = 0.67$) and averaged 82.7%. Excellent and good quality embryos as a proportion of embryos ($P = 0.48$) and of embryo-oocytes ($P = 0.66$) were not different. Number

of blastomeres was similar ($P = 0.79$) for HP and LP, but proportion of live blastomeres tended to be greater ($P = 0.08$) for HP than LP (99.5 vs. 94.8%). Reducing P4 concentrations before and during the Ovsynch program altered E2 concentrations and follicular dynamics, but resulted in minor changes in embryo quality.

Key Words: Dairy Cow, Embryo, Progesterone

TH185 Milk production and rectal temperature during pregnancy in lactating dairy cow recipients. D. T. G. Jardina^{*1}, F. L. Aragon², M. B. Veras², S. Soriano³, N. Sobreira³, A. B. Scarpa¹, P. L. T. Justolin¹, and J. L. M. Vasconcelos¹, ¹FMVZ, Unesp, Botucatu, SP, Brazil, ²Policlinica Pioneiros, PR, Brazil, ³Farm Colorado, SP, Brazil.

The objective of this study was to evaluate factors that can influence pregnancy per embryo transfer (P/ET) in lactating Holstein cows. The trial was conducted between February and November 2007. Cows were milked 3 times a day and fed with total mixed ration. Recipient Holstein cows (n = 468) were synchronized with HeatSynch + CIDR protocol [CIDR in + GnRH (1 mL Fertagyl) - 7d - CIDR out + PGF2 α (5 mL Lutalyse) - 24h - Estradiol Cypionate (0.5 mL ECP)]. Cows were evaluated by ultrasonography for detection of CL and embryo transfers were done, non-surgically, 9 d after injection of ECP. P/ET was determined by presence of an embryo 21 d after transfer by ultrasonography and was analyzed by logistic regression. The regression model included the effects of month, body condition score, parity, days in milk (DIM), milk production, milk components (fat, protein, somatic cell count, urea), serum progesterone, rectal temperature, CL diameter, embryo (fresh vs. frozen/thawed) and interactions. Embryo influenced ($P < 0.01$) P/ET; 48.8% (150/307) with fresh and 28.1% (45/160) with frozen/thawed embryos. There was an interaction ($P < 0.05$) between milk production and rectal temperature, that were grouped by median. Number of cows, milk production, rectal temperature, DIM, serum progesterone, CL diameter and P/ET were: 1) low milk production/normal rectal temperature: n=128, 28.6kg of milk/d, 38.5°C, 264 DIM, 3.03ng/mL, CL 4.27cm² and 42.2%; 2) low milk production/high rectal temperature: n=105, 27.0kg of milk/d, 39.3°C, 292 DIM, 3.4ng/mL, CL 3.9cm² and 36.1%; 3) high milk/normal temperature with n=144, 42.2kg of milk/d, 38.4°C, 138 DIM, 3.1ng/mL, CL 4.6cm² and 47.7%; and 4) high milk production/high rectal temperature with n=91, 41.8kg of milk/d, 39.2°C, 141 DIM, 3.3ng/mL, CL 3.8cm² and 38.4%, respectively. These results indicated that high milk production did not affect pregnancy after ET in recipient lactating cows with normal rectal temperature.

TH186 Nursery performance in gilts farrowed by females housed in individual stalls and/or group pens during gestation. M. J. Estienne* and A. F. Harper, *Virginia Polytechnic Institute and State University, Blacksburg.*

Fetal programming is the process by which a stimulus in utero establishes a permanent response in the fetus impacting physiology later in life. O’Gorman et al. (2007; *J. Anim. Sci.* 85[Suppl. 2]:13) subjected sows to daily restraint for five min during wk 12 to 16 of gestation; Gilts farrowed by stressed sows exhibited puberty 14 d later than gilts farrowed by control females. The objective was to determine the effects of gestation housing on nursery performance in gilt offspring. Yorkshire × Landrace gilts were mated by AI and placed in individual stalls throughout gestation (n = 6); group pens throughout gestation (5 to 6 gilts/pen) (n = 6); or individual stalls for 30 d post-mating and then group pens for the remainder of gestation (n = 7). There were no effects of housing on litter size, although there was a trend (P = 0.11) for a greater number of pigs born alive for females kept in stalls throughout gestation (11.8) or in stalls for the first thirty days post-mating and group pens for the remainder of pregnancy (11.4), compared to gilts kept in group pens throughout gestation (9.2) (SE = 0.9). Barrows were cross-fostered among litters so that females were nursing a similar number of pigs (10.5 ± 0.3). Among treatments BW of gilt pigs were similar at birth (1.65 ± 0.05 kg; P = 0.46) and at weaning (24.6 ± 0.3 d of age; 8.67 ± 0.26 kg; P = 0.86). Gilts were placed in nursery pens each containing three pigs farrowed exclusively by females exposed to one of the three gestation housing systems (n = 9 pens/group). During the 5-week nursery study, ADG (0.53 ± 0.01; P = 0.93) and feed conversion efficiency (gain/feed; 0.57 ± 0.01; P = 0.93) were similar among groups. Gilt growth during the lactation and nursery phases of production was unaffected by the type of gestation housing to which dams were exposed. This suggests that if gestation housing does indeed affect gilt offspring performance via fetal programming, the effects are manifested later and not during early postnatal life. (Funded by the Virginia Pork Industry Board)

Key Words: Gestation Housing, Nursery Performance, Gilts

TH187 Group feeding dairy calves. D. G. Johnson*¹, C. Jergenson¹, and H. Chester-Jones², ¹*University of Minnesota, Morris*, ²*University of Minnesota, Waseca.*

Heifer calves were used to evaluate the effect of early life nutritional level in a group management system on growth, feed costs and health. Calves (n=237) were assigned to groups (n=25) of 10 in super hutches by birth order. Calves were born in March - June and October-December calving seasons, with age within group ranging from 4 days to >2 weeks. Cows calved unattended on pasture or in an open shed during extreme weather. Accelerated (AG) groups were fed 2.2% of birth weight as milk replacer powder reconstituted over 2 equal feedings daily until the youngest calf in the group was 5 weeks old, reduced to once daily feeding for at least one week, then weaned when the group consumption averaged .91 kg starter/calf/day. Conventional (CG) groups were fed 1.1% of birth weight as milk replacer once daily, then weaned when the

group consumed .91 kg of starter/head/day and the youngest calf in the group was >27 days old. Starter consumption (S) was restricted to 2.27 kg/day/calf, by group. Milk replacer (MR) was 22% protein, 20% fat. Calf starter was a premium 18% protein, highly palatable, low-molasses starter, but home ground 18% crude protein mix was utilized after per calf group consumption reached 2.2 kg. TMR was fed to groups that weighed >91kg. Feed cost to weaning per calf was AG, \$116.19 vs CG, \$54.52. Body weight and hip height, was recorded at birth weaning, 90 days, and 180 days. Statistical analysis was by Proc GLM /SAS with independent variables group and year, and birth weight as a covariate for individuals. Pen performance was weaning age (days), AG 55.1 vs CG 46.3 (P<.002); MR (kg), AG 37.2 vs CG 16.8 (P<.0001); S (kg), AG 14.2 vs CG 17.7 (P<.100); Gain at 35 days (kg), AG 10.9 vs CG 7.5 (P<.012); and Gain at 42 days (kg), AG 15.1 vs CG 10.9, (P<.027). Individual performance was weaning weight (kg), AG 67.4 vs CG 54.2 (P<.0001); 90-day weight (kg), AG 97.1 vs CG 94.5 (P<.014); 180-day weight (kg), AG 168.6 vs CG 169.9 (NS); weaning hip height (cm), AG 87.6 vs CG 83.1 (P<.0001); 90-day hip height (cm), AG 92.8 vs CG 92.5 (NS); and 180-day hip height (cm) AG 106.4 vs CG 169.9 (NS). Weights and hip heights of AG were higher than CG at weaning but diminished by 180 days of age.

Key Words: Calves, Group Feeding, Replacement Growth

TH188 Impact of an acidifier in milk replacer or calf starter on Holstein heifer performance and health. M. Raeth-Knight*¹, B. Ziegler², R. Larson², S. Hayes³, D. Ziegler⁴, H. Chester-Jones⁴, G. Golombeski¹, and J. Linn¹, ¹*University of Minnesota, St. Paul*, ²*Hubbard Feeds, Mankato, MN*, ³*Milk Products, Chilton, WI*, ⁴*University of Minnesota, Southern Research and Outreach Center, Waseca.*

The objective of this study was to evaluate the impact of an acidifier (ERASE Micropearls®; 20% fumaric acid, 10% orthophosphoric acid, 10% citric acid, 10% malic acid) added to 20% protein:20% fat milk replacer (MR) or calf starter (CS) on performance and health of individually housed Holstein heifer calves from 2-4 d of age for 56 d. One-hundred-ten calves (40.46 ± 0.73 kg) were randomly assigned to 4 treatments:- 1) 0% acidifier (A) in MR and CS (CON); 2) MR with 0.75% A (MRA) and CS; 3) CS with 0.75% A (CSA) and MR; 4) MRA and CSA. All calves were offered MR at 0.284 kg (as-fed) in 1.99 L water 2X daily for the first 35 d, then 1X daily from d 36 to weaning at 42 d. Respective CS (21% CP, DM basis) and water were offered free choice. Feed intake, fecal scores and treatment costs were recorded daily. Body weight (BW) was measured d 1, 14, 28, 42 and 56 and hip heights d 1 and 56. Data was analyzed as repeated measures using the PROC Mixed procedures of SAS. The addition of acidifier in MR or CS was not effective in improving the performance or health of calves pre or post-weaning. Pre-weaning (d 1 to 42) calves on the CSA treatment consumed 3.5 kg less starter and gained 2.8 kg less BW than calves on the CON or MRA treatments (P=0.06). Treatment costs from d 1-56 were numerically lower for the acidified treatments (\$1.72/calf) as compared to the control (\$2.30/calf). Under the conditions of this study use of an acidifier in milk replacer or starter did not enhance calf performance.

Table 1. Treatments

Item	CON	MRA	CSA	MRA + CSA	SE
Initial BW, kg	40.23	40.45	40.32	40.45	0.7
Final BW, kg	74.97	75.15	72.65	73.92	1.4
Day 1 to 56					
Total DMI, kg	61.97	63.49	58.41	60.95	2.0
Feed/gain, kg	1.83	1.84	1.81	1.83	0.03
Trt cost, \$/calf	2.30	1.93	1.50	1.77	0.5

Key Words: Dairy Calves, Feed Acidifiers, Feed Additives

TH189 Pre- and post weaning performance and health of calves fed different milk replacer programs using non-medicated additives and different feeding rates. S. Hayes^{*1}, B. Ziegler², R. Larson², D. Ziegler³, H. Chester-Jones³, M. Raeth-Knight⁴, J. Linn⁴, and G. Golombeski⁴, ¹*Milk Products, Chilton, WI*, ²*Hubbard Feeds, Mankato, MN*, ³*University of Minnesota Southern Research and Outreach Center, Waseca*, ⁴*University of Minnesota, St. Paul*.

One hundred-twenty-five 2 to 4 d-old dairy heifer calves (42.7 ± 0.84 kg) were randomly assigned to one of 5 medicated (20% protein:20% fat) milk replacer (MR) programs to evaluate their effect on pre- (42 d) and post weaning (43-56 d) calf performance and health. Calves were housed in individual calf pens within a curtain side-wall, naturally ventilated barn. Treatments (Trt) were:- 1), All-milk protein MR (control) fed at 0.284 kg (as-fed) in 1.99 L water 2X daily for 35 d, and then 1X daily from 36 to 42 d (MRC); 2), MRC fed as in Trt 1 for 21 d then reduced at d 22 to 1X daily at 0.46 kg in 3.18 L water to d 35, then 0.23 kg in 1.59 L water from 36 to 42 d; 3), MR including 5% spray-dried animal plasma and nutritional additives (APL) fed as Trt 1 for 21 d, then switched to MRC from 22 to 42 d fed same as Trt 1; 4), APL MR fed for 21 d as in Trt 3, then MRC fed 1X daily from 22 to 42 d as in Trt 2; 5) APL MR fed for 21 d as in Trt 3, then MRC fed at 0.23 kg 2X daily in 1.82 L water from 22 to 35 d, and 1X daily from d 36 to 42 d. Calves were offered a 21.2% CP (DM basis) texturized calf starter (CS) free choice with access to fresh water at all times. Total DMI from MR for 42 d averaged 22.72 kg/calf for Trt 1 & 3 and 20.76 kg/calf for Trt 2, 4, & 5. Milk replacer programs did not affect CS DMI or calf performance (P > 0.05). Overall 56-d daily gain and feed/gain averaged 0.69 and 1.89 kg, respectively. Under the conditions of this study, strategies to reduce MR feeding rate and/or the number of MR feedings resulted in similar performance and health compared to the control calves. Calves fed MR supplemented with APL showed similar performance and health to calves fed all milk protein milk replacers.

Key Words: Dairy Calves, Feeding Strategies, Performance

TH190 Pre- and post weaning performance and health of calves fed texturized calf starters with different processed corn or on a different milk replacer feeding schedule. B. Ziegler^{*1}, R. Larson¹, D. Ziegler², H. Chester-Jones², M. Raeth-Knight³, G. Golombeski³, and J. Linn³, ¹*Hubbard Feeds, Mankato, MN*, ²*University of Minnesota Southern Research and Outreach Center, Waseca*, ³*University of Minnesota, St. Paul*.

One hundred-eight 2 to 4 d-old dairy heifer calves (40.5 ± 0.81 kg) were randomly assigned to one of 4 treatments to evaluate their effect on pre- (42 d) and post weaning (d 43-56) calf performance and health. Calves were housed in 2.29 × 1.17 m individual calf pens, within a frame-steel curtain side-wall, naturally ventilated barn. All calves were fed a 20% fat, 20% protein all-milk protein medicated milk replacer (MR) with 19.7% CP (DM basis) calf starters (CS) fed free choice with access to fresh water. Treatments (Trt) were: 1), Texturized calf starter (CS) based on steam flaked corn, pellet and oats (SF); 2), CS based on whole corn and pellet (WC); 3), CS based on roasted corn, pellet and oats (RC); and 4) CS as in Trt 3 but fed a different MR feeding schedule (RC1X). Treatment 1, 2 and 3 calves were fed MR at 0.284 kg (as-fed) in 1.99 L water 2X daily for the first 35 d, then 1X daily from d 36 to 42 d. Treatment 4 calves were fed as the other calf groups for d 1-14 then offered 0.568 kg MR (as-fed) in 3.98 L water 1X daily from d 15-35 and 0.284 kg in 1.99 L water from 36 to 42 d. There was no effect on calf performance due to CS fed during the first 28 d (P > 0.05). During d 29-42, calves fed WC gained less (P < 0.05) than those fed RC. Calves fed WC had the lowest CS DMI (P < 0.05) during d 29-42. There were no Trt differences (P > 0.05) in overall pre-weaning calf performance. Overall 56 d calf performance was similar (P > 0.05). Daily gain and feed/gain averaged 0.66 and 1.98 kg, respectively. Under the conditions of this study, overall calf performance and health were not affected by corn form in the CS or milk feeding schedule. Once a-day milk feeding did not change CS intake as was anticipated.

Key Words: Dairy Calves, Calf Starters, Performance

TH191 Performance of post weaned Holstein heifer calves transitioned to group housing using different management strategies while fed a common diet. D. Ziegler^{*1}, B. Ziegler², M. Raeth-Knight³, R. Larson², G. Golombeski³, J. Linn³, and H. Chester-Jones¹, ¹*University of Minnesota Southern Research and Outreach Center, Waseca*, ²*Hubbard Feeds, Mankato, MN*, ³*University of Minnesota, St. Paul*.

Our objective was to evaluate the impact of three 14-d post-weaning transition grouping strategies on heifer performance over a 112 d study from 2 to 6 months of age. One hundred-eight Holstein heifer calves (77.38 ± 2.28 kg; 60 ± 1.6 d of age) were randomly assigned to 1 of 3 treatments. Treatments d 1-14 were: 1), Calves moved immediately from the nursery barn to group housing in a grower barn in 6 replicated 9.14 × 4.57 m pens of 6 calves/pen (GM); 2), Calves not moved but changed to group pens in 6 replicated 7.02 × 2.29 m pens of 6 calves/pen within the same nursery barn (GN); or 3), Calves not moved and continued to be individually housed d 1-14 in 2.29 × 1.17 m pens within the same nursery barn (IN). On d 15, calves assigned to GN and IN were moved to the grower barn in 6 replicated pens of 6 calves/pen (GN calves remained in their respective groups). During d 1-7 of the study all calves were fed a complete texturized 20.1% CP (DM basis) calf starter and d 8-14 transitioned to whole corn and pellet 17% CP (DM basis) grain mix. After the feed transition, all group pens were fed 2.73 kg/d of the grain mix for d 1-28 and 2.27 kg/d from d 29-112 with free choice hay. Transition strategy did not affect calf performance (P > 0.05) from d 1-14. Daily gain and feed/gain averaged 0.92 and 2.76 kg, respectively. The GM calves had higher (P = 0.03) daily gains (1.03 kg) from d 15-112 than GN (0.99 kg) calves with IN calves being similar (1.02 kg). Calves assigned to IN had lower feed/gain (P = 0.05) from d 15-112 (3.88 kg) compared to GN (3.99 kg) and GM (4.01 kg) calves.

Under the conditions of this study delaying socialization for 14 d resulted in similar growth as compared to calves grouped housed for 112 d.

Key Words: Dairy Calves, Transition Management, Performance

TH192 Performance and growth of Holstein dairy heifers fed grain mixes supplemented with differing protein and non-protein nitrogen sources. R. Larson^{*1}, B. Ziegler¹, M. Raeth-Knight², G. Golombeski², J. Linn², H. Chester-Jones³, and D. Ziegler³, ¹Hubbard Feeds, Mankato, MN, ²University of Minnesota, St. Paul, ³University of Minnesota Southern Research and Outreach Center, Waseca.

Ninety dairy heifers (88.3 ± 1.73 kg BW) were used in a 112-d study to evaluate feed intake and performance from 9 to 25 weeks of age. Heifers were housed in 9.14×4.57 m pens (6 heifers/pen) within a naturally ventilated bedded-pack pole barn and randomly assigned to 1 of 3 grower diets among 5 replicated pens/treatment. Treatments (Trt) were: -1), 16% CP grain mix (66.25% cracked corn, 32.5% pellet, 1.25% tallow) fed at 2.72 kg/d for 28 d and 2.27 kg/d from d 29 to 112 (CON); 2), Same as CON Trt with 1.01% urea in the grain mix (UREA); 3) Same as CON Trt with 6.01% rumen fermentation enhancer (FERMENTEN[®]; 43% CP, as-fed; FERM). Each treatment group was offered a 16.6% CP (as-fed) hay free choice (FC) for the duration of the trial. During the first 28 d, heifers fed UREA had lower ($P < 0.05$) daily gains than those fed CON, with FERM heifers being similar to the other groups. Heifer performance was similar across all groups from d 29 to 112 ($P > 0.05$). Overall 112 d gain was higher ($P < 0.05$) for CON heifers (1.08 kg/d) compared to those fed UREA (1.02 kg/d), with FERM heifers being intermediate (1.04 kg/d). There were no overall differences in total DMI, DMI as a percentage of BW, feed/gain or body condition score change ($P > 0.05$) which averaged 4.24 kg/d, 3.26%, 4.02 kg/kg gain and +0.80, respectively. Under the conditions of this study, heifers limit-fed a 16% CP grain mix containing urea (average 0.024 kg/heifer daily) with FC hay had lower overall gains from 9 to 25 weeks of age than those fed a grain mix without urea mainly due to the first 28 d of the study. Including a rumen fermentation enhancer in the grain mix (FERMENTEN[®]; average 0.14 kg/heifer daily) did not improve heifer performance.

Key Words: Dairy Heifers, Grain Mixes and Protein Sources, Performance

TH193 Performance and growth of young Holstein dairy heifers limit-fed diets based on body weight. H. Chester-Jones^{*1}, D. Ziegler¹, R. Larson², B. Ziegler², M. Raeth-Knight³, and G. Golombeski³, ¹University of Minnesota Southern Research and Outreach Center, Waseca, ²Hubbard Feeds, Mankato, MN, ³University of Minnesota, St. Paul.

Ninety dairy heifers (91.68 ± 0.72 kg BW) were used in a 112-d study to evaluate feed efficiency and performance from 9 to 25 weeks of age when reducing total DMI as a % of BW below an expected 3% or greater shown from previous studies. Heifers were housed in 9.14×4.57 m pens (6 heifers/pen) within a naturally ventilated bedded-pack pole barn and randomly assigned to 1 of 3 grower diets among 5 replicated pens/treatment. Treatments (Trt) were: 1), 18% CP grain mix control (58.75% cracked corn, 40% pellet, 1.25% tallow) fed at 2.72 kg/d for 28 d and 2.27 kg/d from d 29 to 112 with access to free choice (FC)

15.24% CP (DM basis) hay (CON); 2), 18% CP grain mix fed as for CON with limit hay feeding based on cumulative DMI of grain and hay to equal 3% of projected BW by 14-d periods (3DMI); 3), 18% CP grain mix fed at 2.72 kg/d for 14 d, 2.39 kg/d from d 15-28 and 2.05 kg/d d 29-112 with limit hay feeding based on cumulative DMI of grain and hay to equal 2.7% of projected BW by 14-d periods (2.7DMI). Initial BW and estimated daily gains were based on previous studies of 0.98, 1.07, 1.09, 1.0, 1.0, 0.98 and 0.93 kg by 14-d periods and were used to project period BW. Total DMI and DMI as a % of BW were lowest ($P < .05$) for heifers fed 2.7DMI for each 14-d period from d 15 to 112 except d 29-42 when CON had similar DMI to 2.7DMI ($P > 0.05$). Total DMI d 1-112 were 8.5 and 8.9% less for 2.7DMI than heifers fed 3DMI and CON, respectively. Overall 112 d daily gain was lowest (0.99 kg; $P < 0.05$) for 2.7DMI heifers being 5.7 (1.05 kg) and 9.2% (1.09 kg) less than those fed 3DMI and CON, respectively. There were no Trt differences ($P > 0.05$) in feed/gain. Although limit feeding young heifers under the conditions of this study did not improve feed efficiency, it did offer acceptable growth and body weight gain. Further research on optimum hay quality when limit feeding is needed.

Key Words: Dairy Heifers, Limit-Feeding Diets, Performance

TH194 Pre- and post weaning performance and health of calves fed milk replacers supplemented with trace minerals from differing sources. G. Golombeski^{*1}, S. Hayes², M. Raeth-Knight¹, B. Ziegler³, R. Larson³, D. Ziegler⁴, H. Chester-Jones⁴, and J. Linn¹, ¹University of Minnesota, St. Paul, ²Milk Products, Chilton, WI, ³Hubbard Feeds, Mankato, MN, ⁴University of Minnesota Southern Research and Outreach Center, Waseca.

One hundred-seven 2 to 4 day-old dairy heifer calves (40.1 ± 0.61 kg) were randomly assigned to one of 3 medicated, all-milk protein (20% protein:20% fat) milk replacers (MR) with supplemental trace mineral treatments to evaluate their effect on pre- and post weaning calf performance and health. Calves were housed in 2.29×1.17 m individual calf pens, within a curtain side-wall, naturally ventilated barn. Treatments were: 1), MR control containing inorganic trace minerals (INORGMR); 2), MR containing organic trace minerals (ORGMR); 3), ORGMR with organic selenium (Se; ORGSEMR). Milk replacers were fed at 0.284 kg (as-fed) in 1.99 L water 2X daily for the first 35 d, then 1X daily from d 36 to weaning at 42 d. Calves were offered a 21.4% CP (DM basis) texturized calf starter (CS) free choice and had access to fresh water at all times. Total DMI from MR for 42 d averaged 20.56 kg/calf. There were no pre- and post weaning performance differences by treatments ($P > 0.05$). Pre-weaning total DMI, gain and feed/gain averaged 37.23, 21.33, and 1.83 kg, respectively. Post weaning CS DMI, gain, and feed/gain averaged 25.60, 12.70 and 2.02 kg, respectively. Overall 56-d daily gain and feed/gain averaged 0.61 and 1.91 kg, respectively. Hip height gain was greater ($P < 0.02$) for calves fed ORGMR vs. those fed INORGMR. Calves fed ORGSEMR had higher ($P < 0.03$) serum Se on d 14 compared to those fed ORGMR with INORGMR being intermediate. Health treatment costs/calf were similar across treatments. Under the conditions of this study, feeding a MR containing organic trace minerals with or without organic Se did not affect pre- and immediate post weaning calf performance and health compared to calves fed MR with inorganic trace minerals.

Key Words: Dairy Calves, Milk Replacer Trace Minerals, Performance

TH195 Effect of the origin, month born, and shipment group on growth of Holstein heifers at a raising facility. J. Wohlt*¹, C. Jin¹, and J. Ferguson², ¹Rutgers University, New Brunswick, NJ, ²University of Pennsylvania, Kennett Square.

Twelve groups (9 to 23 head/shipment group) of Holstein heifers (total n = 179, 60 and 40% from PA and DE, respectively) were received at Rutgers University (New Brunswick) from either the University of Pennsylvania (Kennett Square) and/or the University of Delaware (Newark). Some shipments contained heifers from each origin as the same transportation route (161 km) was used. Heifers were approximately 3 months of age at receipt with the 12 shipments occurring between April 2004 and October 2005. Heifers were grouped in pens (5 to 7 head/pen) in a loose housing system and fed (NRC, 2001) diets for an 0.82 kg ADG. Once monthly each heifer between the ages of 3 to 18 months was weighed (Weight-By-Breed Management Tape), height at the withers measured, and body condition (1=thin, 5=fat) scored. Data were analyzed by ANOVA using GLM procedures with shipment groups, origin, and month born being main effects. Body weight increased (P < 0.01) linearly with heifer age, but height and body condition score increases were curvilinear. Growth rate, determined by linear regression analysis, did not differ with heifer origin: DE 0.84 kg/d, PA 0.83 kg/d. Heifer growth did differ (P < 0.01) among groups ranging from 0.73 to 0.97 kg/d. Heifers born between January and June compared to those born between July to December grew at a slower (P < 0.01) rate; 0.74 vs. 0.80 kg/d. The data suggest that early life events (nutrition, illness, etc.) may have long-term carry over effects on heifer growth at a raising facility.

Key Words: Dairy Heifer, Growth, Origin of Heifer

TH196 The association of mortality and 60 day culling rates with housing, feeding and pasture systems. C. D. Dechow*¹ and R. C. Goodling², ¹Penn State University, University Park, ²Pennsylvania State Cooperative Extension, University Park.

The objective of this study was to determine the association of various housing and management systems with measures of cow welfare, including mortality rates and culling by 60 days in milk (CR60). Herd surveys were received from 316 Pennsylvania dairy herds that participate in DHI herd testing and that had data available in 2005. The herd surveys identified feeding system (TMR = total mixed ration, CF = component feeding), housing system (FS=free stall, TS = tie stall, other), and pasture access (regular pasture, occasional pasture, exercise lot, no outdoor access). There was significant confounding of feeding, housing and pasture systems with herd size. Of herds with 100 cows or more (62%), 7% were TS, 22% had pasture access, and 97% fed TMR. Herds with fewer than 100 cows were more likely to have pasture access (62%), house cows in a TS (73%), or use CF (37%). Feeding, housing, and pasture system were analyzed with the GLM procedure of SAS. Least-squares-means (LSM) for mortality and CR60 were significantly higher in TMR fed herds (5.0% and 8.2%, respectively) than in CF herds (3.2% and 6.7%, respectively). Mortality rate was significantly lower in TS herds (3.3%) than in FS herds (4.9%), as was CR60 (6.3% versus 8.8%). Feeding, housing and pasture system were also combined into five total herd management systems. The most optimal herd environment (TS, CF, with pasture access) had LSM for mortality rate of 2.1% and CR60 of 5.3%, whereas the corresponding LSM for the least optimal environment (FS or other, TMR, no outdoor access) were 6.3% and 9.1%, respectively. While management system effects were highly

significant, they explained less than 10% of herd variation in mortality and CR60, which highlights challenges of associating cow welfare with herd type. In particular, the results indicate that legislative efforts to eliminate TS because of concern over limited cow movement may actually compromise cow welfare and reduce pasture access.

Key Words: Mortality, Housing, Pasture

TH197 How winter conditions affect feed intake of steers in different housing systems. H. Koknaroglu¹, Z. Otles², T. Mader³, T. Purevjav*⁴, and P. Hoffman⁴, ¹Suleyman Demirel University, Department of Animal Science, Isparta, Turkey, ²Frontier Science and Technology Research Foundation, Madison, WI, ³University of Nebraska, Lincoln, ⁴Iowa State University, Ames.

A total of 182 yearling steers of predominantly Angus and Hereford breeds, with mean body weight of 327 kg, were used in this study, which started on 8 November and finished on 12 April, to assess the effects of environmental factors on feed intake of steers in various housing systems. Housing consisted of outside lots with access to overhead shelter, outside lots with no overhead shelter and a cold confinement building. Ad libitum corn, 2.27 kg of 35% dry matter whole plant sorghum silage and 0.68 kg of a 61% protein-vitamin-mineral supplement was offered. Feed that was not consumed was measured to determine feed intake. The temperature data were recorded by hygro-thermographs. Hourly temperatures and wind speed were used to develop weather variables. Regression analysis was used and weather variables were regressed on dry matter intake (DMI). When addition of a new variable did not improve R² more than one unit, then the number of variables in the model was truncated. Cattle in confinement tended to have lower DMI than those in open lots and those in open lots with access to an overhead shelter (P > 0.05). Effect of cold was predominantly displayed in January in the three housing systems. In terms of explaining variation in DMI, in outside lots with access to overhead shelter, afternoon and peak temperatures were important factors, whereas in open lots, evening, nocturnal temperatures and windchill index were important factors (P < 0.05). In confinement buildings, daytime, nocturnal temperatures and windchill index were the most important factors explaining variation in DMI. Results show that winter conditions have detrimental effect on performance of cattle and when considering these results, cattle producers wishing to improve cattle feedlot performance should provide overhead shelter which provides more favorable conditions.

Key Words: Cold Stress, Dry Matter, Steers

TH198 Effect of age and breed on reproductive performance in the tropics. II. Beef heifers bred at 11 to 16 months of age. Year 2004. A. C. Pereira*¹, R. L. Remonato², G. R. Pacheco², E. J. Bungenstab¹, and S. P. Schmidt¹, ¹Auburn University, Auburn, AL, ²IACO Agricola S.A., Chapadão do Sul, Mato Grosso do Sul, Brazil.

The objective was to determine the influence of breed and age of eight breeds of beef heifers 11 to 16 mo old when exposed to bulls in a tropical environment. Breeds used were Bonsmara (BN), Boran (BO), Brahman (BR), Composite (CO), ½ Nellore x ½ Angus (F1), Nellore (NE), Senepol (SE), and Tuli (TU). Heifers born from July to December, 2002, (n = 9,235) were allocated by age and exposed to bulls Nov 1 to Dec

31, 2003, at 11, 12, 13, 14, 15, and 16 mo of age. Pregnancy status was determined by trans-rectal palpation. All ages had an effect on pregnancy rate ($P < 0.001$). Heifers at 16 month had a higher ($P < 0.01$) pregnancy rate ($32\% \pm 3.5$) compared with all other ages with exception of 15 month ($21\% \pm 3.4$). There also was a breed effect ($P < 0.01$). More F1 heifers were pregnant ($32\% \pm 1.1$; $P < 0.01$) than all other breeds; next were TU heifers ($18\% \pm 1.1$) which were higher ($P < 0.01$) than all other breeds with the exception of BN ($5.9\% \pm 6.3$) and BO (9.5 ± 6.3). There was an age x breed interaction on pregnancy rate ($P < 0.01$). F1 Heifers at 16 month ($65 \pm 2.9\%$) did not differ from SE breeding at 16 month ($60 \pm 15.8\%$) but had a higher pregnancy rate than all others. The heifer F1 breeding at 15 months (49 ± 2.1) did not differ from SE breeding at 16 months ($60\% \pm 15.8$) but had a higher pregnancy rate than all others. These data indicate that under the condition of this study in a tropical area, F1 and SE heifers were superior in pregnancy rate at 16 month, but F1 heifers may reach maturity as early as 15 mo of age.

Key Words: Beef Heifers, Reproduction, Breeding Season

TH199 Effect of age and breed on reproductive performance in the tropics. I. Beef heifers bred at 11 to 15 months of age. Year 2002.

E. J. Bungenstab^{*1}, R. Remonato², G. R. Pacheco², A. C. Pereira¹, and S. P. Schmidt¹, ¹Auburn University, Auburn, AL, ²IACO Agricola SA, Chapadão do Sul, MS, Brazil.

The objective was to determine the influence of breed and age of four breeds of beef heifers 11 to 15 mo of age when exposed to bulls in a tropical environment. Breeds used were Tuli (TU), Brahman (BR), Composite (CO), and $\frac{1}{2}$ Nellore x $\frac{1}{2}$ Angus (F1). Heifers born from July to December, 2000, ($n = 6,687$) were allocated by age and exposed to bulls from November, 2002 through January, 2003, at 11, 12, 13, 14, and 15 mo of age. Pregnancy status was determined by trans-rectal palpation. Age had an effect on pregnancy rate ($P < 0.01$). Heifers breeding at 15 mo had the highest ($P < 0.01$) pregnancy rate ($46 \pm 1.7\%$) followed by 14 mo ($37 \pm 1.1\%$), 13 mo ($26 \pm 1.0\%$), 12 mo ($14 \pm 0.9\%$) and 11 mo ($9 \pm 1.9\%$) which was not different from 12 mo. There also was a breed effect ($P < 0.01$). The F1 heifers had a higher ($P < 0.01$) pregnancy rate ($42 \pm 1.3\%$) than all other breeds. The TU heifers ($27 \pm 1.4\%$) were next and were higher ($P < 0.01$) than BR ($12 \pm 1.1\%$) but did not differ from CO ($23 \pm 1.1\%$). BR heifers ($12 \pm 1.1\%$) had the lowest ($P < 0.01$) pregnancy rate. There was an age x breed interaction on pregnancy rate ($P < 0.01$). F1 Heifers breeding at 15 mo ($67 \pm 5.1\%$) did not differ from F1 at 14 mo ($62 \pm 2.4\%$) and TU at 15 mo ($56 \pm 2.2\%$); however, those three had higher ($P < 0.01$) pregnancy rates than all others. These data indicate that in tropical areas, F1 heifers matured earlier and could be bred at 14 months of age.

Key Words: Beef Heifers, Reproduction, Breeding Season

TH200 Effect of early weaning of first-calf beef heifers. II. On calf and subsequent open heifer performance in the tropics.

E. J. Bungenstab^{*1}, R. Remonato², G. R. Pacheco², A. C. Pereira¹, and S. P. Schmidt¹, ¹Auburn University, Auburn, AL, ²IACO Agricola SA, Chapadão do Sul, MS, Brazil.

The objective was to investigate the effect of three calf weaning ages from first-calf heifers on subsequent dam and calf performance. From a herd of 650 $\frac{1}{2}$ Angus x $\frac{1}{2}$ Nellore primiparous heifers, 123 that had

male calves born between October 1 and 15 were selected and bred to composite bulls ($\frac{1}{4}$ Tuli, $\frac{1}{4}$ Angus, $\frac{1}{2}$ Brahman) during November and December. In March, following trans-rectal palpation, heifers were stratified by pregnancy status (63 pregnant or 60 open) and assigned randomly to three groups: normal weaning age at 7 mo \pm 7 d (7M), early weaned at 6 mo \pm 7 d (6M), or at 5 mo \pm 7 d (5M). No groups received supplementation. For all observations, d 0 = day 5M calves were weaned. Heifer body weights were taken on d 0, 30, 60, 90 and 315; body condition scores (BCS) were determined on d 0, 60 and 90; calf weights were taken on d 0, 30, 60, 90, 120, 150 and 315. Data reported here are for the 60 first-calf heifers that were not pregnant but were nursing their first calves. Heifer weights (410 ± 41 kg) and BCS (4.30 ± 0.5) were not different ($P > 0.05$) at d 0 when the 5M calves were weaned. By d 30 (420 vs. 395 kg) and continuing to d 90 (444 vs. 399 kg), 5M heifers weighed more ($P < 0.05$) than 7M heifers; 6M heifers were intermediate (426 kg) and not different from either 5M or 7M ($P > 0.05$). Similarly, BCS was greater for 5M than 7M at d 90 (5.4 vs. 4.9 ; $P < 0.05$), and 6M was intermediate (5.1 ; $P > 0.05$). Because these first-calf heifers were open, they were sold after calves were weaned. At d 0, there were no differences in calf weights (154 ± 16 kg). By d 30, 5M calves weighed less ($P < 0.05$) than 6M or 7M calves (170 , 187 , 185 kg, respectively). 5M calves continued to weigh less than 6M or 7M calves through d 150. By d 315, calf sale weights among weaning treatments were similar (290 ± 26 kg; $P > 0.05$). These data imply that early weaning (5M) will not affect calf sale weight, while significantly increasing cow weight, resulting on a heavier sale weight at 90 days after early weaning.

Key Words: Early Weaning Tropics, First-Calf Heifers, Performance

TH201 Effect of early weaning of first-calf beef heifers. I. On calf and subsequent heifer weights and pregnancy for third-parity in the tropics.

A. C. Pereira^{*1}, R. Remonato², G. R. Pacheco², E. J. Bungenstab¹, and S. P. Schmidt¹, ¹Auburn University, Auburn, AL, ²IACO Agricola SA, Chapadão do Sul, MS, Brazil.

The objective was to investigate the effect of three calf weaning ages from first-calf heifers on subsequent dam and calf performance. From a herd of 650 $\frac{1}{2}$ Angus x $\frac{1}{2}$ Nelore primiparous heifers, 123 that had male calves born between October 1 and 15 were selected and bred to composite bulls ($\frac{1}{4}$ Tuli, $\frac{1}{4}$ Angus, $\frac{1}{2}$ Brahman) during November and December. In March, following trans-rectal palpation, heifers were stratified by pregnancy status (63 pregnant or 60 open) and assigned randomly to three groups: normal weaning age at 7 mo \pm 7 d (7M), early weaned at 6 mo \pm 7 d (6M), or at 5 mo \pm 7 d (5M). No groups received supplementation. For all observations, d 0 = day 5M calves were weaned. Heifer body weights were taken on d 0, 30, 60, 90 and 315; body condition scores (BCS) were determined on d 0, 60 and 90; calf weights were taken on d 0, 30, 60, 90, 120, 150 and 315. Data reported here are for the 63 first-calf heifers that were pregnant. Heifer weights (422 ± 47 kg) and BCS (4.61 ± 0.49) were not different ($P > 0.05$) at d 0 when the 5M calves were weaned. By d 30 (436 vs. 402 kg) and continuing to d 90 (467 vs. 406 kg), 5M heifers weighed more ($P < 0.05$) than 7M heifers; 6M heifers were intermediate and not different from 5M (462 kg; $P > 0.05$). Similarly, BCS were similar for 5M and 6M at d 90 (5.7 vs. 5.6 ; $P > 0.05$) and greater than 7M (5.1 ; $P < 0.05$). There was a weaning treatment response for overall pregnancy rate. More ($P < 0.05$) 5M heifers were pregnant (87.5%) compared to 7M (50.0%); 6M heifers were intermediate and not different from 5M or 7M (66.7% ; $P > 0.05$). At d 0, there were no differences in calf weights (150 ± 19 kg).

By d 60, 5M calves weighed less ($P < 0.05$) than 6M or 7M calves (168, 187, 188 kg, respectively). The 5M calves continued to weigh less than 6M or 7M calves through d 150. By d 315, calf weights among weaning treatments were similar (285 ± 28 kg; $P > 0.05$). These data imply that early weaning (5M) will increase pregnancy rate at re-breeding without affecting calf weight when sold.

Key Words: Early Weaning Tropics, First-Calf Heifers, Performance

TH202 Effect of calving scheme, seasonal vs. year-round, on production, reproductive performance, and culling by organically-managed dairy herds in Southeastern Pennsylvania. K. Griswold^{*1}, H. Karreman², and J. High³, ¹Penn State Cooperative Extension, University Park, ²Penn Dutch Cow Care, Gap, PA, ³Lancaster DHIA, Manheim, PA.

The effects of seasonal calving (SC) vs. year-round calving (YRC) on production, reproductive performance and culling were examined using a combination of survey and DHIA data. Initially, 38 organically-managed (OM) herds using Lancaster DHIA services were recruited for the study, but only 29 herds returned completed surveys. The survey consisted of 308 questions concerning herd demographics, milk quality, health, reproduction, nutrition, and young stock. Monthly DHIA 202 report data from 2006 for each herd were used for the study. Data were analyzed using PROC MIXED within SAS. The model included the fixed effect of calving scheme and the random effect of farm. Significant differences were determined at $P < 0.05$, and trends were determined at $0.05 < P < 0.15$. LS means with standard errors are presented in the table below. The results indicate that SC herds produced significantly less total milk and total components per cow per year compared to YRC herds. Milk fat % was not affected ($P > 0.15$), but there was a trend for milk protein % to be greater for SC herds compared to YRC herds. For reproductive performance, SC herds had significantly fewer days to 1st service, greater pregnancy rates, and fewer days open compared to CM herds. The overall cull rate was not affected ($P > 0.15$) by calving scheme, but there was a trend for YRC herds to cull more cows for reproductive reasons whereas SC herds tended to cull more cows for mastitis. These results suggest that among organic dairies, seasonal calving herds have greater challenges with milk production and mastitis while year-round calving herds have greater challenges with reproductive performance.

Table 1. Effect of calving scheme on production, reproduction, and culling by organic dairy herds

Item	Seasonal	SE	Year-round	SE	P

TH203 Influence of horn flies on the behavior of beef cattle. H. T. Boland^{*1} and G. Scaglia², ¹Virginia Tech, Blacksburg, ²Iberia Research Station, LSU Agricultural Center, Jeanerette, LA.

The horn fly (*Haematobia irritans*) is a common pest of cattle. When fly populations are high they can reduce animal performance leading to economic losses for producers. A study was conducted to evaluate the effects of a heavy burden of horn flies on the behavior of beef cattle. Angus-cross steers (n=4) that were being grass-finished on endophyte-free tall fescue (*Festuca arundinacea* Shreb.) were evaluated prior to and after application of 40% organophosphate ear tags. Fly-avoidance activities (head throw, tail or ear flick, front and rear leg kick, and skin twitch) and grazing behavior parameters (bite rate and number of feeding stations) were recorded over two-1 minute periods during morning and afternoon grazing bouts. High resolution digital photographs were taken of each steer from a lateral view at each sampling time. Images were analyzed with computer software to determine the number of flies present. Behavior and fly counts were monitored from 2 d prior until 3 d after fly tag application. Data were analyzed using the SAS procedures CORR and MIXED with Tukey's adjustment for means separation. There were more ($P=0.003$) flies present per animal before tagging (831) than after (203). Prior to tagging steers exhibited a greater number of tail flicks ($P=0.01$) and leg kicks ($P=0.002$). There was a linear effect of day ($P=0.06$) on bite rate (bites/min), with rate increasing after fly tags were applied. Bite rate was negatively correlated to the number of flies on the steers ($r=-0.31$, $P=0.006$) while the number of feeding stations was positively correlated ($r=0.43$, $P<0.0001$). Head throws ($r=0.27$), tail flicks ($r=0.50$), leg kicks ($r=0.47$), and skin twitches ($r=0.45$) were all positively correlated ($P \leq 0.02$) to the number of flies on the steers. High fly populations had a negative impact on the behavior of grazing cattle. Decreasing fly burdens can promote animal well-being by decreasing the display of fly-avoidance activities and increasing bite rate.

Key Words: Grazing Behavior, Bite Rate, Insecticide

TH204 Description of factors influencing reticular temperatures in lactating dairy cows. J. M. Bewley^{*}, M. E. Einstein, M. W. Grott, and M. M. Schutz, Purdue University, West Lafayette, IN.

The Phase IV Cattle Temperature Monitoring System (CTMS, Phase IV Engineering Inc., Boulder, CO) utilizes a passive bolus equipped with a temperature sensor, a stationary panel reader to query the bolus, and software to collect data. The biologically inert bolus resides in the cow's reticulum and is queried each time the cow passes the reader. Cow temperatures were collected immediately after each milking from 298 Holstein cows at the Purdue Dairy Research and Education Center (DREC) from June 1, 2006 to August 31, 2007. Cows were managed in 3 housing systems: a freestall barn (FS) with 128 stalls in 4 quadrants, a bedded-pack barn with an open grass lot (BP), and a geothermally-modified barn with tiestalls for overflow and sick cows and box stalls for recently fresh cows (GM). Ambient weather conditions were recorded at 0.5 h intervals at the Purdue Agronomy Research Farm, which is adjacent to the DREC. Raw cow reticular temperatures were edited to remove erroneous reads and temperatures potentially influenced by water intake. Unadjusted mean reticular temperature for the remaining 131,181 temperatures was $38.77 (\pm 0.44)$. The PROC MIXED procedure of SAS was used to assess the impact of milking time, parity, temperature humidity index (THI), housing system, days in milk, and milk production, on reticular temperatures. All main effects were significant ($P < 0.01$) except for THI which was, however, significant in 2-way interac-

tions (with barn, milk weight, or date). Temperatures decreased as cows progressed through lactation. Temperatures were higher for the PM milking than the AM milking ($P < 0.0001$). Variation in temperatures increased with increasing THI. After accounting for other effects in the model, the impact of increasing THI on reticular temperatures was higher for BP cows than FS or GM cows. An automated temperature monitoring system could be useful for herd management, however, variation caused by several factors must be considered for correct interpretation of temperatures provided by such a system.

Key Words: Temperature Monitoring, Reticular Temperature

TH205 Relationship of temperament and growth in the suckling beef calf. K. J. Matheney^{*1}, J. P. Banta¹, D. A. Neuendorff¹, T. H. Welsh, Jr.², R. C. Vann³, and R. D. Randel¹, ¹Texas AgriLife Research and Extension, Overton, ²Texas AgriLife Research, College Station, ³Mississippi State University, Raymond.

Exit velocity (EV) has been reported as an effective measure of temperament in Brahman calves after weaning (Curley et al., 2006; JAS 84:3100-3103). This experiment was conducted to evaluate the relationship of EV on weaning weight of suckling Brahman calves ($n = 109$). Additionally, evaluation of EV during the suckling period was examined from d 21-24 through weaning. Cows were assigned a temperament score from 1 to 3 (1 = calm, $n = 35$; 2 = intermediate, $n = 47$; 3 = temperamental $n = 27$). Exit velocity and BW were collected on d 21-24 and every 28 d through weaning; weaning BW was adjusted to 173 d according to BIF guidelines. Calves were classified at weaning based on EV, with calves 1 SD slower than the mean classified as calm (C; $n = 16$; 0.72 ± 0.18 m/s), calves 1 SD faster than the mean classified as excitable (E; $n = 23$; 3.61 ± 0.47 m/s), and all others classified as intermediate (I; $n = 70$; 1.77 ± 0.53 m/s). This was repeated with EV measurement taken 28 d prior to weaning, C ($n = 21$; 0.85 ± 0.23 m/s), I ($n = 71$; 2.11 ± 0.52 m/s), E ($n = 17$; 3.83 ± 0.55 m/s), and on d 21-24, C ($n = 13$; 0.24 ± 0.09 m/s), I ($n = 1.01 \pm 0.45$ m/s), and E ($n = 13$; 2.86 ± 0.50 m/s). The statistical model used for analysis included EV classification being tested, calf sex, and cow temperament as fixed effects; calf sire was included as a random effect. Classification by EV at weaning, 28 d prior to weaning, and d 21-24 were not significantly related to calf BW at weaning ($P > 0.10$; Table 1). Correlations were determined between EV on d 21-24 and at weaning ($r = 0.41$; $P < 0.001$), and 28 d prior to weaning with EV at weaning ($r = 0.69$; $P < 0.001$). The results from this experiment suggest that temperament does not affect growth of the suckling calf. These data suggest that calves can be evaluated for temperament using EV as early as 21-24 d of age.

Table 1. Effect of EV classification on adjusted weaning BW, kg

	Calm	Intermediate	Excitable	P =
Day 21-24	195.7 \pm 6.4	204.3 \pm 4.2	202.7 \pm 5.6	0.32
28 days prior to weaning	201.9 \pm 6.0	204.2 \pm 4.3	199.1 \pm 5.8	0.57
Weaning	204.1 \pm 6.1	203.9 \pm 4.3	199.2 \pm 5.4	0.58

Key Words: Temperament, Calves, Growth

TH206 Effect of supplemental saturated fatty acids on production and body temperature in heat-stressed mid-lactation dairy cows. J. P. Wang^{1,2}, D. P. Bu¹, J. Q. Wang^{*1}, X. K. Huo¹, T. J. Guo¹, H. Y. Wei¹, L. Y. Zhou¹, R. R. Rastani³, L. H. Baumgard⁴, and F. D. Li², ¹Chinese Academy of Agricultural Sciences, Beijing, China, ²Gansu Agricultural University, Gansu, China, ³MSC Specialty Nutrition, Dundee, IL, ⁴University of Arizona, Tucson.

Study objectives were to investigate the effect of supplemental saturated fatty acids (Energy Booster 100[®]) on body temperature, production and body condition of mid-lactation Holstein dairy cows ($n=48$; 184 ± 17 DIM; 30.8 ± 3.3 kg of milk/d and parity=2.2) experiencing heat stress. Cows were allocated into three treatments ($n=16$) according to a completely random block design and were fed individually in a tie-stall facility. Three treatment diets consisted of supplemental saturated fatty acids at 0, 1.5 or 3.0% of dry matter (C, LF and HF). The basal diet contained 44% forage and 56% concentrate. The supplemental fat replaced corn and soybean meal in the diet. Diets were isonitrogenous (CP=16.8%) and contained 1.54, 1.60 and 1.67 Mcal NE_L/kg DM in C, LF and HF, respectively. Cows were already heat-stressed at the beginning of the trial, and experimental diets were fed ad libitum as a TMR for 9 additional wk during heat stress conditions. Cows were milked 3 x/d and milk yields were recorded. Milk samples were collected weekly from 3 consecutive milkings and analyzed for composition. Ambient temperature and humidity were recorded 3 x/d, and rectal temperatures were monitored 3 x/d every other day. BCS and BW were measured weekly. During the experiment, the minimum, maximum and average THI were 64.2, 97.3 and 76.6, respectively. Overall rectal temperatures at 1400 h were 39.98^a, 38.98^b, and 39.25^{b,c}°C for C, LF and HF, respectively ($P < 0.05$). There was no treatment effect on DMI (20.1 kg/d), BCS (2.72) or BW (616.8 kg). Fat supplementation increased ($P < 0.05$) milk yield (26.4^a, 28.6^b, 28.5^b kg/d for C, LF, and HF, respectively). Milk fat content and total solids increased linearly ($P < 0.02$) with increasing fat supplementation. Supplemental saturated fatty acids reduced rectal temperatures and improved milk yield in mid-lactation heat-stressed dairy cows.

Key Words: Supplemental Saturated Fatty Acids, Heat Stress, Milk Yield

TH207 Ocular thermography as a measure of body temperature in beef cattle: Influences of environmental factors. S. M. Dray^{*1}, R. C. Vann², A. B. Chromiak¹, J. K. Lyons³, T. H. Welsh, Jr.³, R. D. Randel⁴, and S. T. Willard¹, ¹MAFES, Mississippi State University, Mississippi State, ²MAFES, Mississippi State University, Raymond, ³Texas A&M System, College Station, ⁴Texas AgriLife Research and Extension Center, Texas A&M System, Overton.

Our laboratory has shown that digital infrared thermal imaging (DITI) of the eye may be used as a measure of body temperature (BT) in livestock, with correlations to rectal temperature (RT; J. Anim. Sci. 84 (Suppl.1):354). However as environmental factors may have a negative influence on DITI, the objective of this study was to evaluate the impact of these factors on ocular DITI in beef cattle. Ocular temperature (TEMP) was measured with an infrared camera (FLIR, Wilsonville, OR). A total of 1027 observations were made using heifers (HF; $n=515$) and

steers (ST; n=453) among two breeds, Angus (A; n=658) and Brahman (B; n=368). Data were acquired over 3-months on numerous days at the same or multiple locations (MS, TX). Measures included: ambient TEMP (AMBT; °C), relative humidity (RH; %), TEMP-humidity index (THI), RT (°C) and maximum ocular TEMP (MAX EYE, °C). Analysis among these parameters used the Pearson Correlation Coefficient (r). Environmental measures ranged as follows: AMBT: 6.4°C to 36.2°C; RH: 28.4 to 91.0%; THI: 45.9 to 84.9. MAX EYE was highly correlated ($P < 0.01$) with AMBT ($r = 0.82$) and THI ($r = 0.81$), whereas there was a low correlation between RH and MAX EYE ($r = 0.14$). Overall, AMBT and MAX EYE were moderately correlated ($P < 0.05$) to RT ($r = 0.65$ and 0.74 , respectively). MAX EYE and RT relationships exhibited a similar trend when separated by gender (HF: $r = 0.71$; ST: $r = 0.75$; $P < 0.05$) and breed (A: $r = 0.74$; B: $r = 0.67$; $P < 0.05$). To assess variability of ocular DITI measures, standard deviation (EYE STD) within and among ocular images was examined in relation to environmental parameters. We noted that AMBT and THI were negatively correlated ($P < 0.01$) with EYE STD ($r = -0.87$ and -0.88 , respectively); as AMBT and THI decreased, EYE STD within ocular images increased. RH alone had no influence on EYE STD ($r = 0.02$; $P > 0.05$). In summary, ocular DITI was moderately correlated to RT (as was AMBT) among gender and breed. Changes in environmental TEMP influenced ocular DITI (MAX EYE and EYE STD), which needs to be considered when using ocular DITI as a measure of BT. [USDA-NRI: 2005-35204-15737; Biophotonics: #58-6402-3-0120]

Key Words: Thermography, Cattle, Body Temperature

TH208 Forced-traffic in automatic milking systems effectively reduces the need to fetch cows but alters eating behavior of dairy cattle. A. Bach^{1,2}, M. Devant², and A. Ferrer², ¹ICREA, Barcelona, Spain, ²IRTA-Unitat de Remugants, Barcelona, Spain.

Eighty five lactating Holstein dairy cows in loose housing conditions evenly distributed in 2 symmetrical pens, each containing 28 feeding

places, 2 waterers, and 1 automatic milking system (AMS) were used to evaluate the effects of the traffic type imposed to lactating cows through an AMS on milking frequency, feeding behavior, and milk production. The study followed a cross-over design with 2 periods and 2 treatments. Each period lasted 3 mo, with 1 mo of adaptation between periods. All cows were fed a partially mixed ration twice daily and up to 3 kg/d of a concentrate during the visits to the AMS. Treatments consisted on allowing free-traffic of cows throughout the pen or forcing cows to pass through the AMS before access to the feed bunk could be attained (forced traffic). Individual eating behavior and feed consumption were continuously monitored throughout the study using a computerized system. Individual milk production was recorded at each milking, and milk composition monthly. In addition, the number of cows fetched to the AMS was recorded. The number of voluntary and total milkings was greater with forced traffic (2.4 ± 0.04 and 2.5 ± 0.06 milkings/d, respectively) than with free traffic (1.7 ± 0.06 and 2.2 ± 0.04 milkings/d, respectively). Total DMI was numerically lower and milk production numerically greater with forced (20.4 ± 0.61 and 30.9 ± 0.79 kg/d, respectively) than with free traffic (21.2 ± 0.61 and 29.8 ± 0.79 kg/d, respectively). Milk fat content tended ($P = 0.06$) to be lower and milk protein was lower with forced traffic (3.44 ± 0.08 and 3.31 ± 0.02 %, respectively) than with free traffic (3.65 ± 0.08 and 3.38 ± 0.02 %, respectively). The number of meals was lower whereas meal duration and meal size was greater with forced traffic (6.6 ± 0.3 meals/d, 20.4 ± 0.65 min/meal, and 2.7 ± 0.09 kg/meal, respectively) than with free traffic (10.1 ± 0.3 meals/d, 15.7 ± 0.65 min/meal, and 1.8 ± 0.09 kg/meal, respectively). Forced traffic improved the number of voluntary milkings but altered milk quality and eating behavior of dairy cattle.

Ruminant Nutrition: Fats and Carbohydrates - Beef, Sheep, Misc. Ruminants

TH209 Effect of physical particle size on ruminal and post-ruminal disappearance of nutrients of a mixed concentrate in Holstein steers. H. H. Jahani-Azizabadi¹, M. Danesh Mesgaran^{*1}, and A. Rahmatimanesh², ¹*Ferdowsi University of Mashhad, Mashhad, Iran*, ²*Heram Talae Shargh Feed Mill Company, Nishabour, Iran*.

In situ ruminal and post-ruminal disappearance [dry matter (DM), crude protein (CP) and ether extract (EE)] of a mixed concentrate prepared as fine mesh (fm), fine pellets (fp) and coarse pellets (cp) were studied. All pellets were provided in a condition of 70°C with pressure of 3 bars in 7 seconds. Concentrate was composed of cereal grain, soybean meal, canola meal, fish meal, urea, wheat bran, beet pulp, bagasse, salt, sodium bicarbonate, mineral and vitamin premix, anionic salt, molasses, sugar, protected fatty acid and Mg oxide (318, 60, 150, 15, 3.6, 250, 33, 40, 6.7, 8.6, 8, 15, 55, 30, 5 and 2.1 g/kg DM, respectively). Four Holstein steers (430±50 kg, BW) fitted with ruminal fistulae and T-shaped intestinal cannulae were used. Steers fed (DM basis) 2.5 kg of alfalfa hay, 2.1 kg of corn silage, 1.5 kg of straw and 2.5 kg of concentrate (170 g CP/kg of DM). Approximately 5 g of sample (DM) was placed in polyester bag (12×19 cm, pore size of 48 µm, n=8), then incubated in the rumen for 12 h. After removal from the rumen, bags were washed and dried. Then, 1 g DM of un-ruminal disappeared sample was weighed into a mobile bag (3×6 cm, pore size of 48 µm, n=8) and inserted in small intestine, then removed from the voided feces and rinsed in cold tap water. DM, EE and CP of intact and incubated samples were determined. Data were analyzed using completely randomized design. Ruminal DM, CP and EE disappearance of fm was significantly (P< 0.01) lower than fp and cp. Ruminal DM, CP and EE disappearance of fp was significantly (P< 0.01) higher than cp (0.71, 0.61 and 0.65 vs. 0.67, 0.58 and 0.59, respectively). Post-ruminal DM, CP and EE disappearance of fm concentrate (0.45, 0.50 and 0.80, respectively) was significantly (P< 0.01) higher compared with fp (0.35, 0.38 and 0.68, respectively) and cp (0.39, 0.38 and 0.57, respectively). Results of the present study indicated that the physical particle size of a mixed concentrate might impact on ruminal and post-ruminal disappearance of DM, CP and EE.

Key Words: Physical Processing, Disappearance, Mobile Nylon Bag

TH210 Comparative effects of whole, reconstituted- rolled, reconstituted-whole, dry-rolled and ground sorghum grain on growth and carcass characteristics in lambs. P. Orozco, R. Lazcano, and L. Corona*, *Universidad Nacional Autónoma de México. Facultad de Medicina Veterinaria y Zootecnia. Departamento de Nutrición Animal y Bioquímica, Cd. Universitaria, D.F., México, 04510.*

A growth trial was conducted to simultaneously evaluate five methods of sorghum processing for sheep. Experimental diets contained 73% sorghum grain. Sorghum processing treatments were as follows: 1) whole sorghum (WS), 2) reconstituted-rolled sorghum (RRS), 3) reconstituted-whole sorghum (RWS), 4) dry-rolled sorghum (DRS) and 5) ground sorghum (GS). RRS and RWS were reconstituted to 30% moisture and ensiled for 30d. Treatments effects on performance were evaluated in a 45-d finishing trial involving 20 Pelibuey ram lambs (33 kg±4.7) housed in individual pens. The experimental design was completely randomized

and data were analyzed using PROC GLM (SAS) with initial BW as a covariable. Lambs fed WS had lower (190 vs. 246g; P< 0.05) ADG, DMI (1.19 vs. 1.33kg; P< 0.05), gain: feed ratio (160 vs. 190g; P< 0.10), hot carcass weight (21.2 vs. 22.7kg; P< 0.05), dressing percentage (49.8 vs. 52.8%; P< 0.01), leg weight (5.6 vs. 5.0 kg; P< 0.10), chest weight (1.3 vs. 1.5kg; P< 0.10) and greater loin weight (2.76 vs. 2.21kg; P< 0.05) than sheep fed RWS. No differences (P> 0.05) between treatments were observed in initial weight, back fat thickness, KPF, LM area and shear force. Animals fed RWS had greater (1.2 vs. 1.1kg; P< 0.05) DMI; hot carcass weight (22.7 vs. 21.5kg, P< 0.05) and leg weight (5.6 vs. 4.8kg, P< 0.001) than lambs fed RRS. Lambs fed WS had lower (P< 0.05) dressing percentage (49.8 vs. 51.5%) and loin weight (2.4 vs. 2.8kg) than animals fed processed sorghum treatments. It is concluded that RWS enhances the growth performance and carcass characteristics in feedlot lambs compared to WS.

TH211 Effects of non-fiber carbohydrates supplementation on some blood metabolites of Holstein steers. F. Rezaii, M. Danesh Mesgaran, A. Heravi Mousavi*, and M. Nasiri, *Ferdowsi University of Mashhad, Mashhad, Iran.*

The aim of this study was to evaluate the effect of diets containing different non-fiber carbohydrates (sucrose or starch) on plasma glucose, urea nitrogen (PUN) and insulin in Holstein steers. Four fistulated Holstein steers (BW=280 ± 15 kg) were assigned to a 4 × 4 Latin Square with 21d periods; 17 days of diet for adjustment and 4 days of sample collection. A basal diet was formulated to be contained of alfalfa hay, barley grain, soybean meal and sugar beet pulp (400, 290, 190 and 50 g/kg, respectively). Starch (St) or sucrose (Su) or a 1:1 mixture of starch and sucrose (St+Su) was added to the basal diet at the rate of 70 g/kg DM. Diets were offered as 2-2.5 times of maintenance requirements (7 kg DM/d). Animals were fed twice daily at 0830 and 1630. Blood samples were collected before (0) and 2, 4, and 6 h after the morning feeding in tube containing heparin and immediately were centrifuged at 3000 rpm for 15 minute. The plasma was analyzed for glucose and PUN using commercial kits in the 0, 2, 4 and 6 h samples. The plasma samples were also analyzed for insulin in the 0 and 4 h samples. The data were analyzed using the MIXED procedure of SAS (2001) for a Latin Square design. The model contained the effects of period, cow, and treatment. Plasma glucose significantly decreased after supplementation diet with the non-fiber carbohydrates (p=0.043; 86, 70, 78 and 76 ± 3.7 mg/dL for control, Su, St and St+Su, respectively). The non-fiber carbohydrate supplementation decreased PUN significantly in compare with the control (p<0.01; 19, 15, 14, 13 ± 0.85 mg/dL for control, Su, St and St+Su, respectively). Plasma concentrations of insulin were similar among the diets (p=0.3). The result of this study demonstrated that sucrose and starch supplementations had significant impact on plasma glucose and PUN.

Key Words: Dairy Cow, Non-Fiber Carbohydrate, Sucrose and Starch

TH212 Ruminal and hindgut *in vitro* fermentation and methane production in concentrate-fed lambs. M. J. Ranilla*, M. L. Tejido, S. Ramos, C. Saro, M. E. Martínez, and M. D. Carro, *Universidad de León, León, Spain*.

The objective of the experiment was to study the *in vitro* fermentation characteristics in the rumen and hindgut of growing lambs fed a concentrate diet. Ruminal and caecal contents were obtained from fifteen concentrate-fed lambs (25 ± 0.4 kg body weight), diluted with buffer solution, and used to inoculate batch cultures containing cellulose or starch as substrates. Cultures were incubated at 39°C for 4 h before measuring the production of volatile fatty acids (VFA), gas and methane. There were substrate \times inocula interactions ($P=0.03$ to <0.001) for all measured variables, except for methane production ($P=0.38$). When starch was incubated with ruminal fluid, total VFA production was higher ($P<0.001$) than that with caecal contents (2883 vs 1860 μmol , respectively), and lower ($P<0.001$) proportions of acetate and butyrate, and greater ($P<0.001$) of propionate were observed. With cellulose as substrate, both total VFA production and acetate/propionate ratio were higher ($P<0.01$) for caecal inoculum than for ruminal fluid (730 vs 328 μmol and 3.76 vs 2.05, respectively). Molar proportions of the main VFA followed the same trend than with starch. For both substrates, gas production was greater ($P<0.001$) in cultures inoculated with ruminal fluid compared to those inoculated with caecal content (2.21 vs 1.13 μmol). Methane production tended ($P=0.09$) to be lower for ruminal inoculum compared to caecal (192 vs 226 μmol , mean values for both substrates), and was greater ($P<0.001$) with starch than with cellulose (360 vs 57.8 μmol). These results were probably due to both the high-concentrate diet fed to lambs which could have negatively affected the growth of ruminal cellulolytic microbes, and the short incubation time, since cellulose degradation rate is lower than that of starch. Methane/VFA ratios were lower ($P=0.03$) for rumen than for caecum (0.116 vs 0.157 mol/mol, mean values for both substrates). The calculated hydrogen recoveries for caecum were lower ($P<0.001$) than those for rumen (0.85 and 0.62, respectively), which would indicate that there are alternative hydrogen sinks in the caecum not appearing in the stoichiometric equation used for calculations.

Key Words: Rumen, Hindgut, Fermentation

TH213 Effect of *Bacillus cereus* var. *toyoi* supplementation on performance, metabolism, and histological morphology of the digestive tract in young Holstein bulls fed a high-concentrate diet. S. Martí¹, A. Bach^{1,2}, and M. Devant^{*1}, ¹*Animal Nutrition, Management, and Welfare Group, IRTA-Unitat de Remugants, Barcelona, Spain*, ²*ICREA, Barcelona, Spain*.

Thirty-two Holstein bulls (initial BW of 383 ± 26.5 kg) were distributed by BW in 8 pens randomly assigned to control (CTR) or *Bacillus cereus* var. *toyoi* ($0.2 \cdot 10^9$ CFU BT per kg concentrate, Toyocerin[®], Rubinum, S.A., Spain, BT) treatments. Animal BW and concentrate and straw consumptions, both offered *ad libitum*, were recorded every 4 wk. At 0, 50, and 91 d of the study at 0800 and at 1500 during four consecutive days (16 animals per day) rumenocenteses were performed and rumen pH was measured immediately. On the same days, blood samples were obtained to determine glucose, insulin, cortisol, lipopolysaccharide binding protein (LBP), and alpha1-acid glycoprotein (AGP) concentrations

analyses. Bulls were slaughtered at day 98 of the study, and rumen, jejunum, and cecum content samples were immediately collected to measure pH, and to determine N-NH₃, and VFA concentrations, and BT counts. Tissue samples from these sections of the GIT (gastrointestinal tract) were collected for the histological analyses. Hot carcass weight was recorded and carcass was graded according to the UE classification system. Treatment did not affect performance, feed consumption, feed efficiency, rumen pH, or serum glucose, insulin, cortisol, LBP, and AGP concentrations. Carcass conformation ($P=0.02$) and fatness ($P=0.14$) improved in BT bulls in contrast to CTR bulls. Jejunum pH tended ($P=0.08$) to be greater in BT bulls (6.84) than CTR bulls (6.61). Rumen molar proportion of butyrate, jejunum villus height and crypt depth were greater ($P=0.02$, 0.01, 0.13, respectively) in BT than in CTR bulls. Although no changes were observed in metabolic hormones, BT supplementation improved carcass conformation and fatness. These improvements might have been related to changes in the post-ruminal GIT but more research is needed to further elucidate the repercussions of BT supplementation in young Holstein bulls.

TH214 Blood cell profiles and plasma concentrations of glucose and cortisol of Nellore steers and bulls selected for low and high residual feed intake before and following a mild stressor. R. C. Gomes^{*1}, M. A. Ballou², R. F. Siqueira¹, T. R. Stella¹, J. A. Negrão¹, R. D. Sainz³, and P. R. Leme¹, ¹*University of São Paulo, Pirassununga, Brazil*, ²*Texas Tech University, Lubbock*, ³*University of California, Davis*.

The objectives were to determine whether Nellore cattle stratified into low and high residual feed intake (RFI) influenced the profiles of red and white blood cells and plasma concentrations of glucose and cortisol before and following a 24 h feed and water deprivation. Twenty-month old Nellore steers ($n=72$, 313 kg initial BW) and bulls ($n=48$, 413 kg initial BW) were fed a finishing ration for 74 days. Cattle were weighed every 21 d, and the lowest and highest RFI steers ($n=7$) and bulls ($n=10$) were stratified. Following stratification, cattle were submitted to 24 h of food and water deprivation. Blood was sampled prior to and following the withdrawal period. Hematological analyses included total and differential white blood cell counts and red blood cell count and morphology. Plasma was analyzed for glucose and cortisol concentrations. Low RFI steers had lower serum cortisol concentrations than high RFI steers (19.4 vs. 21.1 ng/mL; $P<0.04$). The 24 h withdrawal of feed and water did not alter serum cortisol concentrations. Variation in RFI did not influence either plasma glucose concentration or blood cell profiles. There was an interaction between castration and stress on plasma glucose concentrations ($P<0.03$). Glucose concentrations in bulls decreased from 114 to 97 mg/dL before and following deprivation, respectively, whereas it remained unchanged in steers. An interaction was evident between castration and stress on the neutrophil to lymphocyte ratio ($P<0.05$). In bulls, the neutrophil to lymphocyte ratio increased from 0.39 to 0.57 before and following the mild stress, respectively; whereas it was not altered in steers. A 24 h feed and water deprivation was a mild stressor in Nellore bulls only. Low RFI steers had lower cortisol concentrations; suggesting a link between RFI and hypothalamic-pituitary axis.

Key Words: Blood Parameters, *Bos indicus*, Feed Efficiency

TH215 Nutritional assessment of banana (*Musa paradisiaca*) leaves and pseudostems for ruminants. E. González-García^{*2}, O. Cáceres¹, H. Archimède², J. Arece¹, Héctor Santana¹, and Ramón Delgado¹, ¹Estación Experimental de Pastos y Forrajes 'Indio Hatuey', Matanzas, Cuba, ²INRA UR143 Unité de Recherches Zootechniques (URZ), Centre INRA-Antilles-Guyane, Domain Duclos, 97170 Petit Bourg, Guadeloupe (French West Indies).

Banana entire plant is, in practice, one of the most important feed resources available for sustainable animal feeding systems in tropics. However, few data are available about the potential use that ruminants can make from its byproducts. This experiment was conducted in order to determine average chemical composition and to assess the nutritive value of banana leaves and pseudostems for ruminant nutrition. Fresh material was daily obtained and transported from a local banana plantation (nearly allocated to the experimental farm), manually chopped (3-4 cm piece size) and individually distributed into two equilibrated meals: 0800 and 1630. The trial lasted 21 d (14 d adaptation, 7 d data collection). Six adult castrated Pelibuey wethers (BW=33±1.9 kg) were used, randomly housed in individual metabolism crates and the INRA French system of *ad libitum* (10% of refusal from previous day) feed supply and total feces collection was implemented. The DM (20.0 and 6.5%) and CP (142 and 25 g/ kg DM) contents were considered acceptable and low for leaves and stems, respectively. The CF was relatively high (> 21%) in both plant fractions. It was noteworthy the high (2.5 mcals/kg DM) ME of pseudostems; however, its low DM, CP and PDIMN affected voluntary intake, hence indicating that high DM (i.e. rice straw) and CP (i.e. forage legumes) feedstuffs are recommended as accompanying components in the diet. Future research opportunities exist for the optimum use of these highly available feed resources, focusing on basic strategic concepts like level of incorporation, productive purpose (milk?, meat?), physiological stage, among others.

Table 1. Nutritive value of banana

Item	DM, %	CP, g/ kg DM	CF, g/ kg DM	ME, mcal/ kg DM	PDIMN, g/ g DM	PDIME, g/ kg DM	Ca, g/ kg DM	P, g/ kg DM
Leaves	20.0	142	231	2.19	85.8	77.7	14.3	1.7
Pseudostems	6.5	25	205	2.50	11.5	42.2	10.4	2.4

PDIMN, microbial protein to be synthesized from degraded dietary N when energy is not limiting; PDIME, microbial protein synthesized from rumen fermented OM when degraded N is not limiting

Key Words: Banana Plant, Ruminant, Nutritive Value

TH216 The effect of replacing corn with glycerol on rumen fermentation and fiber digestibility. A. A. AbuGhazaleh¹, S. Abo El-Nor², and R. Babu^{*1}, ¹Southern Illinois University, Carbondale, ²Egyptian National Research Center, Cairo, Egypt.

The objective of this study was to evaluate the effect of substituting corn with glycerol on rumen fermentation and feed digestibility under in vitro conditions using continuous fermenters. Four fermenters were used in a 4 × 4 Latin Square design with four 10 d consecutive periods. Treatment diets (60:40 forage to concentrate) were fed at 45 g/d dry matter (DM) in three equal portions. The forage consisted of alfalfa pellets. The grain mix contained corn, SBM, soy hulls, minerals and vitamins. Glycerol replaced corn in the grain mix at 0% (T1; control), 15% (T2), 30% (T3) and 45% (T4). 25% of the overflow was collected

from each fermenter on days 8, 9, and 10 of each period, composited into one sample, freeze dried, and then analyzed for chemical composition. On day 10 of each period, rumen samples were collected from each fermenter at 3 and 6 hr after the morning feeding and analyzed for volatile fatty acid (VFA). Rumen acetate (43.44, 39.50, 37.83 and 33.86 mole/100 mole for T1 to T4, respectively) decreased ($P < 0.10$) while rumen butyrate (21.11, 24.96, 26.01 and 26.96 mole/100 mole for T1 to T4, respectively) increased ($P < 0.10$) with glycerol diets when compared with control. Acetate to propionate ratios (1.67, 1.60, 1.40 and 1.22) decreased ($P < 0.10$) only with T3 and T4 when compared with control. Rumen propionate, total VFA, and pH were not affected ($P > 0.10$) by treatment diets. NDF (38.63, 38.86, 33.41 and 31.88 % for T1 to T4, respectively) and ADF (29.50, 29.81, 24.61 and 25.05 % for T1 to T4, respectively) digestibility were lower ($P < 0.10$) with T3 and T4 when compared with control. In conclusion, glycerol could be used to replace corn in ruminant animals' diet at 15% without adversely affecting fiber digestibility. Substituting glycerol at 30 or 45% adversely affected rumen fiber digestion negatively impacting acetate production.

Key Words: Glycerol, VFA, Digestibility

TH217 Effects of replacing barley with corn grain in finishing diets on blood and rumen metabolites of Holstein male calves. F. Fatehi, K. Reza-Yazdi, M. Dehghan-Banadaky^{*}, M. Moradi-Shahrabak, and H. Bahrami, *Tehran University, Karaj, Tehran, Iran.*

Twenty five Holstein Male calves (body weight: 276±79 kg) were used to determine the effects of five different ratios of barley to corn grain (100:0, 25:75, 50:50, 75:25, 0:100) in finishing diets on blood metabolites and rumen parameters for 110 days. Calves were allotted by weight to 5 groups and used in a completely randomized design. Blood and rumen liquor were sampled every 30 days. There were no differences among concentration of blood Beta hydroxyl butyrate (BHBA), cholesterol, total protein, Ca, P and AST of calves. But calves fed diets with ratio of 0:100 and 25:75 (high corn) had significantly higher concentration of blood glucose and insulin and lower blood urea nitrogen (BUN) than other diets. Calves fed diets with ratio of 75:25 and 100:0 (high barley) had more blood concentration of non esterified fatty acids (NEFA) than other calves ($P < 0.05$). There were no differences among calves in rumen ammonia nitrogen concentration, but calves fed the diet with a ratio of 100:0 had lower rumen pH compared with the other calves ($P < 0.05$). Varying the ratio of barley and corn can impact blood and rumen metabolites in calves.

Key Words: Barley, Corn, Calves

TH218 Nutritional and growth patterns of Nellore bulls, steers and heifers, fed diets containing two concentrate allowance levels. P. V. R. Paulino^{*1}, S. de C. Valadares Filho¹, M. A. Fonseca¹, M. I. Marcondes¹, E. Detmann¹, N. K. de P. Souza¹, and R. D. Sainz¹, ¹Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, ²University of California, Davis.

The objective in this work was to assess the effects of gender and concentrate allowance level (0.6 and 1.2% of body weight, BW) on performance, intake, digestibility and body and carcass composition of Nellore cattle. Thirty five animals (12 bulls, 11 steers and 12 heif-

ers) from a same contemporary group were used, being individually fed during 112 days and slaughtered at the end of the trial. The diets had 12% CP, and were corn silage based. The bulls were more efficient and had heavier ($P<0.05$) BW, empty body weight (EBW) and carcass weight, as a result of their increased rate of growth in comparison with the heifers ($P<0.05$). Dry matter and nutrients intakes were superior in the heifers ($P<0.05$) when compared with the bulls, whereas the steers had intermediate values. The digestibilities of all the nutrients, except EE, were not affected by gender ($P>0.05$). Only DM and OM digestibilities were affected by concentrate allowance levels, being greater ($P<0.05$) for the diet in which the concentrate allowance was 1.2% of the BW. Bull's carcasses were heavier and leaner ($P<0.05$) than the heifer's, with steer carcasses obtaining intermediate values. The subcutaneous depot of fat in the heifers was more pronounced than that of the males ($P<0.05$). Visceral and subcutaneous fat in the EBW (%) were greater for the heifers ($P<0.05$), although the rates of fat deposition in the different body depots were not influenced by gender ($P>0.05$). Concentrate allowance level did not affect ($P>0.05$) carcass traits and body and carcass composition of the animals. Protein and ether extract contents of the EBW of the bulls were, respectively, greater and smaller ($P<0.05$), than that of the heifers, with the steers presenting intermediate values. The bulls had more pronounced accretion rates ($P<0.05$) of muscle in the carcass and protein in the EBW than the heifers and steers. The carcass yield of commercial cuts was not affected by concentrate allowance levels ($P>0.05$), but by gender ($P<0.05$). Heifers and steers had higher yields of hind quarter ($P<0.05$) than the bulls, which had fore quarters more developed.

Key Words: Beef Cattle, Performance, Digestibility

TH219 Polynomial regression between ruminal bacteria population and pH in beef steers fed high forage diets. S. J. Liu, J. Q. Wang*, D. P. Bu, S. Liang, L. liu, H. Y. Wei, L. Y. Zhou, and K. L. Liu, *Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of this study was to evaluate regressive relationship between population of ruminal *F. succinogenes*, *B. fibrisolvans*, *R. albus* bacteria and ruminal fermentation parameters including pH value and volatile fatty acids (VFA). Four steers with ruminal cannulas were fed a high forage diets (forage to concentrate ratio 65:35). Ruminal fluid was collected on d 26, 27 and 28 of experimental period, starting at 0730 pre-feeding and at 1130 and 1730 post-feeding from the anterior, dorsal, and mid-ventral region of the rumen and pooled. Subsequently, this mixture was filtered through four layers of sterile cheesecloth, and immediately stored at -70 degrees C. Residual ruminal fluid was used to determine pH at sampling. A 100 mL sample of residual ruminal fluid was analyzed for VFA. Bacteria population was determined by real-time quantity PCR method. All data were analyzed using the MIXED procedure of SAS 8.2, and regression analysis adopted the polynomial regression procedure of SAS 8.2. Significance was declared at $P < 0.05$.

Steers fed high forage diet had no significant change relative to time in rumen acetate, propionate and the ratio of acetate to propionate, while pH significantly decreased over time ($P<0.05$). Our study showed that there existed a polynomial regression between the sum of *F. succinogenes*, *B. fibrisolvans*, *R. albus* number and rumen pH ($y = 397.89421 + 124.9846x + 9.35447x^2$; $R^2=0.55$, $P<0.05$). The relationship between *F. succinogenes*, *B. fibrisolvans*, and *R. albus* population and ratio of propionate to acetate and butyrate content was not strong ($R^2=0.29$, $P>0.05$). These results indicate that pH value is a sensitive index to reflect change of ruminal bacteria population compared with VFA.

TH220 Effect of substitution barley grain with dried sugar beet pulp on venous blood gas of Holstein steers. M. Mojtahedi, M. Danesh Mesgaran*, A. Heravi Moussavi, and A. Tahmasebi, *Ferdowsi University of Mashhad, Mashhad, Iran.*

The objective of the present experiment was to evaluate the effect of substitution of barley grain with dried sugar beet pulp (SBP) on venous blood gas (VBG) of Holstein steers. Four Holstein steers with initial body weight of 368 ± 8 kg fitted with ruminal fistulae were used in a 4x4 Latin square design (28 days of each period). Basal experimental diet consisted of 15% corn silage, 20% alfalfa hay, 33% barley grain, 17% soybean meal, 13.8% wheat bran, 0.5% calcium carbonate, 0.2% salt, and 0.5% mineral and vitamin premix on dry matter basis. Barley grain was substituted with SBP as 0.0%, 33%, 66% or 100% (SBP0, SBP33, SBP66, and SBP100, respectively). Steers were fed 9.5 kg of DM as total mixed ration twice daily at 0800 and 1600 h. At the last day of each experimental period, blood samples were taken from Jugular vein after 4 h the morning feeding. Samples were immediately analyzed using Stat Profile pHox Plus blood analyzer (Nova Biomedical, USA) for pH, CO₂ pressure (pCO₂), O₂ pressure (pO₂), oxygen saturation (O₂Ct), base excess of extracellular fluid (BE_{ecf}), base excess of blood (BE_b), bicarbonate (HCO₃⁻), total carbon dioxide (TCO₂), and total hemoglobin (Hb). Data were analyzed using the GLM procedure of SAS ($Y = \text{Mean} + \text{Treatment} + \text{Animal} + \text{Period} + \text{residual}$) and the means compared by the Duncan test ($P < 0.05$). There were no significant differences ($P > 0.05$) between treatments in any of the blood biochemical parameters studied. Means of pH, pCO₂, pO₂, O₂Ct, BE_{ecf}, BE_b, HCO₃⁻, TCO₂, and Hb were 7.335, 47.28 mmHg, 29.08 mmHg, 6.53 ml/dl, -0.56 mmol/L, 0.26 mmol/L, 25.47 mmol/L, 26.94 mmol/L, and 8.97 g/dl, respectively. Results of the present study demonstrated that partial substitution of barley grain with sugar beet pulp in Holstein steers did not significantly affect blood pH and VBG values.

Key Words: Sugar Beet Pulp, Venous Blood Gas, Steers

TH221 Ruminal, fecal and urine pH of Holstein steers fed diets containing barley grain and(or) sugar beet pulp. M. Mojtahedi, M. Danesh Mesgaran*, A. Heravi Moussavi, and A. Tahmasebi, *Ferdowsi University of Mashhad, Mashhad, Iran.*

The aim of this study was to investigate the effect of diets containing barley grain and/or dried sugar beet pulp (SBP) on ruminal, fecal and urine pH of Holstein steers. Four Holstein steers with initial body weight of 368 ± 8 kg fitted with ruminal fistulae were used in a 4x4 Latin square design (28 days of each period). Basal experimental diet consisted of 15% corn silage, 20% alfalfa hay, 33% barley grain, 17% soybean meal, 13.8% wheat bran, 0.5% calcium carbonate, 0.2% salt, and 0.5% mineral and vitamin premix on dry matter basis. Barley grain was substituted with SBP as 0%, 33%, 66% or 100% (SBP0, SBP33, SBP66, and SBP100, respectively). Steers were fed 9.5 kg of diet DM as total mixed ration twice daily at 0800 and 1600 h. At day 25 of each experimental period, rumen fluid samples were collected, by suction,

before the morning feeding and during 8 hours post feeding (every 30 minute). Fecal and urine samples were collected during the last 7 d of each period. Sample pH was immediately recorded using a portable pH meter (Metrohm 744). Data were analyzed using the GLM procedure of SAS ($Y = \text{Mean} + \text{Treatment} + \text{Animal} + \text{Period} + \text{Time} + \text{Time} \times \text{Treatment} + \text{residual}$) and the means compared by the Duncan test ($P < 0.05$). Mean rumen pH was improved by inclusion of SBP in the diets ($P < 0.05$). Rumen pH for SBP0, SBP66, SBP100, and SBP33 was 6.22, 6.35, 6.36, and 6.49, respectively (SEM= 0.02). Fecal pH of steers fed SBP66 (7.01) and SBP100 (6.93) was significantly higher than SBP0 (6.65) ($P < 0.05$). Additionally urine pH of steers fed SBP66 (8.28) and SBP33 (8.14) was markedly higher compared with those fed SBP0 (7.83) ($P < 0.05$). Results from this study suggested that the inclusion of sugar beet pulp might improve ruminal, fecal and urine pH of Holstein steers fed high level of concentrate.

Key Words: Sugar Beet Pulp, pH, Steers

TH222 Feedlot performance, carcass traits and meat tenderness of *Bos indicus* type bullocks fed high concentrate diets. T. de O. Cucki¹, M. D. B. Arrigoni¹, C. L. Martins¹, L. A. L. Chardulo¹, A. C. Silveira¹, H. N. de Oliveira¹, R. da C. Cervieri¹, D. D. Millen¹, R. D. L. Pacheco^{*1}, S. R. Baldin¹, J. P. S. T. Bastos¹, T. M. Mariani¹, L. M. N. Sarti¹, R. S. Barducci¹, T. C. B. de Silva², ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²Faculdade de Zootecnia/UNESP, Dracena, São Paulo, Brazil.

This study, conducted at São Paulo State University (UNESP) feedlot, Botucatu Campus, Brazil, was designed to evaluate the effect of *Bos indicus* breeds on performance, carcass traits and meat tenderness of bullocks fed high concentrate diet. It was used 96 8-mo-old bullocks (279.9±24.5 kg) of four *Bos indicus* based types (BT): 24 BNA (1/2 Brahman, 1/4 Nellore, 1/4 Angus), 24 PNA (1/2 Braunvieh, 1/4 Nellore, 1/4 Angus), 24 Brangus (5/8 Angus, 3/8 Brahman (BR)) and 24 Nellore (NE). BNA, PNA and BR were fed for 120 days, but NE was 184 days on feed. Rib eye area (REA) and back fat thickness (BFT) were taken by ultrasound. Meat samples were harvested between 12th and 13th ribs for shear force (SF), miofibrillar fragmentation index (MFI) and total lipids (TLIP) analysis. PNA and BR presented greater ($P < 0.05$) average daily gain in kilos (ADG) than BNA and NE (PNA=1.47, BR=1.52, BNA=1.28, NE=1.11). PNA, BR and BNA presented better ($P < 0.01$) feed conversion than NE (PNA=5.54, BR=5.35, BNA=5.43, NE=6.71). PNA and BR had greater ($P < 0.05$) dry matter intake (DMI) in kilos than BNA, but NE did not differ ($P > 0.05$) between BT (PNA=8.11, BR=8.14, BNA=6.98, NE=7.46). When analyzed as percentage of BW, PNA, BR and NE consumed ($P < 0.05$) more feed than BNA (PNA=2.14, BR=2.21, BNA=1.82, NE=2.15). NE presented heavier ($P < 0.05$) hot carcass weight in kilos than BR, but PNA and BNA did not differ between BT (PNA=250.04, BR=245.64, BNA=248.01, NE=252.48). No differences were observed ($P > 0.05$) for dressing percentage (PNA=53.45, BR=53.33, BNA=53.97, NE=56.11) and BFT in millimeters (PNA=5.06, BR=5.14, BNA=5.17, NE=5.05), but NE presented larger ($P < 0.05$) REA in cm² than PNA, BNA and BR (PNA=70.10, BR=72.65, BNA=69.10, NE=75.30). SF in kilograms (PNA=3.48, BR=3.15, BNA=3.75, NE=3.30), MFI (PNA=86.11, BR=78.41, BNA=69.80, NE=73.36) and TLIP in percentage (PNA=1.65, BR=1.65, BNA=1.85, NE=1.99) did not show differences ($P > 0.05$) between BT. Even presenting smaller REA, PNA and BR performed better than NE and BNA, but no effects on meat tenderness and fat deposition were observed.

Key Words: Carcass Traits, Feedlot, Performance

TH223 Frothy bloat-related shifts in the ruminal bacterial population in steers fed Bermuda grass hay and grazing wheat forage. W. E. Pinchak^{*1}, B. R. Min^{1,3}, C. Hernandez², and M. E. Hume², ¹Texas AgriLife Research, Vernon, TX, ²USDA-ARS, Southern Plains Agricultural Research Center, Food and Feed Safety Research Unit, College Station, TX, ³Ichthus Education Center, La Trinitaria, Chiapas, Mexico.

Seven strains of ruminal bacteria (*Streptococcus bovis* strain 26, *Prevotella ruminicola* strain 23, *Eubacterium ruminantium* B1C23, *Fibrobacter succinogenes* ssp. S85, *Ruminococcus flavefaciens* C94, *Selenomonas ruminantium*, and *Ruminobacter amylophilus*) were used to determine the relationships of select individual bacterial populations associated with changes in diet (Bermuda grass hay vs. wheat forage) and bloat severity on individual bacterial populations in the rumen of steers grazing wheat forage. Twelve ruminally cannulated steers grazing wheat forage for 70 day were used to evaluate the influence of bloat on the ruminal microbial biodiversity patterns. Steers were classified as non-bloat and bloat prone post-hoc after bloat was manifested and the classification applied retrospectively. The bacterial DNA density was greatest for *R. flavefaciens*, *S. bovis*, and *E. ruminantium* among tested strains when steers fed Bermuda grass hay (day 0). Steers grazed wheat forage for 50 days prior to the peak bloat period (day 50) resulted decreased density of six bacterial populations in non-bloated steers rumen fluid, but increased the bacterial density of 6 major rumen bacterial populations in bloated steers, indicating that frothy bloat may be associated with species-specific bacterial population. Steers grazed wheat forage over 70 days increased the density of *S. bovis* and *P. ruminicola* bacterial populations in non-bloated steers rumen fluid. The data collectively suggest that ruminal bacterial populations changed when steers experienced frothy bloat.

Key Words: Ruminal Bacteria, Frothy Bloat, Forages

TH224 Beef heifers performance fed with different forage sources. G. R. Siqueira^{2,1}, R. A. Reis^{*1,4}, R. P. Schocken-Iturrino^{1,4}, F. Dutra de Resende², T. T. Berchielli^{1,4}, M. de Toledo Piza Roth^{1,4}, and A. P. de Toledo Piza Roth^{1,3}, ¹São Paulo State University, Jaboticabal, São Paulo, Brazil, ²APTA Regional de Colina, Colina, São Paulo, Brazil, ³Fundaç o de Amparo Pesquisa do Estado de São Paulo, São Paulo, São Paulo, Brazil, ⁴Conselho Nacional de Desenvolvimento Científico e Tecnológico, Brasilia, Distrito Federal, Brazil.

This research aimed to evaluate the Nellore x Angus beef heifers performance fed with different forage: in nature sugar cane (*Sacharum officinarum* L)- ISC, and different silage: corn (CS), in natura sugar cane (ISCS), ISCS plus *Lactobacillus buchneri* NCIMB 40788 -LB (ISCS-LB), burned sugar cane (BSCS), and BSCS plus LB (BSCS-LB). On the CS, and sugar cane (in natura, or silage) diets it were utilized, respectively 44%, and 37% of forage. Total mixed ration content 70.0% TDN, and 13.5% protein was used on the experiment. The trial was conducted during 127 days, using 54 beef heifers 12 months old, distributed in six treatments. The data were analyzed according a randomized block design with nine replications. Burned sugar cane silage showed highest DM losses (47.3%), compared to the ISCS (33.4%). LB reduced the DM losses of the BSCS in 11 unities. The DM intake (Table 1) were highest in CS treatment (7.36a) compared to the silage ISCS (6.32 bc), ISCS-LB (6.56 bc), BSCS (6.23 c). On the other hand, the intake, expressed like % BW (Table 1), showed highest values on the CS (2.62 a), ISC (2.45 ab), and BSCS-LB (2.45 ab). The data related

to the daily weight, and feed efficiency, showed that CS (0.865 kg/day, 9.00 kg/kg WG) can be replaced by ISC (0.874 kg/day, 8.30 kg/kg WG), or sugar cane silage (0.910 kg/day, 7.80 kg/kg WG). However, burned sugar cane silage need to LB to avoid dry matter, and nutritive values losses, consequently intake reduction.

Table 1. Dry matter intake-DMI (kg/day), intake in relation to body weight (%BW), daily gain (ADG), and feed efficiency (FE- kg/kg of weight gain) of the heifers

	Forage ¹						se	P≤F
	CS	ISC	ISCS	ISCSLB	BSCS	BSCSLB

TH225 Effects of hay restriction with additional co-product supplementation on cow and calf performance and hay disappearance during a winter feeding program. A. Brauch*, J. Sexton, B. Wiegand, M. Kerley, D. Wilson, D. Mallory, H. Smith, M. Ellersieck, and J. Williams, *University of Missouri, Columbia*.

Fifty-six fall-calving Angus and Angus-Simmental cows (initial BW 525.1 ± 9.4 kg) with calves were used to determine the effects of limiting time of access to round bales of hay on cow and calf performance and hay disappearance. Average quality hay (8.1% CP; 55.7% TDN) was provided either ad libitum (24-h/d access) or was restricted to 8 h/d. Cows provided with ad libitum access to hay were supplemented with 1.8 kg•hd⁻¹•d⁻¹ of dried distillers' grains with solubles (DDGS) for early lactation and 1.5 kg•hd⁻¹•d⁻¹ of DDGS for mid lactation. Cows provided with restricted access to hay were supplemented with the same amount of DDGS plus 2.7 kg•hd⁻¹•d⁻¹ and 2.3 kg•hd⁻¹•d⁻¹ of soy hull pellets for early and mid lactation, respectively. Cows were assigned to one of eight 0.8-hectare paddocks of grazed tall fescue based on BW, body condition score (BCS), days postpartum (DPP), and parity. This resulted in seven cow-calf pairs per paddock and four paddocks per treatment. Adequate bunk space was provided in each paddock. Electric fencing was used to restrict access to hay from 4:00 PM until 8:00 AM the following morning. Initial results indicate that BW was not affected by treatment ($P>0.92$), nor was back fat ($P>0.14$). Cows receiving ad libitum access to hay showed a trend to maintain greater BCS ($P<0.07$) than cows with limited access. Calf BW and ADG were not affected by treatment ($P>0.18$ and $P>0.29$, respectively). Hay disappearance decreased ($P<0.0001$) when time of access was limited. These results indicate that limiting time of access to hay and providing additional co-product supplementation is an acceptable method for wintering beef cows and for extending hay reserves.

Key Words: Beef Cows, Hay Restriction, Co-Products

TH226 Effects of corn processing method on performance and carcass characteristics of finishing beef cattle fed diets containing sorghum wet distiller's grains plus solubles. J. Leibovich*, J. T. Vasconcelos, J. P. McMeniman, K. E. Hales, R. R. Reuter, R. J. Rathmann, and M. L. Galyean, *Texas Tech University, Lubbock, TX*.

One hundred and sixty crossbred steers (BW = 397.6 kg) were used in a finishing experiment to evaluate the effects of corn processing method on performance and carcass characteristics in diets containing sorghum wet distiller's grains plus solubles (SWDGS). Treatments were: (1) a dry-rolled corn (DRC)-based diet with no inclusion of SWDGS (DRC-0); (2) a DRC-based diet with inclusion of 15% (DM basis) SWDGS (DRC-15); (3) a steam-flaked corn (SFC)-based diet with 0% SWDGS (SFC-0); and (4) a SFC-based diet with 15% SWDGS (SFC-15). All diets were formulated to contain 14.5% CP and equal concentrations of fat. No significant interactions ($P \geq 0.20$) were noted for performance and carcass characteristics, except for marbling score and % of carcasses grading Choice or greater. The ADG by steers fed the DRC-based diets did not differ ($P = 0.72$) from that of steers fed SFC-based diets, but DMI was greater with DRC-based diets, resulting in lower ($P < 0.01$) G:F with DRC-based diets. Steers fed SFC-based diets had greater fat thickness at the 12th rib ($P = 0.03$), greater yield grade ($P = 0.02$), and a smaller LM area ($P = 0.08$) than steers fed the DRC-based diets. Inclusion of 15% SWDGS resulted in lower ADG ($P < 0.01$) and G:F ($P < 0.01$) compared with diets that did not contain SWDGS. In addition, steers fed SWDGS had lower HCW ($P = 0.01$) and dressing percent ($P = 0.03$) than those fed 0% SWDGS. Marbling score was less ($P < 0.06$) for cattle fed the SFC-0 diets than for those fed the DRC-0 and SFC-15 diets. Percentage of steers that graded Choice or greater was less ($P = 0.06$) for SFC-0 than for DRC-0. Results suggest that the response to 15% (DM basis) SWDGS in finishing diets was not affected by corn processing method. The inclusion of 15% SWDGS decreased G:F to approximately the same extent as replacing SFC with DRC.

TH227 Feeding behavior of feedlot cattle from different breed types fed high concentrate diets with different NDF levels. L. M. N. Sarti^{1,3}, M. D. B. Arrigoni¹, C. L. Martins¹, D. D. Millen¹, R. D. L. Pacheco^{*1}, S. A. Matsuhara¹, M. Parrili¹, M. V. Fossa¹, J. P. S. T. Bastos¹, T. M. Mariani¹, R. S. Barducci¹, T. C. B. da Silva², L. F. S. Niero¹, S. R. Baldin¹, H. N. de Oliveira¹, ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²Faculdade de Zootecnia/UNESP, Dracena, São Paulo, Brazil, ³Apoio FAPESP.

The objective was to evaluate the feeding behavior of feedlot cattle from different breed types (BT) fed high concentrate diets with different NDF levels. The experiment was conducted at the experimental feedlot of the Veterinary Medicine and Animal Science College, São Paulo State University, Botucatu campus (UNESP), Brazil. Twelve bullocks, weaned at 8 months of age (258.4±32.7 kg) were randomly assigned according to BT: 4 Nellore (NE), 4 Three-way-cross (1/2 Braunvieh, 1/4 Angus, 1/4 NE (TC)) and 4 Canchim (5/8 Charolais, 1/4 NE (CC)) evaluated in four different diets (DD) containing different levels of concentrate and NDF (Concentrate (%) = 58 (DD1), 73 (DD2), 82 (DD3) and 85 (DD4); NDF (%) = 38.1 (DD1), 30.9 (DD2), 27.7

(DD3) and 23.0 (DD4); respectively) constituting a split plot design. Visual appraisal was used each 5 minutes during 24 hours to collect feeding behavior data as follows: eating time (ET), ruminating time (RT) and idle time (IT) expressed in minutes. ET decreased ($P < 0.05$) in DD4 when compared to the others diets evaluated (DD1=202.08, DD2=207.50, DD3=181.25, DD4=135.00). BT effect was found, where TC presented ($P < 0.05$) shorter ET (151.87) than NE (198.44) and CC (194.06). There was not interaction between BT and DD for ET. RT decreased ($P < 0.05$) in DD4 when compared to the others diets evaluated (DD1=454.58, DD2=415.42, DD3=385.83, DD4=310.42). There was not a BT effect ($P > 0.05$), but an interaction was found ($P < 0.05$) between BT and DD for RT, where a linear decrease was presented for CC (DD1=438.75, DD2=432.50, DD3=410.00, DD4=321.25) and TC (DD1=505.00, DD2=446.25, DD3=378.75, DD4=263.75). There were not DD and BT effects for IT, but an interaction was found ($P < 0.05$), where TC, CC and NE presented longer IT in DD4 (TC – DD1=740.00, DD2=811.25, DD3=880.00, DD4=1022.50; CC – DD1=788.75, DD2=756.25, DD3=788.75, DD4=957.50; NE – DD1=742.50, DD2=831.25, DD3=895.00, DD4=943.75). Bullocks fed high concentrate diets presented shorter ET and RT and longer IT as levels of NDF in diet decreased. TC showed shorter ET than CC and NE during the study, but no differences in RT and IT were found.

Key Words: Behavior, NDF

TH228 Dietary inclusion of crude glycerol changes beef steer growth performance and intramuscular fat deposition. B. A. Verse-
mann*, B. R. Wiegand, M. S. Kerley, J. H. Porter, K. S. Roberts, and
H. L. Evans, *University of Missouri, Columbia.*

The objective of this study was to assess the optimum and maximum levels of crude glycerol for inclusion in beef cattle feedlot diets. Crude glycerol sourced from a biodiesel production facility was included at graded levels in feedlot diets of crossbred steers ($n=72$). Steers (225kg) were randomly assigned in pens of 6 steers each to one of four experimental diets. Diets were formulated to include 0, 5, 10, or 20% glycerol. Glycerol replaced corn at 0, 10, 20 or 40%. Each diet combination was replicated three times. Body weights were recorded at the start, finish, and on 21d intervals throughout the experiment. Calves were fed once daily following a clean-bunk protocol. Pen was the experimental unit. Growth performance data including ADG, feed intake, and feed efficiency were recorded. Steers were humanely slaughtered after reaching an average live weight of 537 ± 12 kg and an average 12th rib fat depth (as determined by ultrasound) of 1.18 ± 0.13 cm. Carcass data was collected and yield and quality grades were determined. Data analysis resulted in a quadratic effect for ADG with 1.34, 1.39, 1.43, and 1.20 kg (SEM = 0.059) for 0, 5, 10, and 20% glycerol, respectively. Feed intake was not significantly affected across the treatment groups. However, in assessing contrasts for gain to feed, significance ($P < 0.02$) was observed between 10% glycerol and control with 0.15 and 0.16 (SEM=0.005), respectively. Furthermore, feed efficiency tended to improve ($P < 0.08$) when glycerol and control diets were compared (0.150 and 0.163, respectively). Efficiency also tended ($P < 0.06$) to follow a quadratic response with 0.15, 0.16, 0.17, and 0.16 for 0, 5, 10, and 20% glycerol, respectively. Intramuscular fat as evaluated by marbling score was different ($P = 0.04$) and measured 522, 503, 562, and 458 (SEM = 27.4) for 0, 5, 10, and 20% glycerol diets, respectively. No other carcass characteristics differed among treatment groups. Feeding glycerol to

beef finishing steers seems to be optimized at 10% dietary inclusion when considering the combination of feed efficiency improvement and intramuscular fat deposition.

Key Words: Glycerol, Beef Cattle, Feed Efficiency

TH229 Supplementation programs for wheat straw-based wintering cow programs. K. M. Wood*, I. B. Mandell, and K. C. Swanson, *University of Guelph, Guelph, ON, Canada.*

Fifty-three individually-fed, multiparous crossbred beef cows were used to investigate feeding of free-choice haylage or use of supplemental haylage, soybean meal, or dried corn distiller's grains plus solubles on performance of dry pregnant cows fed wheat straw-based diets. Cows were randomly assigned to 1 of 5 dietary treatments: free choice haylage ($n=7$; hayFC), haylage offered at 1% of bodyweight (BW) plus free choice access to straw ($n=12$; haycon), haylage offered at 0.5% BW plus free choice access to straw ($n=11$; hayneg), haylage offered at 0.5% BW plus soybean meal and free choice access to straw ($n=12$; SBM), haylage offered at 0.5% BW plus corn dried distiller's grains and free choice access to straw ($n=11$; DDGS). The supplement in SBM and DDGS treatments was included to make the non-straw component isonitrogenous to the non-straw component of haycon. Cows were fed for 16 weeks leading up to parturition. Data were analyzed using Proc mixed in SAS and treatments compared using a Tukey-Kramer test. Parity and pen were included as covariates in the model. There were no significant differences ($P > 0.05$) between treatment groups for changes in backfat, intramuscular fat, plasma urea nitrogen, and glucose between week 0 and week 16. Cows on hayneg had lower ($P < 0.05$) average daily gain (ADG) than all other treatment groups. Cows fed haycon also had lower ($P < 0.05$) ADG than DDGS and hayFC. Change in body condition score was greater in hayFC than hayneg ($P=0.036$). Cows on hayFC had a lower ($P < 0.05$) total dry matter intake than other treatments. Straw intake was significantly ($P < 0.05$) lower for haycon compared to other treatments, and also was lower ($P < 0.05$) for hayneg than SBM. This data indicates that feeding wheat straw-based diets supplemented with haylage, SBM, or DDGS may be an acceptable alternative to minimize winter feed costs without negatively affecting cow performance.

Key Words: Winter Feeding, Beef Cows, Straw

TH230 Effect of n-3 PUFA supplementation on embryo recovery rate, quality and gene expression in beef heifers. S. Childs^{1,2}, F. Carter², C. O. Lynch^{1,2}, J. M. Sreenan¹, P. Lonergan², A. A. Hennessy³, and D. A. Kenny², ¹Teagasc Production Research Centre, Athenry, Co. Galway, Ireland, ²University College Dublin, Belfield, Dublin, Ireland, ³Teagasc Food Research Centre, Moorepark, Fermoy, Co. Cork, Ireland.

The objective was to examine the effect of dietary n-3 polyunsaturated fatty acids (PUFA) on embryo development and gene expression in cattle. Heifers ($n=36$) were individually fed barley straw and concentrate containing a partially rumen-protected source of either (i) palmitic acid (CON), or (ii) n-3 PUFA (n-3 PUFA; 140g of EPA and DHA combined). Diets were isolipid and isonitrogenous and fed for 50 days. Superovulation was induced using FSH, embryos were recovered on

day 7 post AI (day 50) and graded according to IETS guidelines. Grade 1 morula and blastocysts were snap frozen in liquid N₂ and stored for gene expression analysis. Plasma and uterine flushings were collected for fatty acid analysis. Fatty acid methyl esters were separated by gas chromatography. Gene expression was assessed by Q-RT-PCR and quantified using the comparative Ct method for six genes involved in embryo development and/or lipid metabolism: BAX, LIF, Cx43, E-CAD, PPAR- α and PPAR- δ . Data were analysed using the MIXED and GENMOD procedures of SAS. Fold Δ values in gene expression were analyzed using the student's t-test. Dietary n-3 PUFA increased ($P < 0.001$) plasma concentrations of EPA and DHA. Similarly, dietary n-3 PUFA increased EPA ($P < 0.001$) and reduced arachidonic acid ($P < 0.05$) concentration in uterine fluid. The number of degenerate embryo recovered ($P < 0.05$) was lower on n-3 PUFA but diet did not affect embryo recovery or embryo quality ($P > 0.05$). Moreover, there was no effect of diet ($P > 0.05$) on expression of any of the genes analysed. Increased uterine n-3 PUFA and reduced arachidonic acid may lead to a more luteotrophic uterine environment; however, with the exception of a reduction in degenerate embryo numbers, there was no further evidence of an effect on embryo quality or gene expression. Results suggest that any effect of dietary n-3 PUFA on cattle fertility is not mediated through a direct effect on the embryo *per se*.

Key Words: n-3 PUFA, Embryo Quality, Gene Expression

TH231 Qualitative aspects of the carcass and meat of Nellore cattle fed diet with different levels of fat. J. Duarte Messana^{*1}, T. T. Berchielli¹, R. Carrilho Canesin¹, A. Ferreira Ribeiro¹, P. Braga Arcuri², and P. Moura Dian¹, ¹Faculdade de Ciências Agrárias e Veterinárias / UNESP- Campus Jaboticabal, Jaboticabal, São Paulo, Brazil, ²CNPGL/ Embrapa, Juiz de Fora, Minas Gerais, Brazil.

With the objective to evaluate the carcass and the meat qualitative characteristics of Nellore steer, fed diet with different levels of fat, eighteen males were used, castrated, with average weight 320 kg in the completely randomized design. The animals were fed on feedlot during 84 days with diets with different levels of fat (3%, 5% and 7%). The steers were slaughtered weighting 480 kg. After 24 hours chilling the carcass dressing percentage (CDP), rib eye area (REA) and fat thickness (FT) were determined. Two samples of Longissimus dorsi this muscle were collected, of which analyzed for shear force (SF), total cooking loss (TCL), water holding capacity (WHC) determination and sensory evaluation. The results showed that, there were not significant differences ($P > 0.05$) for CDP, REA, FT, SF, TCL WHC. However the treatment with higher levels of fat (7%) showed higher meat tenderness, measured by the taste panel (7,51 vs. 6,64 points) as compared to treatment with 3% of fat, and of better flavor were observed in the steer meat which received diet with 5% of fat. There were differences significant, in the accept global of meat, of animals feeding with 3% of fat as compared to received diets with 5% and 7% of fat. The results show that higher tenderness, flavor and overall palatability meat can be function of higher levels fat of diet.

Table 1. Means value and coefficients of variance (CV) of CDP, RA, SFT, SF, WHC, TCL, F, T, AGM

	Treatment			CV

TH232 Effects of glycerin supplementation on performance and meat quality of young Holstein bulls fed high-concentrate diets. N. Mach^{*1}, A. Bach^{1,2}, and M. Devant¹, ¹Animal Nutrition, Management, and Welfare Group, IRTA-Unitat de Remugants, Barcelona, Spain, ²ICREA, Barcelona, Spain.

Forty-eight bulls (335 \pm 29 kg initial BW) were randomly assigned to 4 glycerin levels (0, 4, 8, and 12% of concentrate DM) with the objective of evaluating the effects of glycerin on performance, ruminal fermentation, metabolism, and carcass and meat quality in young Holstein bulls fed high-concentrate diets. Concentrates were isonitrogenous and formulated to be isocaloric (assuming a glycerin ME content of 3.38 Mcal/kg of DM). Concentrate and straw were fed ad libitum. Animal BW and feed consumption were recorded monthly. Additionally, rumen and blood samples were collected every month. Bulls were slaughtered after 91 d of study (464 \pm 40 kg final BW). A rumen mucosa was excised, and HCW, carcass backfat, and conformation were recorded. The area, Warner-Bratzler Shear Force, and i.m. fat content of LM were determined. Glycerin level did not affect daily concentrate intake (7.1 \pm 0.5 kg/d DM), straw intake (1.37 \pm 0.3 kg/d DM), total DMI (8.3 \pm 0.4 kg/d DM), ADG (1.35 \pm 0.4 kg/d), or feed efficiency (0.17 \pm 0.06). Similarly, rumen molar proportions of propionic, acetic and butyric acids, rumen liquid osmolarity, and the papillae characteristics were unaffected by treatment. However, a lesser rumen pH ($P < 0.05$), and a greater rumen VFA concentration ($P = 0.09$), plasma insulin concentration ($P < 0.05$), and insulin to glucose ratio ($P < 0.05$) were observed in bulls fed 8% glycerin concentrate level compared with those receiving the 0, 4 and 12% levels. No changes were observed in carcass and meat quality. The ME content of glycerin can be assumed to be 3.38 Mcal/kg of DM in young Holstein bulls fed high-concentrate diets. In addition, glycerin supplementation to levels close to 10% of total DMI do not incur in detrimental effects on performance, ruminal fermentation, metabolism, and carcass and meat quality parameters.

TH233 Effect of dietary cation-anion difference on performance and blood acid-base balance of early-lactating dairy cows under heat stress. D. P. Bu, L. Jia, J. Q. Wang*, H. Y. Wei, and L. Y. Zhou, *Chinese Academy of Agricultural Sciences, Beijing, P.R. China.*

The objective of this study was to investigate the effect of dietary cation-anion difference (DCAD = Na + K - Cl - S in mEq/kg of DM) on lactation performance and blood acid-base balance of early-lactating dairy cows in hot weather. Thirty-six Holstein cows, 43 ± 13 d in milk were allocated into three groups (n=12) according to complete random block design. All diets contained 51% concentrate and 49% forage mix, which were fed ad libitum as a total mixed diet. Cows were fed either a low DCAD diet (L, +130.49 mEq/kg DM), a middle DCAD diet (M, +251.54 mEq/kg DM) or a high DCAD diet (H, +383.87 mEq/kg DM). The DCAD difference was provided through a combination of Potassium Bicarbonate and Magnesium Sulfate. Experimental duration was 7 wk. Cows were milked 3 times/d and milk yields were recorded weekly. Milk samples were collected weekly and analyzed for composition. Blood samples were taken on d 42 from coccygeal vein or artery at 4h postfeeding. The average daily minimum temperature, humidity index and THI were 30.09°C, 59.97°RH and 94.63, respectively. Milk yield and milk fat content were 31.5^b, 36.9^a and 34.1^{ab} kg/d, and 3.56^a, 3.20^b and 3.35^{ab} for L, M and H, respectively. With the increasing of DCAD, milk protein (P < 0.05) increased gradually. Blood pH and blood base excess increased predominantly via increased DCAD (P < 0.05). Increasing dietary DCAD tended to increase total carbon dioxide (P = 0.07), HCO₃⁻ concentration (P = 0.07), and glucose (P = 0.06). Increasing DCAD affected blood urea nitrogen (P < 0.002), total protein (P < 0.001) and serum albumin (P < 0.001), and serum creatine kinase (P < 0.05), but blood lactose (P < 0.07) tended to increase linearly as DCAD increased. Overall, diets with the middle level of DCAD (+251.54 mEq/kg DM) improved lactation performance and blood acid-base status in early lactation cows under heat stress.

TH234 Effects of different rates of abomasal infusion of nicotinic acid on plasma NEFA concentrations in feed-restricted Holstein cows. J. B. Pescara*, J. A. A. Pires, and R. R. Grummer, *University of Wisconsin, Madison.*

Five non-lactating Holstein cows were used in a 5×5 Latin square to test the effects of different rates of abomasal infusion of nicotinic acid (NA) on plasma NEFA concentration. From d 1 to 4 cows were fed at 30% of maintenance requirements once a day at 9 AM to increase plasma NEFA concentration. On d 5, feed was offered at the same level but divided in 24 equal doses and administered hourly via ruminal cannula. Treatments were hourly abomasal infusion of NA boluses at a rate of 0, 0.25, 0.5, 1 and 3 mg/kg BW per h for 12 h. Daily blood samples were collected prior to morning feeding. On d 5, blood samples were collected each hour, starting prior to treatment administration, and continuing for 24

h thereafter. Nine days were allowed between experimental periods. Plasma NEFA concentrations were 105, 326, 421, 501 and 467 ± 36 uEq/L from d 1 to 5 of feed restriction (time effect; P < 0.001). Mean plasma NEFA concentration during NA infusion was decreased by the highest dose (P < 0.001). Plasma NEFA concentration decreased (P < 0.001) from 448 to 138 ± 75 uEq/L 1 h after the first bolus of 3 mg NA/kg BW. A transient rebound occurred with plasma NEFA increasing to 303, 503 and 566 ± 75 uEq/L at 2, 3 and 4 h after initiation of infusion of the highest dose (trt x time effect; P < 0.001). However, 6 h after initiation of treatment, plasma NEFA concentration decreased to 105 ± 75 uEq/L and remained below 243 ± 75 uEq/L until termination of infusions. During the 12 h following termination of infusions, mean plasma NEFA concentration was 399, 404, 405, 407 and 743 ± 69 uEq/L, for 0, 0.25, 0.5, 1 and 3 mg NA/kg BW per h, reflecting a post-treatment rebound for only the highest NA dose (trt effect; P < 0.001). Plasma NEFA concentration increased to 794, 1374 and 1391 ± 36.8 uEq/L at 2, 3 and 4 h after termination of the highest dose (trt x time effect; P < 0.001). A dose of NA large enough to cause an antilipolytic effect is accompanied by rebound in plasma NEFA following termination of administration.

TH235 Apparent ruminal synthesis and intestinal disappearance of vitamin B₁₂ analogues in dairy cows. D. E. Santschi*¹, C. L. Girard¹, and R. H. Allen², ¹*Dairy and Swine R&D Centre, Sherbrooke, QC, Canada,* ²*University of Colorado, Denver, CO.*

Vitamin B₁₂ is synthesized only by bacteria provided cobalt supply is adequate. Ruminal bacteria also produce vitamin B₁₂ analogues which may have functional value for the bacteria but could not be used by the host animal. Four lactating Holstein cows equipped with ruminal, duodenal (30 cm from pylorus) and ileal (60 cm from ileo-cecal valve) cannulae were used to evaluate apparent ruminal synthesis and small intestinal disappearance of vitamin B₁₂ analogues. Cows were fed a TMR with chromic oxide in 12 daily meals (DMI: 19.8 ± 0.5 kg/d). Duodenal and ileal samples were collected twice daily over 4 consecutive days (d1: 0800, 1400 h; d2: 1000, 1600 h; d3: 1100, 1700 h; d4: 0900, 1500 h). Analysis of vitamin B₁₂ analogues was done by LC/MS. Apparent daily ruminal synthesis was calculated as the intake of vitamin in the feed subtracted from the duodenal flow. Intestinal disappearance was calculated as the amount disappearing between the two intestinal cannulae. In addition to cobalamine (CBL), the biologically active form of the vitamin, 6 analogues were identified in duodenal and ileal digesta. Although CBL was not the major form synthesized by ruminal bacteria, it was the major form absorbed in the small intestine. Average daily intake of cobalt was 50 mg with 15 mg provided by the mineral premix as cobalt carbonate. Therefore, 11 % of the average daily intake of cobalt was used for apparent ruminal synthesis of analogues of vitamin B₁₂, of which only 4 % were incorporated into CBL.

Table 1.

	CBL ¹	COB ²	CRE ³	MADE ⁴	ADE ⁵	MSADE ⁶	OHBZA ⁷

TH236 Effect of different form of selenium on the polyunsaturated fatty acids of milk fat from dairy cows fed fat diets. L. Q. Wang, J. Q. Wang*, D. P. B u, S. J. Liu, L. Wang, N. Xia, H. Y. Wei, and L. Y. Zhou, *Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of the present study was to evaluate influence of dietary selenized yeast and sodium selenite on polyunsaturated fatty acids of milk fat and selenium contents of plasma and milk from lactating cows fed with rich oil diets. 36 Chinese Holstein dairy cows were allocated into 3 groups as a randomized complete block design for 9 wk periods with measurements made during the last 6 wk. Cows were fed total mixed ration (TMR) with basal diet a forage-to-concentrate ratio of 60:40 and 4% soybean oil (control), basal diet plus 13.6 g of selenized yeast (13.6 mg of selenium/d) (SY), or basal diet plus 3.04 g/d of sodium selenite (13.6mg of selenium/d) (SS). Results showed that selenium concentration of plasma increased by 8.9% and 47.7% in the SS and SY groups compared with control, respectively ($P < 0.001$). At the same time, selenium in milk from SS and SY groups increased by 35.6% and 185.0% compared with control ($P < 0.05$). Polyunsaturated fatty acids in SY group enhanced by 11.6% when compared with control ($P < 0.05$). However, no difference was observed between control and SS group. These results demonstrated that dietary selenized yeast supplementation in rich fat diets could increase polyunsaturated fatty acids of milk fat. Acknowledgement; Research supported by the Ministry of Science and Technology (2006BAD12B03).

TH237 Bone development in dairy heifers fed diets with and without supplemental phosphorus. N. M. Esser*¹, P. C. Hoffman¹, W. K. Coblenz², M. W. Orth³, and K. A. Weigel¹, ¹University of Wisconsin, Madison, ²US Dairy Forage Research Center, Marshfield, WI, ³Michigan State University, East Lansing.

The NRC 2001 P requirements for heifers (0.20-0.35 %) and endogenous levels (0.20-35 %) of P in feeds are similar suggesting supplemental P

in heifer diets may be minimally required. Because long-term studies are unavailable, 183 Holstein and 182 crossbred heifers were fed diets containing 0.38 (supplemented) or 0.28 (unsupplemented) % dietary P from 4-22 mo of age in a replicated pen design to evaluate related impacts on bone development and metabolism. Two sub-populations of heifers were selected mid-trial for measurement of bone development and metabolism. Thirty-two heifers at 21 mo of age, balanced by breed and dietary treatment were evaluated for bone development. External frame measurements included hip height, length, heart girth, hip width, cannon bone circumference, pelvic length, pelvic height, and pelvic width. Heifers were given a spinal block and tails were docked with the 13 and 14th coccygeal vertebrae retained. Tissue was removed from vertebrae, defatted and evaluated for ash and mineral content. The 13th coccygeal vertebrae were scanned using peripheral quantitative computed tomography. Cortical, trabecular and total bone densities were determined. A second sub-population (n=64) of heifers 12 mo, balanced for breed and dietary treatment, were evaluated for pyridinoline and osteocalcin levels to assess bone metabolism. Data were analyzed as a completely randomized design using PROC GLM of SAS with breed, treatment and their interaction. External frame measurements revealed significant differences ($P < 0.07$) in frame size between Holstein and crossbred heifers. Supplementing P had no effect ($P > 0.10$) on external frame measurements, bone density, or bone metabolism markers. Bone P and Mg contents were lower ($P < 0.08$) and bone K content higher ($P < 0.05$) in heifers fed no supplemental P. Data suggest P supplementation to heifers modestly increased bone P content but this increase in bone P was not reflected in frame growth, bone density or bone metabolism.

Key Words: Phosphorus, Bone Growth, Heifers

TH238 Dairy cows might discriminate between vitamin D₂ and vitamin D₃ in the gastro intestinal tract. L. Hymoeller*^{1,2}, S. K. Jensen², and M. O. Nielsen¹, ¹University of Copenhagen, Groenegaardsvej, Frederiksberg C, ²University of Aarhus, Blichers Allé, Tjele.

To study uptake of vitamin D₂ and D₃ from the gastro intestinal tract of dairy cows, rumen content from 5 high yielding cows with rumen fistulas was mixed with 250 mg of both vitamin D₂ and D₃. After mixing, rumen content was returned to the rumen of the respective cows. Blood was collected from cows 0, 8, 24, 32, and 96 hours after introducing vitamins into the rumen and samples of rumen content were collected after 0, 1, 2, 4, 8, 24, and 32 hours (in vivo). From the 1 hour in vivo sample of rumen content, 6 sub-samples from each cow were incubated at body temperature and taken out after 2, 4, 8, 12, 24, and 32 hours (in vitro). Rumen and plasma samples were analysed for content of vitamin D₂ and D₃ and plasma samples also for the physiologically active liver derived metabolites: 25(OH)D₂ and 25(OH)D₃ by HPLC with UV-detection.

In vivo rumen samples showed almost identical D₂ and D₃ concentrations at all sampling times ($P \geq 0.1$). After the 2 hour sample concentrations of D₂ and D₃ rapidly declined due to dilution effects of subsequent feedings and due to rumen contents passing out of the rumen. In in vitro samples there was no degradation of D₂ and D₃.

Plasma concentrations of both D₂ and D₃ increased rapidly within the first hours of the study, from undetectable amounts at 0 hours to peak concentrations of 99 ± 7 and 162 ± 7 ng/ml (mean \pm SEM), respectively, after 24 hours. The concentration of D₃ was significantly higher than the concentration of D₂ at all sampling times after the 0 hour sample ($P \leq 0.01$). Absorption rates and clearance rates were not the same for

D₂ and D₃, respectively. Initial plasma concentrations of 25(OH)D₂ and 25(OH)D₃ were 7 ± 0.8 and 52 ± 4 ng/ml, respectively, and they increased to a plateau of 36 ± 2 and 106 ± 9 ng/ml, respectively, within 32 hours. Concentrations 25(OH)D₃ were at all sampling times significantly higher than concentrations of 25(OH)D₂ (P ≤ 0.01), but curves were parallel. No significant amounts of other metabolites than 25(OH)D₂ and 25(OH)D₃ were detected.

This study shows that when D₂ and D₃ are available for uptake in equal amounts in the gastro intestinal tract of dairy cows, there might be a preference for uptake of D₃ over uptake of D₂.

Key Words: Vitamin D, Discrimination, Dairy Cow

TH239 Effects of supplements of folic acid, vitamin B₁₂ and rumen-protected methionine on whole body kinetics of glucose and methionine (Met) in lactating dairy cows. A. Preynat^{1,2}, H. Lapiere², C. Thivierge¹, M. F. Palin², J. J. Matte², A. Desrochers³, and C. L. Girard², ¹Universite Laval, Quebec, QC, Canada, ²Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, ³Universite de Montreal, St-Hyacinthe, QC, Canada.

In order to determine the effects of rumen-protected methionine (RPM) and/or folic acid + vitamin B₁₂ on glucose and Met kinetics, 24 multiparous cows, assigned to 6 blocks based on previous milk yield, were fed a basal diet estimated to cover energy and protein requirements but only 76% of Met requirement and received supplements from 3 wk before to 16 wk after calving. Within each block, 2 factors were randomly assigned according to a 2 × 2 factorial arrangement: 1) no RPM (M-) or 18 g/d of RPM (M+; Mepron-85, Degussa); 2) no vitamin supplement (Vit-) or intramuscular injections of folic acid and vitamin B₁₂ (160 and 10 mg/wk; Vit+), (4 treatments: M-Vit-, M+Vit-, M-Vit+ and M+Vit+). At 12 wk of lactation, glucose and Met kinetics were measured using continuous infusions on different days of either D-[U-¹³C]glucose, L-[1-¹³C, ²H₃]Met or ¹³C[NaHCO₃]. There was no treatment effect on DMI (P=0.6). Vit+ increased milk production (P=0.01, 34.7 vs 38.9±1.0 kg/d) and yields of lactose, protein and total solids (P≤0.05). Whole body flux of glucose (absorption + gluconeogenesis + glycogenolysis) tended to increase (P=0.11, 802 vs 838±16 mmol/h) with Vit+, by an amount similar to the increase in lactose yield. There was no treatment effect on glucose oxidation, averaging 23% of glucose flux. Met flux increased (P=0.003, 20.0 vs 24.5±0.9 mmol/h) in M+ cows. Met used for protein synthesis increased with M+ (P=0.01, 14.5 vs 17.9±0.8 mmol/h) and Vit+ (P=0.06, 15.1 vs 17.3±0.8 mmol/h). Vit+ decreased the entry of Met in the transmethylation pathway, Met oxidation and plasma cysteine concentrations in M+ cows only, having no effect in M- cows (Met × vitamin, P≤0.06). Therefore, increased milk lactose and protein yields with Vit+, without change in DMI, were supported by a positive effect of B-vitamin supplement on glucose flux and Met used for protein synthesis.

Key Words: Dairy Cow, B Vitamins, Methionine

TH240 Effect of organic trace mineral (4-Plex[®]) supplementation on dry matter intake, milk production, health events, and body weight in dairy cows. K. S. Hackbart^{*1}, R. M. Ferreira¹, M. T. Socha², R. D. Shaver¹, M. C. Wiltbank¹, and P. M. Fricke¹, ¹University of Wisconsin, Madison, ²Zinpro Corp., Eden Prairie, MN.

Cows were assigned at dry-off to receive either inorganic trace mineral supplementation (C; n=32) or organic trace mineral supplementation (T; n=31). Trace minerals were provided through C or T premixes fed at 100 g/cow/d. Diets (both C and T) for dry and lactating cows contained supplemental Zn, Mn and Cu at 75, 65 and 15 ppm (DM basis), respectively. Cobalt was formulated for 2.1 and 1.1 ppm (DM basis) in dry and lactating cow diets (both C and T), respectively. Zinc, Mn and Cu sulfates and Co carbonate were used in the C premix. For T, 14 g/cow/d of 4-Plex[®] was fed through the premix to provide the following percentages of organic supplemental Zn, Mn, Cu and Co: dry cows - Zn (40%), Mn (26%), Cu (70%) and Co (100%); lactating cows - Zn (22%), Mn (14%), Cu (40%) and Co (100%). Premixes (C and T) were fed to dry cows (range = 40-72 d before calving) in 1.8 kg/cow/d concentrate through a computer feeder and to lactating cows (range = 69-116 d after calving) in a TMR. Post-calving daily dry matter intakes (DMI), daily milk production, and health events (lameness, ketosis, mastitis, milk fever, retained placenta) were recorded. Body weight (BW) was assessed at dry-off, calving, and monthly thereafter. Treatment did not affect DMI (C=21.37kg, T=21.35kg) or the incidence of any health events. Treatment did not affect milk production (C=41.43kg, T=42.24kg) until wk 13 (C=41.86kg, T=44.51kg; P=0.074) and wk 14 (C=41.56kg, T=44.71kg; P=0.042) post-calving. Treatment did not affect BW except at month 1, where C cows tended to be heavier (P=0.087) than T cows, and in BW change from calving to month 1, where T cows tended to lose more weight (P=0.053) than C cows. We conclude that supplementing organic trace minerals had no effect on DMI or health events and only affected milk production later in lactation, BW at 1 month post calving, and BW change from calving to 1 month post-calving.

Key Words: Organic Trace Minerals

TH241 Non-acid-base factors partly responsible for increased urinary calcium excretion when anionic salts are fed. L. Irvine¹, M. Freeman¹, D. J. Donaghy¹, and J. R. Roche^{*2}, ¹University of Tasmania, Burnie, Australia, ²DairyNZ, Hamilton, New Zealand.

The reduction in milk fever associated with lower prepartum DCAD is believed to be effected through changes in acid-base balance. However, this mechanism has recently been questioned. Data indicate improvements in calcium absorption when anionic salts are fed in insufficient quantities to affect systemic acid-base balance, and, more importantly, the linear relationship between DCAD and milk fever is inconsistent with the quadratic nature of the relationship between DCAD and blood or urine pH. Fifty-two cows were randomly allocated to 4 groups on the basis of age (7.7±2.44yr), calving date (29 July±3.5d), and milk production in the first 100 d of the previous lactation (2,563±380.9), ensuring groups were balanced for breed, BW (621±52.4), and previous incidence of milk fever. Treatments included a control, a low DCAD (LOW), a high DCAD (HIGH), and a neutral DCAD (NEUTRAL), the latter supplemented with both the LOW and HIGH treatment salts. Cows were orally supplemented with the appropriate mixture of salts in water and molasses twice daily, and the control group received water and molasses. Urine was sampled mid-stream on one day each week precalving, and a blood sample was collected 14d and 7d precalving, the day of calving, and d 1, 2, 3, 4, 7 and 14 postcalving. Covariate samples were collected prior to the trial. Data were analysed using ANOVA. Urine pH was reduced and urinary Ca/creatinine ratio increased in the LOW DCAD group precalving, verifying the effectiveness of the LOW DCAD treatment in increasing Ca absorption. Ca/creatinine tended (P<0.1) to be greater in the NEUTRAL treatment than the HIGH treatment, indi-

cating approximately 25% of the increase in calcium absorbed when anionic salts are fed is not acid-base balance related. Neither blood Ca at calving nor milk production was affected by treatment.

Table 1.

	CONTROL	LOW	HIGH	NEUTRAL	SED	P
Urine pH	8.25	7.57	8.29	8.11	0.131	<0.001
Ca/Creat	0.37	1.36	0.24	0.54	0.237	<0.001
Blood Ca	1.82	1.90	1.69	1.71	0.172	0.61
Milk yield	31.4	30.3	28.3	31.0	1.69	0.27

TH242 Influence of a high potassium diet on the excretion of minerals after calving. M. Rérat¹, A. Philipp^{1,2}, H. D. Hess¹, F. Dohme^{*1}, and A. Liesegang², ¹Agroscope Liebefeld-Posieux Research Station ALP, Posieux, Switzerland, ²University Zürich, Zürich, Switzerland.

The aim of this study was to determine the effect of two diets, fed during the transition period and differing in their potassium content, on the mineral metabolism of dairy cows after calving. Five weeks before calving, 12 cows were paired by breed, age, number of lactations and milk production and randomly assigned to 2 dietary treatments (K₃₅ and K₁₅). The two experimental diets were based on hay and were formulated to be isoenergetic and isonitrogenous, but differed in their K content: 35 and 15 g/kg DM in K₃₅ and K₁₅, respectively. After calving all cows received the same diet based on hay K₃₅. The balance period started 24 to 48 h after calving and lasted for 7 d. Feces and urine were collected quantitatively and concentrations of minerals (Ca, P, and Mg) were analyzed in daily samples. Apart from d 2, urinary excretion of Mg was lower ($P < 0.05$) in group K₃₅ compare to group K₁₅. In contrast, fecal Mg excretion was higher ($P < 0.05$) with the higher dietary K content during the first 2 d of the balance period. Fecal Ca excretion of group K₃₅ was higher ($P < 0.05$) on d 2 and lower ($P < 0.05$) on d 7 compared to group K₁₅. During the last 2 d of the balance period, concentration of P in feces was lower ($P < 0.05$) in group K₃₅ than in group K₁₅. The lower urinary and higher fecal excretion of Mg in group K₃₅ could be related to a lower absorption of Mg in presence of a higher K level in the diet before calving. The higher fecal excretion of Ca on d 2 suggests that the Ca regulation system at the beginning of the balance period was less active in cows in group K₃₅ compared to group K₁₅. However, the lower concentrations of Ca and P in feces at the end of the balance period indicates a change in the Ca regulation system to a more active state. In conclusion these results suggest that the cows receiving a diet with high K level had a delayed activation of the Ca regulation system after calving.

Key Words: Potassium, Mineral Metabolism, Transition Period

TH243 Effect of selenium yeast on selenium status, thyroid hormone concentrations and passive transfer of immunoglobulins in dairy cows and calves. K. M. Koenig* and K. A. Beauchemin, *Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada.*

Forty Holstein cows (primiparous and multiparous) were fed TMR supplemented with 0.3 mg/kg Se as selenized yeast (Se yeast; Seleno-Source AF 2000, Diamond V Mills, Cedar Rapids, IA) or sodium selenite from 60 d prior to the expected calving date until 60 DIM to determine the effect of Se source on Se status of cows and their calves. Selenium status was assessed by measuring the Se concentration in whole blood, serum and milk, thyroid hormone concentrations in serum and the passive transfer of immunoglobulins to the calf. Cows and heifers were fed diets containing 0.38 to 0.40 mg Se/kg with no supplemental Se for 90 d before receiving the dietary Se treatments. The Se concentration of the TMR supplemented with the Se sources ranged from 0.62 to 0.81 mg/kg. Blood was collected from cows at 60 and 30 d prior to the expected calving date, at calving, and at 15, 30 and 60 DIM, and from their calves at 24 h and 56 d of age. Milk was collected at calving (colostrum) and at 15, 30 and 60 DIM. At birth, calves were removed from the dam and fed colostrum in an amount equivalent to 10% of their body weight within 12 h. There was no effect ($P > 0.05$) of dietary Se source on individual feed intake, milk yield and components, and somatic cell count. Whole blood Se concentration averaged 11% higher in cows fed Se yeast compared to selenite (291 vs 262 ± 5.9 ng/mL, $P < 0.05$). Serum Se concentration averaged 13% higher in cows fed Se yeast (128 vs 113 ± 5.8 ng/mL, $P < 0.05$). Maternal supplementation of Se yeast improved the Se status of calves at 24 h of age by increasing ($P < 0.05$) whole blood (252 vs 211 ± 16 ng/mL), serum (94 vs 75 ± 4.7 ng/mL), and colostrum (245 vs 174 ± 5.8 ng/mL) Se concentration by 19, 25 and 41% respectively. There was no effect ($P > 0.05$) of Se source on thyroid hormone concentrations or the transfer of immunoglobulins to the calf. Supplemental organic Se yeast improved the Se status of dairy cows and the transfer of Se to their calves when the dietary Se concentration of the basal diet was > 0.3 mg/kg.

Key Words: Selenized Yeast, Selenium, Thyroid Hormone

TH244 Plasma concentration of nicotinic acid and derivatives in response to abomasal infusions of nicotinic acid. J. A. A. Pires^{*1}, C. L. Girard², and R. R. Grummer¹, ¹University of Wisconsin, Madison, ²Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Lennoxville, QC, Canada.

The objective was to assess plasma concentrations of nicotinic acid (NA), nicotinuric acid (NUA) and nicotinamide (NAM) in response to abomasal NA infusions, given as single (experiment 1) or successive boluses (experiment 2) to feed-restricted non-lactating, non-pregnant, rumen-cannulated Holstein cows. Experiment 1 was a 4 × 4 Latin square with 1 wk periods. Each period consisted of 2.5 d of feed restriction and 4.5 d of ad libitum feed intake. Treatments were abomasal administration of 0, 6, 30 or 60 mg NA/kg BW, given as a single bolus 48 h after initiation of feed restriction. Areas under the curve during the 12 h of sampling were 0, 0.91, 26.6 and 106.1 ± 6.8 uM*min⁻¹ for NA, 0, 5.1, 32.8 and 46.5 ± 5.17 uM*min⁻¹ for NUA and 5.4, 16.3, 23.3 and 27.6 ±

2.7 $\mu\text{M}\cdot\text{min}^{-1}$ for NAM, for 0, 6, 30 or 60 mg NA/kg BW, respectively (trt, quadratic: $P < 0.01$). Approximate NA clearance rate was 0, 3.0, 1.65 and 1.26 ± 0.36 %/min, and half life was 0, 28.6, 44.8 and 58.6 ± 7 min for 0, 6, 30 and 60 NA/kg BW (trt, quadratic: $P < 0.05$). Experiment 2 was a randomized complete block design with 3 treatments and 6 cows. Treatments started 48 h after initiation of feed restriction and consisted of 0, 6 or 10 mg NA/kg BW per h for 8 h. Blood samples were collected for 12 h. Average plasma NA during the 12 h of sampling was 0, 34.7 and 144.1 ± 6.7 μM (trt, trt \times time, linear: $P < 0.001$), NUA was 0, 53.1 and 68.8 ± 8.2 μM (trt, trt \times time, linear: $P < 0.001$), and NAM was 10.8 ± 6.0 , 38.1 ± 6.8 and 35.9 ± 1.7 μM (trt \times time: $P < 0.001$) for 0, 6 and 10 mg NA/kg BW per h, respectively. Observed antilipolytic effects of NA (Pires et al., 2007; JDS 90:3725) were achieved at plasma NA concentration less than 10 μM . Supraphysiological doses of NA are readily cleared from plasma, with concurrent appearance of NUA, which is a catabolite excreted in urine. There was a comparatively modest increase in NAM, a biologically active form of the vitamin niacin.

Key Words: Niacin, Bovine, Pharmacokinetics

TH245 Carry-over effects of iodine and selenium supplements in lactating dairy cows. M. Battaglia, M. Moschini, G. Piva*, and F. Masoero, *Università Cattolica del Sacro Cuore, Piacenza, Italy.*

Iodine (I) and selenium (Se) are essential trace elements due to their roles in the regulation of thyroid metabolism and anti-oxidant properties. An improvement of milk I and Se contents could be important for children and pregnant women. An experimental trial was carried out on lactating cows to determine the I and Se carry-over (CO) in milk. Twelve cows (559 kg body weight, 211 days in milk) were randomly allotted to three diet groups ($n = 4$) and individually fed using a Calan Broadbent[®] feeding system. The diets were basal diet (CTR), CTR + 23.8 mg I + 2.2 mg Se (T1), and CTR + 45.5 mg I + 4.3 mg Se (T2) and were fed to cows for twenty-eight days after a two weeks adaptation period to the CTR diet. Sources of I and Se were KI and Na₂SeO₃. Diet and individual milk samples were collected twice a week at -1, 1, 2, 3 and 4 weeks on treatment, and analyzed using ICP-MS. The average daily I and Se intakes were 41.7, 65.6, 87.3 mg/cow and 1.86, 4.06, 6.2 mg/cow, respectively in the CTR, T1 and T2 groups. Data were subjected to ANOVA using the repeated statement in the Mixed procedure of SAS. The statistical model included the fixed effect of diet, sampling time and diet \times sampling time interaction. The autoregressive order was the covariance structure that fit the model best. The milk CO of I and Se were significantly affected by the treatment ($P < 0.05$) and the sampling time ($P < 0.05$). The CO rate of I increased ($P < 0.001$) linearly and were 0.14 (CTR), 0.27 (T1) and 0.28 (T2). Milk I ($\mu\text{g/L}$) means (and standard deviations) were 245.2 (59) for CTR, 607.8 (119.1) for T1

and 970 (184) for T2. While, the CO rate of Se decreased ($P < 0.001$) linearly and were 0.22 (CTR), 0.12 (T1) and 0.09 (T2). Milk Se ($\mu\text{g/L}$) means (and standard deviations) were 16.4 (4.5) for CTR, 16.6 (4.1) for T1 and 23.6 (5.9) for T2. Considering a milk daily intake of 150 mL, the amount of I in milk from T1 cows would supply 76%, 61% and 46% of the recommended daily I allowance for children, adults and pregnant women respectively.

Key Words: Iodine, Selenium, Carry-Over

TH246 Corn silage versus alfalfa hay for dairy cows: Effects of dietary cations. R. A. Erdman*, L. S. Piperova, and R. A. Kohn, *University of Maryland, College Park.*

Corn silage (CS) is becoming the predominant forage used in the dairy industry because of its cost, DM yield/hectare, ease of harvest, and preservation characteristics. Previous milk production studies suggested that diets containing corn silage alone were inferior to those containing at least some alfalfa hay (AH) or alfalfa silage. We speculated that this could be due to differences in mineral and dietary cation-anion difference (DCAD) concentrations. The objective of this experiment was to test the effects of forage (CS v. AH) and mineral supplementation on production responses with 44 lactating Holstein cows during the first 20 wk postpartum. Treatments included: 1) CS-AH (50:50 forage DM basis); 2) CS as the sole forage; and 3) CS fortified with mineral supplements (CS-DCAD) (limestone and K₂CO₃) to match the mineral and DCAD content of the CS-AH diet. Milk production, fat and protein percentage, and 3.5% FCM of cows fed CS-DCAD was equivalent or greater to that of cows fed the CS-AH. There was a trend ($P = 0.08$) for increased feed efficiency with CS-DCAD as compared to CS-AH and CS. These results suggest that differences in mineral and DCAD levels might explain previously reported negative effects of all corn silage diets as compared to alfalfa-corn silage mixtures.

Table 1. Corn silage-alfalfa hay (CS-AH) vs. corn silage (CS) and corn silage plus minerals (CS-DCAD) effects on intake and milk production

Item	CS-AH	CS	CS-DCAD	SEM

Ruminant Nutrition: Proteins and Amino Acids - Dairy

TH247 Influence of concentrate and protein levels on milk production by Holstein cows. R. P. Lana^{*1,2}, G. F. Sobreira¹, M. I. Leão¹, J. A. Freitas³, D. C. Abreu¹, W. C. Lopes¹, and G. Guimarães¹, ¹Universidade Federal de Viçosa, Viçosa, MG, Brazil, ²CNPq, Brasília, DF, Brazil, ³Universidade Federal do Paraná, Palotina, PR, Brazil.

According to the Biotechnology and Biological Sciences Research Council (1998), formerly AFRC, all existing feeding systems are designed to balance nutrients to meet the animals' requirements, but the authors recognize that in practice, the farmer has no obligation to do that if it is contrary to the economic profitability. An experiment was developed to evaluate the effect of four levels of concentrate - CON (30, 40, 50 and 60%) and four of crude protein - CP (12, 14, 16 and 18%) in the total dry matter (DM) on milk production and composition in confined Holstein cows. Forty-eight animals (640 kg LW) were allotted in two 4 x 4 Latin squares (six cows/pen), in four periods of 28 days, divided in four sub periods of seven days. The CON was distributed in the plots and the CP in the subplots. The forage was corn silage and the CON constituted of corn meal, soybean meal, urea, and mineral supplements. There were no effects ($P > 0.05$) of CP and CP*CON on animal body weight, feed intake (forage, CON, and total DM), milk production and composition, showing that 12% CP was as effective as 18% in the cows performance. The 30% CON diet presented DMI, CON intake and milk production of 17.5, 5.3 and 19.1 kg, respectively. The CON level increased ($P < 0.01$) DM and CON intake, and decreased ($P < 0.01$) forage intake by 0.188 kg, 0.288 kg, and 0.093 kg, and increased ($P < 0.05$) milk production by 0.151 kg per unit (%) of CON level, with no effect on milk composition ($P > 0.05$). Although milk production increased, the marginal response reduced ($P < 0.05$) with increasing CON (0.88, 0.43, and 0.58 kg of milk/kg of CON DM, for the levels of 40, 50 and 60% versus 30% CON). Relation lesser than 1 kg of milk/kg of CON can compromise the profitability, and then diet formulation should consider the cost-benefit ratio and not the balance of nutrients to meet the nutritional requirements of the animals, especially after breeding.

TH248 Blood and ruminal metabolites of early lactating Iranian Holstein cows fed raw or roasted whole soybean. M. H. Fathi Nasri^{*1}, M. Danesh Mesgaran², R. Valizadeh², and H. Farhangfar¹, ¹The University of Birjand, Birjand, Iran, ²Ferdowsi University of Mashad, Mashad, Iran.

This study evaluated responses of early lactation Iranian Holstein cows to feeding roasted whole soybean (SB) or raw SB in diets with lucerne hay and corn silage as the primary forage source. Treatments consisted of a total mixed ration that included 387 g/kg forage supplemented with 1) 120 g/kg of roasted SB and 82 g/kg of cottonseed meal (CSM), 2) 120 g/kg of raw SB and 82 g/kg of CSM or 3) 120 g/kg of soybean meal (SBM) and 82 g/kg of cottonseed (CS), on a dry matter (DM) basis. The diets which were formulated to be iso-nitrogenous and iso-caloric were offered to fourteen multiparous Holstein cows (body weight = 617.0 kg, days in milk = 16.9) that were assigned randomly to one of three experimental diets for a 45-d trial. Roasted SB were obtained by roasting seeds for 1.5 to 2 min in a commercial roaster (exit temperature of seeds was about 140-145°C) and immediately placing, without cooling, in covered wooden barrels for 45 min. A dietary effect on rumen pH

values, glucose and beta-hydroxy butyrate (BHB) concentrations were not detected among cows fed different diets (Table 1). Rumen ammonia N concentration were significantly lower for the cows fed roasted SB compared with those fed raw SB. The lower ruminal ammonia concentration in cows fed roasted SB diet compared with raw SB diet, possibly arose as a consequence of lower ruminal protein degradability of roasted SB. Plasma urea nitrogen (PUN) concentrations were also significantly ($p < 0.031$) lower in cows fed roasted SB than in cows fed raw SB that confirms the reducing of ruminal protein degradability of roasted SB.

Table 1.

Item	SBM plus CS	Raw SB plus CSM	Roasted SB plus CSM	SEM	Contrast ¹

TH249 Endogenous nitrogen (EN) flows: Effects of metabolizable protein (MP) supply in lactating dairy cows. D. Valkeners¹, H. Lapiere¹, U. Schönhusen², P. Junghans², C. C. Metges², and D. R. Ouellet^{*1}, ¹Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, ²Research Unit Nutritional Physiology, Dummerstorf, Germany.

The current NRC model (2001) estimates EN at the duodenum as 1.9 g per d per kg DMI, with no allowance for differences in diet quality. The current study used 4 lactating cows in a replicated incomplete 3x3 Latin square to study the effect of MP supply on EN flows. Cows were fed every 2h a TMR. Three concentrates were formulated to provide NE_L according to requirements (126 MJ/d) and to supply incremental amounts of MP: 1430 (Low), 1920 (Medium) and 2160 (High) g MP/d, which corresponded to 72, 98 and 111% of estimated MP requirements. From d 27 to 35, cows were infused into a jugular vein with L-[¹⁵N] leucine (0.45 mmol/h). On d 34 and 35, rumen and intestinal mucosa, duodenal digesta and feces were sampled (4 samples/d) to determine EN flows (see Table), as previously described (Ouellet et al., 2002; JDS 85:3013). The N flows across the gut are presented in the Table. Total duodenal N flow increased from Low to High MP as did the flow of undigested feed. The duodenal flow of free EN and of total EN increased linearly with increased MP supply, although, contribution of EN to bacteria protein was unaffected by treatments. The EN loss in feces did not vary with treatments and represented 2.1 g/kg of DMI. Overall, total EN varied ($P = 0.03$; linear) with increasing MP supply (4.2, 4.7 and 4.8 ± 0.2 g/kg of DMI), representing 16% of duodenal N flow. Contribution of EN to bacteria flow is about equal to free EN and needs to be included in EN duodenal flows. Fecal EN flow provides a direct estimation of metabolic fecal loss.

Table 1. Duodenal and fecal nitrogen flow in dairy lactating cows fed different level of metabolizable protein

Item	Treatment			SEM	P	
	Low MP	Medium MP	High MP		Linear	Quadratic

TH250 Is D-methionine (Met) used by the dairy cow? H. Lapierre^{*1}, G. Holtrop², A. G. Calder³, J. Renaud¹, and G. E. Lobley³, ¹Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, ²BioSS, Rowett Research Institute, Aberdeen, UK, ³Rowett Research Institute, Aberdeen, UK.

Rumen-protected forms of Met are an equimolar mixture of the two isomers, D and L. Only L-Met can be used for protein synthesis, but it is unclear if the D isomer can be transformed into L in ruminants. Four lactating dairy cows averaging 675 kg BW and 32.5 kg/d of milk received a basal diet (12.0%CP) in twelve equal meals per day plus an abomasal infusion of AA (590 g/d, casein profile without Met). In a first study, they received portal infusions of 5, 10 or 15 g/d of DL-Met, in two incomplete Latin squares. On the last d, six arterial samples were collected at 45 min intervals. Concentrations of L- and D-Met were determined by gas-chromatography-mass spectrometry. Increasing infusion rates of DL-Met increased total Met plasma concentrations (19.7, 25.0 and 34.4 ± 0.6 µM, P<0.001) and the proportion of D (19.4, 30.5 and 37.3 ± 0.7 %, P<0.001). The fractional removal of D-Met from plasma (infusion rate/plasma pool of D-Met) decreased (P=0.02) at the highest infusion rate, averaging 5.6, 5.5 and 5.0 ± 0.1 /h, approximately 7-8 times slower than removal of L-Met (44/h). A second study determined if the removed D-Met was transformed into L-Met. The same cows were infused for 8 h with L-[²H₃]Met (1.3 mmol/h) to determine whole body irreversible loss rate (ILR; 21.2 ± 2.6 mmol/h) based on plasma [²H₃]Met enrichment. At 2h cows received a bolus venous injection of D-[¹³C]Met (6.8 mmol) and arterial samples were collected after 10, 20, 30, 40, 60, 90, 120, 150, 180, 240, 300, 360, 420 and 480 min. The ¹³C enrichments of the D and L isomers were expressed relative to L-[¹²C]Met. Enrichment of L-[¹³C]Met averaged 14.4 ± 3.7 mole percent excess 10 min after the bolus injection and declined exponentially thereafter. The minimum proportion of D-Met transformed into L-Met, calculated from (ILR × area under curve of L-[¹³C]Met enrichment/dose D-Met)

averaged 75 ± 6%. In conclusion, D-Met is transformed into L-Met in dairy cows, but with the rate of removal of the D-isomer much slower than the L form.

Key Words: Methionine, Isomer, Ruminant

TH251 Response in feed intake, blood metabolites, and milk production to varying ruminal protein undegradability in early lactation Holstein cows. M. Jahani-Moghadam¹, H. Amanlou², and A. Nikkiah^{*2,3}, ¹Islamic Azad University, Karaj, Iran, ²Zanjan University, Zanjan, Iran, ³University of Illinois, Urbana.

Effects of different dietary ratios of rumen undegradable (RUP) to degradable (RDP) protein on ruminal digestion, feed intake, blood metabolites, and milk yield were determined in early-lactation cows. Four multiparous (43 ± 5 days in milk) and four primiparous (40 ± 6 days in milk) tie-stall-housed Holstein cows were used in a duplicated 4 × 4 Latin square design trial with four 21-d periods. Each period had 14-d of adaptation. Diets contained, on a dry matter (DM) basis, 23.3% alfalfa hay, 20% corn silage, and 56.7% concentrate. Cows were first offered alfalfa hay at 0700, 1500, and 2300 h, and 30 min after each alfalfa hay delivery were offered a mixture of corn silage and concentrate. Treatments were diets with RUP:RDP ratios of 1) 5.2:11.6% (CO), 2) 6.1:10.6%, 3) 7.1:9.5%, and 4) 8.1:8.5%. Different RUP:RDP ratios were obtained by partial and total replacement of untreated soybean meal (SBM) with xylose-treated SBM. An in situ study showed that DM (27.1 vs 21.3%) and crude protein (CP, 20.4 vs 3.6%) of untreated SBM had greater rapidly degradable fractions. The slowly degradable CP was degraded more quickly in xylose-treated SBM than in untreated SBM (5.8 vs 2.0%/h). Treatment cows produced more milk (32 vs 29 kg/d) and had greater yields of milk protein, lactose, solids-non-fat and total solids than cows fed untreated SBM. Increasing dietary RUP:RDP ratio reduced blood urea N linearly (22.5 vs 18.4, 17.6, 16.7 mg/dL). Feed costs dropped at RUP:RDP ratios of 6.1:10.6 and 7.1:9.5 but not at the ratio of 8.1:8.5%, compared to the control 5.2:11.6% ratio. Intake of DM and CP, rumen pH, blood glucose, albumin and total protein, fecal and urine pH, changes in body weight and body condition score, and milk lactose and solids-non-fat percents did not differ among treatments. Therefore, increasing dietary RUP:RDP ratio from 5.2:11.6% up to 7.1:9.5% improved milk production and reduced feed costs in early lactation cows fed diets based on barley and corn grain, SBM, alfalfa hay and corn silage. Reduced blood urea may suggest reproductive benefits.

Key Words: Rumen Degradability, Soybean Protein, Early Lactation Cow

TH252 Effect of rumen degraded and rumen undegraded protein on microbial protein synthesis in mid-lactation cows. S. K. Ivan-Dinh^{*1}, R. L. Baldwin, VI², and R. A. Kohn¹, ¹University of Maryland, College Park, ²USDA-ARS, Bovine Functional Genomics Laboratory, Beltsville, MD.

The objective of this study was to determine the effect of rumen degraded protein (RDP) and rumen undegraded protein (RUP) on microbial protein synthesis in lactating dairy cattle, and evaluate the ability of the

National Research Council (NRC) 1989 and the NRC 2001 models to predict these flows. Eight mid-lactation Holstein cows were assigned to a repeated 4 × 4 Latin square, balanced for carryover effects. The isoenergetic diets were arranged in a factorial design (RDP at 10.0 and 12.5% and RUP at 5.6 and 8.0% of ration dry matter). The 8.0% RUP diets tended to increase liquid flow out of the rumen (P = 0.06), N flowing with the liquid fraction (P = 0.09), and liquid-associated bacterial N flow (P = 0.10). Potential transfer of excess RUP to the rumen in the form of urea-N did not increase microbial N flow out of the rumen. Rumen degradable protein did not affect flow of total N or microbial N out of the rumen. The NRC 1989 model predicted MN flow, total N flow, and rumen N balance more accurately than the NRC 2001 model. The NRC 1989 model predicted a negative rumen N balance across all four diets with no mean or linear bias, while the NRC 2001 predicted positive rumen N balance for all diets with a significant mean bias. The low estimate of MN flow by the NRC 2001 model resulted in an overestimate of rumen N balance, which could lead to inaccuracies in prediction of RDP and RUP requirements. The NRC 2001 underestimate of MN flow from the rumen resulted because the model does not account for the potential of urea-N recycling to be greater than ammonia absorption from the rumen, which would provide additional N for microbial protein synthesis. An accurate prediction of the RDP and RUP requirements is necessary given the potential negative environmental impact of over-feeding either one of these protein sources. Since MN is an integral part of the RDP prediction equations, model predicted MN flow needs to match actual flow, and currently the NRC 1989 prediction reflects the actual flow better than the NRC 2001 prediction.

Key Words: Rumen Degraded Protein, Rumen Undegraded Protein, Microbial Protein Synthesis

TH253 Nitrogen balance and excretion from grazing lactating cows supplemented with conjugated linoleic acid (CLA). D. E. de Oliveira^{*1}, S. R. de Medeiros², and D. P. D. Lanna³, ¹*Centro de Educação Superior do Oeste, Universidade Estadual de Santa Catarina/CEO, Chapecó, Santa Catarina, Brasil,* ²*Centro Nacional de Pesquisa de Gado de Corte, Campo Grande, Mato Grosso do Sul, Brasil,* ³*Universidade de São Paulo/ESALQ, Piracicaba, São Paulo, Brasil.*

The synthetic conjugated linoleic acid (CLA) has been used to alter milk composition, improve reproductive performance and increase CLA content of bovine milk with potential benefits to human health. Although CLA has been extensively studied, few reports have evaluated the changes in nutrient excretion of CLA-treated cows. The objective of this study was to measure the nitrogen (N) secretion in milk and estimate the excretion of N in cows receiving CLA. Twenty six lactating Holstein × Gir cows (28 to 84 DIM) were used in a complete randomized design, eleven cows were individually fed 150g of CLA (30.5% c9t11, 33.1% t10c12) and the remaining fifteen cows were fed 150 g of Megalac (MEG), mixed in the concentrate (4 kg/day, as fed). All cows grazed a pasture of Stargrass that contained, on average, 14.6% CP, 2.1% fat, 65.8% NDF, 44.0% NDFIP, 29.2% ADF, 13.6% ADFIP, 4.9% lignin, and 9.7% ash on DM basis. The mean chemical composition of the concentrate was 25.1% CP, 5.6% fat, 11.0% NDF, 6.6% NDFIP, 3.9% ADF, 2.5% ADFIP, 3.3% lignin, 16.1% ash. The n-alkanes C₃₂, C₃₁ and C₃₃ were used to estimate individual forage intake. The CNCPS v. 5.04 was used with the inputs above to estimate N balance for each individual cow and the data were analyzed using SAS PROC GLM.

CLA supplementation had no effect on milk yield (CLA = 15.9, MEG = 14.6 kg/day; P=0.25), decreased milk fat content (CLA = 2.1, MEG = 3.1%; P=0.0001) and increased milk protein content (CLA = 3.1, MEG = 2.8%; P=0.005). The DM intakes of forage (CLA = 11.5, MEG = 12.1 kg/day; P=0.46) and concentrate (CLA = 3.5, MEG = 3.4 kg/day; P=0.81) were similar between treatments. There was no effect of treatment on CP intake (CLA = 2.5, MEG = 2.5 kg/day; P=0.68), total N excretion (CLA = 330, MEG = 340 g/day; P=0.49), and N digestibility (CLA = 88.3, MEG = 88.3%; P=0.97). The CLA supplementation affected N distribution (% of total N intake) in milk (CLA = 19.4, MEG = 15.7%; P=0.006), reduced the N excretion as a function of daily milk protein yield (CLA = 647, MEG = 847 g/kg; P=0.009). CLA treatment decrease in N excretion per unit of milk protein produced.

Key Words: Nitrogen Balance, Nitrogen Excretion, Conjugated Linoleic Acid

TH254 Effects of an extruder-expelled soybean meal product on milk production and components for Holstein dairy cows. Y.-H. Chung^{*}, K. S. Heyler, J. A. Hartzell, V. A. Ishler, and G. A. Varga, *The Pennsylvania State University, University Park.*

Soybean meal (SBM) has been treated in various ways to enhance the quantity of rumen undegradable protein, and several commercial sources of treated SBM are available for use in the diets for dairy cattle. An extruder-expeller processed SBM product (SoyChoice; Wenger's Feed Mill, Inc., Rheems, PA) is produced by mechanically pressing the oil out of the meal and its effects on milk yield and components for Holstein dairy cows were evaluated. This extruder-expelled SBM product was fed at 4% ration DM for 17 d. A similar SBM product (Turbomeal; J. L. Moyer and Sons Inc., Turbotville, PA) was fed at 3.6% ration DM and served as the control. Both rations were formulated to a similar nutrient composition and contained 15% CP and 33% NDF (DM basis). Cows were fed once and milked twice daily. Milk yield for individual cows was recorded at each milking, and individual milk was sampled weekly from two consecutive milkings and analyzed for components. In situ degradability of this SBM product was conducted. Milk yield for the treatment group (cow=32, first-calf heifer=26; DIM=132±109 SD) was similar before (41.2 kg/d) and after (42.7 kg/d) the 17-d treatment period and did not differ from the control group (41.4 kg/d) (cow=34, first-calf heifer=26; DIM=126±102 SD). Percentages and yields of milk components were not affected by treatment and were similar before and after treatments. Percentages of milk fat and protein were 3.5 and 3.1% and 3.7 and 3.1% for the treatment and control groups, respectively. The calculated income over feed costs was 3.9% greater for the treatment compared with the control. In situ DM disappearance for this SBM product was 60, 68, and 84% and in situ CP disappearance was 43, 54, and 75% at 12, 16, and 24 hours of rumen incubation. The estimated effective ruminal degradability for this SBM product was 67.8% and fractional degradation rate was 8.5%/h. Based on similar production results, it is concluded that this extruder-expelled SBM product is comparable to a similar SBM product evaluated and offers another source of protein in dairy cow rations.

Key Words: Extruder-Expelled Soybean Meal, Milk Yield and Component, Rumen Degradation Kinetic

TH255 Increasing methionine, lysine or both does not increase milk protein percent in either high producing or low producing dairy cows. H. F. Bucholtz¹, J. S. Liesman¹, P. N. Naaz², M. J. Stevenson³, W. H. Heimbeck³, and R. A. Patton⁴, ¹Michigan State University, East Lansing, ²Upper Peninsula Experiment Station, Chatham, MI, ³Evonik-Degussa AG, Hanau, Germany, ⁴Nittany Dairy Nutrition, Mifflinburg, PA.

The objective was to determine the interaction between production level and predicted levels of lysine (LYS) and methionine (MET) on milk yield and milk protein. Forty midlactation Holstein cows (16 primiparous and 24 multiparous) were randomly assigned within parity to either high or low production blocks and within each block were assigned to 1 of 4 dietary treatments, designed to be isonitrogenous but varying in content of MET and LYS. Diets were: low MET and low LYS (LL); high MET and low LYS (HL); low MET and high LYS (LH); or high MET and high LYS (HH). MET and LYS were increased by adding a RPMet (Mepron[®], Evonik-Degussa Corp.) or by replacing corn gluten meal with blood meal. Mean analyzed nutrient content of diets was 17.1% CP, 18.7% ADF, 28.5% NDF and 27.48% starch. Calculated MET and LYS as % of MP were: LL, 1.88 and 6.07; HL, 2.22 and 6.05; LH, 1.82 and 6.38; HH, 2.11 and 6.37 according to the NRC model. Experiment was for 3 periods of 21 d. Statistical analysis was by the Proc Mixed of SAS. Model included terms for parity (primiparous or multiparous), production level (high or low), block, period and diet. Production data is presented below. Diet had no effect on any production variable, nor were there any diet*parity or diet*production interactions. This may have been due to failure to reach levels of MET and LYS as recommended by NRC. We conclude from this study that increasing MET and LYS as % MP to cows in midlactation does not increase kg milk protein regardless of production levels. This may be due to preset homeostatic regulation.

Table 1.

TH256 Ammonia emissions and olfactometry analysis of limit fed high and low concentrate diets with different forage quality in dairy heifers. G. J. Lascano*, P. A. Topper, A. Adviento-Borbe, D. Topper, R. C. Brandt, E. F. Wheeler, and A. J. Heinrichs, *The Pennsylvania State University, University Park.*

Ammonia emissions and odor are being used to regulate animal production. The objectives of this study were to observe the effects of restricted feeding dairy heifers high concentrate (HC) and low concentrate (LC) diets with different forage quality on NH₃ emissions and odor. A split

plot design with diet type as the whole plot and forage quality as subplot was administered in a 4-period (21 d) 4 × 4 Latin square using 8 Holstein heifers (321 ± 21 kg initial BW). Periods consisted of 17 d adaptation and 4 d total fecal and urine collection. Corn silage-based diets containing either 80 or 20% forage (DM basis) with 0, 20, 40 or 60% of forage provided by corn stover (CS; quality denominator) were evaluated. NH₃ concentration was determined using an infrared photoacoustic gas analyzer over a 24-h period and urine:feces as-collected from first 2 d of total collection. Odor was evaluated by a certified panel of human assessors utilizing a triangular forced-choice dynamic olfactometer (EN 13725: 2003). NH₃ emissions were different between HC and LC (6.98 vs. 10.57 ± 0.44 mgNH₃/g manure; *P* < 0.01), and decreasing quality of forage linearly increased NH₃ emission rate on HC diets (*P* < 0.01). Total daily NH₃ emissions were not different between quality or diet type. Feces:urine was lower for the HC diet (0.48 vs. 2.44 ± 0.44; *P* < 0.01). More feces relative to urine (g/g) was produced as quality of forage decreased (*P* < 0.01). Total manure (kg/d) was significantly higher as forage quality increased (*P* < 0.01), and decreased linearly with the addition of CS in the diets (*P* < 0.01). Results suggest that odor was less offensive as forage quality decreased. We conclude that NH₃ emissions were higher for the LC diets on a unit of manure basis, likely due to a shift in feces:urine. Lower quality forages increased these emissions linearly. Finally, forage quality seemed to have an effect on odor in this study.

Key Words: Ammonia Emissions, Odor, Forage Quality

TH257 Effect of abomasal glucose infusion on splanchnic amino acid metabolism in freshening dairy cows. M. Larsen* and N. B. Kristensen, *University of Aarhus, Tjele, Denmark.*

Six Holstein cows implanted with ruminal cannulas and permanent indwelling catheters in the major splanchnic blood vessels were used to investigate the effect of post ruminal glucose supply on splanchnic metabolism of amino acids. Cows were assigned to one of two treatments: Continuous abomasal infusion (INF) of 1500 g glucose/d (via the rumen) or no infusion (control; CON). Treatments were initiated at the day of second calving. Cows were fed ad libitum and the ration was offered in equal meals with 8 hour intervals. Eight hourly sets of arterial, portal vein, and hepatic vein (n = 2 for CON) samples were collected simultaneously starting 30 min before the morning feeding on 4, 15, and 29 days in milk (DIM). Plasma flows were measured by pAH dilution. Essential amino acids (EAA) analyzed in blood plasma were VAL, LEU, ILE, MET, LYS, THR, PHE and HIS; non-EAA analyzed were ASP, ALA, CYS, GLN, GLU, GLY, PRO, SER and TYR. Data was analyzed as a split-plot design, with cows as whole plots (random factor), treatments as whole plot factor and DIM as sub plot factor. Dry matter intake decreased (*P* = 0.05) with INF compared with CON (11 and 17 ± 1 kg/d, respectively). Net portal fluxes of EAA and non-EAA tended to decrease (*P* < 0.10) with INF compared with CON (EAA: 67 and 139 ± 22 mmol/h, respectively; non-EAA: 41 and 121 ± 23 mmol/h, respectively). However, net portal flux of EAA and non-EAA per kg DMI were not affected (*P* > 0.10) by treatment. Net hepatic fluxes of EAA and non-EAA were not affected (*P* > 0.10) by treatment (EAA: 4 and -7 ± 27 mmol/h, respectively; non-EAA: -52 and -99 ± 33 mmol/h, respectively). Net hepatic fluxes of EAA and non-EAA per kg DMI were not affected (*P* > 0.10) by treatment. Net portal and net hepatic fluxes of EAA and non-EAA increased (*P* < 0.05) with DIM for both treatments. In conclusion, abomasal infusion of 1500 g glucose/d did not increase the amount of amino acids available for peripheral tissues

in freshening dairy cows and an amino acid sparing effect of glucose could not be detected.

TH258 The performance of calves fed a milk replacer containing wheat protein. A. B. Chestnut* and D. L. Carr, *Vigortone Ag Products, Hiawatha, IA.*

The value of wheat protein as a 50% replacement of milk protein in a calf milk replacer was evaluated. The experimental milk replacer (WP) containing wheat protein was formulated to contain 22% crude protein and 18% fat. The control milk replacer (MP) contained 22% crude protein and 20% fat with all the protein derived from milk ingredients. The milk replacers were formulated with similar levels of minerals and vitamins. Both milk replacers were medicated with neomycin (400g/ton) and oxytetracycline (200 g/ton). The trial was conducted with a group of Holstein bull calves that were 10 ± 4 d of age. Calves were randomly assigned to milk replacer treatments. Individual calf weights were recorded on days 1, 21 and 35 of the study. Each calf received 284 g of milk replacer twice daily from d 1 to 28 and once daily from d 29 to 35. Starter feed (18% crude protein) was offered ad libitum beginning d 1 and starter feed intakes were recorded for each calf. Data were analyzed as a completely randomized design using analysis of variance. Differences between means were tested using the least significant difference method. Calves fed WP had similar weight gains as calves fed MP (Table 1). In this study calves fed WP tended ($P < 0.10$) to eat more starter feed than calves fed MP.

Table 1. Effect of wheat protein in milk replacer on calf performance

	Wheat Protein (WP)	All Milk Protein (MP)	P value
No. head	36	34	
Initial age, d	9.9	10.0	ns
Initial wt, kg	46.9	46.3	ns

TH259 Effect of Optigen® and ruminally degradable protein level on fermentation, digestion, and N flow in rumen-simulating fermenters. G. A. Harrison*, M. D. Meyer, and K. A. Dawson, *Alltech Biotechnology, Nicholasville, KY.*

Replacing plant protein with non-protein nitrogen (NPN) from urea or Optigen® (blended, controlled-release urea) increases ruminally degradable protein (RDP) but effects of RDP source on ruminal metabolism are not well defined. Effects of N source in diets and RDP level were investigated in single-flow rumen-simulating fermenter cultures. Cultures were fed diets with 3 N sources (plant protein, Optigen, urea) and

4 levels of RDP (2.1, 2.3, 2.5, 2.7 g/d). Twelve cultures were used in a 3 × 4 factorial design with 12 dietary treatments and 3 experimental runs. RDP was increased by N from plant protein, urea, or Optigen. Cultures were fed 12.5 g as fed of experimental diets twice daily for 6 days. Samples were collected immediately prior to morning feeding during the last 3 days of the experiment for fermentation analysis. A composite effluent sample from each fermenter was used for DM and NDF disappearance. Nitrogen flow measures were estimated by purine to N ratios for effluent and bacteria. Data were analyzed for effects of dietary treatment using the GLM procedure of SAS. Orthogonal contrasts were used to estimate effects of N source and RDP level (linear). N source affected fermentation with isoacids (mM) being higher in plant protein cultures ($P < 0.0001$) and ammonia concentration lower in urea cultures ($P < 0.10$). CP degradability was greater in urea cultures ($P < 0.10$). RDP level affected culture fermentation with linear increases in A:P ratio and ammonia as RDP increased ($P < 0.0001$). True DM digestion, CP degraded, bacterial N yield, and efficiency (g bacterial N/kg DM truly digested) increased in a linear fashion with higher RDP ($P < 0.001$). Nitrogen source did affect fermentation and N partitioning but not digestion and bacterial N yield. Increasing RDP level shifted fermentation and improved digestion and bacterial yield. Interactions between N source and RDP level on suggest that ruminal microbes respond differently to RDP depending on N source.

Key Words: Ruminally Degradable Protein, Non-Protein Nitrogen, Optigen

TH260 Effect of Optigen® and dietary neutral detergent fiber level on fermentation, digestion, and N flow in rumen-simulating fermenters. G. A. Harrison*, M. D. Meyer, and K. A. Dawson, *Alltech Biotechnology, Nicholasville, KY.*

The sustained release of N from Optigen® (blended, controlled-release urea) may be advantageous in diets containing higher neutral detergent fiber (NDF) and lower fermentable carbohydrate. Effects of NPN source and NDF level were investigated in single-flow rumen-simulating fermenter cultures. Cultures were fed diets with 2 NPN sources (urea, 0.58%; Optigen, 0.66% DM) and 3 NDF levels (low=36.5, mid=43.8, high=51.1% DM). Twelve cultures were used in a 2 × 3 factorial design with 6 dietary treatments and 2 experimental runs. Diets were formulated at 16% CP, 75% forage (DM basis) and NDF was increased by changing ratios of corn silage, hay, and straw. Cultures were fed 12.5 g as fed of experimental diets twice daily for 6 days. Samples were collected immediately prior to morning feeding during the last 3 days of the experiment for fermentation analysis. A composite effluent sample from each fermenter was used for DM and NDF disappearance. Nitrogen flow measures were estimated using purine to N ratios for effluent and bacteria. Data were analyzed for effects of dietary treatment using the GLM procedure of SAS. Orthogonal contrasts were used to determine effects of NPN source and NDF level. NPN source did affect culture pH with Optigen cultures being higher (6.40 vs. 6.50, ($P < 0.01$). Compared to low NDF, high NDF cultures had higher pH (6.32 vs. 6.58, ($P < 0.0001$), more ammonia (4.4 vs. 6.5 mg/dl, ($P < 0.05$), lower true DM digestion (65.2 vs. 54.2%, ($P < 0.001$), and lower CP degradability (75.8 vs. 70.1% CP, ($P < 0.05$). Mid NDF cultures had intermediate values. Bacterial N yield tended to be greater in low compared to high NDF cultures (0.350 vs. 0.314 g/d, ($P = 0.11$). On low NDF and high diets, Optigen-fed cultures produced less bacterial N than did urea-fed cultures (-4.8 and -3.3%, respectively). However, on mid NDF diets, Optigen-fed cultures produced 9.7% more bacterial N than their urea-

fed counterparts. Optigen inclusion may be more advantageous when not at dietary extremes.

Key Words: Neutral Detergent Fiber, Non-Protein Nitrogen, Optigen

TH261 Diet formulation strategy and Optigen® effects on fermentation, digestion, and N flow in rumen-simulating fermenters. G. A. Harrison, M. D. Meyer*, and K. A. Dawson, *Alltech Biotechnology, Nicholasville, KY.*

Inclusion of Optigen® (blended, controlled-release urea) in ruminant diets allows for formulation changes due to space created with a condensed N source. Effects of two dietary formulation strategies, increasing degradable protein (RDP) or increasing forage, were investigated in single-flow rumen-simulating fermenter cultures. Twelve cultures were used in a completely randomized design with 6 dietary treatments and two experimental runs. Six diets were formulated at 18% CP (DM basis): control (62.5% RDP, 50% forage), urea (65% RDP, 50% forage), Optigen G1 (65% RDP, 50% forage), Optigen G2 (62.5% RDP, 50% forage), Optigen F1 (65% RDP, 53% forage), and Optigen F2 (62.5% RDP as % of CP, 53% forage). NPN from urea (0.48%) and Optigen (0.55%) primarily replaced N from soybean meal. Cultures were fed 12.5 g as fed of experimental diets twice daily for 6 days. Samples were collected from all cultures immediately prior to morning feeding during last 3 days of experiment for fermentation analysis. A composite effluent sample from each fermenter was used for DM and NDF disappearance. Nitrogen flow measures were estimated using purine to N ratios for effluent and bacteria. Data were analyzed for effects of dietary treatment using the GLM procedure of SAS. Orthogonal contrasts were used to determine effects of RDP and forage level (Optigen diets). Dietary treatment did not affect pH, ammonia, digestion, or N flow measures. Cultures fed higher RDP diets degraded more protein (64.3 vs. 67.1% CP, $P < 0.05$) and had less undegraded feed N (0.251 vs. 0.231, $P < 0.05$). Forage level in Optigen diets did not affect fermentation, digestion, or N flow. Allowing RDP to increase from 62.5 to 65% of CP as Optigen replaced plant protein did not have any negative effects on fermentation or digestion. The formulation strategy of increasing forage (in this case, corn silage) in diets containing Optigen does not appear to have a negative impact on performance in rumen-simulating fermenters.

Key Words: Diet Formulation, Non-Protein Nitrogen, Optigen

TH262 Response of lactating cows to the partial replacement of soybean meal by Optigen® II or urea. J. F. dos Santos¹, M. N. Pereira*¹, G. S. Dias Júnior¹, L. L. Bitencourt¹, N. M. Lopes¹, S. Siécola Júnior¹, and J. R. M. Silva², ¹Universidade Federal de Lavras, Lavras, MG, Brazil, ²Centro Federal de Educação Tecnológica, Januária, MG, Brazil.

Performance and nutrient utilization response of cows to the substitution of soybean meal by two sources of non-protein nitrogen was evaluated. Eighteen Holsteins, 150±82 DIM at the beginning of the trial, were randomly assigned to a sequence of three treatments, in six concurrently run 3x3 Latin Squares, with 21-day periods. The crude protein content of the consumed diet was 16.4% for Optigen® II (Alltech Inc., Nicholasville, USA) and Control and 16.5% for urea. Diet crude protein from Optigen® II was 1.59% of DM and from urea 1.57%. Dietary content of

Optigen® II and urea were 0.61% and 0.56% of DM, respectively. The composition of the Control TMR was (% of DM): Corn silage (41.9), tifton hay (1.8), mature ground corn (14.2), whole cottonseed (7.6), buffer-fat premix (3.9), citrus pulp (12.6), soybean meal (18.0). For the Optigen® II and urea diets, content of soybean meal was 14.1% and citrus pulp was 15.9 and 16.0%, respectively. Data was analyzed with a model containing the effects of square, cow within square, period and treatment. Two orthogonal contrasts were evaluated: 1) Urea vs. soybean meal and 2) Optigen® II vs. soybean meal. The partial replacement of soybean meal by non-protein nitrogen sources reduced intake with no effect on milk yield, there was a tendency for increased milk to intake ratio on these diets. Optigen® II induced excretion of milk urea similar to soybean meal and lower than urea

Table 1. Performance and total tract diet digestibility

TH263 The effects of reducing dietary nitrogen on ammonia emissions from dairy housing. J. Cyriac*, L. Li, K. F. Knowlton, L. C. Marr, J. A. Ogejo, J. Ligon, M. Reed, and M. D. Hanigan, *Virginia Polytechnic Institute and State University, Blacksburg.*

This study investigated the potential of reducing NH₃ emissions from dairy housing by reducing the nitrogen (N) content in lactating dairy cow diets. A replicated crossover design was used with 2 pens per treatment, 2 periods (18 d each) per replicate, and 2 replicates. Forty eight mid-lactation Holstein cows were randomly assigned to one of 4 pens. Pens were randomly assigned to one of the treatment diets. The diets contained 15% or 18% crude protein (CP) which differed in rumen-degradable protein content. Feed intake and milk yield were recorded on d 11 through 18. Milk samples were analyzed for 4 d in the final week of each period. On each of d 11 through 18, manure was allowed to accumulate on the floor of one pen for 8 h, and NH₃ volatilization from the floor was measured for 10 h. Subsequent pens were measured on succeeding days resulting in 2 volatilization rate measurements for each pen during the 8 d period. Manure samples were collected for analysis of N and phosphorus. The Proc Mixed procedure of SAS was used to analyze the data. Dry matter intake was significantly increased for the 15% CP vs the 18% CP diets fed cows (23.2 and 25.4 kg/cow/d,

respectively; $P < 0.0001$) but there were no significant changes in milk yield (35.7 vs 37.2 kg/cow/d, respectively). Milk compositional analysis indicated that milk urea N increased significantly ($P < 0.0001$) as the CP content of the diets increased averaging 17.3 and 21.5 mg/dl, respectively, for the 15 and 18% CP diets. Consistent with the level of protein feeding, the N content of fresh manure samples from the 15% CP diet was significantly lower than from the 18% CP diet (3814 vs 4140 mg N/L; $P = 0.03$). However, the measured gaseous NH₃ loss from the barn floor was not significantly different between 15% CP and the 18% CP diets (116 vs 107 mg/h-m², respectively; $P = 0.75$). This study indicated that reducing N in the diet reduced milk urea N and manure total Kjeldahl N excreted into the environment but did not alter NH₃ emissions from the barn floor.

Key Words: Nitrogen, Manure, Ammonia

TH264 Characterization of wheat-based distiller's dried grain with solubles (DDGS) for ruminants. M Undi*, J. C. Plaizier, K. H. Ominski, and K. M. Wittenberg, *University of Manitoba, Winnipeg, MB, Canada.*

Advanced processing technology in the ethanol industry has improved DDGS quality for when corn is the primary feedstock. This study was designed to characterize wheat-based DDGS from western Canadian processing plants. Chemical analyses were carried out on wheat DDGS obtained from multiple runs of a plant using advanced processing technology and a plant using old processing technologies. For comparative purposes corn-based DDGS was obtained from three US plants. As well, rumen-fistulated animals were used to determine in situ dry matter and nutrient degradability of wheat and corn DDGS. Fistulated animals were fed two diets; a 50:50 concentrate:forage diet and a 95:5 grass forage:DDGS diet. Dacron bags containing 5 g of DDGS were incubated for 0, 2, 4, 6, 12, 18, 24, 48, and 72 h. Chemical analysis of DDGS samples from plants using advanced processing technologies showed that crude fat and starch were low and CP high in wheat DDGS relative to corn DDGS, averaging 66 and 148 g fat kg⁻¹ fat, and 7 and 48 g starch kg⁻¹, and 435 and 323 g CP kg⁻¹, DM basis, respectively. Wheat DDGS advanced processing technologies contained, g kg⁻¹ DM basis, 1.2 Ca, 1.1 P, 4.1 Mg, 10.1 K, and 4.1 S. New-generation wheat DDGS had an effective DM degradability of 65.6% (5% h⁻¹ flow rate), with a, b, and c fractions being 46.3%, 50.6%, and 0.03% h⁻¹, respectively. Diet type did not affect degradation parameters, however, effective DM degradability was higher in the old versus new technology wheat-based DDGS.

Key Words: Wheat, Corn, DDGS

TH265 Digestibility of corn distillers protein treated with glutamic acid fermentation solubles or not and exposed to heat damage. P. Summer*, *Ajinomoto USA, Inc., Eddyville, IA.*

The objective of this trial was to evaluate the effects of glutamic acid fermentation solubles (GAFS) and heat upon the enzymatic digestibility of protein in corn distillers grains plus solubles (DGS). A coproduct from glutamic acid production, GAFS was obtained from Ajinomoto Food Ingredients, Eddyville, Iowa. The trial was a 2 × 2 factorial with GAFS added to DGS to equal either 0 or 10% of the dry weight of DGS and heated at either 50 or 140°C in a forced air oven for 4 hours

followed by drying at 30°C. All treatments were applied in triplicate. Dried samples were rinsed to remove all soluble nitrogen and the water insoluble feed was dried gently (30°C). Samples within treatment were pooled and analyzed for Kjeldahl nitrogen (TKN) and ammonia nitrogen (AN). Intestinal protein digestibility of rinsed samples was estimated by incubating 15mg of nitrogen from each treatment (n=6) with pepsin (1g/L, Sigma P-7012) for one hour followed by pancreatin (3g/L, Sigma P-7545) and thymol (50mg/L) for 24 hours in 50ml polypropylene tubes. Trichloroacetic acid was added to stop digestion and precipitate proteins and large peptides. Three blanks were included. The tubes were centrifuged (3,200 X g) and the supernatant was analyzed for total nitrogen. Protein digestibility of the feed was calculated as the mg of nitrogen in the digest supernatant divided by the original mg of nitrogen in each tube. The TKN (% of DM), AN (% of DM), and protein digestibility of rinsed treatments were 5.16, 0.51, 48.1; 5.06, 0.53, 41.2; 5.16, 0.46, 47.2; and 5.26, 0.48, 48.3 for DGS-50, DGS-140, DGS+GAFS-50 and DGS+GAFS-140, respectively. Treatments were similar in TKN and AN. The main effects of GAFS ($P = 0.13$) and temperature ($P = 0.15$) upon protein digestibility were not significant. There was a significant interaction between GAFS and temperature ($P = 0.05$) as protein digestibility decreased in DGS but not in DGS+GAFS at high temperature. These data suggest GAFS or a component within GAFS protects protein in DGS from heat damage.

Key Words: Distillers Grains, Protein, Digestibility

TH266 Influence of Optigen® on nitrogen behavior in lactating dairy cows. R. L. Stewart, Jr.*¹, J. M. Tricarico¹, D. L. Harmon², W. Chalupa³, K. R. McLeod², G. A. Harrison¹, L. M. Clark², M. D. Meyer¹, R. Garcia-Gonzalez¹, and K. A. Dawson¹, ¹Alltech, Inc., Nicholasville, KY, ²University of Kentucky, Lexington, ³Global Dairy Consultancy Co. Ltd., Holderness, NH.

A study was conducted to compare N balance (Exp. 1) and in situ degradation (Exp. 2) of diets formulated for lactating dairy cows containing Optigen®, a controlled release NPN source, vs. soybean meal. Treatments (isonitrogenous, 16.7 % CP) consisted of: 1) soybean meal (SBM) vs. 2) NPN fed as 150 g/h•d⁻¹ Optigen® to replace a portion of the CP provided by SBM (OPT). In Exp. 1, six mid-lactation, multiparous Holstein cows (BW = 550 kg) were utilized in a crossover design to investigate N balance. Each period consisted of 14-d adaptation and 7-d N balance. In Exp. 2, two 600-kg ruminally cannulated steers were utilized in a crossover design to compare in situ degradation characteristics of DM, N and NDF of the diets above. Incubation times included 0, 2, 4, 6, 8, 16, 24, and 48 h. Dry matter and N disappearance data were fitted to the equation where $y = A + B(1 - e^{-Ct})$; y = disappearance (%), A = fraction available at time 0, B = fraction degraded at a measurable rate, and C = fractional rate of disappearance of fraction B. In Exp. 1, N intake was similar ($P < 0.23$: 518 g/d). Total N output (feces, urine, and milk) did not differ ($P > 0.49$) between the diets (483 g/d) and the resulting N balance was similar ($P > 0.91$; 36 g/d). Nitrogen efficiency (7.9 kg/kg), measured as kg of milk per kg of CP intake, did not differ ($P > 0.91$). In Exp. 2, the A (33.0 %) and B fractions (52.5 %) and the disappearance rate of B (8.0 %/h) for DM were similar between OPT and SBM ($P > 0.21$). Likewise, the A, B, and C fractions of N were similar ($P > 0.33$) between OPT and SBM diets (28.3 %; 61.3 %; and 9.3 %/h, respectively). However, the total degradable fraction of DM (A + B fractions) tended to be higher ($P < 0.06$) in the OPT diet compared to the SBM diet (86.5 and 83.3 %). Neutral detergent fiber digestibility tended ($P < 0.14$) to be higher for OPT at 24h (48.7 vs. 39.9%) but was

similar ($P > 0.24$) at 48 h (61.1 %). These results demonstrate Optigen® can be utilized to provide a portion of the CP without negatively affecting N balance or DM, N and NDF behavior in the rumen.

Key Words: Optigen, NPN, Nitrogen Balance

TH267 Meta-analysis of milk protein yield response data to lysine and methionine supplementation. D. Vyas* and R. A. Erdman, *University of Maryland, College Park.*

Previous reports on milk protein responses to metabolizable amino acid (MAA) supplementation focused on lysine (LYS) and methionine (MET) expressed as a percentage of metabolizable protein and not to the actual amounts of MAA supplemented. The objective of this study was to determine the milk protein yield (g/d, MPG) responses to the amounts of LYS and MET supplemented. Meta-analysis was performed on results from 21 published articles involving 36 treatment comparisons of post-ruminal LYS and MET supplementation in lactating dairy cows. A broken-line regression model using the NLmixed procedure in SAS 9.1 (Robbins et al., 2006, *J. Anim. Sci.* 84(Suppl E):E155–E165) was used. The following statistical model was used: $MPG \sim \text{Normal}(L + (U \times z1) + E + (E \times z1) + \text{lvar}, \text{errvar})$, where: $z1 = (\text{MAA (g/d)} < R) \times (R - \text{MAA (g/d)})$; R is the abscissa of breakpoint; L is maximal milk protein. Slope = 0; U is the slope and lvar and errvar are the variance components of L and error term, respectively.

Experiment (E) effects were removed by designation as random effects within the model. With MET and LYS supplementation, the breakpoints (R) were 121 and 275 g/d, the maximum protein yields (L) were 1212 and 1160 g/d, and the slopes were -3.50 and -2.49, respectively. Assuming MET and LYS concentration of 2.71 and 7.63 g/100g milk protein, this implies only 9.5 % and 19 % efficiency of use of these supplemental MAA for protein synthesis. It should be recognized that overall efficiencies of MAA utilization tends to be underestimated when amino acid supply is close to the animal's needs.

Table 1. Parameter estimates for lysine and methionine

Amino acids	L	U	R	SEM	Adj. R ²
Methionine	1212	-3.50	121	30.75	0.96
Lysine	1160	-2.49	275	47.29	0.89

SEM= Standard error of Mean

Key Words: Metabolizable Amino Acids, Milk Protein

TH268 Do feedstuffs contain a constant protein fraction that is both undegradable in the rumen and indigestible in the small intestine? S. E. Boucher*¹, C. M. Parsons², and C. G. Schwab¹, ¹*University of New Hampshire, Durham*, ²*University of Illinois, Urbana.*

To evaluate differences in intestinal digestibility of rumen undegraded amino acids (AA) within feeds and to determine if feeds contain a constant protein fraction that is both undegradable in the rumen and indigestible in the intestine, as is assumed in the AAT/PBV Protein System (1995), samples of soybean meal (SBM), SoyPlus® (SP), dried distillers grains with solubles (DDGS), and fishmeal (FM) were obtained from FeedAC, Inc. Feeds were analyzed for AA and incubated in situ

for 16 h in the rumen of 4 lactating cows. After incubation, bags were rinsed, washed in methylcellulose solution, and dried. Rumen undegraded residues (RUR) were pooled by sample, analyzed for AA, and ruminal degradation of AA (RDAA) was calculated as disappearance from the bags. Sub-samples of the intact feeds (IF) and RUR were tube fed to 4 cecectomized roosters each, and total excreta were collected for 48 h and analyzed for AA. Endogenous AA losses were estimated from fasted birds, and standardized intestinal AA digestibility (SDAA) of the IF and RUR was calculated. Indigestibility coefficients of the IF were calculated as $100 - \% \text{SDAA}$ and indigestibility of RUR was calculated as $((100 - \% \text{RDAA}) * (100 - \% \text{SDAA})) / 100$. The results indicate that SDAA in RUR differs within feeds, and SDAA coefficients were most often lowest for Lys, His, Cys, and Pro and highest for Trp, Leu, and Met. The observed ranges of SDAA in the RUR of SBM, SP, DDGS, and FM were 88-99, 85-99, 63-100, and 55-99%, respectively. The indigestibility coefficients of the IF and RUR also differed within all feeds and were lower for the RUR than for the IF. It appears that SBM, SP, DDGS, and FM do not contain a constant protein fraction that is both undegradable in the rumen and indigestible in the small intestine, but rather they contain a protein fraction that is indigestible in the intestine but partly degradable in the rumen and/or digestible in the intestine after rumen incubation.

Key Words: Amino Acid Digestibility, Rumen Undegraded Protein, AAT/PBV System

TH269 Effects of 2-hydroxy 4-(methylthio) butanoic acid isopropyl ester (HMBi) on the organic matter digestibility (OMD) and energy value of corn dried distillers grains with solubles (DDGS). E. Devillard*, L. Ducrocq, C. Richard, and P. A. Geraert, *Adisseo, Commeny, France.*

HMBi used in dairy cow rations is a source a metabolisable methionine for the animal. In addition, HMBi presents the particularity to enhance rumen function. Indeed, HMBi was shown to increase the rumen fermentations and consequently the energy value of different feedstuffs (Robert et al. 2002). Corn DDGS being largely available through the biofuel production, the potential of using HMBi to improve energy values of such feedstuffs was investigated. This was carried out using the rumen fermentation simulation technique (HFT gas test) where 4 different corn DDGS with different compositions were incubated with rumen fluid, and HMBi at 2 different doses. Gas production was measured and allowed to calculate OMD, and energy values of corn DDGS. Using a dose of 2.5% HMBi of the substrate dry matter (DM), the OMD of the 4 different DDGS was increased significantly. The increase varied between 2.1 to 3.2 % compared to the untreated control, depending on the DDGS. This corresponded to at least 2.9 % increase of the energy value of the corn DDGS. When the dose of HMBi added to the incubation was lowered to 0.1% HMBi of the substrate DM, OMD and energy values were also improved, numerically for 2 DDGS and significantly for the 2 others. With such a dose, the increase of energy value of DDGS could reach 1.5%. In order to further investigate the results obtained with the HFT technique, batch incubations were performed using the DDGS having exhibited the highest response. Its NDF and ADF digestibilities were improved with 0.1% HMBi supplementation and did not increase further when this dose was increased. These results show that i) HMBi can improve energy values of corn DDGS, ii) the effects of HMBi on corn DDGS vary with their type and composition, iii) improvement observed

at low dose could mainly be due to the increase in fibre degradation, iv) increasing dose of HMBi would not lead to a further improvement of fibre degradation, but could favour other fermentation processes.

Key Words: HMBi, Energy Value, Corn DDGS

TH270 Effects of feeding a controlled rumen release urea on productivity of Holstein cows. A. Highstreet*¹, J. Robison¹, P. H. Robinson², and J. G. Garrett³, ¹California State University, Fresno, ²University of California, Davis, ³Balchem Encapsulates, New Hampton, NY.

While urea is often added to rations of lactating dairy cattle, it is solubilized and converted to ammonia rapidly in the rumen which could lead to inefficient use of dietary N. Our objective was to determine if a controlled rumen release urea (Nitroshure (NS) Balchem, New Hampton, NY), increases performance, and efficiency of capture of dietary N in milk, when it replaced urea in diets of lactating dairy cows. NS was determined to be 45.0% N and 9.9% fatty acids that were 80% C18:0, 17% C16:0 and 3% others. Ruminal in sacco incubation, with hand washing of bags, showed 72, 89 and 99% rumen N solubilization (includes loss at t=0 h) at 0.5, 4 and 12 h respectively. Pens of multiparous lactating cows (2 early and 2 mid-lactation) on a California dairy were fed one of 2 TMR formulated to supply 5% of ration CP as urea or NS. The study was 2 experiments (early and mid-lactation) in 2x2 factorials within switchover designs with 2 experimental periods of 4 weeks. All pens were fed twice daily to appetite with daily intakes recorded by pen. TMR and TMR ingredients were sampled twice in the final week of each period for chemical analysis. Cows were milked thrice daily with milk yield and components measured at the end of each period. Urine samples were collected from 20 cows/pen voluntarily urinating at the end of each period with fecal collections from these same cows 24 h later. There were no differences among TMR in nutrient analyses, with average CP and NDF of 17.9 and 33.4% respectively. DM intakes did not differ due to treatment in either early or mid-lactation. In mid-lactation, there were no differences in milk production, or component levels or outputs, due to replacement of urea with NS in the TMR, while early lactation cows had increased (P<0.01) milk fat and protein %, as well as milk fat, protein and energy outputs. Neither early or mid-lactation cows had different urinary or fecal N output due to treatment, capture of dietary N in milk was not impacted, and whole tract NDF digestibility was unaffected. Feeding a controlled rumen release urea in replacement for urea at about 5% of dietary CP improved performance of early lactation high producing dairy cows.

Key Words: Urea, Dairy, Rumen

TH271 In vitro ruminal protein degradation and microbial protein formation of seed legumes. S. Colombini¹ and G. A. Broderick*², ¹University of Milan, Milano, Italy, ²U.S. Dairy Forage Research Center, Madison, WI.

Seed legumes such as peas, lupins and faba bean are important feeds for dairy cows in Europe and other regions. Ruminal protein degradability was quantified using the inhibitor in vitro (IIV) system for samples of 5 seed legumes: 2 peas (cv. Alembo and Helena), 1 white lupin (*Lupinus albus*, cv. Multitalia), 1 blue lupin (cv. Quilinok), and 1 faba bean (*Vicia*

faba minor, cv. Chiaro). Incubations were stopped by adding acid at 0, 2, 4 and 6 h; ruminal escape was computed assuming a passage rate of 0.06/h. Five standard proteins were included. Additional incubations were conducted without growth inhibitors in an attempt to correct for N incorporation by bacteria. These were conducted for 2, 4 and 6 h with ruminal inoculum containing ammonium sulfate enriched with N-15. Net microbial growth (growth above blank) was estimated from total non-ammonia N (NAN) plus N-15 enrichment of total NAN and isolated bacterial NAN. Significant differences were observed among protein sources in IIV degradation traits (Table 1). Typical estimates of degradation rate and rumen-undegraded protein (RUP) were obtained for the standard proteins. The 2 pea sources had slower degradation rates and greater RUP than the lupins and faba bean. The IIV system ranked the RUP contents of the 5 legumes differently from the Cornell model. Excessive variation prevented reliable estimates of degradability in uninhibited inoculum. However, there was a trend (P = 0.15) for an effect of seed legume on microbial NAN formation; greater content of starch and water soluble carbohydrate may have supported greater formation of bacterial NAN for Alembo peas and Chiaro faba beans. Both microbial growth and protein escape should be considered when evaluating feeds rich in protein and fermentable energy.

Table 1. In vitro ruminal protein degradability and microbial NAN formation

Source	Cultivar	N (%)	Inhibitor in vitro			Cornell model		Uninhibited Microbial NAN [mg/(h*100 ml)]

TH272 In situ ruminal degradation of nitrogen fractions of cottonseed and canola meals. T. Tashakkori, M. Danesh Mesgaran*, A. R. Heravi Mousavi, and H. Nasri Moghaddam, Ferdowsi University of Mashhad, Mashhad, Iran.

The experiment was investigated to determine ruminal degradation of nitrogen fractions [true protein (TP), buffer insoluble protein (BIP), neutral detergent insoluble protein (NDIP) and acid detergent insoluble protein (ADIP)] of cottonseed meal (CP= 280 g/kg DM) and canola meal (CP= 420 g/kg DM) using nylon bag technique. Two Holstein steers (450±50kg body weight) fitted with ruminal fistula were used.

Samples were weighed into nylon bags (19×12 cm, pore size= 48µm, n= 8) and incubated in the rumen for 0, 8, 24, 48 and 72 h. Nitrogen fraction concentrations were determined in intact and incubated samples using standard procedures. Data were applied to the equation of $P = a + b(1 - e^{-ct})$; P= degradability potential, a= rapidly degradable fraction, b= slowly degradable fraction, c= degradable constant, t= time. True protein degradation of cottonseed meal (a= 0.35±0.059, b= 0.49±0.394, c= 0.018±0.028) was markedly different from those of canola meal (a= 0.24±0.041, b= 0.71±0.046, c= 0.08±0.013). BIP degradation of cottonseed meal (a= 0.42±0.031, b= 0.89±0.723, c= 0.01±0.011) was higher than canola meal (a= 0.35±0.035, b= 0.63±0.047, c= 0.06±0.012).

NDIP degradation coefficients of cottonseed meal and canola meal were a= 0.45±0.063 and 0.16±0.086, b= 0.66±1.46 and 0.71±0.01, c= 0.008±0.026, 0.056±0.023, respectively. Ruminal degradation of ADIP of canola meal and cottonseed meal were a= 0.15±0.175 and 0.29±0.102, b= 0.29±0.226 and 0.17±0.126, c= 0.086±0.179 and 0.04±0.114, respectively. Results of the present study indicate that the nitrogen fractions of cottonseed meal and canola meals were degraded in the rumen with different kinetics.

TH273 Influence of production traits on the sheep enterprise profitability: A modeling approach. V. Demers Caron*¹, D. Pellerin¹, and F. W. Castonguay^{1,2}, ¹Université Laval, Québec, Québec, Canada, ²Agriculture and Agri-Food Canada, Sherbrooke, Québec, Canada.

Many production traits have an impact on the net income in sheep production systems. Because these traits are all interconnected, it is difficult to quantify their relative impact on the enterprise profitability. A deterministic model, *SimulOvins*, has been developed to simulate the operation of a sheep flock, either in extensive or intensive production systems (3 lambings in 2 years). This discrete events simulation, built on a daily basis, takes into account the following criteria: production structure (number of breeding groups, interval between matings), herd size, breeds, crossbreeding system, parity, ewe fertility and prolificacy at each mating group depending on the breeding season and the out-of-season breeding techniques used, lamb growth and carcass quality adjusted for litter size, culling and mortality rates, production costs (feed, out-of-season breeding techniques, management...) and revenues from lambs sold (new crop, light or heavy lambs), culled animals and wool. Some of the outputs that could be obtained are: flock fertility and prolificacy, number of lambings attained per ewe per year, number of lambs of each type sold per week, labor and space requirement, revenues, variable costs and gross margin. Productivity can be calculated for each mating group, year, breed or parity. By conducting simulations, it is possible to assess the impact of farm-level management decisions on the flock performances. Then, the conversion of the technical data in economic data allows the estimation of the effects of these changes on the profitability. Special efforts were made to build a user friendly tool so that it can be not only used for research, but also for teaching purposes and, ultimately, to help experts in supporting farmers in their management decisions.

TH274 Estimating average fiber diameter and variability of wool fleeces using Optical Fibre Diameter Analysers (OFDA 100 and 2000). F. A. Pfeiffer*, C. J. Lupton, and D. F. Waldron, *Texas AgriLife Research, San Angelo, TX.*

Average fiber diameter (AFD) and variability (CV) of wool fleeces are important value determining traits that are measured and used to make animal selection decisions. The traits are accurately determined for individual animals by shearing the whole fleece and measuring a representative (cored) sample using standard methodology. Such procedures are time consuming and expensive. Consequently, faster, less expensive methods have been investigated. Mid-side samples shorn from 729 rams participating in central performance tests between 2004 and 2007 were measured as-is with an OFDA2000 instrument (BSC Electronics, Ardross, Australia) to obtain AFD2 and CV2. The samples were also guillotined close to the base of the staple, and sub-samples were cleaned and measured with an OFDA 100 to obtain AFD1 and CV1. Subsequently, the rams were shorn and whole fleeces were sampled and measured (OFDA 100) in a standard manner to obtain AFD and CV. Data were analyzed using MEANS, TTEST, and REG procedures of SAS. AFD1 > AFD > AFD2 (22.5, 21.8, and 21.6 μm , respectively, $P < 0.01$) and CV > CV1 ($P < 0.0001$) = CV2 ($P = 0.56$; 20.2, 16.0, and 16.1%, respectively). Regression analyses are summarized in Table 1.

In conclusion, the r^2 and slope values indicate the faster methods were not capable of accurately estimating AFD or CV of whole fleeces. Estimates of AFD were more accurate and precise than those of CV. In the absence of standard whole fleece measurements, AFD1 and AFD2 would provide useful guidance for selection purposes.

Table 1. Regression analyses

y	x	r^2	SEy	Slope
AFD	AFD1	0.79	0.63	0.76
AFD	AFD2	0.73	0.70	0.73
AFD1	AFD2	0.78	0.75	0.87
CV	CV1	0.16	2.40	0.59
CV	CV2	0.21	2.32	0.69
CV1	CV2	0.56	1.18	0.77

Key Words: Fiber Measurement, Sheep, Wool

TH275 Performance of F₁ crossbred lambs from Dorper and Katahdin rams and Pelibuey and Barbados Blackbelly ewes. G. M. Pérez, F. A. Rodríguez-Almeida*, M. A. Levario, J. C. Ontiveros, J. A. Villareal, B. Piña, O. G. Núñez, J. R. Peña, and J. A. Ortega, *Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, México.*

The objective was to compare growth performance and carcass traits of F₁ crossbred lambs sired by Dorper (Dp) and Katahdin (KH) rams mated to Barbados Blackbelly (BB) and Pelibuey (PB) ewes. Fifty six male lambs from five DP rams and 43 from three KH rams were used. Ewe numbers were 52 for BB and 32 for PB. Lambs were from three different lots according to date of lambing. Weights were recorded at birth (LW), weaning (WW; 90 d of age) and slaughter (SW; after 56 d on feedlot). Feed intake (FI) was calculated as the difference between the daily amount of feed offered and the amount rejected. The feedlot diet was balanced according to NRC requirements, with 13 % CP and 3.15 Mcal of ME/kg of DM through an average of 28 kg of BW, and 11 % CP and 3.17 Mcal of ME/kg thereafter. Carcass traits analyzed were yield (CY), weight (CW), length (CL), depth (CD), ribeye area, back fat depth, and weights of kidney fat (KF), rear leg, thorax and loin. Data were analyzed with PROC MIXED of SAS. The model included fixed effects of sire breed, dam breed, number of lambs born (1, 2 or 3), lot, and the interaction of sire breed by lot, and random effects of sire and dam within their respective breeds. Breed of sire was important for LW ($P < 0.03$), CY ($P < 0.07$), and weights of rear leg ($P < 0.03$) and thorax ($P < 0.06$). Lambs from KH rams were heavier than lambs from DP rams (2.73 ± 0.08 vs 2.19 ± 0.08 kg) at birth, but not thereafter. Lambs sired by DP rams had carcasses with greater CY (53.8 ± 0.5 vs 52.5 ± 0.6 %) and heavier rear leg (2.36 ± 0.05 vs 2.19 ± 0.06 kg) and thorax (2.60 ± 0.06 vs 2.39 ± 0.07 kg) than lambs sired by KH rams. Breed of dam was significant ($P < 0.01$) only for ADG, with a larger mean for lambs from PB than from BB ewes (0.298 ± 0.005 vs 0.275 ± 0.006 kg/d). In conclusion, lambs sired by DP rams had similar growth performance than lambs sired by KH rams, but resulted in larger carcass yield and weight of a high value cut: the rear leg.

Key Words: Growth, Carcass Traits, Hair Sheep Crosses

TH276 Productive performance and carcass characteristics of hair sheep of different genotypes in feedlot. F. G. Rios*, P. Hernandez, J. F. Obregon, D. C. Acosta, R. Cortina, J. J. Ortiz, and J. J. Portillo, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico.*

To determinate the productive performance and carcass characteristics of hair sheep of different genotypes in the feedlot, 48 ram lambs, 16 Dorper × Pelibuey (D×P), 16 Katahdin × Pelibuey (K×P), and 16 Pelibuey (P), (BW=38.97 ± 1.56 kg) were used in a randomized complete block experiment where block was initial weight. The lambs were assigned to consume a diet fed ad libitum with 15.5 % CP and 2.89 Mcal of DE/kg, consisting of 66 % whole corn grain, 12 % Sudan hay grass, 11.7 % soybean meal, 7.0 % molasses cane, 2.7 % mineral premix, and 0.6 % sodium bicarbonate, during 45 d. Feed intake (FI), average daily gain (ADG), feed efficiency (FE) and carcass traits, were recorded. The data were analyzed with ANOVA for randomized blocks design; Tukey test were utilized to examine the effect of genotype. The harvest weight, FI, ADG and FE were similar (P>0.05) among the breed types. Hot carcass weight were heavier (P<0.05) for D×P and K×P (30.58, and 29.01 vs. 28.40 kg; 0.481 SEM), than genotype P; and *Longissimus thoracis* area was largest (P<0.01) for P and D×P carcasses than genotype K×P (12.68, and 12.30 vs. 10.94 cm²; 0.256 SEM). Carcasses of D×P and K×P had greater (P<0.05) fat thickness measurements than P carcasses, and marbling score was greater (P<0.01) in P carcasses than D×P and K×P types. Length of leg was largest (P<0.01) for P carcasses than D×P and K×P. Depth of leg and compact leg index were higher (P<0.05) for D×P and K×P carcasses than genotype P. Carcasses from type P had higher (P<0.01) mesenteric fat and retail product yield than D×P and K×P lambs. Chilled carcass weight (29.07 kg), dressing percentage (58.25 %), body wall thickness (14.28 mm), compact carcass index (0.385), and empty body weight (46.22 kg), were similar (P>0.05) among the breed types. It is concluded that Dorper × Pelibuey hair sheep had superior carcass characteristics but similar productive performance to Pelibuey and Kathadin × Pelibuey types in the feedlot.

TH277 Comparative reproduction characterization among four crossbred groups of hair sheep: Prolificacy. W. R. Getz*, S. Mobini, and S. Gelaye, *Fort Valley State University, Fort Valley, GA.*

The use of hair or shedding breeds of sheep in commercial lamb production systems appears to be increasing in Georgia and the Southeast. Profitability from these enterprises is influenced to a large degree by the number of lambs born and sold. Reproductive rates have been shown to be influenced by breed and type of sheep. Over a six-year period, prolificacy data were collected from 145 ewes in four breed groups. A total of 248 parturitions were recorded including 103 parturitions from crossbred ewes composed of Dorset, Hampshire, Suffolk or western dual-purpose heritage; and three groups of ewes of hair sheep heritage. The hair sheep data included 28 parturitions from halfbred or ¾-bred Katahdin ewes, 26 parturitions from halfbred or ¾-bred Dorper ewes, and 91 parturitions from 50% white Dorper × 50% Katahdin composite ewes. Number of lambs born per ewe across all breed groups was 1.71±.0359. Wool crossbred ewes = 1.67±.0607 lambs; Dorper-cross ewes = 1.69±.0923 lambs; Katahdin-cross ewes = 1.71±.0869 lambs; and Dorper × Katahdin composite = 1.76±.0592 lambs per parturition.

Differences among the individual breed groups were minimal. These data suggest that either of the breed groups would be equally prolific in commercial lamb production systems in middle Georgia.

Key Words: Sheep, Breeds, Prolificacy

TH278 Male effect on heat distribution and pregnancy rate to timed AI and throughout the breeding season in postpartum Santa Ines ewes. M. V. Biehl¹, A. V. Pires*¹, I. Susin¹, C. Q. Mendes¹, F. S. Urano¹, R. S. Gentil¹, E. M. Ferreira¹, G. H. Rodrigues¹, and M. L. Day², ¹*Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo (USP), Piracicaba, SP, Brazil.*, ²*The Ohio State University, Columbus.*

Objectives were to evaluate the effect of presence of the male on distribution of estrus after synchronization and pregnancy rate to timed AI and through the breeding season. Santa Ines ewes (n=270; 45 to 60 days postpartum) were blocked according to parity, lambing date, body weight and body condition score (BCS) and assigned to either: Treatment I (control, n=93) no ram exposure; Treatment II (n=97) presence of teaser rams with lateral deviation of the penis; Treatment III (n=80) presence of vasectomized teaser rams. Rams were introduced into the respective treatments (1 ram:30 ewes) 20 days before the application of an intravaginal progesterone releasing device (Eazi-Breed CIDR[®] with 33 mg of progesterone). The CIDR was withdrawn after 7 days, an injection containing 300 IU of eCG (Folligon[®]) and 5 mg of dinoprost (Lutalyse[®]) was given at that time. Estrous detection was performed continuously from CIDR withdrawal until intracervical timed AI (TAI) 55 hours later. Ewes were exposed to intact rams (3 rams/treatment) for 45 days; beginning 10 days after TAI. Pregnancy status was determined by US at 45 days after TAI and 30 days after the breeding season. Mean BCS was 3.0 ± 0.2. Estrus was detected in 140 (52%) at a mean of 45 ± 13 hours after CIDR withdrawal (21 and 41% between 24-36 and 37-48 hours, respectively), and did not differ between treatments. There was no differences among treatments for pregnancy rate to TAI (34.5%, 93/270) to the first natural mating after TAI (37%, 100/270), or at the end of the breeding season (89.6%, 242/270). These data suggest that TAI approximately 10 hours before recommended by the CIDR manufacturer would coincide with onset of estrus in a greater proportion of ewes. Neither exposure to rams or type of teaser ram used influenced pregnancy rate to TAI or during the breeding season.

Key Words: Male Effect, Hair Sheep, TAI

TH279 Retention of sperm motility, viability and fertility in ram semen after liquid storage at 4°C for up to 96 hours. J. L. Mook, J. R. Collins, and S. Wildeus*, *Virginia State University, Petersburg.*

The availability of reliable overnight shipping has provided new opportunities for the use of sheep semen stored at refrigerated temperatures prior to insemination. This experiment evaluated sperm motility and viability, as well as fertility, of ram semen stored at 4°C for up to 96 h. Semen was collected on 7 consecutive days by artificial vagina from 6 hair sheep rams during the breeding season (November), and 4 ejaculates with the highest initial motility were pooled each day. Pooled semen was diluted in a Tris-egg yolk (2.5%) extender with antibiotics, but without glycerol to a concentration of 400 million sperm/ml, pack-

aged in 0.25 ml straws, and stored horizontally at 4°C. Straws were evaluated in triplicate for motility (Minitube SpermVision CASA) and viability (Giesma staining) at 24 h intervals for 96 h immediately after warming and after incubation at 37°C for 6 h. Fertility was assessed in 0 and 72 h-liquid stored semen using 64 post-pubertal ewes. Ewes were estrus synchronized with flurogestone acetate sponges (40 mg, 12-14 d), and 500 IU eCG at sponge removal, and were inseminated in 4 timed, intrauterine artificial insemination sessions on successive days. Data were analyzed for the effect of day of collection, length of storage and incubation on sperm quality, and for the effect of 72 h-storage on fertility. Day of collection affected ($P<0.01$) total (Tmot) and progression of motility, but had no effect on sperm velocity or viability. There was a linear decline ($P<0.001$) from 0 to 96 h in motility (Tmot 76.4 to 56.6%), curvilinear velocity (218.8 to 176.6 $\mu\text{m/s}$) and viability (79.1% to 68.1%). Incubation had no effect on sperm motility at any stage of storage, but viability and velocity declined ($P<0.01$) following incubation. Fertility was not different between fresh and 72 h-stored semen (45.2 vs. 41.9%, respectively), but fluctuated between insemination sessions (31.3 to 60.0%). Data suggest that liquid ram semen experienced only a moderate decline in motility and viability after extended cooled storage, but further research is needed to account for the variability observed in individual collections.

Key Words: Semen, Ram, Fertility

TH280 Meat characteristics of crossbred lambs fed normal or heated whole cottonseed¹. R. R. P. S. Corte*², P. R. Leme², G. Aferr², A. S. C. Pereira², and S. L. Silva², ¹FAPESP, São Paulo, São Paulo, Brazil, ²Universidade de São Paulo, Pirassununga, São Paulo, Brazil.

Thirty-two crossbred lambs, sixteen males and sixteen females, with average weight and age of 20 kg and 75 days were fed for 63 days to evaluate the effects on the meat characteristics of lambs when there was an inclusion in their diets, in different levels, of normal or heated whole cottonseed. The animals were fed four different experimental diets: CA0, with 0% of cottonseed, CA10, with 10% of cottonseed, CA20, with 20% of cottonseed and CA20H, with 20% of heated cottonseed. For shear force, sensory panel and cholesterol analysis, samples of *Longissimus* muscle were used. Shear force was evaluated with a Warner Bratzler in samples aged 1 or 7 days, trained sensory panel was performed with samples aged 7 days, and cholesterol for enzymatic method was performed with spectrophotometric reading. The animals were assigned to a randomized block design by crossbred type ($\frac{1}{2}$ Dorper $\frac{1}{2}$ \times Santa Inês and $\frac{1}{2}$ Dorper \times $\frac{1}{2}$ Texel). Effects of treatments were evaluated by analysis of variance using the *MIXED* procedure of SAS software. There was no blocked effect and gender effect on objective tenderness characteristics, sensory panel or cholesterol. Meat characteristics, such as objective tenderness, were not affected by treatments and aging, with values for CA0 of 3.74, CA10 2.77, CA20 3.77 and CA20H 3.24 kg. Samples which were aged for 1 day had a mean shear force value of 3.46 kg and those aged 7 days had a mean value of 3.01 kg. Sensory qualities (characteristic flavor, off-flavor, juiciness, texture, characteristic taste and strange flavor) were not affected by the experimental diets. Off-flavor was classified as very weak indicating that the meat did not present any unpleasant characteristics. Grades given by the panelists have suggested that the analyzed lamb meat had an excellent acceptance regardless of gender or treatment. Meat cholesterol was not affected by the diets with a mean value of 90 mg/100g.

Key Words: Sub Product, Small Ruminant, Meat Attributes

TH281 Fatty acid composition of meat from crossbred lambs fed normal or heated whole cottonseed¹. R. R. P. S. Corte*², P. R. Leme², A. S. C. Pereira², G. Aferr², and J. C. C. Balieiro², ¹FAPESP, São Paulo, São Paulo, Brazil, ²Universidade de São Paulo, Pirassununga, São Paulo, Brazil.

To assess the effects of whole cottonseed (at different levels) or heated cottonseed in the diet on fatty acid composition in the meat of lambs, thirty-two crossbred lambs (16 males and 16 females with mean weight and age of 20 kg and 75 d) were fed for 63 days four diets: CA0, with 0% cottonseed, CA10, with 10% cottonseed, CA20, with 20% cottonseed and CA20H, with 20% heated cottonseed. At slaughter, a sample of the *Longissimus* muscle was taken for analysis of fatty acid composition. Lipids were extracted for fatty acid composition, and fatty acids methyl esters were determined by gas chromatography. The experiment had a randomized block design by crossbred type ($\frac{1}{2}$ Dorper $\frac{1}{2}$ \times Santa Inês (D-SI) and $\frac{1}{2}$ Dorper \times $\frac{1}{2}$ Texel (D-T)). Effects of treatments were evaluated by analysis of variance using the *MIXED* procedure of SAS software. The block and the diets had an effect on total saturated fatty acids (SFA) ($P=0.001$, $P=0.03$), monounsaturated fatty acids (MUFA) ($P=0.017$, $P=0.002$) and on the ration of unsaturated/saturated fatty acids (UFA/SFA) ($P=0.002$, $P=0.03$) and monounsaturated/saturated fatty acids (MUFA/SFA) ($P=0.002$, $P=0.002$). The meat of D-SI crossbred type had a higher proportion of SFA (48.30%), lower proportion of MUFA (43.66%) and lower ratio of UFA/SFA (1.08%) and MUFA/SFA (0.91%) when compared to the D-T (SFA=45.62, MUFA=45.14, UFA/SFA=1.20, MUFA/SFA=0.99%). The meat of animals fed diets with whole cottonseed (CA10, CA20 and CA20H) had a higher proportion of SFA (46.96, 48.17 and 47.58%), lower proportion of MUFA (44.23, 43.52 and 43.27%) and consequently lower ratio of UFA/SFA (1.13, 1.08 and 1.11%) and MUFA/SFA (0.94, 0.90 and 0.91%) when compared with the control diet CA0 (SFA=45.12, MUFA=46.58, UFA/SFA=1.22 and MUFA/SFA=1.04%). Whole cottonseed supplementation increased meat SFA and decreased MUFA. The effect of gender was significant for total polyunsaturated fatty acids (PUFA) ($P=0.007$), omega 6 ($\omega 6$) ($P=0.004$) and for the ratio of PUFA/SFA ($P=0.008$) in the animals meat. The male meat presented a higher proportion of PUFA (9.71%) and $\omega 6$ (8.24%) and a higher ratio of PUFA/SFA (0.21%) when compared to the female meat (PUFA=7.57, $\omega 6$ =5.83, PUFA/SFA=0.16).

TH282 Effects of added protein and dietary fat on lamb performance and carcass characteristics when fed differing levels of dried distiller's grains with solubles. M. L. Van Emon*, A. F. Musselman, P. J. Gunn, M. K. Neary, R. P. Lemenager, and S. L. Lake, *Purdue University, West Lafayette, IN.*

The objective of this study was to evaluate the influence of dietary protein and fat in dried distiller's grains with solubles (DDGS) on feedlot performance and carcass characteristics in finishing lambs. Sixty crossbred lambs were allotted (33.17 ± 4.67 kg) into pairs (ewe and wether) and fed one of five isocaloric dietary treatments: 1) a corn based diet with DDGS included to meet CP requirements (25% of DM; CON), 2) CON with DDGS included at twice the amount of CON (50% of DM; 50DDGS), 3) CON with added protein to equal the CP in the 50DDGS diet (CON+CP), 4) CON with added vegetable oil to equal the fat in the 50DDGS diet (CON+VO), and 5) CON with protein and fat added to equal the CP and fat in the 50DDGS diet (CON+CPVO). Lambs were harvested when they obtained an approximate 12th rib fat

depth of 0.51 cm. Average number of days on study did not differ ($P = 0.78$) between treatments. Average daily gain ($P = 0.48$) and final BW ($P = 0.69$) were not influenced by treatments. However, G:F tended ($P = 0.13$) to be lower in CON (0.0480 ± 0.0042), CON+CP (0.0448 ± 0.0053), and CON+VO (0.0476 ± 0.0064) than 50DDGS (0.0732 ± 0.0374) and DMI tended ($P = 0.14$) to be higher in CON (4.92 ± 0.90 kg/pen/d) and CON+VO (4.82 ± 0.66 kg/pen/d) than 50DDGS (3.62 ± 1.34 kg/pen/d). Dietary treatment did not affect HCW ($P = 0.79$), dressing percentage ($P = 0.34$), 12th rib fat depth ($P = 0.71$), LM area ($P = 0.67$), body wall thickness ($P = 0.57$), yield grade ($P = 0.71$), flank streaking ($P = 0.62$), leg score ($P = 0.96$), or ether extract ($P = 0.36$). Although DMI tended to decrease and G:F tended to increase in the 50DDGS treatment, added CP or fat from DDGS had no overall effect on lamb performance or carcass characteristics. Therefore, these data indicate that DDGS can be included in feedlot lamb diets at levels up to 50% of DM without affecting overall performance or carcass quality.

Key Words: Distiller's Grains with Solubles, Lamb, Performance

TH283 Two levels of dried distillers grains with solubles on growth performance and carcass characteristics of Pelibuey sheep. A. Estrada-Angulo*, E. J. Lopez, G. Contreras, B. I. Castro, J. F. Obregon, and A. B. Perez, *CA-205-FMVZ-UAS, Culiacan, Sinaloa, Mexico.*

To determine the effect of two levels of dried distillers grains with solubles (DDGS) substituting partially at whole corn grain on growth performance and carcass characteristics of Pelibuey sheep. 20 Pelibuey ram lambs (BW= 33.1 kg) were fed for 70 days in a randomized block experiment design. The animals were weighed and blocked by weight in 10 groups of two, placed into 10 (2 × 3 m) floor pens, and assigned to one of two diets: 1) DDG25 had 17.3% CP and 3.53 Mcal DE/kg, and contained 25% dry distillers grains with solubles, 12.5% Sudan hay, 52% whole corn grain, without soybean meal, 8% sugarcane molasses, and 2.5% mineral premix; 2) like Control, DDG40 had 18.4% CP and 3.53 Mcal of DE/kg, but contained 40% DDGS and 37% whole corn grain. Feed was offered twice daily under free access conditions. In the first 35 days of the experiment, diet had no effect on ADG (265 and 255 g/day), DMI (1.109 and 1.149 kg/day), or feed/gain (4.132 and 4.556) for DDG25 and DDG40 respectively. Also, for the entire 70-d period, ADG (267 and 263 g/d), final weight (51.69 and 51.65 kg), and feed/gain (4.61 and 4.68) were similar ($P > 0.05$) for DDG25 and DDG40 respectively. Hot carcass weight (29.8 and 29.83 kg), dressing percent (57.6 and 57.7%), fat thickness (0.24 and 0.24 inches), rib eye area (15.74 and 15.23 square centimeters), carcass length (114 and 115.6 cm), leg circumference (45.4 and 46.8 cm), were not affected by DDGS level. It is concluded, that dry distillers grain with solubles can substitute partially in 25 or 40 % at whole corn grain in complete diets for Pelibuey sheep.

Key Words: Dried Distillers Grains, Whole Corn Grain, Pelibuey Sheep

TH284 Dried distillers grains as a supplement for grazing ewe lambs. I. Susin*¹, D. D. Clevenger², G. D. Lowe², P. A. Tirabasso², and S. C. Loerch², ¹*Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo(USP), Piracicaba, SP, Brazil,* ²*The Ohio State University, Wooster.*

Dried distillers grains plus solubles (DDGS) is a by-product of ethanol production and is a good source of protein and energy for ruminants. Frequently, weaned ewe lambs do not meet their nutritional requirements when pasture is the sole source of feed. When nutritional requirements are not met, growth rate is reduced and animals may be more vulnerable to parasite infection. Sixty-two ewe lambs (24.5 ± 0.5 kg BW and 2 mo. old) were used to determine the effects of supplementing DDGS on grazing performance and parasite status. Four orchardgrass paddocks were used with 15 or 16 lambs each. Ewe lambs in each paddock were randomly assigned to one of two experimental treatments: 1) control (only pasture), or 2) DDGS =1.3% BW of DDGS supplementation on pasture. Paddock was considered the experimental unit and a totally randomized design was used. Supplementation of DDGS started one week before weaning and continued throughout the grazing period. Weight and anemia status (via eye scoring=FAMACHA) were recorded for all lambs weekly during the grazing period. An anthelmintic dose was administered orally to ewe lambs that had FAMACHA score of 3 or more. Blood packed cell volume (PCV) and fecal egg count (FEC) were determined for all lambs on d 21, 49 and 69 post-weaning, as well as for those that required deworming based on FAMACHA score. A logarithmic transformation was used for the FEC data. ADG was greater ($P < 0.08$) for DDGS supplemented lambs (147 ± 23 vs. 252 ± 23 g) during the grazing period. Percentage of lambs treated with anthelmintic was greater ($P < 0.07$) for control (65.6 ± 5) compared to DDGS groups (40.0 ± 5). However, there was no effect of supplementation on FEC or PCV. For the ewe lambs not treated with anthelmintic, ADG was greater ($P < 0.03$) for those supplemented with DDGS (249 ± 14 g) compared to controls (132 ± 14 g). On day 21 post weaning, control lambs had a greater ($P = 0.037$) FEC compared to the DDGS group. Supplementation of grazing lambs with DDGS increased ADG and reduced post weaning susceptibility to internal parasite infection.

Key Words: Distillers Grains, Parasite, Sheep

TH285 Dried distillers grains as a supplement for finishing ewe lambs. I. Susin*¹, A. Radunz², D. D. Clevenger², G. D. Lowe², P. A. Tirabasso², and S. C. Loerch², ¹*Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo(USP), Piracicaba, SP, Brazil,* ²*The Ohio State University, Wooster.*

Dried distillers grain plus solubles (DDGS) have a high amount of fat. Fat supplementation can affect performance and ruminant carcass composition. Sixty-two ewe lambs were used in a feedlot experiment to determine the effects of supplementation with DDGS on performance, carcass characteristics and meat quality of lambs fed corn or DDGS based diets. During a preceding 10 wk grazing period lambs were housed in four separate orchardgrass paddocks. Half of the lambs (2 paddocks) were supplemented with DDGS at 1.3% of BW. After the grazing period, lambs were placed in four feedlot pens (maintaining integrity of the groups) for the finishing experiment. Ewe lambs were fed either a corn-based finishing diet (control=CT) or a finishing diet containing 30% DDGS (DDGS) on a DM basis. The DDGS replaced corn and soybean meal in the control diet. A 14d adaptation period was used, at the beginning of the feedlot phase, to gradually adjust lambs to the feedlot diets. When the final average target weight (52kg) was reached, 16 lambs from each feeding regimen were slaughtered. Initial BW in the feedlot was 35.0 and 41.3 kg for CT and DDGS lambs, respectively. There was no difference ($P = 0.70$) in ADG (268 vs. 274 g for the control and DDGS group, respectively). However, total DMI was higher ($P = 0.001$) for control (106.9 kg/head) than DDGS (71.9

kg/head) ewe lambs, because control lambs needed 3 additional weeks to attain the targeted slaughter weight. There were no differences in carcass wt (26.6 vs. 26.4 kg), dressing percentage (53.7 vs. 53.5), back fat depth (0.63 vs. 0.64 cm), body wall thickness (1.83 vs. 1.79 cm), LM area (14.7 vs. 15.2 cm²), slice shear force (14.1 vs. 9.9 kg), cooking losses (17.5 vs. 19.2%), total fat (4.1 vs. 4.2%), color or quality grade due to feeding regimen. However, lambs fed DDGS showed a tendency ($P < 0.10$) to accumulate more soft back fat compared to the control group (6.25 vs. 25%). Supplementing DDGS to grazing and finishing ewe lambs decreased days on feed during the finishing phase. However, DDGS supplementation may change characteristics of the back fat deposited.

Key Words: DDGS, Feedlot, Sheep

TH286 Effects of barley straw treated with different levels of urea and elemental sulfur in diets of late gestation ewes: effects on lambing and dietary In vitro digestibility. K. RezaYazdi*, H. Khalilvandi, and N. Vahdani, *University of Tehran, Karaj, Tehran, Iran.*

The various cereals extensively cultivated for grain production also generate large amounts of straw with a high cell wall content of poor digestibility. Urea ammoniation makes polysaccharides more available to enzymatic hydrolysis. However this treatment may result in additional sulfur needs of the animal for synthesis of sulfur containing amino acids by rumen microorganism, considering that straws have low levels of sulfur. The purpose of the present trial was to assess the sulfur supplementation of urea-treated barley straw on performance of late gestation ewes. This was done using 72 Varamini late pregnant (90 days) ewes until parturition, with 9 dietary levels of urea (5% solution) treated barley straw (UTBS) and elemental sulfur (ES), in 3×3 factorial design in a CRD (3 levels of UTBS: 0, 20 and 40 percent and 3 levels of ES: 0, 0.1 and 0.2 percent). The lambs were fed 9 isocaloric and isonitrogenous diets for 60 days according to NRC. Lambs were weighed immediately after parturition. The method of Tilley and Terry was used for In vitro digestibility.

The results indicated that ewes that received 40% UTBS and 0.2% ES had highest lamb birth weight (4.82 kg). Animals that consumed 67.66 % barley straw without any treatment had lowest lamb birth weight (3.76kg) and DMI. Differences among treatments in the case of DMI and feed conversion ratio (FCR) were not statistically significant. TMRs containing 40% UTBS and 0.2% ES had highest in vitro digestibility of dry matter and organic matter.

Results showed that sulfur supplemented urea treated barley straw improved lamb birth weight and DM and OM digestibility values.

Table 1. Differences of LBW and IVDMD, between dietary treatments

	1	2	3	4	5	6	7	8	9
LBW	3.7 ^a	4.0 ^{ab}	3.9 ^a	4.0 ^a	4.3 ^{abc}	4.7 ^c	4.2 ^{ab}	4.7 ^{bc}	4.8 ^c

1: 0% UTBS, 0% ES, 2: 0% UTBS, 0.1% ES, 3: 0% UTBS, 0.2% ES, 4: 20% UTBS, 0% ES, 5: 20% UTBS, 0.1% ES, 6: 20% UTBS, 0.2% ES, 7: 40% UTBS, 0% ES, 8: 40% UTBS, 0.1% ES, 9: 40% UTBS, 0.2% ES. Means within a row with different superscripts differ. ($p < 0.05$).

Key Words: Barley Straw, Urea, Sulfur

TH287 Effects of urea treated barely straw and inorganic sulfur inclusion on in vitro digestibility of TMR and performance of fattening Varanini lambs. K. RezaYazdi*, N. Vahdani, and H. Khalilvandi, *University of Tehran, Karaj, Tehran, Iran.*

Winter small grains, especially wheat and barley, are an important part of the typical crop rotation system. Providing N requirement of ruminants partly with NPN sources, leading to increase in sulfur requirements for maximizing microbial protein synthesis. It is anticipated that sulfur addition in rations contain different level of urea treated barely straw (UTBS), improved ruminant productivity. An experiment carried out to study effects of different levels of UTBS (5% solution) and elemental sulfur (ES) in fattening lambs, using 72 Varamini lambs (38.38±3.91), in 3×3 factorial method in a CRD. (First factor: 3 levels of UTBS 0, 15 and 30 percent and second factor 3 levels of ES 0, 0.1 and 0.2 percent). The lambs were fed 9 isocaloric and isonitrogenous diets for 90 days according to NRC recommendations. Method of Tilley and Terry was used for In vitro digestibility. The results showed significant ($p < 0.05$) differences among lambs in daily live weight gain, DMI, and feed conversion ratio. The lambs received diets containing 30 % UTBS supplemented with 0.2 % ES, had highest live weight gain (LWG), while control group that consumed 21 % untreated barely straw had lowest LWG (173.3 g/d vs. 126.5 g/d, respectively). No statistically significant interaction among dietary levels of UTBS and ES was observed. Results of In vitro digestibility trial showed that total mixed rations contained 30% UTBS and 0.2 % ES had highest dry matter and organic matter digestibility values than other treatments.

As results showed, dietary levels of 30% UTBS supplemented with 0.2% ES can be used in order to improve live weight gains in lambs.

Key Words: Barley Straw, Urea, Sulfur

TH288 Effects of protein sources on performance and carcass characteristics of feedlot lambs and Small Ruminant Nutrition System estimates evaluation. M. A. A. Queiroz, I. Susin, A. V. Pires, C. Q. Mendes*, O. C. Almeida, R. S. Gentil, R. C. Amaral, A. L. Gastaldello Jr., and G. H. Rodrigues, *Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo (USP), Piracicaba, SP, Brazil.*

Mathematical models have been developed to assess sheep nutritional requirements; however, the challenge in these systems has been to accurately predict dry matter intake. Twenty-eight Santa Ines ram lambs (initial BW 20 ± 2 kg and 75 ± 5 d old) were used to determine the effects of protein sources in high grain diets on performance and carcass characteristics and to evaluate the Small Ruminant Nutrition System (SRNS) performance data estimates. Lambs were assigned to a complete randomized block design according to body weight and age at beginning of the trial and were penned individually. Lambs were fed an isonitrogen, total mixed ration, composed by 90% concentrate and 10% coarstcross hay (*Cynodon* spp) during 56 days. Experimental diets were formulated according to the Small Ruminant Nutrition System (version 1.8.1) and differed on protein source: soybean meal (SM), peanut meal (PM), canola meal (CM) or cottonseed meal (CSM), corresponding to the experimental treatments SM, PM, CM and CSM, respectively. There were no differences ($P > 0.05$) among treatments for dry matter intake (DMI), average daily gain (ADG) and feed conversion (FC). Daily DMI averaged 1.2, 1.1, 1.0 and 1.2 kg, ADG results were 330, 316, 284 and 311 g and FC were 3.5, 3.4, 3.7 and 3.8 kg MS/kg gain for the SM, PM, CM and CSM, respectively. In addition, carcass characteristics were not affected ($P > 0.05$) by protein source. SRNS predicted values for daily

DMI (1.3, 1.2, 1.0 and 1.3 kg) were greater ($P < 0.01$) than observed values. However, ADG estimates (319, 313, 280 and 304 g) were similar ($P > 0.05$) compared to observed experimental data. SRNS evaluation for feedlot lambs, based in these experimental data, showed good estimates for ADG and overestimated values for DMI.

Key Words: Canola, Cottonseed, Peanut

TH289 Total replacement of soybean meal by urea in high grain diets for feedlot lambs. C. Q. Mendes*, I. Susin, A. V. Pires, M. A. A. Queiroz, F. S. Urano, G. H. Rodrigues, R. S. Gentil, E. M. Ferreira, and M. V. Biehl, *Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo (USP), Piracicaba, SP, Brazil.*

Dietary crude protein source for animals fed high grain diets influences ruminal nitrogen and energy utilization as well as small intestine flow of nutrients. Twenty-eight Santa Ines ram lambs (initial BW 21.7 ± 3.0 kg and 93 ± 4.0 d old) were used to evaluate the effects of replacing soybean meal by urea in high grain diets on performance and carcass characteristics. Lambs were assigned to a complete randomized block design according to BW and age at beginning of the trial and were penned individually. Lambs were fed a TMR composed by 90% concentrate and 10% coastcross hay during 56 d. Soybean meal in the control diet (UR0) was replaced by urea at 0.7; 1.4 and 2.1% on a DM basis, corresponding to the experimental treatments UR0.7; UR1.4 and UR2.1, respectively. A 9 d adaptation period was used at the beginning of the feedlot to gradually adjust lambs to the experimental diets with high level of urea. When the final targeted weight (40kg) was attained, lambs were slaughtered and carcass characteristics were recorded. There were no differences ($P > 0.05$) among treatments for dry matter intake (1.11, 1.11, 0.96 and 1.05 kg/d for the UR0, UR0.7, UR1.4 and UR2.1, respectively). However, ADG ($P < 0.02$) and feed efficiency ($P < 0.06$) decreased linearly with higher levels of urea (ADG: 0.296, 0.303, 0.246 and 0.257 g and G:F: 0.27, 0.27, 0.25 and 0.24 for the UR0, UR0.7, UR1.4 and UR2.1, respectively). Carcass parameters (dressing percentage, chilling losses, cooking losses, back fat depth, Longissimus muscle area and shear force) were not affected ($P > 0.10$) when urea was added to the diet. Replacing soybean meal by urea in high grain diets fed to feedlot lambs decreased ADG and G:F with no change on dry matter intake. Although total replacement of soybean meal by urea decreased ADG by 14.3%, its inclusion in the diet provided satisfactory feedlot lamb performance and carcass characteristic.

Key Words: Hair Sheep, NPN, Urea

TH290 Effects of replacing corn by soybean hulls on apparent digestibility of nutrients and ruminal parameters in lambs. E. M. Ferreira, A. V. Pires, I. Susin, C. Q. Mendes*, R. C. Araujo, M. A. A. Queiroz, F. S. Urano, R. S. Gentil, R. C. Amaral, and S. Gilaverte, *Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo (USP), Piracicaba, SP, Brazil.*

Soybean hulls (SH) are an alternative feed source for ruminants and, due to its high level of digestible fiber and energy value, it can partly or totally replace forages or energetic ingredients. Sixteen Santa Ines ram lambs (BW 44.0 ± 5.0 kg), housed in individual metabolism crates were used to evaluate the effects of partial replacement of corn by SH

on apparent digestibility of nutrients and ruminal parameters. Lambs were assigned to one of four treatments in a complete randomized block design. The control treatment (SH0) was a diet containing 70% of corn on a DM basis. On the others diets, corn was replaced by SH at 15, 30 and 45%, corresponding to the experimental treatments SH15, SH30 and SH45, respectively. All diets were isonitrogen, containing 90% of concentrate and 10% coastcross hay (*Cynodon* spp). There was no effect on apparent digestibility of DM, NFC, CP, EE, ruminal ammonia and total VFA concentrations. However, NDF digestibility (55.5; 62.5; 66.6 and 68.1%), acetate concentration (26.0; 30.4; 37.1 and 41.9 mM) and ruminal pH (6.0; 6.0; 6.1 and 6.2) increased linearly ($P < 0.10$), while TDN values (84.5; 83.4; 80.2 and 78.9 % of DM) and digestible energy concentration (3.72; 3.68; 3.54 and 3.48 Mcal/kg of DM) reduced linearly ($P < 0.10$) for the SH0, SH15, SH30 and SH45 treatments, respectively. Propionate concentration (21.9; 29.4; 16.0 and 7.6 mM) showed a quadratic response ($P < 0.05$) for the SH0, SH15, SH30 and SH45 treatments, respectively. Soybean hulls added at 31.5% on DM basis (SH45) improved NDF digestibility, acetate production and ruminal pH. In addition, soybean hulls may reduce ruminal acidosis occurrence in high grain diets for lambs.

Key Words: By-Products, High Grain Diet, Hair Sheep

TH291 Performance and carcass characteristics of lambs fed wet low pectin citrus pulp in partial replacement of dried citrus pulp. G. H. Rodrigues, I. Susin, A. V. Pires, L. G. Nussio, C. Q. Mendes*, R. S. Gentil, E. M. Ferreira, M. V. Biehl, and F. S. Urano, *Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo (USP), Piracicaba, SP, Brazil.*

Dried citrus pulp (DCP) is a co-product with a high pectin concentration. Pectin is used as a gelling and thickening agent and can be obtained by partial extraction from citrus peels. This partial extraction results in a residue containing: 15% DM, 7.5% CP, 69% NDF, and 22% pectin and, in this trial, it was named wet low pectin citrus pulp (WLPCP). The objective of this study was to evaluate the effects of partial replacement of DCP by wet low pectin citrus pulp (WLPCP), wet low pectin citrus pulp silage (WLPCPS) or wet low pectin citrus pulp silage with sodium benzoate (WLPCPS+B) on performance and carcass characteristics of Santa Ines ram lambs. Sixty-four lambs (initial BW 17 ± 2 kg and 75 ± 5 d old) were used to determine average daily gain (ADG), dry matter intake (DMI), gain:feed (G:F). Lambs were allotted in a complete randomized block design according to BW and age at beginning of the trial. Lambs were fed 95% concentrate and 5% sugarcane bagasse diets with 16% CP for 56 days. The control diet contained 69.5% DCP while in the other treatments fresh or ensiled WLPCP replaced DCP by 30% on a DM basis. Diets were fed once a day as a TMR. At the end of the performance trial, 40 animals were slaughtered (BW 36 ± 1.6 kg) to evaluate carcass characteristics. There were no differences ($P > 0.05$) in daily DMI (960, 828, 880, and 889 g) and ADG (226, 216, 218, and 224 g) for DCP, WLPCP, WLPCPS and WLPCPS+B, respectively. However, G:F was greater for lambs fed WLPCP compared to lambs fed DCP (0.265 vs 0.235, $P = 0.03$). Dressing percentage, chilling losses, back fat depth and Longissimus muscle area averaged 49%, 3.7%, 1.7 mm and 13.4 cm^2 , respectively and were unaffected ($P > 0.05$) by experimental diets. Partial replacement of dried citrus pulp by wet low pectin citrus pulp residue can be an interesting alternative for feedlot lambs, without affecting carcass characteristics.

Key Words: Hair Sheep, Pectin, Co-Product

TH292 Apparent digestibility and ruminal parameters of diets containing sugarcane silage with or without additives or fresh sugarcane fed to lambs. R. C. Amaral, A. V. Pires, I. Susin, C. Q. Mendes*, E. M. Ferreira, R. S. Gentil, M. V. Biehl, M. A. A. Queiroz, and G. H. Rodrigues, *Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo (USP), Piracicaba, SP, Brazil.*

Objectives of this experiment were to evaluate the effects of chemical additives in sugarcane silage on dry matter intake, apparent digestibility, and ruminal parameters of cannulated ram lambs fed diets containing experimental silages (50% dietary dry matter). A diet containing fresh sugarcane was also assessed. Sixteen Santa Ines ram lambs, kept in metabolism crates, were distributed in a complete randomized block design. The experimental period was 15 days. Lambs were adapted to the experimental diets for 10 days and feces were sampled in the next 4 days. Ruminal fluid samples were taken at 0,2,4,6,8,10 and 12 hours after feeding in the last day of experimental period. Four experimental diets were used: fresh sugarcane, sugarcane silage without additive, sugarcane silage containing calcium oxide (1% on as-fed basis), and sugarcane silage containing limestone (1% on as-fed basis). There was no difference ($P>0.05$) among treatments for dry matter intake (mean DMI = 0.85 kg/day). Differences ($P<0.05$) were observed for dry matter digestibility, with the highest value (74.6%) observed for diets containing fresh sugarcane. Differences ($P<0.05$) also were observed for digestible NDF intake and the highest value (0.12 kg/day) was observed for diets containing 1% calcium oxide treated silage. There were no differences for treatment, hour after feeding, and treatment x hour interaction ($P>0.05$) effects on total volatile fatty acids, acetate and propionate concentrations, with mean values of 74.4, 42.6 and 18.6 mM, respectively. Butyrate concentration (11.9 mM) was highest for animals fed 1% calcium oxide treated silage. Mean acetate:propionate ratio was 2.4. Ruminal pH was not affected ($P>0.05$) by treatment, with mean value of 6.3. Addition of 1% of calcium oxide and limestone during sugarcane ensilage did not affect intake and digestibilities of diets fed to ram lambs when compared with the diet containing the non-treated silage. Sugarcane silages showed similar ruminal fermentation compared to fresh sugarcane.

Key Words: Calcium Oxide, Limestone, Hair Sheep

TH293 Effects of monensin, sodium bicarbonate and limestone sources on nutrient digestibilities in high grain diets fed to lambs. A. L. Gastaldello Jr., A. V. Pires, I. Susin, C. Q. Mendes*, G. H. Rodrigues, F. S. Urano, M. V. Biehl, R. S. Gentil, and G. B. Mourão, *Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo (USP), Piracicaba, SP, Brazil.*

This trial was performed to evaluate the apparent digestibility and ruminal parameters (pH, total volatile fatty acids and N-NH₃) of diets containing two sources of limestone and sodium bicarbonate (NaHCO₃), with or without monensin (30 mg/kg on a DM basis). Twenty-four lambs were assigned to a complete randomized block design in a 3 x 2 factorial arrangement. Treatments were: L=1.3% limestone; FL = 1.3% Filler limestone; L + SB = 1.3% limestone + 1% NaHCO₃; with or without monensin. Diets contained 90% concentrate and 10% coastcross hay (*Cynodon* spp). FL treatments had greater ($P<0.05$) dry matter (DM=82.6%), organic matter (OM=83.2%) and crude protein

(CP=72.8%) digestibilities compared to the other buffers average (DM=76.9; OM=77.6 and CP=63.4%). Neutral detergent fiber digestibility was higher (59.2%) for monensin treatments compared to treatments without monensin (34.4%). There were no differences ($P>0.05$) in nitrogen metabolism, ruminal pH, water intake, acetate:propionate ratio and butyrate concentration among treatments. There was an interaction between FL and monensin. When monensin was added, there was a reduction of 45.4; 25.8; 19.4 and 34.3% for N-NH₃, total volatile fatty acid, acetate and propionate concentrations, respectively. There was also interaction between L + SB and monensin showing an increase in total volatile fatty acids (18.5%), acetate (16.1%) and propionate (27.9%) concentration. FL did not show benefits on ruminal parameters, however increased DM and CP digestibility and in combination with monensin there was an associative negative effect on ruminal parameters. Sodium bicarbonate showed positive associations in presence of monensin, increasing ruminal total volatile fatty acids concentration, however, had no detrimental effects on nutrient digestibility.

Key Words: Buffer, Ionophor, Hair Sheep

TH294 Use of salt for limiting supplement intake for hair sheep fed buffel grass (*Cenchrus ciliaris* L.). H. Morales-Treviño^{*1}, M. Mireles¹, E. Gutierrez-Ornelas^{1,2}, H. Bernal-Barragan¹, J. Colin-Negrete¹, F. Sanchez-Dávila¹, and C. Rodriguez-Alvarado³, ¹Facultad de Agronomía, Universidad Autónoma de Nuevo León, Marín, Nuevo León, México., ²Consortio Técnico del Noreste de México, Guadalupe, Nuevo León, México, ³Instituto Tecnológico de Altamira, Altamira, Tamaulipas, México.

Intake regulation of supplement by sheep can be a useful practice for semi-intensive production systems. The objective of this study was to estimate the maximum amount of salt intake by hair sheep fed with buffel grass. Five levels of salt in concentrate (1, 6, 11, 16 and 21%) were used in order to allow sheep to consume up to 600 g/d of supplement. Twenty five Saint Croix ewes (BW: 23.6 ± 1.7 kg) were individually fed with ground buffel grass hay (8 cm long) during 63 d. Intake of salt+supplement and buffel hay were recorded daily. Changes in live body weight and daily water consumption were estimated every 14 d. A regression analysis was performed to describe the maximum intake of salt by sheep, and the effect of treatments was analyzed by ANOVA using a completely random design. A substitution effect for DMI was found ($P<0.05$) when lower levels of salt were included in the concentrate. Highest ($P<0.05$) DMI from buffel grass (318.5 g/day) was registered when ewes received supplements with 21% of salt, whereas the least DMI of buffel grass (176.0 g/day) was obtained by 1% salt in the supplement. Dry matter supplement intake (DMSI) and salt intake (SI) were quadratically affected ($P<0.05$; $r^2=0.86$ and $r^2=0.93$, respectively) by salt level (SL), with prediction equations as follows: DMSI, $g = 514.8 - 10.29SL - 0.968SL^2$; SI, $g = -7.75 + 10.17SL - 0.261SL^2$. Maximum daily salt intake in hair sheep was predicted as 91.3 g when salt is included as 19% of the supplement. Ewes receiving supplements added with up to 16% salt had similar ($P>0.05$) ADG (89.6 g) but different ($P<0.05$) than those consuming supplement with 21% salt (37.0 g). Daily water intake was not affected ($P>0.05$) by SL. Hair sheep limited their daily supplement intake when salt consumption was 91.3 g.

Key Words: Salt, Hair Sheep, Buffel Grass

SYMPOSIA AND ORAL SESSIONS

Dairy Foods: Dairy Products and Processing II

509 ADSA Pioneer: Collegiate dairy products evaluation-past and future. R. T. Marshall*, *University of Missouri, Columbia.*

Collegiate Dairy products evaluation was initiated to help train students on the attributes of dairy products and to set standards for good products. Soon team were formed and competitions were initiated. Both regional and national events were organized to increase team participation and training. Over the years milk quality and product quality has improved, thus some defect that were common in the early days of evaluation are no longer a problem. However, as modern technology improved manufacturing other problems became apparent. Thus, collegiate evaluations are as important today as they were 5 decades ago.

510 Performance comparison of ceramic and polymeric microfiltration (MF) membranes for separation of casein and serum protein (SP) from skim milk at 50°C. J. Zulewska*¹, M. W. Newbold², and D. M. Barbano², ¹*University of Warmia and Mazury, Olsztyn, Poland,* ²*Cornell University, Ithaca, NY.*

Skim milk was pasteurized (72°C for 16 s), cooled and split into 3 batches for processing with different MF membranes: 0.1 micron ceramic uniform transmembrane pressure (UTP) 763 kg of milk in 342 min with 1.7 m² of membrane, 0.1 micron ceramic gradient porosity (GP) 780 kg of milk in 264 min with 1.7 m² of membrane, and 0.3 micron polymeric (polyvinylidene fluoride) spiral wound (SW) 1167 kg of milk in 130 min with 20.5 m² of membrane. For all membranes, a bleed and feed filtration was applied for continuous production of 3X MF retentate at 50°C and replicated 3 times. Flux was recorded every 10 or 15 min during the process run and mean flux (\pm SD) for UTP, GP, and SW were significantly different: 54.1 \pm 1.52, 71.8 \pm 1.68 and 16.2 \pm 4.75 (kg/m²/h), respectively. The mean SP content in the MF permeate portion of the skim milk was 0.62%. The true protein content (Kjeldahl total nitrogen minus nonprotein nitrogen multiplied by 6.38) of the MF permeates from UTP, GP and SW were 0.57, 0.56, and 0.38% respectively, with both UTP and GP significantly higher than SW. Therefore, the coefficients

of rejection for milk SP by the 3 membranes were 0.074, 0.090, and 0.383 and mean SP removal was 64.4, 61.0 and 38.6% of the original total weight of SP in the milk for UTP, GP and SW, respectively, with all means being significantly different. The UTP membranes produced a 64 to 65% SP reduced 3X MF retentate in one stage. The SW membranes would require a second stage with diafiltration using UF permeate to produce an MF retentate with about 65% SP reduction and the same background concentration of lactose and soluble minerals. The relative proportions of different SP may differ among the MF permeates and retentates with different systems. The MF permeate opacity increased with increasing L value: UTP 19.4, GP 19.9, and SW 20.5, with all permeates being significantly different from each other. MF permeate clarity may be important when the SP concentrates are used for clear nondairy beverage fortification.

Key Words: Microfiltration, Serum Proteins, Separation

511 Functional properties of whey proteins affected by heat and high pressure shearing. M. Dissanayake and T. Vasiljevic*, *Victoria University, Melbourne, VIC, Australia.*

Whey proteins (WP) are a functionally excellent food ingredient extensively used in various food applications. The major challenge affecting their functionality and applicability is the heat-induced destabilization during WP concentration, processing and preservation of food products containing WP.

The main objective of this study was to examine the effects of complete protein denaturation and extent of dynamic high-pressure shearing on colloidal and surface properties of microparticulated WP to produce novel ingredients with improved heat stability and modulated functionalities.

The study was carried out using randomised full factorial design with heat and high pressure as the major factors. Two different batches of WP retentates (10% protein content, pH 7) were subjected to complete heat denaturation and pressure sheared using different number of passes

at 140Mpa. Microparticulated WP were then spray dried. All powders were assessed for their solubility, heat stability and coagulation time, emulsifying and foaming properties. Effects of denaturation and shearing were also examined using SDS-PAGE and size exclusion HPLC. Heat treatment significantly decreased the solubility of treated samples while the number of passes markedly improved it. The combined effect of heat and pressure significantly improved the heat stability as depicted by the heat coagulation time. The emulsifying activity index also significantly increased upon heat denaturation, which was even further enhanced by pressure. The emulsion stability appeared unaffected by the combined treatment, but the concentration of adsorbed protein on the surface of fat droplets increased significantly. Foaming properties (overrun and foam stability) were detrimentally affected by heating. SDS-PAGE and SE-HPLC revealed disappearance of major WP and creation of high molecular weight aggregates and smaller molecular weight species as a result of heat and shearing. The study showed that this approach could be used to stabilize WP against heat by producing various microparticulated species, which also have different surface and colloidal properties from native WP.

Key Words: Whey Proteins, Microparticulation, Functionality

512 Production of whey protein concentrate 80 with improved clarity and flavor. I. Jarto^{*1}, J. A. Lucey¹, S. Damodaran¹, S. A. Rankin¹, and K. E. Smith², ¹*University of Wisconsin, Madison*, ²*Wisconsin Center for Dairy Research, Madison, WI*.

The objective of our study was to develop a pilot-scale whey pretreatment process that reduced the residual lipids in whey protein concentrate 80 (WPC80) to < 1% by employing chitosan to selectively precipitate lipids (US Patent# 5,436,014). Our hypothesis was that a reduction in the concentration of residual lipids in WPC80 would improve WPC clarity and flavor by removing small fat globules and phospholipids which are prone to oxidation. The process used a low concentration of chitosan (0.01% wt/wt), which formed a complex with membrane lipids at pH 4.5. The chitosan-lipid complex was allowed to settle and a 0.3 µm polymeric microfiltration (MF) membrane was utilized to process the supernatant from this reaction. There were 2 treatments and a control: WPC80 treated with chitosan and followed by MF (WPCC); WPC80 treated with MF only (WPCB); and WPC80 without chitosan or MF (WPCA). Treatments were done in duplicate. No significant differences were observed in flux during processing runs up to 4 hours with final retentate concentration factor of 12X. Fat content of the WPCC, WPCB, and WPCA was 0.46±0.07%, 0.46±0.02%, and 6.56±1.31%, respectively. The turbidity was measured by absorbance at 500 nm (5% protein solution). The absorbance values for the WPCC, WPCB, and WPCA were 0.05±0.01, 0.08±0.01, and 2.61±0.20, respectively. Commercial samples of WPC80 (WPCG) and whey protein isolate had absorbance values of 2.91±0.10 and 0.08±0.02, respectively. Samples were subjected to an accelerated storage (4 d at 60°C). WPCG and the WPCA browned considerably and developed intense off-flavors. WPCC remained white and WPCB underwent slight browning; both exhibited low levels of off-flavor development. Gas Chromatography-Mass Spectrometry was used to evaluate volatiles in WPC samples. Our study showed that chitosan pretreatment in the production of WPC80 resulted in greatly improved clarity and suppressed off-flavor and color development during accelerated storage, which suggested that this ingredient could be used to fortify clear beverages or be used in baking applications where browning was not desired.

Key Words: Whey Protein Concentrate, Chitosan, Clarity

513 Production of structured lipids containing palmitic acid for infant milk formulation and characterization of their oxidative stability. C. O. Maduko¹, C. C. Akoh¹, R. R. Eitenmiller¹, and Y. W. Park^{*2,1}, ¹*University of Georgia, Athens*, ²*Fort Valley State University, Fort Valley, GA*.

Developing infant milk fat similar to human milk fat (HMF) is of great interest and challenge to food processors. The sn-1,3 positions of the triacylglycerols of most vegetable oils are occupied mainly by saturated fatty acids, while these positions of human milk contain mainly unsaturated fatty acids. Structured lipids containing similar fatty acid structure as HMF can be produced by interesterification reactions using an sn-1,3-specific lipase that gives high selectivity and mimics the natural pathways of metabolic processes. This study was to produce structured lipids (SLs) for infant milk formulation by enzymatic interesterification of tripalmitin with vegetable oil blends and fish oil, and characterize oxidative stability of the starting oils, and their SLs with and without tocopherol. SLs were synthesized in a bioreactor by enzymatic interesterification of a 1:3 molar ratio of tripalmitin to oil blends. The SLs were analyzed for fatty acid content and structure, melting profiles, oil stability index (OSI), free fatty acid (FFA) and tocopherol content. The OSIs of different lipid preparations were determined at 110 oC with an Oil Stability Instrument by AOCS method. Oxidative stability was determined by quantifying FFA, peroxides (peroxide value) and aldehydes (p-anisidine value) production. Total oxidation (TOTOX value) was calculated as 2 x (peroxide value) + (p-anisidine value). The structured lipids after purification by distillation had melting profiles, oil stability index, and initial FFA concentration that were similar to that of the starting oils, while the fatty acid composition and structure of the SLs were similar to that of human milk fat. Oxidative stability of the SLs was improved with tocopherol addition as antioxidants and was comparable to that of the vegetable oils and oil blends.

Key Words: Infant Milk Formulation, Structured Lipids, Oxidative Stability

514 The impact of fat globules' colloidal stability on the pre-gelation stages of rennet coagulation process. Z. Gaygadzhiev*, M. Alexander, A. Hill, and M. Corredig, *University of Guelph, Guelph, ON, Canada*.

The effect of the state of flocculation of fat globules on the early stages of rennet-induced gelation of model recombined milk was investigated. Fat globules differing in their degree of flocculation and with well defined sizes were prepared by emulsifying anhydrous milk fat in solution of whey protein isolate. Pre-gelation behaviour of recombined milks was studied in situ using diffusing wave spectroscopy (DWS). In addition, confocal microscopy and small deformation rheology were employed to observe the gel microstructure and viscoelastic properties, respectively. DWS experiments revealed dissimilarity in the structural organization of rennet-induced gels containing non-flocculated and mildly flocculated WPI-stabilized fat globules, as observed by the development of the turbidity parameter, $1/l^*$. The evolution of storage moduli, G' , of recombined milk during the gelation process confirmed the results from the light-scattering experiments. Results demonstrate the importance of the aggregation state of the oil droplets in the formation of rennet-induced gels: mildly flocculated fat globules contributed to the formation of much stiffer gels compared to non-flocculated fat globules.

Key Words: Fat Globules' Flocculation, Rheology, Rennet Coagulation

515 Impact of changing temperature after measurable gelation on the properties of fermented milk gels. Y. Peng^{*1}, D. S Horne², and J. A. Lucey¹, ¹University of Wisconsin, Madison, ²Formerly of Hannah Research Institute, Ayr, Scotland.

Incubation temperature (IT) is an important parameter that affects many properties of yogurt gels including growth rate of culture, aggregation of caseins and strength of protein interactions. We wanted to understand how IT impacted gel properties by altering IT after we could instrumentally detect gel formation had occurred. This approach would help us to understand how IT influences events up to the initial measurable point of gel development as well as during the subsequent development of the gel network. Gels were made at different IT (30, 33.5, 37, 40.5 and 44°C) until gelation, then they were heated or cooled to 37°C at 1°C/min and maintained at 37°C until pH 4.6. Gelation was defined as the point when gels had a storage modulus (G') of ≥ 5 Pa. Control gels were made at these IT (i.e., no IT change during gelation or gel development). A single strain of *Streptococcus thermophilus* was used to avoid variations in the ratios of strains that could have resulted from changes in IT. Dynamic low amplitude oscillatory rheology was performed to monitor the formation of gels. Microstructure at pH 4.6 was studied using fluorescence microscopy. Whey separation was analyzed at pH 4.6. The gelation pH decreased and gelation time increased with a decrease in the IT used up to measurable gelation. There were no significant differences ($P < 0.05$) in G' values at pH 4.6, maximum loss tangent, microstructure and whey separation in gels that were made with different IT up to measurable gelation but had the same IT after that point. There were significant differences in properties of gels where different ITs were used without any IT changes during fermentation. Altering IT after measurable gel formation resulted in a change in the rate of development of G' and loss tangent of gels, indicating that IT altered the rate of rearrangements/fusion of caseins in the network. The results of this study suggested that changing IT during yogurt fermentation might be another approach to modifying the physical properties of yogurt. High IT could be used to reduce the gelation time and lower IT could be used to produce gels with improved textural properties.

Key Words: Gel, Temperature, Gelation

516 Rheological properties of stirred yoghurts made with whey protein isolate-pectin complexes as stabilizing agent. M.-C. Gentés^{*1,2}, S. L. Turgeon¹, and D. St-Gelais², ¹STELA Dairy Research Centre and Institute of Nutraceuticals and Functional Foods (INAF), Quebec, QC, Canada, ²Food Research and Development Centre, Agriculture and Agri-Food Canada, Saint-Hyacinthe, QC, Canada.

Problems of syneresis and viscosity in stirred yoghurts remain despite of the use of stabilizers. Whey protein isolate-pectin complexes can be used as stabilizers. Complex formation could confer different functional properties than individual compounds. Complexes were formed under associative conditions via electrostatic interactions at pH 4.5. As complexes were added at standardization step, they must be stable at pH 6.7. Prior study showed that a heat treatment at 90°C for 2 minutes was sufficient to stabilize them. Syneresis, apparent viscosity, hardness and microstructure were determined in stirred yoghurts produced with

unheated complexes (UC), heated complexes (HC), pectin used in complex formation (PC) and commercial pectin (CP) at 3 concentrations (0.05, 0.1 and 0.2%). Analysis of variance, according to a factorial design, was applied to determine the effect of stabilizers on rheological properties. Significant differences were tested at $P \leq 0.05$. Measurements were made after 4 days of storage at 4°C. Syneresis was significantly lower in CP yoghurts than in other yoghurts. The use of UC at 0.1% gave significantly the greater values of hardness and apparent viscosity comparatively to the use of HC. Microstructure of HC yoghurts showed larger aggregates than UC yoghurts. Double heat treatments (stabilization of complexes and pasteurization step) undergone by HC was not beneficial probably because an extensive whey protein aggregation leading to disruption of the casein network. This work showed that UC can be used to improve rheological properties of stirred yogurt. The stability of complexes in UC after addition into milk should be evaluated.

Key Words: Yogurts, Complexes, Rheological Properties

517 Changes in relative percentages of fatty acids in raw goat milk, its yoghurt and salted yoghurt during manufacture. Z. Guler^{*1} and Y. W. Park², ¹Mustafa Kemal University, Antakya, Hatay, Turkey, ²Fort Valley State University, Fort Valley, GA.

In Mediterranean and Southern regions of Turkey, 'Salted yoghurt' or 'Winter yoghurt' is produced by boiling and salting yoghurt to prolong its storage life. The cooking and salting processes ensure microbiological safety and keeping its quality for smoother and whiter products. The objective of the study was to quantify the changes in fatty acids compositions of raw milk, yoghurt and salted yoghurt from Turkish indigenous milking goats. Fatty acid profiles were assayed using a GC-MS (Agilent model 6890; Palo Alto, CA, USA) with 5973 N (Agilent) mass selective detector. Mean relative percentages (%) for fatty acids of raw milk, yoghurt and salted yoghurt were: acetic acid (C2:0), 4.88, 2.03 and 1.17; butanoic acid (C4:0), 1.30, 0.27 and 1.69; hexanoic (C6:0), 4.28, 2.48 and 4.65; octanoic (C8:0), 1.23, 0.76 and 1.80; decanoic acid (C10:0), 4.91, 3.06 and 6.46; dodecanoic acid (C12:0), 2.26, 1.70 and 2.55; tetradecanoic acid, (C14:0), 8.48, 7.88 and 9.76; pentadecanoic (C15:0), 0.75, 0.21 and 0.18; hexadecanoic acid (C16:0), 37.5, 39.1 and 39.7; heptadecanoic acid (C17:0), 0.88, 0.99 and 0.93; octadecanoic acid (C18:0), 19.9, 23.2 and 17.8; 9-octadecanoic acid (C18:1), 13.6, 16.6 and 12.80, respectively. The highest amount of fatty acids in descending order of the three milk products were palmitic (C16:0), stearic (C18:0), oleic (C18:1), myristic (C14:0), and capric acid (C10:0). Decreases in C2:0 to C15:0 fatty acids were observed during yoghurt-making process, with the most marked reduction in C2:0 to C12:0 acids. This could be attributed to evaporation of these fatty acids during heating process of yogurt. The relative percentages of C4:0 to C14:0 acids increased during salted yoghurt processing procedures, probably due to the fat content increase in total solids. However, percentages of C2:0, C15:0, C18:0 and C18:1 decreased, while C16:0 and C17:0 acids were unchanged during the manufacture.

Key Words: Turkish Goat Milk, Salted Goat Yogurt, Fatty Acids Profile

Symposium: Animal Behavior and Well-Being: Animal Welfare Standards - Who Decides and How?

518 Animal welfare legislation in the European Union. D. Wilkins*, *WSPA, London, UK.*

The debate on animal welfare legislation began in the Council of Europe, not to be confused with the European Union. Between 1977 and 1992, 5 animal welfare Conventions came into force on farm animals, slaughter for food, transport, laboratory animals and companion animals. The first animal protection law in the European Union (then the Common Market) was a 1977 Directive on stunning food animals before slaughter. In the late 1980s and early 1990s many more European laws were agreed and these covered the keeping of pigs, calves and laying hens, animal transport, slaughter, animals used for research purposes, zoos and general farm animal welfare. The circumstances of how this raft of legislation came about make an interesting story. What will happen in the future now that the European Union has expanded to 27 member states and with the influence of international trade rules will also be explored.

Key Words: Well-Being, Legislation

519 Animal welfare assurance programs in food production: a framework for assessing the options. D. Fraser*, *Animal Welfare Program, Faculty of Land and Food Systems and W. Maurice Young Centre for Applied Ethics, University of British Columbia, Vancouver, Canada.*

A variety of animal welfare assurance programs are being used to encourage or require the adoption of animal welfare standards in food production, and to assure the public that such standards are followed. The programs involve five main formats. Non-mandatory codes/guidelines are relatively easy to institute and appear well supported by the industry, but provide only minimal assurance to the public unless measures are taken to ensure compliance. Programs based on government regulations and inter-governmental agreements are more challenging to institute; they are likely to generate less industry acceptance, but may provide more public confidence if enforcement is adequate. Product differentiation programs, and retailer policies requiring products to meet certain standards, serve a range of functions; these may generate public confidence but only for products covered. The programs include several types of requirements. Requirements

designed to maintain animal health and functioning have a widely accepted scientific basis, are often easy to incorporate into existing production systems, and often provide economic benefits, but do not fully address public concerns over animal welfare in some cultures. Requirements that address pain, distress and other affective states, and those that accommodate certain natural behaviour, have a growing but less traditional scientific rationale and seem likely to generate public confidence; however, they sometimes require significant changes to existing practices. Requirements for more natural surroundings (outdoor, free-range) seem to generate public confidence, but appear most likely to increase costs, least likely to be supported by the existing industry, and may involve trade-offs with productivity and with other aspects of animal welfare.

The various formats and requirements provide a range of policy options for addressing animal welfare concerns in different cultural, industry and market contexts.

520 Pressures to regulate animal welfare and food production in the USA. K. Johnson*, *Animal Agriculture Alliance, Arlington, VA.*

The USA faces increasing pressure to regulate animal welfare on America's farms and ranches. The primary drivers of this legislative pressure are animal rights groups. These groups have effectively co-opted the animal welfare issue and are using perceived animal welfare as a wedge to advance an animal rights agenda.

The legislative pressures are being faced at all levels of government, from international to national to state and local. Currently, the greatest concentration of legislative resources is being aimed at state governments.

But these groups' influence isn't just limited to legislation, they are devoting significant resources to legal actions and political campaigns. In 2006, just one group spent \$3.4 million on the elections, more money than ExxonMobil spent, according to *The Wall Street Journal*.

This presentation will cover the issues driving legislation, the groups promoting it, the strategies and tactics being used, and examples of specific legislative initiatives being advanced.

Breeding and Genetics: Computational Issues in Genomic Analysis

521 Genomic selection using low-density SNPs. D. Habier, J. C. M. Dekkers*, and R. L. Fernando, *Department of Animal Science and Center for Integrated Animal Genomics, Ames, IA.*

Genomic selection (GS) using high-density single nucleotide polymorphisms (HD-SNPs) is promising to improve response to selection. GS is based on estimating effects of HD-SNP alleles using phenotypes in a training data set and using these estimates to obtain GS-EBV for selection candidates based only on HD-SNP genotypes. Genotyping HD-SNPs for all selection candidates may not be cost effective in most livestock species. Thus, we propose to use low-density SNPs (LD-SNPs) to trace chromosomal segments from parents to progeny with sufficient accuracy and estimate GS-EBV of selection candidates. This approach requires inferring HD-SNP haplotypes of the training individuals using parental HD-SNPs. Given estimates of HD-SNP effects, effects of chromosomal segments are estimated as the sum of the HD-SNP effects on that haplotype. To estimate GS-EBV in subsequent generations, only LD-SNPs flanking each segment are utilized to follow the inheritance of segments by estimating the probability of descent of a segment (PDS). To test this approach, a training data set of 1000 individuals with 1000 SNP genotypes on a 10 Morgan genome and phenotypes for an additive trait controlled by 100 QTL with heritability 0.5 was simulated. HD-SNP haplotypes of training individuals were assumed known and divided into 100 segments of 10 cM, flanked by a total of 110 LD-SNPs that were genotyped in subsequent generations. HD-SNP allele effects were estimated by Bayes-B. An MCMC sampler was used to first obtain joint probabilities of segregation indicators for every flanking marker pair. These were then used to calculate the PDS as the probability of maternal origin at the midpoint of flanking LD-SNPs. The correlation between true breeding values and GS-EBVs was used to evaluate the loss in accuracy from using LD-SNPs vs. HD-SNPs in generations following training. The accuracy was 0.66 with HD-SNPs and 0.63 with LD-SNPs in the first generation, dropped to 0.63 and 0.60 in the second, and to 0.61 and 0.56 in the third generation following training. Thus, LD-SNPs can be used for selection candidates with limited loss of accuracy which, depending on the costs of LD-SNPs vs. HD-SNPs, can result in a substantial reduction in costs.

Key Words: Genomic Selection

522 Effects of allele frequency estimation on genomic predictions and inbreeding coefficients. P. M. VanRaden¹, M. E. Tooker*¹, and N. Gengler^{2,3}, ¹USDA Animal Improvement Programs Laboratory, Beltsville, MD, ²Gembloux Agricultural University, Gembloux, Belgium, ³National Fund for Scientific Research, Brussels, Belgium.

Genetic calculations often require estimating allele frequencies, which differ across time due to selection and drift. Data were 50,000 simulated markers and 39,985 actual markers for 2391 genotyped Holstein bulls. Gene content of relatives and gene frequencies in the base (founder) population were estimated using pedigrees and a linear model. Ancestors born since 1950 were included, for a total of 22,088 animals. Because pedigrees were very complete, only one unknown-parent group was used. Convergence to 5 digits of accuracy required about 1000 iterations. Total time was 2 processor days and proportional to number of animals times markers, but actual clock time was reduced by processing loci on separate chromosomes in parallel. Simple allele frequencies were obtained from only the known genotypes. True base frequencies were

correlated with estimated base frequencies by 0.98 versus 0.94 with simple frequencies. Genomic predictions and inbreeding coefficients were computed in four ways, using true or estimated base frequencies, simple frequencies, or an "estimate" of .5 for each marker. When allele frequencies estimates were used instead of 0.5 to assign mixed model coefficients, solutions converged more slowly but predictions were more accurate. From simulated data, realized reliabilities for young bulls were 62.8% using either true or estimated base frequencies, 62.6% using simple frequencies, and 62.0% using frequencies set to 0.5. Pedigree and genomic inbreeding coefficients were correlated by 0.73 using true base frequencies, 0.67 using estimated base frequencies, 0.12 using simple frequencies, and 0.72 when frequencies were set to 0.5. Genomic inbreeding coefficients were biased downward by 7% to 9% using either frequency estimate, upward by 31% using 0.5, but were reasonable when true frequencies were used. Frequency estimation had small effects on genomic predictions but large effects on genomic inbreeding coefficients in both simulated and real data.

Key Words: Genotype, Genomic Selection, Allele Frequency

523 Strategies to incorporate genomic prediction into population-wide genetic evaluations. N. Gengler*^{1,2} and P. M. VanRaden³, ¹Gembloux Agricultural University, Gembloux, Belgium, ²National Fund for Scientific Research, Brussels, Belgium, ³USDA Animal Improvement Programs Laboratory, Beltsville, MD.

Most current research on genomic selection is focusing on the accurate prediction of genomic breeding values. However selection solely based on genomic breeding values, despite being theoretically promising, is in practice only suboptimal for several reasons. The two most important are that only few animals are genotyped therefore having genomic prediction directly available and that rankings will change. With genomic breeding values potentially available in the near future, strategies are required to avoid any confusion in the mind of users. The aim of this study is to present three different strategies that could be used to incorporate genomic prediction into population-wide genetic evaluation. The three strategies are: 1) using selection index theory to combine both sources of information into a single set of breeding values; 2) for ungenotyped animals, compute conditional expectation of gene contents for SNP given molecular and pedigree data and use these predicted gene contents; and 3) integrate genomic breeding values as external information into genetic evaluation using a Bayesian framework. If strategy 1) is straight forward, additional steps have to be done to adjust breeding values for changes in those of relatives. A practical implementation is to use reliabilities of the genomic prediction, the population-wide genetic evaluation PA, and PA from the genotyped subset to set up a 3 x 3 matrix for each animal, with off-diagonal elements being functions of the 3 reliabilities. The use of strategy 2) is computationally much more challenging but leads directly to the needed covariance structures combining genomic relationship if known with pedigree relationships. Strategy 3) is potentially a good compromise because the theory is well established and has already been used in beef cattle to incorporate external breeding values. Also current genetic evaluation software can be easily modified to incorporate genomic breeding values.

Key Words: Genomic Prediction, Incorporation, Breeding Value Estimation

524 Selection of single nucleotide polymorphisms and genotype quality for genomic prediction of genetic merit in dairy cattle. G. R. Wiggans*¹, T. S. Sonstegard¹, P. M. VanRaden¹, L. K. Matukumalli^{1,2}, R. D. Schnabel³, J. F. Taylor³, F. S. Schenkel⁴, and C. P. Van Tassell¹, ¹ARS, USDA, Beltsville, MD, ²George Mason University, Manassas, VA, ³University of Missouri, Columbia, ⁴University of Guelph, Guelph, ON, Canada.

A process to prepare high-density genotypic data for use in genomic prediction was developed. Marker genotypes from >51,000 single nucleotide polymorphisms (SNP) were generated for 3,139 Holstein bulls on the Illumina Bovine SNP50 chip. The SNP were grouped by minor allele frequency (MAF); 10,249 SNP with a MAF of <5% were excluded. Number of SNP for each of 45 MAF categories was uniform (800 to 1,009). Hardy-Weinberg equilibrium was assessed by comparing observed to expected heterozygosity for each locus. For 6 SNP assigned to chromosome 7, no bulls were heterozygous, which confirms the latest assembly that places those SNP on the X chromosome. Observed heterozygosity was within 2% of that expected for 96% of SNP. Linkage between adjacent autosomal SNP was analyzed to determine if the data set could be reduced for downstream analysis. For 1,237 pairs of adjacent SNP, marker genotypes were either both homozygous or both heterozygous (<10 bulls differed for each pair), and the first SNP from each pair was excluded; mean physical distance between those SNP pairs was much smaller (37 kb) than between 39,386 autosomal SNP (64 kb). Sire and son data for 2,566 bulls with 204 genotyped sires were compared to validate sample identification and Mendelian inheritance. For those bulls with >100 inheritance errors, correct sire was determined through comparison with other sires of sons. For sons with the correct sire, 99.99% of SNP with genotypes did not conflict. Comparison of genomic and pedigree relationships detected 3 members of a clonal family, a set of identical twins, and some possible pedigree errors. Genotyping consistency was investigated for 9 bulls genotyped twice and for the twins and clones. Most differences were caused by an inability to determine the genotype for one of the paired SNP; however, one clone had 24 SNP conflicts (99.94% concordance). Although evaluation of the SNP set is ongoing, only minor changes are expected for the final set. This largest set of high-quality SNP data for Holsteins to date should provide the basis for successful genomic prediction.

525 Analysis of high dimension marker data in the presence of gene interactions: A machine learning approach. K. R. Robbins, J. K. Bertrand, and R. Rekaya*, *The University of Georgia, Athens.*

In recent years there has been much focus on the use of single nucleotide polymorphisms (SNP) for the fine mapping of genomes in an effort to identify causative mutations and important genomic regions for traits of interest; however, many studies focus only on the marginal effects of markers, ignoring potential gene interactions. Simulation studies have shown that this approach may not be powerful enough to detect important loci when gene interactions are present. While several studies have examined potential gene interaction, they tend to focus on a small number of SNP markers. Given the prohibitive computational cost of modeling interactions in studies involving a large number of SNP, methods

need to be developed that can account for potential gene interactions in a computationally efficient manner. This study adopts a machine learning approach by adapting the ant colony optimization algorithm (ACA), coupled with logistic regression on haplotypes and genotypes, for association studies involving large numbers of SNP markers. The proposed method is compared to genotype (GA) and haplotype analysis, implemented using sliding windows (SW). Each algorithm was evaluated using a binary trait simulated using an epistatic model and HapMap ENCODE genotype data. Two simulation scenarios, varying the strength of the epistatic relationship, were replicated five times each. The ACA yielded increases in the power to detect genomic regions associated with the simulated trait of 66.7% over the next best method in both simulated scenarios. Based on these results it is clear that methods accounting for potential gene interactions are necessary to obtain good power for association studies examining complex traits under the control of interacting genes.

526 Statistical design of validation studies for transcriptional profiling experiments. J. P. Steibel*¹, R. J. Tempelman¹, and G. J. M. Rosa², ¹Michigan State University, East Lansing, ²University of Wisconsin, Madison.

Microarrays and quantitative reverse transcription polymerase chain reaction (qRT-PCR) are the most commonly used techniques for transcriptional profiling in animal tissues. Microarrays are commonly used as a first stage screening step, followed by a qRT-PCR experiment intended to validate the results from the first stage. While the design of microarray experiments has been extensively studied, the design and analysis of qRT-PCR validation studies has not. We address this issue as it pertains to the qRT-PCR validation of genes that are concluded to be differentially expressed based on results from a previous microarray experiment. Required sample sizes and expected significance levels for the validation experiment were determined, assuming that biological replicates are independent from those used in the microarray experiments. The level of replication was set to the minimum necessary to control the false discovery rate (FDR) at a certain level while maximizing the power or sensitivity of the overall experiment. We show that the number of replicates depends on the ratios of the FDR and the sensitivity between the two experiments as they depend on the true effect sizes (true mean differences divided by standard deviations). Our results also indicate that the traditional P-value thresholds of 0.05 or 0.01 for statistical significance are potentially too stringent for a second-stage validation experiment. In particular, if the FDR of the microarray experiment was controlled at 30% and the effect sizes are moderately large (i.e., near 1.0), setting the significance level of the validation experiment to 0.1 can control FDR at 5% while attaining greater than 80% power. Additionally, we consider the case where the same samples are used for the validation and microarray experiments (technical validation). We conclude that re-using the same samples in both stages invariably leads to a reduced power and increased FDR compared to the use of independent biological replicates. This increase in FDR is particularly large when the correlation between the two tests is high.

527 Model selection in gene-specific mixed linear models for microarray data with application to joint analysis of multiple experiments. L. Qu, N. Bacciu*, D. Nettleton, and J. C. M. Dekkers, *Iowa State University, Ames.*

Detecting differential gene expression using microarrays often suffers from low statistical power and accuracy due to small sample sizes and/or high variation. Model selection is hence an important task to obtain accurate significance levels and to improve power, in particular for joint analysis of multiple datasets. We propose four methods that use information across all genes to select one mixed linear model to be fit separately to data from each gene in a microarray experiment. We compare the results of these model selection methods on the joint analysis of two related microarray experiments in pigs. Method 1 is based on the information criteria (e.g., AIC) averaged over all genes to select a model that balances complexity and fit. Method 2 is based on cross-validation which selects the model that minimizes squared best linear unbiased prediction (BLUP) residuals, standardized and averaged over all genes. Method 3 is a multi-gene graphical method that uses principle component analysis on the residuals/BLUPs to compare distributional differences for a candidate factor. Method 4 is similar to method 3, but uses the multiresponse permutation procedure to formally test differences in residuals/BLUPs, ignoring the dependency among subjects. These four methods were applied to joint analysis of two random block design experiments, where the primary question was whether the variances can be pooled across experiments to increase power. Results show that the model that pooled both block and error variances and the one that only pooled block variances performed similarly and were preferred by each method, whereas separate analysis and the model that only pooled error variances were disfavored by each method. Although the methods generally agreed well for this data set, simulations are needed to further investigate which method is preferred and under which situations. In summary, our proposed methods can be useful tools for model selection in microarray analysis, especially when joint analysis of multiple datasets is used to increase statistical power. 528 Reconstruction of metabolic pathways for the cattle genome. S. Seo* and H. A. Lewin, *Institute for Genomic Biology, University of Illinois, Urbana.*

Metabolic reconstruction of microbial, plant and animal genomes is a necessary step toward understanding the evolutionary origins of metabolism and species-specific adaptive traits. The aims of this study were to annotate the recently sequenced cattle genome using a metabolism-centered approach, to reconstruct conserved metabolic pathways, and to identify metabolic pathways with missing genes and proteins. The MetaCyc database and PathwayTools software suite were chosen for this work because they are widely used and easy to implement. An amalgamated cattle genome database was created using the NCBI and Ensembl cattle genome databases (based on build 3.1) as data sources. PathwayTools followed by comprehensive manual curation were implemented for reconstruction of metabolic pathways. The curated database, CattleCyc 1.0, consists of 217 metabolic pathways. A total of 64 mammalian-specific metabolic pathways were modified from the reference pathways in MetaCyc, and two pathways previously identified but missing from MetaCyc were added. Comparative analysis of metabolic pathways revealed the absence of mammalian genes for 22 metabolic enzymes whose activity was reported in the literature. We also identified six human metabolic protein coding genes for which the cattle ortholog is missing from the sequence assembly. CattleCyc is a powerful tool for understanding the biology of ruminants and other cetartiodactyl species. In addition, the approach used to develop CattleCyc provides a framework for the metabolic reconstruction of other newly sequenced mammalian genomes. Having multiple annotated mammalian genomes hosted in BioCyc will facilitate comparative analysis of metabolic pathways among different species and a systems approach to comparative physiology.

Breeding and Genetics: Current Issues in Swine Breeding

529 Genetics of piglet survival: Additive, maternal and foster contributions. E. F. Knol*, M. J. M. Rutten, D. Roelofs-Prins, and J. W. M. Merks, *IPG, Institute for Pig Genetics B.V., Beuningen, The Netherlands.*

Phenotypic and genetic trends for litter size are clearly positive in most parts of the world, similar trends for number weaned are lower. As a consequence phenotypic trends in stillborn and pre-weaning mortality are positive. This is partly the result of reduced input of labor, and partly because of negative correlated genetic trends of litter size. To optimize selection for current markets, we re-addressed the two traditional survival traits: farrowing survival (FS: complement of stillborn) and pre-weaning survival (PWS).

FS was modeled by both additive-genetic and maternal-genetic effects; PWS was modeled including an extra genetic effect for foster-dam. The models log-likelihoods justified inclusion of the direct additive genetic effect. When the majority of the piglets are raised by their own dam, the genetic foster dam effects and genetic maternal effects are confounded. Therefore, sufficient cross-fostering of piglets in the data is required to be able to disentangle these effects.

The dataset consisted of 75,765 records of individually recorded piglets with known cross-fostering status on a closed TOPIGS multiplication farm with a pedigree of 78,572 animals. Variance estimates for FS: error 623.5, additive genetic 3.79, and maternal genetic 15.50; for PWS: error 819.8, additive genetic 7.29, maternal genetic 7.87 and foster dam genetic 30.09. Absolute genetic correlations were lower than 0.1 within traits and lower than 0.4 among traits. Heritabilities were low, but the sum of the genetic variance components of 19.3 for FS and 45.3 for PWS are very promising for selection.

Interpretation: 'maternal' is the influence of the uterine environment and partly of the first colostrum; 'foster' represents the mothering ability of the sow, behavior and quality of the udder, and 'additive' includes contribution of the sire, which is especially relevant in crossbred data. Large scale recording of birth weight, cross-fostering and survival data is necessary for a successful selection program against mortality.

Key Words: Pig, Survival, Mothering-Ability

530 Genetic parameters of farrowing survival in purebred and crossbred pigs. A. Cecchinato*¹, G. de los Campos², D. Gianola², L. Gallo¹, and P. Carnier¹, ¹*University of Padova, Legnaro, Padova, Italy,* ²*University of Wisconsin, Madison.*

In commercial swine production, an important breeding objective is to improve performance of crossbred animals. However, selection is largely carried out in nuclei of purebreds. A question is whether purebred performance (in the nucleus) predicts accurately outcomes in crossbreds (commercial tier). This can be investigated by considering the two performances as different traits in a model and by estimating the genetic correlation. The objective of this study was to infer (co)variance components for farrowing survival in purebred (P) and crossbred (C) pigs; the latter were from crosses between P boars and Large White-derived crossbred sows. If the genetic correlation between C and P traits is large enough, selection in P would produce a correlated response in

C. Data were from 13,643 (1,213 litters) C and 30,919 (3,162 litters) P pigs, produced by mating the same 168 P boars to 319 Large White derived crossbred females and 1,413 P sows, respectively. The outcome variable was pig survival at birth as a binary trait. A Bayesian bivariate threshold model was implemented via Gibbs sampling. Effects of sex, parity of the dam, litter size and year-month of birth were assigned flat priors; those of litters, dams and sires were given Gaussian prior distributions. Marginal posterior means (SD) of the sire, dam and litter variances in P were 0.018 (0.008), 0.077 (0.020), 0.347 (0.025), respectively in the liability scale. For C, corresponding estimates were 0.030 (0.018), 0.120 (0.034), and 0.189 (0.032), respectively. The posterior means (SD) of heritability of survival in P and C, and of the genetic correlation between these traits were 0.049 (0.023), 0.091 (0.054) and 0.248 (0.336), respectively. Heritability estimates were low and in agreement with previous reports. The genetic correlation was also low, and a 95% Bayesian confidence region (-0.406, 0.821) included zero. Even though variation of estimates is large, results suggest that genetic progress expected in C when selection is based on P may be nil.

Key Words: Threshold Models, Pigs, Heritability

531 Heritability of longevity in Yorkshire females. M. D. Hoge*¹ and R. O. Bates², ¹*Western Illinois University, Macomb,* ²*Michigan State University, East Lansing.*

The length of adult sow life is recognized as both an economical and welfare concern. However there are not consistent definitions to measure sow longevity. This study assessed the genetic variation described by six different descriptions of longevity. Heritability was estimated for four different descriptions of longevity using a proportional hazards model with an underlying Weibull distribution. The definitions included herd life (time from first farrowing to culling), lifespan (number of parities a female has accumulated before culling), lifetime prolificacy (the number of piglets born alive during the lifetime of the sow), and a combination of prolificacy and length of productive life (the number of pigs produced per day of life). Data consisted of 7,632 records of Yorkshire females with at least one farrowing record, from both nucleus and multiplication herds across 21 farms from four seedstock systems. A threshold model was used to estimate heritability for two descriptions of stayability (probability of producing 40 pigs or probability of reaching 4 parities) on a subset of the original data (n=5803) that did not include censored observations. Terms for both models included, first litter performance effects of; age at first farrowing, number born alive, number of stillborns, adjusted 21 day weaning weight, and length of lactation along with the number born alive at last recorded farrowing. Additionally, the number born alive, litter birth weight and percentage of gilts born in a female's birth litter and her growth and backfat records were included. These variables were treated as fixed and time-independent. A random effect of sire was included in all models. Heritability estimates ranged from 0.16 to 0.21 for the Weibull analyses and 0.52 for the threshold analyses. Sufficient genetic variation exists, regardless of definition, to improve sow longevity.

Key Words: Sow Longevity, Genetics, Heritability

532 Use of serial pig body weights for genetic improvement. B. Zumbach^{1,3}, I. Misztal^{*1}, C. Y. Chen¹, S. Tsuruta¹, W. O. Herring², T. Long², and M. Culbertson², ¹University of Georgia, Athens, ²Smithfield Premium Genetics Group, Rose Hill, NC, ³Norsvin, Hamar, Norway.

This study examined the utility of serial weights from FIRE (Feed Intake Recording Equipment, Osborne Industries, Inc., Osborne, KS) stations for a longitudinal analysis of body gain. Data included 884,132 body weight records from 3,888 purebred Duroc pigs. Pigs entered the feeder station at age 77-149 d and left at age 95-184 d. A substantial number of records were abnormal, showing weight close to 0 or up to twice the average weight. Plots of weights for some animals indicated two parallel growth curves. Data were cleaned using robust regression based on M-estimation (weight function: bisquare, $c=2$; scale parameter: median), with age used as both a linear and a quadratic covariable. In order to maintain variability in the data and discard outliers at the same time, a cutoff value of $k=1.5$ was chosen. After discarding the outliers detected by the M-estimation, 607,597 body weight records remained. Daily weight (170,443 records) was calculated as an average of cleaned body weight records for each animal in one day. Daily gain was calculated as the difference in body weight between consecutive days. The number of records for daily gain was 152,636, and the average daily gain was 0.85 kg (SD = 1.16 kg). As a second step of cleaning, only animals with ≥ 50 body weight records and a standard error of the residual ≤ 2 kg were included, reducing the data to 89,257 records. After removing records outside of 3 SD from the mean, the final data set included 69,068 records of daily gain from 1,921 animals. Daily gain based on daily, weekly and monthly records was analyzed using repeatability models. Heritability estimates were 0.02%, 3.3% and 13%, respectively. SE of the estimate on daily records was larger than the estimate. After extensive editing, weight records from automatic feeding stations are useful for genetic analyses of daily gain from weekly or monthly but not daily data.

Key Words: Body Weight, FIRE Feeder Station, Robust Regression

533 Estimates of genetic correlations among growth traits including competition effects. C. Y. Chen^{*1}, R. K. Johnson¹, S. D. Kachman¹, and L. D. Van Vleck^{1,2}, ¹University of Nebraska, Lincoln, ²ARS, USDA, U.S. Meat Animal Research Center, Clay Center, NE.

The objective was to estimate genetic parameters of direct and competition effects for traits measured at the end of a growth test utilizing multi-trait analyses. A total of 9,720 boars were tested with 15 boars per pen from about 71 to 161 d of age and weight from 31 to 120 kg. Traits analyzed with initial age on test as a covariate were average daily gain during test (ADG), days to 110 kg (D110), and daily feed intake (DFI). Backfat measured at the p2 point (BF) and muscle depth (MD) were analyzed with age off test as a covariate. Fixed effects of line and contemporary group, with random direct genetic, competition genetic, and competition environmental effects were also in the statistical model. For single-trait analyses, estimates of direct heritability were 0.30, 0.26, 0.20, 0.46, and 0.33 for ADG, D110, DFI, BF, and MD, respectively. Estimates of heritability for competition effects were near to zero for all traits. Estimates of genetic correlation between direct and competition effects were 0.06, -0.13, -0.32, 0.22, and 0.36 for ADG, D110, DFI, BF, and MD, respectively but these are based on very small estimates of variance of competition effects. For two-trait analyses, estimates of direct genetic correlations were -0.96, 0.15, 0.44, -0.14, -0.42, 0.38, 0.16, and 0.04 for ADG-D110, ADG-BF, ADG-MD, D110-BF, D110-MD, DFI-BF, DFI-MD, and BF-MD, respectively.

Estimates of direct genetic correlations for ADG-DFI and D110-DFI, however, could not be obtained because global convergence failed to be met. Estimates of competition genetic correlations among the five traits might have little meaning because estimates of variances of competition effects were close to zero for all five traits. Difficulty of analyses including competition effects with two-trait models was apparent when the average information matrix failed to provide reasonable information. Interpretation of antagonisms among traits associated with competition effects was limited in this study.

Key Words: Competition, Genetic Parameters, Swine

534 Associations between body structure and overall leg action in crossbred gilts. M. Nikkilä^{*1}, K. Stalder¹, B. Mote¹, J. Lampe², B. Thorn³, M. Rothschild¹, A. Johnson¹, L. Karriker¹, and T. Serenius⁴, ¹Iowa State University, Ames, ²Swine Graphics Enterprises, Webster City, IA, ³Newsham Genetics, West Des Moines, IA, ⁴FABA Breeding, Vantaa, Finland.

The goal of this study was to investigate genetic parameters of body structure traits and overall leg action. The study was conducted at a commercial farm and involved 1449 females. The gilts were from two genetic lines and were progeny of 58 known sires and 836 dams. Sire information from 52 animals was unavailable. Gilts averaged 190 ± 7 days of age and 124 ± 11 kg body weight at the time of evaluation. Body structure evaluation included both body size (length, depth, width) and body shape traits (top line, hip structure, rib shape). Structure traits and overall leg action were independently evaluated by two experienced scorers using a 9 point scale. Top line was divided into two traits (weak/high top line) prior to analyses. AI-REML and the DMU-package were used to estimate variance components using a multivariate animal model. The statistical model included gilt line, evaluation day and scorer as fixed effects, animal as a random effect and weight at evaluation as a linear covariate. Heritability estimates were moderate for body size traits ($h^2=0.25-0.34$), low to moderate for body shape traits ($h^2=0.11-0.26$), and relatively low for leg action ($h^2=0.12$). Body size traits were genetically highly correlated with each other ($r_g=-0.80-0.92$) and with top line and rib shape ($r_g=-0.93-0.88$). Among body shape traits, high top line was genetically correlated with hip structure and rib shape ($r_g=0.63-0.92$). Long and shallow body, high top line and steep hip structure were associated with inferior leg action ($r_g=0.56-0.75$). Since body structure has high favorable genetic correlations with overall leg action, genetic progress in leg action can be enhanced not only by selecting animals with superior feet and leg soundness, but also by utilizing information about body structure. Satisfactory leg action is crucial for increasing sow productive lifetime, since lameness is one of the primary causes of early culling.

Key Words: Gilts, Body Structure, Leg Action

535 Genetic parameters for longitudinal feed intake and weight gain in Durocs. C. Y. Chen^{*1}, I. Misztal¹, S. Tsuruta¹, W. O. Herring², T. Long², and M. Culbertson², ¹University of Georgia, Athens, ²Smithfield Premium Genetics Group, Rose Hill, NC.

The objective was to investigate the genetic parameters for daily feed intake (DFI, g) and daily gain (DG, g) with records obtained from elec-

tronic feeder stations. After editing, data included DFI and DG from 81 to 167 d of age of 1,921 Duroc boars. The boars were housed in 112 pens, each equipped with one feeder, and allowed ad libitum feeding; most animals were tested only for 7-8 weeks. Because of large variation in daily records, weekly averages were used. Six traits were defined as DG and DFI during 81-109 (period 1), 110-138 (period 2), and 139-160 d of age (period 3). A six-trait model included age as a covariate with fixed effect of year-week and random effects of pen-year-week, litter, animal, and permanent environment. Variance components were estimated by a Bayesian approach using Gibbs sampling algorithm. Estimates of heritability for respective periods were 10.3, 10.7, and 11.6% for DFI and 7.0, 5.0, and 7.2% for DG. For DFI, genetic correlations between periods 1-2 were 0.76, periods 2-3 were 0.61, and periods 1-3 were 0.08. For DG, the same correlations were 0.68, 0.72, and 0.33. The correlations between DFI in period 1 and DG in periods 1-3 were 0.80, 0.61, and 0.49. The correlations between DFI in period 2 and DG in periods 1-3 were 0.38, 0.52, and 0.33. The correlations between DFI in period 3 and DG in periods 1-3 were -0.24, -0.09, and -0.27. Standard errors of correlations varied from 0.14 to 0.23. Low correlations for DG and DFI between extreme periods suggests that DG and DFI in these periods are different traits. Negative correlations between DFI and DG may indicate compensatory growth, competition for feeders, or the data structure of few animals with records in periods 1 and 3.

Key Words: Daily Gain, Genetic Parameters, Swine

536 Relationship between feed intake during growth and lactation in a mouse model. W. M. Rauw^{*1}, S. Hermes², K. Bunter², and L. Gomez Raya¹, ¹University of Nevada, Reno, ²University of New England, Armidale, Australia.

The major part of selection pressure in pig breeding programs has been directed toward improvement of lean growth efficiency by selecting for

increased growth rate, reduced body fatness, and improved feed efficiency. However, because leanness and feed efficiency are negatively correlated with feed intake, selection for improvement in these traits has led to a decrease in voluntary feed intake. It has been argued that voluntary feed intake should be considered in breeding programs. This study investigated the phenotypic correlation between feed intake during growth, at maturity, and during lactation in a mouse model in a selection experiment for litter size at birth. Data were available on 42 control and 48 selection line dams and litters. Feed intake was recorded every 3 d between 21 and 69 d of age, and daily between littering and weaning. A linear function was fitted to relate individual data on cumulative feed intake to age in virgin females and to days in lactation in lactating females. Selection line females, but not those of the control line, with higher intake during growth and at maturity had higher lactation intakes ($r = 0.37$, $P < 0.05$, and $r = 0.46$, $P < 0.001$, respectively). As this relationship will be positive only when animals eat to their potential, the results suggest that selection line females have been genetically "programmed" to eat to their potential intake capacity as a correlated effect, allowing for maximum litter sizes. Commercial lean types of pigs can be expected to produce to their maximum potential as well. However, when food intake is insufficient to meet the energy requirements during lactation, sows mobilize body reserves. When food intake capacity is limited and increased milk production in lactating sows is accounted for by a considerable mobilization of body reserves, the relationship between feed intake during growth and during lactation may be reflected in the relationship between growth intake and body condition instead.

Key Words: Selection, Feed Intake, Lactation

Dairy Foods: Cheese II

537 ADSA Pioneer: White cheese development. R. Richter*, *Texas A&M University, College Station.*

White cheeses are universally accepted and are a major component of the diet in many cultures. They are manufactured in many cultures and have a wide variety of names but many are similar in texture and flavor. Most of the white cheese varieties are manufactured by rennet coagulation of the milk with little or no acid production in the process. A popular variation is the production of cheeses that melt and stretch. A rich Artisan background for the manufacture of these cheese varieties exists and provides a significant basis for the development of this cheese category. The high pH and high moisture content of many of the white cheese products have caused vigilance for the manufacturing and storage practices to prevent public health problems. Research of these cheeses in the United States has historically been minimal but interest in this area has increased with the changing demographics in the United States and the expansion of the market.

Key Words: Cheese

538 Impact of the type of milk protein used to prepare starter media on properties of Mozzarella cheese. S. Govindasamy Lucey*, B. Dosti, J. Jaeggi, M. Johnson, and J. Lucey, *University of Wisconsin, Madison.*

Reconstituted NDM is commonly used as bulk starter culture medium in cheesemaking although whey protein concentrate (WPC) or milk protein concentrate (MPC) are other possible milk proteins that could be used. We investigated the impact of using WPC34/NDM blend or MPC80 based starter media for the manufacture of Mozzarella cheese. Cheesemilks were produced by blending skim milk (fortified with 1.5% NDM) (10.5% TS, 2.9% casein, 0.7% fat), cream (42.7% TS, 1.5% casein, 36.8% fat). 3% (w/w) starter media made with MPC80 (0.2% fat, 7.8% casein, 10.3% TS) or a blend of 16.3% WPC34 and 3.8% NDM (0.5% fat, 5.5% casein, 19.6% TS) was also added. No bulk starter media was added to control cheesemilk. All cheesemilks were standardized to a similar casein:fat of 1.0. A direct-vat-set starter culture was added to cheesemilks. Three types of cheeses were produced; control and cheeses made with WPC34/NDM and MPC80. Cheese functionality was assessed using dynamic low-amplitude oscillatory rheology (DLAOR) and performance on pizza. Coagula were cut at the same firmness. Addition of WPC34/NDM or MPC80 based starter media resulted in shorter rennet coagulation time. Cheeses made with both types of bulk starter media had slightly higher moisture contents (46.4-46.8%) compared with control (45.7%) cheeses. Nitrogen and fat recoveries were highest in MPC80-fortified cheese compared to control or WPC34/NDM-fortified cheese. Moisture-adjusted cheese yield was significantly higher in cheeses fortified with bulk starter media. Maximum loss tangent (LTmax) values (meltability index from DLAOR) was significantly lower in WPC34/NDM-fortified cheese compared to control or MPC80-fortified cheeses and LTmax values increased during the first two wk of ripening, after which the LTmax decreased. Temperature of LTmax was similar in all three cheeses and decreased with age. TCA-soluble nitrogen levels were higher in cheeses made with bulk starter media compared to control. Performance on pizza was similar for all cheeses. The results of this study indicated that other

types of milk protein powders can be successfully used as starter media in cheesemaking.

Key Words: Cheese Yield, Starter Media, Functionality

539 Characterization of Sicilian Pecorino cheese by area of production. S. Carpino*¹, I. Schadt¹, S. La Terra¹, G. Belvedere¹, T. Rapisarda¹, and G. Licitra^{1,2}, ¹CoRFiLaC, Regione Siciliana, Ragusa, Italy, ²D.A.C.P.A., Catania University, Catania, Italy.

Pecorino Siciliano is a PDO ewes' milk cheese produced in Sicily. The aim of this study was to investigate aroma profile differences for traditional Pecorino Siciliano cheeses produced in different part of Sicily. Cheeses ripened at 2, 4 and 8 months were obtained from 21 farms, from throughout Sicily, that were classed into seven areas by geography: Iblean (A), Etna (B), South-center (C), North-center (D), Western (E), West-center (F), Peloritana (G). Botanical composition of the native pasture grazed were visually evaluated in all these involved farms. Traditional cheese making parameters were also detected and evaluated. A MS-based Electronic Nose (SMartNose) was used to detect organic volatiles components in the mass-to-charge (m/z) range of 10 to 160 amu. Results were statistically elaborated by Principal Components Analysis (PCA). Comparison of the cheeses at 2, 4 and 8 months of ripening, generally showed differences in volatile compounds among the different areas. Cheese samples at 2, 4 and 8 months of ripening showed marked differences, likely due to the increasing lipolytic and proteolytic processes releasing the aroma compounds that characterize the cheese with time. The 8 month cheeses, showed the best separation with PC1 (60%) and PC2 (22%). Comparing two areas per times all the areas showed a good separation, but no differences between the Iblean area (A) versus the South-center area (C) and the Iblean area (A) versus the North-center area (D) were detected, indicating that seven areas are probably too many and we might need to restrict it. These comparison were also related to both differences in botanical composition and cheese making parameters in order to define which kind of parameters might effect Pecorino Siciliano cheese volatile profiles linked to the area of production.

Key Words: Cheese, SMartNose, Volatile Compounds

540 Effect of brine composition on cheese physical properties in Ragusano cheese. N. Fucà*¹, L. Tuminello², S. La Terra², M. Caccamo², M. Manenti², G. Licitra^{1,2}, and D. J. McMahon³, ¹D.A.C.P.A., Catania University, Catania, Italy, ²CoRFiLaC, Regione Siciliana, Ragusa, Italy, ³Utah State University, Logan.

During cheese brining, brine temperature, salt and calcium concentration influence the composition as well as the physical properties of cheese. This study aimed to examine the influence of brine composition and temperature on the protein matrix structure in cheese and its role in salt uptake. Three experimental 3.4-kg blocks of Ragusano cheese were made. The cheeses were cut in 63 pieces (1.7×1.8×13 cm³). One piece from each was chemically analyzed at time 0. All other pieces were measured for weight and volume and then immersed in 4 different

brine solutions (2, 10, 18, and 26% salt; all with 0.1% Ca) at 3 different temperatures (4, 12, and 20°C). The 10%-salt treatment was also performed with brine calcium contents of 0, 0.1, 0.2, and 0.4% Ca. After 24 h brining, the cheese was analyzed for weight, volume, fat, moisture, protein, salt, and Ca content, and by scanning electron microscopy. Cheeses brined in 2 and 10% salt had an average increase in weight ($20.5 \pm 0.06\%$ and $7.3 \pm 0.05\%$, respectively) while the 18 and 26%-brined cheeses decreased in weight ($-7.9 \pm 0.04\%$ and $-15.2 \pm 0.04\%$). Similar changes occurred in volume and cheese protein matrix appeared to be more expanded with low salt concentration and more compact with high salt concentrations. Brining at 4 and 12 °C caused greater expansion when the salt concentration was $\leq 10\%$. At 20 °C, virtually no change in volume occurred in 10%-salt brined cheeses indicating that even though salt was absorbed (salt content after 24 h was 4.9%) there was virtually no change in the protein matrix. When cheeses were brined without added calcium there was an increase in cheese volume ($15.1 \pm 0.09\%$) and weight ($18.6 \pm 0.03\%$) at all temperatures. At high calcium levels (0.4%), syneresis occurred and there was a decrease in volume ($-7.2 \pm 0.08\%$), especially at 20 °C (-16.5%).

Key Words: Cheese, Calcium, Microstructure

541 Studies on various paneer based spreads. H. A. Kumar and H. G. R. Rao*, *Dairy Science College, KVAFSU, Hebbal, Bangalore, Karnataka, India.*

Paneer is a heat-acid coagulated Indian type of soft cheese, used mainly for making culinary dishes. Paneer was made by heating wholemilk to 90°C, cooled to 70-75°C and coagulated by addition of 1percent citric acid. The whey was then drained out through a stainless steel mesh to

obtain paneer curd. Paneer spread (control) was prepared by adding salt (1.5%) and stabilizer (0.5%) to paneer curd and mixture was subjected to grinding by using mixer-grinder.

Dairy spreads available in the world market are high in fat, saturated fatty acids and cholesterol. Hence an attempt has been made in this study to develop various types of paneer based spreads which are low in fat and cholesterol, besides having good spreadability. Incorporation of 10%WPC or 5 % sodium caseinate or 5% soy flour in product preparation resulted in higher yield, better functional (firmness, spreadability, stickiness and adhesiveness were determined by texture analyzer) and nutritional value (considering protein %) comparable to control. Replacement of milk fat with vegetable oils (soy, corn or sunflower) at 25% level was highly acceptable with improved body and texture (texture analyzer) and spreadability. Further, matured cheddar cheese was incorporated at 30% level to paneer curd along with tri-sodium citrate (0.5%) as stabilizer and salt (1.5%). The mixture of cheese, paneer curd, stabilizer and salt was blended and grounded to obtain paneer spread. Incorporation of matured cheddar cheese in paneer spread improved acceptability and received higher flavor scores than control. Incorporation of spices such as pepper, clove, cinnamon and their combinations in the form of powder at 1% resulted in better flavor scores. Pepper and mixture of pepper and clove-flavored paneer spreads recorded highest overall acceptance scores. Among various storage studies undertaken, mere vacuum treatment of paneer spreads resulted in extension of storage up to 35 days at 7°C, as against 14 days in control. Microwave treatment of spreads under similar conditions of temperature resulted in extension of keeping quality up to 63 days. Cheese spreads are not popular in India. Therefore paneer type of product with slight modifications with better functionality to improve their utilization was developed in this study.

Key Words: Paneer, Spreads, Spices

Food Safety Centennial Presentations

542 ASAS Centennial Presentation: Developments and future outlook for preharvest food safety. S. P. Oliver*¹, D. A. Patel¹, T. R. Callaway², and M. E. Torrence³, ¹*The University of Tennessee, Knoxville*, ²*USDA/ARS Southern Plains Agricultural Research Center, College Station, TX*, ³*National Program Leader, Food Safety, USDA/ARS, Beltsville, MD*.

While the United States food supply is one of the safest in the world, CDC estimates that 76 million people get sick, more than 300,000 are hospitalized, and 5,000 die each year from foodborne illness. Consequently, preventing foodborne illness and death remains a major public health concern. Challenges to providing a safe, abundant and nutritious food supply are complex because all aspects of food production from farm to fork must be considered. Given the national/international demand and expectations for food safety as well as the formidable challenges of producing and maintaining a safe food supply, food safety research and educational programs have taken on a new urgency. Remarkable progress has been made during the last century. Sagacious wisdom from a century of animal agriculture research now includes the realization that on-farm pathogens are intricately associated with animal health and well-being, production of high quality food, and profitability. In this review, developments that have occurred over the last few decades will be summarized including types, sources and levels of disease-causing pathogens encountered in food-producing animal environments and their association with food safety; current and future methods to control/reduce foodborne pathogens on the farm; and present and future preharvest food safety research directions. Future scientific breakthroughs will no doubt have a profound impact on animal agriculture and production of high quality food but we will also be faced with moral, ethical and societal dilemmas that must be reconciled. A strong science-based approach that addresses all the complex issues involved in continuing to improve food safety and public health is necessary to prevent foodborne illnesses. Not only must research be conducted to solve complex food safety issues, but results of that research must be communicated effectively to producers and consumers.

Key Words: Food Safety, Foodborne Pathogens, Food Safety Research

543 ASAS Centennial Presentation: Developments and future outlook for postharvest food safety. J. Sofos*, *Colorado State University*.

Humans have consumed meat for thousands of years and consumption has increased with agricultural advances and increases in disposable income. It is natural for raw meat and other foods to become contaminated with spoilage and pathogenic microorganisms during exposure to the environment. Following advances in microbiology in the 19th century, meat safety and quality became of public interest and led to federal inspection regulations early in the 20th century. However, food safety became a major public issue only in recent decades along with changes in animal production, product processing and distribution; increased international trade; consumer preference for minimally processed foods; increased worldwide meat consumption; higher numbers of consumers at-risk for infection; and, increased scrutiny by consumers and news media. The 1906 meat inspection regulation underwent a major revision in the 1990s, following intense public scrutiny of an outbreak of *Escherichia coli* O157 transmitted through undercooked ground beef. The new inspection regulations are based on the principles of hazard analysis critical control point (HACCP) and have as target the prevention of hazards before consumer exposure. In efforts to meet regulatory requirements and commercial specifications for lower contamination, and to provide safer products to consumers, the meat industry, which also expanded along with regulatory developments and scientific advances, has recently employed various decontamination and pathogen control interventions as multiple hurdles. Major current and future meat safety issues and challenges include the need to control pathogens which may be of increased virulence or resistant to antibiotics or other stresses, control of cross-contamination of foods and water with zoonotic pathogens, and manure treatment and disposal issues. Other issues include additives and chemical residues, organic and natural products, animal identification and traceability, rapid pathogen detection, regulatory harmonization at the national and international level, establishment of risk assessment based food safety objectives, and optimization of HACCP implementation based on food handler training and consumer education.

Forages and Pastures: Centennial Presentations

544 ASAS Centennial Presentation: Historical perspective on the advances in forage research. J. Burns*^{1,2}, ¹USDA-ARS, Raleigh, NC, ²North Carolina State University, Raleigh.

The objective of this presentation is to provide a historic overview from 1908 through the present on advances in forage and pasture evaluation as related to ruminant utilization. The nutrition of ruminants resides with the utilization of forages, either in the form of pasture, or if stored and preserved as hay or silage. The diet may be all forage or some ratio of forage to concentrate, but the former is the focus of this presentation. The assessment of nutrients contained in forages, including pasturage, were initially identified and described in the early (pre 1900) literature by proximate analyses (following the Weende System) procedures. Innovation has occurred since then regarding the methods of nutrient identification, including improved characterization and rapid assessment of nutrient concentration in forages. During this same period a number of plant attributes have been identified and recognized as having a potential role in ruminant nutrition. These attributes consist of differences among forage species, differences among cultivar within species, morphological characteristics, herbage mass characteristics (grazing management) and physiological processes, such as regrowth rates diurnal shifts and advancing stages of maturity. Techniques and management strategies including stocking methods, and flexible utilization strategies in grazing environments have emerged during this period and have benefitted ruminants through judicious use of these inherent plant attributes. The process of moving forage innovations into the ruminant domain has occurred through advancements in better understanding of antiquality constituents, importance of diet selection, forage fermentation, and particle breakdown and passage. These are all subsequently reflected in *in vivo* dry matter digestibility and dry matter intake and ultimately expressed in the daily performance of the ruminant.

Key Words: Methods, Utilization, Ruminants

545 ASAS Centennial Presentation: Research and extension needs in forage utilization in the future. F. M. Rouquette, Jr.*¹, L. A. Redmon², G. E. Aiken³, G. M. Hill⁴, L. E. Sollenberger⁵, and J. Andrae⁶, ¹Texas AgriLife Research, Texas A&M System, Overton, TX, ²Texas AgriLife Extension Service, Texas A&M System, College Station, TX, ³USDA-ARS Forage Animal Production Research Unit, Lexington, KY, ⁴University of Georgia, Tifton, ⁵University Florida, Gainesville, FL, USA, ⁶Clemson University, Clemson, SC, USA.

Research and extension activities in forage utilization imply multi-discipline efforts targeted at the plant-animal interface. Future need assessments require a multidimensional response surface to account for discipline emphases-direction, funding level erosion, discipline survival, and stakeholder-commodity group interests. Energy-related costs of fuel, fertilizer, feed grains, and seed production mandate that economic assessments become a regular component of addressing and reporting forage-animal responses. Production and utilization strategies for legumes and reduced-nitrogen requiring forages and forage systems will be required to meet stakeholder demands for economically-viable, sustainable livestock enterprises. Emerging issues include plant food nutrient management on pastures and grazed areas, environment-compatibility with urban encroachment and land-use restrictions, and alternative land use for pasture areas. Reduced allocation of state and federal funding has contributed to a reduction in number of full-time equivalent scientists engaged in forage utilization activities. Enhanced requirements for extramural funding to support agricultural research endeavors has reduced forage utilization emphases due to prioritizing and redirection of commodity and industry-based grant funds. Stakeholder interests and objectives will likely include smaller-sized properties, increased urban proximity, and objective-motive, economic-driven management. Research and extension scientists will encounter a shift in emphasis to accommodate changes in stakeholders and property ownership. States that experience forage utilization discipline disappearance may seek a regionalized effort for expertise and databases to accommodate technology transfer opportunities.

Key Words: Grazing, Animal Performance, Pasture Systems

Horse Species III

546 ASAS Centennial Presentation: History and future outlook of equine science teaching programs. C. H. Wood*, *University of Kentucky, Lexington.*

Many equine programs began shortly after the enactment of the Morrill Act of 1862 which led to the creation of the land grant university system. During that time horses and mules were used as the main means of transportation and work for agriculture production. Their value and worth were vital to business and the economy. The objectives of this paper are to discuss early equine undergraduate programs, the characteristics of current programs, and what factors will affect the future of equine undergraduate programs. Early equine teaching programs focused on husbandry management practices of horses and mules. As modern farming practice and machinery were developed, the role of the horses and mules in transportation and agriculture production diminished and horses were selected more for performance activities. Universities with equine teaching programs began to introduce minors or options in equine science. In the 1960s and 1970s, many equine teaching programs implemented equitation courses that turned out to be very popular with students but were subsequently eliminated due to the expense and the perceived lack of science involved in the courses. Equine teaching programs have enjoyed renewed invigoration in the late 1990s and early 2000s. Most current equine programs offer research and educational programs for undergraduate students and professional students. The emphasis of current horse programs is equine science and technology, combined with practical aspects of horsemanship, horse training, showing and judging. What factors have led to this increased interest in equine teaching programs? Why are so many land grant universities instituting or expanding their equine programs? Has the equine industry as a whole contributed to this renewed interest? What role will innovations in technology and social networks play in future equine programs? As instructors, how will we incorporate technologies in the classroom or in the extended classroom? Exploring the answers these questions and more will shed light on the future of equine teaching programs.

Key Words: Equine, Undergraduate, Teaching

547 Effect of ad libitum concentrate feeding on cribbing behavior in horses. T. R. Fenn*¹, C. A. McCall¹, C. E. Eckert¹, W. H. Brown¹, and W. H. McElhenney², ¹*Auburn University, Auburn, AL*, ²*Tuskegee University, Tuskegee, AL*.

Previous research indicates cribbing behavior in horses increases around concentrate meals. This study used 10 mature cribbing geldings to investigate effects of ad libitum concentrate feeding on cribbing behavior. Horses were randomly assigned to either ad libitum feeding (n=5) or control (n=5) groups and were maintained on Bermuda grass (*Cynodon dactylon*) pasture and free choice hay. Each horse was receiving a baseline ration of 1.8 kg of a commercially available pelleted concentrate twice daily at the start of the study (d 0). Control horses remained on this amount throughout the study. Feed for the ad libitum horses was increased to approximately 3.6 kg concentrate four times daily and maintained at this amount for 102 d. Ad libitum horses then were fed 0.9 kg concentrate four times daily (d 103-136) and finally returned to baseline ration (d 137-176). Number of crib bites and duration of crib bouts were recorded for all horses during six 24-h observation periods (d 0, 28, 66, 102, 136 and 170). Data were analyzed as a repeated measures

design which revealed a period by treatment interaction ($P<0.01$) for both total crib bites and total crib bout duration. Preplanned contrasts showed that controls performed 1222 ± 143 more crib bites ($P<0.01$) and spent 110.6 ± 22.7 min more time performing cribbing behavior ($P<0.01$) than ad libitum horses. When ad libitum horses were fed four times daily (d 103-136), their total crib bites and crib bout duration were not significantly different from control horses. Also, no significant residual effect of ad libitum feeding on cribbing behavior was found when ad libitum horses returned to baseline feeding levels. It is not clear from this study whether the decrease in cribbing behavior seen in the ad libitum horses was the result of additional feed or a change in other factors that accompany concentrate feed delivery in horses. Additionally, ad libitum feeding cannot be considered a viable method to reduce cribbing behavior because of possible negative effects, e.g., obesity, of this feeding regimen on horse health and usefulness.

Key Words: Horse, Ad Libitum Feeding, Cribbing Behavior

548 Epidemiologic and economic study of Hyperelastosis Cutis/HERDA in the quarter horse cutting industry. S. G. Tipton*¹, J. D. Anderson¹, T. S. Smith¹, N. J. Winand², P. R. Ryan¹, R. L. Linford¹, and A. M. Rashmir¹, ¹*Mississippi State University, Mississippi State*, ²*Cornell University, Ithaca, NY*.

Hyperelastosis Cutis (HC) is an autosomal recessive skin disorder in Quarter Horses. Homozygous (Hr/Hr) horses have fragile, hyperextensible skin with skin sloughing and scarring, and are often euthanized. Heterozygous (N/Hr) horses are carriers of the gene, but appear to be normal. The objectives of this study were to evaluate the economic impact of HC within the cutting horse industry and to determine the pedigree relationship of affected and carrier individuals, using SAS Proc Inbreed. Hr/Hr horses (n=194) were identified through DNA and urine testing, or clinical presentation. N/Hr status was then established for an additional 606 horses, including 285 stallions and 265 mares. Records were obtained on the top 100 cutting horses and lifetime earning (LTE) sires within the industry for 1985 through 2006 (Equistat), (N/Hr) horses from these groups were then identified. As of 2006, the cutting horse industry has paid \$388 million to the top 100 sires' offspring, with 23% of those earnings (\$88 million) attributed to the offspring of 12 N/Hr stallions (12%). From 1998 through 2006, these N/Hr sires' offspring earnings increased an average of 0.5% annually, indicating an upward trend. Of the top 100 LTE sires, N/Hr stallions account for 12% and N/N (wild type) for 88%. Thirty three percent of N/Hr sires' offspring earned money with average earnings of \$24,064, compared to N/N sires, with 27% of their offspring averaging \$19,187. In addition, 43% of N/Hr sires' offspring have performed, while only 39% of N/N sires' offspring have performed. Of the approximate 3,500 samples submitted for DNA testing from four continents, 18% of clinically normal cutting horses tested N/Hr. The true prevalence of Hr/Hr horses is difficult to estimate due to the limited number of homozygous horses tested thus far. The large number of heterozygous (N/Hr) horses and the financial impact of this disease on the cutting horse industry emphasize the importance of DNA testing for HC and appropriate breeding selection. This study was supported by AQHA grant number 05070672.

Key Words: Hyperelastosis Cutis, HERDA, Quarter Horses

549 Gastric ulcer incidence rate and relationship to other parameters in 40 Standardbred racehorses. R. E. Cate*, B. D. Nielsen, C. I. O'Connor-Robison, H. S. Spooner, J. L. Feldpausch, and H. C. Schott II, *Michigan State University, East Lansing.*

Many studies report incidence rates of gastric ulcers to be 60 to 90% in racehorses. This study was performed to determine the incidence rate in a population of Standardbred racehorses training in Michigan and to determine the relationship of ulcers to other factors that could be evaluated through a physical examination or by obtaining the horse's history from a trainer. The presence or absence of ulcers was confirmed by gastroscopic examination of 40 Standardbreds on two farms (22 horses on farm A, 18 horses on farm B) and given a grade of 0 to 4 where a grade 0 represents no ulceration found. Examinations were conducted during the last two weeks of December and the first week of January and the age of horses (as of January 1st) ranged from 3 to 12 years. Horses were body conditioned scored on a scale of 1 to 9 and trainers were asked to grade the current racing performance of each horse on a scale of A to F with A being best. For statistical purposes, horses were grouped by gender (15 females, 25 males), age (ages 3 and 4 or 5 years of age and older), body condition score (below a BCS of 4.5 or 4.5 and above), and performance (grades A and B or grade C and lower). The incidence rate of ulcers was similar between farms (50% and 56%) but the average (52.5%) was lower than has been typically reported. Ulcer score was not related to gender ($P = 0.72$), age ($P = 0.48$), body condition score ($P = 0.65$), or performance ($P = 0.55$). These findings suggest that the commonly cited incidence rate of ulcers may be too high to be used universally. Similarly, given that only 7 out of 40 horses (17.5%) had a grade 2 or higher ulcer, the impact that ulcers likely cause on performance or health is probably lower than what is commonly believed. This study also confirms a gastroscopic examination needs to be performed to confirm the presence of ulcers despite the belief by many that performance and body condition score can be indicative of their presence.

Key Words: Horse, Ulcer

550 Use of slow-release urea to facilitate composting of horse manure. S. C. Dilling* and L. K. Warren, *University of Florida, Gainesville.*

Manure and bedding removed from horse stalls often has a high C:N ratio, thus requiring additional N to facilitate composting. Yet, N loss through volatilization can be significant. This study investigated the use of slow-release N (SRN) sources to promote composting and mitigate N loss from horse stall materials. Materials were amended with urea ($n=3$) or one of two SRN sources: urea formaldehyde ($n=3$) or polymer sulfur coated urea ($n=3$). N-amended treatments were compared to materials that were unamended (CON; $n=3$). All materials were composted for 120 d using an on-farm multiple-bin system. Compost temperature, moisture and O_2 were monitored 3 d/wk. Compost samples were collected at 30 d intervals and analyzed for NDF, ADF, lignin, total N, NH_3 , NO_3 , total C, pH and microbial populations. Data were analyzed by ANOVA using proc mixed function of SAS (v 9.1) and pdiff for treatment means separation. Temperatures required to destroy parasites and weed seeds were reached within the first 2 wks of composting in all treatments.

Weight and total C of materials were reduced in response to composting ($P \leq 0.05$), but were not affected by N-amendment. Total N decreased during composting ($P \leq 0.05$) with a greater loss of N in all N-amended treatments compared to CON ($P \leq 0.01$). The largest loss of N occurred with urea ($56 \pm 3\%$) compared to SRN sources ($5 \pm 0.9\%$) ($P \leq 0.01$). NH_3 was affected by treatment ($P \leq 0.05$) with a loss occurring in urea, no change in CON and an increase in SRN sources. Composting resulted in an increase ($P \leq 0.05$) in NO_3 , with CON lower ($P \leq 0.01$) than N-amended materials. N-amendment reduced ($P \leq 0.05$) the pH of materials from 7.5 ± 0.1 to 6.3 ± 0.2 during composting. N-amendment had no effect on NDF, ADF, lignin or microbial populations. Collectively, these results indicate that SRN sources reduce the loss of N during composting of horse stall material, but did not necessarily enhance the decomposition process compared to urea. Use of SRN sources may decrease the risk of environmental pollution and increase the value of the composted horse stall material as a fertilizer source.

Key Words: Composted Horse Manure, Stall Waste, Nitrogen Amendment

551 Phosphorus contribution of six equine bedding types. A. D. Woodward*, B. D. Nielsen, C. I. Robison-O'Connor, and J. M. Witherspoon, *Michigan State University, East Lansing.*

The objective of this study was to determine differences in P contribution from different bedding materials used in an equine facility. A 6×6 Latin Square design was used with 6 horses and 6 bedding materials—shavings (SH), straw (ST), chopped straw (CS), wood pellets (WP), peat moss (PM), and corn cob hulls (CC). Each horse and bedding combination lasted 7 days. Before the commencement of the study, stalls were stripped of any previous bedding material and bedded to an average depth of 12.5 cm with each bedding type. Weight of bedding used was recorded. Waste was removed once daily by the same farm crew, weighed, mixed, and a 10% grab sample was saved. New bedding was weighed and replaced as needed to maintain 12.5 cm. At the end of each 7-d period, all grab samples were pooled, mixed, and a cumulative 10% sample was bagged and frozen at $-20^\circ C$ for further analysis of P. More CS, PM, SH, and ST were added daily compared to CC and WP (6.5, 4.9, 4.6, and 7.2 vs. 0.0 and 1.3 kg, respectively; $P < 0.01$). Removal of CS, SH, and ST was higher daily compared to CC and PM (17.8, 16.7, and 21.1 vs. 10.5 and 10.6 kg, respectively; $P < 0.05$). Concentration of P in the used bedding was higher in CC compared to SH and WP (2.4 vs. 1.1 and 1.1 g P/kg bedding, respectively; $P < 0.05$) and was higher in CS compared to SH (2.1 vs. 1.1 g P/kg bedding; $P < 0.05$). Concentration of P in the used bedding was also higher in PM compared to CS, ST, WP, and SH (3.1 vs. 2.1, 1.7, 1.1, and 1.1 g P/kg bedding; $P < 0.05$). On a DM basis, results were much the same. Concentration of P in the used bedding was higher in CC compared to SH and WP (5.7 vs. 2.5 and 2.4 g P/kg bedding, respectively; $P < 0.05$) and was higher in PM compared to CS and SH (8.1 vs. 4.2 and 2.5 g P/kg bedding, respectively; $P < 0.05$). These results reveal differences in P contribution of six typical bedding materials used in horse facilities. The knowledge gained from these results can be used to create improved nutrient management practices in horse facilities.

Lactation Biology III

552 ASAS Centennial Presentation: Historical perspective on lactation biology. R. S. Kensinger*, *Oklahoma State University, Stillwater.*

Research over the past 100 years has revealed numerous exciting developments in our understanding of the biology of lactation. New assay technology combined with classical approaches to endocrinology contributed greatly to our knowledge of hormonal control of mammary function. The development of unconventional models of investigation (including suckling intensity, altered milking frequency, hemi-mastectomy, induced lactation, and transplantation of mammary glands) lead to greater understanding of factors that affect mammary function; as well as greater appreciation of the plasticity of the mammary gland. This era yielded papers on the characterization of the milk proteins and sequencing of the milk protein genes; elucidation of the complex array of milk lipids; and an appreciation for variation among species in oligosaccharides in milk. From a practical standpoint, this knowledge provided better management strategies to encourage passive transfer of immunity to neonates, and better selection tools for breeding females. Subtle benefits of colostrum and milk to neonates were described in recent years. The defense mechanisms of mammary glands were characterized in this era, and a greater appreciation of the impact of mastitis on livestock productivity was gained. This foundation knowledge lead to development of useful food animal practices and technologies like vaccination programs in pregnant females to enhance immunity in neonates, bST for dairy, and the development of Monensin for lactating cattle. This knowledge also encouraged the biomedical industry to use mammary glands in food animals to produce human pharmaceuticals.

553 ASAS Centennial Presentation: Lactation biology for the 21st century. J. J. Looor*¹ and W. Cohick², ¹*University of Illinois, Urbana,* ²*Rutgers, The State University of New Jersey, New Brunswick.*

Knowledge of general aspects of mammary gland function, including metabolic pathways and hormonal regulation of mammary gland development and lactation, in livestock species was obtained several decades ago. As basic biological information of growth factor action, apoptotic mechanisms, and signal transduction events has exploded, the mouse became the model of choice for studying fundamental mechanisms regulating mammary function. A complete sequenced genome also has made the mouse amenable for studies of mammary gene network expression. Advances in molecular biology techniques currently allow researchers to genetically modify mice to either overexpress or completely lack specific genes, thereby studying their function in an in vivo setting. Furthermore, the use of mammary specific promoters has allowed genes related to mammary gland function to be eliminated from the mammary gland in a developmental and tissue-specific manner. These studies have provided compelling evidence of the underlying complexity that must ultimately allow the ruminant or swine mammary gland to function in a coordinated fashion throughout puberty, pregnancy, lactation, and involution. The challenge for the researcher interested in understanding these complex

mechanisms to enhance the efficiency of milk production in domestic species is how to obtain similar information in much larger, expensive animals. One possible approach is to manipulate gene expression in vitro using mammary cell culture models derived from domestic animals, e.g. genes can be “knocked-down” using small interfering RNA approaches. Ultimately, major advances in understanding lactation biology may come from coupling basic mechanistic information with functional genomics, proteomics, and metabolomics approaches. A strong foundation in bioinformatics will also be required to optimize use of these new technologies. Additional areas that hold promise are stem cell biology and epigenetics. Strong training of our future scientists in these areas should facilitate livestock-focused mammary gland research that will allow basic information to be gained at unprecedented levels, ultimately leading to optimization of livestock production.

Key Words: Genomics, Gene Silencing, Stem Cells

554 The persistent milk yield response to frequent milking during early lactation is associated with persistent changes in mammary gene expression. E. H. Wall*, J. P. Bond, and T. B. McFadden, *University of Vermont, Burlington.*

Four-times daily milking during the first 3 weeks of lactation elicits an increase in milk yield, which persists through late lactation even after twice-daily milking is imposed. We hypothesized that this milk yield response would be associated with changes in mammary proliferation, apoptosis, and gene expression, which would persist throughout lactation. Six multiparous cows were assigned to unilateral frequent milking (UFM; twice daily milking of the left udder half (2X), four-times daily milking of the right udder half (4X)) on days 1 to 21 of lactation, followed by 2X thereafter. Udder halves initially milked 4X produced more milk than 2X glands during ($P < 0.001$), and after ($P < 0.05$) UFM treatment. To determine the mechanisms involved in the persistent milk yield response, we obtained mammary biopsies from both udder halves at 21, 23, and 40 days in milk (DIM). Rates of [³H]-thymidine incorporation into DNA in vitro and mammary cell apoptosis were not affected by UFM or DIM ($P > 0.30$). Using Affymetrix GeneChip® Bovine Genome Arrays, we identified a cluster of 16 genes with a similar temporal pattern of expression that differed between 2x and 4x udder halves ($P < 0.05$). Nine of the genes in the cluster remained differentially expressed at 40 DIM ($P < 0.05$), indicating that they may be involved in the persistent milk yield response. Among these genes were chitinase-like protein (CLP)-1, clusterin, early growth response (EGR)-1, sex determining region Y-box (SOX)-4, and -9. These genes have been associated with mammary development, differentiation and remodeling; all of which may be functionally related to the increase in milk yield. We conclude that frequent milking during early lactation does not alter mammary growth but is associated with coordinated changes in mammary expression of 16 genes. Future experiments will determine the function of these genes in the mammary gland, and will clarify their role in the autocrine regulation of milk production and long-term alteration of mammary function.

Key Words: Frequent Milking, Gene Expression, Mammary Gland

555 Gene network analysis in mammary and liver tissue of lactating mice fed trans10,cis12-CLA. A. K. G. Kadegowda*¹, A. Thatcher², L. S. Piperova¹, S. L. Rodriguez-Zas², R. A. Erdman¹, and J. J. Loo², ¹University of Maryland, College Park, ²University of Illinois, Urbana.

Exogenous trans10,cis12-CLA (10/12CLA) reduces mammary lipid synthesis in bovine and murine mammary tissue (MG). However, genome-wide alterations in MG and liver (LIV) associated with dietary 10/12CLA during lactation remain unknown. To better characterize MG and LIV tissue gene networks sensitive to 10/12CLA during lactation, we fed mice (n = 5/diet) control or control + 10/12CLA (37mg/day) between d 6 and d 10 post-partum. Tissues were harvested on d 10 after sacrifice. A 35,302 gene annotated murine exonic evidence-based oligo (MEEBO) microarray (70-mers) and quantitative PCR were used for transcript profiling. Cy3- and Cy5-labelled cDNA from MG or LIV and a reference standard were used for hybridizations (total of

20 microarrays). Milk fat concentration was 44% lower on d 10 vs. d 6 due to 10/12CLA. ANOVA (FDR-adjusted P = 0.20) identified 1,496 differentially expressed genes (DEG) in MG and 22 in LIV due to 10/12CLA. Among DEG in MG, we found 37 downregulated and 82 upregulated by 1.5-fold or greater. Gene network analysis of upregulated MG genes identified cell cycle (7 genes), cell growth/proliferation (10 genes), cell assembly/organization (27), and small molecule biochemistry (25) as modified families of related genes. Similar analysis of downregulated genes identified lipid metabolism (34 genes), cell death (29), and carbohydrate metabolism (23) as gene families most affected by 10/12CLA. The PPAR-signaling pathway was the most affected by 10/12CLA with a total of 77 DEG including Pparg and Pppard. Overall, results suggest that lower mammary lipid synthesis induced by dietary 10/12CLA in mice is associated with previously-unknown adaptations in gene networks in MG and to a lesser extent in LIV.

Symposium: Meat Science and Muscle Biology: Postmortem Changes in Myofibrillar Protein and the Associated Contribution to Meat Quality

556 Historical perspective of postmortem changes in myofibrillar proteins and their relationship to meat quality. F. C. Parrish*, Iowa State University, Ames.

Myofibrillar proteins make up the largest amount of muscle protein and they are largely responsible for postmortem changes in rigor mortis, tenderness and water holding capacity. The changes of myofibrillar proteins and the mechanism of these changes in the tenderization process have received much attention. Proteolysis has long been thought of as the mechanism of postmortem tenderization. The definitive proof of proteolysis and its relationship to tenderness, however, had eluded scientists until studies were initiated in the late 1960's. A series of innovative studies on the changes in molecular properties of myofibrillar proteins in postmortem muscle led to the discovery of Z disk degradation and myofibril fragmentation by a calcium activated endogenous protease. The protease was subsequently named calcium activated factor (CAF). Further extensive studies found CAF had a high requiring calcium form, m calpain, and a low calcium requiring form, μ calpain, and an inhibitor, calpastatin. Other studies on CAF showed myofibril fragmentation and the simultaneous disappearance of troponin T and appearance of a 30 kDa component were strongly related to beef steak tenderness. The 30 kDa component was only in tender beef steaks. The term "myofibril fragmentation tenderness" was introduced to describe a state of beef tenderness. The degradation of titin and nebulin in postmortem beef muscle was found to be due to CAF. Also, degradation of titin, nebulin, and troponin T was greater and more rapid in a tender than in a tough beef muscle. Titin was more rapidly degraded in muscle from steers, than it was in muscle from bulls and mature cows, too. Degradation of specific structural proteins (titin, nebulin, filamin, desmin, and troponin T) by μ calpain at low pH and temperature was similar to their degradation in postmortem muscle. Other studies on calpain activity and its inhibitor, calpastatin, and the affects of calcium infusion of carcasses and their relationship to tenderization have proven valuable. From these historical studies it can be concluded that limited and specific proteolysis of key structural proteins in the I band of the myofibril are caused by μ calpain and results in postmortem tenderization.

Key Words: Proteolysis, 30 kDa Component, Calpain

557 Calpain biology and postmortem meat tenderization. D. E. Goll*, J. P. Camou, J. A. Marchello, S. W. Novak, and V. F. Thompson, University of Arizona, Tucson.

It is now widely accepted that the calpains have an important role in the postmortem proteolysis that contributes to tenderization. It remains unclear, however, how the calpains function in postmortem muscle, where the temperature after 6-12 h is near 2-4°C, the pH is near 5.8, and the calpain inhibitor, calpastatin, is present. Studies have suggested that μ -calpain is the primary protease responsible for postmortem proteolysis, but μ -calpain has very little activity after 2-3 d postmortem, even when assayed at pH 7.5 and 25°C. It has been suggested that loss of μ -calpain activity during postmortem storage is an artifact caused by exposure to high ionic strength. We have partly purified calpastatin and both μ - and m-calpain from 11-d postmortem bovine muscle without exposing them to ionic strengths above 200 mM during purification.

Both calpains are nearly inactive after 11 d postmortem when assayed at pH 7.5 and 25°C; the inactive μ -calpain can be detected with antibodies. Western analysis shows that postmortem μ -calpain consists largely of 76- and 28-kDa subunits, so the small subunit of μ -calpain is not autolyzed to any appreciable extent during postmortem storage. Based on results of *in vitro* assays, this 28/76-kDa molecule would be expected to be proteolytically active, and it is unclear why it has no activity. *In vitro* assays done at 25°C and using purified calpains show that at-death m-calpain is nearly inactive proteolytically at pH 5.8 but that at-death μ -calpain has some activity at pH 5.8. Zymogram assays, however, show that 1-d postmortem μ -calpain is nearly inactive at pH 5.8, even when assayed at 25°C. After partial purification, calpastatin activity is detected in 11-d postmortem muscle, but this activity is less than the calpastatin activity in at-death muscle. Postmortem calpastatin polypeptides are smaller than 70-kDa and seem less effective (higher K_i values) than at-death calpastatin in inhibiting the calpains. The results thus far suggest that postmortem calpastatin may not be an effective calpain inhibitor, but they raise a number of questions about whether the calpains have any appreciable proteolytic activity after 2-3 days of postmortem storage.

Key Words: Calpain, Tenderness, Postmortem

558 Relationship of postmortem changes in myofibrillar protein to meat quality. E. Huff-Lonergan* and S. Lonergan, Iowa State University, Ames.

Variations in tenderness and water-holding capacity are major quality problems that significantly affect the profitability of the meat industry. It is clear that early postmortem biochemical and biophysical processes, including proteolysis, contribute to the development of water-holding capacity of pork and tenderness of both pork and beef. For decades, it has been known that tenderness of meat is improved by holding the product at refrigerated temperatures for periods of time ranging from 1-4 weeks postmortem. This process is referred to as postmortem aging or conditioning. During the aging period, major structural changes in the tissue occur. Many of these changes are associated with myofibrils and their linkages to the sarcolemma. Since myofibrils make up nearly 80% of the volume of the muscle cell, their disruption will greatly influence meat tenderness. Even prior to 24 hours postmortem, significant proteolysis of proteins linking myofibrils to the sarcolemma and to each other occurs. Other changes correlated with increased tenderness include breakages within the myofibrils leading to their increased fragility and fragmentation. The increase in myofibrillar fragmentation is indicative of the amount of proteolysis and subsequent tenderization that has taken place. Many proteins involved in meat quality are substrates of the protease μ -calpain. Microenvironmental factors such as pH and ionic strength and oxidative conditions influence the ability of calpain to degrade myofibrillar substrates. Both μ -calpain and m-calpain have slower rates of activity against myofibrillar protein substrates at pH values and ionic strengths similar to those found in postmortem muscle. Alterations in pH and/or ionic strengths may cause conformational changes that allow an increase in the hydrophobicity and aggregation of the enzyme. Likewise, pH/ionic strength changes may alter the conformation of substrate proteins and render them less susceptible to

cleavage by μ -calpain. In addition, post-translational modifications of the calpains and their myofibrillar substrates may also contribute to the development of meat quality attributes.

Key Words: Muscle, Meat Quality, Postmortem Changes

559 New methods to investigate changes in meat and myofibrillar proteins. E. Veiseth*, *Matforsk, Ås, Norway.*

Meat tenderness improves during postmortem cooler storage largely due to calpain-mediated proteolysis of key myofibrillar and associated proteins. This proteolysis does not appear to be random, and several studies have been undertaken to determine which specific proteins are degraded and what structural changes are associated with tenderisation. While most structural changes described until now occur at the ultrastructural level (e.g. fracturing of myofibrils), we have focused on changes occurring at the microstructural level (i.e. fracturing of muscle fibres and their detachment from connective tissue).

Our objective was to investigate relationships between microstructural changes, calpastatin activity, and Warner-Bratzler shear force (WBSF) in aged Longissimus dorsi (LD) muscle from fifty Norwegian Red bulls. The LD muscle was conditioned at 12°C for 10h, and then aged for 7 days at 4°C. Samples for calpastatin measurements were extracted between 24 and 31 hrs postmortem using a heated calpastatin procedure. After 7d, WBSF measurements and microstructural analyses (optical microscopy observations of plastic sections stained with toluidine blue) were performed. Before correlation analyses (SAS, 1999), the data were corrected for the fixed effects of age, batch, and pen within batch. The analysis showed a positive correlation (0.62; $P < 0.001$) between calpastatin and WBSF, while negative correlations were found between muscle fibre fractures and both WBSF (-0.33; $P = 0.02$) and calpastatin (-0.55; $P < 0.01$). These results indicate that muscle fibre fractures resulting from calpain-mediated proteolysis is a major microstructural change responsible for variation in WBSF of bovine LD muscle, while muscle fibre detachments from connective tissue have limited impact.

We have recently begun to investigate changes in muscle structural proteins using proteomics. A combination of protein fractionation, two-dimensional gel electrophoresis, image analysis, and mass spectrometry is used to quantify and identify changes in these proteins during post-mortem storage of beef LD muscle.

560 Post harvest processes that influence myofibrillar protein degradation and meat quality. M. N. Lund¹, R. Lametsch*¹, M. S. Hviid², and L. H. Skibsted¹, ¹*University of Copenhagen, Frederiksberg, Denmark,* ²*Danish Meat Research Institute, Roskilde, Denmark.*

Modified atmosphere retail packaging with a high level of oxygen (70-80%) finds an increasing use for fresh meat as high oxygen concentrations preserve the bright red colour of fresh meat and increase shelf-life by reducing microbial growth. However, packaging of fresh meat in high-oxygen atmospheres increases oxidation of meat lipids and proteins leading to undesirable off-flavour formation and reduced meat tenderness. Oxidation of meat lipids has been studied extensively during the last decades, while protein oxidation in fresh meat has not received much attention until recently. Oxidation of proteins includes formation of reactive radicals, amino acid derivatives, and cross-linked protein derivatives, which may cause changes in the functional properties like loss of protein solubility and enzyme activity.

Myosin, which constitutes approx. 50% of the myofibrillar proteins, is very susceptible to *in vitro* oxidation of both its cysteine and tyrosine residues and possibly also other amino acid residues (1). We found that *in vitro* myosin oxidation causes formation of long-lived tyrosyl radicals and intermolecular disulfide and dityrosine cross-links which result in polymerization and aggregation of the protein (1). In fresh meat stored in high-oxygen atmospheres, myosin was found mainly to cross-link through intermolecular disulfide formation, which was consistent with a reduction in meat tenderness. In comparison, storage of meat without oxygen resulted in more tender meat and no observable myosin cross-linking (2). Furthermore, we found that addition of antioxidants capable of inhibiting lipid oxidation like a rosemary extract containing phenolic compounds did not inhibit protein oxidation in meat (3).

It is concluded, that protein oxidation of key myofibrillar proteins is a major consequence for meat quality. Notably, the protection of proteins from oxidation by using antioxidants needs further attention.

Nonruminant Nutrition: Distillers Grains for Swine

561 Digestible energy and metabolizable energy in distillers dried grains with solubles (DDGS) and enhanced DDGS. J. A. Soares*, H. H. Stein, V. Singh, and J. E. Pettigrew, *University of Illinois, Urbana.*

Distillers dried grains with solubles (DDGS) have a high fiber concentration. The elusieve process removes approximately 10% of the material, mostly fiber, yielding a product called enhanced DDGS (E-DDGS) that has a total dietary fiber concentration that is approximately 3.5 percentage units lower than DDGS. The objective of the experiment was to determine DE and ME in 2 sources of DDGS and in E-DDGS produced from each source of DDGS. Thirty growing pigs (average BW: 23kg) and 30 finishing pigs (average BW: 73kg) were used. Pigs were placed in metabolism cages and allotted to a randomized complete block design. Five diets were used at each stage of growth. The basal diet was based on corn and soybean meal and 4 additional diets were formulated by replacing 40% of the basal diet with 40% of each source of DDGS and E-DDGS. Pigs were fed their experimental diets for 14d, and urine and feces were collected during the final 5d. Overall, E-DDGS has greater DE ($P < 0.05$) and ME ($P < 0.05$) than DDGS. The DE and ME values were not different between growing and finishing pigs. In conclusion, removal of some of the fiber from DDGS by the elusieve process increases the energy concentration in the product. Overall, E-DDGS contains approximately 242 and 185 kcal/kg more DE and ME than DDGS.

Table 1. Daily energy balance for DDGS and E-DDGS

Item	Ingredient				SEM	P-value
	DDGS-1	DDGS-2	E-DDGS-1	E-DDGS-2		
Growing pigs						
DE, kcal/kg of DM	3,391 ^x	3,483 ^{xy}	3,703 ^y	3,670 ^y	147	0.001
ME, kcal/kg of DM	3,047	3,159	3,225	3,339	226	0.187
Finishing pigs						
DE, kcal/kg of DM	3,303 ^x	3,436 ^x	3,518 ^{xy}	3,691 ^y	209	0.027

562 Effect of deoiled corn dried distillers grains with solubles (solvent extracted) on growth performance and carcass characteristics of growing and finishing pigs. J. Y. Jacela*¹, J. M. DeRouchey¹, S. S. Dritz¹, M. D. Tokach¹, R. D. Goodband¹, J. L. Nelssen¹, J. M. Benz¹, K. Prusa², R. C. Thaler³, and D. E. Little⁴, ¹Kansas State University, Manhattan, ²Iowa State University, Ames, ³South Dakota State University, Brookings, ⁴DairyNet Inc., Brookings, SD.

A total of 1,215 pigs (BW=29.6 kg) were used in a 99-d trial to determine the effect of deoiled corn dried distillers grains with solubles, solvent

extracted, (dDDGS) on growth and carcass characteristics. This product is dried distillers grains with a majority of the oil removed. Pigs were blocked on pen weight and randomly allotted to 1 of 5 dietary treatments (0, 5, 10, 20, or 30% dDDGS). Diets had equal ME and standardized ileal digestible (SID) lysine content based on a previous study at Kansas State University. Pen weights were obtained every 2 wk from d 0 to 99 and ADFI was recorded on a pen basis. Increasing dDDGS reduced (linear; $P < 0.01$) ADG and ADFI. The greatest reduction was in pigs fed over 20% dDDGS. Carcass weight and percent yield were reduced (linear; $P < 0.01$), loin depth tended to decrease ($P < 0.09$), and jowl and belly IV increased (linear; $P < 0.01$) as dDDGS was increased. There was no difference in backfat ($P > 0.26$), percent lean ($P > 0.16$), or FFLI ($P > 0.20$). In summary, feeding increasing levels of dDDGS reduced ADG, ADFI, yield, and carcass weight and increased IV, but did not affect G:F. These data confirm the accuracy of the previously determined ME (2,506 kcal/kg) and SID values for dDDGS; however, reasons for the reduced ADFI need further investigation.

Table 1.

Item	dDDGS, %					SEM
	0	5	10	20	30	
D 0 to 99						
Final wt, kg	121.4	119.3	118.8	118.2	116.2	0.9
ADG, g	909	893	887	887	873	8.2
ADFI, kg	2.16	2.17	2.10	2.11	2.04	0.03
G:F	2.38	2.43	2.37	2.38	2.33	0.03
Carcass wt, kg	91.1	89.0	89.1	87.7	86.3	1.8

563 Effect of dried corn distillers grains with solubles (DDGS) on growth performance of growing-finishing gilts with previous exposure to DDGS in the nursery. T. E. Burkey*, R. Moreno, E. E. Carney, and P. S. Miller, *University of Nebraska, Lincoln.*

A study was conducted to evaluate the effects of DDGS on growth performance of gilts, during the growing-finishing phase, that were previously fed high concentrations of DDGS (30%) during the nursery phase. A total of 24 crossbred gilts (initial BW 28.09 ± 0.73 kg) were used in a 98-d experiment. Twelve gilts with no prior exposure to DDGS, and 12 gilts that were fed high concentrations of DDGS (30%) in the nursery phase, were used in the current experiment. Pigs were individually penned and had ad libitum access to feed and water. The pigs were randomly allotted to 1 of 4 dietary treatments: 1) 0% DDGS in the nursery + 0% DDGS during the growing-finishing period; 2) 0% DDGS in the nursery + 30% DDGS during the growing-finishing period; 3) 30% DDGS in the nursery + 0% DDGS during the growing-finishing period; and 4) 30% DDGS in the nursery + 30% DDGS during the

growing-finishing period. Body weight and feed disappearance were measured and ADG, ADFI, and G:F were calculated. Final BW were 122.6, 113.7, 112.6 and 106.9 ± 4.4 kg, respectively for treatments 1 through 4. There were no differences among treatments for final BW ($P = 0.13$). Overall, no treatment effects were observed for ADG and ADFI; however, among gilts that were fed DDGS in the nursery, the absence of DDGS in the growing-finishing period resulted in greater G:F compared to gilts that continued to receive DDGS (30%) during the growing-finishing period ($P < 0.03$). The results of this experiment indicate that the growth performance of gilts fed DDGS in the growing-finishing phase of production may not be affected by the feeding of high levels of DDGS during the nursery phase.

Key Words: DDGS, Gilts, Growth Performance

564 Alternating dietary inclusion of corn distillers' dried grains with solubles (DDGS) did not impact growth performance of finishing pigs. N. R. Augspurger^{*1}, G. I. Petersen², J. D. Spencer¹, and E. N. Parr¹, ¹*JBS United, Inc., Sheridan, IN*, ²*University of Illinois, Urbana*.

An experiment was done to compare continuous vs alternating inclusion of corn dried distiller's grains with solubles (DDGS) in growing-finishing swine diets. A total of 480 pigs (52.2 ± 2.9 kg, Monsanto EBX Ultra × GPK 35) were weighed by pen, blocked by weight and sex, and randomly allotted to one of six treatments. Pigs were allowed ad libitum access to their respective diet for a period of 88 d. A total of five dietary phases were fed with body weights and feed intakes recorded at the beginning and end of each phase (the first three phases lasted 3 wk each; the last two phases lasted 2 wk each). Following the final weigh date, pigs were shipped to a commercial packing plant (Tyson Fresh Meats, Columbus Junction, IA) for collection of carcass data. Dietary treatments consisted of 1) corn-SBM diet without added fat; 2) as 1 + 3 (phase 1-4) or 4% (phase 5) added fat (choice white grease); 3) corn-SBM + 15% DDGS; 4) corn-SBM + 30 (phase 1-3)/15 (phase 4)/7.5% (phase 5) DDGS; 5) corn-SBM + 15% DDGS alternated by phase with 4% added fat; and 6) corn-SBM with 0 and 4% added fat alternated by phase. Fat was added at 4% during the last phase for treatments 2-6. Diets were not formulated to be isocaloric. Neither growth rate (g/d) or feed intake (g/d) were affected ($P > 0.39$) by dietary treatment. Gain/feed ratio, however, was increased ($P = 0.008$) through addition of fat (treatments 2, 5, and 6), while DDGS supplementation (treatments 3-5) had no impact ($P = 0.268$). Constant fat supplementation (treatment 2) resulted in the greatest ($P < 0.05$) carcass yield and carcass weight

responses, with an advantage of approximately 3.2 kg over pigs in the other five treatments. Neither backfat depth (mm) or carcass lean (%) were affected ($P > 0.20$) by dietary treatment, but loin depth (mm) tended to be lower ($P = 0.067$) for pigs fed diets containing DDGS relative to the corn-SBM control. These data show that alternating the presence and absence of DDGS in diets for finishing pigs was not detrimental to growth performance.

Key Words: DDGS, Pigs, Fat

565 Effects of excess dietary crude protein from soybean meal and distillers dried grains with solubles in diets for finishing pigs. S. C. Williams^{*}, J. D. Hancock, C. Feoli, S. Issa, and T. L. Gugle, *Kansas State University, Manhattan*.

A total of 180 pigs (90 barrows and 90 gilts with an average initial BW of 67 kg) were used in a 67-d experiment to determine the effects of excess CP from soybean meal (SBM) and distillers dried grains with soluble (DDGS) on growth performance and carcass measurements in finishing pigs. The pigs were sorted by gender and ancestry and blocked by BW with 12 pigs/pen and five pens/treatment. Treatments were a control diet (corn-SBM with 12% CP), a corn-SBM diet formulated to 16% CP, and a corn-SBM-based diet with 40% DDGS that had 16% CP. Feed and water were consumed on an ad libitum basis until the pigs were slaughtered (average final BW of 128 kg) at a commercial abattoir. Pigs fed diets with excess CP had lower ($P < 0.001$) ADG and ADFI compared to those fed the control. However, the reduced ADG and ADFI were apparent only for pigs fed excess CP from DDGS (SBM vs DDGS, $P < 0.001$) and G:F for pigs fed the excess CP treatments was similar to that of pigs fed the control ($P > 0.18$). Final BW and hot carcass weight were lower ($P < 0.001$) for pigs fed excess CP but as with growth performance, the negative effects were apparent only for pigs fed the diet with DDGS ($P < 0.001$). Also, there was a trend ($P < 0.08$) for pigs fed the DDGS treatment to have reduced dressing percentage compared to pigs fed the diet with excess CP from SBM. Means for the control, SBM, and DDGS treatments were 0.96, 0.96, and 0.85 kg/d for ADG, 2.97, 2.91, and 2.64 kg/d for ADFI, 323, 329, and 324 g/kg for G:F, 97.6, 97.0, and 91.1 kg for hot carcass weight, 74.2, 74.2, and 73.3% for dressing percentage, and 54.3, 55.6, and 54.8 for percentage carcass lean. In conclusion, reductions in growth performance, carcass weight, and dressing percentage for pigs fed a diet with 40% DDGS could not be explained by the excess CP for that diet.

Key Words: Pig, Distillers Dried Grains, Excess Crude Protein

Physiology and Endocrinology: Enhancing Reproductive Efficiency

566 ASAS Centennial Presentation: Future research in physiology and endocrinology. G. E. Seidel*, *Colorado State University, Fort Collins.*

Over the next quarter century in North America, the following eventualities are likely for physiology/endocrinology research with agricultural animals.

1. Total funding adjusted for inflation will change little, but will continue to come less from public sources, and most of that will be in the context of human health. Much of the privately funded research will be herd-specific and remain proprietary.
2. Numbers of M.S., Ph.D. and postdoctoral students probably will decrease, but research in the context of credentialing will remain important.
3. Resources such as expanded data bases in genomics and proteomics, and remarkable new tools like small inhibitory RNA will continue to become available, likely at a faster rate than in the previous 25 years.
4. The huge amounts of data from production agriculture will make agricultural animals ideal models for some kinds of basic research such as studying fetal programming, resulting in synergy with more applied research. Most of these experimental animals will be in private, production herds and flocks, even when work is publicly funded.
5. The trend toward more interdisciplinary research will continue, especially considering interactions among reproduction, health, nutrition, selective breeding, management factors, and societal concerns; reductionist research probing deeper into cellular and molecular mechanisms will remain important as will whole animal approaches.
6. Agricultural animals are a product of evolution plus selective breeding. Insights of the former will aid progress in the latter. One focus of research in physiology and endocrinology will be understanding heterosis, inbreeding depression, and epigenetic effects, as it becomes possible to manipulate and identify the allelic structure of individual animals.
7. Additional insightful concepts will evolve that will simplify thinking in some respects, such as the maternal to embryonic shift in transcribed RNA in early embryos; however, animal biology will turn out to be even more complex than most of us currently imagine.

Key Words: Research, Physiology, Endocrinology

567 Effect of antioxidants on oxidative stress during maturation and in vitro culture of pig embryos. B. D. Whitaker* and J. W. Knight, *Virginia Tech, Blacksburg.*

This study evaluated the effects of different concentrations (0, 0.5, 1.0, 1.5, 2.0, 2.5, 5.0 mM) of N-acetyl-cysteine (NAC) supplemented to the oocyte maturation medium on embryo development. Embryo development was analyzed at 48 h and 144 h post-fertilization. There were no differences between cleavage rates for any of the treatment groups. Blastocyst formation in the 1.5 mM NAC ($56.5 \pm 9.2\%$) supplementation was higher ($P < 0.05$) than all other concentrations of NAC supplementation. Identical concentrations (1.5 mM) of NAC and N-acetyl-cysteine-amide (NACA) supplementation were compared by evaluating nuclear maturation, superoxide dismutase (SOD), glutathione (GSH) peroxidase, catalase and intracellular GSH concentrations, DNA fragmentation, fertilization success and embryo development. Supplementation of 1.5 mM NACA increased ($P < 0.05$) the levels of GSH peroxidase in the oocyte compared to the other treatment groups. The concentration of SOD was less ($P < 0.05$) with 1.5 mM NAC

supplementation compared to the control but SOD was higher ($P < 0.05$) with 1.5 mM NACA supplementation compared to the control. The concentration of catalase was less ($P < 0.05$) with 1.5 mM NACA supplementation compared to the control but catalase was higher ($P < 0.05$) with 1.5 mM NAC supplementation compared to the control. There were no differences in the length of DNA migration, intracellular GSH concentration, nuclear maturation or fertilization when comparing 1.5 mM NAC and 1.5 mM NACA supplementation to the maturation media. There was no difference between cleavage rates of 1.5 NAC and 1.5 mM NACA supplementation to the maturation media. Blastocyst formation for 1.5 mM NAC ($44.4 \pm 4.7\%$) and 1.5 mM NACA ($46.2 \pm 3.4\%$) supplementation were higher ($P < 0.05$) than the control ($32.1 \pm 6.2\%$) oocytes. These results indicate that supplementing 1.5 mM of NAC or NACA to the oocyte maturation medium increased the percentage of viable embryos reaching the blastocyst stage of development and antioxidant supplementation may alleviate the free radicals associated with oxidative stress in the maturing porcine oocyte.

Key Words: Swine, N-Acetyl-Cysteine, Antioxidant

568 Glycomic analysis of saccharides that bind porcine sperm. E. D. Collins, C. Korneli, and D. J. Miller*, *University of Illinois, Urbana.*

The objective of this work was to identify glycans that bound different maturation states of porcine sperm. Interactions between glycans and lectins on the cell surface and extracellular matrix are proposed to mediate many cell-cell interactions, including those between sperm and the oviduct and sperm and the egg coat. Immature (uncapacitated) sperm bind to the oviduct, which forms a reservoir and maintains viability. After a final maturation (capacitation), sperm bind to the egg coat (zona pellucida) and undergo the acrosome reaction before penetrating the zona. Studies using competitive inhibitors have identified candidates but the specific glycans in the oviduct or zona pellucida that bind sperm remain controversial. The goal of this work was to use an alternate and unbiased approach to identify the glycans capable of binding sperm. A glycan array, developed to characterize the specificity of lectins and antibodies to glycans, was adapted for use with live cells. An array containing over 300 glycans was used in an adhesion assay to pinpoint glycans possibly involved in sperm-oviduct and sperm-egg interactions. Live porcine sperm from pooled ejaculates of 4-6 boars were either used immediately after collection and washing (uncapacitated), after incubation to capacitate sperm, or after subsequent incubation with A23187 to induce the acrosome reaction. Sperm were stained with DiI or SYTO-16, were incubated with the array and fluorescence of bound sperm was assessed. Sperm binding was specific and depended on structure and charge of the glycans. Uncapacitated sperm bound to only 4 glycans, all of which contained the same trisaccharide motif. Capacitated sperm bound 7 glycans, the 4 that uncapacitated sperm bound and 3 additional glycans, which also contained the same complete or partial trisaccharide motif. Acrosome-reacted sperm did not bind glycans. Identification of these glycans may lead to discovery of the molecules that are important in forming the oviduct storage site and in zona pellucida binding and may underpin the development of more accurate laboratory fertility tests.

Key Words: Sperm, Fertility, Fertilization

569 The relationship between sperm nuclear shape and boar fertility using Fourier Harmonics. K. L. Willenburg*¹, K. J. Rozeboom², and J. J. Parrish¹, ¹University of Wisconsin, Madison, ²ReproQuest, LLC, Fitchburg, WI.

In this study, boar sperm nuclear shape was characterized using Fourier Harmonic analysis (FHA) and then related to boar fertility. Fertility was based on farrowing rates of 26 boars with at least 100 single sire matings and ranged from 88% to 37%. Boars were separated into two fertility groups, acceptable fertility (n=24, farrowing rate >60%) and unacceptable fertility (n=2, farrowing rate <60%). Harmonic amplitudes 0–5 (HA0–HA5), derived from FHA analysis, were previously shown to be an accurate, objective and repeatable measure of sperm nuclear shape. Ejaculates from each boar were evaluated for motility, viability, and FHA. Multivariate analysis of variance using HA0–HA5, found that fertility groups differed in sperm nuclear shape ($P < 0.05$). Univariate analysis found only HA2 and HA4 were different between the groups ($P < 0.05$). Fertility groups also did not differ in various measures of HA dispersion, motility or viability ($P > 0.05$). Discriminate analysis was used to produce the best method to separate the two groups based on nuclear shape, shape dispersion, motility or viability. Diagnostic statistics (DS) were used to determine the best discriminate model for predicting the fertility group membership of a particular boar. The DS evaluated were: true positive (TP, classifying an acceptable boar correctly) and true negative (TN, classifying an unacceptable boar correctly). Various approaches can be used to evaluate diagnostic statistics. We chose the model with the fewest parameters and highest TP + TN value. The best model included viability, motility, HA 2 and 4, skewness, kurtosis and variance of HA 0 with a TP + TN value of 1.95. This model correctly classified 96% of the boars, misclassifying 1 of the acceptable boars. In comparison, a model containing viability and motility had a TP + TN = 1.67, classifying 69% of the boars correctly. The data reveals that there are differences in sperm nuclear shape between boars with acceptable and unacceptable fertility. Further testing is needed on a new group of boars with known fertility to test the current diagnostic model.

Key Words: Boar, Fertility, Fourier Harmonics

570 Effect of number of motile, frozen-thawed boar sperm and number of inseminations on fertility in post-pubertal gilts. K. Spencer*¹, P. Purdy², H. Blackburn², S. Spiller², C. Welsh², T. Stewart³, S. Breen¹, J. Taibl¹, B. Yantis¹, and R. Knox¹, ¹University of Illinois, Urbana, ²National Animal Germplasm Program, ARS, USDA, Fort Collins, CO, ³Purdue University, West Lafayette, IN.

The potential for use of frozen-thawed boar sperm (FTS) as a tool for genetic preservation and advancement has far reaching implications for breeding herd management. Numerous research studies have been carried out with FTS but fertility results are often less than the potential with liquid semen using multiple AI. We hypothesized that pregnancy rates (PR) and litter sizes (LS) would be influenced by both sperm numbers and numbers of inseminations when AI with FTS was performed based on numbers of motile cells. We tested the effects of number of motile FTS and one or two AI. The FTS used was from PIC crossbred boars cryopreserved in 0.5 mL straws at 500 million cells/mL. Each boar was represented across all treatments. Gilts (n = 20) were treated with PG600 then fed a synthetic progestagen (MATRIX), for 14 d to synchronize estrus. Following last feeding of MATRIX (LMF), gilts were checked

once daily for estrus and upon expression of estrus on d 5-8 (n = 17) were inseminated with 1.0, 2.0, or 4.0 billion motile FTS once at 32 h, or twice at 24 h and 32 h. Ultrasound was performed at 12 h intervals to determine time of ovulation and pregnancy at d 24. Reproductive tracts were collected on d 32 following AI. In this first replicate, 90% of the gilts expressed estrus but only 17 were used for AI during d 6-9 following LMF. Estrus occurred at 153 ± 24 h following LMF and ovulation at 37.4 ± 8.4 h following onset of estrus. The interval from the 24 h AI to ovulation was -10.3 h and the interval from the 32 h AI to ovulation averaged -5.4 ± 8.4 h. The PR (76.5%) was not affected by treatment ($P > .10$) as all treatments established pregnancies (range: 50-100%). The LS at d 32 also was not affected by treatment ($P > .10$) and averaged 8.3 ± 4.8 (range: 2-17) fetuses. Further replicates are in progress to clarify the effects of treatment on fertility. Even with few observations, it is clear that a single AI using 1 billion FTS can establish pregnancy using conventional AI. Still, increased sperm numbers and numbers of inseminations may influence pregnancy rate and litter size.

Key Words: Frozen-Thawed Boar Semen, Number of Motile Sperm, Litter Size

571 Comparison of exogenous porcine FSH/LH to PMSG/hCG for inducing follicular development and fertility in prepubertal gilts. S. M. Breen* and R. V. Knox, University of Illinois, Urbana.

PMSG/hCG is commonly used for induction of estrus and ovulation for production of oocytes and embryos. However, inconsistency in fertility responses has been a concern when using this combination. While in many species porcine FSH (pFSH) is used for improved efficacy, little data is available to indicate its potential value for use in pigs. Therefore, the objective of this study was to compare pFSH-LH (Bioniche) treatment with PG600 for induction of follicular development, estrus, ovulation, and embryo production. Terminal line prepubertal gilts were allotted to receive 25 mg of FSH (25F, n=31) and 50 mg of FSH (50F, n=33) each with 5 mg added LH, PMSG/hCG (PG600, n=32), and saline (n=31). The 25F, 50F, and saline were each divided into 6 injections given s.c. every 8 h for 2 d. In addition, the 25F and 50F each received an ovulatory dose of LH (5 mg, Bioniche) in a single injection on d 4. Gilts received PG600 in a single s.c. injection on d 0. Ultrasound was performed to assess follicles and ovulation. Gilts receiving 25F and 50F were AI at d 4.5 and d 5 while saline and PG600 were AI at onset of estrus and 24 h later. Reproductive tracts were collected 10 d following AI for determining ovulation and embryo numbers. The percentage of gilts with large follicles on d 4-5 was similar for 25F, 50F, and PG600 (82%) and greater ($P < 0.01$) compared to saline (24%). A greater ($P < 0.01$) proportion of the 25F and 50F gilts expressed estrus (81%) compared to PG600 (62%) and saline (20%). The percentage of gilts that ovulated was similar for 25F, 50F (80%) and PG600 (68%) but greater ($P < 0.01$) than saline (26%). FSH treated gilts had increased ($P < 0.05$) ovulation rate (20 CL) compared to PG600 (10 CL) and saline (8 CL) but FSH increased ($P < 0.01$) the percentage of gilts with cysts (26-48%) compared to PG600 (15%) and saline (3%). The percentage of gilts pregnant (64%) was similar ($P > 0.1$) between treatments but 25F (8.4) and 50F (10.4) both increased ($P < 0.01$) the number of embryos compared to PG600 (5.4) and saline (4.2). These data suggest that with improved delivery methods, pFSH could be useful as an alternative exogenous gonadotropin for use in swine.

Physiology and Endocrinology: Health and Immunology

572 Energy-related metabolites and hormones as surrogate markers for chronic wasting disease in cervids. J. R. Olsen^{*1}, R. A. Bessen¹, T. Roche², S. D. Wright², J. D. Bailey¹, and J. G. Berardinelli¹, ¹Montana State University, Bozeman, ²USGS National Wildlife Health Center, Madison, WI.

Chronic wasting disease (CWD) is a fatal neurodegenerative disease of cervids that can affect neuroendocrine and endocrine function. Currently, detection of CWD requires post-mortem neural and lymph node tissue evaluation. The objective was to evaluate if oral administration of prion-infected brain tissues alters energy-related metabolites and hormones in elk (Elk; *Cervus canadensis*), mule deer (MD; *Odocoileus hemionus*), and white-tailed deer (WTD; *Odocoileus virginianus*) as a reliable and rapid pre-clinical diagnostic panel for CWD. The null hypotheses were that serum concentrations of glucose, NEFA, ghrelin, glucagon, leptin, cortisol, insulin, thyroxine (T4), and tri-iodothyronine (T3) do not change over a 24-mo interval after oral inoculation with prion-infected cervid brain tissues. Blood samples were collected at time 0, and for animals sacrificed for blood and tissue collection, at 6, 12, 18, and 24 mo after inoculation. Glucose and NEFA concentrations were determined by colorimetric assays. Ghrelin, glucagon, leptin, cortisol, T3, and T4 concentrations were determined using RIA. Insulin concentrations were determined by ELISA. After inoculation, all animals were immunohistochemically positive for PrP^{CWD} in neural and lymph node tissues. Glucose and NEFA concentrations decreased ($P < 0.05$) after inoculation for all species. Ghrelin and leptin concentrations tended to decrease ($P < 0.10$) and T4 concentrations increased ($P < 0.05$) after inoculation in Elk but not in MD or WTD. Glucagon concentrations tended to increase ($P < 0.10$) in WTD but not in Elk or MD. In conclusion, progression of CWD seems to have cervid-specific effects on energy metabolites and conspecific effects on certain hormones. Further research is necessary in order to develop a pre-clinical panel of metabolite and hormone markers leading to a reliable, rapid, and effective method for identifying CWD in cervids.

Key Words: Chronic Wasting Disease, Hormones, Cervids

573 Intrauterine detection and *in vitro* characterization of *Escherichia coli*-Xen14: A model for monitoring infections of the bovine reproductive tract. J. Curbelo^{*}, K. Moulton, S. Laird, D. Moore, S. Bowers, and S. Willard, Mississippi State University, Mississippi State.

Intrauterine infections in the bovine can have detrimental effects on reproductive performance, and *Escherichia coli* (*E. coli*) is a primary causative pathogen. Our objectives were to characterize the photonic properties of *E. coli*-Xen14 (a stably transformed *E. coli* containing the *lux* operon), and conduct photonic imaging of *E. coli*-Xen14 from within the excised bovine uterus. *E. coli*-Xen14 (Xenogen) was grown for 24 h in LB broth with or without Kanamycin (KAN; 30 μ g/mL) and placed in an incubated shaker at 37°C. Inoculums were placed in 96-well plates for imaging, and photonic emissions collected for 2 s. Following imaging, inoculums were sub-cultured over 7 d, and plated daily (on LB agar plates with or without KAN) to determine the CFU/ml and ratio of photonic emitters vs. non-emitters. Excised bovine reproductive tracts (n = 4 tracts; 3 replicates per tract) were acquired and *E. coli*-Xen14 placed in a 1 mL tube for photonic imaging (5 s) pre- and post-insertion into the uterine horns. The CFU/ml did not differ ($P > 0.05$) over time

with or without KAN presence; remaining stable with 99.93 and 99.98% photonic emitters, respectively. However, RLU/s were lower ($P < 0.0001$) in the presence of KAN than Controls (629.8 \pm 117.7 vs. 3,012.0 \pm 423.5 RLU/s, respectively). Photonic emissions from *E. coli*-Xen14 imaged within the uterine horns resulted in a 4,847.1 \pm 215.3 RLU/s loss ($P < 0.05$) through the uterine horns, or an efficiency of photonic detection of 3.98 \pm 0.007% of the original (pre-) emission intensity. The concentration of photonic *E. coli*-Xen14 detected through the uterine horns was 662.5 \times 10⁶ \pm 149.0 \times 10⁶ CFU/ml, with a uterine horn wall thickness of 6.2 \pm 4.2 mm. In summary, *E. coli*-Xen14 remained stable with respect to the percentage of photonic emitters with or without KAN (used to selectively culture *E. coli*-Xen14), however KAN presence suppressed photonic activity. Imaging of *E. coli*-Xen14 was feasible through the bovine uterine horns *ex vivo*, suggesting that further development of this model may facilitate the monitoring of pathogen presence within the reproductive tract of the bovine *in vivo*.

Key Words: Biophotonics, Uterus, *E. coli*

574 Stimulation of appetite and the growth, stress and immune axes of weanling pigs by syndyphalin-33. S. J. Jenkins^{*1}, T. A. Cooper¹, M. P. Roberts¹, J. A. Carroll², A. G. Mathew¹, H. G. Kattesh¹, and C. J. Kojima¹, ¹University of Tennessee, Knoxville, ²USDA-ARS Livestock Issues Research Unit, Lubbock, TX.

Parameters measuring growth, stress and immune response in weanling pigs given the opiate tripeptide syndyphalin-33 (SD) were investigated in three separate trials. In the first trial, 8 nursing pigs were given SD (0.5 μ mol/kg, n = 4) or vehicle (VEH; n = 4) in a single im injection at 13 d of age and weaned 6 d later. Feed intake (FI) was greater ($P < 0.05$) in SD compared to VEH pigs 3 d postweaning, and a numerical increase in BW was observed in SD pigs from d 3 to d 7 postweaning. In the second trial, 8 pigs (19 d of age) were weaned, fitted with jugular catheters, and placed in individual pens. The following day, blood was collected at 30-min intervals for 9 h. Immediately following the second blood sample, pigs received either SD (n = 4) or VEH (n = 4) as in trial one. Feed intake (FI) and body weight (BW) were recorded daily for 7 d. No differences in FI or BW were noted at any time. Plasma cortisol levels and the free cortisol index were elevated ($P < 0.05$) in SD compared to VEH pigs from 3 to 4 h post-injection. Plasma corticosteroid-binding globulin levels were unchanged. Serum growth hormone concentrations were increased ($P < 0.05$) in SD pigs at 2 h post-injection. In the third trial, 8 pigs (19 d of age) were weaned, cannulated, and placed in individual pens. The next day, immediately following blood collection, pigs received either SD or VEH as above, and all pigs received an oral gavage of live *Salmonella enterica*. Blood was collected every 24 h for 4 d. The immune challenge increased ($P < 0.05$) the numbers of neutrophils, lymphocytes and monocytes from 48 h post-challenge to the end of the sampling period. There was a further stimulatory effect of SD on circulating neutrophil and monocyte populations, resulting in an overall increase ($P < 0.05$) in total white blood cell number. Pigs given SD had similar FI and BW as VEH pigs as measured on d 19 to 23. A decrease ($P < 0.05$) in serum glucose levels was observed at 48 h in SD pigs. These results suggest that treatment with SD can affect many aspects of the physiology of weanling pigs, but the timing of injection relative to weaning may modulate the response.

Key Words: Swine, Weaning, Appetite

575 Early weaning alters the acute phase immune response to an endotoxin challenge in beef cattle. J. A. Carroll^{*1}, J. D. Arthington², and C. C. Chase, Jr.³, ¹*Livestock Issues Research Unit, USDA-ARS, Lubbock, TX*, ²*University of Florida-IFAS, Range Cattle Research and Education Center, Ona, FL*, ³*SubTropical Agricultural Research Station, USDA-ARS, Brooksville, FL*.

Previous research indicates that early weaning prior to shipment can reduce transportation-induced increases in acute phase proteins (APP), and can increase subsequent performance in the feedlot. These data suggest that the combination of weaning and transport stress may compromise the immune system of calves, thus hindering subsequent performance and health. Therefore, our objective was to determine if the innate immune response of early weaned calves (EW; 80 d of age) differed from normal weaned calves (NW; 250 d of age) in response to an endotoxin challenge. Eighteen EW (n = 8) and NW (n = 10) Brahman × Angus calves (233 ± 5 kg BW) were used. Prior to the study, calves were maintained on pasture with supplement. All calves were acclimated to their study pens for 1 wk prior to a lipopolysaccharide (LPS) challenge. One d prior to LPS challenge, calves were fitted with an indwelling jugular catheter. Blood samples were collected at 30-min intervals from -2 to 8 h. At 0 h, all calves received an i.v. infusion of LPS (1.0 µg/kg BW). Serum samples were stored at -80°C until analyzed for cortisol (CS), tumor necrosis factor-alpha (TNF), interleukin-1 beta (IL-1), IL-6, interferon-gamma (IFN), ceruloplasmin (Cp) and haptoglobin (Hp). While LPS increased serum CS ($P \leq 0.001$) no weaning effect ($P \geq 0.15$) was observed. A weaning group × time interaction ($P \leq 0.04$) was observed for TNF, IL-1, IL-6 and Cp such that concentrations of these indices were greater in the NW compared to EW calves. For Hp, a weaning effect ($P \leq 0.03$) was observed with NW having greater average Hp concentrations compared to EW calves. Interestingly, the weaning group × time interaction ($P \leq 0.001$) for IFN revealed greater IFN in EW opposed to NW calves. Based upon these data, the innate immune system of EW calves appears to be less naïve than that of NW calves. Additionally, the differential IFN responses indicate that the immune system of EW calves may be more effective at recognizing and eliminating endotoxin. These data suggest that an altered innate immune system may be responsible for the improved feedlot performance previously reported in EW calves.

Key Words: Cattle, Immunity, Early Weaning

576 Relationship of temperament and circulating concentrations of cortisol, total protein, and immunoglobulin G with growth in Angus crossbred calves. K. R. Parker^{*1}, S. T. Willard², A. N. Musselwhite², R. D. Randel³, T. H. Welsh⁴, and R. C. Vann¹, ¹*MAFES/Brown Loam Experiment Station, Raymond, MS*, ²*Mississippi State University, Starkville*, ³*Texas Agrilife Research, Overton, TX*, ⁴*Texas A & M University, College Station*.

The purpose of this study was to determine the relationships among cortisol, total protein (PRT), and immunoglobulin G (IgG) concentrations, temperament and growth in beef calves (n:bulls=114, heifers=82). Plasma was collected for determination of concentrations of IgG and PRT at 24 h, 48 h, 14 d, and 84 d after birth. Calves were classified by IgG as follows: calves with IgG concentrations 1 SD below the mean were considered low (L), those 1 SD above the mean were considered high (H), all others were considered moderate (M). Temperament testing consisted of pen score (PS) and exit velocity (EV: m/s) and was conducted at 28 d pre-weaning, weaning, 28 and 56 d post-weaning, and

yearling. Calves were assigned temperament groups (TPG=EV+PS/2) as follows: calves 1 SD below the mean were considered calm (C), calves 1 SD above the mean were considered temperamental (T), all others were considered intermediate (I). Serum concentrations of cortisol were determined at 28 d pre-weaning, weaning, 28 and 56 d post-weaning. Growth traits included: BW taken at all time periods, and ultrasound measurements; ribeye area (REA), intramuscular fat (IMF), rib fat thickness (FT), and rumpfat (RF), which were taken at weaning, 56 d post-weaning, and yearling. There was a day × TPG interaction for REA and REA/cwt with C and I calves increasing ($P < 0.05$ and $P < 0.08$, respectively) from 56 d post-weaning to yearling, whereas T calves decreased. IMF, FT and RF differed ($P < 0.05$) from 56 d post-weaning to yearling, but did not differ ($P > 0.10$) by TPG. PRT was higher ($P < 0.001$) for H than L IgG calves, and was positively correlated with concentrations of IgG ($r = 0.51$; $P < 0.001$); both PRT and IgG decreased ($P < 0.001$) over time from day 14 to 84. PRT did not differ ($P > 0.10$) among TPG classifications, however cortisol was greater ($P < 0.001$) for T than C calves. In summary, temperament influenced some growth traits (REA and REA/cwt), and secretions of cortisol. Plasma PRT was not influenced by temperament, but was positively correlated to concentrations of IgG. [USDA-NRI: 2005-35204-15737]

577 Influence of bovine temperament, transportation, and lipopolysaccharide challenge on ultrasound body composition traits. R. C. Vann^{*1}, N. C. Burdick², J. A. Carroll³, R. D. Randel⁴, S. T. Willard⁵, L. C. Caldwell², J. W. Dailey³, L. E. Hulbert³, A. N. Loyd², and T. H. Welsh, Jr.², ¹*MAFES-Mississippi State University, Raymond*, ²*AgriLife Research, College Station, TX*, ³*USDA-ARS Livestock Issues Research Unit, Lubbock, TX*, ⁴*AgriLife Research, Overton, TX*, ⁵*Mississippi State University, Starkville*.

This study was designed to determine the influence of bovine temperament on ultrasound body composition traits in response to transportation and endotoxin challenge. Brahman bulls (10 mo of age) were selected based on temperament score which was an average of exit velocity (EV; objective measure) and pen score (PS; subjective behavior score). The bulls with the lowest (C; n = 8; 0.87 m/s EV and 1 PS), intermediate (I; n = 8; 1.59 m/s EV and 2.25 PS), and highest (T; n = 8; 3.70 m/s EV and 4.88 PS) scores were used for this study. Prior to transportation (departure), after transportation (770 km) and post-lipopolysaccharide (LPS) challenge BW and ultrasound body composition measurements for longissimus muscle area (LMA), percent intramuscular fat (%IMF), rib fat (FT) and rump fat (RFT) were collected. Data were analyzed using PROC Mixed of SAS for repeated measures where appropriate. Body weights decreased (average 18.6 ± 5.5 kg) for all temperament groups from date of departure through post-LPS challenge ($P < 0.001$). A temperament score × day interaction ($P < 0.05$) for LMA was evident with the T bulls (0.41 ± 0.22) having a greater change in LMA from departure to post-LPS challenge compared to C (0.24 ± 0.24) and I (0.25 ± 0.22) bulls. There was a numerical trend for bulls classified as T (-0.15 ± 0.11) to have the smallest decrease in %IMF compared to the C (-0.41 ± 0.11) or I (-0.43 ± 0.11) bulls due to transportation or post-LPS challenge. FT was reduced (average 0.015 ± 0.009 cm) due to transportation for bulls in all temperament classifications ($P < 0.03$). Bulls classified as T (0.005 ± 0.003) had the smallest reduction ($P < 0.07$) in FT compared to the C (-0.001 ± 0.003) or I (-0.004 ± 0.003) bulls post-LPS challenge. While many of the observed changes in ultrasound body composition traits due to transportation and post-LPS challenge in the present study were

minimal, we did observe some trends indicating a bovine temperament effect. Further research is needed with larger numbers of animals to fully elucidate these potential effects.

Key Words: Temperament, Ultrasound Body Composition, Transportation

578 Influence of temperament on behavioral, physiological and endocrine responses of cattle to a provocative challenge with lipopolysaccharide (LPS). L. H. Hulbert^{*1}, J. A. Carroll¹, J. W. Dailey¹, R. D. Randel², T. H. Welsh, Jr.³, L. C. Caldwell^{2,3}, N. C. Burdick³, R. C. Vann⁴, and S. T. Willard⁵, ¹*Livestock Issues Research Unit, USDA-ARS, Lubbock, Texas*, ²*Texas AgriLife Research and Extension Center, Texas A&M System, Overton*, ³*Texas AgriLife Research, Texas A&M System, College Station*, ⁴*MAFES, Mississippi State University, Raymond*, ⁵*MAFES, Mississippi State University, Mississippi State*.

Previous studies have indicated that an animal's temperament can influence its health and productivity. Therefore, our objective was to evaluate the effect of temperament on rectal temperature (RT), sickness score (SS) and adrenal function of yearling bulls in response to a LPS challenge. Brahman bulls (10 mo of age) were selected based on temperament score; an average of exit velocity (EV) and pen score (PS) determined

at 177.08 ± 3.23 d of age. Bulls were ranked into 3 groups: calm, lowest score (C; n=8; 0.87 m/s EV and 1 PS), intermediate (I; n=8; 1.59 m/s EV and 2.25 PS), and temperamental, highest score (T; n=8; 3.70 m/s EV and 4.88 PS). Bulls were fitted with indwelling jugular catheters and RT devices that recorded RT at 1-min intervals. The next day blood samples were collected at 30-min intervals from -2 to 8 h relative to an i.v. infusion of LPS (0.5 μ g/Kg BW) at 0 h. Serum was stored at -80°C until analyzed for cortisol and epinephrine. RT data were summed into 10-min intervals for statistical analysis. SS were defined as follows: (1) on side with labored breathing; (2) clinical signs, increase respiration; (3) calm, but head distended; (4) appeared normal; and (5) active/agitated. SS were obtained from 30 min post-LPS until all animals scored at least 4. Cortisol concentrations increased during the first 2 h post-LPS, and remained elevated for 6 h post-LPS ($P \leq 0.01$). LPS-induced cortisol concentrations were not affected by temperament ($P = 0.55$). Concentrations of epinephrine peaked 1 h post-LPS with C bulls having a greater peak epinephrine (849.2 ± 107.1 pg/mL) than I (352.5 ± 87.1 pg/mL) and T bulls (417.2 ± 90.7 pg/ml; $P \leq 0.01$). SS revealed that T bulls showed less signs of sickness 30 min to 3 h post-LPS than I and C bulls ($P \leq 0.01$). I bulls had the greatest increase ($P \leq 0.01$) in RT ($1.74 \pm 0.23^\circ\text{C}$ at 240 min) compared to C ($1.45 \pm 0.36^\circ\text{C}$ at 260 min) and T bulls ($0.86 \pm 0.13^\circ\text{C}$; at 230 min). Based on our data, temperamental bulls appear to be more resilient to immunological challenges and calm bulls appear to be more susceptible.

Ruminant Nutrition: Carbohydrate Byproducts - Dairy

579 Feeding two corn milling co-products to dairy cattle: Intake and milk production. A. M. Gehman* and P. J. Kononoff, *University of Nebraska, Lincoln*.

The objectives of this experiment were to examine the effects of feeding dairy cattle different types of corn milling co-products, modified wet distillers grains plus solubles (WDGS) and wet corn gluten feed (WCGF). Multiparous (n = 20) and primiparous (n = 20) cows averaging 93 ± 29 DIM were used in a replicated 5 × 5 Latin square in which cows were blocked by parity and milk production. During each 20-d period, cows were offered one of 5 rations: 1) CONT, 0% co-products; 2) 15WDGS, 15% DM WDGS; 3) 15WCGF, 15% DM WCGF; 4) 15MIX, 7.5% WDGS and 7.5% WCGF; and 5) 30MIX, 15% WDGS and 15% WCGF. Rations were formulated to be similar in crude protein and metabolizable energy and protein allowable milk. Milk production and DMI were averaged for d 14 – 20 of each period for each cow, and milk components were measured on d 19 – 20 of each period. Dry matter intake was greatest ($P < 0.01$) for cows consuming 30MIX (25.5 kg/d) and lowest for CONT and 15 WCGF (22.7 and 23.2 kg/d). Milk production tended ($P = 0.08$) to be higher for 15MIX and 30MIX as compared to CONT (41.9 and 41.8 vs. 39.9 kg/d). 4% fat corrected milk (40.6 kg/d), fat percent and yield (3.92% and 1.59 kg/d), and milk urea N (14.5 mg/dL) were not different among treatments. Milk protein percent was increased ($P < 0.01$) for all rations containing co-products as compared to CONT (3.03 vs. 2.95 %). Protein yield also tended ($P = 0.07$) to be higher for co-products rations as compared to CONT (1.26 vs. 1.20 kg/d). Cows consuming 30MIX were ($P = 0.02$) the least efficient in producing milk from feed consumed (1.64 kg milk/ kg DMI) while 15MIX was the most efficient (1.83). This research demonstrates that WDGS and WCGF can be fed in combination up to 30% DM with an improvement in DMI, milk production, and protein percent and yield and no negative effect on milk fat.

580 Endosperm type of dry ground corn grain affects ruminal and total tract digestion of starch in lactating dairy cows. M. S. Allen*, R. A. Longuski, and Y. Ying, *Michigan State University, East Lansing*.

Our objective was to determine effects of dry corn grain varying in endosperm type and particle size on ruminal digestion kinetics and ruminal and total tract digestibility of starch in lactating cows. Eight ruminally and duodenally cannulated Holstein cows (132 ± 42 DIM; mean ± SD) were used in a duplicated 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments. Main effects were corn grain vitreousness (floury or vitreous) and particle size (medium or fine). Endosperm was 25% vitreous for floury treatment and 66% vitreous for vitreous treatment. The fraction of ground corn passing through a 1.18 mm sieve was 43% for medium, vitreous; 42% for medium, floury; 57% for fine, vitreous; and 62% for fine, floury. Diets included alfalfa silage, corn treatments, protein supplement, minerals and vitamins and contained 29.2% starch, 27.6% neutral detergent fiber and 18.3% crude protein. Corn grain treatments supplied 86.2% of dietary starch. No

interactions were detected for any measure of starch digestion. Floury treatment increased rate of starch digestion (19.2 vs. 9.9 %/h, $P < 0.01$) and decreased rate of starch passage (16.1 vs. 25.7 %/h, $P < 0.001$), increasing apparent ruminal starch digestibility (53.7 vs. 24.6 %, $P < 0.001$). Total tract starch digestibility was increased by floury treatment (92.2 vs. 85.1 %, $P < 0.0001$) despite greater post-ruminal starch digestion (% of starch intake) for the vitreous treatment (60.7 vs. 38.4 %, $P < 0.01$). Fine grinding increased rate of starch digestion (19.5 vs. 9.51 %/h, $P < 0.01$), which increased apparent ruminal digestibility (47.2 vs. 31.1 %/h, $P = 0.03$) compared to medium treatment. However, total tract starch digestibility was not affected by fineness of grind (mean = 22.2 %/h) because of greater post-ruminal starch digestibility (% of starch intake) for medium compared to fine treatment (57.2 vs. 41.9 %, $P = 0.02$). Endosperm type greatly affects ruminal and total tract starch digestibility independent of corn grain grind size.

Key Words: Vitreous, Digestion Kinetics, Particle Size

581 Effects of two dietary non-fiber carbohydrate levels on ruminal fermentation and animal metabolism of lactating cows. M. Blanch*¹, S. Calsamiglia¹, M. Devant², and A. Bach^{2,3}, ¹*UAB, Spain*, ²*IRTA, Spain*, ³*ICREA, Spain*.

Sixty-two lactating Holstein cows (BW = 654 ± 14 kg, DIM = 186 ± 6.8, 40 multiparous and 22 primiparous), fitted with rumen cannulas (5 multiparous and 3 primiparous) were used to study the effects of two dietary NFC levels on ruminal fermentation and animal metabolism following a cross-over design with 2 periods of 30 d. Treatments were: a traditional ration (TR, 16.5% CP, 33.8% NDF, and 41.8% NFC, on a DM basis), and a high-NFC ration (HC, 17.6% CP, 27.1% NDF, and 47.9% NFC, on a DM basis). Milk yield and feed intake were recorded daily and milk composition biweekly. Animals were blood sampled to determine blood glucose, insulin, and urea concentrations within the first hour after the morning feeding in 2 separate days in each treatment. Fecal samples were taken 1 d in each treatment within the first hour after the morning feeding to determine total tract starch digestibility using lignin as an internal marker. Samples of ruminal contents were collected during 3 d in each treatment at 0, 4 and 8 h post-feeding to determine VFA and ammonia-N concentrations. Rumen pH was recorded electronically at 22-min intervals during 6 d in each treatment. Milk yield was greater (34.4 and 31.9 kg/d), milk fat % was lesser (3.03 and 3.64), and concentrate intake at the milking unit was lesser (2.63 and 3.72 kg/d) in HC compared with TR, respectively. Blood glucose concentration was lesser in TR compared with HC (61.8 and 67.2 mg/dL, respectively), and HC resulted in a lesser total tract starch digestibility (94.7 and 95.9% for HC and TR, respectively) and a greater blood urea level (33.3 and 30.1 mg/dL for HC and TR, respectively). Rumen pH of HC primiparous cows fell below 5.6 for longer periods of time than that of TR cows (6.76 and 0.812 h/d, respectively), but no changes in mean pH were observed (5.93 and 6.26 for HC and TR, respectively). These results indicate that feeding high NFC diets for short periods of time may increase milk yield without incurring in strong negative repercussions to the animal.

Key Words: Dairy Cows, Non-Fiber Carbohydrates

582 Effects of feeding three types of corn milling co-products on ruminal fermentation and digestibility in lactating Holstein dairy cattle. J. M. Kelzer^{*1}, P. J. Kononoff¹, A. M. Gehman¹, K. Karges², and M. L. Gibson², ¹University of Nebraska, Lincoln, ²Dakota Gold Research Association, Sioux Falls, SD.

Replacing traditional feed ingredients with corn milling co-products in total mixed rations may alter ruminal environments in dairy cattle. Three co-products were fed at 15% inclusion to 4 ruminally fistulated Holstein cows averaging (\pm SD) 677 ± 41 kg BW and 124 ± 5 DIM to determine effects on ruminal fermentation and total tract digestibility. Cows and treatments were randomly assigned in a 4×4 Latin square over four, 21-d periods. Treatments were formulated by replacing portions of forage and concentrate feeds with 15% co-product and included: 1) 0% co-product (**Control**), 2) dried distillers grains + solubles (**DDGS**), 3) dehydrated corn germ meal (**Germ**), and 4) high protein dried distillers grains (**HPDDG**). Diets were formulated to be isonitrogenous and similar in metabolizable energy and protein. Neutral detergent fiber (NDF) content was 34.4, 36.9, 37.0, and 38.8 %, and starch was 26.1, 21.9, 22.0, and 22.8 % for Control, DDGS, Germ, and HPDDG, respectively. On d 21, rumen fluid was collected at 10 time points over 24 h post-feeding. Dry matter intake and milk production were not different across treatments and averaged (\pm SEM) 26.1 ± 2.3 and 28.3 ± 3.9 kg/d. Rumenal pH (6.26 ± 0.08), rumen ammonia (14.1 ± 1.0 mg/dL), and total concentration of volatile fatty acids (125.3 ± 4.2 mM) were similar. Acetate concentration for Control was higher ($P < 0.05$) than DDGS, Germ, and HPDDG (81.7 vs. 75.8 , 75.0 , and 78.4 mM). Concentrations of propionate (27.8 ± 1.2 mM) and butyrate (14.3 ± 0.9 mM) were not different. The acetate:propionate ratios for Control, Germ, and HPDDG were higher ($P < 0.05$) than DDGS (3.02 , 2.88 , 2.91 vs. 2.62). Dry matter, organic matter, and NDF digestibilities were similar and averaged 63.5 ± 2.7 , 67.3 ± 2.2 , and 43.5 ± 4.2 %. Feeding corn milling co-products to dairy cows decreased acetate concentration in the rumen; however, total tract digestibility was not affected.

Key Words: Co-Product, Ruminal Fermentation, Digestibility

583 Evaluation of low starch diets for lactating Holstein dairy cattle. H. M. Dann^{*1}, K. W. Cotanch¹, P. D. Krawczel¹, C. S. Mooney¹, R. J. Grant¹, and T. Eguchi², ¹William H. Miner Agricultural Research Institute, Chazy, NY, ²Zen-Noh National Federation of Agricultural Cooperative Associations, Tokyo, Japan.

Proliferation of ethanol production in the US has increased price of corn grain and consequently feeding diets containing less than 20% starch may be economically advantageous. The objective of this experiment was to measure the ruminal and lactational responses of Holstein dairy cattle when fed diets containing 17.7 (LS), 21.0 (MS), or 24.6% (HS) starch (dry basis). Twelve multiparous cows (3 ruminally fistulated) were assigned randomly to these diets in a replicated 3×3 Latin square design with 3-wk periods (14-d adaptation, 7-d collection). Diets were fed as total mixed rations and contained approximately 30.2% corn silage, 18.5% grass silage, and 5.0% alfalfa hay (dry basis). Dietary starch was manipulated by reducing the amount of corn grain (16.9%, HS; 10.1%, MS; 3.4%, LS; dry basis) and increasing the amount of beet pulp (0%, HS; 3.4%, MS; 6.7%, LS), wheat midds (6.8%, HS; 10.1%, MS; 13.4%, LS) and distillers grains (7.8%, HS; 8.7%, MS; 9.7%, LS). In vitro 6-h

starch digestibility of the diet increased as byproducts replaced corn grain (73.6%, HS; 77.3%, MS; 82.5%, LS). Data were analyzed as a replicated Latin square design using the MIXED procedure of SAS. Dry matter intake (26.5 kg/d), solids-corrected milk (SCM) yield (40.8 kg/d), and efficiency of SCM production (1.54) were unaffected ($P > 0.05$) by diet. Diet also had no effect ($P > 0.05$) on total chewing (815 min/d), ruminal pH averaged over 24 h (6.06), or acetate to propionate ratio (2.4). Total tract organic matter digestibility was higher ($P \leq 0.05$) for HS (69.2%) compared with MS (67.3%) and LS (67.0%) diets, but crude protein, neutral detergent fiber, and starch digestibilities were unaffected ($P > 0.05$) by diet. Microbial N synthesized in the rumen (584 g/d) estimated using urinary excretion of purine derivatives was unaffected ($P > 0.05$) by diet. As dietary starch decreased in this study, ruminal fermentability increased and consequently the range between HS and LS in rumen fermentable starch (3.5%-units) was less than the range in starch content (6.9%-units). Under these conditions, dietary starch content had no measurable effect on ruminal microbial production or lactation performance.

Key Words: Starch, Lactation Performance, Dairy Cattle

584 Ground vs steam-rolled barley grain for lactating cows: A clarification into conventional beliefs. A. Soltani¹, G. R. Ghorbani¹, M. Alikhani¹, and A. Nikkhab^{*2}, ¹Isfahan University of Technology, Isfahan, Iran, ²University of Illinois, Urbana.

An optimum processing method of barley grain that controls its rumen degradation rate, synchronizes starch and protein fermentation, and avoids starch overflow into the small intestine and hindgut is one of priorities in managing lactating cows. Grinding is an easy-to-access technique traditionally believed to be a potential risk to feed intake and rumen health. Steam-rolling is thought to overcome such concerns, but it is expensive. Our main objective was to determine if ground barley grain (GB) is as effective in promoting feed intake and maintaining milk production as steam-rolled barley (SB). Eight multiparous Holstein cows (85 ± 9 days in milk) were used in a replicated Latin square design experiment with four 21-d periods. Each period had 14-d of adaptation and 7-d of sampling. Treatments included feeding GB or SB barley grains at either 35% or 30% of dietary dry matter. Diets were prepared as a totally mixed ration and fed twice daily at 0700 and 1600 h. Neither processing method nor barley grain inclusion rate affected dry matter intake, daily eating, ruminating and chewing times, total tract digestibility of dry matter, organic matter, and neutral and acid detergent fibers, milk yield, and milk percents and yields of fat, protein, and total solids. When barley grain was ground, increasing its inclusion from 30% to 35% of diet dry matter tended to reduce milk fat percent (3.7 vs. 3.3%, $P < 0.10$) and reduced milk fat yield (1.38 vs. 1.24 kg/d, $P < 0.05$). Changing dietary level of SB did not change these criteria. Dietary use of 35% instead of 30% barley grain increased percents but not yields of milk lactose and solids-non-fat. Feed efficiency was improved by feeding SB instead of GB (1.57 vs. 1.50, $P < 0.05$) but was unaffected by dietary levels of barley grain. Therefore, GB was as effective as SB in stimulating feed intake and maintaining rumen fermentation and milk production.

585 Replacement of starch from corn with non-forage fiber from distillers grains in diets of lactating dairy cows. S. D. Ranathunga*, K. F. Kalscheur, A. R. Hippen, and D. J. Schingoethe, *South Dakota State University, Brookings*.

Availability of larger quantities of dried distillers grains with solubles (DG) and its greater energy content indicate that one can replace high-priced corn with DG, in dairy cow diets, to lower feed costs. Therefore, this research was to evaluate the partial replacement of starch from corn in dairy cow diets with different amounts of a non-forage fiber source, DG, on lactation performance. Forty Holstein cows were used in completely randomized design with a 2-wk covariate period followed by a 6-wk treatment period. Four diets were formulated: 1) high starch (28% starch, 0% DG), 2) medium starch (24.5% starch, 7% DG), 3) low starch (21% starch, 14% DG), and 4) very low starch (17.5% starch, 21% DG). Diets contained 17% CP, 4.5% fat, a constant forage to concentrate ratio (49:51), and 21% forage NDF. As starch was replaced with DG, DMI linearly decreased ($P < 0.01$; Table 1). Milk production during the study (38.2 kg/d) was not affected by diets. There were no treatment effects on milk fat and protein percentages nor milk fat and protein yields. Other parameters including 4% fat-corrected milk (FCM), total solids (TS), and MUN were unaffected by dietary treatments. There was a linear

tendency to increase feed efficiency as starch was replaced by non-forage fiber ($P < 0.10$). Results from this research suggest that non-forage fiber from DG can partially substitute for starch from corn in dairy cow diets without affecting milk production and milk composition.

Table 1.

Item	High Starch	Medium Starch	Low Starch	Very low Starch	SEM	P ^a
DMI, kg/d	25.6	25.0	23.4	22.9	0.70	L

Ruminant Nutrition: Nitrogen Sources and Utilization

586 Effects of feeding triticale dried distillers grains with solubles as a N source on productivity of lactating dairy cows. M. Oba* and T. D. Whyte, *University of Alberta, Edmonton, AB, Canada.*

The objective of this study was to evaluate the effects of replacing protein sources that are commonly used in North America with triticale dried distillers grains with solubles (TDDGS) as a source of dietary N on the productivity of lactating dairy cows. Experimental diets contained 17.1% TDDGS, 17.5% Corn DDGS (CDDGS), 13.1% canola meal (CM), or 10.2% soybean meal (SBM) on a DM basis so that each feedstuff supplied 30% of total dietary crude protein (CP). All diets, which were formulated to contain 17.2% CP and 21.2% forage neutral detergent fiber (NDF), were fed to twelve multiparous Holstein cows (130 ± 40 days in milk) in a replicated 4 × 4 Latin square design with 21-d periods. Plasma concentrations of arginine, lysine, and threonine were greater for cows fed CM or SBM compared to those fed TDDGS or CDDGS ($P < 0.01$) while plasma concentrations of leucine and phenylalanine were lower for cows fed CM or SBM compared to those fed TDDGS or CDDGS ($P < 0.05$). Dry matter intake and milk yield were not affected by treatment (25.5 and 35.5 kg/d, respectively). Cows fed CDDGS had a lower plasma glucose concentration ($P = 0.04$; 49.3 vs. 53.5 and 52.6 mg/dL, respectively), and decreased yields of milk CP ($P < 0.01$; 1.01 vs. 1.17 and 1.14 kg/d, respectively), and milk lactose ($P = 0.03$; 1.43 vs. 1.66 and 1.59 kg/d, respectively) compared to cows fed CM or SBM. Cows fed TDDGS had similar plasma glucose concentration (53.5 mg/dL), and milk CP (1.10 kg/d), and milk lactose (1.57 kg/d) yields as cows fed CM or SBM. Furthermore, cows fed TDDGS or SBM had a greater body weight gain compared to cows fed CDDGS ($P = 0.05$; 514 and 390 vs. -290 g/d, respectively). These data suggest that TDDGS can replace CM or SBM in the diets of lactating dairy cows without adverse effects on production, and may be better N source than CDDGS.

587 Nutritional profile of distillers dried grains with solubles from 40 ethanol plants. Y. Zhang*, J. Sido, and B. Wrenn, *National Corn-to-Ethanol Research Center.*

One of the barriers to broader use of distillers dried grains with solubles (DDGS) in animal feed is concern regarding nutritional variability of materials produced by different plants and temporal variations within a single plant. The nutritional variability of DDGS was investigated in a broad-based study involving samples collected from 40 ethanol plants over a period of one year. These 40 plants represent one third of the dry-grind plants in the U.S., and their geographical distribution was similar to the national distribution. The moisture, crude protein (CP), crude fat (CF), neutral-detergent fiber (NDF) and fermentable sugars (FS) were measured using either American Feed Industry Association (AFIA) recommended methods or modified AOAC methods. The results are shown in Table 1.

The use of recommended analytical methods for DDGS reduced the variability caused by analytical testing. Plant processing conditions and the characteristics of the corn also contribute to variability among DDGS samples. The correlation between plant processing parameters, such as fermentation time, the fraction of thin stillage recycled to process

water, and dryer type, and the characteristics of DDGS were evaluated. These factors were most correlated with variations in the moisture and fermentable sugar concentrations of DDGS. Variations in crude protein, crude fat, and NDF were controlled primarily by corn composition, but two important performance metrics, the ratio of CP to NDF and CF to NDF, were not correlated with the geographical distribution of ethanol plants.

Table 1. Summary of Proximate Analysis of DDGS from 40 Ethanol Plants in the U.S. (% dry basis)

	Moisture	CP	CF	NDF	FS
Mean	10.8	30.8	10.5	29.4	8.9

588 Digestibility of rumen undegraded amino acids estimated in cecectomized roosters and the modified three-step in vitro procedure. S. E. Boucher*¹, S. Calsamiglia², M. D. Stern³, C. M. Parsons⁴, and C. G. Schwab¹, ¹University of New Hampshire, Durham, ²Universitat Autònoma de Barcelona, Bellaterra, Spain, ³University of Minnesota, St. Paul, ⁴University of Illinois, Urbana.

Three soybean meal (SBM), 3 SoyPlus[®], 5 dried distillers grains with solubles (DDGS), and 5 fishmeal (FM) samples were obtained from FeedAC, Inc. to evaluate the modified three-step in vitro procedure (TSP) for estimating digestibility of rumen undegraded (RU) amino acids (AA). Each sample was incubated in situ for 16 h in the rumen of 4 cows averaging (mean ± SD) 48 ± 4 d in milk, fed a 55% forage, 45% concentrate diet. Rumen undegraded residues were collected and pooled by feed sample, and sub-samples were analyzed for AA. A sub-sample of each residue was also tube fed to cecectomized roosters (4 birds per sample), and endogenous AA losses were estimated from fasted birds. Total excreta were collected for 48 h post-intubation and analyzed for AA. Standardized digestibility (STD) of RUAA was calculated. Sub-samples of each residue were also analyzed via the modified TSP. Five g of residue was weighed in duplicate into polyester bags (pore size of 50 µm) which were then heat sealed and placed into Daisy^{II} incubator bottles. A pepsin/HCl solution was added, and the residues were incubated in constant rotation at 38°C for 1 h. The solution was drained from the bottles, and the bags were rinsed and returned to the bottles. A pancreatic solution was added, and the residues were incubated in constant rotation at 38°C for 24 h. Bags were rinsed, dried, weighed, and undigested residues were analyzed for AA. Digestibility of RUAA was calculated based on disappearance from the bags. Digestibility of RU lysine, methionine, total AA, and total essential AA were correlated to STD estimates measured in the roosters ($R^2 = 0.94, 0.83, 0.93, \text{ and } 0.92$, respectively). In conclusion, the modified TSP may be a good approach for predicting RUAA digestibility in SBM products, DDGS, and FM.

Key Words: Amino Acid Digestibility, Modified Three-Step In Vitro Procedure, Rumen Undegraded Protein

589 In situ degradation characteristics of extruded-expelled cottonseed meal-based supplements. S. J. Winterholler*, T. K. Dye, C. P. McMurphy, C. J. Richards, and D. L. Lalman, *Oklahoma State University, Stillwater.*

Eight ruminally cannulated steers (BW=753 ± 48) were used to evaluate in situ DM, N, and neutral detergent fiber (NDF) degradation characteristics of supplements for beef cows consuming low quality prairie hay. Experimental supplements included (DM basis) 1) extruded-expelled cottonseed meal (ECSM; 33% CP and 55% NDF), 2) extruded-expelled cottonseed meal with linters (ECSML; 25% CP and 59% NDF), 3) solvent extracted cottonseed meal (CSM; 44% CP and 40% NDF), and 4) a blend of 76% wheat middlings with 18% CSM (WMCSM; 22% CP and 40% NDF). Chopped prairie hay (5.8 % CP, 61 % NDF; DM basis) was provided *ad libitum* and steers received 0.38 kg/100kg BW WMCSM daily. Calculated N, NDF and DM fractions included A (immediately soluble), B (degradable at a measurable rate), and C (undegradable). The ECSML supplement had the highest concentration of C fraction N (10.4%; $P < 0.01$), a high concentration of B fraction N (82.7%; $P < 0.01$) and the slowest B fraction degradation rate (1.73%/hr; $P < 0.01$). These characteristics resulted in the lowest estimated RDP (39%; $P < 0.01$) for ECSML. In contrast, ECSM had the highest concentration of A fraction N (41%; $P < 0.01$), and the lowest percentage of N in the B fraction (52%; $P < 0.01$). Rate of B fraction degradation was intermediate for ECSM (2.76%/h; $P < 0.01$). These characteristics resulted in the highest RDP estimate (77%; $P < 0.01$) for ECSM. Extent of NDF disappearance was greatest for CSM (56%; $P < 0.01$), similar for ECSML and WMCSM (41%; $P = 0.63$) and lowest for ECSM (28%; $P < 0.01$). Dry matter disappearance was most extensive ($P < 0.01$) for CSM and WMCSM (64 and 59%, respectively) and lowest ($P < 0.01$) for ECSM (36%) and ECSML (40%). Ruminant N degradation characteristics of ECSM were similar to more traditional supplements containing CSM and CSM with wheat middlings. Rumen degradability of ECSML N was low, indicating this potential supplemental N source may need to be blended with other ingredients containing higher concentrations of degradable N, particularly in situations where forage RDP is low.

Key Words: Byproduct, In Situ, Nitrogen

590 Feeding two corn milling co-products to dairy cattle: Nutrient digestibility, purine derivatives excretion, and nitrogen utilization. A. M. Gehman* and P. J. Kononoff, *University of Nebraska, Lincoln.*

The objectives of this experiment were to examine effects of feeding dairy cattle different types of corn milling co-products, modified wet distillers grains plus solubles (WDGS) and wet corn gluten feed (WCGF). Multiparous ($n = 20$) and primiparous ($n = 20$) cows averaging 93 ± 29 DIM were used in a replicated 5×5 Latin square in which cows were blocked by parity and milk production. During each 20-d period, cows were offered one of 5 rations: 1) CONT, 0% co-products; 2) 15WDGS, 15% WDGS; 3) 15WCGF, 15% WCGF; 4) 15MIX, 7.5% WDGS and 7.5% WCGF; and 5) 30MIX, 15% WDGS and 15% WCGF. Rations were similar in crude protein and metabolizable energy and protein. Fecal and urine samples were collected on d 17–20. Nutrient digestibility was estimated using indigestible ADF, and urinary purine derivatives were used to indicate effects of treatments on microbial protein synthesis. Compared to other treatments, 30MIX had ($P < 0.01$) reduced digestibility of DM (54.6 vs. 63.3%), NDF (34.4 vs. 46.4%), N (58.0 vs. 65.8%), and OM (57.9 vs. 65.9%). Excretion of urinary purine derivatives was higher ($P = 0.04$) for 15WDGS, 15MIX, and 30MIX

than CONT and 15WCGF (396.8, 399.7, and 400.5 vs. 361.0 and 387.3 mmol/d). Fecal N was ($P = 0.02$) greater for 30MIX (295.0 g/d) than 15WCGF and 15MIX (260.3 and 237.1 g/d) but was not different from CONT or 15WDGS (267.1 and 269.4 g/d). Urinary N was ($P = 0.03$) higher for 30MIX (330.0 g/d) than for CONT and 15WDGS (308.5 and 312.2 g/d) but not different from 15WCGF and 15MIX (319.3 and 320.5 g/d). Total manure N was ($P < 0.01$) highest for 30MIX compared to other treatments. Results of this experiment suggest the inclusion of corn milling co-products in dairy rations may negatively affect total tract digestibility but have positive effects on microbial protein synthesis.

Key Words: Nitrogen, Digestibility, Purine Derivatives

591 Milk urea concentration as an indicator of ammonia emission from dairy cow houses in a situation with restricted grazing. G. van Duinkerken*¹, M. C. J. Smits¹, G. André¹, P. F. G. Vereijken², L. B. J. Sebek¹, A. Bannink¹, and J. Dijkstra¹, ¹Wageningen University and Research Center, Lelystad, The Netherlands, ²Wageningen University and Research Center, Wageningen, The Netherlands.

Milk urea concentration was evaluated to assess its potential as an indicator of ammonia emission from dairy cow houses in a situation with restricted grazing. An experiment was carried out with a herd of on average 52 Holstein–Friesian dairy cows. The herd was housed in a naturally ventilated barn with cubicles and a slatted floor and each day was allowed 8.5 hours grazing. The experiment was designed as a 1×3 factorial trial and repeated three times. The experimental factor was the bulk milk urea level which was adjusted to levels of 15, 35 and 55 mg urea per 100 g milk, respectively, by changing the level of N fertilization of the pasture, the herbage mass and grass regrowth age, and the level and type of feed supplement. Ammonia emission from the barn was measured using SF₆ as a tracer gas. A dynamic regression model was used to predict ammonia emission from bulk milk urea concentration, temperature and a slurry mixing index. The total model accounted for 66% of total variation in ammonia emission and showed that emission from the barn increased with 2.6% when temperature increased with 1°C. Furthermore, ammonia emission increased exponentially with increasing milk urea concentration. At a level of 20 mg urea per 100 g milk, ammonia emission increased with about 2.5% when milk urea concentration increased with 1 mg/100 g. At a level of 30 mg urea per 100 g milk ammonia emission increases with about 3.5% when milk urea concentration is increased with 1 mg/100 g. The study showed that bulk milk urea concentration is a useful indicator for ammonia emission reduction from dairy barns.

Key Words: Ammonia Emission, Milk Urea, Restricted Grazing

592 A meta-analysis of the effects of protein concentration and degradability on milk N efficiency in dairy cows. P. Huhtanen*¹, A. N. Hristov², and M. Rinne³, ¹Cornell University, Ithaca, NY, ²Pennsylvania State University, State College, ³MTT-Agrifood Finland, Jokioinen, Finland.

Data sets from North European (NE, 998 diets) and North American (NA, 739 diets) feeding trials with dairy cows were evaluated to investigate the effects of dietary CP concentration and ruminal degradability on the efficiency of milk N production (MNE). NE diets were

based mainly on grass silage, barley grain, and soybean and rapeseed meals. NA diets were based on corn silage, alfalfa silage and hay, corn and barley grains, and soybean meal. Diets were evaluated for RDP and RUP concentrations according to NRC (2001). The average DMI and milk yield (kg/d), dietary CP, RDP, RUP concentrations (g/kg DM), ruminal CP degradability and MNE (g/kg) were 17.9, 25.4, 165, 120, 45, 0.73 and 277 for NE diets. The corresponding values for NA diets were 22.0, 31.3, 178, 122, 56, 0.68 and 245, respectively. A mixed model regression analysis with random study effect was used to evaluate relationships between dietary CP concentration and degradability and MNE (milk N/N intake; g/kg). The following prediction models were derived: $MNE = 475 - 1.21CP$ (NE diets), and $MNE = 497 - 1.40CP$ (NA diets). Residual mean square errors were 9.1 and 14.9 g/kg, respectively. Effects of CP degradability and RDP/RUP on MNE were significant in both models, but the prediction errors were not decreased. Akaike's information criteria were moderately improved by

inclusion of CP degradability variables in the models. Mean prediction error of MNE in NE diets using NA CP model was 13.2 g/kg with bias, slope, and random errors proportionally accounting for 0.54, 0.10 and 0.36, respectively. The corresponding values for validating the NE CP model with NA diets were: 18.9 g/kg, 0.48, 0.06, and 0.46, respectively. Including CP degradability variables did not improve predictions. In conclusion, improved MNE and consequently decreases in N emissions can be obtained by decreasing diet CP concentration, while manipulation of CP degradability is less efficient.

Symposium: Swine Species: Intestinal Barrier Function

594 Stress-induced intestinal barrier dysfunction and its effects. G. P. Lambert*, *Creighton University*.

The intestinal barrier is formed by enterocyte membranes, tight junctions, secreted mucus, and immunologic factors like tissue macrophages. Dysfunction of this barrier can be caused by different types of stress (e.g., physiological, pathological, psychological, pharmacological) and can lead to increased intestinal permeability. Increased permeability to endotoxin, a component of the walls of Gram-negative bacteria, causes local and/or systemic inflammatory reactions. The immune response(s) can then promote more serious conditions. Exertional heat stroke is an example of such a condition. During severe exercise-heat stress, possibly combined with other stresses, reductions in intestinal blood flow and/or direct thermal damage to the intestinal mucosa can cause intestinal barrier disruption and endotoxemia. The resulting inflammatory response is believed to be involved in altered thermoregulation and multiple-organ dysfunction. Possible means for preventing and/or attenuating many stress-induced intestinal barrier problems include environmental, pharmaceutical, and/or nutritional approaches.

595 Dietary plasma proteins and the barrier functions of the intestinal mucosa. M. Moretó* and A. Pérez-Bosque, *Universitat de Barcelona, Barcelona, Spain*.

The intestinal mucosa contributes to homeostasis by preventing the passage of biological and chemical agents across the epithelium, which could alter the stability of the system. This protective function is important at weaning, when animals are exposed to infectious agents and to stresses such as changes in diet composition. Diets supplemented with spray dried plasma or immunoglobulin concentrates improve growth and performance of farm animals and have been proposed as an alternative to antibiotics. We summarize our findings on the mechanism of action of dietary plasma proteins. We used a rat model of intestinal inflammation based on the administration of *Staphylococcus aureus* enterotoxin B (SEB). SEB activates the gut-associated lymphoid tissue (GALT), increasing T-lymphocytes in Peyer's patches and the number of activated T lymphocytes in mesenteric lymph nodes (organized GALT). In the lamina propria SEB increased cytotoxic $T\gamma\delta$ and NK cells populations of the diffuse GALT. SEB significantly increased IFN- γ , TNF- α , IL-6 and LTB4 concentration in both Peyer's patches and mucosa. Plasma protein supplements modulated the mucosal immune response in both organized and diffuse GALT, protecting GALT from excessive activation by the SEB challenge. These effects were accompanied by a reduction of pro-inflammatory cytokine production and increased expression of IL-10 in the mucosa, supporting the view that changes in cytokine production mediate the effects of dietary plasma proteins during intestinal inflammation. The increase in mucosal permeability and intestinal

secretion induced by SEB was associated with decreased expression of mucosal tight-junction and adherent-junction proteins. Both plasma and immunoglobulin supplements could prevent the effects of SEB on intestinal permeability, thus reducing the probability of microbial and food antigens entering the interstitial space. These findings indicate that dietary plasma proteins modulate both functional and structural properties of the intestinal mucosa.

596 Strategies to minimize inflammatory taxation on animal performance. M. E. Cook*, *University of Wisconsin, Madison*.

Collateral damage of inflammatory activation is measured as decreased gain, product production, reproduction, feed efficiency, and increased mortality. A decline in efficient animal performance (>10%) associated with microbial colonization or after vaccination of an animal suggests that current management systems fail to realize the animal's genetic potential for performance. The mechanisms by which pro-inflammatory cytokines redirect nutrient use at the expense of performance have been extensively studied. At least three strategies are available for improving efficient performance of the conventional (as opposed to germ-free) animal: 1. Minimize exposure to environmental immune stimulants: 2. Suppress the immune/inflammatory response: and/or 3. Erect barriers against inflammation-induced collateral damage. The success of a strategy employed may be case dependent, but is likely additive when used in combination. Traditional and successful methods to minimize immune stimulants and hence inflammation of the epithelial surfaces have included the use of antibiotics, pre- or pro-biotics and sanitation. Suppression of the inflammatory response, while seemingly problematic, has long been a pharmacological approach in human medicine. Since the domestic animal maintains the immune capacity of its wild ancestor, but is housed in an environment where diseases are well managed, an acute inflammatory reaction, even to benign agents, is often counterproductive. Barriers to the collateral damage caused by inflammatory responses constitute well-defined and novel approaches to improve efficient animal performance. Barriers erected are designed to target key biochemical or physiological responses to pro-inflammatory mediators in an attempt to assure resources are maintained for efficient animal performance. In this latter approach, neither the animal's environment nor its inflammatory response to the environment is the focus of improving efficient animal performance. Barrier examples to be presented include orally delivered egg antibodies to key targets in the gastrointestinal tract and conjugated linoleic acids that systemically reduce the collateral damage of inflammatory responses.

Forages and Pastures III

597 Performance by spring and fall-calving cows grazing with full access, limited access, or no access to endophyte-infected tall fescue. J. Caldwell*¹, K. Coffey¹, D. Philipp¹, J. Jennings³, D. Hubbell, III¹, T. Hess¹, D. Kreider¹, M. Looper², M. Popp¹, M. Savin¹, and C. Rosenkrans, Jr.¹, ¹University of Arkansas, Fayetteville, ²USDA-ARS, Booneville, AR, ³Cooperative Extension Service, Little Rock, AR.

Although performance by cows is improved greatly when toxic *Neotyphodium coenophialum*-infected tall fescue (E+) is replaced with a non-toxic endophyte-infected fescue (NE+), acceptance of NE+ by producers has been slow. Our objective was to compare performance by spring (S) and fall-calving (F) cows grazing either E+ or NE+ at different percentages of the total pasture area to determine to what extent having limited access to NE+ will enhance cow BW and BCS and calf weaning weights. Gelbvieh by Angus crossbred cows (n=144) were stratified by weight and age within calving season and allocated randomly to 1 of 14 groups representing 5 treatments: 1) F on 100% E+ (F100); 2) S on 100% E+ (S100); 3) F on 75% E+ and 25% NE+ (F75); 4) S on 75% E+ and 25% NE+ (S75); and 5) S on 100% NE+ (NE100; 2 replications). Cow BW and BCS at breeding and BCS at weaning were greater (P<0.05) for F vs. S. Cow BCS at breeding and BW at weaning were greater (P<0.05) for NE100 vs. S75, and cow BCS at weaning was higher (P<0.05) for the mean of F75 and S75 vs. that of F100 and S100. Calf gain, actual and adjusted weaning weight, ADG, and calf value at weaning were higher (P<0.05) from F vs. S. When compared with S75, NE100 calves tended (P<0.10) to have higher actual and adjusted weaning weight, ADG, and calf value, and had higher (P<0.05) preweaning gain. Weaning age did not differ (P>0.19) among treatments. Therefore, a fall calving season may be more desirable for cows grazing E+ pastures, resulting in better BW and BCS at critical times as well as heavier calves with higher value at weaning. Limited use of NE+ during the grazing season may improve cow BW at later stages of lactation. This project was supported by the National Research Initiative of the Cooperative State Research, Education and Extension Service, USDA, grant # 2006-55618-17114.

598 Warm-season legume haylage or soybean meal supplementation effects on the performance of lambs. J. L. Foster*¹, A. T. Adesogan¹, J. N. Carter¹, L. E. Sollenberger¹, A. R. Blount¹, R. O. Myer¹, S. C. Phatak², S. C. Kim¹, T. Kang¹, M. Brew¹, and K. G. Arriola¹, ¹University of Florida, Gainesville, ²University of Georgia, Athens.

This study determined how supplementing bahiagrass haylage (BGH, *Paspalum notatum*) with soybean (*Glycine max*) meal (SBM) or warm-season legume haylages affected the performance of lambs. Forty-two Dorper x Katadhin lambs (27.5 ± 5 kg) were fed *ad libitum* BGH (67.8% NDF, 8.9% CP) alone, or supplemented with SBM (18.8% NDF, 51.4% CP) or haylages of annual peanut (*Arachis hypogaea*; 39.6% NDF, 17.1% CP), cowpea (*Vigna unguiculata*; 44.1% NDF, 14.6% CP), perennial peanut (*Arachis glabrata*; 40.0% NDF, 14.3% CP) or pigeonpea (*Cajanus cajan*; 65.0% NDF, 12.6% CP). Legumes were supplemented at 50% of the diet and SBM fed to the average CP concentration (12.0%) of legume diets. Haylages were harvested, wilted to 45% DM, baled, wrapped in polyethylene and ensiled for 180 d. Each diet was fed to 7 lambs for 21 d, and then to 4 lambs for 21 d.

Intake of DM and OM (g/d) was greatest (P<0.01) in lambs fed annual peanut or SBM (819-748 and 723-668), and least (P<0.01) in lambs fed pigeonpea (421-400). Digestibility of DM was greatest (P<0.01) in sheep fed SBM (69%) and digestibility of OM was greater (P<0.01) in sheep fed BGH, SBM, peanuts, or cowpea (68-71%). Digestibility of NDF was greatest (P<0.05) in sheep fed BGH or SBM (70-72%). Intake of N (g/d) was greatest (P<0.01) in sheep fed annual peanut (18) followed (P<0.01) by SBM and perennial peanut (14-15), and least (P<0.01) in sheep fed pigeonpea (9). Digestibility of N was greatest (P<0.01) when SBM, annual or perennial peanut (67-70%) was fed and least (P<0.01) when pigeonpea (59.2%) was fed. Retention of N (g/d) was greatest (P<0.01) when sheep were fed annual peanut (7), followed (P<0.05) by perennial peanut, SBM and cowpea (4-5). Microbial N production was greater (P<0.05) when sheep were fed peanuts, SBM or BGH (10-12 g/d). Efficiency of microbial N production was not affected (P>0.10) by dietary treatment. The peanut haylages were the most promising legume haylage supplements for the lambs.

Key Words: Legume, Haylage, Digestibility

599 Forage species alters animal performance, carcass quality, and fatty acid composition of forage-finished beef produced in summer months. J. Schmidt*, J. Andrae, S. Duckett, M. Miller, and S. Ellis, *Clemson University, Clemson, SC.*

Thirty Angus-cross steers were finished on either alfalfa (AL), bermudagrass (BG), chicory (CH), cowpea (CO), or pearl millet (PM), to assess the effects of these forages on animal performance, carcass quality and longissimus fatty acid composition. Using a complete randomized block design, ten 5-acre paddocks were blocked and assigned forage species (2 reps per species). Steers (n=3) were randomly assigned to paddocks and grazing began when adequate forage growth for individual species was present. Put and take grazing techniques were utilized. Steers were slaughtered when sufficient forage mass for individual forage species was no longer present to support animal gains or when average steer weight exceeded 568 kg. Data were analyzed using PROC MIXED of SAS. Average daily gains tended to be higher (P = 0.10) for AL than BG. Total grazing days (GD) ha⁻¹ were greatest (P = 0.02) for PM, with BG having more GD than CH. Average forage mass was highest (P = 0.02) for PM. Carcass weight tended to be higher (P = 0.08) for AL and CO than CH and PM. Dressing percentage was higher (P < 0.01) for AL, CH, and CO than BG and PM. Marbling scores were higher (P = 0.03) for CO than BG, CH and PM. Postmortem aging increased tenderness (P < 0.01). Shear force tenderness scores did not differ (P = 0.24) among treatments. Oleic acid concentrations tended to be greater (P = 0.08) for CO than AL and BG. Concentrations of trans-11 vaccenic acid were greater (P = 0.004) in BG and PM than in CH and AL, and CO was greater than AL. Concentrations of linolenic acid were greater (P < 0.01) in CH and CO than AL, BG, and PM. Conjugated linoleic acid (CLA cis-9 trans-11) concentrations were greatest (P < 0.01) in BG and PM. Concentrations of monounsaturated fatty acids were greater (P = 0.04) in AL and BG than CO. Omega-6 to Omega ratio was higher (P < 0.05) in PM than CO. Forage species utilized during the summer finishing period altered animal performance, carcass quality and fatty acid composition in beef cattle.

Key Words: Beef, Forages, Fatty Acid

600 Performance of finishing steers on corn silage or low grain sorghum silage with corn oil supplementation. V. A. Corriher*, G. M. Hill, and B. G. Mullinix, Jr., *University of Georgia, Tifton.*

Beef steers (n=32; initial BW 524.9 ± 63.3 kg; age 24 mo.; Angus-X) were fed a free-choice TMR consisting of 55% corn silage (CS) or low-grain sorghum silage (SS) and 45% concentrate mix (88% ground corn, 10% SBM, 0.019% mineral/Rumensin/vitamin premix) on DM basis, without and with corn oil (7% of DMI). Low grain sorghum silage was used to simulate a grazing environment compared with high corn grain silage diet. Steers were ranked by BW, randomly assigned to dietary treatments and fed with Calan[®] gates for 78d. Steers were implanted with Component[®] on d1 of experiment. Steer BW were means of consecutive daily unshrunk BW. Steers were shipped to Cargill Taylor Beef (PA) and slaughtered at the end of the experimental period. Rib sections and subcutaneous fat samples were retained for fatty acid composition. Steer 78-d ADG had a silage × treatment interaction, ADG was higher for corn silage without corn oil (1.98 vs. 1.51 kg) and sorghum silage with oil (1.54 vs. 1.29 kg). Total DMI was higher for sorghum silage treatments; however, corn oil supplementation was not different (Table). Despite increased DMI for steers on sorghum silage treatments, 78-d ADG was higher for corn silage treatments. Steers on corn oil supplementation had higher concentrations of CLA isomer cis-9 trans-11 in longissimus dorsi and subcutaneous fat samples. A silage × treatment interaction occurred for the concentration of CLA isomer

trans-10, cis-12 in subcutaneous fat samples. Steers on corn silage with oil supplementation diets had higher concentrations of trans-10, cis-12. Steer HCW and QG (12=US Choice-) were higher for steers on corn silage. Corn oil supplementation increased QG however it decreased HCW of steers. Corn oil supplementation had no effect on steer performance; however, it increased CLA isomer concentrations.

Table 1.

Symposium: ADSA Production Division Symposium: Dairy Replacement Heifers: Cost Effective Strategies from Weaning to Calving

601 Potential and limitations associated with manipulating dairy replacement heifer nutrition programs. P. C. Hoffman*, *University of Wisconsin, Madison.*

Goals of a dairy replacement heifer management program are to rear heifers at a low economic and environmental cost without compromising future lactation performance. To meet this objective, heifers are reared to 23-24 months of age and fed diets containing high fiber forages. Historically, research focused on feeding heifers higher energy diets to shorten the rearing period and reduce feed cost. This nutritional manipulation has potential to reduce feed cost but decreasing rearing time frequently results in decreased lactation performance. Decreases in lactation performance are often attributed to suppression of mammary development but some evidence suggest rearing time itself may play a role in mammary development and future milk yield. Another nutritional manipulation is to feed higher energy diets but limit the amount of the diet fed, controlling growth rate, which yields calving ages and body compositions similar to feeding high forage diets. This nutritional manipulation, (limit feeding) also has potential to reduce feed cost and decrease fecal excretion. In recent experiments, limit feeding heifers high energy diets has resulted in 20-25% improvements in feed efficiency and decreased manure excretion 20-30%. To date, negative effects on milk yield have not been observed. Unexplainably, when designed limit feeding experiments are combined with ancillary limit feeding experiments there appears to be a trend in improved milk yield when dairy heifers are limit fed. No biological mechanism is available to support these observations. Limit feeding dairy heifers does however result in behavior changes and interactions between bedding material, bunk space and heifer housing systems have yet to be defined. Finally, precision feeding heifers dietary P is another nutritional manipulation that could reduce economic and environmental cost without compromising future lactation performance. Recent research demonstrates supplementing P above the NRC requirement, results in a primary excretion of P and does not result in improvement of growth, bone or frame development in dairy heifers.

602 Using growth monitoring in heifer management and research. A. Bach*^{1,2}, J. Ahedo³, and A. Kertz⁴, ¹*IRTA-Unitat de Remugants, Barcelona, Spain*, ²*ICREA, Barcelona, Spain*, ³*Rancho Las Nieves, Mallen, Spain*, ⁴*ANDHILL, LLC, St. Louis, MO.*

The ultimate goal of heifer rearing is to grow animals to their maximal production potential using the least amount of resources. Raising dairy heifers properly is a difficult endeavor by itself, but it is even more difficult in the absence of data and records. The main aspects that should be monitored include growth, reproduction, nutrition, wellbeing, and health. This paper will illustrate how to construct a database to monitor heifer performance, as well as the use of statistical and graphing tools to monitor performance. A proper database in combination with adequate analytical tools should allow setting management objectives, target performances, and correct deviations of individual animals. In addition, such a database could generate inferential answers to various aspects of heifer rearing. For instance, it could be utilized to forecast future milk production of an animal based on its up-to-date performance.

However, predicting future performance cannot be accomplished with much precision. Future performance is a random variable, and thus it is only by coincidence that its value will actually be exactly the same as the predicted one. In addition, the prediction of future performance may suffer from a considerable bias due to the omission of one or more variables that should have been included in the model and were omitted. For example, omission of individual intake data, body condition, etc., may deviate the predicted estimate of future milk yield. In addition, such an attempt is likely to also suffer from a relatively large lag due to the time span from birth to the day that milk records become available. The analysis of an existing database involving close to 500 heifers revealed that BW at first-calving was positively and linearly correlated with milk production during the first 150 DIM. No differences were found between AFC (ranging from 21.8 to 29.2 mo) and milk production. A positive relationship was found between ADG during the first 60 d of life and future milk production, whereas this relationship was negative from breeding time to calving. No negative relationship was found between ADG (ranging from 750 to 1100 g/d) during the prepubertal period and future milk yield.

Key Words: Heifer, Analysis, Record

603 Strategies for reproductive success in replacement heifers. R. L. Nebel*¹, J. M. DeJarnette¹, K. E. Hall², I. D. Peeler², and C. E. Marshall¹, ¹*Select Sires, Inc., Plain City, OH*, ²*Virginia Polytechnic Institute and State University, Blacksburg.*

Heifer rearing or replacement cost accounts for ~20% of the operational cost and represent the second largest expense for most dairy operations; therefore, proactive reproductive management of heifers to shorten the interval between birth and parturition is essential to reduce these costs. Puberty in heifers is a function of breed, age, and weight. Recommended body weight for first service is when heifers reach ~55% of the expected mature body weight (250 kg for Jersey and 350 kg for Holstein heifers). Initial rise in weekly blood P4 concentrations as the indicator of first cyclic activity for Holstein heifers occurs at 11 mo of age, 300 kg, and 122 cm withers height. A longer duration of estrus combined with more sexual activity makes the detection of estrus in heifers easier than in lactating cows. A variety of systems for AI will be discussed ranging from visual detection of estrus and PGF based programs to TAI using CIDR inserts in combination with PGF and GnRH. Comparable reproductive performance (number of heifers pregnant within a given time interval) can be obtained with most of the programs that will be reviewed. Development of fluorescence activated cell sorting has made X-bearing sex sorted semen available with conception rates ~80% of conventional semen with a resulting 90% heifer gender bias. The overall goal of a heifer program is to raise heifers to attain a desired age and body weight so that they initiate puberty, establish pregnancy, and calve easily. Sex sorted semen provides an effective method to accelerate genetic progress and maximize dairy profitability. Use of estrous detection aids and controlled breeding programs can improve the success of a heifer AI breeding program by improving estrous detection efficiency and labor associated with an AI program.

Key Words: Heifer, AI, Sexed Semen

604 Raising healthy dairy replacements: How we get the job done. G. Goodell*, *The Dairy Authority, LLC, Greeley, CO.*

One of the biggest expenses in maintaining a profitable dairy is providing for an adequate supply of dairy heifers to meet the demands of culling on the dairy. The science of raising replacement dairy heifers has come a long way in the past decade and this paper describes how some of these things are accomplished in a true farm setting.

Discussion for this paper comes from data accumulated from a 4000 head dairy heifer replacement facility in northern Colorado. This facility receives heifers at 4 to 5 months of age and returns them to the owners as springing heifers. Three diets are fed to heifers on this facility; 5-10 month diet, 11-16 month diet and a bred heifer diet. Diets are fed ad libitum to all heifers. Breeding is accomplished using once per day heat detection, chalk and the utilization of headlocks. Individual weights are collected the week of arrival, pre-breeding and 2-4 days before being shipped home. The breeding program has averaged 55-65% FSCR and 1.8 SPC even with the use of sexed semen.

Feeding heifers for optimal growth has long been identified as one of the top influencers of profitable heifer-raising. ADG was monitored for heifers returning home from this facility where the mean ADG was 2.0 lbs/day. Mean peak milk and peak DIM for these heifers back on their respective dairies were just 88 lbs and 110 DIM.

Monitoring for heifer health remains one of the biggest challenges on a heifer replacement facility of this size with multiple clients. This facility tries to involve the owner monthly by sending out reports on the owners' heifers that include everything from health to performance. This includes a "Poor Doer" report that lists heifers whose ADG was less than 1.25 lbs/day for longer than a 90 day period. Usually this list sparks discussion between the owner and the manager of the feedlot.

Vaccinology in youngstock continues to evolve. The use of an aggressive vaccine program in conjunction with mandatory (individual) BVD testing for persistently infected heifers as well as a recommended vaccine program prior to arrival gives this heifer raising program added performance.

Animal Health VI

605 ASAS Centennial Presentation: The promise of proteomics in animal science. J. D. Lippolis* and T. A. Reinhardt, *National Animal Disease Center, USDA-ARS, Ames, IA.*

Proteomics holds significant promise as a method for advancing animal science research. The use of this technology in animal science is still in its infancy. The ability of proteomics to simultaneously identify and quantify potentially thousands of proteins is unparalleled. In this review, we will discuss the current state of proteomic technology and cover basic principles of its experimental design. In addition, challenges and limitations of proteomics will be considered, stressing those that are unique to animal sciences. The current proteomic research in animal sciences will be discussed and the potential uses for this technology will be highlighted.

Key Words: Proteomic, Animal Science, Genomics

606 Periparturient liver and mammary tissue-explant gene expression is responsive to bacterial lipopolysaccharide (LPS) in vitro: a model to study tissue-specific genomic responses to infection. M. Mukesh*, D. E. Graugnard, M. Bionaz, and J. J. Loor, *University of Illinois, Urbana.*

Periparturient cows experience a state of immunosuppression after parturition that renders them highly susceptible to mastitis pathogens. Objectives were to evaluate the suitability of an in-vitro mammary (MG) and liver (LIV) tissue explant model to study dose and temporal effects of bacterial LPS on gene expression profiles. Percutaneous biopsies of MG and LIV were obtained simultaneously from Holstein cows (7 DIM) that were bacteriologically negative in all mammary quarters. Explants (50-100 mg) were cultured in parallel in DMEM-F12 (MG) or RPMI-1640 (LIV) media at 37 °C and 5% CO₂. In a first study, MG explants were cultured for 2 h with 0 or 20 µg LPS/mL. Similarly, LIV explants were cultured for 2 h with 0, 0.2, 2.0, and 20 µg LPS/mL. In order to evaluate temporal changes in mRNA expression in response to LPS, LIV tissue was cultured with 20 µg LPS/mL and harvested after 2, 4, 6, and 8 h. Genes evaluated included serum amyloid A1 (*SAA1*), tumor necrosis factor-alpha (*TNFA*), complement component 9 (*C9*), haptoglobin (*HP*), and interleukin-6 (*IL6*). LPS challenge of MG resulted in greater ($P < 0.05$) *HP* (2.6-fold), *IL6* (3.9-fold), *SAA1* (3.5-fold), and *TNFA* (22-fold) relative to control. In LIV both *IL6* and *TNFA* increased ($P < 0.05$) markedly in response to incremental LPS, averaging ~5- and 3.5-fold greater expression with 20 than 0 µg LPS/mL. In the time course experiment, an 11-fold increase ($P < 0.05$) in *IL6* mRNA was observed at 4 h post-LPS challenge relative to 2 h, and it continued to increase through 8 h. In contrast, *HP*, *C9*, and *TNFA* mRNA decreased ($P < 0.05$) substantially between 2 and 8 h post-LPS. The present results indicate that mammary and liver tissue explants are suitable to study changes in mRNA expression due to infection. This approach holds promise in terms of allowing researchers to understand transcriptional responses in mammary and liver when stimulated by infectious pathogens. Funded by NRI-USDA project #2007-35204-17758.

607 Effects of long-chain fatty acids on concanavalin A-induced cytokine production by bovine peripheral blood mononuclear cells. C. Caldari-Torres*, M. Perdomo, and L. Badinga, *University of Florida, Gainesville.*

Fatty acids (FA) are known to modulate immune responses in several mammalian species, including the human, pig, and cow. The objective of this study was to examine the short-term effects of long-chain FAs on concanavalin A (ConA)-induced tumor necrosis factor alpha (TNF- α), interferon gamma (INF- γ) and interleukin-4 (IL-4) production by cultured bovine peripheral blood mononuclear cells (PBMCs). Peripheral blood mononuclear cells were isolated by density gradient centrifugation and then incubated with ConA alone (10 µg/mL) or with a combination of ConA and specific FAs for 48 h at 37 °C in a humidified atmosphere of 5% CO₂. Concentrations of cytokines in cell-conditioned media were determined by specific bovine enzyme-linked immunosorbent assays (ELISAs). Incubation of PBMCs with ConA increased ($P < 0.01$) TNF- α , INF- γ and IL-4 production by 8-, 24-, and 24-fold, respectively. Co-incubation with eicosapentaenoic acid (EPA, C_{20:5n-3}) completely abolished ($P < 0.01$) TNF- α , INF- γ and IL-4 responses to ConA. Alpha linolenic acid (ALA, C_{18:3n-3}) was less potent in attenuating TNF- α and IL-4 production in vitro. Docosahexaenoic acid (DHA, C_{22:6n-3}) and monounsaturated FAs (cis or trans-C_{9:1} and cis or trans-C_{11:1}) had minimal effects on ConA-induced cytokine production in cultured bovine PBMCs. Results indicate that ALA and EPA attenuate TNF- α , INF- γ and IL-4 production by bovine PBMCs challenged with ConA. The mechanisms by which these omega-3 FAs modulate cytokine production in bovine PBMCs warrant further investigation.

Key Words: Fatty Acids, PBMCs, Cytokines

608 ASAS Centennial Presentation: Contributions in the *Journal of Animal Science* to understanding cattle metabolic and digestive disorders. J. T. Vasconcelos and M. L. Galyean*, *Texas Tech University, Lubbock.*

Ruminal acidosis, bloat, liver abscesses, and polioencephalomalacia (PEM) were reviewed with respect to contributions published in the *Journal of Animal Science* (JAS) regarding these metabolic and digestive disorders in beef cattle. Increased grain feeding and expansion of the feedlot industry in the 1960s led to considerable research on acidosis. The concept of subacute acidosis was developed in the 1970s. Significant research was published during the 1980s and 1990s on adaptation to high-grain diets, effects of ionophores, and the development of model systems to study ruminal and metabolic changes in acidosis. Recent publications JAS on acidosis have largely focused on individual animal variability in response to acid loads and the role of management strategies in controlling acidosis. Increased grain feeding also was associated with an increase in the incidence of liver abscesses, which were quickly linked to insults to the ruminal epithelium associated with acidosis. The role of antibiotics, particularly tylosin, in decreasing the incidence and severity of liver abscesses was a significant contribution of JAS publications during the 1970s and 1980s. Papers on bloat were among the earliest published in JAS related to metabolic and digestive disorders

in cattle. Noteworthy accomplishments in bloat research chronicled in JAS include the nature of ruminal contents in legume and feedlot bloat, the efficacy of poloxalene, ionophores, and more recently, condensed tannins, in decreasing the incidence and severity of bloat. Although less has been published on PEM, early publications highlighting the association between PEM and ruminal acidity and the role of thiaminase in certain forms of the disorder, as well as more recent publications related to the role of S in the development of PEM, are noteworthy contributions. The JAS has played a significant role as a repository for information pertaining to metabolic and digestive disorders in cattle, particularly through the publication of ASAS-sponsored symposia, and it will no doubt continue to be a premier resource for information on these conditions.

Key Words: Acidosis, Bloat, Liver Abscesses

609 Neutrophil function in response to level of dietary energy pre-partum and post-partum inflammatory challenge in dairy cows.

D. E. Graunard*, M. Bionaz, M. Mukesh, K. M. Moyes, J. L. Salak-Johnson, J. K. Drackley, and J. J. Loo, *University of Illinois, Urbana.*

Dairy cattle experience a state of immunosuppression after parturition that renders them highly susceptible to mastitis pathogens as well as metabolic diseases. We hypothesized that plane of dietary energy pre-partum is a management tool that can affect neutrophil and metabolic tissue function and, thus, transition success. Thirty-two Holstein cows with average SCC of $\sim 128,000 \pm 108,000$ in the previous lactation were assigned (n = 16/diet) to a control (high-straw; $NE_L = 1.33$ Mcal/kg) or moderate-energy (ME; $NE_L = 1.58$ Mcal/kg) diet during the entire dry period. All cows were fed a common lactation diet post-partum. At 7 DIM, cows were assigned to receive an intramammary bacterial lipopolysaccharide (LPS) challenge (200 μ g; n = 8/pre-partum diet) or served as controls (n = 8/pre-partum diet). Cows used were bacteriologically-negative in all mammary quarters. Blood for neutrophil isolation was collected on -14, 7 (prior to LPS), 14, and 30 d relative to parturition. Neutrophils for RNA, phagocytosis, and chemotaxis were promptly isolated by centrifugation after lysis of erythrocytes. Neutrophil migration (3×10^6 isolated cells/mL) was assessed using IL-8 (100 ng/mL) and C5a (10^{-6} M) as chemoattractants. Phagocytic capacity of neutrophils (2×10^5 /mL isolated cells) was assessed with 1.75 μ m fluorescent microspheres followed by quantification via flow cytometry. Differentials for phagocytic cells were assessed by sorting via flow cytometry. Phagocytosis did not differ between late pre-partum (-14 d) and early post-partum (7 d) or due to pre-partum diet. Analysis of LPS-effects (d 7, 14, and 30) showed that phagocytosis in cows fed the control diet pre-partum

increased $\sim 22\%$ by d 14 compared to a $\sim 19\%$ decrease in cows fed ME pre-partum (interaction $P < 0.01$). At 30 d post-partum, phagocytosis was $\sim 30\%$ lower than 7 d (time $P < 0.01$). Results show that neutrophil activity during an infection challenge following parturition might be affected by pre-partum dietary energy intake. Funded by NRI-USDA project #2007-35204-17758.

610 An immuno-evaluation system for anti-inflammatory probiotics using originally established porcine epitheliocyte (PIE) cells.

T. Shimazu*, M. Tohno, M. Moue, H. Aso, T. Saito, and H. Kitazawa, *Tohoku University, Sendai, Japan.*

Intestinal epithelial cells (IECs) are exposed to a variety of antigens, such as pathogenic and commensal bacteria, and are involved in the regulation of the mucosal immune responses. Although probiotics are believed to protect the host from pathogenic inflammation of the IECs, the precise mechanism of the anti-inflammatory effect of probiotics is not well understood. IECs recognize bacterial components through pattern recognition receptors, such as Toll-like receptors (TLRs), to initiate immune responses for pathogen elimination. Despite the importance of swine as a human model for some disease, little is known about the regulation of the immune response of porcine IECs. In the present study, we established and characterized an original porcine intestinal epitheliocyte (PIE) cell line in order to develop a novel immuno-evaluation system for anti-inflammatory probiotics based on the pathogenic inflammatory response of PIE cells. First, we isolated and cloned PIE cells from an unsuckled neonatal swine. These PIE cells expressed TLR1-9 and MD-2 mRNAs, and preferentially expressed TLR4/MD-2. In addition, we confirmed that TLR4 was expressed at the protein level. Upon stimulation with LPS, an antagonist for TLR4, the PIE cells upregulated the expression of several TLRs (TLR2, 3, 4, 5 and 8), Th1 cytokines (IL-1 α , IL-6), and chemokine (MCP-1). Furthermore, Enterotoxigenic *Escherichia coli* (ETEC), a major pathogen of neonatal swine, induced severe inflammatory cytokines through the TLR4 on the PIE cells. Interestingly, pretreatment with several probiotics significantly reduced inflammatory cytokine expression (IL-6, TNF- α) without affecting the TLR4 expression level. These results indicate that PIE cells are a useful cell line for studying the anti-inflammatory mechanism of probiotics with a view to developing new physiologically functional foods with intestinal anti-inflammatory effects.

Key Words: Probiotics, Intestinal Epithelial Cells, Anti-inflammation

Breeding and Genetics: Breeding for Milk Quality and Test-Day Model Applications

611 Quantitative trait loci for milk-fat composition in Dutch Holstein Friesians. A. Schennink*¹, W.M. Stoop¹, H. Bovenhuis¹, J.M.L. Heck², P.D. Koks¹, M.H.P.W. Visker¹, and J.A.M. van Arendonk¹, ¹*Animal Breeding and Genomics Centre, Wageningen University, Wageningen, the Netherlands*, ²*Dairy Science and Technology Group, Wageningen University, Wageningen, the Netherlands*.

This study is part of the Dutch Milk Genomics Initiative and aims at the characterization of genes involved in milk-fat synthesis and milk-fat metabolism. Previous research has shown substantial genetic variation in milk-fat composition: heritabilities were high (0.42-0.71) for short- and medium-chain fatty acids (C4-C16) and moderate (0.22-0.42) for long-chain fatty acids (C18 and longer). A genome-wide scan was conducted to map quantitative trait loci (QTL) affecting milk-fat composition in Dutch Holstein Friesian dairy cattle. The mapping population consisted of 7 half-sib families containing 849 cows in a daughter design. A total of 1378 single nucleotide polymorphisms (SNP) were typed covering all 29 autosomes, to construct a 2829 cM genetic linkage map. The phenotypes under study were 56 milk-fat composition traits, including saturated, mono-unsaturated, poly-unsaturated, and conjugated fatty acids, unsaturation indices, fat percentage and fat yield. A regression interval mapping approach was used to estimate effects and positions of the QTL. In addition to QTL on chromosomes 14 and 26, at which the genes coding for diacylglycerol acyltransferase 1 (DGAT1) and stearoyl-CoA desaturase 1 (SCD1) are located, QTL were detected on several other chromosomes. QTL were detected for short- and medium-chain fatty acids, as well as for long-chain fatty acids. Our results will enable marker assisted differentiation and marker assisted selection, in order to optimize milk quality and to develop innovative dairy products. Prior to implementation of these QTL in breeding programs, additional work is needed to fine map the chromosomal locations and select positional candidate genes influencing milk-fat composition.

Key Words: Milk-Fat Composition, Dairy Cattle, Quantitative Trait Loci

612 Genetic parameters of saturated and monounsaturated fatty acids estimated by test-day model in Walloon dairy cattle. H. Soyeurt*¹, C. Bastin¹, P. Dardenne², F. Dehareng², and N. Gengler^{1,3}, ¹*Gembloux Agricultural University, Gembloux, Belgium*, ²*Agricultural Walloon Research Centre, Gembloux, Belgium*, ³*National Fund for Scientific Research, Brussels, Belgium*.

The contents of saturated (SAT) and monounsaturated (MONO) fatty acids in milk vary through the lactation. The aim of this research was to estimate the genetic parameters for these groups of fatty acids in bovine milk using multi-trait random regression test-day models. The relationship between these fatty acids and the milk production traits was also studied as well as the effects of season and stage of lactation. The model included as fixed effects: herd x date of test, class of 15 days in milk, class of age. Random effects were herd x year of calving, permanent environmental, additive genetic, and residual effects. Since October 2007, all spectra generated by milk recording in the Walloon part of Belgium were collected. The contents of SAT and MONO were estimated by mid-infrared spectrometry. First results were obtained from 100,841 test-day records from 11,626 Holstein heifers. The season and stage of lactation influenced the contents of SAT and MONO in milk

and milk fat. The heritability estimates of SAT and MONO in fat were higher at the beginning of the lactation. The negative energy balance of cows could explain this variation. The values of heritability were also higher at the end of lactation. The genetic and phenotypic correlations among studied traits varied also through the lactation. This study confirms the genetic variability of fatty acids and suggests a possible relation between the contents of SAT and MONO in milk fat and the energy balance of cows.

Key Words: Fatty Acid, Genetic Parameter, Dairy Cattle

613 Genetic parameters of stearoyl coenzyme-A desaturase 9 activity estimated by test-day model. V. M.-R. Arnould*¹, N. Gengler^{1,2}, and H. Soyeurt¹, ¹*Gembloux Agricultural University, Gembloux, Belgium*, ²*National Fund for Scientific Research, Brussels, Belgium*.

Dairy and beef products account for a large part of fat intake in human nutrition and therefore can be linked to dietary diseases. The stearoyl Coenzyme-A desaturase 9 (delta-9) gene was identified as a potential functional candidate gene affecting milk fat composition in dairy cattle. The objective of this research was to estimate the genetic parameters of delta-9 activity indicator traits and to study the relationship between delta-9 activity as described by these indicator traits and common milk production traits. A total of 126,331 test-day records were obtained from 14,259 Holstein (> 84% Holstein gene) heifers belonging to 105 herds. The studied traits were milk yield, percentages of fat and protein, content of monounsaturated fatty acids, and 3 ratios reflecting the delta-9 activity (C14:1/C14:0; C16:1/C16:0 and C18:1/C18). The used model was a multiple-trait random regressions test-day model and included as fixed effects: herd x date of test, class of age, and month x year. Random effects were herd x year of calving, permanent environmental, additive genetic, and residual effects. The fatty acid contents were estimated by mid-infrared spectrometry. Delta-9 activity varied within year and lactation. The obtained heritability estimates of delta-9 as well as the genetic and phenotypic correlation varied also through lactation. This study suggests potential improvements of delta-9 activity and subsequently milk fat composition can be achieved by animal management but also by breeding and animal selection.

Key Words: Delta-9 Desaturase, Genetic Parameters, Dairy Cattle

614 Relationship between lactoferrin, minerals, and somatic cells in bovine milk. H. Soyeurt*¹, V. M.-R. Arnould¹, D. Bruwier¹, P. Dardenne², J.-M. Romnee², and N. Gengler^{1,3}, ¹*Gembloux Agricultural University, Gembloux, Belgium*, ²*Agricultural Walloon Research Centre, Gembloux, Belgium*, ³*National Fund for Scientific Research, Brussels, Belgium*.

Selection for increased mastitis resistance is hampered by lack of available data. Currently, somatic cell count or score are proven indicators. However, it should be a priority to increase the number of available indicator traits for mastitis resistance. The aim of this research was to study the relationships among potential indicator traits as lactoferrin content, concentrations of major minerals in milk (calcium, Ca; sodium, Na; phosphore, P), and somatic cell count. First, 3 calibration equations

were developed using partial least squares regressions to predict the contents of Ca, Na, and P in milk by mid-infrared spectrometry. A total of 1,609 milk samples were collected between March 2005 and May 2006 for 475 cows from 6 dairy breeds. Based on their spectral variability, 100 samples were selected using a principal components approach. The contents of these minerals were estimated by emission spectrometry (ICP-AES). The ratio of standard deviation to standard error of cross validation obtained for the equations predicted the contents of Ca, Na, and P were superior to 2 suggesting the use of these equations in this research. Second, the relationship between lactoferrin, minerals and somatic cells was studied using a random regressions multi-trait animal test-day model. A total of 57,973 milk samples were collected from 94 herds between April 2005 and January 2008 during milk recording in the Walloon part of Belgium.

Key Words: Minerals, Lactoferrin, Bovine Milk

615 Genetic variation in milk protein composition and the effects of genetic variants on the concentration of individual proteins. J. M. L. Heck*¹, A. Schennink², G. C. B. Schopen², H. J. F. van Valenberg¹, H. Bovenhuis², M. H. P. W. Visser², J. A. M. van Arendonk², and A. C. M. van Hooijdonk¹, ¹*Dairy Science and Technology, Wageningen University, Wageningen, the Netherlands*, ²*Animal Breeding and Genomics Centre, Wageningen University, Wageningen, the Netherlands*.

Milk protein composition determines, to a large extent, the nutritional value and technological aspects of milk. To determine the variation in protein composition the concentration of the six major milk proteins, α -lactalbumin (α -LA), β -lactoglobulin (β -LG), α_{S1} -casein (α_{S1} -CN), α_{S2} -casein (α_{S2} -CN), β -casein (β -CN) and κ -casein (κ -CN) was determined by capillary zone electrophoresis in individual milk samples of 2000 cows. This population was especially selected to be able to determine which part of the variation is caused by genetic effects or by factors as herd, stage of lactation, season and cell count. Heritability of every milk protein was determined using an animal model. Genetic variants of the main milk proteins were identified by DNA analyses and their effect on milk protein composition was determined.

The results show large variation in concentration of all individual proteins and a large part of this variation was caused by genetic factors. Milk protein composition has a moderate to high heritability with heritabilities ranging between 0.3 and 0.8. Large variation in combination with high heritability offers great opportunities for changing milk protein composition. The screening of the main milk protein genes resulted, next to the detection of the common genetic variants (α -LA B, α_{S1} -CN B and C, α_{S2} -CN B, β -LG A and B, β -CN A1, A2, A3 and B, κ -CN A and B), into the detection of κ -CN E which was not previously detected in Dutch Holstein Friesian cows. We show that genotypes of β -LG, β -CN and κ -CN have major effects on the concentration of individual proteins and explain a considerable part of the genetic variation in milk protein composition.

This was likely the first study where the total and the genetic variation in detailed protein composition was determined on such a large amount of animals. The effect of genetic variants on all individual proteins, rather than on total protein or total casein, has not been reported frequently. The information resulting from this study shows the possibilities and limits of changing bovine milk protein composition.

Key Words: Milk Protein Composition, Heritability, Genetic Variants

616 Effect of casein genotypes on heritability of milk coagulation ability in Holstein Friesian cows. M. Cassandro*¹, R. Dal Zotto¹, M. De Marchi¹, A. Comin¹, S. Chessa², and G. Bittante¹, ¹*University of Padova, Legnaro, Padova, Italy*, ²*University of Milano, Italy*.

Cheese-making industry plays a fundamental role in Italy, where more than 75% of overall marketable milk is converted into cheese. Therefore, it is important to analyze the genetic aspects of milk coagulation properties (MCP) as coagulation time (RCT, min) and curd firmness (a30, mm). Aim of this study was to estimate the heritability for RCT and a30 estimated with or without the effect of casein genotypes (CSN2 and CNS3) included on the linear model. A total of 1.071 individual milk samples of Italian Holstein cows, daughters of 54 sires, reared in 34 dairy farms of Veneto region (Italy), were analysed for RCT and a30. Moreover, all cows were genotyped for CSN2 and CSN3 loci. Heritability of RCT and a30 traits were 0.25 and 0.15, respectively, without including the effects of CSN2 and CNS3 in the analysis. The use of casein genotypes effect in the model showed a lower heritability estimates (0.15 and 0.09, for RCT and a30, respectively). These results evidenced that MCP can be improved using genetic strategies and that casein genotypes might be considered as major genes for milk coagulation abilities.

Key Words: Milk Coagulation Ability, Genetic Parameters, Casein Genotypes

617 Modeling extended lactation curves in Italian Holsteins. R. Steri¹, F. Canavesi², E. Nicolazzi², G. Gaspa¹, and N.P.P. Macciotta*¹, ¹*Dipartimento di Scienze Zootecniche, Università di Sassari, Sassari, Italia*, ²*Associazione Nazionale Allevatori Frisone Italiana, Cremona, Italia*.

In several countries the average lactation length of dairy cattle has increased markedly in recent years, essentially due to reproductive failures but also to management strategies. The search for suitable mathematical models for extended lactations is of great importance both for genetic evaluations via Random regression Models, and for management decision, especially for the assessment of an economically convenient asymptotic level of production. In this work, 737,011 test day records for milk yield of 69,863 lactation of 45,521 Italian Holsteins (with about 46% of lactations >350 DIM) farmed in four provinces of the North of Italy, were modelled with six common lactation curve functions: Wood (WD), Wilmlink (WIL), Ali and Schaeffer (AS) multiple regression, fifth-order Legendre polynomials (LEG), quadratic (QSPL) and cubic splines (CSPL) with three knots. Moreover, data were modelled with the version of the Dijkstra model specifically suggested for extended lactations. As expected, functions with a larger number of parameters showed better fitting performances for individual patterns, with about 75% of curves showing an adjusted R-squared higher than 0.70 for AS, LEG, QSPL and CSPL. Moreover, fitting performances tend to increase with lactation length due to the larger number of data. Lactations curves exceeding 650 DIM and that showed adjusted R-squared greater than 0.75 when modelled by the modified Dijkstra function, separately by parity, in order to calculate some measures of technical importance. Days at peak were 75, 48 and 48 for first, second and third calving cows; peak yield were kg/d 32.7, 38.3, 39.9. Cumulative yield at 305 and 1000 DIM were different across parities: 9,177 vs 22,154 (1st parity), 9,846 vs 21,925 (2nd parity), 10,115 vs 21,875 (3rd parity). The estimated

asymptotic level of production in the tail of lactation was on average 10 kg/d but together with a marked variability.

Key Words: Dairy Cattle, Extended Lactations, Mathematical Models

618 Issues in modelling lactation curves with regression splines. N. P. P. Macciotta*¹, F. Miglior^{2,3}, A. Cappio-Borlino¹, and L. R. Schaeffer⁴, ¹*Università di Sassari, Sassari, Italia*, ²*Dairy and Swine Research and Development Centre, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada*, ³*Canadian Dairy Network, Guelph, ON, Canada*, ⁴*CGIL, University of Guelph, Guelph, ON, Canada*.

Regression splines are a type of segmented regressions in which the curve is divided into different segments of the independent variable, joined at points named knots, each fitted with different polynomials. Cubic splines are becoming a model of interest for fitting individual lactations in random regression test day models for dairy traits whereas linear and quadratic splines have been proposed to fit growth curves. The main objective in spline modelling is to optimize the number and placement of knots. Non linear procedures allow for the estimation of knot position, treated as parameter of the function. In this study, lactation curves of Canadian Holsteins were modelled with splines of different order by using non linear procedures. Data were 285,340 test day records of Canadian Holsteins each with 10 records. Average curves of different parities (1 to 3) were modelled with linear, quadratic and cubic splines. Models with one, two and three knots were tested. Estimated knots positions were used to model individual curves by linear spline regressions. Fitting of average curves was high for all models considered (adjusted R-square > 0.98). By and large, the increase of the number of knots resulted in convergence problems. Only quadratic splines converged in all the three parities and for all the number of knots considered. The order of splines affected the knot position: for example when only one knot was fitted, the position was between 30-37 days in milk (DIM) for linear, 40-46 DIM for quadratic and 53-62 DIM for cubic splines, respectively. For increasing number of knots, their positions appeared more consistent for quadratic and cubic splines. When three knots were fitted, the first knot was between 10 and 26 DIM, the second between 23 and 59 DIM, the third between 60 and 252 DIM. Finally, no substantial increases of adjusted R-square was observed when increasing the number of knots or moving from quadratic to cubic splines in individual fitting, with about 60% of curves having an adjusted R-square greater than 0.6.

619 Improving stability of test day model bull proofs. F. Canavesi, S. Biffani*, E.L. Nicolazzi, and R. Finocchiaro, *ANAFI, Cremona, Italy*.

Test days are used for the official genetic evaluation in Italy since November 2004. They are used in a multiple trait multiple lactation random regression test day model. Since its introduction a larger variation on average was observed in bull proofs in comparison to the old repeatability model based on 305 days ME lactation records. In order to

improve proof stability several areas were investigated from definition of fixed effects to estimation of genetic parameters. Critical moments in bull proofs variation were the arrival of second and third lactation into the system.

In Italy progeny testing daughter data are coming into the genetic evaluation system at different times depending on efficiency of AI studs in distributing semen, efficiency of farmers in using young bulls doses, age at calving heterogeneity across regions. Therefore young bulls add daughters at every run and this may cause variation in bull proofs. A bull gets its official proofs when there are at least 30 daughters at 120 DIM in 30 herds but there were not limits set for second and later parities daughters. In January 2008 a new procedure was applied and now second and third parity daughters data can be used for bull evaluation only if they meet the following criteria: 5 daughters at 120 DIM in second lactation and 3 daughters at 120 DIM for third lactation. This improved stability of proofs from run to run on average by 10% and moreover reduced the number of bulls that were decreasing one run and increasing the next or viceversa due to the arrival of early and scarce data on second and third parity daughters.

Key Words: Stability of Proofs, Test Day Model, Accuracy of Proofs

620 Genetic parameters for milk, fat and protein in Holsteins using a multiple-parity test day model that accounts for heat stress. I. Aguilar*^{1,2}, I. Misztal¹, and S. Tsuruta¹, ¹*University of Georgia, Athens, GA*, ²*Instituto Nacional de Investigación Agropecuaria, Las Brujas, Uruguay*.

Data included 585,119 test-days (TD) in first to third parity for milk (M), fat (F) and protein (P) from 38,608 Holsteins in GA. Daily temperature humidity indices (THI) were available from public weather stations. Models included a repeatability test-day model (MREP) with a random regression on heat stress index (HIS), and a test-day random regression model (MRRM) using linear splines with 4 knots and HSI, which was defined as THI over 22C from the 3rd day before the TD from a weather station closest to the farm. Knots for splines in MRRM were placed at 5, 50, 200, and 305 days-in-milk (DIM). Random effects were additive and permanent environment in MREP and additive, permanent environment and herd-year for MRRM. Additionally, models included herd test day, age, milking frequency and DIM classes as fixed effects. In MREP and for M, F and P, the phenotypic variance increased by 50-60% from 1st to 2nd parity and additionally by 12-15% in 3rd parity. The regular genetic variance increased by 30-40% from 1st to 2nd parity but slightly declined in 3rd parity for M and P. The heat stress variance doubled from 1st to 2nd parity, and additionally increased by 20-100% in 3rd parity. The genetic correlations between parities in the regular animal effect were ≥ 0.84 , but they were ≥ 0.96 between 2nd and 3rd. The genetic correlations between parities in the heat-stress effect were $\geq 0.56-0.79$. The genetic correlations between regular and heat stress effects across parities and traits were between -0.30 and -0.47. With MRRM, the variance of the heat stress effect was about half of that with MREP. The most negative (-0.42) genetic correlation for milk between regular and heat stress effects was at 50-200 DIM for 1st parity and at 200-305 DIM for parities 2-3. Genetic variance of heat stress strongly increases with parity. It is inflated with MREP due to timing of lactations to avoid the peak production during heat stress.

Key Words: Heat Stress, Variance Components, Multiple Lactations

621 An alternative model to accommodate very large numbers of traits in random regression test-day models. N. Gengler*^{1,2}, ¹*Gembloux Agricultural University, Gembloux, Belgium*, ²*National Fund for Scientific Research, Brussels, Belgium*.

Computing capability has continued to increase following Moore's law allowing the use of full multitrait models in many cases. However there are still situations where current computing algorithms need to be optimized. One of these is large scale multitrait random regression models (MT-RRM), the type suitable for type traits and milk components where potentially 30 and more traits are analyzed together using several random regression effects. An equivalent model to a MT-RRM can be defined as a complete repeated records model where the different traits are standardized according to residual variances or records are weighted accordingly. Trait-specific or across trait fixed effects can be defined. Trait-specific random effects need to be used; however definition of random effects does not need to be identical for all traits. This equivalent model is also an excellent base to use rank reduction as the

potentially large number of random effects (effects x number of traits x number of regressions) can be reduced dramatically based on (co)variance structures among them. Adapted variance component estimation strategies can be used based on REML and Gibbs sampling algorithms. Alternative solving algorithm such as the use of sequential estimation of regressions and effects on regressions can be easily adapted to this framework. This equivalent model has also the practical advantage that it allows for easier models where some traits have been recorded for a long period (e.g., stature, milk, fat, protein) and other traits are recent and have much more sparse data (e.g., rear legs rear view, different fatty acids in milk fat). This can be done by a full or partial transformation of records of different traits to repeated records. This alternative model approach should make MT-RRM practical for many traits and trait groups under selection in dairy populations, today and in the future.

Key Words: Mixed Model, Equivalent Model, Rank Reduction

Breeding and Genetics: Current Issues in Beef Cattle Breeding

622 ASAS Centennial Presentation: Animal breeding and the *Journal of Animal Science*: A century of co-evolution. W. Hohenboken*^{1,2}, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²Oregon State University, Corvallis.

In this paper, I attempt to survey, categorize and characterize papers relevant to animal breeding and genetics that were published in the *Journal of Animal Science* between the initial issue in 1910 and 2008. Graphics and descriptive statistics will be presented that describe allocation of publication effort across species, space and time. I then endeavor to identify and describe the evolution of major themes in research, teaching and extension. When did they begin? How did they expand and contract? Did they mutate or metastasize? Which suffered extinction? Relationships and paths of influence among investigators and among institutions will also be examined. Finally, I will reflect upon changes during the century in the *Journal of Animal Science* and in the manner and style with which animal breeders and geneticists published their findings within its pages.

Key Words: Breeding and Genetics, History, *Journal of Animal Science*

623 Residual feed intake heritability and phenotypic correlations of central tested Simmental bulls. W. C. Rutherford*, L. A. Kriese-Anderson, S. V. Free, M. S. Hittle, and J. K. Grubbs, Auburn University, Auburn, AL.

Feed intake along with weights, hip height, ultrasound carcass traits and scrotal circumference were analyzed for 459 Simmental bulls consigned to the Auburn University BCIA Bull Test from the years 1981 to 2007. All bulls were housed at the Auburn University Beef Evaluation Center for a minimum of 70 days. Bulls were trained to individual Calan Gates® within 21 days of arriving. All bulls were consigned by individual Simmental breeders primarily from Alabama. Bulls were measured for weight and height either biweekly or monthly depending on year. SC and ultrasound measurements for carcass traits were taken at yearling age (330 to 400 days). Residual feed intake (RFI) was determined for each bull by regressing metabolic mid-weight and ADG on intake. Phenotypic correlations among traits were determined using SAS. RFI was positively correlated with total feed intake (Corr=.53211 P<.0001) and has a slight positive correlation with 12th rib fat thickness (Corr=.12117 P=.0125). A mixed model in SAS was used to analyze RFI and determine sire components of variance. Fixed effects included consignor (N=61), and percentage Simmental (7 levels). Sire (n=223) was included as a random effect. Consignor was found to be non-significant (P>.05). Percentage Simmental was found to be significant (P<.0001). LSMEANS separated differences between percentage Simmental for RFI. Bulls that were 37% Simmental had the highest RFI values. The second highest RFI values were with 25% Simmental bulls. The 25% Simmental bulls had greater RFI values than bulls of 50, 62, 75, 87, and 100% Simmental (P<.0105). Heritability of RFI was estimated to be 0.29 ± 0.02.

Key Words: Residual Feed Intake, Heritability, Beef

624 Estimates of genetic variation for feed intake and other characteristics in growing beef cattle. K. M. Rolfe*¹, M. K. Nielsen¹, C. L. Ferrell², and T. G. Jenkins², ¹University of Nebraska, Lincoln, ²US Meat Animal Research Center, Clay Center, NE.

Calves born between 2003 and 2006 at the U.S. Meat Animal Research Center provided data for estimation of genetic and phenotypic parameters for measures of body weight and gain and feed intake during the finishing phase. At average age 278 d, cattle were started on a high energy diet of corn, alfalfa hay, soybean meal, and supplement. They were individually fed for ~138 d in pens of 4 to 8 steers by use of Calan headgates. Cattle were fed to an average optimum end weight, but harvested in four groups per year at a commercial slaughter facility. Steers were produced by randomly mating F1-cross sires to straightbred and F1 females. Nine breeds were represented in various fractions in the steers. These were: Hereford, Angus, Simmental, Charolais, Limousin, Gelbvieh, Red Angus, Pinzgauer, and Red Poll. Fifty-nine sires produced half-sib families. A total of 820 crossbred steers were analyzed with a pedigree file of 4,051 animals. Traits analyzed were ADG, DMI, mid-period body weight (MBW), and residual feed intake (RFI; determined from DMI adjusted for MBW and ADG). Flight time (FT) was collected at least twice (separated by ~60 d) as a possible indicator trait for temperament; two sets of electronic eyes were placed 5.5 m and 10.8 m beyond a scale box where the animals were temporarily detained. REML methods were used in univariate models that accounted for the fixed effects of year, month for only FT, pen size, breed and breed heterozygosity; random effects were animal genetic, pen, permanent environmental for FT only and error. Heritability estimates for ADG, DMI, RFI, MBW, and FT were: 0.21 ± 0.09, 0.21 ± 0.07, 0.40 ± 0.11, 0.45 ± 0.12, and 0.25 ± 0.07, respectively. Repeatability of FT was 0.63. Pen size only had a significant effect on RFI (P<0.001). Month was significant for FT (P<0.001) with flight time increasing as the animal aged.

Key Words: Beef Cattle, Feed Intake, Flight Time

625 Analysis of beef cattle growth with a Kalman Filter. S. Forni*, D. Gianola, G. J. M. Rosa, G. de los Campos, and K. A. Weigel, University of Wisconsin, Madison.

A dynamic model known as Kalman Filter (KF) was embedded into a standard linear mixed model, to analyze longitudinal data. Growth data of Nelore cattle were used to compare a standard multiple trait model (MM) with the KF. A data set consisting of body weight records of 6,856 animals was used. Animals were weighed at 90 d intervals from birth to 540 d of age, and six equally-spaced records were used for each individual. Contemporary groups (CG) consisted of: sex, herd, year and season of birth (rain or dry) combinations. A six-variate mixed linear model with CG, additive genetic and maternal effects was employed. KF introduced a time-dependent association between additive genetic, maternal and residual effects, which were assumed to change over time according to a first order autoregressive process. Under KF, covariances between any two time points can be inferred from combinations of variances estimates. Thus, the (co)variance structure can be modeled with fewer parameters than in the MM. The KF and MM models were compared using the Deviance Information Criterion (DIC) and the Bayes

Factor (BF). Models where KF described additive genetic and maternal effects were favored by DIC. However, KF did not describe residual (co)variation adequately. According to the BF, there was not conclusive evidence in favor of a specific model. The KF allowed fitting additive and maternal effects with a meaningful lower number of parameters than the standard procedure. This reduction avoids problems associated with overparameterized models and makes efficient use of the data. Further, fitting KF to growth traits provides estimates of genetic merit for the entire range of time points and captures differences through time between and within individuals.

626 Bayesian estimation of the covariance between permanent maternal and temporary environmental effects for weaning weight in beef cattle. R. Cantet^{*1,2}, ¹University of Buenos Aires, Buenos Aires, Argentina, ²CONICET, Aregentina.

The magnitude of the additive covariance between direct and maternal effects (CADM) in the presence of an environment covariance between direct and maternal effects (CEDM) for weaning weight in beef cattle is still an open issue. Inclusion of CEDM presents a challenging problem for fitting the model to data. An animal model with maternal effects is presented that includes random additive direct and maternal effects, as well as random permanent environmental effects (PE) that are correlated to a set of temporary environmental effects (TE) on the individual records through the CEDM parameter. In this model, error terms are independent and identically distributed. Two formulations of the covariance matrix for PE effects are studied. The first one accounts for the environmental influences from grand-dams to all her direct descendant dams. An alternative formulation is presented where the only non-zero covariance is between PE effects of a dam and her daughter dam. The covariance matrix for TE effects is modeled after the time elapsed among progeny records from the same dam. To estimate all dispersion parameters a Bayesian method using conjugate prior densities and Gibbs sampling is used. The inversion of the covariance matrix for the joint distribution of PE and TE is avoided by block sampling of all PE effects by line of dams and all TE of calves out of the same dam. A line of dam involves the records of an ancestor dam, their dam descendants and all their progeny, raised naturally (not by embryo transfer). The TE effects within any line of dam are correlated but are independent with those from the other lines. The number of animals involved in any line of dam is small for beef cattle data (for example, at most 20 in a data set of 80,000 Brangus records, or at most 25 in a 10,000 records from an Angus data set). The resulting means of the marginal conditionals densities for the fixed effects, breeding values, PE and TE effects are linear combinations of some matrices related to the MME and some matrices that are not functions of them.

627 ASAS Centennial Presentation: Future needs in animal breeding. R. D. Green*, Pfizer Animal Genetics, Sutton, NE.

The past century has seen animal breeding and genetics evolve and expand from definition and validation of basic population genetics

theory to development of selection index theory to today's relatively sophisticated genetic prediction systems enabling industry genetic improvement. The end of the first century of the ASAS also coincides with the rapid movement of the field into the era of genome-enabled genetic improvement and precision management systems. Led by recent research infrastructure investments by the US and international partners to develop chicken, bovine, swine, ovine, and equine "genome toolboxes", the animal breeding community is poised to play a crucial role in the century to come. These genome toolboxes provide the needed platforms for developing whole genome selection programs based on linkage disequilibrium for a wide spectrum of traits; allow the opportunity to re-define genetic prediction based on allele sharing as opposed to traditional pedigree relationships; and provide for the first time simultaneous information upon which to practice genetic selection and plan precision management of specific genotypes --all early in the life of the animal. An area of major focus will be mining of the genomes through systems biology approaches to better understand gene and metabolic networks --what has previously been lumped into poorly understood GxE, and GxG interactions. Perhaps the greatest obstacle to the successful merger of genomic and quantitative approaches will be the lack of necessary animal resource populations to appropriately define and measure phenotypes, i.e. the so-called "phenomic gap", for difficult to measure traits (e.g. resistance to disease and stress, adaptability, longevity, efficiency of nutrient utilization). Additionally, due to de-emphasis of quantitative genetics and animal breeding programs in academia over the past quarter century, a dearth of qualified young scientists to effectively mine the genomes must immediately be addressed. Whilst the motivating factors may have changed, the need for high quality animal breeding and genetics research and education has never been higher.

Key Words: Animal Breeding, Genomes

628 Genetic trends for production traits of the Montana Line 4 Hereford herd. J. M. Rumph^{*1}, D. D. Kress², K. C. Davis², D. C. Anderson^{2,3}, H. C. Van Wagoner³, and D. L. Boss³, ¹Michigan State University, Lake City, ²Montana State University, Bozeman, ³Montana State University, Havre.

To commemorate the centennial of the ASAS, the researchers thought it was fitting to analyze the genetic trends of the Montana Line 4 Hereford herd, a closed herd descended from the Miles City Line 1 which has also been maintained as a closed population for 74 years. The Line 4 herd has been managed at Montana State University's Northern Agricultural Research Center (NARC) in Havre, Montana since 1963 and has undergone various selection programs since its introduction to NARC. The herd is currently managed at approximately 100 females with an average inbreeding of 37.2% for the 2006 calf crop with individual animals ranging in inbreeding coefficient from 34.0 to 46.6%. The average inbreeding of the herd is increasing at a rate of 0.5% per year. Genetic parameters were analyzed for production traits routinely measured on this herd. All traits were analyzed using a univariate model. Estimates of direct heritability (and associated s.e.) were 0.52 (0.09), 0.24 (0.08), 0.32 (0.12), and 0.23 (0.09) for birth weight, weaning weight, weaning wither height, and weaning condition score, respectively. Estimates of maternal heritability were 0.08 (0.04), 0.09 (0.06), 0.12 (0.07), and 0.09 (0.07), respectively. The estimate of the direct-maternal genetic correlation was non-significant for most traits with estimates of 0.19 (0.27), -0.13 (0.34), 0.53 (0.22), and -0.41 (0.31), respectively. The proportion of variance due to maternal permanent environmental effects

was only significant for weaning weight and weaning condition score with estimates of 0.28 (0.04) and 0.12 (0.04), respectively. Birth weight direct breeding value (DBV), maternal breeding value (MBV), and phenotypic trends were estimated to be +0.008, 0.003, and -0.034 kg/yr, respectively. Weaning weight trends were estimated to be +0.346, +0.051, and +0.276 kg/yr, respectively. Weaning wither height trends were +0.033, +0.006, and -0.130 cm/yr, respectively. Weaning condition score trends were +0.0068, -0.0004, and +0.0040 score/yr. Trends for these traits are relatively flat for the period of time studied.

Key Words: Genetic Trends, Inbreeding, Weaning Weight

629 Clustering of herds to account for heterogeneous variance of docility scores in Limousin cattle. D. W. Beckman* and D. J. Garrick, *Iowa State University, Ames.*

Analyses of docility in Limousin cattle have shown the significance of random maternal and sire by herd interaction effects as artifacts of the data, resulting from heterogeneous variation. The objective of this study was to determine whether heterogeneous variance by herd stems from the subjective method used to allocate docility scores. Animals were assigned to a low (L) or high (H) variance cluster according to phenotypic variation estimated within-herd. Two univariate analyses examined clusters L and H as separate traits using ASReml. Animal models encompassed combinations of random factors: direct genetic, maternal genetic and sire by herd interaction effects. Models ranged from the most basic, containing direct genetic and residual effects (model D), to a model including all random factors. Likelihood ratio tests indicated model D best fit the data for both L and H. A bivariate model D further examined the genetic relationship between clusters. Direct heritability estimates from univariate analyses were 0.24 ± 0.05 and 0.38 ± 0.05 , and estimates of residual variance were 0.2 ± 0.01 and 0.35 ± 0.02 , for L and H, respectively. Similar estimates of direct heritability (0.22 ± 0.05 and 0.38 ± 0.05) and residual variance (0.21 ± 0.01 and 0.35 ± 0.02) were observed in the bivariate analysis for L and H, respectively. The genetic correlation between clusters was 0.8 ± 0.14 . Residual variance and heritability estimates were greatest in H, indicating herds that utilize a greater range of scores are a preferred environment for sire selection, as the accuracy of evaluation is greater. Results indicate variance of

docility scores between herds is not homogeneous, and is due to the subjective nature of scoring.

Key Words: Beef Cattle, Heterogeneous Variance, Temperament

630 Estimation of breed and heterosis effects for growth and carcass traits in cattle using published crossbreeding studies. J. L. Williams*, R. Rekaya, and J. K. Bertrand, *University of Georgia, Athens.*

Current genetic evaluations are performed separately for each breed. Multiple breed genetic evaluations, however, assume a common base among breeds enabling producers to compare cattle of different breed makeup. Breed and heterosis effects are needed in a multi-breed evaluation because databases maintained by breed associations include few crossbred animals which may not be enough to accurately estimate these effects. The objective of this study was to infer breed effects (BE), maternal effects (ME), direct heterosis effects, and maternal heterosis effects for growth and carcass traits using least square means estimates from crossbreeding studies published in the literature from 1976 to 1996. The data set was formed by recording each least square mean along with the breed composition, maternal breed composition, and direct and maternal heterozygosity. A Bayesian approach was implemented to analyze each trait with a fixed linear model which included study as a fixed effect and breed composition as a covariate. Breed solutions for each trait were expressed relative to the Angus breed. Direct BE for weaning weight ranged from -7.0 ± 0.67 kg (British Dairy) to 29.3 ± 0.74 kg (Simmental) and ME ranged from -11.7 ± 0.24 kg (Hereford) to 31.1 ± 2.22 kg (Gelbvieh). Direct BE for birth weight ranged from -0.6 ± 0.14 kg (British Dairy) to 10.1 ± 0.46 kg (Continental Beef) and ME ranged from -7.1 ± 0.13 kg (Brahman) to 5.8 ± 1.07 kg (Continental Beef). Direct BE ranged from -17.9 ± 1.59 kg (Brahman) to 21.7 ± 1.96 kg (Charolais), from -6.1 ± 1.29 kg (Brahman) to 55.1 ± 1.49 kg (Charolais), from -8.1 ± 0.47 cm² (Shorthorn) to 20.9 ± 0.48 cm² (Continental Beef), and from -1.1 ± 0.02 cm (Continental Beef) to -0.02 ± 0.03 cm (Shorthorn) for post weaning gain, carcass weight, rib eye area, and fat thickness, respectively. The use of literature estimates to predict breed and heterosis effects may be an alternative to their direct prediction in a multi-breed evaluation.

Symposium: Companion Animals: Exotic Animal Nutrition

631 Zoo nutrition: In the beginning... D. E. Ullrey*, *Michigan State University, East Lansing.*

This is not a history of zoo nutrition but a personal retrospective on a career in Comparative Nutrition, beginning with life as a farm boy and a traditional undergraduate education in Animal Husbandry. Wise counsel by R.H. Nelson led to a useful MS degree in Pathology at MSU and a PhD in Animal Nutrition, with minors in Physiology and Biochemistry, at the Univ. of Illinois. Thesis research was conducted with cattle and swine, and my first faculty position in the Dept. of Physiol./Pharmacol. at Oklahoma State Univ. involved research with domestic species, as well. A faculty appointment in Animal Science at MSU in 1956 included responsibility for developing an analytical laboratory, and E.R. Miller and I collaborated on studies of swine for 37 years. Our faculty and graduate students were also interested in beef and dairy cattle, sheep, horses, and poultry, and several collaborative studies of their nutrient needs were published. When the Wildl. Div. of the Mich. Dept. of Natural Resources asked for assistance, research began on nutrition and physiology of white-tailed deer. The diets used in white-tailed deer studies, and concern for the welfare of other captive wild animals, ultimately led to development of diets for a number of wild species. A Comparative Nutrition Group was formed at MSU, and a small group of graduate students began on-site training at the Dallas Zoo. They were asked to gather quantitative data on food offered and consumed in all animal exhibits, to calculate nutrient intakes, and, when appropriate, make recommendations for change. Many decisions were founded on extrapolations from knowledge of needs of domestic animals with similar gastrointestinal physiology. Because specific nutrient guidelines were so limited, studies were initiated to develop research-based diet formulations. Over time, the physiology and nutrient needs of 77 species were investigated. These included marsupials (2), primates, including humans (5), rodents (1), whales (1), mammalian carnivores (10), perissodactyls (7), artiodactyls (19), birds (20), turtles & tortoises (2), snakes (3), frogs & lizards (3), fish (2), and insects (2). Examples and contributions of others are presented.

Key Words: Zoo, Nutrition, Comparative

632 Forty-plus years of exotic animal management - A director's perspective. L. Simmons*, *Omaha's Henry Doorly Zoo, Omaha, NE.*

In the beginning, a million years ago, zoo directors and curators formulated diets for exotic animals based on an empirical combination of extrapolations and questions that included:

1. How much was known about the target animal's natural history and diet?
2. What were the diets of the domestic species that the target species was most closely related to?
3. What was the traditional diet fed to the target species in captivity?
4. What did the animal readily eat when given a wide choice of food items?

Sometimes, developing diets based on the answers to these questions worked out well; however, in a substantial percentage of cases, a successful diet was arrived at only after much trial and error. "Successful diets"

were passed down from keeper to keeper, from zoo to zoo and even from country to country. Frequently, diets which were coined "successful" for a species were those diets which were fed to multiple species or genera within a single exhibit and therefore, the animals had access to a large number of foodstuffs to choose from. Anecdotally, there were many observations of species that preferred the "other guy's diets." Defining what was meant by a "successful diet" also was problematic. Did it mean that the animal ate the diet and survived? Did the animal grow up to be a healthy adult? Did the animal reproduce and if it did, how long had it been out of the wild when it reproduced and did it reproduce a second time? Diets were also defined "successful" by monitoring the texture and color of an animal's pelage? Over the past forty-plus years, there have been plenty of examples of diets that did work, diets that did not work, and diets that seemed to work but in fact were altogether wrong. Some of these examples include frog eating toucans, yellow brown bears, and drunk hummingbirds. Today, the field of exotic animal nutrition is applying a science based approach to the development and formulation of nutritious diets for captive exotic animals.

633 Amphibians and reptiles - Trials and tribulations. C. Dikeman*, *Omaha's Henry Doorly Zoo, Omaha, NE.*

Animal science research during the last century has given the field of exotic animal nutrition a knowledge base for extrapolation to exotic species. Unequivocal comparisons often are made between traditional animal science research and that conducted with exotics. For example, comparisons between the horse and zebra or the cat and leopard, seem obvious. However, when dealing with nutrition of endangered amphibians and reptiles, direct comparisons with animal science becomes ambiguous at best. Animal scientists have been improving the diets of domestic animals for decades to provide nutritious products for human consumption. Likewise, feeding captive amphibians and reptiles requires careful attention to the diet of the intended prey, typically live feeder crickets. Compounded with a lack of solid information regarding nutrient requirements for amphibians and reptiles, the successful rearing of these captive creatures becomes onerous. Metabolic bone disorders, caused by imbalances of calcium and phosphorus, have been the focus of feeder insect research for amphibians and reptiles over the past 4 decades. While it may seem irrelevant to animal scientists to consider the importance of feeding frogs, currently a crisis is affecting these bio-indicators that could result in the extinction of up to one-third of the World's amphibian species over the next 5-10 years. While many species of birds and mammals (approximately 12 and 23%, respectively) are threatened with extinction, nearly 50% of known amphibian species are threatened. As a result, many of these species are being brought into captivity for critical conservation efforts. As new species are brought into captivity, additional nutritional concerns are becoming apparent. Captive Wyoming and Puertorican Crested toads appear to have extraordinary dependency on Vitamin A concentrations that are largely misunderstood. While researchers are currently working on feeding regimes to improve the nutrient profile of feeder insects, gaps exist in the connection those vital nutrients play in the health and longevity of preying amphibians and reptiles. Dedicated nutritional and biochemical research is imperative to the conservation of these animals.

Key Words: Exotic species

634 Carnivores: From mouse to moose. E. S. Dierenfeld*, *Saint Louis Zoo, St. Louis, MO.*

Classic metabolic bone disease, diagnosed in the 1800s in lions at the London Zoo fed unsupplemented meat, is perhaps the first published nutritional problem identified in zoo carnivores. Since that time, enzyme studies with cheetahs, other large cats, carnivorous birds, and even crocodylians confirm that domestic felids are an appropriate physiologic model for many obligate carnivores. The unique metabolic adaptations of felids for high rates of protein catabolism and use of the carbon skeletons for gluconeogenesis, dietary requirements for specific amino acids, fatty acids, and both water- and fat-soluble vitamins can be applied with a variety of carnivorous/omnivorous zoo species to determine whether felids or canids may be more suitable models for evaluating nutritional status and dietary adequacy. Despite this wealth of comparative information, actual nutrient requirements are unknown, and physiologic data remain obscure for entire groups of mammalian carnivores (i.e. herpestids, mustelids, generalist insectivores as well as specialists like pangolins and anteaters). Information is even more limited when considering non-mammalian carnivores. Although whole vertebrate prey comprise nutritionally-balanced foodstuffs for a variety of carnivores, there are surprisingly few data on nutrient composition of whole prey, particularly vitamin and micronutrient information (fatty acids, amino acids, trace elements, carotenoids) × all of which may have significant impact on reproductive output, immune function, and overall health. Summarized data that do exist suggest important effects of diet on body composition of whole prey. For example, vitamin A concentrations in free-ranging rodents were found to be significantly and consistently lower (10,000 × 30,000 IU/kg DM) than values measured in laboratory-reared mice and rats of the same body size, likely due to captive diets upon which the feeder animals were raised. The use of domestic carnivore nutrient requirements, developed through controlled experimental studies, provide solid guidelines for development of balanced diets for a variety of exotic carnivores, even given the our current scope of knowledge and limitations.

635 Comparative Avian Nutrition – Lessons learned from domesticated poultry. E. A. Koutsos*, *Mazuri Exotic Animal Nutrition/PMI Nutrition International LLC.*

There are over 9000 species of birds (more than twice as many as mammals), using virtually every wild type feeding strategy described. Due to limited research in most exotic avian species, captive feeding programs are often designed around the known nutrient requirements of domesticated poultry. Domesticated poultry are generally granivorous, consuming nutrient dense seeds in their native habitats. Their GI anatomy is equipped for such diets (e.g., a well-muscled gizzard), and commercial diets often include similar dietary inputs (e.g., grains from domesticated plant species). Many companion avian species are also granivorous (e.g., many finch species, budgerigar), and domestic poultry requirements may be an excellent starting point for these species. However, many avian species have evolved to eat prey (terrestrial vertebrates, insects, fish and plankton), grasses and other plant components, fruits (from wild rather than domesticated fruit species), nectar and pollen, and other components. For these species, poultry nutrient requirements may not be an adequate starting point for diet development. Further, an understanding of GI and beak morphology is critical to design nutrition programs that meet the requirements of the animal, but also promote

consumption, proper GI tract function, ideal excretion properties, and prevents stereotypic behaviors associated with boredom and malnutrition. For example, ratites, which are captively managed in zoos and for production purposes, have significant hindgut fermentation. Thus, these animals have much higher fiber digestion ability than domestic poultry, and as a result, ME values for chickens underestimate the amount of energy that is obtained by growing ratites (Angel, 1993).

Key Words: Avian Nutrition, Comparative

636 Ungulates: Are they cows with long necks? M. S. Edwards*, *California Polytechnic State University, San Luis Obispo.*

Ungulates refer to mammal groups that distribute their weight, while moving, over tips of usually hooved toes. The taxonomic significance of Superorder Ungulata is debatable; however, their shared traits and herbivorous feeding habits allow interesting comparisons. The Orders Perissodactyla (odd-toed ungulates) and Artiodactyla (even-toed ungulates) represent the majority of species with these traits. Although *in situ* work with a species offers insights to its biology, extrapolation to managed environments is often limited. Scientific advances established with domestic ungulates over the past 100 yrs, as well as training professional animal scientists, are a cornerstone of applied nondomestic ungulate management. Comparative nutritionists rely on research of animal scientists and others to support these species programs. A recent example: extrapolation of research on influences of dietary starch fermentation and resulting metabolic changes in dairy cattle. This scientific collaboration led to experimental diets that may address nonclinical, but persistent serum Ca:P below 1:1 ratio in captive giraffe, a physiological measurement inconsistent with observations among free-ranging herds (Koutsos et al., 2007). Opportunities for information transfer are not unidirectional. As modern domestic ungulates demonstrate improved growth and production, the physiological “distance” from their species of origin increases. Nondomestic ungulates, including mouflon, urial, and boar, afford us an opportunity to look back at nutrient requirements and physiology of genetic ancestors and answer questions related to modern breeds. Humans have maintained wildlife species since 2300 B.C., yet significant information gaps exist. Gaps will be filled with experience borne from controlled research and careful documentation of science-based management based on domestic ungulate foundations. Are ungulates cows with long necks? This group’s diversity exceeds a simplistic description. Sizes range from a 2.5 kg royal antelope to a 6000 kg African elephant. However, gastrointestinal tract similarities and resulting physiology allow us to compare and contrast species to advance our scientific understanding of all animals.

Key Words: Ungulate, Nondomestic, Nutrition

637 Omnivores – Models of metabolism. J. Williams*, *Indianapolis Zoological Society, Indianapolis, IN.*

Plant and animal biomass differs substantially in biochemical composition, with plant material greater in carbon than in nitrogen and phosphorus. Due to the carbon skeleton associated with the structural framework of plant fibers, herbivorous animals typically consume feed resources with greater carbon to nitrogen and carbon to phosphorus ratios than are contained within their own biomass. This makes phos-

phorus and nitrogen the principal growth limiting nutrients associated with herbivorous feeding strategies. Conversely, under a carnivorous feeding strategy animal matter is composed of elemental constituents that are similar to those of the animal that is consuming it. Due to the predator's utilization of organic carbon in physiologic processes such as protein synthesis, energy production and respiration, organic carbon as opposed to other metabolites becomes the limiting nutrient in the diet of the strict carnivore. The term omnivore can best be defined as any animal with the capacity to consume and digest feed resources from more than one ecologic trophic level and this unique ecological niche repre-

sents an evolutionary adaptation common to many taxonomic groups. Omnivorous animals are generalists that must possess the ability to not only catch and ingest fellow consumers but also consume and digest primary producers e.g. plant biomass. This feeding strategy enables the omnivore to exploit both the more plentiful but less nutrient dense and less plentiful but more nutrient dense environmental food resources. The factors involved with the development and maintenance of traits enabling omnivorous consumers to exploit food resources from multiple trophic levels will be discussed.

Key Words: Omnivore, Trophic, Feeding

638 The current nutrition environment: Beef lipids in perspective. S. McNeill*, *National Cattlemen's Beef Association, Centennial, CO.*

Consumer beliefs about nutrition, health and wellness “that have for decades underpinned their decisions about what to eat” are rapidly evolving. Obesity is driving a number of trends, including food labeling, nutrition profiling and food bans. Today, pressure to define and promote healthier diets is coming from multiple angles. This presentation will explore this new nutrition environment and identify both the opportunities and potential challenges it presents for beef. Nearly sixty-five percent (65%) of all whole muscle cuts sold at retail and 15 of the top 20 most popular retail whole muscle cuts are “lean.” Additionally, beef is among the top four food sources of 10 essential nutrients in the American diet. Despite these positive nutrition contributions, health professionals and consumers still hold misperceptions about beef’s role in a healthy diet. Research on beef’s role in a healthy diet will be reviewed with a focus on research demonstrating the effects of lean beef on established and emerging cardiovascular disease risk factors.

Key Words: Beef, Nutrition Environment, Heart Health

639 Role of animal protein in optimal health. N. Rodriguez*, *University of Connecticut, Storrs.*

Research over the last decade suggests that higher protein intakes may impart some benefits with specific regard to various health outcomes such as weight management, diabetes, and cardiovascular disease. Further, emerging science based on newer, more sensitive methodologies, indicates that high quality, animal protein may convey particular benefits. This presentation will consider the scientific evidence for the role of animal protein in optimizing human health and identify areas of scientific consensus regarding the health benefits of high quality protein. Potential areas for future research to further delineate the importance of animal protein in optimal health will be highlighted. Special consideration will be given to recommending protein intake at levels approaching the higher end of the Dietary Reference Intakes (DRI) for the purpose of reducing the risk of certain diseases (i.e., obesity, diabetes) and delaying the onset or progression of muscle loss with aging (i.e., sarcopenia).

Key Words: Protein, Health, Nutrition

640 Milk fat and risk of cardiovascular disease. D. E. Bauman*¹ and A. L. Lock², ¹*Cornell University, Ithaca, NY,* ²*University of Vermont, Burlington.*

The last quarter-century has seen increased consumer interest in the link between diet and health. A major focus of this interest has been the effect of dietary fats and recognition that certain dietary fatty acids can impact human health. Both saturated (SFA) and *trans* (TFA) fatty acids in dairy products are significant challenges because of their perceived negative effects on human health, particularly in relation to cardiovascular disease (CVD) risk. This has led to the concept of eating healthy becoming synonymous with avoiding dietary fat, especially saturated

fat, with a low saturated fat diet at the heart of nutritional advice for lowering plasma cholesterol and reducing CVD risk. Furthermore, clinical and epidemiological studies have consistently demonstrated that diets containing TFA from partially-hydrogenated vegetable oils result in an increased risk of CVD. These results have been broadly extrapolated to imply that consumption of any and all TFA isomers is associated with an increased risk of CVD. Individuals do not consume fatty acids as a dietary entity, but rather as fats in foods. Investigations of the relationship of dairy product consumption to cholesterol and CVD in both children and adults challenge the appropriateness of these recommendations. In addition, a number of epidemiological studies have found no association or a slight beneficial association between intake of milk and dairy products with variables related to CVD risk. Likewise, recent animal model and human clinical studies indicate that milk fat-derived TFA show no pattern of negative effects on CVD risk. Overall, the available evidence does not provide support for the concept that consumption of dairy products adversely affects the risk of CVD. The growing body of scientific evidence that some of the fatty acids uniquely present in milk fat may have beneficial effects on human health and disease prevention (e.g. conjugated linoleic acid), and the recognition that not all SFA and TFA have the same biological effects, may ultimately challenge the recommendations and current public perception of dairy fats in human diets.

Key Words: Milk Fat, *Trans* Fatty Acids, Saturated Fatty Acids

641 Milk fat globule membrane components and their interactions with lactic acid bacteria. R. Jimenez-Flores*, *California Polytechnic State University, San Luis Obispo.*

Milk and dairy products are in a constant transition that obeys two forces. On the one hand the traditional view of the healthfulness of milk and its wholesome image, on the other the different nutritional trends of sectors of the population. Examples of the latter are obesity and saturated fats, lactose intolerance, preference for organic or raw milk and other emerging consumer issues. In addition, milk and dairy products as a business is subject to the added dimension of a highly political arena. However, this has been the case through most of the history of industrialized civilization. A big driver for innovation in dairy products has always been the ease in which products can address health issues and how technology has made possible production of valuable commodities. In this talk we will exemplify this trend by focusing on the underutilized milk fat globule membrane (MFGM), which is a component in milk with great health and value potential, and the rapidly growing pre- and pre-biotic arena. Several factors are of importance in this presentation: the biological origin of the membrane, the voluminous literature on its individual components and their relationship with health and wellness, the biological role of milk in nutrition to mammals (and their digestive flora) and the innovations in scientific tools being applied in many fields of chemistry and biology. Finally we will analyze the basic scientific information available or lacking for the judicious development of technology and products that fulfill the requirements of biological activity, flavor, and price.

Key Words: Milk Fat Globule Membrane, Lactic Acid Bacteria, Value Added

Symposium: Dairy Foods: Emerging Non-Thermal Food Processing Technologies- Their Potential in Dairy Systems

642 Introduction to non-thermal processing technologies and dairy systems. G. Smithers*, C. Versteeg, and J. Sellahewa, *Food Science Australia, Melbourne & Sydney, Australia.*

Gone are the days when dairy companies could rely exclusively on sales of milk, cheese, powder and butter to thrive. In the 21st century, innovation in the dairy industry will be essential in enhancing international competitiveness in a truly global market. Such innovation will also be critical in meeting consumer demands for 'miracle foods' that are not only safe and nutritious, but also natural, economical to manufacture, convenient, great tasting, environmentally-friendly, and enhance health and well-being – quite a challenge! In meeting these challenges, we must look beyond the norm and traditional, often to new and novel approaches that when adapted and applied in dairy systems will result in innovation together with consumer acceptability. Several non-thermal processing technologies, notably high pressure, power ultrasonics, and pulsed electric field, are creating an impact in food processing around the world. While these technologies have been largely viewed as alternative non-thermal techniques to enhance microbiological safety and quality, they are increasingly being developed for a range of other applications in dairy systems, including (a) improved processing effectiveness; (b) differentiation of ingredients and products including 'tailored' functionality; (c) preservation of heat-labile bioactives; (d) modulation of enzyme activity; (e) improved microstructure through component interactions; and (f) hypoallergenic products. Commercial exploitation of these developments will be dependent upon a sound understanding of the science and technology of the observed effects, suitably scaled equipment, and economic viability. The major non-thermal processing technologies will be introduced, together with an overview of their current and potential applications in dairy systems. This overview will set the scene for subsequent presentations exploring the science underpinning the observed effects, and how this science understanding can accelerate and strengthen commercialization of these non-thermal dairy processes.

Key Words: Non-Thermal Processes, Dairy Products, Functionality

643 Dairy proteins under pressure: Static high pressure processing to modulate the functionality of dairy proteins. P. Udabage*¹, M. A. Augustin¹, I. R. McKinnon², A. Kelly³, and C. Versteeg¹, ¹*CSIRO Food Futures Flagship, Food Science Australia, Werribee, Victoria, Australia*, ²*Monash University, Victoria, Australia*, ³*University College Cork, Cork, Ireland.*

The effects of high pressure processing (HPP; ≤ 400 MPa) at 25°C and at elevated temperatures ($\leq 90^\circ\text{C}$) on the (1) physico-chemical properties of skim milk (2) properties of stirred yoghurt made from pressure treated skim milk and (3) functional properties of other end products were examined. Changes in the calcium and phosphate equilibria and protein aggregates (composition and size) were observed with HPP, the extent of changes depending on the magnitude of the pressure and heat applied. The particle size of the casein micelles decreased with increasing applied pressure when pressure treated at 25°C, suggesting the disintegration of the micelles. When pressure treated at elevated temperatures, the particle size increased with increasing applied pressure, possibly due to aggregation of disintegrated micelles with eventual

precipitation at 400 MPa. These reformed new micelles are anticipated to have distinct physico-chemical and functional properties compared to the original micelles. When compared to stirred yoghurts made with milk given only a conventional heat treatment (90°C/10 min), the magnitude of the pressure applied at 25°C to milk did not affect the viscosity of the yoghurt when a subsequent conventional heat treatment was given to pressure treated milk prior to inoculation. When milk was pressure treated at elevated temperatures with no subsequent heat treatment prior to inoculation, yoghurts of lower viscosities were obtained. In other applications, pressure treatment of raw materials or end products resulted in products of different functionalities. Taken together, the results suggest the ability to promote physico-chemical changes through HPP of raw material or end products, translating to different degrees of changes in end-products. HPP is opening opportunities to control and create novel protein structuring capabilities, thereby potentially reducing the need for additives in formulations and opportunities for cleaner labels.

Key Words: Casein, High Pressure, Properties

644 High pressure treatment and bovine milk proteins. A. L. Kelly*¹, K. Kothari¹, A. Simpson², D. M. Mulvihill¹, P. M. Kelly², T. P. Guinee², and T. P. Beresford², ¹*University College Cork, Cork, Ireland*, ²*Moorepark Food Research Centre, Fermoy, Co. Cork, Ireland.*

High-pressure (HP) treatment of milk has significant effects on proteins. Casein micelles may aggregate or disintegrate and whey proteins denature, depending on the pressure applied. This may, in turn, alter the functional properties of products like cheese, yoghurt and protein-based ingredients. Milk protein co-precipitates, acid gels and microfiltration retentates made from HP-treated skim milk were studied. Protein co-precipitates were made from milks adjusted to two pH values (6.8 or 7.5) and unheated, heat-treated (HT, 90°C for 10 min) or treated at 250 MPa for 30 min, or 400 or 600 MPa for 10 min at 40°C. Co-precipitate recovery was highest from milks that were either HT or HP-treated at 600 MPa, followed by milk HP-treated at 400 or 250 MPa. Co-precipitates made from HP-treated milks had better emulsification properties and heat stability than those made from HT milk. Differences in the whey protein composition of co-precipitates made from either HT or HP treatment were also clear. In separate experiments, reconstituted skim milk subjected to either heat treatment (HT, 85°C for 10 min) or HP- treatment alone (250 MPa or 600 MPa for 30 min at 20°C) or combined HT and HP treatment was used for making stirred yoghurt using a commercial starter culture. Yoghurt made from milk HP-treated at 600 MPa exhibited significantly higher water-holding capacity and was less susceptible to shear-thinning than yoghurt made from HT milk. Scanning electron micrographs indicated that HP treatment at 600 MPa alone or in combination with HT resulted in a more compact gel network and lower porosity than HT. In separate studies, when phosphocasein (PC) was reconstituted in simulated milk ultrafiltrate, HP-treated, and processed through a laboratory scale micro-filtration (MF) plant using a 1.4-micron membrane with co-current permeate flow, quantitative but not qualitative differences in protein partition between permeate and retentate occurred.

Key Words: High Pressure, Milk, Functionality

645 Microstructural effects in thermo-sonicated yogurt and other dairy products: Understanding and exploiting the science.

G. V. Barbosa-Canovas* and D. Bermudez-Aguirre, *Washington State University, Pullman.*

One of the main goals of nonthermal technologies is to optimize the quality and safety of processed products minimizing the use of heat. Ultrasound has had positive effects on the final quality of milk and other dairy products where important improvements include enhanced color, appearance, texture, and stability. Scientifically speaking, these improvements are due to the homogenization effect in milk generated by ultrasonic waves. From a microstructural perspective, a new and fascinating universe emerges where important changes occur in the milk microstructure and size of fat globules, as reflected in macro scale, revealing whiter color, better appearance and physical properties. Fat globules (average size, 4 µm) in raw milk are disrupted by ultrasound and reduced in size (smaller than 1 µm); thousands are generated with similar volume and appearance. Ultrasound, combined or not with thermal treatments, could reduce specific quality problems in other dairy products like yogurt, a product highly consumed worldwide. Thermo-sonication involves two simultaneous processing steps: pasteurization and homogenization. As with milk, this dual process improves the quality of the yogurt characteristics, yielding a more homogeneous protein/fat matrix, better stability, whiter color, and improved texture, resulting from a reduction and regrouping of milk components and interaction with the yogurt remaining ingredients. Indeed thermo-sonication is a viable alternative for processing milk, yogurt, and other dairy products, with important cost/time savings as well.

646 Membrane and other processing technologies for dairy fluids: Effectiveness of ultrasound in enhancing productivity. R. Mawson¹, S. Kentish², M. Ashokkumar², S. Udabage¹, and M. Golding*¹, ¹*Food Science Australia, Werribee, Victoria, Australia*, ²*University of Melbourne, Melbourne, Victoria, Australia.*

In water the interaction between (ultra) sound waves and dissolved gas nuclei results in acoustic cavitation, nuclei grow by rectified diffusion and inertial collapse of resonance-sized microbubbles. Acoustic cavitation generates physical effects, including agitation, microstreaming, and enhanced mass transport. In some conditions near adiabatic collapse generates very high temperatures and pressures within the cavitation bubbles leading to the formation of reactive radicals that can be managed or used for desired chemical transformations. Ultrasound use in the dairy industry includes cleaning plastic cheese moulds, and at low sub-cavitation intensity for monitoring product quality of Swiss cheeses, the presence of flat sour spoilage in aseptically packaged milk and levels in tanks. Ultrasonic spectroscopy is now an accepted laboratory tool for analysing molecular level transformations that can occur during processing dairy products.

Historically, the main impediment to applying ultrasound in dairy processing was the lack of suitable equipment for large scale application. Currently, equipment suitable for production scale exists, but the specific knowledge of application to dairy processing is lacking. Laboratory studies determine that ultrasound can be effective in reducing microbial counts in milk, inhibiting or enhancing enzymic activity, improving the quality of cheeses and yoghurts, incorporating nutraceuticals, raising the productivity of membrane processing, and reducing fouling of heated surfaces. Based on laboratory studies, the use of ultrasound for killing

microorganisms or inhibiting enzymes have been dismissed as being of little advantage in terms of effectiveness and high energy usage whilst adding to processing complexity. However, for other applications the ultrasonic energy required is low and scaling up to production scale with significant savings in processing cost is feasible.

Key Words: Ultrasound, Membranes, Enzymes

647 Microbial safety and bioactive efficacy: Effectiveness of pulsed electric field processing of dairy fluids. J. Wan*¹, K. Shamsi², Q. Sui³, D. Bermudez-Aguirre⁴, C. P. Dunne⁵, G. Barbosa-Canovas⁴, and C. Versteeg¹, ¹*Innovative Foods Center, Food Science Australia, Melbourne, Australia*, ²*RMIT University, Melbourne, Australia*, ³*University of Melbourne, Melbourne, Australia*, ⁴*Washington State University, Pullman*, ⁵*US Army Natick Soldier Center, MA.*

Value-added dairy ingredients with demonstrated biological properties, including lactoferrin (LF) and lactoperoxidase (LP), have attracted great attention in recent years due to applications in functional foods and nutraceuticals. Most of these bioactive dairy ingredients are proteins and their biological properties are often compromised during conventional heat processing. In the current study, the effect of pulsed electric field (PEF) in combination with moderate temperatures (30-70°C) on the survival of microorganisms and the activity of LF and LP in milk was evaluated.

PEF treatments were conducted using an OSU-4 system with a field intensity of 33 kV/cm, pulse width 2 µs, total treatment time 20 µs, and total specific energy input 120 kJ/L. For each temperature, controls were prepared by processing samples in the PEF unit without the electric pulses.

In the challenge experiments using inoculated (10⁶⁻⁷ CFU/ml) UHT milk, PEF resulted in >6 log reduction on *Pseudomonas fluorescens* ATCC 948 and *Salmonella* Typhimurium ATCC 14028 at 60°C. However, *Listeria monocytogenes* NCTC 11994 and *Enterococcus faecalis* ATCC 19433 required 65 and 70°C, respectively, to achieve a 6-log inactivation. The controls at the respective temperatures had less than 1 log reduction. PEF treatment at 5-10°C below the temperatures identified above resulted in only 1-2 log reduction on each of these target organisms.

PEF treatment at 65°C of cold stored raw milk (with an initial total plate count of 10⁶ CFU/ml) resulted in a 5 log reduction, and the count of enterobacteriaceae was reduced from 10² to <1 CFU/ml. Over 85% of the LF (by ELISA) and LP (by enzyme activity assay) were recovered after the PEF treatment.

These results suggest that PEF in combination with mild heat can be used for effective microbial inactivation in milk while preserving LF and LP activities.

Key Words: Pulsed Electric Field, Lactoferrin, Lactoperoxidase

648 High pressure processing of colostrum. T. Carroll*, *Fonterra Co-operative Group Ltd., Palmerston North, New Zealand.*

Bovine colostrum is rich in bioactive components, such as immunoglobulins and lactoferrin, that may provide health benefits to consumers. Delivering these bioactive components in a consumer-friendly format with a commercially-useful shelf-life is a challenge, because they are relatively sensitive to denaturing by traditional thermal preservation.

Colostrum consumer products are generally formulated dry, in formats such as powders, tablets or capsules or as a fresh pasteurised liquid with a shelf-life of several days. Immunoglobulins in particular can not withstand UHT or heat-sterilisation processes, although they do survive thermal pasteurisation well. Unfortunately immunoglobulin proteins are particularly heat-sensitive under acidic conditions, where microbial stability might be achieved by milder thermal processing than at near neutral pH. The effect of pressure on immunoglobulins as a function of pH is found to be the opposite of the effect of heat; specifically immunoglobulin proteins are less sensitive to pressure denaturation under acidic conditions than they are at near-neutral. This finding creates the possibility of using high pressure processing, a non-thermal food preservation technology, to produce a ready-to-drink colostrum beverage with a commercially-useful shelf-life. High pressure processing offers microbial stability in acidified dairy systems, as spoilage micro-organisms that can grow are inactivated by pressure (eg lactic acid bacteria, yeast and mold) and micro-organisms that are not inactivated by pressure cannot grow (eg bacterial spores). Immunoglobulins and other bioactive components in colostrum are well-retained under the high pressure processing conditions that are required to achieve microbial stability in an acidified colostrum beverage model.

Key Words: High Pressure Processing, Colostrum, Immunoglobulin

649 Enhancing the quality of whey protein functionality using high pressure. S. Clark*, X. Liu, S.-Y. Lim, J. Chauhan, and C. Padiernos, *Washington State University, Pullman*.

Four studies were designed to investigate the potential for high hydrostatic pressure (HHP) of whey protein concentrate (WPC) to improve the

quality of lowfat ice cream and lowfat whipping cream. The initial study investigated flavor-binding properties of WPC treated at 600 MPa for 30 min at an initial temperature of 50°C. The treatments enhanced binding of certain flavor compounds but not others, suggesting a need for follow-up studies in real food systems. Subsequent studies involved treatment of fresh, ultrafiltered Cheddar cheese whey (fresh WPC) at 300 MPa for 15 min at an initial temperature of 25°C. The treatment maintained fresh WPC solubility and demonstrated improved foaming properties of fresh WPC. A variety of lowfat ice cream mix and lowfat whipping cream products were formulated and evaluated using instrumental and sensory analysis tests. Headspace-SPME-GC demonstrated that lowfat ice cream with HHP-treated fresh WPC plus diacetyl exhibited higher concentration of diacetyl than untreated fresh WPC plus diacetyl after 1 day of storage, but the diacetyl binding was not maintained up to day 14. Additionally, sensory evaluation revealed that panelists could not distinguish between ice cream containing untreated or HHP-treated fresh WPC. Although flavor was minimally impacted, HHP treatment of fresh WPC enhanced overrun and foam stability of ice cream and whipped cream. Additionally, sensory panelists were able to distinguish some differences among ice creams and whipped creams. HHP can alter foaming properties of fresh WPC significantly enough for differences to be noted in a product even when the modified ingredient is used at levels as low as 10% in a formulation.

Extension Education: All Species

650 A tool to optimize the length of time a boar is in an A.I. stud. J. S. Fix*¹, M. T. See¹, and D. S. Casey², ¹*North Carolina State University, Raleigh*, ²*Pig Improvement Company, Hendersonville, TN*.

The objective of this study was to develop a decision-tool that determines the optimum length of time a boar should be utilized in an AI program. The time in stud depends on two conflicting perspectives. The semen customer desires semen from genetically superior boars which tends to be the younger boars. The boar stud wants to increase profit margin by dividing costs over large quantities of quality semen. This typically occurs as boars become older. Since the two prefer to be on opposite ends of the boar's life an optimum situation must be determined. Every week the customer receives semen from a boar that could be replaced with a genetically superior boar, there is value lost by the customer. The total value lost per week per boar can be calculated using the following variables: difference in index points between a given boar and a potential replacement, value of an index point per marketed pig, pigs marketed per litter, doses per mating and doses of semen per week. To determine the weekly cost associated with maintaining a boar the following values are needed: boar purchase price (salvage value and % death loss), isolation cost, production cost per boar space (feed, building, etc.), collection labor per collection, post collection costs per dose (lab, shipping, etc.), royalty cost (if applicable), weeks in production and doses per week. These values are then used to determine value lost to the customer per week and a cost per week for the boar stud. The intersection of the two curves is where this optimum occurs. If we assume an average index for replacement boars then an index threshold at which a boar should be culled for a given age can be calculated. A spreadsheet was developed that allows for easy input of boar stud specific inputs and calculates the index level at which culling should occur. Average cull age and annual cull rate are also given based on an assumed index decline and non-index culling levels. This tool allows a boar stud manager to make important culling and management decisions that are balanced between the boar stud's and semen customer's perspectives.

Key Words: Boar Stud, Index Management

651 State funded genetic enhancement programs: An example from Tennessee. M. L. Spangler*¹ and D. Kirkpatrick², ¹*University of Nebraska, Lincoln*, ²*University of Tennessee, Knoxville*.

In 2005, the Tennessee Department of Agriculture started an Agricultural Enhancement program in an effort to provide funds to educate producers and increase their profitability. These funds are available for several areas of production including beef cattle genetics. The program allows producers who are residents of Tennessee and who own a minimum of 10 cows to apply for funds when purchasing or leasing a bull or for the cost of artificial insemination (AI). For the fiscal year 2007-2008, maximum cost share funds per producer are \$1,025 including \$175 for herd evaluations and 35% of the total cost of bull purchase/lease or AI up to \$850. If the producer has completed Tennessee's Master Beef Producer course then the cost share maximum increases to 50% of the cost for bull purchase/lease or AI up to \$1,000. For a producer to receive these funds, bulls must meet certain genetic criteria. Currently those criteria are for a bull to rank within the top 50% of their respective breed for two of four traits: Birth weight (BW), weaning weight (WW), maternal milk (MM), or yearling weight (YW). In the first two years of

the program, approximately 1,600 bulls qualified for cost share, 73% of which were Angus. Although the current system forces commercial producers to consider EPDs in the selection process, it inevitably leads them to single trait selection for growth, or even worse, to bulls who are below breed average for economically relevant traits. Currently, it would be possible for a bull to qualify by ranking in the top 50% of their respective breed for WW and YW, but be above breed average for BW and below breed average for MM. The current study proposes a three-category system including: Heifer safe, terminal, and balanced. The heifer safe category emphasizes low BW animals and places minimums on WW and YW. The terminal category places emphasis on WW and YW and maximums on BW. The balanced category places minimums for WW and YW, maximums for BW, and an acceptable window for MM. The new guidelines attempt to avoid the inevitable single trait selection that the current system allows and to emphasize the original goals of enhancing profitability and education.

652 Transferring technology to beef producers in Missouri to facilitate expanded use of estrus synchronization and AI. D. C. Busch*¹, N. R. Leitman¹, D. A. Mallory¹, J. F. Bader², D. J. Wilson¹, S. E. Pooch¹, M. F. Smith¹, and D. J. Patterson¹, ¹*University of Missouri, Columbia*, ²*Merial Limited, Fulton, MO*.

Limited transfer of existing and emerging reproductive technologies (estrus synchronization and AI) to beef enterprises precludes those enterprises from reaching their economic potential and places them at a competitive disadvantage relative to livestock enterprises where such technologies are being implemented more aggressively. However, pregnancy rates in postpartum beef cows in the range of 60% or higher resulting from AI performed at predetermined fixed times are now achievable. Since the spring of 2006, our extension group at the University of Missouri has worked directly with 23 different cow-calf producers in Missouri to demonstrate on farm use of estrus synchronization and fixed-time AI (FTAI). On those 23 farms, 1860/3107 (60%) cows conceived to a single FTAI (CO-Synch + CIDR with FTAI at 66 h) on the first day of the breeding season based on pregnancy diagnosis via transrectal ultrasonography. Current calving data following FTAI with the field demonstrations indicate an increase in calf age ranging from 6 to 22 days in comparison to the previous year's calving profiles resulting from performing AI based on detected estrus following estrus synchronization or using natural service. This results in older, heavier, and more uniform calves at weaning. In addition, seven educational meetings with approximately 400 people in attendance have been held in conjunction with field demonstrations to review results highlighting successes that are occurring with FTAI in cows in various regions in the state. Information is presented which reviews criteria for beef cows prior to initiation of a FTAI program, ways to implement specific estrus synchronization protocols that work effectively with FTAI, and the expected improvement in calving distribution, genetics, and carcass quality of calves that result from AI sires with high accuracies for various production and carcass traits. In summary, beef operations in Missouri are realizing improvements in reproductive management and genetics resulting from FTAI to genetically proven superior sires. This project is supported by USDA-NRI grant 2005-55203-15750.

653 Evaluation of on-farm pasteurization systems. J. A. Elizondo-Salazar*^{1,2}, C. F. Vargas-Rodríguez², S. C. Donaldson¹, B. M. Jayarao¹, and A. J. Heinrichs¹, ¹The Pennsylvania State University, University Park, ²Estación Experimental Alfredo Volio Mata, Costa Rica.

Waste milk has been fed to calves for many years but concerns with bacteria contamination as well as possible transmission of diseases through feeding waste milk have discouraged many producers from feeding calves with this milk. Pasteurization of waste milk is one option to reduce management risk while utilizing a valuable, low cost liquid feed source for calves. However, many farms lack a protocol to adequately monitor the efficiency of their pasteurizing system. A study was carried out to evaluate on-farm pasteurization systems using 6 farms with different pasteurization systems, including both HTST and batch pasteurizers. Milk samples were taken pre- and post pasteurization and immediately frozen to -20°C for later bacterial culture. Samples were taken for a period of approximately 15 d, twice daily. All milk samples were examined for standard plate count (SPC), coagulase-negative staphylococci (CNS) count, environmental streptococci (ES) count, coliform (CC) count, gram-negative noncoliform (NC) count, *Streptococcus agalactiae* (SAG) count, and *Staphylococcus aureus* (SA) count. The SPC from all farms in the pre-pasteurized samples ranged from 7,415 to 250,822 CFU/mL while in the post-pasteurized samples ranged from 461 to 30,625 CFU/mL. Pasteurization reduced the SPC to < 10% of the original count in 81% (range 53 to 100%) of the samples. CNS count was reduced to < 10% of the original count in 86% (range 52 to 100%), meanwhile CC was reduced in 83% (range 52 to 97%) of the samples, meaning that pasteurization systems effectively reduced the bacteria counts of waste milk. However, 2 farms did not reduce the bacterial population in approximately 50% of the samples, suggesting that incomplete pasteurization may be a common problem and monitoring pasteurizer performance is an important step in assuring the quality of waste milk after pasteurization.

Key Words: Pasteurization, Waste Milk, Bacteria

654 Managing the newly created livestock gross margin for dairy (LGM-Dairy) insurance under seasonal climate variability. V. E. Cabrera*¹ and D. Solis², ¹New Mexico State University, Clovis, ²University of Miami, Tallahassee, FL.

By July 2008, dairy farmers in 35 states will be able to lock-in their margins through the new livestock gross margin for dairy insurance (LGM-Dairy). LGM-Dairy is a risk management tool that allows farmers to hedge against loss of gross margin (market value of milk minus feed costs). LGM-Dairy gives farmers a way to control volatility in feed costs and milk prices. Farmers will estimate the volume of milk to be sold and the amount of feed (equivalents to corn and soybean) to be bought each month. Then, the expected gross margin (EGM) will be calculated using the Chicago Mercantile Exchange Class III milk futures and the Chicago Board of Trade corn and soybean futures. Prices for milk and corn (not soybeans) will be adjusted monthly by state. If the EGM is greater than the actual gross margin, the farmer will be paid an indemnity according to a selected deductible. Seasonal climate variability (e.g., El Niño Southern Oscillation) may impact feed costs and milk prices as well as milk production and feed consumption. Consequently, advancements in

climate forecasting could play an important role in assisting farmers to decide on the most appropriate risk management strategy. The goal of this study is to offer an analytical tool to help farmers select the optimum level of LGM-Dairy when accounting for seasonal climatic variability. This paper (1) characterizes the historical climate impacts on dairy profit margins; (2) systematizes the indemnity calculation of LGM-Dairy; (3) introduces climate uncertainties to the optimal selection of a LGM-Dairy contract; and (4) explores the potential economic outcomes of locking-in margins under uncertain climatic conditions. Preliminary results indicate that seasonal climate variability impacts feed costs, milk production, feed consumption and milk price. Dairy producers could use climate forecasting to decide if it is convenient to purchase LGM-Dairy and at what EGM level. Under El Niño climate forecast, with expected above average feed costs, LGM-Dairy purchase with low or no deductible would be advisable, whereas during La Niña climate forecast a low premium or no LGM-Dairy would be a better option.

655 A stochastic simulation model for assessment of investments in Precision Dairy Farming technologies: Model enhancements and utility demonstration. J. M. Bewley*¹, M. D. Boehlje¹, A. W. Gray¹, H. Hogeveen², S. D. Eicher³, and M. M. Schutz¹, ¹Purdue University, West Lafayette, IN, ²Utrecht University, Utrecht, The Netherlands, ³USDA-ARS, West Lafayette, IN.

A previously described stochastic simulation model of a dairy enterprise was modified for improved robustness. This model was developed to evaluate investments in Precision Dairy Farming technologies and was constructed to embody the biological and economic complexities of a dairy farm system within a partial budgeting framework. The @Risk add-in (Palisade Corp., Ithaca, NY) for Microsoft Excel was utilized to account for the stochastic nature of key variables by Monte Carlo simulation. The model comprised a series of modules, which synergistically provide the required inputs for profitability analysis. Model enhancements included addition of a retention pay-off (RPO) module to calculate cost of culling, an average cow simulation module, a body condition score module, a herd size control algorithm, a best management practice adherence factor, a technology stage adjustment factor, and updated, literature-based estimates for disease impact. Technology benefits are appraised from changes in disease incidence, disease impact, and reproductive performance. The influence of stochastic input and output prices on RPO, days open (DO), and disease was examined with 5000 iterations of a simulation of an average 1000-cow US dairy herd. For example, during the first month of the first lactation, increasing replacement price, slaughter price, milk price, or feed cost by 1 SD changed RPO by +\$196.39, -\$80.08, -\$9.02, and -\$2.16, respectively. As slaughter price, feed cost, milk price, and replacement price increased by 1 SD, the cost of a DO changed by -\$0.24, -\$0.23, +\$0.20, and +\$0.20, respectively. Sensitivity for costs of displaced abomasum, dystocia, ketosis, mastitis, metritis, retained placenta, and milk fever were also investigated. The RPO, DO costs, and disease costs were highly sensitive to stochastic prices and deterministic inputs.

Key Words: Investment Analysis, Precision Dairy Farming, Stochastic Simulation

656 Assessing the potential value of automated body condition scoring through stochastic simulation. J. M. Bewley*¹, M. D. Boehlje¹, A. W. Gray¹, H. Hogeveen², S. D. Eicher³, and M. M. Schutz¹, ¹Purdue University, West Lafayette, IN, ²Utrecht University, Utrecht, The Netherlands, ³USDA-ARS, West Lafayette, IN.

Automated body condition scoring (BCS) using digital images has been shown to be feasible. The primary objective of this research was to identify factors that influence the profitability of investment in an automated BCS system. An expert opinion survey was conducted to provide estimates of potential improvements arising from adoption of this technology. Experts indicated that the most important benefits would be disease reduction followed by nutritional cohort management, reproduction, animal well-being, energy efficiency, and genetics. A stochastic simulation model of a dairy farm was utilized to perform a Net Present Value (NPV) analysis. Benefits of automated BCS were estimated by assessing the impact of BCS on incidences of ketosis, milk fever, and metritis, conception rate at first service, and energy efficiency. Improved reproductive performance had the largest influence on revenues followed by energy efficiency and disease reduction. Stochastic variables having the most influence on NPV were: variable cost increases; odds ratios for incidences of ketosis and milk fever, and conception rates at first service; uncertainty of the impact of ketosis, milk fever, and metritis on days open, unrealized milk, veterinary costs, labor, and discarded milk; and change in the percentage of cows with BCS of ≤ 3.25 at calving before and after technology adoption. The deterministic inputs impacting NPV were herd size, management level, and milk production. Investment in this technology may be profitable, but results were herd-specific. A simulation modeling a deterministic 25% decrease in the percentage of cows with BCS of ≤ 3.25 at calving showed a positive NPV in 87.8% of 1000 iterations. Investment profitability was highly dependent on the current BCS distribution, the magnitude of negative impacts of extreme BCS, and management capacity to make changes necessary to achieve optimal BCS.

Key Words: Body Condition Scoring, Investment Analysis, Stochastic Simulation

657 Analysis of corn distillers grain for expansion of the FeedAC database to include pre-digestion fractionated high protein distillers' grains (HP-DG). T. R. Johnson*¹, J. Goodson², D. P. Casper³, T. J. Applegate⁴, K. E. Ilieji⁴, B. T. Ulrich⁵, F. P. Lundy, III⁶, and C. G. Schwab⁷, ¹Dairy Nutrient Management Systems, Noblesville, IN, ²Degussa, Inc., Kennesaw GA, ³Agri-King, Inc., Fulton, IL, ⁴Purdue University, West Lafayette, IN, ⁵Mor Technology, LLC., Metropolis, IL, ⁶FEED AC, Inc., Homer, NY, ⁷University of NH, Durham, NH.

The Feed Analysis Consortium (FeedAC) was incorporated in 2006 with the mission of creating a cooperatively shared, comprehensive and evolving database of feed analysis. The idea for creating FeedAC sprang from the last author's interaction with feed industry personnel as he helped in the preparation of Nutrient Requirements of Dairy Cattle (NRC, 2001). In this publication, Tables 15-1 to 15-4 were created to reflect the current knowledge of feedstuff composition. However, static tables that do not allow changes in composition or addition of new ingredients have limited usefulness. The web-based nature of the FeedAC database will allow it to follow the evolution of feed ingredients, processing, and analytical techniques and remain current. The rapid expansion of ethanol distilleries, implementation of new and different processing techniques and pre fermentation fractionation creates

challenges. The goal is to collect data using wet chemical analysis and NIRS analysis for creation of better predictive equations. Two specific challenges are grouping and analysis of diverse DG and DDGS products for NIRS derived prediction equations and the inclusion of values far from the mean with elimination of blatant outliers in calibration datasets. Study of statistical models used by plant scientists in the building of prediction models may assist animal scientists in forming models with greater utility and a low prediction error. Mean chemical composition of a sample of fractionated high protein distillers' grain (HP-DG) from S.E.M.O. Milling, (Mor Technology, LLC) is compared with NRC (2001) values for DDGS in the accompanying table.

Table 1. Mean Chemical Composition and HPLC Amino Acid Analysis¹

Item	DM, %	CP, %	ADF, %	EE, %	Ash, %	P, %	LYS, %	MET, %	CYS, %

658 Development of a software to calculate pollutant emissions, resources consumption and best available techniques effects from Spanish farms. C. Pineiro*¹, G. Montalvo², M. A. Garcia², M. Herero³, and M. Bigeriego⁴, ¹PigCHAMP Pro Europa, S.A., Segovia, Spain, ²Tragsega, S.A., Madrid, Spain, ³Feaspor, Segovia, Spain, ⁴Spanish Ministry of Agriculture, Fisheries and Food, Madrid, Spain.

The intensification of animal production has become a serious threat to the environment, mainly in the form of emissions into the air, the ground or the water. There are recent directives, such as the European Integrated Pollution Prevention and Control, or IPPC, which are aimed to decrease the emissions and to save the resources (water and energy) through the promotion of good agricultural practices and the so called Best Available Techniques, or BAT, at farm level. Since this directive considers the whole production chain, including the effects of nutrition, facilities design, slurry storage and spreading, it is not always easy to calculate overall farm emissions and the influence of every BAT applied. That is the reason why a software to integrate all of these factors and its influence in emissions and water and energy consumption has been developed. The data base used for the emission calculations was the same as for the National Emission Inventory. To calculate pollutant emission at each stage, the application used a mass-balance system. With this tool, farmers and technicians are able to calculate ammonia, methane and nitrous oxide emissions, considering the influence of the BAT used along all of the productive process. This information is requested by the European Pollutant Emission Register notifications for farms under European regulation (Council Directive 96/61/EC). Furthermore, it is possible to estimate water and energy savings when BAT are implemented. The software also provides to the user improvement proposals to be implemented at farm. The impact on change in agriculture sector will be that, as an add-on tool, farmers and technicians can achieve further information about the BAT effect in order to improve the environmental situation of their farms. As conclusion, this software

is an interesting tool to promote good environmental practices in farms, indispensable with current international policies.

659 Using an iClicker audience response system to engage participants in extension programs. J. Andrae*, *Clemson University, Clemson, SC.*

Students, producers and Extension professionals are exposed to many Powerpoint presentations at educational events. While Powerpoint slide presentations can be effective, this passive education method can actually discourage audience discussion and interaction. An electronic audience response system (iClicker; <http://www.iClicker.com>) was field-tested to determine its acceptability and usefulness in forage Extension programs. The system was developed for use in college classrooms and is composed of a 915 MHz receiver with up to 1500 hand held transponders. It is compatible with both Windows and OS X operating systems. These remote control style transponders allow the audience to

answer multiple choice questions imbedded in Powerpoint presentations in a Who Wants to Be a Millionaire style. Audience answers are pooled and immediately displayed, allowing reinforcement of information or redirection of programs to fit audience needs. The system was tested in county, multi-county, statewide, and regional Extension programs across the southeastern U.S. Audience members were grouped by table during each presentation and assigned a common transponder (one shared transponder for 4-8 people and typically 20 groups per audience). Approximately 6-8 questions were delivered in each 45 minute presentation on topics including beef cattle management myths, forage species and grazing intensity information. Each group was allowed to debate answers for 30 seconds to 1 minute before responding. The group format encouraged discussion, particularly in large forums, and fostered interaction among audience members. Following each presentation, the audience was asked to "rate the iClicker system for effectiveness of teaching" on a scale of 1-5 (A-E) using the transponder. To date (n=178), over 90% have selected the highest ranking (A) with 9% assigning a rating of B. The iClicker system appears to be an effective tool for fostering audience interaction and improving the educational experience in traditional Extension presentations.

Growth and Development: General Topics

660 Ovariectomy alters myoepithelial cell populations in the prepubertal bovine mammary gland. K. E. Ballagh¹, N. Korn¹, L. Riggs², R. M. Akers³, and S. Ellis*¹, ¹Clemson University, Clemson, SC, ²Louisiana State University, Baton Rouge, ³Virginia Polytechnic Institute and State University, Blacksburg.

Allometric growth of the bovine mammary gland is stimulated by ovarian secretions in pre-weaning calves. Prepubertal ovariectomy inhibits mammary development, but the mechanism of inhibition is not well characterized. Holstein heifers (n=37) were ovariectomized at d40 and sacrificed at d55, 70, 85, 100, 130, and 160 to provide tissues for analysis of ovariectomy effects. Histologic analyses unexpectedly revealed that ovariectomy caused myoepithelial development and striking changes in basal epithelial cell morphology, compared to intact animals. Myoepithelial cells were identified by location, morphology, and positive staining for α -smooth muscle actin (SMA+). At least 1000 cells from 3-5 non-sequential sections and 15 or more randomly selected fields were counted per sample. Vascular smooth muscle staining served as an internal positive control for SMA staining. Z-tests and adjusted P-values (Bonferroni's) were used to compare the proportion of SMA+ basal cells between treatment groups. In d40 heifers, 80% (P<0.05) of basal epithelial cells were SMA+. Significant differences in SMA labeling were observed between ovariectomized (OVX) and intact (INT) animals at d55 (OVX 51% vs. INT 27%; P<0.05), d70 (OVX 59% vs. INT 0%; P<0.05), d85 (OVX 86% vs. INT 0.3%; P<0.05), d100 (OVX 44% vs. INT 0.6%; P<0.05), d130 (OVX 100% vs. INT 0.3%; P<0.05), and d160 (OVX 74% vs. 0%; P<0.05). We hypothesize that ovarian secretions block myoepithelial differentiation. Myoepithelial cells can limit parenchymal development through expression of growth factors, proteinase inhibitors and anti-angiogenic proteins and have been shown to inhibit tumor cell proliferation. Ovariectomy may therefore remove an estrogenic growth stimulus and permit emergence of myoepithelial cell populations that inhibit parenchymal development.

661 Dihydroxy vitamin D affects the myogenic potential of porcine satellite cells. A. Qu¹, R. P. Rhoads², and C. H. Stahl*³, ¹Iowa State University, Ames, ²University of Arizona, Tucson, ³North Carolina State University, Raleigh.

Satellite cells are needed for the growth and development of muscle, but the strict commitment of satellite cells to a myogenic lineage has been challenged recently. Myogenic cultures have been diverted from their myogenic fate into an alternate mesenchymal differentiation pathway. We examined the impact of 1,25 (OH)₂ Vitamin D on porcine satellite cells in vitro. Satellite cells were isolated from the loin muscle of 14 d old pigs, placed in proliferative media (PM, DMEM + 10%FBS), incubated at 37°C in 5% CO₂, and media was changed daily until the cells reached 60-80% confluence. Cells were then harvested, counted, and seeded into poly-L-lysine and fibronectin coated 24-wells plate at 1,000 cells/well. Cells were given 24 h to attach and were then switched to their respective treatment media. The treatments were: control (PM), PM + 2×10⁻⁹ M 1,25 (OH)₂ vitamin D (1X VitD), and PM + 2×10⁻⁸ M 1,25 (OH)₂ vitamin D (10X VitD). Complete media changes were made daily. At 3, 6, and 9 days post treatment, cells were harvested for cytochemical staining and gene expression analysis. All experiments

were repeated as two independent studies. Within each study, n = 2 for cytochemical staining and n = 4 for gene expression analysis. Study, day, treatment and day*treatment were considered fixed effects. Statistical significance was set at P < 0.05.

After 6 days, the vast majority of the control cells (>95%) stained positive for desmin. However, after 6 days of Vit D treatment, only approximately 25% of the cells stained positive for desmin. Although there appeared to be fewer desmin-positive stained cells with the 10X VitD versus the 1X Vit D treatment, this difference was not statistically significant. The gene expression of both MyoD and Myogenin was significantly reduced (P < 0.05), in a dose dependant manner, after 6 and 9 d of treatment with VitD. Based on these data, we conclude that 1,25 (OH)₂ vitamin D inhibits the myogenic differentiation of satellite cells. Since circulating levels of 1,25 (OH)₂ vitamin D are seen with dietary P deficiency, this may help explain the molecular basis for reduced muscle growth seen with dietary P deficiency.

Key Words: Satellite Cells, Vitamin D, Pig

662 Calpain and calpastatin mRNA expressions in skeletal muscle are highly correlated with protein accretion activities in neonatal pigs. Z. Li*¹, B. Zhao¹, X. Yang², M. Z. Fan², and J. Yang¹, ¹University of Hawaii, Honolulu, ²University of Guelph, Guelph, ON, Canada.

The calpain-calpastatin system plays a significant role in the regulation of protein degradation in the skeletal muscle. Rapid gain in skeletal muscle mass during the neonatal period is one of the most significant physiological events in life. Little is known about protein degradation during the muscle gain. To understand the role of calpain-calpastatin system in muscle growth, we randomly selected 36 neonatal pigs from more than 10 litters. The piglets were divided into six groups and slaughtered at the age of 1, 4, 6, 12, 20 and 28 days. The expression patterns of calpain 1A, calpain 2, calpain 3A, calpastatin type 1, type 2, and type 3, obtained by quantitative real-time PCR analysis, and their correlations with the measurements of muscle protein accumulations such as protein content and RNA/protein ratio were studied. The mRNA levels of all the six genes at the age of 4 to 6 days showed a decrease by 2-4 folds compared with 1-day-old piglets. Then they were maintained at relatively low expression levels until 28 days of age. The expressions of the six calpain and calpastatin genes were highly correlated with each other, and showed significant correlations with muscle protein content, RNA/protein ratio and protein/DNA ratio. Expressions of calpain 1A, calpastatin type 1 and type 3 were also negatively correlated with birth weight and fractional rate of growth. Analysis of the expressions of calpain-calpastatin genes by quantitative real-time PCR method can be used for identifications of piglets with increased muscle protein accretion activities.

Key Words: Calpain and Calpastatin, Muscle Protein Deposition, Neonatal Pigs

663 A low-fat liquid diet decreases AMPK and increases mTOR phosphorylation in skeletal muscle of 10-day-old pigs. W. Oliver* and J. Miles, USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.

Previous research shows that neonatal pigs respond to decreases in energy density of liquid diets with increased feed intake, resulting in similar performance to pigs fed a more energy-dense diet. The objective of this experiment was to determine if a high- (25%, HF) or low-fat (2%, LF) liquid diet affects proteins involved in energy homeostasis and protein synthesis in early-weaned pigs. Forty-eight pigs, with an initial body weight of $3,637 \pm 85$ g, were weaned at 10 d of age and utilized in a randomized complete block design. Pigs were blocked by weight and gender, then assigned to pens (8 pigs/pen). Diets were formulated to provide a constant lysine:ME and were fed for 10 d, at which time blood and longissimus dorsi were collected. Blood was analyzed for plasma urea nitrogen (PUN) and NEFA. Longissimus dorsi was analyzed via western immunoblot for mammalian target of rapamycin (mTOR) and adenosine 5' monophosphate-activated protein kinase (AMPK) phosphorylation. Pigs gained 347 ± 11 g/d, which resulted in an ending body weight of $7,035 \pm 170$ g, regardless of dietary treatment ($P > 0.20$). Pigs fed a LF diet consumed approximately 24% more milk than pigs fed the HF diet ($2,853 \pm 23$ vs. $2,309 \pm 65$ g dry feed \cdot pen $^{-1}\cdot$ d $^{-1}$; $P < 0.01$), which resulted in similar calculated ME intakes between dietary treatments (9.9 ± 0.2 vs. 10.7 ± 0.5 Mcal \cdot pen $^{-1}\cdot$ d $^{-1}$; $P > 0.10$). Feed conversion (gain:feed) was 19% higher in HF compared to LF fed pigs ($P < 0.03$). Circulating NEFA (137 ± 37 vs. 39 ± 13 μ Eq/L; $P < 0.02$) and PUN (17.6 ± 0.8 vs. 3.0 ± 0.6 mM; $P < 0.01$) concentrations were higher in HF pigs compared to LF pigs. The AMPK phosphorylation was 29% higher ($P < 0.03$) in HF pigs compared to LF pigs, while mTOR phosphorylation was increased by 22% in LF pigs ($P < 0.02$). Thus, young pigs consuming a low-fat diet have lower activation of AMPK and higher activation of mTOR, which, considering the difference in PUN, may indicate an improved utilization of amino acids in young pigs consuming a low-fat diet.

664 Media components including exogenous lipid and PPAR- γ agonists influence the differentiation of primary bovine adipocytes *in vitro*. A. J. Lengi and B. A. Corl*, *Virginia Polytechnic Institute and State University, Blacksburg.*

Our objectives were to isolate bovine stromal-vascular (SV) cells using explants and determine media components that promote differentiation into mature adipocytes for studies of lipogenic enzyme regulation. Three published differentiation protocols utilizing DMEM were evaluated initially: (A) 10% serum, 50 ng/mL insulin (INS), 0.25 μ M dexamethasone (DEX), 5 mM octanoate, 10 mM acetate; (B) 10 μ g/mL INS, 0.25 μ M DEX, 0.5 mM isobutylmethylxanthine (IBMX), 1 mM octanoate, 2% Intralipid; (C) 5% serum, 2.5 μ g/mL INS, 0.25 μ M DEX, 0.5 mM IBMX, 5 μ M troglitazone. DEX and IBMX were removed from media B and C after 48 h. SV cells were treated with differentiation media for 8 d after reaching confluence. Differentiation was assessed by measuring radiolabeled acetate incorporation into lipids, glycerol-3-phosphate dehydrogenase (G3PDH) activity, and the mRNA expression of aP2, PPAR- γ , and acetyl-CoA carboxylase- α (ACC). After 8 d of differentiation, medium B produced acetate incorporation and G3PDH activity that were 5- and 6-fold greater, respectively, compared with differentiation media A and C. Medium B increased mRNA expression of aP2 and PPAR- γ 180- and 7-fold, respectively, compared to undifferentiated control cells, but ACC mRNA expression was unaffected by differentiation media. Medium B was manipulated to further improve the differentiation protocol. Removal of 2% Intralipid did not improve any differentiation measures. Addition of rosiglitazone (1 μ M), a PPAR- γ

agonist, increased acetate incorporation, aP2 expression, and PPAR- γ expression. Troglitazone (5 μ M), another PPAR- γ agonist, increased acetate incorporation to a similar extent as rosiglitazone and produced the greatest expression levels of ACC, but was not superior for any other measures to media that included rosiglitazone. Cell seeding density influences the cell divisions required to reach confluence and increased plating density (2×10^4 cells/cm 2 vs. 6.7×10^3 cells/cm 2) increased acetate incorporation by 31%. We have developed a method to differentiate primary bovine adipocytes that will allow us to study the regulation of lipogenic enzymes by nutrient and endocrine factors.

Key Words: Adipocyte, Differentiation, Bovine

665 Basal expression of four SLC1 (Na $^+$ -dependent glutamate transporter) mRNA by small intestinal epithelia of beef cattle differs and is altered by ruminal and abomasal infusion of starch hydrolysate. S. F. Liao*, E. S. Vanzant, D. L. Harmon, K. R. McLeod, J. A. Boling, and J. C. Matthews, *University of Kentucky, Lexington.*

High-affinity glutamate uptake in the mammalian small intestine is mediated by SLC1 family members: system X $_{AG}^-$ (EAAC1, GLT-1) or ASC (ASCT1, ASCT2) activity. To determine if the expression of mRNA encoding SLC1 family members by duodenal (D), jejunal (J), and ileal (I) epithelia responds to increased luminal supply of rumen-derived microbes (hence, AA substrates), energy, or both, 18 ruminally and abomasally catheterized Angus steers (BW \approx 260 kg) were assigned (n = 6) to either water (basal), or ruminal or abomasal corn starch hydrolysate (SH, by α -amylase) infusion treatment (at 20% of ME intake) and fed an alfalfa-cube based diet at $1.3 \times$ NE $_m$ requirement. After a 14 or 16-d infusion, steers were killed, small intestinal epithelia harvested, and total RNA extracted. Real-time RT-PCR analysis was conducted to quantify the relative mRNA expression (SLC1 mRNA:18S rRNA). Basal expression patterns by D, J, and I differed ($P \leq 0.10$): EAAC1, D = J, D < I, J = I; GLT-1, D < J = I; ASCT1, I < D < J; ASCT2, D = J = I. Ruminal SH infusion decreased ($P = 0.05$) JAST1 mRNA expression by 46%, compared to basal expression. In contrast, abomasal SH infusion increased ($P = 0.07$) I basal expression of EAAC1 and ASCT1 mRNA, by 40 and 52%, respectively. GLT-1 and ASCT2 mRNA content was not affected by SH infusion. Discovery of ASCT1 mRNA expression by small intestinal epithelia is novel, and may represent a unique role for ASCT1 in the small intestinal epithelium of cattle, especially as ASCT2 mRNA content was insensitive to increased luminal substrate or energy supply while ASCT1 responded to both. The finding that I EAAC1 and ASCT1 mRNA content was increased in the presence of increased luminal SH suggests that their expression was sensitive to the energy status of I epithelia.

Key Words: Bovine, SLC1 Gene Expression, Small Intestine

666 Dry matter intake based on birth weight as weaning criterion in Brown Swiss calves. B. Saremi*, A. Foroughi, and A. Rahimi, *Education Center of Jihad-e Agriculture, Mashhad, Khorasan-e Razavi, Iran.*

Nineteen female Brown Swiss calves were placed randomly in treatments: 1) 1% BW 2) 1.5 % BW 3) 2 % BW dry matter intake as a weaning criterion. Calves were fed milk 8% BW two times daily and

weaned abruptly when aged at least 3 weeks, DMI equal or larger than treatments, total DMI more than 9% and body gain more than 12% of initial body weight. Calf starter (NRC 2001) fed from birth to 8 weeks post weaning ad lib. Blood and rumen liquid samples were taken each 15 days. Daily DMI, body weight and body characteristics include: Body length, wither height, hip height, pin width, hip width, pin to hip, stomach size, heart girth, metacarpus and metatarsus size were measured in 15 days intervals. Nutrient digestibility was determined 5 days at weaning and at the end of experiment. Repeated measurement analysis and a completely randomized design with unequal replicates by mixed procedure of SAS 9.1 were used for statistical analyses. Means were compared using Lsmean ($P < 0.05$). Data showed that milk fed period was increased from treat 1 to 3 ($P < 0.05$). Calf starter intake was significantly higher in treat 3 post weaning ($P < 0.05$). Feed to gain, body weight, average daily gain, stomach size, heart girth, metacarpus and metatarsus size and their increase pre and post weaning were equal pre and post weaning for all treatments. Calves in treat 3 had higher wither and hip height gain pre weaning ($P < 0.05$). This trend was observed nonsignificantly for body length. A reverse trend was observed post weaning with a significantly higher body length for treat 1 ($P < 0.05$). Pin to hip gain pre weaning and pin width at weaning showed significant different ($P < 0.05$). Plasma Glucose, PUN, rumen pH and N-NH₃ was equal between treatments. Nutrient digestibility had no differ pre weaning but reduced significantly for all nutrients post weaning as milk fed time increased ($P < 0.05$). Some data had not been shown in this summary saving brevity. In general, it seems that using DMI as a percent of BW could be used as a criterion for calves weaning at Iranian commercial farms management conditions.

Key Words: Dry Matter Intake, Weaning, Dairy Calves

667 Effects of plane of nutrition and bioavailable trace minerals on growth of transported male dairy calves. J. S. Osorio^{*1}, J. K. Drackley¹, R. L. Wallace¹, D. Rincker¹, D. J. Tomlinson², and T. J. Earleywine³, ¹University of Illinois, Urbana, ²Zinpro Performance Minerals, Jeffersonton, VA, ³Land O'Lakes Animal Milk Products Inc., Madison, WI.

Effects of enhanced milk replacer on growth and health of transported calves are unresolved. Whether organic (bioavailable) trace minerals benefit transported calves also is unknown. Male Holstein calves <1 wk old (n=90) were purchased in 3 groups (blocks) from Wisconsin

and transported to the Illinois research facility. Calves were randomly assigned in a 2x2 factorial arrangement of plane of nutrition (PN) and trace mineral source (TM). Conventional PN received milk replacer (22% CP, 20% fat; 568 g/d) and starter (18% CP), were weaned at 6 wk, received ad libitum starter to wk 12 and 0.5 kg of mixed hay wk 10-12. In wk 13-20 calves received 2.75 kg/d of grower (16% CP) and hay ad libitum. Enhanced PN received milk replacer (28% CP, 20% fat; 810 g/d wk 1, 1136 g/d wk 2-6, 568 g/d wk 7) plus starter (22% CP), were weaned at 7 wk, received ad libitum starter through wk 12, and ad libitum grower + 0.5 kg/d hay wk 13-20. Feeds contained either inorganic salts of Fe, Cu, Zn, and Mn or bioavailable sources (Zinpro Performance Minerals, Eden Prairie, MN). Calves were housed in individual hutches bedded with straw through wk 9, group-housed by diet wk 10-12, and group-housed by diet wk 13-20. All calves had free access to water. Calves were weighed and measured (heart girth, body length, withers height (WH), hip height (HH), and hip width) weekly through wk 10 and then at wk 12, 15, and 20. Data were analyzed with the MIXED procedure of SAS with repeated measures and block as a random effect. Calves fed enhanced PN had greater ($P < 0.01$) body weight (BW) and WH tended ($P = 0.08$) to be greater. Significant interactions between TM and PN were found for WH ($P = 0.05$), HH ($P < 0.05$), and BW ($P = 0.08$). Bioavailable TM increased growth for calves fed enhanced PN, but had no effect in calves fed conventional PN. Transported calves responded to enhance PN, although improvements in growth were less than observed previously with locally born calves. Bioavailable TM may increase growth with enhance PN, at least for calves under transport stress.

Key Words: Trace Minerals, Milk Replacer, Dairy Calves

668 Relationship of ghrelin and leptin with growth performance and carcass composition of beef cattle. J. S. Jennings^{*1}, R. H. Pritchard¹, K. W. Bruns¹, A. Trenkle², D. H. Keisler³, J. A. Daniel⁴, and A. E. Wertz-Lutz¹, ¹South Dakota State University, Brookings, ²Iowa State University, Ames, ³University of Missouri, Columbia, ⁴Berry College, Rome, GA.

Angus steers (n=72) of similar age, weight (292±1.44 kg), and genetic background were used to determine the effects of growing phase diet on the relationship of plasma ghrelin and leptin concentrations with growth performance and carcass composition. At trial initiation (d 0), eight steers were harvested for initial carcass composition. The remaining 64 steers were allotted, by weight, to pen and treatment was assigned randomly. Treatments were 1) 60% forage; 40% concentrate diet fed during the growing period (112 d) followed by 10% forage; 90% concentrate diet during the finishing period (113-209 d) (GRW-FNSH) or 2) 10% forage; 90% concentrate diet fed for the duration of the trial (0-209 d) (FNSH-FNSH). Steers were allowed ad libitum consumption regardless of dietary treatment. Eight steers per treatment were harvested on d 88, 116, 165, and 209, and carcass characteristics were recorded. A blood sample was collected from each steer prior to harvest, and plasma was assayed for ghrelin and leptin concentrations. Hormone and carcass data were analyzed statistically using the MIXED procedure of SAS, and linear, quadratic, and cubic contrasts were performed with the hormone data. At the final harvest, carcass weight was not different between treatment groups, but FNSH-FNSH steers had more ($P < 0.01$) subcutaneous fat and higher ($P \leq 0.001$) marbling scores compared with GRW-FNSH steers. Plasma ghrelin concentrations were different ($P \leq 0.01$) as a result of dietary treatment. Plasma ghrelin concentrations for FNSH-FNSH steers increased quadratically ($P \leq 0.01$) over time, whereas plasma ghrelin concentrations were not different over time for GRW-FNSH. Plasma

leptin concentrations for FNSH-FNSH steers increased ($P \leq 0.001$) from d 0 to 84 and then plateaued whereas, plasma leptin concentrations increased linearly ($P \leq 0.001$) in the GRW-FNSH steers. These data are consistent with the hypothesis that plasma ghrelin and leptin concentrations differ as a result of nutritional status of the animal.

Key Words: Ghrelin, Leptin, Carcass Composition

669 Carcass quality and relative content of glutamate metabolizing enzymes and transporters differ in Polypay and percentage Polypay-White Dorper lambs. A. K. Lunsford*, K. R. Brown, S. F. Liao, D. K. Aaron, J. C. Matthews, M. M. Simpson, D. G. Ely, and J. A. Boling, *University of Kentucky, Lexington.*

L-Glutamate (Glu) transport and metabolism by liver, kidney, longissimus dorsi (LD), and subcutaneous fat (SCF) are essential to N and energy metabolism of growing animals. The effect ($n = 6$) of sheep genetic type [Polypay (PP), 1/2 White Dorper 1/2 Polypay (1/2 D), and 15/16 White Dorper 1/16 Polypay (15/16 D)] on expression of Glu transporters and enzymes by these tissues was evaluated in wether lambs that had grazed a mixed grass pasture and received a grain supplement (2% BW) for 36 to 78 d. All lambs were harvested at a common weight of 50.0 kg and tissues collected. Although age at slaughter did not differ, 15/16 D lambs had heavier rack weights and higher percentage of boneless closely trimmed retail cuts ($P < 0.05$) and tended ($P < 0.10$) to have greater DP, LEA, and leg weights than PP or 1/2 D lambs. The relative content of EAAC1 and GLT-1 (Glu transporters) and Glu synthetase (GS), Glu dehydrogenase (GDH), and alanine transaminase (ALT) in liver, kidney, LD, and SCF was determined by immunoblot analysis. ALT content was lower ($P < 0.05$) in liver (54%), LD (72%), and SCF (51%) and tended to be lower ($P < 0.10$) in kidney (34%), while EAAC1 was 89% lower ($P < 0.05$) in LD of 15/16 D than PP or 1/2 D lambs. In contrast, GS (99%) and GLT-1 (25%) content tended to be increased ($P < 0.10$) and GDH tended to be decreased ($P < 0.10$) 39 and 46% in SCF of 15/16 D and 1/2 D lambs. To determine if altered protein content was by transcriptional control, the relative mRNA content for GS, GDH, and ALT in LD and SCF was determined by real-time RT-PCR. GS mRNA (59%) was highest ($P < 0.05$) and ALT mRNA (44%) tended to be highest ($P < 0.10$) in LD of 1/2 D, indicating post-transcriptional regulation of protein content. These results reveal the increased carcass quality of 15/16 D lambs was concomitant with a reduced ALT protein content of tested tissues and SCF had an increased potential to produce glutamine from plasma Glu.

Key Words: Breed, Gene Expression, Glutamate

670 Sheep differing in exogenous adrenocorticotropin hormone induced cortisol responses are different in body composition and residual feed intake. S. A. Knott¹, L. J. Cummins², F. R. Dunshea³, and B. J. Leury³, ¹Charles Sturt University, Wagga Wagga, NSW, Australia, ²Ivanhoe, Cavendish, Victoria, Australia, ³The University of Melbourne, Parkville, Victoria, Australia.

The objective of this study was to determine whether there were differences in body composition (lean tissue mass, LTM; fat tissue mass,

FTM) and residual feed intake (RFI) in sheep that were identified to have either a low (LC) or high (HC) serum cortisol response to exogenous administration of adrenocorticotropin hormone (ACTH). One hundred maternal sire cross-bred rams (initial weight 52.9 ± 4 kg) received 2 $\mu\text{g}/\text{kg}$ ACTH intramuscularly. Two blood samples were collected, one immediately before and one 45 min after the injection of ACTH. Twenty two rams with low or high post ACTH serum cortisol concentrations were then selected; cortisol concentration post ACTH administration for LC ($n=11$) and HC ($n=11$) groups was 113.3 and 215.6 nmol/L, respectively, ($P < 0.05$). Body composition was measured using dual energy X-ray absorptiometry at the start and end of a 40-day measurement period where ad libitum feed intake and liveweight (LW) were measured for estimation of feed conversion ratio (FCR) and residual feed intake (RFI). LC sheep were significantly more efficient than HC sheep in terms of RFI (-0.49 v. 0.45 , LC v. HC, $P < 0.05$) but not for FCR. There were no significant differences between the HC and LC groups in body composition or LW at the start of the study whereas after 40 days there were significant differences ($P < 0.05$) in the proportion of LTM (0.72 v. 0.75 , HC v. LC) and FTM (0.16 v. 0.13 , HC v. LC) and absolute FTM (10.83 v. 8.91 kg, HC v. LC), but no difference in LW. These data indicate that animals that are more responsive to an ACTH challenge are less efficient and have increased adiposity, both of which may be related to an overall increase in stress responsiveness in these animals.

Key Words: Cortisol, Sheep, Efficiency

671 Wool growth is negatively related to exogenous adrenocorticotropin hormone induced cortisol responses in sheep with a low wool growth potential but not with a high potential. G. M. Butler¹, M. W. Robertson¹, A. J. Tilbrook², F. R. Dunshea¹, and B. J. Leury^{*1}, ¹The University of Melbourne, Parkville, Victoria, Australia, ²Monash University, Clayton, Victoria, Australia.

The objective of this study was to determine whether there were differences in serum cortisol response to exogenous administration of adrenocorticotropin hormone (ACTH) in Merino sheep with either high (HW) or low (LW) wool growth potential. Forty eight merino wethers (42.1 ± 4.8 kg) were selected for HW and LW from a larger grazing flock based on the previous season's greasy fleece weight (GWT). Sheep were yarded and fasted for 15 hours and then injected with 2 $\mu\text{g}/\text{kg}$ ACTH intramuscularly. Two blood samples were collected, one immediately before and one 45 min after the injection of ACTH and plasma cortisol measured. The wethers were then brought indoors and after acclimation to a pelleted ration commenced a study where feed intake, liveweight and mid-side wool growth were measured for up to 27 d. Ten wethers failed to adjust to the pellets and were removed. While there was no difference in basal plasma cortisol, both the incremental (62 v. 40 nmol/L) and the final (104 v. 91 nmol/L) post ACTH cortisol concentrations were greater ($P < 0.05$) in the HW than the LW sheep. As anticipated, mid-side wool growth was correlated ($R=0.46$, $P < 0.05$) with the previous season's GWT and was higher (0.39 v. 0.26 mg/cm² /kg, $P < 0.001$) in the HW sheep. Mid side wool growth was negatively related ($R=-0.55$, $P < 0.05$) to the ACTH increment in cortisol in LW sheep but not in HW sheep. This difference in cortisol response may allow HW sheep to maintain wool growth under a range of environmental conditions.

Symposium: International Animal Agriculture: Welfare in Animal Production, from Science to Practice

672 ASAS Centennial Presentation: The impact of current global challenges in the animal agricultural industry. A. Tewolde*¹ and T. Díaz², ¹*Inter American Institute for Cooperation on Agriculture - IICA, San José, Costa Rica*, ²*Food and Agriculture Organization - FAO, Santiago de Chile*.

The important contribution of animal agriculture to today's main challenges that the world faces is recognized. Globally, animal agriculture employs 1.3 billion people, accounts for almost 40 percent of agricultural gross domestic product, provides one third of total protein intake, and most rural people depend on livestock to survive, and the general contribution of livestock to the gross national product (GNP) will increase with time. It is estimated that almost 42% of the agricultural GNP will be attributable to the livestock sector by 2030, of which 39 and 50% correspond to the developing and developed countries, respectively. It is also expected that global animal production will increase in response to higher income and consumption in developing countries. However, rural poverty, climate change and natural resources degradation may become the main threats to the global animal agricultural industry. For example, it is estimated that in 25 years time meat and cereal production will have to increase by 85 and 50%, respectively, using the same currently available physical resources. Livestock can reduce poverty and food insecurity in most African and some Asian and Latin American countries. Also the different livestock regions can be threatened by the growing biofuel trends. Globalization is increasing sanitary risks and agriculture and livestock systems are becoming highly vulnerable to climate change. All these require collective efforts between the public and private sector and respective stakeholders in designing appropriate research, training and outreach services. Also, biotechnology applications to produce desired product traits are now seen as important tools. In conclusion, it is evident that animal production will continue to contribute to the wellbeing of the human kind, but it is also challenged by social, technological, biological, environmental and economic factors that should be dealt with integrally and via regional cooperation and technological and information sharing.

Key Words: Climate Change, Globalization, Biotechnology

673 Farm animal welfare: The science behind the standards. D. Fraser*, *University of British Columbia, Vancouver, BC, Canada*.

Three broad types of research have been used in the development of "science-based" animal welfare standards. One body of research focuses on the basic health and functioning of animals; it relies on measures such as freedom from disease and injury, indicators of "stress", and rates of survival and growth. Other research looks at the ability of animals to live in reasonably "natural" ways; it uses the performance of natural behavior (especially behavior that animals are highly motivated to perform) as indicating good welfare, and abnormal behavior as indicating the reverse. A third body of research focuses on the "affective states" of animals, especially states of pain and distress; it attempts to identify and quantify such states through a combination of behavioral and physiological responses, and to develop practical mitigative measures. All three of these types of science have been used in animal welfare standards, but they sometimes lead to different requirements because they involve the pursuit of different (although often overlapping) animal welfare

objectives. In order to prevent confusion arising from the conflicting requirements, we need to be clear about the specific animal welfare objectives that different standards are designed to address.

674 Strategies to improve animal welfare in poultry production: From science to practice. J. A. Mench*, *University of California, Davis*.

It is estimated that approximately 23 billion poultry are produced worldwide each year. The poultry industry is diverse and is involved with the production of eggs, meat, and byproducts (e.g. feathers) from a variety of species, including chickens, turkeys, ducks, ratites, and game birds. As consumer demand for poultry products has continued to grow, rearing practices have become increasingly intensive in most segments of the poultry industry in many countries. In turn, this has led to increasing concerns about poultry welfare among consumers and food retailers, and a concomitant attempt to eliminate or modify certain production practices via legislation, retailer purchasing specifications, labeling programs, and/or voluntary or audited guidelines. This has been paralleled by an explosion of research on poultry welfare, particularly on topics related to behavior and health. To what extent has science played a role in these regulations, standards and guidelines, and how has that science been translated into day-to-day practice in such a way as to improve poultry welfare? This question will be discussed with regard to three particularly controversial practices: housing laying hens in cages, the production of foie-grass from ducks and geese, and the use of electrical stunning in processing plants to induce insensibility prior to slaughter in broiler chickens and turkeys.

Key Words: Poultry, Welfare, Guidelines

675 Strategies to improve animal welfare in farm animals: From science to practice. X. Manteca*¹, A. Bach², S. Calsamiglia¹, A. Ferret¹, J. Gasa¹, and B. Jones³, ¹*School of Veterinary Science, UAB, Bellaterra, Barcelona, Spain*, ²*IRTA-Unitat de Remugants & ICREA, Barcelona, Spain*, ³*Animal Behaviour & Welfare Consultant, Edinburgh, Scotland*.

Concern about the welfare of farm animals has increased in many countries over the last decades and animal welfare is fast becoming a global issue. Strategies intended to improve farm animal welfare can be divided into three main categories: improving the quality of stockmanship, improved housing and husbandry, and genetic selection. Fear of human beings is often a major welfare problem in farm animals that has marked negative consequences for production. Fear of humans is largely determined by the behavior of the stockpersons, which normally reflect their beliefs, attitudes and skills. Therefore, training programmes aimed at improving stockmanship have a very positive impact on the welfare of animals. To be fully effective, these must be tailored to the production system and the characteristics of the producers in each country. Improved housing and husbandry is the most frequently used strategy for enhancing farm animal welfare. The range of strategies may vary substantially from those requiring significant changes in the production systems (such as replacing stalls for pregnant sows by group housing

systems) to very moderate alterations, such as increasing feeding space for beef cattle. Although enhanced housing and husbandry practices are undeniably effective in many circumstances, they may have a high economic cost that hampers uptake. Genetic selection is becoming an increasingly important tool for improving farm animal welfare. It can be applied with two different aims: firstly to prevent the negative consequences that selection for certain production traits may have on animal welfare (such as increased prevalence of lameness in broilers due to selection for rapid growth) and to select animals that are better able to cope with existing production systems and perhaps future developments. Examples of the latter include selection for reduced aggressiveness in pigs and for greater sociability in dairy cows.

The categories of welfare improvement strategies mentioned above will be illustrated with examples from work done in the research project Welfare Quality®.

Key Words: Animal Welfare, Farm Animals, Welfare Quality

676 On farm assessment of animal welfare: The ‘Welfare Quality’ experience in the EU. L. J. Keeling*, *Swedish University of Agricultural Sciences, Sweden.*

The project ‘Integration of animal welfare in the food quality chain: from public concern to improved welfare and transparent quality’ (Welfare Quality®) has become the largest piece of integrated work yet carried out in animal welfare in Europe, involving 44 research groups from 17 countries. The main aims are: to develop practical strategies/

measures to improve animal welfare, to develop a European standard for the assessment of animal welfare, to develop a European animal welfare information standard and, to integrate and interrelate the most appropriate specialist expertise in the multidisciplinary field of animal welfare in Europe. Effort is focused on three main species and their products: cattle (beef, dairy and veal), pigs and poultry (broiler chickens and laying hens).

A starting point was that animal welfare is an important part of an overall “food quality concept”. Analyses of public perceptions and attitudes were combined with existing knowledge from animal welfare science and 12 areas of concern that should be covered in measurement systems were identified. To address these areas of concern, 20-30 performance (animal-based) and design measures for each species were selected for inclusion in pilot systems being applied in practice this year. Further fine tuning of the systems will take place. Population surveys have explored the extent of social engagement in farm animal welfare issues and how this is reflected in everyday consumption practices and there have been studies of the supply chains for welfare-friendly products. Clear differences between countries were apparent so strategies to implement welfare schemes under specific conditions of consumer, distributor and producer expectations are being formulated. Work with a formal standard setting body to create the basis of future technical standard documents has also started and the potential importance of such harmonised standards in the setting of future European legislation has been recognised. Future work will focus on further development of the welfare measurements and improvement strategies and on establishing implementation strategies.

Lactation Biology III

677 Inhibitory effect of unsaturated fatty acids on *de novo* fatty acid synthesis in bovine mammary epithelial cells. J. W. McFadden*, I. K. Mullarky, and B. A. Corl, *Virginia Polytechnic Institute and State University, Blacksburg.*

In vitro, unsaturated fatty acids (UFA) inhibit lipid synthesis in rat hepatocytes as well as goat and bovine mammary epithelial cells. A bovine mammary epithelial cell line (BME-UV) was used to determine the effect of saturated, monounsaturated, and polyunsaturated fatty acids (PUFA) on *de novo* fatty acid synthesis. Cells were grown to confluence in DMEM supplemented with 10% serum. Serum or increasing incubation time reduced radiolabeled acetate incorporation into lipids (pmol/ μ g DNA). Addition of insulin (0.1 μ g/ml) and prolactin (1.5 μ g/ml) serum-free media enhanced acetate incorporation (22%). Subsequent experiments included BME-UV cells cultured in the presence of hormones with BSA-complexed fatty acid in the absence of serum for 24 h starting at confluency. Treatment with 50 μ M oleic acid, linoleic acid (LA), *cis*-9, *trans*-11 conjugated linoleic acid (CLA), or *trans*-10, *cis*-12 CLA resulted in 40 to 50% reductions in acetate incorporation. A minor increase (14%) in acetate incorporation was observed with 50 μ M stearic acid (SA) treatment. Fatty acid synthase mRNA was reduced by 29, 9, and 22% for the LA, *cis*-9, *trans*-11 CLA, and *trans*-10, *cis*-12 CLA treatments, respectively. Acetyl-CoA carboxylase mRNA expression remained unaffected by treatment. Expression of peroxisome proliferator activated receptor- γ and liver X receptor (LXR)- α mRNA were unaffected by treatment; however, significant reductions in sterol response element-binding protein (SREBP)-1 mRNA and protein were observed for all PUFA treatments. Cells incubated with a LXR agonist, T0901317, resulted in enhanced acetate incorporation (21% at 1 μ M). Incubating BME-UV cells with LXR agonist rescued the suppressive effect of UFA on lipid synthesis. Presence of a LXR agonist had no effect on acetate incorporation in SA treated BME-UV cells. These results suggest, *in vitro*, that UFA decrease BME-UV cell lipid synthesis by inhibiting the expression of SREBP-1 and this effect may be mediated by suppressing LXR activity.

Key Words: LXR, SREBP-1, Unsaturated Fatty Acids

678 Lipogenic gene expression in MAC-T cells is affected differently by fatty acids and enhanced by PPAR- γ activation. A. K. G. Kadegowda*¹, M. Bionaz², L. S. Piperova¹, R. A. Erdman¹, and J. J. Loo², ¹University of Maryland, College Park, ²University of Illinois, Urbana.

Recent work has focused on *trans*10,*cis*12-CLA (t10c12CLA) and its effect on mammary lipogenic gene expression, while the effects of other fatty acids (FA) remain ill-defined. Objectives were to test individual FA effects on mRNA expression via qPCR of 19 genes with roles in *de novo* synthesis (ACACA, FASN), FA uptake (LPL, CD36), intracellular FA transport (FABP3, FABP4), desaturation (SCD), triacylglycerol synthesis (AGPAT6, DGAT1, GPAM, LPIN1), transcriptional regulation (SREBF1, SREBF2, INSIG1, THRSP), and nuclear receptor signaling (PPARG). A PPARG-specific agonist (Rosiglitazone, ROSI) was used to assess the role of this nuclear receptor on mammary lipogenesis. Lipid droplet (LD) formation was quantified with Oil Red O staining.

MAC-T cells were cultured in triplicate for 12 h with 50 $\hat{1}$ / μ M ROSI or 100 $\hat{1}$ / μ M t10-18:1, t10c12CLA, 16:0, 18:0, c9-18:1, 20:5, or ethanol (control). All FA increased ($P < 0.05$) CD36 expression (\sim 770%) and, except for 16:0 and 18:0, decreased LPL (\sim 150%) and FABP3 (\sim 200%) relative to control. 16:0 and 18:0 elicited greater mRNA of FABP3 (+500%) and FABP4 (+160%) over control. Responses common to 16:0 and 18:0 included greater THRSP (\sim 90%), INSIG1 (\sim 200%), AGPAT6 (\sim 150%), DGAT1 (\sim 60%), and LPIN1 (\sim 90%), coupled with greater LD formation with 16:0. T10-18:1 and t10c12CLA reduced expression of ACACA (\sim 60%), FASN (\sim 50%), SCD (\sim 240%), and LPIN1 (\sim 30%). SREBF1 was lower with t10c12-CLA (\sim 200%), c9-18:1 (150%), and EPA (\sim 140%) over control. C9-18:1 and EPA also decreased ACACA (\sim 40%) and SCD (\sim 300%). No effects were observed for PPARG but ROSI upregulated by $>40\%$ ACACA, FASN, SCD, LPIN1, AGPAT6, DGAT1, SREBF1, SREBF2, and INSIG1 without changes in LD formation over control. Results showed that FA regulate mammary lipogenic gene expression to different extents. Further, PPAR- γ activation of *de novo* lipogenesis coupled with exogenous FA availability might play a role in regulating milk fat synthesis.

Key Words: Mammary Cells, Gene Expression, Fatty Acids

679 Comparative MammOmics™ of milk fat synthesis in *Mus musculus* vs. *Bos taurus*. M. Bionaz* and J. J. Loo, *University of Illinois, Urbana.*

A sequenced genome and low cost are at the root of the preferential use of the mouse to study genome-wide mechanisms of mammary function. Whether mammary tissue from mouse and cow share similar gene expression patterns remains to be determined. We propose that the degree of similarity in relative % mRNA abundance coupled with temporal responses in both species is indicative of the importance of a gene in the process of mammary lipid and protein synthesis. Our objective was to compare temporal patterns and relative % mRNA abundance of lipid synthesis-related genes in mammary tissue from mice (FVB and C57B1) and Holstein cows during pregnancy and lactation. Published mouse mammary microarray data ($>20,000$ genes) and our bovine qPCR data were used in this comparison. Murine data encompassed pregnancy to 9-10 d post-partum, and bovine the last 30 d pre-partum through late lactation. With few exceptions, mouse strains had similar relative % mRNA abundance and temporal patterns across selected genes. Overall, mouse mammary had proportionally lower relative % mRNA abundance of *CD36*, *GPAM*, *AGPAT6*, *INSIG1*, and *LASS2* and larger % mRNA abundance of *ACSL1*, *ACBP*, *FADS1*, *OXCT1*, *SREBF1*, and *THRSP* compared with cow. Genes characterizing mammary tissue of both species included *ABCG2*, *ACSS1*, *ACSL1*, *FABP3*, *FASN*, *SCD*, *BTN1A1*, *XDH*, *OXCT1*, *LPIN1*, *SREBF1*, and *PPARGC1A*. In contrast, we observed lower up-regulation of genes involved in uptake of fatty acids (FA) from blood (e.g., *LPL*, *CD36*, and *VLDLR*) and desaturation (e.g., *SCD*) in murine vs. bovine. Thus, it appears that FA uptake from blood, relative to *SREBF1/THRSP*-regulated *de novo* FA synthesis (e.g., *FASN*), and delta-9 desaturation are more relevant processes in the cow. Intracellular FA trafficking also appears more important in bovine mammary as suggested by larger up-regulation of *FABP3*. Comparative analysis revealed unexpected findings such as down-regulation of

GPAM in lactating murine mammary. Murine mammary data might be partly confounded by the greater amount of adipocytes during pregnancy and the beginning of lactation. Care should be taken when inferring phenomena in bovine mammary using murine data.

Key Words: Genomics, Lactation, Metabolism

680 SREBP1 and Spot14 are acutely down-regulated in mammary tissue during abomasal infusion of *trans*-10, *cis*-12 conjugated linoleic acid (CLA) in the dairy cow. K. J. Harvatine*, Y. R. Boisclair, and D. E. Bauman, *Cornell University, Ithaca, NY.*

Trans-10, *cis*-12 CLA is a potent inhibitor of milk fat synthesis in the dairy cow. We have previously reported down-regulation of the mammary mRNA expression of sterol response element binding protein 1 (SREBP1), SREBP1 regulatory proteins, SREBP-regulated enzymes and thyroid hormone responsive spot 14 (S14) during chronic CLA- and diet-induced milk fat depression (MFD). This provides strong evidence for a central role of the transcription factor SREBP and the nuclear protein S14 in the regulation of milk fat synthesis. To distinguish between primary mechanisms regulating milk fat synthesis and secondary adaptations to the reduction in milk fat, we conducted a time-course experiment. An initial priming dose of 7.5 g of CLA was given at time-zero followed by steady state abomasal infusion of 2.5 g every 4 h for 36 h, and then by 3.75 g every 6 h until 120 h. In a separate previously reported experiment we characterized at high resolution the temporal production response to an identical infusion protocol by milking every 4 h with the aid of oxytocin. In the production experiment, milk fat percent progressively decreased over the first 24 h, although the ratio of *de novo* and preformed fatty acids was not modified until after 24-30 h. In the current experiment, mammary biopsies from 9 cows were obtained at -48, 12, 30, and 120 h relative to initiation of CLA infusion. Expression of fatty acid synthase and lipoprotein lipase were decreased at 30 and 120 h compared to control. Expression of SREBP1 and S14 were also decreased at 30 h and 120 h compared to control. Time course analysis during MFD demonstrates that CLA down-regulates master transcriptional regulators of lipid synthesis and their dependent enzymes during the onset of MFD. This provides additional support for SREBP1 and S14 as primary central regulators of MFD.

681 PPAR-gamma activation and *trans*10,*cis*12-CLA affect gene expression profiles and intracellular lipid droplet formation and secretion to different extents in MAC-T cells. A. K. G. Kade-gowda*¹, M. Bionaz², R. E. Everts², H. A. Lewin², L. S. Piperova¹, R. A. Erdman¹, and J. J. Loores², ¹*University of Maryland, College Park*, ²*University of Illinois, Urbana.*

We showed previously that PPAR-gamma activation induces lipogenic gene expression in MAC-T cells. To examine effects of PPAR-gamma activation on large-scale gene expression profiles, RNA from MAC-T cells cultured in triplicate for 12 h with 50 micro molar rosiglitazone (ROSI; PPAR-gamma agonist), 100 micro molar t10c12CLA (CLA; negative control), or ethanol (control) were hybridized to an annotated 13,257 bovine oligonucleotide (70-mers) microarray in a dye-swap design (i.e., 18 microarrays). Lipid droplet (LD) formation was quanti-

fied with Oil Red O staining and concentrations of triacylglycerol (TG) and glucose in culture media measured by commercial kits. ANOVA identified 769 differentially expressed ($P < 0.05$) genes due to treatment. Relative to control, CLA uniquely increased expression by ≥ 1.5 -fold of 47 genes associated with lipid transport (e.g., ADFP, VLDLR) and cellular proliferation (e.g., IGFBP3, SPP1), and decreased expression of 45 genes associated with TG synthesis (e.g., SCD, IDH1, FABP3) and cholesterol synthesis/transport (e.g., HMGCS, LDLR). Similarly, ROSI distinctively affected expression of 32 genes associated with amino acid (e.g., CTH, SLC7A1) and glucose metabolism (PCK2, PFKFB2), and decreased expression of 35 genes associated with cell morphology (e.g., MCAM, WPIF1, ACTN2). CLA resulted in substantially greater LD (350%) accumulation and 3.6-fold more TG in culture media compared with control. ROSI resulted in 1.6-fold more TG in culture media than control, and also lowered glucose relative to control or CLA. Responses to ROSI or CLA for several genes previously measured by qPCR (e.g., LPIN1, FASN, FABP3, SCD) on the same RNA were confirmed. The suggested increase in glucose utilization inferred by microarray data due to ROSI also was confirmed. Paradoxically, CLA promoted intracellular TG accumulation and secretion into culture media via mechanisms that remain to be determined.

682 *Trans*-10, *cis*-12 conjugated linoleic acid (CLA) induces a dose-dependent reduction in milk fat synthesis in C57BL6J mice. K. J. Harvatine*, M. M. Robblee, Y. R. Boisclair, and D. E. Bauman, *Cornell University, Ithaca, NY.*

Inhibition of milk fat synthesis by fatty acid intermediates originating from rumen biohydrogenation (e.g. *trans*- 10, *cis*- 12 CLA) has been extensively studied in the cow. Inhibition of milk fat synthesis by CLA has also been investigated in rodent models, but a dose response has never been reported. We determined the dose dependent effect of *trans*-10, *cis*- 12 CLA on milk fat synthesis using 24 wild type C57BLJ mice. Starting at 6-8 d of lactation, dams nursing 6-7 pups received daily doses of water (control) or 6, 18, or 54 mg/d of CLA for 5 d. CLA was orally administered in three equal doses. CLA caused a linear decrease in dam feed intake (up to -27%) and pup growth rate (up to -49%). Milk fat percent was progressively decreased up to 20% with the 18 mg/d dose, but the 54 mg dose did not differ from control. All CLA treatments caused a decrease in the concentration of short and medium chain fatty acids in milk fat similar to milk fat depression (MFD) in the dairy cow. In agreement, mammary tissue lipogenesis measured by in vitro tissue incorporation of C14 glucose into fatty acids was decreased at the 18 and 54 mg/d doses. Finally, gene expression was analyzed by real-time PCR for the control and 18 mg/d treatments. Expression of SREBP1, S14, and FASN was decreased by CLA treatment compared to control. We have previously reported decreased expression of SREBP1 and S14 during diet- and CLA-induced MFD in the dairy cow. Overall these data show that MFD can be experimentally induced in the mouse with 18 mg/d of *trans*- 10, *cis*- 12 CLA, although higher doses may cause a more generalized inhibition of milk synthesis. We conclude that the mouse can serve as an experimental model to investigate functional mechanisms mediating the effect of CLA on milk fat synthesis.

683 MammOmics™ in *Sus scrofa*: Uncovering genomic adaptations underlying mammary development during pregnancy and lactation. S. Tramontana^{1,2}, W. L. Hurley², M. Bionaz^{*2}, A. Sharma², D. E. Graugnard², E. A. Cutler², R. E. Everts², P. Ajmone-Marsan¹, S. L. Rodriguez-Zas², and J. J. Loores¹, ¹Università Cattolica del Sacro Cuore, Piacenza, Italy, ²University of Illinois, Urbana.

Elucidating genes controlling growth, development, and metabolism of swine mammary glands can reveal potential metabolic or signaling pathways that might help improve efficiency of milk synthesis. A swine microarray consisting of 13,263 oligonucleotides (70 mer) was used for transcript profiling of mammary tissue from 4-5 sows at -34, -14, -4, 0, 7, 14, 21, and 28 d relative to parturition. Annotation of the microarray was based on similarity searches using BLASTN and TBLASTX against human, mouse, and pig UniGene databases, the human genome, and pig TIGR. Cy3- and Cy5-labelled cDNA from mammary tissue and a reference standard were used for hybridizations. ANOVA (false discovery rate ≤ 0.10) identified 2,664 differentially expressed genes (DEG) due to physiological state. Gene network/pathway analysis revealed that cell growth and proliferation ($n = 548$ genes) and cell signaling ($n = 612$) were among the most affected molecular functions due to physiological state in DEG. A clear switch in metabolic state of mammary gland from pregnancy to lactation was apparent, with up-regulation of genes involved in milk component synthesis (e.g., *LALBA*, *CSN3*, *BTN1A1*) and concomitant down-regulation of genes involved in catabolism and energy production (e.g., *ACOX1*, *NDUFA4*). Peak of lactation (21 d) was characterized by the largest number of DEG with ≥ 1.5 -fold expression (714 up-regulated, 791 down-regulated) relative to late pregnancy (-34 d). A total of 110 transcription regulators with ≥ 1.5 -fold in at least one time point relative to -34 d were identified via gene network analysis. Among these, 14 (e.g., *RARB*, *TP53BP1*) had ≥ 3 -fold up-regulation during lactation relative to pregnancy. The imminent onset of lactation elicited tremendous adaptations in mammary gene expression, including many novel molecular functions. Differential expression of novel transcription regulators might help explain long-term adaptations in mammary gland development and function.

684 Mammary fat pad but not parenchyma is affected by diet in pre-weaned Holstein heifers. K. M. Daniels^{*1}, S. R. Hill¹, K. F. Knowlton¹, R. E. James¹, M. L. McGilliard¹, A. V. Capuco², and R. M. Akers¹, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²USDA-Agricultural Research Service, Beltsville, MD.

Overfeeding prepubertal heifers may impair mammary parenchymal growth and reduce milk production, but dietary impacts in pre-weaned calves are unknown. This study was to evaluate effects of milk replacer (MR) composition on mass and composition of mammary parenchyma and fat pad (MFP). Twenty-four newborn heifers were fed one of four MR diets ($n=6$ /diet): CON (20% CP, 21% fat MR fed at 441 g DM/d), HPLF (28% CP, 20% fat MR fed at 951 g DM/d), HPHF (27% CP, 28% fat MR fed at 951 g DM/d), and HPHF+ (27% CP, 28% fat MR fed at 1431 g DM/d). Water and starter (20% CP, 1.43% fat) were offered ad libitum. Animals were sacrificed and tissues were harvested on d 63 for analysis of protein, lipid, and DNA. Total mammary gland mass was lowest in CON (CON vs. others; 150 vs. 284 \pm 30 g). Increased feeding (HPHF vs. HPHF+; 288 vs. 379 \pm 30 g) as well as addition of fat to an

isonitrogenous diet (HPLF vs. HPHF; 185 vs. 288 \pm 30 g) increased gland mass. Parenchymal mass (CON, HPLF, HPHF, and HPHF+: 9.2, 11.7, 15.5, 15.1 \pm 3.3 g) was not affected by diet nor was parenchymal composition, or concentrations of protein (4.2 \pm 0.30%), lipid (13.8 \pm 2.2%), and DNA (0.21 \pm 0.02%). However, MFP was markedly affected by diet; MFP mass (CON vs. others; 140 vs. 270 \pm 30 g) and total MFP lipid (37 vs. 144 \pm 25 g) were lowest in CON, whereas total DNA content did not differ (60 vs. 54 \pm 12 mg). Added fat increased MFP mass (173 vs. 273 \pm 30 g), tended to increase total MFP lipid (64 vs. 132 \pm 25 g), but decreased total MFP DNA (84 vs. 42 \pm 12 mg). Increased intake of HPHF increased MFP mass (273 vs. 364 \pm 30 g) and MFP lipid (132 vs. 234 \pm 22 g), but did not affect MFP DNA (42 vs. 37 \pm 11 mg). Total protein in MFP was unaffected by diet, but protein concentration of MFP was highest in CON (CON vs. others; 20 vs. 11 \pm 3 mg/g MFP). Added fat decreased MFP protein concentration (20 vs. 9 \pm 3 mg/g), and increased intake of HPHF had no effect on MFP protein concentration (9 vs. 6 \pm 3 mg/g). In conclusion, diet had no effect on mammary parenchyma, but MFP mass and composition were affected. Implications with respect to future milk production remain to be determined.

685 Hormone interactions modulate mammary growth, morphogenesis and local IGF expression in peripubertal gilts. K. C. Horigan¹, J. F. Trott^{1,2}, and R. C. Hovey^{*1,2}, ¹University of Vermont, Burlington, ²University of California, Davis.

Development of the mammary glands is coordinately regulated by hormone interactions during postnatal development. While responses by the mammary gland to the ovarian hormones estrogen (E) and progesterone (P) and pituitary-derived prolactin (PRL) have been characterized across various species, their combined effects have received limited investigation. We therefore determined the individual and combined effects of E, P and PRL on mammary gland growth, morphogenesis and hormone receptor expression in sham-operated and ovariectomized (OVX) peripubertal miniature swine ($n=36$). Females received bromocriptine (Bromo) for 9d after OVX surgery to suppress endogenous PRL. Thereafter females received daily injections comprising all possible combinations ($n=4$ /group) of E, P and/or haloperidol (HAL, to induce PRL secretion) for 5d. Sham-operated females received saline only. The incidence of cells proliferating (BrDU-positive) and expressing E and P receptors (ER and PR) was determined immunohistochemically. Total RNA from mammary glands was analyzed for IGF-I and IGFBP-3 expression by qRT-PCR. OVX plus Bromo blocked proliferation relative to that in Sham controls ($P<.05$) while it was restored by exogenous E. Hal alone failed to stimulate proliferation but positively interacted ($P<.001$) with the effects of E, where maximum proliferation was induced by E+P+Hal. The incidence of ER-positive cells was less when E, P and Hal were administered in combination compared to the individual hormone effects. While E increased PR incidence, this effect was blunted by treatment with P and/or Hal. Expression of IGF-I mRNA in the mammary glands was unaffected by ovariectomy but increased in response to E or Hal. Conversely, E and E+Hal suppressed IGFBP-3 levels, supporting the potential for local modulation of IGF bioavailability. These findings provide important details about the interactive effects of ovarian and pituitary hormones on mammary growth in swine.

Key Words: Mammary Growth, Prolactin, Estrogen and Progesterone

686 Possible involvement of connective tissue growth factor (CTGF) in insulin-like growth factor-I (IGF1) stimulation of proliferation of bovine mammary epithelial cells. Y. Zhou¹, A. V. Capuco², and H. Jiang*¹, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²USDA-ARS, Beltsville, MD.

IGF1 plays an important role in mammary gland development and lactation in part by stimulating proliferation of the milk-producing epithelial cells. In this work, we used the bovine mammary epithelial cell line MAC-T as a model to study the mechanism by which IGF1 stimulates proliferation of the mammary epithelial cells. A microarray analysis revealed that 155 transcripts were up- or down-regulated at least twofold by IGF1 in MAC-T cells ($P < 0.05$). Among the most significantly down-regulated genes was CTGF, a secretory protein that has both proliferative and apoptotic effects, depending on cell type, and also a low-affinity binding protein of IGF1. Quantitative PCR confirmed IGF1 regulation of CTGF and eight other mRNAs in MAC-T cells. Using selective inhibitors of signaling pathways from the IGF1 receptor (IGF1R), it was found that IGF1 suppressed CTGF mRNA in MAC-T cells through the phosphatidylinositol 3-kinase pathway. Administration of growth hormone (GH), a major stimulator of IGF1 production in vivo, decreased mammary expression of CTGF mRNA in cows ($P = 0.07$). However, GH had no effect on CTGF mRNA expression in MAC-T cells, suggesting that IGF1 mediates the reduced expression of CTGF mRNA in the mammary gland. In the absence of IGF1, CTGF stimulated proliferation of MAC-T cells ($P < 0.05$), but in combination with IGF1 it attenuated the stimulation of IGF1 on proliferation of MAC-T cells ($P < 0.05$), and the attenuation was reversed by excess IGF1 ($P < 0.05$). Western blotting analyses indicated that despite being an IGF1 binding protein, CTGF did not affect IGF1-induced phosphorylation of IGF1R or total IGF1R expression in MAC-T cells, indicating that CTGF attenuation of IGF1-stimulated proliferation of MAC-T cells is not mediated by decreasing the ability of IGF1 to activate IGF1R or by decreasing IGF1R expression. Overall, these results suggest a novel biochemical and functional relationship between CTGF and IGF1 in the bovine mammary gland, where IGF1 may inhibit CTGF expression to reduce the attenuating effect of CTGF on IGF1 stimulation of epithelial cell proliferation.

Key Words: IGF1, CTGF, mRNA

687 Stromal changes in the bovine mammary gland during involution and mammogenesis. L. De Vries*, M. VandeHaar, T. Casey, T. Petzke, H. Dover, J. Liesman, and K. Plaut, *Michigan State University, East Lansing.*

The bovine mammary gland undergoes extensive remodeling during involution and mammogenesis between lactations. Changes in mammary epithelium have been well characterized during the dry period, but few studies in dairy cattle have characterized changes in stromal tissue. We hypothesized that stromal fibroblasts are activated and the amount of fibronectin is increased during the dry period to promote remodeling of the mammary gland for the subsequent lactation. Our objective was to determine if changes occur in the number of activated fibroblasts, the percent stromal area, and the expression of fibronectin in the stroma during involution and mammogenesis. Tissue was biopsied from 7 Holstein cows at 4 time points: late lactation, 7 d after dry-off, and at 21 d and 7 d before expected calving date. Smooth muscle α -actin, which is an indicator of activated fibroblasts, and fibronectin were measured by immunohistochemistry with image analysis software. Overall morphology of biopsied tissues was typical of involution and mammogenesis within each cow. The number of activated fibroblasts was similar for the first three time points but tended to increase from 20% to 33% of total fibroblasts between the last two time points ($P=0.04$). The intralobular stromal area decreased relative to the lumen and epithelial area from 48% to 32% between the last two time points ($P<0.01$). Fibronectin expression did not significantly change across time points ($P>0.2$). Based on these preliminary data, we suggest that fibroblast activation may indeed be important for stromal remodeling and that the major changes in the stroma occur in the late stages of the dry period.

Meat Science and Muscle Biology: Meat Science Research: Past, Present, and Future

688 ASAS Centennial Presentation: A century of pioneers and progress in meat science leads to new frontiers. D. H. Beermann*, *University of Nebraska, Lincoln.*

Discoveries, understanding and innovations in meat science led to revolutionary changes during the last century in meat and poultry production, processing, marketing and consumption. American Society of Animal Science members made key contributions in most, if not all, categories of advancement. The first U.S. university meat science program started in Minnesota in 1905. Use of mechanical refrigeration in the “meat packing industry”, improved transportation and packaging, and home refrigeration provided more flexibility, variety and consistency of meat and meat products in the early 1900s. Cooperative meat research was started by 27 universities in 1925, with focus on observational characterization of carcass traits and composition, meat quality attributes, and understanding the causes of wide variation in these variables. Scientific study of the genetic, nutritional, and environmental influences on growth, physiology and postmortem biochemistry of muscle often employed muscle-comparative investigations. Rigor mortis, cold shortening and thaw rigor, postmortem muscle metabolism, post mortem tenderization and tenderness variation, and postmortem myoglobin and lipid oxidation were vigorously studied in the 1960s and beyond, defining the biochemical bases for associated outcomes in fresh and processed products. Value-added benefits result from implementation of electrical stimulation, “boxed beef” and modified atmosphere packaging, restructuring technologies, collagen recovery and muscle profiling work. Isolation, purification and defining the primary structure and biophysical properties of the myofibrillar and cytoskeletal proteins in muscle aided understanding of contraction and postmortem changes. The role of calcium-dependent proteases in meat tenderness and muscle growth is being clarified. The chemistry of meat curing, meat emulsion formation, fermentation, and other processing methods led to new technologies, new meat products, and new benchmarks in product shelf-life and quality. Meat safety assurance and our ability to manage the microbiological causes of food-borne illness and spoilage are imminently important now and in the future.

689 Mapping quality attributes within the pork loin. R. M. Smith*¹, M. J. Anderson¹, J. Viguera², E. Huff-Loneragan¹, and S. M. Lonergan¹, ¹*Iowa State University, Ames,* ²*Company Imasde Agroalimentaria, S.L., Madrid, Spain.*

Muscle location has the potential to be a significant source of variation in fresh pork quality. The objective of this study was to investigate how location affects quality attributes within the longissimus dorsi. Forty pork loins aged 10-12 days postmortem were cut into chops from the blade end, center, and sirloin end. Quality attributes were measured on the longissimus dorsi at each location. Hunter L, a, and b values as well as drip loss were measured in duplicate. Intact desmin and pH were also measured in each location. Two instrumental methods used to determine texture were Warner-Bratzler shear (WBS) and star probe (SP). Measurements of SP of the blade were significantly lower ($P<0.01$) than both the center and the sirloin. WBS values of the center were significantly higher ($P<0.01$) than both the blade and the sirloin ($P<0.01$). pH of the sirloin tended to be higher ($P<0.06$) than the blade and was significantly higher ($P<0.01$) than the center. Hunter L and b values both exhibited location differences between the blade and center and between the blade

and sirloin end. There was significantly more intact desmin in blade ($P<0.05$) than in the center and sirloin. Location did not significantly affect drip loss values or Hunter a values. The differences observed between locations for some quality attributes reiterate the importance of sampling from the same location when examining pork quality.

	Blade	Center	Sirloin	Standard error	P-value
Star Probe (kg)	4.27 ^b	5.87 ^a	5.72 ^a	1.49	<0.01
Warner-Bratzler Shear (kg)	2.58 ^b	3.25 ^a	2.82 ^b	1.15	<0.01
pH	5.65 ^b	5.63 ^b	5.71 ^a	0.02	<0.05
Drip (%)	1.05	1.16	1.13	0.06	0.39
Hunter L	57.15 ^a	54.94 ^b	55.03 ^b	0.41	<0.01
Hunter a	7.03	6.94	7.15	0.28	0.88
Hunter b	12.57 ^a	11.75 ^b	11.82 ^b	0.15	<0.01
Intact Desmin	1.53 ^a	1.27 ^b	1.14 ^b	0.09	<0.01

690 Nitrosylation affects the autolysis of μ -calpain. W. Zhang*, S. Lonergan, and E. Huff-Loneragan, *Iowa State University, Ames.*

Nitric oxide is a signaling compound that can interact with cysteine residues and induce protein nitrosylation to regulate protein function and enzyme activities. This study was designed to examine the hypothesis that S-nitrosoglutathione (GSNO) can induce the nitrosylation of the cysteine protease μ -calpain and regulate its autolysis. GSNO is a natural compound which releases nitric oxide (NO) under physiological conditions and is widely used as a NO donor. SDS-PAGE, western blotting and a nitrosylation assay were used to detect autolysis and nitrosylation of μ -calpain that was exposed to GSNO. The five treatments for autolysis were (in order of addition): 1) control: μ -calpain only; 2) μ -calpain+GSNO; 3) μ -calpain+CaCl₂; 4) μ -calpain+CaCl₂+GSNO; 5) μ -calpain+GSNO+CaCl₂. A sixth treatment in which purified μ -calpain was incubated with 10 volumes of 5 mM dithiothreitol (DTT) for 12 hours was also included in the nitrosylation assay. The final calcium concentrations for autolysis and nitrosylation were 0.5 and 1.0 mM respectively. μ -Calpain was purified from porcine skeletal muscle and 0.83 μ g μ -calpain was used for each treatment. GSNO was added at a ratio of 2:1 (w:w) GSNO to μ -calpain. All treatments were incubated with pH 6.5 HEPES on ice for 60 minutes. μ -Calpain autolysis of the 80 kDa subunit was slowed by GSNO especially when it was first exposed to GSNO before calcium. The calpain was less autolyzed in GSNO+calcium treatment after 5 and 10 minute incubations on ice compared with control treatment. Of particular interest was that native μ -calpain was shown to be nitrosylated. Less nitrosylation was detected in the DTT treated group compared with control group showing calpain may be endogenously nitrosylated. More μ -calpain was nitrosylated in both GSNO, calcium+GSNO and GSNO+calcium groups than control group, although the difference was less remarkable in the absence of calcium. These results indicate that μ -calpain could be further nitrosylated by GSNO. The nitrosylation may be involved in regulating the autolysis of μ -calpain.

Key Words: S-Nitrosoglutathione, μ -Calpain, Nitric Oxide

691 Myostatin is associated with marbling in beef cattle. K. R. Underwood*, J. Tong, M. J. Zhu, W. J. Means, and M. Du, *University of Wyoming, Laramie.*

Marbling, or intramuscular fat, is an important factor in beef quality. Myostatin is a member of the Transforming Growth Factor- β family which functions as a negative regulator of muscle growth. Myostatin mutation leads to double muscling cattle. Though the role of myostatin as a negative regulator of skeletal muscle development has been well-established, its role in adipose tissue deposition and adipogenesis is not well defined. Myostatin's role in marbling deposition of beef cattle is unclear. **HYPOTHESIS:** Myostatin is positively associated with marbling in beef cattle. **OBJECTIVE:** To evaluate the role of myostatin in marbling deposition in beef cattle through both *in vivo* study and *in vitro* 3T3-L1 cell culture study. 3T3-L1 cells are commonly used for studying adipogenesis *in vitro*.

Five steers with high intramuscular fat (High IMF, $5.71 \pm 0.36\%$) and five steers with low intramuscular fat (Low IMF, $2.09 \pm 0.19\%$) were selected from a highly uniform group to measure myostatin mRNA expression using RT-PCR and myostatin protein expression using immunoblotting. In addition, 3T3-L1 cells were incubated in DMEM medium with 10% fetal bovine serum. Adipogenesis in 3T3-L1 cells was induced using a standard adipogenic medium composed of DMEM with 10% Fetal bovine serum supplemented with insulin (20 mIU/ml), dexamethazone (0.1 μM), 3-isobutyl-1-methylxanthine (0.5 mM), and troglitazone (10 μM) for 10 days with 0, 2.5, 5.0, 10.0, and 20.0 μM myostatin. Adipogenesis was then assessed by Oil-Red-O staining ($n = 3$).

Myostatin mRNA expression and active myostatin content tended to be higher ($P < 0.10$) in the High IMF steers compared to Low IMF steers. Oil-Red-O staining showed that myostatin levels of 2.5, 5.0, and 10.0 μM increased ($P < 0.05$) adipocytes differentiated into mature 3T3 cells, but 20.0 μM myostatin did not. These data indicate that myostatin is associated with marbling in beef cattle. Therefore, myostatin may be a target that could control muscle growth and marbling deposition in beef cattle.

Key Words: Myostatin, Marbling, Beef

692 ASAS Centennial Presentation: Current and future meat science research needs. T. H. Powell*¹ and R. D. Huffman², ¹*American Meat Science Association, Savoy, IL*, ²*American Meat Institute, Washington, DC.*

Meat science research continues to evolve and adapt to the ever changing needs and resources of the agricultural research community and the livestock and meat processing industries. Recently, meat scientist from academia, government and industry convened to develop a comprehensive set of current research needs and relative priorities in meat science. The initial forum was convened by the American Meat Science Association and the American Meat Institute Foundation during a 1 day research priority symposium at the 2006 Meat Industry Research Conference. Sixty-five scientists from academia, industry and government heard presentations from key thought leaders in four broad research areas:

1. Product Quality
2. Food Safety
3. Processing, Packaging and Ingredients
4. Consumer Needs

Conference participants then worked in break-out groups for each research area. For each area, they brainstormed current research needs, assigned a relative priority score and identified the most urgent needs. Reports from each breakout group were presented at the conference and will be summarized in this presentation. The document was reviewed and updated during a reciprocation session at the 2007 Reciprocal Meat Conference. This presentation will also take a forward look at what challenges lay ahead for meat science research in the future given the changing dynamics of livestock production, meat consumption patterns, and ever increasing limits on available resources for research.

Nonruminant Nutrition: Energy Utilization

693 Effects of enzyme additions to diets with corn- and sorghum-based distillers dried grains with solubles on growth performance and nutrient digestibility in nursery and finishing pigs. C. Feoli¹, J. D. Hancock¹, T. L. Gugle¹, S. D. Carter², and N. A. Cole³, ¹Kansas State University, Manhattan, ²Oklahoma State University, Stillwater, ³USDA/ARS, Bushland, TX.

Two experiments were conducted to determine the effects of enzyme additions on the nutritional value of diets with corn- and sorghum-based distillers dried grains with solubles (DDGS). For Exp. 1, 180 weanling pigs were fed the same starter diet for 10 d and then used in a 27-d growth assay. There were six pigs/pen and six pens/treatment with an average initial BW of 7.5 kg. Treatments were a corn-soy-based control and diets with 30% corn-based (Hudson, SD) and sorghum-based DDGS (Russell, KS) without and with enzymes (a cocktail of beta-glucanase, xylanase, alpha-amylase, and pectinase to supply 150, 4,000, 1,000, and 25 units of activity, respectively, per kg of diet). Pigs fed the control diet had greater ADG and digestibility of DM, N, and GE ($P < 0.003$) than pigs fed the DDGS treatments. Addition of enzymes improved ADG and decreased ADFI for pigs fed corn-based DDGS (DDGS source \times enzyme interaction, $P < 0.08$). However, addition of enzymes improved G:F ($P < 0.08$) and digestibility of DM ($P < 0.04$) regardless of DDGS source. For Exp. 2, 330 finishing pigs (avg BW of 64 kg) were used in a 65-d growth assay. There were 11 pigs/pen and six pens/treatment. Treatments were the same as in Exp. 1 but 40% DDGS were used for the finishing experiment. Pigs fed the control diet had greater ADG and ADFI and digestibility of DM, N, and GE ($P < 0.008$) than pigs fed the DDGS treatments. Pigs fed the corn-based DDGS treatments had greater G:F, digestibility of DM, N, and GE, and iodine value of jowl fat than pigs fed the sorghum-based DDGS treatments ($P < 0.04$). Enzymes improved digestibility of DM, N, and GE ($P < 0.007$), especially for diets with sorghum-based DDGS (DDGS source \times enzyme interaction, $P < 0.10$). In conclusion, rate of gain and nutrient digestibility were decreased with addition of DDGS to diets for nursery and finishing pigs but adding enzymes partially restored those losses.

Key Words: Pig, Distillers Dried Grains, Enzyme Supplementation

694 A multi-substrate enzyme blend for weaned pigs fed corn- or wheat-barley-based diets and its relationship with water acidification. Y. Han¹, A. Humphreys², P. Lessard³, and M. Vignola⁴, ¹Nutreco Canada Agresearch, Guelph, ON, Canada, ²Nutreco Canada West, Winnipeg, MB, Canada, ³Nutreco Canada East, St. Hugues, QC, Canada, ⁴Nutreco Canada Agresearch, St-Roumuald, QC, Canada.

Different non-starch polysaccharides (NSP) exist in corn- or wheat-barley-based diets. This study evaluated the efficacy of a proprietary enzyme blend for both diet types. Two enzyme blends (A; B) targeting multiple NSP substrates were prepared based on *in vitro* studies. The blends were used in two pig studies conducted at two research locations. Exp. 1 used 900 weaned pigs (BW 6.2kg) allocated to 36 pens (25 pigs/pen, 9 pens/treatment, 4 treatments total) at a Manitoba facility. The same phase 1 (0.5kg/pig) and 2 (1.5kg/pig) diets were given to all pigs. In phases 3 and 4, a wheat-barley based control diet was supplemented with a commercial xylanase, Blend A, or Blend B at 0.75, 0.5, or 0.5 kg per tonne, respectively. The trial lasted for 46 days. Exp. 2 was conducted at a Quebec facility, with 918 weaned pigs (BW 5.6kg)

allocated to 54 pens (17 pigs /pen, 9 pens/treatment, 6 treatments total). The same phase 1 and 2 diets were given to all pigs. In phases 3 and 4, a factorial study of 3 (enzymes) \times 2 (with or without water acidification) was conducted. A corn-based control diet was supplemented with a commercial enzyme (xylanase/glucanase, 1.0kg/tonne) or Blend B (0.5kg/tonne). A water acidifier was used at 500ml per 1000kg water. The trial lasted for 42 days. In Exp. 1, Blend B improved overall feed efficiency (FE, $P < 0.03$) compared with the Control (4.7%), the commercial xylanase (5.7%) or Blend A (5.1%) respectively. In Exp. 2, both enzymes significantly improved ADG (7%, $P < 0.01$) and FE (4%, $P < 0.001$) at week 3. The overall performance was similar in all treatments ($P > 0.05$). The acidifier only improved FE (2%, $P < 0.046$) at week 5. There was no interaction between acidification and enzymes ($P > 0.05$). These results demonstrated the potential to use one common enzyme blend for both diet types in weaned pigs, and the response was more pronounced in wheat-barley based diets than in corn-based diets.

Key Words: Weaned Piglets, Enzymes, Multi-Substrate

695 Gastrointestinal ecology of piglets fed diets containing non-starch polysaccharide hydrolysis products and egg yolk antibodies upon challenge with *Escherichia coli* (K88). E. Kiarie*, B. A. Slominski, D. O. Krause, and C. M. Nyachoti, *University of Manitoba, Winnipeg, MB, Canada.*

Gastrointestinal ecology (GE) of piglets fed diets containing non-starch polysaccharide hydrolysis products (HP) and egg yolk antibodies (EYA) against K88 fimbriae upon oral challenge with enterotoxigenic *E. coli* K88 (ETEC) was studied. The HP were generated by incubating a mixture of ethanol-extracted wheat, soybean meal, canola meal and flax with a blend of carbohydrase enzymes. Forty, 21-d old pigs housed in pairs were assigned one of four diets: control (C; devoid of feedstuffs used to generate HP), C + 5 g of HP/kg (HP), C + 5 g of EYA/kg (EYA) or C + 5 g of EYA + 5 g of HP/kg (EYA + HP) in a completely randomized design to give 5 pens per diet. Piglets were fed the experimental diets for 9 d adaptation period. On d 10 all piglets were orally challenged with ETEC. The incidence and severity of diarrhea was determined on a pen basis using a fecal scoring system (1 = no diarrhea to 5 = liquid diarrhea) at 0 h (1 h before challenge), 6, 24, and 48 h post-challenge. At 24 and 48 h post-challenge pigs (1 pig/pen on each occasion) were sacrificed to collect digesta and intestinal tissue. Compared to pigs fed the C diet, pigs fed additives showed low ileal adherent ETEC counts (4.7 vs. 5.5 log₁₀ cfu/g; $P = 0.01$), low digesta ammonia concentration (104 vs. 132 mg/l; $P = 0.002$) and high villi height to crypt depth ratio (2.3 vs. 1.9; $P = 0.05$) which coincided with less (2 vs. 4; $P = 0.01$) scours within 48 h post-challenge. Feeding HP and EYA in combination resulted in higher ($P = 0.0001$) ileal lactic acid than when fed singly whilst pigs fed diets containing HP showed lower gastric pH ($P = 0.03$) and higher ileal adherent lactobacilli counts ($P = 0.01$) than pigs fed the C diet. In conclusion, the results show that HP and EYA modified piglet GE in the presence of ETEC which may explain the mechanisms through which these additives attenuate ETEC-induced secretory diarrhea in piglets.

696 Expression profiles of iron-related genes in the intestine and liver of young pigs fed three types of dietary inulin. K. Yasuda*¹, H. D. Dawson², E. Wasmuth¹, K. R. Roneker¹, K. Kohn², C. Chen², J. F. Urban², R. M. Welch³, D. D. Miller¹, and X. G. Lei¹, ¹Cornell University, Ithaca, NY, ²USDA-Beltsville Human Nutrition Research Center, Beltsville, MD, ³USDA-ARS U.S. Plant, Soil and Nutrition Laboratory, Cornell University, Ithaca, NY.

Dietary inulin has been shown to improve hemoglobin repletion efficiency in young anemic pigs. To elucidate the mechanism, we compared the expression of 27 Fe-related genes in intestine and liver of pigs fed three types of inulin (BENEO-Orafti, Tienen, Belgium): P95 (oligofructose), HP (long-chain), and Synergy 1 (50:50 mixture of P95 and HP). A total of 20 pigs (5-wk old) were fed a corn-soybean meal based diet (BD) without supplemental inorganic iron, or the BD plus 4% of Synergy 1, HP, or P95. After 5 wks, all pigs were killed to collect total RNA from the liver and mucosa of duodenum, ileum, cecum, and colon. Relative mRNA expression of the 27 genes was quantified using real-time qRT-PCR (ABI 7700, Applied Biosystems, Foster City, CA) and normalized with levels of four housekeeping genes. Dietary inulin affected ($P < 0.05$) 2 genes in the duodenum, 6 genes in the colon, and 7 genes each in the cecum and liver. An additional 1 or 2 genes were marginally affected ($P = 0.06$ to 0.09) by inulin in each of the five tissues. Gene expression of solute carrier family 11 member 1, lactoferrin, and ferritin showed similar responses to dietary inulin in multiple tissues. In conclusion, expression of Fe-related genes was affected by dietary inulin supplementation in young pigs not only in the large intestines but also in the small intestines and liver. The regulatory mechanism and physiological relevance of these responses need further exploration. This project was supported in part by Harvest-Plus, International Food Policy Research Institute (IFPRI) and Centro Internacional Agricultura Tropical (CIAT) and BENEO-Orafti (Tienen, Belgium).

Key Words: Inulin, mRNA, Gene Expression

697 Variation in chemical composition of soybean hulls. F. F. Barbosa*^{1,2}, M. D. Tokach², J. M. DeRouchey², R. D. Goodband², J. L. Nelssen², and S. S. Dritz², ¹Federal University of Viçosa, Viçosa, Minas Gerais, Brazil, ²Kansas State University, Manhattan.

The objective of this study was to examine the variation in chemical composition of soybean hulls. Our goal was to develop regression equations characterizing the nutritive value of soybean hulls for use in swine diets. Samples ($n=39$) were collected from different processing plants across the U.S. and analyzed for CP, GE, crude fiber (CF), ADF, NDF, fat, ash, Ca, and P. One sample was excluded because it contained approximately 10-times the amount of Ca (5.22% vs a mean of 0.57%) as other samples. The results of chemical analysis of the 38 samples were used to determine maximum, minimum, and mean values on a DM basis. Estimated DE values were calculated according to an equation described by Noblet and Perez (1993). Regression equations among the nutrients also were established. A high correlation was observed between CF and CP, with the CF predicting 94.7% of the variation in CP content ($Y = -1.160x + 55.49$; $R^2 = 0.95$). Crude fiber also was highly correlated to ADF ($Y = 1.256x + 0.612$; $R^2 = 0.96$); NDF ($Y = 1.657x + 2.234$; $R^2 = 0.97$); and estimated DE ($Y = -90.86x + 4819$; $R^2 = 0.94$). A high correlation also was observed between CP and estimated DE ($Y = 74.79x + 521.9$; $R^2 = 0.90$). Lower correlations were observed between ash concentration and Ca and P. Also, lower correlations were observed between GE and all the other nutrients. In

summary, the chemical composition of soybean hulls can be highly variable; however, CF content can help explain much of the variation in CP, ADF, NDF, and estimated DE.

Table 1. Nutritional values of soybean hulls on a DM basis

Nutrient	Minimum	Mean	Maximum	SD
Moisture, %	3.39	8.18	9.51	1.16
CP, %	9.90	13.40	29.40	3.99
GE, kcal/kg	4036	4375	4825	177
Est. DE, kcal/kg	1166	1553	2654	365
CF, %	23.90	36.30	39.90	3.35
ADF, %	30.20	46.20	50.50	4.30
NDF, %	41.50	62.40	68.00	5.36
Fat, %	0.70	1.70	4.50	0.90
NFE, %	39.50	42.70	44.90	1.40
Ash, %	4.50	5.30	6.70	0.50
Ca, %	0.46	0.57	0.76	0.06
P, %	0.11	0.16	0.35	0.05

Key Words: Nutritive Value, Soybean Hulls

698 Influence of soybean hulls on active nutrient transport in the gastrointestinal tract of nursery pigs. D. M. Sholly*¹, B. E. Aldridge¹, J. G. Stevens¹, L. L. Snyder¹, J. S. Radcliffe¹, K. E. Bach Knudsen², A. L. Sutton¹, and B. T. Richert¹, ¹Purdue University, West Lafayette, IN, ²University of Aarhus, Tjele, Denmark.

Twenty four barrows and 24 gilts (initial BW=5.65 kg) were used to determine the influence of adding soybean hulls (SH) to nursery pig diets on active nutrient absorption. Pigs were weaned at 17 d of age, blocked by BW, sex and ancestry, and housed in individual pens (0.41×0.86 m). All pigs were provided ad libitum access to a common, pelleted phase 1 diet (d 0-5) followed by a phase 2 diet (d 6-10) in meal form. Pigs were then fed experimental diets for an additional 15-18 d: 1) Control, C; 2) C + 3% SH; 3) C + 6% SH; and 4) C + 12% SH. Diet C (20.5% CP, 1.1% Lys) was corn-SBM based with 10.75% starch, 5 % lactose, 4% fish meal, and 1.25% soy concentrate. Soy hulls were added to experimental diets in place of starch and soy concentrate. Experimental diets were fed at 9% metabolic BW and intake was adjusted every 4 d. After 15, 16, or 18 d of feeding the experimental diets, pigs were euthanized. Jejunal tissue was removed, mounted in modified Ussing chambers, and active nutrient absorption was estimated based on changes in transepithelial short circuit current (Isc) following mucosal challenges with 10 mM glucose (Glc), phosphorus (P), and glutamine (Gln). Osmotic balance was maintained by adding mannitol to the serosal chamber. Overall ADG (0.36 kg/d), ADFI (0.53 kg/d), G:F (0.68) and active transport of P and Gln were not affected by diet or sex ($P > 0.10$). Active Glc transport tended ($P < 0.10$) to be increased in pigs fed diets containing 6% SH (59.3 $\mu\text{A}/\text{cm}^2$) compared to diets with 0 or 3% SH (36.1 $\mu\text{A}/\text{cm}^2$; 34.2 $\mu\text{A}/\text{cm}^2$, respectively), with pigs fed diets containing 12% SH (53.8 $\mu\text{A}/\text{cm}^2$) being intermediate. In summary, enhanced Glc transport observed with the addition of 6% SH could be due to changes in gastrointestinal morphology or an increased abundance of membrane bound SGLT1 resulting from decreased Glc concentrations in the 6% SH diets.

Key Words: Soybean Hulls, Active Nutrient Transport, Pigs

699 Carbohydrate X gut environment modifier interaction in weaned pigs. B. V. Lawrence*, R. J. Harrell, R. A. Anderson, and F. Navarro, *NOVUS International Inc, St. Louis, MO.*

A 21-d nursery trial was conducted to evaluate the interaction of carbohydrate source and ACIDOMATRIX™ LowLac (LowLac), a blend of organic acids, MOS, esters of butyrate, and ethoxyquin, in medicated (Carbadox) weaned pig diets. Pigs (6.16±0.98 kg) were blocked by weight and sex to pen (23 pigs/pen). Pens were assigned to one of 5 treatments (6 reps/trt) fed from day 0-21 postweaning in 2 diet phases. Treatments were 1) Ctrl (20/10% lactose) 2) Neg1 (5/2.5% lactose) 3) LowLac (10/2.5% lactose+0.69% Low-Lac), 4) Alt1 (10/2.5% lactose+0.69% Low-Lac+10/7.5% alternate CHO), and 5) Alt2 (5/2.5% lactose+0.69% Low-Lac+15/7.5% alternate CHO). The alternate CHO was a hydrolyzed sugar, predominantly dextrose. Lactose replaced was from whey permeate. Day 0-7 gain was greater ($P<0.01$) for Ctrl (175 g/d) than for Neg1 (115 g/d), Low-Lac (131 g/d) or Alt2 (136 g/d) pigs. Alt1 pigs (167 g/d) gained faster ($P<0.05$) than either Neg1 or Low-Lac pigs. Gain/feed was lower ($P<0.05$) for Neg1 (0.67) and Low-Lac pigs (0.72) than for Ctrl (0.85) and Alt1 (0.82) pigs. Day 7-21 gain and intake were similar ($P>0.10$) among treatments. Gain/feed day 7-21 was lower ($P<0.01$) for Ctrl pigs compared with other treatments. Day 0-21 gain and intake were not different ($P>0.10$) among treatments. Low-Lac pigs had a higher ($P<0.05$) day 0-21 gain/feed (0.79) than Ctrl (0.75) pigs. Alt2 pigs had a higher ($P<0.05$) gain/feed (0.80) than either Ctrl or Neg1 (0.77) pigs. Day 0-7 feed cost/kg (FCKG) gain was not different ($P>0.10$) among treatments averaging \$0.986±0.14. Ctrl pigs had the highest day 7-21 FCKG (\$0.681), which was higher ($P<0.05$) than for Alt1 (\$0.638) and Alt2 (\$0.639) pigs which were in turn greater ($P<0.05$) than for Neg1 (\$0.564) and Low-Lac (\$0.586) pigs. For the 21-d period, Ctrl pigs had a higher ($P<0.05$) FCKG (\$0.737) than Alt2 (\$0.695), Low-Lac (\$0.662) and Neg1 (\$0.633) pigs. Alt1 pigs had a similar FCKG (\$0.707) compared to Ctrl and Alt2, but higher ($P<0.05$) FCKG than Neg1 and Low-Lac pigs. These results demonstrate importance of CHO source day 0-7 postweaning and suggest use of ACIDOMATRIX Low-Lac with low lactose diets may be economically advantageous.

Key Words: Lactose, Pigs, ACIDOMATRIX

700 Dietary fatty acids can alter markers of inflammation in cartilage and synovial fluid from multiparous sows. C. I. O'Connor-Robison*¹, J. M. Mapes¹, J. D. Spencer², and M. W. Orth¹, ¹Michigan State University, East Lansing, ²JBS United, Sheridan, IN.

Dietary long chain polyunsaturated fatty acids (LCPUFA) including arachidonic acid, eicosapentaenoic acid, and docosahexaenoic acid can alter the production of inflammation mediators. The objective of this study was to characterize the effects of dietary LCPUFA supplementation on indices of cartilage degradation and inflammation in porcine IL-1 beta (pIL-1) stimulated porcine articular cartilage explants. Sows (7 sows/trt) were fed either control corn/soybean meal based diets or the control diet supplemented with 0.75% protected LCPUFA (Gromega 365™; JBS United, Sheridan, IN) during gestation and 1.0% protected LCPUFA throughout lactation for a minimum of 4 parities prior to tissue collection. The cartilage explants (6 mm diameter) were biopsied from the right and left humeral-ulnar joints of fourteen sows within 36 h of slaughter. Synovial fluid was collected from the right carpal joint of

each sow post-mortem. Cartilage explants were allocated to 24-well culture plates with 2 discs per well, 12 wells/sow and cultured over 72 h. Serum free medium (1 mL/well) consisted of Gibco D-MEM:F-12, amino acids, ascorbic acid, and antibiotics. Explants were incubated at 37°C. Six wells per sow were treated with 10 ng/mL of pIL-1. At 24, 48 and 72 h of culture, media were removed from each well and reserved for analysis. Media were analyzed for proteoglycans (PG), nitric oxide (NO), interleukin-6 (IL-6), and prostaglandin E2 (PGE₂) concentrations. The addition of LCPUFA to the diet tended to decrease PG release compared to control (340 vs. 460 ± 45 µg PG/well) when explants were stimulated with pIL-1 (trt x diet effect; $P=0.075$), suggesting a reduction in cartilage degradation. However, LCPUFA, did not alter NO or IL-6 release. Overall, cartilage enriched with LCPUFA tended to have increased PGE₂ release when stimulated with pIL-1 (430 ± 100 pg/mL) compared to control (180 ± 100 pg/mL; $P=0.09$). There was a trend for the LCPUFA fed sows to have elevated levels of PGE₂ in their synovial fluid (270 vs. 1060 ± 300 pg/mL; $P=0.10$). Thus, dietary LCPUFA supplementation can have an effect on the synthesis of at least some inflammatory mediators in both porcine cartilage and synovial fluid.

Key Words: Swine, Cartilage, Inflammation

701 Effect of pelleting and fat content on energy value of corn for pigs. J. Noblet* and Y. Jaguelin, *INRA, Saint Gilles, France.*

The energy value of ingredients for swine depends on their chemical composition, the technological treatment and the BW of animals. The objective of two trials was to measure the DE content and nutrients digestibility of 5 corn samples either as mash or after pelleting (55-65°C); corns differed mainly for their fat (EE) content. Corn was either fed alone with a minerals and vitamins complement (trial 1, 3 corns; 3 diets) or included at 35% in a basal corn and soybean meal diet (2 corns; 3 diets); in this latter case, the energy value of the basal diet was also measured and the energy value of corn was obtained according to the difference method. Diets (n=6) were fed for 3 wk to pigs weighing 55 kg at the start of the trials (5/treatment) as mash feed or as pellets. Excreta were collected for the last 10 d. Average (min-max) chemical composition of corns (% of DM) was: 1.5 (1.4-1.8) % ash, 9.3 (7.8-11.7) % CP, 6.1 (3.5-10.8) % EE and 68.9 (60.4-73.4) % starch; the GE content was 19.19 (18.42-20.29) MJ/kg DM. Pelleting improved fecal digestibility of nutrients and energy of diets ($P<0.01$); this improvement depended on diet characteristics ($P<0.01$). The average fecal digestibility coefficients (%) of organic matter, energy, crude protein and EE of corns were 89.9 and 91.4, 86.9 and 90.0, 81.0 and 84.0 and 57.0 and 78.1 for mash and pelleted forms, respectively. The corresponding DE contents were 16.66 and 17.26 MJ/kg of DM. The difference in DE value between both presentations depended on corn EE content. The DE value of corn (MJ per kg of DM) can then be predicted as 16.44 + 0.038 EE and 16.44 + 0.133 EE for mash and pellet presentations, respectively (EE as % of DM); the corresponding equation for GE was: 17.72 + 0.241 x EE. Data on nutrients digestibility indicate that the improvement in energy digestibility and energy value of corn due to pelleting is exclusively related to a higher EE digestibility. In conclusion, the DE content of corn depends linearly and positively on its EE content and the relationship is dependent on the form of presentation.

Key Words: Pig, Energy Value, Corn

702 Interaction of dietary protein and energy on growth performance in finishing barrows. P. M. Cline*, C. R. Dove, and M. J. Azain, *University of Georgia, Athens.*

The objective of this study was to determine the performance response to changes in dietary fat and protein content in finishing barrows. Previous work has shown that increases in dietary energy density result in decreased feed intake. The experiment was conducted in 3 trials of 18 pens each (4 pigs/pen, total n=216). Within each trial, barrows (PIC C42 × 280, initial wt. = 84 kg) were blocked by weight and assigned to one of 9 experimental diets in a 3 × 3 factorial arrangement, with main effects of crude protein (12, 16, 20%, lysine: 0.60, 0.80, 1.00%) and added Fat (1, 6, 11%). The lowest protein diet with 1% added fat, met the NRC recommendations for pigs in this weight range. Body weight, intake and efficiency were determined initially and on d 14 and 28. There were no significant interactions of dietary protein and fat. There was a main effect of dietary protein on gain ($P < 0.02$). Average daily gain increased as dietary protein increased from 12 (1.04 kg/d) to 16% CP (1.12 kg/d), but no further increase was observed at 20% CP (1.12 kg/d). There were no effects of protein level on feed or caloric intake or on gain:feed ratio ($P > 0.10$). There were main effects of dietary fat on gain ($P < 0.05$), caloric intake ($P < 0.01$) and efficiency ($P < 0.01$). Gain was not different in pigs fed 1 (1.06 kg/d) or 6% added fat (1.07 kg/d), but was increased in pigs fed 11% fat (1.15 kg/d). Daily caloric intake was increased as dietary fat level increased from 1 to 11% (10.5, 10.8 and 11.8 Mcal/d). Gain:feed ratio improved linearly with fat addition (0.33, 0.35 and 0.37). Serum urea, determined at the end of the feeding period, increased as dietary protein increased ($P < 0.01$), but was not affected by dietary fat. These results contradict earlier research that demonstrated decreased feed intake with increasing dietary fat level.

Key Words: Energy Intake, Pigs

703 Effect of crude protein concentration and sugar beet pulp on nutrient digestibility, nitrogen excretion, intestinal fermentation and manure ammonia and odour emissions from finisher pigs. M. B. Lynch*, C. J. O'Shea, T. Sweeney, J. J. Callan, and J. V. O'Doherty, *University College Dublin, Newcastle, Co. Dublin, Ireland.*

A 2x2 factorial experiment was used to investigate dietary crude protein (CP) (200 vs 150 g/kg) and sugar beet pulp (SBP) (200 vs 0 g/kg) on nutrient digestibility, nitrogen (N) excretion, intestinal fermentation and manure ammonia and odour emissions from 24 boars. Pigs offered SBP-containing diets had a reduced digestibility of N (0.822 vs 0.868; $P < 0.05$) and gross energy (0.851 vs 0.872; $P < 0.05$) and an increased digestibility of neutral detergent fibre (0.706 vs 0.558; $P < 0.001$) compared with pigs offered diets containing no SBP. There was an interaction between CP and SBP on the urine: faeces N ratio. Pigs offered the 200 g/kg CP SBP-based diet reduced the urine: faeces N ratio ($P < 0.05$) compared with those offered the 200 g/kg CP diet without SBP. However there was no effect of SBP in pigs offered 150 g/kg CP diets. Manure ammonia emissions were reduced (71.26 vs 107.23 gNH₃/gN intake; $P < 0.01$), however odour emissions were increased (3544.7 vs 2084.1 OuEm-3; $P < 0.05$)

when pigs were offered SBP diets. Decreasing dietary CP to 150 g/kg reduced total N excretion (19.96 vs 34.65 g/day; $P < 0.001$) and ammonia emissions (76.98 vs 101.51 gNH₃/g N intake; $P < 0.05$). There was an interaction between dietary CP and SBP on isovaleric acid ($P < 0.01$) and branch chain fatty acids ($P < 0.001$) in caecal digesta. Pigs offered the 200 g/kg CP SBP-containing diet reduced isovaleric acid and branch chain fatty acids in the caecum compared with pigs offered the 200 g/kg CP diet containing no SBP. However there was no effect of SBP in the 150 g/kg CP diet. In conclusion, pigs offered SBP-containing diets had a reduced manure ammonia emissions and increased odour emissions compared with diets containing no SBP. Pigs offered the 200 g/kg CP SBP-containing diet had a reduced urine: faeces N ratio compared with those offered the 200 g/kg CP diet containing no SBP.

Key Words: Sugar Beet Pulp, Ammonia, Odour

704 Effect of insoluble and soluble dietary fiber on the standardized ileal digestibility of protein and selected amino acids in growing pigs. V. Halas*¹, G. Végvári², and L. Babinszky¹, ¹*Kaposvár University, Kaposvár, Hungary,* ²*Corvinus University of Budapest, Budapest, Hungary.*

Dietary fiber is a diverse fraction of feed, its mode of action in the digestive process depends on its solubility. Our trial was aimed at studying the effect of insoluble and soluble fiber on the standardized ileal digestibility (SID) of protein (CP) and selected amino acids (AAs).

A total of 24 simple T-cannulated barrows (45 kg LW) were used in 2 replicates. Dietary treatments consisted of supplementing the basal corn-soybean diet with 0, 100, 200, 300 g/kg wheat bran (WB) or sugar beet pulp (SBP) as sources of insoluble and soluble fiber, resp. All diets were formulated according to the NRC (1998) recommendations with 5 g/kg Cr₂O₃. Insoluble and soluble non-cellulosic polysaccharide (I, S) content of the diets was between 61-116 g/kg and 19-127 g/kg, resp. The trial consisted of a 14-day adaptation and a 3x12-hour collection period. The SID of CP and AAs were calculated as AID+EndogenousAA [g/DMI kg]/FeedAA [g/DM kg], where AID is the apparent ileal digestibility of CP or AA. Endogenous CP and AA losses were determined in a separate study. The fiber source and dose effects were analyzed by ANOVA, the effect of dietary S and I content on SID values were computed by linear regression (SAS, 2004).

Inclusion of SBP reduced the SID of CP, Lys, Thr and Trp from .84, .85, .73 and .96 to .76, .78, .58 and .88, resp. Increasing the level of SBP did not change the SID of CP and AAs. Inclusion of WB did not reduce the SID values significantly. Increasing WB from 0 to 300 g/kg reduced the SID of Lys from .85 to .74 ($P \leq 0.05$). The regression model showed that SID of CP was affected by I and S, SID of Cys by I and SID of Thr and Trp by S ($P \leq 0.05$).

In conclusion, SBP but not WB reduces the SID of CP and some AAs, however, no dose response was observed. The effect of soluble and insoluble fiber has to be quantified and considered in diet formulation when fiber rich feedstuffs are used.

Key Words: Dietary Fiber, Pig, Digestibility

705 Effects of dietary supplementation of benzoic, formic, and lactic acids on nitrogen balance of pigs. B. J. Min^{*1}, D. A. Monson², J. O. Vaughn³, and S. W. Kim¹, ¹North Carolina State University, Raleigh, ²Texas Tech University, Lubbock, ³Emerald Performance Materials, Kalama, WA.

A total of 384 pigs was used to evaluate the effects of benzoic acid supplementation on nitrogen balance of pigs compared to antibiotics and organic acids. Pigs were weaned at 21 d of age and fed 7 diets for 5 wk based on 3 phase feeding program following nutrient requirements from NRC. There were 8 replicates per treatment and 8 pigs per pen. Treatments were **NC**: negative control without any supplements; **PC**: positive control with Aureomycin during phase 1, 2, and 3 and Tylan during phase 4, 5, and 6; **BA**, and **BB**: benzoic acid supplementation groups with 0.5 and 1.0% benzoic acid (KalamaTM BA Feed, Emerald Performance Materials, Kalama, OR), respectively; and **OA** and **OB**: organic acid supplementation groups with 0.5 and 1.0% organic acids at 1:1 ratio of formic acid and lactic acid. At the end of 5 wk feeding, each pig representing the average body weight of each pen was selected and housed individually in metabolism crates for 4 d adjustment period followed by 5 d collection periods of fecal and urine samples to measure nitrogen balance (n=8). Fecal samples were weighed, freeze dried, ground, and analyzed for nitrogen content. Urine samples were analyzed for nitrogen content. Nitrogen digestibility of PC (83.3%), BA (84.3%), BB (85.1%) was greater (P<0.05) than NC (79.3%). Nitrogen digestibility of OA (82.3%) and OB (82.5%) did not differ to other treatment groups. Nitrogen digestibility of PC, BA, and BB did not differ among each other. The percentages of nitrogen retained in the body were 52.4, 54.6, 61.1, 68.6, 66.8, and 55.7% for NC, PC, BA, BB, OA, and OB, respectively and did not differ among treatment groups. This study shows that dietary benzoic acid supplementation improves the digestion of proteins by pigs.

Key Words: Benzoic Acid, Organic Acid, Pigs

706 Dietary energy density affects response to a dry organic acid blend in late nursery pigs. R. J. Harrell^{*}, B. V. Lawrence, R. Anderson, F. Navarro, and C. D. Knight, *Novus International Inc., St. Charles, MO.*

Meeting dietary energy requirements has become more difficult for swine producers due to ingredient availability and increased cereal grain costs. Organic acids have successfully improved performance of early nursery pigs, especially in non-medicated diets. Previously, we reported improvements in gain by increased feed intake in grow-finish pigs fed a dry organic acid blend (DOAB, ACTIVATE[®]DA). The present trial evaluated the interaction of DOAB and dietary energy density. Forty pens of pigs with an initial weight of 11.5±0.22 kg (21 days post-weaning) were randomly assigned in a 2 x 2 factorial (n = 10 pens/treatment) to energy density (3460 vs. 3280 kcal ME/kg) and DOAB (0 vs. 0.3%) for a period of 21 days. Diets medicated with Carbadox 25 g/ton were formulated to provide a similar level of nutrients other than energy. High energy diets were a corn-SBM diet with 4% choice white grease. Low energy diets contained 10% wheat midds and 1% choice white grease. Ending bodyweights (24.21 vs. 24.12±0.51 kg; P> 0.90), ADG (602 vs. 597±9 g/d; P> 0.69), or ADFI (922 vs. 929±16 g/d; P> 0.74) were not different for high vs. low energy, respectively. High energy diets had

1.5% greater GF than low energy diets (0.653 vs. 0.643±0.003; P<0.01). The DOAB did not affect final bodyweights (24.18 vs. 24.15±0.51 kg; P> 0.95), ADG (601 vs. 598±9 g/d; P> 0.84), or ADFI (935 vs. 917±15 g/d; P> 0.41), but increased GF by 1.6% (0.643 vs. 0.653±0.003; P< 0.01), for 0 vs. 0.3% DOAB, respectively. The DOAB tended to interact with dietary energy density in GF (P = 0.11) with a greater improvement in GF in low (2.5%), but not in high energy diets (0.5%). These results indicate that DOAB improves GF and can mitigate the loss of performance associated with feeding lower energy dense diets.

Key Words: Energy, Organic Acids, Swine

707 Effect of phytobiotics and acidifiers on the performance of post-weaning piglets. Y. Acosta Aragón^{*1}, T. Steiner¹, R. Castillo², and M. Lopez³, ¹Biomim GmbH, Herzogenburg, Lower Austria, Austria, ²Universidad Zamorano, Tegucigalpa, Honduras, ³Biomim America Inc, Guatemala City, Guatemala.

The aim of this study was to investigate the effects of an acidifier (blend of propionic and formic acid) and phytogenics (blend of essential oils) as well as their combination on feed intake (FI), average daily weight gain (ADWG), feed conversion ratio (FCR) and incidence of diarrhea. 262 piglets (Duroc x Landrace x Yorkshire), weaned at 21 days of age, were distributed to 5 treatments: I- negative control (without additive), II- positive control (combination of tiamulin + chlortetracycline, 2 kg/t), III- acidifier (3 kg/t), IV- phytogenic (1 kg/t), and V- acidifier and phytogenic (3 and 1 kg/t, respectively). Feed was offered ad libitum. A completely randomized design was used with 5 replicates per treatment. The study was divided in two phases: Phase I (28th to 42nd day), phase 2 (43rd to 70th day).

In phase 1, significant (p<0.05) differences were obtained in overall weight gain. The best treatments were I, III and V (3.1, 2.1 and 2.6 kg). Also, ADWG in phase 1 differed significantly (p<0.05) between treatments, with 216 and 176 g/day for the treatments I and V. Overall weight gain was numerically higher in the treatments III, IV and V (16.3, 16.0 and 16.4 kg) compared to treatments I and II (15.3 and 15.4 kg); as well as in the final BW (22.9, 23.2 and 23.6 vs. 22.6 and 22.1 kg, respectively). Overall FI was 713, 684, 731, 651 and 744 g/d (p>0.05) in treatments I through V, respectively, and overall FCR was 2.0, 1.9, 1.9, 1.7, and 1.9 (p>0.05), respectively.

In conclusion, the use of adequately designed phytogenics and acidifiers represents an alternative to the use of antibiotic growth promoters.

Key Words: Piglets, Phytobiotic, Acidifier

708 Gut environment modifier x lactose interaction in weaned pigs. J. Lampe¹, B. V. Lawrence^{*2}, R. J. Harrell², G. Gourley¹, R. A. Anderson², and F. Navarro², ¹Swine Graphics Enterprises, Webster City, IA, ²NOVUS International Inc, St. Louis, MO.

ACIDOMATRIXTM LowLac (LowLac), a blend of gut environment modifiers including organic acids, MOS, esters of butyrate, and ethoxyquin, was evaluated in low lactose nursery diets fed for 14-d. Pigs (350) were blocked by weight (5.47±0.24 kg) and sex to pen (11 pigs/pen). Pens were assigned to one of 4 treatments (8 reps/trt) fed

from day 0-14 postweaning in two budget phases (1.36 kg/pig Phase 1 (7-d); 2.27 kg/pig Phase 2 (7-d)). Treatments were 1) Ctrl (19.2/12.2% lactose) 2) Neg1 (5 and 2.5% lactose) 3) LowLac (10/2.5% lactose + 0.69% Low-Lac, 4) Neg2 (10/2.5% lactose). Lactose replaced was from whey permeate. Diets contained 100 g/ton CTC. Zn from ZnO was supplemented at 3,240 ppm Phase 1 and 2,160 ppm Phase 2. CuSO₄ was added at 0.05% Phase 1 and 0.075% Phase 2. LowLac gain (178 g/d) day 0-7 postweaning tended ($P < 0.10$) to be greater than both Neg1 (147 g/d) and Neg2 (161 g/d) gains and was similar to Ctrl (163 g/d). Day 0-7 intake was not different ($P > 0.10$) among treatments. LowLac gain/feed day 0-7 (0.97) tended ($P < 0.10$) to be greater than Neg1 (0.84), Ctrl (0.89) and Neg2 (0.89) gain/feed. Ctrl gain (339 g/d) day 7-14 was greater ($P < 0.001$) than LowLac (291 g/d) which was greater ($P < 0.01$) than Neg1 (251 g/d). Neg2 gain (269 g/d) was intermediate to LowLac and Neg1. Day 7-14 gain/feed was poorer ($P < 0.05$) for Neg1 (0.78) and Neg2 (0.79) than for Ctrl (0.91). LowLac gain/feed was intermediate (0.84). Intake day 7-14 followed a similar pattern to gain. Over the 14-d feeding period, Neg1 and Neg2 gains were similar (199 and 215 g/d) and were lower ($P < 0.01$) than LowLac gains (236 g/d) which were lower ($P < 0.01$) than Ctrl gains (258 g/d). Neg1 and Neg2 pigs day 0-14 gain/feed (0.81 and 0.83 respectively) was lower ($P < 0.05$) than gain/feed for LowLac (0.88) and Ctrl (0.90) pigs. Day 0-7 feed cost/kg gain (FCKG) was \$0.15 - \$0.17/kg higher ($P < 0.01$) for Ctrl vs. other treatments. Day 7-14, FCKG for Ctrl (\$0.55/kg) was higher ($P < 0.05$) than for Neg2 (\$0.50/kg) with Neg1 (\$0.54) and LowLac (\$0.51/kg) being intermediate. These results demonstrate that low lactose diets may be economically fed when accompanied by ACIDOMATRIX LowLac.

Key Words: Lactose, Pigs, Organic Acids

709 Effect of antimicrobial growth-promoters in diets of nursery pigs on growth performance and the development of antibiotic resistant bacteria. J. P. Holt*, E. van Heugten, A. K. Graves, M. T. See, and W. E. M. Morrow, *North Carolina State University, Raleigh.*

A study was conducted with 40 weaned pigs (BW = 5.0 ± 0.8 kg), from a herd kept antibiotic-free for 33 years, to determine the effect of growth-promoting antimicrobials on performance and antibiotic resistance. Pigs were assigned by weight to one of four diets (10 pigs per diet) consisting of a control (CON), or diets containing high levels of zinc (ZN) from ZnO (3000 ppm for 2 wk, 1500 ppm for 3 wk), 240 ppm copper (CU) from CuSO₄, or 110 mg/kg (AB) each of tylosin (TYL) and sulfamethazine (SUL). Feces was collected from 16 pigs (4 per diet) from d 0 to d 7, and on d 14, 24, 31 and 38 for isolation of *E. coli* and *Enterococcus* (ENT). Resistance to TYL, SUL, erythromycin (ERY) and neomycin (NEO) was tested. Performance was unaffected by diet ($P > 0.05$). On d 7, ENT resistant to TYL was greater for AB (23%) than CON (5.8%), CU (0%), or ZN (3.7%; $P < 0.05$). On d 14, ENT resistance to TYL and ERY, respectively, was greater for AB (39, 37%), CU (50, 50%), and ZN (41, 40%) than CON (4.7, 6.6%; $P < 0.05$). On d 14, NEO resistance in ENT was greater for CU (50%) and ZN (45%) than CON (5.3%) and AB (0.9%; $P < 0.05$). On d 38, ENT resistance to TYL and SUL, respectively, was greater for AB (73, 76%) than CON (6.3, 52%) and CU (9.3, 50%; $P < 0.05$). On d 38, ENT resistance to ERY was greater for AB (69%) than CON (9.4%) and CU (12%; $P < 0.05$). *E. coli* resistance to TYL was greater for AB (55%) than CON (26%), CU (20%), or ZN (8.5%) at d 4 ($P < 0.05$), but on d 38, resistance was greater for CU (60%) than CON (34%), AB (28%), or ZN (28%; $P < 0.05$). *E. coli* resistance to SUL was greater for AB (33%) than CON (12%) at d 1 ($P < 0.05$) but on d 7, resistance was lower for AB

(5.5%) than CON (32%). NEO-resistant *E. coli* were isolated only from pigs fed AB (6.3%). Development of antibiotic resistant bacteria can be increased by feeding antimicrobial growth-promoters, but resistant bacteria are present regardless of their use.

Key Words: Antibiotic Resistance, *Enterococcus*, *E. coli*

710 Kinetics of glucose absorption is affected by dietary oat β -glucans in portal-vein catheterized grower pigs. S. Hooda*¹, J. J. Matte², T. Vasanthan¹, and R. T. Zijlstra¹, ¹University of Alberta, Edmonton, AB, Canada, ²Agriculture and Agri-Food Canada, Lennoxville, QC, Canada.

Kinetics of nutrient digestion and absorption may impact intestine health and metabolic status and has, unlike nutrient digestibility, not been studied thoroughly in swine. A catheterized grower pig model was used to study effects of dietary β -glucans on net glucose absorption, which excludes glucose utilization by the gut. Three 35-kg pigs were surgically modified with catheters in the hepatic portal vein and carotid artery and an ultrasonic blood flow probe around the portal vein. Catheters were flushed daily with heparinized saline (200 IU/L). After 10 d, pigs were fed 3 wheat and soybean-based diets containing 0 (control), 3, and 6% concentrated oat β -glucans for 6 consecutive 7-d periods in a double Latin square design. Feed was offered twice daily at 12 h-intervals. On d 7 of each period, serial blood samples were taken for 12 h postprandially: every 15 min from -15 to 60 min, then every 30 min to 240 min, 60 min to 480 min, and at 600 and 720 min; blood flow was measured simultaneously. Plasma was analyzed for glucose. Glucose absorption rate was calculated from blood (via plasma and hematocrit) portal-arterial differences x blood flow. Carotid artery glucose and portal blood flow were not affected by diet, but changed with time ($P < 0.001$). Preprandial portal glucose was 8 mmol/L and increased postprandially to 16 mmol/L, with highest peak for the control diet ($P < 0.05$). Diet influenced ($P < 0.05$) glucose absorption rate at 15, 30, and 60 min postprandial, and was highest for the control diet. Net glucose absorption during first h after feeding was reduced ($P < 0.05$) by β -glucans; 3 and 6% β -glucans did not differ. Diet did not affect daily net glucose absorption (3464, control; 3216, 3% β -glucans; and 3357 mmol/d 6% β -glucans). The impact of reduced elevations of portal blood glucose on systemic utilization of nutrients requires further study; however, oat β -glucans clearly affect the kinetics of glucose absorption, but not daily net glucose absorption.

Key Words: β -Glucans, Glucose Absorption, Pig

711 Evaluation of ractopamine dose and feeding duration on growth performance and carcass characteristics of late finishing market pigs. R. B. Hinson*¹, G. L. Allee¹, M. J. Ritter², C. W. Parks², and S. N. Carr², ¹University of Missouri, Columbia, ²Elanco Animal Health, Greenfield, IN.

The study objective was to compare various doses and durations of ractopamine hydrochloride (RAC; Paylean®, ELANCO Animal Health, Greenfield, IN) on growth performance and carcass characteristics. Late finishing pigs with an average starting weight of 93 kg were allotted to 12 treatments. Treatments consisted of two control diets: negative control (NEG; 13.13 % CP, 0.64 TID Lys), positive control (POS; 17.77

% CP, 0.94 TID Lys); two RAC diets 5 ppm or 7.4 ppm with pigs receiving RAC for 7, 14, 21, 28, or 35 d prior to market. Durations intended for RAC were fed the NEG diet until initiation of RAC when CP was increased to POS in order to comply with label requirements. All diets met or exceeded NRC nutrient recommendations. Pen weights and feed disappearance were recorded weekly. This study was conducted during June and July. At d 35, pigs were marketed by intact pen to a commercial slaughter facility. No differences ($P > 0.05$) were observed between the two RAC doses, therefore only the main effects of RAC and duration will be discussed. The feeding of RAC increased ($P < 0.001$) final BW (119.1 vs. 116.2 kg), overall ADG (0.76 vs. 0.68 kg), and improved F:G (2.99 vs. 3.39) when compared to the NEG with no difference ($P > 0.05$) in ADFI. Average daily gain (7.4 ppm RAC) was linearly increased ($P < 0.007$) and F:G (5 and 7.4 ppm RAC) was linearly improved ($P < 0.001$) with increased feeding duration of RAC. Feeding RAC increased ($P < 0.05$) carcass weight (89.7 vs. 87.3 kg), loin depth (7.01 vs. 6.77 cm), and % lean (55.6 vs. 54.98%) while reducing ($P < 0.05$) BF depth (1.74 vs. 1.85 cm) compared to the NEG diet. Carcass weight (7.4 ppm RAC) and loin depth and % lean (5 ppm RAC) linearly increased ($P < 0.05$) with increased duration and BF depth (5 ppm RAC) was linearly reduced with increased duration. From this data, the feeding of RAC and the increased feeding duration resulted in improved growth performance and carcass characteristics compared to the NEG.

Key Words: Ractopamine, Pigs, Duration

712 Effects of EcoCare® feed on growth performance and nutrient excretion of finishing pigs. T. Walraven*¹, S. Carter¹, M. Lachmann¹, J. Bundy¹, J. Jarrett¹, and B. De Rodas², ¹Oklahoma State University, Stillwater, ²Land O'Lakes Purina Feed, Gray Summit, MO.

Eighty crossbred (D x LY) pigs (30.2 kg BW) were used to determine the effects of EcoCare® Feed (Land O'Lakes Purina Feed) on growth

performance, pit characteristics, and DM, N, and P excretion during a 122-d finishing period. Pigs were blocked by BW and sex, and allotted randomly to 2 dietary treatments. Pigs were housed in an environmentally-controlled building divided into 4 identical rooms (20 pigs/room; 2 rooms/trt) with each having a shallow pit, pull-plug system. A fortified corn-soybean meal-based diet served as the control (20.1, 19.3, 17.9, 16.5, 15.1, and 13.7% CP; 0.37, 0.34, 0.31, 0.29, 0.27 and 0.25% available P for Phases 1 - 6, respectively). The experimental diet (EcoCare, EC) was similar to the control diet with the exceptions that CP was reduced by 2.6% units, available P by 0.11% units, with additions of Lys, Thr, Met, EC Pak (containing phytase) and EC premix. Both diets were formulated on true dig. Lys (1.02, 0.92, 0.83, 0.74, 0.65, and 0.56% for Phases 1 to 6), and Thr and Met were added to EC on an ideal basis. Pigs and feeders were weighed at each phase change, and pit volume and pH were measured. Feed and pit samples were collected for DM, N, and P analysis. Dietary treatment did not affect ($P > 0.10$) ADG (875 g), ADFI (2,370 g), G:F (0.37), or final weight (130 kg). Water disappearance (L/d) and pit volume decreased ($P < 0.05$) for pigs fed EC. Pit pH tended to decrease ($P < 0.06$) with EC. The avg concentration of DM in the pit was similar ($P > 0.10$), but N and P were reduced ($P < 0.01$) for pigs fed EC. Daily DM intake was similar for both diets, but N and P intakes were reduced ($P < 0.05$) for pigs fed EC. Daily DM excreted was similar ($P > 0.10$) between diets. However, daily N and P excretion for pigs fed EC was decreased ($P < 0.05$). Cumulative N and P excreted for the entire 122-d period was reduced ($P < 0.05$) for pigs fed EC. Based on these results, the EC diet did not affect pig growth performance, but reduced daily and total N and P excreted during a 122-d finishing period.

Key Words: Pigs, Diet, Nutrient Excretion

Physiology and Endocrinology: Synchronization of Estrus in Cattle

713 ASAS Centennial Presentation: Development of cattle estrus and breeding management. J. W. Lauderdale*, *Lauderdale Enterprises, Inc, Augusta, MI.*

McKenzie's laboratory (U. MO; 1930s) described the estrous cycle of domestic animals. Brownell (Cornell; 1936) reported AI and bull bred pregnancy rates were similar. Between 1938 (first, EJ Perry, NJ) and 1940, 54 AI organizations in 21 states were formed. Ulberg, Christian and Casida (1951) controlled time of ovulation in cows with progesterone (P) injected daily. Trimberger and Hansel (1955) controlled time of ovulation in cows with P injected daily but conception rate was reduced. Zimbelman (1963) reported the dose-response for MAP in cattle, leading to the first orally active progestogen to synchronize estrus in cattle. Participants at the Brook Lodge Ovarian Regulatory Mechanisms Conference (1965) reviewed P for cattle estrus synchronization; discussions launched discovery and development of prostaglandins (PGF₂alpha) for regressing corpora lutea (CL) in cattle. Laboratories led by Thorburn, Niswender, Scaramuzzi, Henricks and Hansel (1969-1972) reported profiles of reproductive hormones, data crucial to development of successful breeding management programs. Rowson et al., Lauderdale, and Liehr et al. (each 1972) reported PGF₂alpha to be luteolytic in cattle. Lauderdale (1974) reported PGF₂alpha estrus synchronization programs and AI, including AI at a specifically designated day and time (TAI). Hansel and Fortune (1978) reported use of GnRH plus PGF₂alpha enhanced estrus synchronization and pregnancy rate over PGF₂alpha alone in cattle. The Ginther laboratory pioneered and developed transrectal ultrasonography (1982-1998), leading to characterization of follicular waves in cattle (Fortune et al. and Ginther et al., each 1988). Harms, Wiltbank and Randel (1984) reported pulsatile release of LH in cattle, leading to management of follicular waves with GnRH. Knowledge of the estrous cycle of cattle, including follicular waves, and commercially available progestogen, PGF₂alpha and GnRH products led to development of multiple cattle breeding management programs by numerous ASAS members. TAI pregnancy rates of 60%-70% are achieved routinely under commercial cattle breeding management programs using PGF₂alpha, GnRH and progestogen products.

Key Words: Cattle, Breeding Management, History

714 Identification of differential gene expression during transition of bovine corpus luteum from early to mid-phase and their potential role in acquisition of luteolytic sensitivity to prostaglandin F₂ alpha. M. P. Gorvanahally*, M. Salem, J. Yao, K. Inskeep, and J. A. Flores, *West Virginia University, Morgantown.*

Prostaglandin F₂ alpha (PGF₂α) brings about regression of the bovine corpus luteum (CL). This luteolytic property of PGF₂α is used in the beef and dairy cattle to synchronize estrus. A limitation of this protocol is an insensitivity of the early CL to luteolytic actions of PGF₂α. The mechanisms underlying luteal sensitivity (LS) are poorly understood. The early CL has maximum number of PGF₂α receptors; therefore differences in signaling events might be responsible for LS. Hence differential gene expression at two developmental stages, days 4 (D-4) and 10 (D-10) post estrus, might account for differences in signal transduction pathways associated with LS. This possibility was examined in these studies. Microarray analysis (n=3 per stage) identified 180 genes that were differentially expressed (P<0.05). These were categorized

into genes involved in cell signaling (13%), metabolism (10%), protein degradation (5%), RNA processing and transcription regulation (15%), protein biosynthesis and modification (19%), extracellular matrix and cytoskeletal proteins (6%), DNA replication and modulation (2%), antioxidant property (3%), miscellaneous (17%), and unknown functions (10%). Real-time PCR confirmed the differential expression of 9 randomly selected genes, including protein kinase C inhibitor protein-1 (KCIP-1) and regulator of G-protein signaling 2 (RGS2), observed in microarray. Further, the in vivo effect of exogenous PGF₂α (n=3 per stage) on selected genes that were found differentially expressed during this developmental transition was examined. PGF₂α increased the expression of a guanine nucleotide binding protein beta polypeptide 1 (GNB1) in D-4 CL and Ca²⁺/calmodulin dependent kinase kinase 2 beta (Camkk2) in D-10 CL. Therefore, GNB1, Camkk2, KCIP-1, and RGS2 are candidate genes that might play significant role in acquisition of luteal sensitivity to PGF₂α.

Key Words: Corpus Luteum, PGF₂α, Corpus Luteum Insensitivity

715 Synchronizing new follicular wave emergence in *Bos indicus*-influenced heifers with estradiol benzoate: Role of the magnitude of the acute increase in progesterone. J. D. Pack*^{1,2}, I. C. Velez^{1,2}, M. Amstalden^{1,2}, and G. L. Williams^{1,2}, ¹Texas AgriLife Research, Beeville, TX, ²Texas A&M University, College Station.

The hypothesis was that incremental changes in circulating progesterone (P₄) are an important factor in the ability of estradiol benzoate (EB) to successfully synchronize new follicular wave emergence (NFW) and ovulation. Eight pubertal Braford (F-1) heifers were used in a twice replicated Latin square design with four treatments designed to provide differing maximum concentrations of plasma P₄: 1) EB; 2.5 mg EB i.m. only; 2) EB + CIDR; EB and new CIDR; 3) EB + AC-CIDR; EB and new autoclaved CIDR; 4) EB + AC-CIDR + P₄; EB, new autoclaved CIDR and 500 mg P₄ i.m. at CIDR insertion. Heifers received treatments in random order between d 3 and 6 after ovulation (d 0), with a 2 to 3-wk washout period between each experimental period. On d 7, CIDR inserts were removed and all cows were treated with 25 mg prostaglandin F₂-alpha. Transrectal ultrasonography was used to monitor ovarian structures throughout. Jugular blood samples were collected at 0, 30, 60, 120, 240, and 360 min, and at 6-h intervals through 60 h for hormone assays. Treatments 2 through 4 increased (P < 0.01) circulating P₄ concentrations compared to treatment 1 (EB only); however, treatment 4 (EB + AC-CIDR + P₄) created the greatest increase (2-h peak = 42.5 ng/mL) of longest duration (at least 60 h). Groups 2 and 3 (EB + CIDR and EB + AC-CIDR) were intermediate (4-h peaks = 10.7 ng/mL) and did not differ. Plasma progesterone in group 1 (EB only) remained < 5 ng/mL. Suppression of plasma FSH was greatest (P < 0.001) in group 4 (EB + AC-CIDR + P₄), with mean 60-h concentrations (1.5 ± 0.4 ng/mL) less than in all other groups (1.8 ± 0.4 ng/mL). Mean concentrations of LH (0.4 ± 0.1 ng/mL), frequencies of occurrence of NFW (87.5 ± 7.2 %) and ovulation (84.4 ± 6 %), and intervals to NFW (5.0 ± 0.3 d) did not differ among treatments. Elevating circulating P₄ above that created by a corpus luteum or corpus luteum + CIDR, delayed FSH resurgence but failed to alter timing or occurrence of ovarian events.

Key Words: Synchronization, *Bos indicus*, Progesterone

716 Effect of PRID[®] administered 5 to 11 days post-insemination on serum progesterone concentrations in lactating dairy cows. S. J. Scott*, R. B. Walsh, S. J. LeBlanc, J. Woodward, J. S. Walton, and K. E. Leslie, *University of Guelph, Guelph, ON, Canada.*

A high rate of hepatic metabolism could decrease progesterone concentrations important for the maintenance of the developing conceptus, leading to early embryonic loss. The effects of a Progesterone-Releasing Intravaginal Device (PRID[®]) administered at d 5–11 post-insemination, on circulating serum progesterone concentrations was studied in 222 lactating dairy cattle on 4 farms. Cows were randomly assigned to receive PRID or PID (Placebo Intravaginal Device). Blood was collected at both insertion and removal of the device. Serum progesterone concentrations were determined by ELISA analysis (Immulite). At the time of insertion, circulating progesterone levels were not significantly different between cows administered PRID, versus control (2.0 ± 1.42 ng/mL). There tended to be a treatment by time interaction such that the differences in progesterone concentrations between PRID and control cows was significant only for cows that received the device 9–11 d post-insemination ($P < 0.08$) (Table 1). At d 12–18 post-insemination the serum progesterone concentration in cows that became pregnant on the previous service was 4.0 ng/mL and 3.1 ng/mL, in cows that were and were not diagnosed pregnant, respectively. For cows that were diagnosed pregnant the change in progesterone from d 5–11 to d 12–18 was 1.8 ± 1.6 ng/mL, versus 1.1 ± 1.9 ng/mL in cows that were not diagnosed pregnant ($P < 0.005$). These results indicate that the administration of PRID approximately 1 wk post-insemination will increase progesterone levels, potentially affecting reproductive success.

Table 1: Circulating progesterone concentrations at insertion and removal of device.

Days post-AI	n	Mean P ₄ at insertion (ng/mL)	SD	Mean P ₄ at removal (ng/mL)	SD
5–8 PID	58	1.6	1.1	3.7	1.9
5–8 PRID	75	1.7	1.3	3.5	1.9
9–11 PID	48	2.5	1.6	3.1	2.2
9–11 PRID	41	2.5	1.5	3.7	2.0

Key Words: PRID, Progesterone, Post-Insemination

717 Comparison of long-term CIDR-based protocols to synchronize estrus in beef heifers. N. R. Leitman*, D. C. Busch, D. A. Mallory, D. J. Wilson, M. R. Ellersieck, M. F. Smith, and D. J. Patterson, *University of Missouri, Columbia.*

Two experiments evaluated modifications to a long-term CIDR-based protocol to synchronize estrus and compared differences among protocols on the basis of their potential to facilitate fixed-time AI in beef heifers. In Exp. 1 estrous cycling beef heifers ($n = 85$) were assigned to 1 of 2 treatments by age and BW. Heifers in T1 received a CIDR from d 0 to 14, GnRH on d 23, and PG on d 30. Heifers in T2 received a CIDR from d 2 to 16, GnRH on d 23, and PG on d 30. Ovaries were scanned by ultrasonography on d 23 to characterize follicular dynamics and d 25 to determine response to GnRH. In Exp. 2 beef heifers ($n = 353$) were assigned within reproductive tract scores (2 or 3 = prepubertal; 4 or 5 = estrous cycling) by age and BW to 1 of 4 treatments. Heifers in

T1 and T2 received the same treatments described in Exp. 1. Heifers in T3 and T4 received the same treatments as T1 and T2, respectively, minus the addition of GnRH. All heifers were fitted with HeatWatch transmitters for estrus detection and AI was performed 12 h after estrus onset. In Exp. 1 heifers assigned to T1 had larger dominant follicles at GnRH compared to T2 ($P < 0.01$; 10.9 vs. 9.5 mm, respectively) but response to GnRH, estrous response after PG, mean interval to estrus and variance for interval to estrus after PG did not differ ($P > 0.05$). AI conception and final pregnancy rate were similar ($P > 0.05$). In Exp. 2 estrous response after PG did not differ ($P > 0.10$). Differences in mean interval to estrus and variance for interval to estrus ($P < 0.05$) differed based on the 3-way interaction of treatment length, GnRH, and estrous cyclicity status. AI conception and final pregnancy rates were similar ($P > 0.05$). In summary, the 2 d schedule modification failed to improve synchrony of estrus. In Exp. 1 no differences in estrous response or synchrony of estrus were detected between T1 and T2. In Exp. 2 the 3-way interaction suggests that further evaluation of long-term CIDR-based protocols is required with and without the addition of GnRH to determine the efficacy of these protocols for use in facilitating fixed-time AI. This research was supported by USDA-NRI grant 2005-55203-15750.

Key Words: Beef Heifer, Estrus Synchronization, Progesterin

718 Timing of artificial insemination in beef cows following the CO-Synch + CIDR protocol. D. C. Busch*¹, D. J. Schafer², D. J. Wilson¹, D. A. Mallory¹, N. R. Leitman¹, J. K. Haden², M. R. Ellersieck¹, M. F. Smith¹, and D. J. Patterson¹, ¹*University of Missouri, Columbia,* ²*MFA Inc., Columbia, MO.*

The experiment was designed to compare pregnancy rates in postpartum beef cows resulting from fixed-time AI (FTAI) after administration of the CO-Synch + CIDR protocol. Cows ($n = 851$) at two locations over two years (yr 1; $n = 218, 206$; yr 2; $n = 199, 228$) were stratified by age, BCS and days postpartum (DPP) to 1 of 2 FTAI intervals. Cows were administered GnRH (100 µg, i.m.) and equipped with a controlled internal drug release (CIDR) insert (1.38 g progesterone, d 0). CIDR inserts were removed 7 d later at the time PG (25 mg, i.m.) was administered (d 7). Continuous estrus detection was performed at Location 2 using HeatWatch. Transmitters were fitted at the time of PG and removed at the time of AI. Artificial insemination was performed at predetermined fixed-times [54 h (FTAI 54; $n = 424$) or 66 h (FTAI 66; $n = 427$) after PG] and all cows were administered GnRH (100 µg, i.m.) at AI. Two blood samples were collected between 8 to 10 d and immediately prior to treatment initiation to determine pre-treatment estrous cyclicity status of cows [progesterone ≥ 0.5 ng/mL; (FTAI 54, 288/424, 68%; FTAI 66, 312/427, 73%); $P = 0.07$]. At Location 2, more cows exhibited estrus prior to FTAI 66 than FTAI 54 ($P < 0.01$; 107/216, 50% and 57/218, 26%, respectively). Pregnancy rates were higher ($P < 0.01$) among cows that exhibited estrus than those that did not (123/163, 76% and 150/270, 56%, respectively). There were no treatment by location interactions within year ($P > 0.10$) for age, DPP, or BCS; thus the results were pooled for the respective treatments. Fixed-time AI pregnancy rates were higher for FTAI 66 than FTAI 54 ($P = 0.05$; 286/426, 67% and 257/424, 61 %, respectively). Pregnancy rates resulting from FTAI did not differ between year ($P = 0.09$), farm ($P = 0.80$), AI sires ($P = 0.11$) or technicians ($P = 0.64$). There was no difference between FTAI pregnancy rates based on pre-treatment estrous cyclicity status ($P = 0.30$), and no difference between treatments in final pregnancy rates

($P = 0.77$). In summary, fixed-time AI following CO-Synch + CIDR at 66 h resulted in significantly greater FTAI pregnancy rates compared to FTAI at 54 h.

Key Words: Artificial Insemination, Estrus Synchronization

719 Substitution of estradiol benzoate for GnRH in the Select Synch + CIDR protocol with or without temporary calf removal in *Bos indicus*-influenced cattle. J. D. Pack^{*1,2}, I. C. Velez^{1,2}, M. Amstalden^{1,2}, and G. L. Williams^{1,2}, ¹Texas AgriLife Research, Beeville, TX, ²Texas A&M University, College Station.

The hypothesis was that estradiol benzoate (EB) would be more effective than GnRH in synchronizing new follicular wave emergence (NFWE) and subsequent ovulation in Brahman-influenced cows subjected to a controlled intravaginal drug release insert (CIDR)-based treatment protocol. Sixty-four postpartum (PP) Braford (F-1) cows (79 % cyclic) in 2 replicates (32 cows/replicate) were stratified by parity, d PP and body condition score (BCS), and assigned randomly to a 2 x 2 factorial arrangement of groups that contrasted hormone treatments (GnRH vs EB) at time 0 and post-CIDR suckling status (weaned vs suckled). Treatments were: 1) Select-Synch + CIDR; n=16; 2) Select-Synch + CIDR with 48h calf removal; n=16; 3) E-Synch + CIDR; n=16; or 4) E-Synch + CIDR with 48h calf removal; n=16. All females were a minimum of 50 d PP and had a BCS of at least 5 (1 to 9 scale) at treatment onset. On d 0, cows in all groups received a CIDR, with those in groups 1 and 2 receiving a single injection of 100 µg GnRH i.m., and those in groups 3 and 4 receiving a single injection of 2 mg EB i.m. CIDR inserts were removed on d 7 and all cows received a single injection of prostaglandin F2-alpha (25 mg i.m.), with 48-h calf removal in groups 2 and 4. Transrectal ultrasonography was performed daily for a maximum of 144 h after CIDR removal. Proportions of GnRH- and EB-treated cows exhibiting (75 vs 68.9%) and intervals (4.1 ± 0.3 vs 3.8 ± 0.3 d) to NFWE did not differ. Proportions of GnRH- and EB-treated cows ovulating (68.8% vs 78.1%) and their respective intervals to ovulation (88.6 ± 6.3 vs 94 ± 6 h) after CIDR removal did not differ, nor did post-CIDR suckling status affect ovulation frequency (77.4 vs 69.7) or interval to ovulation (87.3 ± 6.5 vs 95 ± 5.8 h). However, ovulation before 72 h was greater ($P < 0.07$) in Select-Synch + CIDR (4/32) compared to E-Synch + CIDR (0/32). Although minor, the latter effect could contribute to a reduction in asynchronous follicle maturity in TAI protocols.

Key Words: Synchronization, Estradiol Benzoate, *Bos indicus*

720 Ovarian and fertility responses of Holstein heifers after GnRH, progesterone, and PGF_{2α} at five stages of the estrous cycle. J. S. Stevenson*, Kansas State University, Manhattan.

Estrus and ovulation were manipulated in 283 heifers by administering GnRH, progesterone (P4), and PGF at 5 stages of the estrous cycle. Estrus was presynchronized with a P4 insert (CIDR) for 7 d before PGF was administered 24 h before insert removal. Successive groups of 10 heifers were assigned to treatments (2 heifers/treatment) beginning on d 2 of the cycle; then groups of treatments on d 5, 10, 15, and 18. Treatments were a CIDR insert placed intravaginally (d 0) for 7 d plus: 1) 25 mg of PGF on d 7 at insert removal (PGF); 2) 100 µg of GnRH on d 0

+ PGF on d 7; 3) PGF 24 h before insert removal (early PGF); and 4) 100 µg of GnRH + early PGF. Controls received no insert (GnRH on d 0 and PGF on d 7). Ovaries were scanned ultrasonically on d 0, 2, 7, 9, and 11 to assess follicular diameters and ovulation. Blood was collected on d 0, 2, 6, 7, 8, and 9 to quantify serum concentrations (ng/mL) of P4. Insemination occurred after detected estrus or by timed AI (TAI) at 64 h after insert removal. Only 15.6% of 141 GnRH-treated heifers ovulated by 48 h after GnRH, with twice as many ovulating when treatment was initiated on d 5 (26%) compared with other cycle days (12.4%). Stage of cycle at treatment influenced serum P4; it was greater in all CIDR-treated heifers on d 2 and 6 of treatment. Progesterone tended ($P = 0.08$) to be greater in GnRH-treated heifers on d 6. Treatment effects on P4 on d 7 and 9 occurred because of the early decrease in P4 in response to PGF 24 h before insert removal. Follicle diameters at 48 h after insert removal (d 9) were unaffected by treatment, but were less ($P < 0.05$) in heifers when treatment was initiated on d 5 (12.0 ± 0.4 mm) compared with other stages of the cycle (13.9 ± 0.3 mm). Pregnancies per AI (P/AI) were unaffected by stage, but tended ($P = 0.10$) to be less after TAI (43.5%) than after detected estrus (56.1%) and in control compared with CIDR treatment. Treatments initiated on d 10 of the cycle produced the greatest P/AI (65.4%) compared with other stages (d 2 = 38.9%; d 5 = 37.7%; d 15 = 47.4%; or d 18 = 41.5%). Compared with control, more P4-treated heifers ovulated by d 11.

Table 1.

Trait	Treatment				Control	Trt	$P <$

721 Relationship between uterine pH at fixed-time AI and pregnancy success in beef cattle. S. F. Lares*, S. D. Fields, B. L. Perry, D. G. Chen, and G. A. Perry, South Dakota State University, Brookings.

Research has shown that cows in estrus within 24 h of fixed-time AI had greater pregnancy rates compared to cows not in estrus. Furthermore, uterine pH decreased at the initiation of estrus and pH has been reported to influence sperm motility and longevity. Our objective was to determine the relationship between uterine pH at fixed-time AI and pregnancy success. Lactating beef cows in two herds were synchronized with the CO-Synch protocol [100 µg GnRH on d -9; 25 mg PG on d -2; and 100 µg GnRH plus timed AI on d 0 (48 h after PG)]; n = 126] or the CO-Synch+CIDR protocol [100 µg GnRH and CIDR insertion on d -10; 25 mg PG and removal of CIDR on d -3; 100 µg GnRH with timed AI on d 0 (60 h after PG)]; n = 97]. Uterine pH was determined

at fixed-time AI (n = 80 and 63 for herd 1 and 2, respectively). Cows were determined to be in standing estrus by activation of an EstroTect estrus detection aid, determined at timed AI and approximately 18 h later. Pregnancy was determined 60 to 70 d after AI. At time of AI, cows that had initiated estrus had decreased ($P = 0.01$) uterine pH compared to cows not in estrus (6.78 ± 0.03 and 6.89 ± 0.03 , respectively). In addition, cows that had initiated estrus by 18 h after AI had decreased ($P < 0.01$) uterine pH at time of AI compared to cows that did not initiate estrus (6.78 ± 0.02 and 6.96 ± 0.04 , respectively). Cows that initiated estrus prior to AI had increased ($P = 0.05$) pregnancy success (52% vs. 38%) compared to cows that had not initiated estrus by AI. Cows that initiated estrus by 18 h after AI tended to have increased ($P = 0.078$) pregnancy success (43% vs. 32%) compared to cows that did not initiate estrus. Furthermore, uterine pH at AI had an approximately linear effect on pregnancy success within the observed pH range. As uterine pH increased pregnancy success decreased ($P = 0.076$, logistics regression). In summary, uterine pH at time of AI was decreased in cows that exhibited estrus and uterine pH tended to have a linear effect on pregnancy success.

Key Words: Uterine pH, Pregnancy Rate, Fixed-Time AI

722 Comparison of pregnancy rates in beef cattle after fixed-time AI using semen processed with two different extenders. D. C. Busch^{*1}, N. R. Leitman¹, D. A. Mallory¹, D. J. Wilson¹, J. F. Bader², J. L. Martin³, M. F. Smith¹, and D. J. Patterson¹, ¹University of Missouri, Columbia, ²Meril Limited, Fulton, MO, ³Accelerated Genetics, Baraboo, WI.

This experiment was designed to compare pregnancy rates in beef heifers and postpartum beef cows after fixed-time AI (FTAI) with semen processed with two different extenders. A single ejaculate of semen was collected from each of 4 bulls. Semen was processed using either a control (C) or Affirm™ (A) semen extenders. The semen was frozen and stored in liquid nitrogen. Heifers (n = 53) at one location were stratified by age and BCS and cows (n = 968) at 7 locations were stratified by age, BCS, and days postpartum (DPP) to 1 of 2 treatments involving the two semen extenders (C or A). Heifers were synchronized using the CIDR Select protocol and cows were synchronized using the CO-Synch + CIDR protocol. Fixed-time AI was performed at 72 and 66 h, respectively, after treatment administration for the two age groups of females. There were no interactions involving semen extender X location ($P > 0.10$) for age, DPP, or BCS; thus the results were pooled for the respective treatments. There was no difference in the resulting FTAI pregnancy rates between heifers and cows inseminated with C (58%) or

A (54%, $P = 0.20$) and there was no difference between sires ($P = 0.47$); however, there was an interaction involving semen extender X sire ($P = 0.02$). One sire exhibited a reduction (-18%, $P < 0.01$) in FTAI pregnancy rates while another exhibited an improvement (+19%, $P = 0.10$) in FTAI pregnancy rates with A versus C. The other two sires exhibited no differences ($P > 0.70$) between C and A. Furthermore, there was an effect ($P < 0.05$) of AI technician, age, BCS, and DPP on FTAI pregnancy rates. Cows ≥ 7 yr of age had lower pregnancy rates ($P < 0.05$) than cows 3 to 6 yr of age but were similar to 2 yr-old cows. Pregnancy rates were higher ($P < 0.01$) for cows that calved > 50 d before FTAI (59%) than those that calved ≤ 50 d before FTAI (41%). In summary, there was no difference in pregnancy rates resulting from FTAI between the C and A semen extenders; however, there were significant differences involving the interaction of sire X semen extender.

Key Words: Artificial Insemination, Estrus Synchronization, Semen

723 The effect of an opioid antagonist on dairy cattle fertility after insemination. V. Fuentes-Hernandez*, A. Bernal-Canseco, P. I. Fuentes-Castro, and R. Orozco-Hernandez, *Universidad de Guadaluajara, Mexico.*

With the objective of studying the effect of naloxone administered im at the onset on estrus in dairy cattle, and to observe the effect of this opioid antagonist on conception rate after insemination, a small cattle holding with 120 cows was selected. There was no discrimination regarding to age and number of parturitions. A double blind experiment was designed to avoid bias in the results. The veterinarian was instructed to inject the drug using multiple dose flasks with no label. When a cow showed the first signs of estrus, im injections of 5 mL containing either saline or 10 mg naloxone were administered at 12 hr intervals and continued for 24 hr after insemination. Note was taken of conception at first insemination after treatment, and the number of inseminations required for positive pregnancy in cows repeating estrus. The experiment was carried out from January 2007 to January 2008. An accumulated total of 43 cows were treated during this period. It was observed that cows treated with naloxone (n = 21) required 1.25 ± 0.25 inseminations and insemination rate in saline treated was 2.5 ± 0.5 . After an ANOVA it was observed that conception rate in naloxone-treated cows was higher ($P < 0.01$) compared with controls. It was concluded that naloxone treatment during the estrous period in dairy cattle reduced insemination rate and gives further support to endogenous opioids as important modulators of reproduction in cows.

724 Heat production and efficiency of energy utilization in finishing steers fed diets containing wet distillers grains with solubles (WDGS). M. J. Spieth*, C. L. Ferrell, J. A. Nienaber, T. M. Brown-Brandl, and S. D. Shackelford, *ARS-USDA, US Meat Animal Research Center, Clay Center, NE.*

This study was conducted to evaluate heat production (HP) and efficiency of energy utilization in feedlot cattle fed diets containing WDGS. Steers ($n=24$, $BW = 452.5 \pm 36.8$ kg) were assigned in a randomized complete block design to diets containing 0, 20, 40, or 60% WDGS on a DM basis providing calculated ME concentrations of 3.11, 3.06, 3.05, and 3.02 Mcal ME per kg and 0.70, 5.89, 7.63, and 9.36% fat, respectively. The trial consisted of three 96 h periods of total urine and feces collection followed by 6 h of indirect calorimetry with 8 steers per period (2/trt). Data were analyzed as a randomized complete block design. Regression analysis was conducted to determine linear and quadratic effects. There was a linear decrease in DMI ($P < 0.01$; $R^2 = 0.29$) with increasing level of WDGS in the diet. As a result, ME intake decreased as levels of WDGS increased in the diet. Heat production was similar for cattle fed all four diets but retained energy (RE) decreased linearly ($P < 0.01$, $R^2 = 0.40$) with increasing inclusion of WDGS in the diet. Due to the high fat content in WDGS, RQ decreased as WDGS increased in the diet. Based on this data, HP for cattle fed diets containing WDGS can be estimated using the following equation: $HP = 174.9 + 16.4 \cdot DMI + 11.5 \cdot \text{proportion of WDGS in diet}$. This study indicates that finishing cattle fed increasing levels of WDGS in the diet have decreased efficiency of energy utilization which could lead to decreased performance in the feedlot, primarily due to lower DMI.

Table 1.

Item	0% WDGS	20% WDGS	40% WDGS	60% WDGS	SEM	<i>P</i> Value
DMI, g/ ($BW^{0.75,d}$)	84.3 ^a	71.7 ^{a,b}	68.3 ^{a,b}	64.0 ^b	2.04	0.013

725 Effects of distillers grains on feedlot performance of crossbred steers. C. Ferrell*, S. Shackelford, and V. Varel, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Objectives were to determine effects of wet distillers grains with solubles (WDGS) on growth rate, feed intake and feed efficiency of finishing steers when fed at 0, 20, 40, or 60% of diet DM. Crossbred, fall-born steers (304) were weaned, moved to the feedlot, and fed a corn silage

based diet. Steers were implanted with Synovex-S (April) and with Revalor-S at study initiation (July). Steers were moved to individual feeding facilities, and trained over 4 wk to headgates (Calan-Broadbent®) in pens of 4 or 10 steers. Steers were blocked by sire breed, dam breed, and pretrial BW and assigned to diets. Alfalfa was included in all diets at 10.6% of DM. Control diet contained 82.7% rolled corn, 5.7% soybean meal, and 1.1% supplement. The 20, 40, and 60 WDGS diets contained 68.2, 48.2, and 28.2% corn and 20, 40, and 60% WDGS on DM basis. The WDGS diets contained 1.2% of a second supplement. Monensin (480 mg•hd•d) and thiamin (200 mg•hd•d) were fed in all diets. The CP, P, S, and fat % increased with increased WDGS inclusion in diets. Initial BW (IBW; 402 kg), 28 d, 56 d, 84 d, and final BW (FBW) were recorded. Feed was recorded daily, and orts weekly. Linear and quadratic effects of proportion WDGS were evaluated. The IBW was included as a covariate. Means were compared by *t* test if $P \leq 0.05$ for *F* test. Linear and quadratic effects of diet influenced ($P < 0.001$) DMI, ADG, and FBW, and linear ($P < 0.001$) effects influenced gain/dmi (G/F). Steer performance traits were improved or unaffected by inclusion of WDGS at 20 or 40% of diet DM. WDGS at 60% decreased DMI, ADG, and FBW, but did not depress G/F. Although inclusion of 60% WDGS significantly decreased ADG, feeding levels of WDGS as high as 60% may be the most profitable choice, depending on the relative costs of feed ingredients and yardage costs.

Table 1.

WDGS	CP, %	P, %	S, %	DMI, kg/d	ADG, kg/d	FBW, kg	G/F
0%	13.44	0.35	0.16	9.48 ^b	1.73 ^b	584 ^b	0.184 ^b

Key Words: Efficiency, Environment, WDGS

726 Effects of increasing level of corn dried distiller's grains with solubles on intake, digestion, and ruminal fermentation in steers fed backgrounding diets. J. L. Leupp*, G. P. Lardy, and J. S. Caton, *North Dakota State University, Fargo.*

Five ruminally and duodenally cannulated steers (500 ± 5 kg of initial BW) were used in a 5×5 Latin square to evaluate effects of increasing level of corn dried distiller's grains with solubles (DDGS) in backgrounding diets (60% concentrate) on OM intake, site of digestion, ruminal fermentation, and microbial efficiency. Diets consisted of 30% grass hay, 6% concentrated separator byproduct, 4% supplement, and 60% dry-rolled corn, sunflower meal, and/or DDGS (DM basis). Treatments consisted of increasing DDGS at 0, 15, 30, 45, or 60% of diet DM replacing a combination of dry-rolled corn and sunflower meal. Diets were balanced for growing steers gaining 1.22 kg/d and included 0.25% (DM basis) chromic oxide as a digesta flow marker. Steers were offered diets ad libitum (10% above previous day's intake) and adapted to diets for 14 d followed by a 7-d collection period. Intake of OM responded quadratically ($P = 0.004$) with greatest intakes at 15% DDGS and lowest at 60% DDGS. No differences ($P > 0.13$) were observed in CP intake or duodenal flow of OM, CP, and NDF. Apparent and true ruminal OM

digestibilities decreased (linear; $P \leq 0.009$) with increasing DDGS inclusion. Total tract CP digestibility increased (linear; $P < 0.001$) with increasing DDGS, however, total tract OM digestibility was not different ($P = 0.74$). Microbial efficiency, expressed as g of microbial N/kg of OM truly fermented, was not affected ($P = 0.22$) by treatment. As dietary DDGS increased, ruminal pH increased (linearly; $P = 0.004$) while ammonia concentration remained unchanged ($P = 0.42$). Acetate proportions decreased ($P < 0.001$) with increasing DDGS while propionate and butyrate were similar ($P \geq 0.19$). A cubic ($P = 0.02$) effect was observed for total ruminal fill (as is basis) with the greatest fill at 30% DDGS and the least fill at 45% inclusion. Replacing dry-rolled corn with moderate to high levels of DDGS in backgrounding diets resulted in no adverse effects on digestion or ruminal fermentation although OM intake was reduced at 60% DDGS inclusion.

Key Words: Backgrounding Diets, Corn Dried Distiller's Grains with Solubles, Steers

727 Effect of feeding distillers grains on performance and marbling deposition in steers fed high-concentrate or high-forage diets. J. P. Schoonmaker*, A. H. Trenkle, and D. C. Beitz, *Iowa State University, Ames.*

One hundred thirty-seven Angus cross yearling steers (init. BW 390 ± 0.5 kg), were allotted by BW to a 3×2 factorial arrangement of 6 treatments (4 pens per treatment) to determine the effect of wet distillers grains concentration (0, 20, 40 % diet DM) in high concentrate (12 % hay) and high forage (50 % hay) diets on growth performance and marbling content. Steers were implanted on d 0 with Component TE-S® and were slaughtered in 3 groups when final BW was estimated to be 579 kg. Final BW was similar among treatments and averaged 578 kg. Concentrate-fed steers gained faster ($P < 0.01$) than did forage-fed steers; amount of distillers grain fed did not affect ($P > 0.25$) daily gain. Hot carcass weight and dressing percentage was greater ($P < 0.01$) for concentrate-fed than for forage-fed steers. Dressing percentage tended ($P < 0.08$) to increase as distillers grain concentration increased. Longissimus dorsi area tended to be greater ($P < 0.08$) and yield grade was greater ($P < 0.01$) for concentrate compared with forage-fed cattle. Longissimus dorsi area and yield grade increased ($P < 0.03$) as distillers grain concentration increased. In concentrate-fed steers, marbling score decreased as distillers grain concentration increased (325, 306, 265), but, in forage-fed steers, marbling score increased from the 0 to 20% inclusion rate, and then decreased from the 20 to 40% inclusion rate (249, 282, 262; diet x distillers grain interaction; $P < 0.01$). Similarly, in concentrate-fed steers, fat thickness tended to decrease as distillers grain concentration increased, but, in forage-fed steers, fat thickness tended to increase from the 0 to 20% inclusion rate, and then tended to decrease from the 20 to 40% inclusion rate (diet x distillers grain interaction; $P < 0.08$). In conclusion, when fed to a common live-weight end-point, starch concentration of distillers grain diets alters lean and adipose tissue deposition. (Supported in part by the Iowa Beef Industry Council and the Iowa Beef Center).

Key Words: Beef, Marbling, Distillers Grains

728 Effect of wheat-, corn-, and triticale-based distillers grains with solubles on performance and carcass characteristics of growing lambs. L. E. McKeown*^{1,2}, A. V. Chaves², M. Oba¹, E. Okine¹,

T. A. McAllister², and D. Gibb², ¹University of Alberta, Edmonton, AB, Canada, ²Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.

The objective of this study was to determine the effect of wheat-, corn- and triticale-based dry distillers grains with solubles (DDGS) on dry matter intake, average daily gain, feed efficiency (FE; g gain / g DM ingested) and carcass traits in lambs. Sixty ram lambs were blocked by live weight (LW; 22.6 ± 3.0 kg) and randomly assigned to one of four experimental diets. Either wheat-, corn- or triticale-based DDGS was included at 20% of dietary DM, replacing 10% canola meal and 10% barley grain in the control diet. The control diet contained 54% barley grain, 16% sunflower hulls, 11.5% beet pulp, 10% canola meal and an 8.5% mixture of oil, molasses, vitamins and minerals. All experimental diets were formulated to contain approximately 17% CP and 23% NDF. The lambs were individually housed, weighed weekly, and slaughtered between 45-50 Kg LW. Saleable meat yield (SMY) was determined from proximal cuts such as short cut leg, sirloin, chine off rack, loin short cut, square shoulder and front shank. Data were analyzed using the MIXED procedure of SAS. Dry matter intake was similar among treatments (1.40 ± 0.05 kg/d; $p=0.32$). Average daily gain was 15% higher ($p=0.05$) for lambs fed the corn-based DDGS (377 ± 14.0 g/d) than for lambs fed the wheat- or triticale-based DDGS (329 and 328 ± 14.0 g/d respectively) although no treatment differed from the control (338 ± 14.0 g/d). There was a treatment by week interaction for FE ($p=0.03$). In week 1, FE was higher ($p < 0.05$) for lambs fed corn-based DDGS (0.49 ± 0.03) compared to lambs fed control, triticale- or wheat-based DDGS (0.35, 0.31 and 0.33 ± 0.03 respectively). Overall, final LW (48.2 ± 1.1 kg), cold carcass weight (21.9 ± 0.07 kg), and SMY (14.5 ± 0.4 kg) were not affected by dietary treatment ($p > 0.05$). This study indicates that the sources of DDGS tested can replace a mixture of barley grain and canola meal at 20% of the dietary DM without adverse effects on intake, growth performance or carcass traits of lambs.

Key Words: Dried Distillers Grains with Solubles, Feed Efficiency, Growing Lamb

729 Feeding dry-rolled or steam-flaked corn with increasing levels of wet distillers grains to finishing steers. C. M. Godsey*, M. K. Luebbe, G. E. Erickson, and T. J. Klopfenstein, *University of Nebraska, Lincoln.*

The objective of this study was to determine the effect of corn processing method, either dry-rolled (DRC) or steam-flaked (SFC) corn, on cattle performance and carcass characteristics in diets containing 0, 20, or 40% wet distillers grains (WDG). The WDG used in this trial did not contain solubles and was 33.6% CP and 10% fat. One hundred twenty individually fed steers (BW = 355 ± 55 kg) were weighed on three consecutive d and assigned randomly to 1 of 8 treatments (15 head/treatment). Diets contained 0, 20 or 40% WDG and 82.5, 67.5 or 47.5% corn respectively, as either DRC or SFC. Two additional diets containing 40% WDG and 11.25 or 15.0% alfalfa were fed with SFC to determine if added roughage improves performance in diets containing WDG and SFC. No significant interaction between corn processing method (DRC or SFC) and WDG (0, 20, or 40) level was observed for DMI ($P=0.27$) or G:F ($P=0.17$). However, a significant interaction was observed for ADG ($P=0.09$), therefore only the simple effects of processing method and WDG level are reported. A quadratic response was observed for ADG in DRC-based diets ($P=0.02$), with 1.38, 1.67, 1.58 kg/d for 0, 20, and 40, respectively. No response was observed for ADG in diets containing

SFC ($P=0.20$). Quadratic G:F responses in DRC-based diets ($P=0.03$) were observed, however no response was observed in SFC-based diets. Feed efficiency was 0.140, 0.164, 0.163 for 0, 20, 40 DRC-based diets and 0.158, 0.169, and 0.165 for 0, 20, 40 SFC-based diets, respectively. For steers fed SFC, increasing roughage level tended to increase DMI ($P=0.07$) and decrease G:F linearly (0.165, 0.153, 0.155 for 7.5, 11.25, and 15.0% roughage; $P=0.09$). In this study, G:F was similar as WDG inclusion increased from 20 to 40% in the diet. However, in corn control diets (0% WDG), steers fed SFC had 12.9% greater G:F than steers fed DRC. Additionally, increasing roughage levels in SFC-based diets containing WDG did not improve feed efficiency.

Key Words: Corn Processing, Feedlot, Wet Distillers Grains

730 Effects of distiller's grain and probiotic on growth and carcass characteristics of finishing beef steers. F. F. Korthaus^{*1}, E. S Vanzant¹, G. Rentfrow¹, K. K. Kreikemeier^{1,2}, D. L. Harmon¹, and K. R. McLeod¹, ¹University of Kentucky, Lexington, ²Vit-E-Men, NE.

To evaluate the effects of modified corn distiller's grain (MDG) and a direct fed microbial (DFM; Vit-E-Men probiotic 10G), 192 crossbred steers (initial BW 394 ± 1.2 kg) were used in a 112 day finishing study. Steers were assigned, within weight blocks, to 6 treatments in a 3x2 factorial arrangement and fed in pens of 4 (8 pens/treatment). Treatments included 0, 20 or 40% (DM basis) of MDG with or without DFM provided at $10 \text{ g} \cdot \text{hd}^{-1} \cdot \text{d}^{-1}$. The diet DM was comprised of 5% corn silage, 5% alfalfa haylage, 10% supplement and 80% concentrate, comprised of varying quantities of MDG, cracked corn, and high moisture corn. The 0 and 20% MDG diets contained 14.2% CP and the 40% MDG diet, 18.6% CP. Body weight measurements were taken on d 0, 1, 28, 56, 84, 111 and 112. Steers were harvested on d 113 and carcass data was collected. There were no interactions between the level of MDG and DFM ($P > .14$). Across the entire feeding period, steers fed 20% MDG consumed more DM (quadratic, $P = .01$; 11.1 kg) and gained more (quadratic, $P = .09$; 2.03 kg/d) compared with the 0% (10.59 kg and 1.91 kg/d) and 40% (10.76 kg and 1.96 kg/d) treatments, such that gain:feed was unaffected ($P \geq .63$) by MDG. Steers fed DFM had greater ADG ($P = .04$; 1.91 vs 2.02 kg/d), HCW ($P = .02$; 369 vs 378 kg), ribeye area ($P = .08$; 83.7 vs 85.6cm) and were more efficient ($P = .07$; gain:feed .186 vs .179). Including MDG at 20% of a finishing diet increased DMI and ADG by 4% and 6%, whereas at 40% MDG, these responses diminished to control levels. Administration of DFM resulted in a 4% increase in growth efficiency concomitant with a 6% increase in ADG which were both consistent across levels of MDG. These data demonstrate the efficacy of DFM and suggest that steer growth can be compromised by MDG inclusion above 20%.

Key Words: Distiller's Grain, Direct Fed Microbial, Carcass Traits

731 Effect of varying ruminally degradable to undergradable protein ratio on feed intake, nutrient digestion and N balance of buffalo calves. J. I. Sultan^{*1}, A. Javed¹, M. Yaqoob², and P. Akhtar², ¹Institute of Animal Nutrition and Feed Technology, University of Agriculture, Faisalabad, Pakistan, Faisalabad, Punjab, Pakistan, ²University of Agriculture, Faisalabad, Pakistan.

A 4 X 4 Latin Square design buffalo calves metabolism trial was conducted with buffalo calves to explore the effects of varying ruminally degradable protein (RDP) to ruminally undegradable protein (RUP) ratio on dry matter intake (DMI), nutrient digestion and N balance. Four Nili Ravi buffalo calves (avg wt, 100kg) were fed diets viz A, B, C and d, having RDP to RUP ratio of 70:30, 65:35, 60:40 and 55:45, respectively. All experimental diets were isonitrogenous (CP 16%) and isocaloric (ME, 2.74 Mcal/kg). Dry matter intake in calves fed diet C was higher ($P<0.05$) than those fed diet D and lower ($P<0.05$) than calves fed diet A, however, it was similar to those fed diet B. Total tract dry matter digestibility (DMD) was higher ($P<0.01$) in calves fed diet A and B than those fed diet C and D. There was a linear decrease in DMI and DMD with decreasing the RDP and RUP ratio. The N retention (g/d) was similar among the calves fed diet B, C and D; however, it was higher ($P<0.05$) than those fed diet A. Decreasing the RDP to RUP ratio resulted in linear increase ($P<0.01$) in N retention. N retention, as percent of N intake was significantly ($P<0.05$) different across all treatments. Decreasing RDP to RUP ratio resulted in linear increase ($P<0.01$) in N retention, as percent of N digestion. Decreasing dietary RDP to RUP ratio resulted in a linear decrease ($P<0.05$) in blood urea nitrogen concentration. A linear increase in weight gain was observed with decreasing RDP to RUP ratio. The diet containing RDP to RUP ratio 55:45 resulted in more weight gain compared to other diets.

Key Words: RDP, Digestibility, RUP

732 Effects of 20% corn wet distillers grain's plus solubles in steam-flaked and dry-rolled corn-based finishing diets. J. C. MacDonald^{1,2}, K. H. Jenkins^{*1}, F. T. McCollum III³, and N. A. Cole⁴, ¹Texas AgriLife Research, Amarillo, TX, ²West Texas A&M University, Canyon, ³Texas AgriLife Extension, Amarillo, TX, ⁴USDA- Agricultural Research Service, Bushland, TX.

Two hundred sixty four crossbred yearling heifers (354 ± 1 kg) were blocked by weight and used in a 2X2 factorial arrangement of treatments to determine effects of wet distiller's grains plus solubles (WDGS) derived from corn on animal performance, carcass characteristics, and the amount of manure harvested in steam-flaked corn (SFC) and dry-rolled corn (DRC) based finishing diets. Heifers were fed DRC or SFC based finishing diets with or without 20% WDGS (DM basis). Control diets with no WDGS were formulated to contain 13.5% CP. The WDGS replaced 15.2 percentage units of corn and 4.8 percentage units of cottonseed meal. All diets contained 10% alfalfa hay, 2% supplemental yellow grease, 4% glycerin, 1.2% urea, and 0.70% Ca. There were 24 pens ($n=6$ per treatment) that housed 8, 10, or 18 heifers with pen size serving as a blocking factor. Heifers were implanted once with Revalor-H[®] approximately 120 days before slaughter and were on feed for an average of 154 d. No corn processing method by WDGS inclusion interactions were found for any response variable ($P > 0.39$). Heifers consuming SFC-based diets had lower DMI ($P < 0.01$), similar ADG ($P = 0.71$), and greater feed efficiency ($P < 0.05$) than heifers consuming DRC-based diets. Corn processing method had no effect on any carcass characteristic ($P > 0.58$). There was a slight tendency for heifers consuming WDGS to have greater final BW ($P = 0.15$), ADG ($P = 0.18$), and hot carcass weight ($P = 0.16$). Inclusion of WDGS did not impact any other animal performance or carcass characteristic ($P > 0.22$). Feeding DRC resulted in increased manure OM harvested •heifer¹•d¹ ($P < 0.01$) compared to SFC and feeding WDGS resulted in a slight tendency

to increase manure OM harvested•heifer¹•d⁻¹ ($P = 0.16$). These data indicate that corn processing method has a greater impact on animal performance and amount of manure harvested than does the inclusion of WDGS when WDGS is included at 20% of diet DM.

Key Words: Corn Processing, Wet Distiller's Grains, Feedlot

733 Effect of supplementation frequency of soyhulls and corn gluten feed based mix on digestion and nitrogen balance of beef steers. M. E. Drewnoski* and M. H. Poore, *North Carolina State University, Raleigh.*

For small producers the labor cost of feeding is often very high. Feeding a supplement less frequently would reduce labor and could therefore have the potential to increase profit. Six ruminally cannulated beef steers were used in a replicated 3 × 3 Latin square design to determine the effect of supplement frequency (daily or alternate days) on digestion and ruminal parameters when feeding hay and supplementing with a mixture of soyhulls and corn gluten feed. Dietary treatments consisted of ad-libitum fescue hay (8.8% CP and 35.8% ADF) that was supplemented at 1% BW daily (SD), supplemented 2% BW on alternate days (SA) or

not supplemented (H). The supplement contained 47% soyhull pellets, 47% corn gluten feed pellets, 2% feed grade limestone and 4% liquid yeast and was 14.6% CP and 29.8% ADF. Each period consisted of a 14 d adaptation phase followed by 6 days of total fecal, urine and ort collection. All supplement offered was consumed within 2 h. Ruminal fluid was collected every 4 h over two days; therefore samples were taken on a day that both SD and SA were supplemented and on a day when only SD was supplemented. Hay intake was reduced by daily supplementation and further reduced ($P < 0.01$) by less frequent supplementation. Hay intake was 1.54, 1.19 and 1.02% BW (SE ± 0.036) for H, DS and SA, respectively. There was a significant ($P < 0.01$) a trt by day interaction for mean ruminal pH. Ruminal pH for SA (6.13), on the day of supplementation was lower ($P < 0.01$) than both SD (6.29) and H (6.52). However, on the day SA did not receive supplement ruminal pH of SA (6.53) did not differ ($P = 0.87$) from H and was higher ($P < 0.01$) than SD. Ruminal pH was lower ($P < 0.01$) for SD than for H on both days. Diet DM digestibility was increased ($P < 0.01$) by supplementation but did not differ ($P = 0.94$) due to frequency. DM digestibility was 57.93, 64.37, 64.42% (SE ± 0.71) for H, SD and SA, respectively. The amount of N retained was higher ($P < 0.01$; SE ± 4.81) for both supplemented trt (23.7 and 19.8 g for SD and SA, respectively) than H (4.22 g) but did not differ ($P = 0.35$) due to frequency.

Key Words: Supplementation Frequency, Cattle, Digestibility

Ruminant Nutrition: Rumen Fermentation Modifiers

734 Effect of Rumensin® and Tylan® in feedlot diets containing wet distillers grains plus solubles fed to beef steers. N. F. Meyer*¹, G. E. Erickson¹, T. K. Klopfenstein¹, J. R. Benton¹, M. K. Luebber¹, and S. B. Laudert¹, ¹University of Nebraska, Lincoln, ²Elanco Animal Health, Greenfield, IN.

The objective of this study was to evaluate the effects of Rumensin and Tylan in feedlot diets containing wet distillers grains plus solubles. Eight hundred beef steers (329 ± 25 kg) were blocked by initial BW and randomly assigned to one of five treatments (20 steers per pen, 8 pens per treatment). Treatments consisted of a corn-based diet with Rumensin and Tylan (CORN+RT) and four treatments with 25% wet distillers grains plus solubles (DG) and either 36.7 mg/kg (R) or 49.0 mg/kg (HIR) of Rumensin and Tylan (T) at 90 mg•hd⁻¹•d⁻¹. Compared to CORN+RT, steers fed DG+RT gained more, were more efficient ($P < 0.05$), and had similar DMI (10.7 vs. 10.6 kg). Feeding Rumensin increased G:F by 3.1% and Rumensin plus Tylan increased G:F by 4.9% when compared to DG alone ($P < 0.05$). With the exception of dressing percentage, there were no differences in performance or carcass characteristics when Rumensin was fed at 36.7 compared to 49.0 mg/kg. Total liver abscesses were significantly greater for DG (42.4%) and DG+R (40.8%), compared to treatments containing Tylan, CORN+RT (17.0%), DG+RT (8.3%), and DG+HIRT (8.9%). Severe liver abscesses were also less for diets containing Tylan ($P < 0.05$). This study indicates that steers fed Rumensin and Tylan in diets containing wet distillers grains plus solubles results in improved feed efficiency and decreased liver abscesses compared to similar diets without these feed additives.

Table 1.

735 Effect of Rumensin® and Tylan® fed separately on in combination on feedlot performance and carcass characteristics of feedlot cattle. G. J. Vogel*¹, S. B. Laudert¹, and R. S. Swingle², ¹Elanco Animal Health, Greenfield, IN, ²Cactus Feeders, Amarillo, TX.

One-thousand six hundred eleven crossbred steers (345 kg) were randomly allotted to 16 pens in a 2 × 2 factorial with 4 replications. Experimental treatments included a non-medicated control (C), Rumensin only (RO), Tylan only (TO) and Rumensin plus Tylan (R+T). Formulated Rumensin (R) and Tylan (T) levels were 36.5 and 10.0 mg/kg (DM basis), respectively. A two ration step-up program was used

to adapt steers to final diets with cattle reaching the final diet by d 20. Steers were fed three times daily during the ration transition phase and twice daily once acclimated to the final diet. The study averaged 142 d (range 139 to 144 d). The final ration was formulated to contain 1.52 Mcal NEg/kg, 13.5% CP, 15.1% NDF, 7.0% EE, 0.56% Ca and 0.32% P. Performance parameters were analyzed using PROC MIXED with treatment as fixed effects and block as random effects. Orthogonal contrasts were used to evaluate main effects of R, T and R*T. Significant R*T interactions were observed for DM Intake and feed to gain. With both variables the magnitude of the effect was greater for steers fed R+T. R decreased ($P < 0.001$) daily feed intake by 4.0% (9.98 vs. 9.55 kg) while feed to gain was improved ($P < 0.001$) by 4.3% (5.52 vs. 5.30). Cattle fed T experienced a 72.4% decrease ($P < 0.0001$) in liver abscess prevalence (26.8 vs. 7.4%) which resulted in a 2.3% increase ($P = 0.06$) in daily gain (1.79 vs. 1.83 kg/d) and a 4.0 kg increase ($P = 0.03$) in carcass gain. Compared to C, steers fed R+T consumed 4.4% less ($P < 0.05$) feed and converted 6.4% more ($P < 0.05$) efficiently. Quality and yield grade were not affected by treatment. These data indicate Rumensin and Tylan improved feed efficiency and decreased liver abscess incidence in steers fed to harvest on a conventional diet.

736 Interactions of monensin with dietary fat and carbohydrate components on ruminal fermentation and production responses by dairy cows. B. Mathew*, E. R. Oelker, M. L. Eastridge, and J. L. Firkins, *The Ohio State University, Columbus.*

Variation in milk fat percentage due to monensin supplementation to lactating dairy cows could be due to altered ruminal fermentation with interactions of monensin with ruminal biohydrogenation of fat and ruminal carbohydrate availability. The objective of the study was to determine the effects of feeding monensin in diets differing in starch availability, effective fiber, and fat. Six ruminally cannulated lactating Holstein cows were used in a balanced 6 × 6 Latin square design with 21 day periods. The cows were fed six diets: 1) C = control diet with ground corn (GC) and long particle size for alfalfa hay (LAH), 2) CR = C plus 12 g/ton DM of monensin (R), 3) CRFL = CR plus 4% added fat (F), 4) CRFS = 4% F, R, GC, and short particle size of alfalfa hay (SAH), 5) SRFL = 4% F, R, steam-flaked corn (SFC), and LAH, and 6) SRFS = 4% F, R, SFC, and SAH. All diets were formulated to have 18% CP, 21% forage NDF, and 40% NFC. Monensin decreased DMI

($P < 0.10$). There was no effect of treatment ($P > 0.12$) on milk yield. Addition of monensin decreased ($P < 0.05$) milk fat yield and tended to decrease milk fat percentage (3.41 vs 2.98%; $P = 0.11$). Interactions between corn processing and hay particle size occurred for milk fat percentage ($P < 0.10$) and feed efficiency (FCM/DMI; $P < 0.05$). With feeding diets containing R: 1) SAH tended to increase milk fat percentage for the ground corn diet while it tended to decrease milk fat percentage with SFC (CRFL + SRFS vs. CRFS + SRFL), and 2) feed efficiency was not affected by particle size of hay with ground corn but was increased for SAH fed with SFC. The SFC increased ($P < 0.10$) NDF digestibility (CRFL + CRFS vs. SRFL + SRFS; 51.1 vs 56%). Addition of fat with monensin decreased ($P < 0.001$) total VFA but increased rumen pH ($P < 0.05$). Fat addition with monensin decreased rumen $\text{NH}_3\text{-N}$ ($P < 0.05$) and MUN (12.8 vs 13.9 mg/dl; $P < 0.01$), and SFC decreased $\text{NH}_3\text{-N}$ ($P < 0.10$). Fat, effective fiber, and ruminal starch availability may explain some responses of feeding monensin on ruminal fermentation and animal production.

Key Words: Monensin, Forage Particle Size, Starch Availability

737 Effects of Optaflexx™ on ruminal ammonia and amino acid concentrations in cattle fed dry-rolled or steam-flaked corn finishing diets with or without dried distiller's grains. C. E. Walker* and J. S. Drouillard, *Kansas State University, Manhattan.*

The effects of ractopamine (Optaflexx™, Elanco Animal Health) supplementation on ruminal concentrations of ammonia and free amino acids were evaluated in a randomized complete block experiment utilizing a $2 \times 2 \times 2$ factorial arrangement of treatments. Factors consisted of grain processing method (steam-flaked or dry-rolled corn; SFC or DRC); level of dried distiller's grain with solubles (0% DG or 25% DG, dry basis); and level of Optaflexx (0 or 200 mg/d). Sixteen ruminally fistulated Holstein steers were randomly assigned to the 8 treatment combinations and adapted to their respective diets for 21 d prior to sampling ruminal fluid. Ruminal fluid was collected during a 3-d sampling period; d 1 at 0, 6, 12, 18 h; d 2 at 2, 8, 14, 20 h; d 3 at 4, 10, 16, 22 h. Ruminal fluid was strained through 4 layers of cheesecloth, mixed in a 4:1 ratio with 25% metaphosphoric acid solution, and frozen. Prior to analysis, samples were thawed, thoroughly homogenized, and then centrifuged at 21,000 x g to remove particulate matter. Concentrations of ammonia and amino acids in the supernatant were measured colorimetrically using an autoanalyzer (Technicon III Auto Analyzer). Ruminal NH_3 concentrations were lower when Optaflexx was fed in combination with DRC, but not when fed in conjunction with SFC (grain processing x Optaflexx, $P < 0.01$). Addition of Optaflexx, SFC, and DG all resulted in lower ruminal ammonia concentrations (main effects, $P < 0.01$). Amino acid concentrations were decreased when Optaflexx was added to diets without DG, but were unchanged in diets with DG added (interaction, $P < 0.05$). Changes in ruminal NH_3 and amino acid concentration with Optaflexx supplementation are dependent on processing method of the grain and the addition of distiller's grains to finishing diets. The results of this experiment suggest that Optaflexx may influence ruminal degradation of dietary protein, which could have important implications for diet formulation.

Key Words: Cattle, Optaflexx, Rumen Fermentation

738 Effects of cinnamaldehyde-eugenol and capsicum on rumen fermentation and feeding behavior in beef heifers fed a high-concentrate diet. M. Rodriguez-Prado¹, S. Calsamiglia¹, A. Ferret¹, J. Zwieten¹, L. Gonzalez¹, and D. Bravo*², ¹*Universitat Autònoma de Barcelona, Spain*, ²*Pancosma, Switzerland.*

Four beef Holstein heifers (BW = 436 ± 17 kg) fitted with a 1-cm i.d. plastic ruminal trocars were used in a 4×4 Latin square design to evaluate the effect of feeding combinations of essential oils on feeding behavior and ruminal fermentation in heifers fed a high-concentrate diet. Animals were fed (DM basis) 10% barley straw and 90% concentrate (32.2% barley grain, 27.9% ground corn, 7.5% wheat bran, 10.7% soybean meal, 10.7% soybean hulls, 7.2% corn gluten feed, 3.1% mineal-vitamin mix; 16.6% CP, 18.3% NDF). Treatments were arranged in a factorial design with cinnamaldehyde and eugenol (CINE, 167 and 334 mg /animal/d, respectively) with or without capsicum (CAP, 500 mg/animal/d). Each experimental period consisted of 25 d (15 d for adaptation, 5 d DM intake continuous measurements and 3 for rumen sample collection). Animals had ad libitum access to water and feed offered once daily at 0800. Data was analysed using PROC MIXED for repeated measures (SAS), and differences were declared at $P < 0.05$. Consumption of water was higher in CAP compared with CTR (33.7 vs. 37.8 L/d). Although there were no differences in total (9.3 kg/d) and concentrate DM (8.6 kg/d) intake, animals fed CAP spent more time eating (11.3 vs 8.0% of the time of the day) and the pattern of intake was more stable during the day compared with CTR. As a result, the pH fell to its lowest level 6 h after feeding but was lower in CTR compared with CAP, suggesting that the modification of the pattern of intake induced by CAP was responsible for controlling the sharp drop of pH after feeding. Total volatile fatty acids tended ($P < 0.07$) to be higher in CAP compared with CTR (162.4 vs. 133.6 mM), but the proportion (mol/100mol) of acetate (59.2), propionate (25.2), butyrate (13.4) and lactate (0.31) was not affected by treatments. Feeding CAP may modify the pattern of intake and help to control the drop of pH after feeding high concentrate diets.

739 Meta-analysis on the effect of a cinnamaldehyde and eugenol mixture on the performance of lactating dairy cows. D. Bravo*¹ and P. Doane², ¹*Pancosma Research, Geneva, Switzerland*, ²*ADM Research, Decatur, IL.*

This abstract presents a meta-analysis of lactating dairy cow studies involving a botanical composition comprised of eugenol and cinnamaldehyde (XT). Data from 16 studies with side by side comparisons of XT to a control diet provided 33 treatment groups which were pooled for evaluation. The model used was a mixed model with a fixed effect (effect of XT: present vs. absent) and a random effect (ie. the trial effect). For each measure of performance, mean value of XT or control, the number of groups involved, partial R^2 , and P value were determined. Addition of XT increased dry matter intake (22.1 vs. 20.6 kg/d; $N=16$, $P < 0.001$, $R^2=0.96$), and milk yield (34.2 vs. 33.1 kg/d; $N=36$, $P < 0.001$, $R^2=0.45$). Feed efficiency (kg of milk/kg of DMI) was equivalent for XT and control, (1.44 vs. 1.46; $N=16$, $P=0.441$, $R^2=0.10$). When XT was present, milk protein content decreased, and milk fat content was

unchanged. However, protein and fat yields were increased because of improved milk yield.

Between trials, correlation between diet composition and XT response were explored to determine the interaction of XT and dietary nutrient profile. For each trial, the efficacy of XT was represented as the ratio of the mean for XT to the mean of the control and assessed with linear correlation and regression procedures. Results suggest an interaction of diet nutrient composition and product efficacy. For example, XT was more efficacious for improving milk yield when diets contained greater amounts of NEL, NFC or digestible fiber.

Meta analysis using a data set consisting of a diverse population of trials avoided emphasis of a particular trial while illustrating the robust nature of XT. Meta analysis is useful for developing a statistically valid framework for additive use in diets of varying composition. The results of meta-analysis demonstrate benefits for using XT to increase DMI and milk yield by lactating dairy cows.

740 Effects of yeast culture on rumen microbial fermentation of heifers challenged with high-concentrate feeding. D. Moya*¹, S. Calsamiglia¹, A. Ferret¹, J. I. Fandiño¹, and L. Castillejos², ¹Universitat Autònoma de Barcelona, Bellaterra, Spain, ²Diamond V Europe, Marum, the Netherlands.

Twelve Holstein heifers (277 ± 28 kg BW) fitted with ruminal trocars were used in a crossover design study to determine the effects of yeast culture on ruminal microbial fermentation during a feed challenge. The challenge consisted of a 3-week adaptation period (100% forage diet) followed by a 2-week transition period when heifers were gradually switched to a 10:90 forage to concentrate diet to cause digestive upset (visual observation of bloat or reduction in feed intake by 50% from the previous day). Treatments consisted of a control diet without (CT) or with yeast culture supplementation at 14 g/hd/d (YC, Diamond V XPC_{LS}TM Yeast Culture, Diamond V Mills, Cedar Rapids, IA, USA). Ruminal fluid samples were collected at 0 and 6 h post-feeding on the first and last day of the adaptation period and daily during the transition into the high concentrate diet. Foam height and strength were determined on the day when a digestive upset was detected as a measure of potential foam production and bloat appearance. The addition of YC had no effect on ruminal fermentation during the 100% forage diet period except for an increase ($P < 0.01$) in ammonia N concentration. Yeast culture did not affect the incidence (83.3%) or the time (7.00 ± 0.62 d) to cause digestive upset. However, YC increased ($P < 0.05$) ruminal pH and branched chain VFA, and decreased ($P < 0.05$) lactate concentration on the day after digestive upset. Yeast culture reduced ($P < 0.05$) ruminal fluid viscosity 3 days prior and 2 days after digestive upset, and foam strength on the day digestive upset occurred. Ruminal population of *S. bovis* or *M. elsdenii* was not affected by treatment. Results indicated that YC had no effect on development of digestive upset during the feed challenge, but contributed to a faster recovery by increasing ruminal pH and reducing lactate production. In addition, YC reduced foam strength which could reduce the risk of developing bloat.

Key Words: Yeast Culture, Microbial Fermentation, Fed Challenge

741 Influence of body condition at calving and feed supplementation with yeast culture on feed intake, peripheral blood metabolites and blood mineral concentrations in early lactating dairy cows. R. Allbrahim*, M. Doherty, L. O'Grady, V. Gath, P. Duffy, and F. Mulligan, University College, Dublin, Ireland.

The influence of body condition score (BCS) at calving and feed supplementation with *Saccharomyces Cerevisiae* live yeast culture (Yea-Sacc1026) on feed intake, blood metabolites and major blood minerals, were determined by randomly allocating thin (mean BCS= 3.25 ± 0.5) or moderate condition (mean BCS=4.00 ± 0.25) forty Holstein/Friesian cows of mixed parity to receive one of two nutritional treatments (yeast supplemented and control diets) from day 14 pre-calving till day 70 post-calving. Daily feed intake was monitored individually. Blood samples were taken via jugular venipuncture on the day of calving and on days 5, 25 and 35 post-calving and analysed for glucose (GLS) non-esterified fatty acids (NEFA), beta-hydroxybutyrate (BHB), calcium (Ca), magnesium (Mg) and phosphorus (P). In weeks 1 and 2 of lactation, cows in moderate condition had a lower ($P < 0.06$) feed intake than thin cows. Moderate condition cows tended to have higher NEFA ($P = 0.08$) on the day of calving, and higher BHB concentrations ($P = 0.09$) on day 5 post-calving, when compared with thin cows. Moderate condition cows also had higher BHB concentrations at days 25 ($P = 0.07$) and 35 ($P < 0.01$) and had higher NEFA concentrations at day 25 ($P < 0.01$) post-calving when compared with thin cows. Thin cows had higher GLS concentrations at days 25 ($P < 0.01$) and 35 ($P = 0.06$) post-calving when compared with the moderate condition group. Cows supplemented with yeast tended to have lower NEFA concentrations at day 25 post-calving ($P < 0.10$) than control cows. On the day of calving, moderate condition cows had a higher ($P < 0.05$) Mg, lower ($P = 0.06$) Ca and tended to have a lower ($P < 0.10$) P than thin cows. Yeast supplementation had no effect ($P > 0.05$) on Ca, Mg or P status on the day of calving. These data clearly indicate that appropriate body condition score at calving and offering yeast supplements, significantly altered feed intake, indices of energy balance and major mineral concentrations in the peripheral blood of early lactating dairy cows.

Key Words: Body Condition Score, Blood Metabolites, Yeast Culture

742 Effect of feeding Diamond V Yeast CultureTM on milk production and dry matter intake in lactating dairy cows: A meta-analysis. A. R. Rabiee¹, I. J. Lean*¹, K. L. Dorton², M. E. Engstrom², and W. K. Sanchez², ¹Bovine Research Australasia, Camden, NSW, Australia, ²Diamond V Mills, Cedar Rapids, IA.

A meta-analytic approach was used to evaluate the effectiveness of supplementation with Diamond V YCTM, XPTM, and XPCTM Yeast Culture (fermented *Saccharomyces cerevisiae*) on milk production and dry matter intake (DMI) in lactating dairy cows. The presence and sources of heterogeneity in responses were also investigated. Published research papers and other reports (n = 60) were considered for meta-analysis. Trials were included if these provided: information on the form and dose of Diamond V Yeast Culture, adequate description of randomization, data on milk production or DMI, a measure of variance (SE or SD), and/or P-value. Switch back trials were not included. A total of 32 studies (milk production trials = 49; DMI trials = 28) met the selection

criteria. Treatment significantly increased milk production by 0.93 kg/day/cow (weighted mean difference = 95% confidence interval (CI) = 0.70 to 1.15, $P < 0.0001$). There was no evidence of heterogeneity in milk production responses ($P = 0.347$). Meta-regression showed that the effect of treatment was not influenced by stage of lactation, type and dose of yeast culture, duration of supplementation before and after calving, type of diet and parity. However, meta-analysis on subgroups (early-mid vs. late lactation trials) showed that the response to Diamond V Yeast Culture was slightly greater in late lactation. The effect of Diamond V Yeast Culture on DMI was not significant (effect size (ES) = 0.084; 95% CI = -0.025 to 0.19), and there was no evidence of heterogeneity ($P = 0.628$). Meta-regression analysis showed that this response was influenced by the delivery method (mixed vs. topdressed) as DMI was significantly greater when the treatment was top dressed (ES = 0.44; 95% CI = 0.18 to 0.70; $P = 0.001$). Dry matter intake was significantly greater during the early stage of lactation (ES = 0.31; 95% CI = 0.084 to 0.53; $P = 0.049$) studies compared to later studies.

Key Words: Diamond V Yeast Culture, Meta-Analysis, Dairy Cows

743 Dose-response effects of Rumensin® supplementation on kinetics of biohydrogenation of fatty acids in the rumen. M. S. Allen* and Y. Ying, *Michigan State University, East Lansing.*

Eight ruminally and duodenally cannulated multiparous Holstein cows were assigned randomly to replicated 4 × 4 Latin squares in a dose-response arrangement of treatments. Treatments were Rumensin® supplementation at 0, 8, 16, and 24 ppm DM. Diets consisted of corn silage and alfalfa silage (2:1 ratio, DM basis), high moisture corn, distiller's grains (6.9% of diet DM), protein supplement, minerals and vitamins. Diets were intended to promote milk fat depression and contained 25% NDF, 18.5% forage NDF, 28.6% starch, and 3.5% total fatty acids (FA). Treatment periods were 28 d with the final 11 d used for sample and data collection. Treatment did not affect concentration or molar percentage of acetate or propionate in ruminal fluid, or ratio of acetate to propionate. Rumensin® tended to decrease rate of biohydrogenation of 18:1 trans FA linearly from 38.9 to 32.6 %/h ($P = 0.09$). This resulted in a quadratic increase in the ruminal pool of 18:1 trans FA ($P = 0.04$) and numerically greater flow of 18:1 trans FA at the duodenum from 61.0 to 80.6 g/d ($P = 0.13$). Linear increases in concentrations of 18:1 t10 and t10, c12 CLA were detected in the milk ($> 2.2X$, $P < 0.05$). Mean daily ruminal pH tended ($P = 0.09$) to decrease from 6.26 to 6.14 with increasing Rumensin® concentration. Rumensin® decreased milk fat concentration from 3.23% for 0 ppm to 2.85% for 24 ppm ($P = 0.03$) but did not affect yield of milk fat ($P = 0.28$). Lack of effect of treatment on milk fat yield is consistent with effects on de novo FA synthesis; total FA < C16 as a % of total FA in the milk was not affected by treatment ($P = 0.75$). Although milk fat yield was not affected by treatment in this experiment, a reduction in rate of biohydrogenation resulting in increased flow of trans 18:1 FA from the rumen may contribute to the development of milk fat depression when supplementing Rumensin® in highly fermentable diets.

Key Words: Milk Fat Depression, Kinetics, CLA

744 Exogenous glucosamine administration alters glucose and insulin homeostasis in sheep. M. W. Robertson*, F. R. Dunshea, and B. J. Leury, *The University of Melbourne, Parkville, Victoria, Australia.*

The objective of this study was to determine whether exogenous glucosamine alters glucose, insulin and NEFA metabolism in sheep by increasing flux through the hexosamine biosynthetic pathway, a purported nutrient sensing pathway. Six cross bred ewes (34.9 kg ± 3.8) were used. Each ewe underwent a saline (C), and a 2.5 (LG) and 5 (HG) mg/kg/min glucosamine infusion for 6h. Blood samples were taken during a 1.5 h baseline period, at 1h intervals throughout the infusion and during a 6h recovery period. There was a significant time × treatment interaction ($P < 0.001$) throughout the sampling period for glucose, insulin and NEFA plasma concentrations. Mean baseline concentrations were not significantly different for glucose (C, 2.61; LG, 2.90; HG, 2.99 mmol/L), insulin (C, 5.66; LG, 6.39; HG, 4.88 mU/ml) or NEFA (C, 724; LG, 576; HG, 589 μmol/ml). Significant differences in plasma concentration of glucose were first observed at 2h (C, 2.34; LG, 3.54; HG, 3.88 mmol/L; $P < 0.002$) and for insulin at 4h (C, 5.66; LG, 6.39; HG, 4.88 mU/ml; $P < 0.003$) from start of infusion. Glucose and insulin concentrations continued to increase in both LG and HG treatments throughout the remaining infusion period. At the end of the 6h infusion there were significant differences ($P < 0.001$) between all 3 treatments (glucose: C, 2.40; LG, 4.28; HG, 5.44 mmol/L and insulin: C, 1.67; LG, 5.98; HG, 17.37 mU/ml). Post infusion, concentrations of glucose and insulin remained higher than C treatment and did not approach C values until around 4h and 6h, respectively. Changes in NEFA concentration were variable throughout the infusion period. At 2h post infusion NEFA concentration in LG and HG treatments fell significantly ($P < 0.003$) below the C treatment (C, 831, LG, 481; HG, 415 μmol/ml), but there were no significant differences in plasma NEFA concentration at 6h post infusion (C, 922, LG, 914; HG, 670 μmol/ml). These data indicate that glucosamine affects glucose and insulin homeostasis in a manner that is indicative of an insulin resistant state and this effect is dose dependant.

Key Words: Glucosamine, Insulin, Sheep

745 Effect of ZADO®, as enzymes from anaerobic bacterium, on extent of ruminal fermentation kinetics, microbial protein synthesis and milk production in dairy cows. H. M. Gado*¹, M. Hassan², and A.-F. Z. M. Salem³, ¹Ain Shams University, Cairo, Egypt, ²Cairo University, Cairo, Egypt, ³Alexandria University, Alexandria, Egypt.

A 2 × 2 factorial experiment was conducted to evaluate the effect of ZADO®, as enzymes preparation containing cellulases, xylanases, α-amylase and proteases from an anaerobic bacterium, on milk production and composition, ruminal fermentation activities and nutrients digestibility in dairy cows. Twenty multiparous lactating Brown Swiss cows (550 kg BW) were randomly assigned in two groups of 10 animals fed a mixed ration (CP 15%, TDN 74%) with or without addition of 40 g/head/d ZADO®. Milk production was recorded daily during 12 weeks of the experiment. Total and individual VFA (acetate, propionate, and butyrate), NH₃-N concentrations, and microbial protein synthesis were significantly ($P < 0.05$) increased for cows fed ZADO® diet. Digestibility coefficients of DM, OM, NDF and ADF were significantly ($P < 0.05$)

improved by addition ZADO® in cow diet. Consequently, total milk yield, 3.5 and 4% fat corrected milk and energy corrected milk improved ($P<0.05$) by 12, 21, 14, and 20% respectively, and there was no affect on milk composition. In conclusion, supplementing dairy cow diets with ZADO® has the potential to enhance milk yield as consequence

for improving the nutrients digestibility, ruminal fermentation activities and microbial protein synthesis. ZADO® confirm its roles in improving the fiber digestibility and suggested positive effects on ruminal fibrolytic microorganisms and increased milk production in dairy cows

Key Words: ZADO®, Microbial Protein Synthesis, Milk Yield

Animal Behavior and Well-Being: Beef and Dairy Cattle

746 Effect of receiving weight on predicted days to onset of respiratory disease in feedlot steers. C. M. McAllister*¹, B. W. Brigham¹, R. M. Enns¹, R. L. Weaber², H. Van Campen³, G. H. Loneran⁴, J. L. Salak-Johnson⁵, C. C. L. Chase⁶, J. J. Wagner¹, and E. J. Pollak⁷, ¹Colorado State University, Fort Collins, ²University of Missouri, Columbia, ³Colorado State University, Fort Collins, ⁴West Texas A&M, Canyon, ⁵University of Illinois, Urbana, ⁶South Dakota State University, Brookings, ⁷Cornell University, Ithaca, NY.

Data were collected to determine the relationship between receiving weight and predicted days until the onset of respiratory disease (PDTs). Crossbred steers (n=1,551) from a single source were shipped from western Nebraska to southeast Colorado. Cattle from 3 ranch units were received in shipments occurring over 3 separate days. Steers were housed overnight in feedlot receiving pens before being processed and allocated to their pens. In some cases, initial processing did not occur until the second day after arrival due to time limitations. Steers were weighed during initial processing and housed in pens until identified as sick by feedlot personnel. Sick animals were treated according to approved protocols and assigned to sick pens until time of recovery. Only animals identified as afflicted with bovine respiratory disease (n=675) were included; (\bar{x} =16.52, σ =9.94). Animals not identified as sick (n=879) were given a constant variable (250 d) as their PDTs representing the predicted days in the feedlot. Alternatively, only observations on sick animals could have been included. Therefore the total data set (n=1,551) had an average PDTs (\bar{x} =148.49) and a standard deviation (s=115.98). Animals identified as sick for other reasons were not included. A mixed effects model was used to analyze the data with SAS PROC MIXED. Ranch unit (n=3)-processing day combinations (n=5), and pen (n=6) were included as fixed class variables. Random effects were animal within ranch unit-feedlot pen. Receiving weight was included in the model as a covariate. Receiving weight and ranch-lot classes had significant effects on PDTs (P<0.001 and P<0.05 respectively). Therefore as receiving weight increased 0.33 ± 0.142 kg the PDTs was expected to increase by one day. These results indicate that heavier cattle are less susceptible to bovine respiratory disease due to processing stress than calves that enter feedlots at lighter weights.

Key Words: Beef Cattle, Bovine Respiratory Disease, Receiving Weight

747 Correlations among measures of temperament, weight and gain of steers at placement and reimplant in a commercial feed yard. R. L. Weaber*¹, R. M. Enns², H. Van Campen², G. H. Loneragan³, J. L. Salak-Johnson⁴, C. Chase⁵, J. J. Wagner², and E. J. Pollak⁶, ¹University of Missouri, Columbia, ²Colorado State University, Fort Collins, ³West Texas A&M University, Canyon, ⁴University of Illinois, Urbana, ⁵South Dakota State University, Brookings, ⁶Cornell University, Ithaca, NY.

Single source, crossbred steers (n=1,551) were shipped from western Nebraska to southeast Colorado. Cattle from 3 ranch units were received over 3 separate days. Steers were housed overnight in receiving pens before processing and allocation to feedlot pens. In some cases, initial processing did not occur until the second day after arrival due to time limitations. Two data sets were collected to determine the relationship between measures of temperament and weight traits of steers at 1) placement into a commercial feedlot and 2) at reimplant approximately 75 d later. All body weight (BW) and temperament measures were recorded in a single processing facility at initial processing and at reimplant (RI). Beef Improvement Federation Chute Scores (CS; 1=gentle, 6=aggressive), collected by 4 independent trained observers (2 at each processing), and exit velocity (EV; m/sec) were used to measure temperament during both processing events. Processing time (PT) and EV were measured using an infrared triggered electronic time recording device as a steer entered the squeeze chute then traveled a fixed distance upon exit. Two CS collected for each animal within each processing were averaged (AVGCS and AVGCS_RI). Partial correlation coefficients were computed using the MANOVA features of SAS PROC GLM. Day of initial processing (n=5) and reimplant processing (n=4) were included as class variables. EV had correlations with EV_RI, AVGCS, AVGCS_RI, BW_RI, and PT of: 0.44, 0.12, 0.15, -0.06, and -0.07, respectively (all P<0.04). EV_RI had correlations with AVGCS, AVGCS_RI, BW_RI, gain, and average daily gain of: 0.15, 0.25, -0.08, -0.06 and -0.06, respectively (all P<0.03). AVGCS was correlated with AVGCS_RI (r=0.24, P<0.01) and PT (r=0.13, P<0.01). AVGCS_RI was correlated with PT_RI (r=0.09, P<0.01). Correlation between CS collected by observers 1 and 2 was 0.73 (P<0.01). The correlation between CS_RI collected by observers 3 and 4 was 0.85 (P<0.01). Increases in EV and EV_RI were associated with increases in AVGCS and AVGCS_RI. Trained observers assigned similar CS within a processing event. EV at reimplant was inversely associated with average daily gain.

Key Words: Temperament, Exit Velocity, Beef Cattle

748 The effect of exit velocity at receiving and re-implant on average daily gain and weight at re-implant. A. R. Pepper^{*1}, R. M. Enns¹, R. L. Weaber³, H. Van Campen², G. H. Loneragan⁴, J. L. Salak-Johnson⁵, C. C. L. Chase⁶, J. J. Wagner¹, and E. J. Pollak⁷, ¹Colorado State University, Fort Collins, ²Colorado State University, Fort Collins, ³University of Missouri, Columbia, ⁴West Texas A&M University, Canyon, ⁵University of Illinois, Urbna, ⁶South Dakota State University, Brookings, ⁷Cornell University, Ithaca, NY.

The objective of this study was to explore the relationship between temperament, as measured by exit velocity at receiving and re-implant, and weight (**IW**) and average daily gain (**ADG**) after 75 d in the feedlot. Crossbred steers (n=1,551) from a single source were shipped from western Nebraska to southeast Colorado. Cattle from 3 ranch units within that source were received in shipments occurring over 3 separate days. Steers were housed overnight in feedlot receiving pens before being processed and allocated to their lots (n=6). Exit velocity was measured at receiving (**EV**; m/s) and approximately 75 d later at re-implant (**EV_RI**; m/s) using 2 infrared electronic triggers to start and stop an electronic time recording device, the first as the steer left the chute and a second 2 m away from the first to finalize the exit velocity. Analyses were conducted using the MIXED procedure of SAS. In the first 2, EV_RI was evaluated as to its influence on IW and ADG (calculated as IW minus receiving weight divided by the number of days on feed). A third analysis evaluated the effect of EV on IW. All 3 models included the fixed effect of ranch-lot class, along with a random animal effect. An increase of 1 m/s in EV_RI resulted in a decrease in IW and ADG of 2.68 kg (P<0.001) and 0.03 kg (P<0.01), respectively. Similarly a 1 m/s increase in EV decreased IW by 2.89 kg (P<0.01). The ranch-lot class effect was significant in all 3 models (P<0.05). These results suggest that cattle with calmer temperaments gain better in the first 75 d of feeding.

Key Words: Average Daily Gain, Beef Cattle, Exit Velocity

749 Effect of processing stress on feedlot cattle sickness. B. W. Bringham^{*1}, R. M. Enns¹, R. L. Weaber², H. VanCampen¹, G. H. Loneragan³, J. L. Salak-Johnson⁴, C. C. L. Chase⁵, J. J. Wagner¹, C. M. McAllister¹, and E. J. Pollak⁶, ¹Colorado State University, Fort Collins, ²University of Missouri, Columbia, ³West Texas A&M University, Canyon, ⁴University of Illinois, Urbana, ⁵South Dakota State University, Brookings, ⁶Cornell University, Ithaca, NY.

Processing time and order were measured to determine their effect on sickness rate in feedlot cattle. Crossbred steers (n=1,551) from a single source were shipped from western Nebraska to southeast Colorado. Cattle from 3 ranch units were received in shipments occurring over 3 d. Steers were housed overnight in feedlot receiving pens before being processed and allocated to their feedlot pens. In some cases, initial processing did not occur until the second day after arrival due to time limitations. All animals to be processed in a single day were removed from the receiving pen and held in alleys until processing was completed. Processing included radio frequency identification tag, visual tags, oral wormer, injectable wormer, growth promotant, 30 ml of blood collected and carcass ultrasound measurements of loin eye muscle area, backfat and percent intramuscular fat. Processing time ranged from 50 to 577 s with an average time of 112 s. An average of 320 animals were processed

daily. Post processing, calves were placed in feedlot pens where they remained unless identified as sick. Individual animals were considered sick if they exhibited clinical signs typical of bovine respiratory disease such as lethargy, depression, coughing, and nasal discharge, as determined by feedlot personnel. Sick animals were treated according to defined protocols and housed separately with other sick animals until recovered. The outcome, sick versus not sick, was analyzed with the GENMOD procedure of SAS on the binomial scale (yes/no). The model included the fixed effects of feedlot pen-unit class, time in the processing chute, and processing order. Fixed effects that influenced outcome included feedlot pen by unit-class (P<0.05), processing time in seconds (P=0.06) and processing order within day (P=0.06). As the processing order each day or processing time increased the probability of becoming sick increased by 0.15 ±0.3 and 0.24 ±0.13 percent, respectively. These results indicate animals that spent more time awaiting processing or being processed had a higher likelihood of becoming sick.

Key Words: Beef Cattle, Processing Stress, Feedlot

750 Effect of daily ambient temperature and wind speed on sickness of feedlot cattle. S. E. Speidel^{*1}, R. M. Enns¹, G. H. Loneragan², R. L. Weaber³, H. Van Campen¹, J. L. Salak-Johnson⁴, C. C. L. Chase⁵, J. J. Wagner¹, and E. J. Pollak⁶, ¹Colorado State University, Fort Collins, ²West Texas A&M University, Canyon, ³University of Missouri, Columbia, ⁴University of Illinois, Urbana, ⁵South Dakota State University, Brookings, ⁶Cornell University, Ithaca, NY.

The objective of this study was to determine the magnitude of the effect of daily temperature range and mean wind speed on the probability an individual animal would be identified as sick. Crossbred steers (n=1,551) from a single source were shipped from western Nebraska to southeast Colorado. Cattle from 3 ranch units were received in shipments occurring over 3 separate days. Steers were housed overnight in feedlot receiving pens before being processed and allocated to their feedlot pens. In some cases, initial processing did not occur until the second day after arrival due to time limitations. Individual animals were considered sick if they exhibited clinical signs typical of bovine respiratory disease such as lethargy, depression, coughing, and nasal discharge; as determined by feedlot personnel. The effects of weather (difference between daily maximum and minimum temperature, TDIFF, and mean wind speed, MWS) from 7 d prior to sickness identification through d 0, the day the animal was observed sick, were evaluated as to their influence on sick observations using binary logistic regression and the GENMOD procedure of SAS; where an animal was coded "1" if diagnosed sick on a particular day or "0" if healthy. The model resulted in a significant pen by ranch interaction (P<0.005) and significant effects of TDIFF and MWS on sickness diagnosis. On d 0, unit increases in both TDIFF (1 ° C) and MWS (1 m/s) increased the probability of an animal being pulled by 5.9 ± 0.02% (P<0.001) and 10.1 ± 0.04% (P<0.03), respectively. At d -2 and earlier, MWS did not have a significant effect on the probability of an animal being pulled (all P>0.23). Likewise, TDIFF had no significant effect on the probability of an animal being pulled prior to d -3 (all P>0.13). These results indicate that TDIFF and MWS can influence whether or not an animal becomes sick in the feedlot up to 3 d prior to the onset of disease.

Key Words: Beef Cattle, Feedlot Sickness, Weather

751 Effect of rubber flooring on cow locomotion and gene expression. K. O'Driscoll^{1,2}, M. M. Schutz³, and S. D. Eicher^{*4}, ¹*Teagasc, Fermoy, Ireland*, ²*NUI Dublin, Dublin, Ireland*, ³*Purdue University, West Lafayette, IN*, ⁴*USDA-ARS, West Lafayette, IN*.

The aim of this study was to evaluate the effect of 2 free stall flooring systems on cow locomotion (including speed) and expression of genes associated with lameness, during the dry and peri-parturient period. Cows were assigned to free-stall housing with either rubber (RUB; n=13) or concrete (CON; n=14) at the feed alley immediately after their first calving, and managed on this system during all subsequent lactations. Between lactations cows remained in a straw bedded-pack dry-cow pen. Cows entered the experiment at the end of either their 1st (n=16) or 2nd (n=11) lactations. Locomotion scores (5 point system each for foot rotation, tracking, back arch, and head carriage, and speed) and blood samples were obtained at approximately -60, -30, 0, +7 and +14 days relative to calving. Expression of genes in blood leukocytes which may be related to pain or lameness; substance-P receptor (TAC1), histamine receptor (HRH1), and metalloproteinase-13 (MMP13) was estimated using qRT-PCR. Treatment effects on locomotion scores, cow speed, and gene expression were analyzed using repeated measures ANOVA. Contrary to expectation, rubber flooring did not improve dairy cow locomotion (1.7 vs 1.8 ± 0.85). However it had an effect on locomotion score (1.7, 1.6, 1.9, 1.9, 1.8 ± 0.8 for d -60, -30, 0, 7, and 14) and speed (6.2, 6.2, 8.4, 7.6, and 7.1 ± 0.48 for d -60, -30, 0, 7, and 14), both peaking on day 0. Post calving, cows on CON were slower than RUB, relative to pre calving (P=0.01). Cows at the end of the 2nd lactation were slower than cows at the end of the 1st (6.0 vs 8.2 ± 0.42), particularly RUB cows (CON = 6.6 and 7.7 ± 0.56 and RUB = 5.4 and 8.8 ± 0.60 for 1st and 2nd lactations). RUB cows had higher expression of MMP13 than CON (0.24 vs 0.19 ± 0.04), which was more highly expressed in lame than in sound cows in previous work by others. Cows in RUB also tended to have higher expression levels of TAC1 (0.47 vs 0.32 ± 0.07). In summary, bedded-pack surfaces during the dry period may have resulted in more pain for cows coming from rubber flooring than from concrete flooring and MMP13 is up-regulated in clinically lame cows and thus this gene holds promise as an objective indicator of lameness.

Key Words: Lameness, Locomotion, PCR

752 Effect of feed bunk sprinklers on attendance at un-shaded feed bunks in dry-lot dairies. B. H. Carter^{*}, T. H. Friend, J. E. Sawyer, and M. A. Tomazewski, *Texas A&M University, College Station*.

Feed bunk sprinklers combined with fans effectively increase feed bunk attendance when bunks are shaded. This summer study characterized feed bunk attendance at a Texas Panhandle dairy where sprinklers were installed above un-shaded feed bunks. Holstein-Friesian cows were housed in pens with shade structures 45 m from and parallel to feed bunks. Three pens were equipped with sprinklers above the feed bunk that sprayed the backs of cows in 1.5 min on, 10 min off cycles when temperature was above 22.2°C. Two pens without sprinklers served as controls. Cow numbers and pen density were similar among treatments. Each pen held 135 to 390 cows. Bunk attendance (proportion of cows within 2 m of the feed bunk) was recorded for each pen at 2-h intervals over a 48-h period. Data were analyzed as repeated measures with sprinkler treatment, time, and their interaction as effects in a mixed model with pen (treatment) as the subject. Means associated with

time-treatment interactions were separated using t-tests. Relationships between bunk attendance, thermal heat index (THI) and wind speed within treatment were evaluated using linear regression. Sprinkler effect on bunk attendance was dependant on time of day (P < 0.01). Bunk attendance was greater in pens with sprinklers than pens without at 1700 h for both 24-h periods (P < 0.02), corresponding to peak daily THI. Bunk attendance was greater for pens without sprinklers at 0900 h of the first 24-h period and 2100, 0300 and 1100 h of the second 24-h period (P < 0.01), all of which occurred at lower THI. Bunk attendance was similar between treatments at all other times (P > 0.09). Bunk attendance decreased with increasing THI in pens without sprinklers (P = 0.02), but was not influenced by THI for pens with sprinklers (P = 0.54). Wind speed did not affect bunk attendance for either treatment (P > 0.10). Sprinklers altered the timing of bunk attendance but did not alter overall mean bunk attendance (P = 0.91). Further research is needed to determine if altered feeding pattern influences feeding duration, intake and milk yield.

Key Words: Sprinkler, Dairy, Feedbunk

753 Effect of shade on panting score of feedlot cattle exposed to heat stress. J. B. Gaughan^{*1}, M. L. Sullivan¹, J. Cawdell-Smith¹, and T. L. Mader², ¹*The University of Queensland, Gatton, Qld, Australia*, ²*University of Nebraska, Concord*.

A 120-d finisher feedlot study using 126 Angus heifers (BW = 350 ± 45 kg) was undertaken to determine the optimal shade area to alleviate heat stress. Four shade treatments (70% solar block) were used: no shade, 2.0, 3.3 and 4.7 m²/animal. The shade was 4 m high with a north-south orientation. Cattle were randomly allocated to pen (9/pen; 19.2 m²/animal). Climatic conditions (ambient temperature, relative humidity (RH), black globe temperature (BG), wind speed (WS)) were recorded every 10 min. From these data the heat load index {HLI; HLI_{BG>25} = 8.62 + (0.38 × RH) + (1.55 × BG) - (0.5 - WS) + [e^{2.4 - WS}], and HLI_{BG<25} = 10.66 + (0.28 × RH) + (1.3 × BG) - WS, (approximate value of e = 2.71828)} and accumulated heat load units (AHLU; based on the time cattle are exposed to HLI > 86) were determined. The HLI and the AHLU were combined to determine climatic stress: low stress: HLI < 70; AHLU < 1, moderate stress: HLI 70.1-77; AHLU 1-10, high stress: HLI 77.1-86; AHLU 20-50, and extreme stress: HLI > 86; AHLU > 50. Individual panting scores were obtained every 2 h from 0600 to 1800. Treatment mean panting scores (MPS) were then determined. A MPS of 0 to 0.4 indicates no stress; 0.4 to 0.8 low stress; 0.8 to 1.2 high stress, and >1.2 extreme stress. Treatment differences were examined using repeated measures analysis. Within treatment, MPS increased (P < 0.01) when climatic stress shifted from low to moderate. There were no between treatment differences. There were small changes in MPS between moderate and high climatic stress, and larger increases (P < 0.01) between high and extreme. The MPS was greatest (MPS = 1.72; P < 0.001) in the unshaded cattle under extreme conditions. There were no differences (P > 0.05) between the shaded treatments (MPS = 1.03) when climatic stress was extreme. The provision of shade reduced the effects of extreme climatic stress conditions. There does not appear to be an advantage of increasing the area of shade above 2.0 m². This project was funded by Meat Livestock Australia P/L.

754 A comparison of behavior of steers raised in hoop buildings or feedlots. R. Baker*, A. Johnson, S. Lonergan, M. Honeyman, K. Stalder, L. Sadler, and P. Lammers, *Iowa State University, Ames.*

The objective of this study was to compare steer behavior between 2 treatments; hoop building (HP n=3; 4.65m² / steer), which is a semi-cylindrical structure, vs. feedlot (FD n=3; 14.7m² / steer) dirt pad with concrete strip for the feed bunks. A total of 240 crossbred *Bos taurus* steers was used. Steers were ear tagged, implanted, and weighed (445 ± 31.7 kg) upon arrival and sorted by weight and breed. All steers were fed a completely balanced diet and offered water ad libitum from 1 drinker/pen. Corn stalks were provided to HP steers for bedding. Behavioral data were collected using a 10 min scan sampling technique using live observation by 2 experienced observers from 0700h to 1600h on d 34, 56, and 91 of the trial. Two behaviors (head in bunk and drinking) and 3 postures (lying, walking, and standing) were recorded. The day after behavior collection, steers were moved through a squeeze chute for subjective temperament scoring. Scores ranged from 1 (calm) to 5 (wild). Behavioral data was transformed using the arcsine of the measure to normalize the distribution and subsequently analyzed using ANOVA (PROC MIXED, SAS). Temperament scores were analyzed using non-parametric methods (PROC GLIMMIX, SAS). There were no (P>0.05) differences for head in bunk behavior between treatments. However there was a difference (P=0.02) for drinking, with HP steers spending more time at the drinker than FD. Lying was greater (P<0.004) for HP vs. FD steers. Fewer (P<0.05) steers exhibited walking or standing behavior in the HP compared to their FD counterparts. Temperament scores were not different between treatments (P=0.13) but day and day*treatment (P<0.001) were significant sources of variation for temperament measures. In conclusion, overall time budget differences were observed with HP steers being less active yet with more time spent engaged in drinking related behaviors, and steer temperament at exit increased over the trial. Therefore, housing steers in a hoop does not result in detrimental behavior or temperament alterations.

Key Words: Behavior, Hoops, Steers

755 Effects of soil surface temperature on daily water intake in feedlot steers. R. A. Arias*¹ and T. L. Mader², ¹*Universidad Católica de Temuco, Temuco, Chile,* ²*University of Nebraska, Lincoln.*

Ambient temperature (AT) has been used as indicator of cattle comfort and productivity. This study explores the relationship between soil surface temperature (SST), 10.2 cm depth soil temperature (ST), and daily water intake (DWI). Equations to predict DWI from SST (99 d) and ST (186 d) were developed with data collected from 2004 to 2006. Data from an experiment conducted during summer of 2007 (60 d) were used to validate these equations. Environmental variables were collected from a weather station located in the feedlot. The DWI was obtained by dividing the amount of water consumed per day in 2 adjacent pens by the number of animals present. Animals (n=116) were crossbred Angus cattle on finishing diets. The procedures included simple and polynomial linear regression. A repeated measures analysis was conducted to compare differences among ST, SST, and AT using SAS software. During July and August the mean of SST and ST were similar and higher than mean

AT being 26.7±.2, 26.5±.07, and 23.5±.12, °C respectively (P<0.001). However, ST was higher than AT between 8 p.m. and 10 a.m. The SST was higher than AT between 7 a.m. and 8 p.m. On the other hand, ST and AT were similar between 9 am and 3 p.m., whereas SST and AT were similar between 9 p.m. and 6 a.m. The data set was analyzed in 2 ways: the overall model representing the period May to October and the summer model representing the period June to August. In the overall model, SST was a better predictor of DWI than ST (r²=0.82 vs. 0.65, P<0.001). The greatest r²=0.86 (P<0.001) was reached with SST in a quadratic model. A similar response was observed in the summer model (SST, r²=0.70, P<0.001). In the validation process, the summer and overall model tended to over predict slightly DWI for the period July to August (13.5% and 12.5%, respectively). In conclusion, ST has a significant effect on DWI, whereas SST appears as the best predictor for DWI compared with other weather variables such as AT. Further studies of variables affecting DWI are required.

Key Words: Soil Temperature, Daily Water Intake, Modeling

756 Effect on performance and animal welfare of an all-concentrate diet fed to heifers. G. Faleiro, L. A. González, A. Ferret*, X. Manteca, J. L. Ruiz de la Torre, and S. Calsamiglia, *Nutrition, Management and Animal Welfare Research Group, Universitat Autònoma Barcelona, Bellaterra, Barcelona, Spain.*

Forty-eight Friesian female calves (Initial BW = 84.5 kg) were assigned to a factorial arrangement of treatments in a randomized complete block design with 2 treatments and 4 BW blocks, to study the effects of an all-concentrate diet on performance and animal welfare. Treatments consisted of concentrate with barley straw (C) and the same concentrate without straw (BP). Ingredients of the concentrate (DM basis) were 31.3, 32.2, 16.0, 8.0, 9.0, 1.1, 1.0 and 1.0% of barley, corn, beet pulp, soybean meal, corn gluten feed, calcium carbonate, sodium bicarbonate and salt, respectively, with the remainder being minerals and vitamins. Feeding management allowed ad libitum consumption of diets, which were fed daily at 0830. During 9 periods of 28 d each, DMI and ADG were measured, and blood samples were taken for haptoglobin determination as a welfare indicator. Animals were slaughtered at 350 kg BW, in a commercial abattoir where hot carcass weight was registered and dressing percentage calculated. A logarithmic transformation was applied to blood haptoglobin concentrations. Variables normally distributed were analyzed using the PROC MIXED of SAS. Concentrate intake was similar in both treatments (6.7 and 6.5 kg ± 0.28 for C and BP, respectively), but there were differences in total feed intake (7.3 and 6.5 kg ± 0.31 for C and BP, respectively; P = 0.045). Because there were no differences in ADG between treatments (1.12 and 1.11 kg/d ± 0.058 for C and BP, respectively), feed efficiency was lower in C (0.151 kg BW/kg DMI) than in BP (0.168 kg BW/kg DMI; SEM = 0.0046; P = 0.019). There were no differences between treatments in dressing percentage and hot carcass weight. Blood concentrations of haptoglobin were not different between treatments (0.233 and 0.221 mg/mL ± 0.027 in C and BP, respectively). In conclusion, performance was not different and well-being as reflected by haptoglobin levels was not affected by treatments.

Breeding and Genetics: Dairy, Sheep & Goat - Crossbreeding, Inbreeding and Breed Conservation

757 Genetic variation in the threshold of sensitivity to heat stress in Holsteins. J. P. Sánchez^{*1}, R. Rekaya², I. Aguilar², and I. Misztal^{2,3}, ¹Universidad de León, Campus de Vegazana, León, Spain, ²University of Georgia, Athens, ³Instituto Nacional de Investigación Agropecuaria, Estación Las Brujas, Canelones, Uruguay.

Past studies in genetics of heat tolerance assumed a fixed threshold in sensitivity to heat stress. The objective of this study was to assess genetic variation in individual variability to that threshold. Data included 379,833 first-parity test day records on 40,986 Holsteins heifers in US, sired by 327 bulls. Inferences were obtained by a Bayesian non-linear hierarchical sire model. Effects in the model included DIM x milking frequency, HYS of the milking day, and two sire effects: the intercept (I_S) and the regression (S_S) on the Temperature-humidity index (THI) above a sire specific threshold (T_S). In the second hierarchical stage the means and (co)variances of I_S , S_S and T_S were estimated using a linear model. The estimated average of the threshold across sires was 22.7(0.20) THI C°, and its variance 4.0(0.74). The marginal posterior mean for the heritability (marginal posterior standard deviation) in the absence of heat stress was 0.083(0.006), and it increased to 0.46(0.047) at 30 THI C°. The DIC indicated a superiority of this model compared to a model where the threshold was fixed for all sires. Genetic variability exists for the threshold of heat stress; however, the threshold can only be well estimated for popular sires. Very fast rise in heritability with increasing THI may be an artifact of a sire model. It would be useful to extend the current methodology to animal models, however, after preliminary analyses, the computing time would be high and convergence could be hard to obtain.

Key Words: Heat Tolerance, Hierarchical Model, Non-Linear Reaction Norm

758 *In situ* goat conservation population and selection for parasite resistance. J. M. Dzakuma^{*1}, B. M. Johnson¹, N. C. Beckford¹, L. C. Nuti¹, and T. M. Craig², ¹Prairie View A&M University, Prairie View, TX, ²Texas A&M University, College Station.

In 2002 the International Goat Research Center at Prairie View A&M University obtained animals from 3 goat breeds - the Tennessee Stiff-legged (TS) or Myotonic, the Spanish (SP) and the Boer (BR) - and established them in live populations (*in situ*) for use in a conservation program. Genetic materials are collected and preserved on this population. Simultaneously, we also collect, and preserve germplasm (*ex situ* conservation) from available breeds and strains of goats.

Kids produced from this population are challenged, orally each year, with one large dose of 5000 infective *Haemonchus contortus* larvae per animal to evaluate the impact of management treatments on growth weight (WT), fecal egg count (FEC), blood packed cell volume (PCV) and serum protein levels (SPL). The objective was to compare resistance or tolerance to parasites. The initial experimental design in 2004 included: (1) 32 kids were maintained on pasture as the control; (2) 74 kids challenged and maintained on concrete floors; (3) 74 kids maintained on concrete floors without challenge; and (4) 72 kids were challenged and maintained on pasture. Body weights, fecal and blood samples were collected on day zero to establish initial baseline samples

before kids were challenged. Weights and samples were taken weekly for 8 weeks. Statistical analyses were performed using SAS Proc Mixed. Variables were: WT, FEC, PCV and SPL. Sources of variation were: breed, sex, treatment, kid ID, time and all interactions.

Results from the 2004 initial trial indicated that progress could be made by selecting goats, for both high and low tolerance to *Haemonchus*, by selecting from those that are artificially challenged and maintained on pasture. From the 3 breeds used in the initial study, and for FEC (egg/gm) and PCV (%), respectively: BR (485.2±61.6; 25.6±0.4), SP (308.2±53.8; 30.5±0.3) and TS (301.9±40.6; 29.4±0.3). The BR breed appears to be significantly less resistant ($P<.02$) to the parasite load than the SP and TS that were similar ($P>.05$). Statistically significant differences were observed for WT and SPL. Results from 2005-2007 (challenged and pastured) followed a similar pattern. Individuals within breed analyses will be presented.

759 Genetic diversity of US sheep breeds. H. Blackburn^{*1}, M. Brown², S. Wildeus³, R. Stobart⁴, D. Bixby⁵, J. Dzakuma⁶, S. Ericsson⁷, W. Getz⁸, N. Cockett⁹, D. Matsas¹⁰, C. Welsh¹, S. Spiller¹, and D. Waldron¹¹, ¹ARS National Animal Germplasm Program, Ft. Collins, CO, ²ARS Grazing Lands Research, El Reno, OK, ³Virginia State University, Petersburg, ⁴University of Wyoming, Laramie, ⁵American Livestock Breeds Conservancy, Pittsboro, NC, ⁶Prairie View A&M University, Prairie View, TX, ⁷Sul Ross University, Alpine, TX, ⁸Fort Valley State University, Fort Valley, GA, ⁹Utah State University, Logan, ¹⁰Tufts University, North Grafton, MA, ¹¹Texas A&M University, San Angelo.

Understanding the genetic relationships between US sheep breeds is useful in developing conservation strategies and actions. A broad sampling of individual sheep from 28 breeds was performed. Breed types included: fine wool, meat types, long wool, hair, prolific, and fat tailed. Blood and semen samples (n=660) were derived from 222 breeders in 38 states. DNA was extracted from the samples and genotyped using the FAO/ISAG panel of 31 microsatellites, however, based on amplification success only 28 markers were used in the analysis. Genotyping data were analyzed using GENALEX, PHYLIP and STRUCTURE. The following breeds were found to have relatively high inbreeding values: Columbia (0.60), Gulf Coast Native (0.54), Jacob (0.52), and Targhee (0.62) suggesting genetic diversity is an issue for rare breeds and some commercially popular breeds. The average number of alleles per breed ranged from 3.67 (Black Welsh Mountain) to 7.89 (Rambouillet). Private alleles ranged from one to five and were found in 22 breeds. There were six breeds with no private alleles. Of interest were the high frequencies of three private alleles in the Tunis (0.62 and 0.15) and Warhill (0.30) breeds. Nei's genetic distances were computed and ranged from 0.08 for Hampshire:Suffolk to 0.80 for the combinations of Blackbelly Barbados:Black Welsh Mountain, and Hog Island:Tunis. Data were clustered using STRUCTURE assuming 28, 20, 19, and 15 clusters; the assignments from these runs suggest the number of clusters for this dataset is 19. Breeds showing a constant grouping with one another included: Rambouillet:Warhill, Hampshire:Suffolk, Barbados Blackbelly:St Croix, Cotswold:Lincoln, and Columbia:Targhee:Dorset:Polypay. These data provide a baseline for determining the degree of

genetic similarity/dissimilarity between many US sheep breeds. With this information germplasm collection activities can be refined, thereby ensuring that germplasm collections capture the genetic diversity needed to safely conserve sheep populations.

Key Words: Genetic Diversity, Sheep, Conservation

760 Heterogeneity of founder-specific inbreeding depression on birth BW of Ripollesa lambs. J. Casellas*¹, J. Piedrafit², G. Caja², and L. Varona^{1,3}, ¹*Genètica i Millora Animal, IRTA-Lleida, Lleida, Spain*, ²*Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Bellaterra, Spain*, ³*Departamento de Anatomía, Embriología y Genética Animal, Universidad de Zaragoza, Zaragoza, Spain*.

Estimates of inbreeding depression are usually obtained by modeling the overall inbreeding coefficient of each individual, without considering that heterogeneity between founders could be anticipated. Inbreeding has special relevance in local and endangered sheep breeds, whose flocks are characterized by small size, limited genetic connectedness and small number of rams per generation. The objective of this research was to examine heterogeneity in founder-specific inbreeding depression (FSID) effects on lamb birth BW. Data were recorded in the Ripollesa experimental flock of the Universitat Autònoma of Barcelona (Spain), between 1986 and 2007, and included 2,459 birth BW records (3.29 ± 0.02 kg) from 1,634 parturitions and 384 ewes. The operational model accounted for birth type, sex, year of birth, environmental dam effect and infinitesimal genetic effect, as well as FSID effects from 9 founders contributing with more than 50 inbred lambs with phenotypic data. Birth BW was analyzed under a linear animal model solved through Bayesian inference, and each FSID effect was appropriately tested by an empirical Bayes factor (BF; model including the FSID effect against model excluding the FSID effect). Four founders showed null FSID effects with BF ranged between 0.05 and 0.42. The remaining 5 founders showed relevant FSID effects, birth BW being reduced between -8 g (BF = 1.42) and -96 g (BF = 8.80×10^{19}) for each 1% increase in inbreeding. Note that those estimates were obtained from a small range of partial inbreeding coefficients (0% to 10%), and they must be seen with caution outside that range of values. These results revealed a substantial degree of between-founders heterogeneity of FSID effects, where null and negative effects were reported on birth BW of Ripollesa lambs.

Key Words: Birth Weight, Inbreeding Depression, Ripollesa Breed

761 Type appraisal of Holsteins, Jerseys, and reciprocal crosses under two classification systems. B. G. Cassell*¹, K. M. Olson¹, and A. J. McAllister², ¹*Virginia Polytechnic Institute and State University, Blacksburg*, ²*University of Kentucky, Lexington*.

Holstein appraisers scored Holsteins (HH) and two reciprocal crosses, (HJ and JH with breed of sire first) while Jersey (JJ) appraisers scored JJ, HJ, and JH crosses in the Virginia Tech and Kentucky university dairy herds. Holstein appraisers visited each herd twice scoring 115 HH, HJ, and JH cows. Jersey appraisers visited Virginia Tech twice and Kentucky once scoring 86 JJ, HJ, and JH cows. Fifty four HJ and JH cows were scored on both systems. Only first available appraisals, whether in first or second lactation, were used. Purebreds were compared to crossbreds

within the Holstein or Jersey appraisal system using a single score per cow and a fixed model including lactation, age fresh within lactation, station, appraiser within station, days in milk when scored, and breed. Interest was in breed differences. Crossbred cows scored on both systems were analyzed using two scores per cow in a mixed model including random cow within breed, the effects in the previous fixed model, plus appraisal system, station by system, and appraiser nested within station and system. Interest was in system differences. From the fixed analysis, HJ and JH scored significantly lower than HH for final classification (70 and 71 points versus 79), were significantly shorter than HH, with less strength and deeper udders. Front teat placement favored HJ and JH over HH. In the Jersey system, final score was not different for HJ, JH, and JJ breed groups, while crosses were taller than JJ with wider rear udders. Crosses and purebreds were not significantly different in either system for almost all other traits. In the mixed model comparing Holstein and Jersey systems, we observed system differences in final score, dairy form, stature, strength, foot angle, udder depth, and front teat placement. Breed systems assigned similar scores for rump angle, rear udder height and width, udder cleft, and teat length. In general, crossbred conformation was more acceptable to Jersey than to Holstein type standards.

Key Words: Crossbreeding, Dairy, Type Appraisal

762 Montbeliarde-sired crossbred cows compared to pure Holstein cows for production, SCS, days open, and body condition score during their first two lactations. A. R. Hazel*, B. J. Heins, L. B. Hansen, A. J. Seykora, D. G. Johnson, J. G. Linn, and J. E. Romano, *University of Minnesota, Saint Paul*.

Montbeliarde-sired crossbred (MX) cows ($n = 83$) were compared to pure Holstein cows ($n = 61$) for 305-d milk, fat, and protein production; SCS; days open (DO); and BCS during their first two lactations. Cows were in two research herds of the University of Minnesota and calved from October 2005 to December 2007. Best Prediction was used to determine actual production for 305-d lactations with adjustment for age at calving, and records less than 305 d were projected to 305 d. For DO, cows were required to be at least 250 d in milk and those with greater than 250 d for DO were truncated to 250 d. First and second lactations of cows were analyzed separately. Independent variables for statistical analysis were the fixed effects of herd, season (fall or spring) nested within herd, breed group, and two-breed (Montbeliarde \times Holstein) vs. three-breed (Montbeliarde \times Jersey/Holstein) crossbred nested within breed group. Age in months at calving and days in milk were also covariates for BCS. The MX and pure Holstein cows were not significantly different for fat plus protein production during first lactation (493 kg vs. 502 kg, respectively) and second lactation (617 kg vs. 618 kg, respectively). Also, MX cows (2.74) were not significantly different from pure Holstein cows (2.66) for SCS during first lactation; however, MX cows (1.53) had significantly ($P < 0.01$) lower SCS than Holstein cows (2.51) during second lactation. During first lactation, MX cows (121 d) had significantly ($P < 0.01$) fewer days open (40 d) than pure Holstein cows (161 d). The MX cows carried significantly ($P < 0.01$) more body condition than pure Holstein cows during both first lactation (3.22 vs. 2.77, respectively) and second lactation (3.27 vs. 2.65, respectively).

Key Words: Crossbreeding, Heterosis, Montbeliarde

763 Jersey × Holstein crossbred cows compared to pure Holstein cows for production, SCS, days open, body condition score, and udder measurements during the first three lactations. B. J. Heins*, A. R. Hazel, L. B. Hansen, A. J. Seykora, D. G. Johnson, J. G. Linn, and J. E. Romano, *University of Minnesota, Saint Paul.*

Jersey × Holstein crossbred (J×H, n = 76) cows were compared to pure Holstein (n = 73) cows for 305-d milk, fat, and protein production; SCS; days open (DO); BCS; and udder measurements during the first three lactations. Cows were in two research herds of the University of Minnesota and calved from September 2003 to June 2007. Best Prediction was used to determine actual production for 305-d lactations with adjustment for age at calving, and records less than 305 d were projected to 305 d. For DO, cows were required to be at least 250 d in milk and those with greater than 250 d for DO were truncated to 250 d. Independent variables for statistical analysis were the fixed effects of herd, season (fall or spring) nested within herd, and breed group. During first lactation, J×H (497 kg) and pure Holstein (515 kg) cows were not significantly different for fat plus protein production. However, during second (577 kg vs. 608 kg) and third (598 kg vs. 641 kg) lactations, J×H cows were significantly ($P < 0.01$) lower for fat plus protein production than pure Holstein cows. The J×H cows were not significantly different from pure Holstein cows for SCS during first and second lactations; however, J×H cows (4.00) had significantly ($P < 0.05$) higher SCS than pure Holstein cows (3.20) during third lactation. The J×H cows tended ($P < 0.10$) to have fewer days open than pure Holstein cows (127 d vs. 150 d) in first lactation and had significantly ($P < 0.01$) fewer days open than pure Holstein cows (130 d vs. 162 d) in second lactation. For BCS, J×H cows had significantly ($P < 0.05$) greater body condition (2.80 vs. 2.71 and 2.96 vs. 2.85) than pure Holstein cows in first and second lactations, respectively. For udder measurements, J×H cows had significantly ($P < 0.01$) less udder clearance than pure Holstein cows in first (47.7 cm vs. 54.6 cm) and second (41.7 cm vs. 50.2 cm) lactations. Furthermore, J×H cows had significantly ($P < 0.01$) greater distance between front teats in first (15.8 cm vs. 14.0 cm) and second (17.0 cm vs. 14.7 cm) lactation than pure Holstein cows.

Key Words: Crossbreeding, Heterosis, Jersey

764 Number of services per conception, estimated calving interval and lactation length in New Zealand and Mexican Holstein cows in Torreon, Coahuila, Mexico, Case study. T. B. Garcia-Peniche*¹ and A. Aranda-Munguia², ¹*Instituto Nacional de Investigaciones Forestales Agrícolas y Pecuarias, Paso del Toro, Veracruz, Mexico,* ²*Establo La Montaña, Torreon, Coahuila, Mexico.*

This work compares calving interval (CI), empty time (Emp), number of services per conception (NuIns), and lactation length (TotDIM) in Holstein cows from 3 origins (breedtyp): imported as pregnant heifers from New Zealand (NZ), born in Mexico, from New Zealand dams (d_NZ) or from American parentage (d_EUA). All the cows were in the same herd in an intensively managed, confined dairy in Torreon, Coahuila, Mexico. Data were obtained from 15 test days from March 2007 to January 2008. Records from 1657 dry cows (73% NZ, 20.6% d_EUA and 6.4% d_NZ) provided information about totDIM, as well as days pregnant (days_preg) and days dry (dd). Assuming a pregnancy length of 283 d, the time that the cows are expected to remain dry can be calculated from 283 d minus the reported days_preg. Thus, CI was estimated as: { [(283-days_preg) + dd] + TotDIM }, and EMP = CI-283. The NuIns were directly obtained from the records of 2006 pregnant

cows in production (68% NZ, 8.4% d_NZ, and 20.6% d_EUA). No interaction was found between breedtyp with either lactation number (1 to 3) or season of conception, yet the models were adjusted for those effects. The data were analyzed using SAS[®] 9.1. Calving interval, EMP and totDIM were analyzed with the MIXED procedure, while NuIns was assumed to follow a poisson distribution and analyzed with the GENMOD procedure. Total time that the cows remained dry was also analyzed, but no differences for breedtyp were found. There were no significant differences between d_EUA and d_NZ for CI, TotDIM and EMP, as the Table shows. The expected NuIns values have the Wald 95% confidence lower and upper limits between parentheses, and the letters a and b show that no significant Chi-square difference was found between NZ and d_EUA. The total time that the cow remains dry is a trait derived from management and showed no breedtyp difference, however, results show that the longer CI in NZ comes both from longer lactations (totDIM) and more difficulties in achieving pregnancies (larger EMP and NuIns) in this study.

Table 1. Calving interval (CI), empty time (EMP), lactation length (totDIM), and number of services per conception (NuIns) in New Zealand (NZ) and Mexican (d_NZ and d_EUA) Holstein cows

Origin	CI (d)	EMP (d)	totDIM (d)	NuIns
NZ	418.3 ± 4.7 a	135.3 ± 4.7 a	332.5 ± 4.3 a	3 (2.67 - 3.36) a
d_NZ	383.2 ± 10.1 b	100.2 ± 10.0 b	297.2 ± 9.2 b	2.5 (2.16-2.99) b
d_EUA	382.0 ± 7.2 b	99.0 ± 7.2 b	297.8 ± 6.6 b	2.9 (2.73–3.03) a

d_NZ are daughters of New Zealand dams, d_EUA are cows with American parentage

Key Words: Fertility, Lactation Length, Mexican Dairies

765 Puberty and conception in Holsteins, Jerseys and reciprocal crossbred heifers. W. J. Silvia*¹, K. G. Hall², C. M. Williams³, A. J. McAllister¹, B. G. Cassell², and S. P. Washburn³, ¹*University of Kentucky, Lexington,* ²*Virginia Polytechnic Institute and State University, Blacksburg,* ³*North Carolina State University, Raleigh.*

Reproductive performance was compared in purebred Holstein (HH, n=54), Jersey (JJ, n=35) and reciprocal crossbred heifers (HJ, n=45 and JH, n=37; sire breed first) from 3 research herds. Blood samples were collected at weekly intervals beginning at approximately 8 mo of age for quantification of progesterone. Age at puberty was defined as difference in days between birth and the first date on which a significant increase in progesterone was observed. Heifers were bred by artificial insemination following visual detection of estrus beginning at 15 mo of age. The number of services required for each heifer to become pregnant was recorded. Age at first service and age at conception were also determined. Genetic group comparisons for quantitative variables were made using a fixed model with additive, maternal, and heterotic genetic effects partitioned. Effects of herd, season of birth (win:Jan-Mar, spr:Apr-Jun, sum:Jul-Sept, fall:Oct-Dec) and year of birth (2003-2006) were also included in the model. Percentages of heifers requiring 2 or fewer services to conceive were compared among breed groups by logistic regression with additive, maternal, and heterotic effects partitioned. Age at puberty differed across breed groups with significant additive and heterosis effects: LSMEANS: HH = 349 ± 11.2 d; HJ = 315 ± 11.0

d; JH = 304 ± 11.7 d; and JJ = 300 ± 10.8 d. Also, proportions of heifers pregnant after 2 services differed by breed group with significant heterosis: HH = 83.6%; HJ = 91.7%; JH = 91.1%; JJ = 66.7%. Trends for heterosis were observed for number of services ($P = 0.10$) and for age at conception ($P = 0.07$). There were no effects of genetic group on age at first service, service interval, or total breeding period. In conclusion, beneficial heterotic effects were observed on age at puberty and percentage of heifers conceiving to 1 or 2 services.

Key Words: Puberty, Conception, Crossbred

766 Production, conformation, health, and fertility of backcross Holstein × Jersey cattle and their Holstein contemporaries. K. A. Weigel*, P. C. Hoffman, C. Maltecca, and T. J. Halbach, *University of Wisconsin, Madison*.

Since 2003, lactating Holstein cows in the University of Wisconsin herd have been randomly mated to Holstein young sires or F1 Jersey × Holstein young sires, resulting in an experimental population of 75% Holstein × 25% Jersey females and a control population of pure Holstein

females. Age at first calving tended to be lower in crossbred cows ($N = 64$) than in Holstein cows ($N = 98$) (721 d vs. 731 d; $P < 0.10$), and crossbred cows weighed less at first calving (562 kg vs. 601 kg; $P < 0.01$). Crossbred cows had higher dystocia scores at first calving than Holsteins (2.27 vs. 1.73; $P < 0.01$), despite the fact that their calves were lighter (37.6 kg vs. 40.5 kg; $P < 0.01$). In first lactation, average daily milk yield of crossbreds was lower than that of Holsteins (26.3 kg vs. 29.4 kg; $P < 0.01$), as was peak daily milk yield (31.0 kg vs. 35.1 kg; $P < 0.01$) and total 305-d milk yield (7647 kg vs. 8737 kg; $P < 0.01$), but protein percentage of crossbreds was higher (3.12 vs. 3.00; $P < 0.05$). On a 50-point scale, crossbred cows had shorter stature (21.2 vs. 35.2; $P < 0.01$), more sloped rumps (32.3 vs. 28.0; $P < 0.05$), narrower rumps (24.0 vs. 30.2; $P < 0.01$), and longer teats (22.1 vs. 17.7; $P < 0.01$) and tended to have deeper udders (21.9 vs. 24.5; $P < 0.10$) than Holsteins. Milking duration tended to be longer in crossbreds than in Holsteins (5.2 min vs. 4.9 min; $P < 0.10$). Differences between breeds in fat percentage, somatic cell score, body condition score, and other linear type traits were not statistically significant ($P < 0.10$), nor were differences in days open, services per conception, or the incidence of mastitis, lameness, retained placenta, ketosis, or respiratory disease.

Symposium: Growth and Development: The Molecular Basis for Feed Efficiency

767 Mitochondrial efficiency in lines of mice divergently selected for heat loss. J. M. McDonald* and M. K. Nielsen, *University of Nebraska, Lincoln.*

Divergent selection (high=MH, low=ML, and control=MC) for heat loss was applied in mice in three replicates. After 16 generations (G) of selection, no selection was practiced for 26 generations; another 9 generations of selection ensued; then selection was relaxed again. A total of 25 generations occurred, and at G51, differences of 55% in heat loss 34% in feed intake:BW^{0.75} in mature males existed between MH and ML mice. Rates of mitochondrial respiration states, degree of coupling and mitochondrial efficiency were measured in liver tissue of G58 mature males using a Clark-type oxygen electrode in an attempt to explain part of the line differences in feed intake. Body weight, body composition, feed intake and liver weight were also measured. Data from 69 mice (total for MH, ML and MC) in Replicate 1 and 67 in Replicate 2 were analyzed with contrasts used to test selection response (MH – ML) and asymmetry of response ($[(MH+ML)/2 - MC]$). There were no significant differences in body weight or percents lean and fat between MH and ML mice ($P>0.15$). However, liver:BW of MH mice was approximately 5.6% larger than in ML mice ($P<0.06$). Selection response ($P<0.01$) in feed intake:BW was similar to that observed at G51 with MH mice consuming 31.7% more than ML mice. States 2 and 4 respiration rates approached significance ($P=0.09$ and $P=0.12$, respectively) with rates for MH mice greater than for ML mice. Differences in State 3 respiration failed to show significance. No differences existed in the degree of coupling, expressed as respiratory control ratio. ADP:O ratio in ML mice averaged 27.2% greater than in MH mice ($P=0.03$), indicating greater mitochondrial efficiency in the liver for ML mice. Asymmetry of response was not observed for any of the characteristics ($P>0.10$). Across all lines, a correlation of -0.32 was observed between feed intake:BW and ADP:O, however within lines this correlation failed to exist. These data indicate that efficiency of mitochondrial respiration explains a portion of the difference in feed intake between mice of the MH and ML lines.

768 The molecular basis for feed efficiency in beef cattle. S. S. Moore*¹, E. L. Sherman¹, J. D. Nkrumah², F. D. Mujabi¹, Z. Wang¹, and P. Stothard¹, ¹*University of Alberta, Edmonton, AB, Canada*, ²*Merial Limited, Duluth, GA.*

Feed intake and feed efficiency are economically important traits in beef cattle as feed is the highest variable cost in production. Feed efficiency can be measured as feed conversion ratio (FCR, intake per unit gain) or residual feed intake (RFI, measured as DMI corrected for BW and growth rate, and sometimes a measure of body composition, usually carcass fatness, RFIbf). In an effort to fine map the genes underlying feed intake and feed efficiency we have used an increasing density of genetic markers to identify quantitative trait loci (QTL). QTL discovery was carried out as a whole genome scan on 400 to 500 steers, depending on analysis, that comprised 20 half sib families. The number of genome wide markers used for the scans increased from an initial 450, to 3,000 and eventually 51,000 SNP. Various statistical approaches were used for analysis and these included single and multiple marker regressions to estimate SNP effects as well as linear mixed models for QTL mapping.

To date we have identified 48 putative SNP markers for residual feed intake. Validation of these markers is ongoing in independent populations of animals with available individual animal intake records. The identification of narrow QTL regions will aid greatly in the identification and testing of positional candidate genes underlying traits associated with feed intake and efficiency in cattle.

769 Associations between mitochondrial function and feed efficiency in poultry and livestock species. W. G. Bottje*¹ and G. E. Carstens², ¹*University of Arkansas, Fayetteville*, ²*Texas A&M University, College Station.*

Meeting future global demands for animal protein in the face of rising feed costs, emerging bioenergy policies and environmental concerns will require substantive improvements in feed efficiency to maintain viable meat production systems in the U.S. In livestock and poultry, genetic variation exists in feed consumed above and below predicted requirements for production and maintenance, which can be quantified as the difference between actual and expected feed intake based on size and weight gain (residual feed intake; RFI). While research has established that inter-animal variation in RFI is favorably linked with variation in total energy expenditure, our understanding of the cellular and biochemical mechanisms responsible for bioenergetic processes associated with feed efficiency is incomplete. There is evidence that mitochondrial function, respiration, and/or biochemistry are linked to the phenotypic expression of feed efficiency (FE; g gain to g feed) and RFI in livestock and poultry. This paper will provide a short overview of biochemical mechanisms controlling mitochondrial energy metabolism and function, and will review the literature that examines the role that these important mitochondrial-linked biological processes could play in accounting for genetic and phenotypic variation in feed efficiency. Enhanced understanding of the mechanisms controlling mitochondrial function will provide useful insight into development of physiological biomarkers and genetic markers that are predictive for RFI or FE in livestock and poultry. Development of new selection tools will enhance the accuracy of identifying livestock and poultry with superior genetic merit for RFI, thereby improving the economic and environmental sustainability of U.S. meat-production systems.

770 Physiological basis for residual feed intake. R. M. Herd*¹ and P. F. Arthur², ¹*NSW Department of Primary Industries, Armidale, Australia*, ²*NSW Department of Primary Industries, Camden, Australia.*

Residual feed intake (RFI) is a measure of feed efficiency that is independent of level of production and hence a useful new trait for studying the physiological mechanisms underlying variation in feed efficiency. Five major physiological processes are likely to contribute to variation in RFI; being processes associated with intake of feed, digestion of feed, metabolism (anabolism and catabolism associated with and including variation in body composition), activity, and thermoregulation. Studies on Angus steers following divergent selection for RFI estimated that heat

production from metabolic processes, body composition and activity explained 73% of the variation in RFI. The proportion of variation in RFI that these processes explain are: protein turnover, tissue metabolism and stress (37%), digestibility (10%), heat increment and fermentation (9%), physical activity (9%), body composition (5%) and feeding patterns (2%). Other studies in cattle and studies in poultry similarly found these processes to be important in explaining RFI. The physiological mechanisms identified so far are based on very few studies, some of which have small sample sizes. The genomic basis to variation in these physiological processes remains to be determined. Early studies have shown many hundred genes to be associated with differences in RFI, perhaps in hindsight not surprising given the diversity of physiological processes involved. Further research is required to better understand the mechanisms responsible for the variation in RFI in target populations and to marry the physiological information with molecular genetics information which will become the basis for commercial tests for genetically-superior animals.

771 Physiological basis for residual feed intake in pigs. C. de Lange* and G. vanderVoort, *University of Guelph, Guelph, ON, Canada.*

Selection for residual feed intake in growing pigs is an important means to improve pork production efficiencies. Differences in pork production

efficiencies between pigs can be attributed largely to between-animal variation in the composition of growth (fat tissue vs lean tissue vs visceral organs), energy and nutrient requirements for body protein deposition, and basal energy expenditure. Visceral organ mass, an important predictor of whole body energy expenditure in growing pigs, is influenced by factors associated with feed (feed intake level and diet composition), environment (i.e. disease) and pig genotype. In isotope tracer studies it has been shown that variation in the ratio between whole body protein synthesis, an important contributor to whole body energy expenditure, and body protein deposition varies between extreme pig genotypes. Between-animal variation in this ratio should be explored further within lines of pigs. Basal energy expenditure can be defined as the available energy requirements at the tissue level to support body functions that are not related to growth and feed intake. Basal energy expenditure, in contrast to maintenance energy requirements, is largely independent of feeding level, diet composition, composition and rate of growth and can thus be related more easily to animal characteristics. The contribution of animal activity to between-animal variability in basal energy expenditure appears quite substantial and deserves further exploring. Key aspects of animal activity in ad libitum fed pigs are time spend standing, feeding frequency and eating rate. At the cellular level, special consideration should be give to the efficiency of oxidative phosphorylation which is influenced by uncoupling proteins, and maintenance of ion gradients across membranes. A better understanding of the biology of energy and nutrient utilization may lead to means to improve the efficiencies of pork production, including the identification of genetic markers that may be used in pig breeding strategies.

Key Words: Residual Feed Intake, Energetic Efficiency, Growing Pigs

Nonruminant Nutrition: Protein and Feed Additives

772 Bacteria composition, richness and diversity differ in colon digesta of piglets fed diets with different levels of protein and challenged with *Escherichia coli* K88. F. O. Opapeju*¹, R. L. Payne², D. O. Krause¹, and C. M. Nyachoti¹, ¹University of Manitoba, Winnipeg, MB, Canada, ²Evonik-Degussa Corporation, Kennesaw, GA.

Feeding excessive amount of protein to weaned pigs will increase the amount of undigested protein reaching the hindgut and may alter the types and the number of bacteria in the hind gut. Forty piglets (average BW = 5.32 ± 0.24 kg) were used to investigate the effect of dietary CP level on microbial composition, richness and diversity in piglets challenged with enterotoxigenic *Escherichia coli* K88 in a 14-d study. Pigs were housed in groups of 4 pigs per pen and were randomly allotted to 2 diets (5 pens/diet) immediately after weaning. Diet 1 contained 22.5% CP and diet 2 contained 17.6% CP supplemented with amino acids. The diets contained the same amount of ME and standardized ileal digestible Lys, Met + Cys, Thr, Trp, Ile and Val based on the ideal protein ratio. Pigs had unlimited access to feed and water throughout the experimental period. On d 8 after weaning, pigs received 6 mL of *E. coli* K88 suspension (10¹⁰ cfu/mL) by gavage. Thirty pigs were serially slaughtered on -1, 3 and 7 d post-challenge (5 pigs/diet/day of slaughter). Colon contents were analyzed for microbial profile and diversity indices using terminal restriction fragment length polymorphism. Pigs fed the 17.6% CP diet had a higher ($P < 0.05$) proportion of order Clostridiales (73 vs. 50%), family Lachnospiraceae (43 vs. 18%), and genus Roseburia (13 vs. 3%) 7 d after challenge compared with those fed the 22.5% CP diet. Pigs fed the 17.6% CP diet had lower ($P < 0.05$) richness and diversity compared with those fed the 22.5% CP diet at -1, 3 and 7 d post-challenge. The results show that a reduction in dietary CP level from 22.5 to 17.6% with amino acid supplementation altered the hind gut microbial profile 7 d post-challenge and reduced the microbial richness and diversity before and after challenge.

Key Words: Microbial Profile, Protein, Weaned Pigs

773 Value of spray-dried egg in pig nursery diets. M. Song*¹, B. G. Harmon², M. T. Che¹, M. U. Steidinger³, and J. E. Pettigrew¹, ¹University of Illinois, Urbana, ²Railsplitter Feed Technology, Wildwood, MO, ³Swine Nutrition Services, Inc., Forrest, IL.

A study was conducted to verify the nutrient contributions of a spray-dried egg (SDE) product containing only unfertilized eggs and to assess potential physiological benefits. Weaned pigs (n=1007, 6 kg, 20 d of age) were used in a randomized complete block design with pen as the experimental unit. There were 4 rooms with 12 pens/room and 21 pigs/pen. There were 3 weight blocks within each room and each weight block had 4 pens with the same number of barrows and gilts. The treatments were formulated to the same ME and standard ileal digestible (SID) AA levels and were: 1a) 6% spray-dried animal plasma (SDAP) (CON A), 1b) CON A + 6% SDE (SDE A), 2a) 3% SDAP (CON B), and 2b) CON B + 6% SDE (SDE B). There was a 4-stage feeding program with declining diet complexity and with phases of 1, 1, 2, and 2 wk, respectively. ADFI, ADG, G:F, removal rate (REM), and frequency of medical treatments per pen and day (MED) were measured. During phase 1 only, pigs fed A treatments or SDE treatments had higher ($P < 0.01$) ADFI and lower ($P < 0.05$) MED than pigs fed B treatments or CON treatments. Pigs fed B treatments had higher ($P < 0.05$; phase 3) ADFI and ADG and lower ($P < 0.05$; phase 3 and overall) MED than pigs fed A treatments. During

the overall experiment, there was a tendency ($P = 0.06$) for a reduction in MED with SDE. In conclusion, SDE provides bioavailable nutrients to nursery pig performance and may provide physiological benefits to the health of nursery pigs.

774 The use of dried bacterial cells in nursery pig diets. R. B. Hinson*¹, J. L. Usry², A. M. Gaines³, and G. L. Allee¹, ¹University of Missouri, Columbia, ²Ajinomoto Heartland LLC, Chicago, IL, ³The Maschhoffs Inc., Carlyle, IL.

Two studies were conducted to evaluate the use of dried bacterial cells (DBC) in nursery pig diets. Dried bacterial cells are yeast cell bodies that remain after the production of synthetic amino acids. In Exp. 1, 528 newly weaned pigs (TR-4 × C22; Initial BW = 5.5 kg) were randomly allotted to treatments consisting of 0, 1, 2, or 3% DBC with 22 pigs/pen. In the diets containing DBC, blood cells and poultry by-product meal were replaced by DBC. Growth performance was evaluated during three dietary phases: Ph. 1 (d 0-7), Ph. 2 (d 7-14), and Ph. 3 (d 14-24). Diets were formulated to contain 1.60, 1.50, and 1.55% total lysine in ph. 1-3, respectively. In Exp. 2, 560 newly weaned pigs (TR-4 × C22; Initial BW = 5.3 kg) were randomly allotted to treatments consisting of 0, 1, 2, or 3% DBC with 22 pigs/pen. In the diets containing DBC, fishmeal was partially replaced by DBC. Growth performance was evaluated during four dietary phases: Ph. 1 (d 0-7), Ph. 2 (d 7-14), Ph. 3 (d 14-21), and Ph. 4 (d 21-42). Diets were formulated to contain 1.43, 1.43, 1.42%, and 1.31% TID lysine in ph. 1-4, respectively. During ph. 4, all treatments received a common diet. In Exp. 1, overall ADG (295, 308, 313, and 299 g/d) and F:G (1.30, 1.28, 1.32, and 1.36) were not affected ($P > 0.05$) by the use of DBC. Overall, a linear increase ($P < 0.03$) in ADFI and a linear improvement ($P < 0.02$) in F:G were observed with increasing DBC inclusion. In Exp. 2, d 0-21 ADG (272, 272, 272, and 259 g/d) and F:G (1.32, 1.34, 1.33, and 1.34) were unaffected ($P > 0.05$) by the inclusion of DBC. Additionally, overall d 0-42 ADG (435, 440, 435, and 435 g/d) and F:G (1.41, 1.41, 1.43, and 1.42) were unaffected by the inclusion of DBC. These data would suggest that at least 3% inclusion of dried bacterial cells can be used in nursery pig

diets replacing other high quality protein ingredients without affecting growth performance..

Key Words: Dried Bacterial Cells, Nursery Pigs

775 Effects of increasing true ileal digestible lysine/metabolizable energy ratios on gilts grown in a commercial finishing environment.

N. W. Shelton*, M. D. Tokach, S. S. Dritz, R. D. Goodband, J. L. Nels- sen, and J. M. DeRouche, *Kansas State University, Manhattan.*

Two four-week experiments were conducted to determine the effects of increasing true ileal digestible (TID) Lys:ME ratio on performance of growing and finishing gilts. All diets were corn-soybean meal based and contained 0.15% L-Lysine HCl and 3% added fat. Desired Lys levels were achieved by altering the corn and soybean meal level in the diet. Each experiment consisted of six treatments with seven replications per treatment and approximately 27 pigs per pen. In Exp. 1, 1,085 gilts (PIC, initially 38.2 kg) were fed TID Lys:ME ratios of 2.01, 2.30, 2.58, 2.87, 3.16, or 3.45 g/Mcal. Both ADG (0.82, 0.87, 0.93, 0.95, 0.97, and 0.97 kg/d) and G:F (0.42, 0.45, 0.48, 0.49, 0.51, and 0.51) improved (quadratic, $P < 0.003$) with increasing the TID Lys:ME ratio and optimal performance was reached at the TID Lys:ME ratio of 3.16 g/Mcal. Increasing the TID Lys:ME ratio resulted in increased daily TID Lys intake (linear, $P < 0.001$) and TID Lys intake per kg of gain (16.8, 18.0, 18.9, 20.3, 21.8, and 23.5 g, quadratic, $P < 0.001$). In Exp. 2, 1,080 gilts (PIC, initially 84.1 kg) were fed TID Lys:ME ratios of 1.55, 1.75, 1.95, 2.05, 2.35, or 2.55 g/Mcal. As TID Lys:ME ratio increased, ADG (0.83, 0.87, 0.87, 0.93, 0.95, and 0.98 kg/d) and G:F (0.33, 0.34, 0.35, 0.37, 0.37, and 0.39) improved (linear, $P < 0.001$) through the highest lysine/ME level of 2.55 g/Mcal. Increasing TID Lys:ME ratio also increased (linear, $P < 0.001$) daily TID Lys intake and TID Lys intake per kg of gain (16.58, 18.08, 19.65, 20.44, 22.05, and 22.98 g). It appears that the optimal Lys level to meet the biological needs of the pig may have increased compared to previous research conducted in the same facility (Main et al., 2002).

Key Words: Lysine, Finishing Pigs, Growth

776 Effects of feeding excess crude protein on growth perfor- mance and carcass traits in finishing pigs.

S. M. Williams*, J. D. Hancock, C. Feoli, S. Issa, and T. L. Gugle, *Kansas State University, Manhattan.*

A total of 176 pigs (88 barrows and 88 gilts with an average initial BW of 95 kg) were used in a 33-d experiment to determine the effects of excess dietary CP on growth performance and carcass measurements in finishing pigs. The pigs were sorted by ancestry and blocked by BW with 11 pigs/pen and four pens/treatment. Treatments were corn-soybean meal-based and formulated to 12, 14, 16, and 18% CP. Feed and water were consumed on an ad libitum basis until the pigs were slaughtered (average final BW of 125 kg) at a commercial abattoir. Increasing CP concentration in the diet had no effect on ADG ($P > 0.41$), ADFI ($P > 0.20$), G:F ($P > 0.24$), and hot carcass weight ($P > 0.20$). With hot carcass weight used as a covariate, there were linear decreases in dress- ing percentage ($P < 0.02$) and loin depth at the last rib ($P < 0.05$) as crude protein concentration in the diet was increased from 12 to 18%. However, fat thickness at the last rib and percentage carcass lean were not affected ($P > 0.34$) as crude protein concentration in the diet was increased. For diets with 12, 14, 16, and 18% CP, ADG was 944, 927,

921, and 936 g/d, ADFI was 2.86, 2.85, 2.83 and 2.79 kg/d, G:F was 330, 325, 325, and 336 g/kg, hot carcass weight was 92.6, 91.6, 91.0, and 91.7 kg, dressing percentage was 73.6, 73.3, 73.1, and 73.2%, loin depth was 6.4, 6.2, 6.2, and 6.1 cm, last rib backfat thickness was 19, 19, 19, and 19 mm, and percentage carcass lean was 55.0, 54.5, 54.5, and 54.4, respectively. Our results indicate that increasing CP in diets for pigs during late finishing from 12 to 18% does not affect growth performance or carcass leanness with only a small negative effect on dressing percentage.

Key Words: Pig, Protein, Growth

777 Effects of organoleptic properties of the feed and diet complexity on nursery pig performance.

R. C. Sulabo*¹, J. M. DeR- ouchey¹, M. D. Tokach¹, C. D. Risley², R. D. Goodband¹, S. S. Dritz¹, and J. L. Nelssen¹, ¹*Kansas State University, Manhattan,* ²*Lucta USA Inc., Northbrook, IL.*

A total of 480 weaning pigs (6.6 kg and 20 ± 2 d, PIC) were allotted to one of eight treatments using a randomized complete block design with exposure to the flavor in the creep feed (no vs. yes), diet complexity (complex vs. simple), and flavor in the nursery diets (no vs. yes) as treat- ment factors. Each treatment had six pigs per pen and ten replications. Experimental diets were the combinations of complex or simple diets with or without the flavor for Phase 1 (d 0 to 10) and 2 (d 10 to 28). Diets with the flavor were supplemented with Luctarom[®] at 1500 and 1000 ppm in Phase 1 and 2 diets, respectively. A tendency for a three-way interaction for ADG from d 5 to 10 ($P < 0.11$), d 10 to 28 ($P < 0.09$), and d 0 to 28 ($P < 0.06$) were observed. Post-weaning ADG of pigs exposed to the flavor in creep feed and fed flavored-complex diets were greater than any other treatment combination. Increasing diet complexity increased ($P < 0.01$) ADG, ADFI, and G:F during both phases. Adding flavor in the creep feed had no effect on G:F ($P > 0.34$) and pig BW ($P > 0.45$) in both periods post-weaning. Adding Luctarom to starter diets tended to improve ADFI ($P < 0.06$; 163 vs. 154 g) during d 0 to 5. In conclusion, pre-weaning exposure to Luctarom[®] improved post-weaning daily gain of pigs fed complex diets supplemented with the same flavor, but did not influence performance of pigs fed simple diets.

Table 1. Interactive effects of flavors and diet complexity on nursery performance.

Flavor in Creep:	No				Yes				SED
	Simple		Complex		Simple		Complex		
Diet Complexity:	No	Yes	No	Yes	No	Yes	No	Yes	SED
Flavor in Nursery:									
D 0 to 10									
ADG, kg	0.18	0.19	0.24	0.24	0.17	0.17	0.24	0.27	0.01
ADFI, kg	0.20	0.20	0.25	0.25	0.18	0.18	0.24	0.26	0.01
G:F	0.95	0.96	0.99	0.99	0.95	0.94	0.98	1.04	0.03
D 0 to 28									
ADG, kg	0.37	0.38	0.43	0.42	0.38	0.37	0.42	0.44	0.01
ADFI, kg	0.48	0.49	0.57	0.56	0.48	0.47	0.55	0.57	0.02

Key Words: Flavor, Nursery, Diet Complexity

778 Effects of adding an enhanced flavor to the creep feed on the proportion of piglets consuming creep feed and pre-weaning performance. R. C. Sulabo*¹, J. M. DeRouchey¹, M. D. Tokach¹, C. D. Riskey², R. D. Goodband¹, S. S. Dritz¹, and J. L. Nelssen¹, ¹Kansas State University, Manhattan, ²Lucta USA Inc., Northbrook, IL.

A total of 50 sows (PIC Line 1050) were used in the study to determine the effects of adding an enhanced flavor to the diet on the proportion of piglets consuming creep feed within litters and pre-weaning performance. Sows were blocked according to parity and date of farrowing and were allotted to two experimental treatments using a randomized complete block design. Treatment 1 was a creep diet with no flavor (Control) and Treatment 2 was the Control diet with the enhanced flavor (Luctarom®) included at 1500 ppm. Both creep diets contained 1.0% chromic oxide and were offered *ad libitum* from d 18 until weaning (d 21) using a rotary creep feeder with hopper. A single lactation diet (3,503 kcal ME/kg, 0.97% TID Lys) was used, and sows were allowed free access to feed throughout lactation. Fecal samples from all piglets were taken twice using sterile swabs between 3 and 12 h before weaning. Piglets were categorized as 'eaters' when the fecal sample was colored green at least once on any of the two samplings. Litter weaning weights (66.7 vs. 66.5 kg; $P>0.94$), total gain (8.9 vs. 8.8 kg; $P>0.77$), and daily gain (3.0 vs. 2.9 kg; $P>0.77$) were not different between litters fed creep with and without the enhanced flavor. For individual pigs, weaning weight (6.5 vs. 6.6 kg; $P>0.53$), total gain (0.87 vs. 0.88 kg; $P>0.89$), and average daily gain (0.29 vs. 0.29 kg; $P>0.89$) between the two treatments also were not different. Flavor added to the creep feed did not influence both total (0.60 vs. 0.63 kg; $P>0.66$) and daily (202 vs. 211 g; $P>0.66$) creep feed intake of litters and the proportion of creep feed eaters (73 vs. 69%; $P>0.41$) in whole litters. When creep was provided for 3 d before weaning, adding the enhanced flavor to the creep feed did not affect litter creep feed intake, the proportion of piglets consuming creep feed, and pre-weaning performance.

Key Words: Flavor, Creep Feed, Piglet

779 Diet preference and growth performance in weanling pigs fed diets with *Morinda citrifolia* (noni). C. Feoli*¹, J. D. Hancock¹, K. C. Behnke¹, and R. G. Godbee², ¹Kansas State University, Manhattan, ²Morinda Agricultural Products, Orem, UT.

Two experiments were conducted to determine the effects of adding 5% *Morinda citrifolia* (Tahitian Noni International, Orem, UT) to diets for weanling pigs. In the first experiment, 48 pigs (average initial BW of 4.2 kg) were used in a 29-d preference study. There were six pigs/pen and eight pens total. The pens were equipped with two identical feeders (for diets without and with noni puree) and each afternoon position of the feeders was switched to prevent feeder location from affecting diet consumption. The diets were corn-soy-based, pelleted, and had 1.8% Lys for d 0 to 5, 1.6% Lys for d 5 to 15, and 1.4% Lys for d 15 to 29. Feed and water were consumed on an *ad libitum* basis. No differences were noted among diets without and with noni for pelleting ease and/or pellet durability index. Feed intake was increased for d 0 to 5 (50 vs 102 g/d, $P<0.05$) and d 0 to 15 (66 vs 167 g/d, $P<0.006$) when noni was added to the diets. However, this effect disappeared for d 15 to 29 so that overall feed intake was not different (183 vs 227 g/d, $P>0.39$) for d 0 to 29. In a second experiment, 96 pigs (average initial BW of 6.7 kg) were used in a 29-d growth assay. There were six pigs/pen and eight pens/treatment. The diets were the same as those used in the first experiment. Results indicated no differences ($P>0.16$) in ADG, ADFI, and G:F for d 0 to 5

and 0 to 15 among pigs fed diets without and with noni. However, for d 15 to 29 and overall (d 0 to 29) ADG and ADFI were decreased ($P<0.04$) for pigs fed diets with noni compared to the control. In conclusion, there was a preference for diets with noni for the first 15 d of the preference study. In the growth assay, prolonged feeding of diets with noni resulted in reduced feed intake and, ultimately, decreased rate of gain. Thus, it seems likely that any advantages to inclusion of noni will be in the early portions of the nursery phase.

Key Words: Pig, *Morinda citrifolia*, Noni

780 Effects of *Morinda citrifolia* (noni) and diet complexity on growth performance in weanling pigs. C. Feoli*¹, J. D. Hancock¹, K. C. Behnke¹, and R. G. Godbee², ¹Kansas State University, Manhattan, ²Morinda Agricultural Products, Orem, UT.

Two experiments were conducted to determine the effects of concentration (none, 0.75, 1.5, 3.0, and 6.0%) of *Morinda citrifolia* (Tahitian Noni International, Orem, UT) and diet complexity in weanling pigs. In Exp. 1, 210 pigs (average initial BW of 6.1 kg) were used. There were seven pigs/pen and six pens/treatment during the 35-d growth assay. Diets were corn-soy-based and had 20% whey, 10% lactose, and 5% plasma protein for d 0 to 7 and 15% whey and 2.5% plasma protein for d 7 to 21. Lysine concentrations were 1.8% for d 0 to 7, 1.6% for d 7 to 21, and 1.4% for d 21 to 35 with feed and water consumed on an *ad libitum* basis. Average daily gain (quadratic effect, $P<0.03$) and G:F (quadratic effect, $P<0.08$) for d 0 to 7 and G:F for d 0 to 21 (quartic effect, $P<0.03$) increased as noni concentration in the diet was increased from none to 0.75%. However, no treatment effects were observed overall (d 0 to 35). For Exp. 2, 168 pigs (average initial BW of 6.3 kg) were used. There were six pigs/pen and seven pens/treatment in the 35-d growth assay. Treatments were arranged as a 2 x 2 factorial with main effects of diet formulation (simple vs complex) and noni addition (none vs 3%). Complex diets were those used in Exp. 1. Simple diets had the same minimum nutrient specifications as complex diets but had no added lactose or plasma protein for d 0 to 7 and only 10% added whey for d 7 to 21. Pigs fed simple diets had lower ADG and G:F ($P<0.07$) for d 0 to 7 and lower ADG and ADFI ($P<0.06$) for d 0 to 21 than pigs fed complex diets. During d 0 to 35 for ADG and d 0 to 21 for G:F, addition of noni to the simple diets had negative effects and addition of noni to the complex diets had positive effects (diet complexity x noni interaction, $P<0.02$). In conclusion of the two experiments, noni tended to improve growth performance early in the nursery phase but those positive responses were observed only with complex diet formulations.

781 Cloning of Ningxiang porcine growth hormone gene and its construction respectively of prokaryotic and eukaryotic expression vector. W. C. Wang¹, W. Y. Chu¹, W. T. Gu¹, M. M. Geng¹, T. J. Li¹, Y. L. Yin*¹, and G. Y. Wu^{1,2}, ¹The Chinese Academy of Sciences, Changsha, Hunan, P. R. China, ²Texas A&M University, College Station.

The Ningxiang pig (a Chinese swine breed) has a relatively small body size but its meat has a special flavor of economic importance. To elucidate the mechanisms responsible for the slow rate of growth in this swine breed, we decided to clone the Ningxiang porcine growth hormone

(nxGH) gene and obtain its prokaryotic and eukaryotic expression vectors for future studies. The nxGH gene was cloned from the porcine pituitary gland. Its entire open reading frame (ORF) was 651 bp and encoded 216 amino acid residues. The identity of nucleotide sequences between the nxGH and the reported porcine GH genes was 99.85 %. Subsequently, the nxGH gene was inserted into a prokaryotic expression vector (pET-32) to generate a recombinant vector pET-GH. In addition, we constructed a eukaryotic expression vector for the nxGH gene. The gene encoding an enhanced green-fluorescence protein (EGFP) and the nxGH cDNA (amplified by RT-PCR using RNA from the Ningxiang pig pituitary gland as the template) were cloned, respectively, into an

eukaryotic expression pCI vector, resulting in the construction of pCI-GH-EGFP that encoded a fusion protein (GH-EGFP). Vero cells were transfected with pCI-GH-EGFP and Lipofectaine 2000 to express the GH-EGFP protein, which was observed under a fluorescent microscope. The fluorescence of the protein remained for 48 h after cell fusion. Collectively, these results indicate that the nxGH gene can be expressed in vero cells and provide a foundation for further studies of growth physiology in Ningxiang pigs

Symposium: Nonruminant Nutrition: Energy Systems and Alternative Energy Ingredients for Swine

782 Recent developments in net energy research for pigs. Jean Noblet*, *INRA, Saint Gilles, France.*

Feed represents the most important cost in pig production and energy represents the greatest proportion of this cost. It is then important to express the feed energy value on an appropriate basis and both energy supply (a diet characteristic) and energy requirement (an animal characteristic) should be expressed using the same system. Feeds can be attributed energy values according to DE, ME or NE bases. Reference methods for evaluating DE or ME contents are based on in vivo digestibility measurements while NE values originate from prediction equations established from energy balance studies. Literature results indicate that energy digestibility of feeds is negatively affected by dietary fiber content but the negative effect is attenuated with body weight increase. This suggests that feeds should be attributed DE values according to pig BW; in practice, two different DE values, one for growing-finishing pigs and one for reproductive sows, are recommended. The energy digestibility of pig feeds can also be affected by feed processing (pelleting, extrusion, etc.); this effect is the most important for some fat rich ingredients (corn, rapeseed, linseed). Metabolic utilization of ME averages 75% but it is dependent on diet chemical composition with efficiencies higher for energy from fat (90%) or starch (82%) than from protein or dietary fiber (60%). The hierarchy between feeds is then dependent on the energy system with overestimation of protein rich feeds and underestimation of starch and/or fat rich feeds in the DE or ME systems. For example, in the system proposed by INRA, the energy values (% of a conventional diet) of corn, soybean meal and animal fat are 100, 104 and 235 on a DE basis, 102, 99 and 244 on a ME basis, and 107, 79 and 289 on a NE basis. The NE system provides an energy value which is the closest estimate of the "true" energy value of a feed and it predicts accurately the performance of the pigs independently of diet characteristics. Furthermore, it allows implementing new feeding strategies such as the use of low protein and/or high fat and/or high fiber diets.

Key Words: Feed, Pig, Net Energy

783 Practical application of the net energy system in swine nutrition. R.T. Zijlstra*¹ and R.L. Payne², ¹*University of Alberta, Edmonton, AB, Canada,* ²*Evonik-Degussa Corporation, Kennesaw, GA, USA.*

Energy is the greatest cost-pressure in swine feed; thus, an accurate system to evaluate energy quality is critical managing feed costs. The NE system has been used for decades in swine feed formulation in Europe, and interest in this system has recently increased in North America due to an apparent competitive disadvantage of the DE and ME systems. Advantages of the NE versus the DE or ME systems are: 1) ensuring consistent growth performance and carcass quality while altering the macro-nutrient composition and thus NE content of feeds; 2) managing the risk of including alternative feedstuffs into swine diets, and 3) reductions in feed costs per kg of feed or lean gain. Other advantages such as higher growth or feed efficiency have been overstated, resulting in reluctance by nutritionists to implement the NE system following lack of positive experimental results. Following a decision to apply the NE system, an implementation plan focused on feedstuff composition and formulated diet NE content is required. For feedstuffs, the focus

is to develop or update a feedstuff data base including macronutrient composition. Used NE systems are solidly based on macronutrient composition of feedstuffs indicating that laboratory analyses and variation in composition should be part of the evaluation. For diets, these can be reformulated or directly recalculated to a NE content. The NE system might be implemented without an evaluation of feedstuff data base; however, ingredients vary regionally in macronutrient profile and thus NE content. Thus, feedstuff evaluation is recommended for risk management. Following the switch to the NE system, feed costs, growth performance, and carcass characteristics should be monitored to ensure that the switch was implemented successfully, and diet DE or ME content can be monitored initially for comfort. Application of the NE system combined with standardized ileal digestible AA and ideal AA profile will allow practical feed formulation providing the pig with the energy and AA required for efficient and predictable growth performance and carcass quality.

784 Impact of the biofuels industry on alternative ingredients available to swine. B.J. Kerr* and T.E. Weber, *USDA-ARS-NSTL, Ames, IA, USA.*

The biofuels industry has exhibited astonishing production advances in the past decade, and in its wake, has led to a wide diversity of co-products available to the livestock industry. During times of historically high prices for grains, proteins, minerals, and fats, this has led to a rapid increase in research activities evaluating the nutritional potential of these products. For example, from the biodiesel industry, research has recently been conducted on the availability of energy from crude glycerin for swine and poultry of various ages, and on the variability of energy from crude glycerin produced from biodiesel plants utilizing different initial feedstock. Likewise, from both the wet and dry corn milling industry there are numerous products produced that vary in CP, AA, P, S, GE, and 'fiber' concentration. Data will be presented showing variations in the nutrient profiles of these co-products, how they might fit into feed formulations, limitations or concerns with product use, and variability of co-product quality.

Key Words: Biofuels Co-Products, Crude Glycerin, Dried Distillers Grains

785 Effects of feeding increasing levels of glycerol with or without distillers dried grains with solubles in the diet on grow-finish pig growth performance and carcass quality. J. Stevens*, A. Schinckel, M. Latour, D. Kelly, D. Sholly, B. Legan, and B. Richert, *Purdue University, West Lafayette, IN.*

Crossbred pigs (N=150; initial BW = 28.2 kg) were assigned to one of 6 dietary treatments to assess the impact of increasing levels of glycerol in grow-finish pig diets on growth and carcass traits. The 6 dietary treatments were: 1) Control, 0% Glycerol (Gly); 2) 5% Gly; 3) 10% Gly; 4) 15% Gly; 5) 20% dried distillers grains w/ solubles (DDGS); and 6)

20% DDGS +10% Gly. Diets were formulated to be equal in ME and dig. Lys. Growth performance was evaluated on a four phase feeding program. Pigs were fed two grower diets (G1 d0-d28; G2 d28-d56) and two finisher diets (F1 d56-d84; F2 d84-d105). A crude glycerol (84% Gly, <100 ppm methanol) was fed for Phases G1-F1 and a food grade glycerol (99.7% Gly) was fed during F2. As glycerol increased in the diet from 0 to 15%, overall ADG (851, 876, 880, 851 g/d, respectively; $P < 0.05$) responded quadratically while linearly increasing ADFI (2.47, 2.54, 2.57, 2.67 kg/d, respectively; $P < .01$) and linearly decreasing G:F ($P < 0.001$). Adding DDGS (0 or 10% Gly) decreased ADG (836 and 831g/d, respectively; $P < 0.02$) and G:F ($P < 0.04$). Increasing Gly to 10% increased final BW 3.0 kg ($P < 0.07$) while DDGS decreased final BW 1.9 kg ($P < 0.03$). Increasing Gly linearly increased tenth rib backfat (21.9, 23.5, 26.8, 25.3 mm, respectively, $P < 0.02$) and linearly decreased percent fat free lean (FFL) (52.1, 51.8, 49.8, 50.4%, respectively, $P < 0.02$). Feeding 20% DDGS increased FFL (53.1%) while feeding DDGS+10% Gly decreased FFL (50.8%; $P < 0.05$). Adding Gly to diets tended to linearly increase liver weights ($P < 0.06$). Adding DDGS tended to increase kidney weights ($P < 0.10$). Visual loin marbling decreased linearly with increasing Gly ($P < 0.01$). Loin Minolta color L* linearly increased with increasing Gly ($P < 0.09$). Feeding Gly up to 10% of grow finish diets can improve ADG and ADFI; however, carcass quality may be impacted by increasing backfat and reducing percent FFL and loin quality characteristics.

Key Words: Swine, Glycerol, Pork Quality

786 Effects of increasing dietary glycerol and dried distillers grains with solubles on growth performance of finishing pigs. A. W. Duttlinger^{*1}, M. D. Tokach¹, S. S. Dritz¹, J. M. DeRouchey¹, J. L. Nelssen¹, R. D. Goodband¹, and K. J. Prusa², ¹Kansas State University, Manhattan, ²Iowa State University, Ames.

A study was conducted to determine the effects of dietary glycerol and dried distillers grains with solubles (DDGS) on grow-finish pig performance and carcass characteristics. The experiment was conducted at a commercial swine research facility in southwest Minnesota. A total of 1,160 barrows (initially 31.0 kg, PIC) were used in a 97-d study. Pigs were blocked by initial weight and randomly allotted to one of six dietary treatments with seven replications per treatment. Pigs were fed corn-soybean meal-based diets with 3% added fat arranged in a 2 × 3 factorial with main effects of glycerol (0, 2.5, or 5%) and DDGS (0 or 20%). There were no glycerol × DDGS interactions ($P > 0.13$). Increasing glycerol did not affect ($P > 0.33$) ADG or G:F. Adding 20% DDGS to the diet did not affect ADG. Pigs fed diets with added DDGS had greater ($P < 0.02$) ADFI than pigs fed diets with no DDGS (2.47 vs. 2.41 kg/d) resulting in decreased ($P < 0.01$) G:F (0.40 vs. 0.39) for pigs fed DDGS. Increasing glycerol tended to increase (linear, $P < 0.11$) yield (74.8, 75.7, and 75.7%). In conclusion, adding up to 5% glycerol to finishing diets did not affect growth performance, but tended to improve carcass yield. Adding 20% DDGS decreased G:F, but did not influence growth rate. Funded by National Pork Board in cooperation with the Minnesota Pork Board.

787 Effect of feeding an alternative carbohydrate source on nursery pig growth performance. B. E. Bass^{*}, C. L. Bradley, C. V. Maxwell, Z. B. Johnson, and J. W. Frank, *University of Arkansas, Fayetteville.*

Lactose is a key ingredient in nursery pig diets due to its digestibility and improvement on performance. The purpose of this study was to examine the impact of replacing whey permeate (WP; 80% lactose) with a carbohydrate blend (CB; 40% lactose, 30% sucrose, 10% dextrose) on growth performance of nursery pigs. In the study, 240 pigs were weaned at 21.1±0.1 d of age (BW = 7.36±0.1 kg) and penned in groups of 6-7 pigs/pen in an offsite nursery facility. Pigs were randomly assigned to one of five experimental diets during phase 1 (10 d) and phase 2 (10 d). The phase 1 and 2 diets were corn-soy based and contained spray-dried plasma, fish meal, and soy protein concentrate. Phase 1 and 2 treatments were: control (CON, 0 and 0%), Low WP (7.5 and 5% WP), High WP (15 and 10% WP), Low CB (7.5 and 5% CB), and High CB (15 and 10% CB), respectively. All pigs were fed a common corn-soy phase 3 (14 d) diet. During phase 1, ADG (110^b, 133^{ab}, 178^a, 153^{ab}, 178^a g/d; $P = 0.06$) and ADFI (232^b, 238^b, 318^a, 254^b, 303^a g/d; $P < 0.01$) were different in CON, Low WP, High WP, Low CB, and High CB fed pigs, respectively. Phase 2 G/F for CON, Low WP, High WP, Low CB, and High CB were different (0.770^{ab}, 0.802^a, 0.797^a, 0.819^a, 0.717^b, respectively; $P < 0.01$). For phase 1 and 2 combined, ADG (323, 347, 385, 378, 355 g/d; $P = 0.12$) and ADFI (466, 470, 531, 495, 526 g/d; $P = 0.07$) were not different for CON, Low WP, High WP, Low CB, and High CP, respectively. Overall (phase 1 through 3), there was no effect of dietary treatment on growth performance. Final BW for CON, Low WP, High WP, Low CB, and High CB (23.90, 23.67, 24.87, 24.28, and 24.66 kg, respectively) were not different ($P = 0.48$). This experiment demonstrates that incorporating lactose into nursery diets improves growth performance. In addition, lactose can be at least partially replaced with simple sugars such as sucrose and dextrose without reducing growth performance.

Key Words: Pigs, Lactose, Sucrose

Ruminant Nutrition: Acidosis, DCAD and Acid-Base Metabolism

788 The relationship between the severity of ruminal acidosis and the expression of genes associated with the absorption and metabolism of volatile fatty acids and glucose in ruminal tissue. G. B. Penner^{*1}, M. Taniguchi¹, L. L. Guan¹, K. A. Beauchemin², and M. Oba¹, ¹University of Alberta, Edmonton, AB, Canada, ²Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.

The objective of this study was to determine the relationship between the severity of ruminal acidosis and the expression of genes related to the absorption and metabolism of volatile fatty acids (VFA) and glucose in ruminal tissue. We hypothesized that cows with lower expression for genes related to the absorption and metabolism of VFA and glucose in ruminal tissue would have more severe ruminal acidosis. Six ruminally cannulated dry Holstein cull cows were fed a diet containing 60.9% barley grain, 30.2% barley silage, 5.7% grass/alfalfa hay, 1.8% mineral, 1.4% canola meal, and 0.1% canola oil (DM basis) to predispose them to ruminal acidosis. After a 28-d diet adaptation period, ruminal pH (4320 data points/72 h/cow), ruminal VFA concentrations, ruminal content volume, and in vivo VFA clearance rates were measured. An acidosis index was calculated by dividing the area below pH 5.8 by dry matter intake (pH × min/kg) in order to describe the severity of ruminal acidosis for each cow. Cows were euthanized and ruminal tissue was harvested (ventral sac) for gene expression analysis using quantitative real-time PCR. The fold change (FC) in gene expression relative to the cow with the lowest acidosis score was determined for each gene. Mean ruminal pH, the area below pH 5.8, and the acidosis index varied from 5.88 to 6.19, 895 to 9250 pH × sec/d, and 84.7 to 459.0, respectively. The acidosis index was not correlated to the fractional rate of VFA absorption or clearance, but was negatively correlated to the FC for butyryl CoA synthetase ($r = -0.919$; $P < 0.001$) and pyruvate carboxylase ($r = -0.884$; $P = 0.02$). Further, the acidosis index tended to be negatively related to the FC for β -hydroxybutyrate dehydrogenase ($r = -0.753$; $P = 0.08$). These data indicate that cows with higher gene expression levels for enzymes involved in butyrate or glucose metabolism in rumen tissue might be more tolerant to ruminal acidosis.

Key Words: Ruminal Acidosis, Gene Expression, VFA Metabolism

789 Effects of bulk density of steam-flaked corn and dietary roughage concentration on performance, rate of intake, and acid-base balance of Holstein steers. K. E. Hales^{*}, K. R. Wilson, J. T. Vasconcelos, J. C. Declerck, M. L. May, M. J. Quinn, and M. L. Galyean, Texas Tech University, Lubbock.

Effects of bulk density of steam-flaked corn and roughage concentration on performance, rate of intake, and acid-base balance were evaluated in 24 Holstein steers (initial BW = 507 kg) in a completely random design. Each steer was housed in a partially slotted-floor pen (12 steers/treatment). The 2 treatments consisted of either: (1) 334.7 g/L steam-flaked corn with 6% (DM basis) coarsely ground alfalfa hay (**LOWBD**); or (2) 387.0 g/L steam-flaked corn with 10% (DM basis) alfalfa (**HIGHBD**). Cattle were fed an 85% concentrate diet, and baseline measurements were collected before they were switched to treatment diets for an experimental period of 29 d. Feed intake was measured at 0.5, 1.0, 1.5, 2.0, 3.0, 4.0, 6.0, and 8.0 h after feeding on d 7, 14, 21, and 28. On d 8, 15, 22, and 29, urine pH was measured, and arterial blood samples were taken for measurement of pH, partial pressures of CO₂ and O₂, hematocrit,

and concentrations of Na⁺, K⁺, and ionized Ca⁺. No differences ($P > 0.10$) between treatments were noted for blood gases and electrolytes or urine pH; however, day effects ($P < 0.02$) were detected for blood pH, partial pressure of CO₂, Na⁺, K⁺, ionized Ca⁺, and urine pH. Rate of intake data were fit to a quadratic model and solved for time required to consume 25, 50, 75, and 100% of the daily intake. A treatment × day interaction was detected ($P < 0.03$) for time to consume 25, 50, and 75% of the daily intake. No differences were noted on d 7, 21, and 28, but on d 14 steers fed the HIGHBD diet consumed 25, 50, and 75% ($P = 0.06$, 0.05, and 0.08, respectively) of their daily intake in less time than those fed the LOWBD diet, with no difference in time to consume 100% of daily intake. Results suggest that bulk density of steam-flaked corn and dietary roughage concentration within the ranges fed in this study have little effect on blood acid base balance; however, the combination of greater bulk density and greater roughage concentration increased rate of feed consumption on d 14 of the experimental period.

Key Words: Acid-Base Balance, Beef Cattle, Bulk Density

790 Effect of dietary cation-anion difference on feedlot performance, N mass balance, and manure pH in open feedlot pens. M. K. Luebbe^{*}, G. E. Erickson, T. J. Klopfenstein, and J. R. Benton, University of Nebraska, Lincoln.

A summer feedlot trial was conducted to evaluate the impact of dietary cation-anion difference on performance and N mass balance. Ninety-six steers (260±56 kg) were stratified by BW and assigned randomly to 12 pens (6 pens/treatment). Steers were fed for 145 d from June to October. Basal diets consisted of high-moisture and dry-rolled corn, fed at a constant 1:1 ratio (DM basis), 20% modified wet distillers grains, 7.5% alfalfa, and 5% supplement. Calcium chloride and sodium bicarbonate were used in the supplement to adjust dietary cation-anion difference (DCAD) to 20 mEq for the positive (POS) diet and -16 mEq for the negative (NEG) diet. Nitrogen excretion was determined by the difference between N intake and individual steer N retention. Total N lost was calculated by subtracting manure and runoff N from excreted N. Dry matter intake was not different ($P=0.17$) among treatments and was 11.1 and 11.4 kg for NEG and POS, respectively. Average daily gain was not different ($P=0.82$) among treatments and was 1.84 and 1.83 kg for NEG and POS, respectively. Gain efficiency was not different ($P=0.11$) among treatments and was 0.166 and 0.160 for NEG and POS, respectively. Carcass characteristics were not different ($P>0.20$) among treatments except for marbling score. Marbling score was greater ($P=0.04$) for POS than NEG (543 and 523, respectively). Intake, retention, and excretion of N were not different ($P>0.10$) among treatments. Manure N was not different ($P=0.67$) among treatments (11.1 and 11.7 kg for POS and NEG, respectively). Percent N lost was not different among treatments (64.6 and 61.3% for POS and NEG respectively). Manure pH was greater ($P<0.01$) for POS than NEG (8.12 and 7.70, respectively). Pen surface soil core pH was not different ($P=0.29$) among treatments (8.01 and 8.07 for POS and NEG, respectively). Amount of DM and OM removed from pens was similar ($P>0.50$) among treatments. Lowering DCAD in diets with wet distillers grains decreases manure pH but not soil core pH. The decrease in manure pH is likely not enough to decrease N losses in open feedlot pens.

791 Grain species and cultivars and ruminal acidosis. I. Determination of challenge level. I. J. Lean*¹, A. R. Rabiee¹, J. L. Black², and R. H. King³, ¹*Bovine Research Australasia, Camden, NSW, Australia*, ²*John L. Black Consulting, Warrimoo, NSW, Australia*, ³*RHK Consulting, Essendon, Victoria, Australia*.

Two grain challenge diets containing (Triticale cv Jackie; and a mix of 20 grains (Wheat (n = 6), Barley (n = 4), Triticale (n = 4), Sorghum (n = 3), Oats (n = 3)) were used to determine the amount required to produce a moderate acidotic change in rumen function following ingestion. Holstein-Friesian heifers, <18 months of age (n = 8), Holstein-Friesian dairy cows (n = 8) were stratified on parity and randomly allocated to the 2 challenge diets, fed at four different levels. There was a pre-adaptation period of 7 days - 1 kg of mixed grain and *ad libitum* grass silage, an adaptation period of 5 days- 1 kg of the test grains and *ad libitum* grass silage. In the challenge period; cattle were withheld from all feed for 14h and fed the challenge diets. The 4 different levels of intake were 0, 0.4, 0.8 and 1.2% of body weight (BW). The trial was a single treatment, repeated measures study conducted with four levels of intake. There was a significant reduction in rumen pH (P = 0.01) of cattle fed at 1.2% BW. Concentrations of VFAs were higher in cattle fed at 0.8% and 1.2% BW than the control (0.0%). Concentrations of valerate (P < 0.001) and ammonia (P = 0.04) were significantly greater in cattle fed 1.2% BW. Rumen concentrations of valerate were significantly (P = 0.05) higher in cattle fed with Triticale than mixed grain. Rumen pH, volatile fatty acids (VFA), lactate and ammonia data were used in a discriminant analysis algorithm derived from earlier field studies to provide an acidosis index. Cattle fed at 1.2% BW had a higher acidosis index compared with cattle fed grain at 0%, 0.4% and 0.8% BW. The acidosis index of Triticale Jackie grain was also greater than the mixed grain.

Key Words: Acidosis, Dairy Cows, Grain

792 Grain species and cultivars and ruminal acidosis. II. Comparisons and validation of a near infra-red reflectance assay. I. J. Lean*¹, A. R. Rabiee¹, J. L. Black², S. Nielsen³, and R. H. King⁴, ¹*Bovine Research Australasia, Camden, NSW, Australia*, ²*John L Black Consulting, Warimoo, NSW, Australia*, ³*NSW Department of Primary Industries, Orange, NSW, Australia*, ⁴*RHK Consulting, Essendon, Victoria, Australia*.

We compared effects of twenty different grains (Wheat (n=6), Barley (n=4), Triticale (n=4), Sorghum (n=3), Oats (n=3)) and a mixed grain control fed to cattle on ruminal pH and ruminal volatile fatty acids (VFAs), lactate (D-and L-) and ammonia. We determined correlations between near infra-red reflectance (NIR) derived *in vitro* estimates of acidotic risk of grains and *in vivo* effects of the same grains. The study comprised 40 rows (heifers) and column (run) with cattle in four groups of 10. Feeding was divided into a pre-trial (mixed silage and 1kg mixed grain), adaptation (1kg of test grain with mixed silage for four days), withholding period (feed withheld for 14 hours), and then were fed test grains at 1.2% body weight. Ruminal samples were collected by stomach tube immediately after the challenge over the next 5h. A 9-day wash out period was used between study phases. Rumen pH significantly changed throughout sampling (P<0.01). Rumen pH 4h after challenge was lower in cattle fed barley, triticale and wheat, than oats or sorghum. Rumen concentrations of propionate, butyrate, isobutyrate, valerate, isovalerate and D-Lactate changed significantly during sampling (P<0.05). Concentrations of propionate, isovalerate, valerate and ammonia were significantly different among grains (P<0.05). The acidosis index based

on discriminant analysis showed that triticale and wheats had the highest acidosis index. The *in vivo* discriminant scores were significantly correlated with rankings of rumen valerate concentrations derived from a mixed effect model (P<0.0001). The coefficients of discriminant scores (P=0.0003) or rumen valerate (P=0.017) were correlated with the NIR results derived from the tests ranking. Only the discriminant scores are related to biological measures of acidosis.

793 Influence of electrolyzed alkaline water on milk production in dairy cows. J. D. Ferguson*, D. Remsberg, and Z. Wu, *University of Pennsylvania, Kennett Square*.

Electrolyzed alkaline water (EAU Technologies) may have some anti-oxidation and rumen stabilization properties. This pilot study examined the influence of electrolyzed water (EAU) on milk production, water intake, and blood physiology over a 12 wk period in 62 lactating Holstein cows (81 ± 56 DIM). Cows were blocked on parity, milk production and DIM and randomly assigned to EAU water or untreated well water (CON) following a 2-wk covariate period. Overall covariate adjusted milk yield was not different between the groups, but a significant interaction between water source and initial DIM (P<0.03) was apparent. Cows <60 DIM consuming EAU produced 2.1 kg/d more milk over the course of the study than the CON cows. Cows >60 DIM at the beginning of the study consuming the EAU water produced less milk than cows consuming CON water (-0.8 kg/d). It appeared that cows required a 4-6 wk period to adapt to the alkaline water. Water coliform counts were consistently lower from EAU waterers. Consuming EAU water may enhance production in early lactation and increase milk fat content.

794 Timothy hays differing in dietary cation-anion difference affect the capability to maintain calcium homeostasis in dairy cows. V. S. Heron*¹, G. F. Tremblay², and M. Oba¹, ¹*University of Alberta, Edmonton, AB, Canada*, ²*Agriculture and Agri-Food Canada, Quebec, QC, Canada*.

The objective of this study was to evaluate the effectiveness of timothy hays differing in dietary cation-anion difference (DCAD) at maintaining calcium homeostasis. Six non-lactating, non-pregnant multiparous cows were fed diets containing timothy (*Phleum pratense L.*) hay with DCAD values of 4.1 ± 3.6 (LOW), 14.1 ± 3.0 (MED), or 25.1 ± 2.5 (HIGH) mEq/100 g DM in a duplicated 3×3 Latin square design with 14-d periods. The LOW and MED hays were produced by fertilizing established timothy fields at a rate of 224 kg CaCl₂/ha, and HIGH hay was obtained from the same field that LOW hay was produced, but from a section not fertilized with CaCl₂. Experimental diets, containing LOW, MED or HIGH timothy hay at 70% of dietary DM, had DCAD values of 0.72, 7.26, and 14.4 mEq/100 g DM, respectively. Animals were limit-fed at 108% of their energy requirement. For each period, after a 12-d diet adaptation, cows were subject to an EDTA challenge (3 cows each on d 13 and 14); infusion of EDTA solution into the jugular vein decreases the availability of blood ionized calcium. The EDTA challenge protocol determined the resistance time and recovery time: the

time required to reduce blood calcium concentration to 60%, and time required for recovery from 60 to 90% respective to the pre-challenge value, respectively. Urine pH was reduced for cows fed LOW compared to HIGH diet (6.88 vs. 7.83; $P = 0.04$), but both of them did not differ from that for cows fed MED diet (7.15). However, immediately prior to the EDTA challenge, blood pH were lower ($P = 0.01$) for cows fed LOW or MED compared to HIGH diet (7.44 and 7.44 vs. 7.47, respectively). Although the resistance time was not affected by treatment, averaging 155 min, the recovery time was shorter ($P = 0.01$) for cows fed LOW compared to MED or HIGH diet (185 vs. 248 and 263 min, respectively). Cows fed LOW or MED diet decreased the extent of metabolic alkalosis, but the capability to maintain calcium homeostasis was enhanced only for cows fed LOW diet, in which the DCAD value was lowered to below 1 mEq/100 g DM.

Ruminant Nutrition: Energy and Carbohydrate Byproducts - Beef

795 ASAS Centennial Presentation: Discovery and application of energetic principles to feeding systems for beef cattle. C. Ferrell*¹ and J. Oltjen², ¹USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, ²University of California, Davis.

Development of nutritional energetics can be traced to the eras of Leonardo da Vinci (1452-1519) and Lavoisier (1743-1794), who discovered the basic concepts. Lavoisier established relationships among O₂ use, CO₂ production and heat production (HP). The laws of thermodynamics were discovered in the 1840's. They state that 1) energy can be neither created nor destroyed, but can be transformed from one form to another, 2) all forms of energy can be quantitatively converted to heat, and 3) heat loss in a chemical reaction is independent of path. These laws enabled the fundamental entity ME = RE + HP to be established. Objectives became 1) establish relationships between gas exchange and HP, 2) devise basis for evaluation of foods that could be related to energy expenditures, and 3) establish causes of energy expenditures. The bomb calorimeter was invented, allowing determination of the energy contents of organic compounds. Concepts and equipment for animal calorimetry were developed. Early systems for evaluation of foods for their value in supplying animal energy needs were based in measurements of ME and HP determined from calorimetry. Work in these areas arguably culminated in 1965 with the Brouwer equation for calculation of HP from O₂ use and CO₂, CH₄, and N excretion. For many years, primary efforts were devoted to measurement of ME and HP, with RE a secondary consideration. The California Net Energy System, developed for finishing beef cattle, was the first net energy system based on RE as determined by comparative slaughter and was the first to use two net energy values (NE_m and NE_g) to describe feed and animal requirements. This system has been broadened conceptually to encompass energy requirements during the life cycle of beef cattle. This system remains useful, but has limited capacity, due to its empirical and static nature, to capture the dynamics of energy utilization by diverse animals as they respond to changing environmental conditions.

Key Words: Calorimetry, Comparative Slaughter, Net Energy

796 ASAS Centennial Presentation: Discovery and application of energetic principles to feeding systems for beef cattle: Use of dynamic models. J. W. Oltjen*¹ and C. L. Ferrell², ¹University of California, Davis, ²USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.

Static feeding systems are being replaced by dynamic simulation models that attempt to capture the underlying biology which is sensitive to a wide range of genetic and environmental conditions. In 1986, the Davis Growth Model used cell number and size mechanisms of growth to predict growth and body composition as affected by frame size, implant status, and energy intake. Fat gain was underpredicted for high energy diets, because fat gain was computed after subtracting energy for maintenance and protein gain. France proposed an integrated model of growth, carbon and nitrogen metabolism. Synthesis and degradation were represented for each body pool based on animal factors and absorbed nutrient levels. Di Marco extended the Davis Growth Model to two pools of protein and included a digestion and metabolism element. Separation of the protein pools accounted for variable maintenance wherein a relatively smaller viscera was associated with

decreased fasting heat production. The metabolism submodel corrected errors in prediction of fat gain since efficiency of each nutrient's use was explicitly represented. Input complexity precludes general use of these larger models. A dynamic sheep model of the visceral and muscle protein and fat pools was developed, with an upper bound for muscle and viscera. Heat production for maintenance depends on viscera size, hence nutritional history. New additions refine predictions at levels of energy intake at, or below maintenance. The model provides the structure for predicting composition of growing cattle, but has yet to be completely parameterized and tested. Generally, with each new system, advances in prediction accuracy came about by adding new terms to conceptually validated models.

Key Words: Modeling, Body Composition, Growth

797 ASAS Early Career Achievement Award Presentation: Advances in modeling ruminant nutrient utilization. E. Kebreab*¹, J. Dijkstra², A. Bannink³, and J. France⁴, ¹University of Manitoba, Winnipeg, MB, Canada, ²Wageningen University, Wageningen, the Netherlands, ³Wageningen University and Research Centre, Wageningen, the Netherlands, ⁴University of Guelph, Guelph, ON, Canada.

Nutrition modeling has been applied to study various aspects of the ruminant such as rumen function, post-absorptive metabolism and product composition. However, the objective of this study will be limited to advances in modeling rumen function with respect to environmental issues and animal health, particularly, rumen disorders. Interest in environmental issues comes from the potential to manipulate rumen functions to reduce energy losses as methane and utilization of nitrogen (N) by rumen microorganisms. Enteric methane production arises principally from microbial fermentation of hydrolysed dietary carbohydrates. A widely used empirical model estimates that 5.5% to 7.5% of gross energy (GE) intake is lost as methane. However, mechanistic models of rumen function are based on the laws of mass and energy conservation and take into account the rumen economy of primary substrates for ruminal methanogenesis (hydrogen and carbon dioxide). Mechanistic models have suggested that 3.8 to 7.4% of GE is lost as methane depending on the diet. They help understand the system under study and therefore provide more insight on how dietary manipulation reduces methane loss than empirical models. One such mitigating option is the use of starch, which, if used excessively, can lead to health problems such as sub-acute rumen acidosis (SARA) due to rumen pH depression. Mathematical models have been developed to describe changes in rumen pH and rumen fermentation. The models were used to determine the maximum amount of nonfiber carbohydrate to be included in the diet above which SARA would likely occur. Models that relate rumen temperature to rumen pH have also been developed and have the potential to aid in the diagnosis of SARA. Several empirical and mechanistic models have been constructed to predict N utilization in the rumen and the form in which N is excreted from the animal. These models show that the magnitude of feces to urine N ratio has implications on ammonia volatilization, nitrate leaching and contribution to greenhouse gas emission as nitrous oxide. A rumen model that integrates nutrient utilization and health has great potential benefit for ruminant nutrition research.

798 Effects of feeding high levels of byproducts in different combinations to finishing cattle. M. F. Wilken*, M. K. Luebke, J. R. Benton, G. E. Erickson, and T. J. Klopfenstein, *University of Nebraska, Lincoln*.

Crossbred steers (n=288; BW=373 kg) were used to evaluate feedlot performance from feeding diets with no grain and different inclusions of wet distillers grains plus solubles (WDGS) and wet corn gluten feed (WCGF). A RCBD was utilized with steers being assigned randomly to 36 pens with 8 steers/pen and 3 weight blocks. Six treatments were tested (6 pens/treatment): 1) control (CON) of 82.5% dry rolled corn (DRC) and 5.0% molasses, 2) 43.8% WDGS and 43.8% DRC (WDGS), 3) low blend (CORN) with 32.8% WDGS, 32.8% WCGF, and 21.9% DRC, 4) soyhulls blend (HULLS) with 32.8% WDGS, 32.8% WCGF, and 21.9% soyhulls, 5) high blend (BYPROD) with 43.8% WDGS and 43.8% WCGF, and 6) WDGS and grass hay (HAY) with 65.6% WDGS and 21.9% grass hay (DM basis). All diets contained 5.0% supplement and 7.5% alfalfa hay. Data were analyzed using mixed procedures of SAS, with weight block fixed, and using a protected F-test. Steers fed HAY had greater DMI ($P < 0.05$) than those fed WDGS and BYPROD. Intake for BYPROD was lowest ($P < 0.05$). Comparing all diets, ADG was greatest for WDGS ($P < 0.05$) and least for HULLS ($P < 0.05$). Steers fed WDGS had greater G:F ($P < 0.05$) compared to all other diets. Steers fed HULLS had numerically lower G:F ($P = 0.06$) compared to HAY and was lowest in relationship to all diets. Interestingly, steers fed HAY and BYPROD were similar ($P > 0.05$) to CON when comparing ADG and G:F, allowing us to conclude it is possible to feed byproduct diets with no corn and not sacrifice feedlot performance.

799 Nutrient digestibility and utilization by cattle consuming cotton gin mote as a replacement for forage. C. M. Welch* and B. J. Rude, *Mississippi State University, Mississippi State*.

Cotton production provides a variety of by-products that can be utilized by beef cattle as an alternative roughage source which can reduce cost of production. The objectives of this study were to evaluate cotton gin mote as a forage replacement when fed to cattle by determining nutrient digestibility and nitrogen and energy retention. A seven day metabolism trial was conducted using twelve steers (249 ± 18.0 kg BW) allotted to one of three treatments: 0% mote (100% hay); 50% mote + 50% hay; and 100% mote. Steers consuming 0% mote consumed less ($P = 0.0029$) DM (1.45% BW/d) compared to those consuming 50% and 100% mote (1.93 and 2.29% BW/d, respectively). Digestibility of DM, OM, CP, and energy was least ($P < 0.0005$) by steers consuming 50% mote (56.3, 58.0, 35.9, 55.8%, respectively) with steers consuming

100% mote digesting more (59.4, 60.5, 42.1, 58.1%, respectively) and steers consuming 0% mote digesting the most (61.5, 63.8, 53.3, 62.4%, respectively). Digestibility of NDF and ADF was greater ($P = 0.0032$) for steers consuming 0% mote (62.1 and 61.3%, respectively) compared to steers consuming 50% mote (58.3 and 57.1%, respectively) and 100% mote (57.2 and 54.8%, respectively). Hemicellulose digestibility was greatest ($P = 0.001$) for steers consuming 100% mote (64.8%) and least for steers consuming 50% mote (60.9%) with 0% mote (63.2%) being in between. Fat digestibility tended to be greatest ($P = 0.0699$) by steers consuming 0% mote (79.7%) and least by steers consuming 100% mote (74.3%) with 50% being intermediate (55.8%). Steers consuming 0 and 50% mote retained less ($P = 0.0065$) protein (17.8 and 13.4 g/d, respectively) than those consuming 100% mote (24.5 g/d). Likewise, steers consuming 0 and 50% mote retained less ($P = 0.0100$) energy (100.1 and 115.3 kcal/d, respectively; no gaseous losses accounted for) than those consuming 100% mote (145.0 kcal/d). It appears that cotton gin mote can be used to replace up to 100% hay. However, additional protein and energy may need to be supplemented as their digestibility may be decreased by animals consuming cotton gin mote.

Key Words: Cotton Mote, Roughage, Digestibility

800 Beef steer intake and performance when fed whole cottonseed free-choice with hay. G. M. Hill*¹, M. H. Poore², D. J. Renney¹, and A. J. Nichols¹, ¹University of Georgia, Tifton, ²North Carolina State University, Raleigh.

Steers were fed whole cottonseed (WCS) free-choice (FC) with hay. Supplement treatments (TRT) were fed for 42 d in a feedlot (Phase 1) to allow adjustment to high WCS intake on the FC diet, and then individually-fed the diets for 17-d (Phase 2). In Phase 1, steers (n=32; 452.9 ± 55.2 kg initial BW; Brahman derivative breeding) were ranked by BW, randomly assigned to four TRT (4 steers/pen; 2 pens/TRT). Steers were fed round bale bermudagrass hay (93.0% DM, 13.4% CP, 78.8% NDF, 52% TDN) FC using hay rings in a feedlot with FC minerals. Supplement TRT included hay without WCS (H); or with WCS (DM basis: 25.4% CP, 45.6% ADF, 59.0% NDF, 15.6% crude fat) fed at three levels (LCS = WCS at 0.25% initial BW; MCS = WCS at 0.5% initial BW; and FCS = WCS fed FC). During Phase 1, DMI and ADG (kg) least squares means with initial BW as a covariable, for H, LCS, MCS, and FCS with SE, were: Hay DMI, 11.13, 8.51, 5.83, 5.21, 1.23, ($P < 0.12$); WCS DMI, 0.0, 1.06, 1.84, 2.99, 0.17, ($P < 0.01$); Total DMI, 10.93, 9.53, 7.70, 8.24, 1.25, ($P < 0.44$); ADG, 0.54, 0.46, 0.85, 0.88, 0.11, ($P < 0.02$). In Phase 2, steers (n=28; 494.2 ± 51.3 kg initial BW) were individually-fed the four TRT for 17 d. Hay (Tifton 85; 92.6% DM, 16.8% CP, 38.9% ADF, 75.2% NDF, 53% TDN) was coarsely ground (5 to 7 cm, length of cut), and WCS (DM basis: 25.5% CP, 45.6% ADF, 61.7% NDF, 15.3% crude fat) was fed as in Phase 1. The DMI (kg) least squares means with initial BW as a covariable, for H, LCS, MCS, and FCS with SE, respectively, were: Hay DMI, 7.43a, 6.75ab, 6.33b, 5.65c, 0.24; WCS DMI, 0.0d, 1.04c, 2.18 b, 3.55a, 0.03, and Total DMI, 7.56a, 7.93ab, 8.64b, 9.34c, 0.24; means followed by uncommon letters differ ($P < 0.01$). Dietary digestibility and blood components are being analyzed. In Phase 1 and Phase 2, steers fed FCS had reduced hay DMI, but higher Total DMI. Feeding FCS increased DMI of WCS above recommendations, which was not cost effective, it increased gossypol toxicity risk, and it has reduced dietary fiber digestibility.

Key Words: Cottonseed, Steer, Hay

802 Influence of roughage source and level in feedlot diets containing wet distillers grains on ruminal metabolism and nutrient digestibility in steers. J. R. Benton*, G. E. Erickson, T. J. Klopfenstein, N. F. Meyer, and C. D. Buckner, *University of Nebraska, Lincoln*.

Six ruminally fistulated steers (347 ± 25 kg) were used in a 6x6 Latin square to determine effects of roughage source and level in feedlot diets containing wet distillers grains plus solubles (WDGS) on ruminal metabolism and nutrient digestibility. Treatments were arranged as a 2x3 factorial with alfalfa hay or corn stalks included at a normal, low, or zero roughage (zero) level consisting of: 1) 8% alfalfa (8ALF); 2) 4% alfalfa (4ALF); 3) 0% alfalfa (0ALF); 4) 6% corn stalks (6STK); 5) 3% corn stalks (3STK); 6) 0% corn stalks (0STK). Diets were balanced to provide equal percentages of NDF from roughage at each level and contained 30% WDGS (DM basis). Periods included a 9-d adaptation and 5-d collection. Steers were fed once daily at 0730 h, and ruminal pH and DMI were continuously monitored during collection. There was not a source x level interaction for digestibility or rumen pH. There were no differences ($P > 0.05$) in DMI (9.4 kg/d) or CP digestibility (77.6%) across diets. No differences ($P > 0.16$) in DM and OM digestibility (DMD, OMD) were observed between cattle fed alfalfa or corn stalks. A linear increase ($P < 0.01$) was observed in DMD and OMD as roughage decreased with 81.7, 82.5, and 86.4% DMD for normal, low, or zero roughage levels, respectively. Cattle fed alfalfa had greater ($P < 0.05$) NDF digestibility (NDFd) compared to corn stalks (75.8 and 72.2%, respectively). A linear increase ($P = 0.02$) in NDFd was observed as roughage level decreased with 72.1, 72.9, and 76.9% NDFd for normal, low, or zero roughage levels, respectively. Average daily ruminal pH decreased linearly ($P < 0.05$) as roughage decreased and measured 5.70, 5.49, and 5.31 for normal, low, or zero roughage levels, respectively. Roughage source did not affect ($P > 0.50$) ruminal pH. Acetate:propionate ratio was lowest for cattle fed 6STK and highest for cattle fed 0ALF, 0STK, and 3STK (source x level interaction; $P < 0.01$). In summary, these data indicate roughages can be exchanged on an equal NDF basis and that roughage levels can be decreased but not removed in feedlot diets containing 30% WDGS.

Key Words: Cattle, Distillers Grains, Roughage

803 Feedlot performance of Holstein steers fed treated-wheat straw-distillers grains diets as a corn replacement pellet. J. R. Sewell¹, L. L. Berger*¹, M. J. Cecava², N. A. Pyatt², and P. H. Doane², ¹*University of Illinois, Urbana*, ²*ADM Animal Nutrition Research, Decatur, IN*.

Thirty-two Holstein steers (BW 185.2 ± 0.9 kg) were utilized in a 120-d study to evaluate growth performance when fed wheat straw (WS) or a corn fiber-wheat chaff (CFWC) corn replacement pellet (CRP) compared with a corn-based diet or native (NAT) WS. Crop residues were processed with 5% calcium oxide (DM basis) and 35% water in a double-shaft enclosed mixer (Readco Kurimoto Continuous Processor) and subsequently pelleted with distillers grain plus solubles (DDGS) to form a CRP. Individual feed intakes were monitored using the GrowSafe® feeding system (GrowSafe Systems, Ltd, Airdrie, AB). Steers were fed a common diet for 14 d prior to allotment and for 7 days before termination of trial. Upon initiation and termination of the trial, the average of two consecutive-day weights served as starting and J. Anim. Sci. Vol. 86, E-Suppl. 2/J. Dairy Sci. Vol. 91, E-Suppl. 1

final weights. All dietary treatments contained 25% DDGS, 15% corn silage, and 10% supplement. The remaining portion of the four dietary treatments were: 1) 50% cracked corn, 2) 50% CFWC CRP (containing 56.25% CF, 18.75% WC and 25% DDGS), 3) 50% WS CRP (containing 75% WS and 25% DDGS), and 4) 50% NAT wheat straw. Digestibilities were estimated using acid insoluble ash by collecting fecal grab samples from individual animals at 7 d after initiation, midterm, and prior to the end of the trial.

Table 1. Performance and DM digestibility of Holstein steers fed corn replacement pellets

Item	Control	Treatment			SEM
		CFWC CRP	WS CRP	Nat WS

804 Characterizing quality and composition of beef from cattle fed combinations of steam-flaked corn, dry-rolled corn, and dried corn distiller's grains with solubles. P. L. Black*¹, G. L. Parsons¹, M. K. Shelor¹, M. E. Dikeman¹, K. K. Karges², M. L. Gibson², and J. S. Drouillard¹, ¹*Kansas State University, Manhattan*, ²*Dakota Gold Research Association, Sioux Falls, SD*.

Color shelf life, lipid oxidation, and sensory attributes were evaluated for longissimus steaks from crossbred heifers ($n=689$, 302 ± 65 kg initial BW) fed finishing diets consisting of combinations of steam-flaked corn (SFC), dry-rolled corn (DRC), and dried corn distiller's grains with solubles (DDG). The study was a randomized complete block design with a 2×2 factorial arrangement of treatments. All diets contained SFC, and factors consisted of levels of DDG (0 or 25%) and DRC (0 or 25%). Heifers were individually weighed and blocked into heavy and light groups. Within block, heifers were assigned randomly to pens containing 25 animals each, with 6 pens per treatment. Heifers were fed once daily *ad libitum*, and the heavy and light weight blocks were harvested after 137 and 157 d, respectively. Four heifers were randomly selected from each of 24 pens (3 pens per treatment at each harvest point), and the wholesale rib sections were removed from one side of each carcass following a 24-h chill. Steaks (2.54-cm thick) were evaluated for color shelf life during a 7-day retail display period, as well as for purge loss during a 21-day aging period, weight loss during cooking, and lipid oxidation (TBARS). Sensory traits of initial tenderness, juiciness, chewiness, beef flavor, residual connective tissue, mealy texture, fiber awareness, bloody/serummy flavors, metallic flavors, and rancidity were evaluated by a 5-member professional profile panel using a 12-point scale. Steaks from cattle fed the different diets did not differ in color display attributes or TBARS values ($P > 0.20$). Weight loss during cooking was greater for steaks from heifers fed DRC diets compared with counterparts without DRC ($P < 0.05$). Replacing portions of SFC with DRC or DDG had no effect ($P > 0.10$) on sensory traits, lipid oxidation, or retail color display attributes.

805 Immune components of colostrum and milk. K. Stelwagen*, T. T. Wheeler, and E. A. Carpenter, *AgResearch, Ruakura Research Centre, Hamilton, New Zealand.*

Colostrum and milk provide for a complete diet for the neonate. In ruminants it is also the sole source of initial immunity for the offspring. However, milk also plays an important role in host defence. The level of immunoglobulins is particularly high in colostrum, with IgG being the predominant immunoglobulin class in ruminant milk, compared to IgA in human milk. Immunoglobulin transport into milk is only partially understood. In addition to immunoglobulins, both colostrum and milk contain viable cells, including neutrophils and macrophages, which secrete a range of immune-related molecules into milk. These include cytokines and some antimicrobial proteins and peptides such as lactoferrin, defensins and cathelicidins. Mammary epithelial cells themselves also contribute to host defence through secretion of a range of innate immune effector molecules, such as lactoferrin, RNAses, lysozyme, cathelicidins and defensins. A detailed understanding of these proteins and peptides offers great potential to 'add value' to milk. This is demonstrated by the wide ranging commercial applications of milk-derived lactoferrin (e.g. as an ingredient in food, toothpaste, cosmetics and fish food). Knowledge of the immune function of milk, in particular how the gland responds to pathogens, can also be used to boost the levels of immune factors in milk through farm management practices and vaccination protocols. The latter approach is currently being used to maximise yields of bovine milk-derived IgA directed at specific antigens for therapeutic and prophylactic use. Increasingly sophisticated proteomics technologies are being applied to identify and characterise the function of the minor components of milk. An overview of immune factors in colostrum and milk as well as the results of research aimed at realising this untapped value in milk will be presented.

Key Words: Milk, Innate Immunity, Mammary Gland

806 Mammary immunology and protection of the neonate. H. Salmon*, *IASP, Lymphocyte et Immunité des Muqueuses, Nouzilly, France.*

Colostrum and milk, secretions of mammary gland (MG) are the two components of the post-natal delivery of maternal immunity to the neonate. In monogastrics, sIgA is the predominant colostrum or milk Ig depending upon to the degree of prenatal Ig transfer, whereas in ruminants IgG1 predominate. In ungulate such as swine and ruminant absence of prenatal Ig transfer is compensated for by IgG enriched colostrum. These immunoglobulins enter neonate circulation and provide the newborn with the maternal serum antibodies that arose from antigenic stimulation of the mother's systemic immune system and sustain the systemic protection of the neonate against invasive pathogens. In contrast, the passive mucosal protection of neonatal mammals is dependent on the continuous supply until weaning of maternally dimeric IgA (Monogastric) and IgG1 (Ruminants), the so-called lactogenic immunity. Based on multistep model of lymphocyte migration between compartments we analyzed the spatio-temporal relationships between adhesion

molecules and chemokines in the gut and/or nasal mucosa and MG. In sows and mice, localization of $\alpha 4\beta 7$ T-cells follows MadCAM-1 development on capillaries. In contrast, $\beta 7/c$ -IgA B plasmablasts increased in mid- and late lactation when MadCAM-1 density declined; this result implicates additional factors; one of these has been identified as chemokine CCL28 (MEC) interacting with CCR10 receptor onto sIgA B cells. As the same pattern of adhesion molecules and chemokines was observed in small gut and nasal mucosa, that indicates the existence of a cellular link between the upper respiratory tract and MG in addition to the entero-mammary link. By comparison, absence of MadCAM-1 in ruminant MG is in agreement with the absence of a link with the intestinal immune system and explains the low levels of IgA in bovine mammary secretions. Further, in ruminants and in mice VCAM-1 is not present on capillaries in lactation but only on larger blood vessels. In conclusion, knowledge of these humoral and cellular factors of mucosa-mammary links may pave the way of optimal route of vaccination to protect the mammary gland itself and to protect the neonate via its secretion.

807 Characterisation of the bovine RNase gene family: Evidence for rapid evolution and acquisition of an innate immune function in the mammary gland. T. T. Wheeler*¹, N. Maqbool², A. Molenaar¹, P. Harris¹, and M. Callaghan¹, ¹*AgResearch, Hamilton, Waikato, New Zealand,* ²*AgResearch, Mosgiel, New Zealand.*

The mammalian RNase A family of genes comprises a cluster of 13 genes on human chromosome 14 that share significant similarity with RNase A (RNase1). Several members of the family are secreted from circulating immune cells and some mucosal epithelia. RNase5, which is secreted by intestinal cells, has been reported to have bactericidal activity. RNase5 is also secreted from mammary epithelial cells and is present in milk. The aim of this study was to address the hypothesis that members of the RNase family have undergone rapid evolution (typical for many innate immune effector proteins) and play a role in the host defence function of bovine milk.

Analysis of the assembled bovine genomic sequence revealed significant expansion of the RNase locus in cattle, with 22 orthologous or paralogous RNase genes being identified within the cluster. As with the human RNases, the protein coding regions of the bovine RNase genes were contained within a single exon. Orthologues for 12 of the 13 human RNase genes were found, the exception being RNase3. An additional 10 genes appeared to be found only in cattle. Two of these encode a significantly shortened protein, and thus appear to be pseudogenes. Phylogenetic and substitution analyses suggest that the bovine RNase locus is under evolutionary pressure, consistent with rapid evolution.

Northern, quantitative PCR, in-situ hybridisation and western analyses of RNase4 and RNase5 revealed these genes are expressed most abundantly in the mammary gland, liver and small intestine. RNase5 was purified from milk and tested for antimicrobial activity. Microbicidal activity was obtained against *Candida albicans*, with a 50% kill rate being obtained at a concentration of 31 μ g/ml. This level of activity was typical among four independent purifications). However, no growth

suppression activity was observed in RPMI medium. The results are consistent with the idea that some members of the RNase family have a role in host defence against pathogens in the mammary gland and/or digestive tract.

Key Words: Lactation, Mammary, RNase

808 Neonatal protection by an innate immune system of human milk consisting of oligosaccharides and glycans. D. S. Newburg*, *Massachusetts General Hospital and Harvard Medical School, Boston, MA.*

Infants not breastfed have a higher incidence of severe diarrhea and respiratory diseases than those breastfed. In the past, this had been attributed primarily to human milk secretory antibodies. However, the oligosaccharides are major components of human milk, and milk is also rich in other glycans, including glycoproteins, mucins, glycosaminoglycans and glycolipids. These milk glycans, especially the oligosaccharides, are comprised of thousands of components. The milk factor that promotes gut colonization by *Bifidobacterium bifidum* was found to be a glycan, and such prebiotic characteristics may contribute to protection against infectious agents. However, the ability of human milk glycans to protect the neonate seems primarily to be due to their inhibition of pathogen binding to their host cell target ligands. Many such examples include specific fucosylated oligosaccharides and glycans that inhibit specific pathogens. Most human milk oligosaccharides are fucosylated, and their production depends on fucosyltransferase enzymes; mutations in these fucosyltransferase genes are common, and underlie the various Lewis blood types in humans. Variable expression of specific fucosylated oligosaccharides in milk, also a function of these genes (and maternal Lewis blood type), is significantly associated with the risk of infectious disease in breastfed infants. Human milk also contains major quantities and large numbers of sialylated oligosaccharides, many of which are also present in bovine colostrum. These could similarly inhibit several common viral pathogens. Moreover, human milk oligosaccharides strongly attenuate inflammatory processes in the intestinal mucosa. These data support the hypothesis that oligosaccharides and other glycans are the major constituents of an innate immune system of human milk whereby the mother protects her infant from enteric and other pathogens through breastfeeding. These protective glycans may prove useful as a basis for the development of novel prophylactic and therapeutic agents that inhibit disease by mucosal pathogens in many species.

809 Immune signaling during mammary development and involution. C. J. Watson*, *University of Cambridge, Cambridge, UK.*

Dramatic changes in cell composition and function occur in the mammary gland during a pregnancy/ lactation/involution cycle. We have investigated the transcriptional changes associated with these biological events using microarray analysis and identified the critical genes involved using genetically modified mice. Two surprising findings arose from these studies. Firstly, our microarray data showed that post-lactational regression was associated with an acute phase/inflammatory response in addition to cell death. Conditional deletion of Stat3, or the NF- κ B regulatory kinase IKK β , resulted in a failure to induce cell

death indicating that these signaling pathways are essential mediators of the involution process. Both Stat3 and NF- κ B have been shown to regulate acute phase gene expression in addition to apoptosis regulators. Four distinct transcriptional profiles are present in the first 4 days of involution while there are three in lactation. At the peak of lactation (day 10 in mouse) over 400 genes reach their maximum expression level before declining dramatically in the first 12 hours of involution. A reciprocal pattern was observed for over 500 genes that were specifically upregulated within the first 12 hours of forced involution. We are now investigating the role of a subset of these genes in involution. We also uncovered a role for genes normally associated with immune cell signaling in differentiation of luminal mammary epithelial cells during pregnancy. Genetic deletion of the transcription factor Stat6 resulted in delayed development during pregnancy and this phenotype was recapitulated in mammary tissue from IL-4/IL-13 doubly deficient mice. Furthermore, we showed that mammary epithelial cells secrete T cell regulatory cytokines. T helper (T_H) type 1 cytokines such as IFN γ and IL12a are secreted by undifferentiated mammary epithelial cells while T_H type 2 cytokines including IL-4 and IL-13 are secreted by differentiated cells. This unexpected finding demonstrates a role for immune cell signaling in mammary epithelial cell fate and function. Support by BBSRC and AICR is acknowledged.

810 Effect of lipopolysaccharides on plasminogen activator activity and lactoferrin mRNA expression in a bovine mammary epithelial cell line. C. Pecorini, R. Rebutti, E. Fusi, F. Galante, L. Rossi, F. Cheli, and A. Baldi*, *University of Milan, Milan, Italy.*

The aim of this work was to examine the urokinase-plasminogen activator (uPA) activity and the mRNA expression of bovine lactoferrin (bLf) after LPS treatment using BME-UV1 (Bovine Mammary Epithelia – University of Vermont 1) cell line as an in vitro model of bovine mammary epithelium. In a preliminary experiment, the effect of LPS on cell growth was examined. Cells were incubated with medium containing 0, 1, 10 or 20 μ g/ml of LPS from *Escherichia coli* O111:B4 for 24 h. The effect of LPS on cell growth was evaluated by MTT test. In order to evaluate the effect of LPS exposure on uPA activity and mRNA bLf expression, cells were treated with 0, 1, 10 or 20 μ g/ml of LPS from *E. coli* O111:B4 for 3, 6, 12 or 24 h. Media were stored at -80°C for the determination of uPA activity using a colorimetric assay and for the quantification of bLf using an ELISA kit. Cells were recovered and total RNA was extracted. The bLf mRNA expression was evaluated by RT-PCR. The experimental design included at least three replicates per treatment and all treatments were repeated twice. Results were evaluated using the GLM procedure of SAS. MTT test provided evidence that LPS treatment did not have any effect on cellular proliferation of BME-UV1 cell line. uPA activity was not affected by LPS treatments at 3 and 6 h, whereas 1 and 10 μ g/ml of LPS significantly stimulated ($P < 0.05$) uPA activity at 12 and 24 h. After 24 h of LPS exposure (1 and 10 μ g/ml) bLf secretion was stimulated compared to the control ($P < 0.05$). RT-PCR analysis confirmed that bLf is constitutively expressed by BME-UV1 cells and LPS treatments slightly modified bLf mRNA expression depending on time and concentrations. Under our experimental conditions, BME-UV1 represented a useful in vitro model to study the inflammatory response in mammary epithelial cells.

Key Words: Lipopolysaccharides, uPA, Lactoferrin

811 Pathogen-dependent variations in the innate immune response to intramammary infection. D. D. Bannerman*, *USDA-ARS, Beltsville Agricultural Research Center, Beltsville, MD.*

Mastitis remains one of the most prevalent diseases among dairy cows and one of the most economically costly diseases to the dairy industry. The majority of cases of mastitis result from intramammary bacterial infection, and numerous genera of bacteria are capable of inducing mastitis. Following penetration of the physical barriers of the teat canal, the innate immune system encompasses the initial and primary mechanism by which the cow defends itself against invading bacterial pathogens. It has been well-described that some pathogens are readily eliminated from the mammary gland, and the accompanying mastitis quickly resolved.

In other cases, bacterial pathogens can persist in the gland resulting in chronic mastitis that may endure throughout the lifespan of the cow. During the past few years, there have been rapid gains in the knowledge surrounding the innate immune responses that are evoked in response to intramammary infection. A major finding from this area of research is that despite the highly conserved nature of the elements involved in host innate immunity, marked variation in innate immune responses to different bacterial pathogens can occur. This review summarizes evidence that the nature of the innate immune response, as well as the rapidity in which it is evoked, influences the outcome of intramammary infection. Furthermore, the utility that immune response modifiers may have in preventing and/or treating mastitis will be considered.

812 Meta analysis of responses of goats to chewing index. D. Sauvant*^{1,2} and S. Giger-Reverdin², ¹Agroparistech, Paris, France, ²INRA - UMR PNA, Paris, France.

The objective was to assess the interest of using a chewing index as predictor of dry matter intake (DMI), milk yield (RMY) and composition in dairy goats by using a meta-analysis. A data base was constructed from 13 (nexp) experiments including 49 (n) treatment groups. The experimental factors were concentrate level (%CO = 27.6 ± SE 30.6 % DM; n = 49), dietary NDF %DM (NDF = 56.3 ± 14.5; n = 41). The following parameters were collected: DM intake % of live weight (DMI = 3.10 ± 1.00 % LW; n = 49), time spent eating (ET = 4.90 ± 1.74 h/d; n = 27), ruminating (RT = 6.77 ± 1.68 h/d; n = 47) or chewing (CT = 11.51 ± 2.79 h/d, n = 29) and the chewing index (CI = 7.89 ± 7.72 hCT/kg DMI, n = 29). When simultaneously measured, CT and RT were closely related (CT = 2.12 + 1.47 RT; n = 27, nexp = 10, R₂ = 0.98, rmse = 0.55). Therefore, 20 values for CI were estimated from RT ones (CI = 11.29 ± 7.57 h/kg DMI, n = 47). The other items were RMY (2.72 ± 1.33 kg/d; n = 25), milk fat (MFC = 3.85 ± 1.07 %; n = 25) and milk protein contents (MPC = 3.20 ± 0.29 %; n = 25). The statistical methods used were either the global regression or the GLM procedure in order to check inter and intra experiment variations.

DMI was negatively correlated with CI, the global relationship being quadratic (DMI = 4.99 - 0.24 CI + 0.004 CI², n = 49, R₂ = 0.80, rmse = 0.30). Also, there was a global negative relationship between RMY and CI (RMY = 5.21 × 0.48 CI, n = 25, R₂ = 0.50, rmse = 0.96). For these two cases, CI estimations did not alter the regression. Due to variations across experiments, there was no global relationship between MFC and CI. In contrast, the within experiment relationship was significant and fairly accurate (MFC = 2.79 + 0.19 CI, n = 25, nexp = 10, R₂ = 0.98, rmse = 0.19). For MPC, there was no global or intra relationship with CI. MFC becomes lower than MPC when CI became lower than 1.8 h/kg DMI.

In conclusion, CI can be valuable to globally explain DMI (fill effect) and RMY variations in goats and to predict MFC in given conditions.

Key Words: Dairy Goat, Chewing Index, Milk Fat Content

813 Is chewing efficiency of dairy cows effected by physiological stage? I. Schadt*¹, J. D. Ferguson², G. Azzaro¹, R. Petriglieri¹, C. Guardiano¹, and G. Licitra^{1,3}, ¹CoRFiLaC Regione Siciliana, Ragusa, Italy, ²University of Pennsylvania, Kennett Square, ³D.A.C.P.A. Catania University, Catania, Italy.

Feed particle size and breakdown have been related to intake, milk production, passage and metabolic disorders. In the present study the particle distribution of swallowed boli during initial feed ingestion from forages fed at various lengths and TMR were measured in both dry and lactating cows. Six ruminally fistulated animals were examined. The study was conducted at two periods. In each period, two dry animals were compared to two animals at >200 DIM. Cows were held off feed for 12 hours, rumens evacuated, and offered 0.25 kg of forage or TMR. Rumen digesta and fecal samples were collected. Swallowed boli were manually retrieved from the reticulo-rumen at the esophageal orifice. Treatments in period 1 were ryegrass hay at various chop lengths: (1) long hay; (2) hay cut to 5 cm lengths; (3) chopped hay retained on a

1.91 cm screen; (4) chopped hay passing a 1.91 cm screen but retained on a 0.787 cm screen, and (5) chopped hay passing a 0.787 cm screen but retained on a 0.127 cm screen. In period 2, in addition to treatments 1-5, vetch hay (6), corn silage (7), grass silage (8) and TMR (9) were examined. Particles were analyzed by sieving with image analysis. Mean particle sizes (mm) for treatments were as follows (superscripts differ by p<.05): (1) long hay, not determined; (2) 43.4^a; (3) 41.4^a; (4) 24.9^b; (5) 5.2^c; (6) vetch hay, not determined; (7) 3.0^{cd}; (8) 4.6^{cd}; (9) 2.2^{cd}. Mean particle bolus sizes (mm) by treatments were as follows (superscripts differ by p<.05): (1) 3.5^{ab}; (2) 2.7^{bd}; (3) 3.5^{ab}; (4) 4.0^{ac}; (5) 2.3^{de}; (6) 3.6^{ad}; (7) 2.3^{de}; (8) 2.6^{de}; (9) 1.5^e. Feed and bolus mean particle size were not affected by stage of lactation. Mean rumen digesta particle size of dry cows (1.0 mm) was significantly shorter than in lactating cows (1.5 mm), p<.05. Mean fecal particle size (0.8mm) was not affected by stage of lactation.

814 Competition at the feeder alters feeding and social behavior of transition dairy cows. K. L. Proudfoot*¹, D. M. Veira², D. M. Weary¹, and M. A. G. von Keyserlingk¹, ¹University of British Columbia, Vancouver, BC, Canada, ²Pacific Agri-Food Research Centre, Agassiz, BC, Canada.

Transition cows require sufficient dry matter intake (DMI) to meet the increasing nutrient demands of lactation. Management strategies that reduce competition can increase feeding activity of mid-lactation cows, but it is unclear if this is true for the transition cow. Moreover, it is often recommended that primiparous cows (PP) be managed differently from multiparous cows (MP), yet little evidence supports this claim. The objectives of this study were to test the effect of an overstocked feeder on transition dairy cow feeding and social behavior, and to identify any differences in the behavior of MP and PP cows. DMI, feeding and social behavior were monitored from 2 wk before to 2 wk after calving for 110 Holstein dairy cows using an electronic feeding system. Cows were assigned to a competitive (C, 2:1 cows:bin) or non-competitive (N, 1:1 cow:bin) treatment. Cows diagnosed with clinical illness were removed from the dataset. Each cow on the N treatment was matched for parity and baseline feeding data with one cow from a pair in the C treatment, resulting in 20 matched pairs (PP=16 and MP=24). Differences in feeding behavior between treatment and parity groups were tested using a mixed model with day as a repeated measure, and a t-test was used to detect differences in social behavior. Although MPC cows visited the feeder more often (34 vs. 28 visits/d, P=0.03), they consumed less feed (14.3 vs. 15.3 kg/d, P=0.01) and ate at a faster rate (123 vs. 106 g/min, P<0.01) than MPN cows. Treatment had no effect on the DMI of PP cows, but PPC tended to eat fewer meals (9 vs. 10 meal/d, P=0.07) and these meals were longer in duration (30.8 vs. 25.4 min/meal, P<0.01) and larger in size (1.6 vs. 1.4 kg/meal, P=0.07) than PPN cows. Regardless of parity, cows on the C treatment encountered more aggressive interactions than cows on the N treatment (24 vs. 8/d, P<0.001). The results of this study indicate that limited access to feeder space can alter feeding behavior and increase aggression in both MP and PP transition cows.

Key Words: Transition, Competition, DMI

815 Animal feed assessment quality by SMartNose®. T. Rapisarda*¹, G. Belvedere¹, F. La Terra¹, A. Cannas², G. Licitra^{3,1}, and S. Carpino¹, ¹CoRFiLaC, Regione Siciliana, Ragusa, Italy, ²University of Sassari, Sassari, Italy, ³University of Catania, Catania, Italy.

Animal feed quality for livestock has an important role in good farm management. In order to have an efficient and effective diet, it is important to have feeds of uniform quality. The objective of this study was to compare animal feed samples, from Sicily and Sardinia, by their content of volatile compounds. Ten feeds from these different Italian regions were analyzed by MS-based Electronic Nose (SMartNose®): Brazilian soybean meal, dehydrated alfalfa, wheat bran, beet pulp, pea seed, tick bean, corn gluten meal, sunflower meal, wheat flour middlings and barley grain. The feeds (three replicates per feed) were analyzed by a MS-based electronic nose (SMartNose®) to detect their organic volatile components in the mass-to-charge (m/z) range of 10 to 160 amu. Results were subjected to a principal components (PCA) analysis. Feed samples showed the best separation with PC1 (50.65%) and PC2 (19.38%). The effect of different volatile compounds was discriminant for five feed samples: Brazilian soybean meal, dehydrated alfalfa, wheat bran, beet pulp, and wheat flour middlings. Electronic Nose technology is simple and fast to use, especially if there are a lot of samples to analyze, and represents a very useful tool for discrimination of different feed qualities. Further studies are needed to create a data base and to study different qualities in animal feeds.

Key Words: Feed, SMartNose®, Volatile Compounds

816 Prediction of in vivo diet digestibility in lactating dairy cows from data based on values obtained using sheep. P. Huhtanen*¹, M. Rinne², and J. Nousiainen³, ¹Cornell University, Ithaca, NY, ²MTT Agrifood Research, Jokioinen, Finland, ³Valio Ltd, Helsinki, Finland.

Traditionally the tabulated feed values are based on the digestibility coefficients measured with sheep fed at maintenance level, and the energy value of the diet is assumed to be the sum of individual components without associative effects between dietary ingredients. These coefficients are applied to cattle fed at higher intakes of diets consisting of several ingredients. The objectives of the present study were (1) to evaluate the combined effects of species (sheep vs. cattle) and feeding level on diet digestibility and (2) to develop equations predicting diet digestibility from sheep data. A meta-analysis of dairy cow data was conducted using 497 diets from 92 studies. Diet digestibility in cows was determined by total fecal collection (n=176) or using acid insoluble ash as an internal digestibility marker (n=321). Diet OM digestibility (OMD) at maintenance level of feeding (OMDm) was estimated using in vivo or in vitro digestibility for forages and tabulated values for concentrate ingredients. A mixed model regression analysis with random study effect was used to analyze the data.

Fecal output of metabolic matter (OM-NDF) averaged 96 (SE 0.7; n=388) g/kg DMI and was not influenced by diet composition or DMI

(P>0.2). Forage OMD was positively associated with OMD of the total diet in cows, but the level of concentrate feeding had no effect on OMD in the cows. Protein supplementation improved quadratically OMD. Increased total DMI (TDMI) depressed OMD by 0.0026 units per kg. The following equation was fitted to estimate OMD in cows: $OMD = 0.252 + 0.702 \times OMDm - 0.0026 \times TDMI + 0.0203 \times CCPI - 0.0144 \times CCPI^2$, where CCPI is concentrate CP intake (kg CP above 170 g/kg DM). Residual error of the model was small (0.0089) indicating that diet digestibility in dairy cows can be estimated accurately and precisely from digestibility coefficients estimated in sheep. The equation takes into account both feeding level effects and associative effects in digestion.

Key Words: Digestibility, Cow vs. Sheep, Feeding Level

817 Depression in nutrient digestibility by lactating dairy cows when dry matter intake is expressed as a multiple of maintenance. D. P. Casper*¹ and D. R. Mertens², ¹Agri-King, Inc., Fulton, IL, ²USDA-ARS Dairy Forage Research Center, Madison, WI.

The latest edition of the National Research Council's (NRC) Nutrient Requirements of Dairy Cattle, 7th Revised Edition in 2001, calculates a reduction in digestibility due to increasing dry matter intake expressed as a multiple of maintenance (MM). Data from nonlactating cows was used to determine the depression in digestibility with increasing MM. Our objective was to evaluate the reduction in nutrient digestibility per MM by lactating dairy cows. The Energy Metabolism Database includes data from all energy and N balance trials that were conducted at the Energy Metabolism Unit of the USDA-ARS (3,018 individual energy and N digestion trials). Only 1,351 of the individual metabolism trials used lactating dairy cows of different breeds and stages of lactation that were fed diets that varied in forage types, grain sources, protein sources, and fat supplements. All data were analyzed using linear regression procedures of SAS. Initial data analysis indicated that ruminal acidosis may have occurred in some balance trials, which could affect the nutrient digestibilities. Thus, metabolism trials of lactating dairy cows having inverted fat and protein ratios (acidosis criteria) were removed, which resulted in 495 observations for evaluating nutrient digestibility related to MM, which ranged from a minimum of 1.36 to a maximum of 4.98. Dry matter digestibility (DMD) was reduced as MM increased ($DMD, \% = 68.7 - 0.54 \times MM$; $R^2 = .012$, $P < .02$), but the relationship was not strong. However, N digestibility (ND) was not affected by MM ($NDP, \% = 63.4 + 0.45 \times MM$; $R^2 = .003$, $P < .18$). While NDF digestibility (NDFD) was increased with increased MM ($NDFD, \% = 37.4 + 2.47 \times MM$; $R^2 = .04$, $P < .01$), but the relationship was weak. It would appear that the reduction in nutrient digestibility per MM by lactating dairy cows across all diets is not as high as the value used by the NRC in calculating the energy values of feeds. Additional analysis is needed to confirm if significant depression in digestibility occurs within diets for MM typical of lactating dairy cows.

Key Words: Digestibility, Intake, Maintenance

Symposium: Triennial Lactation Symposium joint with Lactation Biology: 9th ASAS-EAAP International Workshop on the Biology of Lactation in Farm Animals

818 Nutritional, hormonal and environmental effects on colostrum in sows. C. Farmer*¹ and H. Quesnel², ¹*Agriculture and Agri-Food Canada, Dairy and Swine R & D Centre, Sherbrooke, QC, Canada*, ²*Institut National de la Recherche Agronomique, UMR SENAH, Saint Gilles, France*.

The essential role of colostrum for growth and survival of neonatal piglets is evident, yet very little is known about the factors that can affect its yield and/or composition. Concentrations of IgG in colostrum vary widely between sows and are influenced by parity, season and genotype. Standard colostrum composition is also altered by genotype suggesting that selection strategies could be used to further improve it. Little is known on the environmental effects on sow colostrum; heat stress was shown to decrease IgG concentrations and alter fatty acid composition of colostrum. Endocrine status undoubtedly affects colostrumogenesis and the induction of farrowings reduces both colostrum yield and fat content of colostrum. On the other hand, providing growth hormone or prolactin in late-gestation increases colostrum fat content. A drastic reduction in feed allowance in late gestation also increases colostrum fat content, yet protein intake per se seems to have no effect on colostrum composition. In fact, it is very difficult to change the amino acid composition of colostrum. Supplementing the diet with fat in late gestation not only increases total lipids in colostrum but the source of fat used alters lipid composition. Indeed, inclusion of fish oil in the gestation diet of sows increases the amount of PUFA in colostrum and, interestingly, dietary conjugated linoleic acid also increases colostrum IgG content. Dietary supplementation with vitamin E, but not C, increases its concentration in colostrum and, even though increases in vitamins A and E in the gestation diet do not alter colostrum concentrations of IgG, they improve the IgG status of piglets via unknown mechanisms. Lastly, mineral intake appears to have no effect on mineral content in colostrum. In conclusion, it is apparent that new management strategies to enhance yield and/or composition of sow colostrum could be developed and further research in that area is definitely warranted.

Key Words: Colostrum, Management, Swine

819 Defining gene networks during involution of the mammary gland in dairy cows. P. Piantoni*, W. L. Hurley, S. L. Rodriguez-Zas, R. E. Everts, H. A. Lewin, and J. J. Loo, *University of Illinois, Urbana*.

Gene expression networks in the mammary gland during involution remain largely unknown. Objectives were to evaluate temporal changes in mammary gene network expression profiles due to cessation of milking at peak lactation. At 42 DIM, Holstein cows underwent a period of 5 d during which they were milked once daily until complete cessation of milking. Percutaneous mammary biopsies (n = 5/time point) were obtained on d 1, 5, 14, and 21 relative to the start of once-a-day milking. A 13,257 bovine oligonucleotide (70-mers) array and qPCR were used for gene expression profiling. Annotation was based on similarity searches using BLASTN against human, mouse and bovine RefSeq, human, mouse, and bovine UniGene, and bovine TIGR. Cy3- and Cy5-labelled cDNA from mammary gland and a reference standard were used for hybridizations (40 arrays). ANOVA (false discovery rate = 0.05) identified 75, 374, and 379 differentially expressed genes (DEG) with expression changes >1.5-fold on d 5, 14 and 21, respectively, relative to

d 1. Among DEG, gene network/pathway analysis identified apoptosis (n = 65), cellular growth and proliferation (n = 73), and immune response (n = 38) as the most significant upregulated molecular and cellular functions on d 21 vs. 1. In contrast, lipid metabolism (n = 17) and cellular development (n = 12) were among the most significantly downregulated functions in the same comparison. Downregulated genes on both d 14 and 21 vs. 1 included TNFA (cytokine activity), CD36 (fatty acid transport), SDHD (TCA-cycle), and SREBF1 (transcription factor); whereas, LTF (peptidase activity), CLU (apoptosis), and SPP1 (cytokine activity) were upregulated. Top upregulated signaling pathways among DEG on d 14 and d 21 vs. 1 included epidermal growth factor signaling and acute phase response signaling. Observed gene network expression patterns during “forced” involution were in large part a reflection of diminished milk synthesis and metabolism as the mammary gland transformed into a non-secretory tissue. Immune response-related genes seem to play a central role during mammary involution.

820 Mastitis control on organic and traditional dairies. P. L. Ruegg*, *University of Wisconsin, Madison*.

The U.S.D.A. National Organic Program specifies that organic dairy products may not originate from animals that have received hormones or antibiotics for any reason. As a consequence, organic dairy producers utilize a variety of strategies to manage disease. The purpose of this paper is to review research that describes mastitis control and treatments used on U.S. organic dairy farms. Several studies have indicated that fewer cases of clinical mastitis were reported by ORG farms but there are philosophical differences in the detection of disease and perception of cure and it is possible that more diseases are recorded on CON farms because there are more treatment options. Control of contagious mastitis can be a challenge for ORG farms because use of intramammary antibiotics is prohibited. In a WI study, about half of ORG farms reported administration of a variety of non-antimicrobial products at dry-off. Ultra filtered bovine whey products were most common treatment but other products included vitamin or microbial supplements or vitamin C. Both CON and ORG farmers had similar appraisal of products used at dry off. Organic farmers consistently report that they do not use antimicrobials to treat clinical mastitis. Treatments for clinical mastitis included various intramammary compounds such as isoflupredone, vitamin C, apple cider, aloe vera, and microbial supplements. A bovine whey product was the most common product administered by a parenteral route at both dry off and for treatment of clinical cases. Organic producers also reported the use of garlic tincture administered per os, or in the vulva. While efficacy data for these compounds is not available, the perception of cure after treatment of clinical mastitis was not significantly different between CON and ORG farmers. About half of CON farmers and one third of ORG farmers estimated that less than 50% of the treated cases of mastitis were cured as a result of treatment. Almost 74% of ORG farmers using compounds to treat clinical mastitis were satisfied or very satisfied, while only 40% of CON farmers were satisfied or very satisfied with the products used.

Key Words: Mastitis, Organic, Dairy

821 Association of prion protein genotypes with milk production and milk cheese-making properties in two breeds of dairy ewes. Y. Moussaoui, G. Caja, A. A. K. Salama*, E. Albanell, R. Casals, X. Such, D. P. Jaramillo, and A. J. Trujillo, *Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

Scrapie is a widespread transmissible spongiform encephalopathy of sheep, which is under official eradication programs. Infectious protein (prion) is encoded by an autosomal gene (*PRNP*). Degree of resistance to scrapie depends on *PRNP* polymorphisms: VRQ and ARR haplotypes being the most and least susceptible, respectively. Frequency of haplotypes varies between breeds, but is currently being modified by selection programs. Very little information is available on association of *PRNP* genotypes with sheep dairy traits. In order to improve this knowledge, 28 Manchega (ARR/ARQ, n = 9; ARQ/ARQ, n = 19) and 34 Lacaune dairy ewes (ARR/ARQ, n = 14; ARR/ARR, n = 20) were used to evaluate lactational performance and milk cheese-making properties. Management and feeding was similar for all ewes. Milk yield was recorded and milk sampled at wk 9 of lactation for analysis of main milk components, Na, K, fatty acid profile, SCC and cheese-making properties. Statistical model included, for each breed, the covariate of SCC, the fixed effects of genotype and parity, the random effects of animal and residual error. *PRNP* genotype had no effect on milk yield and most milk components. Exceptions were: log SCC, which was greater in ARR/ARR than ARR/ARQ (5.58 vs. 5.09; $P < 0.05$) in Lacaune; milk fat, which tended to be lower in ARQ/ARQ than ARQ/ARR (7.47 vs. 8.03%; $P = 0.064$) in Manchega; and, C17:0, which tended to be lower in ARR/ARR than ARR/ARQ (1.34 vs. 1.50%; $P = 0.065$) in Lacaune. Regarding cheese-making properties, milk coagulation pH was lower (6.59 vs. 6.70; $P < 0.05$) and curd DM tended to be greater (35.7 vs. 34.9%; $P = 0.098$) in ARQ/ARQ than ARR/ARQ in Manchega. On the other hand, rennet clotting time (12.7 vs. 10.9 min) and cheese whey protein (2.10 vs. 1.82%) were greater ($P < 0.05$) in ARR/ARR than ARR/ARQ in Lacaune. These results indicate that increasing the ARR frequency in Manchega and Lacaune dairy ewes does not seem to have negative effects on milk and cheese-making traits. However, selection towards ARR haplotypes in Lacaune ewes could have a negative impact on SCC, rennet clotting time and cheese whey proteins.

Key Words: Scrapie, Milk, Dairy Sheep

822 Management effects on colostrogenesis in small ruminants. N. Castro*¹, J. Capote², R. M. Bruckmaier³, and A. Argüello¹, ¹*Las Palmas de Gran Canaria University, Arucas, Spain,* ²*Canarian Agronomic Science Institute, La Laguna, Tenerife, Spain,* ³*University of Bern, Bern, Switzerland.*

Colostrum feeding in small ruminants is crucial during their first hours after birth because it is the only immunoglobulin (Ig) source during early life, due to the lack of Ig transfer during pregnancy via the placenta. In addition the immune system of the neonate is unable to produce Ig during the first month of life. Colostrogenesis, i.e. parturition transfer of Ig from blood into mammary secretions, starts several weeks prepartum. In goats plasma IgG concentration decreased by around 38% from third month of gestation until parturition, which coincided with the dry period (DP). Thus, the management during dp is crucial for the course of

colostrogenesis. The colostrum synthesis is affected by nutrition during the DP but the transfer of Ig seems to be independent. The administration of conjugated linoleic acid (CLA) during the DP to dairy goats caused a less pronounced decrease of plasma IgG concentration (6%) but it did not change colostrum IgG levels. In cattle IgG1 is transported from blood into colostrum by an IgG1 specific receptor located on the surface of alveolar epithelial cells during colostrogenesis which is most likely similar in small ruminants. Via inactivation of this receptor, the Ig transfer is downregulated by the increase of prolactin (PRL) during the final stage of lactogenesis. It was recently demonstrated in goats treated with PGF2 α in order to induce parturition that lower colostrum IgG concentrations occurred concomitantly with an earlier increase of plasma PRL as compared to untreated animals. Litter size did not affect colostrum IgG concentration in goats and ewes. Contrary to cows, the number of lactations did not affect IgG in colostrum of goats.

Key Words: Colostrum, IgG, Immune System

823 Haptoglobin, cortisol, A/G ratio and IGF-1 in goat kids around weaning. D. Magistrelli*, L. Pinotti, and F. Rosi, *University of Milan, Milan, Italy.*

Weaning is the most stressful event in the life of young ruminants. Since stress can affect endocrine and immune functions, weaning often results in a period of growth stasis and risk of disease. In light of this, the aim of this study was to evaluate the effect of weaning on growth and on some physiological mediators of stress and immune function.

Eleven Saanen goat kids were studied from day 3 to day 50 of age. Kids were randomly divided into two groups: MILK (6 animals) and WMIX (5 animals). All were fed goat milk to age 29 days. After that, MILK kids continued to receive milk, while WMIX group underwent weaning, in which milk was gradually replaced by solid feed. WMIX kids were completely weaned on day 48.

During the experimental period, dry matter intake (DMI) and body weights (BW) were recorded and blood was analyzed for metabolic traits, for indicators of health status (cortisol, haptoglobin and albumin/globulin - A/G ratio) and for IGF-1, which has a crucial role in postnatal development.

Starting from day 37 of age, DMI began to lower in WMIX group. On day 50, glucose, amino acids and urea were significantly lower in WMIX kids. On the same day, plasma IGF-1 was also lower in WMIX kids, as possible consequence of the lower plasma glucose and amino acids. Despite these differences, BW did not differ between groups, throughout the entire period.

Along the experimental period, plasma cortisol was always low in both groups, signaling no stressful condition, even if from day 44 to 50 of age, cortisol level significantly increased in MILK kids. This last result may indicate a function for cortisol as metabolic hormone involved in glucose homeostasis, rather than as telltale sign of poor health. In fact, no difference was observed neither in plasma haptoglobin, nor in A/G ratio, which are useful tools for suggesting when the animal is pathologically or physically challenged.

Results imply that a gradual transition from milk to solid feed does not affect the health status of goat kids, but it can decrease plasma cortisol, as hormone involved in glucose metabolism.
