POSTER PRESENTATIONS

Animal Health: Mastitis

T1 Dairy herd size and herd expansion are related to dairy cow mortality in Southeastern US dairy herds. G. W. Rogers¹, J. B. Cooper*¹, and J. S. Clay², ¹*The University of Tennessee, Knoxville*, ²*Dairy Records Management Systems, Raleigh, NC*.

Lactation records from dairy herds in 9 Southeastern states processed through DRMS were utilized to determine the relationship between dairy cow mortality and herd size and between mortality and herd expansion. Data analyzed were from herds with a minimum of 10 years of continuous recording between 1982 and 2005. Binary mortality traits (1=CAR code 6 indicating lactation ending in death versus 0=all other CAR codes) were developed separately for 1816 Holstein herds (2,292,630 lactations) and 268 Jersey herds (282,123 lactations) for lactations 1, 2 and 3 or later. Binary traits were analyzed using a logistic regression model including herd, year of calving, season of calving, age at calving and herd expansion [(maximum average herd size for 4 consecutive years)/(average herd size for first 4 years), as %] or herd size or both herd expansion and herd size. Herd size for Holsteins was categorized as: <100, 100 to 200, 200 to 400, 400 to 700 and >700 cows. Herd size for Jersey herds was categorized as: <100, 100 to 200 and >200 cows. Smaller herd size was associated with lower mortality risk except Holstein herd sizes of 200 to 700 had higher mortality risk than herds with >700 cows. Four herd expansion categories were constructed for Holsteins: <30%, 30 to 200%, 200 to 350% and >350%. In Holstein herds, herd expansion <30% had significantly higher mortality risk than herds that expanded >350%; herds with expansion from 30 to 350% tended to have higher mortality risk than herds expanding >350%. Jersey herd expansion categories were <30%, 30 to 200% and >200%. Jersey herd expansion <200% was associated with lower mortality risk compared with expansion >200%. Intermediate-scale expansion was associated with increased risk of mortality in Holstein herds (compared to >350%) but decreased risk of mortality in Jersey herds (compared to >200%). Including herd size and herd expansion in the model resulted in a more dramatic impact of Holstein herd expansion on mortality with expansion >350% favorably associated with mortality.

Key Words: Dairy Cow Mortality, Herd Size, Herd Expansion

T2 Genetic polymorphism of lactoferrin gene and association with mastitis in Holstein cows. J. B. Cheng¹, J. Q. Wang*¹, D. P. Bu¹, G. L. Liu¹, C. G. Zhang^{1,2}, X. L. Dong^{1,2}, H. Y. Wei¹, L. Y. Zhou¹, and K. L. Liu¹, ¹*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*, ²*College of Animal Science and Technology of Yangzhou University, Yangzhou, China*.

Whether lactoferrin (LF) is a candidate genetic marker for mastitis resistance needs to be studied. In this study, by using the method of sequencing to detect the polymorphisms, we found 6 SNPs in a region of 602bp promoter from 128 dairy cows. In the -241bp and -190bp, there were a T to C mutation and a G to A mutation, and those mutations were first discovered. The others mutations were in -28 bp (A/C), +33 bp (C/G) -131bp (T/C) and -156 bp (A/G), respectively. Analysis of association between the genotypes of LF gene and SCS that reflects mastitis traits was carried out with GLM procedure using the SAS software, and the lactation number and lactation month of cow were also be taken into consideration. Statistical results indicated that SCS was significantly correlated with the month of lactation ($r = 0.222$, Spearman correlation test; $P < 0.05$), and with no strong relationships to the LF genotype and lactation number ($P > 0.05$). Yet, the level of SCS tended to be higher as the lactation number increased. The month of lactation could strongly affect the level of SCS in the milk ($P < 0.05$). In the test group cows, the SCS level increased significantly ($P < 0.01$) from month 1, values of 1.707 to a peak of 3.592 on month 4. A dramatic decline of SCS occurred from month 5 to the month 6 with the value of 2.506, followed by an increase from month 7 to the month 9 ($P < 0.05$). The genotypes and diplotypes all did not have significant effect on SCS. Whether LF gene could be used as a genetic marker of mastitis resistance needs further studies to validate. Acknowledgement: Research funded by Ministry of Science and Technology (2006BAD12B03).

Key Words: Genetic Polymorphism, Lactoferrin, Mastitis

T3 Photonic plasmid stability of transformed *Salmonella typhimurium* using Stanford Photonic imaging and three plasmid types.

K. Moulton^{*1}, P. Ryan¹, D. Moore¹, S. Laird¹, J. Curbelo¹, D. Lay², and S. Willard¹, ¹Mississippi State University, Mississippi State, ²USDA-ARS, Livestock Behavior Research Unit, West Lafayette, IN.

Acquiring a highly stable photonic plasmid in transformed *Salmonella typhimurium* for use in biophotonic studies of bacterial tracking *in vivo* is critical to experimental paradigm development. The objective of this study was to determine the stability of transformed *Salmonella typhimurium* (*S. typh-lux*) using three different plasmids and their respective photonic properties. *S. typh-lux* isolates (porcine) were electroporated with either pCGLS-1, pAK1-lux or pXEN-1 plasmids. *S. typh-lux* was then grown over a 24 h period in LB broth or LB broth (10 ml) plus ampicillin (AMP; 50 µg/ml) and placed in an incubated shaker (37° C). After 24 h, inoculums were placed into a black 96-well plate for imaging (100 µl; n = 8 replicates). Photonic imaging was conducted for 5 sec and emissions quantified (RLU/sec). Inoculums were plated on Brilliant Green agar plates (with and without AMP), colony numbers counted (CFU) and plates imaged for the ratio of non-emitting to emitting colonies. Inoculums were sub-cultured daily from d 0 to 10 with and without AMP selection to determine photonic stability over time for the three plasmids. In the presence of AMP, *S. typh-lux* with the pCGLS-1, pAK1-lux and pXEN-1 plasmids remained 100% emitting over the entire 10-d study. Photon emitters of *S. typh-lux* with pCGLS-1, pAK1-lux and pXEN-1 without AMP selection decreased over time ($P < 0.05$), representing only $11 \pm 1\%$, $35 \pm 1\%$ and $43 \pm 1\%$, respectively, of the bacterial population by d 10. Photonic emissions were positively correlated with bacterial concentration ($P < 0.05$) for pAK1lux, pCGLS-1 and pXEN-1 ($r = 0.96$, 0.98 and 0.82 , respectively). These data characterize the photon stability properties for *S. typh-lux* transformed with three different photon generating plasmids that may permit real-time *Salmonella* tracking using *in vivo* or *in situ* biophotonic paradigms. [USDA-ARS Biophotonics Initiative # 58-6402-3-0120].

Key Words: *Salmonella*, Biophotonics, Plasmid

T4 Seasonal variation of mortality rate in dairy cows of the Po Valley (Italy). A retrospective study from 2001 to 2006. A. Vitali¹, L. Bertocchi², N. Lacetera^{*1}, U. Bernabucci¹, A. Cuteri¹, M. Guerini³, and A. Nardone¹, ¹Dipartimento di Produzioni Animali, Viterbo, Italy, ²Istituto Zooprofilattico Sperimentale Lombardia-Emilia Romagna, Brescia, Italy, ³Osservatorio Epidemiologico Veterinario Regione Lombardia, Brescia, Italy.

The present study is aimed to analyze seasonal variations of mortality rate in dairy cows. The analysis was carried out in years 2001-2006 and in the geographic area comprised between 44°- 46°.15' latitude north and 8°.30'- 12°.30' longitude east, known as the area of the Po Valley including the regions Lombardia and Emilia Romagna, Italy. This area is characterized by a subcontinental-temperate climate and a high density of dairy herds (approximately 900,000 dairy cows in 45,000 square kilometres). Data were extracted from the Italian Bovine Spongiform Encephalopathy (BSE) database, which provided data of daily mortality of cows older than 24 months. Data on cow populations were provided by the Italian National Institute of Statistics. The standardized mortality ratio (SMR) for each season and for each year was calculated by the ratio of observed and expected deaths (OD and ED, respectively). The ED for each of the 6 years considered in the study were calculated by the product between annual mortality rate and the population of the area, stratified by 4 age classes. Under the hypothesis of Poisson distribu-

tion, a 95% confidence interval (CI) was calculated for the SMR and its value was considered statistically significant if the value 1 was outside the confidence range. For all years and regions, the analysis of SMR showed that during summer season the OD was significantly higher than the ED. In summer season OD overcame ED by values ranging from +21% (year 2005, Lombardia) to +60% (year 2003, Lombardia); the corresponding 95% CI were 1.17-1.24 and 1.57-1.64 for the years 2005 and 2003, respectively. Results reported herein indicate the relevance to develop appropriate strategies, including management, feeding, genetic selection and insurance plans, to limit economic losses associated with heat stress in dairy cows.

Key Words: Dairy Cows, Season, Mortality Rate

T5 Monitoring body temperature of postpartum dairy cows using an intravaginal device. R. R. Peters¹, B. Erez^{*1}, L. A. Bornt¹, F. Siewerdt¹, and M. E. Iager², ¹University of Maryland, College Park, ²Mid-Maryland Dairy Veterinarians, Hagerstown, MD.

The first objective of this research was to build a system to continuously monitor body temperature (BT) within vagina of postpartum cows with ability to transfer temperature data cow-side to a palm pilot. A Pfizer EAZI-BREED™ Controlled Internal Drug Release (CIDR®) Cattle Insert was modified to hold a data logger button that monitors BT and wired with electrical connections that could be accessed and connected to palm pilot near the vulva. A second objective of this research was to ascertain that system under study provides BT data similar to rectal temperature (RT). Cows (n=12) were vaginally fitted with a CIDR no earlier than 1 day postpartum. Ibuttons were programmed to record BT every 15 min. RT of these cows was taken twice daily at milking time in milking parlor for 10 days. BT and ambient temperature (AT) were collected from Jan to Feb, 2007. AT was from weather station 10 km away. In the initial statistical analysis, temperature data from CIDR and RT taken at similar times were compared. BT (degrees C) averaged 38.6 and 38.9 from ibutton mounted on a CIDR and rectal thermometer, respectively. Because AT and RT had a significant ($P < .0001$) positive correlation (.30) AT was included in regression model. AT did not significantly affect intravaginal temperature. Regression coefficient of RT over CIDR is $.71 \pm .04$. Correlation coefficient and r-square value between CIDR and rectal thermometer were $.75 \pm .05$ and $.56$, respectively. Regression coefficient ($.71 \pm .05$) indicates that ibutton overestimates BT when temperatures are minimal and underestimates BT when temperatures are maximal. A third objective was to determine efficiency of the CIDR in detecting BT over 39.4 C. With CIDR temperatures uncorrected for AT, CIDR found only 30% of temperatures exceeding 39.4 C. When temperature from CIDR was corrected for AT, threshold temperature of 39.4 C decreased to 39.2 C. With adjusted temperature of 39.2 C, efficiency for detecting fever increased to 65%.

Key Words: Body Temperature, Intravaginal Device, Postpartum Cow

T6 A data exchange format and national database for producer-recorded health event data from on-farm management software. J. B. Cole, D. J. Null^{*}, and L. R. Bacheller, USDA-ARS-BA-ANRI-AIPL, Beltsville, MD.

There is great interest in producing dairy cows that are healthy and remain in the herd longer. Direct and indirect costs associated with

disease represent a significant expense to producers, and selection for improved health may reduce these costs significantly. Genetic response to selection for improved health based upon breeding values from genetic evaluations of field-recorded traits has been well-documented. That genetic variation is not now being directly utilized for genetic improvement, and several challenges must be overcome before useful tools to this end can be provided. The Animal Improvement Programs Laboratory, in conjunction with industry partners and veterinary experts, has developed a data exchange format (Format 6) for the transfer of health and management data from on-farm record-keeping systems to a national database. A Format 6 record includes detailed cow identification, a health event code, an event date, and an optional detail field. This format can provide the necessary data for research into, and implementation of, genetic evaluations for economically-important health traits. Format 6 was designed to be easily extensible, as demonstrated by the addition of a locomotion score event to the specification in January, 2008. The database and editing systems were tested using 63,423 health events from 23,332 cows provided by Dairy Record Management Systems (Raleigh, NC). The most common disorders reported were mastitis (38%), metritis (16%), and other reproductive problems (15%). Primiparous cows accounted for 38% of records, and rates of occurrence differed by age for some disorders. For example, 61% of dystocia events were for first parity cows, while only 79% of the cows with milk fever were older cows. A total of 3920 individual events were flagged by the edits system, and the most common data errors were calving dates that did not match event dates for dystocia (26%) and calving dates with no matching test day data (72%). Format 6 records are stored in the national dairy database with cow test day data, and may provide valuable information for genetic improvement.

Key Words: Database, Genetics, Health

T7 Dexamethasone administration increased bovine lymphocyte clock gene expression *in vitro* and *in vivo*. S. S. Pozzo*, M. K. Rankin, and T. F. Gressley, *University of Delaware, Newark*.

Regulation of circadian rhythms in the brain and peripheral tissues occurs via differential expression of clock genes in response to signals including hormonal profiles. Two experiments were conducted to explore the impact of administration of the synthetic glucocorticoid dexamethasone (dex) on clock gene expression in bovine lymphocytes. In the first experiment, lymphocytes were isolated from 5 Holstein cows and treated *in vitro* with 0 or 1.5 nM dex. The 1.5 nM dex dose suppressed *in vitro* lymphocyte proliferation by approximately 50%. Lymphocyte RNA was harvested after 0, 4, 8, 12, 16, 20 and 24h. Quantitative real-time RT-PCR was used to determine mRNA expression of 8 clock genes (*Bmal1*, *Clock*, *Per1*, *Per2*, *CK1ε*, *Cry1*, *Cry2* and *Rev-erba*) relative to housekeeping genes *RPS9* and β -*actin*. Expression of *Per1* and *Per2* were affected by time ($P < 0.01$), with peak expression found for both at 4h. *Per1* expression was up-regulated 67% in response to 1.5 nM dex ($P < 0.01$). In the second experiment, 6 Holstein steers averaging 225 kg were injected with either saline or dex (0.1 mg/kg BW) followed by the opposite treatment 1 wk later. Lymphocytes were harvested from blood sampled 0, 4, 8, 12, 16, 20 and 24h following treatment, and PCR was conducted as described for the first experiment. Dex increased expression of *Bmal1* 53% ($P = 0.06$), *Per1* 70% ($P < 0.01$), *Per2* 32% ($P = 0.09$), *CK1ε* 23% ($P = 0.07$) and *Cry1* 47% ($P < 0.01$). Time effects were found for *Clock* ($P < 0.01$) and *Cry1* ($P = 0.09$), peaking at 12 and 16h respectively. Interactions between treatment and time were found for *Per2* ($P = 0.06$), *CK1ε* ($P < 0.01$) and *Cry2* ($P = 0.03$). Relative to the

saline treatment, dex increased *Per2* expression 8, 12 and 16h after treatment ($P < 0.05$), *CK1ε* expression 8, 16 and 24h after treatment ($P < 0.05$), and *Cry2* expression 12 and 24h after treatment ($P < 0.05$). Our research demonstrates that dex alters bovine lymphocyte clock gene expression patterns both *in vitro* and *in vivo*. Changes in circadian rhythms may be important in regulating response of the bovine immune system to glucocorticoids.

Key Words: Clock Genes, Lymphocytes, Dexamethasone

T8 Negative energy balance (NEB) alters neutrophil (PMN) gene expression in response to a *Streptococcus uberis* (*S. uberis*) mastitis challenge in lactating dairy cows. K. M. Moyes*, J. K. Drackley, D. E. Morin, R. E. Everts, H. A. Lewin, and J. J. Loor, *University of Illinois, Urbana*.

Our objectives were to compare gene expression profiles in PMN during a *S. uberis* mastitis challenge between lactating cows subjected to feed restriction to induce NEB (n=2) and cows fed ad libitum to maintain positive energy balance (PEB; n=5). All cows had composite SCC <200,000 cells/mL prior to the study, and milk from all quarters was bacteriologically negative. NEB cows were feed-restricted to 60% of calculated NE_L requirements for 7 d, whereas PEB cows were fed the same diet for ad libitum intake. After 5 d of feed restriction, one rear mammary quarter of each cow was inoculated with 5,000 cfu of *S. uberis* (strain O140J). Blood PMN were isolated before inoculation and pooled within level of energy balance (NEB and PEB). PMN also were isolated at 12 and 20 h post-inoculation and pooled within cow (i.e., 12 plus 20 h), and then cows were pooled within level of energy balance. A 13,257 oligonucleotide (70-mers) array was used for transcript profiling. Cy3- and Cy5 labelled cDNA from PMN and a reference standard were used for hybridizations (8 microarrays total). Genes with > 2.0-fold change in expression were considered significantly different. In PMN before inoculation, NEB resulted in 76 down-regulated genes by >2.0-fold versus PEB cows. Genes up-regulated by NEB (n=29) were involved in protein metabolism (*USP21* and *FSCN1*); down-regulated genes (n=47) were involved in antigen presentation (*HLA-DXA1*) and elongation of fatty acids (*ELOVL6*). During infection, 175 genes were differentially expressed in NEB versus PEB cows. Genes up-regulated by NEB (n=103) included *OAS1* and *SERTINB4*, which are involved in the immune response. Genes involved in protein metabolism (*PTPRK* and *DPYSL3*), oxidative stress (*GSTA2*), and immune response (*MAP4K4/NIK*) were down-regulated (n=72) in NEB versus PEB cows during infection. Energy balance alters gene expression profiles in blood PMN from cows, both before and during mastitis challenge.

Key Words: Genomics, Energy Balance, Neutrophil

T9 Comparison of minimum inhibitory concentrations of *Staphylococcus aureus* obtained from clinical and subclinical cases of mastitis. L. Oliveira*¹, P. Ruegg¹, H. Langoni², and M. D. Apparao¹, ¹*University of Wisconsin, Madison*, ²*FMVZ - UNESP, Botucatu, SP, Brazil*.

The objective was to compare minimum inhibitory concentrations (MIC) of selected antimicrobials for *Staphylococcus aureus* isolated from clinical and subclinical mastitis. Duplicate aseptic milk samples were collected from all quarters of cows (n = 381) on commercial

dairy herds, with somatic cell counts (SCC) that exceeded 200,000 cell/ml. Additional duplicate quarter milk samples were obtained from cows identified with clinical mastitis. Pathogens were identified using laboratory procedures as defined by the NMC (1999). Minimum inhibitory concentrations were determined for 12 antimicrobial agents using broth microdilution with a custom extended dilution range (Trek Diagnostics,). MIC values were determined for *Staph aureus* obtained from clinical (n = 48) and subclinical (n = 68) cases of mastitis. SAS 9.1 was used to perform survival analysis based on type of mastitis (clinical or subclinical). Antimicrobial concentrations present in wells of the panel of the susceptibility test were used as “time” in the survival analysis. The event was defined as inhibition of bacterial growth, and isolates that not inhibited at the highest concentration tested were right censored. Kaplan-Meier survival curves of the each antimicrobial were performed for each strata of mastitis (subclinical or clinical). *Staph aureus* were resistant to at least 1 antimicrobial obtained from 9 of the 12 enrolled farms. Of isolates (n = 116), 29 (25%) were resistant to one or more antimicrobial agents. Of isolates, 33.8% (subclinical) and 40.0% (clinical) exhibited resistance to at least 1 antimicrobial. The greatest proportions of resistant isolates (11%) were detected for tetracycline. No resistance was observed for ceftiofur or cephalothin. Mastitis type was associated with MIC of erythromycin and tetracycline. Mastitis type was not associated with the MIC of the other antimicrobials. In this study, antimicrobial resistance was uncommon among the *S. aureus* isolated from bovine mastitis and there was homogeneity among clinical and subclinical isolates.

Key Words: Mastitis, *Staphylococcus aureus*, Sensitivity Test

T10 Comparison of in-vitro MIC's of gram positive pathogens isolated from cases of subclinical and clinical mastitis. M. D. Apparao¹, P. L. Ruegg^{*1}, A. Lago², S. Godden², R. Bey², R. Dingwell³, and K. Leslie³, ¹University of Wisconsin, Madison, ²University of Minnesota, St. Paul, ³University of Guelph, Guelph, ON, Canada.

The objective of this study was to compare the in-vitro minimum inhibitory concentrations (MIC) of Gram positive pathogens isolated from cases of subclinical and clinical mastitis. Isolates for this study were obtained from cases of subclinical and clinical mastitis that were enrolled in a multi-site, multi-herd controlled field study conducted in Minnesota, Ontario and Wisconsin. Laboratory procedures were as defined by the NMC (1999) and target pathogens (Gram positive cocci) isolated from milk samples were identified to the species level using the API test (bioMerieux). A broth micro dilution technique employing custom designed panels containing extended dilutions of 12 antimicrobial agents were used to determine the MIC. Statistical analysis was done using Proc Lifetest (SAS 9.1). Gram positive pathogens (n = 187) were isolated from quarter milk samples obtained from clinical (n = 51) and subclinical (n = 136) cases of mastitis. The MIC's were different for isolates obtained from subclinical and clinical mastitis cases for ampicillin, ceftiofur, enrofloxacin, penicillin-novobiocin and tetracycline (P < 0.05). Pathogen specific differences in the MIC's of subclinical and clinical mastitis isolates were also observed. The MIC's of penicillin, penicillin-novobiocin and spiramycin were different for cases of subclinical and clinical mastitis caused by coagulase negative staphylococci (n = 121). The MIC's of enrofloxacin, sulphadimethoxine and tetracycline were different for subclinical and clinical mastitis caused by streptococci (n = 26). The MIC's of tetracycline and oxacillin were different for subclinical and clinical cases caused by *Staphylococcus aureus* (n = 22) and “other” Gram positive mastitis pathogens (n =

18), respectively. The overall and pathogen specific differences in MIC's between subclinical and clinical isolates suggests that nature of infection (subclinical or clinical) should be taken into account while comparing MIC profiles or monitoring resistance of mastitis pathogens.

T11 Nystatin, pathogen-associated molecular patterns and bovine neutrophil activation. M. Worku* and A. Morris, *North Carolina A&T State University, Greensboro.*

Nystatin is an antifungal compound with potent proinflammatory properties, shown to inhibit lipid rafts. Lipid rafts are putative microdomains in the plasma membrane rich in lipids and shown to mediate many signaling events including TLR-4 signaling. A TLR2- and TLR1-dependent process serves as the molecular basis for the pro-inflammatory properties of Nystatin. The objective of this study was to evaluate the effect of Nystatin in LPS mediated TLR signaling and the subsequent proinflammatory cytokine response. Further to determine its effect as a lipid raft inhibitor in bovine neutrophils. Blood was collected from a clinically healthy Holstein Friesian cow. Neutrophils were isolated by differential centrifugation. Isolated Neutrophils were treated with LPS (100ng/1/4l) in the presence or absence of Nystatin (301/4g) for 15 min controls were maintained in PBS. RNA was then isolated using Tri-reagent (SIGMA). The quality and quantity of RNA was determined using the 2100 Agilent Bioanalyzer. Specific primers for CD14, IL1-B, IL-8, TNFa, NRAMP-1 and TLR-4 were used for reverse transcriptase PCR. Amplified products were run on a 2% agarose gel and visualized following staining with ethidium bromide. LPS treated Neutrophils had low levels of IL-1B expression. Expression of TNF- α or TLR-4 or CD14 genes was not observed. Nystatin did not inhibit the expression of IL-8 and Nramp1 genes. Treatment with Nystatin increased expression of the gene encoding IL-8 in both LPS treated and control PMN. Nystatin might have acted through the TLR found on the neutrophil and increased the expression of the gene encoding IL-8. Further studies are needed to ascertain if Nystatin is behaving as pathogen-associated molecular patterns (PAMP) to induce cell activation through TLR, signaling and secretion of cytokines to mediate biologic effects in bovine PMN. Further the results may have implications for the use of “nonimmunologic” drugs that serve as agonists for TLR. The associated activation can result in unintended beneficial and detrimental effects on animal health and well being.

Key Words: Nystatin, Neutrophil, Pro-Inflammatory Cytokine

T12 Macrolide and lincosamide resistance in staphylococci and streptococci isolated from quarters with persistent subclinical mastitis. M. D. Apparao, P. L. Ruegg*, and H. Khatib, *University of Wisconsin, Madison.*

The objective of this study was to examine the relationship between occurrence of ermB and ermC and in vitro susceptibility of staphylococci and streptococci isolated from subclinical mastitis. Cows with subclinical mastitis were randomly allocated to a “treatment” or “control” group. CMT positive quarters (n = 213) of cows in the “treatment” group received intramammary treatments using pirlimycin. No treatment was given to quarters (n = 208) of cows in the control group. Aseptic milk samples were collected pretreatment and 3 weeks later. A

“persistent” infection was defined as isolation of the same bacterial species from both pretreatment and post treatment milk samples. Persistent infections (54 infections; 108 pathogens) were confirmed using a PCR based methodology. Susceptibility of persistently infected pathogens was determined using broth micro-dilution. Identification of ermB and ermC was performed using a published PCR protocol. Statistical analysis was carried out using SAS 9.1. An association between presence of ermC and in vitro resistance was observed for both erythromycin and pirlimycin ($P < 0.05$). Of 16 isolates that demonstrated phenotypic resistance to erythromycin, 10 (63%) were positive for ermC whereas 3 (3%) of 92 erythromycin susceptible isolates were positive for this gene. Of 18 isolates that demonstrated in vitro resistance to pirlimycin, 9 (50%)

were positive for ermC gene whereas only 4 (4%) of 90 susceptible isolates were positive. No ermB were detected. Of 10 isolates positive for ermC that demonstrated in vitro resistance to erythromycin, 2 were susceptible to pirlimycin, indicating probable induction of ermC gene expression. No association was observed between either treatment or sampling period and presence of ermC. In conclusion, the association between the presence of ermC and in vitro resistance to macrolide and lincosamide antimicrobials suggests that routine screening for ermC may serve as an important tool for surveillance of antimicrobial resistance in bovine mastitis pathogens.

Breeding and Genetics

T13 Using logistic regression model to analyse some environmental factors affecting mastitis incidence of primiparous Iranian Holsteins. H. Farhangfar*, A. Abedini, H. Naeemipour, M. R. Asghari, and M. H. Fathi Nasri, *Birjand University, Birjand, Iran.*

To analyze the effects of some environmental factors such as herd, year, season of calving, stage of lactation on mastitis incidence, a total of 101147 monthly test day somatic cell counts collected from 13977 Iranian Holstein heifers calved between 2002 and 2006 in 183 herds were used. The event of mastitis in cows was coded as 1 if their somatic cell count at specific test day was greater than 250000 cells per milliliter of milk yield sample. Although somatic cell score could be also analyzed as a continuous trait, this study aimed to evaluate mastitis incidence in a new approach. Logistic regression statistical method was applied to model the probability of mastitis incidence. In the model, fixed environmental factors of herd, year, season of calving, stage of lactation, milk (linear covariate) and age at first calving (linear covariate) were included. The model was fitted to the data using logistic procedure of SAS programme. The results obtained in this study indicated that all environmental factors had highly statistical significant ($p < 0.001$) effects on mastitis incidence. Spring calvers (April-June) were found to be more susceptible to mastitis than the other cows calving at different seasons suggesting that calving in the seasons other than spring could result in decreasing mastitis in herds. The results also revealed that the probability of mastitis incidence increased (with odds ratio of 1.029) as the age of cow at first calving increased while it decreased when the amount of milk yield (odds ratio of 0.960) during the lactation period increased. Genetic evaluation of animals for somatic cell score could decrease the level of mastitis incidence.

Key Words: Mastitis, Logistic Regression, Iranian Holsteins

T14 Genetic parameters estimation of somatic cell score in Iranian Holstein heifers using a random regression test day model. H. Farhangfar*¹, A. Abedini¹, H. Naeemipour¹, M. Alipanah², K. Shojaeian², and B. Mohammad Nazari³, ¹*Birjand University, Birjand, Iran,* ²*Zabol University, Zabol, Iran,* ³*Animal Breeding Centre, Karaj, Iran.*

A total of 101,147 monthly test day somatic cell scores (SCS, defined as $\ln(\text{SCC} \times 10^{-3})$) belonging to 13,977 Iranian Holstein heifers calving during 2002-2006 and distributed in 183 herds was used to estimate genetic parameters. A random regression test day model was used to estimate genetic and environmental variance and covariance components. In the model, fixed environmental factors of herd-year-season of production-province, age of cow at recording, Holstein gene percentage, stage of lactation, and random direct additive genetic and environmental effects were included. Orthogonal Legendre polynomials of order four (cubic) was applied to take account of the variation of somatic cell score during the lactation course at both genetic and environmental levels. The results found in the present research showed that heritability estimates of SCS ranged from 0.03 (month 2) to 0.07 (month 10) and that the second half of the lactation curve was more heritable than the first half. Phenotypic correlations among SCC at different lactation months were generally lower than the genetic correlations. Genetic correlations among adjacent lactation months were always greater than those obtained among months apart from. The same patterns were also observed for phenotypic and environmental correlations.

Key Words: Somatic Cell Score, Test Day Model, Iranian Holsteins

T15 Genetic parameters and trend estimation for milk and fat yields and fat percentage for primiparous Holstein population of Golestan and Mazandaran provinces of Iran using a univariate animal model. H. Naeemipour*¹, H. Farhangfar¹, I. Tahmasbi², and M. Bashtani¹, ¹*Birjand University, Birjand, Iran,* ²*Zabol University, Zabol, Iran.*

The main objective of the present study was genetic analysis of milk production traits for Holstein heifers in northern provinces of Iran. A total of 7844 first lactation 305-day and 2X milk and fat yields and fat percentage records from 7844 Holstein cows distributed in 139 herd and calved between 1987 and 2003 were used to estimate variance components implementing univariate animal models using DFREML approach. In the model, fixed effect of herd-year-season of calving, age at first calving as well as random effect of additive genetic effect were included. The results obtained in this study indicated that heritabilities for milk yield, fat yield and fat percentage were 0.20, 0.09 and 0.07 respectively. Low estimates of fat yield and fat percentage shows a high environmental variance indicating that little genetic gain could be obtained as the genetic selection is based on these traits. Annual genetic trends were estimated to be 3.4, 0.05 Kg/year and 0.0003% respectively. Positive genetic gain obtained for fat percentage indicates that the average predicted breeding value of animals increased for fat percentage along with milk yield over the period of time.

T16 Genetic relationships between linear type traits, somatic cell score and longevity in Holstein cows of Iran. M.R. Bakhtiarzadeh*, M. Moradi Shahr Babak, and A. Pakdel, *University of Tehran, Tehran, Iran.*

The objective of the present study was to estimate the genetic parameters for 13 linear type traits, somatic cell score (SCS) and longevity in Holstein population of Iran. Two sets of data including 3000 records (for SCS) and 12226 observations (for longevity) for first lactation records on cows distributed across 219 and 1500 herd-year-season groups respectively were investigated. The genetic parameters were estimated by ASREML software and the fixed effects of models were included herd-year-season (in calving year), age in calving, age*age, days in milk and milk (for SCS). Heritability estimates for the type traits ranged from 0.033 to 0.29. The genetic correlation among type traits ranged from 0.01 to 0.83; among type traits and longevity ranged from 0.41 to -0.5 and among type traits and SCS ranged from 0.85 to -0.6. The genetic correlation between longevity and SCS were negative (-0.38) so that cows with more longevity had a lower SCS. The genetic correlation between body size traits and SCS were positive and between body size traits and longevity were negative. Therefore from genetic point of view we can conclude that cows with higher body size have higher SCS and lower longevity. The results of current study showed more attention should be paid to these type traits in the breeding programs for better animal welfare and to get more profit.

Key Words: Type Traits, Longevity, SCS

T17 Breed composition of the United States dairy cattle herd.

R. L. Powell*, H. D. Norman, and J. L. Hutchison, *Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Breed composition of the gene pool of all cows (purebred and crossbred) with pedigree data in the USDA national dairy database was summarized by birth year of cow. Partial breed contributions were assigned for individual cows. For cows born in 2005, 1.1% of all genes and 35.1% of genes in crossbreds traced to a female ancestor with breed reported as unknown; i.e., a dam without reported identification information. When a cow and her sire had the same reported breed but her dam's breed was unknown, the sire's breed was assigned to the dam, which decreased the percentage of unknown genes to 0.7 for all cows born in 2005 and to 6.7 for crossbreds. The percentage of the national herd that was crossbred increased from 0.4 for cows born in 1990 to 0.7 in 2000 and 1.6 in 2005. Since 2000, the proportion of genes from Brown Swiss, Jersey, Milking Shorthorn, and nontraditional US dairy breeds has increased, while the proportion from Ayrshire, Guernsey, and Holstein breeds decreased. For cows born in 2005, genetic composition was 0.4% Ayrshire, 1.0% Brown Swiss, 0.4% Guernsey, 90.8% Holstein, 6.5% Jersey, 0.2% Milking Shorthorn, 0.1% other breeds, and 0.7% unknown. Corresponding composition for crossbreds was 2.4, 9.2, 1.1, 44.0, 25.9, 9.3, 1.4, and 6.7%. The most frequent sire breed for crossbreds was Holstein until birth year 1999 and Jersey since then. Frequency of sire breeds for crossbreds born in 2005 was 42% Jersey, 27% Holstein, 13% each for Brown Swiss and Milking Shorthorn, and 5% for all other breeds. About 95% of all first-generation crossbred cows were mated to bulls of one of the crossbred's parental breeds, most frequently the sire breed. Tracing an animal's genetic background rather than relying on its coded breed provides a more complete and accurate representation of the extent of crossbreeding and changes in the genetic composition of the national dairy herd.

Key Words: Dairy Cattle Breed, Crossbred, National Dairy Herd

T18 Reproductive trends of dairy herds in the United States.

H. D. Norman, J. R. Wright, S. M. Hubbard*, M. T. Kuhn, and R. H. Miller, *Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Trends for reproductive traits were examined for U.S. Holstein and Jersey herds with records in the USDA national dairy database. Traits were days from calving to first service (DFS) and to last service, 70-d nonreturn rates (NRR) and conception rates (CR) for first through fifth services, days open, gestation length, and services per lactation for breedings from 1996 through 2005. Holstein DFS increased from 89 in 1996 to 92 in 2001 and then declined to 86 in 2005; no trend was observed for Jersey DFS. First-service NRR declined from 54 and 57% in 1996 to 46 and 52% in 2005 for Holsteins and Jerseys, respectively; first-service CR declined from 36 and 39% to 30 and 35%. As expected from the NRR decline, services per lactation increased from 2.1 in 1996 to 2.6 in 2005 for Holsteins and from 2.0 to 2.4 for Jerseys. Days to last service also increased by 16 d for both breeds. Days open increased during early years but have stabilized for both breeds. Gestation length showed no change across time for either breed. Data from 2005 breedings were examined for the same traits by parity for both breeds and by geographic region for Holsteins. Later parities (>5) were associated with longer DFS, lower first-service NRR, and increased first-service CR compared with early parities (1 and 2) for both breeds; services per lacta-

tion remained fairly constant for Holsteins and increased slightly with parity for Jerseys. For both breeds, NRR for first and second services and CR for each service through fourth declined across parities. Southwest Holsteins had the fewest DFS (73 d) and lowest first-service NRR (36%); the Mountain region had the greatest DFS (93 d) and the highest NRR (48%). Southeast Holsteins had the lowest first-service CR (23%) and the most services per lactation (3.0); the Northeast had the highest CR (31%) and the fewest services (2.6). Trends likely were impacted by producer preference for animal age for herd retention and increased use of estrous synchronization and timed artificial insemination.

Key Words: Reproductive Trend, Conception Rate, Nonreturn Rate

T19 Impact of selection for increased daughter fertility on productive life and culling for reproduction.

H. D. Norman, J. R. Wright*, and R. H. Miller, *Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Selection for increased daughter pregnancy rate (DPR) over 2 generations was examined to determine if such selection had affected cow fertility and productive life (PL). Holstein artificial-insemination bulls with a predicted transmitting ability (PTA) for DPR based on ≥ 35 daughters were grouped by quintile based on PTA DPR. Then 25 cow groups were formed based on sire and maternal grandsire (MGS) quintiles. Cows had birth dates from 1988 through 1999 and calving dates from 1990 through 2005. Cows that changed herds or had unreported lactations for their first 5 parities were excluded as were herds with <10 cows. Data were available from 4,380,300 cows in 31,759 herds. Mean cow PL was 27.0 mo; time opportunity was a restricting factor. Mean PTA DPR was 2.0 for sires and 2.1% for MGS for the cow group with highest sire and MGS quintiles and -2.1% for both sires and MGS for the group with lowest sire and MGS quintiles. Least squares difference in PL was examined on a within-herd basis with cow birth year in the model. Cows from the highest sire-MGS quintile group had 4.2 mo longer PL than those from the lowest sire-MGS quintile group and were less likely to be culled for reproductive problems (10.0 versus 13.3%) based on reported reason for record termination. Difference in PL between cow groups with highest and lowest sire quintiles for PTA DPR ranged from 2.8 to 3.3 mo; corresponding difference for MGS quintiles ranged from 0.8 to 1.4 mo. Because each month of additional PTA PL is valued at \$29 in the current USDA lifetime net merit index, a 200-cow herd from the highest sire-MGS group for PTA DPR would be worth about \$7,500 more annually than a 200-cow herd from the lowest sire-MGS group without considering any additional income or expense associated directly with DPR. Selection for increased DPR across generations is expected to produce cows with longer herd life because they are less likely to be culled for reproductive problems.

Key Words: Daughter Pregnancy Rate, Productive Life, Fertility

T20 Modeling nuisance variables for phenotypic evaluation of bull fertility.

M. T. Kuhn*, J. L. Hutchison, and H. D. Norman, *USDA-ARS-AIPL, Beltsville, MD.*

This research determined which (available) nuisance variables should be included in a model for phenotypic evaluation of US service sire conception rate (CR), based on DHI data. Models were compared by

splitting data into records for estimation (n=3,613,907) and set-aside data (n=2,025,884), computing predictions using the estimation data, and then comparing predictions to bulls' average CR in set-aside data. There were 803 bulls used for comparison, after requiring a minimum of 50 records for estimation and 100 breedings in at least 30 herds in set-aside data. Correlations and mean differences were used to compare models. Nuisance variables considered were management groups based on herd-yr-season-parity-registry (HYSPR) classes, yr-state-mo, cow age, DIM, a short-cycle variable to account for lower CR for matings preceded by a breeding only 10 to 17 days prior, and various combinations of lactation, service number, and milk yield. Preliminary analysis led to selection of 305d-2x-ME milk yield as the production variable for consideration, and also showed that for each quantitative independent variable, categorical factors provided better bull fertility evaluations than modeling the effects as covariates. Two strategies for management groups were tested, one where HYSPR groups were required to have an absolute minimum number of records and a second where groups were combined across registry, season, and parity subclasses until a minimum group size was achieved. Combining groups to a target size of 20 but still including herd-years with at least 10 breedings maximized correlation with CR in set-aside data. Combining groups implies that some groups have multiple seasons and parities, hence consideration of yr-state-mo and lactation as additional factors. The final variables selected for inclusion were, in addition to HYSPR, yr-state-mo, lactation, service number, milk yield, cow age, short-cycle (yes/no), and the cow effect, partitioned as permanent environment and breeding value. This model maximized correlation with CR in set-aside (55.2%), minimized mean square error (3.25), and mean difference was 0.

Key Words: Bull Fertility

T21 Factors that affect abortion frequency in dairy herds in the United States. R. H. Miller*, M. T. Kuhn, H. D. Norman, and J. R. Wright, *Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Frequency of abortions was studied for lactating cows with 2,980,527 records in the USDA national dairy database. Lactations had been terminated between 1995 and 2005, and cows had been >151 d pregnant at lactation termination. Records without breeding dates were excluded. Abortion frequency for 2005 was 1.6%. Analyses were conducted with PROC GLM to determine effects of herd, year, month, parity (1, 2, ..., 7, ≥8), and gestation stage (152 to 181 d, 182 to 211 d, 212 to 241 d, and ≥242 d pregnant) at lactation termination as well as effects of breed (Holstein, Jersey, and other breeds including crossbreds) and 305-d standardized milk yield. Supplemental analysis examined effects of herd size (50 to 99, 100 to 199, ..., 900 to 999, ≥1,000 cow-years) and location (state). Abortions were most frequent in July and least frequent in December (difference of 0.38%). Abortion frequency decreased from parity 1 to parities ≥8 (difference of 0.52%). Gestation stage had the greatest impact on abortion frequency. Abortions were most frequent at 152 to 181 d pregnant, and trend in abortion frequency was nonlinear across gestation stage. Compared with ≥242 d pregnant, abortion frequency was 3.14% higher at 152 to 181 d pregnant and 1.07% lower at 212 to 241 d pregnant. Abortions for Holsteins and Jerseys occurred more frequently (0.38 and 0.07%, respectively) than for other breeds. Regression of abortion frequency on lactation milk yield was 0.26%, 0.26%, and 0.19% per 1,000 kg of milk for Holsteins, Jerseys, and other breeds, respectively. Regression differences primarily reflect breed differences. Abortion frequency was 0.95% higher for herds with 700 to

799 cow-years than for herds with 50 to 99 cow-years. California herds had the highest abortion frequency (2.18% higher than North Dakota, the state with the lowest frequency). Increased knowledge of factors that affect abortion frequency can aid in the development of management practices for reducing the incidence of abortion, e.g., more intense monitoring of cows 2 to 6 wk after mid-gestation.

Key Words: Abortion Frequency, Gestation Stage, Lactation Termination

T22 Heritability of dairy cow mortality and relationships between mortality and sire genetic evaluations for yield, somatic cell score, productive life and daughter pregnancy rate. G. W. Rogers*¹, J. B. Cooper¹, and J. S. Clay², ¹*The University of Tennessee, Knoxville,* ²*Dairy Records Management Systems, Raleigh, NC.*

Lactation records from 1239 Holstein herds in 9 Southeastern states processed by DRMS were utilized to estimate heritability of dairy cow mortality and the relationships between mortality and sire genetic evaluations for milk, fat, protein, SCS, productive life (PL) and daughter pregnancy rate (DPR). Herds were required to have a minimum of 10 years of continuous recording between 1982 and 2005. Binary mortality traits (1=CAR code 6 indicating lactation ending in death vs. 0=all other CAR codes) were developed separately for lactations 1, 2 and 3 or later (3+). To estimate heritability, binary traits were analyzed using a logistic model where the model included sire (random), herd, year of calving, season of calving and age at calving. Number of cows (sires) ranged from 280,000 (1090) to 614,000 (1913). In addition, the binary mortality traits were analyzed using logistic regression with sire replaced by sire PTA (one trait per analysis). Sire PTA were categorized into quartiles and odds ratios for each quartile compared with quartile 4 were determined. Heritability for mortality on the underlying scale was low and ranged from .03 to .04. Odds ratios indicated that mortality tended to be lower for cows sired by bulls with lower PTA milk, protein and SCS, especially in lactations 3+. Odds ratios for fat percent were not consistent across lactations, but higher sire PTA for fat percent were favorable for mortality in lactation 2 and lactations 3+. Odds ratios for PL and DPR indicated that mortality was significantly higher for cows sired by bulls with lower PTA PL and DPR. Daughters of sires with PTA for PL or DPR in the lowest quartile were 22 to 31% more likely to end the lactation with death compared with daughters of sires in highest quartile. Selection for increased milk yield may have increased cow mortality but intense selection for increased PL and DPR will likely reduce cow mortality in the future.

Key Words: Dairy Cow Mortality, Heritability, Daughter Pregnancy Rate (DPR)

T23 Lactation patterns for dairy cattle in a multibreed dairy population in Central Thailand. A. Seangjun¹, S. Koonawootrittriron¹, and M. A. Elzo*², ¹*Kasetsart University, Bangkok, Thailand,* ²*University of Florida, Gainesville.*

Milk production in Thailand is based on a dairy population composed of Holstein (H) and fractions of various other *Bos taurus* and *Bos indicus* breeds (O). This population structure is the result of a national effort encouraged by the Thai government to increase milk production. Genetic

evaluations have been conducted by Kasetsart University and the Dairy Promotion Organization for milk yield, fat yield, and fat percentage since 1996. To further improve management and the ability to select animals under Thai tropical conditions, a more complete understanding of lactation characteristics is needed. The objective of this research was to study the lactation patterns of 5 lactation traits: initial yield (IY), peak yield (PY), days to peak (DTP), persistency (PST), and 305-d milk yield (MY) in 5 breed groups in a Holstein-Other breeds (HO) multibreed population in Central Thailand. The dataset included 5,713 monthly test-day records from 520 dairy cows raised in 108 farms from 1998 to 2006. Breeds groups were BG1 (purebred H), BG2 ($0.9687 \leq H < 1.00$), BG3 ($0.9375 \leq H < 0.9687$), BG4 ($0.875 \leq H < 0.9375$), and BG5 ($0.50 \leq H < 0.875$). Seasons were 1 = winter (November to February), 2 = summer (March to June), and 3 = rainy (July to October). The model for each trait included the fixed effects of herd-year-season, calving age, and breed group. Random effects were sire of cow and residual. Procedure Mixed of SAS was used for computations. Least squares means ranged from 14.16 ± 0.71 kg (BG5) to 16.04 ± 0.66 kg (BG4) for IY, from 18.23 ± 0.55 kg (BG5) to 19.84 ± 0.51 kg (BG4) for PY, from 36.51 ± 3.78 d (BG4) to 52.04 ± 9.74 d (BG1) for DTP, from 6.45 ± 0.24 (BG1) to 6.71 ± 0.11 (BG3) for PST, and from $4,083.74 \pm 103.50$ kg (BG5) to $4,317.15 \pm 111.56$ kg (BG3) for MY. Breed group differences were non-significant. However, BG3 performed better than BG1 and BG2 suggesting that nutrition, management, and tropical conditions in Thailand may have prevented them from reaching their production potential.

Key Words: Lactation, Multibreed, Tropical

T24 Relationships between reproductive traits of heifers and cows and yield traits for Holsteins in Japan. H. Abe*, Y. Masuda, and M. Suzuki, *Obihiro University of A & VM., Obihiro, Japan.*

The objective of this study was to investigate relationships between reproductive traits in heifers and cows and yield traits for Holsteins in Japan. Insemination and lactation records for cows calved between 1990 and 2003 in Hokkaido were obtained from Hokkaido Dairy Milk Recording and Testing Association. Age at conception (AC) and first service conception rates (CR) were calculated for heifers. Days open (DO) and CR were calculated for cows in first and second parities. The yield traits used were 305-d milk, fat and protein yields. A threshold animal model was applied for CR, and a linear animal model was applied for the other traits. For heifers, the model included herd-year and month of the first insemination as fixed effects. For cows, the model included herd-year of calving, month of calving, and age class of calving as fixed effects. Both models included the random animal additive genetic effect. The numbers of records were around 260,000, 780,000 and 640,000 for heifers, first parity, and second parity cows, respectively. Subsets of records were extracted for the two traits by the random sampling of herds, and genetic parameters were estimated either by the AI-REML method or the Bayesian method using Gibbs sampling. Heritability estimates were 13%, 2% for AC and CR in heifers, 3% for CR in cows, 6% and 4% for DO in first and second parities. Genetic correlations between AC and DO in first and second parities were 0.29 and 0.09, respectively. Genetic correlations among CR ranged from 0.33 to 0.93. Genetic correlations of yield traits with AC and CR in heifers ranged from 0.19 to 0.37, and -0.06 to 0.12, respectively. Genetic correlations between yield and reproductive traits in cows were antagonistic. As a result, reproductive traits in heifers and cows should be considered as separate traits. The relationship between yield and reproductive traits

in heifers was slightly preferable, suggesting that genetic selection of reproductive traits could be performed for heifers in Japan.

T25 Genetic aspects of the somatic cells count in dairy buffaloes reared in Sao Paulo state, Brazil. H. Tonhati*^{1,2}, G. M. Sanches¹, M. F. Ceron Munoz¹, L. G. de Albuquerque^{1,2}, R. R. A. B. Borquis^{1,3}, R. Sesana^{1,3}, and L. El Faro¹, ¹Sao Paulo University, Jaboticabal, Sao Paulo, Brazil, ²Conselho Nacional de Desenvolvimento Cientifico e Tecnologico, Brasilia, DF, Brazil, ³Fundacao de Amparo a Pesquisa do Estado de Sao Paulo, Sao Paulo, Brazil.

The goal of this work was to study the relationship between somatic cell count (SCC) and milk yield (MY). Were analyzed 9404 test-day records for SCC and MY obtained from 2198 lactations of 1052 Murrah buffaloes between 1997 and 2005. To quantify the decreases of MY in relation to SCC, the model included a random animal effect and the fixed effects of farm, calving order, year and season of calving and Somatic Cell Score (SCS) as covariate. For estimating genetic parameters, test day models were used for SCC transformed in SCSt ($SCSt = [\log_2(SCC/1000000)]+3$). For average of somatic cells count in the lactation (SCCt270) and milk yield to 270 days (MY270) the (co) variance components were estimated. SCC of every month of lactation were considered as different traits. The model included additive genetic, permanent environmental (for SCCt270 and for MY270) and residual random effects. Other fixed effects were: contemporary group; test-day and age of cow at calving as a covariate (linear and quadratic effects). For SCSt, contemporary groups were defined as herds-year-month of the control, and for SCCt270 and MY270 as herd-year-season of the calving. It was found that all effect influenced the expression of SCSt. For first parity females, there no relation between MY and SCC was found. The largest decreases of milk production were observed in female with more than one calving. This category should receive a special attention in relation to udder health. The farm, year and calving order effects should be considered in the comparison among animals for genetic evaluations. Heritability estimates obtained from single trait analyses ranged, among the months, from 0.06 to 0.50 for SCSt and 0.28 for SCCt270. Heritability estimates in double trait analyses oscillated between 0.65 and 0.28 for SCSt and up 0.66 for SCCt270. All correlations between SCSt and SCCt270 were positive, ranging from 0.50 to 0.91 (genetic) and from 0.59 to 0.82 (phenotypic). The genetic correlations between SCSt and MY270 ranged from 0.52 to 0.10 and the phenotypic correlation ranged from 0.37 to 0.0. The genetic correlation between SCCt270 and MY270 was 0.11 and the phenotypic correlation was 0.15.

Key Words: Genetic Evaluation, Variance Components, Longitudinal Data

T26 Computing options for multiple-trait test-day random-regression models. I. Aguilar*^{1,2}, S. Tsuruta¹, and I. Misztal¹, ¹University of Georgia, Athens, GA, ²Instituto Nacional de Investigación Agropecuaria, Las Brujas, Uruguay.

Data included 90,242,799 test day records from 5,402,484 Holstein cows in 3 parities. The total number of animals in the pedigree file was

9,326,754. Additionally, daily temperature humidity indexes (THI) from 202 weather stations were available. The effects of herd test day, age at calving, milking frequency and days in milk classes (DIM) were made fixed, and the effects of additive, permanent environment and herd-year were made random. Random effects were fit as random regression. Covariates included linear splines with four knots at 5, 50, 200, 305 DIM, and a function of THI of the 3rd day before the test day from a weather station closest to the farm. The first three lactations were used as separate traits, resulting in 15 by 15 (co)variance matrices for each random effect. The mixed model equations were solved using an iteration on data program with a preconditioned conjugate gradient (PCG) algorithm. Several preconditioners were used: diagonal (D), block diagonal due to traits (BT), and block diagonal due to traits and correlated effects (BTCORR). One run included BT with a "diagonalized" model in which the random effects were reparameterized for diagonal (co)variance matrices among traits (BTDIAG). Memory requirements were 8.7 Gbytes for D, 10.4 Gbytes for BT and BTDIAG, and 24.3 Gbytes for BTCORR. Computing times (rounds) were 14 d (952) for D, 10.7 d (706) for BT, 7.7 d (494) for BTDIAG and 4.6 d (289) for BTCORR. The convergence criterion for BTCORR showed high fluctuation that required either a moving average or a strict stopping criterion. The convergence pattern was strongly influenced by the choice of fixed effects. When sufficient memory is available, the option BTCORR is the fastest and simplest to implement; the next efficient method, BTDIAG, requires additional steps to diagonalization and back-diagonalization.

T27 One predominant and preeminent common ancestor in Bell family. R. D. Shanks* and K. Boesche, *University of Illinois, Urbana*.

Purpose was to improve interpretation of inbreeding. As a means to increase interpretation, inbreeding was partitioned relative to the common ancestor that was the source of the inbreeding. To focus pedigrees, the family of Carlin-M Ivanhoe Bell (Bell) was used as a test sample. Forty sons with high inbreeding coefficients and nine grandsons of Bell were evaluated for their source of inbreeding. All but one evaluated son and all evaluated grandsons of Bell had the opportunity to share alleles identical by descent from Osborndale Ivanhoe (Ivanhoe). Ivanhoe was the grandsire of Bell. For twenty-one of the inbred sons, Ivanhoe was the only common ancestor as the source of inbreeding. Ivanhoe as a source of inbreeding was responsible for inbreeding ranging from .4% to 3.1% for the sons and from .2% to .4% for the grandsons. Additionally, Penstate Ivanhoe Star, a son of Ivanhoe, was a common ancestor for eight inbred sons of Bell. Penstate Ivanhoe Star was responsible for inbreeding of 6.25% or 3.125%. On the maternal side of the pedigrees, Ivanhoe was found within 3 to 6 generations of the sons and 5 or 6 generations for the grandsons. More diversity existed among the grandsons of Bell as only 2 grandsons had all of their inbreeding from Ivanhoe as the common ancestor. Inbreeding of the sample of sons ranged from .4% to 7.8%. Inbreeding of the nine grandsons ranged from .2% to 2.6%. Osborndale Ivanhoe was an Excellent bull and a legend in dairy cattle genetics. In 1992, 40 years after his birth, he was still related to more than 5% of the Holstein population. The vast majority of inbreeding within the Bell family has Ivanhoe as the source. Although the purpose of this study was to improve interpretation of inbreeding, results of the study were that the number of common ancestors was extremely limited. Inbreeding depression would be a function of the alleles available in the common ancestor. If few, but different, common ancestors would be

found in other sire families, the need to determine inbreeding depression within family may be warranted.

Key Words: Inbreeding, Holstein, Common Ancestors

T28 Heritability of genetic tolerance to Johne's disease. R. Zanella*¹, M. Settles¹, T. Fyock², R. Whitlock², Y. Schukken³, J. Van Kessel⁵, J. Karns⁵, E. Hoving⁴, J. Smith⁶, C. Van Tassel⁵, C. Gaskins¹, and H. Neibergs¹, ¹Washington State University, Pullman, ²University of Pennsylvania, Kennett Square, ³Cornell University, Ithaca, NY, ⁴Penn State University, University Park, ⁵USDA, ARS, Beltsville, MD, ⁶University of Vermont, Burlington, VT.

Johne's disease, also known as paratuberculosis, is a prevalent and economically important disease in cattle caused by bacterial infection of *Mycobacterium avium* subsp. *paratuberculosis*(MAP). Johne's disease often results in weight loss, lowered milk production, and death. MAP is excreted in feces and milk of infected animals which helps propagate the disease. Infection generally occurs in neo-natal calves, but clinical disease and detection are often delayed for 2 to up to 6 years, prolonging the exposure of the herd to MAP. Disease prevalence is estimated to be present in 75% of US dairy herds and is increasing. Current vaccination and treatments are ineffective and diagnostic methods detect less than 25% of infected animals, at one time. Cattle exposed to MAP may have three distinct responses: failure to develop disease (resistant animals), disease with little fecal shedding of MAP (tolerant), or disease with significant fecal shedding (intolerant-susceptible animals). The objective of this study was to determine the heritability of genetic tolerance to Johne's disease in 4 Holstein dairy herds. Genetic tolerance was determined by sequential diagnostic testing of 260 animals every 3-6 months followed by post mortem tissue examination. This testing regime represents the gold standard for Johne's diagnosis. MAP testing was conducted on a minimum of 4 tissue samples per animal. Comparison of fecal and tissue testing results was used to determine if cows were classified as resistant, tolerant or intolerant-susceptible. Heritability was calculated using an animal method. Selection of animals with genetic tolerance to Johne's would be advantageous by lowering infection pressure and extending the period between infection and clinical symptoms.

Key Words: Johne's Disease, Heritability, Tolerance

T29 Detection of polymorphism in bovine polymeric immunoglobulin receptor gene promoter region and association with milk IgA and IgM concentration. C. G. Zhang^{1,2}, J. Q. Wang*¹, D. P. Bu¹, G. L. Liu¹, J. B. Cheng¹, X. L. Dong^{1,2}, H. Y. Wei¹, L. Y. Zhou¹, G. Q. Zhao², and K. L. Liu¹, ¹State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, ²Yangzhou University, Yangzhou, China.

The polymeric immunoglobulin receptor (pIgR) transports dimeric immunoglobulin A (dIgA) and tetramer IgM across the epithelial cell layers into the secretions of mammary gland. The object of this study was to detect bovine pIgR gene promoter polymorphism and its association with milk IgA and IgM concentration. Blood and milk samples (n = 189) from each cow were collected randomly from more than 1,600 animals in Beijing. Determination of IgA and IgM in milk samples were performed by a commercial sandwich enzyme-linked immunosorbent assay (ELISA) using the Bovine IgA and IgM ELISA Quantitation Kit.

SNPs were found by 25 dairy cows' blood genome DNA samples by PCR amplifying and sequencing. The SNPstream system (Beckman Coulter, USA) was used for genotyping for 189 individuals. The results indicated that SNP1 (-3128) and SNP2 (-3072) were the G/A variation and SNP3 (-2834), SNP4 (-2348) and SNP5 (-515) were the T/C variation. Seven haplotype block and ten main diplotypes were inferred by phase 2.1. Statistical analysis indicated that diplotypes had no effect on milk IgA and IgM concentration ($P > 0.05$). Duncan's multiple-range test showed the least square mean for milk IgA concentration (mg/ml) of diplotypes H1H1 (0.323 ± 0.042), H1H5 (0.421 ± 0.106) and H3H6 (0.486 ± 0.128) was significantly higher than those of H4H4 (0.206 ± 0.041) and H5H6 (0.051 ± 0.128) diplotypes ($P < 0.05$), whereas other diplotypes had no significant differences on the least square mean for milk IgA and IgM concentration ($P > 0.05$). Therefore, our findings implied that pIgR gene promoter SNPs had effect on milk IgA and IgM concentration.

T30 Effect of marker-assisted preselection in Japanese dairy population. H. Ohmiya* and M. Suzuki, *Obihiro University of Agriculture & Veterinary Medicine, Obihiro, Hokkaido, Japan.*

The utility of the "modified bottom-up" approach to marker-assisted selections in a conventional progeny test scheme was examined on dairy breeding in Japan. In this scheme, genotyping the daughters to decide the genotypes for the quantitative trait locus (QTL) of their sires was not needed as in a usual bottom-up approach, which is the preselection scheme that uses marker information before a traditional progeny test. Because the cows are not tested for markers to be closely linked to a QTL in Japan, the development of selection schemes without genotyping the daughters for markers may benefit the Japanese dairy population. By computing the differences between the deviations of the breeding values and the genetic variance (G) in a population, it can be decided whether their sire is homozygous for locus controlling milk product. If the sires were identified as homozygous with allelic contrast smaller than G, the mean breeding value of the daughters from a sire is more favorable than that in a population used for generating candidate young bulls. Stochastic simulations of dairy population structures, methods of evaluation, and parameters similar to Japanese dairy population were used to evaluate each rate of the additional genetic gains of a traditional scheme using only progeny testing and BLUP with an animal model, a conventional bottom-up approach, and the modified bottom-up approach suggested in this study. These simulations under the 2 QTLs and 40 polygenes each with 4 alleles were replicated 20 times. It was found that these rates were increased by an average of 11.5% and 5% compared with a traditional progeny test scheme when conventional bottom-up and modified bottom-up approaches were used. Additionally, with the modified bottom-up approach, the dairy population improved more with only progeny testing but less than with the conventional bottom-up approach. When only dairy bulls are genotyped in Japan, this approach would be effective.

Key Words: Marker-Assisted Selection, QTL, Bottom-Up Approach

T31 Optimized measured genotype analysis for genome-wide quantitative trait loci mapping using dense SNP chips. J. R. O'Connell*, *University of Maryland School of Medicine.*

The availability of low cost, dense fixed content single nucleotide polymorphism (SNP) chips has changed the landscape of genetics. These chips provide sufficient density for linkage disequilibrium mapping to localize alleles that increase susceptibility to disease, determine variation of quantitative phenotypes or predict genetic merit for economically important traits.

A standard quantitative trait analysis for genome-wide SNP analysis is the mixed model measured genotype approach, which treats the genotype as a measured covariate while controlling for residual familial correlation through a polygenic component. The model easily incorporates dominant, recessive or additive models of single SNPs and joint, conditional or interaction analysis of multiple SNPs and genomic prediction using estimated regression parameters. Mixed model maximum likelihood estimation, however, is computationally challenging due to dense matrix operations required for a single analysis, making genome-wide analysis often infeasible. A computationally efficient approach is presented based on the diagonalization of the covariance-variance structure that replaces operations on dense matrices with diagonal matrices in the maximization.

A genome-wide association analysis of yield and conformation traits measured on 2602 Holstein bulls using the BovineSNP50 chip was performed to evaluate and validate the method. In total 38,000 SNPs with a minor allele frequency > 0.02 were analyzed using an additive model. As expected a SNP located at ~300kb on chromosome 14 near DGAT provided the most significant association for milk yield with a p -value $< 10e-41$. In addition a cluster of SNPs located around 50Mb on chromosome 15 reached genome-wide significance with p -values $< 10e-09$.

Key Words: Pedigree Analysis, Genomic Selection

T32 Effect of varying degree of relatedness in family designs on estimation of IBD probability and other parameters in QTL mapping based on variance component analysis. G. Freyer² and N. Vukasinovic*¹, ¹Newsham Choice Genetics, Saint Louis, MO, ²Research Institute for the Biology of Farm Animals, Dummerstorf, Germany.

In variance component approach the QTL effect is modeled as a function of probabilities that two alleles in the same or in different animals at a particular genomic position are identical by descent (IBD probabilities). Estimates of IBD probabilities and therefore, proper modeling and estimation of QTL variances depend on the number and informativeness of markers, the strength of linkage and linkage disequilibrium of markers and QTL, and the relatedness of animals in the pedigree. In this simulation study we investigate how the level of relatedness of animals in a pedigree influences IBD probabilities, their correlations to the IBD probability at the true QTL-position, and the quality of test statistic profiles. Four multi-generational pedigrees (FS) resembling real dairy populations were simulated. All pedigrees comprised 850 individuals. The final offspring of 9 sires originated from 2 founder (great-grand) sires. FS0 was non-inbred; FS1 contained an inbred sire from an aunt-nephew mating; FS2 contained a 25% inbred sire from a half-sib mating. In both pedigrees, the inbred sires had 78 final offspring each. FS3 was the same as FS2, except for increasing the number of offspring of the

inbred sire to 138. FS4 contained a sire originating from a mother by (inbred) son mating with 73 offspring. This design was used to demonstrate how extreme levels of inbreeding affect QTL mapping. Animals were assumed genotyped for 11 markers within a 55cM long putative QTL region, with one QTL explaining 15% of the phenotypic variance. The number of alleles was 2, 4, or 6, at unevenly spaced markers. Twenty replicates were run for each parameter combination. IBD probabilities for each cM in the segment were calculated using the nearest informative marker bracket. Estimation of QTL parameters was performed using maximum likelihood approach within the ASReml software. The results indicated that the existence of inbred animals in a pedigree may lead to more precise estimates of IBD probabilities and QTL parameters that are less sensitive to variations in simulation parameters.

Key Words: QTL Mapping, Inbreeding, Variance Components

T33 Spermatozoal transcriptome profile as marker for bull fertility and sperm motility: A potential tool to evaluate semen quality. N. Bissonnette^{*1,2}, J.-P. Lévesque-Sergerie^{1,2}, and G. Boissonneault², ¹*Agriculture and Agri-Food Canada, Sherbrooke, Québec, Canada*, ²*University of Sherbrooke, Sherbrooke, Québec, Canada*.

Fertility represents significant costs to the dairy industry and is still a major concern for dairy producers. Efforts are made to evaluate bull fertility in order to offer semen of the highest quality value. In a previous study, we had analyzed the sperm transcript content and found that bulls with different non-return rate, a measure of field fertility, contain a different profile (Lalancette et al. 2007, *Biology of Reproduction*, in press). This transcript panel comprising 3216 EST has been used to construct a microarray by automated spotting. Since motility is a prerequisite of high quality semen, we verified if spermatozoa collected from fresh semen and presenting different motility indexes could also display different transcriptome profiles. The transcript content of fresh spermatozoa isolated at the bottom fraction 90% (highly motile) of a Percoll step gradient was compared by microarray hybridization to the transcript extracted from the spermatozoa harvested at the 70%–90% interface (less motile). Spermatozoa derived from the same ejaculated bull semen, but displaying subtle yet different motility, contain different transcript abundance ($p < 0.001$). Among the genes of which expression was confirmed by real-time PCR, we validated some well-known transcript, notably that of protamine 1, whose encoded proteins are architectural and required for an adequate genome packaging. Uncharacterized gene such as a gene encoding a protein similar to human metalloproteinase was among the differentially expressed genes. Interestingly, expression of this candidate was predicted in December 2006 by automated computational analysis and was found and for which no bovine ortholog sequence has yet been reported. Analyzing the spermatozoal transcriptome would not only be helpful in determining bull fertility but could also be used in a semen quality analysis. Whereas this specialized cell has long been considered a vehicle that contains only a half-genome, it also contains remnant transcripts of spermatogenesis, whose profile can be used as a signature for semen quality.

Key Words: Fertility, Sperm Quality, Genetic Marker

T34 Molecular characterization of the bovine DDX3Y gene. W.-S. Liu^{*1}, A. Wang², Y. Yang¹, E. Landrito³, and H. Yasue⁴, ¹*The Pennsylvania State University, University Park*, ²*Virginia Polytechnic Institute and State University, Blacksburg*, ³*University of Nevada, Reno, NV*, ⁴*National Institute of Agrobiological Sciences, Tsukuba, Ibaraki, Japan*.

The DEAD box polypeptide 3, Y-linked gene (DDX3Y, also known as DBY, DEAD box gene on the Y) encodes a putative ATP-dependent RNA helicase. This gene belongs to the DEAD box protein family, characterized by the conserved motif Asp-Glu-Ala-Asp (DEAD). In the human, DDX3Y is located in the AZFa (azoospermia factor a) interval in the non-recombining region of the Y chromosome. Deletion of the AZFa region has been showed to disrupt spermatogenesis, causing subfertility and infertility in otherwise healthy men. We have characterized the bovine DDX3Y (bDDX3Y) gene. We found two transcripts for bDDX3Y, bDDX3Y-L and bDDX3Y-S, which correspond to the long and short transcripts of the human DDX3Y and mouse Ddx3y gene. The two bDDX3Y transcripts are identical except for a three-base-pair (AGT) insertion in the position of nt 2027 and an expanded 3'UTR (nt 2155-2790) in bDDX3Y-L. The bDDX3Y-S encodes a peptide of 660 amino acids (aa), while the bDDX3Y-L encodes a peptide of 661 aa as a result of the insertion of a serine (S) in the position of aa 634 in the bDDX3Y-L peptide. Both bDDX3Y isoforms contain the conserved motifs of DEAD-box RNA helicases. Expression analysis of the bDDX3Y gene in 12 bovine tissues by RT-PCR showed that both transcripts are predominantly expressed in the bovine testis. This project was supported by grants from USDA-CSREES-NRI to WSL (No. 2005-35205-15455 and No. No. 2005-35205-18653).

Key Words: DDX3Y Gene, Y Chromosome, Bovine

T35 A gene frequency model to map QTL using bayesian inference. W. He^{*1}, R. L. Fernando¹, J. C. M. Dekkers¹, and D. Gianola², ¹*Iowa State University, Ames*, ²*University of Wisconsin, Madison*.

Information for mapping of quantitative trait loci (QTL) comes from two sources: linkage disequilibrium (non-random association of allele states) and cosegregation (non-random association of allele origin). Information from LD can be captured by modeling conditional means and variances at the QTL given marker information. Similarly, information from cosegregation can be captured by modeling conditional covariances. Here, we consider a model where both conditional means and variances are modeled as a function of the conditional gene frequencies at the QTL. The parameters in this model include these gene frequencies, additive effect of the QTL, its location, and the residual variance. Bayesian methodology was used to estimate these parameters. The priors used were: logit-normal for gene frequencies, normal for the additive effect, uniform for location, and inverse chi-square for the residual variance. Computer simulation was used to compare the power to detect and accuracy to map QTL by this method with least squares using a regression model (LSR). LD was simulated in a chromosomal segment of 1cM with one QTL by random mating for 1000 generations in a population of size 500 and for 50 generations in a population of size 100. The comparison was studied under a range of conditions, which included SNP density of 0.1, 0.05 or 0.02 cM, sample size of 500 or

1000, and phenotypic variance explained by QTL of 2 or 5%. Both 1 and 2-SNP models were considered. Power of LSR ranged from 0.66 to 1.0, and was always higher than power of the Bayesian method (BM), which ranged from 0.56 to 1.0. The accuracy of BM to map QTL position, quantified by the root mean squared error, ranged from 0.107 to 0.189 cM, and was always better than the accuracy of LSR, which ranged from 0.134 to 0.260 cM. Results support that given a high SNP density, the gene frequency model can be used to map QTL with considerable accuracy even within a 1 cM region.

T36 The study of gene delivery system in avian species using human adenoviral vector. D. R. Bae*, J. H. Shin, J. M. Reddish, J. D. Latschaw, M. P. Wick, and K. Lee, *The Ohio State University, Columbus.*

Adenovirus has been used in vivo and in vitro as a vector to carry a foreign gene for gene transfer. Several adenoviral vectors have been widely used to transfect a target gene into various cell types and tissues of various animal origins for studying gene function and also clinical application. However, the feasibility of the human recombinant adenoviral vectors system has not been evaluated in avian species. The objective of the present study was to evaluate this system in poultry. The primary muscle cells obtained from chicken, turkey, and quail were cultured and infected with recombinant adenovirus. Over 50% of chicken and turkey cells were infected by adenovirus containing green fluorescence protein (GFP) gene with less infection efficiency in quail. These cells were further tested with recombinant adenovirus containing GFP gene as a tracking marker and 3-hydroxyisobutryl-CoA hydrolase (HIBCH) gene as a target gene. Immunofluorescence analysis revealed that cells infected with adenovirus expressed both GFP and HIBCH protein, showing a successful tracking of the target gene by GFP expression. In addition, our western blot analysis showed that the expression of HIBCH protein in cultured primary muscle cells infected with the recombinant adenovirus. These data demonstrate the feasibility of using human recombinant adenoviral vectors as a tool to express foreign genes in the muscle cells of avian species. Depending

on the target gene, the adenoviral vector system will provide a new approach to study the role of target genes in muscle development and metabolism in avian species.

T37 The use of machine learning techniques for analysis of high-dimension gene expression data sets. K. R. Robbins, W. Zhang, J. K. Bertrand, and R. Rekaya*, *University of Georgia, Athens.*

The analysis of microarray data has become common place in the field of animal science; however, due to the high dimensions and complex structure of many expression data sets, traditional statistical models may be inadequate for the analysis of such data. To address issues associated with commonly used methods for the identification of predictive genes sets, the ant colony algorithm (ACA) is proposed for use on data sets with large numbers of features and complex structures. The ACA is an optimization algorithm capable of modeling complex data structures without the need for explicit parameterization. The incorporation of prior information and communication between simulated ants allows the ACA to search the sample space more efficiently than other optimization methods. When applied to simulated data, as well as, a high-dimensional cancer microarray data set, the ACA was able to identify small subsets of highly predictive and biologically relevant genes without the need for simplifying assumptions. For simulated data, genes selected by the ACA to train a latent variable model yielded increases in prediction accuracy of 24.4%, 6.7%, and 10.3% when compared to genes sets selected by fold change (FC), t-test (T) and penalized t-test (PT), respectively. For the cancer data set, the ACA yielded increases in accuracy of 16.6% and 6.5% over the best performing test statistics and other optimization models. Furthermore, the ACA was able to converge to good solutions without the need for significant truncation of the data, as required by other optimization algorithms. The ACA was also able to achieve higher prediction accuracies using fewer selected genes when compared the test statistics. This was attributed to ability of ACA to model the complex gene interactions, reducing the collinearity in selected genes when compared with FC, T and PT.

Key Words: Ant Colony Algorithm, Machine Learning, Gene Expression

T38 Sensory and microbiological properties of cheddar cheese made with different fat content. M. A. Drake¹, C. J. Brighton², D. J. McMahon², and J. R. Broadbent^{*2}, ¹North Carolina State University, Raleigh, ²Utah State University, Logan.

Production of high quality lowfat (<6% fat) Cheddar cheese is a current industry goal in the U.S., but critical information of how fat reduction, and corresponding compositional changes in lowfat cheese such as lower salt-in-moisture content, influences sensory and microbiological properties is lacking. Specific knowledge of how fat reduction influences these properties could lead to identification of methods to enhance or minimize formation of specific flavors. Our objective was to characterize sensory and microbiological differences in Cheddar cheeses containing 32 (full), 16 (reduced), or 5 % (lowfat) fat (wet wt). Cheeses were manufactured in duplicate with a single-strain *Lactococcus lactis* starter culture and ripened at 8°C. After 2 wks, 3 mo, 6 mo and 9 mo, the cheeses were evaluated by a trained sensory panel using an established flavor language and sampled for starter and nonstarter lactic acid bacteria (NSLAB). Sensory results were evaluated by univariate and multivariate analyses to document the influence of fat reduction and ripening time on flavor. Cheeses with 5 % fat were characterized by a lack of milkfat flavor across ripening. Additionally, these cheeses lacked sulfur and brothy flavor development after 6 and 9 mo ripening compared to reduced and full fat cheeses and were instead distinguished by whey flavor and burnt flavors. Microbiological data also showed some interesting trends. First, starter populations remained stable out to 3 mo in lowfat and reduced fat cheeses before showing any decline, but in full fat cheese generally declined by at least 2 orders of magnitude by 3 mo. Additionally, NSLAB levels in low fat cheese exceeded 10⁶ by 6 wks, but populations in reduced or full fat cheese did not attain that level even after 6 mo. These results provide greater insight into the problems, and potential solutions, related to manufacture of high-quality lowfat Cheddar cheese.

Key Words: Lowfat Cheese, Cheese Flavor, Cheese Microbiology

T39 Comparison of Hispanic cheeses from US and country of origin manufacturers. L. A. Jiménez-Maroto*, A. López-Hernández, and S. A. Rankin, *University of Wisconsin, Madison*.

US-made Hispanic cheeses are routinely criticized by ethnic consumers for a lack of authenticity when compared to cheeses manufactured in the countries of origin. In order to authenticate and characterize such deficiencies several assessments were conducted including microbial testing, sensory profiles, chemical composition, and functional character. Commercial samples of three different types of Hispanic cheeses (fresh, pasta filata, aged) were acquired from domestic (n=44) and country of origin (n=40) manufacturers. Proximate analysis of the cheeses was conducted using standard methods. A modified melt-flow apparatus was employed to ascertain the melt character. Quantitative descriptive analyses (QDA) of cheese flavor, texture, and appearance were conducted by thirteen trained panelists and the results analyzed using principal component analysis (PCA). None of the samples tested positive for the presence of food pathogens. Cheeses from non-US manufacturers had lower salt, higher pH and moisture, similar lipid and protein content, and often contained many non-traditional ingredients including vegetable oil, caseinates, nonfat dry milk, modified starch, stabilizers, and preservatives. Melt character of pasta filata and fresh cheeses were consistent between US-made and foreign Hispanic cheeses, but aged

cheeses varied dramatically in melting character. Cheese color, shape, and packaging varied for all types of cheeses comparing domestic and country of origin manufacturers. The most significant flavor attribute differences between cheeses were salt, bitter, buttery, cowy, milkfat, oxidized, unclean and rancid notes. These results provide some level of understanding of the differences between cheeses made in the US and those made in their countries of origin. Knowledge of these differences will allow manufacturers to improve the perceived authenticity of products in the US market.

Key Words: Hispanic Cheese, Sensory Profile, Melt Character

T40 Evaluation of mineral compositions in reduced-fat and full-fat caprine milks and their Cheddar-type cheeses. W. Nouria*, T. H. Terrill, and Y. W. Park, *Fort Valley State University, Fort Valley, GA*.

Reduced fat dairy products have been increasingly popular among consumers. Although characteristics of reduced fat bovine milk products have been studied, mineral compositions of such products have little been reported, especially in caprine milk products. Two lots each of reduced-fat (RF) and full-fat (FF) Cheddar-type caprine cheeses were manufactured to evaluate 20 major and trace mineral compositions. The cheeses were made at the University dairy plant using bulk milk from Saanen, Alpine, and Nubian goat herd. RF cheeses were made using cream separated goat milk by a separator (Model PG-57, Hoegger Suppl. Co., Fayetteville, GA). Minerals of milks and cheeses were quantitated by an Inductively Coupled Plasma Optical Emissions Spectrometer (Thermo Jarrel Ash Enviro 36, Worcester, MA), using argon as the carrier gas and the EPA method 6010. The maximum fat reduction in caprine cheeses was only 21.4%, from 28 % to 22% (FF vs. RF). Mean major mineral contents (ppm, wet basis) of the RF and FF milks were: Ca 1004, 1128; P 834, 945; K 1198, 1102; Mg 114, 132; and Na 456, 509, while mean trace mineral contents (ppm) of the two treated milks were: Fe 0.786, 0.892; Mn 0.038, 0.075; Cu 6.25, 6.24; and Zn 6.94, 7.24, respectively. For the corresponding RF and FF goat cheeses, the mean major mineral (ppm) were: Ca 9242, 8662; P 6011, 5613; K 1300, 1173; Mg 569, 527; Na 3105, 3035, while mean trace mineral (ppm) were: Fe 13.34, 14.45; Mn 0.559, 0.913; Cu 22.03, 24.06; Zn 38.54, 44.22, respectively. There were no differences in major mineral levels between RF and FF cheeses. However, Ca:P ratio of both RF and FF cheeses were greater than those of milks (1.53 vs. 1.20), indicating Ca was retained more than P in cheese compared to the original milk. Cu and Zn contents of milk and cheeses were higher than those of other reports. Mo content of FF cheese was greater than RF cheese, suggesting that fat globule membrane-bound xanthine oxidase was higher in FF than RF cheeses.

Key Words: Reduced-Fat, Goat Milk Cheese, Mineral Composition

T41 The effect of aging on low, reduced, and full fat cheddar cheese on texture. N. R. Rogers*, M. A. Drake, and E. A. Foegeding, *North Carolina State University, Raleigh*.

There is a desire to produce low fat cheese with textural and flavor properties similar to full fat cheeses. Towards that end, a systematic study

of textural and flavor changes was initiated. This report will address the changes in textural properties. Cheddar cheeses with full (32%) reduced (16%) or low (6%) fat were prepared and aged at 8°C for 9 months at Utah State University. The cheeses were sampled initially at 2 weeks, followed by points at 3, 6, and 9 months. At each time point, cheeses were assessed by a trained texture panel as well as rheological tests that determined fracture properties at three different strain rates, creep/recovery tests, stress sweeps to determine the linear viscoelastic region, and a pressure sensitive tack test using a dental composite probe.

At the initial time point, the low fat cheeses and full fat cheeses were very similar in texture, with the low fat cheeses being slightly more deformable and cohesive ($p < 0.05$). As the cheeses aged, the low fat cheeses lost firmness but maintained their springy texture. The full fat samples also had decreased firmness, but unlike the low fat samples, lost their springiness. Chewdown sensory properties, such as smoothness and cohesiveness, increased in all cheeses with aging; however, the changes in these properties were much greater in full fat as compared to low fat cheeses. During storage, the greatest differences across all cheeses were seen in the first 3 months. Changes over 3 to 9 months were in a similar direction but at a slower rate. The rheological tests conducted also showed that the low fat cheeses were more elastic and deformable than the full fat. Also, similar relative magnitudes and rates of changes were seen in the instrumental analysis as in the sensory.

Low fat Cheddar cheese started out with a similar texture to full fat cheeses; however, within the first three months, changes occurred that resulted in distinctively different textures for low fat and full fat cheeses.

Key Words: Lowfat, Cheese, Rheology

T42 Survey of the fatty acid profile including *cis-9*, *trans-11* conjugated linoleic acid of some Oklahoma cow cheeses. G. Davila El Rassi* and V. Banskalieva, *Oklahoma State University, Stillwater.*

Although Oklahoma cheeses (OKCh) are very well accepted by consumers, no information concerning their fatty acid composition (FAC) was available. The objective of this survey was to study the FAC, particularly the content of the beneficial *cis-9*, *trans-11* conjugated fatty acid (CLA) of OKCh and to compare to some non-OKCh. Fifteen OKCh, Christian: Cheddar Raw Milk and Cheddar Cowboy; Hardesty: Cheddar, Mozzarella and Pepper Jack; Lovera: Caciocavallo; Swan Brothers: Mozzarella Part Skim Milk, Colby Pasteurized Milk, Colby Raw Milk, Sharp Cheddar Pasteurized Milk (SCPM), Sharp Cheddar Raw Milk, Mild Cheddar Pasteurized Milk, Mild Cheddar Raw Milk (MCRM) and Cheddar Hot Pepper Pasteurized Milk; Watonga: Long Horn, and nine non-OKCh: Munster, Baby Swiss, Colby Jack (CJ), Parmigiano Reggiano, Mild Brick, White Cheddar, Sharp Cheddar, Extra Sharp Cheddar and Medium Cheddar were included in this study. The average percentage of saturated (SFA) and monounsaturated fatty acids was not different between non-OKCh and OkCh. In non-OKCh the percentage of cholesterol raising SFA was between 36 and 49%, whereas in OKCh it was between 31 and 42%. The n-6 PUFA/n-3 PUFA ratio varied between 2.1-4.6 and 2.8-5.0, respectively for non-OKCh and OKCh. The proportions of CLA ranged between 0.49 and 0.63% for non-OKCh, whereas in OKCh the proportions of CLA ranged between 0.64% (four cheeses) to 0.83 -1.23% (eleven cheeses). The CLA content in the OKCh was between 4.1 and 11mg/g lipid; the lowest - in Hardesty (4.1-4.8 mg/g lipid) and the highest - in SCPM, MCRM and the two Christian (9.6, 10 and 10.7-11, mg/g lipid, respectively). In non-OKCh the average content of CLA was 5.14 (mg/g lipid), with extreme values for Muenster and CJ

(0.96 and 8.6 mg/g lipid). Across all studied cheeses, a linear positive relationship between *trans-11* C18:1 and *cis-9*, *trans-11* CLA was found. The data obtained show that the FAC and CLA contents of OKCh were in the same range or even better than some of the non-OKCh.

Key Words: Cheese, Fatty Acid, *cis-9*, *trans-11* CLA

T43 Mapping consumer preferences for mild cheddar cheese. S. L. Drake*¹, P. D. Gerard², and M. A. Drake¹, ¹*North Carolina State University, Raleigh*, ²*Clemson University, Clemson, SC.*

Cheese consumption in the United States has tripled in the past thirty years with Cheddar cheese accounting for 4.5 kg per capita in 2005. Flavor is an important factor in consumer selection of cheeses. Mild Cheddar cheese is the classification used to describe Cheddar cheese that is not aged extensively and has a "mild" flavor. In contrast Cheddar cheese labeled as "sharp" is expected to have a stronger flavor and may be more aged. However, there is no legal definition or age limit for Cheddar cheese to be labeled mild, medium, or sharp, nor are the flavor profiles or flavor expectations of these cheeses specifically defined. Little research has focused specifically on mild Cheddar cheese flavor, but studies with Cheddar cheeses suggest that a diverse array of flavors and flavor intensities may be preferred by consumers. The objectives of this research were to document the distinct flavor profiles among commercially labeled mild Cheddar cheeses, and to determine if diverse consumer segments existed for these mild Cheddar cheese flavors. Descriptive sensory profiles of a representative array of mild-labeled Cheddar cheeses ($n = 22$) were determined using a trained sensory panel and an established cheese flavor sensory language. Nine representative Cheddar cheeses were selected for consumer testing. Consumers ($n = 215$) assessed the cheeses for overall liking and other consumer liking attributes. External preference mapping, cluster analysis and discriminant analysis were conducted on the collected data. Mild Cheddar cheeses were diverse in flavor with many displaying flavors typically associated with more age (sulfur, brothy, nutty flavors). Four distinct consumer clusters were identified. The key drivers of liking for mild Cheddar cheese were: color, cooked/milky, whey and brothy flavors and sour taste. An orange color was preferred by three of the four consumer segments. Mild Cheddar cheese acceptance varies among consumers but consumers have distinct preferences for specific flavor profiles and color. These results can help manufacturers understand consumer preferences for mild Cheddar cheese.

T44 Manufacture of cheddar cheese with added sodium gluconate. C. Phadungath*¹ and L. E. Metzger², ¹*University of Minnesota, St Paul*, ²*South Dakota State University, Brookings.*

During the aging process of hard-type cheese especially Cheddar cheese, small white spots that can be seen often without magnification, can appear within and on the surface of cheese between two and six months of aging. The crystals have previously been identified as calcium lactate crystals (CLC). One approach to preventing CLC is to add sodium gluconate to the cheese during salting. Sodium gluconate increases the solubility of calcium and/or lactate in the cheese serum phase. The objective of this study was to determine the manufacture

and composition of Cheddar cheeses with different levels of sodium gluconate addition. Six Cheddar cheeses with two levels of salting (2 and 2.5%) and three sodium gluconate addition levels (0, 0.5 and 1%) were manufactured. All cheeses were made using a stirred-curd procedure and replicated three times. Two salting rates were obtained by dividing cheese curd (at pH 5.6) into two equal-weight halves; each half was salted with 2 and 2.5% (by weight of cheese curd) sodium chloride. In order to obtain six treatments, each of the salted halves was separated into three equal-weight batches and mixed with 0 (control), 0.5, and 1.0% sodium gluconate, respectively. After sodium gluconate addition, the curds were hooped, pressed for 16 hour, vacuum-sealed in polyethylene bags, and transferred to a ripening room at 6 to 8°C. After 1 week of storage, compositional analyses (pH, moisture, salt, fat and protein) and gluconic acid concentration were determined. Mean pH, moisture, salt, fat and protein content of the cheeses ranged from 5.06 to 5.32, 36.98 to 38.15%, 1.65 to 2.13%, 30.96 to 32.98%, and 25.6 to 26.1%, respectively. At both salting levels, the pH and moisture contents were significantly ($p < 0.5$) increased in the treatments with added sodium gluconate. The concentration of gluconic acid in the low salt treatments was 0.26 and 0.61% for the 0.5 and 1.0% addition level, respectively, whereas the concentration in the high salt levels was 0.32 and 0.51%, respectively.

Key Words: Cheddar Cheese, Calcium Lactate Crystals, Sodium Gluconate

T45 Changes in residual sugar and water-soluble organic acids during ripening of Cheddar cheese with added sodium gluconate. C. Phadungath*¹ and L. E. Metzger², ¹University of Minnesota, St Paul, ²South Dakota State University, Brookings.

During Cheddar cheese ripening, lactose is converted to glucose and galactose or galactose-6-phosphate by starter and non-starter lactic acid bacteria. These sugars are primarily converted into lactic acid during the manufacturing process. However, under stressed condition (low pH and high salt) present during cheese ripening, bacteria utilize alternative pathways, which can result in formation of various organic acids. The objective of this study was to determine if the level and type of residual sugar and organic acids produced during ripening was impacted by sodium gluconate addition to Cheddar cheeses. Six cheeses with two salting rates (2 and 2.5%) and three sodium gluconate addition levels (0, 0.5 and 1%) were manufactured. The cheeses were analyzed for residual sugar (lactose) and water-soluble organic acids (acetic, butanoic, citric, formic, gluconic, lactic, orotic, propanoic, and uric) at 1-week, 3-month and 6-month of ripening by using a cation-exchange-column HPLC externally equipped with a refractive index detector. The organic acids were detected using the UV detector set at 210 and 285 nm, and the refractive index was used for quantification of carbohydrates. The results indicated that at 1-week of ripening, Cheddar cheeses with a higher concentration of gluconic acid had significantly lower concentration of lactic acid ($p < 0.05$), but significantly higher concentration of lactose ($p < 0.05$), while there was no differences ($p > 0.05$) in acetic, butanoic, citric, formic, orotic, propanoic and uric acids among treatments at all ripening times. The concentrations of butanoic and propanoic acids gradually increased over time ($p < 0.05$) in all treatments, whereas the concentrations of orotic acid and lactose gradually decreased over time ($p < 0.05$). Minor changes in the levels of acetic, citric, formic, lactic, and uric were also observed throughout ripening in all treatments.

Key Words: Cheddar Cheese, Organic Acids, Cheese Ripening

T46 Flavor chemistry of cheddar cheeses with varying fat contents. R. E. Miracle*¹, D. J. McMahon², and M. A. Drake¹, ¹North Carolina State University, Raleigh, ²Utah State University, Logan.

A current industry goal is to produce a 75 to 80 % fat reduced Cheddar cheese that is tasty and appealing to consumers. Despite previous studies on reduced fat cheese, information is critically lacking in understanding the flavor chemistry of reduced and low fat Cheddar cheeses and how it differs from its full fat counterpart. Specific knowledge of the nature of these differences could lead to identification of methods to enhance or minimize formation of specific key flavor compounds. The objective of this study was to characterize volatile compound changes with fat reduction in Cheddar cheeses. Cheddar cheeses with 5, 16, or 32% fat (wet weight) were manufactured in triplicate with a single strain starter culture and ripened for 2 weeks, 3 mo, 6 mo and 9 mo. At each timepoint, volatile components were extracted by solid phase microextraction (SPME) and by solvent assisted flavor evaporation (SAFE) followed by gas chromatography mass spectrometry (GC-MS) for compound identification. Gas chromatography-olfactometry (GC-O) with aroma extract dilution analysis (AEDA) was also applied to identify aroma-active volatile components. More than 45 aroma-active compounds were characterized in the cheeses by GC-O. Free fatty acids (butyric, hexanoic, nonanoic, and decanoic), furaneol, sotolon and saturated hydrocarbons were present at higher concentrations in low fat cheeses compared to full fat Cheddar cheeses while lactones (gamma nonalactone, gamma decalactone, delta decalactone) were predominant in full fat cheeses. The volatile components of low fat Cheddar cheeses were distinct from full fat cheeses.

Key Words: Cheese Flavor, Flavor Chemistry, Low Fat

T47 Development of cholesterol-reduced block type process cheese made by crosslinked β -cyclodextrin. S. Y. Kim, E. K. Hong, and H. S. Kwak*, *Sejong University, Seoul, Korea.*

The present study was carried out to examine the physicochemical and sensory properties in cholesterol-reduced block type process cheese made by crosslinked β -cyclodextrin (β -CD). For process cheese manufacture, 82% of aged Cheddar cheese, 10% butter, 3% emulsifying salts, 5% skim milk powder and 10% water were added in the cooker. The raw materials were heated at 85°C with a rotary agitation of 500 rpm for 3 min. The composition of process cheese treated by crosslinked β -CD was similar to the control and cholesterol removal reached 91.0%. No significant difference was found in total short-chain free fatty acids between groups. All color values were significantly lower in cholesterol-reduced process cheese than those in the control. All rheological properties except brittleness in the cholesterol-reduced process cheese were not significantly different from those in the control. Most of sensory properties were similar between cholesterol-reduced and the control cheeses. In the cholesterol-reduced process cheese, yellowness was significantly lower, while crumbly texture was significantly higher compared with the control. The overall acceptability score of cholesterol-reduced cheese was significantly higher than that of the control. Based on these results, no profound difference was found in most physicochemical and sensory properties between cholesterol-reduced block type process cheese and the control. Therefore, this study may suggest the possibility to develop the cholesterol-reduced block type process cheese using crosslinked β -CD.

Key Words: Block Type Process Cheese, Crosslinked β -cyclodextrin, Cholesterol Removal

T48 Physicochemical and rheological characterization of cream cheese made from freeze-dried milk powder. S. H. Kim, S. Lee, and H. S. Kwak*, *Sejong University, Seoul, Korea.*

Cream cheese was produced from freeze-dried milk powder milk (FDMP) through a continuous multi-stage process and its physicochemical and rheological properties were characterized. The composition of the FDMP cream cheese was 56.03% moisture, 33.12% fat, and 7.97% protein which was comparable to that of the commercial cream cheese made from raw milk. A slight increase in specific gravity was observed in the FDMP cream cheese while there was no significant difference in color between the samples made from FDMP and raw milk. Furthermore, the viscoelastic properties of FDMP cream cheese were investigated by using dynamic shear measurements. When a strain sweep test was performed at a fixed frequency of 1Hz, the cream cheese sample exhibited the linear viscoelasticity within a strain of 0.005%. In a frequency sweep test, both storage (elastic) and loss (viscous) moduli increased with increasing frequency, showing weak gel-like behaviors. Also, the viscoelastic properties of FDMP cream cheese exhibited temperature-dependence. Even, the storage moduli measured at 5°C were almost an order of magnitude higher than those at 25°C. Thus, the results indicated that the FDMP cream cheese had similar composition and physicochemical properties to the cream cheese made from raw milk. In addition, it was shown to rheologically behave like a weak-gel.

Key Words: Cream Cheese, Freeze-Dried Powder Milk, Rheology

T49 Effects of manufacturing parameters on the chemical, functional, and rheological properties of Queso Chihuahua. D. L. Van Hekken*, M. H. Tunick, R. Kwoczek, J. J. Shieh, and P. M. Tomasula, *USDA-ARS, ERRC, Wyndmoor, PA.*

The quality variations noted among Queso Chihuahua, a semi-hard cheese made in northern Mexico traditionally from raw milk, are due to the diverse manufacturing conditions used to make the cheese, the compositional and microbiological differences in the cheesemilk, and heat treatment (raw versus pasteurized). In this study, we examined the effects of manufacturing parameters on the chemical, functional, and rheological properties of Queso Chihuahua made with pasteurized milk in order to identify the processing steps that result in cheese with properties similar to that of the traditionally made raw milk cheese. Based on the results of our earlier survey of manufacturing protocols and quality traits of Queso Chihuahua made in Mexico, we manufactured 36 2-kg blocks of cheeses using different cooking temperatures (32, 38, or 44°C), pH at the time of drain (6.0 or 6.3), and overnight pressing pressures (0.96 or 1.9 kPa). Temperature during the cooking step and pressure used in overnight pressing significantly influenced the moisture, protein, salt, and ash content of the cheese as well as the hardness, chewiness, and shear stress, strain and rigidity at the point of fracture. Pressing pressure affected lactose content of the cheese and its viscoelastic properties while cooking temperature impacted the pH of the final cheese. All cheeses had excellent melt properties. Queso Chihuahua cheeses made with pasteurized milk and cooked at 38°C, drained of whey at either pH 6.3 or 6.0, and pressed overnight at 1.9 kPa, were the closest in compositional, functional, and rheological properties to the raw-milk cheeses. This study demonstrates that through careful selection of manufacturing conditions cheese makers will be able to develop pasteurized versions of Queso Chihuahua that mimic the traditionally-made cheeses.

T50 Characterization of organic acid and carbohydrate profiles of commercial Swiss cheese samples. H. Zhang* and L. E. Metzger, *South Dakota State University, Brookings.*

The objective of this study was to characterize the profiles of organic acids and carbohydrates in Swiss cheese. Ten commercial Swiss cheese samples from five companies were collected from local grocery stores (Brookings, SD). Cheese samples were extracted with 0.013N H₂SO₄ at 65°C using a high-shear mixer-homogenizer. A high performance liquid chromatograph method with a photodiode array detector set at 210 and 285nm and refractive index detection was employed to simultaneously analyze short-chain, water soluble organic acids and carbohydrates in the cheese samples. Rezex ROA-organic acid H⁺ column (300×7mm, 8 μm, Phenomenex) was used for the separation and isocratic elution was achieved using a mobile phase of 0.013N H₂SO₄ aqueous solution at a flow rate of 0.6 mL per minute. Lactic, acetic, propanoic, butanoic, citric, pyruvic, succinic acid, isovaleric (3-methylbutanoic) acid, and glycerin were detected in all ten Swiss cheese samples. However, their concentrations (g/100g cheese) were varied; the respective ranges for the compounds mentioned above were 0.0506-0.1479, 0.0272-0.1877, 0.0160-1.4185, 0.1804-0.3208, 0.4848-1.5903, 0.0553-0.1476, 0.0259-0.1072, 0.1394-0.5071, and 0.3694-0.8980. Galactose was detected in nine of the ten samples, and samples that had a higher concentration of galactose also had a higher concentration of pyruvic acid. Lactose was detected in five samples and the concentrations ranged from 0.0304 to 0.0958. Formic acid and 2-methylbutanoic acid were only detected in three samples and their concentrations ranged from 0.1065 to 0.1669 and from 0.1095 to 0.1445 respectively. These results and the well-documented organoleptic diversity of Swiss cheese warrant further investigation to determine the association between flavor attributes and organic acid and carbohydrate profiles as well as their relationship to consumer preferences of Swiss cheese.

T51 Surface roughness affects the formation of calcium lactate crystals on Cheddar cheese. P. Rajbhandari*, C. Ogg, and P. S. Kindstedt, *University of Vermont, Burlington.*

Calcium lactate crystals that sometimes form on Cheddar cheese surfaces are a significant expense to manufacturers. Previous researchers have identified several ost-manufacture conditions such as storage temperature and packaging tightness that contribute to crystal formation. Anecdotal reports suggest that physical characteristics at the cheese surface, such as roughness, cracks, and irregularities, may also affect crystallization. The aim of this study was to evaluate the combined effects of surface roughness and packaging tightness on crystal formation. Four 25 mm-thick cross-section specimens were cut perpendicular to the long axis of a retail block (ca. 300 g) of smoked Cheddar cheese using a wire cutting device. One cut surface of each specimen was lightly scored with a cheese grater to create a rough, grooved surface; the opposite cut surface was left undisturbed (smooth). The four specimens were vacuum packaged at 10, 100, 500, 900 mbar (extremely tight to extremely loose, respectively) and stored at 1°C. Digital images were taken 1, 4 and 8wk following the first appearance of crystals. Area occupied by crystals and number of discrete crystal regions (DCR) were quantified by image analysis. The experiment was conducted in triplicate. Effects of storage time, packaging tightness, surface roughness and their interactions were evaluated by Repeated Measures ANOVA. Surface roughness, packag-

ing tightness, storage time and their two-way interactions significantly affected crystal area and DCR number. Extremely heavy crystallization occurred on both rough and smooth surfaces when packaged loosely (500 and 900 mbar), and on rough surfaces with slightly loose packaging (100 mbar). In contrast, the combination of rough surface plus very tight packaging (10 mbar) resulted in dramatic decrease in crystal area and DCR number. The combination of smooth surface plus very tight packaging virtually eliminated crystal formation by eliminating available sites for nucleation. The data suggest that the cut-and-wrap step in commercial Cheddar cheese production is a critical control point for crystal formation.

T52 Influence of native casein concentrates on process cheese texture. P. Salunke* and L. E. Metzger, *South Dakota State University, Brookings.*

Milk Protein Concentrate (MPC) produced with an ultrafiltration based process is commonly used in process cheese product formulations. However, the use of MPC can result in various texture defects including a soft body and restricted melting characteristics. These texture defects are believed to be related to the substantial amount of the whey proteins present in MPC. Recently, Native Casein Concentrate (NCC) produced in a microfiltration based process has been developed. NCC is similar to MPC except a portion of the whey protein is removed. The objective of the current study was to determine the impact of NCC on the texture of process cheese. Three replicates of process cheese product formulations were produced from three different batches of NCC and MPC. Each formulation was standardized to 25.0 % fat, 1.89% salt, 44.0% moisture and 17.0% protein. In each formulation the MPC or NCC utilized contributed 10.5% protein. Other ingredients in the formulation included water, butter, cheddar cheese, deproteinised whey, salt, lactic acid, disodium phosphate and sodium citrate. Each formulation was manufactured in Rapid Visco Analyzer (RVA). In the RVA the blend of ingredients was mixed at 1000 rpm and heated to 95°C in two minutes. Subsequently the cheese was mixed at 160 rpm for a minute. The cheese was then transferred to electroplated copper molds and cooled overnight at 4°C. After cooling five samples of each formulation were evaluated using Texture Profile Analysis (TPA) at 25°C. The hardness, springiness, gumminess and chewiness of the process cheese product were significantly increased with the NCC formulation. The mean value of the three NCC replicates was 5002g, 0.124, 728g, 92g.sec whereas the mean values for the MPC replicates was 3319g, 0.085, 488g, 42g. sec respectively for hardness, springiness, gumminess, chewiness. The results demonstrate that the texture of process cheese products can be modified with the use of NCC.

Key Words: Process Cheese, Native Casein Concentrate, Rheology

T53 The effect of culture combinations on swiss cheese flavor quality. N. A. Kocaoglu-Vurma*¹, A. Eliardi¹, M. A. Drake², L. E. Rodriguez-Saona¹, and W. J. Harper¹, ¹*The Ohio State University, Columbus*, ²*North Carolina State University, Raleigh.*

Propionibacterium freudenreichii is mainly responsible for eye formation and also is a major contributor to the flavor of Swiss cheese. *Lactobacillus helveticus*, in turn, influence the growth and fermentation products of *Propionibacteria*. A better understanding of the effect of such interactions between different strains of the starter cultures on commercial product

quality is useful for industrial culture selection. The objective of this study was to evaluate the effect of culture combinations on the quality of Swiss cheese manufactured under commercial conditions.

Cheeses were produced by four commercial Swiss cheese manufacturers using two different culture combinations. Cultures consisted of the same *P. freudenreichii* and *Streptococcus thermophilus* strains, but varied in the type of *Lactobacillus helveticus* strain (LSA and LSB). Cheese samples were evaluated right out of warm room, at 4 months, and 7 months after the manufacture for bacterial counts, and mid-infrared (MIR; 4000-700 cm⁻¹) spectroscopy. The cheeses were also profiled by a trained sensory panel at 7 months after manufacture. At the end of warm room, there were no differences in *Propionibacteria*, and *S. thermophilus* counts, however total *Lactobacillus* counts were approximately 1 log CFU/g lower in cheeses manufactured with *L. helveticus* LSA. The infrared analysis allowed classification of samples by manufacturer, and culture combinations. The wavenumber 1122 cm⁻¹, corresponding to S-O vibration modes, was shown to give the highest discrimination when samples were classified by manufacturer. For cheeses produced by a single company, the wavenumbers 1330-1377 cm⁻¹ contributed highest to the discrimination of cheese samples by culture combination. The sensory descriptors, vinegar, dried fruit, and cabbage received higher scores when *L. helveticus* LSA was used. The attributes fresh fruit, butyric, and metallic were not detected in any of the samples. The study of culture interactions under commercial manufacturing conditions provides a basis for the selection of starter strains for industrial applications, as the product quality is determined by both the starter cultures and manufacturing conditions.

Key Words: Swiss Cheese, Spectroscopy

T54 Iodine content in sheep and goat cheese produced in Sardinia (Italy). G. Pulina*^{1,3}, F. Aghini-Lombardi², M. Frigeri², G. Battacone¹, R. Rubattu¹, G. Garzella², L. Grasso², and A. Nudda¹, ¹*University of Sassari, Sassari, Italy*, ²*University of Pisa, Pisa, Italy*, ³*AGRIS Sardegna, Olmedo Loc. Bonassai, Sassari, Italy.*

Iodine deficiency disorders have been described in several surveys conducted in European countries. Dairy products could be a valuable source to increase iodine intake in human diet. The aim of this study was to evaluate the iodine content in sheep and goat cheese produced in the Sardinia region (Italy). Cheese samples (n. 23 and n. 49 from sheep and goat milk, respectively) from 9 dairies located in different areas of Sardinia were collected at different months of production (from December to July). Iodine concentration of cheese was determined, after alkaline mineralization, using the Sandell-Kolthoff reaction.

The iodine concentration averaged 23.02 µg/100 g (ranging from 8.03 to 52.84 µg/100 g) in sheep cheese and 21.71 µg/100 g (ranging from 10.57 to 73.95 µg/100 g) in goat cheese. The iodine content did not differ between sheep and goat cheese (P = 0.73).

The iodine concentration was significantly influenced by season. In both species the highest iodine concentration was found in cheese produced during winter months (26.33 and 38.90 µg/100 g in sheep and goats, respectively) compared to spring months (21.13 and 14.23 µg/100 g in sheep and goats, respectively) and summer months (20.61 and 17.42 µg/100 g in sheep and goats, respectively). A significant effect of the different dairies on iodine concentration has been observed (P<0.01).

In conclusion, these preliminary results suggest that the iodine concentration in cheese from sheep and goats milk: a) did not differ between the two species; b) varied markedly with season, being higher in winter; and c) was too poor to provide an adequate iodine intake, even if dairy

products are second only to fish as suppliers of iodine in human diet. *Acknowledgements: Research supported by the Ministry of University and Research (FISR grant).*

Key Words: Iodine, Cheese, Sheep and Goat

T55 Three-dimensional microscopy using stereoscopy applied to scanning electron microscopy imagery. M. Caccamo*¹, G. Impoco², L. Tuminello¹, and G. Licitra^{1,3}, ¹CoRFiLaC, Regione Siciliana, Ragusa, Italy, ²IPLAB, Catania University, Catania, Italy, ³D.A.C.P.A., Catania University, Catania, Italy.

Scanning electron microscopy (SEM) is a powerful tool to study cheese microstructure. Although providing high resolution digital scanning, SEM flattens the 3D scanned surface and therefore does not allow direct in-depth measurements. Stereoscopy mimics the features of the human visual system by reconstructing 3D information from 2D images. Recovering depth is based on the parallax between corresponding points in different images. These algorithms and the underlying equations have been tailored to optical cameras, but are also valid for SEM imagery, the SEM image formation being approximately the same as that of a thin lens. Two kinds of cheese texture, pressed and pasta filata, were analyzed using stereoscopy. Several SEM images of each sample were taken with a small displacement (0.03mm vertically, 0.04mm horizontally) at 1000× magnification. Scans were automatically aligned, such that the structures in small overlapping areas matched between different images. 3D models of the scanned surface were generated using a software that mimics human binocular vision. Results were not satisfactory mostly due to sensor noise and to the lack of well-recognizable objects in the scene. Two experiments were designed to improve the quality of the 3D models: i) displacement with respect to the specimen plane, and ii) tilting of the specimen mount. In the first experiment, the specimen mount was displaced and a series of overlapping images was acquired. We used small displacements to correlate corresponding images and large displacements for 3D reconstruction to enlarge the parallax effect. This choice improved the output 3D models. Displacement values given by the SEM device and needed for reconstruction were not accurate enough. Values were corrected via software to obtain robust metric measurements. The second experiment employed only tilting of the specimen mount. A small angle was preferred to avoid losing track of the surface features. Both methods yielded better results than arbitrary specimen orientation. Reconstructed 3D surfaces showed the possibility to perform direct metric measurements of the surface of the specimen.

Key Words: Electron Microscopy, Microstructure, Stereoscopy

T56 Prediction of curd moisture content by near infrared light scattering over a range of stirring speed and cutting intensity during cheese-making. M. J. Mateo*¹, D. J. O'Callaghan¹, C. D. Everard¹, C. P. O'Donnell², C. C. Fagan², M. Castillo³, and F. A. Payne³, ¹Moorepark Food Research Centre, Teagasc, Fermoy, Cork Ireland, ²University College of Dublin, Dublin, Ireland, ³University of Kentucky, Lexington.

Every cheese has a specification regarding its optimum content of moisture which relates to the final quality of cheese. This crucial parameter determines the shelf-life of the cheese. If the moisture content is higher

than the standard the cheese will be more perishable and will be less acceptable to the consumer. On the other hand, cheeses having less moisture than the standard are more costly to produce. An online fiber-optic light backscatter sensor is being investigated for better control of curd moisture content. The aim of this study was to evaluate light backscatter at 980 nm during syneresis to improve the prediction of curd moisture content under the influence of two experimental variables namely stirring speed and cutting intensity.

The experiment was performed using three stirring speeds (10, 16 and 22 rpm) and three gel cutting intensities (4.2, 8.3 and 12.5 total revolutions), with three replicates (n = 27). The trials were carried out using recombined whole milk in an 11 L double-O cheese vat, in which the light backscatter sensor was installed. The milk was coagulated under constant conditions at pH 6.5 and 32°C. Samples for determining curd moisture content were taken from the cheese vat at 10 min intervals up to t = 75 min.

A linear model was developed for predicting Mc with five significant (P < 0.001) distinct terms, i.e. light backscatter ratio, time after cutting, stirring speed, milk fat content and cutting intensity (SEy = 1.10 g/100g, R² = 0.83).

These results showed the potential of the light backscatter syneresis sensor technology to predict curd moisture content changes during syneresis in the cheese vat under a wide range of stirring speeds and cutting intensities, but in-plant calibration would be required to take account of technological factors.

Key Words: Curd Moisture Content, Light Scattering, Prediction

T57 Effect of various starches on the properties of a processed Swiss-type cheese product. M. C. M. Soledad* and W. J. Harper, *The Ohio State University, Columbus.*

The study explores the possibility of using starch as an ingredient in processed cheese products. Starches are versatile food ingredients which open opportunities for cost and fat reduction, and, control of textural and melting properties. The study aimed to evaluate the effect of various starches on the properties of a processed Swiss-type cheese product and differentiate them based on flavor profile. A Stephan UMC5 processed cheese maker was used to prepare the samples composed of natural Swiss cheese, water, starch, disodium phosphate, lactic acid, and trisodium citrate. Eight starches were compared with a control (without starch), consisting of four native starches, namely: waxy corn, potato, tapioca, and wheat; and, four modified starches, namely: acid-modified dent corn, instant waxy corn, blend of hydroxypropylated and oxidized potato, and thin-boiling potato. Samples were evaluated for texture (texture profile analysis, TPA) and melting behavior (modified Schreiber test). TPA results suggest that starch addition may significantly increase hardness and chewiness. The control had an average hardness value of 385g whereas, 800-2200g for those made with various starches. The average chewiness value of the control was 187 whereas, 440-1400 for those made with various starches. Modified Schreiber test results suggest that starch addition may significantly reduce the spread during melting. The average increase in cheese disc circumference of the control was 122mm whereas those made with the various starches were in the range of 50-100mm. Fourier transform infrared spectrometry coupled with multivariate analysis was used to differentiate the samples based on water-soluble flavor compound profile which provided information on possible differences in ingredient interaction based on the starch

used. This study may contribute to the formulation of processed cheese products and elucidate the effect of varying the type of starch on its properties.

T58 Influence of comminuting curd on curd particle size, moisture content and cohesiveness of 50%-reduced fat cheddar cheese.

D. J. McMahon* and C. Brotherson, *Utah State University, Logan.*

Comminuting cheese curd can be used as a tool for incorporating value-added ingredients into cheese without adversely affecting the whey generated during cheesemaking. Such a reduction in curd particle size does, however, change the physical properties of the cheese and expulsion of whey during pressing. We investigated the influence of comminuting reduced fat cheddar cheese curd on particle size, moisture retention during pressing, and cohesiveness of the resultant cheese. A 50%-reduced fat cheddar cheese was made using a stirred curd method and after salting, 30-lb batches of curd were comminuted in a bowl chopper for 15, 30 or 45 s. Samples of comminuted curd were mixed with an anti-caking agent and passed through a sieve stack with openings from 12.5 to 1 mm. Other portions of the curd were placed in round plastic hoops and pressed at either 35 or 70 kPa for 2, 4, 8 or 20 h. Cheeses were then vacuumed packaged and stored at 6°C and texture profile analysis performed at 1, 3, 6, 10, 15, 30 and 60 d. Non-comminuted curd had a broad size distribution of 1 to 9.5 mm with most of the curd particles being collected on the 2, 4 and 6.3 mm mesh sieves. Chopping for 15 s reduced the particle size to 1 to 4 mm (most of curd being collected on the 2 mm mesh sieve). Further chopping reduced particle size to 1 to 2 mm. Whey expulsion during pressing was retarded in comminuted cheese curd and after 20 h the experimental cheeses contained more moisture (49.1%) than the control cheese (47.4%). After pressing (d 1) the control cheese had 49% cohesiveness while cheeses made from comminuted curd had only 30% cohesiveness. During storage, cohesiveness increased for all cheeses; to 68% by d 15 for the control cheese, while the experimental cheeses initially decreased through d 5 before increasing to 41 to 50% by d 30. Thus, comminuted curd particle knitting is delayed during the initial storage period, but increases proportionally during storage. This may be an advantage in reduced fat cheeses that have a tendency to be more rubbery than full fat cheeses.

T59 Preparation of low fat fresh panela type cheese with ω -3 fatty acid. E. Paz-Gamboa*¹, M. Montero-Lagunes³, S. Cruz-Díaz¹, M. Esquivel-Vera¹, H. S. García-Galindo², C. E. Martínez-Sánchez¹, and E. Herman-Lara¹, ¹*Instituto Tecnológico de Tuxtepec, Tuxtepec, Mexico*, ²*Instituto Tecnológico de Veracruz, Veracruz, Mexico*, ³*Campo Experimental la Posta, Veracruz, Mexico.*

Fresh panela cheese is a product with a high consumption in Mexico, thus it is desirable to improve its nutritional value. In addition, the ω -3 fatty acids have demonstrated benefits to the human health. The docosahexaenoic acid (DHA) is a component of the ω -3 fatty acids and it is important during the fetal development, childhood, and the adult age. However, this component is limited in some foods. Therefore, the objective of this work was to produce a fresh low fat cheese added with DHA and to evaluate its physical-chemical, microbiological and sensory properties.

Panela was elaborated with fat milk concentrations of 1.5 and 2.5 % and 30, 45, and 60 mg/30 g Martek DHA™, respectively. For each treatment, a control cheese was used. Moisture, ash, protein, and fat contents were evaluated. The retention level of DHA was measured by means of gas chromatography. A microbiological test was conducted in order to monitor for the presence of *Salmonella*, *Staphylococcus aureus*, and total coliforms. Additionally, a triangular test with a trained panel was established for the sensory analysis.

Results showed that the addition of DHA did not affect significantly the physical-chemical composition of the cheese when compared with the control product ($P < 0.05$). A retention level of DHA of 3.4165 to 5.4706 mg/g fat was obtained for all the treatments. However, the product elaborated with 1.5% fat milk and the addition of 45 mg of DHA gave an average retention of 5.4706 mg/g fat, thus this treatment was judged as the best option for the enrichment process. The microbiological analysis according to the NOM-121-SSA1-1994 satisfied the sanitary quality. The sensory evaluation demonstrated that cheese with added DHA did not produce odd flavors.

This research demonstrated that there is an alternative to consume a cheese with a high nutritive value and a methodological base for developing new products.

Extension Education

T60 Management practices used in Alabama beef production I: Impact of herd size. W. F. Owsley*, J. B. Elmore, M. F. Elmore, L. A. Kriese-Anderson, W. C. Rutherford, S. V. Free, and L. S. Saunders, *Auburn University, Auburn, AL.*

In the spring and fall of 2007, producers attending two state-wide producer meetings and 21 of the 27 Alabama livestock markets were asked to participate in a survey to assess the level of management on Alabama beef farms. A total of 699 surveys were completed. Survey responses were entered in spreadsheet format, and sorted by the cow inventory: <10, 10-30, 31-50, 51-100, 101-150, 151-250, >250. Over 90 percent of farms in each category were cow/calf. Of the farms reporting 51-250 cows, 15 percent also stockered calves, compared to 34 percent for over 250 cows. Nineteen percent of the farms with <250 cows expected to receive over 50 percent of their income from cattle, compared to 73 percent of farms over 250 cows. Most farms surveyed (59%) calved year-round or had a split calving season. As herd size increased, the number of farms working calves increased. Vaccinations and deworming were the most observed management practices on calves and cows. The number of farms working cows did not vary with herd size (90 percent). Veterinarians were involved in working cows and were the primary source of herd health information on 40 percent farms surveyed. Notebooks were the primary records storage system for farms regardless of size (40 percent). Only 20 percent of farms used computers for keeping cow and/or calf records. Breeding practices were also similar across all farms surveyed, with 67 percent using natural mating with registered bulls. Farms with large cow herds culled a higher percentage open cows, but culling was similar for other traits. Tailoring Extension programs based on herd size may be helpful for some management skills, but herd size had only limited impact on overall herd management.

Key Words: Beef Quality, Management, Herd Size

T61 Management practices used in Alabama beef production II: Impact of source of herd health information. W. F. Owsley, J. B. Elmore*, M. F. Elmore, L. A. Kriese-Anderson, W. C. Rutherford, S. V. Free, and L. S. Saunders, *Auburn University, Auburn, AL.*

In the spring and fall of 2007, producers attending two state-wide producer meetings and 21 of the state's 27 livestock markets were asked to participate in a survey to assess the level of management on Alabama beef farms. A total of 699 surveys were completed. Participants were asked to identify their primary source of herd health information (SOURCE): veterinarian, feed store, magazine, internet, Extension. Responses were sorted by information source to help develop a targeted Extension education program. Of the producers using their feed store as SOURCE, 70 percent expected cattle to make up less than 25 percent of their income, compared to 48 percent (veterinarian) and 44 percent (Extension). Farms with less than 10 cows used veterinarians and feed stores as SOURCE 45 and 34 percent, respectively. Farms with over 250 cows used veterinarians and feed stores as SOURCE 62 and 0 percent, respectively. Extension was SOURCE evenly across herd size (18 to 22 percent) except for farms with less than 10 cows (9 percent). SOURCE

had little impact on whether calves were worked, but did affect specific management practices. Sixty percent of the farms using veterinarians, magazines and Extension as SOURCE castrated calves, compared to 40 and 30 percent for internet and feed stores, respectively. Farmers using feed stores as SOURCE reported a lower incidence of performing routine management practices on the cow herd, calf and cow records. Farms using Extension as SOURCE reported a higher rate of premises ID. Farms using feed stores as SOURCE were less likely to cull cows on disposition, feet, udders, teeth and eyes, and were less likely to cull open cows. Most farms keeping calf or cow records used a notebook for record storage, except for those using the internet as SOURCE. Over 50 percent of those farms used computers for records. Based on the results of this survey, Extension partnering with information outlets like feed stores and livestock markets could have a significant impact on management practices used in beef production.

Key Words: Cattle, Management, Herd Health

T62 Commercial cow and calf data in Alabama herds: 1988 to 2007. L. A. Kriese-Anderson*¹ and M. F. Elmore², ¹*Auburn University, Auburn, AL,* ²*Alabama Cooperative Extension System, Auburn, AL.*

Since 1988, a PC-based cow/calf production program has been available in Alabama through the Alabama Beef Cattle Improvement Association. From 1988 to 1999, birth and weaning information were the only data entered into the program. From 2000 to present, producers were able to input as much performance data into the program as desired. Each producer must have a minimum of nine pieces of information available on each calf. They include unique sire, dam and calf identification, sire and dam breeds, dam and calf birth date, weaning date and weaning weight. From this minimum amount of data, adjusted weaning weights (WW) and ratios are calculated and provided back to the producer to aid in selection and culling decisions. Since 1988, 288 herds have inputted 110,195 WW from over 35,000 dams. Large herds (n>100 head) contributed the most number of records (n=69,715) followed by medium herds (n= 30 to 99 head; 33,241 WW) and small herds (n<30 head; 7239 WW). Editing WW records to fit within BIF Guidelines for calf age at weighing, records within 4 SD of the mean and sire breeds with more than 100 progeny records, provided 74,148 WW records for analysis using the mixed procedure of SAS. Independent variables included herd, year, herds size and sire breed. Herd was considered a random effect. Effects of year, sire breed and herds size were all significant at P<0.01. WW of calves from small herds were significantly heavier (LSMEANS = 250 kg) than from medium (LSMEANS = 243 kg) or large herds (LSMEANS = 243 kg). There were 22 sire breeds or composites in the dataset. Angus- (n=29,515) and Simmental-sired (n=20,132) calves were the most numerous. Simmental sired calves were significantly heavier than Angus sired calves by 6.91 kg. Charolais sired (n=8,436) calves were intermediate for WW. Using a regression approach, WW increased 1.4 kg/yr in these Alabama herds from 1988 to 2007. Examining dam information, commercial cows averaged 3.7 calves before exiting the herd with an average calving interval of 383.6 days.

Key Words: Beef, Commercial Herds, Adjusted Weaning Weight

T63 A single fleece test method improves premium wool traits in range sheep flock. T. Wuliji¹, T. Borda², H. Glimp¹, L. Gome-Raya¹, and W. Rauw¹, ¹University of Nevada, Reno, ²Borda Ranch, Fernley, NV.

The OFDA2000 is the latest wool technology designed for on-farm testing of greasy fleece in assistance to sheep selection and wool clip preparation. The test provides more than a dozen wool characteristics including mean fiber diameter, fiber length, and fiber variation using a small wool staple sample from mid-side of sheep. The test procedure requires only 45 seconds per sample run and can measure at 80 samples per hour speed. We adopted a single fleece test method at pre shearing for replacement ewe selection and color ear tag identification for extra fine (blue), fine (green), medium (red) and coarse (black) categories. These categories correspond to average fiber diameter ranges of 18 μ and less, 18.1 to 20.1 μ , 20.2 to 22.5 μ , and 22.6 μ and coarser fleece category. Six years of single fleece testing has been carried out on the replacement ewes at the ranch. The shearing classes established at two year old ewes were highly repeatable. A random follow-up test of 100 three year old ewes at 2006 shearing indicated that over 96 % of those stayed within the original fleece test assigned category. The single test fleece characteristics on the Borda Ranch showed that an overall fining ($P < 0.05$) in average micron (Mean \pm SE from 23.9 \pm 0.23 to 22.4 \pm 0.09, 21.6 \pm 0.10, 20.8 \pm 0.12 and 20.9 \pm 0.13 μ ; increasing ($P < 0.05$) fiber length (Mean \pm SE from 56.0 \pm 0.68 to 77.0 \pm 0.41, 79.9 \pm 0.31, 75.3 \pm 0.58 and 86.7 \pm 0.48 mm respectively for test year 2003 to 2008; and improving comfort factor and reducing wool trait variation in the replacement ewes. The flock size was increased from 1660 ewes at 2006 shearing to 2400 ewes at 2008 shearing, and the average fleece weight has gradually increased over the last few years (e.g., 4.51 kg per head in 2006 vs. 4.98 kg per head in 2007). Wool price premium between fine vs. coarse categories were varied from 16% to 49% in those sale seasons. The single fleece test information not only allows producers to class their clips in the price premium categories but also assists in flock selection and culling decisions.

Key Words: Range Sheep, Wool, Fiber Diameter

T64 Minimum sampling requirement for prediction of hay forage quality from monoculture or mixed grass fields. R. S. Milliken¹, M. S. Gadberry², E. B. Kegley^{*3}, J. A. Jennings², and J. T. Richeson³, ¹University of Arkansas Division of Agriculture Cooperative Extension Service, Marshall, ²University of Arkansas Division of Agriculture Cooperative Extension Service, Little Rock, ³University of Arkansas Division of Agriculture, Fayetteville.

Accurate forage quality values are critical when developing a balanced supplemental ration for beef cows. Large (1.2 \times 1.5 m), round hay bales from 2 locations in central Arkansas were individually analyzed for chemical composition (CP, NDF, ADF) to determine the minimum sampling rate required to achieve an accurate forage analysis for either monoculture grass hays or mixed grass hays. The monoculture field consisted of 3.24 ha of Tipton 44 bermudagrass, which was determined through forage inventory by step-point method to be 90% of the stand. A 4.9-ha mixed grass field was also inventoried and was highly variable ($P < 0.0001$) in species composition. Fifty-one bermudagrass and 73 mixed grass large round bales were individually core-sampled 6 times with a 1.9-cm i.d., 46-cm-long Star Multi-Forage Sampler (Star Quality Samplers, Edmonton, AB, Canada). Wet chemistry was used to determine CP,

ADF, and NDF concentrations of each bale. From these factors, percentage TDN was calculated using equations developed and currently used in Arkansas; TDN = 111.8 + 0.95(%CP) - 0.36(%ADF) - 0.7(%NDF) and TDN = 73.5 + 0.62(%CP) - 0.71(%ADF) for bermuda and mixed grass, respectively. For each hay lot, the Survey Select procedure of SAS (SAS Inst. Inc., Cary, NC) was used to generate 10,000 random hay samples for sampling rates ranging from 5 to 75% in increments of 5%. Potential sampling outcomes for each sampling rate were generated, and a baseline for an acceptable degree of error within samples was set at the mean \pm 1 percentage unit for TDN and CP. Results indicate that forage samples should include cores from at least 30% of all bales of a monoculture/pure forage stand and 35% of all bales when sampling a mixed/native grass field to achieve a representative hay sample useful for ration balancing.

Key Words: Sampling Rate, Nutrient Composition, Forage

T65 Demonstration of a formulation approach to include corn-milling co-products in lactating dairy rations. K. J. Machacek* and P. J. Kononoff, University of Nebraska, Lincoln.

In 2007, the U.S. dry milling corn ethanol industry produced approximately 13 million metric tons of feed co-products and the dairy industry continues to be a key market. Based on results reported by a commercial feed laboratory, dried distillers grains plus solubles (DDGS) are low in starch (6.0 \pm 5.4%) but contain high levels of NDF (33.3 \pm 4.8%), CP (30.4 \pm 4.1%), and ether extract (13 \pm 3.0%). Numerous research trials at the University of Nebraska-Lincoln have demonstrated that dairy rations may be formulated to contain as much as 30% DDGS (DM basis) and maintain normal production levels. The objective of this demonstration is to outline a practical ration formulation approach (using CPM-Dairy version 3.0) that seeks to include DDGS at 15 and 30% of the ration DM and maintain normal milk production. Thirty random samples of DDGS originating from one ethanol plant were evaluated for CP, NDF, ADF, acid detergent insoluble crude protein (ADICP), and ether extract (EE). In vitro NDF digestibility (24 and 48 h) was also measured (75.5 and 86.3%, respectively). Three rations were formulated to contain increasing amounts of DDGS (0%, 15%, and 30%) while maintaining a similar intake (20 kg/d), and metabolizable protein (MP) and metabolizable energy (ME) allowable milk (35 kg/d). Forages, corn, and soy-based proteins were replaced as the amount of DDGS increased. Rations had similar concentrations of NDF (35%), increased amounts of CP (18, 18, and 19% for 0, 15, and 30% DDGS, respectively), but were formulated to contain decreasing concentrations of starch (26.1, 21.9, 19.7%). With increasing levels of DDGS, model predicted fermentable NDF increased (12.5, 13.8, and 13.4%), and fermentable starch decreased (21.8, 18.3, and 16.5%). In summary, feed co-products such as DDGS are valuable for inclusion into dairy rations and may be included at 15 and 30% of the ration DM and contribute to supplying adequate levels of MP and ME to support lactation.

Key Words: Co-product, Dairy, Ration Formulation

T66 The Virginia Phosphorus Feeding Incentive Program. C. C. Stallings*, K. F. Knowlton, R. E. James, M. D. Hanigan, B. G. Cox, J. L. Welsh, T. M. Horn, S. M. Puffenbarger, and M. C. Scott, Virginia Polytechnic Institute and State University, Blacksburg.

To reduce the potential for phosphorus (P) runoff into streams a project was undertaken to use feed management as a tool to reduce P excreted by dairy cows. A survey was sent to all Virginia dairy farms (806) asking for information related to nutrient management practices, and assessed potential interest in an incentive-payment project to reduce overfeeding of phosphorus. Interested farms were contacted, visited, and signed to the project. The program provides free feed testing for major nutrients and minerals every two months for three years, ration consultation on request, educational materials and updates via a newsletter, and educational meetings for both producers and nutritionists. In addition a P Report is provided to producers after each set of samples are submitted and analyzed. On this report the amount of P fed was calculated and compared to the requirement for cows in that herd. The P requirement and dry matter intake were calculated according to NRC based on producer-reported body weight, milk production, and fat test. The result is expressed as P consumed as a percent of required. There were 215 herds that signed up for the project. Currently 128 herds have completed enough samplings (5) to have a year end summary prepared calculating eligibility for payment. Nine herds fed P within 5% of required and qualified for the highest year-end payment (\$12/cow), 32 fed P at 105 to 115% of required for a \$6/cow pay rate, 25 fed P at 115 to 125% for a \$3/cow pay rate, and 62 herds fed more than 125% of required P and did not qualify for payment. The remaining 87 herds have not completed their first year or submitted enough samples for a summary. The Virginia P Feeding Incentive Program has engaged producers and their advisors in an ongoing dialogue about herd feeding practices. More than 50% of producers completing sufficient sampling for year 1 evaluation have earned an incentive payment, and average dietary P consumed declined by 2.9% or 2.6 grams/cow/day.

Key Words: Phosphorus, Incentive, Feed Management

T67 Financial performance of dairies in Florida and Georgia in 2006. L. O. Ely¹, A. deVries², R. Giesy², M. Sowerby², B. Broadus², and C. Vann², ¹University of Georgia, Athens, ²University of Florida, Gainesville.

The Dairy Business Analysis Project (DBAP) includes an annual survey of the financial performance of dairies primarily located in Florida and Georgia. Its objective is to document the dairies' financial success using standardized, accrual accounting methods in order to calculate benchmarks and provide feedback on the dairies financial strengths and weaknesses.

Twenty-six dairies submitted financial data in 2006. Twenty-two dairies were included in the summary results. Of these, 16 were located in Florida, and 6 in Georgia. The average herd size was 1,163 cows and 684 heifers with 18599 lbs. milk sold per cow. The average culling rate was 31%. There was an average of 20 FTE workers per farm and 1.01 million lbs milk sold per FTE worker. Total revenue per cwt. was \$19.36 / cwt with \$16.79 / cwt milk income. The average total expense was \$18.56 / cwt. The largest expense items were purchased feed (\$7.17 / cwt), labor (\$3.13 / cwt), livestock (\$1.60 / cwt) and milk marketing (\$1.17 / cwt). Net farm income from operations was \$0.53 / cwt and net farm income was \$0.70 / cwt. The debt to asset ratio was 0.40, the rate of return on assets was 0.03, the rate of return on equity was 0.03, and the operating profit margin ratio was 0.03. Total revenue and expenses decreased with herd size in 2006. Herds with 450-1000 cows had the middle total revenue (\$19.06 / cwt) and expenses (\$17.93 / cwt) which resulted in the highest net farm income (\$0.91/cwt). The herds with the highest milk production (>19,800 lbs / cow / year) had the lowest total

revenue (\$19.16 / cwt) and the lowest expenses (\$17.25/ cwt) resulting in the highest net farm income (\$1.59 / cwt).

Key Words: Dairy, Financial, Management

T68 Organic dairy short course for ag professionals. D. G. Johnson¹, J. M. Moynihan², M. J. Forbord³, and L. Paine⁴, ¹University of Minnesota, Morris, ²Minnesota Department of Agriculture, St. Paul, MN, ³Sustainable Farming Association of Minnesota, Starbuck, MN, ⁴Wisconsin Department of Agriculture, Trade and Consumer Protection, Madison, WI.

“Organic Dairy 101: A workshop for dairy support professionals” targeted providers of advice and service to dairy farms, including: veterinarians and vet students, inspectors, lenders, Extension agents, farm management instructors, consultants, mentor farmers, county feedlot officers, state environmental staff, and advisory teams for dairy planning and development. The 6-hour workshop was held in 4 locations in Minnesota and 3 locations in Wisconsin. Wisconsin workshops targeted veterinarians. The core of programs for Minnesota were planned by a broad-based statewide committee with representatives of the target groups, organic farmers, the Sustainable Farming Association of MN, and agency and education personnel. Local planning committees selected from a menu of speakers and topics, emphasizing local resource people when possible. In Minnesota topics included an overview of National Organic Program organic requirements, farmer insights and virtual farm tours, veterinary practice for organic dairy, economics of organic production, organic crop production, grazing, and dairy nutrition. “If a client asked you questions about the following, how well do you think you could answer?” before (A) and after the workshop (B), (Scale 1 to 5 : 1=Not at all; 5=Like an expert). Responses were tabulated from 47 of 90 participants in the first two workshops. A) What is the Federal Organic rule? A 1.26; B 3.38. B) How do farmers/processors get certified organic? A 1.98; B 3.76. C) Does organic require more than not using antibiotics/synthetics A 2.56; B 4.04. D) Does organic farming “work”? A 2.62; B 4.11. E) What motivates farmers to switch to organic? A 2.36; B 3.87. F) How do organic farmers keep cows healthy? A 1.98; B 3.69. G) What veterinary treatments are allowed for organic cattle? A 1.47; B 3.26. H) What is the market outlook for organic dairy? A 2.00; B 3.74. To the question: “Overall, was this workshop worth the time and effort of attending?”. Yes = 46; No=1. Notable comments: Veterinarians want to learn more about treatments for organic cattle and the evidence behind them; farmer perspectives were valuable;an accredited certifying agency should be included in the program.

Key Words: Organic Dairy, Dairy Professionals, Workshop

T69 Good dairy sanitation workshops in Central American countries. G. Pena¹, M. West¹, D. Orellana², A. Young¹, and D. E. Diaz¹, ¹Utah State University, Logan, ²USDA-FAS, Washington, DC.

During 2007 Utah State University in collaboration with the USDA-Foreign Agricultural Service conducted four 3-day workshops on good dairy sanitary practices in Guatemala, El Salvador, Honduras and Nicaragua. These workshops were conducted to support the efforts of the Dominican Republic-Central America Free Trade Agreement. Training workshops include two days of classroom lecture plus a one day hands

on farm visit. Topics covered during these workshops included milking techniques, mastitis; milk quality from the farm to your table; heat stress; vaccination protocols and residues in milk and milk handling, storage and transport. Over 400 participants attended the workshops which included among the participants dairy producers, farm employees, government personnel, and milk cooperatives. A pre and post test of 20 questions was given to all participants utilizing the I-clicker testing equipment and software (Macmillian, New York, US), which ensured anonymity while allowing comparisons between individual pre and post test results. Questions were read and explained to all participants. Data was analyzed utilizing a paired sample t-test to determine workshop impact. Participants at all workshops showed a 29.1% improvement in their post test results ($P < 0.001$). Because of the increase in consumption of imported dairy products from participating countries programs such as this will help improve the quality of the dairy products that enter the United States.

Key Words: Milking Techniques, Workshops, Dairy Sanitation

T70 Spanish language training on proper milking techniques in the state of Utah. D. E. Diaz*, G. Pena, C. Israelson, J. Barnhill, and A. Young, *Utah State University, Logan.*

A series of workshops were conducted on proper milking techniques in the state of Utah for Spanish speaking dairy farm employees. The role

of extension in training this important sector of the dairy industry has been growing in the last decade. The language and cultural barrier make for an often undertrained workforce. The Dairy Extension group at Utah State University offers a series of workshops with hands on demonstration to Spanish speaking employees in our area. The objective of these workshops is to teach proper milking procedures to milkers in their native language to improve their understanding and comprehension of the material. Pre and post tests are conducted to measure impact of the program. These groups are better served in small group workshops with hand on demonstrations that emphasize both technical information and practical skills. A series of 5 workshops were conducted in 2007 in three counties in the state of Utah. Pre and post tests, which consisted of ten questions, were given to all participants utilizing the I-clicker testing equipment and software (Macmillian New York, US) which ensured anonymity while allowing comparisons between individual pre and post tests results. Questions were read and explained to all participants. Data were analyzed utilizing a paired sample t-test to determine workshop impact. Participants at all workshops showed a 31.5% improvement in their post tests results ($P < 0.001$). Spanish language training for Spanish speaking milkers should lead to improved milker knowledge, which in turn should lead to improved milking procedures, lower somatic cells counts and lower incidence of mastitis. This in turn should lead to better productivity of dairy operations and higher quality milk.

Key Words: Spanish Language Training, Workshop, Extension Education

Food Safety

T71 Crisis communications: The dairy plan. K. E. Olson^{*1}, S. L. Stevens², and D. Pelzer², ¹KEO Consulting, Schaumburg, IL, ²Dairy Management, Inc, Rosemont, IL.

Animal health or food safety emergencies whether the result of natural causes or terrorist introduction put producer markets at risk. The dairy industry "Crisis Readiness Program" has been developed to provide quick, accurate and appropriate responses to consumer concerns so market impacts can be minimized. The program is a collaborative effort of four national dairy organizations, each targeting a specific audience. Dairy Management, Inc. - consumers, International Dairy Foods Association - processors, National Milk Producers Federation - producers and U.S. Dairy Export Council - exporters and importers. The American Dairy Science Association (ADSA) provides a science link for the public. Local, state and regional entities, associated with the national organizations extend the program reach to all areas of the nation. The plan is designed to help the industry speak with "One Voice"; however, to be most effective it must be more than just industry. A broad network has been developed to facilitate this. Scientific experts are used to assure that messages are accurate, communications experts assure messages are communicated in a manner easily understood by target audiences. Working relationships with ADSA, federal, state and local government agencies and animal health officials familiarize them with industry plans and help assure that consistent messages are delivered by all parties. Three websites are utilized. www.Dairyreponse.com (producer section) is an open resource on animal health topics. During a crisis it will provide news updates and links to government information on the operational response. A password protected site is provided for industry communicators and a "dark site" is ready to be activated for media and consumers if an emergency strikes. Other tools include a quarterly newsletter with preparedness updates, annual crisis drills, media training and participation in government workshops. Efforts are ongoing to expand the network involved in the plan assuring that all producer and consumers receive accurate, easily understood information about the safety of dairy products in a timely manner in an emergency.

Key Words: Food Safety, Animal Health, Communications

T72 Determination of antibiotic residues in farm hens eggs. H. F. Ahmed^{*1}, I. M. Aman¹, and S. E. Zahran², ¹Kafr El-Sheikh University, Kafr El-Sheikh, Egypt, ²Animal Health Research Institute, Tanta, Egypt.

A High Performance Liquid Chromatography (HPLC) was used for the determination of antibiotic residues in farm hens eggs collected from EL-Gharbia Governorate, Tanta City, Egypt. 26.7%, 36% and 44% of the examined samples contained amoxicillin, oxytetracycline and tetracycline with mean values of 1.67±0.51, 44.8±21.6 and 17.5±4.6 ppm, respectively. The highest distribution of amoxicillin (50%) lies within the range of 0.5 - < 1 ppm, of oxytetracycline (33.34%) lies within the range of 10 - < 20 ppm, while that of tetracycline (55.2%) lies within the range of 4 - < 12 ppm. The drugs were identified as the parent drug after the application of replicate injection of matrix standard of pure (0 to 100 µg/ml). The illustration calibration graphs showed acceptable linearity in this range for the purpose of measuring with correlation coefficient (r²) values of 0.9998 for amoxicillin, 0.9828 for oxytetracycline and 0.9951 for tetracycline. The average recovery rates from egg samples spiked with 50, 20, 10 and 1 ppm ranged from 84 to 90.1% (SD 0.6 to 2.0) for

amoxicillin, from 98.4 to 99.5% (SD 1.0 to 1.2) for oxytetracycline and from 82 to 99.8% (SD 0.5 to 1.0) for tetracycline.

T73 Intestinal microbial affects of yeast products on weaned and transport stressed pigs. S. Weedman^{*1,2}, M. Rostagno², J. Patterson¹, A. Kiess¹, and S. Eicher², ¹Purdue University, West Lafayette, IN, ²USDA-ARS, West Lafayette, IN.

Study objectives were to determine effects of a commercially available yeast product (XPC, Diamond-V Mills) and stress of transportation on *Escherichia coli*, coliforms, and *Lactobacilli* populations in the intestine of weaning pigs. In a RCB design with a 2 x 2 factorial arrangement of yeast (Y) and transport (T), 54 pigs were used (n=12 per treatment and 6 baseline pigs). XPC was delivered orally in milk to provide 0.1g/kg of BW and controls (C) received milk only from d 4 to 21 (weaning). Pigs were transported (n=24) or moved (n=24) to nursery housing then supplemented with 0.2% XPC or a grain blank in wk 1 and 2 diets. Samples collected on d1 pre- and d 1, 4, 7, and 14 post-transport included mesenteric lymph node (MLN) and jejunal (Jj), ileal, and cecal contents. Data in parentheses are for YT, Y, CT, and C, treatments respectively. Jejunal coliforms; ileal *Lactobacilli*, coliforms, and *E. coli*; and cecal *Lactobacilli*, coliforms, and *E. coli* were affected (*P<0.05) by sampling day (Table 1). Transport by d (P=0.01) and transport by yeast (P=0.10) interactions were detected such that pigs had more *E. coli* in the cecum on d 1 post-transport (7.6^{ab}, 6.11^b, 7.9^a, 6.6^{ab}) than on d 7 (5.9^b, 7.5^a, 5.2^b, 6.0^{ab}). Yeast treatment stabilized coliform counts. Day 1 jejunal coliform counts were greatest (P<0.01) in CT (8.4^b, 7.8^b, 9.8^a, 8.1^b). Only one Y pig had *Salmonella* recovered from MLN on d 7 compared to 3 in all other treatments (P=0.07). Data show transport effects on intestinal microbial concentrations and modulation by the yeast product.

Table 1. Mean bacterial counts (cfu/g of sample) by d across treatments

d	Lactobacilli			Coliforms			<i>E. coli</i>		
	Jj	Ileum*	Cecum*	Jj*	Ileum*	Cecum*	Jj	Ileum*	Cecum*
1	8.0	8.3	8.4	8.5	8.5	8.0	6.3	7.5	7.1

T74 Identification of risk factors associated with increased coliform counts in bulk milk. J. Pantoja^{*}, C. Hulland, D. Reinemann, and P. Ruegg, University of Wisconsin, Madison.

The objective was to identify risk factors associated with increased coliform counts of raw bulk tank milk. Data were collected from 16 dairy between July, 2006 and July, 2007. Cows were milked in parallel parlors (n = 10), herringbone parlors (n = 5) or a rotary parlor (n = 1). Most farms (n = 11) had direct loading of milk. Herd size ranged from 200 to 2350 lactating cows. The 13-month average SCC by herd ranged from 89,500

to 316,770 cells/mL. Cows were housed in freestalls with sand (n = 11), shavings (n = 2) or biosolids (n = 3 herds). Farms were visited monthly and daily somatic cell (SCC), standard plate count (SPC), coliform count (COLI) and laboratory pasteurized count (LPC) were downloaded from the processor website. Increased bacterial counts were defined as: 1) COLI > 50; 2) LPC > 200 and 3) SPC > 30,000 CFU/mL. The monthly proportion (MP) of increased COLI was used as a response variable in a generalized mixed model as a function of season (spring, summer, fall and winter), bedding type, udder cleanliness (clean, slightly dirty, dirty and very dirty) teat end condition (no ring, smooth ring, rough and very rough), liner cleanliness (clean, slightly dirty, dirty and very dirty), SCC and MP of increased LPC and SPC. The 13-month proportion of increased COLI counts varied widely among farms (17 to 87%). The MP of increased SPC and LPC were positively associated with the MP of COLI counts ($P < 0.01$). There was a significant seasonal variation in the MP of COLI ($P < 0.01$). The greatest MP of COLI was observed during winter, as compared to the other seasons. Farms that used biosolids as bedding were 1.4 times more likely to have increased MP of COLI counts as compared to farms that used sand or shavings, with the greatest effect observed during summer ($P < 0.01$ for the interaction term between bedding and season). Herds with greater proportions of very rough teat ends were more likely to have increased COLI counts than herds with smaller proportions of very rough teat ends.

Key Words: Coliforms, Bacteria, Milk Quality

T75 Effects of distiller's grains and dry-rolled corn supplementation in steam-flaked corn grain-based diets on fecal shedding of *Escherichia coli* O157:H7 and *Salmonella*. M. E. Jacob*, J. S. Drouillard, D. G. Renter, J. T. Fox, and T. G. Nagaraja, *Kansas State University, Manhattan*.

Escherichia coli O157, a food-borne pathogen normally residing in the gut of cattle, causes illness in thousands of people each year. Previous work indicated a positive association between feeding cattle distiller's grains (DG), an ethanol fermentation byproduct, and fecal prevalence of *E. coli* O157. It is not known whether DG supplementation has any effect on fecal shedding of *Salmonella*, another major food-borne pathogen. Previously, feeding dry-rolled corn (DRC) compared to steam-flaked corn (SFC) diets was shown to reduce fecal prevalence of *E. coli* O157. Our objectives were to determine the effects and interactions of DG and DRC supplementation of SFC-based finishing diets on fecal shedding of *E. coli* O157 and *Salmonella* spp. Approximately 720 cattle were blocked by BW and assigned randomly to one of 28 feedlot pens. Pens were randomly assigned one of four dietary treatments. A 2x2 factorial arrangement of treatments was used; 0 or 25% dried-DG with solubles (DDGS) and 0 or 25% DRC added to finishing diets containing steam-flaked corn and alfalfa hay. Ten fecal samples were collected from the surface of each pen before cattle began treatment diets, and at least once every two weeks after final finishing diets were initiated. Fecal samples were cultured for *E. coli* O157 and *Salmonella*. The overall prevalence

of *E. coli* O157 and *Salmonella*, regardless of treatment diets, in fecal samples were 5.1 and 23.7%, respectively. Prevalence of fecal *E. coli* O157 was not different for cattle fed diets with and without DG ($P > 0.2$). Prevalence also was not affected by the addition of DRC ($P > 0.7$), week of sampling ($P > 0.7$) or the DDG x DRC interaction ($P > 0.4$). Fecal *Salmonella* prevalence was not affected by supplementation of DG ($P = 0.9$) or DRC ($P = 0.7$). Sampling week impacted *Salmonella* prevalence ($P < 0.01$), which ranged from < 1% (week 1) to 77.5% (week 17). In conclusion, DG, with or without DRC supplementation, had no effect on fecal *E. coli* O157 or *Salmonella* prevalence in cattle.

Key Words: *E. coli* O157, Distiller's Grains, Dry-Rolled Corn

T76 Effects of the dicarboxylic acids malate and fumarate on *E. coli* O157:H7 and *Salmonella* Typhimurium populations in pure culture and mixed ruminal culture in vitro fermentations. T. R. Callaway*, T. S. Edrington, R. C. Anderson, N. Krueger, and D. J. Nisbet, *ARS, Food and Feed Safety Research Unit, College Station, TX*.

The dicarboxylic acids malate and fumarate increase ruminal pH, reduce methane production, increase propionate and total VFA production, and reduce lactic acid accumulation in a manner similar to ionophores. The mechanism by which these acids affect the ruminal environment is reported to be through stimulation of the ruminal bacterium *Selenomonas ruminantium* to utilize lactate to form propionate via the succinate-propionate pathway. Therefore dicarboxylic acids have been suggested for use as non-antibiotic modifiers of the ruminal fermentation, but their impact on the overall microbial ecology of the rumen and gut remains unknown. Therefore this study was prepared to determine if the addition of dicarboxylic acids to ruminal fermentations affected populations of the human pathogens, *Escherichia coli* O157:H7 and *Salmonella* Typhimurium. Pure cultures of *E. coli* O157:H7 strain 933 and *S. Typhimurium* were grown with malate and fumarate added at 0, 1, 5, 10 and 20 mM (v/v; n=3 of each acid concentration) at 39 C for 24 h. Neither dicarboxylic acid inhibited ($P > 0.1$) the growth rate or final populations of *E. coli* O157:H7 or *S. Typhimurium*. Ruminal fluid was collected from concentrate fed cows (n=2) and *E. coli* O157:H7 and *S. Typhimurium* were added to separate ruminal fermentations. Fumarate and malate were added to these in vitro pathogen fermentations at concentrations of 0, 5, 10 and 20 mM (v/v; n=2 of each acid concentration) and were incubated at 39 C for 24 h. Again, the addition of malate or fumarate did not affect ($P > 0.1$) populations of *E. coli* O157:H7 or *S. Typhimurium*. However, final pH was increased ($P < 0.05$), the acetate:propionate ratio was decreased ($P < 0.05$), and total VFA production was increased ($P < 0.05$) by > 10 mM dicarboxylic acid addition. These results confirm that dicarboxylic acids can modify the ruminal fermentation, but they do not directly or indirectly influence populations of *E. coli* O157:H7 or *S. Typhimurium* in pure or mixed ruminal fluid fermentations.

Key Words: Organic Acids, *E. coli* O157:H7, *Salmonella*

Forages and Pastures I

T77 Estimating losses of dry matter from alfalfa-orchardgrass mixtures following rainfall events. W. K. Coblenz* and W. E. Jokela, *US Dairy Forage Research Center, Marshfield, WI.*

Studies designed to assess the effects of natural or simulated rainfall events on wilting experimental hays often have been hampered by questionable and erratic estimates of DM recovery following wetting. An alternative methodology for measuring losses of DM may be to use water-insoluble, cell-wall constituents as internal markers. Our objective was to verify this approach using insoluble cell-wall constituents [neutral-detergent fiber (NDF) without additives, NDF with alpha-amylase, NDF with sodium sulfite, NDF with alpha-amylase and sodium sulfite, acid-detergent fiber (ADF), hemicellulose, cellulose, and acid-detergent lignin] as internal markers. Forages consisted of 100, 75, or 50% alfalfa (*Medicago sativa* L.; wet basis), with the balance comprised of orchardgrass (*Dactylis glomerata* L.; 0, 25, or 50%, respectively). Forage mixtures were sealed into 18 × 30-cm custom-made Dacron bags (53-um pore size), dried under forced air (50°C) to determine accurately the initial mass of DM in each bag, and then wetted under a rainfall simulator for either 1, 2, 4, 6, 8, or 12 h at a calibrated rate of 70 mm/h (70, 140, 280, 420, 560, or 840 mm, respectively). These procedures resulted in actual losses of DM ranging from 0 to 10.4%. Following treatment, recoveries of all markers were high (≥90.1%), but deviations from 100% were smallest for the NDF-based markers, as well as ADF and cellulose. Linear regressions of predicted (marker-based) recoveries of DM on actual values determined gravimetrically were especially good ($r^2 \geq 0.775$) when NDF-based markers were used to estimate recovery. In all cases, neither slopes ($P \geq 0.103$) nor intercepts ($P \geq 0.083$) differed from unity and zero, respectively. Among markers requiring multiple digestion steps, ADF exhibited acceptable estimates of slope (0.84) and intercept (14.5%) that did not differ from unity ($P = 0.222$) and zero ($P = 0.231$), respectively. Neutral-detergent fiber appears to be a particularly suitable internal marker for measuring recoveries of DM following wetting; however, this approach remains contingent on complete recovery of shattered leaf particles prior to conducting laboratory analysis.

Key Words: Internal Marker, DM recovery

T78 Influence of cutting time and swath type on intake, site, and ruminal metabolism of alfalfa hay. T. Shenkoru, H. Hussein, and T. Wuliji*, *University of Nevada, Reno.*

Alfalfa (*Medicago sativa*) is important high protein legume forage. However, its nutritional value can be affected by various environmental and managerial factors. Among them cutting time and drying process affect alfalfa composition and nutritive value. This study investigates the effect of cutting time and swath width of alfalfa hay on the extent of ruminal and duodenal digestion of structural, nonstructural carbohydrate components and protein. Four ruminal and duodenal cannulated Suffolk ewes (90.5 ± 9.8 kg initial BW and 18 mo old) were used in a 4 × 4 Latin square design. Acid insoluble ash is used to calculate duodenal flow and digestibility of nutrients. Treatments were arranged as a 2 × 2 factorial with the main factors being cutting time (AM vs. PM), and swath width [narrow (1.3 m.) vs wide (1.6 m.)]. No interaction effect between harvesting time × swath width was found for daily organic matter intake. The daily gram intake of organic matter (OM), neutral detergent fiber, acid detergent fiber, hemicellulose, cellulose and total

nonstructural carbohydrate (TNC) were higher ($P < 0.05$) for the narrow swath than wide swath. PM-harvesting increased ($P < 0.05$) TNC and nitrogen (N) intake from 216 to 260 g/d and 49.3 to 57.5 g/d, respectively. Ruminal digestion of structural carbohydrates, including TNC was not affected by treatments. Total short chain fatty acids, molar proportion of acetate and butyrate were not altered by treatments. However, PM-harvesting increased ($P < 0.05$) molar percentage of butyrate from 7.6 to 8.2 mol/100 mol. Branched chain fatty acids were not affected ($P > 0.05$) by treatments. Microbial N flow to duodenum was greater (16.5 vs. 13.4 g/d, $P < 0.05$) for PM- than AM-harvested alfalfa hays. Duodenal non-ammonia N and dietary N flow, including efficiency of bacterial protein synthesis (averaged 13.2 g N/kg OM digested), were not affected by treatments. The study indicated that PM-harvested hay and hay dried in narrow swath had a better nutritional quality compared with AM hay and hay dried in wide swath.

Key Words: Alfalfa, Cutting Time, Digestibility

T79 Plant maturity and genetic influences on *in vitro* NDF digestibility of alfalfa. A. Palmonari*¹, N. Brogna¹, G. Rossi¹, I. Fusaro², G. Biagi¹, and A. Formigoni¹, ¹*DIMORFIPA Università di Bologna, Ozzano dell'Emilia, Bologna, Italy,* ²*Dipartimento di Scienze Degli Alimenti Università di Teramo, Teramo, Italy.*

Aging and excess of environmental stress conditions negatively affect alfalfa NDF digestibility (NDFd). This study evaluated the influence of plant maturity on *in vitro* NDFd (IVNDFd) of different varieties of alfalfa. Two cuttings from different four alfalfa varieties (A experimental, B, C and D commercial) were analyzed, each in five replicates, for chemical composition (CP, ADF, ADL, NDF) and 24h IVNDFd with Tilley & Terry technique. All varieties were grown in the same location under the same climatic and agronomic conditions. Each variety was cut at two stages of maturity: 20 days (II) and 30 days (III) after previous harvest. During the trial, temperature and amount of rainfall were: (II) 33.1°C max, 17.3°C min and 15.7 mm ; (III) 34.01°C max, 18.2°C min and 34.9 mm. Samples were harvested by hands at a 5.0 cm height and immediately dried at 65°C in a forced air oven. No statistical differences were found among varieties for CP, ADF, ADL and NDF in collection II and III, but differences ($P < 0.01$, Table 1) were observed for IVNDFd. These results demonstrate that variety A maintains better IVNDFd as maturity advances.

Table 1. Least Squares Means.

CUT	Variety	C.P. (%DM)	ADF (%DM)	ADL (%DM)	NDF (%DM)	IVNDFd (%DM)
II	A	24.55	24.87	5.07	45.65	64.23 A

T80 Effect of a lactic acid-*Lactobacillus* product and bale moisture on forage quality, and voluntary intake and digestibility of crabgrass hay by lambs. L. Hardin¹, A. Killion¹, J. Caldwell¹, K. Coffey^{*1}, D. Philipp¹, and W. Coblenz², ¹University of Arkansas, Fayetteville, ²USDA-ARS, Marshfield, WI.

A 1.6-ha field of common crabgrass (*Digitaria ciliaris* [Retz.] Koel.) was divided into 12 plots that were used in a randomized complete block design with a 2 x 2 factorial treatment arrangement to determine the impact of a lactic acid-*Lactobacillus* hay preservative and moisture concentration at baling on post-storage forage quality, and intake and digestibility by lambs. Half of the plots within each block were treated with 81 mL/tonne DM of a solution containing 11% lactic acid and non-viable *Lactobacillus acidophilus* at the time of mowing (T) and half were not treated (U). Within T and U plots, half were baled at 18% (M18) and half at 28% moisture (M28). Six bales per plot were selected at random, weighed, and stored in insulated 6-bale stacks. Core samples were taken from 3 of the bales after 42-d of storage. Black-faced wether lambs (n=16) were allocated randomly by weight to receive 1 of the 4 treatment combinations. Hay was chopped, then offered ad libitum to lambs housed in individual 1.1 x 1.5-m pens with expanded metal floors. Following a 10-d adaptation, total feces were collected for 5 d using fecal bags and dried at 50 C. Ash, CP, and ADF did not differ (P \geq 0.15) among treatments, but NDIN and lignin were greater (P $<$ 0.05) and IVDMD was lower (P $<$ 0.05) from M28 vs. M18. Maximum bale temperature was higher (P $<$ 0.01) from M28 vs. M18 (55 vs. 35 C). Total DMI (g/d and g/kg BW) did not differ (P \geq 0.16) among treatments. In vivo DMD was greater (P $<$ 0.01) from M28 vs. M18 (55.5 vs. 50.1%) and from T vs. U (56.0 vs. 49.7%). Digestible DMI was greater (P $<$ 0.05) from T vs. U (12.7 vs. 10.1 g/kg BW). Therefore, treating crabgrass with a lactic acid-*Lactobacillus* product prior to baling may not affect forage quality, but may improve DM digestion and digestible DMI by lambs. Baling moist crabgrass hay may have negative impacts on some measures of forage quality but may increase DM digestion by lambs.

Key Words: Crabgrass, Digestibility, Lambs

T81 Harvest management effects on Tifton-85 bermudagrass greenchop nutritive value. Y. C. Newman*, C. R. Staples, A. T. Adesogan, A. R. Blount, and C. Mackowiak, University of Florida, Gainesville.

One way of minimizing costs in dairy nutritional programs is to grow forages of high nutritive value and quality that can be used as part of the ration and in addition be used to attenuate excess soil nutrients. Tifton-85 bermudagrass (*Cynodon spp.*; T-85) provides high yield and nutritive value but defoliation management practices and their implications in nutritive value have not been evaluated under intensive greenchop production. The objective of the study was to examine the effects of harvest management (harvest interval x stubble height) on nutritive value (CP, IVTD, TDN, NDF, ADF, NDF digestibility) of T-85 when harvested for greenchop. A factorial combination of harvest interval (21, 24, 27, and 35 d) and stubble height (7 and 14 cm) was arranged in a split-plot design in an on-farm study. Experimental units were 120-m² plots replicated three times. Data were analyzed using mixed model methodology through MIXED procedure of SAS. There were a total of 6, 5, 4, and 3 harvests during the 2007 season (June-Oct) for 21, 24, 27, and 35 d harvest frequencies, respectively. First year data show that stubble height did not have an effect (P $>$ 0.05) on nutritive value. There were interactions with harvest frequency (P \leq 0.01); therefore, data

was analyzed by harvest frequency. Crude protein was highest (217 g kg⁻¹) when forage was cut at 21 d and lowest (201 g kg⁻¹) at 35 d. NDF for 21 d was not affected by season and averaged 685 g kg⁻¹ but NDF digestibility declined toward the fall months; and was 720 g kg⁻¹ at 21 d and lowest (702 g kg⁻¹) at 35 d. In vitro true digestibility followed similar response. Harvest intervals of 21 days provides greenchop of excellent quality but 24 and 27 days seem to provide the best compromise for nutritive value, production and associated pests in production of T-85 greenchop.

Key Words: Tifton-85, Bermudagrass, Greenchop

T82 Chemical composition and nutritive value of forage silages produced in the Italian Po Valley. S. Colombini^{*1}, L. Rapetti¹, N. Rizzi², P. Amodeo², G. Galassi¹, and G. M. Crovetto¹, ¹University of Milan, Milan, Italy, ²Dairy Farmers Association of Lombardy, Crema, Italy.

In order to characterize the nutrient composition and the feed value of ensiled forages produced in the Po Valley, 92 silage samples were collected in 2004 and 2005: 15 corn, 15 wheat, 5 barley, 3 rye, 3 sorghum grain, 18 sorghum forage, 15 alfalfa, 11 Italian ryegrass and 7 permanent pasture. Samples were analyzed for chemical composition, N solubility and fermentative profile. The energetic content was determined according to the gas production (GP) technique (Menke and Steingass, 1989). Data were analyzed by GLM procedures of SAS.

Dry matter and crude protein contents were higher (P $<$ 0.001) for alfalfa (61.0 and 21.0%) and permanent pasture (57.6 and 17.0%) silages due to field wilting. Alfalfa silages were characterized by a high concentration (P $<$ 0.001) of NPN (8.3% DM).

Corn showed the highest gas production (P $<$ 0.001) at 24 hours (58.6 ml/200 mg DM), due to its starch content. Italian ryegrass also was very fermentable because of its highly digestible fibre. The NEI values (Mcal/kg DM) were 1.58 (corn), 1.46 (wheat), 1.45 (Italian ryegrass), 1.36 (permanent pasture), 1.33 (barley), 1.31 (sorghum grain), 1.29 (alfalfa), 1.22 (rye), 1.16 (sorghum forage).

Dry matter concentration was positively correlated (P $<$ 0.001) to pH, CP, fiber-bound N and sugars, and negatively correlated (P $<$ 0.001) to acetic, propionic and lactic acid, total organic acid, ethanol and NH₃-N. Lactic acid concentrations (% DM) were: 10.4% in barley, 8.0% in sorghum grain, 7.8% in Italian ryegrass, 6.9% in corn and wheat. Alfalfa (2.9%) and rye (2.4%) had lower (P $<$ 0.05) lactic acid content compared to barley, sorghum grain and Italian ryegrass. Rye also had the highest (P $<$ 0.05) concentrations of acetic (4.3%), propionic (1.4%) and butyric (2.4%) acids, and NH₃-N (6073 mg/kg DM). All the other silages had low VFA and NH₃-N contents (P $<$ 0.05). In conclusion, corn silage had the highest (P $<$ 0.001) NEI content, while alfalfa had the highest protein content, but with a high proportion of NPN. Italian ryegrass was very fermentable with a high nutritive value.

Key Words: Silage, Nutritive Value

T83 Nutritive value of sunflower silage associated with different by-products. R. H. de T. e Buschinelli de Goes^{*1}, A. C. Martinez², E. S. Miyagi³, C. O. de Abreu², R. de C. M. Tramontini², K. C. da S. Brabes¹, and E. R. de Oliveira¹, ¹Universidade Federal da Grande Dourados, Dourados, MS, Brasil, ²Universidade Estadual de Maringá, Umuarama, PR, Brasil, ³Universidade Federal de Goiás, Goiânia, GO, Brasil.

Sunflower plants (20.0%DM and 10.0%CP) were ensiled in experimental silos to evaluate the effect of adding soybean hulls or crushed sunflower seeds, and ensiling period, on the fermentation and nutritive value of sunflower silage. A 3X3 factorial treatment design was replicated 3 times. Treatments were: Control (100% sunflower plants; SS), SS+5% soybean hulls (SS+SBH) and SS+5% crushed sunflower seeds (SS+CSS) with 14, 21 or 28 days ensiling. At 28 days, pH of SS was lower (3.08; $P < 0.05$) than SS+SBH (3.32) and SS+CSS (3.25). A limitation of SS is DM content (19.93%). Adding soybean hulls or crushed sunflower seeds increased DM% to 31.32% and 27.77%, respectively. There was interaction ($P < 0.05$) between the days of fermentation and the treatments. There was no difference for DM presented by SS+SBH, for 14 and 28 days ensiling; however for SS+CSS, the 21 day ensiling presented mean of 30.37%, and 14 and 28 days ensiling didn't differ. For SS there was effect after 21 days of ensiling. Crude protein, ash, and ADF were not different ($P > 0.05$; mean = 11.62, 8.83, and 46.60 %DM, respectively). However ADIN was higher in SS (0.14%DM; $P < 0.05$) than SS+SBH (0.12) or SS+CSS (0.11). The SS+SBH contained more NDF (64.64%DM) and lignin (30.48%DM) and reflect the higher concentration of NDF in soybean hulls. At the 28 days ensiling, the SS+CSS presents the smallest value (mean = 56.62), and NDF for SS and SS+SBH was 62.98%, and 65.69%, respectively. The values of NDF (59.73%) and ADF (44.68%) in SS are comparable to plants with plants unproved hemicelluloses (HCEL), as the sunflower. Adding soybean hulls or crushed sunflower seeds did not alter the concentration of HCEL (mean = 15.37%DM). Adding soybean hulls or crushed sunflower seeds increased silage DM and NDF but did not affect silage CP and ADF.

Key Words: Soybean Hulls, Sunflower Crushed, Chemical Composition

T84 The use of hybrid or native corn byproducts for the manufacture of nutritional blocks or silages: A simulation model. J. M. Tapia-Gonzalez*¹, A. Tewolde-Medhin², W. E. Grant³, J. C. Martinez-González², H. Diaz-Solis⁴, A. Moreno-Valdéz⁵, O. D. Montañez-Valdez¹, and G. Rocha-Chavez¹, ¹CUSUR, Univ de Guadalajara, Cd. Guzmán, Jalisco, México, ²Unidad Académica Multidisciplinaria Agronomía y Ciencias. UAT, Cd. Victoria, Tamaulipas, México, ³Texas A&M University, College Station, ⁴Área de Recursos Naturales, UAAAN, Saltillo Coahuila, México, ⁵Área de Recursos Naturales, Instituto Tecnológico de Ciudad Victoria, Cd. Victoria, Tamaulipas, México.

A simulation study was carried out using the Software STELLA® II Ver 5 for comparing a real corn production system and corn byproducts (corn straw or green plant) for making multi nutritional blocks or silages respectively. Two types of corn were compared: the native corn against the INIFAP HV-1 variety. Nutritional blocks and silage are intended for cattle feeding during dry season and unspecific genotypes of steers or crosses of *Bos taurus* x *Bos indicus* were used for the present study. The simulation model was formed in several steps following the mathematical approach of seeding both types of corn with or without post seeding management; A hundred runs were performed each year (system simulations). Native corn crops with post-seeding management yielded the highest amount of corn and dry forage according with both the real and simulated model. The model revealed cycles of reduced pluvial precipitation (300 to 400 mm PP) which were insufficient for the proper grow and development of both the native and hybrid corn crops which in turns yielded less grain and byproducts. These data reveals the uncertain and adverse climatic condition of that geographic area. The

hybrid corn variety showed the lowest grain and forage yield out of 100 years of cropping. These values are in agreement with the observed real yields of this production system.

Key Words: Simulation, Multinutritional Blocks, Corn Silage

T85 Factors effecting corn silage starch hydrolysis potential. A. E. Dorshorst*, P. C. Hoffman, N. M. Esser, M. G. Bertram, and T. K. Seeger, *University of Wisconsin, Madison.*

Digestibility of corn silage starch influences lactation performance of dairy cows. To investigate nutritional markers that explain starch digestibility in corn silage a factorial (3x3x3x3) set of corn silages was developed. Three varieties of corn (110,93,74 d), were planted on three planting dates and harvested on three dates. Grain samples for each variety, planting and harvest date were obtained by selecting corn stalks immediately prior silage harvest and hand shelling grain. Grain samples were dried, determined for kernel density, DM, starch, P, CP, globulin-albumin, and zein proteins. Corn silage was chopped, and ensiled without or with two degrees of kernel processing (1 or 3 mm). Approximately 1.5 kg of fresh corn silage was placed into plastic bags, vacuum sealed, and allowed to ferment for 150 d. Triplicate samples were conserved. Corn silages were evaluated for DM, starch, NDF, P, mean starch particle size, starch particles/g, starch surface area and kernel processing score. Starch hydrolysis potential of un-dried, un-ground corn silages was determined by the procedures of Blasel et al., 2006 where the percentage of starch hydrolyzed to glucose by amylase and amyloglucosidase is determined. Main effects and their interactions of the factorial set of corn silages on starch hydrolysis potential were evaluated using the GLM procedures of SAS. As designed, variety, planting date, harvest date and kernel processing significantly ($P < 0.05$) altered starch hydrolysis potential in corn silage. Nutritional markers in corn silage or grain samples and were compared to starch hydrolysis potential in un-dried, un-ground corn silage using the CORR procedures of SAS. Starch hydrolysis potential of corn silages were negatively related ($P < 0.002$) to starch particle size ($r = -0.64$), whole plant DM ($r = -0.53$), zein protein ($r = -0.51$) and positively related to albumin-globulin protein ($r = 0.35$). Data suggest starch hydrolysis potential in corn silage decreases with advancing maturity (increasing DM) due to increased encapsulation of starch by zein proteins.

Key Words: Starch Digestibility, Corn Silage, Zein

T86 Comparing three different methods for assessing corn silage density. R. J. Norell*¹, M. Chahine², S. Hines³, T. Fife², M. De Hario⁴, and S. C. Parkinson⁵, ¹University of Idaho, Idaho Falls, ²University of Idaho, Twin Falls, ³University of Idaho, Shoshone, ⁴University of Idaho, Gooding, ⁵University of Idaho, Preston.

The objective of this study was to compare three methods for estimating corn silage density: core sampling (Core), Wisconsin density calculator (Calculator) and feedout method (Feedout). Eighteen storages were enrolled in the study (9 bunkers, 7 piles, and 2 piles with a bunker wall). Three core samples were collected with a Master Forage probe (DairyOne, Ithaca, NY) during each of two farm visits. Core samples were collected at mid height of the silage mass and were sampled at the center, left, and right of the silage face. The Wisconsin density calculators for silage bunkers and piles are available at (www.uwex.edu/ces/crops/)

uwforage/dec_soft.htm). Required inputs to the silage density calculator include: storage dimensions, loading rate, layer thickness, number of packing tractors, tractor weight, and percent packing time for each tractor. Silage face measurements were obtained during three farm visits (10 to 14 d intervals). With the Feedout method, density was calculated by dividing the weight of silage fed by the volume of silage removed during the interval between farm visits. Mean dry matter density (kg/m³) and SE for Core, Calculator, and Feedout were: 229.4±6.0; 234.8±8.2; and 253.0±16.8; respectively. Mean density did not differ between methods (p=0.18) but the variation in density between storages was significantly higher for Feedout (p<0.001) than Core and Calculator methods. Core density measurements were highly correlated with Calculator estimates (r=0.71, p<0.001) but not with Feedout density estimates (r=-0.06, p<0.82). The Feedout method did not perform satisfactorily due to non-uniform silage faces and the inherent challenges in measuring volume of silage fed at the farm level. Core sampling is recommended for measuring silage density and the Calculator method is recommended for evaluating alternatives during the packing process.

Key Words: Corn Silage, Density

T87 Effect of length of time ensiled on dry matter, starch and fiber digestibility in whole plant corn silage. C. M. Hallada*¹, D. A. Sapienza², and D. Taysom³, ¹Vita Plus Corporation, Madison, WI, ²Sapienza Analytica, LLC, Slater, IA, ³Dairyland Laboratories Inc., Arcadia, WI.

To test the hypotheses that starch and fiber digestibility in whole-plant corn silage change with time ensiled, two separate hybrids from two commercial dairy farms were sampled. All samples were taken from one incoming load of corn forage chopped with a commercial harvester at each farm. For each farm, this forage was divided and 750 g placed into each of 48 vacuum-sealed polyethylene bags (4 replications of 12 ensiling periods). The bagged, ensiled samples were maintained in a temperature controlled room (25°C, 55% RH). Each month over the next 12 months, four silo-bags from each hybrid at each farm were taken and frozen until analyzed. Silage samples were evaluated (fresh basis) for fermentation acids (HPLC, Shimadzu, Columbia, MD). Samples were dried at 62°C (forced air oven, Sheldon Manufacturing, Cornelius OR) to a constant weight, ground to pass a 6mm screen (Wiley Mill, Thomas Scientific, Swedesboro, NJ) and analyzed for total-tract starch digestibility (ttSTRD), 12-hour ruminal starch digestibility (STRD12), 30-hour ruminal NDF digestibility (NDFD30) and ruminal dry-matter digestibility at 12 hours (DMD12) and 30 hours (DMD30) via in-vitro methods (Sapienza Analytica Standard Procedures). Values for all digestibility measures increased with time ensiled (p < 0.05 to 0.001, ANOVA and quadratic effect by non-linear regression analyses (XLSTAT, Addinsoft, NY, NY)). During the six months of active change, ttSTRD changed approximately 1.63 units per month ensiled (p < 0.01) and NDFD30 changed approximately 1.16 units per month ensiled (p < 0.001). All other digestibility traits changed approximately 0.06 units per month ensiled (p < 0.05 to 0.001). The changes in digestibility values appeared to plateau after 6-months of ensiling.

Key Words: Corn Silage, Digestibility, Starch

T88 Effect of month of sample submittal on corn silage nutrient fractions, starch availability, NDF digestibility, and fermentation profiles measured at a commercial forage-testing laboratory. R. T. Ward*¹ and M. B. de Ondarza², ¹Cumberland Valley Analytical Services, Inc., Hagerstown, MD, ²Paradox Nutrition, LLC, West Chazy, NY.

The objective of the study was to determine if nutrient fractions, starch availability, NDF digestibility, and fermentation profiles in corn silage samples significantly differed according to the month in which they were submitted for laboratory analysis. Month of sample submittal was assumed to relate to length of crop fermentation. The dataset (n=19184) included corn silage samples between 25 and 45% DM from New York that were submitted to Cumberland Valley Analytical Services, Inc. between January, 2004 and February, 2008. All samples were analyzed using near-infrared (NIR) technique. Soluble CP (%DM) was lower from Sept through Nov (3.80) vs. from March through July (4.47) (P<0.05). Ammonia (%DM) was lower from Sept through Feb than during the rest of the year (1.24 vs. 1.40) (P<0.05). Sugar (%DM) was higher from Sept to Dec than the rest of the year (1.37 vs. 1.03) (P<0.05). Starch (%DM) was higher in samples received in Nov and Dec than during the rest of the year (30.83 vs. 29.41) (P<0.05). Starch availability was defined as the amount of starch degraded by a one-hour amylase and glucoamylase treatment at 40°C. Available starch (%DM) (n=8662) was lower during Oct and Nov than during the rest of the year (4.62 vs. 5.66) (P<0.05). NDF digestibility (30 h) (%NDF) (n=17745) was higher in samples received from Sept through Jan than the rest of the year (55.38 vs. 51.26) (P<0.05). Titratable acidity (meq/g) was lower from Sept to Dec than the rest of the year (6.56 vs. 8.41) (P<0.05) while pH was higher during that time (3.81 vs. 3.73) (P<0.05). Lactic acid (%DM) was lower from Sept to Dec than during the rest of the year (4.26 vs. 5.06) (P<0.05). Acetic acid (%DM) was lower from Sept to Feb than during the rest of the year (2.41 vs. 3.01) (P<0.05). These data suggest that at least four months are required for full fermentation of corn silage.

Key Words: Corn Silage, Fermentation Profile, Starch Digestibility

T89 Aerobic stability and silage quality parameters. Y. Acosta Aragón*, G. Boeck, A. Klimitsch, G. Schatzmayr, and S. Pasteiner, *Biomim GmbH, Herzogenburg, Lower Austria, Austria.*

The deterioration of silage under aerobic conditions was determined by physical, chemical, and microbiological factors. The aim of the present study was to determine the correlations existing between different silage quality parameters and the aerobic stability (AS).

Five different substrates (grass, alfalfa, clover, green wheat and whole crop maize) were ensiled under laboratory conditions in buckets (5 liters), using silage additives: a negative control (without); 3 variations of the biological silage product Biomim[®] BioStabil Plus in different proportions between homo- and heterofermentative lactic acid bacteria (LAB) (*L. plantarum*, *E. faecium* and *L. brevis*), and dosage in cfu/g silage (A, B and C); and 3 positive controls, two chemical silage additives (3.0 and (2.5l/ ton), and a mixture of *L. plantarum* (2 × 10⁵ CFU/g) and other chemical product. Each treatment had 2 repetitions. The opening of the model silos occurred after 50 days. The changes in the pH values, the fermentation acid contents, ethanol, as well as the AS during 7 days (differences over 2°C between the room temperature and the inner silage temperature were considered as a sign for instability), the dry matter (DM) losses (Honig, 1990) and an organoleptic assessment using a negative point system according to the DLG- Schlüssel

(2006) were measured. Correlations between selected parameters and AS were done using 2-tailed Pearson correlations.

The correlation between the AS and the proportion of hetero- to homofermentative LAB, acetic acid content, and total acid amount was positive ($P < 0.01$) correlated ($r = 0.37, 0.46$ and 0.30 ; for $n = 48, 47$ and 47 respectively). It corroborates the scientific results availing the use of heterofermentative LAB and their production of acetic acid for increasing the AS.

The AS was negatively correlated with fructose content, propionic acid and ethanol content, as well as with DM losses and organoleptic assessment (correlation coefficients of $-0.31, -0.41, -0.33, -0.82$ and -0.75 ; for $n = 44, 44, 42, 48$ and 48 respectively).

Key Words: Silage, Aerobic Stability, Silage Quality

T90 *Streptococcus bovis* as a silage inoculant: A second chance.

F. E. Contreras-Govea¹, R. E. Muck², and J. B. Russell³, ¹University of Wisconsin, Madison, ²USDA-ARS Dairy Forage Research Center, Madison, WI, ³USDA-ARS, Ithaca, NY.

Previous research indicated that *Streptococcus bovis*, a lactate producing ruminal bacterium, was similar or better than commercial silage inoculants (Jones et al., 1991). This study assessed the potential of two *S. bovis* strains, **JB1** (a bacteriocin negative strain) and **HC5** (a bacteriocin producing strain). Four treatments were used, uninoculated (Control), a commercial inoculant *Lactobacillus plantarum* (Ecosyl **MTD/1**), **JB1** and **HC5** using third cut alfalfa (50% DM, **AS1**) in 2005 and third cut alfalfa (38.3% DM, **AS2**) in 2006. All inoculants were applied at 10^5 CFU/g forage. Ten 0.5-L mini-silos were used for each treatment. Silages were allowed to ferment at 39°C for 1, 2, 4, and 60 days and analyzed for pH, ammonia-N, non-protein nitrogen (NPN), organic acids, and ethanol. Two mini-silos per treatment were opened after 1, 2, and 4 d, and four mini-silos on d 60. After 60 d with **AS1**, **MTD/1** was the only inoculant having $pH < 5.0$ (4.84). The pH values for **C**, **JB1**, and **HC5** ranged from 5.36 to 5.44. With **AS2**, pH was lower for **MTD/1** (4.57) and **JB1** (4.62) than **C** (4.73) and **HC5** (4.72) ($P > 0.05$). With **AS1**, ammonia was lower for **MTD/1** (1.62% TN) than **C** (1.97% TN), **JB1** (1.94% TN), and **HC5** (2.21% TN) ($P < 0.05$). With **AS2**, ammonia was lower for **MTD/1** (2.35% TN), **JB1** (2.34% TN), and **HC5** (2.46% TN), than **C** (2.59% TN) ($P > 0.05$). With **AS1**, lactate was greater for **MTD/1** (60.2 g/kg DM) than the other treatments ($P < 0.05$) whereas with **AS2** lactate was similar among treatments ($P > 0.05$). We conclude that *S. bovis* **JB1** was a more effective inoculant than **HC5**, and similar to the commercial inoculant in one of two trials. The inability of **HC5** to perform as well as (or out-perform) **JB1** maybe related a 10% slower growth rate, and the susceptibility of its cell-free bacteriocin to peptidases.

Key Words: *Streptococcus bovis*, Silage Inoculants, Lactic Acid

T91 An evaluation of the effectiveness of *Lactobacillus buchneri* 40788 to improve the aerobic stability of corn silage in farm silos.

L. J. Mari^{1,3}, R. J. Schmidt^{*1}, L. G. Nussio³, C. M. Hallada², and L. Kung, Jr.¹, ¹University of Delaware, Newark, ²Vita Plus Corporation, Madison, WI, ³University of Sao Paulo, Piracicaba, SP, Brazil.

The objective of this study was to determine the effectiveness of inoculants containing *L. buchneri* 40788 (Lallemand Animal Nutrition,

Milwaukee, WI) on fermentation and the subsequent aerobic stability of corn silage stored in farm silos. Corn silage was randomly sampled from farms in Wisconsin and Minnesota using no inoculant ($n = 15$) or using an inoculant ($n = 16$) containing either *L. buchneri* 40788 alone or this organism combined with *P. pentosaceus* during May through June of 2007. All silages had been ensiled in the Fall of 2006. Corn silage that was removed from the silo face during the morning feeding was sampled, vacuumed sealed and shipped immediately to the University of Delaware for analyses. Silage samples were analyzed for DM, fermentation end products, aerobic stability and microbial populations. The population of *L. buchneri* in silages was determined using a real time-qPCR technique. Aerobic stability was measured as the time after exposure to air that it took for a 2°C rise above an ambient temperature of about 23°C. The DM and concentrations of lactic and acetic acid were 35.6 and 34.5%, 4.17 and 4.85%, and 2.24 and 2.41% respectively for control and inoculated silages. The concentration of 1,2 propanediol was greater ($P < 0.05$) in inoculated silages (1.26 vs. 0.29%). Numbers of lactic acid bacteria determined on MRS agar were not different between treatments. However, the numbers of *L. buchneri* based on real time-qPCR analysis was higher ($P < 0.05$) and averaged 6.46 log cfu/g compared to 4.89 log cfu for uninoculated silages. Number of yeasts was lower and aerobic stability was greater ($P < 0.05$) in inoculated silages (4.75 log cfu/g and 74 h of stability) than in uninoculated silages (5.55 log cfu/g and 46 h of stability). This study supports the effectiveness of *L. buchneri* 40788 on dairy farms.

Key Words: Corn Silage, *Lactobacillus buchneri*, Polymerase Chain Reaction

T92 The effect of *Lactobacillus buchneri* 40788 or *Lactobacillus plantarum* MTD-1 on the fermentation and aerobic stability of corn silages ensiled at two dry matter contents. W. Hu*, R. J. Schmidt, E. E. McDonnell, C. M. Klingerman, and L. Kung, Jr., University of Delaware, Newark.

Whole plant corn at normal and high dry matter (DM) contents (33.1 vs. 40.6%) was ensiled in quadruplicate 20-L laboratory silos to investigate the effects of inoculants *Lactobacillus buchneri* 40788 (LB) or *L. plantarum* MTD-1 (LP) on fermentation and aerobic stability. Aerobic stability was defined as the time after silo opening for silage temperature to reach 2°C above ambient. Chopped forage was used in a $2 \times 2 \times 2$ factorial arrangement of treatments: DM contents at 33.1 or 40.6%, LB at 0 (untreated) or 4×10^5 cfu/g, and LP at 0 or 1×10^5 cfu/g of fresh forage. After 240 days ensiling, an interaction effect of LB by forage DM content on concentrations of lactic and acetic acids was observed. For LB-treated silage in normal forage DM content, concentration of lactic acid on DM basis decreased (2.28 vs. 3.76%; $P < 0.01$), and that of acetic acid increased (1.78 vs. 0.93%; $P < 0.01$); whereas, for LB-treated silage in high forage DM content, concentration of lactic acid was unchanged (3.37 vs. 3.05%), and that of acetic acid increased (2.14 vs. 0.58%; $P < 0.01$) when comparing with LB-untreated silage. The effect of LP on concentration of lactic acid occurred only in silage with normal forage DM content (treated, 3.36% vs. untreated, 2.68%; $P = 0.02$). It was also shown that silage treated with LP had greater concentration of acetic acid (1.62 vs. 1.09%; $P < 0.01$) for silage with normal forage DM content, and lower concentration of acetic acid (1.14 vs. 1.57%; $P < 0.01$) for silage with high forage DM content when comparing with the LP-untreated silage. Appreciable amounts of 1,2-propanediol existed in all LB-treated silages with both forage DM contents (average 1.65%). Aerobic stability was improved consistently in all LB-treated silages

(average LB-treated, 189 h vs. LB-untreated, 50 h; $P < 0.01$), the silage with high forage DM content having greater aerobic stability than did the silage with normal forage DM content (268 vs. 109 h; $P < 0.01$). No effect of LP on aerobic stability was found in this experiment.

Key Words: Corn Silage, Inoculants, Aerobic Stability

T93 The effect of combining *Lactobacillus buchneri* 40788 with lactic acid bacteria on the fermentation, microbial populations and aerobic stability of brown midrib corn silage. L. J. Reich*, M. W. Hofherr, R. J. Schmidt, W. Hu, and L. Kung, Jr., *University of Delaware, Newark.*

The objective of this study was to determine the effects of combining *Lactobacillus buchneri* 40788 (LB) (Lallemand Animal Nutrition, Milwaukee, WI) with classical homolactic acid bacteria on the ensiling of corn silage. Mycogen F697, a brown midrib hybrid, was harvested at about 31% DM and was: a) untreated, or treated with b) LB (4×10^5 cfu/g of forage) and *Pediococcus acidilactici* (1×10^5 cfu/g) (LBPA), c) LB (4×10^5 cfu/g of forage) and *L. plantarum* (1×10^5 cfu/g) (LBLP), or d) LB (4×10^5 cfu/g of forage) and *P. pentosaceus* (1×10^5 cfu/g) (LBPC). Forage was ensiled in 20-L silos (quadruplicate per treatment) and the tops were sealed with an oxygen barrier plastic. After ensiling for 210 d, the top 10 cm of each silo was separated from the bottom 26 cm which added an effect of location to the design. Visibly spoiled silage from the top was weighed. Silages from both sections were analyzed separately for fermentation end products and microbial populations. Silage from the bottom section was also analyzed for aerobic stability and populations of LB by using a real time quantitative polymerase chain reaction. Untreated silage had more ($P < 0.01$) visible spoilage on the top than did inoculated silages. Untreated silage also had more ($5 \log$ cfu/g, $P < 0.01$) yeasts than inoculated ($< 2 \log$ cfu/g) silages in the top and bottom of the silos. There were treatment \times location interactions for all fermentation end products but the final concentrations of acetic acid and 1,2 propanediol were greatest ($P < 0.01$) for LBPC $>$ LBPA $>$ LBLP $>$ untreated. Untreated silage contained only 5.62 log cfu of LB per g of wet silage and was less than that found in inoculated silages (range 7.97 to 8.80 cfu/g). The aerobic stability of untreated silage was 186 h but it was greater ($P < 0.01$) for inoculated silages (average > 500 h). Although combining LB with various lactic acid bacteria resulted in differing magnitude of responses in fermentation end products, the combinations were equally effective in improving the aerobic stability of corn silage.

Key Words: *Lactobacillus buchneri*, Silage, Aerobic Stability

T94 Effect of the silage additive and the ensiled substrate on the silage quality parameters. Y. Acosta Aragón*, G. Boeck, A. Klimitsch, G. Schatzmayr, and S. Pasteiner, *Biomim GmbH, Herzogenburg, Lower Austria, Austria.*

Five different substrates (grass, alfalfa, clover, green wheat and whole crop corn) were ensiled under laboratory conditions in buckets (5 liters), using silage additives: a negative control = NC (without); 3 variations of the biological silage product Biomim® BioStabil Plus in different proportions between homo- and heterofermentative lactic

acid bacteria (LAB) (*L. plantarum*, *E. faecium* and *L. brevis*) of 1 : 1 and 1 : 10; and dosage in cfu/ g silage (1×10^5 and 1×10^6) (A, B and C); and 3 positive controls, two chemical silage additives (mixture of acids) D (3.0 l/ ton) and E (2.5l/ ton), and F, a mixture of *L. plantarum* (2×10^5 CFU/g) and a chemical product (mixture of acids and salts). Each treatment had 2 repetitions. Model silos were opened after 50 days. The following parameters were analysed: pH, fermentation acid content, ethanol, aerobic stability during 7 days and dry matter (DM) losses (Honig, 1990). For the analysis of variance between the groups (different silage additive or substrates) a one-way ANOVA procedure was conducted. Silage additives, across all forage species, affected ($P < 0.05$) silage pH ((A $>$ (NC = B = C = D) $>$ E = F), the proportion of acetic acid content in total acid (F $>$ ((NC = A = B = C = D) $>$ E) and aerobic stability ((A = B = C) $>$ (D = E = F) $>$ NC). Other parameters were not different. Propionic acid content and DM losses were not affected by the substrate. The final pH was different ($P < 0.05$) in the following order: alfalfa $>$ green wheat = clover grass = grass $>$ whole crop maize. This corresponds with lactic acid content reached by the substrates. Acetic acid content was very high for clover grass and green wheat (31.85 and 44.11 g/ kg DM, respectively) and not different from grass; but grass was in the range given by the DLG-Schlüssel (2006) of 15 to 30 g/kg DM as optimum. Aerobic stability was closely correlated to the acetic acid content which reached for these substrates (clover grass, green wheat and grass) 7, 7 and 6 days respectively.

Key Words: Silage, Additive, Substrate

T95 Effect of a microbial inoculant producing ferulic acid esterase on the fermentation and NDF digestibility of normal and BMR corn silages. M. W. Hofherr*, L. J. Reich, M. C. Der Bedrosian, M. C. Santos, W. Hu, and L. Kung, Jr., *University of Delaware, Newark.*

Three corn silage hybrids were untreated or treated with the Pioneer inoculant 11CFT (Pioneer Hi-Bred International, Inc., Johnston, IA) to determine its effects on silage fermentation and NDF digestibility (NDF-D). The three hybrids included Pioneer 33A87 (34% DM), Pioneer 33J57 (31% DM) and Mycogen F697 BMR (34% DM). The inoculant contained a strain of *Lactobacillus buchneri* capable of producing ferulic acid esterase and a strain of *L. casei*. The theoretical rate of inoculation achieved a final count of 1×10^5 cfu of *L. buchneri* and 1×10^4 cfu of *L. casei* per g of wet forage. Forages were chopped to a theoretical cut length of 1.9 cm and approximately 600 g were ensiled in quadruplicate, vacuumed and heat-sealed bags for each inoculant, hybrid and day of ensiling. Silos were opened for each treatment after 60, 180 and 360 days of fermentation. Silages were analyzed for nutrients and fermentation end products. The digestibility of silage NDF was determined using dried samples ground through a 6-mm screen in a Wiley mill, weighed into in situ bags (5.5×5.5 cm, 40 ± 15 microns, Ankom Technology) and incubated in rumen fistulated steers for 48 h. Steers were fed a diet consisting of 45% corn silage, 15% alfalfa hay and 40% concentrate. Over all sampling days, inoculation resulted in a lower concentration ($P < 0.01$) of lactic acid (4.34 vs 4.80%, DM basis) but a higher ($P < 0.01$) concentration of acetic acid (1.60% vs. 1.17%) compared to untreated silage. There was an inoculation \times hybrid \times day effect for acetic acid. The NDF-D averaged across all sampling days by hybrid was greatest ($P < 0.01$) for BMR (58.1%) compared to 33J57 (45.3%) and 33A87 (44.3%). However, there was a hybrid \times inoculation effect. Averaged over all sampling days, inoculation did not affect the

NDF-D of BMR (57.6 vs. 58.6%) but it improved NDF-D ($P < 0.05$) for 33A87 (45.3 vs. 43.2%) and for 33J57 (46.3 vs. 44.3%).

Key Words: Ferulic Acid Esterase, Silage, Digestibility

T96 Nutritive value of sorghum silage added bacterial inoculants. R. H. de T. e Buschinelli de Goes*¹, A. C. Martinez², C. O. de Abreu², and K. C. da S. Brabes¹, ¹Universidade Federal da Grande Dourados, Dourados, MS, Brasil, ²Universidade Estadual de Maringá, Umuarama, PR, Brasil.

Thirty six PVC silos (4 in. diameter with 40cm of height and capacity of 3.2L) were utilized to evaluate the addition of corn meal and bacterial inoculants (*L.plantarum*, *S.faecium*, and *Lactobacillus spp.*) on the quality of the sorghum silage harvested 125 days after planting. The inoculant was supplied in the dose of 2.0 forage mg/kg; the product contains 5.26×10^{10} CFU/g. A 3x2x6 factorial design with 3 levels of corn meal, 2 inoculant (none or inoculated), and 6 ensiling periods was applied in a randomized design with 02 replications. Corn meal was included at 0, 10, and 20% of natural matter. Silage was removed from each silo on day 0, 7, 14, 21, 28 and 35 after ensiling. The pH was not altered by the use of corn meal with or without inoculant. Silage DM was increased by corn meal inclusion ($P < 0.05$) but not by inoculant ($P > 0.05$). Neither corn meal inclusion or inoculant affected ($P > 0.05$) CP, EE, ash, NDF, NPN, ADIN, soluble N or total CHO (means = 15.47, 2.10, 10.83, 76.99, 0.72, 0.48, 1.12, 16.87, respectively). Silage crude protein (mean = 15.47%) is due to presence of panicle in the silage; the proportion of panicle might interfere in the ADIN. The length of fermentation, increased silage ADIN, for 20% of corn meal (mean = 0.54); and the CP after 21 days ensiling. The ADIN for 0%, and 10% of corn meal was 0.49. Silage ADF was not affected ($P > 0.05$) by inoculant but as reduced (45.17 vs 49.42 and 48.82%; ($P < 0.05$) with 20% corn meal inclusion. This suggests that 20% corn meal altered silage fermentation. The addition of inoculant not altered the quality of sorghum silage.

Key Words: Chemical Composition, Corn Meal, *L. plantarum*

T97 Microbial inoculant effects on in situ ruminal dry matter and neutral detergent fiber disappearance of corn silage. K. E. Cowles* and M. R. Murphy, University of Illinois, Urbana.

The efficacy of a prototype microbial inoculant on composition, and in situ ruminal dry matter (DM) and neutral detergent fiber (NDF) disappearance, of corn silage was evaluated. Two corn hybrids, Pioneer 31N27 (H1) and 33D31 (H2) were treated after harvest with either a control (no inoculant) or a blend of *Lactobacillus buchneri* and *L. casei* (Pioneer Hi-Bred, a DuPont Business, Johnston, IA) applied at 2 ml/kg of fresh forage in a completely random design with 32 mini-silos. Sixteen silos were opened 60 and 120 d post-ensiling. Disappearance of DM and NDF was measured after 24 or 48 h of ruminal incubation. At harvest, H2 was drier than H1 (34 vs. 40%; $P = 0.01$); crude protein, NDF, acid detergent fiber, nonfiber carbohydrate, ash, and pH were similar. Compositions differed after 60 d: lactate and lactate:acetate increased more, and acetate and propionate decreased more, for the blend applied to H2 than H1 (interactions $P \leq 0.02$). Percentages of DM, nonfiber carbohydrate,

acetate, and propionate increased more after 60 d when the blend was applied to H2 than when applied to H1 (interactions $P \leq 0.02$). Content of NDF, lactate, and lactate:acetate decreased more after 60 d when the blend was applied to H2 than when applied to H1 (interactions $P \leq 0.02$). The DM disappearance in the rumen of H2 after 60 d tended to be higher for the blend than for the control (36 vs. 38%, $P = 0.11$). After 120 d, DM disappearance of H1 was 6% higher (42 vs. 45%; $P = 0.11$) for the blend than for the control; whereas, it was unchanged for H2. An interaction of hybrid, treatment, and time in the rumen ($P \leq 0.02$) indicated that the blend enhanced ruminal DM disappearance of H2 but not H1. Ruminal disappearance of NDF for H2 after 60 d was 110% higher (11 vs. 24%; $P = 0.02$) for the blend than for the control. Neither treatment nor time of ensilage affected NDF disappearance for H1. After 120 d, NDF disappearance in the rumen of H2 was still 14% higher for the blend than for the control. Differences in composition and ruminal degradation of silages indicated that the blend improved conservation and feeding values of H2 but not H1.

Key Words: Corn Silage, Inoculant, Ruminal Degradation

T98 Impact of chloride fertilization and Silo-King® on the nutrient content, digestibility, and mycotoxin concentrations in corn silage. D. H. Kleinschmit*, D. P. Casper, and D. A. Spangler, Agri-King, Inc., Fulton, IL.

Producing corn silage from soils fertilized with Cl has resulted in improved forage quality via reducing the plant's susceptibility to mycotoxins. The feeding value of corn silage may be further enhanced by using a forage fermentation additive. The experiment was conducted using a 2 x 3 factorial randomized complete block design. Three blocks were randomly selected within a corn field and within each block, three plots were assigned to one of three fertilization treatments: 1) no fertilization (CON), 2) fertilization with CaCl at a rate of 227 kg/ha (CaCl), or 3) fertilization with KCl at 227 kg/ha (KCl). Two weeks prior to harvest, plant ears were inoculated via toothpicks with *Fusarium graminearum*. Within each plot, corn silage was either untreated (UNT) or treated with Silo-King® (SK; Agri-King, Inc., Fulton, IL) at a rate of 0.20 kg/tonne of fresh forage in triplicate silos and ensiled for 65 d. With the exception of having the greatest ($P < 0.01$) concentration of Cl (0.11, 0.37, and 0.34% for CON, CaCl, and KCl, respectively), CaCl had little impact on nutrient content of corn silage compared to the other fertilization treatments. Compared to CON, KCl had lower ($P < 0.05$) concentrations of ADF (30.6, 30.1, and 28.4%), NDF (50, 48.8, and 46.2%), and lignin (3.43, 3.38, and 3.16%) and greater ($P < 0.05$) concentrations of starch (24.3, 26.0, and 28.7%), thus numerically improving *in vitro* DM digestibility (64.0, 64.2, and 65.3%; IVDMD). Treating corn silage with SK lowered ($P < 0.01$) concentrations of ADF (31.2 vs. 28.2% for UNT and SK, respectively), NDF (50.5 vs. 46.2%), and lignin (3.47 vs. 3.18%) and increased ($P < 0.01$) concentrations of starch (23.6 vs. 29.0%) and crude fat (2.00 vs. 2.30%), thus improving ($P < 0.04$) IVDMD (63.7 vs. 65.4%). Chloride fertilization or treatment with SK did not affect mycotoxins. In conclusion, fertilizing with KCl shows potential to improve the digestibility of corn silage via reduced fiber components and increased the starch concentrations. Treating corn silage with Silo-King® at ensiling increased the digestibility of DM.

T99 Ruminal and intestinal crude protein digestibility of triticale dried distillers grains with solubles. K. T. Wierenga*, G. B. Penner, and M. Oba, *University of Alberta, Edmonton, Alberta, Canada.*

The objective of this study was to compare in situ ruminal CP and in vitro intestinal CP digestibility (IVID) of triticale dried distillers grains with solubles (TDDGS) to those of soybean meal (SBM), canola meal (CM) and corn DDGS (CDDGS). The feedstuffs were incubated using nylon bags (50 µm pore) in the rumen of three lactating dairy cows fed a diet containing 27.8% NDF and 16.6% CP. Samples were incubated in the rumen for 0, 1, 2, 4, 8, 16, 24, 48 and 72 h to determine ruminal CP degradation. To determine IVID, samples ruminally incubated for 16 h were digested with HCl/pepsin and pancreatin. The soluble protein (%CP) was higher ($P < 0.001$) for CDDGS and TDDGS (30.2 and 31.0%, respectively) compared to CM (15.1%) and SBM (9.0%). The rapidly degradable protein (< 1h, %CP) was highest ($P < 0.001$) for CDDGS (30.9%) followed by TDDGS (22.5%), CM (9.1%), and SBM (6.1%). Degradation rate of slowly degradable protein was faster ($P < 0.001$) for SBM and CM (4.50 and 4.10 %/h, respectively) than CDDGS and TDDGS (1.87 and 1.80 %/h, respectively). Rumen degradable protein after 16h of incubation was higher ($P < 0.001$) for CDDGS and TDDGS (69.3% and 64.5% respectively) than CM (62.2%) and SBM (53.0%). However, as IVID (%CP) was highest ($P < 0.001$) for SBM (33.9%), followed by CM (18.4%), TDDGS (14.0%), and CDDGS (8.5%), estimated total-tract digestibility of CP was higher for SBM (86.8%) compared to CM, TDDGS, and CDDGS (80.7, 78.5, and 77.8%, respectively). Although DDGS has been generally accepted as a high RUP feed, the high RDP and rapidly degradable protein in CDDGS and TDDGS reported herein suggest more degradation in the rumen. Therefore, further investigation is warranted to determine the extent of ruminal CP degradation variations among different types of DDGS.

Key Words: Dried Distillers Grains with Solubles, In Vitro Intestinal Digestibility, In Situ Ruminal Degradation

T100 Heat treatment of bovine colostrum: Effect on viscosity, bacterial count and immunoglobulin G levels. J. A. Elizondo-Salazar*, S. C. Donaldson, B. M. Jayarao, G. R. Ziegler, and A. J. Heinrichs, *The Pennsylvania State University, University Park.*

A study was conducted to identify the optimal temperature and time at which heat treatment of bovine colostrum would least change viscosity and IgG levels yet reduce bacterial count. First milking colostrum with IgG levels > 50 g/L (measured by colostrometer) was collected from 30 Holstein cows and frozen at -20°C. Each sample was thawed at 4°C, thoroughly mixed and ten 10-mL aliquots were taken in sterile 15-mL screw-cap centrifuge tubes. Samples were heat-treated for 0, 30, 60, and 90 min at 63, 60 and 57°C using a water bath. Samples were evaluated for standard plate count (SPC), preliminary incubation count (PIC), coagulase-negative staphylococci (CNS) count, environmental streptococci (ES) count, coliform (CC) count, gram-negative noncoliform (NC) count, *Streptococcus agalactiae* (SAG) count, and *Staphylococcus aureus* (SA) count. IgG₁ and IgG₂ levels were determined in all samples using radial immunodiffusion. Viscosity was also measured using a digital viscometer. All heat-treatments reduced SPC, CC, NC, ES, CNS, SA, and PIC ($P < 0.05$). Heat-treatment at 60°C and above resulted in

significant denaturation of colostral IgG₁. However, colostral IgG₂ levels were not reduced when the temperature was held at 60°C for less than 60 min. Viscosity was not affected when temperature was held at 60°C for less than 60 min. The findings of the study suggest that heat-treatment of bovine colostrum at 60°C for 30 to 60 min may be used as an optimal temperature and timing, at which heat treatment of bovine colostrum would produce no significant changes in viscosity, a small reduction in IgG levels, and a significant reduction in bacterial count.

Table 1. Changes in viscosity, bacterial count and IgG levels in bovine colostrum after heat-treatment.

Temp. (°C)	Time (min)	IgG ₁ (g/L)	IgG ₂ (g/L)	Viscosity (Pa·s)	SPC (CFU/mL)
Control	Control	71.6 ^a	3.2 ^a	388 ^{ab}	39,753 ^a
57	30	66.8 ^{ab}	3.0 ^{ab}	95 ^a	7,019 ^{bc}
57	60	66.7 ^{ab}	3.0 ^{ab}	68 ^a	10,443 ^b
57	90	62.6 ^{ab}	2.9 ^{ab}	168 ^a	3,816 ^{bc}
60	30	56.7 ^{bc}	2.7 ^{abc}	106 ^a	4,283 ^{cd}
60	60	47.9 ^{dc}	2.6 ^{abc}	655 ^b	3,553 ^{bc}

T101 The effects of increased milking frequency during early lactation on milk yield and milk composition on commercial dairy farms. F. Soberon*, C. M. Ryan, D. M. Galton, and T. R. Overton, *Cornell University, Ithaca, NY.*

Holstein cows (n=398) entering either first or later lactation on four commercial farms were used to determine the effects of increased milking frequency (IMF) during the first 21 d postpartum. Cows were assigned randomly at calving within farms either to a control treatment (2× milking) or to an IMF group in which cows were milked 4× during the first 21 d postpartum followed by 2×. Cows assigned to the IMF group were milked at the beginning and again at the end of the normal milking routine during the 4× period. This resulted in minimum milking intervals for the 4× cows of 3.5, 4.5, 5.5, and 6 h for each farm. Results from the analysis of data from the three farms from which 7 monthly test days of production data were available indicated that early lactation IMF increased milk yield by 2.1 kg/d during the first 7 months of lactation (33.9 vs. 31.8 kg/d; $P < 0.01$). Interactions of treatment with lactation group were not significant. Overall percentages of milk fat (3.62 vs. 3.73; $P = 0.02$) and true protein (2.97 vs. 3.03; $P = 0.05$) were decreased by early lactation IMF; however, overall yields of milk fat (1.21 vs. 1.17 kg/d; $P = 0.04$) and true protein (1.00 vs. 0.95 kg/d; $P < 0.01$) were increased by early lactation IMF. Within-farm analysis using all the available test day information for each farm (7, 10, 7, and 5 test days, respectively) indicated that the magnitude of the milk yield response varied from 4 to 10% (3.1, 1.5, 1.8, and 1.8 kg/d for each farm). Early lactation IMF did not affect somatic cell linear score and did not affect body fat mobilization as assessed by BCS; however,

there was a tendency for serum NEFA to increase (485 vs. 427 $\mu\text{Eq/L}$; $P = 0.08$) and an increase in serum BHBA (12.2 vs. 10.4 mg/dl; $P = 0.03$) during the first 21 d postpartum for cows subjected to IMF. The number of cows diagnosed with subclinical ketosis (BHBA > 14 mg/dL) did not differ among treatments ($P = 0.87$). Results suggest that early lactation IMF has the potential to consistently increase milk yield on commercial dairy farms.

Key Words: Milking Frequency, Transition Cow

T102 Effect of abomasal infusion of butterfat, long chain fatty acids or CLA on milk fatty acid composition and mammary tissue lipogenic gene expression in lactating cows. A. K. G. Kadegowda^{*1}, J. J. Loo², L. S. Piperova¹, P. Delmonte³, and R. A. Erdman¹, ¹University of Maryland, College Park, ²University of Illinois, Urbana, ³FDA, College Park, MD.

Mammary tissue lipogenic gene expression and milk fatty acid composition were studied during abomasal infusion of butterfat, long chain fatty acids or CLA mixture in lactating cows. Eight rumen fistulated Holstein cows (49 \pm 20 DIM) were used in a replicated 4 \times 4 Latin square design. Treatments were: 1) Control (no infusion); or abomasal infusion of; 2) 400 g/d Butterfat; 3) 245 g/d LCFA (blend of 59% cocoa butter, 36% olive oil, and 5% palm oil) providing 50% of the 16:0 and the amounts of C18 FA, equivalent to that found in 400 g of butterfat (LCFA); and 4) 100 g/d conjugated linoleic acid (CLA, negative control), providing 10 g of t10c12 CLA. Lipid supplements were infused in equal portions 3 \times daily during the last 2 wk of each 3 wk experimental period. Compared with Controls, Butterfat infusion increased milk fat yield by 21% ($P < 0.02$), CLA decreased milk fat yield by 43% ($P < 0.001$), and LCFA had no effect on fat yield. Infusion of Butterfat increased (21%, $P < 0.05$) the yield of FA with $\leq 16:0$ -carbons. Milk yield of mono- and poly-unsaturated FA was greater in cows infused with Butterfat (by 33% and 29%) or LCFA (by 25% and 24%), compared to Control. Infusion of CLA reduced yield of all FA synthesized de novo (56%, $P < 0.001$) and reduced FA desaturation index (40%, $P < 0.001$). Expression of genes involved in FA uptake (LPL, CD36), intracellular FA activation and transport (FABP3, ACSS2, ACSL1), de novo FA synthesis (ACACA, FASN), desaturation (SCD), and trigacylglycerol synthesis (AGPAT6, GPAM) tended to increase by 30% to 40% due to Butterfat, while LCFA showed opposite effects. The expression of lipogenic genes were not modified by CLA. Results suggest that supply of short and medium chain FA with

Butterfat infusion might potentially up-regulate mammary lipogenic gene expression and increase milk fat yield in lactating cows.

Key Words: Lactating Cows, Fat Supplements, Gene Expression

T103 Production of Holstein and Jersey \times Holstein cattle grazing annual ryegrass/white clover pasture. J. C. Lopes*, A. P. Vilela, K. A. Weigel, K. A. Albrecht, and D. K. Combs, University of Wisconsin, Madison.

The objective of this trial was to compare milk production, milk composition and pasture intake of Holstein (H) and Jersey-Holstein crossbred (JH) cattle grazing high quality annual pasture. Fourteen primiparous 1/4 Jersey \times 3/4 Holstein cows (112 DIM, 495 kg BW) and fourteen primiparous Holstein cows (89 DIM and, 535 kg BW), were randomly assigned by breed to one of four-2.4 hectare paddocks. The four pastures were seeded in the spring of 2007 with a mixture of white clover (*Trifolium repens* L.) and Italian ryegrass (*Lolium perenne* ssp. Multiflorum.). All pastures were managed to offer cows approximately 30 kg of forage DM per day. The daily grazing area was estimated according to the pasture availability and the number of cows in each paddock. Cows were allowed to graze approximately 20 h/d and were milked twice daily. Supplemental concentrate was provided daily after each milking (7.2 kg/cow/d). Pastures were initially stocked with 7 cows per paddock, but as the summer progressed and pasture growth declined, one cow from each of the paddocks was removed to keep pasture availability constant and assure adequate supply of pasture. Pasture intake was estimated by difference in yield estimates from pasture quadrats clipped at a 5 cm stubble height before and after grazing. Pastures quality was high throughout the trial (41 \pm 1.6%, NDF, and 18 \pm 0.5%, CP). Milk yield/cow/d tended lower for JH than H (27.0, 29.8 kg/d, respectively $p < 0.07$) and 3.5% FCM was lower for JH than H (28.0, 30.0 kg/d respectively, $p < 0.01$). Milk fat percentage was similar for JH and H (3.6 \pm 0.1%). Fat corrected milk yield by paddock was higher for H than JH (1349, 1187 kg 3.5%FCM/paddock/week respectively, $p < 0.05$). Pasture DMI did not differ by breed (1133 kg DM/paddock/d). Grazing Holstein primiparous cows produced more milk from high quality pasture than Jersey-Holstein crossbreds. Breed did not affect pasture intake, the advantage was due to higher production per cow of the Holsteins than the Jersey-Holstein crossbreds.

T104 Effect of different moving devices at loading on incidence of downers, and carcass and meat quality in market weight pigs. J. A. Correa*¹, H. Gonyou^{2,3}, S. Torrey⁴, N. Devillers⁴, J.-P. Laforest¹, and L. Faucitano⁴, ¹Laval University, Quebec City, QC, Canada, ²Prairie Swine Centre, Saskatoon, SK, Canada, ³University of Saskatchewan, Saskatoon, SK, Canada, ⁴Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada.

Despite the evidence about the negative effects on animal welfare and meat quality, the electric prod is frequently used by farm handlers and truckers to load pigs onto the truck. The objective of this study was to evaluate the effects of alternative moving devices, such as the paddle and compressed air prod, at loading on the incidence of downers and bruised carcasses and on meat quality (ultimate pH and blood splashes) in pigs. In a three week trial, a total of 284 animals (120±7 kg live weight) were randomly sorted out from the finishing pen in groups of 5 pigs and assigned to one of three moving procedures: 1) moving with an electric prod and board from the finishing pen to the truck (E); 2) moving with a board and a paddle from the finishing pen to the truck (P); 3) moving with a board and a paddle from the finishing pen and using a compressed air prod in the ramp before going into the truck (A). Data were analysed using an ANOVA for factorial designs, with group as the experimental unit. Treatment E resulted in 3 % downer pigs on arrival at the abattoir compared to none in treatments P and A. The proportion of bruised carcasses was lower in P and A pigs than E pigs (32 % vs 57 %). In this study ultimate pH values in the semimembranosus (SM) and adductor (AD) muscles were generally high, but were slightly higher ($P < 0.05$) in the SM and AD muscles from E pigs compared to those from P and A pigs. A higher proportion of blood splashes was found in the SM muscle of E pigs (31 %) compared to that of A pigs (19.4 %), with P pigs being intermediate (28.2 %). These results suggest that the use of a board in combination with a compressed air prod or paddle to handle pigs at loading can be recommended to replace the use of electric prod as it reduces animal losses during transport and decreases the incidence of bruised carcasses and blood-splashes.

Key Words: Pig, Handling, Meat Quality

T105 Identification of boar-tainted carcasses with an electronic nose. S. Ampuero¹, M. Amrhein², S. Dubois¹, and G. Bee*¹, ¹Agroscope Liebefeld-Posieux, Research Station ALP, Posieux, Switzerland, ²Online Control LTD, Lausanne, Switzerland.

Production of intact males on a large scale is greatly hindered by the lack of objective, reliable and fast methods to detect boar tainted carcasses. In a preliminary study we showed that a mass spectrometry (MS) based electronic nose was potentially suited to detect boar tainted samples. The aim of the present study was to develop a system consisting of a MS electronic nose (Smart Nose 151, LDZ, Switzerland) coupled with an automatic-sampler pyrolyser (CDS pyroprobe AS2500 APLUS). The chemometric classification models are established against reference classifications based on HPLC determination of the principal boar taint compounds in the adipose tissue: androstenone (A), skatole (S), and indole (I). The analysis is performed by introducing 0.5 µL of liquefied fat in a capillary tube. The gas phase produced by pyrolysis at 600°C is instantaneously transferred to the ionization chamber of the MS. The

generated data is recorded during 240 s by scanning between 10 to 250 amu at 50 ms/amu. Over a period of 12 months, a total of 353 adipose tissue samples originating mainly from Swiss Large White and Landrace boars and barrows were analyzed. Large variations in the age and BW at slaughter, the rearing conditions and the feeding regimes were present in the set of porcine adipose tissue samples. Between 60 to 80% of the samples were used to develop different classification models by multi-class SVM (Support Vector Machine) and variable selection via genetic algorithms. Based on sensory evaluations the reference classes were defined as (expressed per kg adipose tissue): **strong boar taint:** A > 1.0 mg or S and/or I > 0.16 mg, **no boar taint:** A ≤ 0.5 mg and S and I ≤ 0.16 mg, and **mild boar taint:** A > 0.5 or ≤ 1.0 mg and S and/or I ≤ 0.16 mg. Semi-external validations, with 17 to 42% of new samples not included in the models, reveal 98% of correct identification rates of strong boar tainted samples. The results of this study confirm that a fast, reliable and objective detection of boar tainted carcasses is possible.

Key Words: Boar Taint Detection, Electronic Nose, Pyrolysis

T106 Age at the beginning of the free-range fattening period affects subcutaneous fat quality of Iberian pigs. M. A. Latorre*, B. Prieto, D. G. Valencia, and M. P. Serrano, *Centro de Investigación y Tecnología Agroalimentaria de Aragón, Zaragoza, Spain.*

The traditional productive cycle for Iberian pigs includes a final free-range fattening phase (from November to February) in which animal intake natural feed resources, mainly acorns and grass. This period has important consequences on the fat quality, which is determinant for elaboration of dry-cured products. The high level of monounsaturated fatty acids (FA) is one the most relevant quality aspects in fat from Iberian pigs. Currently, the reproductive planning of this system is based on two births per year (spring and autumn), beginning the free-range period with different age (18 or 12 months) but similar weight (110 kg BW), and being slaughtered with 160 kg BW (21 or 15 months old). In this context, a total of 40 Iberian pigs were used to study the effect of age at the beginning of the free-range fattening period on FA profile of subcutaneous fat; 18 months old (OP) and 12 months old (YP). YP were fed higher quantity of concentrates than P22 (4.5 vs. 2.5 kg/day) during the growing phase to achieve the fattening period at similar weight. Each treatment was replicated 20 times (one pig per replicate). OP had higher proportion of C14:0 ($P < 0.10$) and C15:0 ($P < 0.05$) than YP. However, YP showed higher percentage of C18:0 than OP ($P < 0.05$). In consequence, no effect of age on saturated FA was detected (28.77 vs. 29.14% for OP and YP, respectively; $P > 0.05$). On the other hand, OP had higher proportion of C18:1 ($P < 0.01$) and C20:1 ($P < 0.001$), and therefore higher percentage of monounsaturated FA (60.87 vs. 59.61%; $P < 0.01$) than YP. Fat from OP showed higher proportion of C18:4 ($P < 0.10$) but lower C18:2 ($P < 0.001$) than fat from YP. So OP had lower percentage of polyunsaturated FA than YP (10.36 vs. 11.25%; $P < 0.01$). It is concluded that Iberian pigs starting the free-range fattening period with 12 months of age have adequate fat quality but their results are worse than those showed by pigs starting fattening phase with 18 months of age.

Key Words: Age at the Fattening Period, Fat Quality, Iberian Pigs

T107 Effect of castration of females on meat quality and fatty acid profile of backfat in Iberian pigs reared under intensive production systems. M. P. Serrano¹, D. G. Valencia¹, R. Lázaro¹, A. Fuentetaja², and G. G. Mateos*¹, ¹Universidad Politécnica de Madrid, Spain, ²Copese, Segovia, Spain.

Iberian (IB) pigs are the ancestral dark-haired pigs of Spain. Currently, 80% of IB pigs are reared under intensive production systems and slaughtered at 140–150 kg body weight (BW). Both sexes are castrated. However, the production of heavy white pigs destined to dry-cured products is based on intact females (IF). Therefore, IF might be also an alternative to castrated females (CF) for IB pig production. A total of sixty crossbred (IB dam × Duroc sire) females, 80 d of age (17.6 ± 0.13 kg BW) was used to investigate the effect of castration of females on fresh meat quality and fatty acid profile of backfat (BF) of IB pigs reared under intensive production systems and slaughtered at 144 kg BW (269 d of age). Females were ovariectomized at 93 d of age (26.0 ± 0.19 kg BW). Meat samples were taken at m. Longissimus dorsi at the level of the last rib and BF samples were taken at the tail insertion. Each treatment (coded IF, CF) was replicated five times and the experimental unit was a pen with six pigs. Castrated females had 27.2% more fat and 2.7% less moisture in the m. Longissimus dorsi than IF ($P \leq 0.05$). Muscular fat content was lower for IF than for CF (6.6 vs. 9.1%; $P \leq 0.05$) but in all cases fat content was higher than required to generate high quality dry-cured products. Meat from IF was more lightness (higher L* value; $P \leq 0.01$), redder (10.1 vs. 7.5 for a*; $P \leq 0.001$), and had more intensive colour (16.7 vs. 11.2 for c*; $P \leq 0.001$) than meat from CF. Subcutaneous fat was more saturated (39.1 vs. 38.2%; $P \leq 0.05$) in CF than in IF, mostly because of the higher palmitic acid content ($P \leq 0.05$). Also, CF had lower linolenic acid content (0.61 vs. 0.68%; $P \leq 0.05$) than IF. We conclude that based on animal welfare, cost of castration, meat quality traits, and fatty acid profile, intact females are a good alternative to castrated females to produce high quality Iberian dry-cured products.

Key Words: Iberian Pigs, Female Castration, Meat Quality and Fatty Acid Profile

T108 Effect of conjugated linoleic acid, betaine or both on fatty acid composition of growing Iberian gilts. I. Fernandez-Figares*, J. M. Rodriguez-Lopez, L. Gonzalez-Valero, R. Nieto, M. Lachica, and J. F. Aguilera, *Spanish National Research Council, CSIC, Granada, Spain.*

We have demonstrated that growing Iberian gilts (an obese porcine genotype) fed betaine plus CLA show a trend towards decreased carcass fat content (J. Anim. Sci. 2008, 86:102-). The aim of the present study was to assess the effect of betaine, CLA or both on the fatty acid profile of the subcutaneous adipose tissue, renal fat and intramuscular fat of the semitendinosus and biceps femoris muscles. Twenty gilts (20 kg BW) were individually penned and fed at 95% *ad libitum* barley-soybean meal based diets (12% CP, 0.81% lysine and 14.8 MJ ME / kg DM) containing either no added betaine or CLA, 0.5% betaine, 1% CLA, or 0.5% betaine + 1% CLA. At 50 kg, pigs were slaughtered and samples immediately frozen at -80°C until analysis. Lipids were extracted and fatty acid methyl esters were prepared using sodium methoxide in methanol and used for fatty acid composition. Methyl esters were separated and quantified by gas-liquid chromatography using a Perkin Elmer GC fitted

with a flame ionization detector and a capillary (60m×0.25mm×0.2µm) column. Data were analyzed as a two-way ANOVA in a completely randomized design with treatment as the fixed effect. Significance was set at $P < 0.05$ and differences among means were determined using a Duncan t-test. Overall, betaine effects on fatty acid profile were only observed in the inner layer of fat, with lower percentage of palmitic acid and total saturated fatty acids and greater oleic acid and total mono-unsaturated fatty acids content compared to controls. CLA elicited an increase of both CLA isomers measured and total saturated fatty acids and a decrease of total monounsaturated fatty acids, iodine values and $\Delta 9$ -desaturase index in the fat depots studied and in intramuscular fat. Pigs fed with betaine + CLA presented similar fatty acid profile to those fed CLA diets. It is concluded that CLA altered lipid metabolism, producing lower concentration of monounsaturated fatty acids and increased concentrations of CLA isomers and total saturated fatty acids in the fat depots and intramuscular fat of Iberian pigs.

Key Words: Betaine and CLA, Fatty Acid Composition, Iberian Pig

T109 Effect of L-carnitine supplementation on the performance and pork quality traits of growing-finishing swine fed three levels of corn oil. J. K. Apple*¹, J. T. Sawyer¹, C. V. Maxwell¹, J. C. Woodworth², J. W. S. Yancey¹, and R. E. Musser³, ¹University of Arkansas Division of Agriculture, Fayetteville, ²Lonza, Inc., Allendale, NJ, ³Hubbard Feeds, Inc., Mankato, MN.

Crossbred pigs (n = 216) were used to test the interactive effects of supplemental L-carnitine and corn oil on the growth performance, carcass composition, and pork quality of growing-finishing swine. Pigs were blocked by BW (43.6 ± 1.0 kg), and pens (6 pigs/pen) were randomly assigned within blocks to dietary treatments arranged in a 2 × 3 factorial design, with 0 or 100 ppm L-carnitine and 0, 2, or 4% corn oil. At the completion of the 84-d feeding trial, pigs were slaughtered and bone-in pork loins were captured during carcass fabrication for measurement of pork quality attributes. Supplementing swine diets with L-carnitine did not ($P \geq 0.29$) affect overall ADG, ADFI, or G:F, and, even though overall ADG was similar ($P = 0.60$) across dietary corn oil levels, including 4% corn oil in swine diets reduced ($P < 0.05$) ADFI, leading to improvements ($P < 0.01$) in G:F. Neither L-carnitine supplementation ($P \geq 0.25$) nor dietary corn oil ($P \geq 0.14$) affected hot carcass weight, 10th rib fat and LM depths, or fat-free lean yield. The LM from pigs fed 2 and 4% corn oil received higher ($P < 0.01$) marbling scores and had greater ($P = 0.05$) percentages of i.m. fat than the LM from pigs fed 0% corn oil. Conversely, subjective and objective pork color, firmness, and water-holding capacity were not affected by L-carnitine supplementation ($P \geq 0.19$) or dietary corn oil ($P \geq 0.10$). Lastly, neither dietary corn oil level nor L-carnitine supplementation affected cooking losses ($P \geq 0.14$) or shear force values ($P \geq 0.10$) of LM chops. Therefore, increasing the level of corn oil in swine diets resulted in improvements in growth efficiency, and appeared to increase i.m. fat content of the LM without affecting pork color or water-retention properties; however, supplementing the diets of growing-finishing pigs with L-carnitine had little to no appreciable effects on growth performance, carcass composition, or pork quality.

Key Words: Corn Oil, L-carnitine, Swine

T110 Effect of L-carnitine supplementation on the fatty acid composition of subcutaneous fat and LM from swine fed three levels of corn oil. J. K. Apple^{*1}, J. T. Sawyer¹, C. V. Maxwell¹, J. W. S. Yancey¹, J. C. Woodworth², and R. E. Musser³, ¹University of Arkansas Division of Agriculture, Fayetteville, ²Lonza, Inc., Allendale, NJ, ³Hubbard Feeds, Inc., Mankato, MN.

Crossbred pigs (n = 216) were used to test the interactive effects of supplemental L-carnitine and corn oil on the fatty acid composition of s.c. fat and LM from growing-finishing swine. Pigs were blocked by BW (43.6 ± 1.0 kg), and pens (6 pigs/pen) were randomly assigned within blocks to dietary treatments arranged in a 2 × 3 factorial design, with 0 or 100 ppm L-carnitine and 0, 2, or 4% corn oil. Approximately 12 h after slaughter, samples of backfat were removed at the level of the last lumbar vertebra, whereas samples of LM were removed during pork loin fabrication 36 h postmortem. Supplementing diets with L-carnitine increased ($P < 0.05$) the proportion of minor SFA, *cis*-vaccenic (18:1c11), and minor MUFA, and tended to decrease ($P \leq 0.10$) weight percentages of linoleic (18:2n6) and linolenic acids (18:3n3) in s.c. fat. Conversely, the proportion of all SFA (especially palmitic [16:0] and stearic [18:0] acids), and all MUFA (specifically oleic [18:1c9] and 18:1c11) decreased linearly ($P < 0.001$), whereas the proportion of all PUFA, in particular 18:2n6, increased linearly ($P < 0.001$) in s.c. fat with increasing dietary corn oil. Moreover, the iodine value (IV) of s.c. fat was not ($P = 0.18$) affected by L-carnitine supplementation, but IV increased linearly ($P < 0.001$) from 61.1 to 76.2 as dietary corn oil increased in the diet from 0 to 4%. Even though the proportions of 18:1c9, total PUFA, and IV were similar among LM samples from pigs fed 0 or 4% corn oil, supplementing 2% corn oil diets with L-carnitine increased 18:1c9 and reduced total PUFA levels (especially 18:2n6) and IV (carnitine × corn oil; $P \leq 0.02$). Increasing the dietary inclusion level of corn oil from 0 to 4% increased the polyunsaturation of s.c. fat and the LM by 91 and 32%, respectively, whereas supplementing swine diets with L-carnitine appeared to increase the proportion of 18:1c9, at the expense of 18:2n6, in pigs fed 2% corn oil.

Key Words: Corn Oil, L-carnitine, Fatty Acid Composition

T111 Carcass and *Longissimus dorsi* characteristics of finishing pigs fed sweet potato (*Ipomoea batatas* [L] Lam.) meal. S. Pietroseoli^{*1}, O. E. Moron-Fuenmayor¹, A. Paez¹, and M. J. Villamide², ¹Facultad de Agronomía, La Universidad del Zulia, Maracaibo, Venezuela., ²ETSIA, Universidad Politécnica de Madrid, Madrid, España.

Sweet potato meal (SPM: 70% foliage: 30% tuber) was evaluated as a feed for finishing pigs to determine its effects on carcass and *Longissimus dorsi* (LM) characteristics. Thirty-six commercial hybrid Landrace × Duroc pigs (62.2 ± 1.3 kg and 134 ± 2 days initial BW and age, respectively) were randomly assigned to 12 pens (n = 2 castrated males and 1 female/pen) in a randomized complete block design with four replicates. Final BW and sex were used as covariates. The trial lasted 44 d, divided into two periods (P1 and P2) of three weeks each. Treatments under evaluation were T1: during P1 15%, and during P2 30%, of the commercial concentrate (CC) was substituted by SPM; T2 (control): 100% CC; T3: the levels of substitution of CC were 10 and 20% for P1 and P2, respectively. Pigs had *ad libitum* access to feed and water and were weighed weekly. Pigs averaged 99.6 ± 1.4 kg BW when harvested at a commercial facility. Carcass pH and temperature were recorded at 0, 6, 12 and 24 h *post mortem*. Treatments differed for white viscera ($P \leq 0.01$), loin yield ($P \leq 0.01$) and fat thickness (P

≤ 0.01). Most of the traits were not affected when the maximum level of CC substitution was 20%. These results indicate that SPM can be used as an alternative feedstuff for finishing pigs.

Table 1. Carcass and *Longissimus dorsi* characteristics of finishing pigs fed sweet potato meal

	T1	T2	T3	SE
Carcass yield %	66.5	67.9	67.0	0.51
Leg %	33.8	33.4	33.6	0.28

T112 Relationships of belly-flop measurements with smokehouse yield and fatty acid composition. J. W. S. Yancey^{*}, J. K. Apple, J. T. Sawyer, M. S. Lee, and M. D. Wharton, University of Arkansas Division of Agriculture, Fayetteville.

Boneless bellies (n = 192) were tested to determine the relationship of physical attributes, compression, smokehouse yield, and fatty acid (FA) composition of the primary and secondary lean, and seam and s.c. fat layers. Bellies were measured for thickness, length, width, processing temperature, moisture of fat and lean, and belly flop. Each belly was hung over a bar (skin-side up and skin-side down) at the midline of its widest point, and the distance between the two hanging ends was measured. Bellies were transported to a commercial bacon processor, injected, and smoked to determine smokehouse yield. Smokehouse yield was poorly correlated with belly-flop measurements ($r = 0.38$ and 0.36), but compression was not correlated with smokehouse yield. Throughout the study, values for belly-flop measured skin-side up were more highly correlated to physical attributes and FA composition than were those values for skin-side down. Furthermore, the correlation of belly-flop measurements was slightly higher with the FA composition of the lean than with those of fat. Although total SFA in the fat and lean was poorly correlated ($r = 0.18$ to 0.34), and MUFA content was low to moderately correlated ($r = 0.17$ to 0.59) with belly-flop measurements; palmitic acid (16:0) was highly correlated with belly-flop measurements ($r = 0.60$ to 0.71). PUFA, which comprised 16 to 17% of the seam and s.c. fat and 12 to 13% of the lean, had strong negative correlations with belly-flop measurements ($r = -0.60$ to -0.72), particularly 18:2_{n-6}, 18:3_{n-3}, and 20:4. Belly flop also had a strong negative relationship with PUFA:SFA ($r = -0.59$ to -0.73) and iodine value ($r = -0.60$ to -0.73). Although the relationship of belly-flop with smokehouse yield was low, belly-flop was a good indicator of FA composition, especially PUFA, and is a potential indicator of belly quality in bacon operations.

Key Words: Pork, Belly-Flop, Fatty Acid Composition

T113 Comparisons of fatty acid composition in pork belly primary and secondary lean, and seam and subcutaneous fat. J. W. S. Yancey^{*1}, J. K. Apple¹, J. T. Sawyer¹, M. S. Lee¹, and J. C. Woodworth², ¹University of Arkansas Division of Agriculture, Fayetteville, ²Lonza, Inc., Allendale, NJ.

Pork bellies (n = 192) were obtained from a commercial processing facility to determine differences in fatty acid (FA) composition between primary and secondary lean, and seam and s.c. fat. Total fat and lean layers did not differ ($P \geq 0.21$) in total SFA, C16:0, or C18:0 percentages, but within the fat layers, seam fat had greater ($P < 0.01$) levels of total SFA, C16:0, and C18:0 than did s.c. fat, and primary lean had greater ($P < 0.01$) levels than secondary lean. As expected, MUFA was the most abundant FA type in the bellies. Lean layers had greater ($P < 0.01$) total MUFA than did fat layers. Furthermore, s.c. fat had greater concentrations ($P < 0.01$) of MUFA than seam fat, and secondary lean had greater levels ($P < 0.01$) of total MUFA than primary lean. Fat layers of the bellies had greater levels ($P < 0.01$) of total PUFA, C18:2_{n-6}, and C18:3_{n-3} than did lean. Although seam and s.c. fat layers had similar ($P = 0.36$) concentrations of C18:3_{n-3}, the s.c. layer had greater levels ($P < 0.01$) of all other PUFA studied. Primary lean had greater concentrations ($P < 0.01$) of total PUFA, C18:2_{n-6}, C20:4, but lower concentrations ($P < 0.01$) than secondary lean of C18:3_{n-3}. Levels of CLA were not different ($P = 0.17$) between fat and lean in the bellies, but s.c. fat and secondary lean had greater concentrations ($P < 0.01$) of CLA than seam fat and primary lean, respectively. Fat layers had a greater PUFA:SFA and iodine value (IV; $P < 0.01$) than lean layers; moreover, s.c. fat layer and secondary lean had greater IV ($P < 0.01$) than seam fat and primary lean. Generally, it was found that fat layers of the bellies had more PUFA than lean layers, whereas lean layers had greater levels of MUFA. Within fat layers, s.c fat was more unsaturated than seam fat, and within lean layers, primary lean had greater concentrations of PUFA and SFA, whereas secondary lean had greater levels of MUFA.

Key Words: Pork, Belly, Fatty Acid Composition

T114 Influence of gender and slaughter age on meat and subcutaneous fat quality of heavy pigs destined to high quality dry-cured hams. M. A. Latorre^{*1}, G. Ripoll¹, L. Ariño², and B. Blanco³, ¹Centro de Investigación y Tecnología Agroalimentaria de Aragón, Zaragoza, Spain, ²Integraciones Porcinas S.L., Teruel, Spain, ³Jamones y Embutidos Alto Mijares S.L., Teruel, Spain.

High quality, dry-cured hams under the protection and designation of “Teruel hams” trademark are produced from heavy pigs in a specific area of Spain. Although the star product from these animals is the ham, they also provide a lot of other high quality meat products. The pigs destined to Teruel ham are crossbred (Landrace × Large White) × Duroc barrows and gilts, slaughtered at 130 kg BW. Forty eight pigs, with an average age of 176 d were used to study the effect of gender and slaughter age on Longissimus dorsi quality and fatty acid (FA) profile of pigs destined to Teruel ham. Animals were fed a commercial wheat, barley, and soybean meal diet, containing 2,360 kcal NE/kg and 0.68% total lysine. There were three treatments; barrows slaughtered at 196 d of age (B; 130.8 kg BW), gilts slaughtered at 203 d of age (G1; 130.2 kg BW), and gilts slaughtered at 210 d of age (G2; 134.3 kg BW). Each treatment was replicated 16 times (one pig per replicate). Meat from B showed higher intramuscular fat content than meat from G1, with G2 being intermediate ($P < 0.05$). Also, loin from G1 and G2 had similar protein contents and both were higher than loin from B ($P < 0.01$). Meat

from G2 was more tender than meat from G1, with B being intermediate ($P < 0.05$). No effect of treatment was detected on MUFA proportion ($P > 0.05$) but B showed higher saturated FA percentage than G1, with G2 being intermediate ($P < 0.001$). Also, G1 and G2 had similar PUFA proportions and both were higher than B ($P < 0.01$). Thus, barrows had better meat quality but worse fat quality than gilts when slaughtered at the same BW. However, an increase by two weeks in the slaughter age of gilts, with regard to barrows, improves the quality and homogeneity of meat and fat of pigs destined to Teruel ham.

Key Words: Slaughter Age, Meat and Fat Quality, Pigs

T115 Carcass fatty acid composition of growing calves fed diets containing canola oil supplements. M. Eftekhari, K. Rezayazdi^{*}, A. Nikkhab, and A. Nejati javaremi, University of Tehran, karaj-Tehran-Iran.

The objective of this experiment was to study the effects of increasing dietary fat through the use of canola oil on fatty acid composition of growing calves. Twenty-four male Holstein calves were divided into three groups and submitted to three diets: control diet (C); a diet containing 2% canola oil (LC) and a diet containing 4% canola oil (HC) as DM basis. Diets were offered as ad libitum and twice daily (0800 and 1500). Calves were slaughtered after 4 month of feeding. The 9th through 11th ribs were obtained from the right side of each carcass and used for carcass composition analysis. Meat sample lipids were extracted by the method of Folch et al. (1957) and esterified fatty acids methyl esters were prepared according to Metcalf et al. (1966). The fatty acid methyl esters were analysed using a Unicam 4600 chromatograph, equipped with a flame ionisation detector and capillary column. Data were analyzed using analysis of variance for a completely random design using the GLM procedure of SAS software (2001) with initial BW of the experimental animals as a covariate.

Canola oil feeding had significant effects on fatty acid composition of longissimus muscle (Table 1). Feeding LC and HC diets increased ($P < 0.05$) the percentage of C18:0 and C18:1 and decreased ($P < 0.05$) the percentage of C16:0 and C16:1. There were no differences ($P > 0.05$) in the percentage of C14:0, C17:0, C17:1, C18:2 and C18:3 across treatments. The results of this study showed that canola oil had significant effects on healthful characteristics and fatty acid composition of longissimus muscle of calves.

T116 Effect of canola oil on performance and carcass characteristics of Holstein male calves. M. Eftekhari, K. Rezayazdi*, A. Nikkhah, and A. Nejati Javaremi, *University of Tehran, Karaj-Tehran-Iran.*

The objective of this study was to evaluate diet supplementation with canola oil on performance and carcass characteristics of growing calves. Twenty-four Holstein male calves were randomly divided into three groups and submitted to three diets: control diet (C); a diet containing 2% canola oil (LC) and a diet containing 4% canola oil (HC) as dry matter basis. Diets were formulated to meet or exceed nutrient requirements using the Beef NRC model (NRC, 1996) and to be isonitrogenous and isoenergetic. Diets were offered as total mixed ration (TMR), ad libitum and twice daily (0800 and 1500). Quantity of feed offered and refused was recorded daily and Calves were weighed monthly and slaughtered after 4 month of trial. Carcasses were weighed to obtain the hot carcass weight and graded to determine 12th rib backfat thickness and longissimus muscle area. Data were analyzed using analysis of covariance for a completely random design using the GLM procedure of SAS software (2001) with initial BW of the experimental animals as a covariate and effects of treatments were declared at $P < 0.05$.

Canola oil did not alter final BW and ADG ($P > 0.05$) (Table 1). Dry matter intake decreased significantly with the addition of canola oil whereas G:F was improved ($P < 0.05$). No differences were detected ($P > 0.05$) in carcass measurements except for backfat, in which calves were fed the HCO diet had more back fat compare to those fed the C diet. Empty body weight, hot carcass weight, carcass yield and longissimus muscle area, were not affected significantly by the treatments ($P > 0.05$).

Table 1. Effect of diet on performance and carcass characteristic of calves

	Treatment

T117 Characterization of meat quality and lipid profile from steers fed crude glycerol. H. L. Evans*, B. R. Wiegand, M. S. Kerley, J. H. Porter, K. S. Roberts, and B. A. Verseemann, *University of Missouri, Columbia.*

The objective of this study was to assess the optimum and maximum levels of crude glycerol for inclusion in beef cattle feedlot diets. Crude glycerol sourced from a biodiesel production facility was included at graded levels in feedlot diets of crossbred steers (n=72). Steers (225kg) were randomly assigned in pens of six steers each to one of four experimental diets with three replications each. Diets were formulated to include 0, 5, 10, or 20% glycerol. Calves were fed once daily. Pen was

the experimental unit. Blood samples were collected to measure initial and final circulating triacylglyceride, glucose, and glycerol levels. Steers were humanely slaughtered after reaching an average live weight of 537 ± 12 kg and an average 12th rib fat depth of 1.18 ± 0.13 cm. Meat quality measures of shear force tenderness and Hunter L*, a*, and b* (over 7 d shelf storage) were made. Longissimus dorsi samples were collected and intramuscular fat was extracted and prepared for fatty acid profile determination by gas chromatography. Statistical analysis revealed no differences ($P > 0.60$) for initial and final circulating triacylglycerides, glucose, or glycerol across treatment groups. Total lipid percentage within the longissimus differed ($P = 0.04$) among treatment groups and measured 2.67, 3.68, 2.37, and 2.91% (SEM = 0.29) for 0, 5, 10, and 20% glycerol, respectively. No differences were observed for any saturated fatty acids within the longissimus among treatment groups. However, C14:1 means differed ($P = 0.04$) and measured 0.454, 0.757, 0.751, and 0.481% (SEM = 0.087) for 0, 5, 10, and 20%, respectively. Other changes occurred in PUFA and were observed for C18:2N6 ($P = 0.02$), C20:2N6 ($P = 0.04$), C20:5N3 ($P = 0.10$), and C22:6N3 ($P = 0.06$). These changes tended to show increases with up to 10% glycerol inclusion and subsequent decreases at the 20% glycerol level. The biological significance of these changes is not yet clear. Overall, these data indicate that feeding up to 10% crude glycerol to finishing beef steers has no negative impact on certain blood lipid and energy parameters or meat quality measures related to color and lipid profile.

Key Words: Glycerol, Beef Cattle, Lipid Profile

T118 Sensorial characteristics of beef from heifers fed with different lipid supplements in the finishing phase. M. C. A. Santana*¹, P. H. M. Dian¹, R. A. Reis¹, A. V. Pires², G. Fiorentini¹, A. F. Ribeiro¹, M. A. A. Balsalobre³, and T. T. Berchielli¹, ¹São Paulo State University, Jaboticabal, São Paulo, Brazil, ²São Paulo University, Piracicaba, São Paulo, Brazil, ³Bellman, Mirassol, São Paulo, Brazil.

Meat sensorial or organoleptic characteristics are the attributes that make meat more or less appetizing; they are difficult to measure by instruments. The taste of certain bovine meat products can be influenced by the feed offered to the animal. Sensorial evaluation is important because it is capable of determining the product which will be offered to the consumer. The objective of this trial was to evaluate sensorial characteristics of beef from heifers fed different lipid supplements in finishing phase systems (FPS). The design was completely randomized in a 3×2 factorial arrangement of treatment fat supplements were, soybean grains, soybean oil and protected fat (MEGALAC-E), and two FPS, pasture or feedlot. Beef samples were appraised by 23 habitual beef consumers, randomly selected. The beef was previously thawed and roasted. Temperature was monitored using an insert thermometer until 70°C. Later, the samples were cut in cubes and identified by random numbers of three digits. The test was applied in a structured, hedonic scale of 9 points (1 displeased very much and 9 liked very much), and the flavor, texture and global acceptance attributes were evaluated. The flavor, texture and global acceptance of beef from feedlot animals were not influenced by the supplement. However, the meat from pasture systems showed a greater flavor grade and global acceptance using the MEGALAC-E and soybean oil supplement. The MEGALAC-E supplement had the highest grade for texture compared to the beef from pasture animals. The use of different supplements and FPS can influence the degree of sensorial acceptance on the part of the consumers.

Table 1. Means for the flavor, texture and global acceptance (GA) of the heifer meat from finishing phase systems (FPS) pasture (P) and feedlot (F), supplemented with soybean grains (SG), soybean oil (SO) and supplement with protected fat (ML).

Supplement/ FPS	Flavor/ P	Flavor/ F	Texture/ P	Texture/ F	GA/ P	GA/ F
SG	6.6b	7.0a	5.9b	7.3a	6.2b	7.1a
SO	7.3ab	6.4a	6.3b	6.9a	6.6ab	6.6a
ML	7.8a	7.0a	7.7a	6.9a	7.6a	7.1a

Means followed by different letters in the same column of same variables are different ($P < 0.05$).

T119 Carcass traits of low and high residual feed intake Nellore (*Bos indicus*) steers. R. C. Gomes^{*1}, R. S. Araujo¹, E. Telles¹, S. L. Silva¹, R. D. Sainz², and P. R. Leme¹, ¹University of Sao Paulo, Pirassununga, SP, Brazil, ²University of California, Davis.

Studies aiming to evaluate the effects of breeding beef cattle for the feed efficiency trait residual feed intake (RFI) have shown most efficient animals (low-RFI) may produce leaner carcasses than least efficient cattle (high-RFI). However, most investigations were carried out using *Bos taurus* breeds (Angus and Hereford) which are known to produce fatter carcasses than zebu cattle. In this sense, 72 Nellore steers (313 kg initial BW) were fed a finishing ration for 74 days and had their feed intake measured individually. Cattle were weighed every 21 d and the lowest and highest 12 RFI steers were classed as low- and high-RFI groups. The selected animals were kept in individual pens and fed until reaching market finish. At harvest, carcasses were sectioned at the 12th rib, split into bone, trimmings and retail product yield and internal visceral organs dissected and weighed. Carcass traits were adjusted to a common final BW (503 kg). There were differences ($P < 0.01$) between low- and high-RFI groups for DMI (9.3 vs. 11.1 kg/d), feed:gain (6.4 vs. 7.6) and RFI (-0.80 vs 0.89 kg/d), but not for ADG (1.48 vs. 1.48 kg/d), final BW (441 vs. 448 kg), hot carcass wt (310 vs. 308 kg), dressing percentage (57.3 vs. 60.9 %), kidney, pelvic and inguinal fat (5.81 vs. 6.02 kg), total visceral mass (33.0 vs. 31.1 kg), LM area (72.6 vs. 73.7 cm²), backfat thickness (6.22 vs. 6.27 mm), marbling score (379 vs. 381), trimmings (20.4 vs. 21.0% cold carcass wt) and retail product yield (62.1 vs. 61.7% cold carcass wt, $P > 0.05$). Low-RFI steers tended to have heavier gastrointestinal tract ($P = 0.09$) and had less GI fat mass ($P < 0.01$) than high-RFI cattle. The most efficient Nellore steers produced carcasses of similar quality to those obtained from the least efficient cattle. However, the most efficient cattle stored less fat on the visceral mass, suggesting the chemical composition of BW gain differs between low- and high-RFI Nellore steers.

Key Words: *Bos indicus*, Feed Efficiency, Net Feed Intake

T120 Effects of genetic group and concentrate feeding on pH and temperature of beef carcasses. I. M. de Oliveira, P. V. R. Paulino*, M. I. Marcondes, J. Cavali, S. de C. Valadares Filho, E. Detmann, L. F. Prados, V. R. M. Couto, and M. F. L. Sales, Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.

Post mortem muscle pH and temperature variations can result in different meat quality attributes. Beyond that, pH and temperature are often used by regulatory agencies in Brazil in order to sort carcasses for export markets. Thus, the Brazilian beef cattle industry is concerned about

the main factors that can impact the final pH and temperature of beef carcass. Therefore, this trial aimed to evaluate pH and temperature in bovine carcasses of three genetic groups (Nellore, ½ Nellore × ½ Angus and ½ Nellore × ½ Simmental), finished in a feedlot, fed diets with two concentrate allowance levels (1 and 2% of body weight) and slaughtered at 22 months old, with 412.79, 496.29 and 496.24 kg of body weight, respectively. The experiment was a factorial completely randomized design with two concentrate allowance levels, three genetic groups and six replicates. The carcasses were split and stored in a cooler at 0°C. During chilling (24 h), carcass pH and temperature was measured every 2 h in the LM region. Concentrate level and the interaction between concentrate level and genetic group were not significant ($P > 0.05$) for both pH and temperature. There were differences ($P < 0.05$) among genetic groups for final temperature. The final temperature of Nellore carcasses (9.90°C) was higher ($P < 0.05$) than that observed on the ½ Nellore × ½ Angus carcasses (7.75°C), which did not differ ($P > 0.05$) from the ½ Nellore × ½ Simmental (8.85°C). Brazilian regulations state that bovine carcass temperature should not exceed 7°C after 24 h chilling in a cooler set at 2.5°C. This did not happen as evidenced by the carcass temperatures reported above. However, since the cooler had to be open every 2 hours in order to allow the measurement of pH and temperature, this may have contributed to carcasses not reaching the target final temperature of 7°C. No difference ($P > 0.05$) was observed for initial and final pH of the carcasses, with mean values of 6.35 and 5.47, respectively. The carcasses were adequate in quality as the final pH values were lower than the maximum value permitted (5.9-6.0).

Key Words: Nellore Cattle, Crossbred Steers, Quality

T121 Finishing changes in bovine muscle fiber types as influenced by genetic group and slaughter weight. R. Mello^{*1,2}, A. C. de Queiroz², M. H. de Faria³, P. B. Costa², F. D. de Resende³, G. F. V. Bayão², and C. A. Neves², ¹Universidade Federal de Roraima, Boa Vista, RR, Brazil, ²Universidade Federal de Viçosa, Viçosa, MG, Brazil, ³APTA, Colina, SP, Brazil.

The objective of this study was to investigate the genetic group and slaughter weight related changes of muscle fiber proportions in *Longissimus dorsi*. Thirty six young (20 mo) bulls, 18 crossbred F1 Red Angus × Nellore (½ RA ½ N) and 18 F1 Blonde D'Aquitaine × Nellore (½ BA ½ N) were used. The young bulls were finished in a feedlot and slaughtered at 480, 520 and 560 kg of body weight. A completely randomized experimental design of a 2×3 (2 genetic groups × 3 slaughter weights) factorial arrangement with six replicates was used. Muscle fiber types were determined by histochemistry and classified by a computerized image analysis system. Data were analyzed with SAS, using initial BW as a covariate. The table below shows the least-square means of muscle fiber type frequencies. The interaction between GG and SW was not significant for the different treatments. The relative frequency of type I fibers was not affected by GG and SW. The ½ RA ½ N young bulls had a higher frequency of type IIA fibers and a lower frequency of type IIB fibers than ½ BA ½ N young bulls, or vice-versa. Increases in SW were related to a higher frequency of type IIA fibers. The genetic group and slaughter weight did not influence the modulation of fibers with different twitch speeds, but influenced the proportion of fibers with different energy metabolisms. The crossbred F1 Red Angus × Nellore young bulls and heavier animals had a higher frequency of fibers with oxidative that glycolytic metabolism in the finishing phase on feedlot than F1 Blonde D'Aquitaine × Nellore and lighter animals.

Table 1. Least square means

Muscle fibers	Genetic Group (GG)		Slaughter Weight (SW)		
	½ RA ½ N	½ BA ½ N	480	520	560
Type I, %	21.8	16.9	17.3	21.5	19.3
Type IIA, %	36.8 ^A	29.6 ^B	25.4 ^b	37.8 ^a	36.5 ^a
Type IIB, %	41.3 ^B	53.5 ^A	57.3	40.7	44.2

Within a row, means followed by different capital letters and by different small letters differ ($P < .05$), respectively, among GG and SW by Tukey test.

T122 Meat cholesterol, saturated and unsaturated fatty acids of *Bos indicus* type feedlot heifers. M. P. de Oliveira^{1,3}, M. de B. Arrigoni¹, C. L. Martins¹, É. Rodrigues¹, D. D. Millen¹, R. D. L. Pacheco^{*1}, L. M. N. Sarti¹, R. S. Barducci¹, J. P. S. T. Bastos¹, T. M. Mariani¹, S. R. Baldin¹, T. C. B. da Silva², and H. N. de Oliveira¹, ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²Faculdade de Zootecnia/UNESP, Dracena, São Paulo, Brazil, ³Apoio FAPESP.

Information about cholesterol and fatty acids concentrations of different breed types is needed. This study, conducted at São Paulo State University (UNESP) feedlot, Botucatu Campus, Brazil, was designed to evaluate meat cholesterol, saturated (SFA) and unsaturated fatty acids (UFA) of *Bos indicus* based breed types (BT). The study used 40, 8-mo-old heifers (259.9±19.5 kg) of four BT: 10 Three-way-cross (1/2 Simmental, 1/4 Nellore, 1/4 Angus (TC)), 10 Simbrasil (5/8 Simmental, 3/8 Nellore (SB)), 10 CN (1/2 Charolais, 1/2 Nellore) and 10 CC (3/4 Charolais, 1/4 Nellore) fed for 130 days in a feedlot. Diets contained 50% high moisture corn, 21% cracked corn, 10% soybean meal, 10% sugarcane bagasse, 5% corn silage and 4% supplement (dry matter basis). Heifers were held off feed 16 hours prior to slaughter. After slaughter, LM samples were removed between the 12th and 13th ribs for muscle cholesterol concentration and for analysis of SFA and UFA of backfat. Cholesterol concentration was determined using commercial enzymatic kits. UFA and SFA were analyzed by iodine index. There was no BT effect ($P > 0.05$) on meat cholesterol (TC=73.33, SB=67.08, CN=66.73, CC=64.85 mg/100g), SFA percentage (TC=58.27, SB=57.48, CN=59.88, CC=58.05) and UFA percentage (TC=41.73, SB=42.52, CN=40.12, CC=41.95). In conclusion, the BT evaluated in this study did not affect LM cholesterol, SFA and UFA.

Key Words: Cholesterol, Fatty Acids, Heifers

T123 Effects of implanting and feeding zilpaterol on performance, carcass characteristics and subprimal meat yields of fed cows. S. Neill^{*1}, J. A. Unruh², T. T. Marston², J. R. Jaeger³, M. C. Hunt², and J. J. Higgins², ¹PIC, Hendersonville, TN, ²Kansas State University, Manhattan, ³Kansas State University Agricultural Research Center, Hays.

Our objective was to determine the effects of implanting Revalor-200[®] and feeding zilpaterol (Zilmax[®]) on the performance, carcass charac-

teristics and subprimal yields of cull cows fed for 70 d. Sixty crossbred cull cows were assigned to one of five treatments: 1) grass-fed on pasture (G); 2) concentrate-fed (C); 3) concentrate-fed and implanted with Revalor-200[®] (CI); 4) concentrate-fed and fed Zilmax[®] beginning on d 38 of the feeding period (CZ); and 5) concentrate-fed, implanted and fed Zilmax[®] beginning on d 38 of the feeding period (CIZ). Grass-fed cows were on native grass pasture and concentrate-fed cows were fed a ground sorghum and sorghum-silage diet. Concentrate-fed cows were limit-fed 11.3 kg DM/hd/d for the last 30 d of the feeding period. Although not significant, CIZ cows had the highest and G cows the lowest numerical gains for the final 34 d and total feeding period. Hot carcass weights and dressing percentages were higher ($P < 0.05$) for the concentrate-fed (C, CI, CZ, and CIZ) cows than G cows. Longissimus muscle area (LMA) was largest ($P < 0.05$) for CIZ cows and smallest for the G cows. Grass-fed cows had ($P < 0.05$) fewer kg of total subprimals and a lower percentage of total subprimals than concentrate-fed cows. In addition, CIZ cows had ($P < 0.05$) heavier total subprimal weights and a greater percentage of total subprimals than those from C cows. Feeding cull cows a concentrate diet improved carcass weight, dressing percentage, and subprimal yields compared to feeding cows a grass-based pasture diet. When feeding cull cows a concentrate diet, a combination of a Revalor-200[®] implant and feeding Zilmax[®] can maximize trimmed meat yields as indicated by dressing percentage, LMA and subprimal yields.

Key Words: Cows, Subprimal Yield, Zilpaterol

T124 Effects of implanting and feeding zilpaterol on retail display-color stability and palatability of strip loin and knuckle steaks from fed cows. S. Neill^{*1}, J. A. Unruh², T. T. Marston², M. J. Daniel², M. C. Hunt², M. E. Dikeman², and J. J. Higgins², ¹PIC, Hendersonville, TN, ²Kansas State University, Manhattan.

Our objective was to determine the effects of implanting Revalor-200[®] and feeding zilpaterol (Zilmax[®]) on retail-color display and palatability of strip loin and knuckle steaks from cull cows fed for 70 d. Strip loin (SL) and knuckle (KN) steaks were obtained from 53 crossbred cull cows assigned to one of five treatments: 1) grass-fed on pasture (G); 2) concentrate-fed (C); 3) concentrate-fed and implanted with Revalor-200[®] (CI); 4) concentrate-fed and fed Zilmax[®] beginning on d 38 of the feeding period (CZ); and 5) concentrate-fed, implanted and fed Zilmax[®] (CIZ). After 14 d of aging, trained visual panelist evaluated SL (longissimus muscle) and KN (rectus femoris and vastus lateralis) steaks daily for 5 d. Only on d 0, SL steaks from CIZ cows were darker red ($P < 0.05$) than steaks from CZ cows. No differences ($P = 0.19$) in discoloration of SL steaks were observed among treatments. For KN steaks, no differences ($P > 0.05$) in color (0-2 d) or discoloration (0-1 d) were detected among treatments early in the display period. On d 5, KN steaks from CI and CIZ cows were darker red ($P < 0.05$) than those from G cows. Also on d 5, KN steaks from CI and CIZ cows were ($P < 0.05$) more discolored than steaks from CZ, C and G cows. Sensory panelists found 14-d aged SL steaks from CI, C, and G cows were more tender ($P < 0.05$) than steaks from CIZ cows; and steaks from C and G cows were ($P < 0.05$) more tender than steaks from CZ cows. Off-flavors were highest ($P < 0.05$) for SL steaks from G cows. No tenderness differences ($P > 0.05$) were found among treatments for KN steaks. Feeding Zilmax[®] to Revalor-200[®] implanted cows resulted in SL steaks that were considered less tender. However, sensory panel and WBSF data indicate that further postmortem chemical and/or mechanical

tenderization would be recommended for steaks from all treatments to improve tenderness and acceptability.

Key Words: Cows, Sensory, Zilpaterol

T125 Influence of sarcomere length on aging and hydrodynamic pressure processing of beef muscle. B. Bowker*, J. Eastridge, E. Paroczay, and M. Solomon, *USDA-ARS, Beltsville, MD.*

The interacting effects of sarcomere length and tenderizing treatments on proteolysis and meat texture are not well understood. Extent of thick and thin filament overlap was hypothesized to influence the protein degradation and tenderness improvements associated with postmortem aging and tenderization techniques. The objective of this study was to determine the influence of sarcomere length, hydrodynamic pressure processing (HDP), and aging on the proteolysis and texture of beef longissimus muscle. One side of each beef carcass (n=4) was subjected to hip suspension (HS) while the opposite side was normally suspended (NS). At 48 h postmortem, longissimus muscles were removed and cut into anterior and posterior halves assigned HDP and control treatments. Steaks for Warner-Bratzler shear force (WBSF) determination and protein analysis were removed and aged at 4°C until 3, 7, and 14 days postmortem. Sarcomere length was greater (p<0.0001) in HS samples than NS samples (2.35 vs. 1.73 μm). WBSF was lower (p<0.0001) in HS samples compared to NS samples, regardless of HDP treatment or aging period. NS samples exhibited a greater (p<0.0001) decrease in WBSF with aging than HS samples. HDP treatment decreased (p<0.0001) WBSF in NS samples but had minimal effects on HS samples. SDS-PAGE analysis of whole muscle protein extracts revealed significant suspension method by aging interactions and strong aging effects. In HS samples there was a greater (p<0.05) decrease in the intensity of the 38 kDa band (relative to the actin band intensity) from 3 to 14 days than in NS samples. The intensity of a 95 kDa band was not influenced by aging in NS samples but was diminished by day 14 in HS samples. The intensity of several smaller bands (<14 kDa) in HS samples increased (p<0.05) more with 14 days of aging than in NS samples. Bands corresponding to 110 and 30-32 kDa increased with aging across all treatments. Overall data suggest that sarcomere length plays a major role in determining a muscle's potential for tenderization and further suggests that the impact of proteolysis on tenderness is mediated by sarcomere length.

Key Words: Sarcomere Length, Aging, Hydrodynamic Pressure Processing

T126 Influence of fiber type on palatability attributes of beef round muscles. M. J. Anderson*, E. Steadham, C. Fedler, K. Prusa, S. M. Lonergan, and E. Huff-Lonergan, *Iowa State University, Ames.*

Differences between muscle fiber types, including fiber diameter, method of metabolism, and glycogen content, can potentially affect several aspects of meat quality. The objective of this study was to determine the influence of fiber type, as defined by myosin heavy chain (MHC) isoforms, on palatability attributes of underutilized muscles from the round. Longissimus dorsi (LD), gracillus (GR), adductor (AD), sartorius (SAR), semimembranosus (SM), vastus lateralis (VL), and vastus intermedius (VI) were removed from 10 beef cattle carcasses 1d postmortem. Instrumental texture (star probe), sensory characteristics, pH, western

blotting for troponin-T degradation, and SDS-PAGE to determine the percentage of type I and II MHC isoforms were collected. Three bands were detected in the troponin-T western (Upper intact band, UI; Lower intact band, LI; 30kDa degradation product band, 30kDa) and compared to a 7d postmortem LD reference sample. A sample from bovine diaphragm served as a reference for type I myosin heavy chain. The VI had the highest percentage (P<0.01) of type I fibers and the lowest percentage (P<0.01) of type II fibers when compared to all other muscles (type I, 62.1%; type II, 37.9%). Across all muscles, the proportion of type I fibers was correlated to the intensity of the LI (r = -0.27; P=0.02), the intensity of the UI (r = -0.48; P<0.01), and juiciness (r = 0.26; P=0.03). The intensity of the 30kDa band tended to be correlated to pH (r = -0.22; P=0.07) and the intensity of the UI was correlated to star probe (r = 0.25; P=0.03). The data show that juiciness is associated with fiber type. While effective in the LD, the utility of troponin-T degradation as an indicator of degradation in all muscles may not be feasible. This is potentially due to the specificity of the antibody for individual troponin-T isoforms.

T127 Prevention of internal premature browning in cooked steaks packaged in high-oxygen modified atmosphere by increasing reducing ability through lactate enhancement. Y. H. Kim*, J. T. Keeton, and J. W. Savell, *Texas A&M University, College Station.*

Meats with higher concentrations of oxymyoglobin can develop brown color quicker at a lower temperature resulting in prevalence of "premature browning (PMB)" in cooked meat. Consequently, PMB defects would be a significant food safety issues if consumers rely on appearance of internal meat color for cooked meat as a measure of degree of doneness. A brown color due to metmyoglobin formation can be retarded through the metmyoglobin reducing activity (MRA) of muscle. NADH is the primary substrate for MRA. Lactate injection has been reported to improve color stability by the conversion of lactate to pyruvate via increased lactate dehydrogenase (LDH) flux and concomitant regeneration of NADH. Thus, it can be hypothesized that lactate inclusion may prevent PMB by increasing MRA through replenishing NADH. The objective of this study was to determine the effects of lactate inclusion on internal cooked color development of steaks packaged in high-oxygen MAP.

Eight beef strip loins were divided into 4 equal width sections, and one of four treatments (control, 0.3% phosphate, 2.5% L-lactate, and 2.5% D-lactate) randomly assigned to each loin section. Loins were injected at 10% of their raw weight. Injection with D-lactate was used to test our hypothesis because LDH only reacts with L-lactate to regenerate NADH. Steaks packaged in high-oxygen MAP were stored in the dark at 1°C for 10 days. Instrumental internal color of raw and cooked steaks, total reducing activity (TRA), and NADH concentration were measured. Data were analyzed by using the Mixed procedure of SAS. LSMeans were separated (P<0.05) by using least significant differences. Cooked steaks enhanced with 2.5% L-lactate maintained significantly higher a* values (redness), higher TRA, and had a higher NADH concentration as compared to other treatments. Enhancement with 2.5% D-lactate did not affect cooked color, TRA, and NADH. These results confirm that lactate inclusion prevents PMB of steaks packaged in high-oxygen MAP by increasing reducing ability through the conversion of lactate to pyruvate and the concomitant regeneration of NADH.

T128 The effects of Paylean® and α -lipoic acid on growth performance and carcass characteristics of finishing pigs. J. R. Bergstrom*, J. L. Nelssen, R. D. Goodband, M. D. Tokach, J. M. DeRouchey, and S. S. Dritz, *Kansas State University, Manhattan.*

A total of 48 gilts (initially 96 kg) were used to evaluate the effects of Paylean® and α -lipoic acid on late finishing pig performance and carcass characteristics. Pigs were blocked by weight and randomly allotted to one of four dietary treatments in a 22-d experiment. There were 2 pigs per pen and 6 pens per treatment. Pigs were fed corn-soybean meal-based diets formulated to 0.95% true ileal digestible lysine. Treatments were arranged as a 2 × 2 factorial with main effects of Paylean® (0 or 10 ppm) and α -lipoic acid (0 or 300 ppm). There were no Paylean® × α -lipoic acid interactions ($P > 0.36$) observed. For the overall study, ADG, final weight, and G:F were increased ($P < 0.04$) for pigs fed Paylean®. Pigs fed Paylean® had increased ($P < 0.04$) hot carcass weight (HCW), yield, loin eye area at the 10th-rib (LEA), and standardized fat-free lean (SFFL). Average backfat thickness (Avg. BF) tended ($P < 0.06$) to decrease for pigs fed Paylean®. Tenth-rib backfat increased ($P < 0.05$) for pigs fed α -lipoic acid. In conclusion, pigs fed 10 ppm Paylean® had improved growth performance and carcass characteristics. Feeding 300 ppm of α -lipoic acid did not affect growth performance, but did tend to increase 10th-rib fat depth.

Table 1. Growth and carcass data

T129 Effects of tannin added to low-iron antibiotic-free diet on performance, hematology, iron status, fecal microflora and incidence of diarrhea in weaned pigs. S. H. Lee, P. L. Shinde, J. Y. Choi, I. K. Kwon, S. I. Park, and B. J. Chae*, *Kangwon National University, Chuncheon, Kangwon-Do, Republic of Korea.*

This study investigated the effects of tannin added to low Fe antibiotic-free diets on the performance, hematological status, fecal microflora and incidence of diarrhea in weaning pigs. One hundred and eight weaned pigs (Landrace × Yorkshire × Duroc, 6.46 ± 1.04 kg initial body weight) were allotted to 3 treatments each comprising of 4 replicates with 9

pigs in each. The basal diet for each phase (Phase 1: d 0 to 14; Phase 2: d 15 to 28) was formulated to contain minimum Fe and the mineral premix used was prepared without addition of FeSO₄. Dietary treatments were: basal diet (low-Fe antibiotic free diet, T1), basal diet added with tannin (Albumin tannate, 0.025%, T2) and basal diet added with Fe and antibiotic (T3). Two piglets from each pen were bled at 14 and 28 d of experiment to determine their hematological status and plasma Fe concentration while feces were collected on d 14 to enumerate the microbial populations. Pigs fed with T1 diets had lower ($P < 0.05$) ADG (242 vs 264 and 271 g/d) and higher incidence of diarrhea (37.5%) than pigs fed T2 (26.4%) and T3 (36.1%) diets. The population of total anaerobic bacteria was highest in the feces of pigs fed T1 diet and lowest in those fed T2 diet, while the populations of *Bifidobacterium* spp. and *Lactobacillus* spp. was higher in pigs fed T1 diet than pigs fed T2 and T3 diets. The hematological status on d 14 was not affected by dietary treatments but on d 28 pigs fed T2 diets had lower ($P < 0.05$) erythrocyte count, hemoglobin and hematocrit values. The plasma Fe concentration on d 14 was lower ($P < 0.05$) in pigs fed T2 (87 μ g/dl) diet than pigs fed T3 (128 μ g/dl) diet while on d 28 pigs fed T1 and T2 diet had lower ($P < 0.05$) plasma Fe (86 and 70 vs 127 μ g/dl) than pigs fed T3 diet. These results suggest that tannin added to diets low in Fe without antibiotics resulted in performance of pigs comparable to pigs fed high Fe diets with antibiotics but tannin added to diets reduced incidence of diarrhea. However, tannin added to low Fe diets had a negative influence on the hematological and plasma Fe status.

Key Words: Tannin, Weanling Pigs, Fecal Microflora

T130 Effect of *Euchaena mexicana* Schrad diets on nutrient digestibility and nitrogen metabolism for Wulong Goose. B. W. Wang*, M. A. Zhang, X. P. Wu, G. L. Liu, and X. H. Jia, *Qingdao Nongye University, Qingdao, Shandong Province, China.*

One trial was conducted to study nutrition digestibility of *Euchaena mexicana* Schrad (EMC) diets for Wulong Goose. Thirty-two geese of 9 months old were selected and divided into four groups randomly, with eight geese in each group. Four groups were fed with the isocaloric and isonitrogenous diets of different EMC contents (12, 19, 25 and 31%), respectively. The results showed that, as dietary EMC increased, dry matter (DM) digestibility was decreased significantly, meanwhile the digestibility of crude fiber (CF), neutral detergent fiber (NDF) and acid detergent fiber (ADF) increased significantly ($P < 0.05$). The ratio of apparent essential amino acid (EAA) digestibility (except Leu) among the four groups had significant difference ($P < 0.01$). the content of NH₃-N in feces dropped ($P > 0.05$). There were no significant differences in net protein utilization (NPU), N apparent digestibility, N deposition and Ca apparent digestibility in different groups ($P > 0.05$). The apparent digestibility of P in different groups elevated, while there was significant difference between group D and A ($P < 0.01$), and there was significant difference between group D and B ($P < 0.05$).

Key Words: Wulong Goose, *Euchaena mexicana* Schrad, Nitrogen Metabolism

T131 Feeding different levels of zearalenone on growth, vulva size, and organ weight in postweanling female pig. Z. B. Yang¹, H. Zao¹, C. C. Chen², and F. Chi³, ¹Shandong Agricultural University, Taian, Shandong, PRC, ²Chaoyang University Technology, Taichuang, Taiwan, ROC, ³Oil Dri Corporation of Amercia, Chicago, IL.

A total of twenty postweanling female pigs (L × Y × D) weaned at d-21 with an average of 6.77±0.46 kg were used in the study. The pigs were randomly divided into four treatments with 5 pigs per treatment. Pigs were fed a corn-soybean meal-whey based diet with an addition of 0, 1, 2, or 3 ppm of zearalenone (ZEA, Fermentek, Israel) for 18 days. Feeds contained 0.90, 1.67, 2.33 and 4.33 ppm of ZEA in the four test diets individually. Pigs were weighed at the beginning and the end of trial. Feed intakes were recorded daily. Vulva length and width were measured at 3 days intervals. Pigs were killed at the end of trial, and individual organs were obtained and weighed. No differences were observed between treatments on weight gain, feed intake, or feed efficiency. However, vulva length and width were increased significantly (P<.05) as dietary ZEA concentration increased. When comparing the vulva size between d-1 and d-18 of each treatment, the size were 111, 174, 173, and 430% increased respectively in treatments 1, 2, 3, and 4. Organ sizes including uterus, ovary, kidney, liver, heart, lung, spleen, stomach, and intestines are shown in the Table 1. The size of reproductive system, kidney and liver were increased linearly as dietary ZEA increased (P<.05) On the other hand, heart, lung, spleen, and GI etc organ sizes showed no difference between treatments after feeding 18 days of ZEA. Due to increased size of liver, kidney and reproductive tract, a trend of decreased dressing percentage as dietary ZEA concentrations increased was obtained although it was not significantly different between treatments (P>.05).

Table 1. Percent organ weights to body weight of individual pig feeding different levels of zearalenone

Treatment	ZEA Intake, ppm	Ovary, Uterus	Kidney	Liver	Dressing %
1	0.90	.0625 a	.430 a	2.429 a	73.47
2	1.67	.0986 ab	.451 ab	2.535 ab	75.11

T132 Effect of probiotic and enzyme on fatty-liver performance and major cecum microorganisms in Landes Goose. B. W. Wang*, S. H. Yu, M. A. Zhang, L. Wang, B. Yue, L. Z. Jing, X. X. Wei, Y. C. Wang, Y. C. Fan, Q. L. Wang, Q. Zhang, and P. Sun, *Qingdao Nongye University, Qingdao, Shandong Province, China.*

To study the effect of probiotics and enzyme on fatty-liver performance, ninety 13-week-old Landes geese were selected and divided into three groups randomly, with five replicates each group and six each. The group one was the control and fed the basal diets, group two and three were the experiment groups fed the diets with an inclusion level of 0.3% probiotics and 0.3% enzyme respectively. The feeding trial lasted four weeks to measure the somatotype indexes, quality of fatty-liver and selected the cecums to culture microorganism. The results showed that,

in comparison with the control, the body oblique length, body weight and carcass weight in group two and three increased significantly (P < 0.05). With an average liver weight exceeding 1000g, there was an significant increase between the two groups and the control (P < 0.05), while the content of water, crude protein, crude fat and composition of fatty acid of liver in the two groups were not influenced (P > 0.05). The number of lactobacillus in the second group was 7.63 ± 0.52, increased by 4.53 times (P < 0.01), and the number of bifidobacterium was 6.34 ± 0.62, increased by 3.64 times (P < 0.01), and the number of escherichia coli was 5.43±0.46, reduced 66.62% (P < 0.01). The number of lactobacillus in third group was 7.48 ± 0.41, increased by 3.89 times (P < 0.05), the number of bifidobacterium was 5.62 ± 0.36, increased by 3.24 times (P < 0.05) and the number of *Escherichia coli* was 5.62±0.36, reduced 48.71% (P < 0.05). It was showed that, probiotic and enzyme preparation could promote the growth of lactobacillus and bifidobacteria, inhibit the growth of *E.coli* and maintain the good microorganism environment in intestinal in different extent; and promote the growth of Landes geese and formation of fatty-liver, improve the fatty-liver level, with no influence on the quality of fatty-liver.

Key Words: Landes Goose, Fatty-Liver Weight, Cecum Flora

T133 Study on the ferment characteristics and application effect of *Penicillium oxalicum* Currie & Thom producing pectinase. B. W. Wang*, L. Z. Jing, F. Y. Long, B. Yue, M. A. Zhang, S. H. Yu, Y. C. Wang, X. X. Wei, Q. Zhang, and Q. Feng, *Qingdao Nongye University, Qingdao, Shandong Province, China.*

Pectin was anti-nutrition determinant in animal feed. If one kind of effective enzyme which could degrade pectin was produced, the feed cost would be reduced and the problem that foodstuff competition between human and livestock would be eased. In order to determine process conditions of crude enzyme of pectinase and its effect on digestion and absorption of goose, the ferment condition was determined and the crude enzyme of pectinase was made. While twenty-four-month -old Wulong geese were selected and divided into four groups at random, and six geese in each group. Total feces collection method was adopted to determine the digestion of some nutrients. The content of pectinase in each experiment diet was 0.0%, 0.1%, 0.2% and 0.3%. The results indicated that the optimal composition of substrate was glucose 0.9g, (NH₄)₂SO₄ 1.2g, KH₂PO₃ 0.7g relative to 15g substrate; The best primary pH and time of ferment were 4.5 and 60h; The best temperature and optimum inoculum size were 30°C and 1.5ml. Combination with 5-fold concentration produced the highest gain rate of 89.89% (P<0.01). Under the same level of nutrition, the digestion of crude fiber was respectively 20.55%, 26.33%, 37.59%, 30.76% with the increasing of pectinase content; The concentration of NH₃-N in the third group was 1.20 mg/kg and significantly lower than other groups (P<0.01); The digestion of AA were relatively high (72.19%~94.27%). The apparent digestibility of Ca, P and the bacterium number of *Bifidobacterium*, *Lactobacillus* and Yeast in the feces in different groups first increased and then decreased with the increasing level of pectinase. So, supplementation with pectinase could increase the availability of nutrient in diet.

Key Words: *Penicillium oxalicum* Currie & Thom from Goose, Fermentation Characteristics, Digestion

T134 Live weight dependent responses to adding an enhanced milky flavor (Luctarom® Advance) to a piglet nursery feeding program. E. Roura*¹, G. Tedó¹, X. Puigvert², and I. Ipharragere¹, ¹Lucta SA, R+D Feed Additives, Barcelona, Spain, ²Universitat de Girona, Girona, Spain.

A trial was conducted with 192 Landrace × Large White newly weaned 23d-old pigs to study different dosing programs of an enhanced milky flavor (Luctarom® Advance) in feeds. Piglets were randomly allocated in a factorial design with 3 blocks of 8 pens according to initial body weight (light=5,78 kg; intermediate =6,66 kg; heavy=7,38 kg) and 4 dietary treatments differing only in amount of flavor. The pre-starter phase (0 to 14 d) flavor doses were 0 (T1) or 1500 ppm (T2, T3 and T4). The starter phase (14 to 28 d) flavor doses were 0 (T1), 500 (T2), 1000 (T3) or 1500 (T4) ppm. In the 1st week post weaning, the 3 equally flavored treatments on average resulted in 25% higher ADFI ($p < 0.05$) than T1 (90 vs 72 g). In the 2nd week, a flavoring by block interaction ($p < 0.05$) was observed because adding flavor increased ADG more in the light (from 182 to 242 g) than in the heavy (231 to 269 g) while decreased ADG in the intermediate (238 vs 223 g) groups. In the 1st week of the starter phase, T4 pigs ADG (555 g) was significantly higher ($p < 0.01$) than gains for T1 (485 g), T2 (457 g) or T3 (470 g). Furthermore a treatment by block interaction ($p < 0.05$) was observed showing that lowering the flavor dose to only 500 ppm (T2) compared to T4 (1500 ppm) had a live weight dependent response on ADG such that the light pigs grew similarly in both treatments (500 vs 498 g) but grew less in the intermediate (503 vs 554 g) and heavy (382 vs 609 g) groups. Overall piglets in T4 compared to T1 showed a 10% increase in ADG (345 vs 314 g, $P = 0.16$). We conclude that adding the enhanced milky flavor to feed results in higher ADG in weanling pigs compared to a non-flavored group. In the pre-starter phase, flavor addition is more effective among the lightest pigs. Decreasing flavor doses from pre-starter to starter diets results in a live weight dependent response in ADG such that the heavier the pigs the bigger the drop in the improvement in performance compared to the fully flavored group.

T135 Identification of the porcine umami taste receptor dimer responsible for the taste of amino acids. E. Roura*¹, R. Holt², and K. C. Klasing², ¹Lucta SA, R+D Feed Additives, Barcelona, Spain, ²University of California, Davis.

Humans and mice perceive the umami taste via a trans-membrane heterodimeric receptor consisting of T1R1 and T1R3 proteins that are G-protein coupled to intracellular calcium release. To identify the porcine umami taste receptor, vallate papilla tissue samples were obtained from a 6-month-old male pig and total RNA was extracted, purified, and reverse transcribed. A porcine expressed sequence tag (EST) with high homology to human T1R3 was located in a public domain library (pig ESTs database from Iowa State University). The RACE PCR technique was used to obtain cDNA for adjacent 3' and 5' regions of the T1R3 EST sequence. Candidate PCR products were sequenced and the RACE process was repeated until the full length 2568 nucleotide sequence was determined. To obtain the pig T1R1 receptor sequence, degenerate PCR primers were designed that covered areas of high homology to the mouse, human, and cat genes. Primer sets were found that amplified a portion of the T1R1 and the complete 2535 nucleotide T1R1 sequence was obtained using the RACE PCR technique. Full length products of T1R1 and T1R3 were amplified by PCR, sequenced, and found to have

high (>80%) homology to respective genes from other mammals. The open reading frame of T1R1 and T1R3 was recombined into pcDNA6.2/V5-DEST Gateway vectors for expression in mammalian cells. CHO-K1 cells were transfected with both full-length pig taste receptors constructs and a mouse G alpha 15 G protein sub-unit construct. Transfected cells were seeded into 96-well-plates, loaded with a calcium detection dye cocktail and then exposed to individual amino acids. Ligand binding was determined by fluorescence using an ELISA plate reader. The porcine umami taste receptor was most sensitive to non-essential amino acids, with glutamic acid and alanine giving strong responses. In general, essential amino acids gave lower responses. These results indicate that the porcine umami receptor is tuned to detect amino acids.

Key Words: Pig, Umami, Taste Receptor

T136 Effect of virginiamycin on apparent ileal digestibility of amino acids by growing pigs. L. L. Stewart*¹, B. G. Kim¹, B. R. Gramm², R. D. Nimmo², and H. H. Stein¹, ¹University of Illinois, Urbana, ²Phibro Animal Health Co., Ridgefield Park, NJ.

Virginiamycin (VIR) improves the digestibility of energy and phosphorus, but effects of VIR on AA digestibility have not been documented. Thus we investigated the influence of VIR on apparent ileal digestibility (AID) of AA in growing pigs. A total of 15 barrows with an initial BW of 35.0 ± 2.7 kg were surgically equipped with a T-cannula in the distal ileum. Animals were randomly allotted to 3 dietary treatments during a 4-wk experiment. Dietary treatments included: 1) basal diet based on corn-soybean meal, 2) basal plus 11 ppm VIR, and 3) basal plus 22 ppm VIR. During wk 1, pigs were fed only a basal diet; during wk 2 to 4, treatment diets were provided. Ileal samples were collected on d 6 and 7 of each week. As presented in Table 1, the AID for most indispensable AA were improved in pigs fed 11 ppm VIR (Ile, Leu, Lys, Met, Phe, Trp, and Val; $P < 0.05$) or 22 ppm VIR (Ile, Leu, Met, Phe, Thr, Trp, and Val; $P < 0.05$) during wk 2 to 4. The AID for some dispensable AA were also increased in pigs fed 11 ppm VIR (Ala, Asp, and Tyr; $P < 0.05$) or 22 ppm VIR (Ala, Cys, Glu, Pro, and Tyr; $P < 0.05$). However, the AID of AA was indifferent between pigs fed 11 ppm VIR and those fed 22 ppm VIR. The present results indicate that dietary VIR improves ileal digestibility of most indispensable AA and that this effect is not further enhanced by providing more than 11 ppm VIR.

Table 1. Apparent ileal digestibility of indispensable AA during wk 2 to 4

Item	Virginiamycin, ppm			SEM	P-values

T137 Effect of β -glucanase on performance and apparent nutrient digestibility in weaned piglets. E. Grilli^{*1}, I. Kühn², A. Panciroli¹, and A. Piva¹, ¹*DIMORFIPA, Ozzano Emilia, Bologna, Italy*, ²*AB Enzymes GmbH, Darmstadt, Germany*.

Aim of the study was to evaluate the addition of β -glucanase (ECON-ASE[®] Barley P 700, AB Enzymes GmbH) on piglets growth performance and nutrient digestibility during 6 post-weaning weeks. Three-hundred and twenty four male piglets weaned at 21-28d (7.5 \pm 0.5 kg BW) were divided into 3 groups of 18 pens each (6 pigs per pen): a control group, receiving a barley-based diet (CTR); the ECO1 group, receiving the same diet added with β -glucanase at 17,500 BU/kg, and the ECO2 group, with enzyme added at 24,500 BU/kg. Animals were fed a 2-phase diet with no antimicrobials added. Piglets were weighed on the day of the study start (d0), at the end of the first phase (d19), and at the end of the study (d42). Feed intake was recorded daily. ADG and G:F were calculated between 0-19d, 20-42d, and 0-42d. From d15 to d19, and from d38 to d42 samples of fresh feces from 14 pens per treatment were collected daily to be analyzed for nutrient digestibility. Data were analyzed with 1-way ANOVA. During the period 0-19d ECO1 and ECO2 piglets had higher feed intake than piglets fed the CTR diet (+9.4% and +6.9%, respectively; $P < 0.05$). The ECO1 group piglets had higher ADG and BW at 19d when compared to CTR (+15%, and +5.7%, respectively; $P < 0.05$). Throughout the study (0-42d), ECO1 and ECO2 piglets tended to have higher ADG and higher BW when compared to CTR (ADG: +5.8%, and +7.6%, respectively, $P = 0.12$; BW: +4.6% and +5.1%, respectively, $P = 0.13$). Despite increased feed intake, G:F (0-42d) was significantly higher for the ECO2 group than for other groups (+6% than CTR group, $P = 0.047$). During the first phase (d15 to d19) DM fecal digestibility was improved by 5.6% in ECO1 than in CTR ($P = 0.02$) and crude protein and gross energy digestibilities were higher in ECO1 group than in CTR (+7.1%, and +8.6%, respectively; $P < 0.05$). Effects were similar but not significant in ECO2 group. Data demonstrated that especially during the first phase the enzyme stimulated feed intake and fecal apparent digestibility, thus improving growth performance of weaning piglets when their diet was supplemented with β -glucanase either at 17,500 BU/kg or at 24,500 BU/kg.

Key Words: Barley, β -Glucanase, Piglets

T138 Dietary supplementation of oregano essential oils on the performance of broilers under high altitude condition. L. Betancourt¹, C. Ariza-Nieto^{*2}, F. Rodriguez², V. Phandanouvong², A. Padilla¹, M. Hernandez¹, M. Hume³, D. Nisbet³, and G. Afanador-Tellez², ¹*Universidad Salle, Bogota, Colombia*, ²*CORPOICA, Bogota, Colombia*, ³*USDA, ARS, FFSRU, College Station, TX*.

This study evaluated the supplementation of the essential oils (EO) of different varieties of oregano in a feeding program for broilers maintained at high altitude. Two hundred and seventy 1-d old Hybro male broiler chicks were placed in 30 brooder cages under a completely randomized design. Cages were randomly assigned to 6 treatments: 1) control (C); 2) antibiotic, 500 ppm Chlortetracycline (AB); 3) 50 ppm of EO from *O. vulgare* H ground in Greece (OG); 200 ppm of EO from 3 varieties ground in Sabana of Bogota-Colombia, 4) *O. vulgare* H. (OBH), 5) *O. vulgare* L. (OBL) and 6) *O. marjoricum* (OBM). Broiler performance was determined at 3, 7, 14, 21, 28, 35 days of age. From day 21 to 25 chromium oxide (Cr₂O₃) was added at 0.5 g/kg of diet as indigestible marker for the digestibility study. Four chicks from each treatment were randomly selected for morphology measurements. Intestinal tissues were

collected from duodenum, jejunum, and ileum to measure crypt depth and villus height. The composition of essential oils was analyzed by GC/MS. Clear differences were observed between the oregano varieties with wide ranges in the content of carvacrol (3.7% to 50.8%) and thymol (4.7% to 21.5%). The minimal inhibition concentration (MIC) of the EO were tested on *Salmonella* Typhimurium ATCC 14028 and *Escherichia coli* ATCC 25922 using microdilution in broth. OBL showed the highest inhibitory activity with a MIC of 1.25 mg/ml and 0.63 mg/ml on *S. Typhimurium* and *E. coli*, respectively. Broilers supplemented with OBM had greater villus: crypt ratio in duodenum compare to OG group. Broilers supplemented with AB showed greater ileum protein digestibility (88.9%) when compared to C, OBGL, and OBGH (84.0, 82.8, and 76.2%, respectively), but similar to OBM (85.7%) and OG (84.7%). Broilers supplemented with OBM had greater ($P < 0.05$) body weight gain compared to OG on days 7 and 14 (101.9 vs. 93.9 g) and (244.0 vs. 222.6 g), respectively. Group OBL reduced mortality in 11.1% compared to group C. Oregano EO supplementation showed a biological growth potential on broilers under high altitude conditions.

Key Words: Oregano Essential Oils, Broiler, Gastrointestinal Health

T139 Isolation of a *Bacillus licheniformis* DK42 producing cellulase and xylanase, and properties of the enzymes. M. J. Kim, S. J. Lim, and D.-K. Kang^{*}, *Dankook University, Cheonan, Chungnam-do, Rep. of Korea*.

Cellulase and xylanase play an important role in improvement of the nutritional value of animal feeds. A bacterium DK42 producing xylanase and cold-active cellulase was isolated from pig feces. The isolate, DK42 strain, was found to be the Gram-positive, non-motile, catalase-positive, and spore-forming strain. Under an electron microscope, the cells were observed to be rod-shaped. The isolate was named as *Bacillus licheniformis* DK42, on the basis of carbon utilization and 16S rRNA gene sequences analysis. The extracellular cellulase and xylanase were partially purified by ammonium sulfate precipitation. Cellulase exhibited an optimum temperature and pH at 45C and 6.0, whereas xylanase exhibited an optimum temperature and pH at 55C and 6.0. Especially cellulase maintained approx. 50% of its maximum activity even at 4C, indicating that it is cold-active. Both cellulase and xylanase were stable after 2hr at 35C, whereas they lost their activities after 30min at 65C. The zymogram analysis of ammonium sulfate-precipitated fraction showed a distinct cellulase activity band on native PAGE.

Key Words: Cellulase, Xylanase, *Bacillus*

T140 Effect of dietary probiotic and/or prebiotic on humoral immune response of Ross broiler chickens. H. Ziaei^{*1}, M. A. Karimi Torshizi², M. Bashtani¹, H. Farhangfar¹, H. Naemipour¹, and A. Zeinali¹, ¹*Birjand University, Birjand, Iran*, ²*Tarbiat Modarres University, Tehran, Iran*.

An experiment was conducted on 240 one-day old male Ross broiler chickens to evaluate the efficiency of antibiotic alternatives growth promoters on bird immune response system. Chicks were fed in a block completely randomized design with 4 replicate pens (15 birds per pen). Experimental treatments were: (T1= control, T2= control + 15 ppm of Virginiamycin, T3= control + 15 mg probiotic Protexin /kg diet, T4=

control diet + 10 mg prebiotic Immnuwall /kg diet). For experimental immunization, four birds of 18 and 27 days old from each replicate were injected intravenously (brachial vein) with 0.1 ml of 0.5% sheep red blood cells (SRBC). Blood samples were collected after 5 days of inoculation to measure the antibody production. The results of the present study indicated that the antibody production was significantly ($P<0.05$) higher in experimental units treated under T3 and T4 as compared with the other treatments in 24 and 32 days of age. In addition, for the traits under consideration, non-significant difference ($P>0.05$) was found between treatments 1 and 2. It is therefore suggested that supplementation of diets with Probiotic and Prebiotic could increase immune function against the pathogens resulting in improving growth performance of broilers.

Key Words: Broiler, Probiotic, Prebiotic

T141 Assessment of the antimicrobial activity of carvacrol, cinnamaldehyde and capsicum oleoresin in stomach, jejunum, and cecum digestive content of weaned pigs using fermentation assay.

E. G. Manzanilla¹, M. Anguita¹, S. Martin-Orúe¹, J. P. Meunier*², and J. Gasa¹, ¹Universitat Autònoma de Barcelona, Spain, ²Pancosma Research, Geneva, Switzerland.

The measurement of gas produced as a fermentation end product in vitro was used to study the antimicrobial effect of a plant mixture (XT) containing carvacrol (CAR), cinnamaldehyde (CIN) and capsicum (CAP). Increasing doses from 0 to 10000 µg/mL of the mixture were tested in stomach, jejunum and cecum contents 1 and 2 weeks after weaning at 21 days of age. No inhibition of the gas production was found in stomach and cecum content using 10000 µg/mL of XT. In jejunum, 10000 µg/mL produced a partial decrease on the gas production (20.0 vs. 29.5 mL, $P=0.001$). The different components of XT were tested separately using intestinal content of animals 1 week after weaning. Formic acid (FA) was included in the tests as a reference. In the stomach, CAR totally inhibited the gas production at 10000 µg/mL, whereas CIN and FA induced a partial inhibition (0.8 and 4.5 vs. 14.3 mL, $P<0.001$, respectively). CAP did not show any effect on stomach gas production until 10000 µg/mL. All compounds produced a decrease of gas production in jejunum content at 1000 µg/mL. However the effect of CAR, CIN and FA was more marked than the CAP effect compared to negative control (15.5, 16.0, 21.0 and 25.8 vs. 29.5 mL, $P<0.001$, respectively), and all three inhibited gas production at 10000 µg/mL whereas the CAP effect was unchanged. CAR, CIN and CAP were then tested in older animals, 5 weeks after weaning. CAR at 1000 µg/mL and CIN at 500 µg/mL both reduced gas production in jejunum (17.5 and 14.0 vs. 37.7 mL, $P<0.001$, respectively). The doses of 3000 µg/mL of CAR and 2000 µg/mL CIN partially inhibited gas production in cecum (21.5 and 24.4 vs. 28.8 mL, $P<0.001$, respectively). CAP was only active at doses higher than 10000 µg/mL. These experiments demonstrate that CAR and CIN present good antimicrobial activity at doses similar to the acidifiers.

Key Words: Plant Extracts, Formic Acid, Pig

T142 Effects of essential oils supplementation on growth performance, nutrient digestibility, blood characteristics, fecal noxious gas concentration and meat quality in growing-finishing pigs.

J. S. Yoo*¹, J. H. Cho¹, Y. J. Chen¹, C. Y. Lee², H. G. Moon³, and

I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Jinju National University, Gyeongnam, Korea, ³National Institute of Animal Science, Korea.

Ninety six crossbred pigs (Landrace×Yorkshire×Duroc) were used to determine the effects of essential oils (AROMEX[®] ME) supplementation on growth performance, nutrient digestibility, immune response, fecal noxious gas and meat quality of growing-finishing pigs. Treatments were 1) NC (control diet without antibiotics), 2) PC (NC + 44 mg/kg tylosin to 6th wk; 20 mg/kg avilamycin to 16th wk) and 3) AROMEX[®] ME (NC + 0.01% AROMEX[®] ME). At 16 weeks body weight was higher ($P<0.05$) in PC and AROMEX[®] ME treatments (110.972 kg and 113.491 kg) than in the NC treatment (102.206 kg). During the all period of the trial, ADG (0.854 kg) and G/F (0.474) were significantly improved ($P<0.05$) by AROMEX[®] ME supplementation compared with NC treatment (0.802 kg and 0.436). Both of antibiotics (1.798 kg) and AROMEX[®] ME (1.802 kg) supplementation significantly decreased ($P<0.05$) ADFI compared with NC treatment (1.838 kg). At the end of 16 weeks, total protein and lymphocyte concentration of blood were increased ($P<0.05$) in PC (7.99 g/dL and 65.48%) and AROMEX[®] ME (7.93 g/dL and 64.48%) treatments compared with NC treatment (7.83 g/dL and 57.40%). IgG concentration was increased ($P<0.05$) in AROMEX[®] ME treatment (1428 mg/dL), compared with NC (1296 mg/dL) and PC treatments (1303 mg/dL). WHC was increased ($P<0.05$) in AROMEX[®] ME treatment (38.64%) compared with other treatments (32.05% and 34.24%). TBARS of NC (0.032 MDA mg/ 1000g) and PC (0.030 MDA mg/ 1000g) treatments were higher ($P<0.05$) than AROMEX[®] ME treatment (0.012 MDA mg/ 1000g). AROMEX[®] ME supplementation significantly reduced ($P<0.05$) ammonia (84.18ppm) and mercaptans (0.62ppm) emission compared with NC (92.92ppm and 0.75ppm) and PC treatments (94.02ppm and 0.87ppm) at the 7 days of the gas evaluation. In conclusion, the dietary addition of essential oils and antibiotic into diets for growing-finishing pigs improved growth performance, nutrient digestibility, and immune response. Essential oils can be used to partly replace antibiotics in diets for pigs without negative affects on growth performance, meat quality and reduced noxious gas emission.

Key Words: Essential Oil, Fecal Noxious Gas Concentration, Blood Profile

T143 Effects of dietary *Rhodopseudomonas capsulata*, *Rhizopus oligosporus* & *Aspergillus oryzae* on growth performance nutrient digestibility and blood characteristics in growing pigs.

J. S. Yoo*¹, H. J. Kim¹, S. O. Shin¹, Y. Haung¹, J. D. Kim², I. C. Kim³, and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²CJ CheilJedang, Seoul, Korea, ³National Institute of Animal Science, Korea.

The current study was conducted to investigate the effects of dietary complex probiotics supplementation on growth performance, nutrient digestibility, blood characteristics and noxious gas emission of manure slurry in growing pigs. A total of forty eight pigs with an initial body weight of 20.12 kg were allotted to three dietary treatments (two pigs per pen with eight pens per treatment). Probiotics contained *Rhodopseudomonas capsulata*, *Rhizopus oligosporus* & *Aspergillus oryzae*. Dietary treatment included: 1) CON (basal diet), 2) Pro1 (basal diet + 0.1% complex probiotics) and 3) Pro2 (basal diet + 0.2% complex probiotics). The experiment lasted six weeks. Blood samples were acquired from the cervical vein into K₃EDTA vacuum tubes and clot activator vacuum tubes from 2 pigs in each pen at the end of the

experiment. Collected fresh feces and urine samples were stored in 2.6 L plastic boxes. After fermentation period, Gastec fas sampling pump was used for gas detection. One hundred mL of the headspace air in each plastic box was sampled approximately 2.0 cm above the slurry surface. Through the entire experimental period, ADG was increased with the increased complex probiotics supplementation level (linear effect, $P < 0.05$). However, neither ADFI nor gain/feed was influenced by the dietary treatments. Complex probiotics supplementation increased DM digestibility (linear effect, $P < 0.05$). Also, N digestibility was improved, with the Pro1 treatment having the highest value (linear and quadratic effect, $P < 0.05$). Supplementation of complex probiotics did not affect the WBC, RBC, lymphocyte and BUN concentrations in blood. The NH_3 -N emission from manure slurry was decreased with the increased level of complex probiotics supplementation (linear and quadratic effect, $P < 0.05$). Similarly, H_2S emission of manure slurry was also decreased significantly when complex probiotics was included in diet (linear effect, $P < 0.05$). In conclusion, dietary supplementation of complex probiotics can increase growth performance and decrease noxious gas emission of manure slurry in growing pigs.

Key Words: Complex Probiotics, Noxious Gas, Pig

T144 Effect of dietary organic acid mixture (lactic acid, formic acid, citric acid, butyric acid and phosphoric acid) on growth performance, organ weight, blood immunological parameter and intestinal villi morphology in broilers. H. D. Jang^{*1}, J. S. Yoo¹, Y. Huang¹, T. X. Zhou¹, J. H. Cho¹, J. D. Hancock², and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Kansas State University, Manhattan.

The study was conducted to evaluate the effects of dietary organic acid mixture (lactic acid, formic acid, citric acid, butyric acid and phosphoric acid) on growth performance, organ weight, blood immunological parameter and intestinal villi morphology in broilers. Dietary treatments were included 1) CON (basal diet), 2) OA1 (basal diet + 0.1% organic acid mixture) and 3) OA2 (basal diet + 0.2% organic acid mixture). Each treatment were allotted to twenty broilers per pen with eight replicate pens per treatment in a completely randomized design. Daily weight gain, feed intake and feed/gain were not significantly different among the treatments. In organ weight, gizzard was significantly higher in OA2 than CON (Linear effect= 0.034). However, spleen and intestine were not significantly different among the treatments. In blood immunological parameters, RBC, WBC and lymphocyte were not significantly different. In intestinal villi morphology, villi length was increased in OA1 compared to CON (Quadratic effect=0.050). Water content of feces was not significantly different among the treatments. In conclusion, 0.1% organic acid mixture was effective to improve gizzard and villi length in broilers.

Key Words: Complex Organic Acid, Blood Immunological, Intestinal Villi

T145 Effects of dietary supplementation of blended essential oil on growth performance, nutrient digestibility, blood profiles, fecal characteristics in weanling pigs. Y. Huang^{*1}, J. S. Yoo¹, H. J. Kim¹, Y. Wang¹, Y. J. Chen¹, J. H. Cho¹, J. D. Hancock², K. Y. Whang³, and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Kansas State University, Manhattan, ³Korea University, Seoul, Korea.

One hundred and twenty five crossed [(Duroc × Yorkshire) × Landrace] pigs (6.21 ± 0.02 kg initial body weight and 21 d average age) were used in the current experiment to determine the influence of dietary supplementation of blended essential oil on growth performance, nutrient digestibility, blood profiles, fecal characteristics in weanling pigs. Treatments were 1) NC (antibiotic free diet), 2) PC (NC diet + 44 mg/kg of tylosin), 3) T1 (NC diet + 0.1% of essential oil), 4) T2 [NC diet + 0.1% of essential oil (with 0.3% Benzoic acid)] and 5) T3 (NC + 22 mg/kg of tylosin and 0.05% of essential oil). ADG was improved ($P < 0.05$) in pigs fed 0.1% of essential oil with 0.3% Benzoic acid (295 g) at d 14 compared with PC and T1 treatments (266 g and 269 g). At the end of experiment, dry mater digestibility was improved ($P < 0.05$) in T3 treatment (78.67%) compared with T1 treatment (77.09%). Lymphocyte concentration in blood was greater ($P < 0.05$) in T3 treatment (64.78%) compared with NC treatment (50.14%). Fecal pH was the greatest ($P < 0.05$) in PC treatment (8.36) compared with NC, T1, T2, and T3 treatments (8.07, 8.06, 7.61 and 7.58, respectively). Amonia emission was increased ($P < 0.05$) in PC treatment compared with T1, T2, and T3 treatments (146.67, 70.00 and 74.67). Diarrhea appearance and score were tended to decrease in essential oil treatments partially. In conclusion, supplementation of blended essential oil could replace antibiotics to improve growth performance and remain the amonia emission with Benzoic acid supplementation.

Key Words: Essential Oil, Growth Performance, Fecal Characteristic

T146 Effects of reducing dietary crude protein, yucca and multi-carbohydase supplementation on egg production performance, nutrition digestibility, and fecal noxious gas contents in laying hens. Y. Huang^{*1}, Y. Hyun², H. S. Kim², Y. Wang¹, H. J. Kim¹, S. O. Shin¹, and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Seoul Feed, Co. LTD., Seoul, Korea.

The emissions of fecal noxious gases, including ammonia (NH_3), constitute principal concerns for the Korean poultry industry. The principal objective of this study was to determine whether different crude protein (CP) levels and several different supplementation techniques could reduce fecal gas emission and maintain the production performance of laying hens. Chickens were fed with the following diets: 1) T1 (CP 18%); 2) T2 (CP 16.5% + yucca 0.02%); 3) T3 (CP 15% + yucca 0.02%); 4) T4 (CP 15% + yucca 0.02% + α -1,6-galactosidase and β -1,4-mannanase multi-carbohydase 0.05%). Egg production, egg weight, eggshell breaking strength, eggshell thickness, nutrient digestibility, and fecal noxious gas emission characteristics were evaluated. Egg production and egg weight were not consistently altered by any of the treatments. Eggshell breaking strength and eggshell thickness were both significantly reduced by T3 and T4 treatments at the end of experiment ($P < 0.05$). Digestibility of amino acids (AA), with the exception of Gly, were significantly decreased by feeding low CP diet ($P < 0.05$). However, carbohydase supplementation significantly improve the digestibility of AA in the low CP treatments ($P < 0.05$). Dry matter (DM) digestibility was increased with reducing dietary CP levels ($P < 0.05$). Fecal sulfureted hydrogen (H_2S) and NH_3 emissions were significantly decreased in T3 and T4 treatments ($P < 0.05$). In conclusion, our results indicate that 1) Eggshell breaking strength, eggshell thickness, nutrient digestibility, and noxious gas emissions may be decreased by reductions in dietary CP. 2) Considering the decreasing levels of CP in the yucca treatment groups, yucca may exert some positive effects on egg production and weight. 3) Multi-carbohydase supplementation can significantly improve AA digestibility. 4) The reduction of dietary CP and yucca and multi-

carbohydrase supplementations would be expected to improve nutrient digestibility and fecal noxious gas emission in laying hens.

Key Words: Laying Hens, Yucca, Amino Acid Digestibility

T147 Effect of dietary microbial phytase on laying performance, egg quality, phosphorus utilization and nutrient utilization in laying hens. H. D. Jang^{*1}, Y. Hyun², H. S. Kim¹, I. W. Hwang³, J. S. Yoo¹, Y. J. Chen¹, J. H. Cho¹, and I. H. Kim¹, ¹*Dankook University, Cheonan, Chungnam, Korea*, ²*Seoul Feed, Co. LTD., Seoul, Korea*, ³*EASY BIO System, Inc, Seoul, Korea*.

The study was conducted to evaluate the effects of dietary microbial phytase on egg productivity, egg quality, phosphorus utilization and nutrient digestibility in laying hens. The animals used in the experiment were a total of 120 ISA brown laying hens (32 weeks old). Dietary treatments included 1) CON (basal diet), 2) LP (Low phosphorus diet) 3) NG (Low phosphorus diet + 0.03% Natuphos[®]Granule), 4) NC (Low phosphorus diet + 0.03% Natuphos[®] Classic). The laying hens were allotted at 6 laying hens per block with five replicate pens per treatment by completely randomized design. Through the whole period of experiment, egg production was significantly increased in CON and NG treatments compared to LP treatment ($P < 0.05$). CON, NG and NC treatments significantly increased their egg shell breaking strength and egg shell thickness compared to LP treatment ($P < 0.05$). Albumin height was higher in CON and NG treatments than LP treatment ($P < 0.05$). CON, NG and NC treatments resulted higher yolk color and haugh unit than LP treatment ($P < 0.05$). Calcium and Inorganic phosphorus contents in blood were higher in NG treatment compared to LP treatment ($P < 0.05$). Calcium retention of CON, NG and NC treatments were higher than LP treatment ($P < 0.05$). Phosphorus retention was increased in NG and NC treatments compared to CON and LP treatments ($P < 0.05$). LP treatment significantly increased their nitrogen, calcium and phosphorus excretion compared to CON, NG and NC treatments ($P < 0.05$). Dry matter digestibility and nitrogen digestibility were greater in NG treatment than CON, LP and NC treatments ($P < 0.05$). Crude ash was increased in CON, NG and NC treatments compared to LP treatment ($P < 0.05$). Calcium digestibility and phosphorus digestibility were significantly improved in NG and NC treatments than CON and LP treatments ($P < 0.05$). In conclusion, NG treatment improved egg production, egg quality, inorganic calcium and phosphorus, calcium and phosphorus retention and nutrient digestibility and decreased nitrogen and phosphorus excretion in laying hens.

Key Words: Microbial Phytase, Egg Quality, Laying Hens

T148 Effects of dietary biotite on growth performance, blood immunological parameters, stress concentration of serum and fecal malodor gas emission in growing pigs. H. D. Jang^{*1}, J. D. Kim², J. W. Hong³, J. S. Yoo¹, J. H. Cho¹, Y. K. Jeong⁴, and I. H. Kim¹, ¹*Dankook University, Cheonan, Chungnam, Korea*, ²*CJ CheilJedang, Seoul, Korea*, ³*DAESANG Famsco, Anseong, Korea*, ⁴*SEOBONG Biobestech, Co., LTD, Seoul, Korea*.

This study was conducted to evaluate the effects of biotite on growth performance, blood immunological parameters, stress concentration of serum and fecal malodor gas emission in growing pigs. 96

pigs[(Landrace × Yorkshire) × Duroc, 29.45 ± 1.35kg average initial body weight] were used in 42d growth trial. Dietary treatments included CON (basal diet), Solt2 (Basal diet+ Biotite 0.2%), Solt4 (Basal diet + Biotite 0.4%) and Solt6 (Basal diet + Biotite 0.6%). The pigs were assigned to the treatments according to body weight and each treatment had 6 replicates of 4 pigs per pen in a randomized complete block design. Nitrogen digestibility was significantly higher in Solt4 treatment than CON and Solt2 treatments (Linear effect = 0.016). Gross energy in Solt4 and Solt6 treatments was higher than CON treatment (Linear effect = 0.008, Quadratic effect = 0.019). There were not significantly difference on blood immunological (RBC, WBC, Lymphocyte and IgG) and stress parameter (cortisol, epinephrine and norepinephrine) among the treatments. At 5 day and 10 day, hydrogen sulfide was reduced in Solt treatment compared to CON treatment (5 day, Linear effect = 0.009, Quadratic effect = 0.037; 10 day, Linear effect = 0.009). At 5 day, acetic acid was significantly reduced in Solt treatments compared to CON treatment (Linear effect < 0.001, Quadratic effect < 0.001). At 15 day, acetic acid was significantly decreased in CON and Solt6 treatments compared to Solt2 and Solt4 treatments (Quadratic effect = 0.023). At 5 day and 10 day, Solt treatments was significantly decreased their total mercaptans compared to CON treatments (5 day, Linear effect = 0.029, Quadratic effect = 0.037; 10 day, Linear effect = 0.029). For the whole period, ammonia was significantly reduced in Solt2 and Solt4 treatments compared to CON and Solt6 treatments (5 day, Quadratic effect = 0.038; 10 day, Quadratic effect = 0.045; 15 day, Quadratic effect = 0.038). In conclusion, biotite improved nitrogen digestibility and gross energy digestibility. Also, it decreased fecal malodor gas emission in growing pigs.

Key Words: Biotite, Growth Performance, Fecal Malodor Gas Emission

T149 Use of fluidized bed technology for the development of sustained-release carvacrol pellets for a feed additive application. J.-P. Meunier^{*1}, J.-M. Cardot², and M. Alric², ¹*Pancosma Research, Geneva, Switzerland*, ²*University of Auvergne, France*.

In the field of animal feeding, the development of microencapsulated plant extract formulations intended to prolong the release of the active ingredients in the digestive tract requires to take into account a major technical limitation. The microparticles, before being consumed by the animal, must be incorporated in the feed and the whole must undergo a steam-pelleting phase. The feed will be subjected to high temperature and pressure before passing through a die to be transformed into pellets. The objective of this study was to assess the benefit of fluidized bed spray granulation applied to carvacrol microencapsulation into a core based on maltodextrin. Different amounts of hydrogenated rapeseed oil were applied on the core as coating to modify carvacrol release kinetics. The efficacy of the coating was tested in vitro using a flow through cell apparatus (CFC system). The time to achieve T90% values of dissolution increased with the increase in coating level from 10% to 30% (w/w) ($P < 0.05$), indicating the ability of the process to slow down release depending on the amount of hydrogenated rapeseed oil applied. Nevertheless, as CFC systems are ill suited for experiments with solid feed and thus limit their predictive values, follow-up studies were performed on the formulation coating at 30% using an in vitro dynamic model (TIM) that simulated more closely the digestive environment. A lower quantity of carvacrol dialyzed was recorded under fed condition vs. fasting condition with 19.1% ± 1.0 vs. 37.5% ± 2.7 respectively. This suggests a possible interaction between carvacrol and the feed matrix. Moreover, 47.7 ±

3.9% of the total carvacrol was dialyzed after 8 h digestion when feed had been granulated vs. $19.1 \pm 1.4\%$ when feed had not, which suggests that the feed granulation process could lead to a partial degradation of the microspheres. This study demonstrates the potential and the limitations of this technology to encapsulate feed additives.

Key Words: Carvacrol, Microencapsulation, In Vitro Model

T150 Effects of phytase and/or 25-hydroxyvitamin D3 inclusion on the performance, mineral balance and bone parameters of finisher pigs fed low phosphorus diets. D. A. Gahan, J. J. Callan, and J. V. O'Doherty*, *University College, Dublin, Ireland.*

Two 2×2 factorial experiments, a performance experiment and a mineral balance study were conducted to investigate the effects of *Peniophora lycii* (*P. lycii*) phytase enzyme and/or 25-hydroxyvitamin D3 on growth performance, mineral balance and bone parameters when offered to grower-finisher pigs (42 to 101 kg live weight). The dietary treatments were (T1) low-phosphorus (P) diet; (T2) low-P diet + 750 U/kg phytase; (T3) low-P + 25-hydroxyvitamin D3 (25-OHD3) diet, and (T4) low-P + 750 U/kg phytase and 25-OHD3 diet. Pigs offered both phytase (734 vs 710 g/day; se 0.008) and 25-OHD3 (736 vs 708 g/day; se 0.008) diets had higher carcass daily gains compared with non-phytase and non-25-OHD3 diets ($P < 0.05$). There was an interaction between phytase and 25-OHD3 on the apparent digestibility of ash ($P < 0.01$), P ($P < 0.001$), calcium (Ca) ($P < 0.001$) and on P ($P < 0.05$) and Ca ($P < 0.05$) retention. Pigs offered phytase only diets had higher ash ($P < 0.01$), P ($P < 0.001$) and Ca ($P < 0.01$) digestibility, and a higher P and Ca ($P < 0.05$) retention than pigs offered unsupplemented diets. However, when the combination of phytase and 25-OHD3 were offered, there was no effect on ash, P and Ca digestibility while P and Ca retention decreased compared with 25-OHD3 only diets. Pigs offered phytase diets had higher bone ash ($P < 0.01$), bone P ($P < 0.01$) and bone Ca ($P < 0.05$) concentrations than pigs offered non-phytase diets. Pigs offered phytase diets had significantly lower faecal P ($P < 0.05$) and higher urinary P excretion ($P < 0.05$) compared with non-phytase diets. Pigs offered 25-OHD3 diets had a higher nitrogen retention ($P < 0.05$) compared with non-25-OHD3 diets. In conclusion, pigs offered either phytase or 25-OHD3 diets had higher carcass daily gains compared with non-phytase and non-25-OHD3 diets. The beneficial effects of microbial phytase supplementation on ash, Ca and P digestibility were adversely affected when the combination of phytase and 25OHD3 were offered to pigs.

Key Words: Pigs, Phytase, 25-Hydroxyvitamin D3

T151 Effect of reducing dietary crude protein, yucca and multi-carbohydrase supplementation on growth performance, meat quality, nutrient digestibility, and fecal noxious gas contents in broilers. Y. Huang*¹, Y. Hyun², H. S. Kim², H. J. Kim¹, Y. J. Chen¹, J. H. Cho¹, J. D. Hancock³, and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Seoul Feed, Co. LTD., Seoul, Korea, ³Kansas State University, Manhattan.

Increased attention by regulatory agencies regarding agriculturally-generated atmospheric pollutants necessitates the consideration of emission reduction strategies in the feeding of broilers. The emissions of noxious gases, including ammonia (NH_3), are principal concerns of

the Korean poultry industry. The principal objective of this study was to determine whether different crude protein (CP) levels and several different supplementations could reduce the gas emission characteristics and effects on the growth performance of broilers. A total of 480 2-d-old Arbor Acre broilers were allotted to 4 treatment groups, each group included 6 replicates of 20 birds. The birds were fed on period 1: 1) T1 (CP 21%, ME 2969 kcal/kg); 2) T2 (CP 19%, ME 2863 kcal/kg + yucca 0.02%); 3) T3 (CP 17%, ME 2885 kcal/kg + yucca 0.02%); 4) T4 (CP 17%, ME 2881 kcal/kg + yucca 0.02% + α -1,6-galactosidase and β -1,4-mannanase multi-carbohydrase 0.1%) and period 2: 1) T1 (CP 19%, ME 3086 kcal/kg); 2) T2 (CP 17%, ME 2977 kcal/kg + yucca 0.02%); 3) T3 (CP 15%, ME 2978 kcal/kg + yucca 0.02%); 4) T4 (CP 15%, ME 2978 kcal/kg + yucca 0.02% + α -1,6-galactosidase and β -1,4-mannanase multi-carbohydrase 0.1%). Growth performance, carcass yield, nutrient digestibility, and fecal noxious gas emission characteristics were evaluated. Dry matter (DM) and nitrogen (N) digestibility were negatively affected ($P < 0.05$) by low dietary CP without carbohydrase. Digestibility of amino acids (AA) were significantly decreased by low CP diet ($P < 0.05$). However, carbohydrase supplementation can significantly improve AA digestibility in low CP treatment ($P < 0.05$). Breast yield was decreasing while abdominal fat yield was increasing with the decline of dietary CP levels ($P < 0.05$). Fecal NH_3 emission was significantly decreased in low CP treatments ($P < 0.05$). In conclusion, carbohydrase can be used to maintain AA digestibility when reduced CP diet is supplied and yucca supplementation and reduction in the CP level exert beneficial effects on the reduction of ammonia emissions.

Key Words: Broiler, Low Crude Protein, Carbohydrase

T152 Effect of dietary phytase on growth performance, carcass parameter, meat quality, nutrient digestibility and phosphorus utilization in broilers. H. D. Jang*¹, J. S. Yoo¹, H. J. Kim¹, S. O. Shin¹, Y. Huang¹, T. X. Zhou¹, Y. J. Chen¹, J. H. Cho¹, Y. K. Han¹, and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Sungkyunkwan University, Suwon, Korea.

The study was conducted to evaluate the effects of dietary phytase on growth performance, carcass parameter, meat quality, nutrient digestibility and phosphorus utilization in broilers. The experiment 1 was a total of 480 broilers (BW: 37.79g). Dietary treatments were included 1) CON (basal diet), 2) LP (Low phosphorus diet) and 3) CP (Low phosphorus diet + 0.05% coating phytase). The Broilers were allotted at 20 broilers per block with 8 replicate pens per treatment by completely randomized design. The experiment 2 was a total of 96 broilers (BW: 1,038g). Dietary treatments were included 1) CON (control), 2) LP (Low phosphorus diet), 3) NP (Low phosphorus diet + 0.05% normal phytase) and 4) CP (Low phosphorus diet + 0.05% coating phytase). The broilers were allotted at 3 broilers per block with 8 replicate pens per treatment by completely randomized design. Weight gain was significantly increased in CON compared to LP and CP treatments ($P < 0.05$). Calcium contents in blood was improved for CP treatment compared to LP treatment ($P < 0.05$). Carcass and CIE a^* of breast were significantly increased in CON compared to LP treatment ($P < 0.05$). WHC of breast was improved for CON and CP treatments compared to LP treatment ($P < 0.05$). Digestibility of dry matter and nitrogen were higher in CON compared to LP treatment ($P < 0.05$). Crude ash was greater in CON than CP treatment ($P < 0.05$). Calcium was improved for broiler fed CON and CP treatments compared with those fed LP treatment ($P < 0.05$). Digestibility of phosphorus was significantly reduce in LP treatments than CON and CP treatments ($P < 0.05$). Calcium retention was higher in

CON and CP treatments than LP treatment ($P < 0.05$). Phosphorus excretion was significantly reduced in NP treatment compared to CON and LP treatments ($P < 0.05$). Nitrogen and calcium excretion were significantly reduced in CON treatment compared to others ($P < 0.05$). In conclusion, CP treatment improved calcium contents in blood, WHC and pH of meat, digestibility of calcium and phosphorus, dry matter and calcium intake, nitrogen retention and calcium retention and decreased F/G and phosphorus excretion in broilers.

Key Words: Phytase, Meat Quality, Broilers

T153 Effects of δ -aminolevulinic acid and vitamin C supplementation on egg performance and quality and hematological characteristics in laying hens. Y. J. Chen^{*1}, I. H. Kim¹, K. Y. Whang², J. C. Park³, J. H. Cho¹, J. S. Yoo¹, Y. Wang¹, Y. Huang¹, H. J. Kim¹, and S. O. Shin¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Korea University, Seoul, Korea, ³National Institute of Animal Science, RDA, Cheonan, Chungnam, Korea.

This experiment was conducted to evaluate the effects of δ -aminolevulinic acid (ALA) and vitamin C supplementation on egg performance and quality and hematological characteristics in laying hens. A total of 252 Hy-line brown hens were randomly allotted to 6 dietary treatments: 1) CON (basal diet), 2) VC (basal diet with vitamin C 500 ppm), 3) ALA1 (basal diet with ALA 5 ppm), 4) ALA2 (basal diet with ALA 10 ppm), 5) AV1 (ALA1 diet with vitamin C 500 ppm) and 6) AV2 (ALA2 diet with vitamin C 500 ppm). There were 7 replications with 6 layers in adjacent three cages per each. During the 6-week experimental period, egg production was increased ($P < 0.05$) in AV2 (85.1%) treatment compared to other treatments (81.5, 79.7, 79.2, 79.7, 79.8) whereas egg weight was not influenced by dietary treatments. Egg shell color, thickness and breaking strength were not affected by ALA or vitamin C addition. Egg albumin height ($P < 0.05$) was higher in two AV (9.35, 9.42) treatments than other treatments (8.73, 8.44, 8.50, 8.76). Haught unit was greater ($P < 0.05$) in AV2 treatment (93.35) compared to CON (83.37), VC (86.10) and two ALA treatments (83.74, 83.18). Yolk color unit concentration was higher ($P < 0.05$) in ALA2 (8.85) and two AV treatments (8.90, 8.65) than other treatments (7.64, 8.08, 7.87). For the hematological characteristics, ALA and vitamin C had no effects on WBC, hematocrit, total protein, albumin and total iron binding capacity. Two AV treatments had greater ($P < 0.05$) RBC, hemoglobin and iron concentration compared to other treatments. The AV2 treatment (79.0%) also had greater ($P < 0.05$) lymphocyte concentration compared to CON, VA and AV1 treatments (70.8, 71.0, 66.5%). In conclusion, combine administration of ALA and vitamin C has positive influence on egg quality and can improve iron status of laying hens.

Key Words: δ -Aminolevulinic Acid, Egg Quality, Laying Hens

T154 Evaluation of supplemental α -aminolevulinic acid and vitamin C on growth performance, blood characteristics, immune organ weight and iron status in broilers. Y. J. Chen^{*1}, C. Y. Lee², I. H. Kim¹, J. H. Cho¹, J. S. Yoo¹, Y. Wang¹, Y. Huang¹, H. J. Kim¹, and S. O. Shin¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Jinju National University, Gyeongnam, Korea.

To evaluate the effect of δ -aminolevulinic acid (ALA) as immune modulator, 480 Arbor Acre male broilers were administrated 1 of 6 dietary

treatments. There were 4 replications per treatment and 20 broilers per cage. Dietary treatment included: 1) CON (basal diet); 2) VC (basal diet + vitamin C 500 mg/kg); ALA1 (basal diet + ALA 5 mg/kg); ALA2 (basal diet + ALA 10 mg/kg); AV1 (ALA1 + vitamin C 500 mg/kg) and AV2 (ALA2 + vitamin C 500 mg/kg). Treatment diets were provided for 5 weeks. The growth performance was not affected throughout the experimental period. Serum total protein (3.50 vs. 2.68 g/dL), albumin (1.62 vs. 1.32 g/dL) and hematocrit (26.7 vs. 24.2%) concentrations were higher ($P < 0.05$) in AV2 treatment than that in CON treatment. Serum hemoglobin concentration was increased ($P < 0.05$) 20%, 22%, 15% and 13% in AV2 treatment compared with CON, VC, ALA1 and ALA2 treatments, respectively. Iron concentration in serum was elevated ($P < 0.05$) in AV2 treatment (111.6 μ g/dL) compared with CON (73.0 μ g/dL) and VC (111.6 μ g/dL) treatments. However, the total iron binding capacity was not influenced by dietary treatment. The RBC concentration was higher ($P < 0.05$) in AV2 treatment than CON and VC treatments. AV2 treatment had greater ($P < 0.05$) liver weight than CON, VC and ALA1 treatments (2.74 vs. 2.33, 2.34, 2.35 g/100g BW). Liver iron concentration was higher ($P < 0.05$) in AV treatments (100.5, 93.5 μ g/dL) than other treatments while breast meat iron concentration was only increased in AV2 treatment (7.9 μ g/dL) compared to other treatments. The evaluated lightness of breast meat color was higher ($P < 0.05$) in AV1, AV2 and VC treatments (54.8, 54.7, 53.8) than other treatments. However, redness and yellowness were not affected by dietary treatment. In conclusion, dietary supplementation of δ -aminolevulinic acid combine with vitamin C can improve the immunity and iron status of broiler.

Key Words: δ -Aminolevulinic Acid, Iron Status, Broiler

T155 Effects of a microencapsulated blend of organic acids and natural identical flavors supplement to weaned pig diet. E. Grilli^{*1}, V. Pizzamiglio¹, M. R. Messina¹, L. Jørgensen³, H. Maribo³, R. Manini², and A. Piva¹, ¹DIMORFIPA, Ozzano Emilia, Bologna, Italy, ²Vetagro Srl, Reggio Emilia, Italy, ³Danish Pig Production, Copenhagen, Denmark.

Aim of the study was to investigate the effect of a microencapsulated supplement containing citric, sorbic acids, and natural identical flavors on piglets growth performance, mortality, and productivity during the 9 post-weaning weeks. The study was conducted at Danish Pig Production with the approval of the Danish Plant Directorate. Piglets were weaned at 5 weeks (7.6 kg BW), immediately divided in 2 groups (38 pens each, 7 pigs per pen), and were fed 2 experimental diets: the control non-medicated diet (CTR), or the control diet added with the microencapsulated blend at 3,000 ppm (Aviplus[®]; EP1391155B1, Vetagro Srl, Italy). Piglets received a 2-phases diet: the phase 1 was fed from d0 to d14 (20.7% CP, 6.3% EE), and the phase 2 from d14 to d63 (19.7% CP, 5.7% EE). The pigs were weighed per pen on d0, d14, and d63; the feed consumption was calculated at the same time intervals; mortality and treatments for diarrhea and other diseases were recorded. Performance data were analysed for normal distribution and prevalence of outliers, and were subjected to ANOVA with SAS; mortality was analysed with chi-square test. The Aviplus[®] group had higher ADG and G:F values than CTR in phase 1 (+22%, and +18%, respectively, $P < 0.05$), and higher G:F in phase 2 (+2%). The improvement registered in phase 1 was reflected in the overall period of the study (0–63 d: +5.7%, and +2.9% for ADG, and G:F, respectively, $P < 0.05$). Mortality was numerically higher for CTR than Aviplus[®] fed piglets (2.6% vs 1.2%, respectively, $P = 0.2$). The production value index calculated according to the Danish Pig Production procedure, was significantly higher for

the Aviplus® group than for the CTR one (+7%, $P < 0.05$). These results demonstrated that the supplementation of the diet with the lipid micro-encapsulated blend can improve productivity of weaners during the first weeks after weaning, thus improving the growth rate during the 7–30 kg body weight interval.

Key Words: Piglets, Microencapsulation, Organic Acids

T156 The effect phytase on growth performance, metatarsal and 10th rib bone characteristics, and tissue phosphorus levels in growing pigs. T. C. Tsai*, C. R. Dove, and M. J. Azain, *University of Georgia, Athens.*

The primary objective of this study was to determine the effect of phytase on phosphorus balance in various tissues. Barrows ($n=24$ barrows, 7-wk, average weight 18.50 kg) were randomly assigned to one of six diets. Diets 1 to 4 contained 0.13% available phosphorus (aP), and were supplemented with 0 (negative control), 500, 2500, and 12,500 U/kg phytase (Quantum, *E. coli* Phytase). Diets 5 (positive control) and 6 contained 0.35% aP, and 0 or 12,500 U/kg phytase. All diets met or exceeded NRC requirements except for phosphorus level in diets 1-4. Diets and water were ad libitum for 18 d. Phytase addition to the low aP diets improved ADG over that in the unsupplemented diet. Body weight and ADG were normalized in pigs fed high levels of phytase (2500, 12500 U/kg) relative to the positive control. Metatarsal bone ash and percent bone ash were increased by phytase addition. Similarly, phytase supplementation improved 10th rib bone weight, dry matter, and ash weight significantly. There were no phytase or dietary phosphorus effects on phosphorus concentration of heart, kidney, liver, muscle, and spleen. Phytase supplementation in the low aP diets improved growth performance, metatarsal and rib bone characteristics. Addition of a high level of phytase to a diet that is adequate in aP also resulted in improved performance and increased bone strength and ash. These results suggest that the phosphorus released by phytase is absorbed and contributes to improved bone growth and strength, which allows for greater rates of tissue accretion and increased body weight, but does not change tissue P concentrations.

Table 1. Effect of Phytase on Growth Performance and Bones Characteristics.

Diet	1	2	3	4	5	6	SEM	P Value
Gain, kg								
Day 0-18	8.32 ^a	9.6 ^{ab}	11.11 ^{bc}	11.09 ^{bc}	12.08 ^c	12.9 ^c	0.68	0.0037

T157 Copra meal supplementation with mannanase on growth performance, pork quality and nutrient digestibility in growing-finishing pigs. D. H. Kim*, J. H. Yoon, W. S. Ju, Y. K. Hong, and Y. Y. Kim, *Seoul National University, Seoul, South Korea.*

This experiment was conducted to evaluate the effects of copra meal supplementation with mannanase on growth performance, pork quality and nutrient digestibility in growing-finishing pigs. Treatments were: 1) A: Negative control (basal diet), 2) B: Positive control (0% copra meal + 0.1% mannanase 800 IU), 3) C: (6% copra meal + 0.1% mannanase 800 IU), 4) D: (12% copra meal + 0.1% mannanase 800 IU), 5) E: (18% copra meal + 0.1% mannanase 800 IU). A total of 80 crossbred pigs ([Landrace x Yorkshire] x Duroc) with an average body weight of 27.2 kg (SE:0.720) were allotted to 5 treatments and 4 replicates with 4 pigs per pen in a randomized complete block design. Although copra meal contains high level of mannan which can not be digested by endogenous enzyme of the pig, it is very cheap and good source of energy like corn or sorghum. Mannan digestive enzyme, mannanase, was invented and manufactured commercially by CTCbio Ltd in Korea. During the experimental period, average daily gain (ADG) in treatment E (848 g) tended to be lower ($P > 0.09$) than treatment A (883 g), B (909 g), C (930 g) and treatment D (911 g). And feed:gain ratio (F:G ratio) of treatment E (2.93) was also higher ($P < 0.05$) than other treatments (A:2.75, B:2.59, C:2.69, D:2.79). During growing phase, the nutrient digestibility of crude protein in treatment E (79.7%) was lower ($P < 0.05$) than treatment A (89.8%), B (93.8%), C (88.9%) and treatment D (90.1%) which support the results of growth performance. Thiobarbituric acid reactive substance (TBARS) values of C (0.154), D (0.201) and E treatments (0.172) were higher ($P < 0.05$) than control treatment (A:0.141, B:0.128) which represented less saturated fatty-acid was accumulated when pigs were fed copra meal. These results suggest that 12% of copra meal can be supplemented in swine diet at the expense of corn and soy-bean meal resulted in reducing feed production cost.

Key Words: Copra Meal, Mannanase, Growing Pig

T158 Effects of virginiamycin on microbial ecology in ileal digesta and feces of growing pigs. M. Song*¹, L. L. Stewart¹, J. Barnes¹, B. R. Gramm², R. D. Nimmo², H. H. Stein¹, and J. E. Pettigrew¹, ¹University of Illinois, Urbana, ²Phibro Animal Health Co., Ridgefield Park, NJ.

A study was conducted to evaluate effects of virginiamycin on microbial ecology in ileal digesta and feces of growing pigs. Pigs ($n=15$, 35.0±2.7 kg BW) were surgically equipped with a T-cannula in the distal ileum. Pigs were assigned randomly to one of 3 dietary treatments: 1) a corn-soybean meal diet (CON), 2) CON + 11 mg/kg virginiamycin (V11), and 3) CON + 22 mg/kg virginiamycin (V22). During a 6-wk experiment, all pigs were fed the CON diet during wk 1, 5, and 6 and their respective treatment diets during wk 2, 3, and 4. Pigs were allowed *ad libitum* access to feed and water. Ileal digesta and fecal samples were collected on d 6 and 7 of each period to measure the number of bacterial cells by Gram's method and to use denaturing gradient gel electrophoresis (DGGE) to estimate the species diversity of the bacterial population (the number of bands) and quantitative measures of the similarity of population structures (banding pattern expressed by Sorenson's pairwise similarity coefficients (C_s)) among pigs within and between treatments. Virginiamycin treatments reduced ($P < 0.05$) the number of bacterial cells in ileal digesta for V22 (10.45 vs. 10.56 (CON), log (/g digesta), overall) and in feces for V11 and V22 (11.36 and 11.19 vs. 12.00 (CON), log (/g digesta), wk 4; 11.73 and 11.72 vs. 11.90 (CON), log (/g digesta),

overall) when virginiamycin treatments were imposed. Pigs fed V22 had fewer (22.13 vs. 26.83; $P < 0.05$) bands in ileal digesta than pigs fed CON over the entire experiment. There was no virginiamycin effect for the number of band in feces. In a few cases, specific bands were present in most pigs fed CON, but absent from most pigs fed virginiamycin treatments. There were no virginiamycin effects on intratreatment or intertreatment C_s values. In conclusion, virginiamycin reduces the number of total bacteria in ileal digesta and feces and eliminates some species of bacteria.

Key Words: Virginiamycin, Microbial Ecology, Growing Pigs

T159 Quantitative in vitro assay to evaluate yeast products concerning their binding activity of enteropathogenic bacteria. A. Ganner*, L. Fink, and G. Schatzmayr, *BioMin Research Center, Tulln, Lower Austria, Austria.*

Certain yeast products play an important role in protecting animals by displaying alternative adhesion sites to enteropathogenic bacteria. In the gastrointestinal tract those pathogens preferentially bind to the yeast cell wall and therefore animals are protected against infectious diseases. According to literature Mannan oligosaccharides (MOS) are the substances in the yeast cell wall which are responsible for binding of pathogens. Thus they have been discussed as antibiotic replacements in the past years.

In some publications it is questioned if the amount of MOS in the yeast cell wall is the substance responsible for immobilizing the enteric pathogens. Some test procedures are available to investigate the binding capacity of yeast products, however, there is no test assay described that aims on a quantitative measurement of the bacterial adhesion. Therefore we developed an in vitro microplate-based assay to determine the quantitative adhesion between enteric bacteria such as *E. coli* F4 and various yeast products by measuring the growth of the adhering bacteria by its optical density. The exponential phase of the adhering bacteria was determined and compared with the CFU/ml on the agar plate. A linear regression is compiled and the bacterial number bound to the yeast product is determined.

Different commercially available yeast cell wall, nucleotide and beta-glucan products have been tested for their ability to bind *E. coli* F4 quantitatively. The different cell wall products bound variably amount of *E. coli* F4, however binding capacity was not dependent on the amount of MOS. One cell wall product with 25% MOS bound 102 CFU/ml while another cell wall product with only 8% MOS bound 105 CFU/ml. In contrast, beta-glucan did not bind any bacteria. The nucleotide product bound 103 CFU/ml, suggesting that there is still a certain amount of cell wall fractions in that product. We believe that the cell wall structure plays an important role in pathogen immobilization, rather than just the total amount of MOS.

Key Words: *E. coli* Adhesion, Yeast, Bacterial Growth

T160 Exopolysaccharide produced by *Enterobacter cloacae* Z0206 improves the humoral and cellular responses of immunologically intact and immunocompromised mice. C. Xu, Y. Wang*, M. Jin, X. Yang, and Z. Xu, *Zhejiang University, Hangzhou, Zhejiang, P. R. China.*

The objective of the present study was to investigate the immunomodulatory activity of an exopolysaccharide produced by *Enterobacter cloacae* Z0206 (ECZ-EPS-1) on cellular and humoral immunity. The immunosuppressed mice were induced by cyclophosphamide (CP). 192 ICR male mice (18±2g) were randomly divided into 6 groups, each of which was designed 4 replicates with 8 mice in one cage per replicate. Three immunosuppressed groups were treated per os with ECZ-EPS-1 (0 mg/kg, 200 mg/kg and 400 mg/kg body weight (B.W.)) for 14 days, and CP was given intraperitoneally in a single dose of 50 mg/kg B.W. on the 12th day. Two immunologically intact groups were treated per os with ECZ-EPS-1 (200 mg/kg and 400 mg/kg B.W.) for 14 days. The dose volume was 0.4 mL. Control animals received same volume of normal saline. Indexes of immune organs, plaque forming cell (PFC) assay, quantitative hemolysis of sheep red blood cell (SRBC) (QHS), splenic lymphocytes proliferation, levels of subset of T lymphocyte, NK cell, IL-2 and TNF- α were studied in these animals. CP showed suppressive effects on immune organs weight and cellularity and other parameters of humoral immunity ($p < 0.01$) compared to control. ECZ-EPS-1 treatment (400 mg/kg B.W.) significantly ($p < 0.01$) increased PFC response in CP-treated animals compared to CP-treated animals alone. In QHS assay, ECZ-EPS-1 showed protection in CP-treated animals. ECZ-EPS-1 (400 mg/kg B.W.) can relieve immunodepression and significantly ($p < 0.01$) increase the spleen and thymus index, decrease CD8+ cells and stimulate the proliferation of T and B lymphocytes compared to CP-treated animals alone. ECZ-EPS-1 treatment itself produced no toxicity. The administration of ECZ-EPS-1 to CP-exposed animals resulted in improved humoral and cellular responses. ECZ-EPS-1 may be developed into a new kind of immunomodulation agent.

Key Words: Exopolysaccharide, Cyclophosphamide, Immunosuppressed Mice

T161 Feeding an encapsulated nutritional blend in combination with ractopamine improves feed conversion and loin depth in finishing pigs. J. W. Frank*¹, C. V. Maxwell¹, Z. B. Johnson¹, S. A. Hansen², and R. E. Musser³, ¹University of Arkansas, Fayetteville, ²Ridley Inc., Mankato, MN, ³SODA Feed Ingredients LLC, Mankato, MN.

Finishing pigs (GPK35 × EBX; n = 180, BW = 100 ± 0.7 kg) were allotted to 4 dietary treatments arranged as a 2 × 2 factorial (9 replicates/treatment) to evaluate the effects of feeding an Encapsulated Blend (EB) using Micropearls™ encapsulation technology fed at 2.27 kg/ton in combination with ractopamine (RAC; 4.5 g/ton) on growth performance and carcass measurements. The EB contained: fumaric, malic, citric, phosphoric, and lactic acids, L-carnitine, chromium picolinate, inulin, d-pantothenic acid, and niacin. All pigs were fed typical corn-soy diets with 0.05% L-lysine-HCl and 3% added fat. The control (CON) and EB blend diets were formulated to 0.7% total lysine and RAC and RAC+EB diets were formulated to 0.86% total lysine. There was no effect of feeding the EB or RAC on ADG or ADFI. RAC improved G:F compared to pigs fed diets without RAC ($P = 0.04$) and the EB improved G:F compared to pigs fed diets without EB ($P = 0.04$), however the interaction was not significant. Over the 24 d period, G:F for CON, EB, RAC, and RAC+EB treatments were 0.265, 0.296, 0.295, and 0.322, respectively. The final BW of CON, EB, RAC, and RAC+EB pigs were 123.1, 124.1, 124.1, and 125.9 kg. Feeding RAC increased the percentage carcass lean and ham lean, as well as, loin depth compared to pigs fed diets without RAC ($P < 0.02$). Feeding EB increased loin

depth (61.3 vs. 58.9 mm, $P = 0.04$) compared to pigs fed diets with no EB. Feeding EB also improved carcass lean (53.4 vs 53.0%) and ham weight (11.4 vs 11.1 kg) but these differences were not significant. The percentage carcass lean of CON, EB, RAC, and RAC+EB pigs were 52.5, 53.1, 53.4, and 53.7%. RAC and EB did not significantly increase ADG, ADFI, or final BW. However, RAC and EB significantly improved G:F and loin depth in an additive manner. This study demonstrates that RAC and EB can improve production parameters which are economically beneficial for swine production.

Key Words: Pigs, Encapsulated, Conversion

T162 Comparison of two encapsulated nutritional blends in combination with ractopamine on growth performance and carcass characteristics in finishing pigs. J. W. Frank^{*1}, C. V. Maxwell¹, Z. B. Johnson¹, S. A. Hansen², S. L. Johnston², M. De La Llata², and R. E. Musser³, ¹University of Arkansas, Fayetteville, ²Ridley Inc., Mankato, MN, ³SODA Feed Ingredients LLC, Mankato, MN.

Finishing pigs (GPK35 × EBU; n = 208, BW = 72.7 ± 0.6 kg) were allotted to 4 dietary treatments (9 replicates/treatment) to evaluate the effects of feeding two Encapsulated Blends (EB) using Micropearls™ technology in combination with ractopamine (RCT) on growth and carcass measurements. The first EB (EB1: 2.27 kg/ton) contained a blend of encapsulated fumaric, malic, citric, phosphoric, and lactic acids, added to L-carnitine, chromium picolinate, inulin, d-pantothenic acid, and niacin; while the second EB (EB2: 0.91 kg/ton) contained a blend where organic acids, L-carnitine, inulin, d-pantothenic acid, and niacin were encapsulated together. Phase 1 (d 0 – 18) diets were CON (0.8% Lys), RAC (0.8% Lys + 0 g/ton RCT), EB1 (0.8% Lys + EB1), and EB2 (0.8% Lys + EB2). Phase 2 (d 18 – 47) diets were CON (0.8% Lys), RAC (1.05% Lys + 4.5 g/ton RCT), EB1 (0.85% Lys + EB1 + 4.5 g/ton RCT), and EB2 (0.85% Lys + EB2 + 4.5 g/ton RCT). There was no effect of dietary treatment on ADG or ADFI during the study. Although G:F was lower in CON compared to RAC, EB1, or EB2 (0.282, 0.293, 0.296, or 0.297; respectively) these differences were not significant ($P = 0.15$). The final BW of the CON, RAC, EB1, and EB2 pigs were 124.0, 124.3, 125.6, and 126.2 kg, respectively ($P = 0.30$). Hot carcass weights were lower in CON compared to RAC, EB1, and EB2 fed pigs (92.8, 93.9, 94.1, and 95.2 kg; respectively), but these differences were not significant ($P = 0.34$). Carcass lean was lower ($P = 0.02$) in CON (52.4%) vs. RAC (53.5%) and EB1 (53.4%) pigs, with EB2 pigs being intermediate (53.0%). This research demonstrates that encapsulated blends fed to pigs with lower dietary lysine levels will provide equal or more efficient performance compared to ractopamine alone. In conclusion, feeding ractopamine and EB in combination provides improvement in traits economically beneficial to swine producers.

T163 Effects of mannan oligosaccharide on growth performance and serum cytokines of weaned pigs. M. T. Che^{*}, R. W. Johnson, K. W. Kelley, and J. E. Pettigrew, University of Illinois, Urbana.

The experiment was conducted to determine responses of growth performance and serum cytokines to the dietary supplementation with mannan oligosaccharide (MOS) for weaned pigs. Weaned pigs (n=160, 6.5 kg,

20 days old) were randomly assigned to one of five dietary treatment groups on basis of body weight, gender, and origin of litter. There were 8 pens (replicates)/treatment and 4 pigs/pen. The 5 treatments were 1) 0% MOS (control); 2) 0.2% MOS fed for 2 weeks; 3) 0.2% MOS fed for 4 weeks; 4) 0.4% MOS fed for 2 weeks; and 5) 0.4% MOS fed for 4 weeks. Pigs were fed a 3-phase diet (1, 1, & 2 weeks per phase) with declining diet complexity. For the first 2 weeks, data from treatments 2 & 3 were pooled as 0.2% MOS, and 4 & 5 as 0.4% MOS because they had the same dietary level of MOS. Blood samples from each treatment (n=8, one/replicate) were collected weekly for determination of pro-inflammatory (TNF- α) and anti-inflammatory (IL-10) cytokines by ELISA. Over a 4-week study, there were no significant differences in average daily gain (ADG), average daily feed intake (ADFI), and gain:feed (G/F) among the treatment diets. Similarly, no treatment effects ($P > 0.05$) on the serum levels of TNF- α and IL-10 were seen. Interestingly, serum levels of TNF- α were high at Day 7 and declined at Day 14 whereas serum levels of IL-10 were low at Day 7 and increased at Day 14 (Table 1). In conclusions, addition of MOS to nursery diets showed no improvement in growth performance and seemed not to affect serum levels of cytokines in weaned pigs.

Table 1. Growth performance and serum cytokines of nursery pigs fed different dietary levels of MOS (means ± SEM)

Items	Dietary levels of MOS (%)			P
	0 ^a	0.2 ^b	0.4 ^b	
Days 0-14				
ADG, g	274±18	247±12	260±10	0.38
ADFI, g	327±24	284±11	292±9	0.10
G/F, g/kg	852±15	870±19	887±15	0.44
TNF- α , pg/mL				
Day 7	150.1±53.2	207.7±44.6	158.9±37.4	0.61
Day 14	33.4±2.4	34.3±4.1	32.0±3.4	0.90
IL-10, pg/mL				
Day 7	28.9±1.7	29.1±1.1	30.5±1.1	0.59

T164 Fecal-oral transmission from sow to piglet of a *Bacillus* based direct-fed microbial (Adsero™) and its effect on clostridial shedding. A. Baker^{*1}, E. Davis¹, J. D. Spencer², R. Moser², and T. Rehberger¹, ¹Agtech Products, Inc., Waukesha, WI, ²JBS United, Inc., Sheridan, IN.

Two studies were conducted to determine the effect of a *Bacillus* based direct-fed microbial (Adsero™) on clostridial shedding in the sow and pig and transfer of Adsero™ spores from the sow to pig by fecal-oral transmission. In Exp. 1, 36 sows were divided into 4 treatments: control and Adsero™ (3.75 × 10⁵ cfu/g feed) fed for 2, 4, and 6 weeks prior to and throughout lactation. Fecal samples were collected to determine clostridial counts from 5 sows/treatment before Adsero™ supplementation, on d -1 prior to farrowing (d 0), and on d 3 and d 14 after farrowing. Pig fecal clostridial counts were also determined on d 14. Samples were also plated for the presence of Adsero™ on d -1 from 5 sows/treatment, on d 3 and d 5 from 3 piglet litters/treatment and on d 14 from sows and their respective litters. Clostridial counts in fecal samples did not differ

between control and treated sows ($P > 0.97$) or pigs ($P > 0.52$). Adsero™ was detected in the fecal samples of treated sows on d -1 and d 14 and in litters from treated sows on d 5 and d 14, documenting the fecal-oral transfer of Adsero™ from sow to pig. In Exp. 2, Adsero™ and control diets were fed 6 weeks prior to farrowing and throughout lactation to 30 sows. Gastrointestinal (GI) tracts from 15 pigs were collected on d 3 and d 10 of lactation for a total of 30 pigs/treatment. *Clostridium* was evaluated in the ileum and distal colon. *Clostridium* was reduced ($P = 0.07$) in the GI tract of pigs from treated litters on d 3. Pig GI tracts were plated for the presence of Adsero™ on d 3 but were not detected suggesting the reduction of *Clostridium* in the pig GI tracts resulted from clostridia reduction in the sow and environment. These data demonstrate the fecal-oral transmission of Adsero™ from sow to pig and indicate that pigs from sows fed Adsero™ harbor less *Clostridium* than those from unsupplemented sows. Although reduced clostridial shedding could not be demonstrated from fecal sampling, decreased *Clostridium* in the GI tract due to Adsero™ indicates GI tract measurements provide a more accurate assessment of clostridial populations.

Key Words: *Bacillus*, Swine, *Clostridium*

T165 Effect of carbohydrase enzyme supplementation on the performance and nutrient digestibility in growing pigs fed barley-wheat distillers dried grains with solubles based diet. I. A. Emiola*, B. A. Slominski, and C. M. Nyachoti, *University of Manitoba, Winnipeg, MB, Canada.*

An experiment was conducted to determine the growth performance and nutrient utilization in growing pigs fed barley-wheat distillers dried grains with soluble (DDGS) based diet supplemented with carbohydrase enzymes. Forty-eight growing pigs, housed 2 per pen, were randomly to 4 experimental diets (6 pens/treatment) on the basis of sex and BW. Treatments consisted of four diets; a positive control (PC) formulated to meet NRC (1998) nutrient requirement of growing pigs; a negative control (NC) formulated with energy and lysine reduced by 4 and 5% respectively, from the PC; NC supplemented with enzyme preparation A; and NC supplemented with enzyme preparation B. Enzyme A contained 2,600 units of xylanase, 1,200 units of glucanase, and 1,300 units of cellulose per kg of feed; Enzyme B contained 5,200 units of xylanase, 2,400 units of glucanase, and 2,600 units of cellulase per kg of diet. Chromic oxide was used as an indigestible marker and diets were fed as mash. The ADG was higher ($P < 0.05$) in the PC diet compared with the NC diet. Supplementing NC diet with enzyme preparations improved ADG ($P < 0.01$). Pigs fed enzyme supplemented diets had similar ADG compared with those fed with the PC diet. The ADFI was not influenced by the dietary treatments. Feed:gain ratio was higher ($P < 0.05$) in pigs fed the PC diet compared with those fed the NC diet, but not different from pigs fed the NC diets supplemented with enzyme. Addition of enzyme to the NC diet tended ($P < 0.10$) to improve F:G ratio. Compared with the NC diet, addition of enzyme preparations to NC diet improved ($P < 0.05$) ATTD of nitrogen, ADF, and crude fats and tended ($P < 0.10$) to improve NSP digestibility. The result indicates growing pigs can effectively utilize wheat DDGS at 30% inclusion level provided appropriate enzyme combination is included in the diet.

T166 Pooled-analysis of data demonstrating the performance benefits of including mannan oligosaccharides in swine nursery diets. B. Corrigan*, D. Koehler, and G. Grinstead, *Vita Plus Corporation, Madison, WI.*

Data sets from seven separate trials having similar protocols were pooled for the purpose of strengthening the evidence concerning the effects of the addition of Mannan Oligosaccharides (MOS) to swine nursery diets. MOS are derived from yeast cell walls and are believed to bind and suppress enteric pathogens in the gut and have been shown to increase piglet ADG. Seven separate trials were conducted to evaluate the effect of the addition of MOS (Bio-MOS; Alltech, Nicholasville, KY) to nursery diets on piglet performance for the first 42 days post-weaning. The data represents performance from a total of 1,092 weaned pigs, 156 pigs/trial, with a pooled starting weight of 5.90 kg (17 to 22 days old). For each trial, pigs were randomly blocked by body weight to one of two treatments in a 30-pen nursery facility (13 pigs per pen) resulting in a pooled total of 36 reps. A typical four-phase nursery diet containing antibiotics was used as the **Control**, while the **MOS** treatment included 0.20, 0.10, and 0.05% MOS in diet phases I, II and III, respectively. Diet phases I,II,III and IV were fed from approximately d 0 to 7, 7 to 14, 14 to 28 and 28 to 42, respectively. Pig BW and feed disappearance were measured on approximately d 0, 7, 14, 21, 28 and 42 days post-weaning. ADG, ADFI, and G/F were calculated for all trials. The data were then pooled and analyzed to include the main effects of trial, rep and trt using the Proc Mix procedure of SPSS. Pigs consuming MOS were heavier on d 28 ($P < 0.01$; 15.34 vs. 15.01kg) and d 42 ($P = 0.07$; 24.93 vs. 24.57kg) than pigs fed the Control. ADFI was significantly ($P < 0.05$) increased by MOS from d 0 to 28 (0.432 vs. 0.419kg) and for the period from d 0 to 42 (0.623 vs. 0.609kg). Pigs fed MOS had greater ADG ($P < 0.05$) from d 0 to 28 (0.337 vs. 0.326kg) and d 0 to 42 (0.434 vs. 0.426kg). However, ADG was similar ($P > 0.05$) between trts from d 28 to 42 (0.604 vs. 0.605kg, respectively). F/G was similar ($P > 0.05$) between Control and MOS throughout the trial period. The pooled data demonstrate that the addition of MOS to nursery diets increases ADFI and ADG of piglets.

Key Words: Pigs, MOS

T167 Development and validation of a mastication simulator. A. Woda*¹, A. Mishellany¹, J. P. Meunier², O. François¹, M. Alric², and M. A. Peyron¹, ¹Faculty of Odontology, Clermont Fd, France, ²Faculty of Pharmacy, Clermont Fd, France.

The feed bolus obtained after mastication and the corresponding feed disruption process could be an important parameter to be studied for a better understanding of feed intake. However, the feed bolus collected before swallowing does not represent the whole feed bolus being swallowed. Therefore, a simulator of mastication was developed which allows collecting the whole amount of feedstuff.

The first aim of this study was to complete a simulator of mastication reproducing human masticatory behavior and producing a food bolus with similar texture than an in vivo food bolus. The second aim was to validate the simulator by comparing the food boluses obtained in vitro and in vivo.

Food boluses were obtained from both the simulator and 30 young (23.7 ± 2.2 years old) healthy and full dentate subjects chewing pea-

nuts and carrots. The food boluses were characterized by the particle size distribution. The boluses were cleaned in a 0.1 mm aperture sieve, dried and scanned. The photos were analysed with a specific software (PowderShape®, IST-Ag, Vickers, Switzerland). The average particle size (D50) was chosen as the dependent variable. Simulator calibration was realized by adjusting the different parameters (number of masticatory cycles, rotation and translation amplitudes of the mandibular piston head, masticatory force, temperature of the chamber, addition of artificial saliva).

Number of cycles and applied force were the predominant parameters in determining the in vitro particle size (D50). Setting the number of cycles at the mean value observed in vivo and choosing the force of the simulator allowed to obtain agreement between in vitro and in vivo values for each food. Addition of artificial saliva and control of the temperature only marginally influenced the D50 values.

The food boluses obtained in vitro with the simulator displayed the same D50 values that the food boluses produced in vivo. This apparatus could be an interesting tool to simulate the mastication of numerous animal species.

Key Words: Mastication, Simulator, In Vitro

T168 Effect of supplying mannan oligosaccharide (MOS) to pig diets on response to an immune challenge. I. F. Hung*¹, M. D. Lindemann¹, G. L. Cromwell¹, B. G. Kim¹, and M. G. Holt², ¹University of Kentucky, Lexington, ²VI-COR, Mason City, IA.

A modified yeast culture feed additive (Celmanax®; Vi-COR, Mason City IA) containing MOS, was used to evaluate the effects of supple-

mental MOS on responses in pigs challenged with lipopolysaccharide (LPS). Weaned pigs (BW: 6.0 ± 0.96 kg) were assigned to 3 treatments with 3 pigs/pen. The treatments included: 1) control basal diet [n = 24], 2) basal + low level MOS diet [0.02%, 0.01% for Wk 1-2 and 3-4, respectively; n = 12], and 3) basal + high level MOS diet [0.04%, 0.02%; n = 12]. After 4 wk, 32 pigs (2 pigs/pen; BW: 16.8 ± 0.62 kg) continued on test to examine the response to LPS injection. At 0 h (0600 on d 29), each pig received an i.p. injection of phosphate buffered saline (PBS; for half of Trt 1 pigs) or LPS (for all other pigs). At 2 h post-injection, the control pigs challenged with LPS lost weight compared with PBS-injected pigs (-145 vs. 341 g; P < 0.01) and had lower cumulative feed intake (CFI; 43 vs. 181 g; P = 0.01). Cumulative weight gain (CWG) or CFI differences were not detectable (P > 0.20) at 48 h post-injection. MOS supplementation had no effect on CWG or CFI. Respiratory rate of LPS-injected control pigs was higher than PBS-injected pigs at 3 h post-injection (83 vs. 38 breaths/min; P < 0.01) and was linearly decreased as MOS inclusion was increased in LPS-injected pigs (83, 68, and 64 breaths/min, respectively; P < 0.01). Rectal temperature was higher in the LPS-injected control pigs than in the PBS-injected pigs at 2 h (40.2 vs. 39.4°C; P < 0.01) and at 4 h (40.2 vs. 39.5°C; P < 0.01); MOS fed pigs had a lower rectal temperature than the LPS-controls at 2 h post-injection (40.2 vs. 39.9°C; P = 0.03). Serum cortisol values were higher in the LPS-injected control pigs than in the PBS-injected pigs at 2 h (16.3 vs. 10.0 mcg/dL; P = 0.03) and at 4 h (22.8 vs. 8.9 mcg/dL; P < 0.01) but were not moderated by MOS supplementation. The results showed that LPS challenge affects CWG, CFI, rectal temperature, respiratory rate, and cortisol levels and that dietary MOS supplementation reduced LPS-induced effects on respiratory rate and rectal temperature, but not on CWG, CFI or cortisol levels.

Physiology and Endocrinology: Immune Function and Health

T169 Alpha-linolenic acid exerts anti-inflammatory effect in 3T3-L1 adipocytes through mechanisms that involve activation of AMPK. K. M Ajuwon*¹, T. A Winters², B. Whisenhunt², and W. Banz², ¹Purdue University, West Lafayette, IN, ²Southern Illinois University, Carbondale.

Alpha-linolenic acid (ALA) (18:3n-3) is an omega-3 fatty acid that is found in abundance in many seeds and oils such as those from soybean, flaxseed and walnuts. It is the only plant derived omega-3 fatty acid that is consumed in large quantities in the U.S and in many parts of the world. Whereas the longer chain omega-3 fatty acids, docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), have been shown to have cardiovascular and other health benefits, significant controversy still exists regarding the overall health benefits that can be obtained from ALA. Because adipose tissue inflammation is implicated in systemic inflammation that may eventually cause cardiovascular disease and insulin-resistance, we examined the possibility that ALA could exert anti-inflammatory effect in the 3T3-L1 adipocyte model. Fully differentiated adipocytes were pretreated with 150 and 250µM ALA for 6 h and then treated with lipopolysaccharide (LPS) (100 ng/mL) for 3 h. We then measured interleukin 6 (IL-6) mRNA expression with RT-PCR and protein secretion with ELISA. Treatment of adipocytes with LPS led to an induction of IL-6 mRNA and protein secretion ($P < 0.05$). This was attenuated by pretreatment of adipocytes with ALA ($P < 0.05$). To explore possible involvement of AMPK in the anti-inflammatory effect of ALA, we examined the abundance of phosphorylated and total AMPK using western blotting. We observed an induction of AMPK phosphorylation in ALA treated cells ($P < 0.05$). These results indicate that ALA exerts anti-inflammatory effect in adipocytes and also raise the possibility that AMPK is a mediator of this effect. Taken together, ALA could have health and growth benefits in both humans and animals due to its ability to attenuate inflammation.

Key Words: Adipocytes, Inflammation, AMPK

T170 Polarized interleukin-8 (IL8) secretion by swine jejunal epithelial cells (IPEC-J2) treated with soluble beta-glucan (BG). T. E. Burkey* and S. S. Shepherd, *University of Nebraska, Lincoln.*

Yeast BG may be a potential immunomodulator that could serve as a natural alternative to antimicrobial growth promoters. Beta-glucans are (1,3)-β-D-glucose polymers isolated from the yeast *Saccharomyces cerevisiae*. It has been established that BG induce enhanced phagocytic activity, increased production of reactive oxygen species and increased production of cytokines and chemokines. Beta-glucans may potentially activate receptors within the gastrointestinal tract, elicit a priming effect and initiate signaling cascades that may modulate innate as well as adaptive immune responses directed at potential pathogens. Intestinal epithelial cells are sources of chemokines, such as IL8, which lead to the recruitment of macrophages, lymphocytes, and polymorphonuclear leukocytes and may further initiate both the innate and adaptive immune responses. The objective of the current study was to evaluate the effect of soluble BG on IL8 protein secretion in IPEC-J2 cells. IPEC-J2 cells were grown to confluency on Costar Transwells, and treated apically with media alone (CTL), LPS (10 ng/ml), Zymosan A (100 µg/ml) or soluble BG (100, 10 or 1.0 µg/ml). IPECJ2 cells were exposed to the respective treatments for 6 h, and then the apical and basolateral media

were collected for subsequent quantification of IL8 by ELISA. No significant treatment by position (apical or basolateral) interaction was observed. However, this experiment resulted in a significant main effect of position where IL8 secretion was polarized in the apical direction when averaged across all treatments ($P < 0.0001$). In addition, when averaged across both positions, BG (100 µg/ml) tended to increase IL8 secretion compared to all other treatments ($P = 0.07$). The data suggest that soluble beta-glucan elicits IL8 secretion in IPEC-J2 cells and that this secretion is polarized in the apical direction.

Key Words: Swine Jejunal Epithelial Cells, Beta-Glucan, Interleukin 8

T171 The variation of IgG1, IgA and IgM concentration in blood and milk of dairy cows after implanting antigen-releasing device (ARD). C. G. Zhang^{1,2}, J. Q. Wang*¹, D. P. Bu¹, G. L. Liu¹, J. B. Cheng¹, X. L. Dong^{1,2}, K. L. Liu¹, H. Y. Wei¹, L. Y. Zhou¹, and G. Q. Zhao², ¹Chinese Academy of Agricultural Sciences, Beijing China, ²Yangzhou University, Yangzhou, China.

The objective of the study presented here was to determine if the variation in total immunoglobulin follows a similar pattern to the variation in specific anti-lipase antibody in blood and milk after implanting the ARD. Twenty healthy adult dairy cows in mid-lactation were divided into two groups (n = 20) according to milk yield (26.0 ± 3.5 kg), and days in milk (114 ± 34 d). Each cow of the test group was implanted with the three types of ARD (ARD1, ARD2 and ARD3) in the right iliac lymph node using an implantation gun. The trial period was carried out over 40 d. Milk samples were collected at d 0, 5, 7, 9, 15, 17, 20, 26, 30, 40 and blood samples were collected every 10 d. Total IgG1, IgA and IgM were measured by sandwich enzyme-linked immunosorbent assay (ELISA) using the Bovine IgG1/IgA/IgM ELISA Quantitation Kit. The results showed that total immunoglobulin concentration (mg/mL) in blood of test group animals (5.831 ± 0.284) was higher than control group animals (5.348 ± 0.245). IgG1 concentration (mg/mL) in milk reached a peak at d 9 (0.57 ± 0.11), 17 (0.52 ± 0.09) and 32 (0.51 ± 0.10), respectively, corresponding with the release of ARDs at d 0, 14 and 28. The IgA and IgM concentration failed to show the same regular patterns when compared with IgG1. In conclusion, the ARD implantation successfully increased total immunoglobulin, especially IgG1 concentration in blood and milk of dairy cows. (Research funded by Ministry of Science and Technology; 2006DFB32160).

Key Words: Immunoglobulin, Antigen-Releasing Device, Blood and Milk

T172 Canonical correlation of milk immunoglobulins, lactoferrin concentration and Dairy Herd Improvement data of Chinese Holstein cows. G. L. Liu¹, J. Q. Wang*¹, D. P. Bu¹, J. B. Cheng¹, C. G. Zhang^{1,2}, X. L. Dong^{1,2}, H. Y. Wei¹, L. Y. Zhou¹, and K. L. Liu¹, ¹Chinese Academy of Agricultural Sciences, Beijing, China, ²Yangzhou University, Yangzhou, China.

Immunoglobulins (Igs) together with lactoferrin (Lf) constitute an important antimicrobial system in milk and play key roles in the defense

mechanisms of mammary gland of lactating cows. The purpose of this work was to establish the relationship among the data in Dairy Herd Improvement (DHI) report and milk Igs and Lf concentration. We collected 299 individual milk samples randomly from more than 2,800 animals across six dairy farms in the greater Beijing area, and obtained the corresponding DHI data from the China DHI system. Concentrations of Igs and Lf in milk were determined by ELISA assay. The relationship among DHI data and milk Igs and Lf concentration was established using canonical correlation analysis. The results indicated that 4 canonical variables relating milk IgG1, IgA, IgM and Lf concentration as y variables with lactation number, stage of lactation, daily milk production, milk fat, protein, lactose, milk total solids and somatic cell score (SCS) as x variables were created. The canonical correlations of first and second pair of canonical variables were 0.662 and 0.469 respectively with highly significance ($P < 0.01$), and accounted for 91.6% of the data variability. Stage of lactation, daily milk production, milk protein and SCS were the significant factors affecting Lf concentration, and lactation number was the significant factors affecting IgG1. The first standardized canonical variation combination could be regarded as a predictable measure of Lf and IgM concentration, the second as a predictor of IgG1. These results may be useful for dairy producers to select cows with increased production of Igs and Lf using DHI data directly. (Research funded by Ministry of Science and Technology; 2006DFB32160)

Key Words: Dairy Herd Improvement Data, Immunoglobulin, Lactoferrin

T173 Mifepristone (RU486) modulation of dexamethasone-induced suppression of in vitro proliferation of equine lymphocytes. K.A. Gutierrez^{*1}, N. C. Burdick¹, J. G. Lyons¹, C. L. Barton¹, J. C. Laurenz², N. D. Cohen¹, N. H. Ing¹, and T. H. Welsh, Jr.¹, ¹Texas A&M University, College Station, ²Texas A&M University, Kingsville.

Adverse actions attributed to hypercortisolemia associated with Cushing's syndrome are reduced by the glucocorticoid receptor antagonist RU486 (Eur. J. Endocrinol. 157:561; 2007). Immunity may be compromised by cortisol and its synthetic analog dexamethasone (Dex; Am. J. Vet. Res. 56: 997; 1995). This study was designed to determine whether proliferation of equine lymphocytes is adversely affected by Dex, and if RU486 could modulate this negative effect. Jugular blood samples from 15 horses (4 breeds; 12 stallions; 3 geldings; 5-to-15 years of age; 450-to-800 kg BW) were collected and used to isolate lymphocytes by density gradient centrifugation. Separate cultures were established for each horse. Isolated lymphocytes (100,000 cells per well) were cultured in 96-well plates for 96 h in a humidified CO₂ incubator at 37°C in either medium alone (DMEM/F12), or medium containing concanavalin A (ConA; 0-to-5 µg/ml) with or without 1 µM Dex in the presence and absence of 1 µM RU486. Cell proliferation was determined by Promega CellTiter96 assay. Stimulation indices were determined relative to Control (medium alone) and differences in proliferation were determined by ANOVA. ConA dose-dependently increased ($P < 0.01$) lymphoproliferation (ED50 1.2 µg/ml). Dex inhibited ConA-induced proliferation

($P < 0.01$). Specifically, Dex reduced basal proliferation by 37%. At 0.625 and 1.25 µg/ml ConA, Dex reduced proliferation by 19.4 and 18.3%, respectively. Co-addition of RU486 reduced or prevented inhibitory action of Dex ($P < 0.01$). Specifically, RU486 attenuated by 1.59-fold Dex-inhibition of basal lymphoproliferation. The 4.1-fold increase in proliferation induced by 5 µg/ml ConA was reduced 24.9% by Dex; however, the presence of RU486 completely prevented Dex's action. Glucocorticoid antagonists may be used to study how immune functions are suppressed in horses that are phenotypically hypercortisolemic due to: 1) stress; 2) dexamethasone therapy; 3) Cushing's syndrome; or, 4) metabolic syndrome.

Key Words: Equine, Immune Function, RU486

T174 Bovine viral diarrhea virus, abnormal cervical mucous discharge and fertility in cows. S. Yavru^{*1}, M. Kale², M. S. Gulay², O. Yapici¹, O. Bulut¹, and A. Ata², ¹Selçuk University, Konya, Turkey, ²Mehmet Akif Ersoy University, Burdur, Turkey.

The aim of the present study was to describe whether Bovine Viral Diarrhea virus (BVDV) and appearance of cervical mucus discharge (CMD) have effects on reproductive performance of cows in estrus. For this purpose, CMD of 97 Holstein cows in estrus were evaluated visually before AI. To exclude the possible effects of reproductive problems related to nutrition deficiency, cows with body condition score lower than 2.5 were not included in the study. All cows were healthy and free of anatomical abnormalities of the reproductive tract. The CMD of cows in estrus was evaluated visually before AI. Animals having clear discharges (n = 50) with normal viscosity and without bad odor were grouped as normal cervical mucous discharge (N-CMD) group. The other cows (n = 47) with opaque mucus or mucus containing flecks of pus and purulent or mucopurulent material were grouped as abnormal cervical mucous discharge (A-CMD) group. Cows in estrus were inseminated with BVDV free frozen semen. Blood samples were tested by enzyme linked immunoassay (ELISA) for antigens (Ag) and antibodies (Ab) of BVDV. Presence of BVDV genome in mucus samples were tested by Polymerase chain reaction (PCR). No differences in hematocrit or plasma protein concentrations were observed between N-CMD (31.9 and 6.18%) or A-CMD groups (32.8 and 6.26%). First service conception rates (FSCR) were 64 and 61.7% for N-CMD and A-CMD groups, respectively ($P > 0.1$). Total of 55.7, 18.6 and 2.7% of cows were BVDV-Ag, BVDV-Ab and BVDV-PCR (+), respectively. Presence of BVDV-Ag, BVDV-Ab or BVDV-PCR (+) was not associated with A-CMD. FSCR was similar between BVDV-Ab positive (62.9%) and BVDV-Ab negative cows (62.8%). However, presence of BVDV-Ag decreased FSCR (27.8 vs. 70.9%; $P < 0.01$). Thus, the current study suggested that effect of A-CMD on FSCR is minimal. However, presence of BVDV-Ag in blood samples at the time of AI has a negative effect on fertility of Holstein cows.

Key Words: BVDV, Fertility, Cervical Mucus Discharge

Physiology and Endocrinology: Nutritional and Metabolic Effects on Growth, Reproduction and Lactation

T175 Measurement of adiponectin in lactating dairy cows. J. R. Raddatz*, A. N. Elias, and C. S. Whisnant, *North Carolina State University, Raleigh.*

Adipose tissue is now known to be part of the endocrine system as well as an energy storage depot. One of the recently discovered adipose secreted hormones is adiponectin. In rodents and humans adiponectin concentration decreases with increasing adiposity and has been reported to increase tissue sensitivity to insulin. No report of adiponectin secretion in cattle could be found. In the current project we used a commercially available human adiponectin kit (HADP-61 HK, Linco, Millipore) to measure adiponectin concentrations in lactating Holstein ($n = 26$) cows for the first 11 wk of lactation. Insulin and progesterone concentrations were also determined in weekly blood samples. Body condition scores and milk production data were recorded. Adiponectin concentrations increased from 8.3 ± 1.4 ng/mL in the first wk to 16.0 ± 2.7 ng/mL ($P < 0.01$) at wk 4 postpartum and then declined to remain at 12-13 ng/mL for the remainder of the study. Insulin concentrations increased from 5.6 ± 0.7 mIU/mL at wk 1 to 17.6 ± 2.2 mIU/mL at wk 3 and then declined to remain at 9-11 mIU/mL for the remainder of the study. Individual cows had consistently high or low adiponectin levels throughout the sampling period. Adiponectin concentrations did not correlate with body condition score or energy corrected milk yield. Nor did time of resumption of estrous cycles have any effect on adiponectin. Dilution of plasma as recommended by the manufacturer resulted in samples being below the sensitivity of the assay. Using undiluted plasma, adiponectin concentrations ranged 1-80 ng/ml whereas in other species concentrations were reported to be in the ug/ml range. Similarly samples collected from growing bulls were undetectable when diluted but in the 0-40 ng/ml range when assayed undiluted. Equine samples were assayed along with the bovine samples and the equine samples after the recommended dilution (1:500) were in the ng/ml range and after adjustment for dilution were 1-3 ug/ml, similar to values reported for horses in the literature. The human adiponectin kit may not accurately measure bovine adiponectin.

Key Words: Dairy Cattle, Adiponectin, Insulin

T176 L-carnitine stimulates the early postnatal myofiber formation in pig skeletal muscle. D. Loesel*, C. Kalbe, G. Nuernberg, and C. Rehfeldt, *Research Institute for the Biology of Farm Animals, Dummerstorf, Germany.*

Piglets of low birth weight exhibit a lower total number of skeletal myofibers at birth and throughout life compared with piglets of middle and heavy birth weight, which is associated with impaired (lean) growth, carcass and meat quality at market weight. To investigate, whether L-carnitine is effective in stimulating the early postnatal increase in the number of skeletal myofibers, 30 piglets of low (LW) and middle (MW) birth weight (each within one third of frequency distribution) from 6 German Landrace sows were supplemented once daily with 400 mg L-carnitine ($n=16$) or a placebo ($n=14$) from d 8 to 28 (weaning) of age. Offspring were slaughtered at d 29 of age to analyze blood plasma components, *semitehdinosus* (ST) muscle structural and functional prop-

erties, and body composition. Live weight gain and final body weight as well as the plasma concentrations of glucose, free fatty acids, urea, and IGF-I remained unchanged by treatment. Carnitine concentration in ST muscle more than doubled in response to treatment ($P < 0.0001$). The total number of ST myofibers was increased by 19% ($P < 0.05$) in treated LW pigs thereby reaching the unchanged level of MW littermates. Myofibers tended to be smaller ($P = 0.13$), and protein concentration and protein/DNA ratio were lower in treated pigs ($P < 0.05$). Specific ICDH activity as a marker of oxidative metabolism was increased ($P = 0.06$), whereas no differences were observed in muscular LDH, CK, and fiber type composition. Body composition was unchanged by treatment. Notwithstanding, the perirenal fat percentage tended to be decreased ($P = 0.10$), and L-carnitine-treated females exhibited lower percentages of dry matter and crude fat ($P < 0.05$). The results suggest that L-carnitine stimulates early postnatal myofiber formation in pig skeletal muscle, which may attenuate the negative consequences of low birth weight on growth, carcass and meat quality of pigs at market weight.

Key Words: Birth Weight, Body Composition, Muscle

T177 The assessment of complex I concentration in muscle mitochondria of crossbred steers with high and low residual feed intake (RFI). M. P. Davis*, J. H. Porter, and M. S. Kerley, *University of Missouri, Columbia.*

The objective of this study was to evaluate the relationship between complex I concentration in muscle mitochondria and RFI of steers fed a concentrate based-ration. Individual feed intake was recorded for 81 crossbred steers over approximately 150 d using the GrowSafe feed intake system. Residual feed intake was computed as the residual of actual intake minus expected intake. Expected intake was calculated using coefficients for averaging daily gain and mid-weight. The coefficients were generated from the linear regression of dry matter intake on metabolic mid-weight and average daily gain. Three efficient steers (average RFI of -0.78) and 2 inefficient steers (average RFI of 0.90) were selected for further evaluation. Tissue samples were taken at slaughter from the LM and mitochondria isolated using differential centrifugation. Complex I concentration was quantified from mitochondria. Immunocapture of complex I from the mitochondria was done using MitoProfile complex I Immunocapture kit (Mitosciences, Eugene, OR 97403). Complex I protein concentration was determined using bicinchoninic acid colorimetric procedures. Concentration of complex I tended ($P \leq 0.15$) to be greater in Low RFI (6.33 ± 0.48 $\mu\text{g}/\text{mg}$) steers than high RFI (4.08 ± 0.73 $\mu\text{g}/\text{mg}$) steers. The correlation between RFI and complex I protein concentration was -0.69. While only tending to be significant ($P \approx 0.19$) the magnitude of correlation is similar to that reported but the relationship between RFI and complex I is opposite than reported. The association of low RFI (improved efficiency) and higher complex I concentration does however agree with research reported for broilers. These results show that complex I may be influencing RFI and further research is needed to determine if complex I concentration can be used as a predictor of RFI.

Key Words: Muscle Mitochondria, Complex I, Residual Feed Intake

T178 Madin-Darby Bovine Kidney (MDBK) cells and liver tissue of periparturient cows share remarkable similarity in gene expression profiles. M. Bionaz*, R. E. Everts, H. A. Lewin, J. K. Drackley, and J. J. Loor, *University of Illinois, Urbana*.

The importance of fatty acids (FA) in regulating liver metabolism has been well-established in mammalian species and is becoming of interest in periparturient dairy cattle nutrition. Use of in vitro models to assess the effects of FA on bovine cells is crucial due to high costs of in vivo experiments as well as confounding effects of ruminal FA metabolism (e.g., biohydrogenation). In this regard, work from our laboratory with MDBK has demonstrated they represent a useful tool to study potential metabolic effects of FA. The objective of this study was to compare transcript abundance between MDBK cells and liver tissue of periparturient cows. For this purpose, transcript profiles of MDBK cells cultured in high-glucose DMEM and liver tissue from cows at -14, 1, 14, and 28 d relative to parturition were compared. A 13,257 bovine oligonucleotide (70-mers) array was used for transcript profiling. A total of eight microarrays in a direct dye-swap design were hybridized. Using a t-test, we identified 1,983 (15%) genes with different expression and 1,091 showing ≥ 2 -fold expression between MDBK and liver. We also selected 4,850 genes involved in several liver-specific functions (e.g., apolipoprotein metabolism, urea cycle) or metabolism (e.g., fatty acid metabolism, apoptosis) to assess their level of expression in MDBK vs. liver tissue. Analysis indicated that $60 \pm 14\%$ of the chosen genes had similar expression pattern between MDBK and liver. Genes involved in apolipoprotein metabolism, urea cycle, gluconeogenesis, and β -oxidation had greater abundance in liver vs. MDBK, while genes involved in glycolysis, TCA-cycle, and cell cycle had greater abundance in MDBK. Among transcription factors, liver was characterized by larger expression of *HNF4A* (27-fold), *RXRG* (2.2-fold), and *PPARA* (1.5-fold), while MDBK had greater abundance of *PPARG* (1.3-fold) and *NR1H2* (1.4-fold). This analysis allowed characterization of MDBK-specific transcripts and uncovered high similarity (60%) between this cell line and liver tissue of periparturient cows.

Key Words: Genomics, Microarray, Nutrition

T179 Effect of 17 β -estradiol on distal colon contractions and L-arginine-NOS-NO-cGMP-cGMP-PK1 pathway. A. Bulbul¹, K. Altunbas¹, H. A. Celik¹, G. Avci¹, O. Yildiz-Gulay*¹, and M. S. Gulay², ¹*Afyon Kocatepe University, Afyonkarahisar, Turkey*, ²*Mehmet Akif Ersoy University, Burdur, Turkey*.

Objectives were to determine the effect of estrogen on distal colon contractions and L-arginine-NOS-NO-cGMP-cGMP-PK1 α/β pathway. Six month-old female Sprague Dawley rats (n = 72) were divided equally into four groups (n = 18/group) and ovaries were removed. The control group (Ov) received sesame oil, whereas rats in E1, E2 and E3 groups received 25, 50 and 100 μg im injections of 17 β -estradiol in sesame oil, respectively. To determine time effect of estradiol injections, each treatment group was further divided into three sub-groups; the first sub-groups received single dose, the second sub-groups received 3 doses, and the third sub-groups received 6 doses of sesame oil or estradiol (24 h intervals). Rats in all sub-groups were sacrificed 18 h after the last estradiol injections. Distal colons were removed immediately after sacrifice. Smooth muscle contractions were recorded by force transducer and acquisition system to evaluate L-arginine-NOS-NO-cGMP pathway in colon. Expression of nNOS and cGMP-PK1 α/β in distal colon was also tested. The statistical significance was set at $P < 0.05$. The results

indicated that 17 β -estradiol injections decreased the distal colon contractions in a dose and time dependent manner. Moreover, L-arginine-NOS-NO-cGMP pathway was effective on the smooth muscle contractions in distal colon. Results from immunohistochemistry revealed that nNOS expression was not affected by estradiol injections. However, expression of cGMP-PK1 α/β declined significantly. In conclusion, although estrogen injections decreased the smooth muscle contractions in distal colon, this effect did not use L-arginine-NOS-NO-cGMP pathway.

Key Words: 17 β -estradiol, nNOS, cGMP

T180 Effect of ovarian steroids on distal colon contractions and L-arginine-NOS-NO-cGMP-cGMP-PK1 pathway. A. Bulbul¹, A. Yagci¹, K. Altunbas¹, H. A. Celik¹, G. Avci¹, O. Yildiz-Gulay*¹, and M. S. Gulay², ¹*Afyon Kocatepe University, Afyonkarahisar, Turkey*, ²*Mehmet Akif Ersoy University, Burdur, Turkey*.

The current study addressed the effect of ovarian steroids on spontaneous distal colon contractions and L-arginine-nitric oxide synthase (NOS)-nitric oxide (NO) pathway. Ovariectomized three to six-month old Sprague-Dawley rats were assigned to control (Ov; sesame oil; n = 10), estrogen (E; 10 $\mu\text{g}/\text{d}$; n=10), progesterone (P; 2 mg/d; n = 10), and progesterone and estrogen (EP; 10 $\mu\text{g}/\text{d}$ estrogen and 2 mg/d progesterone; n = 10) groups. Daily intramuscular injections were continued for 10 d. Rats in all groups were sacrificed 18 h after the last injection. Distal colons were removed immediately after sacrifice, tissue samples were replaced in isolated organ baths, and contractions against different solutions were examined. The level of statistical significance was set at $P < 0.05$. Results indicated that among the treatment groups, intensity of colon contractions decreased only in E group. Moreover, L-arginine-NOS-NO pathway reduced the intensity of contraction induced by electrical field stimulation (EFS). In E group, L-arginine decreased the efficacy of sodium nitroprusside (SNP), whereas cGMP was not effective on smooth muscle contractions. Among the groups, level of nNOS expression was similar in non-adrenergic non-cholinergic (NANC) neurons. However, cGMP-PK1 α/β expression in smooth muscle cells was decreased in E group. In conclusion, results from the current study indicated that NO induced the relaxation in distal colon via cGMP-cGMP-PK pathway. Estrogen also reduced the distal colon contractions. However, the data suggested that estrogen uses cGMP-PK to reduce the effectiveness of L-arginine-NOS-NO-cGMP-cGMP-PK pathway.

Key Words: Ovarian Steroids, cGMP, nNOS

T181 Effect of diets containing soybean meal or canola meal on blood metabolites in early lactation Iranian Holstein cows. F. Hosseini, A. Heravi Moussavi*, M. Danesh Mesgaran, and J. Arshami, *Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran*.

The aim of this study was to evaluate substitution of soybean meal with canola meal and measure its effects on serum glucose, cholesterol, urea nitrogen (BUN), and aspartate aminotransferase (AST) in early lactation Iranian Holstein cows. From d 5 to 56 postpartum, cows were fed diets that were isoenergetic containing soybean meal (SBM; n = 5) or canola meal (CM; n=5). Cows were housed in tie stalls and fed the TMR two times a day to allow 5 to 10%orts (as-fed basis). Blood samples were collected weekly throughout the study via venipuncture

from coccygeal vessels prior to the morning feeding and serum was separated using centrifugation. Serum metabolites were analyzed by enzymatic colorimetric assays using procedures modified from available kits. The data were analyzed using the MIXED procedure of SAS (2001) for a completely randomized design with repeated measures. The model contained the effects of treatment, week of treatment, cow within treatment and the interaction of treatment by week. The overall effect of treatment was tested using cow within treatment as the error term. Least squares means are reported throughout, and significance was declared at $P < 0.05$. Plasma glucose concentrations were similar among diets (60.38 and 60.76 ± 1.65 mg/dL, respectively). The effect of time was significant ($P < 0.05$). Diet and time had no effect on BUN. Plasma cholesterol concentrations were similar among the diets (143.38 and 141.21 ± 7.5 mg/dL, respectively). The effect of time was significant ($P < 0.01$) and plasma cholesterol increased over the study. Diet had no effect on AST (72.00 and 72.43 ± 4.63 U/L, respectively). The effect of time also was not significant. The results of this study demonstrated that substituting soybean meal with canola meal in the early lactation cows had no apparent effect on the blood metabolites.

Key Words: Dairy Cow, Soybean Meal, Canola Meal

T182 Effects of carbohydrate source and processing on serum progesterone and insulin concentrations of dairy cattle. P. Moriel^{*1}, T. S. Scatena¹, O. G. Sa Filho¹, R. F. Cooke², and J. L. M. Vasconcelos¹, ¹FMVZ-UNESP, Botucatu, Brazil, ²University of Florida, Gainesville.

Two trials were conducted to investigate the effects of carbohydrate source and processing on serum progesterone (P4) and insulin (INS) concentrations. In Exp. 1, 12 ovariectomized grazing Gir \times Holstein cows were stratified by BW and randomly assigned, in a crossover design, to receive a supplement based on finely ground corn (FC) or citrus pulp. Treatments were offered individually 2 \times /day at a rate 11 kg of DM/cow. Within each of the 2 experimental periods, cows were adapted to treatments from d 0 to d 14 and received an intravaginal P4-releasing device (CIDR) prior to the beginning of the study. On d 7 after CIDR implant, blood samples were collected immediately prior to, and 1, 2, 3, 4, 5, and 6 h after the first feeding of the day. In Exp. 2, the cows utilized in Exp. 1 were re-stratified by BW and randomly assigned to receive, in a crossover design, a supplement based on coarsely ground corn (GC), finely ground corn (FC), or high-moisture corn (HM). Treatments were offered individually 2 \times /d at a rate 11 kg of DM/cow. Within each of the 3 experimental periods, cows were adapted to treatments from d 0 to d 7. Blood samples were collected on d 7 after CIDR implant as in Exp. 1. Time effects ($P < 0.01$) were detected in Exp. 1 and 2 because P4 concentrations decreased 3 h after feeding, whereas INS concentrations increased 1 h after feeding. In Exp. 2, HM cows tended ($P = 0.09$) to have decreased P4 concentrations compared to GC cows (1.7 vs. 1.9 ng/mL), and had greater ($P < 0.01$) INS concentrations compared to GC and FC cows (8.8, 5.7, and 6.1 μ UI/mL, respectively). Data combined from both experiments indicate that cows with INS ≥ 4.5 μ UI/mL prior to treatment feeding had greater P4 concentrations at 1 h, but decreased P4 concentrations at 5 h compared to cows with INS < 4.5 μ UI/mL. In the present study, carbohydrate processing, but not carbohydrate source, affected serum P4 and INS concentrations of non-lactating dairy cows.

Key Words: Carbohydrate, Insulin, Progesterone

T183 Effects of prepartum 2,4-thiazolidinedione on plasma leptin and insulin sensitivity in transition dairy cows. K. M. Schoenberg^{*}, K. L. Smith, R. M. Ehrhardt, Y. R. Boisclair, and T. R. Overton, Cornell University, Ithaca, NY.

Administration of thiazolidinediones (TZD) has been shown to alter lipid metabolism in transition dairy cows. The objective was to determine the effect of prepartum TZD treatment on plasma leptin and insulin response. Holstein cows ($n = 40$) entering second or greater lactation were administered 0, 2.0, or 4.0 mg TZD/kg BW by intrajugular infusion once daily from 21 d before expected parturition until parturition. Plasma samples collected daily from 22 d before expected parturition through 21 d postpartum were analyzed for glucose, NEFA, and insulin. Plasma samples collected on d -14, -3, -1, 1, 3, 7, 14, and 49 relative to parturition also were analyzed for leptin. Data from 40 cows were used for prepartum analyses and 31 cows were used for periparturient (d -7 to +7) and postpartum analyses. Prepartum BCS was not affected by treatment but postpartum BCS was higher for TZD-treated cows (2.8, 2.9, 3.1; $P = 0.001$). There was a trend ($P = 0.15$) for a treatment by time effect on plasma leptin prepartum such that values were similar on d -14 but cows receiving 2.0 mg/kg BW TZD tended to have lower leptin as calving approached. Postpartum leptin tended ($P = 0.14$) to increase linearly in TZD-treated cows (2.3, 2.4, 2.5 ng/mL). Insulin response was assessed using the revised quantitative insulin sensitivity check index (RQUICKI = $1/[\log(\text{glucose}) + \log(\text{insulin}) + \log(\text{NEFA})]$) as applied to dairy cattle, and results suggested that TZD-treated cows had greater insulin sensitivity as calving approached (treatment by time; $P = 0.05$). During the periparturient period, there was a tendency for RQUICKI to increase linearly with increasing TZD (0.43, 0.43, 0.46; $P = 0.10$). Postpartum RQUICKI was increased linearly in cows treated with TZD prepartum (0.43, 0.44, 0.47; $P = 0.02$). These results suggest that TZD treatment may alter plasma leptin, but postpartum effects may be confounded with BCS differences. Changes in RQUICKI suggested that TZD treatment altered insulin sensitivity in periparturient dairy cows.

Key Words: Transition Cow, Thiazolidinedione, Leptin

T184 The effects of prepartum 2,4-thiazolidinedione administration to dairy cows on energy balance, growth hormone, and insulin-like growth factor-I during the transition period. L. A. Winkelman^{*}, K. L. Smith, R. M. Ehrhardt, and T. R. Overton, Cornell University, Ithaca, NY.

Administration of thiazolidinediones (TZD) to prepartum dairy cows has been shown to reduce plasma NEFA concentrations in the periparturient period and postpartum body condition loss. Data from Holstein cows ($n = 31$) entering second or greater lactation were used to determine whether late prepartum administration of TZD would affect periparturient energy balance (EB), plasma growth hormone (GH) and insulin-like growth factor-I (IGF-I) concentrations, and the ratio of GH:IGF-I. During the pre- and postpartum periods, cows were fed a common TMR for ad libitum intake. Cows were administered 0, 2.0, or 4.0 mg TZD/kg BW by intrajugular infusion once daily from 21 d before expected parturition until parturition. Plasma samples collected on d -14, -7, -3, -1, 1, 3, 7, 14, 28, and 49 relative to parturition were analyzed for GH and IGF-I by RIA. Prepartum plasma GH and IGF-I concentrations, and the GH:IGF-I ratio were unaffected by TZD treatment. Calculated postpartum EB increased linearly ($P = 0.05$) with increasing TZD dose (-4.9, -5.4, and -1.7 ± 1.2 Mcal/d for 0, 2.0, and 4.0 mg TZD/kg BW treatments, respectively). After parturition, there was a tendency for a

linear effect of prepartum TZD dose on plasma GH ($P = 0.07$) such that an increasing TZD dose prepartum was associated with lower postpartum GH concentrations (9.55, 8.26, and 6.82 ± 1.12 ng/ml for 0, 2.0, 4.0 mg TZD/kg BW treatments, respectively). Prepartum TZD treatment did not affect postpartum IGF-I, but there was a linear trend ($P = 0.12$) for a decreased postpartum ratio of GH:IGF-I (0.258, 0.240, and 0.174 ± 0.040 for 0, 2.0, 4.0 mg TZD/kg BW treatments, respectively). A more positive calculated EB after parturition was associated with lower GH concentrations in cows receiving the 4.0 mg TZD/kg BW treatment, but there was no apparent relationship between postpartum EB and IGF-I concentrations.

Key Words: Transition Cow, Thiazolidinedione, Growth Hormone

T185 The metabolic status during the dry period influences the ovulation of the first follicular wave postpartum in dairy cows. N. Castro^{*1,2}, C. Kawashima³, H. A. van Dorland¹, S. Richter¹, I. Morel⁴, A. Miyamoto³, and R. M. Bruckmaier¹, ¹University of Bern, Bern, Switzerland, ²Las Palmas de Gran Canaria University, Arucas, Spain, ³Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Japan, ⁴Agroscope Liebefeld-Posieux, Posieux, Switzerland.

The aim of this study was to investigate the effect of the nutritional status, liver function and key metabolic factors in the liver during the

dry period (dp) and early lactation on the resumption of the ovarian activity in dairy cows. 23 high yielding dairy cows were allocated in two groups based on the first ovulation postpartum (pp) as detected by milk progesterone (P4) profiles. Milk samples were collected thrice per wk from d 7 pp until a new pregnancy. Ovulations were identified by an increase of P4 to more than 1 ng/mL. 47.8% of cows showed the first ovulation within 3 wk pp (OC), while in the others, ovulation occurred later (AC). Blood samples were obtained biweekly from 9 wk antepartum (ap) to wk 9 pp and plasma concentration of β HB, NEFA, Glucose (Glu), T-cholesterol, IGF-I, Insulin (Ins), T3, T4, AST and GGT were measured. Liver biopsies were taken ap and pp to analyze mRNA expression levels of hormone receptors (GH-R, IR, IGF-R1) and key metabolic enzymes (PC, PEPCKc, PEPCKm). In addition BCS and energy balance (EB) during dp and pp were assessed. Data were analysed by repeated measures ANOVA. Areas under the curve were calculated for the entire periods dp and pp, respectively. OC during dp showed higher Glu, Ins, IGF-I and T3 than AC (3.64 ± 0.03 vs 3.42 ± 0.06 mmol/l, 5.99 ± 0.99 vs 3.89 ± 0.44 μ g/l, 173.09 ± 11.50 vs 133.04 ± 11.56 μ g/l and 1.26 ± 0.06 vs 1.07 ± 0.06 nmol/l, respectively). During the pp period only higher T4 and BCS in OC were found (48.38 ± 2.23 vs 44.46 ± 0.98 nmol/l and 2.93 ± 0.07 vs 2.72 ± 0.09 , respectively). Liver mRNA expressions and EB did not differ in dp and pp. In conclusion the metabolic status during the dp is crucial for the ovulation of the first follicular wave pp.

Key Words: Ovulation, Metabolism, Dry Period

Physiology and Endocrinology: The Hypothalamic-Somatotrophic Axis

T186 Assessment of third-ventricle cerebrospinal fluid concentrations of GHRH in cattle: Correspondence with serum concentrations of GH and influences of appetite-regulating peptides. M. G. Thomas^{*1}, M. Amstalden², D. M. Hallford¹, G. A. Silver¹, M. D. Garcia¹, D. H. Keisler³, and G. L. Williams⁴, ¹New Mexico State University, Las Cruces, ²Texas A&M University, College Station, ³University of Missouri, Columbia, ⁴Texas AgriLife, Beeville, TX.

Hypothalamic hormones, GHRH and somatostatin, are important regulators of adenohipophysal secretion of GH. Direct evaluation of these neuroendocrine events is an anatomical challenge in cattle. Objectives were to: 1) characterize the relationship of third-ventricle cerebrospinal fluid (CSF) concentrations of GHRH with concentrations of GH in circulation, and 2) assess the influence of acute administration of appetite-regulating peptides, leptin (anti-orexigenic) and neuropeptide Y (NPY; orexigenic) on release of GHRH. Six mature, well-fed, Braford cows fitted with third cerebroventricle and jugular vein cannulae were treated intracerebroventricularly with saline, leptin (600 µg), or NPY (500 µg) in a replicated 3 × 3 Latin Square. Third-ventricle CSF and blood were collected 10 min before and for an additional 220 min after delivery of treatments. Concentrations of GHRH in CSF and GH in blood were evaluated with RIA. Hormone secretion patterns were assessed with Pulse_XP software. Mean concentrations of GHRH and GH were similar among treatments as was frequency of pulses of GHRH and GH. Mean concentrations of GHRH and frequency of pulses were 2.2 ± 0.13 ng/mL and 1.2 ± 0.15 pulses/240 min, respectively. Concentrations of GHRH in CSF were weakly correlated ($r = 0.15$; $P < 0.03$) with serum concentrations of GH; however, 58.2% of the GH pulses were preceded by a pulse of GHRH and 90% of the GHRH pulses occurred within 2 samples preceding a pulse of GH. Area under the curve (AUC) values for saline, leptin, and NPY treatments were 4,887, 3,719, 6,058 ± 444, respectively. Relative to saline, leptin tended ($P < 0.10$) to suppress GH AUC. Concomitantly, NPY tended ($P < 0.10$) to increase GH AUC, which appeared to be a consequence of increased ($P < 0.05$) pulse amplitude. Infusion of NPY also increased ($P < 0.05$) AUC of GHRH relative to saline. Sampling CSF from the third-cerebroventricle appears to be a viable procedure for assessing hypothalamic release of GHRH coincident with anterior pituitary gland secretion of GH in cattle.

Key Words: Bovine, GHRH, GH

T187 IGF-I modulation of GH and LH secretion in the pig. C. R. Barb and G. J. Hausman^{*}, USDA, ARS, Russell Research Center, Athens, GA.

Three experiments (EXP) were conducted to determine the role of IGF-I in modulating GH and LH secretion. In EXP I, prepuberal gilts, 65 ± 6 kg BW and 140 d of age received intracerebroventricular (ICV) injections of saline ($n = 4$), 25 µg ($n = 4$) or 75 µg ($n = 4$) IGF-I and jugular blood samples were collected. In EXP II, anterior pituitary cells in culture collected from 150 d old prepuberal gilts ($n = 6$) were challenged with 0.1, 10 or 1000 nM [Ala¹⁵]-h growth hormone-releasing factor-(1-29)NH₂ (GRF), or 0.01, 0.1, 1, 10, 30 nM IGF-I individually or in combination with 1000 nM GRF. Secreted GH was measured at 4 and 24 h after treatment. In EXP III, anterior pituitary cells in culture collected from 150 d old barrows ($n = 5$) were challenged with 10, 100 or 1000 nM GnRH or 0.01, 0.1, 1, 10, 30 nM IGF-I individually or in

combinations with 100 nM GnRH. Secreted LH was measured at 4 h after treatment. In EXP I, serum GH and LH concentrations were unaffected by ICV IGF-I treatment. In EXP II, relative to control all doses of GRF increased ($P < 0.01$) GH secretion. Only 1, 10, 30 nM IGF-I enhanced ($P < 0.02$) basal GH secretion whereas by 24 h all doses except for 30 nM IGF-I suppressed ($P < 0.02$) GH secretion compared to control wells. All doses of IGF-I in combination with 1000 nM GRF increased ($P < 0.04$) the GH response to GRF compared to GRF alone at 4 h. In contrast by 24 h all doses of IGF-I except for 1 nM suppressed ($P < 0.04$) the GH response to GRF. In EXP III, all doses of IGF-I increased ($P < 0.01$) basal LH levels while the LH response to GnRH was unaffected by IGF-I ($P > 0.1$). In conclusion, under these experimental conditions the results suggest that IGF-I may directly modulate GH secretion at the level of the pituitary gland and although IGF-I increased basal LH secretion from pituitary cultures further examination of the role of IGF-I on LH secretion is needed.

Key Words: LH, GH, IGF-I

T188 Growth hormone directly stimulates insulin production from the bovine pancreatic islets. J. Feng^{1,2}, F. C. Gwazdauskas¹, and H. Jiang^{*1}, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²Zhejiang University, Hangzhou, Zhejiang, China.

The objective of this study was to determine the effect of GH on insulin secretion in cattle and the mechanism responsible for this effect. Administration of 500 mg of recombinant bovine GH in a slow-release formulation caused a continuous increase ($P < 0.01$) in serum concentration of insulin and IGF-I in nonlactating, nonpregnant beef cows ($n = 8$) during the 7 d following the administration, with serum concentration of insulin being nearly 5 times greater on d 7 after GH administration than on d 1 before GH administration ($P < 0.01$). Treatment of isolated bovine pancreatic islets with 100 ng/mL of GH for 1 h, 10 ng/mL of GH for 24 h, or 100 ng/mL of GH for 24 h in the presence of 3.3 mM of glucose each increased secretion of insulin in the culture medium by 20 to 30% as compared to 3.3 mM glucose only ($P < 0.05$, $n = 6$). Treatment of the islets with 100 ng/mL of GH for 24 h in the presence of 3.3 mM of glucose increased insulin mRNA abundance in the cultured islets by nearly 200% ($P < 0.05$, $n = 4$) as compared to 3.3 mM glucose only. Immunohistochemical analyses using antibodies recognizing the bovine GH receptor and insulin indicated that GH receptor protein is expressed in at least some of the insulin-producing beta cells in the bovine pancreatic islets. Taken together, these results suggest that GH administration increases serum concentration of insulin in cattle and that this effect is at least in part due to direct action of GH on insulin gene expression and secretion from the pancreatic beta cells.

T189 Milk composition is not affected by retail milk labels regarding farm management practices. J. L. Vicini^{*1}, T. D. Etherton², P. M. Kris-Etherton², J. M. Ballam¹, R. D. Cady¹, M. F. McGrath¹, M. C. Lucy³, A. C. Fitzgerald¹, T. D. Klusmeyer¹, and M. F. Migliazzo¹, ¹Monsanto Co., LC, St. Louis, MO, ²Pennsylvania State University, University Park, ³University of Missouri, Columbia.

A survey was conducted to determine if composition of retail milk is affected by label claims related to dairy farm management. Retail milk samples (n = 334) from 48 states were collected. Samples were blocked in complete or incomplete blocks such that within a block all samples were collected on the same date, by the same collector, in the same city and state and were shipped in the same container. Milk was purchased with one of three types of labels: 1) conventional (no claims about type of management), 2) recombinant bovine somatotropin (rbST)-free (processor certified not from cows supplemented with rbST) and 3) organic (follows USDA organic practices). Only samples not labeled as ultra-pasteurized (UP) were selected but it is known that some organic milk was UP and this was not indicated on the label. None of the samples tested positive for antibiotics. An analysis for all samples was conducted and least-squares means within whole milk are presented below (values with unlike superscripts are different ($P < 0.05$)). Although some significant differences were detected, values were within normal ranges and indicate that management labels predict no meaningful differences in

composition. Consumption of all dairy products should be encouraged to achieve nutrient adequacy.

T190 Effects of beet pulp substituted for barley grain in fat cows ration at the late lactation. E. Mahjoubi*, H. Amanlou, D. Zahmatkesh, M. Ghilichkhan, and N. Aghaziaraty, *Zanjan University, Zanjan, Iran.*

In order to examine the effects of increasing concentrations of beet pulp (lipogenic nutrient) substituted for barley grain (glycogenic nutrient) on productive performance, BCS loss, and blood metabolites, 18 Holstein cows were used. The cows were 171 ± 16 d in pregnancy and 289 ± 35 d in milk at the beginning of the experiment. The cows's BCS were 4.12 ± 0.35 at the beginning of the trial. The cows were assigned randomly to three dietary treatments containing 1) 23.47% barley (0% beet pulp), 2) 14.87% barley (8.6% beet pulp), or 3) 6.27% barley (17.2% beet pulp). Substituting beet pulp for barley grain didn't affect FCM 3.5%, milk protein, lactose, total solid, and SNF percentage, but milk fat percentage (4.37, 4.91, and 5.18, $P < 0.003$) and milk energy (0.76, 0.82, and 0.84 Mcal/kg, $P < 0.02$) increased as beet pulp were replaced barley, respectively. A tendency was detected for a more negative BCS change (0.13, -0.09, and -0.12, $P < 0.13$) and back fat thickness (2.5, -0.4, and -1.6 mm, $P < 0.13$) with added beet pulp. Plasma glucose (65.83, 58, and 57.16 mg/dl, $P < 0.01$) and cholesterol (157.33, 122.4, and 120.8 mg/dl, $P < 0.03$) decreased as beet pulp were substituted for barley grain, respectively. No difference was found in the plasma content of insulin and NEFA between treatments. In summary, these results suggest that with inclusion beet pulp in fat cows diet during late lactation may be slightly reduce BCS safely and inhibit of concomitant low production with diet diluting.

Key Words: Fat Cow, Beet Pulp, Barley

T191 Intake and ponderal development of dairy heifers fed sugar cane and different protein levels diets. M. F. S. Queiroz^{1,2}, T. T. Berchielli^{1,2}, R. D. Signoretti³, A. F. Ribeiro^{1,2}, and P. H. M. Dian^{1,2}, ¹Faculdade de Ciências Agrárias e Veterinárias-UNESP, Jaboticabal, São Paulo, Brasil, ²Fundação de Amparo à Pesquisa do Estado de São Paulo-FAPESP, São Paulo, Brasil, ³Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brasil.

The objective of this work was to evaluate the intake, performance and ponderal development of heifers fed sugar cane and four different protein levels diets. The sugar cane (IAC 862480) was evaluated during August to November (winter/spring) and the diets concentrate was compound by corn meal, soybean meal, urea, ammonia sulfate and mineral mix, in different proportions, to obtain the protein levels (10, 12.5, 15 and 17.5% of crude protein) in 70:30 relation forage and concentrate. Twenty-four Holstein × Zebu crossbred heifers were maintained in individual stalls and *ad libitum* fed twice on day (8 and 16h) during the adaptation and experimental period, 15 and 62 days, respectively. The animals were distributed in a block-randomized design, with four treatments and six replicates. The heifers were weighed and their thoracic perimeter, hip and croup height were determined at the beginning and at the end of the experimental period, at every 21 days. There was no difference ($P > 0.05$) between different protein levels for intake, daily weight gain and ponderal development of dairy heifers. However, although similar statistic results, the high protein level diet, 17.5% crude protein, promoted the best feed conversion (8,3).

T192 Effects of different ratios of nonfiber carbohydrate to ruminal degradable protein on the performance of Holstein cows in barley based diets. H. Rafiee¹, A. Afzalzadeh¹, A. Khadem¹, and A. Asadi², ¹University of Tehran, Aboureihan Campus, Tehran, Iran, ²Isfahan University of Technology, Isfahan, Iran.

Nine multiparous midlactation Holstein cows averaging 171 ± 17 days in milk and 24.1 ± 3.2 Kg of milk/d were assigned into a replicated 3×3 Latin square design to study the effects of altering nonfiber carbohydrate (NFC) to ruminal degradable protein (RDP) ratio on performance and nutrient digestibility. NFC:RDP ratios were 4.07, 3.71 and 3.34. Ratios were achieved through altering RDP content of diets while NFC was held constant at 40% DM. Urea was supplemented as a source of RDP to decrease the ratio. Crude protein (CP) contents were 14.3, 15.3 and 16.3% DM respectively. Each period lasted 21 days with last 7 days for milk and feces sampling. Results were analyzed by MIXED models with effect of cow(square) as a random and days of sampling in each period as repeated measures. Differences declared as significant where $P < 0.05$. Results showed that indicators of nitrogen metabolic efficiency were more affected than milk yield confirming that low producing cows are less likely to respond to altering NFC:RDP ratio. Hence, balancing rations to further improve the nitrogen utilization efficiency may be of higher priority value.

Table 1: Effect of NFC:RDP ratios on milk production and composition, nutrient intake and digestibility

T193 An alternative low-starch compared with a traditional high-starch calf starter results in similar growth rate and rumen development at weaning. M. Vestergaard*, L. Puggaard, A. Kosiorowska, S. K. Jensen, N. B. Kristensen, and J. Sehested, *Faculty of Agricultural Sciences, University of Aarhus, Foulum, Denmark.*

The objective was to evaluate the consequences on growth performance and rumen development of using an alternative low-starch concentrate (ALT) compared with a traditional high-starch concentrate (TRA) fed at normal (N) (6.4 kg/d) or low (L) (3.2 kg/d) milk feeding level until weaning at 8 weeks. In total, 64 new born HF calves in 8 male and 8 female blocks of 4 were used in a 2 × 2 factorial design. All calves received 6.4 kg/d of cow's whole milk (M) from d 3 to d 13 of age. From d 14, half the calves (treatment L) received only 3.2 kg/d of M. All calves had free access to artificially-dried grass hay (9.8 MJ ME/kg DM), to water, and to either TRA or ALT concentrates from day 3. TRA contained 350 and ALT 107 g starch/kg DM, whereas NDF was 136 and 296 g/kg DM, respectively. Protein content (203 g/kg DM) was similar, but ME was lower in ALT than in TRA (11.2 vs. 12.2 MJ ME/kg DM). L-calves had higher concentrate intake than N-calves (P<0.001). TRA resulted in higher hay intake than ALT (P<0.01). L-calves had lower (608 g/d) ADG than N-calves (766 g/d) with no effect of concentrate type. At 8 weeks of age, size of reticulo-rumen (P<0.001) and weight of rumen epithelium (P<0.02) were lower in N- compared with L-calves. Rumen papillae length was not affected by treatments. In conclusion, if calves have access to a nutritious hay-product, feeding low- or high-starch concentrate will both result in normal rumen development and similar growth performance at the given milk feeding level.

T194 Rumen available soluble, insoluble and total structural and non-structural carbohydrates and protein and their ratios: Effect of barley variety and growth year. P. Yu* and K. Hart, *University of Saskatchewan, Saskatoon, SK, Canada.*

The objective of this study was to investigate rumen available soluble, insoluble and total protein (CP), estimated structural (SC) and non-structural carbohydrate (starch: ST), degradation characteristic ratio of six barley varieties during three consecutive growth years of 2003, 2004, 2005) in order to determine the magnitude of the differences between the varieties and growth years which affect optimizing a diet composition with regard to rumen fermentation. All the barleys were coarsely rolled with a roller gap of 1.12 mm. Measured degradation kinetics in fistulated dairy cows were soluble fraction (S: ST, CP), undegradable fraction (U: SC, CP), lag time (T0: SC, CP) and rate of degradation (Kd: SC, ST, CP) of the insoluble but degradable fraction (D: SC, ST, CP). Rumen available soluble, insoluble, and total N, structural and non-structural carbohydrate and rumen degradation characteristic ratio were determined using the Rumen Degradation Ratio System. Based on the measured kinetics, degradation ratios were calculated between the total rumen available N and carbohydrates (FN/FCHO), rumen available soluble N and carbohydrates (SN/SCHO), and rumen available insoluble N and carbohydrates (EN/ECHO). The ratios showed significant differences among the varieties in FN/FCHO, ranging from 16.6 to 19.0 g/kg (P<0.01), no differences in SN/SCHO (P>0.05) with an average of 4.9 g/kg. The EN/ECHO was tended to be significant among the varieties (P=0.069) ranging from 18.4 to 21.3 g/kg. Also the year affected FN/FCHO (P<0.01) and EN/ECHO (P<0.01) ranging from 15.3 to 18.6 g/kg and 17.0 to 21.4 g/kg, respectively, but no effect on

SN/SCHO with an average of 4.8 g/kg. In conclusion, both the barley variety and growth years significantly affect rumen degradation kinetics of protein, estimated structural and non-structural carbohydrates. There were significant differences in FN/FCHO ratio (average 17.2 g N per kg CHO) among the barley varieties.

Key Words: Degradation Ratio, Barley Varieties, Growth Year

T195 Effects of dietary starch and unsaturated fat with Rumensin on milk fat depression in lactating dairy cattle. M. E. Van Amburgh*¹, J. L. Capper¹, G. D. Mechor², and D. E. Bauman¹, ¹*Cornell University, Ithaca, NY*, ²*Elanco Animal Health, Greenfield, IN.*

This experiment investigated the effects of starch level, polyunsaturated fatty acids (PUFA) from corn oil and Rumensin (Elanco Animal Health, Greenfield, IN), and their interactions on milk fat synthesis and fatty acid profile. Eighty Holstein cows were assigned to eight treatments within a randomized, blocked design with cross-over on oil addition. Cows were housed in tie stalls and fed ad libitum TMR for approximately 10% refusals. Each treatment consisted of three 21-day periods: in the first period a high- (267 g/kg DM) or low- (203 g/kg DM) starch TMR was fed, followed by the addition of Rumensin (13 mg/kg DM) and/or corn oil at 1.2% DM (280 to 310 g/d); this provided eight different diets formulated for an average DM intake of 22.9 kg/d in period two. In the third 21-day period, cows randomized to diets containing corn oil were switched to diets without corn oil, and vice versa. Data were analyzed using a mixed model approach and the model included period, random effects of cow and fixed effects of starch, Rumensin and oil and their interactions. Dry matter intake and milk yield were increased (P<0.01) in cows fed diets with added corn oil. Further, the addition of corn oil was the primary dietary factor responsible for the observed milk fat depression (MFD) 3.35 versus 3.05% (P<0.004). Milk fat concentration decreased by approximately 12% with the addition of corn oil and 16% with the addition of both Rumensin and corn oil. Rumensin did not induce milk fat depression in cows fed either high or low starch diets (P>0.05), but increased milk protein concentration from 2.99 to 3.07 (P<0.03). Cows fed the high starch diets also had greater milk protein concentration and yield (P<0.04). Comparing the milk fat concentration of t-10, c-12 18:2 of cows with MFD with previously reported data and equations related to MFD, the fatty acid profiles suggest that this CLA isomer was primarily responsible for the milk fat depression observed in this study.

Key Words: Rumensin, Milk Fat Depression, CLA

T196 Effects of conventional or brown mid rib hybrid silage fed at two levels on intake, milk yield and composition, and rumen fermentation of dairy cows. T. D. Edwards*, G. A. Varga, R. H. Chung, V. A. Ishler, and M. Martinez, *The Pennsylvania State University, University Park.*

The objective of this study was to evaluate the effects of Brown Mid Rib (BMR) vs. conventional corn silage fed at two levels on production and rumen fermentation. Eight lactating (DIM=160; four rumen-cannulated) Holstein dairy cows were used in a replicated 4x4 Latin-Square design with 2x2 factorial dietary arrangement (silage type and level). The diets were formulated to contain either 35 or 50% of ration DM from corn

silage, using conventional (CONV) and BMR genotype silage. The diets contained 16% CP, 34% NDF and 28% forage NDF; DM basis. Each experimental period was 14 d, 7 d adaptation and 7 d sampling. Daily milk weights were collected, with sampling from four consecutive milkings the last two days of each period for components. Rumen samples were taken at set points over the last 24 hours of the sampling period. Intake was higher (level effect: $P \leq 0.01$) for cows consuming the 35% vs. 50% level of corn silage inclusion (28.2 vs. 26.4 kg/d). There was an interaction ($P \leq 0.01$) on DMI such that cows on the BMR silage maintained DMI (27.5 kg/d) on both levels of corn silage inclusion while those provided CONV reduced DMI (28.8 vs. 25.4 kg/d). Cows fed the BMR corn silage at 50% produced significantly more milk (corn silage type effect: $P \leq 0.05$) than cows fed the CONV hybrid at 50% (48.6 vs. 43.64 kg/d). Efficiency for converting feed to milk was greater (level effect: $P \leq 0.05$) for 50% vs. 35% inclusion rate (1.76 vs. 1.67, respectively). Yields or percentages of milk fat, protein, and lactose were not significantly different across diets. Rumen pH and ammonia concentration were similar across treatments. No differences in VFA profiles were observed except that concentrations of isobutyrate and isovalerate were higher (corn silage type effect: $P \leq 0.05$) for cows fed CONV vs. BMR corn silage. Feeding BMR corn silage at 50% of ration DM did not affect DMI and maintained milk yield compared with CONV corn silage. Efficiency of converting feed to milk was affected more by the level of corn silage inclusion in the ration than type.

Key Words: Conventional Silage, BMR, Silage Hybrid

T197 The effect of dietary sucrose on dry matter intake, plasma metabolites, and lactation performance for Holstein cows during the first 4 weeks of lactation. G. B. Penner* and M. Oba, *University of Alberta, Edmonton, Alberta, Canada.*

This study was conducted to determine the effect of dietary sucrose concentration during early lactation on dry matter intake (DMI), plasma metabolites, and lactation performance. Fifty-three Holstein cows free of clinically diagnosed transition disorders were used in this study. Cows were fed one of two experimental diets immediately after parturition which contained either 0% (LS) or 4.5% sucrose (HS). Diets consisted of 40% barley silage, 10% alfalfa hay, and 50% of a common concentrate mix which differed in the sucrose concentration by including either sucrose plus urea or cracked corn grain. Both diets were formulated to contain 23.2% forage NDF and 18.7% CP. Data and samples were collected over a 3-d period each in wk 2, 3, and 4 of lactation. Milk yield and composition data were analyzed for wk 3 and 4 only. Dry matter intake was not affected by treatment, averaging 17.4 kg/d. Plasma glucose concentration tended ($P = 0.07$) to be higher for LS compared to HS treatment (54.9 vs. 52.5 mg/dl). A parity \times wk interaction ($P = 0.03$) was detected for plasma glucose: multiparous cows had lower plasma glucose than primiparous cows (51.1 vs. 56.2 mg/dl); however, plasma glucose increased from wk 2 to wk 4 (48.5 to 58.0 mg/dl) for multiparous cows, whereas there was no change in the plasma glucose concentration for primiparous cows. A parity \times treatment interaction was detected ($P = 0.02$) for plasma β -hydroxybutyrate (BHBA) concentration; multiparous cows fed HS (30.9 mg/dl) had higher plasma BHBA than multiparous cows fed LS (11.3 mg/dl) and primiparous cows fed HS (15.3 mg/dl) and LS (14.7 mg/dl). Milk and crude protein yields were not affected by treatment averaging 38.3 and 1.13 kg/d respectively. Feeding HS increased the milk fat yield (1.52 vs. 1.33 kg/d; $P = 0.02$) and tended to increase the milk fat concentration (3.91 vs. 3.60%; $P = 0.09$) compared to LS. These data indicate that feeding sucrose during

early lactation does not affect DMI or milk yield but can increase the yield and concentration of milk fat.

Key Words: Sucrose, Transition Period

T198 Efficacy of glycerol as a replacement for lactose in calf milk replacer. R. A. Ebert*¹, G. M. Willis², and J. K. Drackley¹, ¹*University of Illinois, Urbana,* ²*MSC, Dundee, IL.*

Glycerol (glycerin) is increasingly available from biodiesel manufacture and edible oil refining and has been used successfully in diets for chickens, pigs, and adult cattle; however, no information is available on its nutritional value in young calves. Our objective was to determine the effects on calf growth and health when glycerol replaced a portion of lactose in milk replacer. Holstein calves (6 male, 6 female) born at the University of Illinois dairy unit were assigned alternately to each of 2 treatments (24 calves total): control milk replacer or milk replacer supplemented with 15% glycerol. The experimental base milk replacer contained greater protein, fat, minerals, and vitamins so that when glycerol was added the composition would be the same as control, except that glycerol replaced some lactose. Calves were housed in individual hutches bedded with straw and had water freely available; no starter was offered until d 36. Calves were fed milk replacers twice daily from d 3 of life. Milk replacers contained 28% protein (all from whey proteins), 2.6% lysine, and 15% fat. Control milk replacer contained 40% lactose; glycerol milk replacer contained 25% lactose. Both replacers were reconstituted to 15% solids. Glycerol (liquid) was added to reconstituted base milk replacer at each feeding. During wk 1 milk replacers were fed at a rate of 0.25 Mcal/kg metabolic BW (about 1.5% of BW daily as powder) and from wk 2 - 6 at of 0.30 Mcal/kg metabolic BW (about 2% of BW daily). Starter was offered beginning on d 36. Milk replacer offered was reduced by half on d 43; calves were weaned at d 49. Measurements of BW and stature were made weekly through d 56. Calf BW through d 35 did not differ significantly between treatments (0.68 vs. 0.64 kg/d for controls and glycerol, respectively). Stature measurements (withers height, body length, heart girth) and measures of health (fecal scores, medical treatments) did not differ between treatments. Glycerol could be an acceptable replacement for at least 37.5% of the total lactose in milk replacer if economically favorable.

Key Words: Glycerol, Milk Replacer, Calves

T199 Effects of varying forage proportion and particle length on supply of amino acids. W. Z. Yang and K. A. Beauchemin*, *Research Center, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

Forage proportion and particle length are the main factors that contribute physically effective fiber (peNDF) to the diet, which helps prevent ruminal acidosis. This study aimed to investigate whether the supply of AA to the duodenum and digestibility of those AA in the intestines vary with particle length and forage proportion. Four ruminally and duodenally cannulated lactating cows were used in an experiment designed as a 4 \times 4 Latin square with a 2 \times 2 factorial arrangement of treatments. Four diets were formulated using two cuts of alfalfa silage, short (7.9 mm) and long (19.1 mm), combined with two ratios of forage to barley grain concentrate (35:65 and 60:40, DM basis). The content of N was 20.2% and 21.7% (DM basis), respectively, for low and high forage

diets. Intake of AA (range of 2.9 to 3.3 kg/d) was not affected by forage proportion although DMI was higher with low (20.6 kg/d) forage than with high (18.3 kg/d) forage diets. Overall, flows of microbial and total AA at the duodenum, and digestibility of AA (% of duodenal flow) in the intestine were higher with low forage (1.8 kg/d, 3.3 kg/d, and 67.6%, respectively) than with high forage diets (1.4 kg/d, 2.5 kg/d, and 63.6%, respectively). However, varying forage particle length did not affect the flow (short vs. long; 2.94 vs. 2.89 kg/d) or intestinal digestibility (short vs. long; 66.2 vs. 65.0%) of AA. The profiles of individual essential AA in the duodenal digesta were not affected by the dietary treatments. The proportion of duodenal essential AA (40.9% of total AA) was higher than the original diets (36.9%). The increase of essential AA proportion in the duodenal protein resulted from the higher essential AA in the microbial protein (45.9%) that flowed to the duodenum. These results indicate that increasing forage proportion to increase dietary peNDF reduced overall AA supply because flow and intestinal digestibility of AA were reduced. However, increasing particle length had only marginal effects on AA supply.

Key Words: Forage Proportion and Particle Length, Amino Acids, Dairy Cows

T200 Effects of barley grain processing and source of supplemental dietary fat on nutrient digestion and microbial protein synthesis in dairy cows. G. N. Gozho*, M. R. Hobin, and T. Mutsvangwa, *University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

The objective was to determine the effects of method of barley grain processing and source of supplemental fat on ruminal nutrient digestion, duodenal nutrient flow, and ruminal microbial protein synthesis. Four Holstein cows (656 kg BW; 80 DIM) fitted with ruminal and duodenal cannulae were used in a 4 × 4 Latin square design with 28-d periods and a 2 × 2 factorial arrangement of dietary treatments. Treatments were dry-rolled barley + whole canola seed (DC), pelleted barley + whole canola seed (PC), dry-rolled barley + flaxseed (DF), and pelleted barley + flaxseed (PF). Cows fed dry-rolled barley consumed 1.8 to 3.5 kg/d more DM compared to those fed pelleted barley. Ruminal pH and NH₃-N concentration were higher in cows fed dry-rolled barley compared to those fed pelleted barley. Cows fed dry-rolled barley consumed 1.8 to 3.5 kg/d more DM compared to those fed pelleted barley; consequently, intakes of OM ($P = 0.02$), NDF ($P = 0.007$) and ADF ($P = 0.03$) were higher in cows fed dry-rolled barley. Starch intake tended to be higher ($P = 0.08$) in cows fed dry-rolled compared to pelleted barley. Ruminal digestibility coefficients for starch, OM, and ADF were not affected by treatment; however, ruminal NDF digestibility tended to be higher for cows fed dry-rolled compared to pelleted barley. Duodenal flow of starch was greater ($P = 0.003$) in cows fed dry-rolled compared to those fed pelleted barley. Duodenal flow of microbial N was unaffected by diet,

and was 267, 287, 260 and 252 g/d in cows fed DC, PC, DF, and PF diets, respectively. The efficiency of microbial N synthesis (expressed as g microbial N per kg of OM truly digested in the rumen) were not affected by diet, and were 25.3, 28.8, 23.9 and 22.7 for cows fed DC, PC, DF, and PF diets, respectively. Attempts in our study to shift starch digestion to the rumen through barley grain pelleting were negated by a higher DM intake in cows fed dry-rolled barley diets.

Key Words: Dairy Cow, Duodenal Nutrient Flow, Microbial Protein Synthesis

T201 Wheat, barley, or corn grain based starters with different alfalfa meal levels for Holstein calves. M. Noroozi¹, H. Amanlou¹, G. R. Ghorbani², and A. Nikkhah^{*1,3}, ¹Zanjan University, Zanjan, Iran, ²Isfahan University of Technology, Isfahan, Iran, ³University of Illinois, Urbana.

Wheat grain (WG) has recently become more available in Iran's feed market, thus attracting new interest to its major use in ruminant diets. Given WG's lower cost and higher starch and protein fermentability than corn and barley grains, our objective was to determine the effects of offering either corn, barley, or WG based starters at three levels of alfalfa meal (AM) on weight gain, feed intake, blood metabolites, fecal properties and calf health. Following 3 days of colostrum and transition milk feeding, 54 Holstein calves were assigned to nine starters and received 4 L of whole milk daily at 0900 h and 2100 h from day 4 until day 70 of age in individual hutches. Treatments were starters made of either ground corn, barley or WG (47.9-60.9%) with 0, 5 or 10% AM, on a dry matter basis. Starters were formulated to maintain crude protein (21% of DM), NEm (2.20-2.44 Mcal/kg) and NEg (1.67-1.86 Mcal/kg) as comparable as possible among treatments. Body weight was recorded weekly between 1400 and 1500 h. Feces form, rectal temperature, diarrhea incidence, and general calf health were recorded twice daily. DMI (57.2 vs 62.2 and 62.8 kg), weight gain (33 vs 37.3 and 38.3 kg), and fecal firmness were lower ($P < 0.05$) in WG fed calves than in other calves, respectively. The type of grain did not affect blood metabolites and feed conversion ratio. Inclusion of AM at 5 and 10% reduced ($P < 0.05$) weight gain (36.7 and 32.8 vs 38.9 kg) and blood glucose (114 and 113 vs 129 mg/dl), increased feed conversion ratio (1.66 and 1.94 vs 1.65) and fecal firmness (1.81 and 1.78 vs 1.97; 1 = quite firm, 5 = watery), but did not affect blood total proteins and urea, compared to AM free starters. Results suggest that under current calf raising practices, WG may be used as the sole dietary cereal in calf starters when corn and barley are less available. These data did not support a necessity of using >5% AM in the starter for a superior weaning performance. Whether a blend of WG with other cereals may optimize rumen development and lower weaning age warrants future studies.

Ruminant Nutrition: Fats - Dairy

T202 Effect of supplementation with sunflower oil (SO) or seeds (SS) combined or not with fish oil (FO) on conjugated linoleic acid (CLA) in milk from grazing dairy cows. G. A. Gagliostro^{*1}, M. A. Rodríguez², P. Pellegrini², P. Gatti², G. Muset², D. Garciarena¹, A. Ferlay³, and Y. Chilliard³, ¹*Instituto Nacional de Tecnología Agropecuaria, INTA, Balcarce, Buenos Aires, Argentina*, ²*Instituto Nacional de Tecnología Industrial, INTI, Buenos Aires, Argentina*, ³*Institut National de la Recherche Agronomique, INRA, Saint Genès Champanelle, France*.

The effectiveness of C18:2-rich supplements (SS vs SO) combined or not with FO to increase milk CLA (cis-9, trans-11C18:2) was evaluated in 64 Holstein grazing cows. During each milking corn grain (1.3 kg DM/cow) and a mineral-vitamin mix (0.25 kg) were consumed. Between the a.m. and p.m. milkings cows grazed a pasture at 11 kg DM/cow allowance. After the p.m. milking, cows (16/treatment) received four TMR diets over a 5-wk period: 1) SS = 74.7% corn silage (CS); 25.3% SS, 2) SO = 76.7% CS, 12.3% sunflower meal (SM), 11% SO; 3) SS-FO = 72.4% CS, 24.5% SS, 3.1% FO and 4) SO-FO = 74.3% CS, 11.9% SM, 10.6% SO, 3.2% FO. TMR intake (kg DM) averaged 7.52, 7.33, 3.45 and 4.63. Every week milk samples were collected and FA composition (GLC) were analyzed in a completely randomized design with repeated measures. A pre-trial period represented basal FA concentrations and used for covariance analysis. The average 5-wk concentrations (g/100g FA) of C12:0 (1.52) and C14:0 (6.39) were similar. Concentration of C16:0 was higher (P<0.01) when FO was included in the diet (20.49 vs 17.94). FO supply reduced (P<0.01) milk content of C18:0 (13.54 to 6.30) and cis-9 C18:1 (31.39 vs 19.2) and increased total trans-C18:1 (21.8 vs 10.56). Interactions (P<0.05) between sources of C18:2n6 (SS and SO) and FO were detected for C18:2n-6 and CLA. Concentration of C18:2n-6 was: SS (2.78), > SS-FO (2.10), >SO (2.04), >SO-FO (1.73). Concentration of C18:3n-3 was higher (P<0.03) with treatments including FO (0.68 vs 0.62). Pre-trial CLA concentrations averaged 1.08, 1.15, 1.12, and 1.11 for SS-FO, SS, SO-FO and SO respectively. Milk CLA content was sharply increased after lipid supplementation reaching a maximal value of 8.49 g/100g FA (± 2.25) at wk-5 in SS-FO. The highest average CLA concentration over the 5-wk was observed in SS-FO (6.07) followed by SO-FO (4.37), SS (2.96) and SO (2.36) treatments. Mixing lipid supplements with corn silage represents a feeding-strategy that may be easily carried out by the farmer in order to improve milk CLA and trans-C18:1 concentrations.

Key Words: Conjugated Linoleic Acid, Sunflower, Fish Oil

T203 Effect of dietary vegetable oil and antioxidant supplementation on dairy cattle performance and milk fat depression. M. He¹, H. S. Xin² and L. E. Armentano¹, ¹*University of Wisconsin, Madison*, ²*China Agricultural University, Beijing, China*.

This experiment was conducted to evaluate the effect of dietary supplementation of free vegetable oil with or without a commercial antioxidant (Agrado® plus, Novus International) on dairy cattle performance and milk fat depression. Twenty four multiparous Holstein cows (138±31 DIM) were divided by production into 2 blocks (Hi or Lo) of 12 cows each. Agrado (0 or 0.025% of DM, -A or +A) was randomly assigned to 6 cows per block resulting in a main plot randomized block design

with 20 df for error. These 4 groups of 6 cows each (-AHi, -ALo, +AHi and +ALo) were each fed 6 diets in a 6X6 Latin square design that was a split plot with 3wk periods. Dietary treatments were no added oil (CTRL), or 5% DM as free oil from palm (PALM), high-oleic safflower (OSAF), high-linoleic safflower (LSAF), linseed (LNSD) or corn oil (CORN). Diets were formulated to be iso-CP and iso-NDF, and consisted of approximately 40% alfalfa silage, 20% corn silage and 40% grain mix (DM basis). Data reported were analyzed using the mixed model of SAS (Y = agrado + block + block*agrado + oil + oil*agrado + oil*block + period + period*agrado + period*block). There was no main effect of Agrado feeding nor an Agrado by oil interaction for milk production parameters, but Agrado by block interaction was found for milk yield (P=0.09) and milk protein yield (P=0.08). Negative effects were associated only with the unsaturated fatty acids and linoleic acid appeared to be the most deleterious of the unsaturated fatty acids fed.

Table 1. Effect of vegetable oil on dairy cattle performance

	CTRL	PALM	OSAF	LSAF	LNSD	CORN	SEM
DMI, kg/d	22.44 ^{ab}	22.97 ^{ab}	24.80 ^a	22.97 ^{ab}	23.27 ^{ab}	21.13 ^b	0.99

Key Words: Vegetable oil, Antioxidant, Milk fat depression

T204 Effect of close-up fat supplementation on first 90 days milk production of Holstein dairy cows. M. Danesh Mesgaran* and A. R. Heravi Mousavi, *Dept. of Animal Science (Excellence Center for Animal Science), Ferdowsi University of Mashhad, Mashhad, Iran*.

Effect of close-up fat supplementation and body condition score on first 90 days milk production was evaluated in high producing lactating Holstein cows. Data of 6 herds with average 112 milking cows were used. Body condition scores were recorded 50 days before and 45 days after the calving. All cows in each herd were dried off 50-70 days before expected calving and moved to a far-off dry herd with dry matter intake of 3 kg alfalfa, 5 kg corn silage, 1.5 kg wheat straw and 3 kg far-off concentrate (CP: 162 g/kg; ME:12.4 MJ/kg). The cows were moved to the close-up dry herd around 25 days before calving. Close-up dry ration (DM basis) was consisted of 2.2 kg alfalfa, 6.1 kg corn silage, 1.9 kg wheat straw, 5.2 kg concentrate (CP: 176 g/kg; ME: 13.2 MJ/kg), and 300 g of anionic salts. In 3 herds, the close-up ration was supplemented with 0.25 kg palm fat prills (99.5% fat). After parturition, all cows were fed a total mixed ration (as DM) based on 24% alfalfa, 14% corn silage and 60% concentrate. This ration met the requirements of high producing cows (CP: 180 g/kg; ME: 12.2 MJ ME/kg DM). Cows were inseminated around 60-85 days in milk after a presynch-ovsynch estrous synchronization program. During the first

90 days of lactation, weekly milk production was recorded. Data were analyzed using GLM procedure of SAS. Retained placenta, metritis and endometritis were lower in cows fed fat supplemented close-up ration compared with the non-supplemented cows. First 90 days milk yield was significantly influenced by close-up fat supplementation ($P < 0.05$). Milk yield of fat supplemented and non-supplemented cows was 41.3.8 and 39.6 kg/d/head, respectively. Milk yield appeared to be depressed in postpartum thin cows (BCS= 2.4) compared with normal cows (BCS= 2.9). Results of the present study indicated that fat cows (BCS more than 4.6 before dry off) resulting in lower milk production. It was concluded that relationship between close-up period fat supplementation and milk production in the first 90 days was a critical point.

Key Words: Close-Up, Fat, Milk

T205 Soybean oil and linseed oil supplementation affect profiles of ruminal microorganisms and fermentation parameters in dairy cows. D. P. Bu¹, S. L. Yang¹, J. Q. Wang^{*1}, Z. Y. Hu¹, D. Li¹, H. Y. Wei¹, L. Y. Zhou¹, and J. Loo², ¹State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, P. R. China, ²University of Illinois, Urbana.

The objectives of this study were to evaluate changes in ruminal microorganisms and fermentation parameters due to dietary supplementation of soybean and linseed oil alone or in combination. Four primiparous Holstein cows with permanent ruminal cannulas were randomly assigned to control (CK, 60:40 forage to concentrate) or CK with 4% soybean oil (LOC1), 4% linseed oil (LOC2), or 2% soybean oil plus 2% linseed oil (LOC3) in a 4 × 4 Latin square with 12-week periods. Forage and concentrate mixtures were fed at 0800 and 2000 h daily. Ruminal fluid was collected every 2 h over a 12 h period on d 19 of each experimental period. Ruminal pH and concentrations of acetate and propionate did not differ but butyrate (10.4 vs. 9.5 mmol/L) and total VFA (109 vs. 104 mmol/L) were lower ($p < 0.05$) with oil supplementation compared with CK. Concentration of ruminal NH₃-N (13.6 vs. 17.4 mg/dL) was greater ($p < 0.05$) due to oil compared with CK. Compared with CK, cows fed oil had lower ($p < 0.05$) cellulolytic bacteria (3.25×10^8 vs. 4.66×10^8 CFU/mL) and protozoa (9.04×10^4 vs. 12.92×10^4 CFU/mL) colony counts. Proteolytic bacteria (7.01×10^8 vs. 6.08×10^8 CFU/mL) counts, however, were greater ($p < 0.05$) in response to oil compared with CK. Among oil treatments, the amount of *B. fibrisolvans*, *F. succinogenes*, and *R. flavefaciens* in ruminal fluid (measured by real-time PCR) was substantially lower ($p < 0.05$) due to oil supplementation primarily when LOC2 was fed. *R. albus* concentration decreased by an average of 40% regardless of oil level or type. Overall, results indicate that some ruminal microorganisms, except proteolytic bacteria, are more susceptible to dietary PUFA supplementation above 2% of DM, particularly when linolenic acid-rich oils are fed. Dietary oil effects on ruminal fermentation parameters seemed associated with the profile of ruminal microorganisms.

Key Words: Soybean Oil, Linseed Oil, Rumen Fermentation

T206 Effects of soybean oil and linseed oil supplementation on digestibility of nutrient and milk composition in dairy cows. D. P. Bu, Z. Y. Hu, J. Q. Wang^{*}, S. L. Yang, D. Li, H. Y. Wei, and L. Y. Zhou,

State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, P. R. China.

The objectives were to examine the effects of dietary supplementation of soybean and linseed oil alone or in combination on intake, apparent ruminal digestibility, and total tract digestibility of DM, OM, NDF, ADF, milk production and composition in dairy cows. Four primiparous Holstein cows with permanent ruminal cannulas were randomly assigned to control (CK, 60:40 forage to concentrate) or CK with 4% soybean oil (LOC1), 4% linseed oil (LOC2), or 2% soybean oil plus 2% linseed oil (LOC3) in a 4 × 4 Latin square with 12-week periods. Forage and concentrate mixtures were fed at 0800 and 2000 h daily. The results indicated that intake, apparent ruminal digestibility, and total tract digestibility of DM, OM, NDF, ADF were not affected by the oil supplementation ($P > 0.05$), however the fat supplement tended to reduce the digestibility of DM, OM, NDF, ADF on rumen and total tract ($P > 0.05$). Cows fed diets with fat supplementation did not alter milk production, milk Lactose and milk protein percentage or production ($P > 0.05$). Milk fat percentage, however, numerically decreased for cows fed diets supplemented with fat compared with that for cows fed the control diet (3.45% vs. 3.21%; $P < 0.01$). Cows fed supplemented fat had lower concentration of C16:0 and C16:1 ($P < 0.01$), but higher concentration of C18:0, trans-18:1, cis-18:1, C18:2, and C18:3 ($P < 0.01$) than did cows fed the control diet. The proportions of cis9, trans11 CLA were increased by 236%, 156% and 176% in LOC1, LOC2 and LOC3 treatments compared with cows fed control diet, respectively. Results showed fat supplementation (4% of diet DM) in dairy cows appeared to have a negative influence on rumen and total tract digestibility, but did not affect milk production, milk Lactose and milk protein percentage or production.

Key Words: Soybean Oil, Linseed Oil, Digestibility

T207 Effect of dietary linoleic acid and forage level on conjugated linoleic acid content in plasma and milk. D. P. Bu, J. Q. Wang^{*}, S. J. Liu, H. Y. Wei, and L. Y. Zhou, State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, P. R. China.

The objective of the study was to examine the effect of dietary linoleic acid (LA) and forage level on conjugated linoleic acid (CLA) content in plasma and milk. Twenty-four Chinese Holstein dairy cows, 117.6 ± 52 d in milk and 23.6 ± 4.63 kg/d milk were allocated to four treatments arranged in a 2 × 2 factorial design. Four treatments were a high forage (60% of dry matter basis) diet without LA (HFC), a high forage (60%) diet with LA (HFLA), a low forage (40%) diet without LA (LFC), or a low forage (40%) diet with LA (LFLA). LA was added through sunflower oil (contained 59% LA) by replacing the corn in the diet. Diets were isonitrogenous (average of 16.5%) and were fed as a total mixed ration 3 times a day. Milk yields were recorded twice a week and milk samples were collected weekly. Measurements were made during the last 6 wk of the 9 wk experimental period. Blood samples were taken from coccygeal vein or artery at 4h postfeeding at the end of the 9 wk experimental period. Data were analyzed with animal, period, LA level, forage level and two-way interaction between LA and forage level in the model. LA intake was increased when cows were fed either LA (140.2 vs. 446.6 g/d, $p < 0.001$) or low forage diet (284.0 vs. 302.8 g/d, $P < 0.001$). Milk fat content was 3.81^a, 3.11^{ab}, 3.60^a and 2.66^b in HFC, HFLA, LFC and LFLA respectively. Percentages of 8:0 to 14:0 and 16:0 in milk fat were decreased with LA addition ($p < 0.05$) Dietary forage

level did not alter de novo fatty acids (8:0 to 12:0), 14:0 and 16:0. Percentage of t11-C18:1 in plasma (1.50 vs. 3.69 %, $p>0.05$) and milk fat (1.12 vs. 5.67 %, $p<0.001$) were greater when cows fed LA. Despite a lack of difference in plasma percentage of c9t11 CLA, cows fed LA had greater c9t11 CLA (0.69 vs. 4.08 %, $p<0.001$) in milk fat. Overall, increasing dietary LA level decreased short and medium-chain fatty acids ($P < 0.05$) and increased ($P < 0.001$) t11-C18:1 or c9t11 CLA in milk fat. However, there was no interaction between forage level and LA addition on percentage of t11-C18:1 or c9t11 CLA in plasma and milk fat under present experiment condition.

Key Words: Forage Level, Linoleic Acid, Conjugated Linoleic Acid

T208 Milk fatty acid composition of dairy cows fed increasing amounts of linseed oil. C. Benchaar^{*1}, M. Eugène¹, C. Côrtes¹, A. V. Chaves¹, H. V. Petit¹, T. A. McAllister², A. D. Iwaasa³, and P. Y. Chouinard⁴, ¹Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, Quebec, Canada, ²Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada, ³Agriculture and Agri-Food Canada, Semiarid Prairie Agricultural Research Centre, Swift Current, Saskatchewan, Canada, ⁴Laval University, Quebec, Quebec, Canada.

The objective of this study was to examine the effects of increasing dietary concentrations of linseed oil (LO) on milk fatty acid (FA) composition of dairy cows. Four primiparous cows (BW=566 kg, DIM=52 d) used in a 4x4 Latin square design (28-d periods) were fed a control TMR (CTL) or a TMR supplemented (DM basis) with LO at 2% (LO2), 3% (LO3), or 4% (LO4). Milk samples were collected during the last week of each experimental period. Preplanned contrasts (PROC MIXED, SAS) were: LO vs. CTL, linear and quadratic effects of LO supplementation. Significance was declared at $P < 0.05$. Milk fat content (g/100 g of FA) of C16:0 linearly decreased (27.0, 21.0, 19.1, and 17.4% for CTL, LO2, LO3, and LO4; respectively), whereas the concentrations of C18:0 (8.11, 10.2, 11.1, and 11.3%) and *cis*-9 C18:1 (14.2, 16.8, 17.1, and 17.6%) linearly increased with LO addition. The concentrations of several intermediates of ruminal biohydrogenation of polyunsaturated FA were also higher for the CTL vs. LO and linearly decreased with LO addition; including *trans*-10 C18:1 (0.25, 0.43, 0.51, and 0.76%), *trans*-11 C18:1 (0.78, 1.54, 2.05, and 2.86%), *cis*-9-*trans*-11 C18:2 (0.36, 0.68, 0.87, and 1.22%), *trans*-11 *cis*-15 C18:2 (0.050, 0.56, 1.03, and 1.68%), and *cis*-9 *trans*-11 *cis*-15 C18:3 (0.01, 0.07, 0.10, and 0.12%). The concentration of *cis*-9-*cis*-12 C18:2 linearly decreased with LO addition (2.06, 1.99, 1.91, and 1.83% for CTL, LO2, LO3, and LO4; respectively). Milk fat concentration of *cis*-9 *cis*-12 *cis*-15 C18:3 increased as the level of LO in the diet increased up to 3% but no further increase was observed when 4% of LO was fed (0.33, 0.79, 0.86, and 0.86% for CTL to LO4; respectively). Milk fat contents of *cis*-5 *cis*-8 *cis*-11 *cis*-14 *cis*-17 C20:5 (0.044, 0.058, 0.055, and 0.051% for CTL to LO4; respectively) and *cis*-5 *cis*-7 *cis*-10 *cis*-13 *cis*-16 C22:5 (0.051%; 0.011, 0.017, 0.014, and 0.012% for CTL to LO4; respectively) were quadratically affected by LO addition. Results of this study showed that adding LO to dairy cow diets can improve the nutritive value of milk fat by enhancing the concentrations of health promoting FA such as conjugated linoleic and omega-3 FA.

Key Words: Linseed, Dairy Cow, Milk Fatty Acids

T209 Digestion, milk production, and milk composition of dairy cows fed increasing amounts of linseed oil. C. Benchaar^{*1}, M. Eugène¹, C. Côrtes¹, A. V. Chaves¹, H. V. Petit¹, T. A. McAllister², A. D. Iwaasa³, and P. Y. Chouinard⁴, ¹Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, Quebec, Canada, ²Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada, ³Agriculture and Agri-Food Canada, Agriculture and Agri-Food Canada, Semiarid Prairie Agricultural Research Centre, Swift Current, Saskatchewan, Canada, ⁴Laval University, Quebec, Quebec, Canada.

The objective of this study was to examine the effects of increasing amounts of linseed oil (LO) on digestion, milk production, and milk composition of dairy cows. Four primiparous cows (BW=566 kg, DIM=52 d) used in a 4x4 Latin square design were fed a control TMR (CTL) or a TMR supplemented (DM basis) with LO at 2% (LO2), 3% (LO3), or 4% (LO4). Each experimental period consisted of 21 days of adaptation and 7 days for sample collection. Preplanned contrasts (PROC MIXED, SAS) were: LO vs. CTL, linear and quadratic effects of LO supplementation. Significance was declared at $P < 0.05$. Dry matter intake (18.9 kg/d) and total-tract digestibilities of DM (63.5%), OM (65.1%), CP (65.3%), and ADF (46.6%) were not affected by LO addition. Milk production tended ($P=0.05$) to be higher for LO diets vs. CTL and linearly increased with LO supplementation (26.1, 27.3, 27.4, and 28.4 kg/d for CTL, LO2, LO3, and LO4; respectively). Production of FCM (26.5 kg/d) was not changed by LO supplementation. Feed efficiency (kg of FCM/kg of DMI) was linearly improved by LO addition (1.33, 1.38, 1.45, and 1.46 for CTL, LO2, LO3, and LO4; respectively). Milk contents of fat (3.78%) and lactose (4.70%) were not changed by LO supplementation. However, milk protein content was lower for LO diets vs. CTL and linearly decreased with LO addition (3.41, 3.33, 3.29, and 3.22% for CTL, LO2, LO3, and LO4; respectively). Somatic cell counts were lower with LO diets vs. CTL and tended ($P=0.06$) to linearly decrease with LO addition (22, 14, 15, and 14×10^3 /mL for CTL, LO2, LO3, and LO4; respectively). Supplementation with LO had no effect on milk yields of fat (1.04 kg/d) and protein (0.90 kg/d). However, milk yield of lactose was lower with CTL vs. LO diets and linearly increased with LO supplementation (1.20, 1.28, 1.28, 1.39 kg/d for CTL, LO2, LO3, and LO4; respectively). Results from this study showed that supplementing dairy cow diets with LO at 2, 3, or 4% of dietary DM had no effect on nutrient digestibility, milk fat percentage and yield, but decreased milk protein concentration without affecting milk protein yield.

Key Words: Linseed Oil, Nutrients Digestion, Milk Composition

T210 Effects of increasing amounts of linseed oil on ruminal fermentation, protozoa counts, and forage in situ ruminal degradation in dairy cows. C. Benchaar^{*1}, M. Eugène¹, C. Côrtes¹, A. V. Chaves¹, H. V. Petit¹, T. A. McAllister², A. D. Iwaasa³, and P. Y. Chouinard⁴, ¹Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, Quebec, Canada, ²Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada, ³Agriculture and Agri-Food Canada, Semiarid Prairie Agricultural Research Centre, Swift Current, Saskatchewan, Canada, ⁴Laval University, Quebec, Quebec, Canada.

The objective of this study was to examine the effects of increasing amounts of linseed oil (LO) supplementation on ruminal fermentation characteristics, protozoa counts and forage in situ ruminal degradation

in dairy cows. Four ruminally cannulated lactating cows (BW=566 kg, DIM= 52 d) used in a 4×4 Latin square design were fed a control TMR (CTL) or a TMR supplemented (DM basis) with LO at 2% (LO2), 3% (LO3), or 4% (LO4). Preplanned contrasts (PROC MIXED, SAS) were: LO vs. CTL, and linear and quadratic effects of LO supplementation. Significance was declared at $P < 0.05$. Ruminal pH (6.35), ammonia-N (12.04 mM) and total VFA concentrations (139.1 mM) were not affected by LO addition. Supplementation with LO caused a quadratic change in acetate (A) proportion (61.9, 61.4, 61.2, and 62.3% for CTL, LO2, LO3, and LO4; respectively) and linearly decreased propionate (P) proportion (21.8, 21.8, 21.2, and 20.4% for CTL, LO2, LO3, and LO4; respectively). However, no change was observed in the proportions of A and P when LO diets were contrasted against CTL. Adding LO caused a quadratic increase in A:P ratio (2.88, 2.84, 2.91, and 3.07 for CTL, LO2, LO3, and LO4; respectively), but no difference in A:P was observed when LO diets were contrasted against CTL. Butyrate proportion was lower with CTL vs. LO diets and linearly increased with LO supplementation (12.2, 12.5, 13.1, and 13.0% for CTL, LO2, LO3, and LO4; respectively). Rate of ruminal degradation of DM of timothy hay was lower with LO diets vs. CTL and linearly decreased with LO addition (4.5, 3.8, 3.7, and 2.8 %/h for CTL, LO2, LO3, and LO4; respectively). Consequently, effective degradability of DM was also lower with LO diets vs. CTL and linearly decreased with the addition of LO to the diet (51.5, 50.3, 51.2, and 48.4% for CTL, LO2, LO3, and LO4; respectively). Total protozoa numbers (10.5×10^5 /mL) were not affected by LO addition. This study showed that supplementing dairy cow diets with LO at 2, 3, or 4% of dietary DM resulted in increased A:P ratio, decreased ruminal degradability of DM, but had no effect on total protozoa numbers.

Key Words: Linseed, Dairy Cow, Ruminal Fermentation

T211 The effects of long-term lipid supplementation on milk production traits and metabolic profile in dairy goats. G. Battacone^{*1}, A. Nudda¹, P. Nicolussi², A. H. D. Francesconi¹, P. Bonelli², and G. Pulina^{1,3}, ¹Dipartimento di Scienze Zootecniche, University of Sassari, Italy, ²Istituto Zooprofilattico Sperimentale della Sardegna, Sassari, Italy, ³AGRI Sardegna, Olmedo Loc. Bonassai, Sassari, Italy.

The use of lipid supplements to alter the fatty acid composition of ruminant dairy products has increased lately. Since these supplements have a high net energy value, they can influence the production traits of animals and increase their hepatic activity. This work aimed to evaluate the effects of long-term lipid supplementation on milk yield, milk composition and blood metabolic profile in dairy goats. Forty crossbreed dairy goats were divided into 2 iso-productive groups: one was fed the control diet (CON) and the other group was supplemented with 200 g of extruded linseed (LIN), which supplied 70 g of fat per day per head. The trial lasted 8 weeks. Once a week milk yield was recorded and milk samples were collected. Every two weeks blood samples were collected and analyzed for total bilirubin, creatinine, glutamic oxaloacetic transaminase, glutamic pyruvic transaminase, gamma glutamyl transpeptidase, alkaline phosphatase, total protein and urea nitrogen. Milk yield was about 15% higher in the LIN group than in the CON group (2369 vs. 2049 g/d; $P < 0.01$). LIN supplement increased milk fat content (3.77 vs. 3.33%; $P < 0.01$) and protein content (3.1 vs. 2.9%; $P < 0.01$) content compared to the CON group. The milk fatty acid profile was markedly influenced by lipid supplementation. The blood parameters evidenced a significantly higher glutamic oxaloacetic transaminase and glutamic pyruvic transaminase activity in goats

supplemented with fat than in the control. These data suggest that dairy goats fed the studied dose of lipid supplement for a long-term period might have had their hepatic metabolic activity increased compared with goats fed no lipid.

T212 Effects of feeding whole linseed to Lacaune dairy ewes on lactational performances and CLA and N3 fatty acids content of the milk. R. Casals, M. V. Pol, E. Albanell, X. Such, M. A. Bouattour*, and G. Caja, *Universitat Autònoma de Barcelona, Bellaterra, Spain.*

This study was performed to investigate in dairy ewes the effects of feeding whole linseed (WLS) on dairy performances and milk fatty acids (FA) profile, particularly conjugated linoleic acid (CLA) and n3 FA. A total of 24 Lacaune dairy ewes were blocked in 2 pens of 12 animals, and used in a cross-over design with 2 periods of 21 days each. Treatments were: 1) C (control); 2) WLS (8.0% of total DM). Diets consisted of 52% forage (dehydrated whole plant corn and dehydrated alfalfa, 1/1) and 48% concentrate. Diets were isonitrogenous (16% CP) but with different EE (C: 1.5; WLS 3.5%). The addition of WLS had no effect on dry matter intake (3.6 kg/d) and milk yield (2.26 L/d), but increased ($P < 0.001$) milk fat content (6.0 vs. 6.9%) and yield (135 vs. 154 g/d). Milk protein (5.7%) and casein (4.4%) contents remained unchanged. Milk fatty acids composition was widely modified by the treatment, since short (19.3 vs. 14.8 mg/100 mg of total FA) and medium chain FA (55.3 vs. 41.1) were decreased, while long chain FA (25.1 vs. 43.8) were increased ($P < 0.001$). The milk from ewes receiving WLS had less saturated FA (80.3 vs. 68.2) content and more unsaturated fatty acids (19.3 vs. 31.7), being increased ($P < 0.001$) both MUFA (17.9 vs. 27.9) and PUFA (1.6 vs. 3.8). The enhanced milk fat quality was also evident through the higher amounts of n3 FA (0.6 vs. 2.1, $P < 0.001$), trans vaccenic acid (0.8 vs. 1.6, $P < 0.01$) and CLA (0.6 vs. 1.0, $P < 0.01$) and the lower atherogenicity index (4.9 vs. 2.3, $P < 0.001$). In conclusion, feeding WLS to dairy ewes is a useful way to obtain milk with a healthier profile of FA.

T213 Effects of high oil corn (HOC) grain supplementation on milk production and plasma metabolites in grazing dairy cows. F. Luparia, D. A. Garcarena, C. A. Cangiano, and G. A. Gagliostro*, *Instituto Nacional de Tecnología Agropecuaria, INTA, Balcarce, Buenos Aires, Argentina.*

The effect of HOC (6.6% ether extract) vs conventional corn (CC, 2.25% ether extract) was evaluated in 44 Holstein cows in early lactation in a 2 x 2 factorial arrangement of two levels (4 and 8 kg/cow/d) and two genotypes of corn grain. During the first 17 days of lactation, cows were fed pasture ad-libitum, 4 kg/d of CC corn grain, 2 kg/d soybean meal and 0.2 kg/d of a mineral-vitamin premix. After a covariate period (8 to 17 DIM), herbage allowance was fixed at 11 and 17 kg pasture DM/cow/d for treatments with 8 and 4 kg of grain respectively. Supplements were thoroughly consumed by cows. Pasture intake averaged 12.2 and 9.1 kg DM/cow/d when cows consumed 4 and 8 kg of grain respectively. After 3 adaptation weeks, milk production was recorded daily and milk

composition was measured two days a week during 6 additional weeks. Body weight (BW) and body condition score (BCS) were recorded weekly. Blood was sampled at 10, 40 and 70 days postpartum. Data were analyzed as a completely randomized design with repeated measures adjusted by covariate. Milk yield (22.8 kg/d) and FCM (19.9 kg/d) did not differ ($P>0.05$). Milk composition was not affected by level of corn grain. HOC increased ($P<0.01$) milk fat content (32.5 vs 30.3 g/kg). Milk protein content was numerically increased ($P<0.18$) with HOC feeding (32.1 vs 31.3 g/kg). The efficiency of milk to cheese yield (kg of cheese/100 kg milk) was significantly ($P<0.02$) improved by HOC (9.04 vs. 8.69). Milk fat (0.715 kg/d) and milk protein yields (0.723 kg/d), changes in BW gain (0.51 Kg/d) and in BCS (-0.025) did not differ. Plasma concentrations of glucose (60.8 mg/dL), urea (22.8 mg/dL), triacylglycerides (214 mg/dl), cholesterol (124 mg/dl), NEFA (606 meq/L), insulin (0.9 ng/ml) and IGF-1 (211.7 ng/ml) where not affected by corn level or genotype. In spring pastures milk production was not affected by corn level or genotype but HOC improved fat and protein concentration and the efficiency of milk to yield cheese.

Key Words: High Oil Corn, Milk Composition, Grazing Dairy Cows

T214 Effects of high oil corn (HOC) on milk fatty acid composition in grazing dairy cows in early lactation. F. Luparia¹, P. Pellegrini², A. Rodríguez¹, D. A. Garciarena², and G. A. Gagliostro*¹, ¹Instituto Nacional de Tecnología Agropecuaria, INTA, Balcarce, Buenos Aires, Argentina, ²Instituto Nacional de Tecnología Industrial, INTI, Buenos Aires, Argentina.

The effect of high oil corn (HOC, 6.6% ether extract) vs conventional corn (CC, 2.25 % ether extract) on milk fatty acid (FA) composition was evaluated in 44 Holstein cows in early lactation in a 2 × 2 factorial arrangement of two levels (4 and 8 kg/cow/d) and two genotypes of corn grain.

During the first 17 days of lactation, cows were fed pasture ad-libitum, 4 kg/d of CC, 2 kg/d soybean meal and 0.2 kg/d of a mineral-vitamin premix. From day 17 postpartum, herbage allowance was 11 and 17 kg pasture DM/cow/d for treatments with 8 and 4 kg of grain respectively. Supplements were thoroughly consumed by cows. Pasture intake averaged 12.2 and 9.1 kg DM/cow/d when cows consumed 4 and 8 kg of grain respectively. At day 40 postpartum, milk FA composition was determined by GLC. The model used included corn genotype, corn level and interaction. Significant genotype × corn level interaction was not detected. The concentration of short (4.09 g/100g FA), medium (37.81) and long chain (50.26) FAs were not affected. The concentration (g/100g FA) of the hypercholesterolemic fraction of milk fat (C12:0, 2.01; C14:0, 7.84 and C16:0, 22.97) and the atherogenicity index of milk (1.66) were not affected. Concentration of vaccenic acid (VA, trans-11 C18:1) in milk fat resulted higher ($P<0.01$) when cows consumed 4 kg/d (3.17 g/100g FA) instead of 8 kg/d of corn grain (2.78 g/100g FA). Conjugated linoleic acid (CLA, 9c, 11t C18:2) tended ($P<0.08$) to be higher when cows consumed 4 kg/d (1.03 g/100g FA) instead of 8 kg/d (0.94 g/100g FA) of corn grain. The higher concentration of VA (+ 0.39 g/100 g FA) and cis-9, trans-11 C18:2 (+ 0.09 g/100 g FA) at the lower level of corn grain were probably explained by the higher pasture intake and pasture/corn grain ratio in the total diet. Supplementary HOC feeding did not induce changes in milk fatty acid profile of grazing dairy cows when pasture intake represented 50.1 to 69.5 % of total DMI.

Key Words: High Oil Corn, Conjugated Linoleic Acid, Grazing Dairy Cows

T215 Effects of dietary docosahexaenoic acid and free linoleic acid supplementation on fatty acid ratio in milk fat from dairy cows. S. J. Liu, J. Q. Wang*, D. P. Bu, S. Liang, L. Liu, H. Y. Wei, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of this study was to evaluate fatty acid ratio in milk and milk composition from dairy cows supplemented with dietary docosahexaenoic acid (DHA) and free linoleic acid (LA). Four dairy cows with ruminal, ileac and duodenal fistulas were randomly assigned to control (CK, without additional oil supplement) or basal diet with 2.45% LA (LA), 2.45% LA plus 0.45% DHA (LA + DHA) and 0.45% DHA (DHA) in a 4 × 4 Latin square with 12-wk durational periods. Milk samples were collected on d 20 and d 21 of each experimental period and pooled for each animal. Pooled milk samples were analyzed milk composition and milk fatty acid profiles. Separation of fatty acids was achieved by gas chromatography. All data were analyzed using the MIXED procedure of SAS 8.2. The significance was declared at $p < 0.05$. Compared with CK, milk yield and milk fat content decreased when DHA was supplemented, but they did not differ among four treatments ($P>0.05$). Tricosanoic acid content of milk fat in DHA treatment increased, while total saturated fatty acid concentration did not change. In contrast to CK, total polyunsaturated fatty acid was improved by 100% in milk fat from combinational addition of LA and DHA ($P < 0.05$). In addition, saturated fatty acids to unsaturated fatty acids ratio in milk fat decreased ($P < 0.05$) from 3.18 in CK to 1.24 in LA treatment, while monounsaturated to polyunsaturated fatty acid ratio decreased ($P < 0.05$) from 5.94 in CK to 3.00 in DHA treatment. Taking together, our study indicated that fatty acid ratio was changed by dietary LA and DHA supplementation.

Key Words: Docosahexaenoic Acid, Free Linoleic Acid, Milk Fat

T216 Effects of rumen-protected fat feeding on glucose metabolism in high-yielding dairy cows. H. M. Hammon*, A. K. Langhof, K. Duske, F. Schneider, and C. C. Metges, *Research Institute for the Biology of Farm Animals (FBN), Dummerstorf, Germany.*

In dairy cows, feeding rumen-protected fat (RPF) influences milk production by increasing dietary energy density but at the same time, affects glucose metabolism. As glucose availability is important for milk production, the present study has investigated effects of RPF feeding on glucose metabolism in high-yielding dairy cows. Dairy cows (98 DIM; 2nd lactation) were fed for four weeks either a diet containing 5.6 % RPF with Ca-soaps mainly of C16:0 and C18:1 (F) or a control diet (C) based on corn starch (n=9 per group). Feed intake and milk yield were measured daily. Blood samples were taken once a week to measure plasma triglyceride (TG), NEFA, glucose, insulin, and glucagon concentrations and during a glucose tolerance test (GTT; 1 g/kg BW^{0.75} i.v.) after 12 h without food at the end of the study. Areas under the concentration curves for glucose and insulin were calculated. After slaughtering, liver samples were collected for quantification of mRNA levels of pyruvate carboxylase (EC 6.4.1.1), cytosolic phosphoenolpyruvate carboxykinase (EC 4.1.1.32), and glucose 6-phosphatase (G6-Pase; EC 3.1.3.9) by real-time RT-PCR. Data were analyzed using the Mixed Model or GLM of SAS, respectively, with diet and time or only diet as fixed effects. DMI, but not energy intake was slightly lower ($P < 0.05$) in F than C and plasma concentrations of TG and NEFA were higher ($P < 0.05$) in F than C. Plasma insulin concentrations decreased ($P < 0.05$), but the glucagon to insulin ratio increased with RPF-feeding.

During GTT, basal glucose concentrations were lower ($P < 0.05$) and basal glucagon concentrations tended to be higher ($P < 0.1$) in F than C. Hepatic mRNA levels of G6-Pase mRNA were lower ($P < 0.05$) in F than C and were positively related ($P < 0.01$) to basal plasma glucose. Feeding RPF did not affect milk yield, but reduced basal plasma glucose and hepatic gene expression of G6-Pase that might affect glucose availability for milk production.

Key Words: Dairy Cow, Fat Feeding, Glucose Metabolism

T217 Feeding rumen-protected fat (RPF) during the dry period: Effects on milk production and glucose metabolism in high-yielding dairy cows. H. M. Hammon*, K. Duske, A. K. Langhof, F. Schneider, H. M. Seyfert, and C. C. Metges, *Research Institute for the Biology of Farm Animals (FBN), Dummerstorf, Germany.*

The objective of the study was to determine effects of rumen-protected fat (RPF) in diets during late lactation and dry period on milk production and glucose metabolism after parturition in high-yielding dairy cows. Cows ($n=18$) were divided into 2 feeding groups 12 wk before expected calving and were fed either starch-based control diets (SD) or diets containing 3–5% RPF (FD) during late lactation (wk -12 to -9) and during far-off (wk -8 to -4) and close-up (wk -3 to -1) dry period. Diets were calculated to be isonitrogenous and isoenergetic. After parturition, all cows received a starch-based diet up to 98 DIM. Feed intake and milk yield were recorded daily. Plasma concentrations of glucose, NEFA, insulin, and glucagon were measured in blood samples taken at selected d before and after calving. Liver biopsies were taken 10 d before and at 1, 10, 28, and 95 d after calving to measure glycogen and fat content and mRNA levels of pyruvate carboxylase (PC, EC 6.4.1.1), cytosolic phosphoenolpyruvate carboxykinase (PEPCK; EC 4.1.1.32) and glucose 6-phosphatase (G6-Pase; EC 3.1.3.9). Data were analyzed by the Mixed Model of SAS with diet and time as fixed effects. DMI was higher ($P < 0.05$) during the far-off period in SD than FD. Milk yield was higher ($P < 0.05$) in SD than FD. Plasma glucose concentrations were lower ($P < 0.05$) in FD than SD during transition to lactation. Plasma glucagon tended to be higher ($P < 0.1$) in FD than SD before parturition. In liver, glycogen content decreased and fat content as well as PC, PEPCK and G6-Pase mRNA levels increased with onset of lactation, irrespective of prepartum feeding. PC mRNA levels were positively related to fat, but negatively related to glycogen content ($P < 0.05$, resp.). Feeding RPF during the dry period decreases milk yield and plasma glucose around parturition, but barely affect hormonal levels as well as hepatic glucose and lipid metabolism.

Key Words: Dairy Cow, Prepartum Feeding, Glucose Metabolism

T218 Influence of sunflower oil supplementation on milk conjugated linoleic acid and mammary tissue stearoyl-CoA desaturase, lipoprotein lipase, and acetyl-CoA carboxylase gene expression in Xinong Saanen goats. D. P. Bu¹, J. Q. Wang^{*1}, H. Y. Wei¹, L. Y. Zhou¹, and J. J. Loo², ¹*Institute of Animal Science, Chinese Academy of Agriculture Sciences; State Key Laboratory of Animal Nutrition, Beijing, China,* ²*University of Illinois, Urbana.*

This study examined the effect of supplemental sunflower oil (SFO) on milk fat trans-11-18:1 (vaccenic acid; VA) and cis-9 trans-11 conjugated linoleic acid (CLA) concentration and mRNA expression of stearoyl-

CoA desaturase (*SCD*), lipoprotein lipase (*LPL*), and acetyl-CoA carboxylase (*ACACA*) in mammary tissue from lactating goats. Twelve Xinong Saanen goats (36 ± 3 DIM) were fed a basal diet (CTL, 50:50 forage:concentrate) or CTL supplemented with 4% SFO in a cross-over design with 4 wk experimental periods. Mammary percutaneous biopsies were collected on d 27 of each experimental period. DMI (1.76 vs 1.84 kg/d) and milk yield (1.35 vs 1.63 kg/d) were greater ($P < 0.05$) with SFO. However, SFO resulted in lower ($P < 0.05$) milk fat % (3.70% vs. 4.33%). Concentrations of VA (1.7% to 5.7% of total fatty acids) and cis-9 trans-11 CLA (0.55% to 1.4%) in milk fat increased by ~3-fold due to feeding SFO. The mRNA abundance of *LPL* and *ACACA* in mammary tissue was 75% and 60% greater ($P < 0.05$) with SFO but *SCD* mRNA was 26% lower ($P < 0.05$). Increased supply of dietary lipid might explain greater *LPL* mRNA in mammary from goats fed SFO. Ruminant biohydrogenation of SFO likely resulted in production of trans-18:1 and/or CLA isomers that might have reduced *SCD* mRNA abundance. Despite the negative effect on *SCD* by supplemental SFO, greater supply of VA ensured that cis-9,trans-11-CLA synthesis in mammary tissue increased.

Key Words: Lactation, Milk Fat, Lipogenesis

T219 Feed intake, apparent digestibility, and milk composition of dairy cows fed whole flaxseed or/and Ca-salts of flaxseed oil. C. Côrtes^{*1}, D. C. Silva^{1,2}, R. Kazama^{1,2}, N. Gagnon¹, C. Benchaar¹, G. T. Santos², L. M. Zeoula², and H. V. Petit¹, ¹*Agriculture and Agri-Food Canada, Sherbrooke, Quebec, Canada,* ²*Universidade Estadual de Maringá Brazil and CNPq Brazil, Maringá, Paraná, Brazil.*

The objective of this study was to examine the effects of dietary whole flaxseed and Ca-salts of flaxseed oil on feed intake, apparent digestibility, and milk composition of dairy cows. Four lactating Holstein cows (BW = 602 kg; DIM = 64 d) fitted with ruminal cannulae were used in a 4 x 4 Latin square. Each experimental period consisted of 21 d of adaptation and 7 d of data collection. Cows were milked twice a day at 0730 and 1930 h. All cows were fed twice daily (0830 and 1530 h) for ad libitum intake (10% refusals). Four total mixed rations were formulated and contained no flaxseed product (CO), 5% (DM basis) whole flaxseed (WF), 2% Ca-salts of flaxseed oil (CF), or a mixture of 2.5% whole flaxseed and 1% Ca-salts of flaxseed oil (MF). Dry matter intake, apparent digestibility of DM, and milk composition were analyzed using the MIXED procedure of SAS. Tukey-Kramer multiple-comparison test was applied to separate means. Significance was declared at $P < 0.05$. Dry matter intake (DMI) and apparent digestibility of DM (DMD) were not affected by treatments. Milk yield and milk concentrations of fat and lactose were similar among treatments. Milk protein percentage tended ($P = 0.09$) to be higher for cows fed WF than for those fed CF (3.32% vs. 3.17%), however milk protein yield was similar ($P = 0.15$). This study suggests that feeding whole flaxseed or/and Ca-salts of flaxseed oil have no negative effect on cow performance.

Table 1.

Key Words: Dairy Cows, Flax Product, Milk/Digestibility

T220 Effect of dietary flax products on concentration of the mammalian lignan, enterolactone, in ruminal fluid, plasma, milk, and urine of dairy cows. N. Gagnon^{*1}, C. Côrtes¹, D. C. da Silva^{1,2}, R. Kazama^{1,2}, G. T. dos Santos², L. M. Zeoula², and H. V. Petit¹, ¹*Agriculture and Agri-Food, Sherbrooke, QC, Canada*, ²*Universidade Estadual de Maringá, Brazil, CNPq Brazil*.

Four rumen fistulated lactating Holstein cows were used in a 4 × 4 Latin square design to study the effects of dietary addition of flax products on concentration of the mammalian lignan, enterolactone (EL) in ruminal fluid, urine, plasma, and milk. All cows were fed the same diet for ad libitum intake. Flax hulls (1800 g/d) and flax oil (400 g/d) were placed in the rumen three times daily and/or infused for 23 h a day in the abomasum. Treatments were: 1) oil and hulls placed in the rumen + abomasal infusion of water (RUM); 2) oil and hulls infused in the abomasum (ABO); 3) oil infused in the abomasum and hulls placed in the rumen (ABORUM); and 4) oil placed in the rumen + hulls infused in the abomasum (RUMABO). Water was the carrier for infusion of hulls (ABO and RUMABO) and the same amount of water was infused in the abomasum when hulls were placed in the rumen (RUM and ABORUM). Experimental periods consisted of 21 d with 15 d of adaptation. Milk samples were collected twice daily from d 16 to 20 and pooled for lignan assay. Blood was withdrawn from the jugular vein 6 h postfeeding on d 20. Rumen contents were sampled on d 21 at 0, 2, 4, and 6 h after the morning meal and urine samples were taken 2 h postfeeding. Concentration of EL in ruminal fluid was determined at 0 h (baseline) and on samples pooled for 2, 4, and 6 h. Concentrations of EL in urine ($p < 0.001$), milk ($p = 0.001$), and plasma ($p = 0.04$) were significantly higher when hulls were placed in the rumen than when they were infused in the abomasum. Adding flax oil in the rumen or abomasum had no effect on EL concentrations in urine, milk, blood, and rumen. This study suggests that the rumen plays an important role in the metabolism of flax lignans and that urine and milk are good indicators of the mammalian lignan, EL, metabolism in dairy cows fed flax products.

Key Words: Enterolactone, Rumen, EIA

T221 Effect of four levels of lauric acid on ruminal protozoa, milk production and composition in dairy cows. A. P. Faciola^{*1}, G. A. Broderick², A. N. Hristov³, and J. A. Pires¹, ¹*University of Wisconsin, Madison*, ²*U. S. Dairy Forage Research Center, Madison, WI*, ³*Penn State University, University Park*.

Ruminal protozoa (RP) are the main contributors to bacterial protein turnover in the rumen; therefore, reducing RP may improve N utilization.

Medium-chain saturated fatty acids such as lauric acid (C12:0) have been shown to suppress RP. We tested lauric acid (LA) as a practical defaunating agent and assessed the effects of partial defaunation on N utilization, fermentation patterns, nutrient digestibility, milk production and milk composition. Forty-eight Holstein cows (8 fitted with ruminal cannulae) were blocked by DIM into 12 blocks of four cows (2 blocks of cows with ruminal cannulas) and randomly assigned within blocks to four balanced 4 X 4 Latin square diet sequences. The basal diet contained (DM basis) 29% alfalfa silage, 36% corn silage, 7.5% high-moisture corn, 6% soybean meal, 8% dry molasses, 12% ground corn, vitamin and mineral premix, 15.5% CP and 30% NDF. Diets differed in LA content: A) zero, B) 240, C) 480, and D) 720g/d. Each experimental period consisted of 21d for adaptation plus 7d for data collection. Data were analyzed using proc mixed in SAS. The results are reported in the table below. LA was effective in reducing RP; however, it also decreased DMI. LA fed at 240 g/d did not reduce yield of milk or FCM; however, higher levels were detrimental to milk production and composition.

T222 Effects of differential supplementation of calcium salts of fatty acids (CSFAs) on dairy cows. F. T. Silvestre^{*}, T. S. M. Carvalho, J. E. P. Santos, C. R. Staples, and W. W. Thatcher, *University of Florida, Gainesville*.

Effects of CSFAs (Virtus Nutrition) on milk yield (MY), cervical discharge (CD), metabolic status, pregnancy rates (PR) and losses (PL) at 1st and 2nd AI were evaluated. Cows were randomly allocated to diets at -27 days postpartum (dpp; PO [Palm oil, 47% C16:0] vs SO [Safflower oil, 64% C18:2n-6]) and fed until 30dpp when within each diet further allocated to either PO or FO (Fish oil, 11% of C20:5n-3 + C22:6n-3) and fed until 160dpp. CSFAs were fed at 1.5% of the diet. Contrasts were PO vs SO, PO vs FO and interaction. CD (clear/flacks, mucopurulent and purulent) was evaluated at 8dpp (n=1118). Plasma samples were collected 3x/weekly from 0 to 35dpp for metabolite measurements (n=32). At 43dpp cows initiated a presynch comprised of PGF_{2α} 14d apart, followed by Ovsynch 14d later for 1st AI. All cows received a CIDR device at 18d after 1st AI, followed in 7d by CIDR removal and GnRH injection. At 32d after 1st AI, cows were ultrasounded (US) for pregnancy. Non-pregnant cows received PGF_{2α}, GnRH 56h later, a 2nd AI at 72h, and US at 32d after 2nd AI. PL was evaluated at 60d of pregnancy. Plasma progesterone at 2nd PGF_{2α} and

start of Ovsynch determined cyclicity. Plasma NEFAs, BHBA, glucose, BUN, and frequency of CD did not differ between PO and SO cows. Cyclicity was not affected by diets (80%, n=1117). PR for 1st AI at 32d (37.4%, n=1055) and 60d (33.3%, n=1048) was not affected by diets, but PL was lesser ($P<0.05$) in FO (6.3%, n=190) vs. PO (13.6%, n=198). PR for 2nd AI was higher at 32d ($P<0.05$) and 60d ($P<0.05$) in FO (36.9% [n=295], 34.4% [n=293]) vs. PO (27% [n=309], 23.7% [n=303]), respectively; PL was not affected by diets (6.5%, n=185). Overall PR was 54.5% (n=1084) at 32d and higher ($P<0.05$) at 60d in the FO (52.8%, n=528) vs. PO (45.4%, n=541). Overall PL was lesser ($P<0.05$) in FO (6%, n=297) vs. PO (12%, n=279). Monthly MY was greater ($P<0.02$) in SO (41.9kg, n=532) vs. PO (41.2kg, n=534). Feeding differential CSFAs during transition and breeding periods can benefit fertility and milk production of dairy cows.

Key Words: Fatty Acids, Reproduction, Milk Yield

T223 Effects of rumen protected CLA supplemented to dairy cows in late pregnancy and early lactation on milk yield and some milk features. G. Bertoni*, E. Trevisi, M. G. Maianti, and A. Gubbiotti, *Istituto Di Zootecnica, Universita' Cattolica Del Sacro Cuore, Piacenza, Italy.*

Dairy cows in the transition period suffer for the negative energy balance (NEB), which causes some metabolic diseases, as well as lower fertility. Conjugated linoleic acid (CLA) is quoted to reduce milk fat content and therefore the energy output that could alleviate the NEB. Nevertheless, the great change of milk composition could have some consequences on the creaming activity and overall on the cheese making traits, both of great importance in Italy. To evaluate the effects of CLA on milk traits, 8 dry cows (kept in a tied barn) were divided in two homogeneous groups receiving 20 g/d of rumen protected CLA (equivalent to 100 g of Luta-CLA® 20P, BASF, Germany) or 100 g/d of a mixture of rumen protected fats. Supplementation began approximately 30 days before calving and lasted 28 days after it. Besides daily milk yield, morning milk samples were taken two times a week for the first 3 months of lactation. Milk yield was numerically lower (45 vs 47 kg/d at 28th DIM) in the CLA cows, but the main results during the first month of lactation are those regarding milk composition and its technological traits: CLA has reduced milk fat content (2.8 vs 3.6%, $P<0.05$ at 28th DIM) and its creaming activity (61 vs 68%, N.S., average of 3rd and 4th week). On the contrary, the milk protein content of CLA supplemented cows was slightly higher and the curd firmness was increased (26 vs 21 mm, N.S., average of 3rd and 4th week) despite a similar clotting time. It is worthwhile that one-two weeks after the end of CLA supplementation, the above differences disappeared. The overall results suggest that CLA feeding at the end of pregnancy and in first month of lactation can contribute to lower the milk energy output. Nevertheless, the reduction of milk fat content could impair the fat creaming activity, which is essential for some typical cheeses (i.e. parmesan), although the short period of CLA use could minimize the risk.

Key Words: Conjugated Linoleic Acid, Milk Traits, Transition Period

T224 Energy balance indexes and blood changes of dairy cows supplemented with rumen protected CLA in late pregnancy and early lactation. E. Trevisi*, A. Ferrari, F. Piccioli-Cappelli, and G.

Bertoni, *Istituto Di Zootecnica, Universita' Cattolica Del Sacro Cuore, Piacenza, Italy.*

Transition dairy cows suffer for the negative energy balance (NEB) and for inflammatory-like conditions. Both can negatively affect DMI and incidence of metabolic diseases as well as fertility. Conjugated linoleic acid (CLA) is quoted to reduce milk fat content and hence the severity of NEB, but also to attenuate inflammatory phenomena. To evaluate the effects of CLA on DMI, BCS and metabolic profile in the transition period, 8 dry cows (kept in a tied barn) were divided in two homogeneous groups receiving 20 g/d of rumen protected CLA (equivalent to 100 g of Luta-CLA® 20P, BASF, Germany) or 100 g/d of a mixture of rumen protected fats (CTR). Supplementation began approximately 30 days before calving and lasted 28 days after it. Besides health status, daily DMI and milk yield, cows were checked weekly for body weight and BCS. Moreover, blood samples were taken two times a week when dry and for the first 90 days in milk (DIM), but daily 10 days before and after calving. The results suggest that a supplement of CLA improves the blood indexes of energy metabolism: glucose, NEFA and BHB (0.8 vs 1.6 mmol/l of CTR at 1-5 DIM; $P<0.01$). Moreover, it reduce the urea level, lower at 23-27 DIM (4.0 vs 5.2 mmol/l; $P<0.1$). The consequences of inflammatory conditions, that typically occur at calving time, appear also smaller after calving: e.g. CLA cows have showed higher levels of some negative acute phase proteins like lipoprotein as cholesterol (5.0 vs 4.3 mmol/l, $P<0.05$ at 20-30 DIM), albumin (36.3 vs 34.4 g/l, $P<0.1$ in the first 28 DIM) and thiol groups (less important reduction after calving). These changes agree with some other results: slightly lower rectal temperature around calving, higher DMI (19.3 vs 18.2 kg/d on average in first 28 DIM) and slightly lower reduction of body weight and BCS (0.29 vs 0.37 points). Thus CLA supplementation seems to improve some aspects of dairy cows transition: e.g. energy balance and inflammatory conditions.

T225 Effect of different levels of fish oil and canola oil on milk production and composition of high producing Holstein dairy cows in early lactation. T. Vafa*, A. Naserian, A. Heravi Moussavi, M. Danesh Mesgaran, and R. Valizadeh, *Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran.*

The aim of this study was to evaluate the effect of different levels of canola oil or/and fish oil supplementation on dry matter intake (DMI), and milk production and composition in early lactating Holstein dairy cows. Eight multiparous early lactation Holstein cows (42±12 DIM, 40±6 kg daily milk yield) were fed a total mixed ration supplemented with either 0% oil (Control), 2% canola oil (CO), 2% fish oil (FO), or 1% canola oil + 1% fish oil (CoFo), according to a double 4 × 4 Latin square design. Each period lasted 3 wk; experimental analyses were restricted to the last week of each period. Diets were formulated to be isonitrogenous using NRC 2001. Cows were housed in tie stalls and fed the TMR two times a day to allow 5 to 10% orts (as-fed basis). Cows were milked 3 times per day and yields were recorded. Milk samples were collected from each milking on 1 d per wk and composited for analysis of fat, protein, and lactose. Data were analyzed as a replicated 4 × 4 Latin square using the GLM procedure of SAS (2001). The model included effects caused by diet, period, and cow. Least squares means are reported throughout, and significance was declared at $P<0.05$. Diet had no effect on DMI (24.92, 25.60, 23.70, and 25.84 ± 0.79 kg/d; for control,

CO, FO, and CoFo, respectively). Milk production was similar among the groups (34.41, 34.15, 32.93, and 34.55 ± 0.84 kg/d, respectively). Milk fat content (2.87, 2.70, 2.45, and 2.89 ± 0.21%, respectively), milk protein content (2.88, 2.86, 2.92, and 2.89 ± 0.07%, respectively), and milk lactose content were all similar among the diets. The results of this study demonstrated that the canola oil or/and fish oil supplementation in the diet of early lactation cows had no apparent effect on the DMI, and milk production and composition.

Key Words: Dairy Cow, Canola Oil, Fish Oil

T226 Effects of degree of unsaturation of supplemental dietary fat on ruminal fermentation, nitrogen metabolism, and urea nitrogen recycling in dairy cows. T. Mutsvangwa*, G. N. Gozho, and D. Kiran, *University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

The objective of this study was to evaluate the effects of degree of unsaturation of supplemental dietary fat on ruminal fermentation, nitrogen metabolism, and urea-N recycling. Four Holstein cows (693 kg BW; 92 DIM) with ruminal cannulae were used in a 4 x 4 Latin square design with 21-d periods. Dietary treatments contained 0% supplemental fat (control), 3.52% canola oil, 3.52% tallow, and 1.76% canola oil + 1.76% tallow. Diets were offered twice per day as TMR made up of 55% forage and 45% barley-based concentrate. Nitrogen balance was measured from d 16 to d 20, with concurrent measurements of urea-N kinetics using a single dose intra-jugular infusion of [¹⁵N¹⁵N]-urea on d 16. Dry matter intake, milk yield and milk composition were not affected by fat supplementation; however, milk fat content tended to be lower ($P = 0.10$) for cows fed canola oil. Ruminal protozoa were 2.63 x 10⁵, 2.75 x 10⁵, 3.72 x 10⁵, and 2.82 x 10⁵ counts/ml for control, canola oil, tallow, and canola + tallow mixture, respectively. Protozoal counts were higher ($P = 0.03$) in cows receiving supplemental tallow compared to those fed the control diet. Ruminal pH, and concentrations of NH₃-N, and individual and total VFA were not affected by source of supplemental fat. Urea-N production (189.9, 178.4, 182.8, 182.3 g/d), and urea-N entering the GIT (185.3, 174.6, 180.0, 177.8 g/d) were similar for the control, canola oil, tallow, and canola + tallow diets, respectively. Fractional urea-N transfers were unaffected by treatment. Results show that the source of supplemental fat did not affect protozoa counts or change ruminal fermentation patterns and, consequently, had no impact on urea-N recycling.

Key Words: Dairy Cow, Urea Kinetics, Nitrogen Metabolism

T227 Influence of dietary fats on hepatic gene expression in transition dairy goats. A. Agazzi¹, G. Invernizzi^{*1}, A. Campagnoli¹, M. Ferroni¹, A. Galmozzi², M. Crestani², and G. Savoini¹, ¹*Department of Veterinary Science and Technology for Food Safety, Milan, Italy,* ²*Department of Pharmacological Sciences, Milan, Italy.*

The aim of the study was to evaluate the dietary fats influence on hepatic gene expression in transition dairy goats. Eighteen second parity alpine goats from wk 2 before to wk 3 after kidding were assigned to 1 of 3 dietary treatments: C (n=6) basal diet, FO (n=6) basal diet plus 47g/d of protected fish oil, PO (n=6) basal diet plus 47g/d of hydrogenated palm oil. Feed consumption, live body weight (BW), milk yield and composition were assessed weekly. Blood samples were collected on 15,

7, and 2d before, and 2, 7, 15, and 21d after kidding for ALAT, ASAT, NEFA, glucose, BHBA, and cholesterol content. Bioptic samples were obtained 7d before and 21d after kidding and analyzed for mRNA content of peroxisome proliferator-activated receptor- α (PPAR α), carnitine palmitoyltransferase I (CPT1), long chain acyl-CoA synthetase (ACSL), very-long-chain acyl-CoA dehydrogenase (ACADVL), acetyl-CoA carboxylase (ACC1) and malonyl-CoA decarboxylase (MCD) by real time Q-PCR. Data were analyzed by a mixed procedure of SAS. No effects were observed on BW, plasma metabolites and milk composition. Milk yield was increased in PO vs. C (3.65kg/d, 2.42kg/d; $P < 0.05$). Higher expression of CPT1 and ACADVL were detected in C vs. PO goats before kidding ($P < 0.05$), while on day 21 PO increased PPAR α expression as compared to C ($P < 0.05$), and increased ACSL values as compared to C and FO animals ($P < 0.01$). Hepatic gene expression in an intra-group analysis evidenced decreased values in C from pre to post kidding for ACADVL and ACSL ($P < 0.05$), while ACSL was significantly decreased after kidding in FO subjects ($P < 0.05$). No variations were evidenced in PO animals from dry period to lactation. Correlation analysis evidenced a negative feedback of PPAR α on cholesterol plasma content by 42% ($P = 0.03$). Results suggest different mechanism of action of dietary saturated and unsaturated fatty acids in transition goat on hepatic gene expression.

T228 Reproductive performance of cows fed rolled flaxseed on two commercial dairies. N. R. Bork^{*1}, G. P. Lardy¹, J. W. Schroeder¹, K. A. Vonnahme¹, P. M. Fricke³, K. B. Koch², M. L. Bauer¹, and K. G. Odde¹, ¹*North Dakota State University, Fargo, ND, USA,* ²*Northern Crops Institute, Fargo, ND, USA,* ³*University of Wisconsin, Madison.*

The objective of this field trial was to study the effects of supplementing early lactation dairy cows with rolled flaxseed on reproduction. We hypothesized that fatty acids in flaxseed, namely C18:3n-3, may improve reproductive performance of dairy cows. Conducted on 2 commercial dairies with cows naive to flaxseed, treatments consisted of either their existing early lactation ration (CON; n = 252) or a similar ration, equal in protein, energy and fat, re-formulated with rolled flaxseed (FLX; n = 339; 0.85 kg DM/d). Cows were assigned randomly to treatment upon leaving the fresh pen (approximately 10 d postpartum) within parity (primiparous, P or multiparous, M; P-CON, M-CON, P-FLX, M-FLX). Statistical analysis for conception rate data included all cows in the study, and was performed using a mixed model. Cow was the experimental unit and data were analyzed as a split plot with pen being the whole plot error term (random term was treatment by parity by farm). Statistical analysis for other reproductive parameters including all pregnant cows was performed with a categorical model using logistical regression. First and second-service analysis included 1422 AI services. First-service conception rates did not differ ($P = 0.27$) among treatments (P-CON = 46.8 ± 4.0%; M-CON = 34.3 ± 3.1%; P-FLX = 41.1 ± 3.1%; M-FLX = 30.0 ± 2.8%). Treatment did not interact ($P \geq 0.27$) with season of the year, breeding method (AI at estrus vs. Ovsynch and timed AI), or farm. Analysis of services per conception for pregnant cows (CON = 1.92 ± 0.12; FLX = 1.95 ± 0.12; $P = 0.87$), days to first insemination (CON = 76.6 ± 0.8; FLX = 73.9 ± 0.7; $P = 0.11$), and days open (CON = 113.5 ± 3.7; FLX = 109.9 ± 3.2; $P = 0.53$) included 591 cows and did not differ between treatments. We conclude that feeding 0.85 kg/d (DM basis) of flaxseed during early lactation does not affect reproductive performance of dairy cows.

Ruminant Nutrition: Methods, Models and Other

T229 Measurements of net portal flux of nitrogen (N) compounds in ruminants: First step of a meta-analysis. R. Martineau^{*1}, I. Ortigues-Marty², J. Vernet², and H. Lapierre¹, ¹*Agriculture and Agri-Food Canada, Sherbrooke, Quebec, Canada*, ²*Institut National de la Recherche Agronomique, Theix, St Genès Champanelle, France*.

A first step in developing mechanistic models of nutrient use by ruminants is to accurately predict net portal absorption (NPA) of nutrients in relation with feed intake and composition. From the FLORA database (FLux of Nutrients through the Organs of Ruminant Animals; *Reprod. Nutr. Dev.* 46:527-546), all the studies simultaneously reporting apparently digested N and NPA of NH₃, urea, and AA were selected (n = 33 publications; 40 cattle and 71 sheep treatments). It was hypothesized that differences between inputs (digested N + urea-N uptake) and outputs (NH₃-N + total AA-N) across the portal-drained viscera, called NPA residuals, should average 0 assuming that unaccounted N (e.g. salivary N, peptides, nucleic acids) sums to 0. The NPA residuals [g N/(d•kg BW)] were different from 0 at the 95% confidence level (CL). Single corrections were applied to standardize the reported observations: NPA of urea-N and NH₃-N on plasma were corrected to a blood basis (hematocrit; 25%: sheep; 27%: cattle); NPA of NH₃-N measured with the Berthelot reaction were corrected to a glutamate dehydrogenase (GDH) basis (× 1.38); and finally, NPA of α-amino-N were corrected to a total AA-N basis (× 1.35). With all corrections applied, NPA residuals were not different from 0 but variability did not improve. These results suggest that before performing a meta-analysis on reported NPA, some corrections would need to be applied to better reflect the biology and chemistry of the nutrients absorbed.

Table 1.

NPA residuals (n = 111), g N/(d•kg BW)	Mean	SD	Min	Max	95% CL
No corrections	0.092	0.118	-0.31	0.44	± 0.022
With all corrections	-0.023	0.132	-0.39	0.33	± 0.025
When single corrections are made:					
- urea-N (blood basis; 22 corrections)	0.099	0.121	-0.31	0.52	± 0.023
- NH ₃ -N (blood basis; 21 corrections)	0.073	0.135	-0.34	0.39	± 0.025
- NH ₃ -N (GDH basis; 99 corrections)	0.036	0.120	-0.39	0.38	± 0.023
- AA-N (total AA-N basis; 81 corrections)	0.047	0.116	-0.31	0.38	± 0.022

T230 Diversity of rumen bacteria as revealed by multivariate analysis of 16S rDNA gene sequences. K. L. Liu¹, J. Q. Wang^{*1}, D. P. Bu¹, S. G. Zhao^{1,2}, H. Y. Wei¹, and L. Y. Zhou¹, ¹*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*, ²*Gansu Agricultural University, Gansu, China*.

To improve our understanding of the composition of rumen microbial community and factors may affect its composition, 2023 16S rDNA

sequences with length >1200 bp were retrieved from Ribosomal Database Project II and then subject to multivariate analysis. Using 97% minimum similarity as the threshold for any pair of sequences in a operational taxonomic unit (OTU), a total of 915 bacterial OTU were identified, among them 90% represented sequences from yet uncultured species. The terminal Chaol richness estimates suggested that the rumen microbial community could consist of 1720 species. Land distribution analysis by fLAND software indicated that *Firmicutes* and *Bacteroides* were the dominant groups in rumen, accounting 91% of the total taxa. *Cytophaga-Flavobacterium-Bacteroides* (CFB) bacterium from rumen appeared to be the farthest away from the common ancestor of the division, suggesting a strong host selection pressure and co-evolution. To investigate factors may affect the composition of rumen microbial community, six 16S rDNA libraries which totaled 905 sequences were collected from database. Principal component analysis (PCA) and hierarchical clustering were performed by UniFrac. On PCA plots, libraries from cows clustered together and separated clearly with that from castrated cattle, indicating host sex as the most important factor shaping the composition of rumen bacterial community. In addition, dietary forage: concentrate ratio was identified as the second important factor. Acknowledgement: Research funded by Ministry of Science and Technology (2006BAD04A08).

T231 Screening of ureases from a bovine rumen metagenomic library. K. L. Liu¹, J. Q. Wang^{*1}, D. P. Bu¹, S. G. Zhao^{1,2}, Y. X. Zhu³, H. Y. Wei¹, L. Y. Zhou¹, and Z. Y. Dong³, ¹*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*, ²*Gansu Agricultural University, Gansu, China*, ³*State Key Laboratory of Microbial Resources, Institute of Microbiology, Chinese Academy of Sciences, Beijing, China*.

Lack of sufficient protein forage has promoted the utilization of urea as a protein supplement in ruminant forage, which could be hydrolyzed by urease secreted by ureolytic bacterium in rumen. To get more information about rumen urease gene sequence, gene cluster structure, protein structure and function, rumen contents of a Holstein cow were collected and used as raw materials to construct a metagenomic library. A series of ways to clean bacterium cells and make plugs were developed, and high molecular weight DNA fragments with the size in excess of 2 Mb were finally extracted. After digestion with *Hind* III and separated by pulse field gel electrophoresis, DNA fragment ranged from 50-100 kb were collected and ligated to pCC1BAC vector to construct the library. The metagenomic library consisted of 153, 600 clones with the total capacity estimated to be 857 Mb. To screen ureolytic active clone from the library, a urease screen agar that take advantage of the visible phenotype of urease activity was employed. Eight clones were identified as ureolytic positive. Restrictive digestion analysis and enzymatic analysis suggested a high level of diversity existed among these clones. Further study addressing urease gene sequence, gene cluster structure, protein structure and function characterization is currently on the way. Acknowledgement: Research funded by Ministry of Science and Technology (2006BAD12B03).

T232 Effect of fatty acids and malic acid on total gas production and methane release by batch culture. L. Liu, J. Q. Wang*, D. P. Bu, S. J. Liu, K. L. Liu, H. Y. Wei, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of this study was to determine the effect of different concentrations of malic acid (0, 5, 10 mM) and degree of unsaturation of the fatty acids (stearic acid-SA; oleic acid-OA; linoleic acid-LA; linolenic acid-LNA) on total gas production and methane release using an automated cumulative gas production estimation system *in vitro*. The substrate (500 mg) contained alfalfa hay and corn (50:50). Rumen fluid was collected from two ruminally fistulated lactating cows. Substrate was incubated in 60 mL fermentation fluid (rumen fluid to McDougall buffer ratio was 1:2). Individual fatty acids were dissolved in 0.5 mL ethanol and added in fermentation fluid at 3.5% of diet DM. Each treatment contained four flasks. Incubations were carried out in batch cultures at 39°C for 36 h two times at a two-week intervals. The gas samples were collected by gas collecting bags and then methane content determined with a gas chromatograph. The results showed that total gas production and methane release decreased ($P < 0.01$) when the degree of unsaturation of the fatty acids increased. In contrast, total gas production increased ($P < 0.01$), whereas methane release decreased ($P < 0.01$) with malic acid level increment. The interaction of fatty acids and malic acid were characterized by decreased ($P < 0.01$) methane release. Results suggested that addition of unsaturated fatty acids and malic acid could inhibit methane release, and fatty acids-mediated depression in methane release was associated with the degree of unsaturation of the fatty acids.

Acknowledgement; Research supported by Ministry of Science and Technology (2006BAD12B03).

T233 The use of simultaneous models for estimate in vivo nutrient digestibility of alfalfa hay and barley grain. H. Jahani-Azizabadi, M. Danesh Mesgaran*, R. Valizadeh, and H. Nasirimoghadam, *Ferdowsi University of Mashhad, Mashhad, Iran.*

In vivo total tract nutrients digestibility [Dry matter (DM), Crude protein (CP), Organic matter (OM) and Digestible organic matter in dry matter (DOMD)] from alfalfa hay and barley grain were evaluated using a direct

calculation (difference method) or simultaneous models. Eight Balochi lambs (49.5 ± 3.5 kg, body weight) were fed experimental diets made of four alfalfa hay: barley grain ratio (DM basis) as 1.0:0.0, 0.75:0.25, 0.50:0.50 and 0.25:0.75 in a 4×4 repeated Latin squares design. Each period consisted of 28 d with 7 d for feces collection. Nutrient concentrations of feed samples and feces were determined using standard procedures. For direct calculation, the data of first and third diets were used. Simultaneous models were provided using Polynomial regression models of SAS. Apparent DM, CP, OM and OMD digestibility of alfalfa hay and barley grain calculated by direct calculation were 0.61& 0.78, 0.74 & 0.69, 0.64 & 0.80 and 0.59 & 0.79, respectively. When simultaneous models were considered, a linear equation was significant ($P < 0.01$) for all nutrients. Therefore, the nutrient digestibilities of the feed samples were determined using this model (Table 1). Results of the present study might suggest that the simultaneous models appeared to give reasonable estimate rather than direct calculation.

Table 1. Simultaneous models and mean nutrient digestion coefficients of barley grain and alfalfa hay

T234 In situ ruminal degradability of soybean and sunflower by-products. R. H. de T. Buschinelli de Goes*¹, R. de C. M. Tramontini², G. D. de Almeida², S. T. Cardim², J. Ribeiro², L. A. de Oliveira², and F. Morotti², ¹Universidade Federal da Grande Dourados, Dourados, MS, Brazil, ²Universidade Estadual de Maringá, Umarama, PR, Brazil.

The ruminal degradation of the dry matter (DM) and crude protein (CP) of the sunflower and soybean crushed, originating from of the cold compressing for the extraction of vegetable oil, was evaluated by the in situ technique, using three rumen fistulated zebu steers at pasture. The foods were grounded through 2mm screen and incubated directly in the rumen in nylon bags, in the times of 72, 48, 36, 24, 18, 12, 06, 03, and 0 hour. The potential degradation (PD) for the disappearance of DM, in the different incubation times were adjusted by a no-linear regression by Gauss-Newton's method, according to the equation $PD = A+B*(1-\exp(-ct))$, being PD = potential degradability, A = soluble fraction, B = potentially degradable fraction, c = degradation rate of the fraction B, and t = time of incubation. The effective degradability was calculated by the formula: $ED=a+(b.c)/(c+k)$, where k = rate of passage of 5%/h. The sunflower crushed contents a dry matter (DM) of 90.0% and crude protein (CP) of 22.0%, the soybean crushed presented 90.5% DM and 53.0% CP. The potentially degradable fraction of DM by the sunflower crushed was of 40.2% and 26.2% for to DM and CP, what provided medium ruminal degradation. The effective degradability for

the sunflower crushed was of 51.0% and 38.7%, with a soluble fraction of 22.4% and 29.9%, for to DM and CP. The soybean crushed presented soluble fraction of 36.6% and 20.7%, for to DM and CP, with a effective degradability of 72.5% and 69.9%, with a potentially degradable fraction of 66.2% and 81.5%, for DM and CP respectively. The sunflower crushed presented low values for the degradation rate of the fraction "b" of 2.5%/h for CP due to the high oil tenor (10%) and the high value of ADF (20.8%) that might have interfered in the degradation of this food, while the soybean crushed presented medium values of 7.5%/h for the degradation rate of CP. The ruminal degradation of the nutrients by the studied foods presented low soluble contents for the sunflower crushed different from the soybean crushed that presented extensive degradations rates for the insoluble fraction, that the sunflower crushed.

T235 Rumen phosphorus metabolism in sheep. R. S. Dias¹, T. Soares², R. M. P. Pardo³, J. C. Silva Filho³, D. M. S. S. Vitti², E. Kebreab⁴, and J. France¹, ¹University of Guelph, Guelph, Ontario, Canada, ²Centro de Energia Nuclear na Agricultura, Piracicaba, Sao Paulo, Brazil, ³Federal University of Lavras, Lavras, Minas Gerais, Brazil, ⁴University of Manitoba, Winnipeg, Manitoba, Canada.

The objective of this work was to study the effect of different levels of P on its presence in saliva and the rumen. Moreover, other factors such as specific activity of P in rumen, saliva and plasma were assessed to provide information on P metabolism in ruminants. Twelve Santa Inês male sheep, weighting 30 kg were fed a basal diet comprising roughage, concentrate mixture (cassava flour, soya bean meal, and urea) and a mineral mixture. The treatments consisted of the basal diet supplemented with different amounts of monoammonium phosphate to provide 0, 2, 4 and 6 g P/animal/d, representing treatments T0, T2, T4 and T6, respectively. The % P in dry matter was considered highly deficient, deficient, adequate and excessive respectively. Animals were injected with ³²P and thereafter samples of blood were collected over 7 d, and rumen fluid and saliva samples were collected 96 and 144 h after injection. Phosphorus intake affected P in ruminal fluid, whereas P in saliva was not affected. The values for ruminal P turnover and endogenous entry calculated from P measurements were all affected by P intake. The percentage of endogenous P entering the rumen decreased with increased levels of P intake indicating lower endogenous P secretion for higher dietary P. The specific activity of P in saliva, rumen fluid and plasma were also all affected by P intake, and were statistically different between treatments, though they were numerically similar when compared with each other. The possibility of presence of an endogenous ruminal P source besides saliva is discussed (Smith et al. 1955). It is concluded from the results that P in ruminal fluid is maintained at adequate levels to attend the needs of micro-organism regardless of P intake.

T236 Evaluation of modeling procedure for fitting in situ degradation profiles. G. I. Zanton* and A. J. Heinrichs, *The Pennsylvania State University, University Park.*

In situ degradation of feeds is a common methodology used for describing the digestion rate and potential for ruminant feedstuffs. When the population estimates of parameters of nonlinear equations are required, nonlinear mixed modeling (NLMM) of in situ data may be more appropriate than a two-stage approach [TS; in which individual kinetic parameter estimates (PE) are obtained in the first stage and population estimates are obtained in the second by averaging], since NLMM allows information in common across subjects to be shared during estimation. Therefore, the objective of this experiment was to evaluate the accuracy and precision of PE determined by TS and NLMM using simulation techniques. Four in situ profiles were represented: long lag with degradation rates of 0.05 and 0.02/h and moderate lag with degradation rates of 0.12 and 0.05/h. For all analyses, a minimum of 3200 degradation profiles were simulated with time points representing 0, 1, 2, 4, 8, 16, 24, 48, 72, and 96 h of ruminal incubation. Parameters were simulated with a systematic source of variation associated with animal and period effects and normally distributed, random residual error. Under these conditions, acceptable levels of bias and precision were found for some models evaluated. Bias of PE of the models examined was different from 0 ($P < 0.05$) for more parameters (2.23X) with TS than NLMM, whereas PE were determined with lower precision for TS than NLMM 3.25X more. Study of the lagged, exponential model revealed that PE bias for TS were more sensitive to enhanced residual variation, level of replication, and sampling schedule than NLMM. When residual variation was low, precision of PE was not substantially affected by estimation procedure; when residual variation was high, precision of PE was generally improved by NLMM (>3X, maximally). Averaging skewed individual animal PE, resulted in considerably biased estimates of population parameters. From the results of these simulations it is concluded that, in most cases, NLMM is more appropriate than TS for producing unbiased, precise PE.

T237 Assessment of free amino acid supplementation on rumen microbial efficiency and nitrogen metabolism using a continuous culture system. M. A. Brooks*, J. H. Porter, and M. S. Kerley, *University of Missouri, Columbia.*

This purpose of this experiment was to study microbial efficiency (MOEFF) and nitrogen (N) metabolism in the rumen environment when differing levels of free crystalline amino acids were added to the diet. A continuous culture system with a fractional dilution rate 0.06 was set up to accommodate 6 treatments with 4 fermenters per treatment. Treatments contained a ground corn, soybean meal, and soybean hull basal diet with additional levels of an equal mix of L-Lys, L-Arg, and DL-Met added to the diet at varying levels (0%, 3%, 6%, 12%, 18%, and 6% blood meal as a positive control). After a 4 day acclimation, ammonia and pH of the fermenters were analyzed 1 h before feeding and 4 h after feeding for 3 days. At the end of study, N and organic matter (OM) were analyzed for the diets, bacteria, and effluent and MOEFF calculated. Ammonia concentrations rose as the free AA supplementation in the diets increased ($P < 0.001$). MOEFF was increased by protein supplementation ($P < 0.001$) compared to the free AA diets, and MOEFF responded quadratically ($P < 0.05$) to free AA supplementation. We concluded that peptide N was needed to maximize MOEFF. Free AA supplementation in the diet does not appear to supply peptides required for maximizing MOEFF. Our data agreed with previously published data that concluded AA degradation rate was more rapid than AA outflow

at feasible feeding levels. OM digestion was greatest for the 3% AA treatment ($P < 0.05$). The culture pH, measured 4 h after feeding was different among treatments ($P < 0.001$); however, the ranged within only 0.1 pH unit. Diet formulations will continue to move in the direction of formulating for AA requirements. In this process, provisions for the form of microbial N requirement must be met.

Key Words: Microbial Efficiency, Amino Acids, Rumen Fermentation

T238 Effect of pH on rumen fermentation and biohydrogenation of extruded soybean and linseed fatty acids in continuous culture.

M. C. Fuentes*¹, S. Calsamiglia¹, V. Fievez², and M. Blanch¹, ¹UAB, Bellaterra, Spain, ²Ghent University, Belgium.

Eight dual-flow continuous culture fermenters (1320 mL) were used in two replicated periods of 7 d (4 d adaptation plus 3 d sampling) to study the effects of pH (6.4 vs. 5.6) and diet (Soybean (SB) vs. Linseed (LS)) on rumen microbial fermentation, lipolysis and biohydrogenation, and DNA concentration of bacteria involved in lipolysis and biohydrogenation processes. Diets had a 40:60 forage to concentrate ratio (17.3 % CP, 29.2 % NDF) and similar ingredient composition, differing only in the fat supplement, with SB having extruded soybean (5.4 % DM) and LS having extruded linseed (6.2 % DM). Low pH reduced OM and NDF digestibility, ammonia N concentration and flow, bacterial N flow and CP degradation, and increased non-ammonia and dietary N flow. Low pH reduced linoleic acid (LA) and linolenic acid (LNA) apparent biohydrogenation (LA = 0.44 vs. 0.82; LNA = 0.54 vs. 0.84) and lipolysis (LA = 0.92 vs. 0.99; LNA = 0.94 vs. 0.99). Low pH reduced C18:0, t11-C18:1, c9,t11-conjugated linoleic acid (CLA), and increased t10-C18:1, C18:2, C18:3, t11,c15-C18:2 and t10,c12-CLA proportions in the effluent. Low pH reduced *Anaerovibrio lipolytica* (1.85 vs. 67.0 pg / 10 ng total DNA) and *Butyrivibrio* VA subgroup (315.5 vs. 1148.5 pg / 10 ng total DNA) and increased *Butyrivibrio* SA subgroup DNA concentrations (1907.0 vs. 1215.5 pg / 10 ng total DNA). Linseed diet increased ammonia N concentration and flow and tended ($P = 0.06$) to increase CP degradation. Lipolysis of LA and LNA was higher in LS compared with SB diet (LA = 0.98 vs. 0.92; LNA = 0.98 vs. 0.94). Linseed reduced C18:2 and t10,c12-CLA, and increased C18:3 and t11,c15-C18:2 proportions in the effluent. Concentration of *A. lipolytica* DNA was higher (43.4 vs. 25.6 pg / 10 ng total DNA) and that of *Butyrivibrio* VA subgroup was lower in LS compared with SB diet (652.5 vs. 811.5 pg / 10 ng total DNA). Low pH inhibited lipolysis and biohydrogenation. Extrusion of soybean seems to protect fat against lipolysis more than extrusion of linseed.

Key Words: pH, Lipolysis, Biohydrogenation

T239 Effect of pH and level of concentrate in the diet on biohydrogenation intermediates in a dual flow continuous culture.

M. C. Fuentes*, S. Calsamiglia, and P. W. Cardozo, UAB, Bellaterra, Spain.

Milk fat depression in cows fed high grain diets has been related to an increase in trans-C18 fatty acids (FA) in milk. Trans-C18 FA are produced as a result of the incomplete biohydrogenation of dietary polyunsaturated FA in the rumen. There seems to be a confounding effect between ruminal pH and quantity of concentrate in the diet on

biohydrogenation intermediates production. In the current experiment, the effect of pH (6.4 vs. 5.6) and two different forage to concentrate ratios (F:C) in the diets (70:30 F:C vs. 30:70 F:C) on rumen microbial fermentation, effluent FA profile and DNA concentration of bacteria involved in lipolysis and biohydrogenation processes was investigated in continuous culture. The study consisted of two experimental periods of 8 d (5 d adaptation plus 3 d sampling), with a 2 x 2 factorial arrangement of treatments. Both diets had a similar FA profile (44.0 % C18:2, 9.77% C18:3 of total FA). Low pH reduced OM and NDF digestibility, ammonia N concentration and flow, CP degradation and tended to reduce bacterial N flow, and increased non-ammonia and dietary N flow. Low pH decreased C18:0, t11-C18:1 and c9,t11-conjugated linoleic acid (CLA) and increased t10-C18:1, C18:2n6, C18:3n3 and t11,c15-C18:2 concentrations in the effluent. Low pH reduced *Anaerovibrio lipolytica* (32.7 vs. 72.1 pg / 10 ng total DNA) and *Butyrivibrio* VA subgroup DNA concentrations (588 vs. 1394 pg / 10 ng total DNA). The 30:70 F:C diet increased OM and NDF digestibility, non-ammonia and dietary N flow, and reduced ammonia N concentration and flow. The 30:70 F:C reduced t11-C18:1, c9,t11-CLA and tended to reduce ($P < 0.10$) t10-C18:1, and increased C18:2n6, C18:3n3 and t11,c15-C18:2 compared with the 70:30 F:C diet. Moreover, the 30:70 F:C diet increased *A. lipolytica* DNA concentration (65.2 vs. 39.7 pg / 10 ng total DNA). Results confirm that the low pH is responsible for the accumulation of biohydrogenation intermediates which cause milk fat depression, and not the concentrate of the diet.

Key Words: pH, Concentrate, Fatty Acid Biohydrogenation

T240 Comparison of *in vitro*, *in situ*, and *in vivo* methodologies to assess nutrient digestibility in ruminants.

L. E. Sims*¹, N. A. Pyatt², P. H. Doane², and S. S. Block², ¹Oklahoma State University, Stillwater, ²ADM Research Center, Decatur, IN.

This study compared *in situ*, *in vitro*, and *in vivo* methods of estimating digestibility of substrates having variable starch content. Starch content of substrates was 65% (corn; high), 39% (corn-forage; med-high), 28% (forage-corn; med-low) or 22% (corn fiber; low). Lactating dairy cows and beef steers were used for *in situ* evaluation. *In vitro* digestibility was determined using the Ankom Daisy System with ruminal inoculum from steers fed high-starch diets or lactating dairy cattle fed moderate starch diets. The mobile bag method was used to estimate post-ruminal digestibility of residue collected from *in situ* and *in vitro* incubations. The med-high and med-low substrates were fed as complete diets to 20 lambs to assess *in vivo* total tract digestion. Rate and extent (48 hr) of ruminal *in situ* DM, CP, NDF, and ADF digestion was greater for dairy versus beef whereas rate and extent of starch digestion was less. *In vitro* rate of DM digestion was similar whether beef or dairy ruminal fluid inocula was used but extent was greater for dairy. Across substrates, *in vitro* DM digestion estimates were about five to 10 percent greater versus *in situ* estimates. Med-high and med-low substrates had similar ($P > 0.10$) *in vivo* total tract digestibility. Ruminal (*in situ* or *in vitro*) and post-ruminal (mobile bag) digestibility or the sum of ruminal and post-ruminal estimates were compared with *in vivo* total tract digestion of med-high or med-low substrates. *In vitro* and *in situ* methods gave similar relative ranking among substrates but rate and extent of nutrient digestion differed. Selected methods can provide comparable estimates of nutrient digestion obtained in more time-consuming and expensive *in vivo* methods.

Table 1. Substrate Starch Content

Item	High (Corn)	Med-High (Corn-forage)	Med-Low (Forage-corn)	Low (Corn Fiber)
Ruminal DM digestion				
In situ – Beef (48 hr)	82.0	72.0	73.4	42.3
In situ – Dairy (48 hr)	90.4	78.9	83.3	60.7
Ankom – Beef Inocula	96.6	90.2	88.7	76.9
Ankom – Dairy Inocula	97.8	91.7	90	81.3
Total tract DM digestion				
Lamb in vivo	—	75.0	74.8	—
In situ residue in mobile bag	76.0	80.2	79.3	43.9
Ankom residue in mobile bag	90.6	87.8	86.6	57.8

Key Words: In vitro, In situ, Digestibility

T241 Effect of an enzymatic extract from *Agaricus bisporus* on *in vitro* digestibility of cell wall and dry matter. A. Ayala-Martinez^{*1}, S. S. Gonzalez-Muñoz², C. Vazquez-Gonzalez¹, G. Mendoza-Martinez³, M. Meneses-Mayo², and O. Loera-Corral⁴, ¹FMVZ-UNAM, Mexico D.F., ²Colegio de Postgraduados, Montecillo, Edo. Mexico, Mexico, ³UAM Xochimilco, Mexico D.F., ⁴UAM Iztapalapa, Mexico D.F.

The objective of this trial was to determine the effect of a commercial enzymatic extract (CE) from *Trichoderma* spp. and an extract from *Agaricus bisporus* (AE) on residual NDF, ADF and DM *in vitro* digestibility (IVDMD) of alfalfa, crop residues, barley straw, Taiwan grass and orchard grass. The experimental design was completely randomized with a factorial arrangement of treatments (5 × 3); an analysis of variance was performed and means were compared with Tukey test (P<0.05). For alfalfa residual NDF there were differences (P<0.05) between the treatment without extract, AE and CE at: 1) 12h: 91.8a, 79.45b, 75.4b; 2) 24 h: 83.9a, 72.1b, 71.4b; 3) 48 h: 68.7a, 49.9b, 59.9b; ± 1.1%. For alfalfa residual ADF there were differences (P<0.05) between the treatment without extract, AE and CE at: 1) 12 h: 75.1b, 95.7a, 82.2b; 2) 24 h: 74.0b, 94.0a, 59.0b; 3) 48 h: 66.2b, 95.7a, 50.0b; ± 1.1%. There were differences of DM *in vitro* digestibility (P<0.05) between the treatment without extract, AE and CE: 1) crop residues at 72 h (52.2b, 66.2a, 58.2a; ± 1.2%); 2) barley straw at 24 h (36.8b, 41.39a, 42.65a; ± 1.02%), 48 h (38.0b, 44.09a, 45.2a; ± 1.02%) and 72 h (41.2b, 48.1a, 48.9a; ± 1.02%); 3) Taiwan grass at 48 h (30.07b, 40.1a, 41.0a; ± 1.03%) and 72 h (31.9b, 46.2a, 42.3a; ± 1.03%). No differences were found for alfalfa and orchard grass (P>0.05). Therefore, it may be concluded that *in vitro* digestibility of residual NDF, ADF and DM, for different forages, do not change when using a commercial enzymatic extract from *Trichoderma* spp. or an extract from *A. bisporus*.

Key Words: Fibrolytic Enzymes, Cell Wall Digestibility, Fungi

T242 In situ dry matter degradation parameters of treated and untreated Sainfoin (*Onobrichis vicifolia*) a tanniferous legume forage. H. Khalilvandi*, K. RezaYazdi, M. Dehgan-Banadaki, N. Vahdani, and H. R. Khazanehei, *University of Tehran, Karaj, Tehran, Iran.*

Condensed tannins are phenolics belonging to the plant secondary compounds, which bind to plant proteins and other nutrients. Sainfoin is tannin rich, temperate legume forage, which its CT concentration fluctuated from 2.5 to 7.7 % of dry matter. Detrimental effects of CT are more probable in the case of high tannin concentration (more than 40 g/ kg DM).

In order to investigate different chemicals to improve degradation characteristics of sainfoin, an *in situ* experiment was carried out using 3 ruminally fistulated Holstein cows. Samples of forage were chopped 3-5 cm length, and then treated with solutions of KMnO₄ (0.03 M), NaOH (0.05 M), sodium bicarbonate (0.1 M), wood ash (180 g/L) with forage to reagent volume ratio of 1:4 (W/V), and one water soaking considered as blank for 6th and 7th treatment. 5% solution of PEG (6000 MW) was sprayed to forage with 1:1 ratio and urea (20g/ 100 ml/1 kg of DM) treatment applied respectively. All of above treatments carried out in 25°C temperature, for 20 min, with hand shaking. Urea treatment was done using adhesive rubber to create anaerobic conditions for 1 week. Treated forages then exposed to 40°C temperature in a forced air oven, for 48 hours. All forage samples were ground to pass 2 mm screen size (Wiley mill). Followed grinding, these feeds were sieved to remove particles > 0.45 mm. 5 g of forage samples were weighed into nylon bags (10×20 cm) with 53 µm pore size, to create sample size: surface area of 12.5 mg/cm². Duplicates were incubated for 4, 8, 12, 24, 48, 72 and 96h in ventral rumen.

Results showed that PEG treated forage has greater rapidly soluble fraction (a), but PEG could not increase potentially degradable fraction (b). Rate of degradation of b fraction was highest for wood ash (0.10240), and lowest for KMnO₄ (0.05113). Effective degradability in different rumen dilution rates were high for PEG treated Sainfoin compared to others. Treatment with KMnO₄ resulted in lowering effective degradability.

Key Words: Sainfoin, In situ Degradability, Tannin

T243 Accuracy of the n-alkanes technique for intake estimates in beef cattle fed with palisade grass (*Brachiaria brizantha* cv. Marandu). J. A. S. Morais¹, T. T. Berchielli¹, M. F. S. Queiroz^{*1}, A. Keli², A. de Vega², R. A. Reis¹, C. López², S. F. Souza¹, and G. Fiorentini¹, ¹Faculdade de Ciências Agrárias e Veterinárias/UNESP, Jaboticabal, São Paulo, Brazil, ²Facultad de Veterinaria, Universidad de Zaragoza, Zaragoza, Spain.

Animal performance is mainly determined by diet intake and digestibility, being the estimation of those parameters a difficult and not yet fully resolved task in grazing conditions. The objective of this research was to evaluate the n-alkanes methodology as markers to estimate the dry matter intake (DMI) in eight Nelore steers grazing palisade grass. Animals, in metabolism cage, were fed twice daily on (30 or 60 days regrowth) at 2.0% body weight. Animals were dosed twice daily during twelve days with paper pellets containing equal amounts of octacosane (C28), dotriacontane (C32) and hexatriacontane (C36). From day 10 to day 15 spot faecal samples were collected, directly from the rectum, at the same time of alkane dosing. N-Alkanes profiles in samples of grass, urine and faeces were extracted following the technique of the

ethanolic saponification for fourteen hours with alkane analysis carried out by gas chromatograph. The DMI estimates were not affected by the forage regrowth period ($P > 0.05$). Only the pair of alkanes C32/C33 did estimate adequately the DMI, underestimating the total intake at just 8%, while the pairs C31/C32 and C35/C36 under and overestimated the forage DMI in -15.3 and +18.8%, respectively, ($P < 0.05$). The n-alkanes methodology presented potential to estimate the forage DMI in tropical conditions.

Table 1. Forage dry matter intake (DMI) observed and estimated with C31/C32, C32/C33 and C35/C36 alkane pairs in steers fed with tropical forage (São Paulo – Brazil).

	Regrowth age, days		Mean	SEM ¹
Methods	30	60		
Actual DMI	4.20	4.32	4.26 ^b	0.147
Estimated DMI				
C31/C32	3.50	3.72	3.61 ^c	
C32/C33	3.60	4.15	3.88 ^{bc}	
C35/C36	4.46	5.65	5.06 ^a	

¹ Standard error of the mean; ^{abc} Means values within columns with different superscripts are significantly different ($P < 0.05$).

T244 The effect of non fibre carbohydrate on in vitro first order NDF disappearance of alfalfa. M. Danesh Mesgaran*, F. Rezaei, and A. R. Heravi Mousavi, *Ferdowsi University of Mashhad, Mashhad, Iran.*

The aim of this study was to determine the effect of supplementing sucrose or starch on in vitro first order NDF disappearance model of alfalfa. Samples of alfalfa were ground to pass 0.75 mm screen and dried at 80 °C for 48 h. One gram of non-supplemented or non-fiber carbohydrate supplemented samples (70 mg/g DM of feed sample as starch or sucrose) were incubated in a medium containing 40 ml cell-free rumen fluid, 60 ml mineral mixtures and 5 ml of cloth-cheese strained rumen fluid in a 200 ml bottle. Each bottle was finely bubbled with CO₂. Rumen fluid was obtained from 4 Holstein steers fed corn silage, alfalfa hay, wheat straw, barley grain and soybean meal (3.4, 2.4, 0.8, 1.6 and 0.8 kg/d DM, respectively). Bottle of each sample was incubated for 24, 48, and 96 h at 39°C (n=4). Then, bottle content was filtered through a 22 µm filter paper. Unfiltered NDF was determined. Data were analyzed using GLM procedure of SAS and applied to a non-linear first order model [$D(t) = D(i) \cdot \exp(-k \cdot \text{time}) + I$; where $D(t)$ is potentially digestible fraction of DM, $D(i)$ is potentially digestible residues, k is fractional rate constant of digestion (h^{-1}) and I is indigestible fraction]. Indigestible fraction of NDF of alfalfa hay was significantly ($p < 0.05$) increased when it was supplemented with starch (0.63, 0.64 and 0.76 for alfalfa, alfalfa+sucrose and alfalfa+starch, respectively). The lowest constant rate of digestion was observed when sucrose (0.007) was added to alfalfa. Constant rate of digestion of alfalfa and alfalfa+starch was 0.01 and 0.02, respectively. Results of the present study showed that the first order fractional rate of digestion of NDF of alfalfa might be influenced by source of NFC. Therefore, there is a need to determine the associated effect of a feed and nature of NFC on fractional rate constant of digestion and indigestible fraction for each forage or a composed diet.

Key Words: NDF, Model, Disappearance

oil sunflower meal treated with formaldehyde or sodium hydroxide. T. Mohammadabadi, M. Danesh Mesgaran*, and M. R. Nasiri, *Excellence Center for Animal Science, Ferdowsi University of Mashhad, Mashhad, Iran.*

This study was conducted to evaluate the effect of formaldehyde or sodium hydroxide on in situ ruminal disappearance and in vitro intestinal digestion of high oil (165 g/kg DM) sunflower meal (SM). Samples were: Untreated SM (USM), sodium hydroxide treated SM (SHSM, 40 g/kg DM), formaldehyde treated SM (F30SM and F60SM, 30 and 60 g/kg DM, respectively). Ruminal disappearance of sample was determined using four fistulated Holstein steers (400±12 Kg, body weight). Samples were weighed into nylon bags (19×12 cm, pore size 48 µm, n=6) and incubated in rumen for 12 h. An in situ/ in vitro enzymatic 3-step procedure was conducted to determine post-ruminal disappearance of the samples. In this procedure, a part of ruminal-undegraded nitrogen (after 12 h rumen incubation) was included in pepsin and pancreatin to determine post-ruminal protein disappearance of the sample. DM content of all intact and incubated samples was determined using air-forced oven (65°C, 48 h). Nitrogen concentration of the samples was determined using Kjeldahl method. Data were analysed using GLM procedure of SAS. Results indicated that ruminal DM and CP of F60SM was significantly ($P < 0.05$) lower (0.42 and 0.39, respectively) than USM (0.7 and 0.65, respectively). Formaldehyde and sodium hydroxide caused an increase in post-ruminal CP disappearance (0.44, 0.4, 0.33 and 0.27 for F60SM, F30SM, SHSM and USM, respectively). Total tract CP digestibility for F60SM, F30SM, SHSM and USM was 0.83, 0.85, 0.88 and 0.93. It was concluded that both formaldehyde and sodium hydroxide caused an increase in the ruminal and post-ruminal CP disappearance of high oil content sunflower meal.

T246 The effect of feed iodine supplementation on milk production traits in dairy goats. A. Nudda*¹, M. Decandia², G. Epifani², G. Battacone¹, G. Spanu¹, and G. Pulina^{1,2}, ¹University of Sassari, Sassari, Italy, ²AGRI Sardegna, Sassari, Italy.

Iodine requirements are higher for goats than for other ruminants. An adequate supply of dietary iodine can prevent iodine deficiency disorders in goats and increase the iodine content in milk. However, the effects of iodine-enriched diets on milk production traits of lactating goats have been poorly investigated. This work aimed to determine the effect of iodine supplementation to dairy goats on milk yield and composition. Thirty crossbred dairy goats were divided into 3 homogeneous groups. Each goat was supplemented with potassium iodide (KI) at 0 (control group), 400 (group 1), or 950 µg of KI/day (group 2). The dose of KI (76.5% of iodine) was dissolved in water and administered every day for 8 weeks. Milk yield and milk composition (fat, protein, urea) were recorded weekly. Milk yield was not influenced by KI supplementation and averaged 1229, 1227 and 1179 g/d per head in groups 0, 1 and 2, respectively. Milk fat content was higher ($P \leq 0.01$) in group 1 (4.12%) compared to group 0 (3.78%) and group 2 (3.84%). The protein content was similar in groups 1 and 2 (on average, 3.43%), and tended to be higher than in the control group (3.36%). On the contrary, the milk urea concentration was significantly lower in the groups that received KI supplementation (32 and 33 mg/dl in groups 1 and 2, respectively) than in the control group (37 mg/dl). In conclusion, the doses of KI used in this study did not influence milk yield and had favorable effects

on urea and, to a lower extent, protein contents in goats, suggesting an improvement of rumen activity, mainly of nitrogen utilization.

T247 An examination of the intake and digestibility characteristics of ground ear maize for beef cattle. P. O'Hanlon, D. A. Kenny, T. M. Boland, G. P. Keane, and M. B. Lynch*, *UCD School of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Ireland.*

Feed is the largest single cost in cattle production and as demand for cereal grain for non-agricultural purposes increases, elevating feed grain costs will impact on profitability. Ground ear maize (GEM) is a novel approach to potentially utilising the maize plant as a high energy forage based substitute for grain based diets and essentially consists of the corn and cob mix with a portion of the leaf material retained. The objective of this short term experiment was to compare the intake and digestibility characteristics of GEM with barley grain as a feed source for high producing beef cattle. GEM was ensiled for two months in round plastic wrapped bales. Young beef bulls (n=24) with a mean \pm sd liveweight of 356 \pm 20 kg were blocked on liveweight and age and randomly allocated within block to one of two treatments (1) GEM-based diet (GEM) (2) Barley-based diet (BAR). All animals were individually fed and soybean meal and barley straw were added to make both diets isonitrogenous (13.5% CP), isofibrous (27% NDF) and isoenergetic (17 MJ GE/kg DM). GEM was fed as a TMR, while concentrate and straw were offered separately for BAR. Feed intake was recorded for 14 days and diet digestibility was determined using the chromic oxide technique with faecal samples were collected on days 13 and 14. Animals on GEM had higher DMI (P = 0.07) compared with BAR. However, animals on BAR had higher (P < 0.01) digestibility of neutral detergent fibre, organic matter and dry matter and a tendency towards higher digestibility of N (P = 0.09) compared with those on GEM. In conclusion, these data indicate that ground ear maize is worthy of further investigation as a substitute for grain based diets. Longer term studies are required to assess effects on animal production and carcass quality.

Key Words: Ground Ear Maize, Beef Cattle, Feed Intake

T248 Comparison of procedures to detach particle-associated microbes from ruminal digesta in Rusitec fermenters. M. E. Martínez, M. J. Ranilla*, S. Ramos, M. L. Tejido, C. Saro, and M. D. Carro, *Universidad De León, Campus De Vegazana, León, Spain.*

Three different detachment procedures (DP) were evaluated for their ability to remove particle-associated microbes from incubation feed residues in Rusitec fermenters fed a 70:30 concentrate:alfalfa hay diet. Concentrate and hay were incubated in separate nylon bags, and incubation residues were treated independently. In the methylcellulose procedure (MET) feed residues were incubated at 38°C for 15 min with saline solution (0.9% NaCl) containing 0.1% methylcellulose with continuous shaking. In the stomacher procedure (STO) residues were

mixed with saline solution and homogenized with a stomacher for 5 min at 230 rev min⁻¹. In the freezing procedure (FRE) residues were immediately frozen at -20°C for 72 h, thawed at 4°C, and mixed with saline solution. All solutions were added at a rate of 3 mL/g of residue. Common to all treatments was storing at 4°C for 24 h after the treatment, homogenization, filtration, and resuspension of residues two times in the treatment solutions. Filtrates were centrifuged at 20,000 g for 25 min at 4°C to obtain microbial pellets. Microbial removal was estimated indirectly from removal of ¹⁵N. Each procedure was repeated in three consecutive days (n=3). There were no feed x DP interactions (P=0.15 to 0.91) in any variable. Both detaching efficiency and total recovery were affected by the DP (P<0.001), STO presenting the greatest values (mean values for both substrates of 63.2 and 25.5%, respectively), and FRE the lowest ones (44.3 and 18.4%). There were no differences (P=0.71) among the pellets obtained by the different DP in their N content, but pellets from MET had greater (P<0.05) ¹⁵N enrichments than those from STO and FRE. Pellets detached from hay presented greater (P<0.001) N content and ¹⁵N enrichments than those obtained from concentrate (mean values of 63.3 vs 55.7 mg N/g dry matter, and 0.152 vs 0.132% atoms in excess). Results suggest that STO was the most effective method to detach ruminal microbes from both concentrate and hay incubated in Rusitec fermenters

Key Words: Adhesion, Ruminal Microbes, ¹⁵N

T249 Effects of varying levels of fish oil, fed as a calcium salt, on rumen fermentation and biohydrogenation in continuous culture. C. M. Klein*¹, T. C. Jenkins¹, and K. D. Murphy², ¹*Clemson University, Clemson,* ²*Virtus Nutrition, Lancaster, PA.*

Fish oils, including docosahexaenoic acid (C22:6, DHA) and eicosapentaenoic acid (C20:5, EPA) have been found to have human health benefits and are used as fat supplements in ruminants. Transfer of omega-3 fatty acids from the ruminant diet, to meat and milk products, depends on their escape from microbial biohydrogenation in the rumen. Fatty acids are often fed as calcium salts to reduce biohydrogenation and lessen the negative effects on fermentation. To determine if fish oil protection was enhanced when incorporated in a matrix of palm oil fatty acids, this study examined the effects of varying the ratio of fish oil and palm oil calcium salts on ruminal fermentation and biohydrogenation. Ruminal microorganisms maintained in continuous culture were exposed to diets with 5% added fat as soybean oil or as calcium salts of fish oil and palm fatty acids in three combinations (45/55, 75/25, and 90/10). A control diet and the four fat diets were fed to fermentors in a 5x5 Latin square with 10 d periods. As expected, the acetate/propionate ratio decreased (P < 0.05) when soybean oil was added to the diet (1.78 for the control and 1.30 for SBO). The acetate/propionate ratios for the fish oil diets were not different from the SBO diet (1.22, 1.07, and 1.07 for the 45FO, 75FO, and 90FO diets, respectively). Of the three combinations of fish oil tested, the 45FO and 75FO did not differ in the amounts of EPA (43.8% and 40.8%) or DHA (40.8% and 33.3%) that disappeared. There were however, differences in EPA and DHA lost between 75FO and 90FO. Losses of EPA (59.8%) and DHA (55.8%) were greater (P < 0.05) for FO90 compared to either 45FO or 75FO. These results indicate that rumen protection of DHA and EPA is diminished when fish oil comprises more than 75% of a fish oil/palm oil calcium salt mix.

Key Words: Biohydrogenation, Fish Oil, Continuous Culture

T250 By-product of biofuels processing in the feeding of ruminant. J. A. G. Azevedo^{1,2}, D. S. Pina², N. K. P. Souza², J. C. M. Lima², A. S. Oliveira², C. V. Xavier², S. C. Valadares Filho², and H. J. Fernandes^{*3,2}, ¹Universidade Estadual de Santa Cruz - FAPESB, Ilhéus, Bahia, Brazil, ²Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, ³Universidade Estadual do Mato Grosso do Sul- FUNDECT, Brazil.

This experiment was carried out aiming to evaluate the effects three levels (0.0, 8.0 and 24.0; and 0.0, 5.0 and 16.0 % of dietary DM) of inclusion of two by-products: sunflower (*Helianthus annuus*) and turnip (*Raphanus sativus*), respectively, on the intake and apparent total tract digestibility of DM, OM, CP, EE, NFC and NDF. Twelve crossbred heifers with averaging BW 263.0 ± 34.0 kg were used. The experiment was performed in two periods of 15 days, in which the last three days were used to make total fecal collection. The animals were held at individual sheltered pens of approximately 3 m² and fed twice daily at 08:00 and 16:00 h, allowing for up to 10% oforts. The corn silage was the only roughage in the diet, in which was incorporated a mix of urea/ammonium sulfate (9:1) aiming to maintain the same dietary CP levels among the diets (13.0% of DM). The animals were allocated in six 2×2 Latin square design in a simple reversion arrangement and all statistical analyses were performed using PROC MIXED of SAS. The intake and apparent digestibility of DM in the diet contain sunflower ranged 34 and 18% respectively, with the average of 1.8% BW and 62%, respectively. In the diet contain turnip, the DMI ranged from 1.2 to 2.6% BW and the apparent digestibility of DM ranged from 57.8 to 66.9%. The quadratic effects ($P < 0.05$) were observed by the levels of sunflower on the intake of DM, OM, CP, EE, NDF and apparent digestibility of EE. The levels of turnip affected quadratically ($P < 0.05$) the intake and apparent digestibility of EE. These results indicated that the level of inclusion of sunflower by-product that maximizes the intake of nutrients is the 7%, however the maximum level (16% of DM) did not affect the apparent digestibility of all nutrients with exception the EE. The maximum level of inclusion of turnip by-product (24% DM) did not affect either intake or apparent digestibility of DM, OM, CP, NFC and NDF.

Key Words: Alternative feed, Sunflower, Turnip

T251 In vitro gas production kinetics of biofuels by-products. J. A. G. Azevedo^{1,2}, D. S. Pina², J. C. M. Lima², N. K. P. Souza², C. V. Xavier², A. S. Oliveira², S. C. Valadares Filho², and H. J. Fernandes^{*3,2}, ¹Universidade Estadual de Santa Cruz, Ilhéus, Bahia, Brazil, ²Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, ³Universidade Estadual do Mato Grosso do Sul- FUNDECT, Brazil.

This study was conducted aiming to evaluate the in vitro gas production digestion kinetics of biofuels by-product (sunflower, turnip, palm and castor). Four samples of each by-product were pre-dried in a forced air oven (60°C) and ground in a Wiley mill (1 mm screen). Samples (200mg) were weighed into 100 mL graduated glass syringes with pistons lubricated with Vaseline. Buffered mineral solution was prepared and placed in acclimatized room at 39°C under continuous flushing of CO₂. The ruminal fluid inoculum used in all experiment was obtained from the rumen fistulated heifers fed with corn silage and concentrate (70:30 DM ratio). Ruminal fluid was transferred into pre-warmed thermo flasks, filtered through four layers of cheesecloth and flushed with CO₂. Ruminal fluid was added to the buffered mineral solution (inoculum),

which was maintained in acclimatized room at 39°C under continuous flushing of CO₂. Inoculum (30 mL) was dispensed into syringes containing by-product samples. The clip was closed, the initial volume recorded, and gas readings for each syringe were manually recorded at 2, 4, 6, 8, 10, 12, 24, 26, 28, 30, 32, 36, 48, 52, 54, 56, 60 and 72 h after incubation. The recorded volumes were corrected for a blank incubation (i.e., buffered rumen fluid without sample). The rate and extent of gas production was determined by fitting of gas production profile with dual-pool logistic by Gauss-Newton algorithm (SAS NLIN procedure). The final gas volume yields from nonfiber carbohydrate (NFC) were highest to turnip and sunflower by-product (23.5 and 18.0 mL), while the gas yielded from fibrous carbohydrate (FC) were highest to castor and palm by-product (19.3 and 17.2 mL). The degradation rate of the NFC and FC to palm, sunflower, castor and turnip by-product were 0.0912 and 0.0255; 0.1533 and 0.0390; 0.1824 and 0.0267; 0.1297 and 0.0306 h⁻¹, respectively. The highest lag time was observed to palm by-product (5.08 h). It was concluded that the NFC presented the higher digestion rate than FC as expected. Therefore, by-product with high levels of NFC could provide more energy supply than by products with high levels of FC.

T252 Bacterial diversity in rumen fluid samples collected via oral lavage or rumen cannula. J. Pisel, S. L. Lodge-Ivey*, J. Browne-Silva, and M. B. Horvath, *New Mexico State University, Las Cruces.*

There are inherent limitations associated with cultivation-based methods for characterizing the composition of bacterial communities in the rumen. Cultivation-independent methodologies are available. Denaturing gradient gel electrophoresis (DGGE) of amplified fragments of 16S rRNA genes has become a widely used tool to assess the diversity of complex bacterial communities in a variety of environments. A study was conducted to determine if sampling the rumen contents ruminally via a cannula or orally via lavage tube would yield similar DGGE profiles of the bacterial community. Two species of ruminally cannulated animals were used for this study (cows n=2; sheep n=3). All animals were allowed ad libitum access to feed. Cattle were allowed fed a poor quality forage consisting of baled unprocessed sorghum-sudan straw (5% CP, 68% NDF; DM basis) while sheep were maintained on chopped alfalfa (18% CP, 40% NDF; DM basis). Ruminal fluid was collected once a week for 4 weeks from each animal using a plastic tube equipped with a suction strainer with a handheld suction pump through the rumen cannula or oral cavity. DGGE analysis and principal component comparison demonstrates that yield of bacterial diversity was not different between the two sampling methods ($P = 0.15$). However, species and/or diet sampled did influence the number of bands in the DNA band pattern in the DGGE analysis. Sheep had fewer bands per lane on DGGE gels which is equated to less diversity than cattle ($P < 0.01$; 25.1 vs 30.0). Additionally, when samples were grouped according to DNA band patterns groups were most stable according to individual animal and species rather than sampling method. These data indicate that collecting samples via a lavage tube or rumen cannula is more influenced by species and individual animal than sampling method. This knowledge will allow for sample collection from a greater population of animals and a reduction in cost associated with developing and maintaining ruminally cannulated animals.

Key Words: DGGE, Rumen Sampling, Rumen Microbiology

T253 Image analysis and microscopy in animal by-products characterization. A. Campagnoli, C. Paltanin, L. Maggioni, G. Savoini, V. Dell'Orto, F. Cheli, and L. Pinotti*, *Department of Veterinary Sciences and Technology for Food Safety, Veterinary Medicine Faculty, Milan, Italy.*

Aim of this study was to evaluate the potential of microscopic methods in association with computer image analysis to identify the source of meat and bone meal. For this purpose reference samples (SAFEED-PAP Project; VSA, University of Milan) containing ruminant (bovine and ovine) and non-ruminant (pig, rabbit, chicken, turkey) meat and bone meals were analysed by microscopic method (as described in Commission Directive 2003/126/EC). Through a CCD camera and an image analysis software (Image-for Plus 4.5.1, USA), 890 bone fragment lacunae images at X40 were obtained. Images have been enhanced and processed in order to obtain for each lacuna a monochrome mask on which 26 dimensioned and 4 no-dimensioned shape variables (constructed by combining the various size variables so that dimension units cancel out) were measured. Data were analysed by a cross-validated non-parametric classification method (kernel model applied in prediction by PROC DISCRIM of SAS statistic software). The results obtained indicated that: (i) the variables that best discriminated ruminants from non-ruminants were almost exactly the same as reported previously for mammalian and poultry; (ii) 87.54% of ruminant lacunae were correctly classified, and 12.46% incorrectly as non-ruminant. However 47.06% of non-ruminant lacunae were correctly classified (and 52.94% incorrectly classified as ruminant). To conclude, the use of microscopic methods in association with computer image analysis to identify ruminant from non-ruminant material in feedstuffs appears promising although further improvements (e.g. more defined statistical methods) are required. This work is funded by the European Commission, within the framework of the FOOD-CT-2006-036221 Project SAFEED-PAP

T254 Influence of a diet enriched in extruded linseed on fatty acid composition of goat cheese. A. Nudda*¹, G. Battacone¹, M. Addis², A. Pirisi², A. Mazza¹, and G. Pulina^{1,2}, ¹University of Sassari, Sassari, Italy, ²AGRIS Sardegna, Sassari, Italy.

This study aimed to assess the effect of long-term dietary supplementation with extruded linseed on goat milk and cheese fatty acid composition.

Forty-eight crossbreed dairy goats were allocated to 2 groups: one was fed the control diet (CON) and the other one was supplemented with 200 g of extruded linseed (LIN) which supplied 70 g/d of fat. The trial lasted 8 weeks. Bulk milk from each experimental group was collected weekly to produce a soft cheese type. Fatty acids were determined in milk and in 1-day and 20-day-old cheese. The FA content did not differ between milk and cheese. The cis-9, trans-11 CLA was higher in cheese produced from LIN milk than in cheese made from CON milk (1.22 vs. 0.85 g/100 g of fat; $P < 0.01$). The concentration of cis-9, trans-11 CLA in LIN cheese produced from supplemented-goat milk increased gradually until the fifth week (1.81 g/100 g of fat) of the trial and decreased afterwards. The C18:1 trans11 content was significantly higher in LIN cheese than in CON cheese (2.82 vs. 1.60 g/100 g of fat; $P < 0.01$). The content of linolenic acid (LNA) was much higher in LIN cheese than in CON cheese (1.6 vs. 0.67 g/100 g of fat; $P < 0.01$) and remained stable during all the experimental period. The CLA and LNA concentration did not differ between 1-day and 20-day-old cheeses. Goat diet

supplemented with a fat source rich in LNA for a long period resulted in an enhanced CLA content in cheese compared with the control diet. However, the concentration of CLA did not remain stable throughout the fat supplementation period.

T255 Relationship between vaccenic acid content of ruminal bacteria and duodenal bacteria. S. J. Liu, J. Q. Wang*, D. P. Bu, S. Liang, L. Liu, H. Y. Wei, L. Y. Zhou, and K. L. Liu, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Isomers of Conjugated linoleic acid (CLA), especially *cis*-9, *trans*-11 CLA and *trans*-10, *cis*-12 CLA have a wide range of benefits on human health. It was proved that some unique microorganisms could absorb vaccenic acid (VA) to reduce biohydrogenation, followed increasing CLA synthesis by Δ^9 -desaturase in mammary gland and adipose tissue. However, few reports have referred to the relationship between vaccenic acid of ruminal bacteria and duodenal bacteria. The objective of this study was to evaluate relationship of vaccenic content between mixed ruminal bacteria and duodenal bacteria in beef cattle. Four steers with ruminal cannulas were randomly assigned to control (CK, without additional oil supplement) or CK with 3% sunflower oil plus 1% fish oil (SF1), 2.5% sunflower oil plus 1.5% fish oil (SF2) and 2% sunflower oil plus 2% fish oil (SF3) in a 4x4 Latin square with iso-nitrogenous and 12-wk durational periods (forage to concentrate ratio was 65:35). Ruminal and duodenal digesta were collected every 4 h over a 24 h period on d 20, and d 21 of each experimental period and pooled for each animal, and pooled samples were stored at -20°C for bacteria separation according to different centrifuge method and fatty acids analysis was described by M. Sönnichsen. Regression analysis adopted the linear regression procedure of SAS8.2.

Our study showed that there existed linear regression relationship of vaccenic acid content between mixed ruminal bacteria and duodenal bacteria in beef cattle ($y = 1.15x + 0.09$; $R^2 = 0.87$, $P < 0.0001$). In the linear regressive equation, vaccenic acid content from duodenal bacteria (y value) was higher than that from rumen (x value). In conclusion, ruminal bacteria can effectively inhibit vaccenic acid hydrogenated in rumen, which increase vaccenic acid concentration of duodenal bacteria.

T256 Isolation of prominent lipolytic rumen bacteria. N. A. Krueger*, R. C. Anderson, T. R. Callaway, T. S. Edrington, and D. J. Nisbet, *USDA, ARS, Food and Feed Safety Research Unit, College Station, TX.*

Ruminant-derived foods contain high proportions of saturated fats, a result of ruminal biohydrogenation which rapidly saturates and thus limits the availability of free unsaturated fatty acids for assimilation. Strategies to enrich ruminant-derived foods with unsaturated fatty acids are desired as these are considered beneficial for good human health.

Lipolysis is a pre-requisite for biohydrogenation because saturase enzymes act only on free fatty acids. We conducted a descriptive study to isolate and characterize prominent lipolytic bacteria from the bovine rumen. Serial dilutions (10^{-1} to 10^{-10}) of ruminal fluid (from a pastured cannulated cow) were inoculated to roll tubes or plates containing buffered rumen fluid based agar supplemented with triolein, olive oil or linseed oil (2.5% wt/vol) as substrate for lipolytic bacteria. Medium within plates also contained rhodamine B dye specific for detection lipase expressing colonies. Inoculated roll tubes were incubated under 100% CO₂ and plates under N₂:CO₂:H₂ (90:5:5) for up to 7 days. Four colonies exhibiting characteristic zones of clearing and 15 colonies exhibiting fluorescence were isolated media inoculated with 10^{-4} to 10^{-10} ml of rumen fluid indicating that some were among the predominant flora containing 10^{10} colonies/ml. Biochemical and 16S rRNA gene sequence characterization revealed that none of these isolates were *Anaerovibrio lipolytica* or *Butyrivibrio* spp., bacteria considered major contributors to ruminal lipolysis but not isolated in this study. Recovered isolates were identified as *Clostridium chauvoe*, *Clostridium sporogenes*, *Propionibacterium acnes*, *Propionibacterium avidum* and *Staphylococcus epidermidis*. Results indicate that the ruminal population of lipolytic organisms is more diverse than previously thought and that efforts targeting this activity as a way to protect unsaturated fat from biohydrogenation will likely need to target more than just *A. lipolytica* or *Butyrivibrio* spp.

Key Words: Biohydrogenation, Lipolysis, Rumen Bacteria

T257 Biohydrogenation of vaccenic-1-¹³C acid by ruminal microbes in vitro. E. E. Mosley* and M. A. McGuire, *University of Idaho, Moscow.*

Efforts in the human food industry have focused on the elimination of trans fatty acids (TFA) from foods. Thus, it is vital for producers to limit the amount of TFA in beef and milk. Typically, the major trans isomer in beef and milk fat is vaccenic acid (VA). Understanding the rumen microbial modifications of VA will provide necessary information concerning biohydrogenation pathways. Our objective was to determine if VA is isomerized to other 18:1 isomers and if the isomerization and/or biohydrogenation to stearic acid is altered by other fat sources. Rumen in vitro cultures (25 ml) containing ¹³C-labeled VA at 0.25 mg/ml alone or combined with stearic acid, oleic acid, linoleic acid, linolenic acid, cis-9, trans-11 conjugated linoleic acid, corn oil or fish oil at varying concentrations (0.5, 1.0, or 1.5 mg/ml) were run under standard conditions. After 48 h, cultures were frozen, freeze dried, and direct methylated using methanolic-HCl and sodium methoxide. Fatty acid methyl esters (FAME) were converted to dimethyl disulfide derivatives (DMDS). The FAME and DMDS were analyzed by GC-MS. Significant ¹³C enrichment was found in stearic acid, cis- and trans-9, 12, 13, 14, 15, 16, and trans-10 18:1 isomers. All concentrations of fish oil inhibited the biohydrogenation of VA to stearic acid and increased the isomerization of VA to various 18:1 isomers when compared to cultures containing only VA ($P < 0.0001$). Cultures containing fish oil or oleic acid at 0.5 mg/ml contained the greatest enrichment for trans-13, 14, and 15 when compared to all other treatments ($P < 0.0001$). The biohydrogenation of VA by ruminal microbes in vitro involves the formation of positional isomers of cis- and trans-18:1 and stearic acid. Identifying the extent and profile of the TFA produced from VA in the rumen will allow the beef and dairy industries to be proactive in identifying new ways to provide more healthful products to the consumer. Supported in part by the Idaho Agricultural Experiment station and National Research

T258 WITHDRAWN

T259 Use of inter-organ glycerol fluxes to assess abdominal versus peripheral fat mobilization in transition dairy cows. M. Larsen and N. B. Kristensen*, *University of Aarhus, Tjele, Denmark.*

Glycerol flux data from 6 Holstein cows assigned to one of two treatments: No infusion (control; CON) or continuous abomasal infusion (INF) of 1500 g glucose/d (via the rumen) were used to test if fat mobilization differ between abdominal and peripheral tissues. Treatments were initiated at the day of second calving. Cows were fed the same dry-diet and the same lactation-diet, and both were fed in equally sized meals at 8 h intervals. Eight hourly sets of blood samples ($n = 2$ for hepatic vein with CON) were collected simultaneously starting 30 min before the morning feeding 12 days pre partum, as well as 4, 15, and 29 days in milk (DIM). Data was analyzed as a split-plot design and Student's *t*-test was used to test by treatment differences between pre partum and 4, 15 or 29 DIM, respectively. A strong correlation between arterial concentration of glycerol and arterial concentration of non-esterified fatty acids (NEFA) was observed across the data set ($P < 0.01$; $r = 0.88$; Glycerol = NEFA \bullet 0.070 ± 0.002). Except at 4 DIM with CON, the net portal flux and net hepatic uptake of glycerol were relatively constant at a level of 2 ± 1 and 11 ± 2 mmol/h, respectively. From pre partum to 4 DIM, the net portal flux and net hepatic uptake of glycerol tended to increase more ($P = 0.06$) for CON compared with INF (net portal flux: +5 and +1 mmol/h, respectively; net hepatic uptake: +29 and +1 mmol/h, respectively). Assuming no net absorption of dietary glycerol and that glycerol is metabolized solely in the liver, the ratio of abdominal to total fat mobilization was estimated by dividing net portal flux of glycerol by net hepatic uptake of glycerol. The ratio of abdominal to total fat mobilization was not increased ($P > 0.10$) from pre partum to 4, 15 or 29 DIM, or affected by treatment ($P = 0.94$). Thus, the ratio was remarkably constant across the data set (0.18 ± 0.02). In conclusion, the present study indicated similar rates of fat mobilization between abdominal and peripheral adipose tissues in transition dairy cows.

Key Words: Mobilization, Transition, Glycerol

T260 Correlation between UT-B mRNA abundance in ruminal epithelium and net portal flux of urea in transition dairy cows. B. A. Røjen*, P. K. Theil, M. Larsen, and N. B. Kristensen, *Faculty of Agricultural Sciences, University of Aarhus, Tjele, Denmark.*

The objective of the study was to test the hypothesis that abundance of UT-B mRNA in ruminal epithelium can explain variation in net portal flux of urea in transition cows. Six Holstein cows fitted with a ruminal cannula and permanent indwelling catheters were assigned to continuous abomasal infusion of 1500 g glucose/d (INF) or control (CON; no

infusion). Cows were fed the same dry and lactation rations in equally sized portions at 8 hour intervals. Eight hourly sets of blood samples were obtained from arterial, portal and hepatic catheters starting 30 min before morning feeding 12 days pre partum, as well as 4, 15, and 29 days post partum. Rumen papillae from the atrium were harvested at each sampling day. Abundance of UT-B mRNA was determined using real time RT-PCR and normalized by GAPDH mRNA abundance. Data was analyzed as a split-plot design using the mixed model procedure of SAS. The net portal flux of urea decreased (being less negative; $P < 0.05$) with INF compared with CON (-75 and -135 ± 13 mmol/h, respectively), and tended to decrease ($P = 0.08$) between 4 and 15 days post partum for INF compared with CON. Post partum abundance of UT-B mRNA was lowered to less than half (0.44) of the pre partum level ($P < 0.05$). No correlation ($P > 0.10$) between UT-B mRNA abundance and net portal flux of urea was detected when both pre- and post partum data were analyzed reflecting the large influence of reproductive stage on the UT-B mRNA abundance. However, weak correlations ($P = 0.04$ to 0.08) between arterial urea concentration and net portal flux of urea with UT-B abundance were observed when analysing only post partum data ($r = 0.487$ and $r = -0.426$, respectively). In conclusion data showed that UT-B abundance in ruminal epithelium appears to be strongly affected by time relative to calving. However, UT-B mRNA abundance only explained a small proportion of the variability in net portal flux of urea across individual cows, treatments, and days in lactation.

Key Words: Urea Transporter, Ruminal Epithelium, Dairy Cows

T261 Hepatic metabolism of alcohols in freshening Holstein cows. B. M. L. Raun* and N. B. Kristensen, *Faculty of Agricultural Sciences, University of Aarhus, Tjele, Denmark.*

Eight lactating Holstein cows (26 ± 7 kg milk/d; 14 ± 1 kg dry matter intake/d) implanted with a ruminal cannula and permanent indwelling catheters in major splanchnic blood vessels were used to investigate hepatic alcohol metabolism at day 4 of lactation. The hypothesis was that freshening dairy cows would have a low capacity for hepatic alcohol metabolism. Cows were randomly allocated to a 2 by 2 factorial design with one factor being level of branched chain alcohol (isopropanol from HMBi; 0.26 % of dry matter; Adisseo, France) compared with no addition of isopropanol (calcium carbonate) and the second factor being source of straight chain alcohols ethanol (1.5 % of dry matter) compared with propanol (1.1 % of dry matter). Cows were fed the same dry ration and fed the experimental rations from time of calving. The rations were fed in three equally sized portions daily at 8 hour intervals. Eight hourly sets of arterial, portal vein, and hepatic vein samples were collected. Data was analyzed as a 2 by 2 factorial design with samples within day as repeated measurements using the mixed procedure of SAS. The net portal flux of ethanol increased from 30 ± 8 to 74 ± 9 mmol/h with ethanol compared with propanol ($P < 0.01$) and the net portal flux of propanol increased from 16 ± 6 to 64 ± 5 mmol/h with propanol ($P < 0.001$) compared with ethanol. The net portal flux of isopropanol increased from 2 ± 4 to 13 ± 3 mmol/h ($P = 0.04$) with HMBi compared with calcium carbonate. Numerically net hepatic uptake of all three alcohols mirrored net portal flux and an increased hepatic uptake of propanol and isopropanol could be detected ($P = 0.04$ to $P < 0.001$). In agreement with the responsiveness in hepatic alcohol metabolism to increased alcohol absorption there were not detected any net splanchnic release of ethanol, propanol or isopropanol. In conclusion no limitation in liver capacity for metabolism of ethanol, propanol, and isopropanol

could be detected in freshening dairy cows fed rations containing alcohol levels spanning commonly observed variation in silage based rations.

Key Words: Alcohol, Dairy Cow, Metabolism

T262 Use of ARISA to monitor shifts in rumen microbial populations caused by changes in diet. S. E. Stebulis*¹, D. M. Stevenson², G. J. M. Rosa¹, and R. R. Grummer¹, ¹*University of Wisconsin, Madison,* ²*USDA-ARS-US Dairy Forage Research Center, Madison, WI.*

The objective was to determine whether automated ribosomal intergenic spacer analysis (ARISA) is sensitive enough to detect shifts in rumen microbial populations caused by dietary changes. Six ruminally cannulated, non-lactating, non-pregnant Holstein cows were sampled for rumen contents in a randomized cross-over design. Treatments were either high forage (HF) or low forage (LF) diets offered for ad libitum intake. High forage was composed of 43.7% neutral detergent fiber (NDF) and 31.2% non-fiber carbohydrate (NFC), while LF contained 25.5% NDF and 44.6% NFC. The trial consisted of 3 periods, an adaptation period (30 d), period 1 and period 2 (14 d each). Cows were switched between periods with no adaptation. Treatment sequences, including the initial adaptation period, were HF-LF-HF and LF-HF-LF. Rumen samples were collected 4 h after feeding on d 14 of each experimental period. Bacterial DNA was extracted from each sample, and the ribosomal intergenic spacer region was PCR amplified and used for ARISA. The effects of diet, fraction (liquid vs. solid), period, and cow on changes in rumen microbe population were analyzed using principal components methodology and Chi-squared tests. Rumen pH, analyzed with a mixed model, was significantly greater for HF than for LF (6.7 vs. 6.1 ± 0.08 ; $P < 0.001$). There were 253 total phylotypes (unique PCR amplicon lengths) detected using ARISA. Of these phylotypes, 25 were unique to an individual cow. There were 12 phylotypes only found in liquid and 3 only in solid fractions, and 16 only in LF and 2 only in HF. Treatment had a significant effect ($P < 0.05$) on 19 phylotypes. Thirty-two phylotypes were affected ($P < 0.05$) by fraction, and 19 were significantly different between cows ($P < 0.05$). Period affected only 6 phylotypes ($P < 0.05$). These results suggest that ARISA is sensitive enough to pick up differences in rumen microbial populations due to diet composition changes, and other factors such as rumen fraction and cow.

Key Words: Microbial Population, Diet, Rumen

T263 Evaluation of n-alkanes, chromic oxide and lignin as indigestible markers to estimate duodenal and fecal flows in lactating dairy cows. S. O. Juchem*¹, E. J. DePeters¹, J. M. Heguy¹, S. J. Taylor¹, and J. E. P. Santos², ¹*University of California, Davis,* ²*University of Florida, Gainesville.*

The objective was to compare estimates of duodenal and fecal flows obtained from 3 markers, being n-alkanes (ALK; internal, C31 and C33; external, C32 and C36), chromic oxide (CrO; external) and lignin (LIG; internal). Four lactating primiparous Holstein cows cannulated in the rumen and duodenum were utilized in a 4x4 Latin Square design experiment. Each period lasted 14 d, 10 d of adaptation and 4 d of sampling, whereas cows were subjected to 97% feed restriction during the last 4 d to prevent refusals. A new n-alkane slow releasing capsule (CAPTEC, Auckland, NZ) was placed into the rumen at d 0 of each

period in each cow. Chromic oxide was added at 0.11 % of diets DM. All diets had similar chemical composition, and alfalfa hay was the only forage source (47.7 % of DM). Five samples of duodenal digesta (2.5 L) and feces (~500 g) were sampled during the last 4 d of each period at different times in relation to feeding to create an average composite sample. Data were analyzed by the MIXED procedure of SAS, with a model that included effects of cow, period, diet, marker and the marker by diet interaction. DM intake was not affected by dietary treatments (20.1; 18.5; 19.5; 18.8 kg/d). Apparent whole tract digestibility of OM was highest ($P < 0.01$) for CrO (71.9%), intermediate for C31, C33 and LIG (64.0; 65.3; 65.5%), and lowest for C32 and C36 (59.6; 60.7%). Duodenal DM flow was highest ($P < 0.01$) when C32 and C36 dosed ALK were utilized (14.3; 14.4 kg/d), smallest for C31 and C33 dietary ALK (11.0; 10.9), and intermediate for CrO and LIG (12.3; 12.8 kg/d). Fore-stomach disappearance of NDF-ash free was highest ($P < 0.05$) for C31 and C33 (41.7; 42.1%), intermediate for CrO and LIG (34.8; 32.2%), and lowest for C32 and C36 (24.6; 23.9%). Disappearance of starch was lower ($P < 0.05$) for C32 and C36 ALK (52.4^c; 53.2^c%), however C31, C33 and CrO provided similar estimates (63.9^a; 64.2^a; 60.1^{ab}%), whereas LIG was intermediate (58.1^{bc}%). N-alkanes from feed provided estimates of diet digestibility that were close to CrO estimates, and can be utilized as an alternative indigestibility marker.

T264 The use of flow cytometry to assess rumen bacteria in dairy heifers limit fed different forage to concentrate ratios with *Saccharomyces cerevisiae*. G. J. Lascano* and A. J. Heinrichs, *The Pennsylvania State University, University Park.*

Counting total viable bacteria using colony-unit forming assays lacks accuracy, as this method only includes culturable bacteria capable of initiating cell division. Thus, viable bacterial counts are often underestimated and total counts unknown. Both live and total bacteria populations can be enumerated using fluorescent characteristics of cell membranes and flow cytometry. The objective of this experiment was to investigate viable and total rumen bacteria counts using LIVE/DEAD Backlight kit (Invitrogen, Corp.) when 3 levels of forage:concentrate (F:C) were fed to heifers at restricted levels of intake with or without the addition of *Saccharomyces cerevisiae* (YC, Yea-Sacc¹⁰²⁶, Alltech, Inc). Three cannulated, post-pubertal Holstein heifers (age 18 ± 1 mo) were fed corn silage (CS)-based diets in a 3-period (35 d) Latin Square design. Heifers were fed F:C treatment diets for 21 d, followed by 14 d with YC added (1 g/kg, as fed). High concentrate (HC) TMR (40% CS, 60% grain; 12.6% CP, 25% NDF), medium concentrate (MC) TMR (60% CS, 40% grain; 12.3% CP, 28% NDF), and low concentrate (LC) TMR (80% CS, 20% grain; 12.4% CP, 35% NDF) were fed once/d. Rumen fluid was sampled at -2, 0, 2, 4, 6, 8, 10, 12 h after feeding. Samples were immediately stained with LIVE/DEAD kit and analyzed with a Coulter XL-MCL single laser flow cytometer (Beckman Coulter, Inc.). Mean live bacteria count was not different among treatments ($6.75, 4.77, 4.97 \times 10^{11} \pm 0.53 \times 10^{11}$ cells/mL; $P = 0.10$) for HC, MC and LC, but YC addition increased number of viable bacteria in all treatments ($P < 0.01$). There was also a ration by YC interaction with greatest differences in the HC diet ($P = 0.01$). Total live bacteria counts decreased after feeding ($P < 0.01$) and began to increase 4 h after feeding. We conclude that feeding different ratios of F:C did not change total viable bacteria population, but YC increased this count in all 3 diets in this experiment.

Key Words: Viable Bacteria Count, Flow Cytometry, Yeast Culture

T265 Updates to the Cornell Net Carbohydrate and Protein System: Effects of changes in feed digestion rates and passage rate assignments on metabolizable energy and protein predictions. E. B. Recktenwald*, D. A. Ross, T. R. Overton, L. E. Chase, P. Huhtanen, and M. E. Van Amburgh, *Cornell University, Ithaca, NY.*

Evaluations of the Cornell Net Carbohydrate and Protein System (CNCPS) v6 were made with data from individually fed lactating dairy cows from three independent studies. As implemented, CNCPSv6 accounted for a similar proportion of the variation (86%) in first limiting (ME or MP) milk production as CNCPSv5 but with a lower bias (Tylutki et al. 2007). Further evaluations of observed data from cows fed more MP limiting diets demonstrated large biases in the MP allowable milk (up to 9 kg/d) and this was investigated. Pool sizes and rates of carbohydrate digestion were updated based on the data of Lanzas et al. (2007). In CNCPS v6, NDF degradation rates were linked to NDIN rates to based on the available data on pool degradation characteristics. The soluble protein pools sizes and rates were also evaluated and modified based on the available literature data on protein degradation and flow out of the rumen. For example, the protein A pool rates were decreased from 10,000%/h (Sniffen et al. 1992) to 200%/h. Further, the standardized precipitation method (Licitra et al. 1996) underestimated the peptide content of many forages; thus modifications to the NPN pool were made based on the available feed chemical data. Finally, within the structure of the model the soluble pools (both carbohydrate and protein) were linked to the liquid passage rate equations; they were previously linked to the solids passage rates. Data from 141 observations from individual cows and from means of independent studies were used to re-evaluate CNCPSv6 after these modifications; improvements were demonstrated in ME and MP allowable milk predictions (Table 1).

Table 1.

Prediction	CNCPS Version	Mean prediction	Mean prediction bias	RSMPE	Residual error	Obs vs pred slope
MP	6.0	37.04	-2.57	5.52	4.88	0.73
MP	6.1	41.34	1.66	5.21	4.94	0.74
ME	6.0	44.97	5.35	7.84	5.73	0.66
ME	6.1	44.76	5.08	7.60	5.66	0.67
Most limiting	6.0	36.91	-2.70	5.49	4.77	0.74
Most limiting	6.1	40.60	0.92	4.70	4.61	0.77

Key Words: CNCPS, Metabolizable Protein, Modeling

T266 Dynamics of ruminal fiber digestion of corn milling co-products. L. O. Tedeschi¹, P. J. Kononoff², K. Karges³, and M. L. Gibson³, ¹Texas A&M University, College Station, ²University of Nebraska, Lincoln, ³Dakota Gold Research Association, Sioux Falls, SD.

The corn-ethanol dry milling industry is a major producer of feedstuffs, namely distillers dried grains plus solubles (DDGS). This industry has also produced new feeds that differ in chemical composition and possibly nutrient availability. The objective of this study was to evaluate the dynamics of ruminal fiber digestion of several co-products. Thirty samples of four corn milling co-products were evaluated in this study:

DDGS, high protein DDGS (HP-DDGS), bran (BRAN), and dehydrated germ (GERM). Alfalfa hay (HAY) was used as a standard feed in the in vitro fermentation dynamics analysis. Neutral detergent residue (without sodium sulfite; NDR) averaged 32.9, 34.8, 21.9, 33.5 % for DDGS, HP-DDGS, BRAN and GERM respectively. The CP and ether extract averaged 30.8 and 11.2 %, 44.6 and 4.18 %, 15.3 and 9.49 %, and 17.4 and 17.4% for DDGS, HP-DDGS, BRAN and GERM, respectively. The feeds were fermented in vitro for a 48 h period. Gas production was measured using a computerized system and data was fitted to an exponential model to compute the fractional degradation rate (kd). Statistical analyses were performed using the random coefficients model assuming an incomplete block design. The TDN for each feed was predicted using a summative equation with the kd of NDR. The kd of NDR and defatted fiber residue (DFR) were significantly different ($P < 0.05$) for DDGS, HP-DDGS, BRAN and GERM, and was estimated to be 6.88 and 8.44 %/h, 11.8 and 11.7%/h, 6.14 and 8.52%/h, 7.24 and 9.14%/h, respectively. Robust regressions were developed to compute kd of NDR using standard chemical analysis. The results suggested that the proportion of fiber digested in the rumen were affected by degree of sample processing and fat removal. Although tabular values for the rate of NDF digestion in the CPM-Dairy model are generally indicative of many feed co-products, these results suggest that the digestion rates of fiber may vary greatly across different types of co-products. Furthermore, the use of model simulations in this study demonstrated that observed differences in fermentability and chemical composition result in differences in the supply of TDN for lactating dairy cows.

Key Words: Fiber, Co-Products, Rumen

T295 Use of the mobile nylon bag method to determine phosphorus disappearance in common dairy cattle ration ingredients. N. M. Cherry*¹, B. D. Lambert^{1,2}, and J. P. Muir¹, ¹Texas AgriLife Research, Stephenville, TX, ²Tarleton State University, Stephenville, TX.

Phosphorus (P) excretion in manure and has become a major problem facing dairy producers in much of the United States. Excess P released into the environment may pollute surface waters leading to eutrophication and excess algal growth. One approach to reducing P excretion is to avoid excess dietary P. Data regarding P availability in feedstuffs is limited and more precise ways of measuring P availability in the digestive tract are needed. In this experiment the mobile nylon bag method was used to determine the disappearance of dry matter (DM) and P in ground corn, corn silage, alfalfa hay, coastal bermudagrass hay, and Tifton-85 bermudagrass hay in steers after ruminal (24 hrs), ruminal + pepsin/HCL (rumen + PH), and ruminal + pepsin/HCL + intestinal (rumen + PH + I) incubation. Ruminal degradation of both P and DM differed ($P < 0.05$) between feedstuffs, and by site of incubation. DM total-tract (rumen + PH + I) availability for ground corn, corn silage, alfalfa hay, coastal bermudagrass hay, and Tifton-85 bermudagrass hay were 90.35, 51.89, 41.66, 69.04, 71.79% respectively. Total tract (rumen + PH + I) P availability for ground corn, corn silage, alfalfa hay, coastal bermudagrass hay, and Tifton-85 bermudagrass hay were 99.22, 92.22, 94.81, 84.55, and 85.36%, respectively. The variability in the availability in P (~15%) indicates that inclusion of a P availability coefficient in ration balancing software could have a measurable impact on subsequent P excretion from dairy cattle. More data concerning P availability as affected by feed ingredient or plant species, maturity and quality are needed to more accurately define P availability in dairy cattle feeds.

Small Ruminant: Goats

T268 Evaluation of the FAMACHA(R) system, fecal egg counts, hematocrits and weight of sheep and goats associated with parasitism fed varying levels of herbs and protein/energy grain. H. A. Swartz*¹, A. Stewart¹, D. Sommerer¹, F. Wulff¹, and M. Ellersieck², ¹Lincoln University, Jefferson City, MO, ²University of Missouri, Columbia.

A study was conducted to determine the effects of feeding various levels of protein/energy grain in an herbal mixture to Katahdin (K) hair sheep (n=39), Dorset(D) wool sheep (n=36) and Boer (B) goats (n=52), evaluating the FAMACHA[®] system for anemia compared to the red blood cell volume (hematocrit). The FAMACHA[®] system has been shown to be a useful tool in sheep in identifying clinical anemia associated with parasitism. However, the application of FAMACHA[®] to goats has not been evaluated. The FAMACHA[®] system has a scale based on the color of the ocular conjunctiva; 1-2 red and healthy, 3 borderline and 4-5 pale pink to white indicating anemia. The herbs consisted of 40.5% wormwood (*Artemisia absinthium*). Treatment groups were Dorsets, 1) control, 2) .11 gm/hd herbs plus .227kg/hd 14% protein/corn based diet daily (grain), 3) .11 gm/hd herbs weekly plus .227 kg/hd grain weekly. Katahdin sheep received 4) control, 5) 5.5 gm/hd herbs weekly and .113 kg of grain daily, 6) 5.5 gm/hd herbs plus .113 kg/hd grain weekly. Boer goats were fed 7) .113 kg/hd grain weekly 8) 5.5 gm/hd herbs plus .227 kg/hd grain daily and 9) 5.5 gm/hd herbs plus .113 kg/hd grain daily. Fecal egg counts (FEC), hematocrits (HEM), FAMACHA[®] (FAM) readings and weight (WT) were collected at the beginning of the project in all treatments and every four weeks. Data were analyzed in the SAS system for Pearson correlation coefficients and MIXED procedure in all treatments. The correlations of FEC to HCT ($r = -.37$), FEC to FAM ($r = .27$), HCT to FAM, ($r = -.27$) & HCT to WT ($r = .43$) with the K & D, significantly related ($P < .05$). The FAM to HCT in the Boer goats was not applicable showing no relationship in differences. There were no significant differences in treatment groups of K, D & B. The daily feeding of grain compared to the weekly feeding in sheep and goats and increase in feed from .113 to .227 in D and one group of B showed no significant differences in treatments. The FAM readings were effective in the sheep but not in the meat goats in HCT.

Key Words: FAMACHA, Deworming, Herbs

T269 The effect of garlic on *Haemonchus contortus* infection in goats. Z. Wang*, E. Loetz, A. L. Goetsch, S. P. Hart, and T. Sahl, American Institute for Goat Research, Langston University, Langston, OK.

Garlic has been used in some countries as an ingredient in deworming remedies for humans and animals for many years. The study reported here determined the efficacy of garlic for treatment of *H. contortus* infection and effect on immune responses in goats. Twelve Spanish wethers (1.5 yr, 35 ± 1.5 kg BW) naturally infected with *H. contortus* were allocated to two groups of six each and housed individually. Goats were fed hay-based diets (ME = 8.7 MJ/kg DM; CP = 10%) without or with 2% of garlic powder. The diets were offered for 4 wk at a maintenance level of intake. The initial mean fecal egg counts (FEC) were $4,983 \pm 1,973/g$ (range of 1,125 to 13,652/g) for the Control group and $8,654 \pm 3,548/g$ (range of 2,050 to 22,225/g) for the Garlic group. There was not a time x treatment interaction in FEC ($P > 0.05$). With initial FEC as a covariate, the garlic treatment reduced FEC (geometric mean:

$7,872 \pm 38.6/g$ for Control and $699 \pm 38.4/g$ for Garlic, respectively; $P < 0.001$) during the experimental period. Serum concentrations of IgA, IgE, and IgG on d 0, 14, and 28 were not affected ($P > 0.05$) by garlic intake. The BW of goats did not change during the experiment and was not affected by treatment ($P > 0.05$). These data suggest that the decline in FEC may be attributable to cell mediated immunity rather than a humoral immune reaction or direct garlic toxicity to the parasites. The results demonstrate that garlic is a potent anthelmintic herb and warrant more work to elucidate the mechanism.

Key Words: Goats, Garlic, *Haemonchus*

T270 Efficacy of wormwoods (*Artemisia* spp.) as an anthelmintic in goats. S. P. Hart*¹, J. F. S. Ferreira², and Z. Wang¹, ¹American Institute for Goat Research, Langston University, Langston, OK, ²Appalachian Farming Systems Research Center, USDA-ARS, Beaver, WV.

Gastrointestinal nematodes (GIN) are the greatest health problem in goat production and control of GIN has become difficult due to development of anthelmintic resistance. Therefore, there is a need to investigate plant materials with potential anthelmintic activity. The objective of this study was to investigate the efficacy of two wormwood species against GIN in goats. A native wormwood (*Artemisia ludoviciana*) was harvested at the mature stage and whole plants were air-dried and fed to goats (B). *Artemisia annua* was cultivated and harvested at the late vegetative stage and air-dried; leaves were stripped from the stalks, dried at 45°C in a forced-air oven and crushed (L). Dry open Boer and Boer cross does (average BW = 42.3 kg) adapted to Calan headgates were used in this study. Does were housed in a barn and fed a control diet, 0.45 kg of a grain supplement (13% CP and 75% TDN) and 0.9 kg of a low quality hay (7% CP and 68% NDF) for a 7-d adaption period. Goats were randomly assigned to treatments. Seven does received the control diet throughout the study. Four animals received 0.34 kg B, 0.34 kg grain supplement, and 0.68 kg hay for 4 d and then received the control diet for the remainder of the study. Six animals were fed 0.45 kg L, 0.45 kg supplement, and 0.45 kg hay for 6 d and then received the control diet for the rest of the study. Fecal samples were taken for two consecutive days prior to feeding treatment diets and then on alternate days for 14 d. Fecal egg counts (FEC) were conducted by the McMaster procedure. The FEC were log transformed prior to statistical analysis. There was a significant time (pre-treatment vs post treatment) by treatment interaction ($P < 0.002$). Control FEC increased from 1,266/g to 1,673/g whereas B FEC decreased from 3,998/g to 2,979/g. Conversely, FEC for L was unchanged (2,510/g vs 2,419/g). The apparent anthelmintic activity of *Artemisia ludoviciana* merits further investigation, especially at a younger stage of maturity.

Key Words: Anthelmintic, Gastrointestinal Nematodes, Alternative Dewormer

T271 Influence of sericea lespedeza pellets on gastrointestinal parasite fecal egg counts in goats. N. C. Whitley*¹, T. H. Terrill², J. E. Miller³, J. M. Burke⁴, and M. C. Gooden¹, ¹University of Maryland Eastern Shore, Princess Anne, ²Fort Valley State University, Fort Valley, GA, ³Louisiana State University, Baton Rouge, ⁴USDA-ARS-DBSFR, Booneville, AR.

The objective of the experiment was to determine the influence of sericea lespedeza pellets (SLP) on gastrointestinal parasite fecal egg counts (FEC) in goats. Naturally infected, mixed sex Boer crossbred goat kids were used at 22.5 ± 0.74 kg body weight. Animals housed on pasture and being supplemented at approximately 2% BW concentrate daily were removed from pasture at an average FEC of 2468 ± 302 epg. Goats were placed in individual pens with concrete-slatted or expanded metal flooring with goats allotted to treatments of 0 (CON), 20, 40, or 60% SLP (20SLP, 40SLP, 60SLP) to account for sex, body weight, pasture FEC and flooring type with 13, 10, 9 and 13 goats per treatment, respectively. Diets were mixed to be isonitrogenous and isocaloric, and included alfalfa pellets to provide a pelleted legume forage control. Blood samples for packed cell volume (PCV; packed red blood cell level/serum level $\times 100\%$) and fecal samples for FEC (using the Modified McMasters technique) were collected on d-1, 7, 14, 21 and 28. Larval culture for speciation was conducted on fecal samples collected on d 28 of the study. Statistical analysis was conducted using the MIXED procedure of SAS for repeated measures and Pearson Product Moment correlations were conducted using the CORR procedure of SAS. In this study, PCV and FEC were negatively related ($r = -0.37$; $P < 0.0001$) as were FEC and body weight ($r = -0.20$; $P < 0.004$). Mean PCV and FEC were not influenced by treatment, averaging $27 \pm 1.5\%$ for CON, $33 \pm 1.8\%$ for 20SLP, $33 \pm 1.7\%$ for 40SLP and $31 \pm 2.2\%$ for 60SLP. The FEC averaged 2690 ± 483 epg for CON, 1406 ± 551 epg for 20SLP, 1517 ± 529 epg for 40SLP and 1266 ± 690 epg for 60SLP diets. Larval speciation through fecal culture indicated that at the end of the study, *Haemonchus contortus* larva were 43, 39, 35 and 31% of the sample for CON, 20SLP, 40SLP and 60SLP, respectively. So, overall larval cultures and PCV indicated a modest to low infestation level of *H. contortus*, which might have been selectively reduced by SLP. However, more research is needed to determine the influence of SLP on gastrointestinal nematodes in goats.

Key Words: Parasites, Tannin, FEC

T272 Effect of somatic cell count in goat milk on yield and sensory quality of semi-hard cheese. S. S. Chen^{1,2}, L. Zhang^{1,3}, B. Bah¹, and S. S. Zeng*¹, ¹American Institute for Goat Research, Langston University, Langston, OK, ²College of Food Science & Nutritional Engineering, China Agricultural University, Beijing, China, ³Northeast Agricultural Research Center of China, Changchun, China.

This study investigated the effect of somatic cell count (SCC) in goat milk on yield and sensory quality of semi-hard cheese. Thirty kilograms of goat milk with SCC levels of 410,000 (Low), 770,000 (Medium), and 1,250,000 cells/ml (High) was obtained from the Alpine herd of the American Institute for Goat Research for the manufacture of semi-hard cheese in the Langston University dairy processing pilot plant for two consecutive weeks at three stages of lactation. Cheese milk prior to cheesemaking was analyzed for SCC, total solid (TS), protein, and fat in the Langston Dairy Herd Improvement (DHI) laboratory. Cheese yield was recorded on day 1 and cheese samples on days 1, 60 and 120 of aging were analyzed for scores of total sensory, flavor, and body/texture, and contents of moisture, protein, and fat. Results indicated that there were no significant differences ($P > 0.05$) in cheese yield among milk with different SCC levels. However, goat milk with high SCC resulted in significantly lower ($P < 0.05$) scores of total sensory and body/texture than milk with low or medium SCC, although no difference was observed in flavor score. A higher ($P < 0.05$) cheese yield was obtained from goat milk in early lactation (April) than in mid- (July) or

late lactation (October) probably because of a higher total solids content in early lactation milk. Aging for 60 days or more improved ($P < 0.05$) scores of total sensory, flavor, and body/texture in cheese as expected. It is concluded that SCC in goat milk did not affect the yield of semi-hard cheese but high SCC resulted in inferior sensory quality.

Key Words: Somatic Cell Count, Goat Milk, Cheese

T273 Replacement of coastcross hay by soybean hulls in lactating dairy goat diets. R. S. Gentil*, C. Q. Mendes, I. Susin, A. V. Pires, G. H. Rodrigues, F. S. Urano, E. M. Ferreira, R. C. Amaral, and M. F. Ribeiro, *Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo (USP), Piracicaba, SP, Brazil.*

Soybean hulls (SH) can be used to replace either grain or forage in diets for lactating dairy ruminants. Most of research has been directed towards dairy cows, while for lactating goats there is little information about the effects of SH on intake, milk yield and composition. Thirty-six lactating Saanen goats (45 ± 8 DIM) were assigned to a complete randomized block design (according to milk production, DIM and number of lactation) to determine the effects of replacing coastcross hay neutral detergent fiber (NDF) by soybean hulls NDF on dry matter intake (DMI) and milk yield and composition. Goats were housed individually in a tie stall for a period of 8 weeks. Does were fed a 50:50 (concentrate:roughage ratio) TMR with 15% crude protein and with similar amount of NDF. Soybean hulls replaced hay by 0%, 33%, 67% or 100% on a DM basis, corresponding to the experimental treatments OSH, 33SH, 67SH and 100SH, respectively. Does were milked twice a day and milk samples were saved in-bromo-2-nitropropane-1-3-diol to determine composition by infrared absorbance. There was a linear decrease in daily milk production (2.76, 2.48, 2.58 and 2.05 kg), 3.5% fat-corrected milk (2.93, 2.54, 2.42 and 2.05 kg), lactose (4.51, 4.44, 4.38 and 4.33%) and total solids (12.45, 12.14, 11.60 and 11.63%) for OSH, 33SH, 67SH and 100SH, respectively, when SH were added to the diet. However, milk fat (3.86, 3.63, 3.23 and 3.56%) and milk protein concentration (2.99, 3.03, 2.94 and 2.85%) were similar ($P > 0.05$) among treatments. There was a quadratic response ($P < 0.01$) on daily DMI (2.18, 2.70, 2.46 and 1.89 kg) and feed efficiency (1.33, 0.93, 0.98 and 1.10 3.5% FCM.DMI-1) when SH replaced coastcross hay in the diet. These data suggest that partial replacement of coastcross hay by SH improves DMI. However, there was no beneficial effect on milk production and composition.

Key Words: Co-Products, Fiber, Saanen

T274 Classification tree analysis of grazing behavior in goats. T. A. Gipson*, A. R. Askar, A. Beker, R. Puchala, A. Asmare, G. D. Detweiler, and A. L. Goetsch, *American Institute for Goat Research, Langston University, Langston, OK.*

Electronic monitoring equipment may allow for characterization of grazing behavior without potential effects of human visual observation. Translating equipment output into specific activities, however, is challenging. Therefore, this study was conducted to develop means of predicting grazing behavior based on visual observation from output of currently available electronic monitoring systems. There were 1,538 5-min observations of grazing activity (G = grazing; RL = resting, lying; RS = resting, standing; W = walking) at two locations collected by four

observers on 28 goats over 4-d periods. There were 390, 627, 478, and 43 observations for G, RL, RS, and W, respectively. Goats were fitted with GPS collars (GPS 3300, Lotek, Newmarket, Ontario, Canada) to ascertain distance between consecutive GPS fixes. Collars were equipped with left-right (X-activity), forward-backward (Y-activity), and head-down motion sensors. A leg activity/position sensing system (IceTag, IceRobotics, Midlothian, Scotland, UK) was employed to determine stepping, standing, and lying. Classification tree analysis was conducted using CART[®] software. A decision tree, which is a diagram representing a classification system, with a minimum relative cost criterion of 0.560 yielded 18 terminal nodes. Prediction success rate for G was 70.3% (i.e., 274, 35, 48, and 33 G observations were classified into G, RL, RS, and W terminal nodes, respectively). Success rate for RL was 74.0% (57, 87, and 19 RL observations classified as G, RS, and W, respectively). Success rate for RS was 48.5% (93, 106, and 47 RS observations classified as G, RL, and W, respectively). Success rate for W was 83.7% (5, 1, and 1 W observations classified as G, RL, and RS, respectively). Output from currently available electronic monitoring equipment systems can be used to predict grazing behavior of goats based on visual observation; however, prediction success rate is less than optimal. Other potential monitoring equipment should be evaluated to improve success rate.

Key Words: Goats, Grazing, Predictive Model

T275 Integration of meat goat production into pine silvopasture.

R. C. Lawler^{*1}, N. K. Gurung¹, M. S. Goodman², and O. Bolden-Tiller¹, ¹Tuskegee University, Tuskegee, AL, ²Auburn University, Auburn, AL.

Little is understood about how meat goat production can be included as a value added product to high value saw log production in pine silvopasture. Understanding animal-plant interactions in these systems is key to their sustainable management. The objectives were to determine the optimum stocking rates of Boer cross wethers goats on recently thinned and pruned loblolly pine plantation. Three stocking rates (SR) at 0.50 animal unit equivalent (AUE)/ha (low), 0.75 AUE/ha (medium), and 1.0 AUE/ha (high) (equivalent to 10, 15, and 20 goats/ha, respectively) were evaluated in a randomized complete block design at the Federation of Southern Cooperatives, Epes, AL. Goats were weighed at 30 d intervals over a 90-d period to determine ADG. Available plant biomass quality and quantity were determined before and after the grazing period. Blood samples were collected to assess blood urea nitrogen (BUN). The ADG were higher ($P < 0.05$) for the low SR compared to the medium and high SR while no differences were observed ($P > 0.05$) between the latter two treatments. The BUN concentrations were not different among treatments during the first 30 days ($P > 0.10$), but as the season progressed, goats on higher SR tended to have higher BUN values ($P < 0.08$), particularly at d 60 and 90. At the start of the trial, average plant biomass was 1071, 862, and 1033 kg DM/ha for low, medium, and high SR, respectively. Corresponding values at the end of the trial were 1445, 560 and 813 kg DM/ha. The control paddocks contained an average of 1014 kg DM before and 1852 kg DM at the end of the trial. Biomass DM declined at a faster rate on plots with higher SR; percentage changes were +82.8, +35.0, -35.1, and -21.3 for the control, low SR, medium SR, and high SR, respectively. Nutrient composition of plant biomass, measured as CP, NDF, ADF and acid detergent lignin did not differ ($P > 0.05$) among treatments. Because the study year occurred during a drought year, further studies are required in average or above average precipitation years.

Key Words: Goats, Silvopasture, Stocking Rate

T276 Mineral requirements for growth of Moxoto goats grazing in the semi-arid region of Brazil. M. J. Araújo¹, A. N. Medeiros¹, S. Gonzaga Neto¹, R. G. Costa¹, I. A. M. A. Teixeira^{*2}, K. T. Resende², C. A. T. Marques¹, G. M. P. Melo², and S. F. Souza¹, ¹Universidade Federal da Paraíba/UFPB, Areia, PB, Brazil, ²Universidade Estadual Paulista/UNESP, Jaboticabal, SP, Brazil.

Indigenous goats play an important role for the semi-arid region of Northeastern Brazil as a biological resource with great genetic variability. In addition, they are a source of animal protein of high biological value available to people of low income. However, there is a lack of information about these animals; mainly regarding their nutritional requirements. Therefore, the objective of this study was to determine net mineral requirements for growth of thirty-six male Moxoto goat kids (15.69 ± 0.78 kg initial BW), grazing in the semi-arid region of Brazil. Four kids were slaughtered at the beginning of the experiment (baseline group, 15.37 ± 0.30 kg BW) and the remainder (n = 32) were allocated randomly to one of the four levels of supplementation (treatment groups: 0, 0.5, 1.0 and 1.5% BW). There were eight kids per treatment. When the animals in the 1.5% BW treatment group reached 25 kg BW, the animals in all treatment groups were slaughtered. The individual whole empty body was weighed, ground, mixed and sampled for chemical analyses. The body composition (g/kg empty body weight; EBW) ranged from 10.80 to 11.50 g Ca; 7.86 to 8.74 g P; 0.37 to 0.42 g Mg; 1.57 to 1.61 g Na and 1.58 to 1.74 g K, for Moxoto kids between 15 and 25 kg BW. The net mineral requirements (g/kg empty body weight gain; EWG) were determined by comparative slaughter technique which ranged from 9.53 to 10.65 g Ca; 7.41 to 8.65 g P; 0.36 to 0.43 g Mg; 1.31 to 1.41 g Na and 1.47 to 1.70 g K for animals with BW ranging from 15 to 25 kg. In conclusion, our study indicated that indigenous goats grazing in the semi-arid region of Brazil have different mineral requirements from those values recommended by international committees for dairy and meat goats.

Key Words: Body Composition, Caatinga, Indigenous Goats

T277 Mineral requirements of Saanen growing kids. K. T. Resende^{*1}, D. Oliveira¹, I. A. M. A. Teixeira¹, A. N. Medeiros², and A. C. D. Ferreira³, ¹Universidade Estadual Paulista/Unesp, Jaboticabal, SP, Brazil, ²Universidade Federal da Paraíba, Areia, PB, Brazil, ³Universidade Federal do Sergipe, Aracaju, SE, Brazil.

The aim of this study was to determine the calcium (Ca), phosphorus (P), magnesium (Mg), sodium (Na) and potassium (K) requirements for growth of 20 Saanen intact male kids (5.30 ± 0.34 kg of initial BW). The kids were fed for ad libitum intake, and were slaughtered when they reached an average BW of 5.30 ± 0.14 kg (n = 6), 12.90 ± 0.32 kg (n = 6), and 21.03 ± 0.36 kg (n = 8) kg. Individual body components (head plus feet, hide, internal organs plus blood, and carcass) were weighed, ground, mixed, and samples were taken to chemical analyses. A completely randomized design was used with 3 treatments (slaughter weight). The allometric equations used to estimate the relationship between calcium, phosphorus, magnesium, sodium and potassium contents on the empty body and empty body weight (EBW) presented good data adjustment (R^2 ranged from 0.92 to 0.98). Whereas the proportions of Ca, P, Mg, Na and K in the empty body ranged from 9.91 to 10.85 g Ca/kg of EBW; 8.75 to 8.99 g P/kg of EBW; 0.78 to 0.65 g Mg/kg of EBW; 2.01 to 1.09 g Na/kg of EBW and from 2.71 a 1.62 g K/kg of EBW at 5 and 20 kg of BW, respectively. The net requirements for gain of BW ranged from 903 to 988 mg Ca/day/100 g, from 759 to

779 mg P/day/100 g, from 56 to 47 mg Mg/day/100g; from 84 to 46 mg Na/day/100g, from 132 to 79 mg K/dia/100g BW, for Saanen kids at 5 and 20 kg BW. Our results suggest that the mineral requirement for growing dairy goats raised under tropical conditions differ from the established recommendations.

Key Words: Body Composition, Goat, Major Mineral

T278 Effects of induced copper deficiency with added molybdenum on health and immune responses of male goat kids. S. Solaiman, S. Roper, K. Beguesse*, G. Reddy, N. Gurung, and K. Copedge, *Tuskegee University, Tuskegee, AL.*

Eighteen male goat kids (BW = 25.6 +/- 1.04 kg) were randomly assigned to three treatment groups. Groups (1) received grain mix (GM) with no added molybdenum (Mo), (2) received GM with 5 ppm additional Mo, and (3) received GM with 10 ppm additional Mo. Animals were housed individually and fed a 50:50 GM: bermudagrass hay twice daily for 12 wks. Blood was collected every 4 wks to determine blood metabolites and complete blood count. Parasite load was measured through egg counts per g of feces (FEC). Vital signs and body condition scores were recorded every 4 wks. Humoral immunity was evaluated through injection of chicken ovalbumin on wk 10 to measure IgG antibody titer. Cell-mediated immunity was measured via sub-dermal injection of phytohemagglutinin on wk 12, and post measurement of lymphocyte proliferation via caliper measurement of skin folds. Animals were slaughtered and liver and kidney samples were analyzed for copper content. Vital signs and body condition scores were not affected by treatments; however, rumen contraction tended to be lower in goats receiving 5 ppm added Mo (quadratic, $P = 0.07$). There was no difference in FEC between treatment groups. Blood serum chemistry did not change except for creatine decreased (linear, $P = 0.005$), alkaline phosphatase increased (linear, $P = 0.002$), and gamma-glutamyl transferase tended to increase (linear, $P = 0.07$) as Mo increased in the diets. Creatinine kinase tended to be higher (quadratic, $P = 0.1$) in goats receiving 5 ppm added Mo. Serum copper did not change, liver copper decreased (linear, $P = 0.003$) and kidney copper increased (linear, $P = 0.0001$) as Mo increased in the diets. Red blood cells decreased (linear, $P = 0.02$) and white blood cells were higher (quadratic, $P = 0.01$) in goats receiving 5 ppm Mo with no difference in differential counts. Immune response measured by skin thickness, was lower after 24 hours (linear, $P = 0.007$) and 48 hours (linear, $P = 0.01$) as level of Mo increased in the diets. Antibody titer decreased ($P = 0.04$) with added 10 ppm Mo in the diet. Goats on 5 or 10 ppm added Mo had no apparent copper deficiency symptoms, except lowered immune responses.

Key Words: Copper-Molybdenum, Goats, Immune Response

T279 Effects of synchronizing the release of energy and nitrogen in the rumen on nitrogenous flow at the duodenum of cashmere goats. D. P. Bu^{2,1}, D. X. Lu^{*2}, W. Cui⁴, J. Loo³, and J. Q. Wang¹, ¹Chinese Academy of Agricultural Sciences, Beijing, P. R. China, ²Inner Mongolia Agricultural Science And Technology, Hohhot, P. R. China, ³University of Illinois, Urbana, ⁴Ningxia University, Yinchun, P. R. China.

Twelve cashmere goats with a cannula in rumen and proximal duodenum were used in a 2 x 2 factorial design to examine the effects of

synchronizing (S) the release of energy and nitrogen in the rumen as well as feeding frequency (F) on nitrogenous flow at the duodenum. All diets were isonitrogenous and isoenergetic but differed in their synchrony index (SI). To calculate SI, based on previous results from our laboratory, we set optimum microbial protein synthesis at 23g rumen-digestible-nitrogen (RDN)/kg digestible organic matter (DOM). Calculated SI (0 to 1.0) was 0.92, 0.84, 0.82, or 0.56 for the greater S diet fed 4 x d (GSF4), lower S diet fed 4 x d (LSF4), greater S fed twice per d (GSF2), or lower S fed twice per d (LSF2), respectively. Goats receiving LSF4 or GSF4 were fed at 0600, 1200, 1800, and 2400 h. Goats receiving LSF2 or GSF2 were fed at 0600 and 1800 h. Flow of DM at the duodenum was estimated using Co-EDTA as indigestible marker, during the last 6 d of each experimental period. Duodenal digesta was collected every 6 h/d during the last 6 d of each experimental period and pooled within each animal. Nitrogen intake averaged 11.9, 11.3, 11.6 and 11.0 g/d in GSF4, LSF4, GSF2 and LSF2 ($P > 0.05$), respectively. Flow of total-N at duodenum was 13.8, 11.4, 14.9 and 10.6 g/d ($P > 0.05$), separately. Microbial-N flow was greater when goats were fed either greater-S diets (3.2 vs. 2.1 g/d; $P < 0.05$) or at a greater frequency (3.0 vs 2.3 g/d; $P < 0.01$). Duodenal flow of non-ammonia N (NAN) tended to be greater (2.1 vs 2.72 g/d; $P = 0.09$) in animals fed lower-S diet compared with greater-S diets. There was a linear correlation between flow of microbial-N and rumen SI ($R^2 = 0.87$; $n = 12$). Overall, these results indicated that synchronizing the rate of supply of RDN and DOM in the rumen increased the efficiency of microbial protein synthesis and microbial protein flow to the duodenum. We conclude that flow of microbial-N might be improved by increasing rumen SI.

Key Words: Rumen Fermentation, Synchronization, Feeding Frequency

T280 Effects of protein and energy supplementation on *in situ* disappearance of low-quality Coastal Bermudagrass hay in goats. M. S. Reinhard^{*1}, B. D. Lambert^{1,2}, J. P. Muir², and R. Harp¹, ¹Tarleton State University, Stephenville, TX, ²Texas AgriLife Research, Stephenville, TX.

Cattle grazing forages with crude protein (CP) of 6% or less often need protein supplementation to maximize ruminal forage utilization. Because of the selective foraging ability of goats, it is not known if goats consuming low CP forages have a similar need for supplemental protein and/or energy. The purpose of this study is to determine the digestibility of low-quality forages with protein and energy supplements in goats. Four mature ruminally cannulated goats were used in a 4 x 4 Latin square design experiment. Treatments consisted of either casein (0.122% BW), corn starch (0.15% BW), or dextrose (0.15% BW) administered daily into the rumen, compared to a hay-only control. Goats had *ad libitum* access to Coastal Bermudagrass (CB) hay (5.8% CP) and clean drinking water at all times during the experiment. Each period consisted of 14 days for treatment adaptation followed by 7 days incubation of *in situ* bags. *In situ* hay samples were analyzed for dry matter disappearance after 0, 2, 4, 8, 16, 24, 48, and 72 hours of ruminal incubation. Dry matter disappearance was not affected by any of the treatments in this experiment. More research is needed to define the effects of protein and energy supplements on ruminal forage degradation in goats.

Key Words: Goat, Protein, Energy

T281 Energy requirements for maintenance and growth of Boer crossbred kids. I. A. M. A. Teixeira¹, K. T. Resende¹, J. M. Pereira Filho², R. C. Canesin¹, and T. T. Berchielli¹, ¹Universidade Estadual Paulista/Unesp, Jaboticabal, SP, Brazil, ²Universidade Federal de Campina Grande, Patos, PB, Brazil.

Two experiments were conducted to determine the energy requirement for maintenance and growth of 64 ½ Boer ½ Saanen crossbred, intact male kids (5 and 15 kg of initial BW for experiment 1 and 2, respectively). In the first experiment, the baseline group was 6 randomly selected kids, averaging 5.6 ± 0.8 kg of BW. An intermediate group consisted of 6 randomly selected kids, fed for ad libitum intake, that were slaughtered when they reached an average BW of 10.0 ± 0.4 kg. The remaining kids (n = 18) were randomly allocated to one of 3 levels of DMI (ad libitum and restricted to 70% or 40% of the ad libitum intake) within 6 slaughter groups. Kids were slaughtered when the ad libitum treatment kid reached 15 kg of BW. In the second experiment, the baseline group was composed by 7 kids, averaging 15.3 ± 0.3 kg of BW. An intermediate group consisted of 6 kids, fed for ad libitum intake, that were slaughtered when they reached an average BW of 20.4 ± 0.7 kg. The remaining kids (n = 21) were randomly allocated to one of 3 levels of DMI, similar to the first experiment, within 7 slaughter groups. Kids were slaughtered when the ad libitum treatment kid reached 25 kg of BW. Individual empty bodies were weighed, ground, mixed, and samples were taken to chemical analyses. For young animals (experiment 1) the calculated NE and ME requirements for maintenance were 50.0 and 76.2 kcal/kg^{0.75} of empty BW (EBW), respectively, and the partial efficiency of use of ME for NE was 0.66. On the other hand, older kids presented greater requirements, whereas the daily maintenance requirement were 101.0 kcal NE/kg^{0.75} of EBW and 181.1 kcal ME/kg^{0.75} of EBW and lower partial efficiency of use of ME for NE of 0.56. Net energy requirement for growth ranged from 1.7 to 2.2 Mcal/kg of EBW gain at 5 and 25 kg of BW. These results suggest that meat goats present energy requirement different from the established recommendations. (Sponsored by FAPESP, 04/06626–0).

Key Words: Body Composition, Goat, Nutritional Requirement

T282 Effects of acclimatization on energy expenditure by meat goats. A. K. Patra, R. Puchala, G. Anicut, T. A. Gipson, T. Sahl, and A. L. Goetsch*, *American Institute for Goat Research, Langston University, Langston, OK.*

Seven Spanish and seven Boer yearling wethers were used to assess relationships between energy expenditure (EE) and temperature (Temp), relative humidity (Hum), and temperature-humidity index (THI). The two breed groups were confined separately in 8 x 6 m pens in an enclosed facility with a concrete floor without cooling. Only enough heat was provided to prevent damage to waterers and water lines from excessive freezing. Thus, the intent was to have minimal Temp and Hum control and to incur fluctuations corresponding to outside conditions. Energy expenditure was determined over 2-d periods 13 times during a 1-yr period based on EE:heart rate (HR) measured at 13-wk intervals. Climate variables were averaged over 2, 4, 6, and 8 wk preceding EE measurement. Wethers were fed for the maintenance energy requirement (ME_m). Mean, minimum, and maximum values during the 2 wk preceding EE determination were 19.9, 7.9, and 31.8°C for Temp and 53.6, 36.1, and 62.5% Hum, respectively. Neither Temp nor THI were correlated with or had significant effects in regression equations to predict the difference between EE at measurement times and the 1-yr mean (EE_{diff}).

Conversely, Hum was correlated (P < 0.01) with EE_{diff}. When the 13 HR measurement times were assigned to Cool and Warm periods, EE_{diff} was affected (P < 0.01) by a genotype x period interaction. Nonetheless, the effect of Hum in models including genotype, period, and genotype x period was significant for 2, 4, 6, and 8 weeks (P < 0.01). The R² of linear regressions of EE_{diff} against Hum were slightly greater for 2 and 4 vs 6 and 8 wk (0.11, 0.10, 0.08, and 0.07, respectively); regression coefficients for 2 and 4 wk were 1.265 and 1.163 kJ/kg BW^{0.75} per 1% Hum, respectively. With a median Hum of 50%, average regression coefficient of 1.2 kJ/kg BW^{0.75} per 1% HUM, and average ME_m of 390 kJ/kg BW^{0.75}, predicted ME_m is 374 and 406 kJ/kg BW^{0.75} at minimum and maximum Hum, respectively. In conclusion, without extremes eliciting cold or heat stress, Hum appears to have a slight effect on ME_m of meat goats in both cool and warm periods of the year.

Key Words: Goats, Energy, Acclimatization

T283 Effect of length of grower/finisher ration supplementation on chevon production and net return from crossbred meat goats. M. Lema*, S. Kebe, C. Pierfax, and N. Adefope, *Tennessee State University, Nashville.*

Forty weaned crossbred kids were blocked by body weight and genotype and divided into four treatment groups. Each treatment group was replicated in two 0.4 ha choice chicory paddocks with 5 kids per paddock and supplemented with identical total amount of commercial grower/finisher goat ration over variable lengths of time (0 (control), 45, 90 or 135 days). While total grower/finisher ration cost and consumption (27.5, 30.1 and 27.1 kg for the 45, 90 and 135 day supplemented groups, respectively) did not differ statistically, total live weight gain (0.77, 4.95, 6.43 and 7.23 kg, respectively) and net return over feed cost (2.13, 3.44, 6.46 and 9.87 dollars, respectively) increased linearly (P < 0.05) from 0 to 135 days of supplementation indicating that when unpaid family labor is utilized, supplementation of weaned meat goats with the same total quantity of grower ration over a longer duration is economically beneficial than over a shorter duration. When labor cost was factored into the equation, supplementation over a longer period resulted in negative net returns (-1.06, -2.54 and -3.63 dollars for the 45, 90 and 135 day supplemented groups versus +3.13 dollars for the non-supplemented group) making the non supplemented group economically beneficial than the other three supplemented groups. Boneless retail cuts from the leg, loin, shoulder and rack were highest (P < 0.05) for the 135 days supplemented group while the non-supplemented control and those supplemented for 45 and 90 days were not different. No significant difference was observed in back fat thickness, loin eye area and kidney pelvic and heart fat among treatments.

Key Words: Meat Goat, Length of Supplementation, Net Return

T284 Pelleted soybean hulls or cottonseed and corn as supplements for weanling Boer-cross wethers grazing bermudagrass pastures. M. H. Poore*, J.-M. Luginbuhl, H. M. Glennon, A. D. Shaeffer, and H. A. Deihl, *North Carolina State University, Raleigh.*

A trial was conducted over two years to determine the influence of supplementation with pelleted soybean hulls (SBH) or whole cottonseed plus corn (WCS) on post-weaning growth and carcass characteristics of Boer-cross wether kids (initial BW 21.2 kg). Kids were born mid-

February to mid-March, and weaned in mid-May at 10 to 14 weeks of age. During the weaning period kids were fed grass hay and 1% of BW as a mixed pelleted concentrate. Kids were divided into 3 BW blocks and assigned from within blocks to make 9 groups (3 wethers and 3 does per group in yr 1, and 4 wethers and 2 does in yr 2). Kids were placed on 9 bermudagrass pastures arranged in 3 blocks of 3 pastures each in mid-June. Pastures averaged 0.067 ha of Tifton-44 Bermudagrass (0.075 ha in yr 1 and 0.058 ha in yr 2), and each pasture had an adjacent equal sized pasture of Coastal Bermudagrass as a potential emergency expansion area. Each pasture was divided into 5 paddocks and kids were rotated to a fresh paddock each 3 to 5 d. Pastures were clipped behind the kids as necessary to maintain forage quality. After 2 wk adaptation to the pastures, kids were allotted to three supplement treatments; 1) minerals only (MIN), 2) minerals plus 1% BW SBH, or 3) minerals plus 1% BW of a mix of 65% corn, 33% whole cottonseed, and 2% limestone. In yr 1 all kids remained on the original Tifton-44 pastures for 70 d after treatments were initiated, but in yr 2 pastures were doubled to include all the Coastal Bermudagrass area early in the trial due to dry weather. In yr 2 all doe kids were also removed after 28 d, and the trial was ended after 56 d. Average forage mass was 3606 kg/ha in yr 1 and 1945 kg/ha in yr 2. At the termination of the trial all wethers were harvested. Carcass grade was determined on a scale where 1 to 1.9 = Prime and 2.0 to 2.9 = Choice. Supplementation at 1% BW improved post-weaning growth and carcass characteristics of kids grazing bermudagrass pasture, while supplement type had little influence on growth or carcass characteristics.

Table 1. Influence of supplements on meat goat growth and carcass

T285 Influence of dietary condensed tannins in meat goats on fatty acid composition of carcasses. J. Lee*, G. Kannan, B. Kouakou, D. Moore, and T. Terrill, *Fort Valley State University, Fort Valley, GA.*

Sericea lespedeza hay decreases nematode infections in goats, although the effect of its high condensed tannin (CT) content on carcass quality has not been adequately studied. Twenty Boer × Spanish meat goats (6 mo of age; BW = 19.2 ± 0.74 kg) were used to determine the effect a high CT diet on fatty acid profiles of tissue samples from different carcass sites. Goats were assigned randomly to pens (5 goats/pen), and each pen was allotted to one of two dietary treatments of 75% hay: sericea hay (SER; high in CT) or Bermuda grass hay (BER; n = 10 goats/treatment) plus a 25% corn-based supplement (18 % CP) consisting predominantly of corn and soybean meal for 14 wk. At the end

of the feeding trial, goats were slaughtered using standard procedures. The *Longissimus dorsi* (LD) muscle, intermuscular, subcutaneous, and kidney fats were obtained from each carcass. Total lipid from each fat depot sample was extracted by the chloroform (0.013% BHT)-methanol method. Extracted lipids were prepared for the fatty acid methyl esters (FAME) and then analyzed by gas chromatography. Palmitic (16:0), stearic (18:0), oleic (18:1n9), and linoleic (18:2n6) acids were the four major fatty acids in the LD muscles and intermuscular fats from goats fed either SER or BER diet. The subcutaneous and kidney fats mainly consisted of myristic (14:0), 16:0, C18:0, and C18:1n9 acids. No significant differences were found in the four major fatty acids on the site of fat depots between SER and BER groups. However, compared with goats fed the BER diet, goats fed the SER diet had lower ($P < 0.05$) concentrations of *trans*-7-hexadecenoic (16:1t) and margaric (17:0) acids in LD muscles; a higher ($P < 0.05$) concentration of linolenic (18:3n3) acid in intermuscular fat; higher ($P < 0.05$) concentrations of C18:2n6 and 11-eicosenoic (C20:1n9) acids in subcutaneous fat; and a higher ($P < 0.05$) concentration of C20:1n9, but a lower ($P < 0.05$) concentration of C17:0 in kidney fat. The results indicated that a diet high in condensed tannins may not influence the major fatty acids in the different fat depot sites in meat goats.

Key Words: Goats, *Sericea lespedeza*, Fatty Acid Profile

T286 Effects of long term feed restriction and monensin on growth, feed efficiency and body measurements in Anglo Nubian does. P. Turiello*, V. Coniglio, S. Posadas, M. Chaves, L. Godio, and G. Cufre de Lenardón, *Universidad Nacional de Río Cuarto, Río Cuarto, Córdoba, Argentina.*

Periods of feed restriction results from seasonal deficits of food. The experiment evaluated effects of long term feed restriction and monensin on liveweight gain, BCS, and body measurements to test usefulness of monensin to ameliorate feed restriction. Nineteen weaned Anglo Nubian does (BW 11.9±1.6 kg) were randomly assigned to control (fed ad libitum; n = 5) (C), restricted (78% of C per unit BW; n = 7) (R) and R + 12.5 mg/head/d of monensin (n = 7) (M). A 247-d trial used a 70:30 ground mixture of alfalfa hay:corn grain; ME of the diets was 2.4 Mcal/kg DM and CP was 16 %. Minerals and vitamins were supplemented. Urea was added to restricted diets to equalize CP intake to that of C. Individual feed intake was recorded daily, does were weighed weekly, body measurements and BCS (0-5) were recorded every 28 days. Data analysis was by ANOVA for a completely randomized design; when the F-test was significant, differences between means were determined by Tukey's-test. Average daily DMI was greater in C (.65 vs. .37 and .34 kg/d M and R, respectively) ($P < 0.001$). BW at termination differed among treatments ($P < 0.001$). BW of goats fed ad libitum was higher than M and R (29±1.7). Whereas M does also had greater BW than R (18±0.9 vs. 15±1.0 kg, respectively). Average daily gain was highest for C ($P < 0.01$), whereas M also had higher ADG than R (67±4, 25 ± 4 vs. 12±5 g/d, resp.). Score for BC was highest for C, 3.9, and M had greater BCS than R, 2.2 vs. 1.4 respectively ($P < 0.05$). F: G ratios were 9.7, 15.4 and 26.9. Withers height, chest girth and hip height were greater in does with heavier weight (C > M > R; $P < 0.01$). Monensin lessened the effects of long term restriction, demonstrating its potential to be used with restricted feeding to improve performance.

Key Words: Feed Restriction, Monensin, Goat

Teaching/Undergraduate and Graduate Education: Teaching in the Animal Sciences

T287 Use of an informal taste panel to teach students concepts related to beef palatability. J. A. Daniel*¹ and T. D. Pringle², ¹Berry College, Mount Berry, GA, ²University of Georgia, Athens.

As a lab experience, students (n = 31) enrolled in Introduction to Agriculture (ANS 105; a general education science course for non-science majors) at Berry College participated in an informal taste panel. Students received no classroom instruction in beef palatability assessment prior to this lab. At the beginning of the lab, students completed a quiz (pre-quiz) consisting of 12 questions. Ten of the questions were designed to test the students' knowledge of different attributes of beef quality, and two of the questions were designed to assess students' steak preferences. A rating sheet was then distributed to the students and they moved to a desk with apple juice and crackers. Students were presented with the following bite sized samples (approximately 2x2x2 cm cubes) for evaluation: an infraspinatus steak cooked to 66°C, 71°C, or 82°C, a longissimus steak aged for 1, 7 or 21 days, and a low, medium, and high choice longissimus steak. All longissimus steaks were cooked to 71°C. The longissimus steaks aged for 1, 7 or 21 days were all obtained from the same animal, choice infraspinatus steaks were purchased from a local grocery store, and all steaks were stored frozen until the day prior to the experiment. Students were asked to take a bite of cracker and drink of apple juice between each sample. After completion of the taste panel, evaluation sheets were collected and results and beef palatability attributes were discussed with the class. Students then completed the previously mentioned quiz (post-quiz). Scores on the 10 questions designed to test students' knowledge of different attributes of beef quality were improved ($58.5 \pm 0.2\%$ on the pre-quiz vs $82.8 \pm 0.2\%$ on the post-quiz; $P < 0.0001$). For the 2 questions accessing students' steak preference, one addressed preferred degree of doneness and the second asked students to choose a steak based on USDA Quality Grade, weight, cut, aging, and degree of doneness. Interestingly, 24 of the 31 students changed one or more of their answers for these questions, and 10 students changed their preferred degree of doneness following the taste panel. These results suggest an informal taste panel is an effective means of teaching students beef palatability attributes.

T288 Student demographic profile for Mississippi State University riding courses. M. Nicodemus*, *Mississippi State University, Mississippi State.*

Management of a riding herd for University riding courses is costly, and yet, the popularity of such courses attracts new students to equine programs. Laboratory fees attached to these courses have assisted in paying for associated management fees, but this approach requires offering of courses that attracts large student enrollment. In preparation for recent expansion of the equine courses offered at Mississippi State University, students (n = 44) enrolled in riding courses were asked to fill out a researcher-developed, 16-item survey instrument with questions focusing on student academic history and horse background. Eighty-three % of students were majors outside of the Animal & Dairy Sciences department with the largest number of these students coming from the biology department (17%) followed by the business department (13%). Fifty-two % of the students were seniors and were taking the course as a free elective (78%). While these riding courses were open to all levels of riding, 39% of students had ridden a limited number of

times (1-5 times) followed by 35% of students having ridden between 6-30 times. Majority of students (57%) had never taken a formal riding lesson nor had they ever had any experience in training a horse (74%). Eighty-three % of the students were not current horse owners and 48% had never owned a horse. Forty-eight % of students had only ridden in trail rides for recreational purposes with 47% of students riding mostly stock-type breeds (Quarter Horse, Paint Horse, Appaloosa). While the majority of students (57%) were not planning on a career in the equine industry, 65% planned on owning their own horse in the future. Forty-three % of students planned on taking another University riding course and of those students 86% were students with limited riding experience (ridden 1-5 times). Results from this survey suggest riding courses geared more towards less experienced riders with the focus more on recreational riding will attract more student enrollment. Plans for the equine curriculum are to offer an additional introductory riding course in the upcoming semester.

T289 Developing an internet-based course on milk and dairy products. A. D. Fogleman*, C. R. Summers, H. J. Hickman, L. G. Turner, and J. C. Allen, *North Carolina State University, Raleigh.*

With fewer dairy farms and processing plants in NC and the Southeastern States, students and citizens have less opportunity to become familiar with the dairy industry, technology, safety, and regulations required to bring milk and dairy products to the table. New distance education technology provided an opportunity to bring a new course titled "Milk and Dairy Products", delivered entirely by Internet, to our students and others around the country. Two graduate teaching assistants, with guidance from two faculty and a technician, developed a course outline, investigated available literature and requested that the library purchase needed reference material. Lecture outlines, text and illustrations were developed in PowerPoint™ and reviewed by the team. An audio track of the lecture content was attached to each PowerPoint™ presentation using LecShare Pro™. The program created higher quality and smaller virtual lecture files than traditional video-taping. Other videos gave a virtual guided tour of the NCSU dairy farm and dairy processing pilot plant. Homework and quizzes accompany the 15 weekly course units. Background reading assignments were posted on the library's electronic reserve system, saving the students the need for a textbook purchase. The course is available to the campus and to individuals around the country through distance.ncsu.edu. The course is able to take advantage of the diverse experience and knowledge of dairy products of two faculty, and combine the perspective of a team of developers to make a consistent and uniform presentation of course content. Students enrolled had little prior knowledge or experience in dairy processing, but are very excited by their overview of the course outline and website. Increasing the number of students and citizens who have a sound knowledge of milk and dairy processing methods will help the dairy industry assure the public of the need for land preservation for agriculture, of the safety of the dairy food supply, and dispel misinformation about the healthfulness and nutritional importance of milk consumption. Students in this course will be more interested in employment in the dairy industry.

Key Words: Teaching, Milk Processing, Distance Education

T290 Species preference of incoming animal science freshmen at North Carolina State University. J. A. Moore*, W. L. Flowers, and R. L. McCraw, *North Carolina State University, Raleigh.*

Understanding student interests is important when assessing and updating curricula and courses. Incoming freshmen (12 years of data) answered a survey at orientation to indicate their first and second choices for species preference. Species were companion animal (comp), horse, beef, dairy, small ruminant (SR), and other. Data were blocked by year (1996-1999, 2000-2003, 2004-2007) in order to evaluate changes over time. The number of students annually taking the survey for the three blocks was 88^a, 93^a, and 124^b, respectively ($P < 0.02$); there was a 95% response rate for the past 6 years, but numbers of actual incoming Animal Science majors prior to 2002 are not available because students did not have to declare a major prior to attending. The percentage of students indicating pre-vet as their career choice was 75^a, 81^{a,b}, and 85^b for the three blocks, respectively ($P < 0.02$). There was no block by species interaction for first or second choices ($P > 0.51$), indicating a consistent response over the 12 year period. In Table 1, means within a row that do not share a superscript differ ($P < .05$). The data show consistent interest in companion animals as first choice and horses as second choice over the 12 year period, and livestock species accounted for just 10% of first choice responses and 23% of second choice responses. Students who chose "other" were asked to specify, and responses commonly included exotic animals, marine animals, and reptiles. These data help us understand the interests of our incoming students as we work to keep our curricula and courses current.

T291 Changes in species preference reported by animal science graduating seniors at North Carolina State University. J. A. Moore*, W. L. Flowers, and R. L. McCraw, *North Carolina State University, Raleigh.*

Understanding changes in student interests over time assists in the evaluation of our curricula, courses, and extracurricular opportunities. Graduating seniors (5 years of data) were asked what their first and second choice species had been upon arrival and at graduation (average = 22% external transfer students). Species were companion animal (comp), horse, beef, dairy, small ruminant (SR), and other. An average of 45% of graduating seniors (42 of 94 per year) completed the survey. In Table 1, means within a row that do not share a superscript differ ($P < .05$), and "Leaving minus arrival" is the sum of "leaving" first plus second choice minus sum of "arriving" first plus second choice (a positive number indicates a shift in preference toward that species

while a student was enrolled as an undergraduate). The data show a shift in preference away from companion animals and horses toward livestock and "other" animals, but the top two first choice preferences remained companion animals and horses. Graduates indicated that livestock accounted for 15% of first choice preferences on arrival and 27% of first choice preferences upon graduation. The data indicate that experiences while enrolled as undergraduates have an impact on student species preference.

T292 Equine internships: Factors that predict success. K. Bennett-Wimbush*, *Ohio State Agricultural Technical Institute, Wooster.*

Traditional employee screening processes usually are based on academic performance, however, there can be a dichotomy between academic achievement and employee job performance. This study examined the records from 140 equine industry internships from students enrolled in an Associate of Applied Science program from 1999 to 2006. Employers evaluated employees on thirteen criteria including: punctuality; willingness/learn; dependability; work quality; acceptance of constructive criticism; personal appearance; cooperation w/co-workers; productivity; professionalism; supervisor acceptance; customer acceptance; technical knowledge and overall performance using a Likert scale of 1-5 (1=poor, 2=fair, 3=average, 4=good, 5=excellent). Pearson's correlation analysis was performed between employer evaluation and employee salary (0=no pay, 1=below minimum wage (mw), 2=mw, 3=above mw, 4=50% above mw); cumulative grade point average (gpa) at the time of the internship; practicum gpa and graduation status. The cumulative gpa at the time of the internship was not different between students who graduated (2.88 ± 0.49) compared to students who did not graduate (2.47 ± 0.58) so data was combined for analysis. The average intern earned minimum wage. Those areas that were scored the lowest by employers were work speed (4.3 ± 0.77) and technical knowledge (4.2 ± 0.76) while cooperation w/co-workers and acceptance by supervisors were evaluated the highest (4.6 ± 0.55). Quality of work was positively correlated ($p < 0.05$, $r = 0.16$) with both cumulative gpa and salary. Technical knowledge was positively correlated ($p < 0.01$, $r = 0.20$) with salary. Based on this data, academic success may not be the best predictor of employee performance and students with a higher degree of technical skills may receive higher starting salaries.

T293 Technical note: Equine gastrointestinal tract preservation techniques to enhance teaching effectiveness. B. T. Gutierrez* and J. S. Pendergraft, *Sul Ross State University, Alpine, TX.*

When the decision was made to euthanize a Quarter Horse mare suffering from chronic colic, students from the Department of Animal Science preserved the gastrointestinal tract (GIT) organs and tissues for use as a teaching tool. The specimens were removed from the horse within 1 h of death, separated into sections (stomach, small intestine, cecum, large colons, and small colon) and immediately cleaned with water. Digesta was flushed continuously from the GIT sections with water until the exiting water was clear. The fresh specimens were trimmed of any excess tissues and then filled with and submerged in a 10% formalin solution for 5 d. The GIT were then removed and rinsed with water and allowed to air dry for 2 h. Each section of the GIT were individually dried with forced air. The external portions of the GIT were allowed to remain moist to prevent tearing. The dried internal sections were filled with expanding polyurethane foam. The foam was administered throughout the GIT and then each end of the tracts were sealed. The GIT were positioned and orientated as in situ and the foam was allowed to expand and cure for 1 d. Excess foam, external fat, and other unwanted tissues were removed from the GIT. A clear coat of polyurethane was applied to the outside of the tract and allowed to dry for 1 d. This process was repeated three times. This method of GIT preservation resulted in a durable light weight specimen that has no unpleasant odor and is reasonably resistant to handling. The impact from the project will be the continual enhance of the educational experiences of future animal science students by the use of this visual learning tool.

T294 Impact of a herpes (EHV-1) outbreak on incoming equestrian students, horse numbers and outside generated revenue at The University of Findlay. E. D. Bonnette*, F. D. McCarthy, and R. Koehler, *The University of Findlay, Findlay, OH.*

In January 2003, a neurologic strain of the Equine Rhinopneumonitis (EHV-1) virus infected the majority of the horses at one of The University of Findlay horse farms. Over a five week period, roughly 80% of the 140 horses housed at the university's English equestrian facility showed clinical symptoms and fourteen of those horses were ultimately euthanized. The farm was put on a self-imposed quarantine, while access to the university's western equestrian facilities was severely limited. Once the causative agent was identified and the affected horses treated, policies were implemented to reduce the likelihood of another outbreak of this kind. Because of the significance of this event in the equestrian world, publicity regarding this outbreak was intense and created concerns that incoming fall equestrian students, retention of existing students and outside owned horses for the training programs might be adversely affected. Significant income generating events were potentially at risk with a negative public perception of the facility and programs. Data obtained from various university sources were summarized for the academic years 2003 - 2007. Total number of equestrian majors over the five year period following the outbreak indicated a linear increase in students at the end of each academic year. During that same period, applications and acceptance of outside-owned horses trained by equestrian students remained relatively consistent to those before the outbreak. The most notable adverse effect was to the non-academic revenue being generated by non-university organizations utilizing either equestrian facility. Gross revenue for the first fiscal year following the outbreak was reduced by nearly 50% and has shown a steady increase to overtake the pre-outbreak levels. From the data, The University of Findlay has apparently seen no long-term detrimental effects to student enrollment, incoming outside owned horse numbers or total outside revenues in the five years after the initial outbreak event.

SYMPOSIA AND ORAL SESSIONS

Animal Health I

1 Obesity in horses: An equine metabolic syndrome? P. J. Johnson*, V. K. Ganjam, and N. T. Messer, *University of Missouri, Columbia.*

Similar to the situation in human society, obesity is common in domesticated equids. Broad parallels exist between causative factors with relevance to both species. Horses develop obesity when they are fed rations that exceed nutritional requirements under management systems that fail to provide substantive physical inactivity. Obese humans often develop insulin resistance (IR), hypertension, atherogenic dyslipidemia, chronic inflammation, and a tendency to a procoagulative state. This constellation of clinical disorders has been termed the “metabolic syndrome” and its presence signifies high risk for many potentially fatal conditions including cardiovascular diseases (atherosclerosis, myocardial infarction, stroke), diabetes mellitus, liver disease, cancer, neurodegenerative disease, and polycystic ovarian disease. An “equine metabolic syndrome” (EMS) has been described in which obesity and IR are risk factors for laminitis (“founder”). Laminitis is a painful, crippling affliction of the equine digit (hoof), which often necessitates euthanasia for severely affected individuals. The extent to which other aspects of the human syndrome may or may not play a role in EMS is less certain, controversial, and the subject of substantial current investigation.

Horses and (especially) ponies evolved as a thrifty species. Health was assured by the persistent physical mobility associated with seeking out native prairie grassland species and the evasion of predators. Horses and ponies tended to migrate over considerable distances to obtain sufficient food for survival. Evolutionary forces ensured that the modern horse was thoroughly adapted to the available grassland forage species that grew abundantly in their domain. The impositions of the needs of human management have been such that domesticated horses are (usually) fed rations that differ greatly from those anticipated by evolutionary selection. Coupled with enforced physical confinement and the elimination of predators, modern horses commonly develop obesity and the attendant endocrinopathic health consequences.

Key Words: Horse, Obesity, Metabolic Syndrome

2 Steers grazing toxic *Neotyphodium coenophialum*-infected forages have increased hepatic gluconeogenic capacity. K. R. Brown*¹, J. L. Klotz², J. R. Strickland², L. P. Bush¹, J. A. Boling¹, and J. C. Matthews¹, ¹*University of Kentucky, Lexington,* ²*Forage-Animal Production Research Unit, USDA-ARS, Lexington, KY.*

Impaired growth performance and clinical parameters constituting summer slump in cattle grazing toxic endophyte-infected tall fescue are well documented. To test the hypothesis that fescue toxicity affects carbon chain and amino acid N metabolism in the liver of cattle grazing this forage, 19 Angus steers were randomly assigned to graze either a low-endophyte (LE; 6.8% infection) mixed grass-tall fescue pasture (n = 9; BW = 266 ± 10.9 kg; 5.7 ha) or a high-endophyte (HE; 62.8 % infection) tall fescue pasture (n = 10; BW = 267 ± 14.5 kg; 5.7 ha) for 89-105 d. Pasture samples were collected on d 37, 59, 88 and 109, pooled, and analyzed for alkaloid content. Blood was collected on d 85 for serum prolactin (PRL) analysis and steers then killed over a 17-d period, with treatment animals equally distributed over d of kill. HE pasture samples contained (µg/g) 24 and 38 times more (P < 0.01) ergovaline (0.322) and lysergic acid (0.065), respectively, than did LE pastures. Serum PRL of HE steers was (P < 0.01) 10% (3.60 ng/mL) that of LE steers. Whereas liver alanine transaminase content did not differ, aspartate transaminase (AST) and cytosolic phosphoenolpyruvate carboxykinase (PEPCK-C) content was 56% and 90% greater (P < 0.01), respectively, in HE steers. In contrast, hepatic content of glutamate synthetase, glutamate dehydrogenase, and 3 transport proteins responsible for high-affinity aspartate/glutamate uptake in the liver did not differ. Together, the increased hepatic content of AST and PEPCK-C of HE steers indicates that increased alkaloid challenge, depressed serum PRL, or both, induces a greater capacity for liver gluconeogenesis, met in part through an increased expression of proteins that metabolize aspartate carbons to oxaloacetate and oxaloacetate to phosphoenolpyruvate.

Key Words: Endophyte, Gluconeogenesis, Liver

3 Grazing endophyte-infected tall fescue alters serotonin receptor-induced contractility of bovine lateral saphenous veins.

J. L. Klotz*¹, K. R. Brown², Y. Xue², J. C. Matthews², J. A. Boling², L. P. Bush², and J. R. Strickland¹, ¹USDA-ARS, FAPRU, Lexington, KY, ²University of Kentucky, Lexington.

Concurrent with grazing of endophyte-infected tall fescue is the consumption of toxic alkaloids that negatively affect cardiovascular function and result in fescue toxicosis. Vascular effects of ergopeptine alkaloids are mediated by stimulation of various biogenic amine receptors yet to be fully characterized. The objective was to evaluate the effect of grazing 2 levels of toxic endophyte-infected tall fescue on the vasoconstrictive activities of (\pm)-1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane hydrochloride (DOI), BW 723C86 (BW), CGS-12066A (CGS), and 5-carboxamidotryptamine hemithanolate maleate (5CT), agonists for 5-hydroxytryptamine (HT)_{2A, 2B}, 5-HT_{1B} and 5-HT₇ receptors, respectively. Segments (2-3 cm) of the cranial branch of the lateral saphenous vein were collected at time of slaughter from steers follow-

ing a 114 to 127-d grazing period of either a low endophyte-infected (LE) mixed grass pasture (10% infection; n=8; BW=333 \pm 10 kg) or a high endophyte-infected (HE) tall fescue pasture (92% infection; n=8; BW=311 \pm 9 kg). Veins were sliced into 2-3 mm sections and suspended in a myograph chamber containing 5 mL of oxygenated Krebs-Henseleit buffer (95% O₂/5%CO₂; pH=7.4; 37°C) and allowed to equilibrate at 1 g of tension for 90 min. Increasing concentrations of DOI, BW, CGS, and 5CT were administered every 15 min. Data were normalized (%) to the contractile response induced by a reference dose of norepinephrine (1x10⁻⁴ M) and data for each treatment were analyzed for effects of concentration and endophyte level. Maximal contractile intensities achieved with DOI were decreased 35% ($P < 0.05$) in steers grazing HE pastures, whereas those achieved with 5CT were increased 37% ($P < 0.05$). The contractile response to CGS did not differ between pasture groups and there was an absence of contractile response to BW in both groups. Grazing HE pastures alters vascular responses which may be mediated through modified serotonin receptor activities.

Symposium: Beef Species: The Evolution of Beef Cattle Genetic Evaluation

4 Milestones in beef cattle genetic evaluation. L. L. Benyshek*, *University of Georgia, Athens.*

The first national beef sire evaluation summary was published in 1971. Since 1971 beef breeds that have serious genetic improvement programs have adopted this genetic evaluation technology. Today it is rare when a bull is offered for sale without Expected Progeny Differences. Initially, application of methodology was limited by hardware and software constraints. The current genetic evaluation summaries show that the industry has taken genetic evaluation seriously with more traits than producers can assimilate into breeding program. This has spawned an effort in decision making software including selection indexes. The advent of DNA technology for beef cattle has begun to blossom with the sequencing of the beef genome. Genetic evaluation began in the 1930's with research in performance testing. In the 1940's large regional research programs were funded leading to state beef cattle improvement associations in the 1950's. In the late 1950's some breed registry associations began to formalize the collection of performance data. In 1968, a major milestone was achieved with the establishment of the Beef Improvement Federation which standardized the collection and analysis of data. In 1972 C. R. Henderson presented an invited ASAS paper that formalized his mixed model procedures providing best linear unbiased predictions (BLUP) of breeding value. Established breeds produced estimated breeding values; however, mixed model procedures were first applied only to designed progeny tests. With the advent of increased artificial insemination the data structure evolved to warrant national sire evaluation using BLUP in the 1970's. In the 1980's animal model procedures began to evolve particularly after the first genetic prediction conference in 1983 where the reduced animal model was elucidated. In 1984 the reduced animal model was applied to field data for four breeds resulting in the first published evaluations using the technology. In the years following, the animal model became the standard for genetic evaluation. Currently, researchers continue to look at improved models leading to across breed evaluations and the incorporation of genomic information in the procedures.

Key Words: Beef, Genetic Evaluation, Mixed Model

5 Producing and using genetic evaluations in today's beef industry. D. Garrick*, *Iowa State University, Ames.*

Genetic change is a straightforward consequence of selection. Genetic improvement is more difficult to achieve because it requires the cumulative value of favorable changes to exceed the costs incurred by unfavorable changes, data collection and recording and infrastructural investments. The principal technology that has been available to assist breeders make informed selection decisions has been the expected progeny difference or EPD. The nature and scope of EPDs has grown enormously over the last few decades, to encompass a large array of easily measured attributes. Breed Associations have acted individually in the production of EPDs, gaining scientific and servicing support from land-grant Universities, principally, Colorado State, Cornell, Georgia and Iowa State Universities. This approach is now structurally, financially and technologically challenged, unable to meet current or future demands of industry. Bull buyers are now demanding across-breed EPDs including crossbred or composite bulls, most commonly Angus derived. The Breed Association data systems are not well structured to unambiguously record crossbred animals or any external pure-bred

parents. The land-grant service providers are keen to pass on their subsidized servicing roles in favor of software licensing and research support. The advent of small panels of molecular test information has created challenges with new kinds of data that have not been able to be harnessed by Breed Associations. This will likely get worse with the adoption of high-density SNP marker panels. Finally, in contrast to other industries, beef cattle EPDs have failed to move to properly reflect economic rather than just productive characteristics of alternative bulls. These challenges must be addressed if the beef industry is to retain its competitiveness, nationally and internationally.

Key Words: Genetic Evaluation, Selection, Beef Cattle

6 DNA technology: Estimation of genetic merit from large DNA marker panels. R. L. Fernando*¹ and C. Stricker², ¹*Iowa State University, Ames,* ²*Applied Genetics Network, Davos, Switzerland.*

Given trait and marker data on a sufficient number of individuals, the effects of all markers can be estimated accurately and used for genetic evaluation of future candidates using only marker genotypes. In practice, however, the number of marker effects in the model is much greater than the number individuals with trait phenotypes. Several strategies have been proposed to overcome this problem. One strategy includes markers in the model as random effects with a constant variance for all markers. We will show that as the number of independent markers increases, this approach converges to pedigree based BLUP, which does not use any marker information. As markers on a chromosome are not independent, even though the accuracy drops with the number of markers included in the model, this approach gets higher accuracies than pedigree based BLUP. Better results are obtained, however, when locus-specific variances are estimated from the data. We used computer simulated data to investigate the relationship between the accuracy of prediction and the number of markers included in the model for a Bayesian method that uses a zero-inflated inverse chi-square prior for the locus-specific variances. A genome of 30 chromosomes, each 1 Morgan in length, was simulated. Random mating in a population with an effective size of 100 for 1000 generations was used to generate linkage disequilibrium. Marker effects were estimated with trait phenotypes and marker genotypes on 2120 animals. The estimated effects were used to predict the breeding value of 2000 animals in the following generation. Accuracy of prediction was quantified by the square of the correlation between the predicted and true breeding values. Accuracies were obtained with 3,000, 30,000 and 60,000 markers in the model from four replications of the simulation. The mean values of the accuracies were 0.82, 0.88, and 0.88 for the three marker densities. This Bayesian method seems to be well suited for estimation of genetic merit from large DNA marker panels.

7 Integrating genetic evaluations with DNA technologies for the ultimate selection tool. R. J. Tempelman*¹ and S. D. Kachman², ¹*Michigan State University, East Lansing,* ²*University of Nebraska, Lincoln.*

Various genomics companies have recognized the value of marker assisted selection for beef cattle improvement by marketing estimated molecular values (EMV) based on genetic markers as determined from tissue samples submitted by participating breeders for animals of interest. These EMV are typically based on dozens or hundreds of markers whose individual effects have been estimated from reference populations as based on extensive records on a large number of phenotypes on thousands of cattle. Only the EMV, as the sum of these estimated effects, and not the marker genotypes themselves, are generally reported back to the breeder. We will address how EMV can be integrated with existing phenotypic and pedigree data, as currently used to provide expected progeny differences (EPD), to enhance the accuracy of national beef cattle genetic evaluation. Attention will be drawn to computational issues, improvements in accuracy of EPD and its concomitant potential

for earlier selection, potential ascertainment bias, and selection for traits that are not extensively recorded. These assessments will be based on various assumptions on how well the EMV correlate with the true genetic merit. The drawbacks from not having individual marker genotype information will be directed towards issues that are particularly relevant for beef cattle production, such as multibreed genetic evaluation, genotype by environment interaction, multiple trait selection, multi-sire pastures, and selection for uniformity. Whole genome selection based on emerging high throughput single nucleotide polymorphism (SNP) chips appears to offer substantial promise in addressing some of these limitations.

Breeding and Genetics: Current Issues in Dairy Cattle Breeding

8 Improved accuracy of computer programs that optimize breeding and replacement decisions for dairy cattle. A. De Vries*, *University of Florida, Gainesville.*

Objective was to improve the accuracy of computer programs that optimize breeding and replacement decisions for individual cows to support economic decision making. Most recently published optimization programs characterize cows by a limited number of discrete states, a combination of (at least) parity, level of milk production, stage of lactation, and pregnancy status. The number of states is necessarily limited to make computations feasible. Consequently, cows may not be well represented by a state and the program's decisions may be significantly different from optimal. For example, a small number of lactation curves (for example Wood's curves) are typically used depending on parity and level of milk production. In practice, every cow has a unique lactation curve. A significant improvement in accuracy of prediction of cow performance can be obtained when the states for the current lactations of the cows currently in the herd are separated from the states for their next lactation and replacement heifers. The states for cows currently in the herd can then be dramatically increased with few extra computations. These adjustments allow for much more accurate predictions of individual cow performance in the current lactation than previously available. Predicted cow performance for the remainder of the lactation can be updated daily. Consequently, optimized breeding and culling decisions are more accurate. To illustrate, 400 cows from the University of Florida dairy research herd were used. Individual lactation curves were predicted by Best Prediction. The resulting 400 lactation curves predicted milk yields in the remainder of the lactation better than the few standard Wood's curves in traditional programs. Optimal breeding and culling decisions were frequently different. The program currently runs as an add-on to existing dairy herd information systems using automated data exchange. The proposed improvement in accuracy is an important step towards more realistic computerized decision support on dairy farms.

9 Genetic analysis of profitability of Canadian Holstein cows. J. Bohmanova*¹, J. Jamrozik¹, K. Hand², D. Lazenby², and F. Miglior^{3,4}, ¹*CGIL, University of Guelph, Guelph, ON, Canada*, ²*CanWest DHI, Guelph, ON, Canada*, ³*Dairy and Swine Research and Development Centre, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada*, ⁴*Canadian Dairy Network, Guelph, ON, Canada.*

Profitability functions, developed by Dairy Herd Improvement (DHI) in Canada, are widely used by Canadian farmers to evaluate profitability of their cows. Profit of a cow is defined as the difference between revenues and expenses. Revenues are functions of total amount of fat, protein and other solids, adjusted for amount of fluid in milk. Expenses are calculated as sum of overhead, maintenance feed, marginal feed and quota opportunity costs. Costs associated with fertility and health are not considered due to unavailability of data. The aim of this study was to estimate variance components and breeding values (EBV) for profit in the first 3 lactations and to calculate correlations between EBV for profit and other traits currently evaluated in Canada. Multi-trait (MT) and random regression models (RRM) were applied. The four traits

estimated in MT were rearing costs and daily profits in first, second and third lactation. In the RRM analysis, profit was assumed to be a continuous trait, defined as function of age. The rearing cost was evaluated as a correlated trait with the same effects as in MT. Variance components were estimated by Gibbs sampling using a sub-sample of data consisting of records from 68,434 cows. Breeding values were estimated for 3,329,689 animals. In MT, heritability of rearing cost and daily profit in first, second and third lactation were 0.22, 0.28, 0.28 and 0.43, respectively. Rearing cost was lowly and negatively correlated (-0.18) with daily profit in first and uncorrelated with profit in later parities. In RRM, heritability of rearing cost was 0.36. Heritability of profit increased with age and ranged between 0.32 and 0.45. Medium and negative correlations were found between rearing cost and profit across all three lactations. Profit EBV were highly correlated with EBV for production traits (0.85), moderately with Lifetime Profit Index and negatively correlated with fertility, longevity and daughter calf survival. No correlations were found between EBV for conformation traits and profit, except for angularity and bone quality.

Key Words: Profitability, Rearing Cost, Random Regression Model

10 Alternatives for evaluating daughter performance of progeny-test bulls between official evaluations. H. D. Norman*¹, J. R. Wright¹, and K. A. Weigel², ¹*Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD*, ²*University of Wisconsin, Madison.*

In August 2007, USDA changed from calculating official genetic evaluations quarterly to triannually to coincide with the schedule for international evaluations. Industry cooperators requested that unofficial interim evaluations be initiated between official evaluations for progeny-test (PT) bulls to offset part of the delay in receiving information due to the schedule change. To determine whether interim evaluations could provide accurate information for semen collection and storage (banking) for bulls of potentially superior genetic merit, interim evaluations were calculated with the current USDA animal model system and 4 data subsets of milk yield records from daughters of Holstein PT bulls with official August 2006 evaluations: 1) most recent 12 mo of calvings from cooperator herds with ≥ 1 PT daughter, 2) most recent 18 mo of calvings from herds with ≥ 1 PT daughter, 3) most recent 12 mo of calvings from herds with ≥ 5 PT daughters, and 4) most recent 18 mo of calvings from herds with ≥ 5 PT daughters. Interim evaluations from each data subset were compared with previous and subsequent official USDA evaluations. Correlations between interim and official evaluations were high (0.95 to 0.98 for bulls of interest) for all 4 subsets, which indicated that interim evaluations could provide valuable information between official evaluations. Correlations were highest when data were included from the most recent 18 mo of calvings from herds with ≥ 1 PT daughter. Interim evaluations had a higher reliability than that of previous official evaluations for almost all PT bulls that added daughters and had a lower reliability for almost all non-PT bulls. The Council on Dairy Cattle Breeding and dairy records processing centers supported June, September, and November interim evaluation with release limited to PT bulls with ≥ 10 daughters and an increase in reliability since the most recent official sire evaluation.

Key Words: Interim Evaluation, Genetic Evaluation, Progeny Test

11 Comparison of herds that currently supply young bulls to progeny testing programs with large commercial herds that could serve as dedicated suppliers. A. D. Coburn*^{1,2}, K. A. Weigel¹, S. A. Schnell², and G. Abdel-Azim², ¹University of Wisconsin, Madison, ²Genex Cooperative Inc, Shawano, WI.

Young dairy bulls for artificial insemination (AI) programs have traditionally been provided by seed stock producers. However, the number of seed stock herds has decreased due to changing dynamics of the dairy industry, including increases in average herd size, changes in business priorities, and attrition of stereotypical registered Holstein herds. Our objective was to compare the genetic profiles of herds that supply young AI sires at present with those of large commercial herds that might serve as dedicated suppliers of young sires to specific AI organizations in the future. A total of 693 current supplier herds were identified; these were the herd of record for the dam of a Holstein bull sampled by a major AI stud from 2005 to 2007. In addition, 976 large commercial herds were identified; these had more than 300 Holstein cows that contributed to the most recent routine national genetic evaluation. Frequency of 3X milking was greater in large commercial herds (55%) than in current supplier herds (19%). Among testing plans, DHIR was most common in current supplier herds (73%), whereas DHI-AP was most common among large commercial herds (71%). Mean lactation yield was higher in large commercial herds than in current supplier herds for milk (11,408 kg vs. 11,012 kg), fat (416 kg vs. 414 kg), and protein (348 kg vs. 339 kg), whereas mean lactation somatic cell score (SCS) was lower (2.69 vs. 2.74). Among large commercial herds, 208 herds had mean milk yield > 12,273 kg; 173 herds had mean fat yield > 455 kg; 273 herds had mean protein yield > 364 kg; 207 herds had mean SCS < 2.40; 238 had data collection rating (DCR) for milk > 90%, and 492 had DCR for components > 90%. Mean predicted transmitting abilities (PTA) were similar for current supplier herds and large commercial herds, although the range was less for commercial herds. Current supplier herds had a greater percentage of cows designated with elite status, but the total number of cows with elite status was similar for both groups of herds.

Key Words: Progeny Testing, Dairy, Artificial Insemination

12 Genetic analysis of Canadian dairy cows milked by an automatic milking system. M. Nixon*¹, J. Bohmanova¹, J. Jamrozik¹, L. R. Schaeffer¹, G. Mason¹, J. Rodenburg², F. Miglior^{3,4}, and K. Hand⁵, ¹University of Guelph, Guelph, ON, Canada, ²Ontario Ministry of Food, Agriculture and Rural Affairs, Woodstock, ON, Canada, ³Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, ⁴Canadian Dairy Network, Guelph, ON, Canada, ⁵CanWest DHI, Guelph, ON, Canada.

Twice a day milking is currently the most often used milking schedule in Canadian dairy cattle. However, with the use of an automatic milking system (AMS), dairy cows can be milked more frequently. One of the major drawbacks of an AMS are cows that attend the milking system less than twice a day, and therefore have to be manually brought (or fetched) to the AMS by the farmer. The objective of this study was to examine milking intervals of the fetched dairy cow and to estimate genetic parameters for milking frequency of dairy cows milked in an AMS. The data collected was 166,712 daily records of 1,786 primiparous cows from 14 farms in Ontario and Quebec. Majority of cows visited milking robot 2 (47%) or 3 (37%) times a day. A two-trait random regression model was used for estimation of (co)variance components for 24-h milk yield and milking frequency. The model included fixed effect of herd x test-date, fixed regression on days in milk nested within season and random

regression for additive genetic and permanent environmental effects. Both fixed and random regressions were fitted by Legendre polynomials of order four. The variance components were estimated using restricted maximum likelihood. Heritabilities for the daily milking frequency and daily milk yield ranged between 0.06 and 0.19 and 0.20 and 0.39, respectively. Genetic correlations between daily milk yield and daily milking frequency were highest at the peak of lactation (0.86) and lowest in mid-lactation (0.45). Further investigation is needed into later parities and estimating breeding values for milking frequency.

Key Words: Dairy Cattle, Automatic Milking System, Heritability

13 Impact of selection for decreased somatic cell score on productive life and culling for mastitis. H. D. Norman*, R. H. Miller, and J. R. Wright, *Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Impact of continued selection for decreased somatic cell score (SCS) was examined to determine if such selection produced cows with difficulty responding to bacteria within the mammary gland as expressed by greater mastitis susceptibility and shorter productive life (PL). Holstein artificial-insemination bulls with a predicted transmitting ability (PTA) for SCS based on ≥ 35 daughters were grouped by quintile based on PTA SCS. Then 25 cow groups were formed based on sire and maternal grandsire (MGS) quintiles. Cows had birth dates from 1993 through 1999 and calving dates from 1995 through 2005. Cows that changed herds or had unreported lactations for their first 5 parities were excluded as were herds with <5 cows. Data were available from 2,556,402 cows in 27,167 herds. Mean cow PL was 27.1 mo; time opportunity was a restricting factor. Mean PTA SCS was 3.26 for sires and 3.25 for MGS for the cow group with highest sire and MGS quintiles and 2.77 and 2.76 for the group with lowest sire and MGS quintiles. Least squares difference in PL was examined on a within-herd basis with cow birth year in the model. Cows from the lowest sire-MGS quintile group had 3.2 mo longer PL than those from the highest sire-MGS quintile group and were less likely to be culled for mastitis (9 versus 13%) based on reported reason for record termination. Advantage for cows with a sire or MGS with lower PTA SCS was nearly linear across groups within MGS or sire quintile, respectively. Difference in PL between cow groups with highest and lowest sire quintiles for PTA SCS ranged from 2.0 to 2.4 mo; corresponding difference for MGS quintiles ranged from 0.8 to 1.2 mo. Because each month of additional PTA PL is valued at \$29 in the current USDA lifetime net merit index, a 200-cow herd from the lowest sire-MGS group for PTA SCS would be worth nearly \$6,000 more annually than a 200-cow herd from the highest sire-MGS group without considering any additional income or expense associated directly with SCS. Selection for decreased SCS across generations is expected to produce cows that are less likely to be culled for mastitis.

Key Words: Somatic Cell Score, Productive Life, Mastitis

14 Derivation of factors to estimate daily yield from single milkings for Holsteins milked two or three times daily. M. M. Schutz*¹, J. M. Bewley¹, and H. D. Norman², ¹Purdue University, West Lafayette, IN, ²USDA-ARS, Beltsville, MD.

The objective was to derive factors to predict daily yield when milk weights are recorded once when cows are milked twice (2x) or once or

twice when cows are milked thrice (3x) per d. Data were from herds enrolled in Dairy Herd Improvement and automatically recording milking weights and times. Following edits, 83,690 daily records of 1842 first lactation cows and 143,670 records of 2957 later lactation cows in 5 2x herds and 41,657 records of 779 first lactation cows and 84,131 records of 1999 later lactation cows in 4 3x herds remained. Factors currently in use to adjust single milking yields for milking interval (MINT) were applied. Also, 3 methods were compared to estimate factors or equations to predict daily yield. Factors were estimated as the ratio of the sum of daily milk to the sum of partial milk within a parity-MINT class (24 intervals in 2 parities) [Method 1] or as the sum of the ratios of daily milk to partial daily yield for each cow-day divided by the number of cow-days within parity-MINT class [Method 2]. Resulting factors from both methods were smoothed, applied to data, and residuals were regressed on days in milk (DIM). Regression equations (n=168) were also developed within parity-MINT-DIM classes (2x7x12) [Method 3] to simultaneously account for MINT and DIM. Separate factors and equations were derived for each milking in 2x or 3x herds. Method 3 resulted in consistently stronger correlations between estimated and actual yields and smallest root mean squared error (rMSE) for all milkings and parities. For 2x herds, Method 3 resulted in rMSE of 2.3, 3.0, 2.6, and 3.4 kg for AM milkings for Parity 1 and 2 and PM milkings for parity 1 and 2, respectively; compared to rMSE of 2.6, 3.2, 4.1, and 4.8 kg from current factors for the same milkings and parities. Likewise for 3x herds, Method 3 had smallest rMSE, while Method 1 had rMSE similar to those from current factors. Work is ongoing to determine whether equations from Method 3 will allow accurate estimation of daily yield when applied to other herds and traits fat, protein, and somatic cell score.

Key Words: Milking Interval, Adjustment Factor, Milking Frequency

15 Genetic correlation of live weight with price and calves' commercial values. R. Dal Zotto*, M. Cassandro, M. Penasa, M. De Marchi, and G. Bittante, *University of Padova, Legnaro, Padova, Italy.*

Aim of this study was to estimate heritabilities and genetic correlation of live weight and commercial values of Brown Swiss calves. A total of 23,911 individual live weight (kg) and commercial value (Euro/kg and Euro/calf) of Brown Swiss calves were recorded by Kovieh, the wholesale cattle organization of Bolzano province (Italy), from January 2003 to December 2007. Data were derived by 239 weekly auctions of calves sold at age from 7 to 50 days, with a live weight from 30 to 110 kg, and with a commercial value from 1.0 to 5.0 Euro/kg. Only calves with registered breed of sire and dam have been considered. Age at auction (24 ± 8 d) has been classified into three classes, (young, intermediate and old). (Co)variance components were estimated with a multiple-trait animal model based on Restricted Maximum Likelihood (REML) procedure using VCE package (Groeneveld, 1998). The pedigree file included all animals with at least a phenotypic record on one trait and all known ancestors of animals with phenotypic record. For all traits a linear model was used considering the following fixed effects: herd of birth (3116 levels), auction test-day (239 levels), age (3 levels). Animal and residual effects were considered as random and assumed to be independents. Heritabilities were 0.364 ± 0.015 for live weight (kg), 0.112 ± 0.036 for price commercial value (Euro/kg) and 0.175 ± 0.023 for calves commercial value (Euro/calf). Genetic correlations between live weight and price and between liveweight and calf commercial value were 0.046 ± 0.096 and 0.707 ± 0.047 , respectively. Genetic correlation between price and calves commercial values was, as expected, high and equal to 0.734 ± 0.041 .

These estimates of (co)variance components should provide the parameters for breeding value estimation of Brown Swiss bulls for these beef traits useful as additional information to increase the breed profit.

Key Words: Genetic Parameters, Commercial Values, Dairy Calves

16 Relationship between milk production and female fertility traits in Holsteins. A. Sewalem*^{1,2}, G. Kistemaker², and F. Miglior^{1,2}, ¹*Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, Quebec, Canada,* ²*Canadian Dairy Network, Guelph, ON, Canada.*

Milk production and reproductive traits are major factors with respect to overall efficiency and profitability of the dairy industry. Various reports indicated that breeding for increased production in dairy cattle has negative side effects on health and fertility traits. The aim of this study was to assess the relationship between production trait and selected female fertility traits. Data consisted of Canadian test day and breeding records of the Holstein breed with first calving occurring between 1997 and 2007. A total of 15,000 records randomly selected herd were used for genetic parameter estimations. Traits studied were calving to first service (CTFS), first service to conception (FSTC) and test day milk yield close to 90 DIM (TD90M). The data included only records of first parity cows. The mean CTFS, FSTC and TD90M were 89.35 ± 33.86 , 31.39 ± 44.78 and 30.24 ± 61.73 , respectively. The genetic correlation between CTFS and TD90M was 0.29 and between FSTC and TD90M was 0.12, showing that cows with high milk production at time of first insemination tended to have longer intervals of CTFS and FSTC.

Key Words: Reproductive Traits, Production, Canadian Dairy Breeds

17 Genetic correlations between conception rates and test-day milk yields using a threshold-linear random-regression model. S. Tsuruta*¹, I. Misztal¹, C. Huang¹, and T. J. Lawlor², ¹*University of Georgia, Athens,* ²*Holstein Association USA Inc., Brattleboro, VT.*

The objective of this study was to estimate genetic correlations between conception rates (CR) and test-day milk (TDM) yields for different DIM. The data included 245,214 first parity service records of 102,929 first-parity cows born in NY between 1999 and 2003. The CR was defined as the outcome of a single insemination. CR and TDM were analyzed by using a bivariate model with herd-year, age, AI status, service month, cubic regressions on DIM using Legendre polynomials as fixed effects, herd \times sire interaction, sire additive genetic and permanent environment with cubic random regressions on DIM, service sire, and residual as random effects. Variance components were estimated using a Bayesian method via Gibbs sampling. Farms were categorized into small (≤ 50 cows) and large operations. Larger herds produced more test-day milk (33.7kg, 30.4kg), have lower CR (31%, 36%), start breeding earlier (77 d, 94 d to first service), and have fewer days open (137 d, 145 d). A more stressful relationship between CR and DIM was observed during the higher production periods of the lactation curve for large herds. For large herds, the genetic correlation between CR and TDM was 0.4 at DIM=50, dropped to 0 at DIM=90, was -0.55 at DIM=155, and rose to 0 at DIM=240. For small herds, the correlation was 0.1 at DIM=50, dropped to 0 at DIM=70, was -0.2 at DIM=120, and rose to 0 at DIM=240. For large (small) herds, the average correlation across

DIM between CR and TDM was -0.2 (-0.1). The average heritability estimate for CR was 2.4% (5.3%). The chi-square test showed that the frequencies of service records were significantly different during a week for 60% of large herds and for 11% of small herds, suggesting more timed AI services in large herds. Large herds may be more advantageous for identifying bulls with superior fertility, but small herds may be more advantageous for identifying bulls that sire more fertile daughters.

Key Words: Conception Rate, Test-Day Milk, Threshold-Linear Model

18 Study on genetic parameters of conception rate and heat detection/expression. C. Huang*¹, I. Misztal¹, S. Tsuruta¹, and T. J. Lawlor², ¹University of Georgia, Athens, ²Holstein Association USA Inc., Brattleboro, VT.

The purpose of this study was to indirectly estimate genetic parameters of heat detection/expression (HDE). Days open (DO) is a composite trait with many components, including conception rate (CR) and HDE. An insemination outcome (IO) is mainly influenced by CR. A genetic correlation between DO and IO contains information about the genetic correlation between the HD/E and CR. Field data were obtained from DRMS, Raleigh, NC, and included milk and service records on 109,278

cows in first lactation from 2,952 herds in NY from 1999 to 2003. A bivariate sire model included DIM, season, milk yield, age, AI status as fixed effects, herd-year, service sire, additive genetic, and permanent environment as random effects. Because of a single record per animal in DO, estimability required that the residual variance for DO be fixed. The data were split by herd size (≤ 50 , ≥ 100); tests indicated that many larger farms use timed AI while few small ones do. The genetic correlation between DO and IO was 0.991 with small herds and 0.996 with large herds. A data set for DO and IO was simulated assuming a range of genetic correlations between CR and HDE. For a range of 0.1-0.9, the genetic correlations between DO and IO were all ≥ 0.99 . Subsequent studies looked at correlations of IO and HDE. In simulated data, records analyzed for HDE existed until the insemination resulted in conception. In field data, HDE was estimated as $1/[(DO-df+21)/21 \times ns]$, where df is days at first insemination, and ns is number of services. With the field data set, the genetic correlations between HDE and IO were 0.996 with small herds and 0.994 with large herds. With the simulated data set, these correlations were 0.992, 0.984, and 0.538 when the simulated genetic correlations between HDE and CR were 0.9, 0.5, and 0.1, respectively. Heat detection as present in DO is censored, and very high genetic correlations between DO and IO are estimated even if the true correlations between HDE and CR are low.

Dairy Foods: Dairy Food Chemistry and Microbiology

19 ADSA Pioneer: Milk quality - Developments in testing and grading of raw milk. W. S. LaGrange*, Iowa State University, Ames.

Milk testing was initiated due to consumer pressure to have wholesome uniform products. Initially, the buyer smelled and sometime tasted the milk. When the Babcock test came along milk richness or fat content could be standardized. Older milk could be determined from titration and alcohol tests. Then keeping quality tests such as Methylene blue and Resazurin became important to manufacturers. A lot of time was spent in identifying spoilage and pathogenic organism in raw milk. As technology became available rapid and sophisticated tests became the standard of the milk industry. In the developed world many tests are determined prior to the milk being unloaded at the manufacturing plant.

20 Transglutaminase polymerization of a modified whey protein ingredient. D. A. Clare* and C. R. Daubert, North Carolina State University, Raleigh.

Transglutaminase promotes protein crosslinking reactions through an acyl transferase mechanism involving protein-bound glutaminy residues and primary amines including the ϵ -amino group of lysine residues in soy, myosin, gluten, oat globulin, peanuts, casein and whey. In this study, a modified whey protein concentrate (mWPC) was prepared to varying protein concentrations, 5.6% - 10% or 8% - 14.3% solids (w/w), in deionized water, pH 8.0, and crosslinked with microbial transglutaminase (TGase) at an enzyme/substrate ratio of \sim 5 units of activity/g mWPC. Test mWPC dispersions, prepared in the presence and absence of 10 mM dithiothreitol (DTT), were then incubated with the enzyme for various time intervals at 40°C. Representative samples were analyzed with respect to their (a) SDS-PAGE banding profile, (b) degree of crosslinking as determined by OPA assays, (c) apparent viscosity measurements, (d) gelation parameters, and (e) emulsion properties.

SDS-PAGE results showed that polymer formation occurred in all experimental mWPC dispersions treated with TGase, even those devoid of dithiothreitol (DTT); however, the rate of the reaction was slower. For example, quantitative OPA analyses revealed \sim 30% cross-linking in whey protein samples containing 10mM DTT after a 3h treatment period compared to 15% polymerization in equivalent solutions prepared under non-reducing conditions. These finding were attributed, in part, to maintenance of the redox status of the active cysteine residue found in the enzymatic catalytic site.

Pseudoplasticity was observed in all shear rheological experiments. Furthermore, the apparent viscosity and gel strength of TGase-mWPC dispersions was slightly lower than non-treated controls while the gelling temperature was raised. Notably, both the viscosity and stability of emulsions, prepared with these dispersions, were significantly improved. Scanning electron microscopy revealed a larger pore size in mTGase crosslinked mWPC samples, attributed to polymer formation. Ultimately, these approaches may provide novel whey-based food ingredients with unique functional characteristics for expanded application within the world marketplace.

21 Production of conjugated linoleic acid in milk by lactic acid bacteria. A. J. Pandit*, S. K. Anand, K. F. Kalscheur, and A. N. Hassan, South Dakota State University, Brookings.

Geometrical and positional isomers of conjugated linoleic acid (CLA) have several reported health benefits. Dairy products like cheese are increasingly being viewed as a possible dietary source of CLA. Increasing CLA level in these products could help bridge the gap between daily CLA requirement and effective dietary intake. This study was undertaken to evaluate CLA production and their isomeric distribution in milk during fermentation by lactic acid bacteria (LAB). A total of 155 cultures of LAB, including 46 cultures from the Dairy Science Department's culture collection, 68 isolates from retail cheeses, and 41 raw milk isolates were screened for CLA production. Cultures were individually inoculated in milk at 2% levels and incubated for 4 h at 37°C. Fat was extracted from milks at the end of incubation and the butyl esters were analyzed by gas chromatography. Control milks had an average CLA content of 0.41 ± 0.10 gm/100 gm of fatty acids (FA). The 13 cultures (7 *Lactococcus* and 6 *Lactobacillus*) from the Department collection produced CLA values ranging from 0.43 ± 0.03 to 0.63 ± 0.14 gm CLA/100 gm FA in milk. A higher CLA level was produced by five isolates from retail cheeses (4 *Lactococcus* and 1 *Lactobacillus*). The highest CLA production by one of the *Lactococcus* strains was 1.12 ± 0.35 gm/100 gm FA. The remaining 4 isolates (3 *Lactococcus* and 1 *Lactobacillus*) produced 0.87 ± 0.22 , 0.63 ± 0.16 , 0.56 ± 0.15 , 0.62 ± 0.10 gm CLA/100 gm FA, respectively. These cultures increased mainly the cis-9, trans-11 isomer and also produced 3 to 5 unidentified CLA isomers. On an average, cis-9, trans-11 represented 62.62%, and trans-10, cis-12 represented 17.77% of the total CLA. This study shows that lactic acid bacteria can increase levels of CLA in fermented milk and possibly be used for making dairy products enriched with CLA.

Key Words: Conjugated Linoleic Acid, Lactic Acid Bacteria, Milk

22 Immuno-stimulatory AT oligodeoxynucleotide from *Lactobacillus gasseri* requires a specific self-stabilized structure. T. Shimosato*¹, M. Tohno², T. Sato³, Y. Kawai², T. Saito², and H. Kitazawa², ¹Shinshu University, Minamiminowa, Nagano, Japan, ²Tohoku University, Sendai, Miyagi, Japan, ³Yokohama City University, Yokohama, Kanagawa, Japan.

Some probiotics (*live microorganisms which when administered in adequate amounts confer a health benefit on the host*) enhance the secretion of anti-inflammatory cytokines by innate immune cells. We have been studying immuno-stimulatory DNA from probiotics as an immuno-active factor in probiotics. Recently, we found an immuno-stimulatory AT oligodeoxynucleotide (ODN) containing a unique core sequence (5'-ATTTTAA-3') in *L. gasseri* genomic DNA. Interestingly, although the AT-ODN does not contain any CpG sequences, it exerts mitogenic activity and augments Th1 type immune responses via Toll-like receptor (TLR) 9. We then identified 280 different AT-ODNs in *L. gasseri* genomic DNA, and mitogenicity and NF- κ B reporting assays showed that 13 of these 280 AT-ODNs were strongly immuno-stimulatory in the TLR9 transfectant. Of these, AT-ODNs LGAT-145

and LGAT-243 were the most potent. LGAT-243 had the greatest activity and was more potent in the induction of Th1 type cytokines than the swine prototype, ODN D25. We further found that a six-base secondary loop structure containing a self-stabilized 5'-C...G-3' stem sequence is important for induction of the potent immuno-stimulatory activity. The present study identified novel strong immuno-stimulatory AT-ODNs in the genomic DNA of probiotics. Moreover, these results are the first to demonstrate that AT-ODNs with a specific loop and stem structure are important for immuno-stimulatory activity. Finally, the data shows that TLR9 is a receptor for not only CpG but also for AT ODNs. These findings may help our understanding of intestinal immuno-regulation mediated by probiotic DNA through TLR9, for the development of new probiotic foods.

Key Words: AT-ODN, *Lactobacillus gasseri*, TLR9

23 Complete genome sequence and comparative genome microarray of *Lactobacillus casei* provides evidence for genome expansion and reveals significant intraspecies differences. H Cai^{*1}, J. R. Broadbent², and J. L. Steele¹, ¹University of Wisconsin, Madison, ²Utah State University, Logan.

Lactobacillus casei are industrially important lactic acid bacteria (LAB) that have been primarily used as probiotics and specialty cultures for cheese flavor development. They have remarkable ecological adaptability to diverse habitats. The genome sequence of *L. casei* ATCC334 had been analyzed. It contained a 2,895,264-bp chromosome and a 29,061-bp plasmid with a GC% of 46.6 and 42.2, respectively. A total of 2,951 ORFs was predicted. Several unique features of the genome supported the hypothesis that the genome had been expanded for versatile adaptation to diverse ecological niches: (i) a correlation was observed between the relatively high GC% of the genome and versatile adaptability of LAB, (ii) relatively low numbers of rRNA and tRNA genes relative to genome size likely indicated presence of large amount of unessential genes; and (iii) significantly higher number (~3.25% of total ORFs) and larger diversity of transposases (11 families) suggested the key role of transposases in genome expansion and horizontal gene transfer of the species. Additionally, the genome contained relatively high number of transcriptional regulators (>4% of total ORFs) and transporters. About 361 secreted proteins, 19 glycosyltransferases and several mucus- and fibronectin-binding proteins were identified. About 28 peptidases and homologs for PrtP and PrtM were predicted. Comparative genome microarray between ATCC334 (a cheese isolate) and a silage isolate 12A revealed ~14.4% of the genes that are present in ATCC334 are missing in 12A, most of which are transposase- and bacteriophage- associated genes or genomic regions. Loci involved in sugar transport, metabolic enzymes and transcriptional regulators also differ. Collectively, the genomic features of *L. casei* provided evidence for genome expansion that may have facilitated its diverse ecological adaptability. Significant gene content differences were identified between the cheese and silage isolates, which may underlie the ecological adaptation of these strains to their specific ecological niches.

Key Words: *Lactobacillus casei*, Genome Sequence, Adaptation

24 Effect of feeding pasture and long chain omega-3 fatty acid

(LCn-3FA) supplements on the composition and oxidative stability of milk & butter. M. C. Rose^{*1}, H. P. V. Rupasinghe¹, S. M. Budge², K. Glover¹, and A. H. Fredeen¹, ¹Nova Scotia Agricultural College, Truro, NS, Canada, ²Dalhousie University, Halifax, NS, Canada.

Enriching milk with LCn-3FA, namely docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), to improve its nutritional profile may also increase rate of lipid oxidation and the production of off-flavors. Antioxidant content of forage may ameliorate the effect, but antioxidant content of forages is reduced by ensiling. The objective of this experiment was to determine the effect of feeding LCn-3FA and forage type with different anti-oxidant potential on the oxidative stability of milk. Eight mid-lactation Holstein cows (BW 612.5 ± 9.49kg; BCS 2.71 ± 0.03 out of 5; milk yield 16.83 ± 0.56kg) were used to evaluate four treatments: pasture (with concentrate fed twice daily at milking according to milk yield 1:4 w/w) or total mixed ration (TMR containing ensiled forage and 11.06 kg concentrate DM per cow daily) with or without a supplement of rumen-protected LCn-3FA. Cows were assigned randomly to treatment in two 4x4 Latin squares with 28 d periods. Milk was collected on days 27 and 28. No significant differences (P>0.05) in gross milk composition among the treatments were observed, which averaged 4.11 ± 0.23% fat; 3.10 ± 0.09% protein; 4.69 ± 0.03% lactose. Butter was made by centrifugation at 15,000 x g for 15 min at 4°C. Oxidation of raw milk and butter was determined using the Thiobarbituric Acid Reactive Substances (TBARS) method. TBAR absorbance at 530nm was significantly higher (P=0.02) in milk and butter of cows fed TMR supplemented with LCn-3FA compared with those fed pasture and LCn-3FA. These results indicate that a pasture-based diet may improve the shelf life of milk and butter enriched with LCn-3FA.

Key Words: Long Chain Omega-3 Fatty Acids, Lipid Oxidation, Forage

25 The protective effect of processed cheese against hyperlipidemia in rats. M. H. Abd El-Salam* and D. A. Mohamed, National Research Centre, Cairo, Giza, Egypt.

The effects of ingestion of processed cheeses containing different types of fats on plasma lipid profile and lipid peroxidation of hypercholesterolemic rats were studied. The study included three types of processed cheeses; the first two contained vegetable oils and the third contained milk fat only. Five groups of rats (8 animals each) were fed balanced diet (normal control), hypercholesterolemic diet (control) and hypercholesterolemic diet containing one of the tested processed cheeses respectively for 8 wks. The body weight and food intake were recorded and gain in body weight and food efficiency ratio were calculated. Blood analysis was carried out at the end of the experiment for total lipids and cholesterol, LDL, HDL, triglycerides (Tg) and plasma malondialdehyde (MDA). Feeding the different processed cheeses with hypercholesterolemic diet showed variable reductions in the plasma lipids except HDL which was increased as compared to control. The highest reduction was observed in group that received processed cheese containing milk fat only. Also, this group showed significant reduction in lipid peroxidation as measured by MDA. These results reflect the potential beneficial effects of consumption of processed cheese containing milk fat only towards cardiovascular diseases.

Key Words: Processed Cheese, Hypercholesterolemia, CLA

26 Antimicrobial activity of dried spearmint and its extracts for use as soft cheese preservatives. M. Foda¹, M. El-Sayed*¹, M. E-Mogazy¹, A. Hassan², and N. Rasmy², ¹*National Research Center, Cairo, Egypt*, ²*Faculty of Agriculture, Cairo, Egypt*.

Spearmint which is common herb in the Mediterranean region was evaluated (dried or its extracts) as inhibitor factor against the growth of four strains of bacteria, four strains of yeast and four strains of moulds, using filter paper disc agar diffusion technique. Obtained results showed that water and ethanolic extracts had no inhibitory effect on all strains under test except the moderate activity of ethanolic extract against Gram positive bacteria (*Bacillus cereus* and *Staphylococcus aureus*). Essential oil was the strongest antimicrobial inhibitor, so, its antifungal activity and minimum inhibitory concentration (MIC) were examined. To evaluate the antimicrobial activity of spearmint, two types of UF-soft cheese were prepared using different concentrations of dried spearmint and its essential oil. Spearmint essential oil showed significant reduction on counts of total bacteria, proteolytic bacteria and psychrotrophic bacteria compared with control samples. Moulds and yeasts were totally inhibited by using the essential oil.

Key Words: Soft Cheese, Antimicrobial Activity, Spearmint

27 Is Levowitz–Weber the appropriate confirmatory stain for direct microscopic somatic cell counting of ovine milk? K. H. Petersson*¹, L. Connor¹, C. S. Petersson-Wolfe², and K. A. Rego¹, ¹*University of Rhode Island, Kingston*, ²*Virginia Polytechnic Institute and State University, Blacksburg*.

The stain approved for regulatory use in bovine and ovine milk is the non-specific methylene blue based Levowitz–Weber (L–W) stain in

contrast to the approved stain for goat milk, the DNA specific Pyronin–Y–Methyl Green (PMG) stain. Due to the presence of cytoplasmic particles in ovine milk the use of the L–W stain has the potential to artificially elevate the MSCC, particularly in late lactation. The objective of the current study was to compare the MSCC of sheep (n=42) over an entire lactation using 3 different counting methods: 1.) Direct Microscopic Somatic Cell Count (DMSCC) with L–W stain, 2.) DMSCC with PMG stain, and 3.) MSCC using the automated Fossomatic cell counter (FOSS). All staining procedures were conducted in accordance with U.S. regulatory procedures. Composite milk samples were collected from Friesian ewes (1–7 yr of age) within 2 wk of lambing and then monthly thereafter throughout the entire lactation. Each milk sample was divided into 2 aliquots. The DMSCC staining procedures (L–W and PMG) were conducted on one aliquot within 48 h of sample collection. The second aliquot was bronopol–preserved and Fossomatic cell counting began within 72 h of sample collection. The same bronopol–preserved sample was tested for fat, protein, milk urea nitrogen and total solids content. Sample collection began in October 2007 and will continue until May 2008. Descriptive statistics on the preliminary data have been summarized. To date, all study animals have been sampled from lambing through 90 days in milk. The average MSCC for L–W, PMG and FOSS were $98 \pm 9 \times 10^3$ (Mean \pm SEM), $72 \pm 7 \times 10^3$ and $345 \pm 40 \times 10^3$ cells/ml, respectively. Preliminary statistical analyses suggest significant interactions between the counting method and milk components fat, protein and total solids, as well as month of lactation. Additionally, milk urea nitrogen level appears to have a significant negative association with MSCC. A full statistical analysis will be examined following the completion of data collection in May 2008.

Key Words: Ovine Milk, Somatic Cell Count, Staining Procedure

Symposium: ESS Program: Horse Genome Toolbox for Animal Science Applications

28 Exploiting the public genome databases for equine science. L. C. Skow*, *Texas A&M University, College Station.*

Improved technologies developed during and consequent to the human genome project have resulted in the complete genome sequences of more than a thousand species of microbes and eucaryotes, including 25 species of mammals and 10 non-mammalian vertebrate species. These vast sources of publicly available data represent invaluable potential information for inquiry at all levels of biological processes. This presentation will provide an introductory overview to on-line genome databases, gene mining tools and genome annotation resources as a prelude to the following speakers who will speak to specific genome resources and tools recently developed for equine science based on the horse genome sequence. Emphasis will be on functional genomics applications.

Key Words: Equine, Genome Tools, Functional Genomics

29 Identification of genes for health and performance traits in horses through whole genome analysis. J. Mickelson*, *University of Minnesota, St Paul.*

An extraordinary and sustained effort by the equine genome research community, and the excellent downstream potential of the horse as a biomedical model, played a significant role in the selection of the horse for full genome sequencing and genome structure analysis by the National Human Genome Research Institute. As a result, we are now extremely well-positioned to address our long-term research goals, which can briefly be summarized as identifying genes and pathways associated with normal health, disease, performance, growth, development, fertility, and disease resistance in horses. With focused research investments we can now expect advances in our understanding of equine biology, improvement in health, performance and well being, as well as the development of equine models of significant human health concerns.

The equine research community now has the technology to rapidly genotype tens of thousands of single nucleotide polymorphism (SNP) DNA markers on a single horse for less than \$300. These whole genome SNP chips can, in principle, allow the identification of genes having a major influence on traits of interest provided that a sufficient population of well phenotyped horses can be acquired. In this presentation the principles, practice, and limitations to such whole genome scans to identify the chromosomal location of genes contributing to a trait, and the means to find the specific genes and alleles that may be responsible, will be presented.

30 Transcriptional profiling for gene expression analyses of equine samples. J. N. MacLeod*, *University of Kentucky, Lexington.*

Analyses of gene expression are widely performed in experimental biology to investigate cell and tissue function, cellular differentiation,

disease pathogenesis, and the molecular mechanisms of different therapies. The basic premise is that valuable insight about a tissue or cell type can be obtained from studying qualitative and quantitative changes in the patterns of gene expression. Several laboratory techniques are used routinely to evaluate gene expression on a transcriptional level. Selection of a specific procedure is usually dependent on the experimental objectives, amount of sample available for analysis, investigator preferences and resources, and cost considerations. One challenge in quantitative analyses of gene expression can be trying to select the individual genes that will be most interesting and biologically relevant to study. Transcriptional profiling enables scientists to initially make a broad assessment of the approximately 22,000 genes in the mammalian genome. Using cDNA and oligonucleotide microarrays, expression across large subsets of genes and even the entire genome can be evaluated in a single experiment. These screening procedures often enable a more informed decision to be made on which individual genes, or groups of functionally related genes, should be most interesting to focus on at greater detail in subsequent experiments. Essentially, the scientist can evaluate the "forest" before making a decision on which individual "trees" should be investigated further. This presentation will overview transcriptional profiling concepts and microarray platforms, concentrating on procedures that are currently being used to profile gene expression in equine RNA samples. Emergent technologies based on "next generation sequencing" and mRNA resequencing will be discussed.

Key Words: Equine, Transcriptional Profiling, Microarray

31 Let the genome give your project a leg-up: Real-time qPCR strategies in equine research. S. Brooks*, *Cornell University, Ithaca, NY.*

Sequencing of the equine genome has opened-up a multitude of possibilities in research techniques for equine scientists. During the last 100 years great discoveries have been made using antibodies, histochemistry, biochemistry and population or quantitative statistics. Unfortunately, reagents needed for traditional assay methods, like antibodies, are not as readily available in the horse as they are in other species. Furthermore, the methods often require special expertise. In some cases, Real-Time qPCR can offer a convenient alternative. With a genome sequence literally at our fingertips we can now design primers and probes for virtually any target in record speed. As the complexity of gene regulation is unraveled, use of gene expression studies has likewise expanded. Real-Time qPCR, using mRNA as a template, can measure changes in gene expression for proteins of interest faster and more accurately than ELISA or western plot can for the protein itself. Additionally, purified nucleic acids and more easily acquired and stored than fresh tissue or protein. In addition to gene expression Real-Time platforms are currently being used for genotyping, quantification of copy-number variants, mutation scanning, mirco and siRNA detection, DNA-methylation analysis and finally, coming full circle, in immuno-qPCR, which can improve sensitivity up to 1000-fold over traditional ELISA.

Extension Education: Symposium: Has the Land Grant College Left the Farm?

32 Why there is less applied agricultural research conducted at land grant colleges. R. L. Plain*, *University of Missouri, Columbia.*

Over the past 20 years, there has been a steady shift in the type of research conducted by colleges of agriculture at land grant universities, away from applied research and toward basic research. There are two primary reasons for this shift. First, formula funds available through USDA have held constant, more or less, for much of this period. Thus, the purchasing power of these federal dollars has shrunk by the rate of inflation. This has forced researchers to increasingly rely on competitive grants for funding. By their nature, competitive grants tend to be more oriented to basic research. The second reason for the shift away from applied research relates to changes that have taken place in agriculture. Farms have gotten much bigger. For land grant universities to do many types of applied research, they need facilities and equipment comparable to those used by producers. This is particularly a problem for applied livestock research, where replicating the production systems used by modern swine and dairy farms can be quite costly.

Key Words: Research, Land Grant, Funding

33 What I did when I had an extension/research appointment and what I do now: How times have changed. R. L. Nebel*, *Select Sires Inc., Plain City, OH.*

For 22 yrs I had an extension/research appointment first at North Carolina State University and then Virginia Tech. My appointment and performance expectations changed from 100% extension to 75% extension 25% research. Additionally, for 16 yrs I taught an applied reproductive management class in the associate degree program and during my last 5 yrs I taught a senior level physiology of reproduction class. Extension focus at the county level switched to specialized multi-county or regional area dairy agents of which there are currently three. I was the major advisor to fifteen MS students with most doing large field studies to obtain data to answer their thesis objectives. Funding for applied field studies in the area of reproduction of dairy cattle was and still is difficult to obtain. In 2005, I started my present position as senior reproductive and herd management specialist at Select Sires Inc. My primary responsibility is to elevate the reproductive expertise of all Select Sires member cooperatives and international distributor personnel and develop programs to ensure Select Sires is the recognized industry leader in applied reproductive management programs at the producer level. To conduct workshops on basic AI training, advanced AI training, herd management evaluation, synchronization and heat detection protocols, herd record analysis using on-farm records and the RePRO Analysis™ program, and on-farm consulting with dairy producers and their employees on reproductive and herd management issues. The objective of my presentation is to compare and contrast my career paths as a reproductive specialist in academia and now in the AI industry.

Key Words: Extension Education, Applied Reproduction, AI Industry

34 Serving the beef industry by re-defining your comfort zone. M. Siemens*, *Cargill Meat Solutions, Wichita, KS.*

In planning a career everyone makes decisions how best to obtain the desired outcomes, including the sort of job one wants to do until they retire. Dr. Siemens earned a Ph.D. in ruminant nutrition with the objective of finding a job supporting the beef industry through a university extension position. Such a position was obtained. After 10 years in academia an opportunity arose which allowed Dr. Siemens to seek new challenges outside of academia, so he left his university position for one in industry. Seeking the ability to have a broader impact Dr. Siemens found himself in industry working in animal welfare, beef procurement, swine procurement, beef/pork/turkey marketing, process verification, beef/pork/turkey retailer/foodservice support, biotechnology and other industry issues. Not too much on the pure ruminant nutrition side of the business anymore, and all areas where Dr. Siemens had limited formal training. To be successful and valuable to the livestock industries Dr. Siemens has had to re-define his comfort zone from ruminant nutrition to a variety of subject matters where expertise was needed. This has required him to obtain knowledge and information from a variety of sources and to find ways to generate new knowledge when gaps existed. Sources have included university extension, but also other academics as well as colleagues in industry. Generation of new knowledge within industry has proven invaluable to him as a source of continuing professional development. The new knowledge is neither peer reviewed nor shared widely (i.e. in scientific journals), which is different than that generated through the Land Grant system. It is, nonetheless, extremely valuable to those with access to it.

Key Words: Extension, Production Research, Industry

35 A transition from extension-research to industry swine genetics. W. O. Herring*, *Smithfield Premium Genetics Group, Rose Hill, NC.*

Much like the way of poultry, over the last 15 years, swine production has shifted to an integrated, contract production model. Today, the top 20 pork producers in the U.S. account for approximately half of the sow herd inventory. All of those top 20 producers currently have employees that are licensed veterinarians, nutritionists, physiologists and/or geneticists. Because of more homogenous production systems, scientists at these companies provide the technical assistance directly to growers where in the past that assistance was provided by Extension. These scientists can also focus on problems that improve production and reduce costs associated with those businesses. Their research is either generated internally, or they seek out those research programs at universities or other technology companies with whom they can collaborate to answer specific questions. If university research programs lose touch with the specific needs of these livestock producers, their research programs may not provide a benefit to improving livestock food production. A more specific example in livestock genetic improvement is emerging. Over the past fifteen years, research funding in genetics has shifted away from quantitative genetics to almost completely molecular strategies. However, we have struggled to come up with sweeping examples of how molecular-based genetic improvement has significantly improved livestock production over the last decade. While this has brought in

large grant dollars with attractive overhead for universities, it in turn has yielded a shortage of qualified, young scientists adequately trained with state-of-the-art quantitative genetics skills. While some have argued that nearly all of the needed research has been done utilizing quantitative strategies for livestock improvement, we have much research underway with our datasets for problems that have not yet been addressed in the literature. With a continually shifting U.S. livestock production paradigm, those businesses, researchers, universities and policy makers will have to openly communicate to maintain appropriate research priorities.

Key Words: Extension, Swine, Genetics

36 Why our farm is supporting MS research programs for the University of Illinois. B. F. Wolter*, *The Maschhoffs Inc., Carlyle, IL.*

For over a century, the Land Grant Extension System has created and disseminated knowledge throughout agricultural industries. The utilization of such knowledge has resulted in significant improvement in the biological efficiency of animal production systems. Arguably, Extension's applied science-based research is an important catalyst to increasing animal performance through development of management strategies on the basis of quantified improvements in genetic makeup of animals, facility design, animal health, and nutritional programs

among other factors. Such factors differ among modern animal production systems; therefore, specific research programs focused on system level improvement of biological output are increasingly necessary. The importance of observing science-based principles in study design, analysis, interpretation of results, and a systems-based approach to implementation remains constant among the changes in animal production. Moreover, a multi-disciplined approach involving the use of scientific results found in literature, as well as careful observations made by trained scientists within practical animal environments proves effective for providing incremental improvements in biological efficiency. Ultimately, this approach enhances profitability of animal production systems in competitive business climates. To that end, the Maschhoffs collaborated with the University of Illinois over the last decade to apply such an approach; the efforts resulted in science-based animal management strategies that increase its competitiveness within the pig production sector. Moreover, future scientists and managers are trained collaboratively through the research-based program, and these individuals are likely candidates for providing the leadership to the future of the pig industry. The Maschhoffs experience suggests careful consideration of the objectives in both private industry and public Land Grant Institutions, on behalf of the collaborative parties can provide a closer alignment of interests leading to definitions for the program. Resulting programs may provide for a long-term model for innovating today's animal production sector.

Symposium: Forages and Pastures: Fiber Fermentation: Influence of Supplemental Nonstructural Carbohydrates

37 Factors affecting activity of cellulolytic microbes in the rumen. P. J. Weimer*^{1,2}, ¹USDA-ARS, Madison, WI, ²University of Wisconsin, Madison.

Ruminant diets that contain high levels of readily fermentable carbohydrates often display reduced fiber digestibility, but separating direct from indirect effects has proven difficult. Laboratory culture studies have revealed that the most widely studied ruminal fibrolytic bacteria cannot use starches, and while often capable of using simple sugars, cannot compete effectively for these with typical saccharolytic ruminal bacteria. Glucose and cellobiose are known to inhibit cellulase enzymes *in vitro*, but their effect *in vivo* appears to be reduced by their low concentrations and by the fact that polysaccharide hydrolase enzyme complexes of the fibrolytic bacteria are cell-bound and somewhat protected from the bulk rumen liquid phase. At high sugar concentrations *in vitro*, rapid sugar fermentation appears to lengthen lag time before initiation of fiber digestion, without necessarily reducing digestion rate. Low ruminal pH (<5.9) inhibits growth of the most well-studied ruminal fibrolytic bacteria, but studies with mixed ruminal microflora *in vitro* suggest that cellulose degradation continues at substantially lower pH, apparently due to cellulose hydrolysis by cellulase complexes of nongrowing fibrolytic bacteria, coupled with rapid consumption of the released sugars by more acid-tolerant, noncellulolytic bacteria. Cellulose hydrolysis decreases rapidly at pH values < 5.3, apparently due to loss of adherence to cellulose fibers by the fibrolytic bacteria. Unlike starches, pectin does not appear to reduce fiber digestibility, in part because it is degradable by some fibrolytic bacteria, and because its fermentation does not result in dramatic declines in ruminal pH. Available data suggest that complex interactions among the microflora modulate the effects of concentrates on fiber digestion. Moreover, recently developed molecular techniques for characterizing bacterial populations suggest that most ruminal bacterial species have eluded isolation in pure culture, introducing the possibility that additional species may contribute to ruminal fiber digestion.

Key Words: Cellulose, Fiber Digestion, Rumen

38 The source and degradability of dietary starch influences forage and fiber utilization by lactating dairy cows. D. P. Casper*, D. Schauff, D. Kleinschmit, D. Jones, E. Lanka, and G. Ayangbile, *Agri-King, Inc., Fulton, IL.*

Milk production by the modern lactating dairy cow is often limited by the intake and supply of nutrients through digestion and absorption in both the rumen and intestine. Optimal nutrient intake and supply is achieved through ration formulation and orchestration of forages, feeds, and feeding management on the farm to maximize digestion and absorption. The lactating dairy cow is well adapted to use forages to meet these nutrient requirements. However, the range in forage quality and subsequent ruminal fiber digestion can be quite dramatic based on forage types, environmental conditions, varieties, harvest management, etc. Ultimately, it is the rate and extent of ruminal fiber digestion of the forage that will determine the maximum nutrient supply by the ration to the lactating dairy cow. Starch sources are used in the ration to supply the difference between the nutrient requirements of the cow

and the nutrients supplied by the forages. However, the rate and extent of starch digestion of these sources can negatively or positively influence ruminal fiber digestion. The objective of this presentation will be to discuss the interactions between the rate and extent of various starch sources (corn, barley, wheat, etc.) and their interaction on ruminal fiber digestion from various forage sources to meet the nutrient requirements for milk production. For example, our work with summarizing the data from the USDA-ARS Energy Metabolism Unit Database demonstrates that lactating dairy cows exhibiting symptoms of ruminal acidosis (inverted fat and protein ratios) caused by excessive ruminal starch digestion resulted in significant reductions in ruminal fiber digestion when fed different forage sources. These reductions in ruminal fiber digestibility also lead to a lower supply of nutrients, milk production, milk components and feed efficiency by the lactating dairy cow.

Key Words: Forages, Starch, Digestibility

39 Manipulation of rumen microflora to improve ruminant production. R. J. Forster*, K. A. Beauchemin, and S. Ohene-Adjei, *Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

The addition of large quantities of non-structural carbohydrates to the diet of ruminants has often been associated with increased risks for ruminal acidosis and decreased activity of cellulolytic bacteria. Previously, the commonly accepted scenario for the occurrence of rumen acidosis was the overgrowth of lactic acid producing *Streptococcus bovis* and a decrease in lactate-utilizing bacteria. The subsequent accumulation of lactic acid and drop in rumen pH would then adversely affect the acid sensitive cellulolytic bacteria. However, recent studies utilizing molecular techniques to quantify rumen bacterial populations have not supported the theory that *S. bovis* always increases dramatically when starch is supplemented to cattle. Furthermore, lactic acid does not necessarily accumulate in rumen fluid of animals experiencing rumen acidosis. The inoculation of lactate-utilizing bacteria into the rumen before the onset of increased starch supplementation has had some success in establishing these bacteria before natural populations can increase. Recent studies of the microbial diversity of the rumen have shown that most of the rumen bacteria have not been cultivated and that even coherent phylogenetic groups can vary widely in their functional attributes. This presents challenges for the interpretation of results based on the characterization and enumeration of a few cultivated strains. It has also been found that populations of bacteria traditionally thought to be dominant in the rumen of cattle (such as the *Prevotella* and *Butyrivibrio* groups) may not always be present in significant numbers. To fully understand how the rumen microflora can be manipulated to ameliorate the effects of excess starch on fiber fermentation, we must obtain a thorough knowledge of the bacteria present under different dietary regimens and how they respond to dietary stress. Molecular techniques are being developed and are helping to better understand the dynamics of rumen microbial populations and how they may be manipulated to improve animal production.

Graduate Student Paper Competition: ADSA Dairy Foods

40 Effects of sucrose on the foaming and interfacial properties of whey protein isolate and egg white protein mixtures. X. Yang^{*1,2}, T. K. Berry^{1,2}, and E. A. Foegeding^{1,2}, ¹North Carolina State University, Raleigh, ²Southeast Dairy Foods Research Center, Raleigh, NC.

Whey proteins form wet foams with properties similar to egg white but lack stability when incorporated in an angel food cake. Sucrose is a major component of cakes; however, its effects on foaming, interfacial and baking properties have not been investigated. In this work, 12.8% (w/v) sucrose (the amount found in angel food cake foams) was added to 10% (w/v) protein solutions. The effects of sucrose on the foaming and interfacial properties of egg white protein (EWP), whey protein isolate (WPI), and mixtures of the two were evaluated. Two types of WPI (one based on ion-exchange separation and the other on membrane filtration) and five EWP/WPI ratios were investigated. Physical properties of foams (drainage 1/2 life and yield stress) and dynamic viscosity of pre-foam solutions were measured. Interfacial rheology was determined by a pending drop method. Normal and no sucrose angel food cakes were prepared and evaluated for volume and structure.

Addition of sucrose caused a 79% increase in drainage 1/2 life of EWP foams, whereas drainage 1/2 life of WPI and EWP-WPI mixtures were increased by no more than 32%. Sucrose significantly ($p < 0.05$) increased dynamic viscosities of all protein solutions but only increased the interfacial dilational elastic modulus of EWP, suggesting that the improved interfacial elasticity of EWP effectively slowed down foam drainage. The yield stress values and interfacial dilational elastic moduli of WPI and EWP-WPI mixtures were decreased with sucrose addition, with a positive relationship established between yield stress and interfacial dilational elastic modulus. The presence of sucrose increased angel food cake volume when EWP proportion was higher than 50%, but showed no improvement in the coarse structure of EWP-WPI mixed cakes. These results indicated that sucrose increased foam stability, interfacial elasticity, and angel food cake volume when combined with egg white. This was not observed in whey proteins and EWP-WPI mixed systems, suggesting that one functional difference between whey and egg white proteins is how they interact with sucrose.

Key Words: Whey Proteins, Sucrose, Foam

41 Rheological and chemopreventive properties of milk fermented with exopolysaccharide-producing lactic cultures. D. H. Purohit^{*}, A. N. Hassan, E. Bhatia, and C. Dwivedi, *South Dakota State University, Brookings.*

The objectives of this research were to evaluate the rheological and chemopreventive properties of milk fermented with different exopolysaccharide (EPS)-producing lactic cultures. Reconstituted (11% wt/vol) skim milk was fermented with single strains of EPS-producing and non-producing cultures. They collected on the surface of undisturbed fermented milk samples and after cutting was measured. All EPS-producing cultures reduced the amount of whey present on the surface of the undisturbed samples, while only three out of five strains reduced syneresis measured after cutting. All EPS-producing cultures except a strain of *Lactobacillus delbrueckii* ssp. *bulgaricus* reduced viscoelastic moduli in fermented milk. In the chemoprevention study, 140 male Fisher rats were divided into 7 groups of 20 each. Rats in 6 groups were fed diets supplemented with fermented milks made with single strains of EPS-producing and non-producing cultures, while rats in

group 7 (control) were fed a diet supplemented with milk acidified with glucono- δ -lactone (GDL). All rats were injected with azoxymethane (15 mg/kg, subcutaneous) at weeks 7 and 8 of age to induce tumors in the gastrointestinal tract and fed their respective diets ad libitum throughout the study. After 30 weeks of initiation, rats were anesthetized with ether, intestinal tissues were isolated, washed with normal saline, and number and size of tumors were recorded in the colon and small intestine. Rats fed diets supplemented with fermented milk made with two EPS-positive and one EPS-negative strains significantly lowered colon tumor incidence and colon tumor multiplicity. Cyclooxygenase-2 (COX-2) enzyme activity (enzyme implicated in colon tumor development) was significantly lower in colon tissue of rats fed diets containing milk fermented with four EPS-producing and one non-EPS-producing cultures than that in rats fed diet supplemented with GDL acidified milk. Differences in the chemopreventive effects among EPS-positive cultures could be due to variations in the type of EPS or other metabolites.

Key Words: Fermented Milk, Rheology, Chemoprevention

42 Effect of different types of emulsifiers on the functional properties of low-fat process cheese. E. M. Salim^{*1}, S. Govindasamy-Lucey², M. E. Johnson², and J. A. Lucey¹, ¹University of Wisconsin, Madison, ²Wisconsin Center for Dairy Research, Madison, WI.

In this study, the impact of different types of emulsifiers (EM) on the textural and rheological properties of low-fat process cheese (LPC) was investigated. After a preliminary screening of 9 different types of EM, small lab-scale LPC were prepared from fat-free cheese base (that was made by direct acidification of skim milk to pH 5.6 using citric acid), and the addition of 5 different EM at 4% level; citric acid esters (CAE), diacetyl tartaric acid esters of monoglycerides (DATEM) (Anionic), N-cetyl-N,N,N trimethylammonium bromide (CTAB) (Cationic), distilled monoglycerides (DM), and mono-diglycerides (MD) (Non-ionic). No citrate or phosphate-based salts were used for LPC manufacture. Control nonfat process cheese was made without any EM. Moisture content and pH of LPC were kept constant at 63.0% and 5.5, respectively. Texture profile analysis was used to determine adhesiveness and hardness at 40 and 80% compression levels (CL). Meltability was measured by UW Melt-Profiler as the degree of flow (DOF). Small amplitude oscillatory rheometry determined storage modulus (G' or stiffness) and loss tangent (LT; a meltability indicator) during heating from 5 to 85°C. LPC with EM were softer than control at 40% CL but harder than control (except for DATEM and CTAB) at 80% CL. LPC made with DATEM and CTAB had similar properties except that DATEM exhibited fracture during compression while CTAB cheese was sticky. LPC with DM, MD, and CAE were generally similar and had higher DOF than control. The only major difference between these cheeses was that MD had similar G' values at 8°C to control whereas DM and CAE had higher G' values. The addition of all types of EM produced cheeses with lower maximum LT and higher G' values at 85°C relative to control cheese. These results demonstrate that different types of EM can be used to modify both low temperature properties (hardness, fracture) and high temperature properties (melt, flow) of LPC, which would be useful for various applications like slices, blocks and shreds. These LPC cheeses are currently being scaled-up to further investigate their physicochemical properties.

43 Manufacture and characterization of whey protein concentrate from microfiltration of milk. H. S. Somni* and V. V. Mistry, *South Dakota State University, Brookings.*

Whey protein concentrates (WPCs) are widely used in the dairy industry due to their nutritive and functional properties. There is a high degree of variability in composition, functional, and sensory properties of WPCs. Commercial WPCs can also develop stale flavor due to the presence of lipid and protein impurities. These attributes limit the extent of their use in the food industry. Whey proteins from microfiltration (MF) permeate are unique; they have not been subjected to cheese making process, are in native state, its composition is similar to cheese whey, practically free of bacteria and impurities of fat and protein. Such whey proteins have the potential of providing useful applications in various products. Raw skim milk was microfiltered at 50-55°C to separate whey protein (MWP). MWP was further concentrated by UF and spray drying to obtain MWP concentrate (MWPC). At no stage were any of the fractions in the stream pasteurized or diafiltered. The average composition (4 replicates) of MWPC powder was; 49% protein, 4.5% ash, 0.6% fat and 6.1% moisture. The functional properties of the product were compared with two commercial WPCs (samples A and B) at pH 7. The minimum concentration to gel at 80°C/30 min for all the samples was 8% protein. For emulsion stability, 33% fat emulsion was prepared in 100 ml of 2% protein solution and the fat content in bottom 50 ml was measured after 2 hrs. The stability was expressed as percent ratio of fat in bottom layer to total fat. The emulsion stability was 61.4, 68.2 and 62.1% respectively, for MWPC, sample A and sample B. The foaming properties were expressed as % overrun and foam stability. The average overrun for NPWC and sample A was 963.1 and 486.8 respectively. Only 44% foam collapsed after 30 min whereas for sample A the foam collapsed in less than 5 min. For sample B the foam was very unstable to measure even overrun

Key Words: Whey Protein Concentrate, Functional Properties

44 Transport of glucose by *Bifidobacterium animalis* ssp. *lactis* occurs via facilitated diffusion. E. P. Briczinski*, A. T. Phillips, and R. F. Roberts, *The Pennsylvania State University, University Park.*

Bifidobacterium animalis ssp. *lactis* strains are often studied as potential probiotics. Colonization by and survival of probiotics in the large intestine depend on utilization of fermentable carbohydrates not absorbed or metabolized by the host. Although carbohydrate utilization is critical to bifidobacterial activity in the gut, relatively little is known about carbohydrate transport in this genus. While most strains of bifidobacteria are able to ferment glucose, glucose non-fermenting strains (GNF) have been reported. The objective of this research was to develop an understanding of the difference in glucose utilization between strains that grow on glucose compared to GNF strains. Two closely related strains of *B. animalis* ssp. *lactis*, DSMZ 10140 (type strain) and RB 4825 (obtained from a commercial starter culture manufacturer), were compared. DSMZ 10140 (glucose-positive) and RB 4825 (glucose-negative) were indistinguishable using nucleic acid-based techniques (PFGE, RAPD-PCR, gene sequencing). A low-affinity facilitated diffusion glucose transporter was identified in DSMZ 10140 by performing uptake assays with D-[U-¹⁴C] glucose. Based on kinetic analyses, mean values for K_t and V_{max} were 14.8±3.4 mM and 0.13±0.03 μmole/min/mg cell protein, respectively. When competitor carbohydrates were included in uptake assays, stereospecificity was exhibited, with greater competition by methyl-β-glucoside than methyl-α-glucoside. There was no inhibition

of glucose uptake by sodium fluoride, iodoacetic acid, sodium arsenate, sodium azide, 2,4-dinitrophenol, monensin, or valinomycin, which often block active transport; however, significant inhibition (>30%) was observed with phloretin, an inhibitor of facilitated diffusion of glucose. Glucose uptake by four additional commercial strains of *B. animalis* ssp. *lactis* was also inhibited by phloretin, indicating the activity of facilitated diffusion glucose transporters. The glucose transporters characterized in this work are the first identified in *B. animalis* ssp. *lactis* and the first identified facilitated diffusion transporters of glucose in actinobacteria.

Key Words: *Bifidobacterium animalis* ssp. *lactis*, Probiotics, Glucose Transport

45 Characterizing stress responses of bifidobacteria strains of industrial importance. A. K. Abdalla*^{1,2}, M. A. Mohran¹, S. C. Ingham², J. R. Broadbent³, and J. L. Steele², ¹Assiut University, Assiut, Egypt, ²University of Wisconsin, Madison, ³Utah State University, Logan.

Delivery of probiotic bifidobacteria in foods would benefit from the development of technologies to enhance their survival in foods and during gastric passage. This research aims to better understand how bifidobacteria respond to stress and identify potential strategies to enhance their survival. Intrinsic resistance to acid (HCl) for three strains each of *Bifidobacterium animalis* ssp. *lactis* and *Bifidobacterium longum* were screened at pHs ranging from 2.0 to 6.5. In general, *B. lactis* strains had a higher intrinsic acid resistance than *B. longum*. For example, while no significant reduction in viability of the *B. lactis* strains was observed after 2h at pH 3.5, the *B. longum* strains decreased by 3 log₁₀ CFU/mL. Also, strain to strain variations were observed within the same species. For example reductions of 1.5, 1 and 3 log₁₀ CFU/mL in viable numbers of *B. lactis* strains RH-1, DSM 10140 and D 2908 was observed after 2h at pH 2.0, respectively. For all of the strains examined, conditions to induce an acid tolerance response (ATR) have been identified. Observed increases in survival during acid challenge after ATR induction ranged from 0.5 to 2 log₁₀ CFU/mL. Additionally, intrinsic resistance to NaCl has been examined with the *B. lactis* strains examined. No significant reductions in viability were observed after 20h in NaCl concentrations up to 12% (W/V). These results indicate the importance of both strain selection and culture treatments for enhancing the survival of bifidobacteria in foods and during gastric passage.

46 Growth substrates for nonstarter lactic acid bacteria. Biochemistry and transcriptional profile of *Lactobacillus casei* ATCC 334 in a Cheddar cheese model system. M. Budinich*¹, I. Diaz-Muniz¹, H. Cai¹, V. Smeianov¹, J. Broadbent², and J. Steele¹, ¹University of Wisconsin, Madison, ²Utah State University, Logan.

Cheese ripening is a dynamic, poorly understood process that is essential for development of cheese flavor and requires non-starter lactic acid bacteria (NSLAB). The energy sources utilized for growth by NSLAB are unknown. However, potential energy sources include simple carbohydrates, citrate, nucleic acids, glycopeptides and phosphopeptides. *Lactobacillus casei* is the typical dominant species of NSLAB present

in ripening cheddar cheese. Cheddar cheese extract (CCE) was used as a model system medium to examine the growth substrates present in Cheddar cheese at 2, 6 and 8 month of ripening. A decrease in both growth rate and maximum cell density of *Lb. casei* ATCC 334, a cheese isolate, indicate that substrates are being consumed and or changing during ripening process. Analysis of volatiles by SPME GC/MS indicated the appearance of several potential cheese flavor compounds. The completed genome of *Lb. casei* ATCC 334 permitted us to observe global gene expression patterns during fermentation of 2 month old CCE and identified 42 genes differentially expressed related to energy and metabolism. A putative pathway to derive energy from nucleic acid degradation was proposed and tested in chemically defined media. *Lb. casei* ATCC 334 was able to grow on milk derived glycopeptides and glycolipids and on *Lc. lactis* spp. *cremoris* SK11 derived nucleic acids but not on cheese derived phosphopeptides. Single carbohydrate studies showed that the ability to ferment carbohydrates also depends on the composition of the media and prior history of the bacterium

47 Production of conjugated linoleic acid in cheese slurry by lactic acid bacteria. A. J. Pandit*, S. K. Anand, A. N. Hassan, and K. F. Kalscheur, *South Dakota State University, Brookings.*

Certain lactic acid bacteria (LAB) produce conjugated linoleic acid (CLA) from linoleic acid. Such CLA producing LAB, when used in cheese manufacture, can possibly increase CLA. Previous studies conducted in our laboratory have screened and identified CLA producing LAB. In the present investigation a slurry method was used to screen these CLA producing LAB for their suitability in cheese manufacturing with higher CLA levels. Cheese slurry (60% moisture, pH 6.6) from Cheddar curd was steamed, cooled to room temperature, inoculated in duplicates with respective cultures, and incubated for 5 day at 37°C. Treatments used were: 1) 4b cheese isolate (CI) (*Lactococcus* isolated from Cheddar cheese), 2) 4b + *Lb. helveticus* (ATCC 15807), 3) 4b + CI (*Lactobacillus* isolated from Cheddar cheese), 4) 850 + *Lb. helveticus*, 5) 850 + CI (*Lactobacillus*), and 6) CLA negative commercial starter culture (850, control). Cheese slurries were analyzed on day 0, 1, 3, and 5 for pH, Free fatty acids (FFA), bacterial counts on M17 and MRS, and CLA content. The CLA content of slurries before inoculation was 0.73 gm/100 gm fatty acids (FA). On day 1, CLA values of 0.94, 0.82, 0.78, 0.79, 0.73, and 0.74 gm/100 gm FA were observed in treatments 1, 2, 3, 4, 5, and 6, respectively. Maximum CLA content was observed in treatments 1 (0.99 gm/100 gm FA) and 2 (0.855 gm/100 gm FA) after 3 d of incubation. The CLA in treatment 1 (1.10 gm/100 gm FA) after 5 d of incubation was higher ($p < 0.05$) than that in the control (0.73 gm/100 gm FA). Counts on M17 agar declined from 10^{10} cfu/ml (d 1) to 10^7 cfu/ml (d 5), while counts on MRS agar increased from 10^7 cfu/ml (d 1) to 10^8 cfu/ml (d 5). None of the slurries were rancid after 5 d of incubation. This study provides useful information on the feasibility of some CLA-producing starter culture in cheese manufacture. It was also useful in anticipating the behavior of different CLA producing cultures during ripening.

Key Words: Cheese Slurry, Conjugated Linoleic Acid, Lactic Acid Bacteria

48 Profiling flavor related biochemical changes in cheddar cheese during ripening using infrared spectroscopy. A. Subramanian*, J. Harper, and L. Rodriguez-Saona, *The Ohio State University, Columbus.*

Composition and flavor quality of Cheddar cheese, which influence the consumer acceptance, price and food processing application, develop during the ripening process. However, ripening is not well understood due to the heterogeneous nature of cheese. Profiling cheese ripening by means of few selected variables can save time and money for the cheesemaker. Mid infrared (MIR) spectroscopy is an attractive technology for rapid, sensitive, and high-throughput analysis of food components. Preliminary results have shown that MIR could classify Cheddar cheese based on flavor quality. The objective of this research was to use MIR to further the understanding on biochemical changes during ripening and their influence on flavor.

Twelve different Cheddar cheese samples were ripened for a period of 73 days. Samples were collected on days 7, 15, 30, 45 and 73 during ripening and analyzed for organic acid and amino acid content using liquid and gas chromatography, respectively. For MIR analysis the samples were treated using organic solvents and the extracts were scanned between 4000-700 wavenumbers. The spectra of samples were matched with the composition and quality data to develop multivariate statistical regression and classification models. The spectra correlated well (r -value > 0.95) with the flavor quality as well as the changes in organic and amino acid levels. Furthermore, age of the cheese could also be predicted within a standard error of 1.6 days. Some of the prominent infrared marker bands that were responsible for the correlation were 1411 (amino acids), 1710-1450 (fatty acids), and 1200-1050 cm^{-1} (organic acids). Interestingly, greatest change in composition of cheeses was observed between the days 15 and 30. This could be valuable information for prediction of cheese flavor quality early in the ripening process. Early identification of flavor quality will assist in controlling ripening parameters, and deciding the marketability and application of cheese. FT-IR spectroscopy shows great promise as a rapid, simple and cost-effective analytical and quality control tool for monitoring and understanding cheese ripening.

Key Words: Cheddar Cheese, Flavor, Infrared Spectroscopy

49 Sensory evaluation of reduced fat cheddar cheese fortified with omega-3 fatty acids for oxidized, rancid and fishy flavor attributes.

J. E. Thurgood*^{1,2}, C. Brothersen^{1,2}, S. Martini^{1,2}, and D. J. McMahon^{1,2}, ¹Utah State University, Logan, ²Western Dairy Center, Logan, UT.

Omega-3 fatty acids reduce inflammation and help prevent risk factors associated with certain diseases. However, because the body cannot synthesize them they must come from diet. Therefore, interest in fortifying cheddar cheese with omega-3 fatty acids exists, but there is concern that doing so may have detrimental effects on the flavor of the final cheese product.

Fifty percent reduced fat cheddar cheese was manufactured to contain 16, 32 (typical fortification level), and 64 mg docosahexaenoic/eicosapentaenoic acids (DHA/EPA) per 28-g serving (in triplicate). This was accomplished by comminuting to particles about 2 mm in diameter, adding an encapsulated fish oil powder, pressing to form a cheese block overnight, and storing at 8 °C. Control cheese contained no fish oil. Samples were rated on a five-point categorical scale (No, Slight,

Moderate, Strong, and Extremely Strong Flavor) by 11 trained panelists for oxidized, rancid, and fishy flavor attributes at 1, 7, 30 and 90 d. For analysis, numerical values of 0 to 4 were assigned respectively. Omega-3 fatty acid fortification caused no change in oxidized ($p = 0.08$) or rancid flavor ($p = 0.35$). Mean oxidized flavor scores were from 0.2 to 0.4 throughout 90 d for all cheeses. Rancid flavor increased during storage ($p < 0.0001$) with mean scores of 0.4 at d 1 and 0.9 at d 90 (score of 1 = "Slight Flavor"). Fishy flavor increased with level of DHA/EPA fortification ($p < 0.0001$), but decreased during storage ($p < 0.0001$). At d 1, average fishy flavor scores for control, and the fortified cheeses

were 0.2, 0.3, 0.8, and 1.2 respectively. By 30 d these had decreased to 0.1, 0.1, 0.2, 1.0, and by 90 d to 0.0, 0.0, 0.2, 0.5 leaving the 64 mg DHA/EPA sample with fishy flavor significantly different from control. Thus, cheddar cheese can be fortified with up to 32 mg DHA/EPA per serving using an encapsulated fish oil without causing an increase in oxidized, rancid or fishy flavors provided the cheese is stored for 30 d because initial fishy flavor diminishes during storage.

Key Words: Omega-3 Fatty Acids, Cheese, Flavor

Graduate Student Paper Competition: ADSA Production Division

50 Osteopontin immunoreactivity in peripheral blood mononuclear cells, ileum, and ileocecal lymph node of dairy cows naturally infected with *Mycobacterium avium* subsp. *paratuberculosis*. E. L. Karcher^{*1}, C. S. Johnson¹, J. P. Bannantine², D. C. Beitz¹, and J. R. Stabel², ¹Iowa State University, Ames, ²USDA-ARS, National Animal Disease Center, Ames, IA.

Osteopontin (Opn), a highly acidic glycoprotein, plays a role in initiating the innate immune response to mycobacterial infections by promoting cellular adhesion and recruitment of inflammatory cells from the peripheral blood. The formation of granulomas at the site of *Mycobacterium avium* subsp. *paratuberculosis* (MAP) infection is critical for the early control of infection. The objective of this experiment was to identify Opn in peripheral blood mononuclear cells (PBMCs), ileum and ileocecal lymph node (ICN) of dairy cows naturally infected with MAP and to compare the frequency and intensity of staining between noninfected healthy controls, subclinical, and clinical cows. For analysis of peripheral blood, PBMCs were isolated weekly from naturally infected periparturient dairy cows 3 weeks prior to calving through 4 weeks postpartum. Western blot detected Opn protein bands at 24-, 37-, 50-, and 62-kDa in the PBMC lysates of all animals. The densities of the 24-, 37-, and 62-kDa proteins varied extensively between cows and the variation did not seem to be related to infection group. Immunohistochemical analysis was used to determine the location and expression of Opn in the ileum and ICN. The frequency and intensity of staining also was reported. Confirmation of the acid-fast bacilli in the tissue sections was achieved by the Ziehl-Neelsen method. Within the ileum, macrophages, lymphocytes, and plasma cells stained positive for Opn. Clinical cows expressed Opn at a greater frequency in the lamina propria. Control and subclinical cows did not have areas of granulomatous inflammation, but cells staining for Opn were equally intense for the three groups. Osteopontin expression in the ICN was not affected by MAP infection. Results of this study confirm for the first time Opn localization in the peripheral blood and in the intestinal tract of MAP-infected cows and differences in Opn expression at the site of infection.

Key Words: Osteopontin, *Mycobacterium avium* subsp. *paratuberculosis*

51 Effect of linoleic acid and dietary vitamin E supplementation on sustained conjugated linoleic acid production in milk fat from dairy cows. A. M. O'Donnell^{*}, N. S. Mittelman, J. L. Capper, and D. E. Bauman, Cornell University, Ithaca, NY.

Conjugated linoleic acid (*cis*-9, *trans*-11 18:2, CLA), a bioactive fatty acid (FA) found in milk and dairy products, has potential human health benefits due to its anticarcinogenic and antiatherogenic properties. Milk fat CLA concentrations can be markedly increased by dietary manipulation; however, high levels of CLA are difficult to sustain as rumen biohydrogenation shifts and milk fat depression (MFD) is induced. The objective of the present study was to feed a typical Northeastern corn based-diet and investigate whether vitamin E and soybean oil supplementation would sustain an enhanced milk fat CLA content while avoiding MFD. Holstein cows (n = 48) were assigned to a randomized complete block design for 28 d and received one of four treatments: 1) control (C), 2) 10,000 IU/d vitamin E (E), 3) 2.5% soybean oil (Oil), and 4) 10,000 IU/d vitamin E plus 2.5% soybean oil (Oil/E). A 2 wk

pre-treatment control diet served as the covariate. Milk fat percent was reduced by both high oil diets (3.52, 3.55, 2.94, and 2.98% for C, E, Oil, and Oil/E, respectively). However, milk yield was increased by the Oil/E diet, therefore milk fat yield was lowest in cows fed the Oil diet (1.35, 1.35, 1.06, and 1.25 kg/d for C, E, Oil, and Oil/E). Milk protein percent was higher for cows fed the Oil diet (3.06, 3.06, 3.29 and 3.03% for C, E, Oil and Oil/E), implying that nutrient partitioning was altered in response to the reduction in milk fat. Milk fat concentration of CLA more than doubled in cows fed the oil diets, with concurrent increases in *trans*-10 18:1 and *trans*-11 18:1 FA. Moreover, milk fat from cows fed the two oil diets had 31.0% less *de novo* synthesized FA and 33.7% more long chain preformed FA. In conclusion, dietary supplements of soybean oil caused a reduction in milk fat percent and a shift in fatty acid composition characteristic of MFD. Dietary vitamin E did not overcome the oil-induced reduction in milk fat percent or changes in FA profile, but partially mitigated the reduction in fat yield by increasing milk yield.

Key Words: Conjugated Linoleic Acid, Milk Fat, Vitamin E

52 CD4⁺ and CD8⁺ T cell response in neonatal calves fed *Morinda citrifolia* (Noni). V. J. Brooks^{*1}, R. G. Godbee², S. F. Peek¹, and B. J. Darien¹, ¹University Wisconsin, Madison, ²University Nevada, Reno.

Developmental immaturity of the immune system renders neonatal calves vulnerable to high rates of morbidity and mortality. Ingesting colostrum containing maternal immunoglobulins, leukocytes and cytokines is critical in ensuring calf health and survival. Juice made from the *Morinda citrifolia* fruit (noni) reportedly has immune enhancing effects, including anti-inflammatory activity and inhibition of tumorigenesis. The objective of this study was to evaluate the immune modulating effects of feeding neonatal calves noni puree by measuring lymphocyte proliferation and CD25 expression on CD4⁺, CD8⁺ and $\gamma\delta$ T cells. Eighteen newborn Holstein bull calves were acquired in pairs from local dairies. All calves received 4.0 L of pooled colostrum by 12 h of age and were confirmed to have adequate passive transfer (>1200 mg/dL IgG). The calves were divided into two groups. Group 1 was comprised of control calves, while Group 2 received 30 mL of noni puree twice daily in milk replacer. Day 0 samples were obtained between 36 and 48 h of age and before the first feeding of puree. Peripheral blood mononuclear cells were collected and isolated from each calf on days 0, 3, 7, and 14. To measure lymphocyte proliferation, a mitogen induced Lymphocyte Blastogenesis Test (LBT) was performed. Mitogen induced activation of CD4⁺, CD8⁺ and $\gamma\delta$ T cells was evaluated by the up-regulation of the IL-2 receptor, CD25, on these cells with two-color flow cytometry. For both tests concanavalin A (ConA) and phytohemagglutinin were used as global mitogens. Results showed a significant increase in CD25 expression on CD8⁺ T cells in noni puree fed calves on day 3 of the study or approximately 5 days postpartum. Similarly, CD25 expression on CD4⁺ T cells was also higher in noni puree fed calves on day 3. Both findings were in response to ConA stimulation, whereas the LBT did not show a significant difference between the two groups in their response to either mitogen. The precise mechanism and impact on long term health are not explained by the current study and are important areas deserving further study.

53 Effects of alfalfa inclusion rate on productivity of lactating dairy cattle fed wet corn gluten feed based diets. C. R. Mullins^{*1}, K. N. Grigsby², and B. J. Bradford¹, ¹*Kansas State University, Manhattan*, ²*Cargill, Inc., Blair, NE*.

An experiment was conducted to evaluate the effects of varying alfalfa inclusion rate in diets containing 31% (DM basis) wet corn gluten feed product (Sweet Bran, Cargill, Inc.). Eighty primiparous and multiparous Holstein cows averaging 178 ± 90 DIM (mean \pm SD) were randomly assigned to one of four sequences in a 4×4 Latin Square with 28-day periods. Treatments were diets containing 0, 7, 14, and 21% alfalfa on a dry matter basis, with corn silage, corn grain, soybean meal, expeller soybean meal, and mineral supplements varying across diets to maintain uniform nutrient densities. Diets were formulated for similar crude protein, neutral detergent fiber, and non-fiber carbohydrate concentrations. Feed intake, milk production, body weight, and body condition score were monitored, and linear and quadratic effects of increasing alfalfa inclusion rate were assessed using mixed model analysis. As the inclusion rate of alfalfa increased, dry matter intake increased linearly ($P = 0.05$; 26.7, 27.3, 27.4, and 27.5 kg/d for 0, 7, 14, and 21% alfalfa, respectively), and solids-corrected milk ($P = 0.07$; 29.9, 30.2, 30.8, and 30.5 kg/d) and energy-corrected milk production ($P = 0.09$; 32.9, 33.3, 33.8, and 33.6 kg/d) tended to increase linearly. Body weight gain decreased linearly ($P = 0.02$; 22.9, 18.0, 11.2, and 9.5 kg/28 d) with increasing alfalfa inclusion rate. Although increasing the inclusion rate of alfalfa increased the proportion of large particles in diets, treatments had no effect on milk fat yield or concentration. Feeding more alfalfa (up to 21% of DM) tended to increase milk yield while decreasing body weight gain, suggesting that metabolizable energy utilization shifted from body weight gain to milk production in these treatments. However, removing alfalfa from the diet had only minor effects on productivity.

Key Words: Dairy Nutrition, Byproduct, Forages

54 Diet does not affect putative mammary epithelial stem cells in pre-weaned Holstein heifers. K. M. Daniels^{*1}, A. V. Capuco², R. E. James¹, M. L. McGilliard¹, and R. M. Akers¹, ¹*Virginia Polytechnic Institute and State University, Blacksburg*, ²*USDA-Agricultural Research Service, Beltsville, MD*.

Overfeeding prepubertal heifers can impair mammary epithelial growth and development, processes that depend on stem cells. We evaluated effects of milk replacer (MR) composition on putative bovine mammary epithelial stem cell populations using a 5-bromo-2-deoxyuridine (BrdU; a thymidine analog) label retention method. Stem cells retain BrdU over time through selective segregation of labeled template DNA strands during mitosis, whereas the label is diluted in non-stem daughter cells. Twenty-four newborn heifers were fed one of four MR diets ($n=6$ /diet): CON (20% CP, 21% fat MR fed at 441 g DM/d), HPLF (28% CP, 20% fat MR fed at 951 g DM/d), HPHF (27% CP, 28% fat MR fed at 951 g DM/d), and HPHF+ (27% CP, 28% fat MR fed at 1431 g DM/d). Calves were fed twice daily; water and starter (20% CP, 1.43% fat) were offered free choice. At 30 d of age heifers were given 5 mg BrdU per kg BW daily for 4 d. Heifers were euthanized 29 d later. Mammary tissue was collected from two peripheral and two cisternal parenchymal regions in the left front quarter. Histological sections were prepared and processed for dual-label immunofluorescent detection of Ki67 and BrdU. Digital images were obtained at 40x magnification from 10 regions per slide. Labeled cells were counted manually and total number of epithelial cells determined using image analysis software. Diet had

no effect on percentage of labeled mammary epithelial cells, nor was there a diet by region interaction. Percentage of BrdU-labeled epithelial cells was largest in cisternal regions of the gland ($2.39 \pm 0.44\%$) and decreased toward the periphery ($0.73 \pm 0.45\%$). The opposite was true for Ki67-labeled epithelial cells (8.97 ± 0.81 vs. $10.88 \pm 0.77\%$). This is consistent with decreased proliferation and increased cell cycle arrest in cisternal regions. In peripheral regions, percentage of BrdU-labeled epithelial cells averaged $0.12 \pm 0.11\%$. These data provide no evidence that putative mammary epithelial stem cells are affected by protein and fat differences in MR fed to pre-weaned calves.

Key Words: Heifer, Mammary, Stem Cell

55 Gene expression for enzymes involved with volatile fatty acid and glucose metabolism are affected by the dietary forage-to-concentrate ratio. G. B. Penner^{*1}, M. Taniguchi¹, L. L. Guan¹, K. A. Beauchemin², and M. Oba¹, ¹*University of Alberta, Edmonton, Alberta, Canada*, ²*Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada*.

The objectives of this study were to determine the effects of the dietary forage-to-concentrate ratio on in vivo volatile fatty acid (VFA) clearance, and the expression of genes related to ruminal absorption and metabolism of VFA and glucose. Twelve ruminally cannulated dry Holstein cull cows were fed either a control diet (HF) or a diet to pre-dispose cattle to a high VFA load (LF), which contained 92% and 36% forage on a DM basis, respectively. After a 28-d diet adaptation period, ruminal pH, ruminal VFA concentrations, and in vivo VFA clearance were measured. Cows were subsequently euthanized and ruminal tissue (ventral sac) was harvested for gene expression analysis using quantitative real-time PCR. Mean ruminal pH was 0.45 pH units lower (6.03 vs. 6.48 ; $P < 0.01$) and total VFA concentration was 25 mM higher (138 vs. 113 mM; $P < 0.01$) for the LF compared to the HF treatment. The fractional liquid passage, VFA clearance, and VFA absorption rates were not different between treatments and averaged 8.3 ± 0.8 , 21.5 ± 0.9 , and $13.2 \pm 1.0\%/h$, respectively. With respect to butyrate metabolism, the LF treatment had a 1.34 ± 0.12 fold greater expression of β -hydroxybutyrate dehydrogenase ($P = 0.04$) and tended to have a 1.72 ± 0.35 fold greater expression of acyl CoA synthetase ($P = 0.09$). However, the expression of hydroxymethylglutaryl CoA synthase tended to be reduced (0.83 ± 0.07 fold; $P = 0.06$) for the LF relative to the HF treatment. Furthermore, the expression of hexokinase tended ($P = 0.08$) to be increased by 1.30 ± 0.13 fold but sodium glucose linked transporter and pyruvate dehydrogenase were decreased by 0.44 ± 0.11 ($P < 0.01$) and 0.70 ± 0.11 ($P = 0.04$) fold for the LF treatment relative to the HF treatment. These data indicate that the VFA load does not affect the rate of VFA absorption in vivo but may affect the pathway of butyrate metabolism and the utilization of glucose as an energy source.

Key Words: Real-Time PCR, VFA Metabolism, VFA Absorption

56 Lactation performance and amino acid utilization of cows fed increasing amounts of de-oiled dried distillers grains with solubles. K. Mjoun^{*1}, K. F. Kalscheur¹, A. R. Hippen¹, D. J. Schingoethe¹, and D. E. Little², ¹*South Dakota State University, Brookings*, ²*DairyNet Inc., Brookings, SD*.

As the ethanol industry continues to grow, innovative products are emerging; deoiled dried distillers grain with solubles (dDGS), a low fat (3.7% Ether Extract) product, is an example of this evolution. The effects of feeding increasing quantities of dDGS on lactation performance and amino acid utilization were evaluated with 23 multiparous and 19 primiparous Holstein cows in a randomized complete block design for 8-wk including a 2-wk covariate period. The dDGS were included in diets at 0, 10, 20, and 30% of the diet on a DM basis. Increasing dDGS in diets tended to affect DMI in a quadratic manner ($P = 0.09$), such that cows fed the 20% dDGS had the greatest DMI (24.4 kg/d) and those fed the 30% dDGS had the least (22.1 kg/d). Milk production (34.9 kg/d) was not affected by the inclusion of dDGS. Milk fat percentage tended to increase linearly ($P = 0.09$) from 3.21 to 3.64% as dDGS increased in the diets. Similarly, milk fat yield tended to increase linearly from 1.09 to 1.29 kg/d as dDGS increased from 0 to 30% of the diet. Milk protein percentage (2.98, 3.08, 3.11, and 2.98%) and milk protein yield (1.02, 1.08, 1.10, and 1.03 kg/d) responded in a quadratic manner ($P < 0.01$). Milk urea N decreased linearly ($P < 0.01$) from 15.5 to 13.1 mg/dL. The efficiency of N utilization for milk protein synthesis was not affected by including dDGS and averaged 25.9%. The efficiency of milk production (ECM/DMI) increased linearly ($P < 0.05$) with increasing dDGS in the diet. Arterial Lys decreased linearly (66.0, 57.6, 51.9, 44.8 $\mu\text{M/L}$; $P < 0.01$) whereas arterial Met increased linearly (16.5, 17.9, 22.5, 29.3 $\mu\text{M/L}$). Arteriovenous difference of Lys linearly decreased (42.6, 37.1, 36.6, 32.5 $\mu\text{M/L}$) while that of Met was unaffected. The extraction of Lys by the mammary gland increased linearly (64.3, 64.4, 70.7, 72.2%) while that of Met decreased linearly (71.6, 57.5, 50.8, 42.7%). These results indicate that addition of up to 30% of dDGS in mid-lactation diet supported lactation performance similarly to that of a control diet based on soybean products.

57 Development of a mechanistic model to predict feed intake in domestic and wild ruminants of various physiological states. T. Hackmann* and J. N. Spain, *University of Missouri, Columbia.*

Understanding the regulation of feed intake is important in nutritional management of domestic and wild ruminants. A mechanistic model of ruminant feed intake and digestion was formulated to investigate hypotheses of intake regulation and to serve as a predictive tool. The model is a compartmental model and represents fluxes of nutrients across pools in the reticulorumen, small intestine, and large intestine. Similar to a model published by D.S. Fisher, predicted intake is the level of intake that reaches an optimum balance among chemostatic, distention, and protein feedbacks. Unlike in previous models, the chemostatic setpoint is varied with the energetic demands of the animal in order to investigate how intake is affected by these demands, which vary with species, body weight, physiological state, and level and stage of production. Data from 15 studies that report ad libitum DMI of all-forage diets were used to compare model-predicted DMI with actual DMI for animals of a range of physiological states (gestation, lactation, growth, and no production), levels and stages of production, body weight (16 to 907 kg), and species (14 bovids, 4 cervids, and 1 giraffid). The coefficient of determination (R^2) between actual and predicted DMI was 0.701 and 0.910 when DMI was expressed as percentage of BW and kg/d, respectively ($n = 158$). For domestic species (cow, sheep, goat) alone, agreement was higher, with values of R^2 of 0.718 and 0.954 when DMI was expressed as percentage of BW and kg/d, respectively ($n = 107$). The good agreement between predicted and actual DMI and other considerations support the hypotheses of intake regulation embodied in the model, namely that energetic demands of the animal regulate intake. The model shows promise as a predictive tool for application to domestic and wild ruminant species and awaits further development to model non-all-forage diets.

58 Effect of milk replacer composition on growth and rumen development of neonatal Holstein calves. A. J. Bridges*, C. C. Williams, C. F. Hutchison, J. M. Laborde, A. N. Howard, and C. Leonardi, *Louisiana State University, Baton Rouge.*

A study was conducted to determine effects of different fat and protein levels in commercial milk replacers on the growth performance and rumen development of neonatal Holstein calves. Fifty-three calves (23 male; 30 female) were assigned to one of three dietary treatments which included 3 milk replacers (20%CP: 20% fat; 25%CP:15% fat; 28%CP: 20% fat) fed once per day at 10% of birth weight through weaning on day 42. Calves were offered a 20% CP calf starter and water free choice beginning on day 5. All calves were weaned on day 42. Body weights were measured at birth and weekly through weaning. Additionally, hip height, wither height, and body length were measured weekly. Feed intake and fecal scores were recorded daily. Beginning on day 7 and continuing weekly through weaning, blood samples were collected prior to morning feeding for analysis of IGF-I and on days 14, 28, 42, and 56 for PUN and beta-hydroxybutyrate concentrations. On days 28, 56 and 84 rumen fluid was collected for analysis of pH and short chain VFAs to evaluate possible differences in rumen development. Calves fed 28:20 milk replacer had greater ($P < 0.01$) average daily gain, starter intake, PUN, and beta-hydroxybutyrate concentrations when compared to the other treatments. Also, a treatment by week interaction was observed ($P < 0.01$) for starter intake, with calves on 28:20 milk replacer increasing after week 3 and maintaining the greater starter intake through week 8. No differences were observed ($P > 0.05$) in fecal scores among any treatments. Average weekly wither height and body length were greater ($P < 0.05$) in calves fed 28:20 milk replacer. There were no effects ($P > 0.05$) of treatment on IGF-I concentrations, rumen pH, or concentrations of VFA. Acetate and propionate, as a percent of total VFA, tended ($P < 0.10$) to be greater in calves fed 28:20 milk replacer. These data indicate that increasing the dietary protein content of milk replacer without reducing fat content improved growth in young dairy calves without compromising health or rumen development.

Key Words: Milk Replacer, Growth, Rumen Development

59 Effects of ThermalCare-D[®] on efficiency and production of lactating dairy cows during hot weather. J. Boyd*¹, J. W. West¹, J. Bernard¹, and S. Block², ¹*University of Georgia, Tifton*, ²*ADM Research, Decatur, IN.*

A trial was conducted to evaluate effects of ThermalCare-D[®] v1(T1), ThermalCare-D[®] v2(T2), and ThermalCare-D[®] v1 with glycerol(T1G) on milk yield, efficiency of yield, and nutrient digestibility in hot weather. Thermal Care D[®] is comprised of proprietary additives selected for the potential ability to improve physiological response to heat stress. Forty-eight Holstein cows averaging 183 DIM and 43.9 kg/d of milk were used. The study was conducted June to Aug. 2007. Cows were fed a common diet during a 2 wk standardization period, blocked into groups of 4 based on parity, milk yield, and ECM and randomly assigned within block to one of 4 treatments for 8 wks. Experimental design was a randomized complete block. Diets were corn silage based and balanced to be iso-caloric and iso-nitrogenous. No effects on DMI, milk yield,

or energy corrected milk ($P < 0.53$) were noted. Yet, multiparous cows offered T2 and primiparous cows on T1G treatments showed similar milk yield which was greater than cows fed C or T1 diets ($P < 0.02$). An increase ($P < 0.01$) in milk yield was observed for primiparous versus multiparous cows on T1G. Decreased ($P < 0.02$) milk fat percentage was observed for T1 versus C while T2 and T1G had numerically lower fat percentage versus C. An increase in NE balance by week was observed for T1G (42.2 Mcal/d) compared to C, T1, and T2 (22.8, 20.6, and 36.1 Mcal/d, respectively). Cows fed T1G had numerically the greatest weekly weight gain compared with other treatments. No effect on respiratory rate, skin temperature, body temperature or concentrations of serum glucose, urea N, or non-esterified fatty acid was noted. Cows offered Thermal Care-D[®] treatments tended ($P < 0.13$) to increase DMI versus C when digestibility measurements were recorded. Cows fed T1 and T2 exhibited ($P < 0.05$) improved digestion of DM, NDF and ADF compared with C or T1G. Results suggest ThermalCare-D[®] may improve feed DMI and nutrient digestion by cows during hot weather. The addition of glycerol to ThermalCare-D[®] v1 was more beneficial to primiparous cows than multiparous cows.

Key Words: Heat Stress, ThermalCare, Glycerol

60 Effect of starch and casein infusions in the abomasum of lactating dairy cows. A.G. Rius*¹, J. A. D. R. N. Appuhamy¹, D. Kirovski², J. Cyriac¹, and M.D. Hanigan¹, ¹*Virginia Polytechnic Institute and State University, Blacksburg*, ²*University of Belgrade, Belgrade, Serbia.*

The objective of this study was to evaluate the effects of abomasally infusions of starch, casein or the combination of both on milk and protein yields in lactating cows fed restricted diet. We hypothesized that abomasal infusions of starch plus casein could maintain milk and protein yields when cows were fed 70% of requirements for protein and energy. Six primiparous mid-lactation ruminally cannulated Holstein cows were randomly assigned to treatments using a replicated incomplete 4x4 Latin-square design. All animals received the same diet (17.6 % CP and 1.58 Mcal NEI) throughout the study. Beginning on d 13 of each period, cows were restricted to 70% of ad libitum intake and abomasally infused for 36 h with starch (S; 3 kg/d), casein (C; 1.3 kg/d) the combination (S+C) or water (W) using peristaltic pumps. On d 14, milk samples were collected. Milk yield and components were analyzed using the Proc Mixed procedure of SAS to test main effects and differences among treatments. Milk yields were not significantly affected by treatments ($P < 0.55$) and the LSM were 1.23, 1.02, 1.01, 1.05 kg/h for C+S, W, S and C respectively (SEM=0.11). Milk protein yields were also not significantly affected by treatments ($P < 0.36$) with LSM of 39, 29, 30 and 33 g/h for C+S, W, S and C respectively (SEM=3.6). As expected, MUN (milk urea nitrogen) was significantly affected by treatment ($P < 0.05$) and the LSM were 13.43, 10.57, 8.58, 15.17 mg/dl for C+S, W, S and C respectively (SEM= 0.69). Although it was not significant the MUN difference between C+S and C was 1.74 ($P < 0.09$; SEM=0.92) and the difference for W and S was 1.99 mg/dl ($P < 0.06$; SEM<0.92). Other milk components were not significantly affected by treatments. In conclusion the MUN results indicate that nitrogen can be used more efficiently if starch absorption is enhanced.

61 The value of marbling in consumer acceptance of beef. L. R. Corah*, *Certified Angus Beef LLC, Wooster, OH.*

In 1925, the USDA implemented the quality grading system to address consumer confusion related to meat quality. Since that original role, marbling has become an important component of meat quality in both the domestic and global marketplace. Most research studies have shown that as marbling levels increase, the overall consumer acceptability increases. The triad of flavor, tenderness, and juiciness are considered by most scientists to be the key components of eating satisfaction. Although the magnitude will vary by study, marbling contributes to each of these three attributes. Recent research at Texas Tech University shows that tenderness is important, but flavor is two and a half times as important in overall consumer acceptability of beef. In the past eight years, cattle markets have started to reflect these consumer preferences as the Choice-Select and Premium Choice-Low Choice spreads have widened from historical levels of \$2-4/cwt to \$10-12/cwt in the last three years. A recent Cattle-Fax analysis suggests that the impact of Premium Choice and Prime adds \$500 million plus annually of added value to the producer.

62 Renewing the interest on marbling in pork products. C. M. Schultz Kaster*, R. C. Johnson, and J. O. Matthews, *Farmland Foods Inc., Kansas City, MO.*

This presentation will describe some of the current information on the impact of marbling in pork. The pork industry has dramatically changed its definitions of quality over the past twenty years progressing from weight to leanness to muscle quality and more recently to measure of palatability. Marbling is a means for a visual assessment of perceived product quality, and already has consumer meaning due to its use with quality grades in the beef industry. However, marbling had been allowed to diminish in pork as pigs were made leaner. The contribution of marbling to palatability has been debated particularly as it relates to tenderness. Color and pH are both key indicators of quality, and are widely used for selection in the pork industry. Marbling has emerged as a means to differentiate high end product, particularly for the foodservice industry driven by celebrated chefs and menu nomenclature. Ideal amounts of marbling are still being determined, and may vary depending on the market, and increasing marbling may come with negative effects like steatosis in ham muscles, increased fat content for nutritional labeling, and negative consumer perceptions of too much fat. Increasing marbling may come at a cost that impacts production or genetic costs depending on the level desired. Demand for this product is still being determined directly by retail outlets offering a higher tier of pork, or by chefs using it on menus on a limited basis. The possibility exists that increase marbling in all pork may indirectly increase demand if it contributes to the improvement of palatability in the general pork population.

Key Words: Pork, Marbling, Quality

63 Cellular regulation of intramuscular adipose tissue deposition and composition. S. B. Smith*¹, H. Kawachi², C. B. Choi³, C. W. Choi⁴, and J. E. Sawyer¹, ¹Texas A&M University, College Station, ²Kyoto University, Kyoto, Sakyo-ku, Japan, ³Yeungnam University, Gyeongsan, Korea, ⁴National Institute of Animal Science, Suwon, Korea.

It is well documented that grain feeding stimulates adipogenesis in beef cattle, whereas pasture feeding depresses the development of adipose tissues, including intramuscular (i.m.) adipose tissue. Production practices that depress adipogenesis also limit the synthesis of monounsaturated fatty acids (MUFA). Insulin stimulates glucose incorporation into fatty acids *in vitro* in s.c. and i.m. adipose tissues of long-fed cattle fed a high-concentrate diet, but has no effect on adipose tissues of long-fed cattle fed a hay-based diet. Marbling scores and s.c. adipose tissue MUFA are depressed by hay feeding, even when cattle are raised to the same BW endpoint. Conversely, the accumulation of i.m. adipose tissue in beef cattle is enhanced by feeding supplemental vitamin C and zinc, and is depressed by supplemental vitamin A. In preadipocyte cultures, vitamins A and D both decrease glycerol-3-phosphate dehydrogenase (GPDH) activity, an index of adipocyte differentiation, whereas incubation of bovine preadipocytes with L-ascorbic acid-2-phosphate increases GPDH activity. Exposing bovine preadipocytes to zinc also stimulates adipogenesis, putatively by inhibiting nitric oxide (NO) production. However, incubation of bovine preadipocytes with arginine, a biological precursor of NO, strongly promotes differentiation in concert with increased expression of stearoyl-CoA desaturase (SCD). This suggests that the effect of either arginine or zinc on adipogenesis is independent of NO synthesis in bovine preadipocytes. Enhanced expression of SCD is associated with a greater accumulation of MUFA both in bovine preadipocyte cultures and during development in growing steers. In bovine preadipocytes, *trans*-10, *cis*-12 conjugated linoleic acid (t10,c12 CLA) strongly depresses adipocyte differentiation and SCD gene expression, thereby reducing MUFA concentrations. This suggests that any production practice that elevates t10,c12 CLA in bovine adipose tissue will reduce i.m. adipose tissue development, in concert with a depressed accumulation of MUFA.

Key Words: Adipose Tissue, Fatty Acid, Growth

64 Nutritional regulation of intramuscular fat deposition. J. S. Drouillard* and C. D. Reinhardt, *Kansas State University, Manhattan.*

Demand for high-value, well-marbled beef products has spawned interest in nutritional strategies that increase marbling. USDA statistics for yield and quality grades reported during the last 10 years reveal an alarming trend for production of fatter carcasses with less marbling. Escalation of feed prices, particularly energy sources, has pushed production costs to unprecedented levels, suggesting that feeding to fatter compositional endpoints may become cost prohibitive. This forces beef producers to seek alternative means of affecting beef quality while feeding to lean, efficient endpoints. There is evidence to suggest that rigorous grain processing methods, such as flaking, decrease marbling scores relative to overall fat deposition and retail yield. Roughages, which are essential for maintaining digestive health, are costly relative to nutrient density.

Some studies suggest that low roughage levels lead to fatter carcasses with less marbling. Feeding fats and oils has, until recently, been practiced widely by feedlots, particularly in the Southern Plains. Though low levels can enhance carcass quality, levels often determined necessary to optimize efficiency (3-4%) may reduce marbling accretion relative to other body fat depots. Similarly, distiller's grains can enhance carcass quality when fed at low levels, while higher levels can have deleterious consequences for marbling, or at least can have a negative impact on the ratio of marbling to external fat deposition. Ruminant degradability and concentration of dietary protein also can influence marbling deposition. Higher levels of dietary protein have consistently increased quality grade of cattle fed diets consisting of flaked, rolled, or ensiled grains. This may have implications for diets containing distiller's grains, as the protein has low to moderate ruminal degradability. Methyl donor compounds, including choline and betaine, have improved marbling in several experiments, though results have been variable. Radical changes in ingredient and nutrient price relationships may force producers to re-evaluate diet composition as it relates to marbling.

Key Words: Beef, Marbling, Nutrition

65 Genetic regulation of intramuscular fat deposition. D. W. Moser*, *Kansas State University, Manhattan.*

Like most carcass traits, marbling score and percent intramuscular fat are highly heritable, and should respond well to selection. Significant breed differences exist in both beef and swine, but within-breed variation is

also great. In swine, long term selection for lean growth has decreased marbling. The Angus beef breed has recently shown an increasing genetic trend for marbling, but most other beef breeds have shown little or no change in the past few decades. Direct measurement of marbling requires harvest of the animal, so producers practice selection on genetic predictions generated from progeny test data and ultrasound measurements of sires and progeny, as well as genetic marker tests. Progeny testing is the most accurate, but requires the greatest amount of time, and usually, the most expense. Automated grading of carcasses and electronic animal identification may allow greater volumes and quality of carcass data to be collected for use in genetic evaluation. Ultrasound measurement of intramuscular fat in live cattle has been used successfully in cattle for many years, and has gained wider use in swine. Serum leptin has also been suggested for use as a selection criterion to increase marbling. Genetic tests for marbling have been developed for both species. In beef, tests for thyroglobulin gene mutations for use in predicting marbling score and quality grade have been marketed since 2000, but validation studies of these tests generally show modest effects. Other genes, such as leptin, have also been suggested as having effects on marbling, and for most commercial genetic marbling tests, the underlying genes are unknown or not publicly revealed. In swine, the *rendement napole* gene has been shown to affect marbling. Most swine breeding companies have proprietary marker tests for a variety of production and meat quality traits. The most promising opportunities for increased rate of genetic change for intramuscular fat in both species lie with genetic analyses that combine carcass data, ultrasound measures of live animals, and test results from large panels of genetic markers.

Symposium: Nonruminant Nutrition: Mineral Absorption: What is Known?

66 Transporters in the absorption and utilization of Zn and Cu. G. M. Hill* and J. E. Link, *Michigan State University, East Lansing.*

Before the discovery and elucidation of transporters, mammals were thought to co-transport Cu or Zn as an anionic complex such as binding with an amino acid as a chelate or a receptor such as transferrin. In 1995, the first mammalian transporter gene, ZnT1, was identified. However, it is now thought that two protein families are involved in Zn transport. The ZnT family reduces intracellular Zn by aiding in efflux from the cell or promoting the influx into intracellular vesicles. As noted by Cousins et al., (2006) the mechanism of ZnT transport against a Zn concentration gradient is unknown. However, only the ZnT1 transporter appears to be located at the plasma membrane. It has been shown to respond in tissues in a variety of manners to Zn reduction and supplementation. Our laboratory (Martinez et al., 2004) have found ZnT1 and metallothionein to work in concert during pharmacological Zn supplementation. The second protein family, Zip proteins, provide Zn transport from extracellular fluid or intracellular vesicles into the cytoplasm and has not been identified in a livestock species. Like Zn, no good indicator of status has been identified for Cu. However, the recent identification of Cu transporters and chaperones give researchers the opportunity to understand the regulation of Cu-trafficking where the proteins are modified by post-translational mechanisms. Two Cu transporters, Ctr1 and Ctr3, mediate high affinity Cu uptake. Murr1, a small cytoplasmic protein, has been identified in human hepatic tissue, but its role in Cu metabolism is unknown. The discovery of Cu chaperones that are involved in facilitating Cu absorption into proteins may provide an excellent status indicator. It has been shown that the protein of the Cu chaperone for Cu/Zn superoxide dismutase (CCS) is increased in tissue of Cu deficient rats induced when moderately high Zn diets were fed. We have recently found CCS in the young pig. It is essential that these new molecular findings be utilized to evaluate bioavailability and nutritional needs of Cu and Zn in livestock.

67 Absorption and metabolism of iron and manganese. J. W. Spears* and S. L. Hansen, *North Carolina State University, Raleigh.*

This presentation will discuss our current understanding of iron (Fe) and manganese (Mn) metabolism. Iron metabolism and its biochemical functions are closely linked to the ability of Fe to undergo oxidation and reduction. Prior to absorption, ferric Fe (Fe^{+3}) must first be reduced to ferrous Fe (Fe^{+2}) by dietary reducing agents or reductases that reside on the duodenal apical membrane. Divalent Fe is then transported into enterocytes by divalent metal transporter 1 (DMT1). Absorbed Fe is exported from the enterocyte by ferroportin 1 (FPN) and immediately oxidized via hephaestin, a copper-dependent ferroxidase. Iron is then transported in the blood in the Fe^{+3} form bound to transferrin. Transferrin receptors on tissues allow for the uptake of transferrin-bound Fe by cells. Whole body Fe homeostasis is controlled at the level of intestinal absorption, due to limited ability to excrete absorbed Fe. Cellular Fe concentrations are controlled by Fe regulatory proteins in the cytosol that bind to iron responsive elements located on the mRNA of proteins involved in Fe absorption (DMT1, FPN), uptake (transferrin receptor), and storage (ferritin). The same DMT1 protein that transports Fe^{+2} into

the intestine also transports Mn^{+2} . Based on limited research with pigs less than 1% of dietary Mn is absorbed. Absorbed Mn is transported to the liver bound to albumin and α -2-macroglobulins. Biliary excretion of Mn from the liver plays an important role in Mn homeostasis. Manganese leaving the liver is transported bound to transferrin; however, the number of transferrin binding sites occupied by Mn is very low relative to Fe. In summary, the last decade has provided incredible amounts of information about absorption and metabolism of Fe, but several steps involved in absorption and metabolism of Mn remain to be elucidated.

Key Words: Iron, Manganese, Metabolism

68 Active phosphate absorption: What do we know and is it important? J. S. Radcliffe*, *Purdue University, West Lafayette, IN.*

Phosphorus has probably been the most researched mineral over the last decade. However, research has focused primarily on enhancement of P digestibility, with very little emphasis on the mechanisms of absorption. When abundant in the diet, P, in the form of phosphate is absorbed passively via a paracellular route. However, as phosphate concentrations in digesta decrease, phosphate can be absorbed through an active, sodium dependent route. Historically, diets have been over-formulated with P, and therefore the passive absorption route dominates. However, as the concentration of P in swine diets have been lowered to reduce excretion, active absorption may be more important. Furthermore, most experiments evaluating phytase contain a negative control treatment, where dietary P concentrations are often 0.1-0.2 %-units below the requirement, which will result in an increased active transport of phosphate. To optimize dietary P utilization it is necessary to better understand active phosphate absorption, and how this transport system is regulated. Active phosphate absorption occurs through the sodium phosphate co-transporter, NaPi2b. Data from rodents, and more recently from swine, have demonstrated that as the concentration of P in the diet is decreased, active phosphate absorption is increased. This increase is the result of an increased translocation of NaPi2b from a subapical pool to the brush border membrane. Gene expression data is mixed, with the majority of experiments reporting no change in NaPi2b mRNA. The response to decreasing dietary P concentrations has been observed in as little as 3 d in pigs. Active phosphate absorption has been reported to be responsive to serum vitamin D concentrations in rodents, but not to dietary vitamin D concentrations in rodents or swine. Ultimately a better understanding of active phosphate absorption will result in improved diet formulation that will enhance P absorption and retention.

Key Words: Phosphate, Absorption, Phosphorus

69 Intestinal calcium absorption: Mechanisms learned from transgenic and knockout mice. J. C. Fleet*, *Purdue University, West Lafayette, IN.*

Although the role of calcium (Ca) in bone health has been well appreciated for nearly a century, in the last decade the use of transgenic and knockout mice has revealed many things about the mechanisms by which this essential nutrient enters the body. Ca crosses the intestinal barrier

using both a paracellular/diffusional pathway that responds solely to the luminal content of Ca and by a transcellular pathway that is active and saturable. While passive diffusion occurs throughout the intestine and accounts for 65-75% of the Ca that enters the body, the active, saturable component is thought to be limited to the proximal small intestine. The hormonally active form of vitamin D (1,25 dihydroxyvitamin D or 1,25 D) is the primary regulator of intestinal Ca absorption. Deletion of the vitamin D receptor (VDR) in mice reveals that the loss of intestinal Ca absorption is the primary defect responsible for disruption of Ca metabolism in these mice. Transgenic recovery of VDR into either the

proximal small intestine or throughout the intestine suggest that there vitamin D-regulated Ca absorption is also present in the lower bowel. Recently the facilitated diffusion of transcellular Ca absorption has been challenged by knockout mouse studies. Deletion of the apical membrane transporter gene (TRPV6) or of the gene for the putative Ca ferry protein calbindin D9k, have a minimal impact of basal or vitamin D regulated intestinal Ca absorption. New work will be necessary to fully understand the mechanism of transcellular, intestinal Ca absorption.

Physiology and Endocrinology: Nutrition and Growth, Reproductive and Lactational Performance

70 Adipose triglyceride lipase is a novel lipase in dairy cattle. D. Elkins* and D. Spurlock, *Iowa State University, Ames.*

Dairy cattle undergo negative energy balance during early lactation when increased energy requirements are not offset by energy intake. As a result, cows in negative energy balance mobilize adipose tissue to help meet their energy requirements. Excessive mobilization of adipose tissue has been associated with reproductive and health problems. Traditionally, phosphorylation of hormone-sensitive lipase (HSL) by protein kinase A has been viewed as the rate-limiting step of lipolysis. More recently, adipose triglyceride lipase (ATGL) has been identified as an additional lipase capable of hydrolyzing triglycerides to diglycerides. The objective of this research was to determine if ATGL is expressed in adipose tissue of lactating dairy cows, and to determine if its expression differs with stage of lactation. Adipose tissue was biopsied from 10 early [5-14 DIM] and 10 mid [176-206 DIM] lactation multiparous Holstein cows. Semi-quantitative western blots were used to evaluate HSL, phosphorylated HSL, and ATGL protein using commercially available antibodies. Blood samples were collected for analysis of lipolytic indicators, nonesterified fatty acid (NEFA) and glycerol. As expected, glycerol and NEFA were significantly greater in early compared to mid lactation cows ($P < 0.0001$), confirming a significant difference in lipolytic activity between stages. Expression of phosphorylated HSL, but not total HSL, was significantly greater in early compared to mid lactation cows ($P = 0.001$). Additionally, phosphorylated HSL was highly correlated with NEFA ($r = .66$; $P = 0.03$) and glycerol ($r = .77$; $P = 0.006$). ATGL protein was detected in adipose tissue of early and mid lactation cows, and its expression was significantly greater in mid compared to early lactation cows ($P = 0.002$). ATGL expression was not significantly correlated with NEFA or glycerol. These results confirm that ATGL is expressed, but likely makes a small relative contribution to lipolysis in early lactation cows. Increased expression of ATGL in mid lactation may indicate a more significant role for ATGL in basal lipolysis during positive energy balance.

Key Words: Dairy, Lipase, Adipose

71 Peripartal changes of adiponectin, adiponectin receptor 1, adiponectin receptor 2, leptin and leptin receptor mRNA expression in subcutaneous adipose tissue of dairy cows. A. Lemor, M. Mielenz*, A. Hosseini, and H. Sauerwein*, *University of Bonn, Germany.*

The transition from pregnancy to lactation is of critical importance for health, production, and profitability of the dairy cow. Within the homeostatic regulation of the adaptation to the metabolic changes involved, the adipocytokine adiponectin is attracting increasing interest due to its role in lipid metabolism, insulin resistance and glucose homeostasis. Data on the expression of adiponectin and its receptors, adiponectin receptor 1 (AdipoR1) and adiponectin receptor 2 (AdipoR2) as well as comparisons with the leptin system are mainly limited to monogastric species, whereas for ruminants corresponding data are lacking. We therefore aimed to characterize the mRNA expression for these adipokines and their receptors during the transition period in sc adipose tissue in dairy cows.

Biopsies from sc fat were taken at the tail head from 10 dairy cows (Holstein-Frisian) first between 13 - 2 d antepartum (AP) and second between 20 - 23 d postpartum (PP). Total mRNA was extracted and

purified by spin columns. The mRNA expression of adiponectin, AdipoR1, AdipoR2, leptin and leptin receptor (obRb) was quantified by real-time RT-PCR. Leptin protein was measured via ELISA in blood samples collected at the biopsy dates. Data were analysed by Wilcoxon Matched-Pairs Signed-Ranks Test and Spearman Rank Order Correlation (SPSS).

For adiponectin mRNA time-related changes were not detectable, whereas for AdipoR1 and AdipoR2 the PP expression was reduced ($P \leq 0.05$) to 57% of the AP values. Serum leptin was decreased ($P \leq 0.05$) PP, the analogous decrease in leptin mRNA did not reach the level of significance; obRb mRNA expression was 2.6-fold higher ($P \leq 0.05$) PP compared to AP. Positive correlations between AdipoR1 and AdipoR2 ($r = 0.82$, $P \leq 0.05$) were observed.

Our results indicate that the local effects of adiponectin and leptin in fat may differ between pregnancy and early lactation whereby the difference seems to be mediated at the receptor level rather than at the level of the ligand.

Key Words: Adiponectin, Leptin, Transition Cow

72 Propionate effects on the mRNA expression of adiponectin in two adipose depots and its receptors AdipoR1 and AdipoR2 in liver, skeletal muscle and adipose tissue of goats. M. Mielenz*, C. Seybold, A. Lemor, and H. Sauerwein, *University of Bonn, Germany.*

Adiponectin, an adipocyte-derived hormone, is an insulin sensitizing agent in monogastric mammals. In contrast to man, less information is available concerning the importance of the adiponectin system in ruminants. Propionate increases insulin secretion in ruminants but also acts directly through short chain fatty acid (SCFA) sensitive receptors (GPR41/43) in monogastrics. Here we characterize the effects of iv infused propionate on adiponectin and its receptors AdipoR1 and AdipoR2 in goats. Castrated male goats (Deutsche-Edelziege, 10 to 12 mo old) were allocated to infusions through jugular catheters after an over-night fast. They received propionate infusions (96 $\mu\text{mol/kg/min}$, pH 7.4; $n = 4$) or NaCl-solution of the equivalent Na-concentration ($n = 5$). Infusions were carried out for 260 min. The mRNAs for adiponectin, AdipoR1 and AdipoR2 were quantified by real-time RT-PCR after euthanasia in perirenal and subcutaneous adipose tissue. The receptor mRNAs were also tested in liver and semitendinosus muscle. Data analysis showed no effect of propionate on adiponectin mRNA in both adipose tissues. AdipoR1 and AdipoR2 tended to increase in subcutaneous ($P = 0.087$ and $P = 0.092$, respectively) but not in perirenal adipose tissue after propionate infusion. In liver, AdipoR1 increased ($P = 0.01$) and AdipoR2 tended to increase ($P = 0.068$) by stimulation with propionate. No effect was observed in skeletal muscle.

There was no effect on adiponectin mRNA in adipose tissue, at least in the small number of animals examined. With the exception of muscle, the mRNAs for both receptors were up-regulated in the different tissues analyzed. This effect might have been mediated by a general increase in energy intake, by insulin effects and/or signal transduction through SCFA sensitive receptors. The relevance of the propionate effects on the adiponectin system in ruminants has to be clarified in the future, as well as the role of the SCFA sensitive receptors in ruminants.

Key Words: Adiponectin, Propionate, Goat

73 Effect of ghrelin or obestatin continuously infused to dairy cows on grazing and ruminating behaviour and plasma hormone and metabolite concentrations. J. R. Roche*¹, A. J. Sheahan¹, D. P. Berry², L. Chagas¹, D. Blache³, and J. Kay¹, ¹DairyNZ, Hamilton, New Zealand, ²Teagasc Moorepark, Fermoy, Ireland, ³University of Western Australia, Perth, Australia.

Fifty-one cows were randomly allocated to one of three groups; a control and cows continuously infused with either 0.74 $\mu\text{mol/d}$ of ghrelin or obestatin sc. Infusions began 20 DIM and treatments continued for 8 wk. During wk 6 and 8, cows were observed over four 24-hr periods and grazing behaviour noted every 10 min. During wk 7, blood samples were collected every 4 h over 2 d, with the bleeding schedule staggered by 2 h on d 2 to ensure a blood sample was collected every 2 h of the 24 h period. Where necessary, data were transformed to be normally distributed. The effect of treatment on grazing behaviour and the concentration of blood metabolites and hormones was determined using mixed models, with cow included as a repeated effect. The concentration of metabolites varied with time. Ghrelin-infused cows had greater ($P < 0.01$) plasma growth hormone concentrations than either control or obestatin cows, consistent with ghrelin's role as a growth hormone secretagogue. However, this difference was only evident during a long period of ingestive inactivity between midnight and 0800 h, suggesting a possible role for ghrelin in growth hormone secretion during periods of negative energy balance. Leptin concentrations were greater ($P < 0.001$) in ghrelin than obestatin cows, with control cows intermediate. In comparison, NEFA concentrations increased ($P < 0.001$) from control to ghrelin to obestatin, although the effect is of little biological significance (0.09, 0.10, and 0.11 mmol/L, respectively). Plasma ghrelin concentrations were not affected by treatment, but plasma glucose was less in ghrelin- and obestatin-infused cows than control cows. Treatments did not affect time spent grazing or ruminating, although the length of the first grazing bout was longer in ghrelin and obestatin cows between the am and pm milking. Research is required to confirm or deny the role of ghrelin or obestatin in the feeding behaviour of grazing dairy cows.

Key Words: Ghrelin, Obestatin, Grazing Behavior

74 Evaluation of insulin-like growth factor-I and temperament as selection tools in Brahman heifers. L. C. Caldwell*^{1,3}, R. O. Dittmar III^{1,3}, T. D. A. Forbes², T. H. Welsh Jr.¹, and R. D. Randel³, ¹Texas AgriLife Research, College Station, TX, ²Texas AgriLife Research and Extension Center, Uvalde, TX, ³Texas AgriLife Research and Extension Center, Overton, TX.

In an effort to detect feed efficient beef cattle, researchers are exploring the use of insulin-like growth factor-I (IGF-I) concentrations and temperament scoring as tools for selection. Studies have revealed that temperament can affect ADG. Reports from Johnston et al. (2002) suggest that concentrations of IGF-I may be associated with the prediction of residual feed intake (RFI) in beef cattle. However, when tested in Brangus females, Lancaster et al. (2007) failed to find a correlation between IGF-I concentration and RFI. The purpose of this study was to assess the relationship of IGF-I concentrations and temperament with RFI and ADG in Brahman heifers. Using a Calan gate system, 3 separate Brahman heifer calf crops from 2004 ($n = 31$; 16-19 mo), 2005 ($n = 50$; 10.5-13.5 mo) and 2006 ($n = 56$; 5-8 mo) were limit fed a complete ration at 2.2% BW in 70-d feeding trails. Performance and feed intake

data were collected throughout the trials to determine feed efficiency. Temperament, determined by exit velocity and pen score, was evaluated at weaning. IGF-I concentrations were determined by RIA from samples collected on d 0 and 70. Correlations between IGF-I and RFI were weak ranging from $r = -0.064$ to 0.222 ($P > 0.05$). Temperament had no significant effect ($P > 0.05$) on RFI. The 2004 heifers categorized by temperament as calm, moderate or excitable showed mean RFI of 0.029 ± 0.08 , -0.178 ± 0.16 and 0.111 ± 0.09 , respectively. Year 2005 heifers averaged -0.001 ± 0.01 , -0.004 ± 0.01 and -0.007 ± 0.01 . The 2006 heifers averaged -0.002 ± 0.02 , -0.018 ± 0.02 and 0.021 ± 0.02 . Weak correlations were seen between IGF-I and ADG ($r = -0.056$ to 0.311) ($P > 0.05$). Correlations between ADG and temperament were significant. The 2004 heifers categorized by temperament had ADG of 0.678 ± 0.05 , 0.628 ± 0.04 and 0.647 ± 0.04 ($P = 0.07$), respectively. Year 2005 heifers averaged 0.88 ± 0.05 , 0.745 ± 0.03 and 0.791 ± 0.04 ($P = 0.07$). The 2006 heifers averaged 0.579 ± 0.03 , 0.606 ± 0.03 and 0.481 ± 0.04 ($P = 0.03$). These results suggest that IGF-I concentration is unrelated to RFI; however, temperament may be associated with ADG in Brahman heifers.

Key Words: IGF-I, Residual Feed Intake, Brahman

75 Variation in metabolic regulation in the liver of dairy cows during the dry period and in early lactation. H. A. van Dorland*¹, S. Richter¹, I. Morel², and R. M. Bruckmaier¹, ¹Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, ²Agroscope Liebefeld-Posieux (ALP), Posieux, Switzerland.

The metabolic status and simultaneously the hepatic regulation during the dry period, after partum, and in early lactation were studied in dairy cows. Liver biopsies were obtained from 28 cows in wk 10 antepartum (a.p.), and on d 1, and in weeks 4 and 14 postpartum (p.p.). Blood samples were collected every two wk during this period. Liver samples were analyzed for mRNA expression levels of hepatic factors of the carbohydrate-, lipid metabolism, and citric acid cycle (PEPCKc, PEPCKm, PC, ACSL, CPT 1A, CPT 2, ACADVL, HMGCS1, HMGCS2, PPAR α , PPAR γ , SREBF1, ACLY, and CS). Blood plasma was assayed for concentrations of glucose, BHBA, NEFA, cholesterol, triglycerides, insulin, IGF-1, T3, and T4. For evaluation, cows were divided into 2 groups based on the plasma concentration of β -hydroxybutyric acid (BHBA) at four weeks p.p. (group H, BHBA > 0.75 mmol/L; group L, BHBA < 0.75 mmol/L, respectively). In both groups, plasma parameters followed a pattern usually observed in dairy cows. However, changes were moderate and the energy balance in cows turned positive in week 7 p.p. Significant group effects were found in week 10 a.p., when plasma concentration of triglycerides was higher in L than in H, and in week 4 p.p., when plasma concentration of glucose and IGF-1 was lower in H than in L. Similarly, moderate changes in mRNA expression of hepatic factors between the different time-points were observed. One significant group difference was found in week 10 a.p., when a higher relative expression of mRNA of PEPCKc was observed in H than in L. Significant Spearman Rank Correlation Coefficients between the variables were not similar at each time-point and were not similar between the groups at each time-point, suggesting that metabolic regulation differs between cows. Conclusive, metabolic regulation in dairy cows is obviously a dynamic system, and differs between cows at different metabolic stages related to milk production.

Key Words: Metabolism, Liver, Gene Expression

76 Mild metabolic acidosis in sheep alters renal and skeletal muscle expression, but not liver, of amino acid enzymes and transporters. Y. Xue^{*1}, S. F. Liao¹, S. Greenwood², B. W. McBride², J. A. Boling¹, and J. C. Matthews¹, ¹University of Kentucky, Lexington, ²University of Guelph, Guelph, ON, Canada.

In metabolic acidotic rodents and humans, the altered expression of glutamine (Gln), glutamate (Glu), and alanine (Ala) metabolizing enzymes and transporters by the kidney, skeletal muscle, and liver is important to maintain blood acid-base balance. To test the hypothesis that mild metabolic acidosis (acidosis) induces an analogous response in sheep, the relative content of mRNA, protein, or mRNA and protein, for 6 metabolizing enzymes and 5 plasma membrane transporters of Gln/Ala/Glu was determined by real-time PCR and immunoblot analyses in homogenates of kidney, skeletal muscle, and liver of control (n = 5) vs acidotic (n = 5) sheep (Las et al., 2007, *J. Anim. Sci.* 85:2222). In kidney, where Gln use is increased in acidotic rodents, SN1 (Gln transporter) mRNA content was 790% greater ($P=0.05$), whereas Gln synthetase protein and mRNA was 56 ($P=0.01$) and 43% ($P=0.04$) lower, respectively, in acidotic sheep. In contrast, no change in phosphoenolpyruvate carboxykinase (protein and mRNA), renal glutaminase (mRNA), or Glu dehydrogenase (protein) was found, although their expression is highly increased in acidotic rodents. In skeletal muscle, a net releaser of Gln and net user of Ala in acidotic sheep, the protein content of aspartate transaminase was 101% greater ($P=0.03$) while Glu dehydrogenase tended to be ($P=0.11$) 33% greater in acidotic sheep. However, no change in the content of Ala transaminase protein, SNAT2 (Ala,Gln transporter) mRNA, or 3 Glu/aspartate transport proteins was found. In acidotic rodents, the liver is a net releaser of Gln. However, the mRNA or protein content of any enzyme or transporter did not differ in control vs acidotic sheep. These results indicate that the potential for aspartate and Glu use by skeletal muscle, and Gln absorption by the kidneys, is increased in mildly acidotic sheep, whereas liver capacity for Gln, Ala, and Glu metabolism remains constant.

Key Words: Acidosis, Amino Acid Metabolism, Sheep

77 Effects of prepartum 2,4-thiazolidinedione on metabolism and performance of transition dairy cows. K. L. Smith*, W. R. Butler, and T. R. Overton, *Cornell University, Ithaca, NY.*

Thiazolidinediones (TZD) are potent, synthetic ligands for peroxisome proliferator activated receptor-gamma (PPAR- γ) that reduced plasma concentrations of NEFA and increased dry matter intake (DMI) during the peripartum period in a previous experiment. Data from Holstein cows (n = 31) entering second or greater lactation were used to determine whether late prepartum administration of TZD would affect periparturient metabolism and milk production. Cows were administered 0, 2.0, or 4.0 mg TZD/kg BW by intrajugular infusion once daily beginning 21 d before expected parturition until parturition. Plasma samples were collected daily from 22 d before expected parturition through 21 d postpartum and twice per week from wk 4 through 9 postpartum. With increasing doses of TZD prepartum, plasma NEFA concentrations decreased linearly during the peripartum ($P = 0.01$) and postpartum ($P = 0.02$) periods (d -7 to d +7; 268, 246, 193 \pm 22 μ Eq/L and d 0 to d +21;

342, 296, 224 \pm 35 μ Eq/L, respectively). Postpartum liver triglyceride content was decreased linearly (11.0, 9.1, 4.7 \pm 1.9%; $P = 0.02$) and glycogen content increased linearly (2.16, 2.26, 2.75 \pm 0.19%; $P = 0.02$) with prepartum TZD administration. Peripartum DMI (16.2, 17.6, 17.6 \pm 0.5 kg/d) was increased linearly ($P = 0.04$) by TZD administration. Cows administered TZD prepartum had increased ($P = 0.001$) postpartum BCS (wk 1 through 9). Yields of 3.5% fat-corrected milk were affected quadratically ($P = 0.04$) by prepartum TZD administration (52.4, 54.1, 47.0 \pm 1.8 kg/d). Generally, cows administered 4.0 mg TZD/kg BW had the lowest ($P < 0.10$) milk component yields. Prepartum TZD administration linearly decreased ($P = 0.03$) the number of days to first ovulation (28.9, 25.0, 18.1 \pm 3.6 d) and increased ($P = 0.05$) the number of cows ovulating on or by d 21 postpartum. These results indicate that prepartum administration of TZD improves metabolic health and DMI of periparturient dairy cows, decreases reliance on body fat reserves, and may promote return of ovarian function during early lactation.

Key Words: Transition Cow, Thiazolidinedione, PPAR- γ

78 Glutamine synthetase is up-regulated in the liver of old beef cows by estradiol implants. E. D. Miles^{*1}, B. W. McBride², K. R. Brown¹, K. K. Schillo¹, J. A. Boling¹, and J. C. Matthews¹, ¹University of Kentucky, Lexington, ²University of Guelph, Guelph, ON, Canada.

Previous research in our laboratory has shown that old beef cows have reduced hepatic expression of glutamine synthetase (GS) and alanine transaminase (ALT), two enzymes in the liver that are critical for optimal N recycling. This experiment was conducted to characterize the effect of supplemental estrogen on these two proteins and other indicators of hepatic glutamate metabolic capacity. Fourteen old (> 10 yr) non-pregnant beef cows were housed in a dry lot with ad libitum access to alfalfa hay and water for 28 d. On d 1 of the study, cows received (n = 7/group) either a sham (Control) or CompuDose (25.7 mg estradiol; Elanco Animal Health) implant. On d 14 and 28, jugular blood and liver biopsy samples were collected. The effects of estrogen treatment (TRT), time after implant (DAY), and their interaction (TRT \times DAY) were assessed by ANOVA, using the repeated measures option of PROC MIXED (SAS). Plasma estrogen concentration of implanted cows (5.07 pg/mL) was 222 % more ($P = 0.01$) than for control cows (1.5 pg/mL). Plasma ammonia, and serum urea N levels, aspartate transaminase (AST), and ALT concentrations were not affected ($P \geq 0.21$). Immunoblot analyses were performed to quantify the relative liver content of GS, ALT, AST, glutamate dehydrogenase (GDH), and two System X-AG transporters (GLT-1 and EAAC1). For GS protein content, TRT ($P = 0.01$), DAY ($P = 0.03$), and TRT \times DAY ($P = 0.03$) effects were observed. Specifically, GS content was increased 350% by d 14 ($P = 0.002$) and 200% by d 28 ($P = 0.05$). In contrast, the protein content of ALT ($P \geq 0.37$), AST ($P \geq 0.71$), GDH ($P \geq 0.21$), GLT-1 ($P \geq 0.43$), or EAAC1 ($P \geq 0.19$) was not affected by estrogen implant. Hepatic content of GTRAP3-18, an inhibitor of EAAC1 activity, also was not altered ($P \geq 0.36$). These results indicate that the hepatic expression of GS in old beef cows is sensitive to stimulation by supplemental estrogen, whereas expression of other proteins that support hepatic glutamate metabolism is not.

Production, Management and the Environment: Measuring and Evaluating Environmental Stress

79 Dairy cows and the environment: Were we better off 83 years ago? A. D. Garcia*¹ and J. G. Linn², ¹*South Dakota State University, Brookings*, ²*University of Minnesota, St. Paul*.

Concerns on the environmental impact of dairy cattle have increased recently. There's been unsubstantiated speculation that current emissions from dairy cows are far worse than in the past. This paper compares the environmental impact of dairy cows early in the 1920's with those in 2007.

In 1924 there were 12 million more dairy cows in the U.S. than in 2007. In spite of this, yearly milk production was 43.7 million kg less as production per cow was 1,892 kg per lactation (NASS). According to Hopkins (JDS 2:208), of 595 farms surveyed 62% grazed their cows 6 months of the year. Grazed and confined cows were fed a yearly average of 1 Ton of silage, 1.9 Ton of forage, and 1 Ton of grain DM.

In the 1920's the U.S. dairy herd was more breed diverse, with the first true-type for Holsteins not developed until 1922. Haecker et al. (Minn. Agr. Exp. Sta. Bul. 140, 79 p.), used 454 kg as a cow's average body weight with feeding standards aimed to maintain it. Cows were thus fed on average 3,541 kg of dry feed, produced 1,898 kg of milk yearly, with a feed efficiency of 0.52 kg milk/kg feed. Using the Ellis et al. (JDS 90:3456) model to predict methane emissions based on daily DM intake, a dairy cow in the 1920's consuming 9.7 kg would emit 11.1 MJ of methane/d.

In 2007, there were 9.15 million dairy cows in the US producing on average 9,196 kg of milk yearly. A national summary on feed amounts and types being used on today's dairy farms is not available. Assuming an efficiency of 1.5 kg milk/kg feed DM and a DM intake of 12.7 kg/d for 60 days dry, the average daily DM intake over 365 days for a dairy cow in 2007 would be about 18.9 kg/d. Using the Ellis et al. model, the average cow emitted 18.5 MJ methane/d. This is a methane emission of 0.73 MJ/kg milk compared to 2.14 MJ/kg milk for cows in the 1920's. The reduction of 12 million dairy cows since 1924 results in total methane emissions reduction of 68.4 million MJ/d, or 39% less methane from dairy cows today than in 1920's. In addition, feed efficiency has increased three-fold over the last 8 decades.

Key Words: Methane, Dairy, Environment

80 Impact of using feedline soakers in combination with Korral Kools® to cool early lactation cows housed in desert style barns. J. F. Smith*¹, B. J. Bradford¹, A. Oddy², J. P. Harner¹, and M. J. Brouk¹, ¹*Kansas State University, Manhattan*, ²*NADA Al-Othman, Al Ahsa, Saudi Arabia*.

An experiment was conducted at a dairy located in Saudi Arabia in September 2007 to evaluate the impact of feedline soakers, in combination with Korral Kools®, on the body temperature of early lactation cows. Feedline soakers were installed in two pens of cows. The feedline soakers were set to come on at a barn temperature of 21°C with a soaking frequency of 5 min (36 s on and 264 s off). Korral Kools® were spaced every 6 m over the resting area and were operated, with the fans coming on at a barn temperature of 27°C and the water at 30°C. Feedline soakers were alternately turned on and off for 24 h periods over 4 d. Hourly ambient temperature, humidity and temperature-humidity index (THI)

were collected from a weather station located on the dairy. Vaginal temperatures of 7 primiparous (53 d in milk, 41.2 kg/d milk production) and 6 multiparous cows (28 d in milk, 48.1 kg/d milk production, 2.8 lactations), located in separate groups, were collected every 5 min using data loggers (HOBO U12) attached to a blank CIDR. Vaginal temperature data was analyzed with a mixed model including fixed effects of pen, treatment, day within treatment, time of day, and treatment by time of day interaction, and the random effect of cow within pen. Repeated measures over time were modeled with a variance component covariance structure, and denominator degrees of freedom were estimated using the Kenward-Roger method. Ambient temperature during the trial was 29.7°C (range: 21.7 to 38.5°C), relative humidity was 44.4% (16 to 85%) and THI was 75.6 (68 to 82). Feedline soakers significantly decreased mean 24-h vaginal temperatures from 38.98 to 38.80°C ($P < 0.001$). Treatment by time interaction was also significant ($P < 0.001$), with greatest treatment effects during peak heat stress; feedline soakers reduced vaginal temperatures from 39.72 to 39.42°C at 2400 h and from 39.32 to 38.98°C at 500 h. Additional research is needed to determine how to operate the Korral Kool® system with feedline soakers.

Key Words: Heat Stress, Dairy Cattle, Cooling

81 Impact of using evaporative pads and fans in combination with feedline soakers to reduce heat stress of prepartum cows. J. F. Smith*, B. J. Bradford, J. P. Harner, and M. J. Brouk, *Kansas State University, Manhattan*.

An experiment was conducted at the KSU dairy in August 2007 to evaluate the impact of evaporative pads and fans, in combination with feedline soakers, on the body temperature of prepartum cows. To complete this trial, an addition was constructed to the maternity barn to incorporate the use of evaporative pads and fans to cool the bedded pack area. Evaporative pads were alternately turned on and off for 24 h periods over 4 days. When the pads were on, water was circulated through the evaporative pads from 830 h to 230 h. The fans pulling air through the evaporative pads were operated anytime the barn temperature was above 21°C. The feedline soakers were set to come on at a barn temperature of 21°C with a soaking frequency of 15 min (5 min on and 10 min off). Logging devices collected ambient temperature and relative humidity data at 15-min intervals. Vaginal temperatures of 8 cows located in the same group were collected every 5 min using data loggers (HOBO U12) attached to a blank CIDR. Vaginal temperature data was analyzed with a mixed model including fixed effects of treatment, time of day, and treatment by time of day interaction, and the random effects of cow and day within treatment. Repeated measures were modeled with a variance component covariance structure, and denominator degrees of freedom were estimated using the Kenward-Roger method. Evaporative cooling significantly decreased mean 24-h barn temperature by 3.8°C and temperature-humidity index (THI) by 2.3 units. The greatest differences in barn temperature and THI occurred at 1700 h, when temperature was reduced by 6.8°C and THI by 3.1 units. Evaporative cooling significantly decreased mean 24-h vaginal temperatures from 38.95 to 38.79°C ($P < 0.001$). The treatment by time interaction was also significant ($P < 0.001$), with the greatest treatment effects during peak heat stress times (39.2 vs. 38.9°C at 1500 h, 39.3 vs. 39.1°C at 2300 h for pads off and

on, respectively). Evaporative cooling in combination with feedline soakers can be used to reduce body temperatures of prepartum cows experiencing heat stress.

Key Words: Heat Stress, Dairy Cattle, Transition Period

82 Differences in thermoregulatory ability between slick and normal-haired lactating Holstein cows in response to acute heat stress. S. Dikmen^{*1,2}, E. Alava², E. Pontes³, J. M. Fear², B. Y. Dikmen⁴, T. A. Olson², and P. J. Hansen², ¹University of Uludag, Bursa, Turkey, ²University of Florida, Gainesville, FL, USA, ³Universidade de São Paulo, São Paulo, Brazil, ⁴University of Uludag, Keles Vocational School, Keles, Bursa, Turkey.

The slick gene is a major dominant gene in cattle that controls hair growth. The aim of this study was to determine whether slick-haired Holsteins are better able to regulate vaginal (VT) and skin temperature (ST), respiration rate (RR) and sweating rate (SR) than normal-haired Holsteins during exposure to an acute increase in heat stress. Lactating slick and normal-haired cows were kept in one of two environments: an indoor environment (n=10) with fans and evaporative cooling and an outdoor environment (n=10) only with shade cloth. VT, RR, ST and SR were measured at 1200, 1500, 1800 and 2100 h and blood samples were collected for plasma cortisol concentrations. Cows in the outdoor environment had higher VT, ST, SR and RR than cows in the indoor environment (P<0.001). VT was lower (P=0.05) in slick-haired animals in both environments. The least-squares means \pm SEM for VT at 1200, 1500, 1800 and 2100 h were 39.4 \pm 0.1 vs 39.9 \pm 0.1, 39.7 \pm 0.1 vs 40.0 \pm 0.1, 39.8 \pm 0.1 vs 40.3 \pm 0.1, 39.4 \pm 0.1 vs 40.0 \pm 0.1 $^{\circ}$ C for slick vs normal, respectively, in the outdoor environment and 38.8 \pm 0.1 vs 39.0 \pm 0.1, 38.5 \pm 0.1 vs 38.9 \pm 0.1, 38.8 \pm 0.1 vs 39.0 \pm 0.1, 38.5 \pm 0.1 vs 38.9 \pm 0.1 $^{\circ}$ C for slick vs normal in the indoor environment. SR tended to be higher for slick-haired cows in both environments (P=0.07). The least-squares means \pm SEM for SR at 1200, 1500, 1800 and 2100 h were 113.6 \pm 6.5 vs 88.6 \pm 6.5, 93.5 \pm 6.5 vs 75.2 \pm 6.5, 90.2 \pm 6.5 vs 82.0 \pm 6.5, 25.1 \pm 6.5 vs 24.7 \pm 6.5 g/hm² for slick vs normal, respectively, in the outdoor environment and 70.4 \pm 6.5 vs 60.1 \pm 6.5, 52.7 \pm 6.5 vs 37.3 \pm 6.5, 47.7 \pm 6.5 vs 55.2 \pm 6.5, 14.5 \pm 6.5 vs 16.8 \pm 6.5 g/hm² for slick vs normal in the indoor environment. RR was lower for slick-haired cows in both environments (P<0.05). There was no difference in ST between hair type and cortisol concentrations were not affected by environment or hair type. Results indicate that slick-haired cows can regulate their body temperature more effectively than normal cows during heat stress. The superior thermotolerance of the slick-haired cows is likely to reflect increased heat loss via conduction and convection as well as increased SR.

Key Words: Heat Stress, Holstein, Slick Hair Gene

83 Development of models for predicting management practices and conditions that alleviate heat stress in large commercial dairy farms. J. M. Schefers^{*}, K. A. Weigel, and N. B. Cook, University of Wisconsin, Madison.

During the summer of 2007, 29 dairy herds in the Alta Advantage[®] progeny testing program were selected to participate in a heat stress study to determine the importance of different types of heat abatement systems and facility designs for alleviating heat stress in lactating dairy cows.

For each herd, intravaginal temperatures were recorded from lactating cows using a continuous temperature logging device (HOBO[®]) attached to a blank intravaginal insert (CIDR). The observational period was 39 hr, and temperatures ($^{\circ}$ Celsius) were recorded at 2-min intervals. The temperature data loggers were inserted in 7 to 8 early lactation cows per herd. Ambient temperature ($^{\circ}$ Celsius) and relative humidity were collected at 2-min intervals over the same 39-hr period as the temperature data loggers in the freestall barns on each dairy. Overall, 16 variables related to facilities and heat abatement systems were considered in this study. Mean intravaginal cow temperature was calculated for each lactating cow from the temperature data logging devices over the 39-hr observational period. Mean intravaginal cow temperature was used to calculate the mean herd temperature for each herd participating in the study. Mean temperature humidity index (THI) was the most significant predictor (P<0.01) of mean herd temperature for herds that participated in the heat stress study. As THI increases, mean herd temperature also increases. Also, mean herd temperature was significantly higher (P<0.05) for dairy herds that had a north-south (NS) orientated barn than herds with barns orientated in the east-west (EW) direction. Least squares means were 38.97 $^{\circ}$ C and 38.84 $^{\circ}$ C for the NS orientated barns and EW orientated barns, respectively. Furthermore, the holding pen was identified as a major risk area for heat stress. Airflow in cubic feet per minute per cow (cfm/cow) and stocking densities in the holding area were both found to be significant at P<0.05. As the airflow rate in cfm/cow increased, there was a significant decrease in mean herd temperature and as stocking densities increased, cows got hotter.

Key Words: Heat Stress, Dairy Cattle, Environment

84 Is the temperature–humidity index (THI) the best indicator of heat stress in lactating dairy cows in a subtropical environment? S. Dikmen^{*1,2} and P. J. Hansen², ¹University of Uludag, Faculty of Veterinary Medicine, Bursa, Turkey, ²University of Florida, Gainesville.

Several temperature–humidity indexes (THI) have been developed to estimate the degree of thermal stress experienced by mammals. THI's are based on formulae that include meteorological variables related to air temperature and humidity. Many of these were originally derived for species other than cattle and many were not derived by performing regression analysis to estimate the optimal weighting of temperature and humidity. The objective of this study was to develop an equation using meteorological variables that best predicted rectal temperature of lactating cows in a subtropical environment and compare the accuracy of prediction of rectal temperature of this equation to that obtained using dry bulb temperature (DBT), 7 different THIs, and DBT or THI in combination with other meteorological variables. Rectal temperature was measured between 1500 and 1700 h in 1280 lactating Holstein cows in north central Florida. Dry bulb temperature, relative humidity (RH), black globe temperature (BGT), dew point, and wind speed were recorded at each cow's location. Data were recorded from August to December 2007. Regression analysis to predict rectal temperature was performed using various models that included parity, stage of lactation, farm, milk yield, the meteorological variables mentioned above as well as seven separate THIs. Stepwise regression analyses were performed to identify equations with highest coefficient of determination (r²) for predicting rectal temperature. The r² using DBT (0.407) was similar to that for models using THI (r² between 0.420 and 0.425) or BGT (r²=0.389). The r² for equations using DBT could be improved by adding RH (r²=0.428) or RH and RH² (r²=0.437) to the model. In conclusion, DBT is nearly as good a predictor of body temperature of lactating

Holsteins in a subtropical environment as THI and inclusion of RH in the model results in r^2 as good as THI.

Key Words: Heat Stress, Temperature–Humidity Index

85 Evaluation of accuracy and variation of ThermoChron® iButtons®. S. M. Garey*, T. H. Friend, and B. H. Carter, *Texas A&M University, College Station.*

The ThermoChron iButton DS1921H temperature logger has been useful in a wide range of biological studies. The objective of this study was to determine if the accuracy or variability of these devices change as they age or when they are used over a range of temperatures. Individual iButtons were grouped into new (4000 to 6000, $n=11$) and old (32000 to 35000, $n=12$) categories by number of lifetime readings. The iButtons were exposed for 1 h to 20°C, 30°C, 38°C and 44°C in a thermostatically controlled water bath in ascending order, and the temperature treatments were subsequently replicated in descending order. After the iButtons stabilized at each temperature, 60 readings at 1-min intervals per iButton were evaluated for accuracy against a calibrated certified thermometer (accuracy $0.1 \pm 0.05^\circ\text{C}$) by calculating the average mean of the differences at each reading. The variation of each iButton was then compared using the standard deviation of those differences. The effect of age on deviation from the certified thermometer was determined using independent t -tests. Overall, the new iButtons were more accurate ($P < 0.01$), differing from the certified thermometer by -0.26°C , while the old iButtons differed by -0.46°C . Additionally, new iButtons had a tendency ($P < 0.05$) to be less variable with a mean SD of 0.07°C , versus 0.09°C for old iButtons. The performance of the iButtons in different temperatures was analyzed using paired t -tests with a Bonferroni correction. As the temperature increased, the accuracy of the iButtons improved ($P < 0.01$) with average differences of -0.41°C at 20°C, -0.40°C at 30°C, -0.36°C at 38°C and -0.31°C at 44°C. These results suggest that data collected with these devices, regardless of age, should be individually corrected to a standard reference for cross-study comparison. Alternatively, a correction to a group mean by allowing the iButtons to equilibrate in a temperature range similar to that in which it will be used will improve within-study comparisons.

Key Words: ThermoChron, iButton, Temperature

86 Addition of skin temperature to whole body temperature measures improves relationship to Temperature Humidity Index under moderate climatic conditions. R. B. Zimbelman*, J. B. Wheelock, M. D. O'Brien, J. Muumba, A. Alex, R. P. Rhoads, L. H. Baumgard, and R. J. Collier, *University of Arizona, Tucson.*

The Temperature Humidity Index originally developed by Thom (1958) and extended to cattle by Berry and colleagues (1964) is used to estimate cooling requirements of dairy cattle. However, correlation of THI to measurements of core body temperature is not adequate. Our objective was to determine if incorporation of skin surface temperature to mean body temperature measures would improve Pearson Correlation Coefficients between THI and physiological measures of heat stress. During a three-month span, three groups of cows ($n=12$) were housed in the environmental chambers at the University of Arizona for a total of 22 days. Each group experienced a total of three environments where THI was at a minimum of 49, maximum of 79 and an average 62.9. We uti-

lized NRC 1971 THI calculation $(0.18 \times \text{Tdb} + 32) \times (0.55 - (0.0055 \times \text{RH}) \times (1.8 \times \text{Tdb} - 26))$ for estimate of environmental heat load. Physiological measures of heat strain included respiration rate (RR/min), infrared surface temperature (ST, °C), rectal temperature (RT, °C), heart rate (HR/min), and evaporative heat loss (EVHL, g/m²). Mean body temperature (BT, °C) was calculated using the formula $\text{BT} = (0.33 \times \text{ST} + 0.67 \times \text{RT})$. Respiration rates, ST, RT, EVHL, and HR were routinely collected 4 times per day and hourly for 24 hours once biweekly for a total of 2096 measures. Correlations of these measures to THI were as follows: THI and RR ($r=0.63$; $P < 0.0001$), THI and RT ($r=0.42$; $P < 0.0001$), THI and SR ($r=0.64$; $P < 0.0001$), THI and ST ($r=0.86$; $P < 0.0001$), THI and BT ($r=0.85$; $P < 0.0001$), and THI and HR ($r = -0.45$; $P < 0.05$). Correlations between BT and RR ($r=0.48$; $P < 0.0001$), BT and SR ($r=0.69$; $P < 0.0001$), BT and RT ($r = 0.63$; $P < 0.0001$). We conclude that under moderate climatic THI conditions investigated addition of ST to BT improved the correlation of BT to THI over RT alone. In addition, the correlation of RR, ST, and BT are improved over RT alone implying that ST has a greater effect on RR than RT.

87 Facility characteristics of U.S. dairy operations and their impact on cow health and productivity. J. E. Lombard*¹, C. B. Tucker², M. A. G. von Keyserlingk³, and C. A. Kopral¹, ¹USDA:APHIS:VS:Centers for Epidemiology and Animal Health, Fort Collins, CO, ²University of California, Davis, CA, ³Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada.

Assessments and questionnaires were administered to evaluate cow health, productivity and facility characteristics on 491 dairy operations in the top 17 dairy states as part of the USDA's National Animal Health Monitoring System's Dairy 2007 study. The objectives of this portion of the study were to quantify characteristics of cow housing and how these features correspond with cow health and productivity on U.S. dairy operations. Data were collected from March through August 2007. The percentage of operations assessed by housing types were tiestall (39.0%), stanchion (13.0%), freestall (38.4%), drylot (5.0%) and other multiple animal areas (4.6%). Stanchion barns were the oldest with the mean building year of 1949 compared to freestall housing with a mean building year of 1989. Mean stall widths were widest for tiestalls (1.2 m) compared to stanchions or freestalls (both 1.1 m). In general, freestall operations had more bedding than tiestall and stanchion operations. Overall disease incidence, including hypocalcemia and displaced abomasum, was lowest on drylot operations compared to other housing systems. Operations with stanchion housing had lower cow removal rates compared to tiestall and freestall operations and a lower percentage of deaths compared to freestall operations. Rolling herd average milk production was higher for operations with tiestall (9647 kg) or freestall (9706 kg) housing compared to stanchion (7966 kg) or drylot (8065 kg) facilities. Facilities constructed in the last 20 years, such as freestall housing, have placed greater emphasis on cow comfort and may be associated with increased health and production compared to older facilities. However, results of this study indicate that freestall facilities are not associated with improved health compared to other housing systems, suggesting that further improvements in facility design and management must be identified.

Key Words: Housing, Health, Productivity

88 The effects of supplementing a dietary novel yeast culture on body temperature indices, production and metabolism in heat-stressed lactating cows. G. Shwartz¹, J. B. Wheelock¹, L. L. Hernandez¹, M. D. O'Brien¹, K. A. Dawson², M. J. VanBaale¹, R. P. Rhoads¹, R. B. Zimelman¹, and L. H. Baumgard^{*1}, ¹University of Arizona, Tucson, ²Alltech Inc., Nicholasville, KY.

Multiparous, lactating Holstein cows (n= 23; 120±30 DIM, 690±67 kg BW) housed in climatic chambers were randomly assigned to 1 of 2 dietary treatments (TRT): a diet containing Yea-Sacc[®] HD (a formulated yeast culture for heat stress, n=12, 10 g/d) or control diet (n=11). The trial length was 28d and consisted of a 7d thermal-neutral acclimation period (18°C, 20% humidity) followed by 21d of heat stress (HS; cyclical daily temps ranging from 29.4 to 37.8°C and 20% humidity). Cows were individually fed a TMR consisting primarily of alfalfa hay and steam flaked corn. During acclimation, yeast supplementation had no effect on temperature or production variables. During HS, TRT had no effect on rump temperature, respiration rate, or sweating rates. Tail head (39.52 vs 39.24°C) and shoulder (39.59 vs 39.31°C) temperatures tended (P<0.08) to be higher for controls. Controls had increased (P<0.05) rectal temperature at 1200 and 1800 h (40.29 vs 40.02°C; 40.35 vs 40.12°C, respectively), and tended to be higher (39.48 vs 39.26°C; P=0.05) at 0600 h compared to yeast fed cows. There was no TRT effect on BW loss (58 kg) during HS. Although DMI decreased (29%) during HS, there was no TRT effect on intake. HS progressively decreased milk yield, reaching a nadir (33%) on the 3rd week, but TRT had no effect on milk yield (28.16 kg), 3.5% FCM (29.05 kg) or ECM (28.14 kg). Although TRT had no effect on milk composition, HS decreased (P< 0.05) protein (7%) and lactose (5%), but did not alter fat levels. HS cows were in negative EBAL (-1.0 Mcal/d), but TRT had no effect on EBAL or feed efficiency (1.71). Independent of TRT, HS decreased plasma glucose (11%), but neither TRT nor HS altered basal NEFA levels. PUN was increased (≥45%) and also tended to be lower in yeast-fed cows (13.5 vs 14.6 mg/dL; P<0.10). Despite yeast-fed cows having reduced body temperatures and PUN concentrations, production parameters were not improved during HS.

Key Words: Heat Stress, Yeast Culture

89 Effects of nutrition and feeding management on production, health and culling by organically-managed dairy herds in south-eastern Pennsylvania. K. Griswold^{*1}, H. Karreman², S. Dinh¹, and J. High³, ¹Penn State Cooperative Extension, University Park, PA, ²Penn Dutch Cow Care, Gap, PA, ³Lancaster DHIA, Manheim, PA.

The effects of nutrition and feeding management on production, health, and culling were examined using a combination of survey and DHIA data. Initially, 38 organically-managed (OM) herds using Lancaster DHIA services were recruited for the study, but only 29 herds returned completed surveys. The survey consisted of 308 questions concerning herd demographics, milk quality, health, reproduction, nutrition, and young stock. Monthly DHIA 202 report data from 2006 for each herd were used for the study. Data were analyzed using PROC MIXED and PROC REG within SAS. The supplemental forage model included the fixed effects of feeding haylage (HYL), baleage (BL), alfalfa hay (AH), mixed-grass hay (MGH), and corn silage (CS). The supplemental grain model included the fixed effects of feeding shelled corn (SC), high-moisture shelled corn (HMSC), ear corn (EC), high-moisture ear corn (HMEC), oats (OA), speltz (SP), soybean meal (SBM), and a grain mix (GM). LS means with standard errors are presented in the table below.

The results indicate that herds feeding BL produced less milk with greater milk fat % and protein % compared to herds not feeding BL. Corn silage supplemented herds produced more milk than herds not receiving corn silage. Regression analysis revealed no significant (P > 0.05) relationship between level of CS supplementation and milk yield. Feeding oats significantly increased milk fat %, but milk fat yield (kg per cow per year) was not affected (P = 0.91). All other supplements examined had no effects on milk yield and components (P > 0.10). Both herd cull rate % and death loss % were not affected (P > 0.10) by supplemental forage or grain choices. These results suggest that supplemental forage choice has more potential impact on milk production and components in OM dairy herds than supplemental grain choice. Supplementation of forage to enhance milk yield does not deleteriously affect culling and death loss in OM dairy herds.

Table 1. Effects of supplemental feeds on milk production in organically-managed dairy herds

Supplement	Milk yield, kg/cow/year		P
	Yes	No	
Corn Silage	7,837 ±341	6,501 ±479	0.0007
Baleage	6,594 ±481	7,745 ±364	0.008
Ear Corn	7,346 ±577	7,171 ±909	NS
Oats	7,035 ±1,033	7,482 ±1,020	NS
	Milk Fat %		
Supplement	Yes	No	P
Corn Silage	3.84 ±0.08	3.88 ±0.12	NS
Baleage	3.97 ±0.12	3.75 ±0.09	0.038
Ear Corn	3.63 ±0.17	3.90 ±0.12	0.084
Oats	3.87 ±0.14	3.65 ±0.14	0.037
	Milk Protein %		
Supplement	Yes	No	P
Corn Silage	3.06 ±0.06	3.11 ±0.08	NS
Baleage	3.18 ±0.08	3.00 ±0.06	0.01

90 Identification of efficient sets of artificial insemination reproductive management programs: A stochastic dominance analysis. N. J. Olynk^{*} and C. A. Wolf, Michigan State University, Lansing.

Reproductive success is critical to the financial success of the dairy farm. Several reproductive management technologies have been developed to aid in effective and efficient reproductive management. Farm managers have heterogeneous risk preferences. The riskiness of a program's outcome (i.e., range of potential conception or heat detection rates) and the risk preferences of the farm manager will affect technology adoption decisions. Further, on-farm costs and goals will affect the reproductive program chosen. The objective of this research was to identify optimal programs for farms with a given set of characteristics (e.g., manager characteristics, on-farm costs, goals). Stochastic dominance, a method to rank risky alternatives without specific information on decision maker preferences, was utilized to determine efficient sets of programs for farm managers with given risk preferences and for various on-farm cost scenarios. First degree stochastic dominance (FSD) identified the

efficient programs for decision makers who simply prefer 'more to less', or in this case prefer the program with lower total cost. Second degree stochastic dominance (SSD) compared programs based on relative riskiness, and identified the efficient programs for decision makers who prefer 'more to less' at a diminishing rate – and therefore are risk averse. Prior reproductive study results were used to parameterize the analysis of reproductive technologies including visual heat detection, Ovsynch, and Cosynch. No FSD was identified which highlights that no single

reproductive program was preferred by all managers. SSD of Ovsynch over Cosynch was identified under given scenarios, indicating that risk averse managers would prefer Ovsynch over Cosynch. By identifying efficient sets of reproductive programs we can make better technology adoption recommendations to dairy farm operators and further understand why farms adopt specific reproductive technologies.

Ruminant Nutrition: Forages

91 Optimizing forage use in total mixed rations for lactating cows. R. Kowsar¹, G. R. Ghorbani¹, M. Alikhani¹, M. Khorvash¹, and A. Nikkhah^{2,3}, ¹Isfahan University of Technology, Isfahan, Iran, ²Zanjan University, Zanjan, Iran, ³University of Illinois, Urbana.

The principal objective was to determine the effects of partial replacement of short-length alfalfa hay (AH, peNDF>8 mm = 14%) with corn silage (CS, peNDF>8 mm = 45%) in yellow grease supplemented total mixed rations on feed intake, chewing activity, rumen fermentation, and productivity of lactating cows. Four multiparous (138 ± 3 days in milk) and four primiparous (115 ± 10 days in milk) Holstein cows were used in a replicated 4 × 4 Latin square design study with four 21-d periods. Each period had 14-d of adaptation. Treatments were diets (dry matter based) with 1) 40% alfalfa hay (ALF), 2) 24% alfalfa hay + 16% corn silage (CS40), 3) 20% alfalfa hay + 20% corn silage (CS50), and 4) 16% alfalfa hay + 24% corn silage (CS60). All diets contained 2% yellow grease. Cows had greater ($P < 0.05$) intakes of net energy, neutral detergent fiber, and physically effective fiber when CS replaced 40, 50, and 60% of short AH. Replacing short AH with CS lengthened daily eating and chewing times in all cows, and increased rumen pH at 4-h post-feeding in multiparous cows ($P < 0.05$) but did not affect it in primiparous cows. Apparent total tract digestibility coefficients for dry matter, organic matter and crude protein were not different among ALF, CS40 and CS50 fed cows but were lower ($P < 0.05$) in the CS60 fed cows (71, 72, 71%) than in the ALF group (75, 77, 76%). Energy corrected milk yield was greater ($P < 0.05$) in CS40 (33.8 kg) and CS60 (34.0 kg) groups than in the ALF group (31.9 kg). Milk protein yield was increased ($P < 0.05$) when CS replaced 40, 50, and 60% of AH. Milk lactose was higher only in the CS60 fed cows, but milk lactose yield was greater in CS50 and CS60 fed cows, compared to the ALF fed cows. Milk percent and yield of fat and total solids and changes in body condition score did not differ among treatments. Therefore, partial replacement of short-length AH with CS enhanced diet palatability, stimulated energy and physically effective fiber intakes, and increased milk protein yield.

Key Words: Alfalfa Hay, Corn Silage, Yellow Grease

92 Fenugreek as forage for dairy cows 1. Effect on productivity. A. W. Alemu* and L. Doepel, *University of Alberta, Edmonton, AB, Canada.*

Fenugreek (*Trigonella foenum-graecum L.*) is a novel forage crop to Canada that is being studied as an alternative forage to alfalfa for dairy cows. The objective of this study was to evaluate the effect of fenugreek haylage relative to alfalfa haylage on productivity of dairy cows. Six 2nd lactation Holstein cows (56 ± 8 DIM) fitted with ruminal cannula were used in a replicated 3x3 Latin square design with 18 d periods, the last 7 d being used for collection. A TMR consisting of 40% haylage, 10% barley silage and 50% concentrate on a DM basis was fed once daily. The haylage component constituted the dietary treatments: 1) AAFC F70 fenugreek (F70), 2) CDC Quatro fenugreek (QUAT) and 3) Alfalfa (ALF). Apparent total tract digestibility of the diets was determined by feeding chromic oxide at 21 g/d as an indigestible marker. Data were analyzed using orthogonal contrasts of alfalfa vs. fenugreek (FEN) and F70 vs. QUAT. DMI, milk yield, and milk protein and lactose yields

were higher ($P < 0.05$) for cows fed ALF than FEN, whereas milk fat yield and percent were unaffected by treatment. Milk urea N (MUN) was lower in the ALF fed cows than the fenugreek fed cows ($P = 0.003$). Total-tract digestibility of DM (77.4%), CP (78.3%), NDF (63.5%) and ADF (59.5%) was unaffected by treatment. Our results suggest that although the digestibility of the fenugreek diets was equivalent to that of the alfalfa diet, fenugreek haylage has a lower feeding value than alfalfa for lactating dairy cows due in part to lower DMI, resulting in lower milk yield. As such, it may not be a suitable alternative to alfalfa haylage.

Table 1.

	Treatment				Contrasts	
	F70	QUAT	ALF	SEM	ALF vs. FEN	F70 vs. QUAT
DMI, kg/d	16.8	18.7	22.9	0.7	<0.001	0.10

93 Brown midrib corn silage fed during the transition period can result in a persistent increase in production. W. C. Stone¹, L. E. Chase¹, T. R. Overton¹, J. L. Lukas¹, and K. E. Nestor², ¹Cornell University, Ithaca, NY, ²Mycogen Seeds, Wooster, OH.

Holstein cows (n = 66) entering second or greater lactation were used to determine whether feeding Brown Midrib (BMR; Mycogen F2F444) or conventional (a mixture of varieties) corn silage (CS) would improve performance and metabolism. Cows were fed diets that differed in source of CS from 3 wk precalving until 3 wk postcalving. Diets were formulated to keep all parameters the same with the exception of NDF digestibility. The NDF-d (30 h) for conventional and BMR silages averaged 56.8 and 73.8%, respectively. Prepartum rations contained about 47% CS, 18% wheat straw, 7% alfalfa haylage (AH), and 28% concentrate (DM basis). Postpartum rations contained about 40% CS, 15% AH, 1% straw, and 44% concentrate. All cows were fed a separate ration containing only conventional CS as the CS source from wk 4 to 15. Cows were housed in tiestalls and had milk weights (3X/d) and DMI recorded daily and milk composition measured weekly. Blood samples collected weekly during the transition period were analyzed for NEFA and BHBA. Cows fed BMR had higher DMI during the 2 wk period before calving and 3 wk period postcalving. Yields of milk, fat-corrected milk (FCM), and solids were increased for the first 15 wk of

lactation period for cows fed rations containing BMR. Concentrations of peripartur NEFA and postpartur BHBA were not affected by treatment. Feeding BMR CS during the transition period resulted in increased milk and milk solids yield during the first 15 wk of lactation.

Table 1. Effects of BMR or conventional corn silage on cow performance

	Control	BMR	SE	P value
Prepartur DMI, d -21 to -1, kg/d	13.8	14.6	0.38	0.14

94 Production response of lactating cows to combinations of BMR corn silage and Tifton 85 bermudagrass hay. J. J. Castro*, N. A. Mullis, and J. K. Bernard, *University of Georgia, Athens.*

The effect of feeding combinations of forages with improved NDF digestibility on performance was evaluated in an 8-wk randomized design trial. Treatments were arranged as a 2 x 2 factorial to include silage from either normal (NCS) or brown midrib silage (BMR) with or without Tifton 85 (T85) bermudagrass hay. Experimental diets contained 50% forage with 3 to 5 % of DM provided by ryegrass silage. Treatments were 1) NCS; 2) BMR; 3) NCS plus T85; and 4) BMR plus T85. Diets were formulated to be isocaloric and isonitrogenous but differed in NDF concentrations: 30, 31, 34, and 34% of DM for treatments 1 through 4, respectively. Forty Holstein cows averaging 82 ± 19 DIM, 41.6 ± 8.9 kg/d milk, and 3.2 ± 0.2 % fat were assigned randomly to treatments at the end of 2 wk standardization period. Mean DMI, milk yield, fat and protein percentage and ECM yield during the trial were 24.7, 40.6, 3.12, 2.94, and 38.8; 26.4, 41.0, 3.31, 2.86, and 40.0; 24.7, 38.1, 3.65, 2.87, and 38.8; and 25.6 kg/d, 39.8 kg/d, 3.35 %, 2.85 %, and 39.0 kg/d for treatments 1, 2, 3, and 4, respectively. Cows fed diets with BMR had higher ($P < 0.01$) DMI than those fed NCS. Milk yield was lower ($P < 0.05$) but fat percentage was higher ($P < 0.05$) when cows were fed diets with T85 hay compared with those that did not receive T85. No differences were observed in milk protein concentrations or yield of fat, protein, or ECM among treatments. Blood glucose was higher ($P < 0.05$) in cows consuming diets with BMR than with NCS and averaged 64.2, 69.7, 67.2, and 68.7 mg/dl for treatments 1, 2, 3, and 4, respectively. An interaction ($P < 0.05$) between corn silage type and T85 was observed for plasma urea concentrations because of higher concentrations with BMR than NCS diet when T85 was added; (15.7, 13.7, 16.3, and 18.0 mg/100 ml for treatments 1, 2, 3, and 4, respectively). The results of this trial indicate that including T85 at 10 % of DM in diets based on normal or BMR plus ryegrass silage can maintain acceptable DMI and overall performance.

Key Words: Forage Evaluation, NDF, Tifton 85

95 Effect of wheat forage maturity and preservation method on dietary passage kinetics and DM digestibility of mixed diets fed to growing beef calves. P. Beck*, F. Nacer, B. Stewart, D. Shockey, M. Morgan, and S. Gunter, *University of Arkansas Division of Agriculture, Hope.*

Wheat (*Triticum aestivum* L.) forage was harvested at the boot or hard dough stage of maturity, preserved as hay or silage, and fed in total mixed diets (80:20 concentrate:forage ratio, DM basis) in order to measure the effect of maturity at harvest and preservation method on particulate passage rate and apparent DM digestibility. Six 1.2-ha wheat fields were harvested at either boot or dough stage of maturity and either ensiled or stored as hay. Hay or silage was incorporated into 14.5% CP diets using soybean hulls, corn, and cottonseed meal as primary concentrate sources. Beef calves (n=16, BW=187 ± 9.4 kg) were individually fed 2.0% of BW diets for 15 d in a completely randomized design with a 2 x 2 factorial arrangement of treatments. Calves received a pulse dose of 2.5 g YbCl₃ and fecal samples were collected at 6, 12, 24, 36, 48, 60, 72, and 96-h post dosing. Extraction of Yb was completed using an EDTA procedure and analyzed with Inductively Coupled Plasma spectrometry. Fecal Yb excretion curves were analyzed by nonlinear regression procedures of SAS using a one-compartment model (Marquardt method). Ruminant particulate passage rate (PPR) was determined by rate of ruminal mixing x 0.59635, mean ruminal retention time was calculated by 1/PPR, and fecal output was determined by Yb dose/K0. Acid detergent insoluble ash (ADIA) was used as an internal marker to determine diet DM digestibility. Data were analyzed using the GLM procedure of SAS using animal as the experimental unit. Ruminant PPR, RRT, fecal output, and diet DM digestibility averaged 4.6%/h, 22.7 h, 3.7g/kg BW, and 81.6%, respectively and were not affected ($P \geq 0.15$) by forage maturity, preservation method, or the interaction. This study indicates that maturity of wheat forage at harvest and preservation method has no effect on kinetics of dietary passage or digestibility when fed as 20% of a total mixed diet.

Key Words: Digestibility, Passage Rate, *Triticum aestivum* L.

96 Effect of maturity and preservation method of wheat forage on the performance of growing beef calves fed mixed diets. M. Morgan*, P. Beck, F. Nacer, B. Stewart, D. Shockey, and S. Gunter, *University of Arkansas, Division of Agriculture, Hope.*

Wheat (*Triticum aestivum* L.) forage was harvested at the boot or hard dough stage of maturity, preserved as hay or round-bale silage, and fed to growing calves in total mixed diets to determine the effects of maturity at harvest and preservation method on animal performance. Six 1.2-ha wheat fields were cut using a disc mower at either the boot or dough stage of maturity. One-half of each field was either round baled within 24 h and ensiled or baled as hay. Fresh cut forage contained 24 and 57% DM, 15 and 8% CP, and 19 and 23% NFC, for boot and dough harvest, respectively. After 3 months of storage, boot cut silage contained 22, 17, and 18% DM, CP, and NFC, respectively; while hay contained 91, 15, 5.5% DM, CP, and NFC. Dough cut silage contained 47, 10, and 18% DM, CP, and NFC, respectively; while hay contained 91, 9, 22% DM, CP, and NFC. The hays or silages were incorporated into 14.5% CP diets at 20% (DM basis) using soybean hulls, corn, and cottonseed meal as the concentrate sources. Growing beef calves (n=84, BW=229 ±

6.0 kg) were randomly assigned to the 4 diets and fed at 3% (DM basis) of BW for 63 d in a 2 x 2 factorial arrangement with 3 pens/treatment. Animal performance data were analyzed as a completely randomized design using the mixed procedure of SAS. Forage yield, feed intake and G:F was analyzed using the GLM procedure of SAS. Forage yield at the dough harvest was greater ($P < 0.01$) than at boot harvest (2,781 vs. 6,259 \pm 246 kg/ha, respectively). Average daily gain (1.20 \pm 0.05 kg), DMI (7.4 \pm 0.15 kg), and feed efficiency (0.16 \pm 0.01) were unaffected ($P \geq 0.55$) by maturity at harvest, preservation method, or their interaction. The results indicate that forage maturity at harvest and preservation method has no affect on animal performance of growing beef steers when fed at 20% of mixed diets.

Key Words: Cattle, Hay, Silage

97 Comparison of grazing stockpiled tall fescue versus feeding hay or hay plus supplement to beef cows in late gestation and early lactation. A. M. Meyer*, R. L. Kallenbach, and M. S. Kerley, *University of Missouri, Columbia.*

Ninety-three beef cows (avg BW = 624.5 \pm 11.7 kg, avg BCS = 5.0 \pm 0.1) were allocated by BW, BCS, age, and calving date to 1 of 3 treatments (3 replicates each): grass hay fed to cows on dormant, previously grazed pastures (HAY), grass hay with supplementation (1.1 kg corn and 0.9 kg DDGS•cow⁻¹•d⁻¹) to meet predicted NRC requirements (HS), and strip-grazed non-endophyte infected stockpiled tall fescue pasture (STF). The trial was conducted from mid December to late March and split into 2 periods: from initiation to 1 wk precalving (P1, d 1 to 68) and from precalving until conclusion (P2, d 69 to 103). Average nutrient composition of STF was better than that of hay (11.8% vs. 8.0% CP, 67.2% vs. 74.2% NDF). Stockpiled pastures had an average yield of 2,691 kg DM/ha and average utilization rate of 60.6%. Hay offered did not differ ($P > 0.05$) between HAY and HS (12.4 vs. 11.8 kg•cow⁻¹•d⁻¹, respectively). During P1, HAY cows lost BW while HS and STF cows gained BW (-9.7 vs. 21.1 and 14.5 kg, respectively; $P < 0.05$), despite having similar BCS and ultrasonic back fat (BF) thickness. Although no differences were observed in BW or BF during P2, HAY cows lost more BCS ($P < 0.05$) than HS and STF cows (-0.6 vs. -0.2 and -0.1, respectively). Over the entire trial, HAY cows lost more ($P < 0.05$) BW, BCS, and BF than HS and STF cows (BW: -85.0 vs. -49.3 and -52.0 kg, BCS: -0.9 vs. -0.3 and -0.2, BF: -0.53 vs. -0.33 and -0.28 cm). No differences ($P > 0.05$) were observed for cow BW changes post-trial through weaning, pregnancy rates, or calf birth and weaning weights.

Post-trial, HAY cows gained more ($P < 0.10$) BCS than HS (0.7 vs. 0.3), and HAY ($P < 0.05$), and HS ($P < 0.10$) gained BCS compared to a loss in STF cows (-0.1) through weaning. Results of this study indicate that grazing STF is a viable option for wintering spring-calving beef cows. Because typical grass hay used is often of lower quality than STF, cows fed hay require supplementation to achieve similar performance to that observed while grazing STF.

Key Words: Beef Cows, Stockpiled Tall Fescue, Supplementation

98 Associative effects of leguminous (C3; Lucerne) and nonleguminous (C4; Corn & sorghum) fodders on In-situ digestion kinetics of fiber. M. Yaqoob*¹, J. I. Sultan², A. Javed², and P. Akhtar³, ¹*Department of Livestock Management, University of Agriculture, Faisalabad, Punjab, Pakistan,* ²*Institute of Animal Nutrition and Feed Technology, University of Agriculture, Faisalabad, Punjab, Pakistan,* ³*Department of Animal Breeding and Genetics, University of Agriculture, Faisalabad, Punjab, Pakistan.*

An in sacco Nylon Bag study was conducted to evaluate the associative effects of leguminous (C3; Lucerne) and nonleguminous (C4; corn & sorghum) fodders. Lucerne was replaced at the rate of 15, 30 and 45% with corn and sorghum fodders respectively. The respective fodder samples were filled in each Nylon bag (10g) and incubated in the rumen of fistulated buffalo calf at 0, 0.5, 1, 2, 4, 6, 10, 12, 24, 36, 48 and 72 hours respectively. The bags were suspended in reverse order so that all the bags were pulled out together. The data regarding lag time rate of disappearance and extent of digestion were analyzed using analysis of variance techniques. Lucerne substitution increased ($P < 0.05$) the in sacco DM and NDF digestibility (48h) of corn and sorghum with maximum value at 30% replacement level. However, a declining trend was observed with the higher substitution level. A similar trend was noticed in rate of disappearance of DM and NDF of corn and sorghum. Lucerne substitution decreased the ($P < 0.05$) the lag time for DM and NDF disappearance in sacco upto 30% replacement level for both nonleguminous fodders however, an increasing trend was observed at 45%, substitution level. The extent of in sacco DM and NDF digestion was unaffected ($P < 0.05$) by Lucerne substitution. A positive associative effect was observed by replacing the Lucerne (C3) with corn and sorghum (C4) fodders, which was maximum at 30% Lucerne replacement.

99 Impact of copper deficiency in the presence or absence of high dietary manganese on iron status of cattle. S. L. Hansen* and J. W. Spears, *North Carolina State University, Raleigh.*

Iron (Fe) and copper (Cu) metabolism are closely intertwined, and a deficiency of Cu may lead to a secondary Fe deficiency. The impact of a severe Cu deficiency on proteins involved in Fe metabolism in the bovine has not been studied. Therefore, a 493 day study was conducted to determine the effect of a severe long-term Cu deficiency on Fe metabolism in beef cattle. Twenty-one Angus calves were born to cows receiving one of the following treatments: 1) adequate Cu (+Cu), 2) Cu deficient (-Cu), and 3) Cu deficient plus 500 mg Mn/kg DM (-Cu+Mn). Following weaning, calves remained on the same treatment as their dam through growing (basal diet analyzed 7 mg Cu/kg) and finishing (analyzed 3 mg Cu/kg) phases. Plasma Fe concentrations were positively correlated ($P < 0.01$; $R^2 = 0.49$) with plasma Cu concentrations. Reciprocally, there was a negative relationship ($P < 0.01$; $R^2 = -0.31$) between liver Cu and Fe concentrations. This relationship is likely explained by lower ($P < 0.01$) ceruloplasmin activity in -Cu. vs. +Cu calves. Based on Western blotting of duodenal mucosal scrapings collected at harvest, concentrations of hephaestin (Hp), a Cu-dependent ferroxidase, were greater ($P = 0.01$) in -Cu+Mn compared to -Cu calves. Similarly, concentrations of the Fe export protein ferroportin (FPN) tended ($P = 0.07$) to be higher in -Cu+Mn vs. -Cu calves, likely due to lowered Fe status of -Cu+Mn calves. However, concentrations of divalent metal transporter 1 (DMT1), a protein responsible for import of Fe, Mn and Cu into cells, were lower ($P = 0.04$) in -Cu+Mn calves vs. -Cu calves. Concentrations of Hp, FPN and DMT1 did not differ ($P > 0.1$) between +Cu and -Cu calves. In summary, while Fe status of calves was impacted by changes in Cu status, Cu deficiency alone did not impact duodenal concentrations of proteins important in Fe metabolism. However, excessive dietary Mn appeared to regulate DMT1, and this regulation was able to override low body Fe signals.

Key Words: Cattle, Copper, Iron

100 The effects of trace mineral source on performance and health of newly received steers and the impact of cobalt concentration on performance and lipid metabolism in finishing steers. J. S. Schutz*¹, E. D. Sharman¹, J. J. Wagner¹, C. K. Larson², N. E. Davis¹, and T. E. Engle¹, ¹Colorado State University, Fort Collins, ²Zinpro Corporation, Eden Prairie, MN.

Two hundred and sixteen Angus cross steers purchased from salebarns (230 kg \pm 3.6) were utilized to determine the impact of trace mineral source and concentration on performance, tissue metabolites, and lipid metabolism. Treatments during the 27 d receiving phase consisted of: 1) Inorganic trace mineral (INORG; 125 mg Cu from CuSO₄; 360 mg Zn from ZnSO₄; 200 mg Mn from MnSO₄; and 12.5 mg Co from CoCO₃ h₂O) and 2) Organic trace mineral (ORG; iso-amounts of Cu, Zn, Mn as amino acid complexes, and Co glucoheptonate). On d 0 and 27, blood samples were collected from three steers per pen. On d 28, steers were transitioned to a high concentrate finishing diet containing different concentrations of Co. Treatments during the finishing

phase consisted of: 1) Control (no supplemental Co); 2) 0.10 mg Co/kg DM from cobalt glucoheptonate; 3) 1.0 mg Co/kg DM from cobalt glucoheptonate. The same three steers per pen were bled on d 27, 84, and 224 of the finishing phase. During the receiving phase, red blood cell superoxide dismutase activity was higher ($P < 0.03$) for ORG vs. INORG supplemented steers. During the finishing phase, overall ADG tended ($P < 0.06$) to be higher for steers receiving 1.0 mg Co/kg DM (1.65, 1.62, 1.71 kg \pm 0.03 for control, 0.10 mg Co/kg DM, 1.0 mg Co/kg DM treatments, respectively). Steers receiving 1.0 mg Co/kg DM had higher YG ($P < 0.04$; 2.53, 2.29, 2.73 \pm 0.11 for control, 0.10 mg Co/kg DM, 1.0 mg Co/kg DM treatments, respectively) and back fat thickness ($P < 0.04$; 1.54, 1.39, 1.71 cm \pm 0.08 for control, 0.10 mg Co/kg DM, 1.0 mg Co/kg DM treatments, respectively) than steers receiving 0.10 mg Co/kg DM. Serum, liver, and longissimus muscle B12 concentrations increased ($P < 0.04$) as dietary Co concentration increased.

Key Words: Cattle, Cobalt, Trace Mineral

101 The effect of ZinMet® brand zinc methionine on feedyard performance and carcass merit in crossbred yearling steers. J. J. Wagner¹, J. J. Wagner*¹, T. E. Engle¹, and G. Walker², ¹Colorado State University, Fort Collins, ²Global Animal Products, Amarillo, TX.

One hundred forty four crossbred yearling steers were utilized in a randomized block study to evaluate ZinMet® brand zinc methionine as a source of supplemental zinc for yearling feedlot steers. Treatments examined included: Control, 100 mg/kg DM supplemental zinc from zinc sulfate; and, ZinMet®, 40 mg/kg DM supplemental zinc from ZinMet® brand zinc methionine and 60 mg/kg DM supplemental zinc from zinc sulfate. There was a trend for increased live weight at d35 ($P = 0.07$) and d70 ($P < 0.18$) for steers fed ZinMet® as compared with steers fed the control trace minerals. Finished weight was similar for control and ZinMet® treatments (569.5 and 574.3 kg, respectively). The largest difference ($P < 0.05$) in average daily gain between treatments was observed for day 1 through 35 of the study (1.96 versus 1.63 kg/hd/d for the ZinMet® and control treatments, respectively). Average daily gains from day 1 through harvest were similar between treatments. Treatment was not a significant source of variation for dry matter intake (DMI). The greatest difference in DMI between treatments (0.16 kg per day, $P < 0.14$) occurred from day 1 through 34. Treatment had no effect on feed to gain or gain to feed ratio d1 through slaughter. The largest difference between treatments for feed to gain ($P < 0.17$) or gain to feed ($P < 0.16$) occurred from day 1 through 34. Treatment was not a significant source of variation describing recovered net energy for maintenance (NEm) or recovery of net energy for gain (NEg). Carcass weight, dressing percentage, yield grade, and quality grade were similar for control and ZinMet® treatments. Liver abscess rate was not different for the control and ZinMet® treatments. These data indicate that overall feedlot performance and carcass merit were similar for yearling steers fed ZinMet® brand zinc methionine or zinc sulfate as sources of supplemental zinc. Steers fed ZinMet® brand zinc methionine achieved greater ADG, DMI, and feed efficiency from d1-34 as compared with control steers.

Key Words: Zinc, Zinc Methionine, Organic Trace Minerals

102 Effect of trace mineral source on lactation performance, claw integrity and fertility of dairy cattle. J. L. Siciliano-Jones¹, M. T. Socha^{*2}, D. J. Tomlinson², and J. M. DeFrain², ¹*FARME Institute, Homer, NY*, ²*Zinpro Corporation, Eden Prairie, MN*.

Two hundred fifty multiparous and primiparous cows were assigned to a study at approximately 70 d prepartum to determine the effect of trace mineral source on lactation performance, claw integrity and fertility. Cows received treatments from 3 wk prepartum through wk 35 postpartum. Treatments consisted of 1) Sulfate, all supplemental Zn, Mn, Cu and Co provided in sulfate form; and 2) CTM, where 360 mg Zn, 200 mg Mn, 125 mg Cu and 12 mg Co supplied daily by sulfate minerals were replaced with similar amounts of minerals supplied by Availa^{®4} (Zinpro Corporation). Individuals involved with daily animal care and/or data recording were blinded to treatment assignments. Cows from all treatments were housed in common pens and treatments were dispensed to cows via a computerized feeder. All claws of cows were examined prior to treatment administration and at 16 and 36 wk postpartum by personnel trained in identifying claw lesions. Cows fed the CTM diet tended to produce more ($P \leq 0.10$) milk and energy-corrected milk than cows fed the Sulfate diet. Cows fed the CTM diet also produced more ($P \leq 0.05$) milk protein and solids (fat + protein) than cows fed the Sulfate diet. Replacing Sulfate minerals with those supplied by CTM decreased ($P \leq 0.05$) incidence of sole ulcers at wk 36 postpartum, and tended to decrease ($P \leq 0.10$) incidence of interdigital dermatitis at wk 16 and 36 postpartum. Severity of heel erosion tended to be less ($P \leq 0.10$) for cows fed CTM than cows receiving the Sulfate diet. Despite first service conception rates tending to be greater ($P \leq 0.10$) for cows fed the Sulfate diet, there was no effect of treatment on the rate at which cows became pregnant. A greater percentage of cows fed the Sulfate diet tended ($P \leq 0.10$) to be culled from the herd prior to wk 36 postpartum than cows fed the CTM diet. Replacing Sulfate minerals with CTM resulted in improved lactation performance and claw integrity.

Key Words: Trace Mineral, Dairy Cattle, Claw Lesion

103 Effect of nano selenium and organic zinc supplementation on lactation performance and milk selenium and zinc concentrations in dairy cows. W. Wen-Xuan^{*1}, X. Xian-Lin¹, Z. Yun-Guo², and W. Heng-Jin¹, ¹*Guizhou University, Guiyang, Guizhou Province, P. R. China*, ²*Xifeng Agricultural Bureau, Xifeng, Guizhou province, P. R. China*.

Both selenium and zinc are essential trace elements, and their deficiency has been to be associated with insufficient performance in dairy cows. In this study, twenty-seven clinically healthy multiparous Holstein cows in middle lactation (DIM=180) were randomly allocated to three blocks of 9 cows to examine the effects of nano selenium and organic zinc supplementation on lactation performance and milk selenium and zinc concentrations. Animals were fed one of three following diets: conventional diet (control), conventional diet and nano selenium (0.5mg/kg DM) (Treatment 1, T1); and conventional diet and nano selenium (0.5mg/kg DM) and organic zinc (37.8mg/kg DM) (Treatment 2, T2). There were no significant difference ($P > 0.05$) for the 10-day prefeeding data of dry matter intake (DMI); milk production and compositions of fat, and protein; and milk selenium and zinc concentrations in three blocks. The DMI in cows fed diet T1 tended to decrease compared with those on diet control (16.0 vs. 13.2; $P < 0.1$), but not for diet T1 (14.4; $P > 0.05$). Cows receiving diet control also produced increased milk

production relative to cows fed diet T1 and T2 (28.07 : 25.44 : 25.12; $P < 0.1$). There were no significant difference for milk fat (3.69 : 4.06 : 4.02; $P > 0.05$) and milk protein (2.98 : 2.95 : 3.02; $P > 0.05$) among three dietary treatments. Addition of nano selenium (T1 and T2) had no effect on milk selenium concentration (0.024 : 0.027 : 0.026; $P > 0.05$); however, zinc supplementation resulted in significant higher milk zinc level than diets control and T1 (3.80 : 4.00 : 9.00; $P < 0.05$). It is suggested, from the above-mentioned parameters, that organic zinc supplementation in the diet is beneficial for increase of milk zinc concentration; whereas the palatability should be improved due to the reduced DMI in the current study.

Key Words: Nano Selenium, Organic Zinc, Dairy Cows

104 The influence of calf Se status on glutathione peroxidase-1 and glutathione peroxidase-3 activities, and liver GPx-1 messenger RNA. G. Lum^{*}, J. Rowntree, K. Bondioli, M. McCarter, L. Southern, and C. Williams, *LSU Agricultural Center, Baton Rouge, LA*.

The purpose of this research was to determine the influence of dietary Se on erythrocyte glutathione peroxidase (GPx-1) and plasma glutathione peroxidase (GPx-3) activities and relative liver GPx mRNA levels in growing Holstein bull calves. Calves ($n = 14$) were started 28 d after birth on either a Se adequate (0.15 ppm Se) or deficient (0.01 ppm Se) diet until 180 d of age. Blood samples were taken from each calf at trial initiation, every 28 days, and at experiment end for determination of GPx-1 and GPx-3 activity. Four calves from each treatment were euthanized at d 180 of age for determination of liver GPx-1 relative mRNA level. Feed intake and average daily gain were not affected by Se level. The GPx-1 activity was greater for Se adequate than Se deficient calves ($P < 0.001$) but not until d 84 of age. The GPx-3 activity was more variable than that of GPx-1, and GPx-3 activity of the Se adequate group was only greater than that of the Se deficient group ($P < 0.05$) on d 180 of age. N-fold differences were calculated for relative GPx-1 mRNA levels between groups. There was a 50% decrease in GPx-1 mRNA for Se-deficient calves ($P < 0.05$) compared with Se-adequate calves. Regression analysis was performed on the data to determine the relationship between the various response variables. There was only a moderate relationship ($r^2=0.579$) between the n-fold difference in GPx-1 mRNA transcript levels and GPx-1 activity at d 180 of age, despite a correlation coefficient of 0.76. The relationship between the n-fold difference in GPx-1 mRNA and GPx-3 activity at d 180 of age was much stronger ($r^2=0.8087$), with a correlation coefficient of 0.899, which was unexpected, as GPx-3 is generally considered a more variable response and therefore a short-term indicator of Se status. In our trial, GPx-1 activity reflected diet Se concentration earlier than GPx-3. Although GPx-1 mRNA was positively correlated to both enzyme activities, n-fold differences on the transcript level were most associated with GPx-3 activity.

Key Words: GPx-1, mRNA, Selenium

105 Selenium partitioning between body compartments in lactating dairy goats supplemented with various sources and levels of Se. G. Caja^{*1}, C. Flores¹, A. Salama¹, and G. Bertin², ¹*Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain*, ²*Alltech France, Levallois-Perret, France*.

Four concentrates supplemented with different Se sources (SS, sodium selenite; SP, Sel-Plex[®] selenized *Saccharomyces cerevisiae* CNCM I-3060) and Se levels (control, 0.039; SS, 0.418; SP-1, 0.423; SP-2, 0.548 mg/kg DM), were fed to 4 balanced groups of Murciano-Granadina dairy goats (7 goats/group) from early- (35 DIM) to mid-lactation (147 DIM). Ration consisted of concentrate (0.72 kg DM/d) and a Se deficient forage mixture offered ad libitum (65% chopped tall fescue hay and 35% alfalfa hay pellets) to each goat group. Forage intake measured daily (1.33 ± 0.01 kg DM/d; 0.087 mg Se/kg DM) and FCM-3.5% yield (1.76 ± 0.13 L/d) recorded weekly did not vary between goat groups. Supplementation of dietary Se dramatically increased ($P < 0.001$) the Se content in all compartments studied in a dose dependent manner. Increase in Se contents were faster in plasma and milk, peaking at wk 6 to 8 from the start of supplementation. Passage from feed to milk and hooves was related to casein and keratin contents and was more efficient, for the same Se daily dose, when the selenized yeast form (SP) was used. Se speciation indicated dramatic increases in selenomethionine and selenocysteine, which were greater in milk with SP diets ($P < 0.001$). Dietary Se correlated exponentially ($R^2 = 0.78$) with Se in milk. Content of Se in hair was more than twice the Se content in hooves, but no differences between hair and hooves were found when SS and SP were compared at the same dose. Regarding the negative control group, Se content in hair decreased during the experiment from 500 to 450 ng/g which may be useful as reference value when Se is under the requirements in red and black coated goats. In conclusion, organic Se was more effective than inorganic Se for increasing Se content in the different compartments of lactating dairy goats, indicating a greater bioavailability of Se from selenized *Saccharomyces cerevisiae* CNCM I-3060 and the possibility of producing Se enriched goat milk and cheeses as functional foods.

Table 1. Partitioning of Se according to dietary source and dose in lactating goats

Se, ng/g	Control	SS	SP-1	SP-2	SEM	P
Whole blood	155 ^c	329 ^b	313 ^b	391 ^a	13	0.001

106 Effectiveness of potassium bicarbonate to increase dietary cation-anion difference in early lactation cows. R. White¹, J. Harrison¹, R. Kincaid², E. Block³, and N. St. Pierre⁴, ¹Washington State University, Puyallup, ²Washington State University, Pullman, ³Church and Dwight, Princeton, NJ, ⁴The Ohio State University, Columbus.

Thirty Holstein cows (15 per treatment) were used in a continuous design lactation study to evaluate the effectiveness of potassium bicarbonate as a cation to increase dietary DCAD from ~ 25 to 42. The study was conducted from mid August to mid December. Cows were fed individually via Calan[®] feeding gates one of two treatment diets formulated to be equal in all nutrients except potassium. The potassium level of the control diet was ~ 1.2% of DM and increased to ~ 1.8% of DM using potassium carbonate (DCAD Plus[®], Church & Dwight, Princeton, NJ) for the DCAD+ treatment. Diets consisted of (%DM): alfalfa hay (13.4), corn silage (12.1), blue grass straw (8.6), corn distillers grains with

solubles (10.3), whole cottonseed (6.2), and grain-mix (49.4). Cows were assigned at random to one of the two dietary treatments at ~ 15 DIM and continued through ~ 105 DIM. Production data and composition were analyzed as a mixed model with the fixed effects of treatment, week, and their interactions, and the random effect of cows within treatment, using an AR(1) correlation structure for the errors. Linear and quadratic orthogonal polynomial contrasts were used, and weekly means were compared with the slice option of the MIXED procedure (SAS V9.1) when one of the polynomial degree was significant. The treatment x week quadratic effect was significant ($P < 0.0002$) for milk production indicating that the milk production curves were significantly different between the two treatments. Significant differences ($P < 0.065$) in milk production were noted at weeks 5, 6, 7, and 8 of the study. Milk production was 43.9, 43.2, 44.2, and 42.2 kg/d for DCAD+ treatment, and 40.5, 39.7, 40.2, and 39.2 kg/d for control treatment, at weeks 5, 6, 7, and 8 of the study, respectively. Milk fat % was significantly different ($P < 0.05$) and was 4.31 for DCAD+ and 3.96 for control. Milk true protein % was significantly ($P < 0.05$) different and was 2.79 for DCAD+ and 2.96 for control. Results indicate that potassium bicarbonate can be used to effectively increase DCAD in early lactation cows with a resulting increase in milk production and milk fat percent.

Key Words: Dairy, DCAD, Potassium Bicarbonate

107 Phosphorus excretion in lactating cows fed diets supplemented with fat. Z. Wu*, J. D. Ferguson, and D. W. Rensburg, *University of Pennsylvania, Kennett Square.*

The effect of supplemental fat on P utilization in dairy cows was determined using the following 4 dietary treatments formed in a 2×2 factorial arrangement: low P, low fat (LPLF); low P, high fat (LPHF); high P, low fat (HPLF); and high P, high fat (HPHF). The P content of the diet was 0.34 or 0.43%, and the fat content 3.0 or 5.4%. The levels were varied by adding monosodium phosphate and soybean oil to LPLF that contained no supplemental P or fat. Soy oil was top-dressed onto the TMR. Two thirds of the diet was provided by corn silage and grass silage for all treatments. Forty mid-lactation (172 ± 32 DIM) Holsteins (16 primiparous) were used among the 4 treatments for 5 wk following a 2-wk covariate period; however, one primiparous cow in HPLF was culled during trial for reasons unrelated to treatments. Dietary P amount did not affect lactation performance, whereas increasing dietary fat reduced milk fat content. Increasing dietary P increased fecal P concentration, whereas supplementation of the diet with fat tended to reduce fecal P content. Consistent with the 2001 NRC, 0.34% dietary P appeared adequate for mid-lactation cows milking 30 kg/d, and increasing the level may increase fecal P excretion; supplemental fat may reduce P excretion. (Research was supported in part by Pennsylvania Department of Agriculture)

108 Effect of feeding rumen-protected niacin on core body temperature and milk production in lactating Holstein dairy cows during summer heat stress. R. B. Zimbleman*, R. J. Collier, and T. R. Bilby, *University of Arizona, Tucson.*

Niacin has been shown to increase resistance to thermal stress in cattle by increasing whole body evaporative heat loss and cellular heat shock response to thermal stress in vitro. As raw niacin is extensively degraded in the rumen, this study utilized encapsulated niacin (NIASHURE[®]) to determine effects on body temperature, milk yield and composition. A total of 400 lactating primiparous and multiparous Holstein cows were randomly assigned to a switchback design (two 30d periods) of either control (C, no niacin n=200) or rumen-protected niacin (RPN, cows supplemented with 12g/d/cow of encapsulated niacin, n=200). Groups were balanced for DIM (166 +/- 11), milk yield, and parity prior to start of the study which was conducted from August 7th thru October 7th, 2007 on a commercial dairy in Arizona. Milk yields were recorded 3X daily and a monthly milk sample was collected for milk components. Vaginal temperatures were collected using thermochron iButtons (MAXIM Integrated Products Inc., Sunnyvale, CA) temperature loggers attached to an intravaginal device and inserted into a random sub-sample of cows (n=16) from each pen (n=2) with similar DIM, milk yields, and parity for 7 d. Body core temperatures were decreased for the RPN group during periods of peak thermal load from 1300 to 1600 h (P<0.01). Milk fat and protein percent was elevated in the RPN versus C groups (3.65 vs. 3.38 and 3.09 vs. 3.05 %, respectively; P<0.01). Subsequently both fat- and energy-corrected milk was greater for cows in the RPN group compared with cows in the C group (39.7 vs. 38.2 and 39.6 vs. 38.4 kg, respectively; P<0.01). In addition, both fat- and energy-corrected milk was increased in multiparous compared to primiparous cows (40.7 vs. 37.2 and 40.7 vs. 37.3 kg; P<0.01). However, groups did not differ in milk yield or DMI. In conclusion, supplementing lactating cows with rumen-protected niacin during summer heat stress reduced core body

temperature and increased both fat and protein percent, in turn, elevating fat- and energy-corrected milk yields.

Key Words: Niacin, Heat Stress, Dairy Cattle

109 Biological activity of vitamin E in dairy cows. S. K. Jensen*, *University of Aarhus, Tjele, Denmark.*

α -Tocopherol (α -toc) demonstrate the highest vitamin E activity, and is available both as natural RRR- α -toc isolated from plant sources, and as a synthetic racemic mixture of all eight possible stereoisomers α -all-rac- α -toc. The increased use of vegetable oil for technical purposes increase the possibility for isolating different natural by-products from the oil residue, including tocopherols. Assessing the correct biological activity in form of bioavailability and biopotency is a great challenge, due to difficulties by measuring clinical endpoints in larger animals than rats and poultry. Due to the lack of good biological markers for bioactivities, bioavailability is often used as one of the surrogate markers for bioactivities. Therefore, analysis of the individual stereoisomers of α -tocopherol, is an important tool in order to quantify relative bioavailability of the individual stereoisomers. I.m. injection of 2.5 g all-rac- α -toc acetate into 4 dairy cows produced a rapid increase in plasma concentration of α -toc, and for all stereoisomers maximal concentration (Cmax) was achieved 1 day after injection, with a total α -toc concentration of 16.9±0.8 μ g/ml plasma. The highest Cmax was obtained by RRR- α -toc in plasma, followed by the sum of the four 2S stereoisomers, leaving the three synthetic 2R-stereoisomers with the lowest Cmax (P<0.001). The relative bioavailability in plasma of the 2R stereoisomers was significant higher than the 2S stereoisomers (P<0.001). Expressed in terms of relative availability the average availability of 2S- α -toc is six times lower than RRR- α -toc. In milk the absolute secretion of the individual stereoisomers varied from 0.67 % of the injected amount for the 2S stereoisomers over 6.5 % on average for the three synthetic 2R stereoisomers to 16.3% for RRR- α -toc. A calculation of total α -toc secretion into the milk after a single injection of 2.5 g all-rac- α -toc acetate gave an average secretion of 6.4±0.9% (mean ± SD) of injected amount.

110 Conjugated linoleic acids and their effect on dairy marketing. R. M. Haines*, B. A. Corl, and D. R. Winston, *Virginia Polytechnic Institute and State University, Blacksburg.*

Conjugated linoleic acids (CLA) are 18 carbon fatty acids with two conjugated double bonds. Several CLA isomers exist in ruminant food products; the placement and type of double bonds help determine the chemical properties and health benefits associated with that isomer. Of these CLA isomers, *cis-9, trans-11* is most important, exhibiting cancer fighting properties when found in high enough tissue concentrations. Specifically *cis-9, trans-11* prevents and reduces the incidence of malignant mammary tumors in both rodents and more recently in human studies. Milk products are the leading source of *cis-9, trans-11* CLA in the diet as this isomer comprises 90% of the CLA in milk fat. While supplements are available to supply higher levels of CLA in the body, dairy products are a better source of the compound. Specifically, consumption of milk products produces higher *cis-9, trans-11* tissue concentrations than chemically prepared supplements because dairy products contain vaccenic acid, a precursor to the *cis-9, trans-11* isomer. Vaccenic acid can be used to synthesize CLA in body tissues as demonstrated in cows, rodents, swine and humans. Dairy products also produce higher tissue concentrations of *cis-9, trans-11* because this isomer is in higher concentrations in milk fat than in supplements. While *cis-9, trans-11* comprises 90% of CLA in milk fat; the average supplement is only 44.81% *cis-9, trans-11* isomers. The *trans-10, cis-12* isomer is found in commercial supplements in roughly equal quantities to *cis-9, trans-11* CLA. *Trans-10, cis-12* has been linked to hyperinsulinemia and insulin resistance in rodents which makes future research necessary to investigate the safety of this isomer. Additionally, high-CLA milk products are acceptable to consumers, with taste panels identifying no significant difference in color, taste, or overall quality when compared to traditional milk. Because of this lack of sensory difference and health benefits associated with consumption of high-CLA dairy products, consumers expressed a willingness to pay generous price premiums for high-CLA milk products that could provide opportunities to expand milk marketing and increase revenue for the dairy industry.

Key Words: Conjugated Linoleic Acid

111 Probiotics: For life. S. Quarles*, *Clemson University, Clemson, SC.*

Dairy product consumption transforms with the landscape of the U.S. population. Consumer standards, wants, and needs are ever changing. Recent commercialization identifies a growing consumer demand; probiotics. Easy enough for the manufacturers, as these microscopic flora have been part of the dairy industry for centuries. What has caused this new attraction to these beneficial products? Knowledge. With all the information available it is easy to see why these products are a good investment; given society is growing more health conscious. According to a conference held by the National Center for Complimentary and Alternative Medicine (NCCAM), specific aims for probiotics include treatment of intestinal irregularities and the prevention of certain infections of the female reproductive tract, cancer recurrence, and atopic dermatitis in children. Microorganisms are naturally found in the human gut and most are beneficial for the digestive process; however, some may have detrimental effects on the human system. Diarrhea is a common

ailment caused by viral or bacterial infections and can be exacerbated by the use of antibiotics. Research has found the most beneficial bacterial strains are those of *Lactobacillus* which remedy digestive disturbances and are known to maintain a healthy environment in the female reproductive system. Lactose intolerance, a condition involving low levels of lactase, can be eased by the ingestion of probiotics which aid in the body's digestion of lactose. A correctly operating digestive system will benefit the immune system by providing vitamins and minerals allowing probiotics to concurrently boost immune defenses. By incorporating probiotics into their products, dairy manufacturers have a chance to boost sales and improve the consumer image of dairy products. According to market reports, the probiotic's sector is expected to increase in the coming years with yogurt and yogurt beverages being the biggest contenders. Continuing education will solidify this growth. Product innovation is a key factor in increasing market share, says the author of the Frost and Sullivan report on the U.S. probiotics market; a market that will continue to expand for probiotics are for a healthy life.

112 No spoon required: The changing face of yogurt. A. J. Koons*, *Pennsylvania State University, University Park.*

Drinkable yogurt is one of the fastest growing food segments in the world. This product is defined as a dairy-based yogurt in a liquid form, usually containing fruit or fruit flavoring. According to Nielsen market research, annual sales of drinkable yogurt from 2005 to 2006 rose 18.4%, with a 2006 value of \$7.76 billion. Drinkable yogurts offer many health benefits that may enhance both digestive and immune functions. The Dannon Company surveyed 565 physicians throughout the nation and found that doctors who regularly discuss nutrition with patients recommended consuming yogurt with live and active cultures. Many studies have demonstrated the health benefits of probiotics found in yogurts and other fermented milk products. Additionally, drinkable yogurts often contain the prebiotic inulin, a natural dietary fiber, which enhances calcium absorption and stimulates the growth of probiotic organisms. Yogurt preferences differ by consumer age and other factors. A study conducted by the University of Helsinki compared the importance of sensory properties of yogurt-type snack foods between the young and elderly. When evaluating the importance of taste, texture, and aroma, the elderly subjects gave taste a 46% importance rating compared to younger subjects who only assigned it an 8% rating. Aroma was the most significant factor in both age groups but was much more important for the younger subjects who rated its importance at 80%. A North Carolina State University study showed that preferences among strawberry drinkable yogurts differed due to ethnicity; however, it was not the sole reason affecting the choice of product. Color, sweetness, aroma, perceived health benefits, and other factors influenced consumer preference. Researchers at Washington State showed that yogurt products provide satiety. They found liquid yogurts and conventional yogurts reduce hunger and increase fullness when compared to fruit drinks and dairy fruit drinks. The popularity of drinkable yogurts should continue to increase as new products are introduced to target specific audiences in the marketplace.

Key Words: Drinkable Yogurt, Probiotic, Prebiotic

113 More than what meets the eye: Labeling of milk. A. L. Pitre*, *Louisiana State University, Baton Rouge.*

Labeling of milk has always been important in the industry; however, over the past few years, it has become somewhat of an enemy to our dairy producers. Labels are extremely important for the saleability of milk and its products. Farmers want the consumer to be informed and want their products to be marketed as to not mislead the consumer. They want the consumer to be able to make an educated healthy choice that is safe for all. Several problems arise in this feat. For example, some companies use what is known as “absence labeling”. In absence labeling, such phrases as “antibiotic free” or “hormone free” appear on the label. This is often found with companies who try to distinguish themselves from others. These “inaccurate” labels have caused a huge uproar in our industry. Some of the labels have little to no scientific research to prove or support what they are trying to sell. Producers that are selling “hormone free” milk are claiming that their milk is bST-free but what about the amount of bGH that naturally occurs in the cow? Even if cows are not injected, a small amount of growth hormone is present in all milk, including organic milk. For more than twenty years, this specific claim has been studied extensively. There are no indications that milk used from treated and non-treated cows is compositionally different. Producers work extremely hard at keeping all food items as safe and healthy as possible. Producers strive to inform the public that all milk is safe and antibiotic free. It is their main goal to produce safe, high quality milk by caring for their cows in order to create a wholesome product. All producers are mandated by the state and federal government and must meet certain standards and pass rigorous inspections. We want all consumers to know that milk is safe and ‘does a body good’. DRINK MORE MILK!!!

Key Words: Milk, Labeling, Food Safety

114 Use of whey proteins in food products. M. Welper*, *Iowa State University, Ames.*

Whey protein is comprised of four main types of protein: β -Lactoglobulin, α -Lactoglobulin, bovine serum albumin, and Immunoglobulin G. They can be extracted from raw milk in a variety of ways, including micro-filtration, ultra-filtration, and ionization. Whey proteins are often added to foods as a binding agent, egg replacement, or as a functional ingredient in products such as ice cream and milk replacer. In addition to these traditional uses, nutrition experts are now investigating the use of whey protein in dietetic and health foods, as well as a key ingredient in infant formulas. Recent research has shown that, when used along with a healthy diet and exercise, whey proteins may have a positive affect on muscle mass, bone density, cardiovascular health, and immunity; also reducing/preventing symptoms of hypertension and type II diabetes. One of the main reasons for these beneficial characteristics may be the protein’s ability to enhance absorption, transportation, and synthesis of several key nutrients, like calcium, in the body’s digestive system. Whey protein also contains a broad array of essential amino acids and immunoglobulins; both of which are critical components in the diets of many teens and adults. The novel uses of whey proteins will not only provide a highly nutritional and versatile food additive but also additional revenue for today’s dairy producers.

Animal Health II

115 Wildlife threat for disease transmission to domestic livestock. S. C. Olsen*, *National Animal Disease Center, Ames, IA.*

The role of wildlife as reservoirs for emerging or re-emerging diseases in domestic livestock has increased in importance over the last decade. Although this review will primarily focus on diseases issues in the United States, disease issues related to the interface between wildlife and domestic livestock are being increasingly recognized worldwide. Pathogens transmitted between wildlife and domestic livestock include viruses, bacteria, and protozoa, which in many instances are zoonotic. For some diseases, wildlife were initially infected from domestic livestock, whereas in others, the disease was most likely endemic in wildlife hosts. Examples of cattle diseases transmitted from wildlife include: brucellosis, tuberculosis, Johne's disease, bovine viral diarrhoea, and neoplasia. Examples in swine, include brucellosis, pseudorabies, influenza, and exotic viruses. Rabies, West Nile, and equine protozoa myelitis (*Sarcocystis neurona*) are examples of diseases transmitted from wildlife to horses. In poultry, influenza and Newcastle's disease are examples. Changes in livestock housing and husbandry practices have influenced transmission of diseases from wildlife. Disease transmission has also been impacted by human recreational activities, changes in land use and demography, and changes in wildlife populations and their behaviour. Current knowledge would suggest that reservoirs of disease in wildlife will continue to impact domestic livestock. New vaccines, diagnostics, treatments, and changes in husbandry/management will be necessary to minimize the economic impact of wildlife diseases on domestic livestock.

Key Words: Disease, Transmission, Wildlife

116 Providing veterinary healthcare to underserved counties in Pennsylvania through credentialed veterinary technicians. D. W. Rensburg*, D. T. Galligan, and J. D. Ferguson, *University of Pennsylvania School of Veterinary Medicine, Kennett Square.*

Providing healthcare and preventative medicine to food animals is critical to maintaining food safety, national biosecurity and farm sustainability. Based on 2006 data obtained from the AVMA and AABP seven Pennsylvania counties (10%) have farms in dairy or beef production without a resident veterinarian in food supply veterinary medicine (FSVM). Based on a profile of Pennsylvania farm size and expected expenditures to bovine veterinarians, counties with at least one FSVM practitioner had a mean veterinary healthcare expenditure of \$1.2 million, \$274,421 per food animal veterinarian. Counties with no FSVM practitioners were assumed to have little or no veterinary service but based on dairy and beef animal numbers, had a potential mean veterinary healthcare expenditure of \$220,729; this represents approximately 80% of the expected expenditures needed to support a veterinarian. Counties with FSVM veterinarians had a mean value of 6,515 total cattle (6,220 beef and 2029 dairy) per vet; counties without FSVM practitioners had on average 7,329 total cattle including 5,757 beef and 1,571 dairy cattle. However, the density of veterinary expenditures was substantially lower in counties without FSVM practitioners (\$383/sq. mile) compared to counties with FSVM veterinarians (\$1,877/sq. mile). This may account for the disparity in veterinary service since veterinarians wishing to

engage in bovine practice would have to travel farther between farms, thereby diluting earnings at each farm. Credentialed veterinary technicians could expand the range of current neighboring practices or be remotely supervised by their veterinary employers in satellite practices. This provides veterinary practices the opportunity to increase the number of farms served and thereby increase their market for high profit margin services or products. Additionally, it provides a cost-effective solution that will ensure Pennsylvania's dairy and beef producers have access to the veterinary healthcare resources required to remain sustainable.

Key Words: Veterinary Technician, Veterinary Shortage, Rural Veterinary Service

117 A Bootstrap method for the estimation of reference intervals of biochemical parameters. C. Dimauro*¹, P. Bonelli², P. Nicolussi², N. P. P. Macciotta¹, and G. Pulina³, ¹*Dipartimento di Scienze Zootecniche University of Sassari, Sassari, Italy,* ²*Istituto Zooprofilattico Sperimentale per la Sardegna, Sassari, Italy,* ³*AGRIS Sardegna, Sassari, Italy.*

Reference intervals are largely used in veterinary medicine being a fundamental element for making clinical diagnosis on animals. The International Federation of Clinical Chemistry (IFCC) recommends the use of both parametric and non-parametric methods to estimate reference intervals. For both methods, the necessary condition is that a sample of at least 120 apparently healthy individuals has to be used. In this paper we suggest a method based on bootstrap procedure to reduce, without losing accuracy, the minimum number of requested apparently healthy individuals to discover reference intervals for biochemical parameters. Bootstrapping is a computer intensive resampling method that allows to estimate the population mean and its standard error (SE). Reference intervals for biochemical parameters are then calculated as $(m \pm 2s) \pm 1.96 \sqrt{(s^2(1/n + 2/(n-1)))}$, where m is the bootstrap mean, n is the sample size and $s = SE \cdot \sqrt{n}$ where SE is the bootstrap standard error. Reference intervals were calculated using a decreasing sample size on a dataset of 14 biochemical parameters measured on 120 apparently healthy Sarda dairy sheep. An example of estimated reference intervals for alanine aminotransferase (ALT) and aspartate aminotransferase (AST) using this approach is shown in table 1. Results suggested that the limits of reference intervals were efficiently estimated until a minimum sample of around 60 animals and began to diverge below this limit.

Table 1: Bootstrap reference intervals and 95% CI (in brackets) for ALT and AST for decreasing sample size in dairy sheep

Sample size	ALT(U/L)		AST(U/L)	
	Reference limits		Reference limits	
	Lower	Upper	Lower	Upper
120	9.4 (7-12)	37.7 (35-40)	63.3(52-75)	212.8(201-224)
80	9.4 (7-12)	37.6 (35-40)	62.7(48-77)	214.8(200-229)
70	9.2 (6-12)	37.7 (35-41)	62.4(47-79)	213.8(198-229)
60	9.2 (6-12)	37.5 (34-41)	63.1(47-80)	211.4(195-228)
50	8.9 (5-13)	38.1 (35-44)	61.4(43-80)	213.0(195-231)

118 Feeding heat-treated colostrum increases IgG absorption in neonatal dairy calves. J. A. Elizondo-Salazar*, A. J. Heinrichs, R. F. Roberts, and M. R. Long, *The Pennsylvania State University, University Park.*

Newborn Holstein heifer calves were studied to compare absorption of immunoglobulins G, total serum protein levels, and T cells from unheated or heat-treated colostrum. First milking colostrum with > 50 g IgG/L (measured by colostrometer) was collected from Holstein cows and frozen at -20°C until a total of 106 L were accumulated. Once collected, colostrum was thawed at 4°C and pooled in a commercial batch pasteurizer to create a uniform batch. Colostrum was thoroughly mixed at 4°C for about 20 min. 53 L of colostrum were transferred into 1.89 L containers and frozen at -20°C until needed for feeding. The remaining 53 L were heated at 60°C for 30 min, transferred into 1.89 L containers, and then frozen at -20°C until needed for feeding. A total of 28 calves weighing ≥ 35 kg at birth were systematically enrolled into 1 of the 2 treatment groups. Calves were separated from their dams at birth before suckling occurred. Before feeding colostrum, a jugular blood sample was collected from each calf. For the first feeding, 3.8 L of colostrum were bottle fed by 1 to 2 h of age. To ensure that all calves received an equal amount of colostrum, an esophageal feeder was used in calves with reduced appetite. For the second and third feeding, pasteurized whole milk at 5% of birth BW was fed. For the remaining time, calves were fed milk replacer (20% CP, 20% fat) at 10% of birth BW in 2 daily feedings until wk 5. Then it was reduced to only a.m feeding until weaning at 6 wks of age. Blood samples were collected, at 24 and 48 h of age and at wk 1 to 6. Serum from samples was used to measure IgG levels, total serum protein and T cells. Calves fed heat-treated colostrum had significantly greater IgG₁ and total IgG concentrations compared with calves fed unheated colostrum. There was no effect of treatment on total serum protein or T cells.

Table 1. Total serum protein and IgG levels.

Age	Total Serum		Protein (g/L)		IgG ₁ (g/L)		IgG ₂ (g/L)	
	Heated	Unheated	Heated	Unheated	Heated	Unheated	Heated	Unheated
24 h	5.6	5.5	21.5 ^a	18.6 ^b	1.1	1.0		
48 h	5.7	5.6	21.2 ^a	18.4 ^b	1.1	1.0

119 Mammary and liver lipogenic gene expression in lactating mice fed diets supplemented with trans-18:1 isomers or t10c12 CLA. A. K. G. Kadegowda*¹, E. E. Connor², B. B. Teter¹, J. Sampugna¹, L. S. Piperova¹, and R. A. Erdman¹, ¹University of Maryland, College Park, ²USDA-ARS, Beltsville, MD.

The coordinated suppression of lipogenic pathways during milk fat depression (MFD) has suggested the involvement of a global regulator of lipogenic gene expression. Recent studies (Peterson et al., 2004; Harvatine et al., 2006) have implicated SREBP1 as the central regulator of fatty acid (FA) synthesis. The objective of this study was to examine the effects of trans-18:1 isomers or t10c12 CLA on mammary and liver lipogenic gene expression in lactating mice. Thirty lactating C57Bl6J mice were randomly assigned (n=5) to 6 diets supplemented with one of the following isomers t-7-, t-9-, t-11-18:1, t10c12-CLA (CLA) or PHVO (partially hydrogenated vegetable oil) from d6 to d10 postpartum (PP). Milk, mammary and liver samples were collected on d10 PP. Expression of genes involved in de novo FA synthesis (ACACA, FASN), desaturation (SCD1, SCD2), triacylglycerol (TG) synthesis (AGPAT), FA uptake (LPL), transcriptional regulation (SREBP1, ChREBP, INSIG1, SCAP, MLX, THRSP) and nuclear receptor signaling (PPARA, PPARG, LXRA, RXR) were tested by qPCR. Milk fat percentage was decreased by CLA (44%; *P*<0.001), t-7-18:1 (27%; *P*<0.001) and PHVO (23%; *P*<0.001), compared to Control. In the mammary gland, CLA decreased (*P*<0.001) the genes related to de novo FA and TG synthesis and desaturation, and genes involved in transcriptional regulation including SREBP1, ChREBP, PPARA and THRSP (*P*<0.05). PHVO and t-7-18:1 decreased the expression of AGPAT, SCD1 and THRSP (*P*<0.05). Similar to CLA, PHVO decreased SREBP1 and PPARA (*P*<0.05), while t-7 up-regulated SCAP and MLX (*P*<0.05). The measured genes were not altered by t-9- or t-11-18:1 in mammary gland. In liver, AGPAT was down regulated (*P*<0.05) with MFD, while expression of other lipogenic genes was not altered. Opposite to mammary gland, CLA up-regulated SREBP1 and PPARA (*P*<0.05) and decreased PPARG (*P*<0.05). The results showed that, in addition to SREBP1, other transcriptional regulators could be involved in milk fat synthesis.

Key Words: Lactating Mice, Trans Fatty Acids, Gene Expression

120 Photoperiod regulates diurnal expression patterns of genes related to immune function in PBMC of heifers. L. E. Lord*, X. S. Revelo, and T. B. McFadden, *University of Vermont, Burlington.*

Photoperiod can be manipulated to enhance efficiency of animal production. Skeletal long day photoperiods (SLD) involve exposure to brief pulses of light during photosensitive periods to mimic long day photoperiods (LD). Thus, SLD could be used to alter photoperiod while minimizing energy costs. We hypothesized that exposure to SLD would elicit changes in gene expression similar to those under exposure to LD. Holstein heifers were exposed to short day photoperiod (SD; 9 h light: 15 h dark; 9L: 15D, n=10) for 3 wk, followed by LD (15L: 9D, n=5) or SLD (2L: 11D: 2L: 9D, n=5) for 4 wk to test for effects on gene expression in peripheral blood mononuclear cells (PBMC). Blood was collected at 0600, 1200, 1900 and 2400h on the last day of treatments. PBMC were isolated to quantify expression of major histocompatibility complex Class I (MHC), indoleamine 2,3-dioxygenase (IDO), and long form prolactin receptor (PRLr) genes, which are photoperiod-responsive and play a role in immune function. Under SD, expression of IDO and PRLr varied during the day (*P*<0.02). Expression of all 3 genes showed significant (*P*<0.07) diurnal variation during exposure to LD or SLD, however expression patterns differed markedly from SD. Expression of MHC and IDO did not differ (*P*>0.16) between LD and SLD treatments

whereas expression of PRLr tended to be lower in SLD compared to LD ($P = 0.09$). These data demonstrate diurnal variation in expression of these 3 genes in PBMC. The similarity of gene expression profiles on SLD or LD suggest that skeletal photoperiods could be used to alter immune function in heifers.

Table 1. Effects of photoperiod and time of day on gene expression in PBMC

		Treatment Means				P-value
		0600h	1200h	1900h	2400h	Time
MHC	LD	0.73 ^a	0.82 ^a	1.55 ^b	0.62 ^a	0.004 ¹
	SLD	1.20 ^a	0.68 ^b	1.30 ^a	0.45 ^b	
	SD	0.67 ^a	1.05 ^b	0.83 ^{ab}	0.79 ^{ab}	0.11
IDO	LD	0.73 ^a	0.75 ^a	1.24 ^b	0.83 ^{ab}	0.007 ¹
	SLD	0.99 ^a	1.16 ^a	1.74 ^b	1.08 ^a	
	SD	1.61 ^a	1.36 ^{ac}	1.01 ^{bc}	0.71 ^b	0.019
PRLr	LD	1.16 ^a	0.98 ^{ab}	0.65 ^b	0.93 ^a	0.07 ¹
	SLD	0.57 ^a	0.65 ^a	0.54 ^a	1.03 ^b	
	SD	0.12 ^a	0.44 ^b	0.52 ^b	0.18 ^a	0.0002

^{a, b, c} Means within a row differ ($P \leq 0.05$); ¹Main effect of time across LD and SLD treatments.

121 Colicin E1 and EDTA have additive antimicrobial effects against *Escherichia coli* isolates in bovine milk. J. M. Scudder^{*1}, C. H. Stahl², and M. R. Waldron¹, ¹University of Vermont, Burlington, ²North Carolina State University, Raleigh.

Colicins are antimicrobial proteins produced by some strains of *E. coli* that are lethal against other strains of *E. coli* and species of bacteria. Milk components, such as calcium and magnesium have been shown to inhibit the activity of antimicrobial peptides; however, the addition of EDTA displaces these cations and destroys the casein micelles. The objective of the current study was to determine the efficacy of purified colicin E1 (ColE1), EDTA, and a ColE1/EDTA combination against a variety of mastitis-causing bacterial strains in several media. A factorial arrangement of treatments was used to test ColE1 and EDTA at concentrations of 0, 100 and 250 μ g/ml and 0, 10 and 20mM respectively, in media, whole, and skim milk. Antimicrobial activity of the treatments was determined after quantification of bacteria at several incubation time-points by serial dilution and direct plating. ColE1 did not inhibit the growth of *Klebsiella pneumoniae*, *Staphylococcus aureus*, or *Streptococcus uberis* in Luria-Bertani media (LB) at a concentration of 250 μ g/ml ($P > 0.50$), eliminating further investigation of antimicrobial effects against those microbes. The antimicrobial effects of ColE1 were similar against both *E. coli* 25922 and *E. coli* P4:O32; thus, the results for these *E. coli* strains were pooled prior to statistical analysis. When *E. coli* were incubated in LB, combinations of ColE1 \geq 100 μ g/ml and EDTA \geq 10mM resulted in killing and complete growth inhibition ($P = 0.02$). In whole milk, combinations of ColE1 \geq 100 μ g/ml and 20mM EDTA resulted in killing and complete growth inhibition of *E. coli* ($P < 0.01$). In skim milk, *E. coli* growth was completely inhibited by 4 hours when 250 μ g/ml ColE1 and 20mM EDTA were added to the growth cultures ($P = 0.02$). Taken together, these results show that

a ColE1/EDTA combination is effective at both killing and inhibiting growth of *E. coli* in bovine milk.

Key Words: Colicin, Antimicrobial, EDTA

122 Skeletal muscle satellite cells do not spontaneously adopt adipogenic fates. J. D. Starkey^{*}, M. Yamamoto, S. Yamamoto, and D. J. Goldhamer, University of Connecticut, Storrs.

Muscle satellite cells are known to play key roles in the growth and maintenance of skeletal muscle tissue. Accumulation of intramuscular adipose tissue is commonly observed in aged and dystrophic skeletal muscle and its abundance is a key factor in determining meat quality. The myogenic regulatory factor, *MyoD*, is involved in embryonic myogenic lineage commitment and is expressed in satellite cell precursors. Recent reports indicate that skeletal muscle satellite cells have the capacity to adopt adipogenic phenotypes in culture. We investigated the myogenic commitment state of skeletal muscle satellite cells in mice using novel Cre/loxP recombination lineage tracing technology. To facilitate the permanent labeling of the vast majority of satellite cells, we developed mice with *Cre recombinase* knocked into the *MyoD* locus (*MyoD^{Cre}*) and crossed them with Cre-dependent reporter mice (*R26R^{EYFP}*) to generate offspring carrying both alleles. Cells from these mice that have expressed the *MyoD* locus constitutively express *enhanced yellow fluorescent protein* (EYFP) from the Cre-recombined reporter locus. Single *extensor digitorum longus* myofibers were isolated from adult *MyoD^{Cre/+};R26R^{EYFP/+}* mice and cultured for 14 d followed by immunocytochemistry to detect labeled (EYFP+) cells. The adipogenic cells observed in single myofiber cultures from adult mice were not labeled, indicating that they had never expressed *MyoD* and were thus most likely not of satellite cell origin. Clonal analysis of individual satellite cells from *MyoD^{Cre/+};R26R^{EYFP/+}* mice revealed that Cre/loxP-labeled cells did not spontaneously differentiate into lipid-filled adipocytes. We did, however, observe lipid accumulation in EYFP+ satellite cell cultures following exposure to 100 μ M γ -linolenic acid for 10 d. These results indicate skeletal muscle satellite cells are committed to myogenesis and do not readily differentiate into lipid-filled adipocytes without exposure to potent adipogenesis-inducing agents.

Key Words: Skeletal Muscle, Satellite Cell, Adipocyte

123 Presence of mammary epithelium modulates expression of growth-regulating genes in stroma of bovine mammary gland. J. G. Titus^{*}, S. B. Simpson, and T. B. McFadden, University of Vermont, Burlington.

The mammary fat pad acts as a paracrine regulator of mammary growth; however, the specific action of this developmental regulation is not completely understood. We hypothesized that epithelial-stromal interaction modulates stromal expression of estrogen- and growth hormone-responsive genes known to regulate mammogenesis. An epithelium-free mammary fat pad was prepared in one gland of each of 20 Friesian calves at 1 mo of age. At 18 mo of age, heifers were assigned to one of four treatments: control (C), estrogen (E), growth hormone (GH) or estrogen plus growth hormone (GE). Heifers in E and GE groups were injected s.c. with estrogen (0.1 mg/kg BW). Heifers in GH and GE groups were injected i.m. with recombinant bovine somatotropin (Posilac[®], 500mg).

Heifers in the C group received no hormone. Heifers were slaughtered 24 h after hormone treatment and stromal tissue was collected from both the epithelium-free (**CFP**) and intact fat pads (**MFP**). Total RNA was isolated from tissues and qualitative PCR was performed to determine expression of five genes in cDNA pooled from each fat pad group. Expression of estrogen receptor (**ER**)- α , transforming growth factor (**TGF**)- β and epidermal growth factor receptor (**EGFR**) mRNA was greater in MFP than CFP (10, 6 and 2 fold difference, respectively). TGF- α and progesterone receptor (**PR**) expression was similar in CFP and MFP. Quantitative real-time PCR was used to measure the rela-

tive expression of ER α and PR in the stroma. Expression of ER α was reduced in CFP relative to MFP ($P < 0.05$), however there was no effect of hormone treatment nor was there an interaction between hormone treatment and tissue type ($P > 0.05$). Neither presence of epithelium nor hormone treatment affected PR expression ($P > 0.05$). We conclude that the presence of epithelium directly affects the stromal expression of several genes involved in regulation of mammary development.

ADSA-SAD (Student Affiliate Division) Undergraduate Competition: Dairy Production

124 WITHDRAWN.

125 Nutrigenomics: A new direction for the dairy industry. D. G. Wilson*, *Pennsylvania State University, University Park.*

Nutrigenomics, the study of how specific dietary nutrients influence gene expression, is a new and exciting science that shows promise of improving efficiency in many areas from milk production to reproduction. Extracting RNA for microarray analyses both before and after a ration change can indicate which genes are up-regulated, or “turned on,” and which are down-regulated, or “turned off,” when new nutrients are added to the diet. In this process, fluid RNA is placed on a computer chip, treated with a special dye, and exposed to a laser. The original microarray is then compared to the microarray completed after the dietary change. Those genes that are up-regulated by the dietary change will fluoresce, and those genes that are down-regulated will turn dark. Several research trials have demonstrated the linkage between nutrients and gene expression. In a Washington State study, cows with supplemented chromium propionate showed improved fat metabolism and increased milk production. When chromium was supplemented to 10 mg/d at measured intakes, milk pounds increased 2.6 kg/d between d 1 and d 90 of lactation, with a 4.6 kg/d increase between d 57 and d 90. McNamara et al determined that these changes were due to the up-regulating of five major genes. Another mineral that offers nutrigenomic promise is selenium. Research studies in mice, poultry, and pigs have shown reduced early embryonic loss and improved antioxidant function in reproductive tissues when diets were supplemented with this mineral. In future years, selection criteria may involve choosing animals who respond most efficiently to dietary changes. New trials involving minerals, fatty acids, and other targeted nutrients will refine our knowledge in this rapidly expanding field. Although this research is still in early phases, especially in dairy cattle, the ability to increase efficiency and profitability through the use of nutrigenomics shows great potential.

Key Words: Nutrigenomics, Chromium, Microarray

126 Genetics of feed conversion efficiency: using a dynamic metabolic model to investigate the patterns of nutrient flux in the most efficient dairy animals. C. Schachtschneider* and J. McNamara, *Washington State University, Pullman.*

Productive efficiency depends on processes such as feed intake and composition, synthetic ability of the mammary gland, and metabolic flux in visceral, muscle, and adipose tissues. These metabolic fluxes are functions of genotype, phenotype, and intake, including hormonal and neural responses. In order to identify patterns of metabolic flux in dairy cattle of varying genetic merit and intakes, an existing mechanistic metabolic model (Molly, UC Davis) was used. Data were collected from 2nd to 4th parity cows, including nutrient intake, milk component output and changes in adipose tissue and body protein (28 d prepartum to 90 DIM). Explicit inputs into the model included nutrient intake, initial body fat and protein, milk production, fat and protein output. Each cow (n = 42) was simulated separately from 0 to 120 DIM and fluxes in body and visceral energy and protein were output. Body fat, body protein

(skeletal muscle) and visceral protein all varied ($P < 0.05$) in their daily flux and overall change from 0 to 120 DIM for the top 20% most efficient versus lowest 20%, based on energy efficiency (absorbed energy/feed energy) during that period. Means (ranges) for all cows were 112 (89 to 139) Mcal/d for intake energy, 32.3 (19.9, 41.9) for maintenance; -0.51 (-1.74, -0.015) for change in body energy; and 0.843 (0.826, 0.862) for Net E efficiency (milk energy/(energy absorbed maintenance E)). These data are consistent with variations in maintenance (body nutrient fluxes) affecting overall efficiency while mammary efficiency approaches the theoretical maxima. Nitrogen intake was 0.66 (0.52, 0.81) kg/d; milk N, 0.21 kg/d (.16, .27), change in body N, -0.016 (-0.06, -0.004), N in urea was 0.31 (.26, .37) and N balance was -0.018 (-0.032, -0.008). Animals varied in non-mammary E and N use, and the model identified ($P < 0.05$) optimal differences in E and N in the 20 % top versus 20 % lowest efficient cows. We can use this approach to help identify the most efficient patterns of metabolism in non-mammary tissues, and eventually alter breeding strategies toward more efficient cows.

Key Words: Lactation, Efficiency, Model

127 The effects of inbreeding in Holstein dairy cattle. M. B. Rhoderick*, D. R. Winston, B. G. Cassell, and K. M. Olson, *Virginia Polytechnic Institute and State University, Blacksburg.*

Inbreeding in the Holstein breed has increased as a result of selection to improve an objective such as type or production for a long period of time. Inbreeding is the mating of related individuals and the concept is based on the probability of two genes being present at a locus that are identical by descent. Inbreeding is measured by the coefficient of relationship among cattle to determine a correlation between inbreeding level and performance traits. Analysis of data from Holstein Association USA, Inc. and the Animal Breeding Center at Cornell University from 1970 to 1998 indicated that the level of inbreeding increased over time. While the rate of inbreeding has declined, there are many negative effects associated with the level of inbreeding. Milk production losses per lactation were 35 kg per percentage of inbreeding greater than 1%. The amount of production lost increased to 55 kg per percentage of inbreeding within the range of 7 to 10%. Longevity of inbred cattle decreased as a result of decreased reproductive efficiency, decreased production and a slight increase in somatic cell score. Therefore, inbreeding has negative effects on management, profits, and cow health. Dairy managers should know the consequences of excessive inbreeding and should implement strategies including better record keeping and outcrossing to keep inbreeding at optimal levels.

Key Words: Inbreeding, Holsteins

128 Colostrum nutrition, immunization, and management when raising young dairy calves. A. Aguiar* and E. Jaster, *California Polytechnic State University, San Luis Obispo.*

Calves require proper nutrition, immunization and management in order to have proper growth and development. Calves need colostrum in order for passive transfer of immunoglobulins to assist the immune

system in resisting pathogens and diseases. With proper colostrum quality and quantity, calves have the ability to fight calf hood diseases. A method to evaluate passive transfer of colostral immunoglobulins is to evaluate serum protein content of calf blood. Relatively high levels of serum protein indicate calves may have received the proper passive transfer of immunoglobulins. Vaccination of calves to provide immunity is necessary to assist the calf in disease prevention. Early intervention and use of vaccines to provide immunization is necessary for calf survival. Vaccines require evaluation by the calf ranch to determine the suitability and immunization efficacy. By providing proper colostrum management, vaccines that provide adequate immunization and proper management, the calf will have the opportunity to survive and grow to its genetic potential.

Key Words: Calves, Colostrum, Vaccine

129 Enhancing fertility with omega-3 fatty acids. J. A. Tekippe*, *Iowa State University, Ames.*

Meeting the energy demand of high producing dairy cattle in early lactation can be difficult and failure to do so affects several physiological functions especially reproduction. Current evidence suggests that dietary supplementation of certain essential fatty acids (FAs), specifically omega-3 FAs, may improve reproductive efficiency in dairy cattle. Feeding supplemental fat provides additional energy, enabling the cow to achieve positive energy balance quicker and return to a normal estrus sooner. Both linoleic (C18:2) and linolenic (C18:3) are essential FAs that must be provided in the diet. Approximately 55% if the FA in flaxseed is linolenic (an omega-3 FA), whereas both soybeans and cottonseed contain 54% and sunflower seeds 68% linoleic (an omega-6 FA). Cows fed diets supplemented with various fats developed larger follicles and subsequently 23% larger corpus luteums (CL) on average. In another study, conception rates following an initial timed AI protocol were greater in cows fed flaxseed (72.6%) than for cows fed sunflower seed (47.5%). Early embryonic loss occurring in the first 28 days post insemination was reduced from 27.3% in cows fed sunflower seed compared to a 9.8% loss in cows fed flaxseed. Cows fed a mixture of omega-3 (linolenic) and omega-9 (oleic) FAs produced 22% more high quality embryos compared to those fed an omega-6 (linoleic) FA. Production of series 2 and series 3 prostaglandins occurs from separate pathways, both utilizing and competing for the same enzymes. Omega-3 FAs are the precursor for series 3 PGs, while omega-6 FAs are the precursor for series 2 PGs. Increasing the amount of omega-3 FAs in a cow's diet should result in the production of more series 3 prostaglandins (PG-3) and proportionately less series-2 PG. Since PG-2 is more biologically active in regressing the CL and reducing progesterone production, a shift from PG-2 to PG-3 should benefit pregnancy. In conclusion, feeding a source of omega-3 FAs such as flaxseed may enhance reproductive efficiency of dairy cows.

Key Words: Fertility, Omega-3, Flaxseed

130 Grazing under irrigation: A novel approach to pasture-based dairying. E. Waggoner*, *Clemson University, Clemson, SC.*

The goal of the dairy industry has been and always will be to efficiently produce milk. This may sound simple, but dairymen will tell you that

this task is not easily accomplished. With increasing feed costs and variable milk prices, it is a battle to make a living as a dairy farmer. At a time when dairies are either commercializing or leaving the industry, many are seeking other options. New methods of increasing efficiency and lowering costs are being explored to promote the survival of smaller farms. Pasture grazing is an appealing opportunity. The Southeastern United States is subject to high temperatures and humidity much of the year. These environmental factors have tremendous negative effects on cattle health and milk production, leaving cows seeking refuge in shade rather than consuming valuable forages. Many producers have made substantial investments in cooling systems; yet, have not addressed decreased forage consumption. A novel way to address both concerns is pasture grazing under irrigation. This form of pasture-based dairying maximizes forage utilization while also managing heat stress. With this plan, cattle are intensively grazed in fields managed by irrigation systems. As the irrigation equipment rotates around the pasture, cows follow the water, enjoying the cooling effects while consuming forages in a strip-grazing motif. Pasture grazing under irrigation provides advantages on a multi-discipline level to increase cattle comfort and milk production while lowering costs associated with confinement farming. Cropland irrigation and heat stress management are essential to farming in the Southeast. This plan integrates and improves upon both ideas. In addition to lower feed costs, improved cattle health, and maximized pasture based milk yield, irrigated grazing provides benefits of natural fertilization and improved field conditions as the cattle move throughout the pasture rather than congregating in one area. Consumers applaud efforts to produce milk in a natural, non-confined method with cow welfare in mind. Pasture grazing with irrigation is the alternative that is needed to make production possible and profitable on the small scale, pasture-based dairy.

Key Words: Grazing, Irrigation, Dairy

131 The natural fertilizer. K. M. Bridges*, *Louisiana State University, Baton Rouge.*

Often manure is thought of as useless waste that should be removed as quickly as possible. It harbors pathogens, smells bad, and just gets in the way. However, manure can be a valuable asset to the farmer. Many of the nutrients in the diet are not all used by the cow, and therefore some are excreted in the manure. These nutrients can be utilized as fertilizer if managed properly. The major nutrients used by plants are nitrogen, phosphorus, and potassium. The average lactating dairy cow excretes approximately 0.8 pounds of N, 0.12 pounds of P, and 0.45 pounds of K. The plant available amounts of these nutrients are mainly affected by storage, distribution, and other handling techniques. Manure can also be composted and sold for landscaping and home gardening, and it can be burned to produce methane, a valuable fuel. There are other management practices that can reduce pathogens, odor, and prevent environmental contamination. These practices include aerobic and anaerobic digestion and wetland production. Without sound waste management practices, environmental contamination may take place. Excess nutrients on cropland may become runoff and contaminate waterways, which could lead to eutrophication. Improper irrigation may cause nutrient buildup in the soil surface or leaching into groundwater. Denitrification of ammonia will contribute to greenhouse gases. There are agencies and regulations in place to prevent this occurrence. Manure, properly managed, is a versatile asset that can be used in many ways to possibly save or even make money for the farmer. If it is improperly managed, its value

decreases and pollution can occur. Therefore, manure, although it is waste, should not be thrown away.

Key Words: Manure, Fertilizer, Nutrients

132 Effects of heat stress and milk replacer strategy on calf growth, starter intake, and fecal scores. L. J. Berger*, G. A. Holub, and J. E. Sawyer, *Texas A&M University, College Station.*

The objective of this study was to evaluate the effects of heat stress and milk replacer strategy on calf performance. Holstein bull calves < 7 d of age were housed in fiberglass hutches in either a moderate heat stress period (MS; May 5 to July 2; n=47) or a high heat stress period (HS; July 25 to Sep 22; n = 43). Within period, calves were fed either a low input (LI; 454 g/d, 20% CP, 20% fat) or a high input (HI; 908 g/d 28% CP, 15% fat) milk replacer program beginning on d 7 until d 56. Calves had ad libitum access to a commercial starter diet and water. Intake of starter diet and fecal scores (1 = firm, 4 = watery) were recorded daily. Body weight was recorded every 7 d through d 56 (pre-weaning) and

from d 56 until d 104 (post-weaning) of each period. Rate of BW gain (ADG) was estimated from the regression of BW on time by calf pre- and post-weaning. Time required for calves to consistently consume starter diet and ADG were compared with heat stress period, replacer strategy, and their interaction as fixed effects. Fecal scores were evaluated as repeated measures with the above effects, time, and all interactions where calf was the subject. Calves fed HI had greater pre-weaning ADG ($P < 0.01$) than LI (0.73 vs. 0.48 ± 0.02 kg/d). Effect of replacer type on post-weaning ADG depended on heat level ($P = 0.03$). Calf ADG was similar for HI and LI during MS, but was greater ($P=0.05$) for HI in HS. More days were required to reach weaning (0.9 kg/d of starter diet for 3 consecutive days) during HS ($P < 0.01$, 39.3 vs. 48.6 ± 0.97). Heat stress, replacer strategy, and their interaction influenced fecal scores. Calves fed HI had higher ($P < 0.01$) fecal scores than those fed LI (2.18 vs. 1.82 ± 0.02). For calves fed HI, fecal scores increased as heat level increased from MS to HS ($P < 0.01$, 2.07 vs. 2.29 ± 0.02), while for calves fed LI fecal scores were similar under MS or HS ($P = 0.56$, 1.81 vs. 1.84 ± 0.03). High input milk replacer strategies resulted in higher calf ADG and appear to mitigate the effects of heat stress on post-weaning growth, despite reducing firmness of fecal matter.

Key Words: Calf, Growth, Nutrition

Symposium: Dairy Foods: Advances in Low Fat Cheese Research

133 Low fat cheese opportunities. J. Montel*, *Dairy Management Inc., Rosemont, IL.*

With over 90% household penetration, cheese is enjoyed by virtually everyone; consumed in everything from pizzas to cheeseburgers, salads and cheese snacks. Cheese is everywhere, both in home and away-from-home. In 2006, per capita consumption of cheese reached an all-time high of 32.4 pounds.

Today food choices are driven by three needs: convenience, taste and health & nutrition. In fact, health is the #1 driver of the food industry world wide. Consumers have certain health needs, whether that is less fat, less calories, less cholesterol or less sugar.

Even though consumers demand fat reduction, they are not willing to sacrifice taste or functionality in the foods they eat. In fact, a recent consumer survey recorded 86% of consumers stating taste as having an impact on their decision to buy foods and beverages. In other words, they want it all - both taste and less fat.

Since 2002, manufacturers have introduced 223 new low/no/reduced fat cheese items in the marketplace - the second highest segment of new product introductions in the cheese category. Despite these efforts low fat and fat free cheese account for only 2% of sales.

How big of an opportunity is good tasting, functional low/reduced fat cheese for the industry? Recent research found that 49% of consumers are interested in purchasing a "great tasting cheese with half the fat". In addition, DMI funded custom research with TNS (a well regarded research company) to quantify the sales opportunity for a great tasting reduced fat cheese with "cheese restrictors" consumers who love the taste of cheese but restrict their consumption because of fat concerns. They would significantly increase consumption of cheese with great tasting low fat cheese products.

In addition to retail opportunities, the foodservice channel offers significant volume especially in the schools channel where cheese could be at risk due to the implementation of wellness policies and the recent Institute of Medicine (IOM) guidelines. Cheese as an ingredient in pizza, sandwiches/burgers and a la carte represent cheese volume that the industry cannot afford to lose. Opportunities also exist within commercial foodservice as operators look to improve the nutritional profiles of menu items as well as create new good-tasting reduced fat menu items.

134 The impact of fat content on flavor of cheddar cheese. M. A. Drake*, *North Carolina State University, Raleigh.*

Consumer emphasis on health and nutrition is driving increased demand for nutritious and lower-fat foods. Despite previous studies on reduced fat cheese, information is critically lacking in understanding the flavor and flavor chemistry of reduced and low fat Cheddar cheeses and how they differs from their full fat counterparts. The objectives of this study were to characterize the flavor and flavor chemistry of low fat, reduced fat and full fat Cheddar cheeses. Cheddar cheeses with 32, 16, or 5 % fat were manufactured in triplicate with a single strain starter culture and ripened for 2 weeks, 3 mo, 6 mo and 9 mo. At each timepoint, cheeses were evaluated by sensory and instrumental volatile analyses. Flavor and volatile components of low fat Cheddar cheeses were distinct from full fat cheeses. Decreases in fat content resulted in decreases in milkfat flavor, higher whey flavor and a decrease in the rate of aged cheese flavor development compared to full fat cheeses. Free fatty acids

(butyric, hexanoic, nonanoic, and decanoic), furaneol, sotolon and saturated hydrocarbons were present at higher concentrations in low fat cheeses compared to full fat Cheddar cheeses while lactones (gamma nonalactone, gamma decalactone, delta decalactone) were predominant in full fat cheeses. Differences between the flavor of low fat and full fat Cheddar cheeses are due to differences in the biochemistry and are not solely a result of differences in volatile flavor compound release.

Key Words: Cheddar Cheese, Flavor, Low Fat

135 Effect of composition on the microbial ecology of low fat cheese. J. R. Broadbent*, *Utah State University, Logan.*

The absence of desirable flavor in reduced fat and low fat natural Cheddar cheeses limits consumer acceptability of these products. Flavor development in bacterial-ripened cheeses like Cheddar is largely a biochemical process that is driven by microbiological activity in the ripening curd. Although knowledge of the relationship between cheese bacteria and flavor development has advanced significantly in recent years, critical information is still lacking on how fat reduction, and corresponding compositional changes in low fat cheese such as lower salt-in-moisture content, influence the microbiology of cheese. Specific knowledge of how fat reduction influences the microbial ecology of cheese could lead to the identification of methods to enhance flavor development in low fat products. The objective of this work was to characterize microbiological differences in Cheddar cheeses containing 32 (full), 16 (reduced), or 5 % (lowfat) fat (wet wt). Cheeses were manufactured in duplicate at 3 locations with a single-strain *Lactococcus lactis* starter culture and ripened at 8°C. After 2 wks, 3 mo, 6 mo and 9 mo, the cheeses were sampled for starter and nonstarter lactic acid bacteria (NSLAB), and DNA was collected from cheese and cells for analysis by denaturing gradient gel electrophoresis (DGGE) of 16S rDNA fragments. Microbiological data showed interesting differences between cheeses made with different fat contents at all 3 sites. First, starter populations remained stable out to 3 mo in low fat and reduced fat cheeses before showing any decline, but in full fat cheese generally declined by at least 2 orders of magnitude by 3 mo. Additionally, NSLAB levels in low fat cheese exceeded 10⁶ by 6 wks, but populations in most reduced or full fat cheese did not attain that level even after 3-6 mo. DGGE studies are still ongoing, but results to date suggest the NSLAB fraction of all cheeses includes *Lactobacillus curvatus*, but several other species of bacteria have also been identified. A more complete understanding of the relationship between fat content and cheese microbiology should provide greater insight into the problems, and potential solutions, related to flavor development in lowfat Cheddar cheese.

Key Words: Lowfat Cheese, Cheese Microbiology, Nonstarter Bacteria

136 Effect of composition on the microbial metabolism of low fat cheese. J. Steele*, *University of Wisconsin, Madison.*

Low-fat cheeses differ significantly from that of their correspondent full fat varieties with regard to flavor. If we are to understand these

flavor differences, an understanding of how changes in cheese composition influences the structure and metabolism of the cheese microbiota is essential. Changes in chemical attributes during ripening such as simple and modified carbohydrates, organic acids, nucleic acids, serine-phosphate (free and bound), and glycoproteins; as well as starter culture enzyme activities: general aminopeptidase activity (AP), X-prolyl dipeptidyl aminopeptidase (PAP) and post-prolyl endopeptidase (PEP) were studied in cheeses made at 3 different dairy plants. Cheddar cheeses made with full, reduced and low fat content as well as the inclusion of a washing step in the making of the full fat cheeses were chemically analyzed. An HPLC method for the extraction and analysis of trace level carbohydrates was developed. Carbohydrate profile shows that as fat levels decreased, the levels of lactose and galactosamine and D-Lactate increased, however, only slight decreases of enzyme activities (PAP and PEP) were observed. Soluble nitrogen had no apparent change as fat content was decreased. The effect of the wash step decreased the levels of lactose, galactosamine and glucosamine from the available energy sources in cheese, yet only slight increases in heterofermentative products were observed, suggesting that the washing step did not remove all the energy sources available for the starter and non-starter bacteria present in these cheeses. Overall, this research demonstrates that the carbohydrates present to support microbial growth and metabolism differ in Cheddar cheese in a fat-dependant manner. These changes may influence the structure and metabolism of the cheese microbiota and hence cheese flavor.

Key Words: Low Fat Cheddar Cheese, Energy Sources, Microbiota

137 Impact of fat content on cheese texture. E. A. Foegeding*, *North Carolina State University, Raleigh.*

Fat is a key component in cheese as it impacts flavor and texture. However, there is a desire to produce reduced fat foods as a way to lower overall caloric intake. Therefore, the ultimate goal is to manufacture a cheese with a reduced level of fat while maintaining a desirable level of flavor and texture. A common problem in low fat cheeses is that the texture becomes rubbery with minimal breakdown during chewing. This implies that a basic understanding of what regulates the rheological and fracture properties of cheese microstructure may shed some light on how texture can be improved. There are two models that may explain the microstructural basis of texture. A filled gel model predicts that texture is based on the amount of filler particle, if the filler particle interacts or does not interact with the gel network, and the relative ratio of the network and filler particle rigidities. In this model, the casein gel network surrounds the fat particles. An alternative model is that of a closely packed system. In this model, protein particles are tightly packed with lipid particles. It is also possible to view cheese as starting out as a filled gel then being converted to a closely packed particle system when moisture is removed during manufacturing. Cheddar cheeses were manufactured containing 32%, 16% or 6% fat, and aged for 9 months. Sensory texture and fracture/rheological properties were determined initially at 2 weeks, then at 3, 6, and 9 months. The results from this investigation on cheddar cheese, along with published investigations on other cheeses, will be discussed based on filled gel and closely packed particles models.

138 Effect of fat reduction on the functional properties of slice on slice process cheese. L. E. Metzger*¹, S. Chandran¹, C. R. Daubert², M. Yurgec², and S. Ramsey², ¹*South Dakota State University, Brookings,* ²*North Carolina State University, Raleigh.*

A common form of process cheese called slice on slice (SOS) is manufactured using a chill roll or chill belt which forms and cools the molten cheese into a thin sheet; then cuts and stacks the slices into a loaf. As a result of machineability issues, low fat process cheese is not produced using a SOS manufacturing process. The objective of this research was to characterize the effect of fat reduction on the functional properties of SOS process cheese. Four process cheese formulations were developed including: full fat (30% fat); 25% reduced fat (22.5% fat); 50 % reduced fat (15% fat); and low fat (6.00% fat). Each formulation utilized the same skim milk natural cheese (1.4% fat) as the primary ingredient. Each formulation also contained 12% aged Cheddar cheese, was standardized to 2.2% salt, and was standardized to the appropriate fat content with butter oil. Each formulation was prepared on a small scale using a rapid visco analyzer to determine their cooked apparent viscosity. The cooked apparent viscosity of each formulation was similar and ranged from 3,149 to 3,328cP. Each formulation was then prepared in a Stephan Universal Cooker on a larger scale (1,500 g) and the rheological properties of each formulation were evaluated. Rheological analysis included: small deformation, compression, torsion, and tack. Rheological analysis demonstrated that the torsion stress, compression stress, tack extension, and tack energy significantly ($P < .05$) increased as the fat content decreased. These results demonstrate that fat reduction impacts the functionality of SOS process cheese. Subsequent research will evaluate the effect of formulation modifications on the functionality of SOS process cheese.

Key Words: Process Cheese, Low Fat

139 Advances in nonfat/lowfat process cheese for melting and ingredient use. J. A. Lucey*, *University of Wisconsin, Madison.*

In recent work at the University of Wisconsin, we have investigated various approaches to improving the melting and baking properties of lowfat/nonfat process cheese (PC). We have developed a novel approach to solve some of the critically important defects in lowfat/nonfat cheese. These defects include poor color, excessively hard or sticky texture, scorching during baking and surface skin formation. The first critical step is to manufacture a skim curd cheese base that has suitable properties for process cheesemaking. One method is to use direct acidification of skim milk to pH 5.6 with a calcium chelating agent, such as citric acid. This base could be used for process cheesemaking the same day of manufacture or stored and used within a few weeks to produce a softer, more meltable PC performance. In our method, we do not use any phosphate or citrate salts to chelate calcium. The acidification of base with citric acid is sufficient to reduce the crosslinking of caseins in curd formed by calcium phosphate. High concentrations (>0.5%) of traditional emulsifiers, such as mono- or diglycerides, are added to alter casein interactions. This produces a nonfat (or lowfat if the glycerides are included in the estimation of total fat) PC that has a white color and slices easily. The slices are not sticky. The cheese shreds easily, melts and flows during baking, maintains a white color during heating and after cooling and is bland in flavor. Another important benefit is this

product can be classified as a low sodium cheese as the only sodium that is added is what is added as a salt (preservative) in the base. This approach can also be used for lowfat natural cheese (e.g. Mozzarella) as the Nutrition Labeling and Education Act (NLEA) (21CFR 130.10) allows the addition of nonstandard ingredients to improve the texture of lowfat versions as long as the cheese is nutritional equivalent to the standard version. These novel approaches are very promising for producing lowfat or nonfat cheeses that have excellent functional properties for ingredient use.

Key Words: Lowfat Cheese, Process Cheese, Functionality

140 A novel technology for making lowfat cheese. N. Y. Farkye* and M. Arnold, *California Polytechnic State University, San Luis Obispo*.

Low fat Cheddar cheese containing less than 6% fat was manufactured by combining pre-determined portions of ripened full fat or reduced-fat Cheddar and/or enzyme-modified cheese with freshly made nonfat Cheddar cheese using novel mixing and stuffing technologies to produce a uniform product. Under normal conditions, mixing two streams of curds results in uneven distribution and mottled appearance of finished cheese. This technique results in cheese with a uniform appearance. Pasteurized and pre-acidified nonfat milk was used to make Cheddar-type cheese using commercial mesophilic lactic starter and Chymax™ as coagulant. After coagulation and cutting, the curd was cooked to the desired firmness and whey drained. The curd was mixed with pre-chopped ripened cheese or enzyme-modified cheese to provide flavor, then salted. Ingredients to help hold moisture may be added. Salted curds were pressed in Wilson-style cheese hoops for block cheese or stuffed into casings for logs. Both methods of curd treatment produced acceptable cheese. Finished cheese had characteristic flavor of the ripened cheese used in blend.

Key Words: Lowfat Cheese, Blending

141 Alternative manufacturing protocols for low fat cheese. M. Johnson*, *University of Wisconsin, Madison*.

Manufacturing protocols for cheese are often dictated by time and cost of manufacture. How the cheese will be used and shelf-life requirements also impact how the cheese should be made. Consequently, manufacturing methods that produce a cheese suitable for one application may not produce a cheese that fulfills the requirements for another. In addition, natural cheese used directly as a snack food, referred to as “table cheese”, is often made differently than a cheese that will be used as an ingredient. Cheese making technologies for low fat cheese have generally fallen into two categories; firstly, substantial acidification of the milk prior to rennet addition followed by either whey dilution or curd rinsing with cold water and secondly, limited acidification prior to rennet addition and limited water addition or curd rinsing. Major differences in both body and flavor characteristics can result depending upon which method is used. Slight modifications to both manufacturing methods include milk or cream homogenization, high pasteurization temperatures and addition of fat mimetics or whey protein aggregates. To reduce the cost of manufacture, standardization of milk through use of concentrated milk solids is commonly practiced and has introduced additional challenges but has also provided opportunities. This presentation will describe the preliminary results on the use of different acidulants, and characteristics of low fat cheese made without use of acidulants. A combination of lactic acid and citric as an acidulant enhanced softening and smoothness of body compared to just lactic acid but a curd rinse may be necessary to prevent making a cheese with excessively low pH. Cheese made using a non-wash method was prone to excessive acidity. However, the body and flavor of this cheese may be better for certain applications compared to a wash-curd cheese.

Symposium: ADSA Southern Section Symposium: Responding to Hot Topics in Dairy Management

142 Biosecurity: Dealing with problem diseases. K. E. Olson*, *KEO Consulting, Schaumburg, IL.*

Biosecurity has always been important for the dairy industry, but it is a term that has expanded in meaning and come into the national consciousness in recent years. The reemergence of bovine tuberculosis and economic impact that a limited number of cases of bovine spongiform encephalopathy (BSE) has had in the U.S. and Canada, as well as the devastation that BSE and foot and mouth disease inflicted on the livestock industry in the United Kingdom, coupled with concerns over potential terrorist actions have been major drivers. There are national as well as individual farm components to biosecurity that need to be considered, but the ultimate goal regardless of the implementation level is to adopt practices that will prevent the introduction of disease causing agents. The primary producer focus must be on the farm level application of a biosecurity program that will help to address diseases of potential concern to their operation such as Leukosis, BVD, bovine tuberculosis and Johne's disease. Expanding operations and changing management practices increase the need for planning in this area. While some components are common to most biosecurity plans and are effective against multiple diseases, it is important to work with a veterinarian to develop a program suited to the individual operation. The presentation will explore trends in adoption of various practices commonly used. Factors to be considered in developing individual plans include diseases currently present on the operation and their prevalence, the risk of introducing other diseases, practices that are effective in limiting the potential of introducing or spreading the diseases of concern. Plans must be reviewed periodically to assess their effectiveness, with modifications made as needed. Properly implemented, farm level biosecurity plans will assist the operation in addressing their concerns while also complementing national plans that help to limit risk for all producers.

Key Words: Biosecurity, Farm Plan

143 Defending against mycoplasma mastitis. J. C. Beagley and M. W. Overton*, *University of Georgia, Athens.*

Mycoplasma is a unique class of pathogenic and nonpathogenic bacteria which lack a cell wall. Bovine mycoplasma diseases include mastitis, pneumonia, arthritis, otitis, genital infections, and keratoconjunctivitis. A variety of mycoplasmas have been isolated from infected mammary glands including *M. californicum*, *M. bovis genitalium*, *M. canadense*, and *M. alkalescens*, but *Mycoplasma bovis* is considered to be the most common and pathogenic species and its isolation from dairy herds has increased in recent years. Generally considered a contagious mastitis pathogen, differences between mycoplasma and other contagious pathogens have raised questions regarding the epidemiology of this disease. Introduction of infected animals into a herd is believed to be the most common source of new infections, but other clinically important sources include hematogenous spread from other body sites such as the respiratory or urogenital tract. These sites may serve as sources for other herd mates or for autoinfection in the mammary gland. Once established, mycoplasma mastitis can be highly contagious and rapidly

spread through a herd when inadequate control measures are utilized. Strict milking hygiene should be employed to reduce transmission risk and all herd additions should be properly screened. On-going herd surveillance including regular monitoring by bulk tank and individual milk cultures is important. Sensitivity of bulk tank cultures will depend upon how many cows are infected, degree of shedding, and method of culture. Multiple, repeated cultures should be taken before declaring an animal or a herd as negative. Positive cultures should be speciated in order to differentiate pathogenic from non-pathogenic mycoplasmas and acholeplasma. Once identified in a previously uninfected herd, string and individual sampling should be done to identify positive animals. Infected animals should be culled or segregated from uninfected herd mates to prevent further spread. The appropriate management approach utilized will depend upon how many animals are affected, the risk tolerance of the herd owner, and economics at the time of diagnosis.

Key Words: Mycoplasma, Mastitis

144 The use of distillers grains in dairy cattle diets. D. J. Schingoethe*, *South Dakota State University, Brookings.*

Distillers grains with solubles (DGS) is the major coproduct of ethanol production, usually made from corn, which is fed to dairy cattle. Distillers grains is a very good protein source (>30% CP) high in ruminally undegradable protein (~55% of CP), and is a very good energy source (NEL ~2.25 Mcal/kg of DM) for lactating cows. The modest fat concentration (10% of DM) and readily digestible fiber (~39% NDF) contribute to the high energy in DGS. Animal performance was usually similar when fed wet or dried products, although some research results tended to favor the wet products. Diets fed to dairy cattle can contain DGS as replacements for portions of both concentrates and forages, but usually replace concentrates. If replacing forages in lactating cow diets, adequate effective forage fiber is needed to avoid milk fat depression. With adequate forage fiber, milk fat content is not affected by any level of DGS feeding. Nutritionally balanced diets can be formulated that contain 20% or more of the diet dry matter as DGS. Such diets supported similar or higher milk production than when cows were fed traditional feeds. There is usually no advantage of feeding more than 20% DGS because the diet may contain excess protein and phosphorus, although production performance was very high even with more than 30% dried DGS in the diet. With more than 20% wet DGS in diets containing other moist feeds, gut fill may limit DM intake and production. While DGS can be fed with all forages, milk production may be slightly higher with alfalfa rather than corn silage, possibly due to an improved amino acid balance. The fiber in DGS, which often replaces high starch feeds, does not eliminate acidosis but minimizes its problems. Distillers solubles, which are often blended with distillers grains to provide DGS, can be fed separately such as "condensed corn distillers solubles". Additional distillers coproducts besides DGS are resulting from innovations in processing technology. Besides condensed distillers solubles, other products will include high protein DG, low fat DG, corn germ, and other products that can be utilized in dairy cattle diets.

Key Words: Distillers Grains, Dairy Cattle

145 Challenges of improving dairy cow fertility during summer heat stress: An ovum's perspective. J. L. Edwards*, *University of Tennessee, Knoxville.*

Since pregnancy is requisite for milk production, infertility in cows experiencing summer heat stress is an important economic problem facing the dairy industry. In spite of the widely accepted magnitude of this problem, progress towards developing a solution has been greatly hampered due to the multitude of factors and physiological processes altered by heat stress. This may explain in large part why a single strategy like modifying cow environment and/or use of other management protocols such as timed AI are not entirely beneficial for restoring fertility. Heat-induced reductions in fertility are pronounced when cows

experience heat stress at or near the time of estrus and are due in large part to direct effects of elevated temperature to compromise the maturing ovum and early embryo. While dependent on severity and duration, negative effects of heat stress on the maturing oocyte are concerning as the ovum contributes half of the genetic material and >99% of cytoplasm to the resulting embryo. In this presentation, data will be presented for providing new insight as to the specific processes within the maturing ovum that are altered by heat stress, consequences thereof and possible strategies for increasing dairy cow fertility. In addition, thermolability of the few embryos that do develop after fertilization of heat-stressed ova will be discussed.

Symposium: ALPHARMA Beef Cattle Nutrition and Beef Species Joint Symposium: Producing Quality Beef in a Bio-Based Economy

146 ASAS Centennial Presentation: Development and current issues of a corn-based beef industry. L. R. Corah*, *Certified Angus Beef LLC, Wooster, OH.*

The development of a beef industry, heavily dependent on corn utilization, began to occur in the 1940s. Started as a means to add value to the grain while improving consumer acceptance of beef, corn has become an integral part of beef production. Developments in the 21st Century—including unprecedented cattle prices, changes in beef demand, BSE, surge in energy costs, pricing differentiation of cattle prices based on quality, and industry consolidation—have dramatically changed the price of corn and cost of beef production. The future of the beef industry will be dependent on our ability to continue producing high-quality beef for a global market through effective use of genetics, new technologies, and economic management strategies.

Key Words: Corn, Feedlot, Beef Quality

147 Feeding strategies to reduce corn use. R. H. Pritchard*¹, D. D. Loy², and D. L. Boggis³, ¹*South Dakota State University, Brookings,* ²*Iowa State University, Ames,* ³*Kansas State University, Manhattan.*

The equilibrium among industries competing for corn grain has been disturbed by the dramatic increase in demand for corn use in ethanol production. The current situation differs from previous episodes of high corn prices in that there will be a long term increase in corn usage rather than a short term decrease in corn supply. This will alter cropping plans and reduce access to alternative grains. Biofuels development will increase competition for fats and oils, high fiber feeds, and the amount, form, and cost of ethanol by-products available. Having alternative feedstocks more available to substitute for corn in finishing diets will likely be the exception rather than the norm in many situations. These alternatives will often contain less energy than corn and limitations may exist on dietary substitution levels. Corn is substituted for roughage in finishing diets to increase ADG and to reduce feed/gain. In doing so, the corn per unit of live weight gain (LWG) increases. We can increase final diet roughage from <10% to levels of 20% or 30%, and achieve high growth rates and produce high Quality Grade beef. This requires access to a roughage source and imposes logistical challenges to larger capacity feedlots where most cattle are fed. We can reduce the corn/LWG by 8 to 10% by switching from rolled corn to steam flaked corn. Other potential savings in corn/LWG can be found in managing grain processing \times roughage source \times roughage level interactions. In older cattle (> 18 mo) reducing the targeted ribfat endpoint at harvest from the current 1.5 cm to 1.0 cm will greatly reduce corn use per unit of retail product; but would be less effective in younger cattle. While implants cause increased intake and final BW, they along with other technologies, effectively reduce corn/LWG. The most dramatic effects in reducing corn usage will come from extensive cattle production systems that increase the amount of growth occurring outside the feedlot. This will likely coincide with a change in the genetics and phenotype of cattle as well as a reduction in total beef cow numbers.

Key Words: Beef, Feeding, Corn

148 Environmental considerations of feeding bio-fuel co-products. N. A. Cole*¹, M. S. Brown², and J. C. MacDonald³, ¹*USDA-ARS-CPRL, Bushland, TX,* ²*West Texas A&M University, Canyon,* ³*Texas AgriLife Research, Amarillo, TX.*

The high concentrations of some nutrients in distiller's grains (DG) make formulation of diets difficult and can lead to environmental concerns. These concerns will differ with feedlot location, feedlot size, diet formulation, and grain processing method used. Feeding DG in dry-rolled corn-based diets (DRC) does not apparently affect DM digestion or total DM excretion; whereas, with steam-flaked corn-based diets (SFC) the feeding of DG decreases DM digestibility. With SFC-based diets the quantity of pen manure collected increased about 10% for each 10% increase in dietary DG concentration (DM basis); whereas it increased 0 to 7% with DRC-based diets. With SFC-based diets, the N and P concentrations of collected manure were not affected by feeding of DG. Phosphorus excretion (and acres of cropland required for manure removal) increases approximately 10 to 25% for each 10% increase in dietary DG concentration. The effects of feeding DG on subsequent ammonia emissions may vary with season and dietary N concentrations. In our studies, N volatilization as a percentage of N intake, decreased about 20% when DG was fed (15 or 20% of DM); however, because of greater N intake, total N volatilization losses (kg/steer) were not affected. During production and storage, DG emit volatile organic compounds (VOC) that could potentially contribute to odors or ozone formation. High sulfur concentrations in DG could affect animal health as well as emissions of hydrogen sulfide and other odorants. British and Nebraska studies suggest that feeding of DG can decrease enteric methane production in high-roughage diets; however, the effects in high-concentrate diets are not known. To our knowledge, the effects of feeding DG on excretion of physiologically active compounds (antibiotics, hormones, etc.) have not been studied. In conclusion, it appears that the feeding of DG may have environmental effects that need to be considered when determining ingredient value and optimal diet formulations.

Key Words: Distiller's Grains, Beef Cattle, Environment

149 Precursors to enhance marbling. S. B. Smith*, J. E. Sawyer, R. D. Rhoades, and M. A. Brooks, *Texas A&M University, College Station.*

The overall process of lipid synthesis in marbling (intramuscular; i.m.) and s.c. adipose tissues is similar in that both incorporate the same long-chain fatty acids into neutral lipids, and both adipose tissues synthesize fatty acids *de novo* from acetate and glucose. However, the relative rates of incorporation of specific fatty acids, acetate, and glucose differ markedly between adipose tissue depots. Oleic acid (18:1n-9) and linoleic acid (18:2n-6) are incorporated into lipids in s.c. adipose tissue at nearly twice the rate observed in i.m. adipose tissue. Thus, any dietary treatment that increases absorption oleic or linoleic acid may promote adiposity of s.c. adipose tissue disproportionately. The rate of synthesis of lipids from acetate *in vitro* is as much as 10-fold greater in s.c. than in i.m. adipose tissue. However, the overall metabolism of glucose (to CO₂, lactate, and fatty acids) typically is greater in i.m. than in s.c. adipose tissue and, in i.m. adipose tissue, glucose can be the predominant *de novo* precursor

of fatty acids *in vitro*. Recent investigations have demonstrated that, as adipose tissue depots mature, response to insulin *in vitro* is reduced. In 24-mo-old, corn-fed steers, insulin had no effect on the incorporation of glucose into lipids in s.c. adipose tissue, but stimulated lipid synthesis from glucose in the less mature i.m. adipose tissue. In adipose tissues of hay-fed steers fed to the same BW as corn-fed steers, insulin was completely without effect on the conversion of glucose to lipid. The same pattern was confirmed in 16-mo-old, corn-fed steers, in that insulin nearly doubled the rate of glucose incorporation into lipids in i.m. adipose tissue, but had no effect in s.c. adipose tissue. Feedlot steers fed dry-rolled corn (DRC) plus 30% wet distillers grains (WDG) had nearly three times as much fecal starch as steers fed steam-flaked corn (SFC) plus 30% WDG. Marbling scores were greater in carcasses of steers fed DRC (540) than in steers fed SFC (496). These data indicate that greater passage of starch into the small intestine may increase free glucose absorption which in turn may stimulate insulin secretion; this would promote i.m. adipose tissue development.

Key Words: Beef Cattle, Marbling, Precursors

150 Post-harvest strategies to enhance beef quality. J. O. Reagan*, NCBA, Centennial, CO.

Producing a consistent, high quality beef product has been identified in beef quality audits as a primary key to increasing customer satisfaction and consumer demand. Improving beef quality traits, such as tenderness, flavor and juiciness, is complex as these traits are influenced by genetic and environmental factors (nutrition, health, management) at the production level, harvest and post-harvest management strategies and cooking methodology. While efforts are being made to improve beef quality through genetic evaluation and marker assisted selection, the primary pre-harvest strategy to enhance beef quality has been to utilize extended feeding periods on highly concentrated grain diets. Increased grain prices, driven partially by increased demand for grains from the biofuels industry, bring doubt to whether this feeding strategy will be economically viable in the future. Numerous post-harvest technologies have been utilized over the years with the primary target being the improvement of tenderness. Early technologies included post-mortem aging to increase protein degradation through enhanced enzyme activity, altering the rate of carcass chilling to prevent cold-shortening of muscle fibers, and mechanical tenderization to physically cut myofibrils via processes such as grinding and blade tenderization. High- and low-voltage electrical stimulation have been used to increase pH decline, to enhance the aging process and to create physical tearing of muscle fibers. Cutting and muscle stretching strategies have also been employed to increase

sarcomere length through pre-rigor stretching. More recently, injection or marination of beef with enzymes, calcium, phosphates, salts, and anti-oxidants have been used to chemically tenderize beef by enhancing degradation of connective tissues or by increasing pH and water holding capacity. Continued high feed prices will potentially reduce beef quality due to reduced energy levels in diets and shorter feeding periods making post-harvest beef quality enhancement processes even more critical to maintaining consistent supplies of high quality beef.

Key Words: Beef, Quality, Post-Harvest

151 ASAS Centennial Presentation: Using grain and biomass for feed versus fuel. J. Lawrence*, Iowa State University, Ames.

Agriculture is amidst one of the largest changes since the move from horses to tractors. Ironically, as Ray points out, when we adopted petroleum we took land that was used to produce fuel for work animals or woodlots to heat our homes and moved it to food production. Currently, the US and the rest of the world are emphasizing renewable energy. This policy shift, reflected in the 2007 Energy Bill, grew out of a perfect storm of higher oil prices, national security interests since September 11, 2001 and lobbying efforts from agriculture and environmentalists. The mandated targets in the Energy Bill of 36 billion gallons a year of renewable fuels with 15 billion gallons coming from conventional (grain) sources by the year 2022 is an aggressive goal, but there is construction, earth moved and announcements made to reach these goals a decade ahead of schedule if economics cooperate. The demand for biofuel feedstock that was formerly feedstuffs is driving up prices for grains, forages and the land to produce them. Yet, in spite of near record high corn prices in early 2008, red meat and poultry production is forecast to be at record high levels. The impacts for animal agriculture will vary from producers to consumers. While feed cost is often 50-70% of animal production cost, it is typically less than 20% of the retail meat price and meat is a fraction of the consumer's food bill. Economics will serve as governor on the pace of ethanol expansion and will dictate the size of the livestock and poultry production sector in the future. The economic interactions are complex and given time and technology will find a new equilibrium where we produce both food and fuel, but in perhaps a different ratio than we have in the recent past. Economic modeling to date shows a rather modest change in long-run livestock and poultry production. This paper will discuss the winners and losers, and potential unintended consequences?

Animal Health III

152 Stress and Immunity: Implications on animal health and production. J. A. Carroll^{*1}, T. H. Elsasser², J. C. Laurenz³, R. D. Randel⁴, J. L. Sartin⁵, and T. H. Welsh, Jr.⁶, ¹*Livestock Issues Research Unit, USDA-ARS, Lubbock, TX*, ²*Growth Biology Laboratory, USDA-ARS, Beltsville, MD*, ³*Department of Animal and Wildlife Science, College of Agriculture, Natural Resources and Human Sciences, Texas A&M University System, Kingsville, TX*, ⁴*Texas AgriLife Research and Extension Center, Texas A&M System, Overton, TX*, ⁵*Department of Anatomy, Physiology & Pharmacology, College of Veterinary Medicine, Auburn University, Auburn, AL*, ⁶*Departments of Animal Science and Veterinary Integrative Biosciences, Texas AgriLife Research, Texas A&M System, College Station, TX*.

Throughout their production cycle, domestic livestock experience various stressors and varying magnitudes of stress that inhibit health and productivity. As researchers have continued to explore the complex interactions between stress and production parameters such as growth, reproduction, and health, multidisciplinary efforts emerged that have led to a greater understanding of homeostatic regulation. Based upon these efforts, our knowledge has extended beyond the “all or none” biological activity strictly associated with the “fight or flight” response. For instance, researchers have demonstrated that the combined immunological effects of glucocorticoids and catecholamines result in a well-orchestrated biological event designed to prevent over-stimulation of innate immunity and the production of proinflammatory cytokines while simultaneously priming the humoral immune response in an effort to provide adequate immunological protection. The perception of stress in domestic animals has evolved as well, now including indices such as environmental stress, nutritional stress, social stress and prenatal stress. Animal stress is now identified as a unique event that elicits a specific behavioral, physiological, neuroendocrine, endocrine, and/or immune response that may be as unique as the stressful event itself. Additionally, there has been an increased effort to elucidate the interactions between stress responsiveness and immunological parameters in animals that may be either predisposed to or resistant to the detrimental effects of stress due to genetic programming and/or prior experiences. Of particular interest are animals that demonstrate differential stress and immunological responses due to previous exposure to various managerial, environmental, nutritional, or pathogenic stressors or due to varying temperaments within a genetically similar group of animals. Continued research efforts into these complex interactions may allow the implementation of alternative management practices, improved selection programs, and/or implementation of various nutritional strategies to prevent or overcome significant production losses and animal health care costs for livestock producers.

Key Words: Stress, Immunity, Health

153 Neck rails improve udder and stall hygiene but increase risk of lameness. F. Bernardi^{*1,2}, J. Fregonesi^{1,3}, C. Winkler², D. M. Veira⁴, M. A. G. von Keyserlingk¹, and D. M. Weary¹, ¹*University of British Columbia, Vancouver, BC, Canada*, ²*University of Natural Resources and Applied Life Sciences, Vienna, Austria*, ³*Universidade Estadual de Londrina, Londrina, PR, Brazil*, ⁴*Agriculture and Agri-Food Canada, Agassiz, BC, Canada*.

Housing conditions for dairy cows are thought to affect lameness but almost no experimental work has addressed this link. The aim of the

current study was to assess the effect of one feature of free stall design, the position of the neck rail, testing the prediction that cows housed in pens with neck rails would spend less time standing inside the stall and have reduced gait scores relative to cows housed in pens without neck rails. Cows (n = 32) were housed in 8 pens. Treatments were tested using a crossover design; treatments were allocated alternately to pen at the beginning of the experiment and switched half way through the 10-wk experiment. Cows spent approximately 30 min /d standing with all 4 hooves in stalls without neck rails, but almost never performed this behavior when neck rails were present. Instead, cows in pens with neck rails spent more time spent standing with only the front 2 hooves in the stall. Over the 5 weeks on each treatment, gait scores worsened for cows kept in pens with the neck rail compared to pens without. Of 13 new cases of lameness 11 occurred in pens with neck rails. Similarly, of the 16 new cases of sole lesions, 15 occurred during the period when cows were housed in with neck rails. Stalls without neck rails were 9 fold more likely to be contaminated with fecal matter and urine, and cows using those stalls had 30% dirtier udders and 15% longer teat cleaning times. This study provides the first experimental evidence that aspects of stall design can reduce the risk of lameness and hoof disease. The results also illustrate that changes in design that result in improvements in cow comfort and hoof health can come at the expense of cow and stall cleanliness.

Key Words: Lameness, Udder Hygiene, Stall Design

154 Cytokine secretion in periparturient dairy cows naturally infected with *Mycobacterium avium* subsp. *paratuberculosis*. E. L. Karcher^{*1}, D. C. Beitz¹, and J. R. Stabel², ¹*Iowa State University, Ames*, ²*ARS-USDA, National Animal Disease Center, Ames, IA*.

Johne's disease, caused by *Mycobacterium avium* subsp. *paratuberculosis* (MAP), has a devastating impact on the dairy industry. Cows typically are infected as neonates, and stressors, such as parturition, may induce the transition from the subclinical to a more clinical stage of disease. The objective of this study was to characterize cytokine secretion in periparturient dairy cows naturally infected with MAP. Twenty-five Holstein cows were classified according to infection status into three groups consisting of 8 noninfected healthy cows, 10 subclinical cows, and 7 clinical cows. Peripheral blood mononuclear cells (PBMCs) were isolated and cultured at 1.4×10^6 cells/mL with either medium alone (nonstimulated, NS), concanavalin A (ConA), or MAP whole cell sonicate (MPS). Culture supernatants were removed and analyzed by ELISA to detect the secretion of IFN- γ , IL-4, IL-10, and TGF- β . Production of IFN- γ by MPS-stimulated PBMCs was greater ($P < 0.01$) in subclinical cows compared with control cows and tended to be greater ($P < 0.11$) than in clinical cows. Similarly, when PBMCs were stimulated with either ConA or MPS, IL-10 secretion was greater ($P < 0.04$) in subclinical cows compared with controls. In contrast, secretion of IL-4 by MPS-stimulated PBMCs was greater in clinical cows compared with control ($P < 0.004$) and subclinical cows ($P < 0.04$). There was a tendency for NS PBMCs from infected cows to have increased secretion of TGF- β compared with the control, but secretion of TGF- β by ConA and MPS-stimulated PBMCs was not affected by infection group. Parturition evoked significant effects on cytokine secretion with observed increases in IFN- γ , IL-10, IL-4, and TGF- β , depending upon infection status of the cows and the in vitro stimulant used. Results of this study indicate that in dairy cows the secretion of

many key cytokines is modulated by natural infection with MAP and by the periparturient period.

Key Words: Cytokines, Periparturient, *Mycobacterium avium* subsp. *paratuberculosis*

155 A clinical trial evaluating MorindaMax™ Calf® immune-supplement on health and performance of preweaned, Holstein, heifer calves. V. J. Brooks¹, T. J. Paulus¹, T. DeWolfe¹, R. G. Godbee², S. F. Peek¹, S. M. McGuirk¹, and B. J. Darien*¹, ¹University Wisconsin, Madison, ²University Nevada, Reno.

Neonatal calves are at high risk for disease as their immune system is developmentally immature and incapable of mounting an adequate response to infectious pathogens. While adequate colostrum intake and properly used antibiotics can provide much protection for the neonate, increased antibiotic scrutiny and consumer demand for organic products has prompted investigations of natural immunomodulators for enhancing calf health and production. The objective of this clinical trial was to evaluate the effects of MorindaMax™ Calf® on health and performance of preweaned, Holstein heifer calves on a commercial calf-raising farm. MorindaMax™ Calf® is a commercially-available supplement for bovine neonates made from the *Morinda citrifolia* (noni) fruit. Noni is a natural product that has a broad range of immune-enhancing effects including: antibacterial, anti-inflammatory, anti-tumorigenesis, anti-oxidant and anti-fatigue activity. Two formulas (A and B; n=143) were tested against a control group of newborn calves (n=73). Calves received 0, 15 or 30 ml q 12 hr of either formula for the first 3 weeks of life. The effect of formula type on weaning age, weight gain, morbidity and mortality were analyzed through weaning (~5-8 weeks). Calf health was evaluated through daily physical exams which were recorded as health scores and dictated whether the calf required medical treatment or not. Results demonstrated a significant increase in number of calves weaned by 6 weeks of age that had received 15 ml q 12 hr of formula A relative to control calves. Additionally, calves receiving 30 ml q 12 hr of formula B had a significant reduction in respiratory, gastrointestinal and total medical treatments required relative to control calves. Early weaning and fewer required antibiotic treatments may result in monetary savings for the farmer through the production of healthier animals that require less time and treatments in the preweaning stage.

Key Words: MorindaMax, Immune-supplement, Calves

156 Effect of weaning strategy on immunological, hematological and physiological responses of beef calves. E. M. Lynch*^{1,2}, B. Earley¹, M. McGee¹, and S. Doyle², ¹Teagasc, Grange Beef Research Centre, Dunsany, Co. Meath, Ireland, ²National University of Ireland, Maynooth, Co. Kildare, Ireland.

The effect of weaning strategy on immunological, hematological and physiological responses was determined using 36 beef calves (276, s.d. 37.0 kg). Following abrupt weaning, calves were either 1) housed (WH) immediately in a slatted floor shed and offered grass silage *ad libitum* and supplementary concentrates or 2) remained at pasture (WP) and housed on day 35 post-weaning. Blood samples were collected by jugular venipuncture at weaning (day (d) 0) and on d 2, 7, 14, 21, 28, 35 (housing), 37, 42, 49 and 56. Plasma fibrinogen and haptoglobin concentration, in vitro interferon- γ (IFN- γ) production, plasma cortisol

and dehydroepiandrosterone (DHEA) concentration, total leukocyte number and subsets were determined. Plasma fibrinogen and haptoglobin increased ($P < 0.05$) in WH and WP calves for 21 d post-weaning. Post-housing, fibrinogen decreased ($P < 0.05$) and haptoglobin was unchanged ($P > 0.05$) in WP calves. IFN- γ production decreased ($P < 0.01$) in WH calves post-weaning, whereas no change ($P > 0.05$) was observed for WP calves post-weaning or -housing. Total leukocyte number decreased ($P < 0.05$) by d 7 post-weaning in WH calves and did not return ($P < 0.001$) to pre-weaning baseline, whereas in WP calves, it increased ($P < 0.01$) until d 21 post-weaning and subsequently decreased ($P < 0.02$) post-housing. Neutrophil number in WP calves increased ($P < 0.02$) on d 2 and d 7, whereas lymphocyte number was unchanged from d 0 to d 7. Neutrophil number in WH calves decreased ($P < 0.05$) on d 14 until d 56 whereas lymphocyte number increased ($P < 0.05$) on d 21 to d 56. Plasma cortisol increased ($P < 0.05$) from pre-weaning baseline to d 21 in WH and WP calves, but was unchanged ($P > 0.05$) in WH and WP calves from d 28 to d 56. Plasma DHEA was unchanged ($P > 0.05$) throughout the study. In conclusion, abrupt weaning altered leukocyte populations and acute phase protein profiles in WH and WP calves. The lower circulating leukocyte count and reduced IFN- γ response observed for WH calves suggests that abrupt weaning may be exacerbated by immediate housing.

Key Words: Weaning, Immunity, Cortisol

157 Dietary Colicin E1 prevents experimentally induced post-weaning diarrhea but does not provide a growth promoting effect. S. A. Cutler¹, N. A. Cornick¹, S. M. Lonergan¹, and C. H. Stahl*², ¹Iowa State University, Ames, ²North Carolina State University, Raleigh.

Post-weaning diarrhea (PWD) causes significant economic losses to the U.S. swine industry despite the use of antibiotic prophylaxis. While the dietary addition of sub-therapeutic levels of antibiotics is used for disease prevention, it has also been suggested to have an independent growth promoting effect. In a proof of concept study, we have demonstrated that dietary inclusion of Colicin E1 is effective in preventing PWD. In the current study, we examined the efficacy of dietary supplementation with Colicin E1 in preventing PWD using a seeder pig model as well as in promoting growth independently of a disease challenge. Eight pigs were orally inoculated with 10^9 CFU of an ETEC strain isolated from piglets with PWD. Two animals (paired by body weight) that exhibited severe diarrhea two days post-inoculation were placed into pens of piglets that were either fed a basal diet or the basal diet plus 20 mg Colicin E1/kg. An additional group of littermates were fed the same diets, in the absence of the ETEC challenge to investigate the effect of dietary inclusion of Colicin E1 alone. In the first week of exposure to the seeder animal, the challenged control animals gained less weight ($P < 0.05$) than the Colicin E1 treated pigs. A trend existed for lower body weight in the challenged control animals as compared to the Colicin E1 fed pigs at weeks 2, 3, and 4 ($P < 0.1$). No significant differences in body weight between the control and Colicin E1 fed non-challenged pigs were seen at any point in the study, nor were there differences in body weight between the challenged Colicin E1 fed animals and the non-challenged animals. In the first week after the seeder challenge, 4 of the control animals lost weight and two of those pigs lost more than 10% of their initial body weight. In total, over 75% of the control pigs had PWD by the end of the first week of the study, compared with 30% of the Colicin E1 fed pigs. Dietary addition of Colicin E1 is effective in preventing PWD under industry relevant conditions; however, no

growth promoting effect in the absence of a disease challenge was seen in this experiment.

Key Words: Post-weaning Diarrhea, Pig, Bacteriocin

158 Effects of PCV2 vaccine on growth performance and mortality rate of pigs in a PCV2-positive commercial swine herd. J. Y. Jacela*, S. S. Dritz, M. D. Tokach, J. M. DeRouchey, R. D. Goodband, J. L. Nelssen, R. C. Sulabo, and J. R. Bergstrom, *Kansas State University, Manhattan*.

A total of 1,470 pigs (8.8 kg) were used in a swine farm with a history of Porcine Circovirus Disease (PCVD) to evaluate the effects of two commercial Porcine Circovirus Type 2 (PCV2) vaccines on growth and mortality rates. The first vaccine was administered a week after weaning (1-dose; Suvaxyn™ PCV2 One Dose, Fort Dodge®) while the second was administered at weaning and three wk later (2-dose; Circuvent™ PCV, Intervet®). A group of unvaccinated pigs served as a control group. Individual weights were taken at d 0 (weaning), 113, 143, and 152 (off-test). Pigs commingled during the growing period. A subsample of necropsied pigs had histopathologic lesions associated with PCVD. On d 113, the 2-dose group was heavier ($P < 0.05$) than the control group (86.5 vs 82.5 kg) with the 1-dose group intermediate (85.4 kg). At d 143, both the 1-dose and the 2-dose pigs were heavier than the control pigs by 3.4 and 4.6 kg ($P < 0.05$), respectively, with the two vaccinated groups not significantly different. The 2-dose group was heavier ($P < 0.05$) than the controls (120.2 vs 116.4 kg) while the 1-dose group was intermediate (118.8 kg) at off test. Weight gap between vaccinates and controls were smaller at off-test compared to d 143 due to a wider on-test days variability as a result of multiple marketing days. The 1-dose and 2-dose groups had greater ADG ($P < 0.05$) compared to the controls from d 0 to 113 (676 and 689 vs 653 g), d 0 to 143 (717 and 726 vs 694 g), and at off-test (726 and 735 vs 703 g). From d 113 to 143 and off test, ADG between groups were not different suggesting that the increase in growth rate in vaccinated pigs occurred from d 0 to 113. No significant difference in mortality rates between treatments were observed but each vaccinated group had numerically lower mortality than control pigs (7.8 and 7.7 vs 11.0%). Both vaccines in this trial were effective in mitigating the effects of PCV2 virus on growth performance of pigs in a PCV2-positive herd.

Key Words: PCVD, PCV2, Vaccine

159 Effect of feeding *Mucuna pruriens* to sheep on helminth parasite infestation in lambs. C. M. Huisden*, A. T. Adesogan, J. M. Gaskin, C. H. Courtney, A. M. Raji, and T. Kang, *University of Florida, Gainesville*.

Mucuna pruriens is a tropical legume anecdotally reputed to have anthelmintic properties. The aim of this study was to determine if ingestion of *Mucuna* seeds reduces helminth parasite infestation in lambs. Thirty-six Dorper x Katahdin ram lambs (\pm 6 months old, 28.8 \pm 5 kg body weight) were dewormed subcutaneously with levamisole (2 ml/45.4 kg), balanced for fecal egg counts and body weight, and randomly allocated to 3 treatment groups. The 12 lambs in each treatment group were randomly assigned to 4 pens, each containing 3 lambs. All lambs were fed ad libitum amounts of an isonitrogenous (14% CP), isocaloric (64% TDN) total mixed ration in which the main protein supplement was cotton seed

meal or *Mucuna*. Treatments consisted of a control diet, a diet in which *Mucuna* replaced cotton seed meal and a further treatment that involved administering levamisole (2 ml/45.4 kg) to lambs fed the control diet. Lambs were adapted to diets for 2 wk and trickle infected three times per wk by gavage with infectious *Haemonchus contortus* larvae (2000 larvae/lamb) for 3 wk. Subsequently, 2 lambs per pen were necropsied and the third lamb was grazed on bahiagrass pasture for 14 d and then necropsied. Levamisole treatment decreased fecal egg counts by 87% (58 vs. 445 eggs/g) and abomasal worm counts by 83% (1170 vs. 202 worms/lamb). *Mucuna* intake did not affect fecal egg counts (412 vs. 445 eggs/g) or abomasal worm counts (958 vs. 1170 total worms), though a numerical ($P \geq 0.10$) reduction was evident. Neither levamisole nor *Mucuna* treatment affected anemia indicators [FAMACHA (2), packed cell volume (32.4%) and blood protein (6 g/dl)], daily feed intake (2.5 kg), final body weight (37.9 kg), average daily gain (0.31 kg/d) and dressing (48.8%). *Mucuna* intake did not reduce infection in lambs fed a high quality diet. Pathological signs of infection were obscured, most likely by a combination of well balanced rations and lambs of breeding known to be at least somewhat inherently resistant to this parasite as compared to highly improved breeds. Future studies should examine if *Mucuna* exhibits anthelmintic properties in more susceptible lambs fed poorer quality diets.

Key Words: *Mucuna*, *Haemonchus*, Anthelmintic

160 The effect of the synthetic glucocorticoid dexamethasone on clock gene expression in bovine neutrophils. S. J. Nebzdoski*, L. M. Nemeč, and T. F. Gressley, *University of Delaware, Newark*.

Glucocorticoid induced suppression of neutrophil function contributes to cattle disease. Although circadian rhythms drive immune function in other species, the role of circadian rhythms on bovine neutrophil function is unknown. A study was conducted to determine the influence of the synthetic glucocorticoid dexamethasone (dex) on circadian rhythms of gene expression in bovine neutrophils. Six Holstein steers averaging 225 kg were injected with either saline (control) or dex (0.1 mg/kg BW). One wk later the opposite treatments were administered. Photoperiod was controlled with lights on at 0700h and off at 1700h which roughly coincided with the natural sunrise and sunset. Neutrophils were collected from blood sampled by jugular catheters at 0, 4, 8, 12, 16, 20 and 24h following administration of treatment. Quantitative real-time PCR was used to determine mRNA expression of *L-selectin* and multiple clock genes including *Bmal1*, *Clock*, *Per1*, *Rev-erb α* and *CK1 ϵ* relative to the expression of the housekeeping genes *RPS9* and β -*actin*. A mixed model was used to quantify the effects of treatment (dex vs. control), time (0, 4, 8, 12, 16, 20, 24h) and their interaction on gene expression. Treatment affected expression of *L-selectin*, *Clock*, *Per1* and *Rev-erb α* ($P < 0.001$) and tended to affect *Bmal1* ($P = 0.07$). Relative to the control treatment, dex decreased expression of *L-selectin* 2-fold, *Bmal1* by 14%, *Clock* by 79% and *Rev-erb α* by 47%. Expression of *Per1* increased 26-fold. Time affected *Clock*, *Per1*, *Rev-erb α* and *CK1 ϵ* ($P < 0.01$). Expression of *Clock*, *Per1* and *CK1 ϵ* peaked at 4h and reached a nadir at 24h. *Rev-erb α* expression peaked at 4h and was lowest at 16h. An interaction between treatment and time was found for *Clock* and *CK1 ϵ* ($P \leq 0.001$). Relative to the saline treatment, dex depressed *Clock* expression at all times with the greatest difference at 8h and the least difference at 20h. Additionally, *CK1 ϵ* expression increased at 4 and 8h but decreased at 20h after dex treatment ($P \leq 0.05$). Glucocorticoid induced changes in circadian rhythms of gene expression may be important in regulating the functionality of bovine neutrophils.

Key Words: Clock Genes, Dexamethasone, Neutrophils

Symposium: ASAS Cell Biology: The Role of MicroRNA on Cell Function

161 MicroRNA: Mechanism of gene regulation. T. G. McDaneld*, USDA/ARS U.S. Meat Animal Research Center, Clay Center, NE.

MicroRNA (miR) are a class of small RNAs that regulate gene expression by inhibiting translation of protein encoding transcripts through activation of a specific cellular pathway. The small RNA classified as miR are short sequences of 18-26 nucleotide long, encoded by nuclear genes with distinctive properties that comprise 1-5% of known genes. During processing from the primary transcript, the mature miR sequence is loaded into an RNA:protein complex known as the "RNA induced silencing complex" (RISC). The sequence of the miR loaded in the complex targets the RISC to specific binding sites in the 3'UTR of mRNA transcripts, resulting in either degradation of the miR:mRNA complex or translocation to P-bodies. In either case, association of RISC with mRNA causes decreased translation of the targeted gene product. Approximately 40% of genes have transcripts that are potential targets for miR, suggesting that miR play an important role in multiple cellular processes. A single miR can target numerous distinct mRNA for decreased translation, and as a result miR appear to be intimately involved in developmental decisions including cell fate, cell cycle progression, apoptosis, adipocyte differentiation, and processes that alter muscle development and growth. Implication of miR in such a wide array of cellular processes has increased interest in evaluating miR in multiple biological models.

Key Words: MicroRNA, Gene Regulation

162 Role of MicroRNAs in hepatocarcinogenesis in an animal model. K. Ghoshal*, J. Datta, and H. Kutay, *Ohio State University, Wooster.*

In the post-genome era lot of effort has been expended to elucidate the function of noncoding regions of the genome that was previously considered as "junk DNA". Majority of these DNAs codes for RNAs ranging in size from ~100 to ~10,000 nucleotides. MicroRNAs (miRs) are ~21-nucleotide-long RNA that regulate expression of protein-coding genes by post-transcriptional mechanisms. Most of these miRs, highly conserved among animals, function by base pairing with the 3'-UTR of mRNA resulting in translational repression or mRNA degradation. MiR genes transcribed by RNA polymerase II, can be intergenic, intronic or polycistronic. Primary miRNAs are processed by ribonucleases to mature miRs. Like mRNAs, some miRs are ubiquitously expressed whereas others are tissue specific. Each miR targets several mRNAs, which in turn, are regulated by multiple miRs, underscoring their complex regulatory role. MicroRNAs are involved in every aspect of biology that include differentiation, development, immune response, drug resistance etc. Aberrations in microRNA expression appear to play a causal role in different disease processes including cancer. Studies from several laboratories have shown that microRNA signature is altered in

primary hepatocellular carcinomas that can be used as a prognostic marker. In an animal model of diet-induced hepatocarcinogenesis we have shown that miR expression profile in the rodent liver tumors is quite similar to those in humans. Some miRs are deregulated an early stages of tumorigenesis implicating their role in preneoplastic transformation of hepatocytes. Currently we are pursuing potential role of some of the deregulated miRs in hepatocarcinogenesis.

Supported, in part, by grants CA122694 and CA086978 from NIH.

163 MicroRNAs in the ovary and female reproductive tract. L. Christenson*, M. Carletti, S. Fiedler, L. Luense, and X. Hong, *University of Kansas Medical Center, Kansas City.*

Post-transcriptional gene regulation plays a vital role in male and female germ cell function, but our understanding of this regulatory process in somatic cells and its impact on reproductive tissue development and function is not understood. In mammalian cells, microRNAs (miRNA) are key post-transcriptional regulators and function primarily by modulating translation of their target mRNAs. Mature miRNAs are synthesized through a multi-step process that concludes with the cleavage of stem-loop pre-miRNAs by the RNase III enzyme, Dicer. To understand the role of miRNA mediated post-transcriptional gene regulation in somatic cells of the female reproductive tract and in ovarian granulosa cells, mice with loxP insertions in the Dicer gene were crossed with mice expressing Cre-recombinase driven by the anti-Mullerian hormone receptor-2 (AmhR2) promoter. Female *Dicer^{fl/fl};AmhR2-Cre* mice (n=6) mated to fertile males failed to produce offspring. Mating was confirmed, thus estrus and presumably normal follicular estrogen synthesis occurred in these mice. General morphological and histological evaluation of these tissues indicated that the oviduct and uterus were half the size of their littermate controls and a severe disruption of the oviductal lumen at the utero-tubal junction was evident. Ovarian function was also not normal in the *Dicer^{fl/fl};AmhR2-Cre* mice as evidenced by reduced ovulation rates and the relative absence of corpora lutea. To further understand the role of miRNAs in the ovulatory process, expression of ovarian granulosa cell miRNAs, before (0 h) and 4 h after the luteinizing hormone (LH/hCG) surge was evaluated. More than 200 miRNAs were detected in granulosa cells and 15 of these exhibited differential expression ($P < 0.05$). Three miRNAs, miRNA-21, -132 and -212 exhibited a pronounced (7.5 to 20-fold) up regulation in response to in vivo hCG treatment. Subsequent in vitro studies with granulosa cells and antagonists (i.e., anti-mirs and complementary LNA primers) to these specific miRNAs has implicated these miRNAs in regulation of apoptosis and general translation control. This work is supported by NIH grant HD051870.

Symposium: Bioethics: Value of Bioethics Leadership for Food Animal Agriculture

164 Bioethics across the disciplines: Leadership and mutual respect. G. Varner*, *Texas A&M University, College Station.*

What must philosophers and animal scientists do in order to work productively together in the debate about animals ethics issues? A clarion call from animal scientists to philosophers was given by David Fraser in his 1999 article "Animal ethics and animal welfare science: bridging the two cultures." Fraser argued that several features of what he called "type 1 philosophy" had driven a wedge between philosophers and animal scientists. He described "type 1 philosophy" as endorsing a monolithic and individualistic moral principle, and as tending to lump together diverse animals and diverse practices involving them. Fraser held up as examples of "type 1" philosophy both Tom Regan, who is a rights theorist, and Peter Singer, who is a utilitarian. I agree that good philosophical leadership in the discussion of animal ethics requires us to avoid the problems that Fraser identified, but in this presentation I will stress that this does not require us to abandon utilitarian thinking in ethics. On the contrary, the two-level utilitarianism of R.M. Hare (who happens to have been Peter Singer's dissertation advisor) can endorse a diverse and context-sensitive set of what Hare called "intuitive level" rules. As a result, diverse animals and practices will not be "lumped together" and decisions about animals will sometimes involve conflicting principles, some of them focused at the population- or ecosystem-level. This must surely be a welcome result from the animal scientists' perspective, since defenders of agriculture and other uses of animals so often use utilitarian arguments. For their part, what must animal scientists do? For one thing, if they are going to think like utilitarians, then they must take seriously questions about animal consciousness. For utilitarianism is a sentientist doctrine: it ascribes intrinsic value to positive states of consciousness. So to apply utilitarian reasoning to our treatment of animals, animal scientists will have to include references to consciousness in their definitions of animal welfare. They must also be willing to admit that traditional assumptions about various practices could turn out to be mistaken. For while utilitarian thinking has an inherent conservative bias - insofar as all of the costs of proposed reforms must be taken into consideration-utilitarian thinking can also ground revolutionary changes, especially over the long haul.

Key Words: Ethics, Animal Science, Utilitarianism

165 Bioethics: The need for leadership and how societies should respond. M. G. Hogberg*, *Iowa State University, Ames.*

The symbiotic relationship between people and animals is well documented over time. As societies in the developed countries have changed from agrarian to industrial, consumer expectations on how and where animal are raised and used have also changed. This paper will focus on trends in society that impact animal agriculture and implications for professional societies in the animal agriculture field. Professional societies have a responsibility to create, distribute and use knowledge to meet society goals and do this in a socially responsible manner. In addition, societies have a role in providing science-based information to consumers and policy makers. Specific examples will be discussed on pro-active approaches that societies can do to meet the challenges of social responsibility in the area of bioethics.

166 Bioethics: The need for leadership and how the societies should respond. M. P. Lacy*, *University of Georgia, Athens.*

More and more scrutiny is being given to the use of animals in research and teaching. The use of animals for almost any reason (food, companionship, exhibit, etc.) has been questioned by some from an ethical perspective. Animal, dairy and poultry scientists obviously are trained and most interested in the science of animals, their production and use. We have left the discipline of ethics to philosophers. Bioethics is a complex, controversial and polarizing subject. Its origins go back at least to the Nuremberg War Crimes Trial, but recent advances in human medicine including stem cell therapies, cloning, genetic screening, etc. have resulted in accentuated attention to this area. Although bioethics has primarily focused on research or medical treatment related to humans, some want to apply bioethics to any living organism that can sense pain or fear. Physicians have found it necessary to insert themselves into the debate regarding medical bioethics. Likewise, animal, dairy and poultry scientists will have to venture into the debate regarding ethical use of animals. Doing so will be neither easy nor pleasant. Critics will claim we cannot be unbiased in such a debate, and it will be challenging to counter such arguments. Most of us believe the use of animals for research, instruction, food and companionship is certainly ethical, and it is difficult for some of us to see another side to the debate. As I consider the future of our disciplines and industries, it appears the next generation of animal, dairy and poultry scientists will have to be as well educated in ethics as in science. It will be important that these future scientists be trained and prepared to counter the argument that they are biased about the ethics of animal use simply because they are trained as animal, dairy or poultry scientists. Professional societies will need to continue to strive to be involved in the bioethics debate and provide unbiased, science based information just as they are involved today in controversial issues such as animal welfare, environmental protection and food safety.

Key Words: Poultry Science, Bioethics

167 ASAS Centennial Presentation: Role of industry leaders in addressing bioethical issues. J. W. Lauderdale*, *Lauderdale Enterprises, Inc., Augusta, MI.*

Food animal agriculture has numerous organizations recognized as providing leaders to address bioethical issues associated with food animal agriculture, such as: production, processing, marketing, production and health products, news media, and research and extension. This presentation is limited to the animal agriculture commercial organizations (Animal health companies) supplying products to enhance animal productivity and animal health. Animal health and productivity products reach the market only following exhaustive research and development (science) and approval by national and worldwide regulatory bodies (science in the USA through the Food & Drug Administration, Center for Veterinary Medicine). Until the 1990s, leaders in the commercial industry relied on science to defend products to enhance animal productivity and animal health. However, in the 1990s bioethics began to be used in discussions as to what products are "acceptable from a bioethics perspective", with bovine somatotropin being an excellent example. Currently, declaration of ethics associated with animal agriculture is promulgated primarily from academically based and advocacy groups

in the USA. Therefore, commercial industry leaders must become proactively engaged in bioethical issues in order to influence direction and outcome of decisions regarding bioethical issues that will influence food animal agriculture. If such engagement is based on understanding both the science and bioethics of the issues, with commitment to understand and act responsibly, leaders from animal health companies will contribute positively to the advancement of food animal agriculture. Such contribution will enhance the ability to provide animal products that are safe to consume, are produced consistent with environmental preservation, are produced in a manner consistent with bioethics, and are in sufficient quantity and quality to meet the increasing world population demand for animal derived foods.

Key Words: Bioethics, Food Animals, Industry Leadership

168 Summary and perspective from within. D. J. R. Cherney*,
Cornell University, Ithaca, NY.

Post-World War II changes in society and government policy led to drastic changes in animal production in the United States. Animal scientists led the way with better production systems, better breeding, better vaccinations, and better health care. Lifestyles of our society changed, leading to greater leisure time, and greater time to reflect on societal ills. Production efficiency has continued to increase, but at what costs? Do our societies and animal industries pay attention to societal needs, including animal welfare, worldwide food shortages, environmental pollution problems and ethics? Our animal sciences have undergone drastic changes in the ways we do science and the questions we research. The background of the people in our societies has changed. Our leaders in industry and the animal societies have been catalysts for some of these changes and will need to continue to be at the forefront of these issues to keep our industries viable in this ever changing world.

Key Words: Bioethics

Symposium: Breeding and Genetics: Training of Future Animal Breeders

169 Training graduate students in animal breeding: A historical prospective. E. J. Pollak*, *Cornell University, Ithaca, NY.*

The training of animal breeding students has historically been based on the blending of information from basic and population genetics, statistics, and animal science. Statistics provided breeding students with the foundation in methods of estimation of effects and variance components and modeling strategies for varying types of phenotypes (e.g., continuous, categorical or survival data). Genetics provided foundations in understanding of the biology of inheritance, of additive and nonadditive effects and population theory for selection. Animal science provided the biological understanding of traits within our domestic species of interest as well as insight into industry needs, management practices, and constraints. The advent of a computer science curriculum provided for the skills to develop computational tools for analysis of data to meet research needs, especially in cases where large volumes of data are analyzed. Concepts and tools from these disciplines were brought together in animal breeding courses that focused on developing and implementing strategies for genetic assessment, selection and mating plans. What changed over the decades of training students in animal breeding were not the foundation disciplines but rather the nature of the information gleaned from those disciplines and from the changes in technology for implementing animal breeding plans. Focus in this presentation will be on understanding the history of educating animal breeding students in quantitative genetics theory with an eye on how this history should guide us into the future given the impending large impact of molecular biology on animal agriculture and particularly on opportunities for application in animal selection.

Key Words: Training, Animal Breeder, Quantitative Genetics

170 Graduate education utilizing distance learning. R. M. Lewis*¹, B. B. Locke¹, M. S. Ames¹, R. M. Enns², J. M. Rumph³, T. W. Wilkinson¹, and E. J. Pollak⁴, ¹*Virginia Tech, Blacksburg*, ²*Colorado State University, Fort Collins*, ³*Michigan State University, Lake City*, ⁴*Cornell University, Ithaca, NY.*

Graduate-level education in animal breeding and genetics is in a state of dilemma: there are too few faculty members with expertise in this discipline at individual institutions to provide comprehensive training. A potential solution is an inter-institutional distance education curriculum. A consortium of universities is attempting to address this challenge by developing seven online courses to supplement Masters degree-level instruction in existing degree programs. The choice of courses was based on a national survey. In total 125 faculty members from 46 land-grant institutions were contacted, and nearly 50% responded. Feedback was sought on the extent and comprehensiveness of graduate-level training in breeding and genetics at their institution, and whether modularized online courses might offer a vehicle for addressing gaps in their program. Ninety-three percent of respondents believed online courses were an acceptable method to deliver advanced training, and 86% believed that a comprehensive distance learning curriculum was needed. The ADDIE instructional design model - analyze, design, develop, implement, evaluate - is being used for course construction. Evaluation is

central. In addition to student evaluations, each course will undergo review by four content experts, two from outside the consortium, and a specialist in instructional design. In order to be sustainable, the curriculum requires an organizational infrastructure. Thus, another aim is to coordinate partner institutions in the accreditation, delivery and cost-recovery of the resulting curriculum. The structure established will be designed to encourage participation of other institutions in the development of additional distance learning courses. Thus far two courses have been prepared, with one taught and the other in progress. Twenty students from 11 universities have participated in each course. Feedback has been very positive. The inter-institutional sharing of distance education programming appears to be a viable strategy to meet student, industry and academic needs for advanced training in animal breeding and genetics.

171 Challenges of training quantitative graduate students. I. Misztal* and J. K. Bertrand, *University of Georgia, Athens.*

Acute shortage of quantitative geneticists (QG) in animal breeding has occurred in the U.S.; therefore, despite recruiting efforts, including those by professional companies, demands are not met. This is because the supply of quality graduates is low.

The QG shortage is partly a result of a past shift in funding from quantitative to molecular genetics. Consequently, new types of training were needed, notably in lab techniques. Now, as the molecular information becomes available through commercial products, the lab experience is less important, and the training required by current molecular geneticists has de facto become similar to those of quantitative geneticists. In particular, future success in the hot area of genomic selection will be largely dependent on scientists with quantitative skills: manipulating the genomic information requires quantitative skills and good genomic EBV requires good conventional EBV.

Several steps should be taken to provide more and talented graduates for animal breeding in QG. Currently, the supply of QG Ph.D. candidates is limited and those applying often have limited background and motivation. One way of increasing the number of U.S. candidates is to substantially raise scholarships, at least to a level comparable to that paid at EU institutions. Many generic courses fail to excite students and specialized courses with low enrollment lack the critical mass. Replacement of these courses by short courses with specific focus can provide strong motivation to excel due to peer competition, while also creating a social environment among graduates from different institutions. As a student can easily be overwhelmed by too many courses, some semesters need to be designated for short courses only, and a mechanism to provide credits to students from non-home institutions needs to be worked out. Finally, much larger competitive, special grants, and industry (including matching funds) QG funding should be made available to interested faculty, to provide incentives to departments to retain and hire more QG faculty.

Key Words: Quantitative Genetics, Graduate, Training

172 Alternative teaching techniques for new and smaller animal breeding programs. C. D. Dechow*, *Penn State University, University Park.*

Animal breeding programs at many universities consist of one or two faculty members who also have a large undergraduate teaching or extension appointment. A small number of animal breeders within a department combined with limited support for their research program create obvious teaching challenges. Effective upper level animal breeding courses require a critical mass of students and if all animal breeding courses are taught by the same instructor, the curriculum focus can be limited. Animal breeding students might also feel isolated because of limited interaction with other animal breeding students. There is a strong demand for well trained animal breeding students despite these challenges and faculty members must pursue alternate avenues to train students. The challenges associated with low course enrollment have led to the development of online animal breeding courses that are recently available. While online courses alone will not satisfy all teaching needs, they will help fill the classroom void. Alternative teaching or learning techniques are not limited to online courses. Short courses and professional meetings provide learning opportunities and interaction with other faculty and future animal breeders. Many students would benefit from a semester spent studying abroad or at a peer institution with a larger faculty and student base in animal breeding. An example program is the Traveling Scholar Program of the Committee on Institutional Cooperation, which facilitates tuition and stipend payments for graduate students studying at different Big Ten universities. Partnerships between industry and university faculty can provide support for graduate training while exposing students to practical industry research needs. Finally, undergraduate student research and honors projects can be an effective tool to generate interest in animal breeding and complete small research projects with limited cost. The landscape for training animal breeding students has changed. There are new challenges to overcome, but tools to meet those challenges are in place and small animal breeding programs can help provide tomorrow's animal breeders.

173 Quantitative genetics training to meet the needs of the breeding industry. M. M. Lohuis*, *Monsanto Company, St. Louis, MO.*

The supply of well-trained graduate students for quantitative genetics roles in the plant and animal genetics industries is not keeping up with demand. With the apparent reduction in supply/demand, breeding companies are now also hiring graduates with degrees in statistics, bioinformatics and computer science into quantitative genetics roles traditionally held by animal or plant breeding graduates. Although, the breeding industries continue to consolidate, and reliable and comprehensive software packages are increasingly available, the demand for quantitative geneticists is remaining constant or increasing. Breeding companies continue to run breeding programs that require data manipulation, variance component estimation and genetic evaluations. However, they are also adding new dimensions to their programs that can involve the incorporation of genetic marker data, longitudinal data and/or more complex mixed models. With the availability of relatively affordable SNP multiplex genotyping platforms, very large datasets (i.e. greater than 150M SNP data points) are becoming more commonplace. Simultaneously, considerable work is required for optimization, simulation and breeding strategy to make these high-dimension breeding programs tractable and profitable in an industry setting. Traditional strengths of quantitative genetics graduates continue to be solid training in quantitative genetics principles, applied statistics, selection theory and computing skills. Traditional shortcomings tend to be limited knowledge of molecular and structural/functional genomics, inconsistent training in bioinformatics and breeding strategies and a lack of collaborative research and networking skills. Demand continues to grow for quantitative genetics graduate students that have a comprehensive knowledge of both quantitative and molecular genetics principles and techniques, together with the ability to collaborate with scientists from related fields and continue to grow and adapt to new technologies as they develop.

174 Diet transition time and stabilization of apparent digestibility in the feline. S. K. Martin*¹, M. R. C. de Godoy¹, D. L. Harmon¹, E. S. Vanzant¹, R. M. Yamka², K. G. Friesen², and K. R. McLeod¹, ¹University of Kentucky, Lexington, ²Hill's Pet Nutrition, Inc., Topeka, KS.

An experiment was conducted to determine the effects of length of dietary adaptation time on apparent nutrient digestibility in felines. Ten adult female shorthair cats were used to evaluate nutrient digestibility of 2 extruded dry test foods; differing only in inert marker included (Cr and Ti). Each experimental period (n=5/diet) consisted of 7 d adaptation and 21 d of total fecal and urine collection. Prior to each experimental period, cats were fed an extruded dry maintenance food for at least 3 wks. In comparison to the maintenance food, test foods were designed to have differing nutritional profiles with lower amounts of protein (29.7 vs. 33.7%) and fat (20.2 vs. 24.3%) and higher amounts of total dietary fiber (8.5 vs. 3.0%), and differences in ingredient composition. Foods were fed to meet maintenance energy requirements for adult cats. Dietary transition was conducted by incrementally increasing the proportion of test food by 25% on d 1, 3, 5, and 7 of each period. Fecal and urine samples were collected daily. Cats did not produce fecal samples on a daily basis, and accordingly samples were composited by week. Data were analyzed as a crossover design with repeated measures over time. Across test foods, dry matter digestibility (DMD) was unaffected (P = 0.86) by adaptation time; averaging 79.7, 80.1, 80.3% for wk 1, 2, and 3 respectively. Coefficients of variation were 4.07, 3.37, 4.78% for wk 1, 2, and 3 respectively. Similarly, nitrogen digestibility (ND) was unaffected (P = 0.61) by time, averaging 80.7, 81.5, 81.7% for wk 1, 2, and 3, respectively. Coefficients of variation were 4.32, 2.84, 3.58% for wk 1, 2, and 3 respectively. Results indicate that 7-d food adaptation period is satisfactory for apparent total tract nutrient digestibility stabilization in cats undergoing transition between dry extruded foods.

Key Words: Cat, Digestibility, Food Adaptation

175 Low-level fructan supplementation is effective in modifying stool protein catabolite concentrations but not gut microbiota populations in adult dogs. K. Barry*¹, D. Hernot¹, I. Middelbos¹, C. Francis², B. Dunsford², and G. Fahey, Jr.¹, ¹University of Illinois, Urbana, ²GTC Nutrition, Golden, CO.

Five ileal-cannulated adult dogs were utilized in a 5 x 5 Latin square design to determine the effects of fructan type and concentration on nutrient digestibility, stool protein catabolite concentrations, and microbiota in ileal digesta and feces. Five diets were evaluated that contained either cellulose alone or with inulin or short-chain fructooligosaccharides (scFOS) at 0.2 or 0.4% of the diet. Dogs were fed 175 g of their assigned diet twice daily. Chromic oxide served as a digestibility marker. Nutrient digestibility; ileal and fecal pH, ammonia concentrations, short- and branched-chain fatty acid concentrations, and microbial populations; ileal IgA concentrations; and fecal concentrations of phenols, indoles, and biogenic amines were measured. No differences were observed in ileal pH or concentrations of ammonia, acetate, or isobutyrate, or fecal concentrations of indole or valerate. Ileal dry matter (DM), organic matter (OM), and crude protein (CP) digestibilities; total tract DM and OM digestibilities; fecal concentrations of phenylethylamine; and

ileal concentrations of *E. coli* increased linearly (P<0.05) with inulin supplementation and fecal concentrations of phenol decreased linearly (P<0.05). Fecal concentrations of acetate and propionate decreased quadratically (P<0.05) with inulin supplementation. Ileal DM, OM, and CP digestibilities increased linearly (P<0.05) with scFOS supplementation and fecal concentrations of phenol decreased linearly (P<0.05). Total tract DM and OM digestibilities; ileal butyrate concentrations; fecal p-cresol, butyrate, and isobutyrate concentrations; and ileal Clostridium perfringens concentrations increased quadratically (P<0.05) with scFOS supplementation. Both supplemental fructans modified stool protein catabolites, but scFOS appeared to result in more significant modifications than did inulin. While a higher level of inclusion would be recommended to modify gut microbiota populations, low-level inclusion of either fructan is effective in modifying stool protein catabolite concentrations in the terminal ileum and feces of adult dogs.

Key Words: Fructan, Dog, Protein Catabolite

176 Influence of dietary protein content and source on digestibility patterns, osmolality and fecal quality in dogs differing in body size. J. Nery*¹, C. Tournier², V. Biourge², L. Martin¹, H. Dumon¹, and P. Nguyen¹, ¹Ecole Nationale Veterinaire de Nantes, Nantes, France, ²Royal Canin, Aimargues, France.

Large breed dogs are known to be more sensitive to diet than smaller ones and consequently to produce feces of poorer quality. A higher overall total apparent digestibility was previously associated to higher fermentation rates and higher luminal osmolality, in the colon of large breed dogs. The use of highly digestible protein and a reduction of crude protein (CP) level could constitute a solution to decrease colonic osmolality and improve large dog's fecal quality. The aim of this study was to assess the effect of protein source and level on total digestibility, osmolality and fecal quality in dogs differing in body size.

27 healthy female dogs were divided in 4 groups according to body weight and propensity to produce soft feces. Five diets varying in protein source (wheat gluten and/or poultry meal) and level (20%, 28% and 36% CP as fed) were tested. Feces were collected and scored on a daily basis during a 7-day test period preceded by a 7-day adaptation period. Moisture, and apparent digestibility coefficients (ADC) of DM, energy, fat, CP and ash, were determined from the feces collection pool. Osmolality was analysed from freshly voided feces. Data were analyzed using Kruskal-Wallis nonparametric test and Bonferroni/Dunn post-hoc test.

Fecal quality decreased with dog size (p<0.0001) and was lower for poultry meal diets (p<0.0001). ADC increased with dog size, was lower when poultry meal was the major protein source and varied inversely to dietary protein level. Fecal osmolality varied with source (p<0.001) but not with CP content of diet, being higher for poultry diets. No effect of dog size was found for this parameter.

Conclusions: Protein source has proven to be a good mean to modulate fecal quality in sensitive dogs due to its effect on digestibility and fecal osmolality. Conversely differences of fecal quality between different dog's size and levels of CP fed do not seem to be related with fecal osmolality.

Key Words: Fecal Quality, Dog, Osmolality

177 Evaluation of high protein diets in kittens during their first year of life. B. M. Vester*¹, K. J. Liu², T. L. Keel¹, T. K. Graves¹, and K. S. Swanson¹, ¹University of Illinois, Urbana, ²Natura Manufacturing, Inc., Fremont, NE.

Diets containing high concentrations of protein are now available on the mass market for cats. The objective of this experiment was to evaluate cats through their first year of life while being fed either a high(HP)- or moderate-protein(MP) diet. Eight dams were randomized onto 1 of the 2 test diets (53 and 34% protein, respectively). These dams were fed the diets for 1 mo prior to mating, and were all mated to 1 male. Upon queening, the male offspring were evaluated for 14 mo. All kittens were weaned at 8 wk of age onto the same treatment diet as the dam and were allowed to consume ad libitum throughout the study. Food intake and refusals were measured daily. Kittens were housed by litter from wk 8 to 16 then pair housed by diet. Blood samples were collected at 6 mo, and 12 mo after birth and analyzed for glucose, leptin, insulin, NEFAs, and triglycerides. Body composition using DEXA was determined at 8 wk, 8 mo, and 14 mo of age and an intravenous glucose tolerance test was conducted at 8 mo and 14 mo of age. Kittens were castrated and an adipose biopsy taken at 8 mo of age. Activity was quantified using Actical monitors at 6, 9, and 12 mo of age. Dry matter intake and body weight were not different between the 2 diet groups. Leptin did not differ between diets, but increased (P<0.05) over time from 6 mo to 12 mo of age. NEFAs were highest (P<0.05) at 6 mo of age and tended to be higher (P<0.10) in kittens fed the HP diet. Triglycerides were increased (P<0.05) in kittens fed the HP diet at 8 wk of age, but were not different at 6 mo or 12 mo. Activity was not affected by diet, but activity during the light period tended to decrease (P<0.10) as the cats aged. Kittens fed the HP diet tended to have increased (P<0.10) grams of lean mass compared to kittens fed the MP diet. Glucose area under the curve (AUC) was decreased (P<0.05) at 14 mo compared to 8 mo, but was not affected by diet. Insulin AUC was higher (P<0.05) in kittens fed the HP diet compared to the kittens fed the MP diet at 14 mo of age. Based on indices measured in this study, a HP versus MP diet appears to be a suitable replacement to the carbohydrate-based diets mass marketed to feline owners.

178 Influence of feeding raw or extruded feline diets on nutrient digestibility and nitrogen metabolism in African wildcats. B. M. Vester*¹, S. L. Burke², K. J. Liu³, C. L. Dikeman², L. G. Simmons², and K. S. Swanson¹, ¹University of Illinois, Urbana, ²Henry Doorly Zoo, Omaha, NE, ³Natura Manufacturing, Inc., Fremont, NE.

The African wildcat is one of the closest ancestors to the domestic cat and is believed to have similar nutrient requirements to domestic felids, but research is lacking. Small exotic cats housed in captivity are often fed a raw meat-based diet, which poses a risk of bacterial contamination. The objective of this experiment was to determine the effects of feeding a high protein extruded kibble diet versus a raw meat diet on nutrient digestibility, nitrogen balance, and blood metabolite concentrations in African wildcats. Five African wildcats were randomized onto either a high-protein extruded kibble diet or a raw meat carnivore diet. The study was executed as a crossover design, consisting of 21 d periods, with a 16 d adaptation phase, a 4 d fecal and urine collection phase, and

1 d for blood collection. Cats were housed individually in metabolism cages and fed to maintain body weight. Food offered and refused was measured daily. Both fresh and acidified urine was collected during the 4 d collection period for urinalysis and nitrogen measurement. A fresh fecal sample was collected for short chain- and branched chain- fatty acid analysis. Blood was analyzed for serum chemistry and leptin. Overall, both diets appeared to be well digested by the cats. Protein digestibility was higher (P<0.05) when cats were fed the raw meat diet versus the kibble. Nitrogen balance was positive for both diets (1.95 kibble diet versus 0.76 raw meat diet) and mirrored body weight changes (baseline 3.4 kg, kibble 3.6 kg, and raw meat 3.4 kg). Fecal propionate concentrations tended to be higher (P<0.10) when cats were fed the raw meat diet, however, fecal butyrate concentrations tended to be higher when cats were fed the kibble diet. Blood analysis showed few differences between diets, but alanine aminotransferase activity was higher (P<0.05) when cats were fed the raw meat diet. These data indicate that feeding an extruded kibble diet to African wildcats appears to be a suitable replacement to a raw meat diet.

Key Words: African Wildcat, Raw

179 Vitamin and mineral comparisons between captive and free-ranging koalas (*Phascolarctos cinereus*), possible explanations for hip dysplasia. D. A. Schmidt*¹, W. A. Ellis^{1,2}, F. B. Bercovitch¹, Z. Lu³, T. C. Chen³, C. Hamlin-Andrus¹, G. W. Pye¹, and M. F. Holick³, ¹Zoological Society of San Diego, San Diego, CA, ²University of Queensland, Brisbane, Australia, ³Vitamin D, Skin and Bone Laboratory, Boston University School of Medicine, Boston, MA.

A retrospective/prospective study of koalas (*Phascolarctos cinereus*) bred at the San Diego Zoo has documented 55 cases of moderate to severe hip dysplasia, with varying degrees of bone malformation. While the cause of the dysplasia is likely genetic, abnormal bone development due to insufficient concentrations of vitamin D for calcium absorption needed investigation. Most koalas housed at the San Diego Zoo are managed indoors without access to direct, unfiltered sunlight. Zoo koalas only consume eucalyptus leaves and few plants have significant concentrations of vitamin D₂ and D₃. Serum samples from 22 zoo and 19 free-ranging koalas were analyzed for Ca, Cl, Co, Cu, Fe, Mg, Mn, Mo, P, K, Se, Na, Zn, and vitamins A, D, and E. Zoo and free-ranging koalas and males and females were compared using student's t-tests (P≤0.05). No differences were found between genders within the zoo population. Calcium concentrations were different between zoo and wild koalas, averaging 10.7 and 10.3 mg/dL, respectively. However, these concentrations are considered within the normal range for other species. Chloride and Se concentrations were also higher in zoo koalas than in wild koalas, while P and Zn concentrations were higher in the wild animals. Although Mo concentrations averaged 4.8 ng/ml in captive koalas, concentrations were not detectable in the free-ranging population. Manganese concentrations ranged from not detectable to 2.5 ng/ml for captive koalas, but averaged 11.09 ng/ml for the free-ranging animals. Vitamin D (25-hydroxyvitamin D₂ and D₃) was analyzed using an RIA kit for humans. Concentrations were detected in the captive koalas with results near the minimal functional detectable limits of the assay. The free-ranging koalas had no detectable serum concentrations of vitamin D₃, raising concerns about the validity of the test in this species.

Key Words: Koala, Vitamin, Mineral

180 Using regression analysis to determine the quantities of browse component dry matter on branches of Carolina willow (*Salix caroliniana*). M. L. Schlegel^{1,2}, A. McComb^{2,3}, and E. V. Valdes², ¹The Zoological Society of San Diego, San Diego, CA, ²Disney's Animal Programs, Lake Buena Vista, FL, ³North Carolina State University, Raleigh.

One challenge in determining browse intake of zoo animals is quantifying the initial component composition. Depending on the animal species, animals will consume not only the leaves, but also the stems, bark, and wood. The objective of this project was to determine the relationship between branch diameter and the quantity of browse component DM on branches of Carolina willow (*Salix caroliniana*). Eighteen branches of willow were harvested in central Florida between April and May, weighed wet (range = 0.05 to 2.9 kg), and the base branch diameter measured (range = 7.75 to 42.25 mm) using calipers. Each branch was separated into five components (leaves, green stems, woody stems < 0.5 cm in diameter, bark from stems > 0.5 cm in diameter, and wood from stems > 0.5 cm in diameter). Components were dried at 55 °C to determine quantity of DM and to calculate total branch DM. Regression analysis of branch diameter versus branch component DM and total branch DM was done using Microsoft Excel. All prediction equations (branch component DM, g = diameter coefficient × branch diameter, mm + intercept) contained significant ($P < 0.05$) regression coefficients (Table 1). Using these predictive regression equations, the quantity of DM offered from each browse component can be estimated and the quantity of browse consumed determined when the browse components refused are separated and dried. Although this set of predictive equations is useful for Carolina willow only, the concept can be applied to other browse species fed.

Table 1. Regression coefficients to predict Carolina willow (*Salix caroliniana*) branch component DM (g) based on branch diameter (mm)

Branch Component	Coefficients				
	Intercept	SE	Diameter	SE	r ²
Leaves	-55.20	18.75	5.92	0.93	0.70
Green stems	-16.77	5.88	1.86	0.29	0.70
Woody stems < 0.5 cm in diameter	-22.37	3.48	2.33	0.17	0.91
Bark from stems > 0.5 cm in diameter	-69.69	10.42	6.19	0.52	0.89
Wood from stems > 0.5 cm in diameter	-186.82	27.23	16.20	1.35	0.89
Total branch	-350.86	52.24	32.50	2.59	0.90

181 An epidemiological study into the effect of captive diets on reproductive success in Humboldt and African penguins. R. McClements^{1,3}, K. Slifka², and A. Ward³, ¹University of Sydney, Camperdown, NSW, Australia, ²Dallas Zoo and Aquarium, Dallas, TX, ³Zoo Nutrition Services, Fort Worth, TX.

Captive breeding of exotic avian species for conservation and species management programs have received considerable attention in recent years. These programs promote self-sustaining populations, however production is often less successful than anticipated. Reproductive success among institutions holding African (*Spheniscus demersus*) and Humboldt (*Spheniscus humboldti*) penguins varies considerably, thus it was the aim of the experiment to determine whether nutrition was a factor. Commencing in 2003, a two-year epidemiological study was conducted through the collection of fish, eggs, and reproductive histories from sixteen institutions holding a minimum of six penguins. Fish and egg samples were analyzed for fatty acids and fat soluble vitamins and the results correlated with historical success. The most significant finding was higher concentrations of linoleic acid in the eggs from the institutions with the best reproductive success ($8.55 \pm 0.45 \mu\text{g/g}$) compared to those with only moderate success ($1.43 \pm 0.44 \mu\text{g/g}$). The increase in linoleic acid resulted in the ω -3 to ω -6 fatty acid ratios becoming similar to those observed in the eggs of free-ranging piscivorous and carnivorous birds. Additionally, all eggs contained relatively high concentrations of α -tocopherol ($175.7 - 353.0 \mu\text{g/g}$). These concentrations were considerably higher than previously observed in free-ranging piscivorous species, suggesting that the dietary supplementation resulted in egg concentrations higher than probable needs. These data suggest nutrition may be a factor in the lower reproductive success among institutions, however determining the magnitude and effect of these differences require a subsequent controlled study.

182 Reduced ferulate cross link concentration is associated with improved fiber digestibility of corn stover at silage maturity. H. G. Jung*^{1,2} and R. L. Phillips², ¹USDA-ARS, St. Paul, MN, ²University of Minnesota, St. Paul.

Ferulate cross linking of lignin to arabinoxylan is correlated with fiber digestibility in perennial cool-season grasses; however, similar data have not been reported for warm-season grasses. Our objective was to determine if ferulate cross link concentration is associated with fiber digestibility in corn stover at silage maturity. Four mutant corn lines selected for low ferulate ester concentration in seedling leaves, parental control line, and four backcross lines were grown in a replicated field trial and evaluated for NDF, ADL, and ferulate cross link concentrations, and in vitro NDF digestibility (IVNDFD) of leaf blades, sheaths, and stems at silage maturity. Low ferulate corn lines had lower concentrations of NDF, and less ADL and ferulate cross links as a proportion of NDF, and higher 24- and 96-h IVNDFD than did the control line. Backcross lines were intermediate for all traits. While growth environment (year and location) influenced all forage quality traits, corn lines generally maintained differences across environments. Ferulate cross link concentration was negatively correlated with 24- and 96-h IVNDFD for leaves ($r = -0.52$ and -0.92 , respectively), sheaths ($r = -0.47$ and -0.52 , respectively), and stems ($r = -0.71$ and -0.78 , respectively). NDF concentration was always correlated with IVNDFD ($r = -0.38$ to -0.95) and ADL was similarly correlated with IVNDFD except for leaves. Ferulate cross link concentration was correlated with NDF ($r = 0.81, 0.68,$ and 0.75 for leave, sheath, and stem, respectively) and ADL ($r = 0.41$ and 0.84 for sheath and stem, respectively) concentration. Correlations of NDF and ADL with ferulate cross links indicate the inter-relatedness of forage quality traits, and preclude concluding that ferulate cross links are a mechanism that controls IVNDFD. However, because ferulate esters are required for cross link formation and the mutant corn lines selected for low seedling ferulate esters had reduced ferulate cross links as predicted, our data support the hypothesis that ferulate cross links modify cell wall structure such that digestibility is altered.

Key Words: Ferulate Cross Links, Fiber Digestibility, Corn Silage

183 Evaluation of alfalfa hays with down-regulated lignin biosynthesis. D. R. Mertens*¹ and M. McCaslin², ¹US Dairy Forage Research Center, Madison, WI, ²Forage Genetics International, Nampa, ID.

Our objective was to assess the impact of down-regulating the COMT or CCOMT enzymes in the lignin biosynthesis pathway on the intake and digestibility of alfalfa. Two genetic lines were developed: one with COMT down-regulated or not (COMTnull) and the other with CCOMT down-regulated or not (CCOMTnull). Hays were harvested at first-cutting in ID. Amylase-treated NDF organic matter (aNDFom), ADF and ADL were (% of DM): 38.2, 31.3, & 5.3 for COMT; 39.0, 32.0, & 5.8% for COMTnull; 39.4, 32.6, & 5.2 for CCOMT; 39.4, 32.8, & 5.9 for CCOMTnull; 38.4, 23.7, & 1.3 for corn silage; and 7.5, 2.6, & 0.2 for the concentrate mixture (Mix). Chopped hays were fed as hay-only and in TMR containing 50% hay, 10% corn silage and 40% Mix to young lambs during four 5-week trials. Lambs were blocked by BW and 3 were assigned to each treatment. Digestibility and intake were determined on a reference alfalfa as a covariate. Digestibility was measured at ad libitum (AL) and restricted intakes (RESTR = ~1.8% BW/d). Data was analyzed

using GLM: hays were compared using a split-plot in time design with BlockXTreatment as the error variance and TMR were compared using a replicated Latin-square design with the residual as the error variance. Down-regulating COMT and CCOMT lowered ADL with little change in other components. When hay-only was fed at AL intakes, COMT had greater DMD (.675 vs .645) and greater NDFD (.575 vs .491) than its null ($P < .05$). Down-regulated CCOMT yielded smaller differences in DMD (.653 vs .637) and NDFD (.501 vs .464) that were significant when adjusted for the covariate. Intake of NDF (%BW/d) was greater for COMT than its null (1.60 vs 1.42), but not for CCOMT (1.38 vs 1.32). Responses were similar during RESTR, but generated higher probabilities. Differences in DMD and NDFD were less when hays were fed in TMR and only those for COMT were significant. In TMR, NDFD was lower than hay-only. We conclude that down-regulating COMT and CCOMT in alfalfa results in improved digestibility and this effect is negatively affected by feeding hays in TMR.

Key Words: Alfalfa, Digestibility, Lignin

184 Lactating cow responses to alfalfa hays with down-regulated lignin biosynthesis. D. Weakley*¹, D. R. Mertens², and M. McCaslin³, ¹LongView Animal Nutrition Center, Gray Summit, MO, ²US Dairy Forage Research Center, Madison, WI, ³Forage Genetics International, Nampa, ID.

The objective was to assess the impact of down-regulating the COMT or CCOMT enzymes of the lignin biosynthesis pathway in alfalfa on production, intake and digestibility responses by lactating dairy cows. Two genetic lines were developed: one with COMT down-regulated or not (COMTnull) and the other with CCOMT down-regulated or not (CCOMTnull). Hays were harvested at first-cutting in ID. Chopped hays were fed in TMR containing 50% hay, 10% corn silage and 40% of a concentrate mixture containing finely ground corn, soybean meal and fat supplementation as the major ingredients. Ration CP, NDF, and ADF were (% of DM): 18.1, 31.1, & 20.2 for COMT; 18.4, 29.3, & 19.6% for COMTnull; 18.1, 31.2, & 20.6 for CCOMT; and 18.3, 31.1 & 20.6 for CCOMTnull. Twelve multiparous cows were used to compare each down-regulated treatment to its null in a two-period crossover design (3-week periods) in two separate experiments. Cows were blocked into two levels of milk production and three cows of each block were assigned to the treatment or null in period 1. Data was analyzed using GLM: treatments were compared within genetic lines using a replicated crossover design with the residual as the error variance. Production of FCM (kg/d) was higher for COMT than its null (38.5 vs 37.3) at $P < .10$, but was not different between CCOMT and its null (38.4 vs 39.4). Compared to nulls, milk fat (%) was not different for COMT (3.05 vs 3.06) or CCOMT (3.35 vs 3.40) nor was DMI (kg) different for COMT (23.2 vs 23.2) or CCOMT (26.0 vs 25.9). Digestibility of NDF was increased by down-regulation of both COMT (.535 vs .425) and CCOMT (.486 vs .445) at $P < .01$. The .97 kg additional digestible matter in the COMT diet compared to its null resulted in 1.3 kg more milk (3.05% fat), but the .36 kg greater digestible matter in CCOMT did not increase milk yield. We concluded that down-regulating COMT and CCOMT in alfalfa results in improved fiber digestibility and this effect appears to be greater for COMT than for CCOMT.

Key Words: Alfalfa, Digestibility, Lignin

185 Digestibility, milk fatty acid profile, and plasma amino acids in lactating dairy cows fed alfalfa cut at sundown or sunup. A. F. Brito*¹, G. F. Tremblay², C. Benchaar¹, A. Bertrand², Y. Castonguay², G. Bélanger², R. Michaud², H. Lapierre¹, D. R. Ouellet¹, H. V. Petit¹, and R. Berthiaume¹, ¹Dairy & Swine R&D Centre, Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada, ²Soils & Crops R&D Centre, Agriculture and Agri-Food Canada, Quebec, QC, Canada.

Alfalfa (*Medicago sativa*) cut at sundown has been shown to contain more total nonstructural carbohydrates (TNC) than that cut at sunup. Our objective was to test the effects of cutting alfalfa at sundown (PM) vs. sunup (AM) on digestibility, milk fatty acid (FA), and concentration of plasma AA. Alfalfa was conserved as baleage (530 g/kg DM) into individually wrapped large rectangular bales. Sixteen multiparous lactating Holstein cows were randomly assigned to 1 of 2 treatments: PM or AM alfalfa in a crossover design. Cows were fed only baleage that contained (g/kg DM): 179 vs. 189 CP and 128 vs. 105 TNC for PM vs. AM, respectively. Feces (total collection) and milk were collected for 5 consecutive days (n = 8 cows). Total tract OM digestibility was greater in cows fed PM while the opposite was observed for N. No differences between treatments were found for DM and NDF digestibilities. Minor changes in milk FA profile were observed as C14:1, C16:1, and C20:4n6 were all significantly lower in cows fed PM. Feeding PM baleage increased plasma concentration of Lys, Met ($P = 0.07$), nonessential AA (NEAA), and total AA (TAA) but had no effect on branched-chain AA (BCAA) and essential AA (EAA). In summary, cows fed PM baleage had higher OM digestibility and plasma concentration of Lys, NEAA, and TAA.

Table 1.

186 Effects of cutting alfalfa at sundown or sunup on omasal flow of nutrients in lactating dairy cows. A. F. Brito*¹, G. F. Tremblay², C. Benchaar¹, A. Bertrand², Y. Castonguay², G. Bélanger², R. Michaud², H. Lapierre¹, D. R. Ouellet¹, and R. Berthiaume¹, ¹Dairy & Swine R&D Centre, Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada, ²Soils & Crops R&D Centre, Agriculture & Agri-Food Canada, Quebec, QC, Canada.

Alfalfa (*Medicago sativa*) cut in the afternoon has been shown to contain more total nonstructural carbohydrates (TNC) than that cut in the

morning. Our objective was to investigate the effects of diurnal cut (PM vs. AM) on omasal flow of nutrients. Alfalfa was conserved as baleage (530 g/kg DM) into individually wrapped large rectangular bales. Eight multiparous lactating Holstein cows fitted with ruminal cannulae were randomly assigned to 1 of 2 treatments: PM or AM alfalfa in a crossover design. Cows were fed only baleage that contained (g/kg DM): 179 vs. 189 CP and 128 vs. 105 TNC for PM vs. AM, respectively. Cobalt-EDTA and YbCl₃ were continuously infused into the rumen to estimate digesta passage of nutrients using the omasal sampling technique. Intakes and omasal flows of DM and OM tended to be higher in cows fed the PM compared to the AM baleage suggesting increased availability of nutrients to the animals. Intake of N and omasal flows of N fractions did not differ significantly between treatments. The same was observed for the omasal flows of Lys, Met, branched-chain AA (BCAA), essential AA (EAA), nonessential AA (NEAA), and total AA (TAA). In conclusion, feeding alfalfa baleage with contrasting TNC levels had no effect on omasal flow of N compounds in lactating dairy cows.

187 Which native Sicilian pasture plants make the difference for milk aroma quality? I. Schadt*¹, T. Rapisarda¹, G. Belvedere¹, F. La Terra¹, G. Azzaro¹, P. J. Van Soest², G. Licitra^{3,1}, and S. Carpino¹, ¹CoRFiLaC, Regione Siciliana, Ragusa, Italy, ²Cornell University, Ithaca, NY, ³D.A.C.P.A., University of Catania, Catania, Italy.

It has been shown that cheeses produced from cows consuming native pastures versus total mixed ration (TMR) differ in aroma compounds and sensory properties (Carpino et al. 2004, J. Dairy Sci. 87:816-830; Carpino et al. 2004, J. Dairy Sci. 87:308-315). In the present study *Anthemis arvensis*, *Calendula arvensis*, *Sinapis arvensis*, *Chrysanthemum coronarium*, and Geraniaceae spp. were evaluated individually for their capacity to influence milk aroma. The plant species were collected at flowering age, and part of the forage was dried to produce hay. Single doses of fresh and dried forage were fed individually *ad libitum* to two dairy cows in mid lactation. The cows were adapted to a TMR ration and TMR was given to the cows, at the middle and the end of the experiment as controls. A time of seven days between treatments was maintained. Animals were held off feed for five hours before and after treatments. Feed intake was recorded by weighing provided forage, TMR and refusal. Milk was sampled the day before and the same day of the

treatment during the evening milking before and after feeding. Aroma profiles of the milk samples were analyzed with a MS-based Electronic Nose (SMartNose), and differences were statistically evaluated using Principal Components Analysis. SMartNose showed different aroma profiles for milk samples collected after forage provision, before and after TMR feeding. With exception of *Sinapis arvensis*, the milk samples obtained from fresh forage were different from those obtained from hays. In conclusion, all examined forage species, both fresh and dried, had impact on milk aroma as detected by SMartNose. Feeding of the fresh forage may have a different effect compared to the respective hay.

Key Words: Pasture, SMartNose, Milk Aroma

188 Effects of supplementing tanniferous sainfoin hay on nitrogen metabolism of grass-fed dairy cows. F. Dohme*¹, A. Scharenberg¹, and M. Kreuzer², ¹*Agroscope Liebefeld-Posieux, Research Station ALP, Posieux, FR, Switzerland*, ²*ETH Zurich, Institute of Animal Science, Zurich, ZH, Switzerland*.

Condensed tannins (CT) are able to form complexes with feed proteins. This property may reduce the metabolic stress of lactating cows fed grass-based diets which often result in a high ammonia load. In a replicated 3 × 3 Latin Square arrangement, 6 ruminally cannulated Holstein cows were randomly assigned to 3 treatments. In treatment GF cows received only cut pasture grass, whereas in treatments GH and SH 3 kg of hay obtained either from grass-clover or sainfoin swards, respectively, were additionally supplied. From a milk yield of 22 kg/d onwards, cows were fed 0.5 kg/d of barley per kg additionally produced milk. Each of the 3 consecutive experimental periods consisted of a 14-d adaptation and a 7-d balance period where feed intake was recorded daily and feces and urine were collected quantitatively. On the last d of each balance period ruminal fluid and blood were sampled every 4 h from 0700 to 1900. Data were analyzed by the MIXED procedure of SAS and means were separated using the PDIF option. Intake of total DM (19.6 kg/d) and grass DM (14.3 kg/d) did not differ among treatments. Although the amount of hay DM consumed in treatment SH (1.27 kg/d) was less than offered and lower than in treatment GH (1.83 kg/d), the higher CP content of sainfoin hay (201 g/kg DM) compared to grass-clover hay (131 g/kg DM) and fresh grass (124 g/kg DM) caused the highest daily N intake with SH (412 g) followed by GH (405 g) and GF (392 g; P<0.05). Concomitantly, fecal N excretion was higher (P<0.05) with SH compared to GF and GH resulting in the highest (P<0.05) proportion of fecal N in total N intake. In contrast, no (P<0.05) differences were observed in excretion of urinary N. Ruminal ammonia and plasma urea concentration were lowest (P<0.05) with GH compared to GF and SH. Plasma urea concentration decreased over the day (P<0.001). In conclusion, the lack of positive effects of CT might be explained by their relatively low content in sainfoin used (55 g/kg DM) or the low proportion of sainfoin

in the total diet or both. Moreover, in this study ammonia load might be too low as that CT could have had an impact.

189 Modeling manure OM and N composition of dairy cows fed grass silage based diets. J. Dijkstra*¹, A. Bannink², E. A. Lantinga³, and J. W. Reijs⁴, ¹*Animal Nutrition Group, Wageningen University, Wageningen, The Netherlands*, ²*Animal Sciences Group, Wageningen UR, Lelystad, The Netherlands*, ³*Biological Farming Systems Group, Wageningen University, Wageningen, The Netherlands*, ⁴*Agricultural Economics Research Institute, Wageningen UR, Wageningen, The Netherlands*.

Nitrogen pollution in dairy farming may be lowered by reducing N output in excreta and by optimizing manure C:N ratio and N composition. An extant mechanistic model of digestion and fermentation processes was modified to simulate the fecal and urinary composition of dairy cattle fed grass silage (*Lolium perenne* L.) based diets. Total N excretion was partitioned into three fractions representing availability of N to plants, viz. immediately available N (N_M; mainly urea), easily decomposable N (N_E; urinary non-urea N, endogenous N and microbial N) and resistant N (N_R; N in undigested feed). Four different types of grass silages were explored at high (HF) and low (LF) N fertilization level and early (EC) or late (LC) cutting. For each grass silage, 10 supplementation strategies that differed in level and type of supplement were studied. Simulated urinary N excretion showed large variation between silages, but variation in simulated fecal N excretion was small. Urinary N excretion and the N_M fraction decreased considerably with lowered fertilization level and, to a smaller extent, with delayed cutting. The simulated N_E and N_R excretion (in g/d) were relatively constant though. A lower fertilization level or delayed cutting increased simulated manure C:N ratio.

Table 1. Simulated excretion and manure composition (means across 10 supplementation strategies)

	HFEC	LFEC	HFLC	LFLC	Range
Milk N, % feed N	24.9	30.8	26.7	32.7	22.6 - 37.1

190 Effect of phytic acid on apparent ileal digestibility of minerals in piglets. T. A. Woyengo¹, A. Cowieson², O. Adeola³, and C. M. Nyachoti¹, ¹University of Manitoba, Winnipeg, MB, Canada, ²Danisco (UK) Limited, Marlborough, UK, ³Purdue University, West Lafayette, IN.

An experiment was conducted to determine the effects of phytic acid (PA) on apparent ileal digestibility (AID) of minerals in piglets. Seven ileal-cannulated weanling pigs were fed a casein-corn starch-based diet with PA (as sodium salt) at 0.0, 0.5, 1.0, or 2.0% in 4 × 4 Latin square design with 3 added columns to give 7 replicates per treatment. The basal diet was formulated to meet NRC (1998) requirements for energy, AA and minerals for weanling pigs and contained chromic oxide (0.3%) as a digestibility marker. The AID of ash, and of 2 multivalent macro-minerals, that is, Ca and P were both linearly and quadratically reduced ($P < 0.05$) by an increase in the level of PA in diet; whereas that of another multivalent macro-mineral, that is, Mg was only linearly reduced ($P < 0.05$) by the PA. An increase in dietary level of PA also resulted in reduced AID of monovalent macro-minerals, that is, Na and K (linear and quadratic, $P < 0.05$), though the differences between diets without and with PA were only significant when PA was added at 2% (49.2 vs -37.9% for Na and 87.6 vs 81.1% for K). The AID values for ash, P, Na and Mg were negative, that is, -54, -27.7, -37.9 and -3.0%, respectively, when PA was supplemented at 2%. The results suggest that PA can reduce the AID of minerals in piglets. The reduced AID of minerals due to PA is partly attributed to their increased endogenous losses as evidenced by negative AID values of some of the minerals and ash at the highest dose of PA used in the current study. The increase in endogenous flow of Na and K may particularly be important as an increased presence of these minerals in the gut will effectively alter electrolyte balance and hence the capacity of the enterocytes to transport AA, glucose and other nutrients. These data are suggestive of potentially adverse consequences of PA on secretion and absorption balance.

191 Impact of steeping high-moisture corn with phytase on growth performance and phosphorus utilization in liquid-fed starter pigs. D. Columbus*, S. J. Niven, C. L. Zhu, and C. F. M. deLange, University of Guelph, Guelph, ON, Canada.

The application of phytase in conventional dry pig diets has been studied extensively and improves digestibility of phosphorus (P). The efficacy of phytase may be improved by steeping feedstuffs with phytase prior to feeding. A performance study was conducted to determine the value of steeping high-moisture corn (HMCorn) with phytase for use in P-limited liquid diets. Five pens of 16 pigs (weaned at 19 to 23 days of age; 6.7 ± 0.24 kg BW) were assigned to each of five 3-phase feeding programs for 7 weeks (total P was 0.69, 0.48, and 0.45 % in phase I, II and III diets, respectively). The HMCorn based diets were formulated to contain graded levels of added phytase (0, 62.5, or 125 FTU/kg DM HMCorn) which was added either to a mix of HMCorn and water and allowed to steep for a minimum of 24-h or to the dry feed supplement and mixed with the HMCorn at the time of feeding. The addition of phytase had no impact on ADG or G:F ($P > 0.10$). The soluble P content in duodenal digesta was increased with the addition of phytase (63.3 vs. 49.6 % of total P; $P < 0.05$). Allowing HMCorn to steep prior to feeding did not

increase solubilization of P in digesta (65.6 vs. 61.1%; $P > 0.10$). There was no impact of dietary treatment on total tract digestibility of P ($P > 0.05$). Urinary P excretion was higher in pigs fed diets with added phytase (280 vs. 7.59 $\mu\text{g}/\text{mL}$; $P < 0.05$). Addition of phytase to the diets resulted in greater contents of P in carcass (1.56 vs. 1.32%; $P < 0.001$) and metacarpal bones (5.67 vs. 5.40 %; $P < 0.05$). Metacarpal breaking strength was higher in pigs fed diets with 125 FTU/kg vs. 62.5 FTU/kg added phytase (33.0 vs. 30.3 kg; $P < 0.05$). Added phytase improved retention of P in starter pigs fed P-limited HMCorn based liquid diets, however, there appears to be no benefit to steeping HMCorn with phytase prior to feeding. Responses to both levels of phytase were similar and indicate greater efficacy of phytase in liquid diets than dry diets.

Key Words: High-Moisture Corn, Phytase, Starter Pigs

192 The effects of dietary calcium to total phosphorus ratio (Ca:tP) in diets containing 1000 FTU/kg of phytase on performance in 10-25 kg pigs. K. L. Saddoris*, S. B. Williams, D. W. Dean, and D. R. Cook, Akey, Lewisburg, OH.

Crossbred pigs ($n=924$) with an average initial weight of 10.8 ± 0.13 kg were used to determine the optimal Ca:tP ratio in 10-25 kg pigs fed diets supplemented with 1000 FTU/kg of phytase (Phyzyme XP[®]). The experimental design was a split plot with sex serving as whole plot and diet serving as subplot. Pigs (22 pigs/pen) were randomly allotted to one of six dietary treatments within sex and block and fed ad libitum for 23 d. Dietary treatments consisted of a basal corn-soybean meal diet with 1000 FTU/kg of Phyzyme XP[®] and 0.45% tP (0.15% aP) provided by corn, soybean meal, and dicalcium phosphate. Dietary Ca concentration of the basal diet was 0.40% and Ca:tP ratios were altered by addition of calcium carbonate to achieve Ca concentrations of 0.50, 0.60, 0.70, 0.80, or 0.90%. Calculated Ca:tP ratios were 0.88, 1.11, 1.33, 1.55, 1.77, and 2.0 for dietary treatments 1 thru 6, respectively. Increasing dietary Ca concentrations from 0.40 to 0.90 resulted in a linear ($P < 0.01$) decrease in ADG (595 to 532 g/d) and G:F (0.666 vs. 0.613). Additionally, ADFI decreased (linear, $P < 0.05$) by 3% as dietary Ca concentrations increased from 0.40 to 0.90%. Pigs fed the 0.40% Ca diet were 5% heavier ($P < 0.01$) at the end of the trial period compared to pigs fed diets with 0.90% Ca (24.60 vs. 23.36 kg). Overall, increasing the dietary Ca:tP ratio from 0.88 to 2.0 by increasing Ca concentrations resulted in an 11.8, 3.0, and 8.6% reduction in ADG, ADFI, and G:F respectively. These data indicate Ca:tP ratios as low as 1.11:1 negatively impact performance traits, and that dietary Ca may have a negative effect on the efficacy of phytase to release P from phytate. In conclusion, P release values assigned to phytase may be dependent upon dietary Ca concentrations. Further research is necessary to determine the Ca:tP ratio necessary to optimize phytate-P release with usage of 1000 FTU/kg of phytase.

Key Words: Swine, Phytase, Calcium

193 MINTREX[®]Zn provides similar performance to ZnO in nursery pigs at lower inclusion. R. J. Harrell, B. V. Lawrence*, R. Anderson, F. Navarro, and C. D. Knight, Novus International Inc., St. Charles, MO.

Zinc is a trace mineral with multifunctional properties including a role in normal growth, immunity, skin integrity, and an essential component in a multitude of enzyme reactions. Organic trace minerals offer the opportunity to feed less total mineral because of improved bioavailability compared to inorganic sources. MINTREX[®]Zn (ZnMin) contains 2 HMTBa ligands chelated with one Zn molecule. This study examined the effect of Zn source and level on weaned pig performance. Pigs with an average initial weight of 7.06±0.13 kg were blocked by sow parity (1 vs. 2-4 vs. 5+) and randomly assigned to one of five Zn diets: 120:0, 0:0, 60:0, 30:30, and 0:60 ppm Zn as ZnO:ZnMin, respectively. Complex diets were formulated to meet or exceed the requirements of weaned pigs except for Zn. Diets were fed in 3 different phases (0 to 10, 11 to 21, and 21 to 35 days postweaning). No differences in ADG or ADFI were detected from 0 to 10 or 11 to 21 days of study ($P > 0.15$). Pigs fed the 0:0 (0.933±0.050) zinc diet had 13% lower GF than pigs fed the 120:0 (1.074±0.050) and 30:30 (1.079±0.050) ppm Zn diet ($P < 0.05$) from 0 to 10 days. No differences in GF were detected between treatments from 11 to 21 days of study ($P > 0.15$). Pigs fed the 120:0 (563±15 g/d) had 10% greater ADG ($P < 0.05$) than the 0:0 (507±15 g/d) and 60:0 (520±15 g/d) fed pigs, but similar ADG to pigs fed the 30:30 and 0:60 Zn diets ($P > 0.10$) from 21 to 35 days. Pigs fed the 120:0 (0.696±0.007), 30:30 (0.692±0.007), and 0:60 (0.683±0.007) had similar GF ($P > 0.15$), but higher than pigs fed the 0:0 Zn diet (0.663±0.007; $P < 0.05$) from 21 to 35 days. Overall, from 0 to 35 days, no differences in final bodyweight, ADG or ADFI were detected between treatments ($P > 0.10$). Pigs fed the 120:0 (0.742±0.005), 30:30 (0.747±0.005), and 0:60 (0.738±0.005) had similar GF ($P > 0.20$), but were all higher than the 0:0 Zn diets (0.717±0.005; $P < 0.05$). These results suggest that at least 21 days postweaning are needed to elicit signs of a Zn deficiency and dietary Zn concentrations can be reduced by feeding MINTREX[®]Zn.

Key Words: Zinc, Source, Swine

194 Combination of organic and inorganic trace minerals for sows and weaned pigs. G. J. M. Lima^{*1}, F. Catunda², W. Close³, L. C. Ajala¹, and F. Rutz⁴, ¹Embrapa – Swine and Poultry Res. Center, Brazil, ²Alltech, Brazil, ³Close Consulting, U.K., ⁴UFPel, Brazil.

This study was conducted to determine the effects of combining inorganic and organic sources of trace minerals (TM) on the performance of sows along five consecutive parities and their offspring. In Experiment 1, 80 gilts were randomly divided and given two diets: T1 – TM supplemented with inorganic sources (120 ppm Zn, 40 ppm Mn, 120 ppm Fe, 15 ppm Cu, 0.3 ppm Se); T2 – TM supplemented with a combination of inorganic and organic sources in the following amounts: 80 + 40 ppm Zn, 20 + 20 ppm Mn, 30 + 90 ppm Fe/kg, 5 + 10 ppm Cu, 0 + 0.3 ppm Se, 0 + 200 ppb Cr, respectively. In Experiment 2, 96 weaned piglets from T1 and T2 fifth parity sows were equally allotted to receive diets with either inorganic or inorganic + organic TM, at the same levels described, in a 2 X 2 factorial experiment. In both experiments there was no significant interaction among main factors ($P > 0.05$). Sow reproductive variables as well as piglet weights at birth and at weaning were not affected by treatments ($P > 0.05$). Combination of inorganic and organic TM significantly increased the number of live piglets at birth (10.93 ± 0.17 vs. 11.80 ± 0.17, $P = 0.0003$) and at weaning (10.16 ± 0.16 vs. 10.90 ± 0.15, $P = 0.0008$) and decreased the number of stillbirths (0.48 ± 0.05 vs. 0.30 ± 0.05, $P = 0.007$) and mummies (0.10 ± 0.03 vs. 0.04 ± 0.03, $P = 0.12$). Milk selenium was increased (28.71 ± 1.99 vs. 38.94 ± 2.00 ppb, $P = 0.0004$) with the inclusion of organic TM. In Exp. 2, there was no significant effects of sow or piglet dietary treatments or their

interaction ($P > 0.05$) except for feed conversion ratio, which was better for piglets born from sows that were fed T2 diets (1.67 ± 0.02 vs. 1.62 ± 0.02, $P = 0.06$). While the combination of inorganic and organic TM confirms previous positive effects on litter size, this finding has yet to be completely understood. It may be hypothesized that the increase of bioavailability of the organic TM sources is responsible for part of the verified benefits. In addition, it may be that inorganic TM at NRC levels have detrimental effects.

Key Words: Litter Size, Reproductive Performance, Milk Composition

195 Effects of copper sulfate, tri-basic copper chloride, and zinc oxide on weanling pig growth and plasma mineral levels. N. W. Shelton^{*1}, M. D. Tokach¹, J. L. Nelssen¹, R. D. Goodband¹, S. S. Dritzt¹, J. M. DeRouchey¹, and G. M. Hill², ¹Kansas State University, Manhattan, ²Michigan State University, East Lansing.

Two four-wk experiments were conducted to determine the effects of increasing dietary Zn and Cu levels on weanling pig performance. In each experiment, 180 21-d old weanling pigs (PIC; 5.65 kg in Exp. 1, and 5.98 kg in Exp. 2) were allotted to six treatments with five and six replications in Exp. 1 and 2, respectively. Control diets contained 165 ppm Zn and 16.5 ppm Cu provided by the trace mineral premix. In Exp. 1, treatments were arranged as a 2 × 3 factorial using two levels of added Cu from tri-basic copper chloride (TBCC; 0 or 150 ppm) and three levels of added Zn from ZnO (0, 1500, or 3000 ppm from d 0 to 14 and 0, 1000, or 2000 ppm from d 14 to 28). From d 0 to 28, TBCC increased ($P < 0.01$) ADG (375 vs 344 g/d) and ADFI (509 vs 469 g/d) over control pigs. Increasing dietary Zn increased (linear, $P < 0.003$) ADG and ADFI from d 0 to 14 (184, 192, and 233 g/d; 226, 238, and 279 g/d) and d 0 to 28 (342, 352, and 385; 463, 479, and 525). Dietary Cu had no ($P > 0.63$) effect on plasma Cu. The only Cu × Zn interaction was for plasma Zn ($P < 0.03$) with plasma Zn increasing to a greater extent when Zn was added to diets without TBCC than when added to diets with TBCC. In Exp. 2, treatments were arranged as a 2 × 3 factorial using two levels of added Zn from ZnO (0 or 3000 ppm from d 0 to 14 and 0 or 2000 ppm from d 14 to 28) and three Cu treatments (control, 125 ppm from TBCC, or 125 ppm from CuSO₄). There were no Zn × Cu interactions ($P > 0.21$). From d 0 to 28, adding TBCC and CuSO₄ increased ($P < 0.01$) ADG (304, 333, and 359 g/d), ADFI (465, 490, and 506 g/d) and G:F (0.65, 0.68, and 0.71). Adding dietary ZnO also increased ($P < 0.01$) overall ADG (315 vs 349 g/d) and ADFI (466 vs 507 g/d). The greatest response to ZnO was from d 0 to 14 where ADG (175 vs 225 g/d), ADFI (227 vs 255 g/d), and G:F (0.77 vs 0.88) were all increased ($P < 0.02$). Contrary to many earlier trials, the growth responses from Zn and Cu were additive in these experiments.

Key Words: Weanling Pig, Zinc, Copper

196 Effects of various copper sources on copper bioavailability in broiler chickens. B. J. Min^{*1}, S. J. Park², R. A. Samford³, and S. W. Kim¹, ¹North Carolina State University, Raleigh, ²Texas Tech University, Lubbock, ³Albion Advanced Nutrition, Clearfield, UT.

A total of 560, 1 d old, broiler chickens was used to determine bioavailability of copper when various dietary copper sources were used. Twenty

birds were killed at d 0 and ground for carcass sampling. Remaining 540 birds were allotted to 6 dietary treatments: NC (without Cu supplementation); PC (with 25 ppm Cu from Cu-sulfate); CUGLY (with 25 ppm Cu from Cu-glycine chelates); CULYS (with 25 ppm Cu from Cu-lysine chelates); CUAX (with 25 ppm Cu from Cu amino acid complex); and CUAC (with 25 ppm Cu from Cu amino chelates). There were 6 replicates per treatment with initially 15 birds per stainless steel brooder cage with the heater. Birds had feed and water ad libitum during 21 d feeding period. Body weight and feed intake were measured on d 3, 5, 7, 14, and 21. Groups of 3 birds were randomly selected and killed at d 3, 5, 7, 14, and 21, ground together for each day, sampled, and analyzed for Cu. The ADG, ADFI, and gain:feed ratio did not differ among treatment groups. Contents of Cu (mg/bird) in PC (18.08), CUGLY (19.90), CULYS (21.92), CUAX (19.83), and CUAC (19.43) were greater ($P < 0.05$) than NC (6.47) at d 21. Bioavailability of Cu from CUGLY (48.1%), CULYS (52.4%), CUAX (49.5%), and CUAC (47.7%) was greater ($P < 0.05$) than NC (42.0%) during week 1. Bioavailability of Cu from CUAC (50.5%) and CULYS (49.8%) was greater ($P < 0.05$) than NC (44.5%) and CUAX (46.1%) during week 2. Bioavailability of Cu from CULYS (52.4%) was the greatest ($P < 0.05$) and that of CUAC (47.7%), CUGLY (48.9%), and CUAX (49.5%) was greater ($P < 0.05$) than NC (39.0%) and PC (44.1%) during week 3. During the entire period, bioavailability of Cu from CULYS (52.4%) was not different from CUAC (49.0%) but greater ($P < 0.05$) than CUGLY (47.8%), CUAX (47.7%), NC (36.3%) and PC (45.8%). This study indicates that supplement of Cu at 25 ppm from Cu-lysine and Cu amino acids chelates have beneficial effects on Cu bioavailability compared to the use of Cu from Cu sulfate by broiler chickens until d 21 of age.

Key Words: Bioavailability, Broilers, Copper Amino Acid Chelate

197 Supplementing inorganic or organic Se to diets using grains grown in various regions of the United States. D. C. Mahan^{*1}, J. E. Pettigrew¹, M. D. Lindemann², G. L. Cromwell¹, P. S. Miller¹, E. van Heugten¹, S. W. Kim¹, T. D. Crenshaw¹, M. J. Azain², and C. R. Dove², ¹NCCC-42 Committee on Swine Nutrition, ²AS 1012 Committee on Swine Nutrition.

Grains grown in various regions of the US vary in their indigenous Se contents that could affect pig tissue Se concentrations and performance responses. A regional study was conducted to evaluate the effects of adding inorganic Se (Na selenite) or organic Se (Se enriched yeast) at 0.15 or 0.30 ppm to grower-finisher pig diets on subsequent tissue Se and performance responses. A basal diet without supplemental Se served as a negative control. The study was a $2 \times 2 + 1$ factorial conducted in a randomized complete block design in 18 total replicates using a total of 240 pigs. Similar diet formulas were used but incorporated locally grown corn and soybean meal into the diets and were fed from 25 to 115 kg BW. The study was conducted at 9 stations (IL, KY, NE, NC, OH, TX, SD, WI, and GA) with each station completing 2 replicates. Serum Se and glutathione peroxidase (GSH-Px) activity were determined. Samples of liver, loin, and hair were collected at harvest and analyzed for Se. The corn fed and the loin Se at harvest for each station (expressed as mg/kg) were: IL, 0.028, 0.126; KY, 0.017, 0.096; NE, 0.283, 0.345; NC 0.074, 0.082; OH, 0.044, 0.119; TX, 0.132, 0.289; SD, 0.234, 0.527; WI, 0.075, 0.264; and GA, 0.026, 0.130, respectively, and differed ($P < 0.01$) by station. There were increases ($P < 0.01$) in loin, liver, and hair Se concentrations as dietary Se increased within each station, but a greater increase occurred when organic Se was fed. This resulted in a Se source \times level interaction ($P < 0.01$). Serum Se and GSH-Px activity increased

($P < 0.01$) when both Se sources were fed. These results indicate a large difference in grain Se concentrations among the states, that organic Se was incorporated at greater concentrations in the loin, liver, and hair tissues of grower-finisher pigs than inorganic Se, and that this increase occurred in the pigs from each state.

Key Words: Pigs, Selenium

198 Effects of dietary selenium on expression of selenoproteins and activity of antioxidant enzymes in endocrine tissues of growing male pigs. J. C. Zhou¹, J. G. Li¹, K. N. Wang¹, X. Xia¹, Y. J. Zhang¹, Y. Liu¹, Y. Zhao¹, and X. G. Lei^{*1,2}, ¹Int. Ctr of Future Agriculture for Human Health, Sichuan Agri. Univ., Ya'an, China, ²Cornell University, Ithaca, NY.

Expression and function of selenoproteins in endocrine tissues remain unclear. The present study was conducted to determine responses of mRNA levels of 12 selenoproteins and activities of four antioxidant enzymes in three endocrine organs of pigs to dietary Se deficiency or excess. A total of 30 weanling male pigs (3-wk old) were fed a corn-soybean meal based, Se-deficient (0.02 mg/kg) diet for 4 wk to adjust body Se status and then fed the basal diet supplemented with 0, 0.3 or 3.0 mg Se/kg as Se-enriched yeast (Angel Yeast, Hubei, China). After 8 wk, six pigs from each group were killed to collect plasma, liver, pituitary, thyroid and testis for analysis. Concentrations of Se in the four tissues and plasma increased ($P < 0.05$) with the increment of dietary Se. While dietary Se supplementation enhanced ($P < 0.05$) glutathione peroxidase activity in the four tissues, it did not affect activities of glutathione reductase, glutathione S-transferase, or total superoxide dismutase in any tissue. As determined by quantitative real-time RT-PCR, mRNA levels of *GPX1*, *Txrd1*, *SelN* and *SelW* in liver were lower ($P < 0.05$) in the Se-deficient group than the Se-supplemented groups. However, mRNA levels of *Txrd1* and *Sep15* in testis were decreased ($P < 0.05$) by supplementing 3 mg of Se/kg compared with the other two groups. Relatively high expressions of *GPX4*, *ID3*, *Sep15*, *SelK* and *SelN* were detected in pituitary, which was fairly independent of dietary Se concentrations. In conclusion, dietary Se deficiency and excess affected tissue Se concentrations in the three endocrine organs similarly to that in liver, but exerted less impact on the mRNA expression of multiple selenoprotein genes.

This project was supported in part by the Chang Jiang Scholars Program of the Chinese Ministry of Education (XGL) and Chinese Natural Science Foundation (XGL and JCZ).

199 Effects of sodium bisulfate on growth performance, slurry characteristics, and nutrient excretion of finishing pigs. J. Jarrett^{*}, S. Carter, J. Bundy, M. Lachmann, and T. Walraven, *Oklahoma State University, Stillwater.*

Sodium bisulfate (NaHSO_4) is a strong acid that has been used in the poultry industry as a litter additive to reduce pH and ammonia emissions. Little is known about the effects of NaHSO_4 in swine slurry when administered as a feed additive. A total of 80 crossbred ($D \times (L \times Y)$) pigs were used to determine the effects of NaHSO_4 addition to a traditional corn-soybean meal diet on growth performance, slurry

pH and electrical conductivity, and DM, N, and P excretion during a 100-d finishing period. Pigs were blocked by BW, sex, and ancestry and allotted to one of two dietary treatments. The control was a fortified corn-soybean meal diet and the treatment diet consisted of the control diet + 0.30% NaHSO₄. Diets were fed in four phases (40 to 62, 62 to 90, 90 to 108, 108 to 128 kg) and formulated on true digestible lysine (0.92, 0.79, 0.65, 0.56%). NaHSO₄ was added at the expense of sodium chloride to maintain sodium levels. Pigs were housed in 4 identical, environmentally-controlled rooms equipped with a shallow pit, pull-plug system (20 pigs/room, 2 rooms/trt). Feed intake, pig weight, pit volume, and slurry pH and EC were measured on a weekly basis. Feed and slurry samples were collected weekly and analyzed for DM, N, and P. During the 100-d finishing period, there was no difference ($P >$

0.10) in ADG (0.79 vs. 0.81 kg), ADFI (2.11 vs. 2.19 kg), or G:F (0.37 vs. 0.37). Also, no difference ($P > 0.10$) was observed in pit pH (7.15 vs. 7.20). However, electrical conductivity (8.22 vs. 9.18 mS) of the slurry tended to increase ($P < 0.09$) for pigs fed NaHSO₄. There was no difference ($P > 0.10$) in daily DM (230 vs. 237 g), N (33.7 vs. 31.4 g) or P (6.0 vs. 6.2 g) excretion between the 2 diets. NaHSO₄ addition did not affect ($P > 0.10$) excretion of sodium or ammonium-N. Sulfur excretion (2.4 vs. 4.0 g) tended to increase ($P < 0.09$) in pigs fed NaHSO₄. These results suggest that dietary addition of NaHSO₄ does not affect growth performance, pit characteristics, or DM, N or P excretion of finishing pigs.

Nonruminant Nutrition: Protein and Amino Acids

200 Is niacin (vitamin B₃) a modulator of the effect of supplementary tryptophan on tryptophan metabolism and growth responses in early-weaned pigs? J. J. Matte*¹, A. Giguère¹, D. Melchior³, and N. LeFloch², ¹*Agriculture and Agri-Food Canada, Sherbrooke (STN-Lennoxville), QC, Canada*, ²*INRA-SENAH, St-Gilles, France*, ³*Ajinomoto-Eurolysine SAS, Paris, France*.

The present experiment aimed to determine if tryptophan (Try) metabolism and growth responses to dietary Try are modulated by dietary niacin (B₃) in weanling piglets. A group of 104 piglets (52 pens of 2 animals), weaned at 3 wk of age, were distributed, at 4 wk of age (BW:7.6 kg, SE:0.2), in 4 factorial dietary treatments: 2 additions of B₃, 15 (LB₃) vs. 45 ppm (HB₃) and 2 additions of Try, 0 (-Try) vs. 0.10% (+Try) for Try/Lys ratios of 0.16 vs. 0.23, respectively. Growth performance was recorded every wk from 4 to 10 wk of age. Fasting blood samples were taken at 4, 6, 8 and 10 wk of age. At 11 wk of age, repeated blood samples were collected after a meal on 6 piglets per treatment for measurements on Try and insulin metabolisms. No treatment effect was observed on overall ADG, ADFI or G:F ($P > 0.3$). However, ADFI tended to be higher ($P < 0.10$) in HB₃ than LB₃ (685 vs. 652 g, SE:21) from 4 to 6 wk of age as well as ADG (716 vs. 699 g, SE:12, $P < 0.06$), from 6 to 10 wk of age. No treatment effect ($P > 0.2$) was observed on plasma Try or kynurenin (Kyn), an intermediate metabolite of Try catabolism. The response of plasma nicotinamide (Nam), a product of Try catabolism and indicator of B₃ status, to dietary B₃ differed according to dietary Try ($P < 0.01$), with overall values of 1.4, 3.3, 4.1 and 5.3 μM (SE:0.1) in -Try LB₃, -Try HB₃, +Try LB₃ and +Try HB₃, respectively. Post-meal plasma Try (96.2 vs. 72.3 μM , SE:0.1) and Kyn (1.7 vs. 1.3 μM , SE:0.1) were higher ($P < 0.01$) in +Try vs. -Try. There was no treatment effect on post-meal C-peptide and glucose ($P > 0.12$) but insulin (280.5 vs. 343.7 pM, SE:25.2) and the ratio insulin:C-peptide (0.39 vs. 0.43, SE:0.02) were lower ($P < 0.05$) in +Try vs. -Try. The treatment effects on both growth and plasma Nam suggest that the LB₃ level was suboptimal. Dietary treatment effects on plasma Nam and on post-meal plasma Try and Kyn suggest a lack of sparing effect of dietary B₃ on Try, part of supplemental Try being directed through catabolism whatever the dietary B₃. Supplemental Try also accelerated insulin clearance after a meal without apparent consequence on glucose utilisation.

Key Words: Tryptophan, Niacin, Piglets

201 Effect of replacing fish meal with synthetic amino acids on the growth performance of nursery pigs. C. L. Bradley*¹, C. V. Maxwell¹, Z. B. Johnson¹, J. L. Ustry², and J. W. Frank¹, ¹*University of Arkansas, Fayetteville*, ²*Ajinomoto Heartland LLC, Chicago, IL*.

Rising feed costs are challenging producers to find alternative protein sources for swine rations. The objective of this study was to determine if fish meal (FM) could be replaced with synthetic amino acids (AA) in phase 1 and 2 nursery diets. Weaned pigs ($n = 200$; Monsanto GPK35 \times EBU; 21.7 ± 0.2 d of age; initial BW 7.43 ± 0.01 kg) were used in a 34 d growth study. The pigs were blocked by weight in a randomized complete block design (5-6 pigs per pen and 7 pens per treatment). Pigs were fed one of five dietary treatments that contained decreasing levels of FM. Phase 1 (d 0-4; 1.6% Lys) diets ranged from 8 to 0% FM and 0.075 to 0.544% added L-Lys. Phase 2 (d 4-19; 1.52% Lys) diets ranged

from 6 to 0% FM and 0.275 to 0.627% added L-Lys. Other AA (DL-Met, L-Thr, and L-Val) were used in the diet formulations to maintain ideal ratios of Met + Cys, Thr, and Val at minimums of 0.58, 0.60, and 0.65 to lysine, respectively. Pigs were fed a common corn-soy diet supplemented with 0.333% L-Lys, 0.154% DL-Meth, and 0.100% L-Thr in phase 3 (19-34 d; 1.47% Lys). None of the diets were supplemented with L-Trp. There were no differences ($P > 0.12$) in ADG and ADFI throughout the study. There was a linear decrease ($P < 0.01$) in G:F as FM was replaced with AA in the diet during phases 1-2 (0.768, 0.800, 0.739, 0.740, and 0.718); however, there was no effect of dietary treatment on G:F during phase 3 ($P = 0.27$) or overall ($P = 0.23$). Final BW were not different as FM was replaced with AA (23.75, 24.07, 23.08, 23.42, and 23.64 kg; respectively, $P = 0.32$). Although G:F decreased as FM was replaced with AA during phase 2, there were no effects on overall growth performance or final BW. These results suggest that synthetic amino acids may be used to replace fish meal in nursery diets without compromising overall growth performance of the pigs.

Key Words: Pigs, Fish Meal, Amino Acids

202 ASAS Early Career Achievement Award presentation: Balancing amino acids for reproductive performance of sows. S. W. Kim*, *North Carolina State University, Raleigh*.

Improving efficiency of protein utilization is important for pregnant sows under restricted feed allowance to support the growth of fetuses and mammary glands especially during late gestation and for lactating sows with limited feed intake to support the mammary gland growth and milk production especially for primiparous sows. Series of studies were conducted to characterize requirements and ideal ratios of amino acids for (1) fetal growth, (2) mammary gland growth, and (3) maternal tissue gain for gestating sows and for (4) mammary gland growth, and (5) maternal tissue gain for lactating sows. A total of 97 pregnant sows and their fetuses and a total of 174 lactating sows and their nursing piglets were used for these studies to collect fetal tissues, mammary tissues, and maternal tissues for amino acid analysis. Requirements and ideal ratios of amino acids for sows changed dynamically depending on stages of pregnancy. Suggested daily Lys requirements were 6.83 and 15.26 g and relative ideal ratios for Lys:Thr:Val:Leu were 100:79:65:88 and 100:71:66:95 for 0 to 70 and 70 to 114 of gestation, respectively. Requirements and ideal ratios of amino acids for lactating sows changed dynamically depending on potential amounts of protein mobilization from maternal tissues which are related to voluntary feed intake and milk production. Suggested ideal ratios for Lys:Thr:Val:Leu were 100:59:77:115 and 100:69:78:123 if body weight losses of sows during 21 d lactation are 0 and 33 to 45 kg, respectively. To optimize efficiency of dietary protein utilization by sows, the dietary amino acid content and ratios can be adjusted by stages of pregnancy and by expected feed intakes or parities of sows during lactation considering the dynamic changes in the requirements and ideal ratios of amino acids. Acknowledgements to RA Easter, IK Han, WL Hurley, DH Baker, G Wu, and F Ji.

203 Adaptation of protein metabolism to changes in lysine intake in growing pigs. J. J. G. C. Van den Borne*, S. Borgjink, J. Dijkstra, and W. J. J. Gerrits, *Wageningen University, Wageningen, The Netherlands.*

The indicator amino acid technique is a well-known tool to estimate amino acid requirements within a subject. It involves measurement of responses in protein metabolism to step-wise changes in amino acid imbalance. The objective of this experiment was to compare lysine requirement estimates from increasing vs. decreasing titration strategies, and to study adaptive responses to changes in lysine intake. Pigs (n=14; 27.1±0.2 kg) were housed in metabolism crates and assigned to one of two treatments, with digestible lysine intake either increasing from 4.7 to 14.0 g/kg (INCR) or decreasing from 14.0 to 4.7 g/kg feed (DECR) in 7 equidistant steps, at identical intakes of other nutrients. Each step lasted 4d. Four complete 24h urine collections were performed from all pigs for each lysine level. Total urinary N and urea excretion were determined for all 24h collections. [¹⁵N]glycine was provided orally at d 3 of each lysine level and enrichment was measured in urinary urea. A linear-plateau model was fitted to N efficiency (in %) data. Treatment effects on slopes and inflection point estimates of the model were then analyzed statistically. Based on the F-test, for 11 of the 14 pigs the linear-plateau model fitted data better ($P<0.01$) than a straight line. The slope was higher ($P<0.01$) for DECR than for INCR (4.7 vs. 3.8 %/g). The lysine requirement, estimated from the inflection point, was lower ($P<0.05$) for DECR (10.1 g/kg) than for INCR (11.4 g/kg). Protein turnover increased linearly with lysine intake. With increasing lysine intakes, the increase in protein turnover rates was markedly greater for DECR than for INCR ($P<0.05$). No consistent changes in urinary N output were observed between the 4 subsequent 24h collections, although it was lower ($P<0.05$) for d 1 and 3 compared with d 2 and 4. In conclusion, increasing and decreasing lysine titration strategies resulted in different estimates for lysine requirement in pigs, indicating that adaptive processes in protein metabolism interfere with requirement estimates in within-subject titration techniques.

Key Words: Pig, Lysine, Protein Metabolism

204 Effects of fortifying low crude protein diet with crystalline amino acids on ammonia and uric acid production and excretion in broilers. N. F. Namroud, M. Shivazad*, and M. Zaghari, *University of Tehran, Karaj, Tehran, Iran.*

A study was conducted to evaluate the effects of providing all EAA in low CP diets equal to that of higher CP diets in broilers. Also, the effects of additional mixture of Gly and Glu or supplementation of excess EAA to low CP diets on the live performance, body composition, and excreta characteristics including pH, moisture, nitrogen, uric acid, ammonia concentration, and some blood factors related to nitrogen metabolism were measured to assess the reason of decreasing performance, especially appetite in low CP diets that have adequate amount of EAA. Male broiler chickens growing from 10 to 28 days of age were fed 8 experimental diets. Reducing dietary CP below 19% affected live performance and fat deposition in whole-body and abdominal cavity significantly ($P\leq 0.05$). Adding the Gly and Glu mixtures to low CP diets improved live performance and decreased fat deposition ($P\leq 0.05$). Nitrogen content, ammonia, uric acid level, moisture, and acidity of excreta were influenced by dietary CP ($P\leq 0.05$). Blood ammonia level was increased, and plasma uric acid was decreased with reduction of CP to 17% ($P\leq 0.05$). Supplementing Gly and Glu to low CP dietary treat-

ments increased plasma and excreta uric acid level in spite of decreasing level of ammonia production ($P\leq 0.05$). Reduction of dietary CP had no significant influence on the most free plasma amino acid levels; however, appetite was depressed ($P\leq 0.05$). The liver weight was elevated with increase in blood ammonia level ($P\leq 0.05$). This difference may be due to adaptation process of liver to high blood ammonia level. Therefore, our suggestion is that blood ammonia level, which has fatal effects on living cells may regulate appetite, besides the aminostatic mechanism in broilers.

Key Words: Crude Protein, Ammonia, Broiler

205 The effect of the level of crude protein and dietary fiber on the productive performance and health status of piglets. R. G. Hermes*, F. Molist, M. Iwazaki, M. Nofrarias, J. Gasa, and J. F. Pérez, *Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

Protein (CP) and dietary fiber (DF) are considered factors involved on the digestive maturation and health status of piglets. In the present study, ninety six 35-days-old piglets (7.66 ± 0.92kg BW) were placed in 32 pens of 3 animals each, and allotted to four dietary treatments for 21 days. The four diets were formulated based on rice, dairy products and soybean meal in a 2×2 factorial design, with 2 levels of CP (LP, 16%CP and HP, 19%CP) and 2 levels of DF (LF, 5%NDF and HF, 7% NDF). The HF diet was obtained by the supplementation of the basal diet with 4% of wheat bran and 2% of sugar beet pulp. Animal performance was weekly registered, and samples of feces collected for microbiology on days 1 and 21. On day 21, one pig from each pen was sampled for blood analyses of the acute-phase protein (PigMap) and sacrificed to register the digestive tract weight and colon histology. Animals fed on the HF diet increased the average daily gain (390 vs. 457 g/d; $p\leq 0.001$), and the large intestine weight (4.4 vs. 5.4% of BW; $p\leq 0.05$). It coincided with a decrease ($p\leq 0.05$) on the *E. coli* counts (7.77 vs. 6.86 log of CFU/g feces), and an increase ($p\leq 0.05$) on the ratio Lactobacilli:Enterobacteria (0.76 vs. 1.37). On the other hand, CP level did not modify the productive performance, but HP increased the weight (% of BW) of the small (6.5 vs. 7.7), and large intestine (3.8 vs. 4.3) ($p\leq 0.05$). In the large bowel, HP diet increased the numbers of goblet cells (4.6 vs. 5.4/100µm; $p\leq 0.05$), while reduced the numbers of intraepithelial lymphocytes (1.8 vs. 1.3/100µm; $p\leq 0.05$). In relation with the health status, a significant interaction was observed, with the LP-HF treatment showing the highest incidence of diarrhea, antibiotic interventions and PigMap concentration ($p\leq 0.05$). As a whole, CP has major effects on the gastrointestinal growth, while DF promotes major changes on the microbial colonization. An early increase on DF supplementation appears to promote a healthier status when this change is concomitant with a high CP level.

Key Words: Piglets, Dietary Fiber, Health Status

206 Pea protein as a substitute of soy bean protein in diets for young pigs: Effects on nutrient digestibility and digestive traits. D. G. Valencia¹, M. P. Serrano¹, C. Centeno², R. Lázaro¹, and G. G. Mateos^{*1}, ¹Universidad Politécnica de Madrid, Spain, ²Instituto del Frio, C.S.I.C., Madrid, Spain.

A trial was conducted to study the effects of using pea protein concentrate (PPC), soybean meal (SBM) or fullfat soybean (FFSB) as a substitute

of soy protein concentrate (SPC) on coefficient of ileal apparent digestibility (CIAD) of nutrients and digestive traits of piglets. The design was completely randomized with four treatments and six replicates of one piglet each. Four isonutritive diets (2,490 kcal NE/kg and 1.28% available Lys) were formulated and fed to pigs from 26 to 48 d of age. The main difference among these diets was the protein source used. In all cases the source tested supplied 5.5% of the dietary protein (CP). The CIAD of dietary components, the pH of the gastro intestinal tract (GIT), and the weight of digestive organs and spleen were measured at 48 d of age. Protein source had no effect on CIAD of CP or amino acids. However, the CIAD of organic matter (0.813 and 0.813 vs. 0.789 and 0.768) and gross energy (0.810 and 0.816 vs. 0.789 and 0.768) was greater for pigs fed SPC and SBM than for pigs fed PPC and FFSB ($P \leq 0.01$). The weight of the GIT was greater for pigs fed FFSB and PPC than for pigs fed SBM with pigs fed SPC being intermediate (61.0, 60.3, 52.8, and 55.9 g/kg body weight, respectively; $P \leq 0.05$). The poorer nutrient digestibility observed in pigs fed PPC and FFSB as compared to pigs fed SBM or SPC might be related to the higher TI content of these protein sources (4.9 and 4.7 vs. 2.7 and 1.6 g/kg). In summary, the inclusion of pea protein concentrate and fullfat soybean in the diet impairs ileal digestibility of organic matter and gross energy at 48 d of age. The replacement of soya bean meal by pea protein or soy protein concentrate in piglet diets, to improve nutrient digestibility, is not justified.

Key Words: Pea Protein Concentrate, Soy Bean Products, Digestibility in Piglets

207 Metabolizable energy and nitrogen-corrected metabolizable energy of meat and bone meal for pig. O. A. Olukosi* and O. Adeola, *Purdue University, West Lafayette, IN.*

Apparent metabolizable energy (AME) and nitrogen-corrected AME (AMEn) of 14 meat and bone meal (MBM) samples were determined using barrows. Treatments consisted of 1 standard corn-soybean meal (SBM) diet and 14 test diets in which each of the 14 MBM samples replaced equal quantities of corn and SBM in the standard diets such that the ratio of corn:SBM was the same in all the 15 diets. Each dietary treatment had 9 barrows. The barrows were allowed 5 d of adjustment to metabolism cages and diets and 5 d of feeding and total collection of feces and urine. The diets, urine and feces were analyzed for gross energy (GE) and N. Correlation, regression, partial correlation and model development and selection analyses were used to determine relationship among proximate fractions and AME or AMEn and for choosing the optimum prediction equation. The AME values were significantly different ($P < 0.05$) among the 14 MBM samples and ranged from 2,611 to 3,890 kcal/kg, whereas AMEn ranged from 2,512 to 3,794 kcal/kg and was not significantly different among the MBM samples. Proximate components were correlated to AME and AMEn of the MBM samples. There were negative correlations between AME and Ca, P, and ash ($r^2 = -0.43, -0.48$ and -0.49 , respectively), AMEn was also negatively correlated to the same chemical components with similar r^2 values. Both AME and AMEn were positively correlated to fat ($r^2 = 0.42$ and 0.43 for AME and AMEn, respectively) and protein ($r^2 = 0.17$ and 0.16 for AME and AMEn, respectively). The best two-model predictors were protein and fat, adding GE to these two improved the precision of the prediction equation. The best prediction equation for AME was based on 5 variables and was $7,756 - (0.84 \times \text{GE}) + (704 \times \text{P, \%}) + (156 \times \text{Ca, \%}) + (129 \times \text{Fat, \%}) - (268 \times \text{Ash, \%})$. For AMEn, the best prediction equation was $7,664 - (0.85 \times \text{GE, kcal/kg}) + (707 \times \text{P, \%}) + (154 \times \text{Ca,$

$\%$) + $(132 \times \text{Fat, \%}) - (268 \times \text{Ash, \%})$. In conclusion, although no single chemical component explained more than 50% of the variations in AME and AMEn of the MBM, but in combination provide information that may be used to predict the energy value of MBM.

208 Amino acid and energy digestibility in soybean meal from high-protein and low-oligosaccharide varieties of soybeans fed to growing pigs. K. M. Baker* and H. H. Stein, *University of Illinois, Urbana.*

Two experiments were conducted using 5 sources of soybean meal (SBM) that included hexane extracted SBM produced from high-protein soybeans (SBM-HP) and from conventional soybeans, and mechanically expelled SBM produced from high-protein soybeans, low-oligosaccharide soybeans (SBM-LO), and conventional soybeans. The standardized ileal digestibility (SID) of CP and AA in the 5 sources of SBM were measured in Exp. 1. Five diets that each contained 1 source of SBM as the only AA-containing ingredient and a N-free diet were formulated. Twelve growing barrows (initial BW: 67.7 kg) were allotted to a replicated 6×6 Latin square design with 6 periods and 6 diets. Each period lasted 7 d and ileal digesta were collected on d 6 and 7 of each period. With the exception of Trp, no differences in SID values between the extracted SBM-HP and the extracted conventional SBM were observed. The expelled SBM-HP and SBM-LO had greater ($P \leq 0.05$) SID for His, Ile, Lys, Thr, and Val than the expelled conventional SBM. The SID for all indispensable AA in the expelled SBM-HP were greater ($P \leq 0.05$) than in the extracted SBM-HP, and for the conventional SBM, the SID for Arg, Ile, Leu, Phe, and Trp were greater ($P \leq 0.05$) in the expelled meal than in the extracted meal. Experiment 2 was conducted to measure ME in the 5 sources of SBM using 48 growing barrows (initial BW: 38.6 kg) that were placed in metabolism cages and randomly allotted to 6 diets with 8 replicates per diet. A corn-based diet and 5 diets based on a mixture of corn and each source of SBM were formulated. Urine and feces were collected during a 5-d collection period, and values for ME in each source of SBM were calculated using the difference procedure. Results showed that ME in the extracted SBM-HP was greater ($P \leq 0.05$) than in the extracted conventional SBM (4,074 vs. 3,672 kcal/kg DM). The ME in the expelled SBM-HP was also greater ($P \leq 0.05$) than in the expelled conventional SBM and in the SBM-LO (4,059 vs. 3,620 and 3,721 kcal/kg DM). It is concluded that SBM-HP has a greater feeding value than conventional SBM.

209 Standardized ileal amino acid digestibilities in grain legumes for pigs. D. Jeziorny*¹, R. Mosenthin¹, M. Eklund¹, and M. Rademacher², ¹*University of Hohenheim, Stuttgart, Germany,* ²*Evonik Degussa GmbH, Hanau-Wolfgang, Germany.*

It has been agreed upon to use standardized ileal digestibilities (SID) of CP and AA in diet formulation for pigs. This study with grower pigs was conducted to determine SID values in different cultivars of faba beans, peas and lupins. Moreover, ileal digestibilities of starch in faba beans and peas were also determined. Three consecutive experiments

were conducted with 6 barrows each (initial BW 23.2 ± 1.9 kg). The pigs were fitted with a simple T-cannula at the distal ileum. In total, 18 assay feed ingredients, including 6 cultivars of faba beans (25 to 30% CP, as-fed) or peas (20 to 23% CP, as-fed), 5 cultivars of lupins (31 to 42% CP, as-fed) and 1 soybean meal (SBM) (49% CP, as-fed) as reference component were tested in a randomized row-column-design with 6 periods in each experiment ($n = 6$ per assay feed ingredient). The assay feed ingredients were added to a corn starch casein-based basal diet at the expense of corn starch. Each assay diet supplied approximately 50% of the total CP and AA content from the assay feed ingredient and casein, respectively. Both SID of CP and AA and ileal digestibility of starch in legume seeds were determined according to the principles of the difference method. The SID of CP differed ($P < 0.05$) between faba beans, peas and lupins, ranging between 69 to 81, 77 to 82 and 85 to 89%, respectively. The SID of Lys, Met, Trp, Ile and Phe in these grain legumes were lower compared to SBM ($P < 0.05$). The SID of most AA in faba beans and peas were lower compared to lupins or SBM ($P < 0.05$). The SID of CP and AA in faba beans was partly affected by cultivar ($P < 0.05$). The ileal digestibilities of starch in peas and faba beans were similar ($P > 0.05$), ranging between 78 to 89 and 77 to 84%, respectively. In conclusion, mean SID values for CP and AA in grain legumes are in good agreement with tabulated values, however, for individual cultivars these values may vary.

Key Words: Standardized Ileal Amino Acid Digestibility, Grain Legumes, Pig

210 True ileal amino acid digestibility in cecectomized roosters and lysine bioavailability in chicks fed distillers dried grains with solubles. A. A. Pahn*, J. E. Pettigrew, C. S. Scherer, D. H. Baker, C. M. Parsons, and H. H. Stein, *University of Illinois, Urbana*.

The concentration of true ileal digestible (TID) Lys and relative bioavailable Lys in 7 sources of distillers dried grains with solubles (DDGS)

fed to poultry were compared. We also evaluated the use of 2 in vitro procedures, reactive Lys and color score, to predict the concentration of TID Lys and bioavailable Lys in DDGS. The TID of AA in all sources of DDGS were measured using cecectomized roosters. Relative bioavailable Lys in all sources of DDGS were measured using standard curve methodology. Initially, 9-d total gain of chicks fed increasing levels of L-Lys HCl was measured and a regression equation was derived by plotting the bioavailable Lys intake against 9-d total gain of chicks. Seven additional diets were formulated to contain each of 7 sources of DDGS, and 9-d total gain of chicks fed these diets was measured. The 9-d total gain of chicks fed diets containing DDGS was used in the regression equation to predict the relative bioavailable Lys. The 7 DDGS sources were analyzed for reactive Lys using the guanidination procedure, and Hunterlab L, a, and b scores were measured to determine the degree of lightness, redness, and yellowness in the samples. Results showed that the TID for Lys among the 7 DDGS sources varied ($P < 0.05$) from 52.7 to 70.4%. The average TID for Lys was 61.4%. Concentration of relative bioavailable Lys did not differ among the 7 sources of DDGS. The average concentration of TID Lys in DDGS was not different from the concentration of bioavailable Lys (0.47% and 0.53%, respectively). The concentration of TID Lys was correlated ($r^2=0.84$, $P < 0.05$) with the concentration of reactive Lys in the samples. Hunterlab L scores of DDGS was correlated ($r^2=0.90$, $P < 0.05$) with the concentration of bioavailable Lys. In conclusion, the concentration of TID Lys in DDGS is close to the concentration of bioavailable Lys in chicks. Values for reactive Lys and Hunterlab L may be used to estimate the concentration of TID Lys and bioavailable Lys in DDGS, respectively.

211 Evaluating residual feed intake on performance of growing and finishing steers. C. O. Trejo*, L. L. Berger, D. B. Faulkner, J. M. Dahlquist, and T. G. Nash, *University of Illinois, Urbana*.

Improving feed efficiency in the beef cattle industry has become increasingly important as feed costs continue to rise. Residual feed intake (RFI) has been proposed as an efficiency trait that appears to be independent of most other performance traits. The objective of this trial was to evaluate RFI on performance of growing and finishing steers. Residual feed intake was calculated as the difference between the actual dry matter intake (DMI) and a predicted DMI. The predicted DMI was defined as a linear regression of DMI, average daily gain (ADG), and metabolic body weight ($BW^{0.75}$). Two groups were classified for the growing and finishing phase: Low RFI (<0.5 SD) and High RFI (≥ 0.5 SD). One hundred and sixty Angus, Simmental, and Angus-Simmental cross bred early weaned steers were fed during 112 days either of two diets: high concentrate (65% cracked corn, CC) or high fiber (38% soy hulls). Steers were fed with a common finishing diet (50% CC and 25% dry distillers grains with solubles) for approximately 152 more days. There was no significant interaction ($P > 0.05$) between the two diets and the RFI classification groups during the growing phase in performance. No differences were found for ADG ($P = 0.28$) and DMI ($P = 0.13$). Steers with low RFI were heavier ($P = 0.037$) at the end of the growing phase and had higher ($P = 0.003$) feed efficiency than the low RFI steers. There was a significant difference ($P < 0.001$) between the individual RFI values of each group. For the finishing phase, there were no differences for final BW and ADG between each of the RFI groups. However, steers in the low RFI group ate 1.24 kg/d less ($P = 0.0001$) and had higher ($P < 0.001$) gain:feed ratio than the high RFI group. There was 1.54 kg/d difference on RFI between the two groups. Identifying steers with low RFI potential can help improve feed efficiency and profitability during the growing and finishing phase.

Key Words: Residual Feed Intake, Early Weaned Steers

212 Relationships between residual feed intake and carcass-quality traits in Santa Gertrudis steers. F. R. B. Ribeiro*¹, R. K. Miller¹, E. G. Brown², P. A. Lancaster¹, L. O. Tedeschi¹, S. Moore³, D. DeLaney³, and G. E. Carstens¹, ¹Texas A&M University, College Station, ²Stephen F. Austin State University, Nacogdoches, TX, ³King Ranch, Kingsville, TX.

Our objective was to examine the phenotypic associations between residual feed intake measured during the growing (GRFI) and finishing (FRFI) phases, and carcass traits and tenderness in Santa Gertrudis steers ($N = 113$). Individual intakes were measured while steers were fed high-roughage (ME = 2.26 Mcal/kg) and high-grain (ME = 3.0 Mcal/kg) diets for 77 and 88 d during the growing and finishing phases. For each phase, RFI was calculated as the residual value from linear regression of DMI on mid-test $BW^{0.75}$ and ADG. For each phase, steers were categorized into low, medium and high RFI groups based on ± 0.50 SD from the mean of 0.0 ± 0.84 and 0.0 ± 0.98 for GRFI and FRFI, respectively. Steers were harvested at about one cm 12th rib fat thickness (BF). After 24 h, a LD sample was removed for calpastatin activity (CAP). At 48 h, carcass traits (hot carcass weight (HCW), LD muscle area (LMA), kidney, pelvic and heart fat (KPH), BF and marbling score (MS)) were measured, and yield grade (YG) calculated. Two 12th rib steaks were aged 1- (WSF1) or 14-d (WSF14) for Warner-Bratzler shear force.

RFI during the growing phase was weakly correlated (0.19 ; $P < 0.05$) with WSF14, but not ($P > 0.05$) with HCW, LMA, BF, KPH, YG, MS, WSF0 or CAP. Steaks from low and medium GRFI steers had lower ($P < 0.05$) WSF14 (2.2 and 2.1 vs 2.4, respectively) than steaks from high GRFI steers. FRFI was correlated ($P < 0.05$) with BF (0.27) and CAP (0.19), but not with other carcass traits. Carcasses from low-FRFI steers had less ($P < 0.01$) BF (0.97 vs 1.24 cm), lower ($P < 0.05$) YG (2.7 vs 3.2), but similar LDA (78 vs 75 cm²) and MS (475 vs 481) than carcasses from high-FRFI steers. Steaks from medium-FRFI steers had lower ($P < 0.05$) WSF14 than steaks from high FRFI steers. The low-FRFI steers had lower ($P < 0.05$) CALP (2.57 vs 2.81) than high-FRFI steers. Carcasses from low FRFI steers (more efficient) were leaner, but had similar marbling scores as carcasses from high RFI steers. Results suggest that selection for improved RFI will not have a negative impact on marbling and beef tenderness.

Key Words: Carcass Traits, Tenderness, Residual Feed Intake

213 Predicting water intake by yearling steers during the summer. J. L. Lacey*, J. J. Wagner, and T. E. Engle, *Colorado State University, Fort Collins*.

Four hundred and thirty-two crossbred yearling steers ($339 \text{ kg} \pm 4.8$) housed in 48 pens were used to study relationships between water intake (WI), dry matter intake (DMI), various measures describing the weather, and water quality. Because every two pens shared a common water fountain, 24 observations were available for this analysis. Water sources included: reverse osmosis water (RO) versus high sulfate well water. Average sulfate concentrations for the RO water treatment was $253.14 \pm 101.12 \text{ mg per L}$ versus $637.4 \pm 36.81 \text{ mg per L}$ for well water. Mean daily temperature (TEMP), humidity (HUM), dew point (DP), wind speed (WIND), and precipitation (RAIN) data were obtained from the weather station located at Lamar Municipal Airport located approximately 2 km from the Southeast Colorado Research Center. Equations predicting WI were developed using mixed model procedures. Water intake increased $1.25 \pm 0.17 \text{ L per kg increase in DMI}$ ($P < 0.0001$), $0.82 \pm 0.07 \text{ L per degree C increase in TEMP}$ ($P < 0.0001$), $0.68 \pm 0.07 \text{ L per degree C increase in DP}$ ($P < 0.0001$), and $2.12 \pm 1.25 \text{ L per head if RO water was used as compared with well water}$ ($P < 0.11$). Water intake declined $0.19 \pm 0.04 \text{ L per \% unit increase in HUM}$ ($P < 0.0001$) and was reduced by $0.05 \pm 0.02 \text{ L for each km/h increase in WIND}$ ($P < 0.04$). There was no significant difference in water intake due to precipitation ($P > 0.95$). Predicted WI from the current study was reasonably close to WI predicted by equations listed in NRC (2000).

Key Words: Steer, Feedlot, Water Intake

214 Combinations of steam-flaked corn, dry-rolled corn, and dried corn distiller's grains with solubles for feedlot heifers. P. L. Black*¹, G. L. Parsons¹, M. K. Shelor¹, K. K. Karges², M. L. Gibson², and J. S. Drouillard¹, ¹Kansas State University, Manhattan, ²Dakota Gold Research Association, Sioux Falls, SD.

Crossbred heifers ($n = 689$, $302 \pm 65 \text{ kg}$ initial BW) were used to evaluate finishing performance of cattle fed combinations of steam-flaked corn

(SFC), dry-rolled corn (DRC), and dried corn distiller's grains with solubles (DDG). The study was conducted as a randomized complete block using a 2 × 2 factorial arrangement of treatments. All diets contained SFC, and factors consisted of the levels of DDG (0 or 25%) and DRC (0 or 25%). Heifers were individually weighed and blocked into heavy and light groups. Within block, heifers were assigned randomly to pens containing 25 animals each, with 7 pens per treatment. Heifers were fed once daily *ad libitum* for 137 to 157d. ADG, DMI, and feed conversion efficiency were not different among treatment groups ($P < 0.05$). Heifers fed DRC had greater dressing percentages than their counterparts fed diets without DRC ($P < 0.05$). Feeding DDG also increased dressing percentage ($P < 0.05$). There were no differences among treatments with respect to HCW, quality grade, yield grade, 12th rib fat thickness, KPH, longissimus muscle area, incidence of liver abscess, or total carcass value. Partial substitution of SFC with DRC or DDG yielded comparable feedlot performance and carcass value with lower input cost.

Table 1. Performance and carcass traits of cattle fed SFC finishing diets with 0 or 25% DDG and 0 or 25% DRC.

	SFC		SFC/DRC		SEM

215 Cow live weight is negatively related to feed efficiency of cow/calf pairs from birth to weaning¹. T. Z. Albertini^{*2}, S. R. de Medeiros³, R. A. de A. Torres Júnior³, and D. P. D. Lanna², ¹Fapesp, Embrapa, ²ESALQ-USP, Piracicaba, SP, Brazil, ³Embrapa Beef Cattle, Campo Grande, MS, Brazil.

Feed efficiency of beef cows and their calves from birth to weaning was determined. Cow/calf pairs were individually fed from 26±12 d (mean±standart deviation) of life to weaning at 210 d. Forty adult non-pregnant cows were evaluated: 20 1/2 Caracu x Nelore, 10 1/2 Angus x Nelore and 10 Nelore. The 1/2 Caracu x Nelore and Nelore cows were bred to Red Angus bulls and the 1/2 Angus x Nelore were bred to Canchim (5/8 Charolais) bulls. The diet (2.3±0.1 Mcal ME/kg and 11.2±2.3% CP) was fed in variable amounts and adjusted every 28 days to keep the weight and body scores of the cows unchanged. The same diet was offered *ad libitum* to the calves (beginning at 2 months *postpartum*). Milk production was determined by milking each cow, at a minimum of 8 points in lactation. Correlations among efficiency indexes were evaluated using MANOVA option of Proc GLM in SAS. Regression analysis was used to compare the efficiency of cow/calf pairs and live weight of cows. The model included the effects: start of

feeding period, genetic group, sex and age of calf at beginning of the experiment. Efficiency of cow/calf pairs was 33.9±3.6 g LWG_{210d}/Mcal metabolizable energy. Efficiency of calves was 89.1±8.2 g LWG_{210d}/Mcal of total MEI (milk+solid diet). The live weight of cows was 450±55 kg. Phenotypical correlations showed a strong negative correlation between the live weight (LW) of cows and the efficiency of cow/calf pairs ($r=-0.65$; $P<0.001$). The linear regression of efficiency of cow/calf and cow's LW was: $y = -0.0397x + 52.61$ ($R^2 = 0.43$). There was a positive, although less dramatic, correlation between cows LW and the efficiency of progeny efficiency (g gain_{210d}/Mcal of calves MEI; $r=0.35$; $P<0.05$). In conclusion, heavier cows were associated with lower cow/calf pair efficiencies. However the progenies of heavier cows are more efficient in pre-weaning.

Key Words: Growth, Bioenergetics, Milk

216 Effects of using wheat gluten and rice protein concentrate in calf milk replacers. T. M. Hill^{*}, H. G. Bateman, II, J. M. Aldrich, and R. L. Schlotterbeck, Akey, Lewisburg, OH.

There is limited information in the literature on feeding milk replacers (MR) containing either hydrolyzed wheat gluten (HWG; 80% CP) or rice protein concentrate (RPC; 80% CP) to calves under 2 months of age. These protein sources appear to have little or no antinutritional properties unlike several other plant proteins and they are widely used in MR. Trial 1 compared feeding 26% CP, 17% fat MR that contained A) 0, B) 6, or C) 12% HWG replacing whey CP. The MR were fed at 0.681 kg/d (reconstituted to 4.6 L) halved into AM and PM feedings for 39 d, followed by 0.341 kg/d for d 40 to 42 (AM feeding only). Holstein calves (43 kg BW and 5.0 mg serum protein/dL initially) 2 to 3 d old from one source were used. Trial 2 compared feeding 26% CP, 17% fat MR that contained A) 0, B) 8, or C) 16% RPC replacing whey CP. The MR were fed at 0.681 kg/d (reconstituted to 4.6 L) halved into AM and PM feedings for 25 d, followed by 0.341 kg/d for d 26 to 28 (AM feeding only). Holstein calves (42 kg BW and 4.8 mg serum protein/dL initially) 2 to 3 d old from one source were used. Within trial, the MR were formulated to have equal concentrations of CP, fat, Lys, Met, Ca, P, and added trace minerals, vitamins, and decoquinat. All MR were adequate in essential amino acids. Each trial was analyzed as a completely randomized design using the MIXED procedure of SAS. Means were separated using linear and quadratic contrast statements. In Trial 1, pre-weaning ADG (0.640, 0.561, and 0.505 kg/d), starter intake, and hip width change decreased linearly ($P < 0.05$) with increasing concentration of HWG in the MR. In Trial 2, ADG (0.389, 0.340, and 0.178 kg/d) and feed efficiency declined linearly ($P < 0.05$) as RPC increased in the MR. Post-weaning performance did not differ among MR treatments in Trials 1 and 2. In these trials, pre-weaning ADG of calves less than 2 mo old was reduced when either HWG or RPC replaced whey protein in a MR.

Key Words: Wheat Gluten, Rice Protein Concentrate, Milk Replacer

217 The effects of controlled feeding a high concentrate or high forage diet at four nitrogen intakes on nitrogen utilization in dairy heifers. G. I. Zanton^{*} and A. J. Heinrichs, The Pennsylvania State University, University Park.

The hypothesis of this experiment is that N provided in a high concentrate (HC) ration will be utilized with a greater efficiency than a high forage ration (HF) by postpubertal dairy heifers and that the response will be affected by level of N intake (NI). To test this hypothesis, 8 Holstein heifers (beginning at 362 ± 7 kg and 12.3 ± 0.4 mo) were fed eight rations according to a split-plot, 4×4 Latin square design. Treatments were formulated to contain 75% or 25% forage (corn silage and chopped wheat straw) and 4 levels of NI (0.94, 1.62, 2.30, 2.96 g N/kg $BW^{0.75}$ per d) and were fed to equal ME intake (182 kcal/kg $BW^{0.75}$). Blood samples were collected over d 19-20 and feces and urine were collected the final 8 d/28 d period. Concentration of BUN was significantly higher for HC and with increasing NI. Urea-N excretion was not different between forage levels, but increased significantly and linearly with NI. Urea clearance rate (L/h) did not differ between forage levels and increased, but at a decreasing rate, as NI increased. A significant interaction resulted from urea clearance increasing at a greater rate and obtaining higher values for HF, whereas clearance of urea for heifers fed HC obtained significantly lower maximal values. Like urea-N excretion, daily urinary N excretion was affected only by NI. Retained N responded linearly to increased levels of NI. As a result of a significant interaction between forage level and NI on fecal N excretion and numerical differences in urine N, retained N at maximum NI was greater for HC than HF. In spite of this observation, gross N efficiency (GNE) only tended to be affected by an interaction and was not significantly affected by forage level. Linear and quadratic responses in GNE to increases in NI occurred such that the statistical maximum GNE was achieved when N intake was 1.62 g N/kg $BW^{0.75}$. To conclude, differences in N utilization between HC and HF in this trial were small and were not evident until NI increased to impractical levels.

Key Words: Dairy Heifer, Forage:Concentrate, N Intake

218 Effects of ractopamine HCL on growth performance and carcass characteristics of feedlot heifers. J. W. Himm^{*1}, W. J. Platter¹, M. J. Corbin¹, J. J. Wagner², N. E. Davis², J. S. Drouillard³, and C. E. Walker³, ¹Elanco Animal Health, Greenfield, IN, ²Colorado State University, Ft. Collins, ³Kansas State University, Manhattan.

Two studies were pooled to evaluate the effects of ractopamine hydrochloride (RAC) on growth performance and carcass characteristics in beef heifers. The studies consisted of 2 treatments (0 and 200 mg $hd^{-1} \cdot d^{-1}$ RAC), 16 replications per treatment and 1016 heifers (491.3 kg; 8 to 9 head/pen). Days on feed averaged 172 (CO site) and 186 (KS site), with the RAC diets fed the last 14, 28, and 42 d prior to harvest. Steam flaked corn-based rations met or exceeded National Research Council nutrient requirements and Rumensin[®], Tylan[®], and MGA[®] were fed at label dosages. One way ANOVA was used to estimate treatment effects on live animal performance and carcass characteristics. The statistical model included treatment as a fixed effect with random effects of replicate nested in study site, treatment and replicate nested in study site, study site and the study site by treatment interaction. Repeated measures analysis was used to evaluate live weight response over time. Treatments were pooled into control and RAC, the statistical model included treatment, time, and the treatment by time interaction. The response in live weight gain to feeding RAC was quadratic over the 42 d period with RAC treated heifers having a live weight gain of 5.9, 9.6, and 11.2 kg over controls at 14, 28, and 42 d, respectively. Hot carcass weight tended ($P = 0.12$; 5.5 kg) to increase after 28 d on RAC and was heavier ($P < 0.05$; 8.3 kg) after 42 d. After 42 d ribeye area was larger ($P < 0.05$) for RAC treated heifers. Dressing percentage, marbling score, yield grade,

and dark cutters were similar among treatment groups. USDA quality and yield grade distributions were similar between treatment groups. These data indicate that performance on a live and hot carcass weight basis continues to increase with RAC supplementation throughout a 42 d feeding duration.

Key Words: Ractopamine HCL, Heifers, Growth and Carcass

219 Interaction of growing and finishing production system and sorting by weight. D. R. Adams^{*}, T. J. Klopfenstein, G. E. Erickson, M. K. Luebke, and J. R. Benton, *University of Nebraska, Lincoln.*

Cattle are commonly sorted at weaning into different production systems. Our objective was to determine if sorting cattle by BW decreases variation in HCW and decreases overweight carcasses (431 kg). Steers (n=288) were purchased from a sale barn in the fall. All the cattle were assigned randomly into sorted or unsorted groups (n=144). The unsorted group was then assigned randomly to one of three feeding times: calf-fed, summer yearling or fall yearling. The calf-feds were fed from November to May. The summer and fall yearlings grazed cornstalks together through the winter until spring and then grazed cool season grass until May. The summer yearlings entered the feedlot in May and were fed until October. The fall yearlings grazed pasture until September when they entered the feedlot and were fed until January. In the sorted group, the heaviest 1/3 were fed as calf-feds. When the cattle were brought off of grass in May, the heaviest 1/2 of the remaining sorted group were fed as summer yearlings, while the lightest 1/2 went to pasture and then were fed until January. When entering the feedlot, the cattle were assigned randomly to six pens per group per feeding time and pen was experimental unit. Design was a 2 X 3 factorial. There were interactions ($P < 0.05$) for initial feedlot BW and HCW (by design), and for G:F and percent of carcasses > 431 kg. Sorted cattle had heavier initial feedlot BW and HCW as calf-feds but lighter as fall yearlings compared to controls. Sorted cattle had fewer overweight carcasses as fall yearlings (2.8% vs. 10.5%), but there were few overweight carcasses among either sorted or control cattle fed as calf-feds or summer yearlings. Unsorted calf-feds had higher G:F than sorted with no differences due to sorting within summer or fall yearlings. Sorting decreased variation of HCW (SD=27 vs. 39 Kg) and number of overweight carcasses without effecting fat thickness or quality grade.

Key Words: Carcass Characteristics, Feedlot Cattle, Sorting

220 Effect of the addition of plant extracts (Queen of Calves) to milk and differing levels of milk on gastro intestinal tract development of calves. J. K. Margerison^{*}, G. W. Reynolds, and R. Laven, *Massey University, Palmerson North, New Zealand.*

This research assessed the effect of plant extracts added to milk on the development of the gastro intestinal tract. Using a randomised block design, 18 (Male) dairy calves were randomly selected and allocated (48 h) according to; birth date, breed and live weight to one of three treatments; 4 l/h/d of whole milk (M); 4 l/h/d whole milk 4 l, plus 200 g plant extracts (MP); 2 l/h/d whole milk, plus 200 g plant extracts (0.5MP) and 3 calves per treatment diet were euthanized at 7 and 14 weeks of age to assess the physical and histological development of the gastro intestinal tract. Histological examination of the reticulum: pole and cranial, ventral

and dorsal rumen showed that calves offered plant extracts, at 7 weeks, had greater dorsal rumen papillae thickness (M:0.202^b; MP: 0.295^a; 0.5MP: 0.346^a (0.0294, P<0.05) and height (M: 0.336^b; MP: 0.378^b; 0.5MP: 0.716^a (sem 0.0710 P<0.001) and at 14 weeks (M: 0.334^{ab}; MP: 0.293^b; 0.5MP:0.388^a, sem 0.0710 P<0.05) dorsal rumen (M: 1.02^{ab}; MP: 1.08^a; 0.5MP: 0.810^b, sem 0.0396 P<0.05) and ventral rumen wall thickness (M: 0.631^b; MP:0.791^a; 0.815^a, sem 0.0421 P<0.05), greater full stomach weights (14 weeks: M: 16.6^b; MP: 21.6^a; 0.5MP: 16.9^b, sem 1.09 P<0.05), at 7 weeks had greater small intestine villi height height (M: 0.556^b; MP: 0.763^a; 0.5MP: 0.541^b sem 0.0381, P<0.001) and lower caecum mucularis (M: 0.756^a; MP: 0.586^b; 0.5MP: 0.449^b, sem 0.0541 P<0.001) (μm) compared with calves offered milk. Rumen fluid pH, VFA concentrations of acetic, propionic, isobutyric, butyric, valerate were not significantly different. The addition of plant extracts to milk increased rumen and small intestine development, but did not affect rumen volatile fatty acid concentrations.

Key Words: Gastro Intestinal Tract, Plant Extracts, Calves

221 Determination of the optimal amino acid concentration in milk replacers for calves less than five weeks of age. T. M. Hill*¹, H. G. Bateman, II¹, J. M. Aldrich¹, R. L. Schlotterbeck¹, and K. G. Tanan², ¹Akey, Lewisburg, OH, ²Provimi, Brussels, Belgium.

The amino acid requirements of herd replacement calves less than 5 wk old and fed milk replacers (MR) are not clearly defined. The objective

of these four studies was to investigate the effect of supplementing MR containing 24 to 28% CP (from milk sources) and 17% fat with Lys, Met, and Thr in order to estimate their optimal concentrations for calves less than 5 wk of age. Holstein bull calves (initially 3 and 4 d old, 43 & PLUSMN; 1 kg BW) were fed an 18% CP (as-fed) starter ad libitum and weaned at 31 to 32 d of age (28 d studies). Calves were housed in an unheated, curtain-sided nursery. In Study 1, six MR treatments were fed based on the combination of three CP concentrations (24, 26, and 28% CP) each with or without added Lys and Met. In Studies 2 and 3, 26% CP and 2.34% Lys MR treatments were fed to test the concentration of Met (0.64, 0.68, and 0.72% Met in Study 2, and 0.64, 0.72, and 0.80% Met in Study 3). In Study 4, 26% CP, 2.34% Lys, and 0.72% Met MR treatments were fed to test the concentration of Thr (1.06, 1.43, and 1.80%). There was a 17% improvement (P < 0.05) in ADG in Study 1 from adding Lys and Met that was maximized with 2.34% Lys. The ADG response to added Met in Studies 2 (linear, P < 0.05) and 3 (quadratic, P < 0.05) were 13 and 7%, respectively, with a plateau at 0.72% Met. There was no ADG or efficiency response to added Thr in Study 4. Formulating 17% fat, whey-based MR fed at 0.68 kg/d to 26% CP, 2.34% Lys, and 0.72% Met appeared optimum based on responses of ADG, feed efficiency, and serum concentrations of urea nitrogen. Feeding calves more CP and essential amino acids did not improved ADG and efficiency. Amino acid requirements of calves less than 5 wk old, averaging 48 kg BW, consuming 204 g CP/d, and gaining 0.46 kg BW/d, appeared to be met with 17 g Lys, 0.31 Met to Lys ratio, 0.54 Met+Cys to Lys ratio, and a Thr to Lys ratio less than 0.60.

Symposium: Ruminant Nutrition, and Production, Management & Environment Joint Symposium: Designing Field Studies to Evaluate Nutrition Effects on Production, Reproduction and Health of Dairy Cows

222 Utilizing appropriate statistical designs and techniques for data collected from commercial dairies. R. J. Tempelman*, *Michigan State University, East Lansing.*

Due to increasing constraints placed on conducting large studies at universities, more research is being conducted on commercial dairies thereby raising some implications for experimental designs and data analysis. For example, experimental units are often specified to be pens of animals in on-farm studies, thereby requiring that at least two pens be used per treatment group in a single dairy study. Even when treatments are compared within pens, the precision of inference on treatment differences is still primarily limited by the number of pens in the study, rather than the number of cows per treatment in each pen. Other challenges with on-farm studies include proper blocking and randomization of cows or pens to treatments. On the other hand, multiple farm studies are attractive as they facilitate a broader scope of inference on treatment effects across a wider range of management and/or climatic conditions and genetic backgrounds compared to single-site university studies. Furthermore, studies based on multiple farms or multiple pens within a single large farm can facilitate greater power for treatment comparisons on binary reproduction or health responses than can be achieved at a smaller research herd. Since quantitative geneticists have been analyzing commercial dairy data for decades, they have developed useful data analysis techniques that should be harnessed to facilitate even greater statistical scope and power for on-farm studies, such as accounting for genetic effects, stage of lactation, differences in variability across farms or management groups, and farm-specific covariates such as ambient temperature. Finally, multivariate ANOVA should be used to facilitate greater information recovery on treatment effects when analyzing several different but correlated response variables of interest.

Key Words: Experimental Design, Experimental Unit, Scope of Inference

223 Examples of experimental designs to study production responses. N. R. St-Pierre*, *The Ohio State University, Columbus.*

There are increasing opportunities to conduct field research in commercial herds where cows are invariably grouped in pens. Dedicated research facilities are best suited for determining mechanisms of treatment effects. Field studies on commercial farms are better suited for quantifying the magnitude of the response to dietary treatments over a broader range of environments. In nutrition field experiments, the experimental unit is generally the pen, while cows serve as sampling units. Among the many types of designs available for field studies, the best one depends on many factors, including what production trait is of primary importance. Generally, cows require 6 to 10 weeks to fully express a milk yield response to dietary treatments. This often forces the use of longitudinal designs where pens remain on their assigned treatments throughout the trial. Milk fat and protein contents and yields generally show much quicker responses, typically 2 to 4 wk. When these are the traits of importance, a vast array of rotation designs can

be used with considerably more power. With longitudinal designs the use of an appropriate covariate on the sampling units (cows) generally doubles the efficiency of the experiment. Rotation designs such as the cross-over, Latin square, switchback, and double cross-over estimate treatment effects within the experimental units (pens). This generally results in considerably more power than longitudinal designs of similar size. The optimum pen size is dependent on the variation between pens (V_p) and the variation between cows (V_s). As long as all cows in a pen are participating in the experiment, the variance due to competition is not a factor in determining the optimal pen size. In this instance, $V(Y) = V_p + (V_s/k)$, where k is the number of cows per pen. Estimates of these variances in combination with the cost per cow and the cost per pen can then be used to calculate an optimal pen size. A uniformity trial can be conducted to estimate the variance components. Numerous examples with the appropriate SAS code will be presented.

Key Words: Field Trials, Statistics, Experimental Designs

224 Field studies to study reproduction in dairy cows. J. D. Ferguson*, *University of Pennsylvania, Kennett Square.*

Due to limited power to detect differences within university herds, it is attractive to do reproductive trials on dairy farms. Benefits include the potential to examine effects across multiple locations and diverse management systems. Field trials may examine treatment effects on cattle health which may impact on fertility, management interventions to control reproductive efficiency, and specific therapies to alter reproductive function in cows. Outcomes may comprise effects on uterine involution and endometritis, days to first ovulation, conception rate(s), pregnancy rate and overall reproductive performance, estrus expression, and pregnancy wastage. Categorical data analysis and event time models would be most appropriate to analyze reproductive data. An advantage of field studies is the ability to enroll large numbers of cows in trials; a disadvantage is the loss of control of experimental conditions. Therefore study designs need to control for extraneous variables by collecting data on potential confounders, which may have limitations based on the herd management and cost to collect it. Study designs may include split herd, random assignment of cows to treatment groups, blocked by age and season of calving. A challenge with split herd designs is ensuring similar management of each treatment group and blinding management to treatment. Alternatively, cows may be matched within herd and followed in a prospective, longitudinal trial. Herds may be matched and treatment assigned to one herd and the alternative herd untreated to act as a control. This would be an attractive approach to examine management interventions to alter reproductive performance. Challenges in field trials include ensuring herd compliance with treatment assignments, control of selective management of treatment groups, and loss of meticulousness in control of extraneous variables through study design. Studies need to be larger and more information collected on each cow to control for confounding variables.

Key Words: Field Studies, Dairy Cows, Reproduction

225 Examples of designs to study health responses and the role of meta-analysis. I. J. Lean*¹, A. R. Rabiee¹, and T. F. Duffield², ¹*Bovine Research Australasia, Camden, NSW, Australia*, ²*University of Guelph, Guelph, Ontario, Canada*.

Many diseases are infrequent, rare, or sporadic in incidence, are often poorly defined and pose particular challenges in study design. The best forms of evidence are randomized controlled trials which need many cattle to study effects of interventions on infrequent health disorders. Studies conducted across several farms are more robust and have greater external validity. Other study designs that have been effective in increasing knowledge of disease include prospective cohort and case-control studies. Studies need to account for effects of time in assessing causality. Studies that evaluate surrogate measures of health such as serum chemistry and rumen parameters are helpful in understanding an intervention. These are easier to conduct but cannot be used solely to predict impacts on health.

A powerful tool for evaluating disease is meta-analysis; a formal study design used to provide a synthesis of previous studies. Typically, but not necessarily, randomised clinical trials are used to provide data. Outcomes include a more precise estimate of the effect of a treatment or risk factor on disease. Identifying sources of heterogeneity and determining the generalizability of responses can lead to more effective treatment or modification of management to prevent disease. The pooling of numerous studies allows sample size to be increased and potentially allows the effects of environment, including nutrition, on treatment responses to be evaluated. Recent examples include milk fever risk, disease and monensin treatment and impact of reproductive treatments. Despite a relatively low number of cattle used per trial, publication of disease information from physiological studies will help to evaluate the impact of interventions on health in future meta-analyses.

226 Collecting research data with dairy management software. L. Jones*, *FARME Institute, Inc, Homer, NY*.

Central to managing a modern dairy farm is an on-farm dairy management database system (on-farm system). Data relating to animal identification and performance are recorded and integrated to provide management information for the dairy farm manager. Data may include real-time milk production, milk quality, reproduction, health information, and general descriptive statistics. These on-farm systems are designed first and foremost to support managerial decisions and not as research data collection tools. Nonetheless, under certain circumstances, they can be used to collect research data. Paramount to collecting research data with on-farm systems is an appropriate experimental design. For a small scale trial, there are three prerequisites to a valid data collection project. First, the trial must be blind. Producer actions and decisions are inherently biased, and knowledge of treatments may result in biased management and biased results. Second, all data required from the producer should be entered through the on-farm system as part of the general course of herd management. Relying on the producer for supplemental data is problematic and unreliable. Third, the researcher must understand generally how data are handled by the specific on-farm system and how the individual producer defines variables on their farm. Variables with the same name can have completely different definitions between farms. The major on-farm systems have the ability to export data in a format that can be utilized by statistical analysis systems. A common feature of on-farm systems is the practical limitation of the number of events that can be recorded for each animal. Some systems have an audit feature which records variables changes, but this is not a common requirement for herd management. Prior to initiating a research trial, the historical records from the on-farm system should be exported and analyzed to ensure they support the experimental design employed. Large scale trials can be performed when the only data of interest are predefined by the on-farm system and the interpretation is unambiguous (e.g., sire identification).

Key Words: On-Farm Systems, On-Farm Research

Symposium: Small Ruminant: The U.S. Goat Meat Industry and Recent Sheep and Goat Activities at the National Research Council of The National Academies

227 Goat meat production, processing, and marketing in the U.S. K. W. McMillin*, *Louisiana State University Agricultural Center, Baton Rouge.*

The goat meat industry is the fastest growing segment of the U.S. livestock industry. Numbers of all goats were 3,015,000 in January of 2008, with an increase of 4% to 2.5 million head of meat and other goats from the previous year. Drought and other conditions contributed to increased total goat slaughter of 828,000 in 2007 compared with 749,300 in 2006. The annual supply of goat meat available to American consumers from domestic and imported sources continues to increase, but the true demand by ethnic and non-ethnic consumers has not been accurately determined. Imports of goat meat, primarily from Australia as frozen carcasses, have increased by about 10% annually over the past decade, with increasing proportions of the goat meat in boxes as frozen primal pieces or cubes each year. Marketing of live goats is mainly through auctions and livestock traders, although direct on-farm and farmer market sales appear to be increasing. Kid goat carcasses have a dressing percentage of 42 to 52%, with the trotters and kidney and pelvic fat left in carcasses until fabrication. Lean yields of 50 to 70% of cold carcass weight depend upon carcass size, fatness, and amount of bone. A Meat Goat Selection, Carcass Evaluation & Fabrication Guide provides information on assigning selection classification conformation scores to live goats and goat carcasses, evaluating goat carcasses, and introducing fabrication procedures of goat carcasses. Goat meat and muscles can be processed with all of the normal unit processing and preservation operations used for the other meat species. However, more convenient or processed goat meat products, such as precooked or cured items, have not become common in wholesale or retail offerings of goat meat or goat meat products. Ethnic retail consumers are driving goat meat demand for raw chilled meat as cubes even though USDA Institutional Meat Purchase Specifications for Fresh Goat provide for consistent cutting, ordering, and merchandising of primal and retail cuts by institutional and retail meat buyers. Populations of the ethnic groups who are primary purchasers of goat meat have increased at more than twice the 5.3% total U.S. population growth since 2000.

Key Words: Goat, Meat, Processing

228 New NRC recommendations for energy and protein requirements of goats and sheep. B. W. Hess*, *University of Wyoming, Laramie.*

Expression of energy and protein values is one of the first items to consider when discussing new recommendations for energy and protein requirements of goats and sheep. The NE system was used for sheep whereas energy requirements of goats were expressed in terms of ME because NE is not as commonly used in evaluating feedstuffs and insufficient data are available on expressing NE requirements of goats. The metabolizable protein (MP) system was viewed as the most appropriate method of defining protein requirements. This system requires information on factors that influence microbial protein synthesis, the extent of ruminal outflow of intact feed protein, and intestinal digestibility of rumen undegraded protein. Whenever possible, databases of treatment mean observations were constructed from the literature to evaluate components of the Cornell Net Carbohydrate and Protein System for

sheep and the previous Sheep NRC. Although the independent evaluation revealed that one method was not appreciably superior to the other, the Cornell Net Carbohydrate and Protein System was used to describe energy and protein requirements of sheep because this method considers energy and protein requirements and supplies in concert and also includes assumptions allowing prediction of negative BW change. Recommendations for energy and protein requirements of goats were based primarily on a special issue published in the journal *Small Ruminant Research*. An independent evaluation of recommendations for energy and protein requirements of goats was not necessary because this was already conducted by authors of the special issue of *Small Ruminant Research*. Recommendations for energy and protein were felt most appropriate given the information available and interpretation possible when the new NRC was drafted. It was recognized that future research will lead to enhancement or substitution of current energy and protein expressions with more appropriate ones.

Key Words: Goats, Sheep, Energy and Protein Requirements

229 The Small Ruminant Nutrition System (SRNS) model for prediction of energy and protein requirements of goats and sheep. A. Cannas*¹, L. O. Tedeschi², A. S. Atzori¹, and D. G. Fox³, ¹*University of Sassari, Sassari, Sardinia, Italy*, ²*Texas A&M University, College Station*, ³*Cornell University, Ithaca, NY*.

In previous NRC publications, simple empirical equations have been used to estimate energy and protein requirements for sheep and goats. This approach has limited the number of variables that could be accounted for and their accuracy when applied over widely varying production situations. To address this problem, the 2007 NRC small ruminant committee decided to utilize recently developed models to predict site-specific nutrient requirements and supply for sheep. The nutrient requirement tables for sheep were based on the Cornell Net Carbohydrate and Protein System (CNCPS) for sheep, as published by Cannas et al. (2004). Recently, a submodel for goats was added to this model and the name was changed to the Small Ruminant Nutrition System (SRNS). The main goals pursued in its development were: (1) to use a mechanistic approach, (2) to integrate accumulated research knowledge published by different research groups, (3) to differentiate the equations used for different species and breed type only when justified by sound biological reasons, and (4) to integrate energy and protein requirements with a nutrient supply submodel. The main differences between the SRNS submodel for sheep and that for goats are: (1) the energy requirements for basal metabolism differ among genotypes and are higher in goats than in sheep; (2) sheep maintenance energy requirements are adjusted to account for the increase in the size of the visceral organs as energy intake increases, but this correction is not applied for goats; (3) body fat content composition and the energy cost of gain is higher in sheep than in goats; and (4) protein requirements for maintenance are higher in sheep than in goats due to the cost of wool production. Robust evaluations, performed with independent research data, indicated the SRNS accurately predicted the energy balance and live weight gains of sheep and goats.

Key Words: Sheep, Goats, Requirements

230 Historic trends in U.S. sheep production and prospects for the future. H. A. Glimp*, *University of Nevada, Reno.*

Sheep were an important component of the food and fiber chain in the early European settlements in the eastern U. S. With settlement of the west and improved transportation systems, the sheep population began migrating to the western U. S., peaking at 54 million sheep and lambs in 1884 and reaching an all-time high of 56 million in 1942. The industry then began declining, dropping to 30 million in 1940 and continuing to decline until some stability has occurred in recent years. Concurrent with the decline in sheep and lamb numbers has been a decline in wool production and the downstream marketing, processing, and support services for the sheep and wool industry. The National Academy of Sciences report analyzes the factors contributing to these historic trends, the current status of the industry, and identifies current challenges and opportunities for the future viability of the industry. Even though numbers have declined to critical levels to maintain a viable industry infrastructure, the report identifies new developments and opportunities for the future of lamb, wool and milk production through improved genetic, management and marketing strategies.

Key Words: Sheep, Production, Trends

231 Marketing of sheep products: situation, challenges, and opportunities. G. Williams*, *Texas A&M University, College Station.*

The U.S. sheep industry is composed of many allied industries linked together along a complex value chain anchored by sheep production

and extending to varied end use markets. Each of the major industries along the value chain (live sheep, dairy sheep, lamb, wool, and sheep by-products) faces unique demand conditions but also are all linked on the supply side of their markets to sheep production. Consequently, the fortunes of each industry are inextricably linked to one another and depend particularly on the economic health and prosperity of the sheep production enterprise. The dominant feature of sheep production in the United States and, thus, the focus of much producer and policy concern over the years, has been the steady decline in sheep and lamb inventories since the mid 1940s. In turn, the decline in sheep and lamb numbers has restricted supplies of sheep and lamb products to the allied industries and created difficulties in the flow of those products through a shrinking marketing system as producers have struggled to respond to market signals while maintaining profitability. Concerns about the future of the industry led to a Congressional request in 2006 to the National Academies to review the development and current status of the sheep industry in the United States and to examine challenges and opportunities for the future. The committee of industry experts charged with the review by the National Academies has been studying all sectors of the sheep and allied industries since early 2007. Although not ready for public release, the committee's report examines the production and marketing side of each segment of the sheep industry value chain and focuses particularly on the challenges and opportunities facing each segment. On the marketing side, the study considers the factors affecting the flow of live sheep, lamb, wool, dairy sheep products, and other sheep products along the chain to consumers and changes needed and in the offing to improve the profitability and competitiveness of the industry.

ADSA-SAD (Student Affiliate Division) Undergraduate Competition: Original Research

232 Milk production, calving, and calf health in lines of dairy cattle selected for high versus low dairy form. M. B. Kron* and M. M. Schutz, *Purdue University, West Lafayette, IN.*

Dairy form (DF) comprises body condition and strength, with thinner, narrower cows assigned higher linear scores. Over time, DF has increased as a correlated response to selection for milk yield. Two selection lines of Holstein cows are being developed at Purdue University by mating cows to AI bulls with high (H) or low (L) Standardized Transmitting Abilities for DF. Resulting heifers are mated to sires from the same line to develop the divergent lines, HDF and LDF. This study's aim was to examine line effects on production and calving traits of first generation cows and health and growth of their second generation calves. For production and milk composition in first lactation, mixed models including year-season of calving, days in milk, line, and random sire effects did not reveal significant line differences, although LDF cows had a numeric advantage for all traits except milk yield. Heifers in LDF had numerically less dystocia, and significantly fewer cases of retained fetal membranes ($P < 0.001$). For second generation calves; birth weights, weekly heart girth, hip and wither heights, feed consumption, and scores for appearance, fecal consistency, and respiration, were recorded. The LDF calves had lower birth weights (40.6 ± 1.25 kg) compared to HDF (42.7 ± 1.11 kg) calves. Mean heart girths in wk 1 and 4 were 84.3 ± 1.10 cm and 90.7 ± 0.95 cm for LDF calves versus 83.3 ± 1.25 cm and 89.9 ± 0.38 cm for HDF calves, respectively. Calves in the LDF line averaged 81.3 ± 1.00 cm for hip height in wk 1, 76.8 ± 0.90 cm for wither height in wk 1, 81.9 ± 2.23 cm for hip height in wk 4, and 78.0 ± 0.73 cm for wither height in wk 4; while calves in the HDF line averaged 83.1 ± 1.10 cm, 79.3 ± 1.68 cm, 85.7 ± 0.73 cm and 80.0 ± 0.85 cm for the same traits, respectively. Scores for feed consumption, fecal consistency, general appearance, and respiration did not differ between LDF and HDF calves. Because of the preliminary nature of this study, numbers in each line were small. However, it does not appear that short term directional selection for low DF adversely affects cows or their calves.

Key Words: Dairy Form, Milk Yield, Calf Health

233 The effect of feeding high protein dried distillers grains on milk production. K. J. Hubbard*¹, A. M. Gehman¹, P. J. Kononoff¹, K. Karges², and M. L. Gibson², ¹*University of Nebraska, Lincoln*, ²*Dakota Gold Research Association, Sioux Falls, SD.*

The objectives of this study were to evaluate the effects of feeding a high protein dried distillers grains (HPDDGS) on milk production and components and dry matter intake. Concentration of CP, NDF, and ether extract of HPDDGS was 45.4 ± 0.09 %, 22.5 ± 0.16 %, and 4.0 ± 0.57 %. Ruminal DM digestibility of HPDDGS was evaluated *in situ* by incubating nylon bags containing 1.0 g of sample in the rumen of two steers for 48 h. Ruminal DM digestibility was observed to be 80.7 ± 3.6 %. Sixteen lactating Holstein cows (12 multiparous and 4 primiparous) averaging 80 ± 14 DIM were randomly assigned to one of two dietary treatments in a 2×2 crossover design. A portion of forage and all soy-based protein in the control diet was replaced by HPDDGS (20 % DM). Milk production and dry matter intake were recorded daily and averaged for d 15–21 of each 21-d period. Milk samples were collected on d 20–21 of each period. Milk yield increased ($P = 0.02$) with the

inclusion of HPDDGS (33.4 vs. 31.6 ± 2.11 kg/d), and 3.5% FCM was also higher ($P < 0.01$) for the HPDDGS ration (36.4 vs. 33.1 ± 2.21 kg/d). Percent protein was not affected by treatment (average 3.03 ± 0.08 %), but protein yield increased ($P = 0.01$) with inclusion of HPDDGS (0.95 to 1.00 ± 0.05 kg/d). Milk fat concentration was not different between treatments (average 3.97 ± 0.19 %), but fat yield increased ($P = 0.01$) for the HPDDGS ration (1.36 vs. 1.20 ± 0.08 kg/d). Dry matter intake tended ($P = 0.06$) to be lower for HPDDGS than control (21.2 vs. 22.6 ± 0.7 kg/d). Due to lower dry matter intake and greater milk production, feed conversion was improved ($P < 0.01$) by the addition of HPDDGS (1.47 to 1.73 ± 0.09). Milk urea N was greater ($P < 0.01$) for the HPDDGS ration than the control (14.6 vs. 12.8 ± 0.66 mg/dL). This research suggests the dairy rations may be formulated to contain up to 20% DM of HPDDGS and result in increased milk production and efficiency without negatively affecting milk components.

Key Words: Dairy Cow, High Protein Distillers Grains, Milk

234 The relationship between proinflammatory cytokines levels and onset of milk fever in dairy cows. E. A. Smith*, K. F. Knowlton, C. S. Petersson-Wolfe, I. K. Mullarky, and D. R. Winston, *Virginia Polytechnic Institute and State University, Blacksburg.*

Parturient paresis, or milk fever, is a common and debilitating disease that occurs at the onset of calving and results in paralysis and death if not properly treated. Current treatment protocols include administration of intravenous calcium (Ca). To date, there are few definite prevention strategies outside of altering cation-anion levels in the diet prior to parturition. Levels of parathyroid hormone (PTH) regulate Ca serum concentrations and may in part be responsible for the decrease in Ca associated with milk fever. Inflammatory mediators, such as tumor necrosis factor (TNF)- α have been shown to decrease secretion of PTH and thereby alter Ca levels at parturition. In order to identify a possible link between TNF levels and onset of milk fever, levels of TNF in animals diagnosed with milk fever as compared with control animals that did not exhibit milk fever symptoms were evaluated. Blood plasma TNF levels were measured by ELISA in samples collected at day -7, -3, -1, 0, 1, 3, and 5 relative to parturition. Results indicate lower levels of TNF- α in milk fever animals both prior to and following parturition as compared to animals without milk fever symptoms. TNF- α may be a regulator of blood Ca and an indicator of onset of milk fever at parturition. Ongoing studies will evaluate levels of PTH in milk fever animals and the mechanisms of TNF- α regulation of Ca homeostasis.

Key Words: Milk Fever, Cytokines, Calcium

235 Effects of a non-steroidal anti-inflammatory drug prior to dehorning on growth and physiological measures in calves. A. E. Smith*, A. L. Magliaro, J. R. Werner, and R. S. Kensingler, *The Pennsylvania State University, University Park.*

Dehorning of calves is a routine procedure in the dairy industry; dehorned cattle cause less harm to each other and are safer to handle. Producers are constantly trying to decrease stress in calves in order to improve growth and health while reducing costs. The objective of this

study was to determine whether treatment with Banamine (flunixin meglumine) prior to dehorning would affect growth rate and plasma haptoglobin and cortisol concentrations. Holstein heifer calves ($n = 52$, 40 ± 2.3 d old, 56.9 ± 4.9 kg) were blocked by age and randomly assigned to Banamine (B) or control (C) treatment groups. Calves in group B received 1.1 mg/kg of Banamine intravenously 15 min prior to dehorning. Calves in group C were dehorned without Banamine. All calves were dehorned using an electric hot iron dehorner with a mean contact time of 18.8 s per horn bud. Body weights were measured on d 0, 2, 7, and 14 relative to dehorning using an electronic scale with a weigh-average-hold function. Blood samples were collected on d 0, 2, and 7, and analyzed for hematocrit, plasma protein, haptoglobin, and cortisol. Data were analyzed using PROC MIXED within SAS. Calves exhibited good health, and mortality rate was 0 % during the study. Average daily gains from d 0 to d 2 were 0.68 and 0.52 kg for groups B and C, respectively, and were not affected by treatment ($SE = 0.08$, $P = 0.18$). Average daily gains from d 0 to d 7 for groups B and C were 0.69 and 0.68 kg, respectively, and were not affected by treatment. Mean haptoglobin concentrations were 33.0 and 22.9 $\mu\text{g/ml}$, and mean cortisol concentrations were 2.6 and 2.7 ng/ml for groups B and C, respectively. For all calves, mean hematocrit was 28.7 %, and mean plasma protein was 5.4 %. Blood and plasma measures were not significantly affected by treatment. Treatment with a single dose of Banamine alone 15 min prior to dehorning was not found to be beneficial to growth and did not reduce physiological measures of inflammation in 5-6 week old calves.

Key Words: Dehorning, Banamine, Haptoglobin

236 The effect of milk feeding method on cross-sucking behavior in pasture-based dairy calves fed once daily. K. A. Jackson* and S. P. Washburn, *North Carolina State University, Raleigh.*

Cross sucking among group-managed dairy calves increases concerns of udder malformation and mastitis due to irritation of the sucked area. We investigated whether pasture-raised dairy calves differed in cross-sucking activity when fed milk once daily in an open trough (Group 1, $n = 8$) compared to those allowed to suck from a barrel teat feeder (Group 2, $n = 8$). Calves of both genders were used and balanced across groups among Holsteins, Jerseys, and crossbreeds. Each group received one 30.5 L milk meal a day and had free-choice access to a calf starter and water on adjacent pasture paddocks. The hypothesis was that lack of sucking during eating might lead trough-fed calves to increased cross-sucking behavior. Calves were observed during 13 periods over 8 wk from the time they reached pasture until after weaning. Scan sampling using direct observation began upon delivery of milk and continued at 5-min intervals until 60 min after milk was fed. Additional observations were made during the same time post weaning. Data recorded by visual observation included general postures of calves (standing, lying head up, or lying head down) as well as specific activities such as, drinking or sucking milk, self-grooming, licking another calf, licking or nibbling on object, cross sucking, eating, or inactivity. The average number of observations per calf was 12.3 ± 0.02 per period. Incidence of cross sucking at and just after feeding time within the trough-fed group averaged 2.2 ± 0.4 , whereas the teat-fed group averaged only 0.15 ± 0.05 incidences of cross sucking. This behavior accounted for 18% of total activity for trough-fed calves and 1% of activity for teat-fed calves. In contrast, during post weaning the trough-fed group reduced cross-sucking behavior to 0.8 ± 0.3 incidences but the teat-fed average increased to 0.6 ± 0.3 incidences. Although trough-fed calves had higher cross-sucking behavior before weaning, occurrences of cross sucking

were similar for both trough-fed and teat-fed groups post weaning so long-term effects may be minimal.

Key Words: Calves, Cross-Sucking, Teat-Fed

237 Comparison of circulating progesterone and metabolic profiles in Holstein heifers and lactating cows. W. A. Smith*¹, D. H. Keisler², W. Silvia³, and L. E. Davis Rincker¹, ¹*Eastern Kentucky University, Richmond*, ²*University of Missouri, Columbia*, ³*University of Kentucky, Lexington.*

Reproductive efficiencies in lactating dairy cows have steadily declined during the last several decades while milk production has increased. In contrast, conception rates in dairy heifers have remained fairly constant. Declining fertility in lactating cows is likely due to a combination of genetics, management, and physiological factors. Our objective was to compare concentrations of circulating progesterone and metabolic hormones in one complete estrous cycle of heifers and lactating cows. Postpubertal, nonpregnant heifers ($n = 15$) and lactating, nonpregnant cows ($n = 15$; < 65 DIM) were synchronized using the following protocol: insertion of an intravaginal progesterone device (CIDRTM) with an injection of 100 μg GnRH (Factrel[®]) on d 0, an injection of PGF2 α (Lutalyse[®]) and removal of the device on d 7, and an injection of GnRH on d 9. Starting on d 10 of the synchronization protocol, 10 ml of blood were taken every other day for 24-d. All animals were scored for body condition and milk data was collected for cows. Statistical analysis used the GLM procedure of SAS. Body condition scores were different and averaged 3.19 and 2.37 for heifers and cows, respectively ($P < 0.01$). Progesterone and metabolic hormone analyses are ongoing. Correlations between factors measured for both heifers and cows will be performed to better understand the potential relationships between parameters.

Key Words: Fertility, Progesterone, Leptin

238 Evaluation of rumen microbial digestion of corn stover with cellulose treatment. B. Bosma*, R. Jimenez-Flores, and J. Howard, *California Polytechnic State University, San Luis Obispo.*

The bulk of feed consumed by dairy cattle is digested by microbes in the rumen. The efficiency of microbial digestion has a direct effect on rate and extent of cellulose breakdown from the diets they consume. Microbes begin the process of digestion by attaching to feed particles by secreting a sticky, mucous-like envelope onto the feed. Microbial cells then multiply to form colonies at the site of attachment and begin to release digestive enzymes, such as cellulase, which break down the feed. Previous research has indicated a milk cow ration treated with cellulase has increased the efficiency of cellulose digestion, therefore increasing milk production. For further research in this area, an in-vitro model system was developed in which dried corn stover in rumen fluid was inoculated with *Trichoderma reesei* cellulase and growth as related to CO₂ production was measured. The CO₂ production was doubled with the addition of 50 μL of cellulase and more than tripled with the addition of 500 μL of cellulase. The addition of *Trichoderma reesei* cellulase improved the fermentation profile of corn stover during in-vitro fermentation.

Key Words: Corn Stover, In Vitro Fermentation, *Trichoderma Reesei*

239 Change in the prevalence of mastitis pathogens in an organic dairy farm as it transitioned from a conventional dairy farm. W. M. McMahan* and L. K. Larry, *Washington State University, Pullman.*

The objectives were to collect aseptic composite milk samples from all cows before (Phase I), during (Phase II), and after (Phase III) the transition to organic status on two dairies and to culture milk samples for isolation of mastitis pathogens. Cows enrolled were those at parturition, dry off, and clinical mastitis. During Phase I antibiotics were used in dry cow therapy and were eliminated in Phases II and, III. Staphylococcus species mastitis increased at parturition samples from 31% Phase I, 35%

Phase II, and 49% in phase III. At parturition prevalence of Streptococcus species was 8% in Phase I and 23% in Phase III. The prevalence of Streptococcus species at dry off changed from 6% in Phase I to 4% in Phase III. The prevalence of cows without mastitis pathogens at parturition was 53 percent in Phase I, 39 percent Phase II, and 30 percent Phase III, indicating mastitis at parturition had increased over time in the transition to organic. The data also show that the number of cows without mastitis pathogens is 60% at dry off in all three phases. Data suggests cows under organic management freshen with more mastitis but that the increased prevalence subsides such that at dry off the prevalence is very similar to that of the conventionally managed cows.

POSTER PRESENTATIONS

Animal Health: Immunology

W1 Absorption of total immunoglobulin G in dairy calves fed a colostrum replacement. J. A. Elizondo-Salazar*¹, R. F. Leuer¹, J. M. Campbell², and A. J. Heinrichs¹, ¹*The Pennsylvania State University, University Park*, ²*APC, Inc., Ankeny, IA*.

Proper colostrum management is an important step in preventing disease in neonatal calves, but failure of passive transfer of immunity is still a problem in the US dairy industry. It is generally considered that transfer of passive immunity is adequate if serum IgG concentration is > 10 g/L in colostrum-fed calves. Colostrum replacers providing ≤ 125 g of globulin protein have increased in popularity and are designed to be an alternative to colostrum. However, it is important to make sure these products are effective and are capable of providing adequate serum Ig concentrations. The objective of this study was to evaluate the effect of a commercially available serum-based colostrum replacement product on serum total IgG concentration. The study included 28 Holstein calves (14 males and 14 females) from a single dairy. Calves were bottle fed a single package of colostrum replacer (125 g IgG; Acquire, APC, Inc.) mixed in 2 L of warm water. After colostrum replacer feeding, calves were fed whole milk for the second and third feeding at 10% of birth weight daily in 2 feedings. Blood samples from all calves were collected at 24 h after birth and analyzed for total IgG concentration using single radial immunodiffusion. Overall, plasma IgG levels were 10.8 ± 2.4 g/L and indicated successful passive transfer of immunity. There were no significant differences in serum IgG levels attributable to gender (females: 10.3 ± 2.1 g/L; males: 11.1 ± 2.6 g/L), birth weight (> 41.5 kg: 11.1 ± 2.5 g/L; < 41.5 kg: 10.1 ± 2.4 g/L), age at first feeding (> 60 min: 11.4 ± 3.0 g/L; < 60 min: 10.3 ± 2.0 g/L), or time of d at first feeding (a.m.: 11.3 ± 2.7 g/L; p.m.: 10.0 ± 1.9 g/L). Results indicate that the colostrum replacer evaluated in this study provided adequate IgG concentrations for newborn calves when fed according to label directions and thus can be considered an effective alternative to colostrum in dairy calves.

Key Words: Colostrum Replacer, Dairy Calf, Immunoglobulin G

W2 Feeding heat-treated colostrum does not affect growth parameters in pre-weaned heifer calves. J. A. Elizondo-Salazar*, R. F. Leuer, and A. J. Heinrichs, *The Pennsylvania State University, University Park*.

Colostrum not only provides nutrients and passive immunity for the newborn calf, but it can also have profound effects on their development. Heat-treatment of colostrum reduces IgG concentrations yet increases IgG absorption, but effects on short- and long-term calf performance are unknown. For this reason, a study was conducted to evaluate effects of feeding heat-treated colostrum on calf growth. First milking colostrum with > 50 g IgG/L (measured by colostrometer) was collected from Holstein cows and frozen at -20°C until a total of 106 L were accumulated. Once collected, colostrum was thawed at 4°C and pooled in a commercial batch pasteurizer to create a uniform batch. Colostrum was mixed at 4°C for about 20 min. 53 L of colostrum were transferred to 1.89 L containers and frozen at -20°C until feeding. The remaining 53 L were heated at 60°C for 30 min, transferred to 1.89 L containers, and then frozen at -20°C until feeding. A total of 28 calves weighing ≥ 35 kg at birth were systematically enrolled into 1 of the 2 treatment groups. Calves were separated from their dams at birth before suckling occurred. For the first feeding, 3.8 L of colostrum were bottle fed by 1 to 2 h of age. To ensure that all calves received an equal amount of colostrum, an esophageal feeder was used in calves with reduced appetite. For the second and third feeding, pasteurized whole milk was fed at 5% of birth BW. Subsequently, calves were fed milk replacer (20% CP, 20% fat) at 10% of birth BW in 2 daily feedings until week 5. Growth measures including heart girth, hip height, BW, and withers height were taken at birth and weekly 4 h post a.m. feeding. Total serum protein at 24 h of age was 5.6 and 5.5 g/L for the heated and unheated colostrum, respectively. No differences were detected between treatment groups for any of the variables. Weight at 2, 4 and 6 wks of age was 191.0, 235.6, and 288.2 kg for calves receiving heat-treated colostrum and 196.7, 242.9, and 297.8 kg for calves receiving untreated colostrum. The results of this study indicate that feeding heat-treated colostrum did not negatively impact growth in pre-weaned heifer calves.

Key Words: Colostrum, Growth, Heifer Calves

W3 The use of a mini-batch pasteurizer is a suitable system for small farms. J. A. Elizondo-Salazar*, R. F. Leuer, B. M. Jayarao, and A. J. Heinrichs, *The Pennsylvania State University, University Park*.

The adoption of commercial on-farm pasteurization systems for the purpose of pasteurizing non-saleable milk and colostrum has resulted

in significant health and economic benefits for calves and producers, respectively. However, these systems are expensive and not suitable for small farms. With this in mind, a Mini-Batch Colostrum/Milk pasteurizer is available in the market and we wanted to determine its performance on different liquid calf feeds. A 3 × 2 factorial design with 3 replicates was used. Three different liquid feeds (first milking colostrum, transition milk, and waste milk) at 2 different volume levels (full capacity = 12 L and half capacity = 6 L) were pasteurized at 63°C for 30 min. 10 mL samples were taken before and after pasteurization and frozen to -20°C. All samples were thawed at 4°C and evaluated for standard plate count (SPC), coagulase-negative staphylococci (CNS) count, environmental streptococci (ES) count, coliform (CC) count, gram-negative noncoliform (NC) count, *Streptococcus agalactiae* (SAG) count, and *Staphylococcus aureus* (SA) count. Total IgG levels were determined in all colostrum samples using radial immunodiffusion. Viscosity was also measured using a digital viscometer. The mini-batch pasteurizer effectively reduced SPC, CC, NC, ES, CNS, and SA ($P < 0.01$). However, pasteurization denatured IgG ($P < 0.01$) and increased the viscosity in colostrum samples. The effects were greater when small batches were used. The findings of the study suggest that a mini-batch pasteurizer can be used as an on-farm pasteurization system to effectively pasteurize transition milk and waste milk. However, for colostrum only full batches should be used and a lower temperature could help reduce the denaturing of immunoglobulins.

W4 Animal performance and blood gas variables of steers pulled and/or treated for Bovine Respiratory Disease. K. M. Bischoff*, L. Carlos-Valdez, B. P. Holland, L. O. Burciaga-Robles, D. L. Step, and C. R. Krehbiel, *Oklahoma State University, Stillwater.*

Bovine Respiratory Disease (BRD) is the most economically important disease in cattle. The objective was to characterize performance, blood gases and metabolites of high-risk steers diagnosed with BRD. Steers were evaluated daily for clinical signs associated with BRD (depression, appetite, respiratory stress, and temperature). Steers identified as morbid were assigned a depression score (1=mild to 4=moribund) and pulled to a processing facility where rectal temperature and BW were recorded. Two blood samples were collected; one for blood gas and the second for serum haptoglobin analysis. If a steer had a rectal temperature greater than 40°C, an antimicrobial was administered. If a steer did not meet the

rectal temperature criteria, no antimicrobial was administered unless the animal had a depression score of 3 or 4. During the first 21 d, a total of 89 out of 240 steers were enrolled in the study. For data analysis, steers were grouped based on whether they were pulled but not administered an antimicrobial (PULL), or had received one (TX1), two (TX2), or three (TX3) antimicrobial treatments. From the 89 animals enrolled, there were 19 PULL, 23 TX1, 29 TX2, and 17 TX3. Depression scores were lower ($P < 0.001$) for PULL compared with TX1, TX2 and TX3. Arrival BW was greatest ($P = 0.005$) for PULL and TX1, intermediate for TX3, and lowest for TX2. Average daily gain tended ($P = 0.09$) to be greatest for PULL steers. Rectal temperature was lowest ($P < 0.001$) for PULL as fever ($> 40^\circ\text{C}$) was prerequisite for the remaining groups. Haptoglobin concentration at arrival was not different ($P = 0.57$) among treatments. Blood variables including pH, pO₂, glucose, lactate, hematocrit, sodium, and SO₂ were not affected ($P > 0.10$) due to number of antimicrobials administered. Calcium concentrations were lowest ($P = 0.02$) for PULL, intermediate for TX1 and TX2, and greatest for TX3. In addition, K was greater ($P < 0.001$) for TX1 vs. PULL; TX2 and TX3 were intermediate. Bicarbonate and pCO₂ were lower ($P < 0.03$) in TX1 and TX2 steers. Our results suggest that some blood gases and metabolites are altered by BRD, and may be useful indicators of disease.

Key Words: Blood Gas, Bovine Respiratory Disease, Cattle

W5 Relationship between total microbial colostrum contamination and IgG absorption in newborn dairy calves. M. Terre*¹ and A. Bach^{1,2}, ¹IRTA-Unitat de Remugants, Barcelona, Spain, ²ICREA, Barcelona, Spain.

Fifteen newborn Holstein calves (41.2 ± 6.15 kg BW) from 5 different farms were used to study the relationship between colostrum microbial contamination and IgG absorption 6 h after colostrum consumption. Furthermore, colostrum bacteria contamination from the udder to different colostrum containers was also studied. Within 5 h after each calf birth, an initial blood sample was obtained before colostrum was fed, and calves were weighed to estimate plasma volume concentration (assuming plasma represented 8% BW). After that, a first-milking colostrum sample was collected directly from the udder. Then, a second colostrum sample was obtained from the milking bucket, and a third sample was taken from the bucket or teat-feeder where calves were fed to perform total bacterial counts in Nutrient Agar plates and total Enterobacteria counts in MacConkey Agar plates. Then, 1.7 ± 0.64 L of colostrum were fed to calves, and 6 h after the first colostrum consumption another blood sample was harvested. Colostrum IgG concentration from the third colostrum sample, and serum IgG concentration at 0 and 6 h after the colostrum was fed were determined to calculate IgG absorption 6 h after the first colostrum consumption. Total bacteria and Enterobacteria counts increased ($P < 0.001$) from the udder to the milking bucket (from 3.66 to 5.39 ± 0.209 log total bacteria counts, and from 2.45 to 4.69 ± 0.231 log total Enterobacteria counts), but they did not increase from the milking bucket to calf bucket. Furthermore, a negative relationship was observed between log total bacteria counts in colostrum from calf buckets and IgG absorption 6 h after colostrum was fed ($R^2 = 0.26$; $P = 0.05$). However, there was no relationship between log total Enterobacteria counts and IgG absorption 6 h after colostrum consumption. Although there exist many factors that affect IgG absorption (time elapsed from birth to colostrum consumption, IgG colostrum quality) keeping colostrum with low bacteria contamination may help to improve IgG absorption and calf health.

Key Words: Calves, Colostrum, IgG Absorption

W6 Comparison of growth, feed intake, and feed efficiency of female calves fed aureomycin plus lasalocid or monensin. G. E. Higginbotham*¹, R. C. Chebel², and L. Pereira³, ¹University of California, Fresno, ²University of California-Davis, Tulare, ³California State University, Fresno.

Objectives were to evaluate growth, feed intake, and feed efficiency of female Holstein calves fed aureomycin and lasalocid (AL) compared to those fed monensin (M). Holstein female calves from a commercial dairy herd located in the central valley of California were enrolled in the study within 12 h after birth. At enrollment, blood was sampled for evaluation of concentration of total proteins and calves were weighed and allotted randomly into 1 of 2 treatments: monensin (M) or aureomycin plus lasalocid (A+L). Feed supplements were mixed into their respective grain starters to provide 60 g/T of monensin and 350 g/T of aureomycin and 60g/T of lasalocid for M and A+L treatments, respectively. During the first 3 wk of life, calves were fed reconstituted commercial non-medicated milk replacer. After 3 wk of age, calves were fed pasteurized waste milk in addition to or as a replacement for milk replacer. From birth to 12 wk of age, calf starter was fed once daily and no hay was offered, feed intake was measured and feces were scored for its consistency (1 = firm, 2 = soft, 3 = runny) daily, and calves were weighed weekly. Feed analysis demonstrated that the amounts of monensin, aureomycin and lasalocid added to the grain starters were actually 44.2, 222.8, and 42.7g/T, respectively. Treatment did not affect average daily weight gain (M = 0.66 ± 0.03, A+L = 0.68 ± 0.03 kg/d; P = 0.59) or average body weight (M = 60.20 ± 0.90, A+L = 60.38 ± 0.92 kg; P = 0.88) during the study. Similarly, there was no effect of treatment on grain intake (M = 648.2 ± 0.04, A+L = 663.4 ± 0.04 g/d; P = 0.79) or feed efficiency (M = 0.76 ± 0.06, A+L = 0.72 ± 0.06; P = 0.49). Fecal score during the study period also was not affected (P = 0.25) by treatment (M = 1.73 ± 0.04, A+L = 1.66 ± 0.04). Treatment did not affect the proportion of calves diagnosed with at least one event of diarrhea (M = 79.5, A+L = 65.0%; P = 0.16) or pneumonia (M = 30.8, A+L = 25.0%; P = 0.53). Supplementation with aureomycin and lasalocid did not improve performance of calves compared to those supplemented with monensin.

Key Words: Calves, Aureomycin, Lasalocid

W7 An international survey on the occurrence of mycotoxins in dried distillers grains with solubles (DDGS). U. Hofstetter*¹ and E. Pichler², ¹Biomim GmbH, Herzogenburg, Austria, ²Quantas Analytics GmbH, Tulln, Austria.

Bioethanol production is booming especially in North America. The inclusion of the resulting by-product DDGS – dried distillers grains with solubles – is becoming popular in the global raw material market. However the mycotoxin menace is not eliminated by the fermentation processes during ethanol production. Mycotoxins are toxic metabolites formed by fungi species that colonize crops and thus pose a potential threat to animal health. Mycotoxin contamination of crops may cause economic losses at all levels of food and feed production. Raw material contamination is augmented during the bioethanol production. This study was initiated to provide customers insights in the occurrence of mycotoxins in DDGS samples worldwide thereby enabling better feed management. A total number of 191 samples were analyzed for the major mycotoxins of interest (aflatoxins, zearalenone, deoxynivalenol or vomitoxin, T-2 toxin and fumonisins). The tests have been conducted by Quantas Analytics, Austria, and Romer Labs, Singapore. Aflatoxins, ZON and total FUM were analyzed by HPLC (High Pressure Liquid

Chromatography) whereas DON values were obtained by TLC (Thin Layer Chromatography). From all samples analyzed, zearalenone accounted for a 87% contamination rate; 70% of tested DDGS were positive for vomitoxin and 88% for fumonisins. The presence of so-called field mycotoxins (ZON, DON, FUM) produced by different *Fusarium* sp. which – despite Good Agricultural Practice – cannot be avoided totally is very frequent. Almost no aflatoxins and T-2 toxin were found in the DDGS samples collected. Only 13% of the samples were positive for aflatoxin with an average contamination level of 1 µg/kg and only 12% for T-2 toxin with an average contamination level of 11 µg/kg. 96% were tested positive for at least one mycotoxin whereas only 8 samples (4%) of the analyzed DDGS didn't show mycotoxin levels above the detection limit. More interesting was the fact that 97% of the positive samples have shown a co-occurrence of 2 or more mycotoxins. This study confirmed previous literature stating the high levels of mycotoxins in distillers grains.

Table 1. Occurrence of mycotoxins in a total number of 191 DDGS samples

	AfB1	ZON	DON	FUM	T-2
% positive	13	87	70	88	12
Avg. level [µg/kg]	1	208	1504	767	11
Max. level [µg/kg]	89	8107	12000	9042	226

Key Words: DDGS, Mycotoxins

W8 Incubation temperatures affect secretion of TNF-alpha and IL-6 by peripheral blood mononuclear cells from Brown and Holstein cows. N. Lacetera*¹, M. Amadori², U. Bernabucci¹, and A. Nardone¹, ¹Dipartimento di Produzioni Animali, Viterbo, Italy, ²Istituto Zooprofilattico Sperimentale Lombardia-Emilia Romagna, Brescia, Italy.

This study aimed at evaluating spontaneous and concanavalin A (ConA)-stimulated secretion of tumor necrosis factor alpha (TNF-alpha) and interleukin 6 (IL-6) by peripheral blood mononuclear cells (PBMC) from Brown (Br) and Holstein (Ho) cows exposed to different treatments (T). PBMC from 7 Br and 7 Ho cows were alternatively subjected to each of the following T: T39) 39°C continuous, T40) 40°C for 39 h and 39°C for 26 h, T41) 41°C for 39 h and 39°C for 26 h, T42) 42°C for 39 h and 39°C for 26 h, and T43) 43°C for 39 h and 39°C for 26 h. Under T40, 41, 42 and 43, three 13 h cycles at 40, 41, 42 or 43°C were alternated with two 13 h cycles at 39°C. T39 mimicked normothermia; T40, 41, 42 and 43 mimicked conditions of hyperthermia alternated with normothermia, which may occur in dairy cows in hot seasons. TNF- alpha and IL-6 were evaluated in supernatants collected at the end of the incubation period by MTT biological assays on WEHI164 and 7TD1 cells, respectively. In both breeds, compared to T39, cultivation of PBMC under T40, 41, 42 and 43 reduced both spontaneous and ConA-stimulated secretion of TNF-alpha. Furthermore, spontaneous secretion of TNF-alpha under T39, was higher in Ho compared to Br cows. In both breeds, IL-6 tended to be higher in PBMC cultured under T40, 41 and 42 compared to T39. Only in Ho cows, IL-6 secretion was reduced in PBMC cultured under T43 compared to T39. Finally, under T39, secretion of IL-6 in ConA-stimulated PBMC was higher in Ho compared to Br cows. Differential regulation of proinflammatory cytokines has been already reported for mammalian cells exposed to stimuli other than temperature. Changes of both TNF-alpha and IL-6 reported

herein may be conducive to a successful adaptation to the perturbation caused by high temperatures. Different responses of the two breeds to temperatures simulating normothermia may reflect differences of the steady state endogenous inflammatory response associated with different levels of production stress.

Key Words: Temperature, Peripheral Blood Mononuclear Cells, Cytokines

W9 Association of tumor necrosis factor- α (*TNF- α*) gene promoter polymorphisms with *TNF- α* response to endotoxin (LPS) in calves. S. Kahl*, M. Proszkowiec-Weglarz, E. E. Connor, and T. H. Elsasser, *USDA, Agricultural Research Service, Beltsville, MD, USA.*

Attenuation of *TNF- α* gene expression is a NF- κ B-mediated regulatory process essential to avoid deleterious effects of excessive or prolonged synthesis of *TNF- α* , especially in response to gram-negative bacterial infection or LPS. An uncommon G to A transition polymorphism in the promoter region of *TNF- α* gene (designated the *TNF- α 2* allele) was shown to be highly associated with excessive *TNF- α* production and *TNF- α* -mediated pathologies in humans. We performed a preliminary survey to determine if similar polymorphisms exist in Angus \times Hereford calves that might suggest a potential for particular animals to have excessive *TNF- α* responses to LPS challenges. A 574-bp *TNF- α* gene promoter fragment was generated by PCR from bovine genomic DNA and evaluated by bi-directional automated fluorescent sequencing. Two linked single nucleotide polymorphisms were located between NF- κ B binding sites at positions -701 (C/T) and -526 (A/G). Calves ($n=17$; 279 \pm 10 kg) were assigned to groups by genotype (4 TT-AA, 5 CT-AG, 8 CC-GG), fed a TMR diet (15% CP) to appetite, and challenged with two consecutive LPS injections 4 d apart (LPS1, LPS2; 0.2 μ g *E. coli* 055:B5/kg BW, i.v.). Jugular blood samples were obtained at 0, 1, 2, and 4 h relative to each LPS injection. Plasma *TNF- α* was measured by RIA and *TNF- α* response was calculated as area under the time \times concentration curve (AUC; ng/mL \times h). After LPS1, mean *TNF- α* responses were greater in TT-AA than CT-AG and CC-GG calves (4.9, 2.2, and 3.0, respectively; $P < 0.05$). While for each calf the *TNF- α* response to LPS2 was numerically lower than that calculated for LPS1 (indicating LPS tolerance attenuation was achieved), mean *TNF- α* responses to LPS2 were still greater in TT-AA than CT-AG and CC-GG calves (3.3, 1.0, and 1.1, respectively; $P < 0.01$). The magnitude of the attenuation was less in TT-AA than in CC-GG calves ($P < 0.05$). The results suggest that polymorphisms in the *TNF- α* gene promoter may play a role in the intensity of the *TNF- α* response to proinflammatory stimuli in cattle.

Key Words: Cattle, SNP, Tumor Necrosis Factor- α

W10 Efficacy of a polyclonal antibody preparation against respiratory disease pathogens on cattle morbidity and performance during the step-up period. C. R. Dahlen*, N. DiLorenzo, and A. DiCostanzo, *University of Minnesota, St. Paul.*

A polyclonal antibody preparation (PAP) against respiratory pathogens including *Mycoplasma bovis*, *Haemophilus*, *Pasteurella multocida* and *Mannheimia haemolytica* reduced morbidity and mortality during the first 32 d on feed in lightweight, high morbidity (212 kg and 29%, respectively) calves. However, it is not known whether PAP reduces morbidity in heavier, lower risk ($> 15\%$ morbidity) calves, or its effects

on intake and gains during the step-up period. Thus, the current study was designed to determine the efficacy of PAP in heavier, lower risk calves. One hundred thirty six Angus and Angus crossbred steer calves (276 kg) were randomly assigned to one of two treatments (Control or intranasal dosing 1.5 mL PAP/nostril on arrival and 7 d later) on arrival at the NWROC research feedlot. Within treatment, calves were then allocated (9 or 10/pen) to one of each of 12 pens for a 27-d diet step-up period. On arrival, at d 7 and 27, rectal temperatures were measured. Calves were considered morbid if rectal temperature recorded $> 39.7^{\circ}\text{C}$. Body weights, pen and intakes were measured from d 7 to d 27 of the step-up period. Dosing cattle on arrival and 7 d later with PAP reduced ($P = 0.01$) morbidity (5% vs 14%) detected 7 post-arrival. Rectal temperatures did not differ on arrival or at day 27 (38.8 vs 38.9 $^{\circ}\text{C}$ and 38.6 vs 38.7 $^{\circ}\text{C}$ for Control and PAP, respectively). At day 7 rectal temperatures were lower ($P < 0.05$) for cattle dosed with PAP (39.0 vs 38.8 $^{\circ}\text{C}$ for control and PAP, respectively). No effects ($P > 0.10$) of PAP dosing were observed on DMI, ADG or feed conversion during the step-up period. A reduction in morbidity of 9 percentage units represents economic savings in medication and labor costs.

Key Words: Antibodies, Health, Cattle

W11 Effect of rubber flooring on leukocyte activation during the periparturient period. K. O'Driscoll^{1,2}, M. M. Schutz³, and S. D. Eicher^{*4}, ¹Teagasc, Fermoy, Ireland, ²NUI Dublin, Dublin, Ireland, ³Purdue University, West Lafayette, IN, ⁴USDA-ARS, West Lafayette, IN.

This study aimed to evaluate the effect of 2 dairy cow housing systems on innate immune status during the peri-parturient period. Leukocyte counts, phagocytic ability and neutrophil and monocyte differentiation were examined. Cows were assigned to free-stall housing with either rubber (RUB; $n=13$) or concrete (CON; $n=14$) at the feed-face immediately after their first calving, and managed on this system during all subsequent lactations. Between lactations cows remained in a straw bedded-pack dry cow pen. A year-round calving system was utilized. Cows entered the experiment at the end of either their 1st ($n=16$) or 2nd ($n=11$) lactations. Blood samples were obtained approximately -60, -30, 0, +7 and +14 d relative to calving. Differential leukocyte counts were obtained using an automated cell counter. Phagocytic activity, and cells positive for CD14 and CD18 expression were measured by flow cytometry using labelled micro-beads and antibodies. Treatment effects were determined using repeated measures ANOVA. An interaction of treatment and d ($P < 0.05$) on neutrophil and lymphocyte counts ($P < 0.05$) was found. RUB cows had higher neutrophil and lower lymphocyte numbers post calving than CON. Neutrophil to lymphocyte ratio tended ($P = 0.1$) to be higher for RUB than CON cows post calving. There was no effect of treatment on phagocytosis or percentage of cells positive for CD14 or CD18. However, d tended ($P = 0.1$) to have an effect on phagocytic events, with the highest value at d -60. Cells positive for CD14 were greatest on d 0 ($P < 0.05$), and a treatment by d effect was found for cells positive for CD14. CD14 percentages were greater for RUB than CON cows post calving. A high neutrophil to lymphocyte ratio is associated with physiological stress, but suppressed leukocyte function is associated with peri-parturient period. Thus, the ability of RUB cows to activate neutrophils and monocytes is indicative of an improved immune response.

Key Words: Rubber Flooring, Cow Locomotion, Innate Immune Activation

W12 Functional evaluation of polymorphisms in the bovine IL-8 gene promoter. S. Kandasamy*, K. L. Haddock, and D. E. Kerr, *University of Vermont, Burlington.*

An early event in the response of the host to infection is the release of chemokines to attract neutrophils and other immune cells to the site of infection. An early robust response may be critical in containing and eliminating the pathogen, but the potential exists for an exaggerated response leading to collateral tissue damage. Our objectives were to determine if SNPs exist in the 5'-regulatory region of the bovine IL-8 gene and if so to determine if they affected functionality of the gene in response to LPS treatment. We located 5 SNP sites through individual sequencing of PCR products (extending 1 kb upstream from the translation start site) from DNA of 28 Holstein cattle. In all cases the 5 SNPs were linked resulting in two haplotypes (A or B). We have now genotyped an additional 10 animals by PCR-RFLP giving a total of 14 AA, 16 AB, and 6 BB genotypes (61%A, 39%B). The two haplotypes were cloned into luciferase expression vectors (pGL-3 basic), with subsequent transfection into bovine mammary epithelial cells (Mac-T). Cells were also co-transfected with a GFP expression plasmid (pCMV-GFP) as a transfection control. Following LPS exposure (100ng/ml, 24h), cell extracts were prepared and assayed for fluorescence then combined with Bright-Glo Reagent (Promega) and assayed for luminescence. Substantial levels of luciferase activity were recorded from both haplotypes under control and LPS-stimulated conditions. However, the A haplotype generated more luciferase activity (1.25 vs 0.85 relative units) although there was no direct effect of LPS nor an LPS*haplotype interaction in this model. In a second experiment, heparinized whole blood from homozygous AA or BB animals (n=3) was stimulated with LPS (1, 10, and 100 ng/ml, or vehicle) for 3h or 6h. The concentration of IL-8 in the subsequently obtained plasma was highest following 6 h exposure to 100 ng/ml dose of LPS (157±13 pg/ml vs 42±14 in control). Overall the concentration of IL-8 was significantly (P<.01) affected by LPS, by exposure time, and was greater in blood from AA animals. It remains to be determined if differences exist between AA and BB animals in their response to infectious pathogens.

W13 Genomic response of immune associated genes to LPS challenge in bovine mammary gland and epithelial cells. D. E. Kerr*, M. Latshaw, and R. Parik, *University of Vermont, Burlington.*

The innate immune response to bacterial entry into the mammary gland is critical in determining the outcome of mastitis. Our goal was to profile the transcriptional response of mammary tissue and epithelial cells to an LPS challenge to further our understanding of the bovine innate immune system. Sources of RNA applied to Affymetrix GeneChips included biopsy samples from LPS-challenged (1 ug/gland) and contralateral control mammary glands of 3 lactating cows 4 h post-LPS challenge (COW); and from LPS-stimulated (100 ng/ml) or control cultures of primary mammary epithelial cells from different cows 3 h (C3), 8 h (C8), and 24 h (C24) post-LPS exposure. Filtering the data at a fold change ≥ 2.0 or ≤ -2.0 , and P<.05 revealed differential expression of 3.0%, 0.6%, 1.5%, and 1.6% of the 24,128 probe sets contained on the chip for COW, C3, C8, and C24, respectively. A common core of 47 induced probe sets included 3 of 26 genes on the GeneChip associated with the TLR4 signaling pathway (NFKB1, NFKBIA, and NFKBIZ), 4 members of the neutrophil attracting, ELR positive CXC chemokines (CXCL1,

CXCL2, CXCL6, and IL-8), 2 additional chemokines (CX3CL1, CCL2) and inflammatory associated proteins (IL6, LTF, SAA3, PLAU, SOD2, S100A8). Key differences between cells and biopsies in the TLR4 signaling pathway included induction of CD14 by cells and of TLR4 in the tissue. Additional differences between cells and tissue included marked induction (>5 fold) of IL1B, CCL5, and CCL20 in the cells and marked induction of CCL4, CCL8, CCL23, and IL1RN in the tissues. Notable time dependent changes in the cell response included a continual increase (P<.01) in the fold change response of SAA3 and S100A8 and the delayed induction of interferon regulated proteins MX1, MX2, IFI6, and ISG15. These studies have revealed a rapid, robust response of the bovine mammary gland and epithelial cells to LPS. The genomic response includes a core of common genes and distinct time and source differences, yet appears dominated by activation of the NF-kB complex leading to upregulation of inflammatory cytokines and multiple members of the chemokine gene family.

W14 Genetic analysis of dairy calf health traits and survival. L. Henderson*¹, F. Miglior^{2,3}, D. Kelton¹, J. Robinson⁴, J. Wormuth⁵, A. Sewalem^{2,3}, and K. Leslie¹, ¹*University of Guelph, Guelph, ON, Canada*, ²*Dairy and Swine Research and Development Centre, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada*, ³*Canadian Dairy Network, Guelph, ON, Canada*, ⁴*University of Guelph, Guelph, ON, Canada*, ⁵*CY Heifer Farms, Batavia, NY.*

Genetic selection for improved health and longevity is a major initiative of dairy cattle breeding programs. Recently, extensive efforts have been made to improve selection indices for calf survival at birth in Canadian dairy cattle. To date, little effort has been put into exploring the genetic components of measures of calf health, survival and performance from birth until the post-weaning period. The objective of this study is to evaluate the heritability and genetic correlations of calf health traits based on measures of passive transfer of immunity, disease occurrence, survival and growth from birth to weaning for a large population of Holstein calves. Health and performance records were available from approximately 10,000 dairy heifer calves from a commercial heifer raising facility in western New York. Data was recorded from arrival of the calf at 2-5 days of age for the duration of stay at the facility. At enrollment, calves were weighed and evaluated for passive transfer of immunoglobulins from colostrum feeding. A standard protocol was followed for health management practices, disease recording and therapy throughout the growing period. All disease occurrences, treatments, management events and weight measurements were recorded in DairyComp 305 to create a complete record for each animal. In a subset of these data, 650 calves from 20 Holstein sires have been analyzed. The number of calves per sire ranged from 16 to 82, with an average of 35 per sire. The average serum total solids in calves by specific sire group ranged from 6.2 to 7.2 g/dL. The average daily gain for the growing period by sire group ranged from 650 to 900g/day. These data along with mortality rates suggest that there may be significant genetic differences among Holstein calves for health status in the early neonatal period, susceptibility to neonatal disease problems, and for survival to weaning.

W15 Performance and carcass alteration of Nellore and F1 Brangus × Nellore steers supplied with organic chromium finished on grass. A. Polizel Neto*¹, A. M. Jorge¹, P. S. A. Moreira², H. F. B. Gomes¹, and R. D. O. Roça¹, ¹São Paulo State University, Botucatu, São Paulo, Brazil, ²Federal University of Mato Grosso, Sinop, Mato Grosso, Brazil.

Chromium works as Glucose Tolerance Factor – GTF, which causes muscle glucose input stimulus. The present work aimed to evaluate the effect of breed and mineral protein supplementation with organic chromium addition on performance and carcass traits in steers finished on grass. 18 Nellore and 18 F1 Brangus × Nellore steers with initial age of 16 months and live weight of 77.31±18.15 kg were used. Two treatments of mineral protein supplementation (22% crude protein, with 0.25 cottonseed meal, 0.25 grind corn and 0.50 commercial mineral supplement) with and without organic chromium addition (2 mg/animal/day of chromium), finished on *Brachiaria sp* grass were assigned. After 14 hours of solid fasting, at initial and final moment, cattle were weighed and calculated the daily weight gain (ADG), on 190 days of experiment. Carcass traits were evaluated by means of ultrasound measurements: rib eye area (REA), subcutaneous fat thickness at the back (between 12th and 13th rib) and at the rump (SFTB and SFTP8). A randomized design was used and all data were analyzed using analysis of variance with two variance source (breed and chromium) using Statistical Analysis System. Regarding ADG, no difference was observed (P≥0.05) between breeds (means of 457 g/day). On the other hand, animals supplied with chromium showed better ADG (494 g/day) than control animals (420 g/day). Once again, there were no observed differences (P≥0.05) among experimental treatments in carcass traits measured by ultrasound, reaching final average values of 63.42 cm², 5.46 mm and 5.58 mm, respectively to REA, SFTB and SFTP8. The Nellore and F1 Brangus × Nellore show similar production potential and the mineral protein supplementation with the organic chromium increasing the weight gain, but not influencing the carcass traits.

Key Words: Crossbreed, Mineral, Ultrasound

W16 Carcass and beef traits of Nellore and F1 Brangus × Nellore steers supplied with organic chromium finished on grass. A. Polizel Neto*¹, P. S. A. Moreira², A. M. Jorge¹, H. F. B. Gomes¹, and R. D. O. Roça¹, ¹São Paulo State University, Botucatu, São Paulo, Brazil, ²Federal University of Mato Grosso, Sinop, Mato Grosso, Brazil.

Chromium works as Glucose Tolerance Factor – GTF, which causes muscle glucose input stimulus. This project aimed to evaluate the effect of organic chromium supplementation and of breed on productive carcass traits and some beef quality parameters of steers finished on grass. For this purpose, 18 Nellore and 18 F1 Brangus × Nellore steers were raised on *Brachiaria sp* grass, distributed equally in mineral protein supplementation (22% crude protein, with 0.25 cottonseed meal, 0.25 grind corn and 0.50 commercial mineral supplement) with and without organic chromium addition (2 mg/animal/day of chromium); and were slaughtered at 22 months of age and 451.22±13.22 of shrunk weight. Hot carcass was measured (HCW), and the carcass yield (YC) was calculated by relation of HCW:shrunk weight. Longissimus dorsi muscle pH was measured at 2, 10 and 24 hours post-mortem. After 24 hours of chilling, L. dorsi muscle samples (between 12th and 13th rib)

were collected in order to evaluate the cooking loss, shear force and chemical composition. A randomized design was used and all data were analyzed using analysis of variance with two variance source (breed and chromium), using SAS. Means of 235.01 kg to HCW and 52.09% to YC, with a superiority (P≤0.05) to chromium treatment (238 kg) versus control (231 kg) were observed, but without difference (P≥0.05) to YC; neither difference between breeds to HCW and YC. No treatment differences were detected in carcass pH and some quality beef parameter (P≥0.05) with means of 6.8, 6.2 and 5.7 to pH after 2, 10 and 24 hours, respectively, and cooking loss of 22% and shear force of 6.53 kg/F. The chemical composition was close to normal reference values, with means: 74.01% to moisture, 1.19% to ash, 23.89% to crude protein, 0.9% to ether extract. The Nellore and F1 Brangus × Nellore steers show equal production potential of quality beef on grass. Organic chromium increases the carcass weight, but does not influence the carcass yield or the beef quality parameters evaluated.

Key Words: Crossbreed, Mineral, Supplementation

W17 Estimation of some effects on longevity of beef cows using survival analysis. F. Szabó* and I. Dákay, *University of Pannonia, Keszthely, Hungary.*

Longevity of beef cows measured with the length of productive life from first calving to culling was estimated in this study. Data of 1800 cows belonging to Hereford, Angus, Simmental, Charolais, Limousin and Blonde d'Aquitaine breeds were estimated using Cox regression survival model. The results indicate significant (P<0.05) effect of calving season, calving difficulty, and breed on longevity, however age at first calving of the cows, sex and weaning weight of their calves did not affect (P>0.05) the length of productive life. Hereford had significantly highest (10.28 years) estimated longevity than the other breeds, following by Angus (8.14 years), Simmental (7.88 years), Charolais (7.13 years), Limousine (5.93 years) and Blonde d'Aquitaine (5.2 years). However either Angus, Simmental and Charolais or Limousin and Blonde d'Aquitaine did not differ significantly. Higher productive life (6.23 years) was estimated for cows whose calving took place without assistance or with a little assistance (6.96 years) than those needed veterinary assistance (2.75 years) or had stillbirth (4.63 years). Cows that firstly calved in spring or summer were estimated to reach higher productive life (7.22 years and 9.93 years) and less risk to early culling, then those calving in autumn (5.69 years) and in winter (5.05 years).

Key Words: Breed, Calving Season, Calving Difficulty

W18 Evaluation of MultiMin™ to enhance weaned calf productivity. A. E. Fisher*¹, W. W. Gill³, C. D. Lane, Jr.¹, R. L. Ellis², S. B. Blezinger⁴, and G. M. Pighetti¹, ¹University of Tennessee, Knoxville, ²University of Tennessee, Greeneville, ³Middle Tennessee State University, Murfreesboro, ⁴MultiMin USA, Inc., Sulphur Springs, TX.

This 56-day trial utilized 131 weaned heifers to evaluate the effectiveness of MultiMin™, Ralgro™ and their interaction to overcome mineral deficiencies and poor growth/health status of weaned beef calves in fall 2006. Heifers were randomly allotted to one of four treatments

including 1) Control, no mineral injection, no implant; 2) injection of MultiMin™ (no less than 40 mg/ml zinc, 10 mg/ml manganese, 5 mg/ml selenium and 15 mg/ml copper), no implant; 3) no mineral injection, Ralgro™ (36 mg zeranol) growth promotant; and 4) injection of MultiMin™, Ralgro™ growth promotant. All injections were administered subcutaneously in the neck. Cattle grazed tall fescue dominated pasture and were supplemented with pelleted corn gluten feed at 0.5% average initial body weight. Individual animal weights were recorded on days 0, 1, 28, 55 and 56 and blood was drawn via jugular venapuncture on days 1 and 56 for glutathione peroxidase (GSH-Px) activity analysis. All data were analyzed using the mixed procedure of SAS, with differences determined at $P < 0.05$. Initial weights did not differ among treatments. Average daily gain for MultiMin™ supplemented calves was not different from unsupplemented calves (0.52 vs. 0.52 kg/d, respectively; $P > 0.05$). Ralgro™ administered calves gained more weight than unsupplemented calves (0.55 vs. 0.48 kg/d, respectively; $P < 0.03$). No MultiMin™ by Ralgro™ interaction was observed as any differences can be related to implant. There was no difference in initial GSH-Px activity between groups; however MultiMin™ supplemented calves had higher final GSH-Px activity values than unsupplemented calves (71.8 vs. 54.7 nmol/min/ml; $P < 0.02$). Additionally, the change in GSH-Px activity from day 1 to day 56 was higher for MultiMin™ supplemented calves than unsupplemented calves (29.9 vs. 14.2 nmol/min/ml, respectively; $P < 0.01$).

Key Words: Beef Cattle, Weaning, MultiMin™

W19 Variation of MUFA ratio in several muscles of Japanese Black cattle cloned from somatic cells. Y. Nakahashi*¹, T. Okumura², M. Hada², Y. Fujishima³, K. Yamauchi², S. Hidaka¹, and K. Kuchida¹, ¹Obihiro University of A & VM, Obihiro-Shi, Hokkaido, Japan, ²National Livestock Breeding Center Tokachi Station, Otofuke-Cho, Hokkaido, Japan, ³The Ministry of Agriculture, Forestry and Fisheries of Japan, Chiyoda-Ku, Tokyo, Japan.

Many studies have been performed on the topic of monounsaturated fatty acids (MUFA) because of the positive correlation with the flavor of marbling. However, few studies have investigated the fluctuation of MUFA ratios within finely sliced muscles, especially in Japanese Black (JB) cattle. Our objective was to investigate the changes in fatty acid composition of muscles and specific cuts from JB cloned steers. Five JB steers were cloned from 2 animals and were fed in the same environment until slaughter at 20 mo of age. The following muscles were taken from each animal and sliced at 2cm intervals from the cranial to caudal side: *M.semimembranosus* (SE), *M.quadriceps femoris* and *M.tensor fasciae latae* (QU & TE), *M.supraspinatus* (SU), *M.psoas major* (PS), *M.gluteus medius* and *M.biceps femoris* (GL & BI), *M.longissimus* (LO). LO was classified into 3 parts (Chuck eye: cranial part from the 6-7th rib, Rib roast: from 6-7th to 10-11th rib, Sirloin: caudal part from the 10-11th rib). Carcasses were graded at the 6-7th rib in Japan, and rib roast and sirloin were separated at the 10-11th rib in the meat market. Adipose samples were taken from all slices and analyzed using gas chromatography. The tendencies of fluctuation for the ratios of MUFA and oleic acid differed by muscle, as some increased toward the caudal side while others decreased or remained. GL & BI had the highest ratios of MUFA and oleic acid (54.01 and 49.14%, respectively), whereas PS had the lowest (48.90 and 45.57%, respectively). For each part of LO, sirloin revealed the highest oleic acid and MUFA ratio, but the 6-7th cross section was the lowest. Simple correlations between the 6-7th and the average of all the slices in each muscle were 0.92-0.98 in MUFA.

This may suggest that the MUFA ratio at the 6-7th rib-eye represented the MUFA of the whole carcass.

Key Words: Japanese Black, MUFA Ratio, Muscles

W20 Influence of feed efficiency on profitability of individually fed feedlot cattle. A. L. Shreck*¹, C. O. Trejo¹, J. W. Homm², L. L. Berger¹, and D. B. Faulkner¹, ¹University of Illinois, Urbana, ²Elanco Animal Health, Greenfield, IN.

Data from 828 steers by Simmental or Angus sires (n=47) were analyzed to evaluate effects of feed efficiency on profitability. Cattle were fed corn or corn-byproduct based diets (n=11), and marketed on three strategies: live price, quality based grid (Quality grid), and yield based grid (Yield grid). Cattle were harvested in three groups based on ultrasound data to optimize carcass value. Cattle were stratified by weight and sire then randomly assigned to diets. Individual daily intakes were obtained using the GrowSafe® feeding system (GrowSafe Systems Ltd., Airdrie, Alberta, CA). Five year average price data were collected for feedstuffs, live cattle price (\$85.75/45.4 kg), dressed beef price (\$138.18/45.4 kg), and grid premiums and discounts. Corn price was \$2.63/25.5 kg. Wet corn-byproduct prices were calculated at 90% the value of corresponding dry corn-byproducts (DM basis). Choice-select spread was \$15/45.4 kg for Quality grid and \$12.72/45.4 kg for Yield grid. Discounts were given for hot carcass weight extremes (<250 kg -\$15.82; 432 to 454 kg -\$4.73; >454 kg -\$19.17). Input costs included steer purchase price and feed markup (\$24.2/mt). Veterinary, medical, labor, and transportation costs were \$50/per animal and yardage was \$0.25/d per animal. Steer purchase price was \$121.00/45.4kg based on a 227 kg animal with a \$1.50 slide per 11.3 kg. Days on feed averaged 163.5±22.7 d. Marbling score (MS), hot carcass weights (HCW), and yield grade (YG) were similar across the range of F:G ratios. These data show that small improvements in feed efficiency dramatically improve profitability in feedlot steers

Table 1. Effect of feed efficiency on profitability of feedlot cattle

F:G	n	MS	HCW (kg)	YG	Live*	Quality Grid*	Yield Grid*
<4.50	5	544	370	2.96	103.38	104.56	107.13

W21 Characterization of intracellular copper homeostasis regulatory genes in bovine liver. H. Han, T. E. Engle, J. K. Sakugawa, S. L. Archibeque, and K. Partyka*, Colorado State University, Fort Collins.

Copper is an essential trace mineral for growth and development. Copper serves as a cofactor for enzymes involved in a variety of biological

functions. Copper homeostasis within the cell is mediated by the expression of the copper transporter protein (CTR1), ATPase7A (ATP7A), ATPase7B (ATP7B), and Cox17, which help to regulate copper uptake, export and intracellular compartmentalization in non-ruminants. Liver tissue from six Holstein bull calves (average BW 201kg, 7 mo. old) from a previous experiment (25.2mg Cu/kg diet) was utilized to examine the relationship of CTR1 mRNA to ATP7A, ATP7B and Cox17 mRNA expression. Liver samples were collected at the time of harvest and snap frozen. Liver copper concentration was determined via flame atomic absorption and total RNA was extracted from 100mg of liver tissue using TRI reagent and purified using RNeasy. Primers for CTR1, ATP7A, ATP7B and Cox17 were designed for real time PCR analysis. Liver copper concentrations were: 290, 312, 351, 354, 611, and 801 mg of Copper/kg DM. Real time PCR analysis of these genes revealed that relative expression of CTR1, was positively correlated with ATP7A ($r=0.90$; $P < 0.02$), ATP7B ($r=0.98$; $P < 0.01$) and Cox17 ($r=0.94$; $P < 0.01$) gene expression at all copper concentrations. These data indicate that genes involved in bovine liver copper homeostasis, ATP7A, ATP7B and Cox17 are correlated with CTR1 gene expression in the bovine liver which is similar to those reported for non-ruminants.

Key Words: Copper, Liver, Gene Expression

W22 Evaluation of methods to estimate individual intakes of cattle fed in group pens. G. D. Cruz*, J. W. Oltjen, and R. D. Sainz, *University of California, Davis.*

Feed efficiency measures such as residual feed intake (RFI) require individual determination of intake, a laborious and expensive process. Several methods developed to predict individual intakes in group pens were evaluated with a dataset of 60 Angus x Hereford steers. Models 1 (Perry and Fox (1997) *J. Anim. Sci.* 75:300) and 2 (Guiroy et al. (2001) *J. Anim. Sci.* 79:1983) are based on growth, carcass composition and nutrient requirements. Model 3 is based on solution of simultaneous equations and the heterogeneity of subgroups through a rotational system (Trovo et al. (2006) *Proc. Soc. Bras. Zootec.*). Steers (296 kg initial BW) were fed a corn-based ration (1.68 Mcal NEm/kg, 13% CP on a DM basis) twice daily and refusals were measured daily. Animals were stratified by BW and placed in 30 individual pens and five group pens (six animals each). Every day three steers from each group pen were randomly transferred to another group pen. After 60 days, animals were switched from group to individual pens and vice versa for another 60 days. Average daily individual intakes (in group pens) were estimated by multiplying each animal's average daily individual intake (in individual pens) by an adjustment factor which was calculated as the ratio between the mean intakes in individual and group pens for the same group of animals. Models 1 and 2 used the combined pen data as input, and Model 3 used the daily rotation data. The Mean Square Errors of Prediction (MSEP) were 4.56, 3.71 and 3.29 kg/d for Models 1, 2 and 3, respectively. The decomposition of the MSEP indicated different patterns in the errors of prediction between models. For Model 3, random error accounted for nearly 60% of the MSEP, whereas for Models 1 and 2 the slope bias accounted for more than 50% of the errors of prediction. Considering that mean RFI values for high and low RFI groups are typically around 1 kg/d above or below zero respectively, none of these models predicted intake with the precision required for estimation of RFI. At present there is no substitute for measuring individual intakes.

Key Words: Cattle, Feed Intake, Models

W23 Carcass characteristics of Alabama calves fed in four regions of the United States. W. C. Rutherford, J. B. Elmore, S. V. Free, J. K. Grubbs*, M. Hittle, and L. A. Kriese-Anderson, *Auburn University, Auburn.*

Carcass data were collected from 10,778 calves enrolled in the Alabama Beef Connection Program (ABC) from 2003 to 2007. Calves were enrolled by 78 different producers. Calves were fed in Midwestern ($n=2116$), Northern High Plains ($n=6033$), Southern High Plains ($n=2140$) or Western ($n=487$) commercial feedyards. Calves were fed diets traditional to the feedlot and region. All traits were analyzed using the generalized linear models procedure in SAS. Traits analyzed included average daily gain (ADG), hot carcass weight (HCW), 12th rib backfat (BF), longissimus dorsi area (REA), USDA marbling score (MS) and USDA yield grade (YG). Independent variables in the model included year, feeding region and year by feeding region interaction. The interaction was non-significant ($P>0.05$). Compared to the 2000 Beef Quality Audit, Alabama calves were similar to audit values for HCW and BF. Alabama calves had more muscle, which translated into lower YG. MS averages for Alabama calves were lower (489 vs. 523) than 2000 audit averages. However, of Alabama calves grading USDA choice, 43% ($n=2167$) qualified for quality branded beef programs. Since 2003, HCW of Alabama calves trended down ($P<0.10$) with less BF and more MS. Additionally YG held constant from 2003 to 2007 while REA trended upward.

Table 1. Growth and carcass LSMeans by feeding region

Trait	Midwest	No. High Plains	So. High Plains	Western
ADG (kg/d)	1.27 ^b	1.27 ^b	1.33 ^a	1.24 ^c
HCW (kg)	360 ^a	358 ^a	372 ^b	367 ^b
BF (mm)	12.2 ^c	11.9 ^c	9.4 ^a	11.2 ^b
REA (cm ²)	85.2 ^d	87.1 ^c	94.2 ^a	91.6 ^b
MS ¹	480 ^b	489 ^a	458 ^c	490 ^a
YG	2.5 ^b	2.5 ^b	2.2 ^a	2.4 ^b

W24 Relationship between residual feed intake and reproductive performance in Brangus heifers. P. A. Lancaster*¹, G. E. Carstens¹, P. Chen¹, D. W. Forrest¹, T. H. Welsh, Jr.¹, R. D. Randel², and T. D. A. Forbes², ¹Texas A&M University, College Station, ²Texas AgriLife Research, Overton, TX, ³Texas AgriLife Research, Uvalde, TX.

The objective of this study was to examine the relationships between residual feed intake (RFI) and reproductive traits in heifers. Average (\pm SD) initial age and BW of Brangus heifers (Camp Cooley Ranch) were 225.8 \pm 9.1, 236.0 \pm 10.7 and 235.6 \pm 14.6 d, and 285.1 \pm 28.0, 268.5 \pm 23.8 and 267.8 \pm 25.8 kg for year 1 (N = 114), 2 (N = 115) and 3 (N = 119), respectively. Heifers were individually fed a roughage-based diet (ME = 1.98 Mcal/kg DM) for 70 d. RFI was calculated as the difference between actual DMI and expected DMI from linear regression of DMI on mid-test BW^{0.75} (MBW), ADG, year and year by MBW and ADG interactions (year and year by MBW and ADG interactions were considered random effects). Weekly blood samples were assayed in duplicate for progesterone by RIA (Diagnostic Systems Laboratories). Heifers exhibiting a progesterone concentration \geq 2 ng/mL for one wk or \geq 1 ng/mL for two consecutive wk were considered pubertal. Overall

ADG, DMI and RFI were 0.90 ± 0.15 , 9.10 ± 1.11 and 0.00 ± 0.75 kg/d, 1.06 ± 0.16 , 9.47 ± 1.04 and 0.00 ± 0.68 kg/d, and 1.00 ± 0.13 , 9.92 ± 1.06 and 0.00 ± 0.70 kg/d for year 1, 2 and 3, respectively. Heifers with low RFI (< 0.5 SD) had 16% less ($P < 0.01$) DMI and 15% lower ($P < 0.01$) feed conversion ratio than heifers with high RFI (> 0.5 SD), even though ADG and final BW were similar. RFI was correlated with gain in fat thickness (0.27). Across the 3 years, 30% of the heifers were pubertal by d 70. Chi-square analysis revealed that the percentage of pubertal heifers by d 70 within low (32.1%), medium (28.3%) and high (29.6%) RFI phenotypes was similar ($P = 0.80$). Of those heifers that were pubertal by day 70, age at puberty was similar ($P > 0.20$) between low (279 d), medium (273 d) and high (271 d) RFI phenotypes. After returning to Camp Cooley Ranch 18, 18 and 16 heifers with low, medium and high RFI were sold prior to the breeding season. Rectal palpation results indicated that pregnancy rates were similar ($P = 0.17$) for heifers with low (89.4%), medium (85.7%) and high (79.3%) RFI. These results indicate that postweaning RFI was not phenotypically associated with age at puberty or pregnancy rate in Brangus heifers.

Key Words: Residual Feed Intake, Reproduction

W25 Fatty acid profile, meat cholesterol and total lipids of *Bos indicus* based types bullocks fed monensin or polyclonal antibodies against lactate-producing rumen bacteria. M. V. Fossa^{1,2}, R. D. L. Pacheco^{*1,2}, D. D. Millen^{1,2}, T. M. da Cunha Leme¹, M. P. de Oliveira¹, C. R. de Oliveira¹, A. E. Mathias¹, J. C. Hadlich¹, A. DiCostanzo³, N. DiLorenzo³, M. De Beni Arrigoni¹, C. L. Martins¹, M. Parrili¹, and S. A. Matsuhara¹, ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²Supported by FAPESP, São Paulo, São Paulo, Brazil, ³University of Minnesota, Saint Paul.

Our objective was to study the effect of biotype [GG; Nellore (NE), Canchim (CC- 5/8 Charolais, 3/8 Nellore) and 3-way cross (1/2 Brangus, 1/4 Nellore and 1/4 Angus)] and feed additive [FA; 300 mg of monensin/day (MO) or 10ml of polyclonal antibody preparation against lactate-producing rumen bacteria/day (PAP)] on fatty acid profile of subcutaneous fat (FP) and cholesterol (CO) and total lipids (TL) of *Longissimus dorsi* muscle. Two bullocks (260 kg) were randomly selected from a population of four in each of 18 pens allocated to the 2 X 3 factorial arrangement of FA and GG. Samples were collected from the longissimus dorsi muscle between the 12th and 13th rib. The fatty acid profile of subcutaneous fat was from total lipids and determined by gas chromatography. No difference ($P > 0.05$) was found for miristic acid between all treatments. Palmitic acid (C16:0) was found in greater concentrations ($P < 0.05$) in steaks from bullocks fed MO (255.95 vs 243.76 mg/g) and in lower concentrations in NE bullocks (229.82 vs. 264.30, 255.44 mg/g for NE, CC, and TC). No differences ($P > 0.05$) were found for stearic acid due to either GG or FA. Oleic acid (C18:1) was affected ($P < 0.05$) by GG (474.37 vs. 423.11, 420.43 mg/g for NE, CC, and TC, respectively) but not by FA ($P > 0.05$). Linoleic (C18:2) acid was not affected ($P > 0.05$) by GG or FA. Steaks from NE had greater concentration ($P < 0.01$) of CLA (C18:2, c-9, t-11; 5.79 vs. 3.23 and 3.68 mg/g for NE, CC and TC). Linolenic acid (C18:3, Ω 3) did not differ ($P > 0.05$) due to GG or FA. Steaks from NE had lower ($P < 0.01$) saturated fatty acid concentration (414.86 vs. 479.49, 485.65 mg/g or 42.09% vs 48.48%, 49.13% for NE, CC and TC). There was no FA or GG effects ($P > 0.05$) for CO and TL in meat. Steaks from NE had greater concentrations of (C18:1), (CLA) and lower concentrations of saturated fatty acids and (C16:0).

Key Words: PAP, Fatty Acid Profile, Cholesterol

W26 Evaluation of growth, carcass characteristics and meat tenderness of bullocks fed monensin or polyclonal antibodies against lactate-producing rumen bacteria. R. D. L. Pacheco^{*1,2}, D. D. Millen^{1,2}, T. M. da Cunha Leme¹, C. R. de Oliveira¹, A. E. Mathias¹, J. C. Hadlich¹, A. DiCostanzo³, N. DiLorenzo³, M. De Beni Arrigoni¹, C. L. Martins¹, S. A. Matsuhara¹, M. Parrili¹, M. V. Fossa¹, J. P. S. T. de Bastos¹, T. M. Mariani¹, ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²Supported by FAPESP, São Paulo, São Paulo, Brazil, ³University of Minnesota, Saint Paul.

The objective of this study was to evaluate effects of feed additive (300 mg of monensin/day, MO, vs 10 mL of polyclonal antibody preparation against lactate-producing bacteria/day, PAP) or biotype (Nellore, NE, Canchim cross, 5/8 Charolais, 3/8 Nellore, CC, or a 3-way cross, 1/2 Brangus, 1/2 Nellore and 1/2 Angus, TC) on ultrasound (US)-assessed measures of fat and ribeye area, carcass characteristics, and *Longissimus dorsi* tenderness (shear force, SF, and myofibrillar fragmentation index, MFI) of bullocks fed high-concentrate diets. Two bullocks (259.6±26.39 kg) were randomly selected from a population of four in each of 18 pens allocated to the 2 X 3 factorial arrangement of feed additive (FA) and biotype (GG), and monitored monthly for a 107-d (CC and TC) or 147-d (NE) feeding period. Analyses of variance included the initial measurement covariate when appropriate ($P < 0.05$) were used. Final (BW) and hot carcass weight (HCW) were unaffected ($P < 0.05$) by FA, but were lower ($P < 0.05$) for NE than CC and TC. Dressing percentage (DP) was lower ($P < 0.05$) for TC than NE and CC bullocks. An interaction between FA and CC ($P < 0.05$) revealed that TC bullocks fed MO had greater ($P < 0.05$) DP than TC bullocks fed PAP (51.6% vs 54.0% TC bullocks fed MON vs those fed PAP). There was no effect ($P > 0.05$) of FA on monthly measurements of fat depth (BFT), rump fat (P8), ribeye area (REA), or visceral fat (VF), SF and MFI. Bullocks of CC biotype were leaner ($P < 0.05$; less BFT and P8) than those of TC and NE biotypes. Bullocks of NE biotype had smaller ($P < 0.05$) REA than those of CC and TC biotypes. Steaks of TC biotype had lower ($P < 0.05$) SF values than those of the other biotypes. There were no differences ($P > 0.05$) in MFI or VF due to biotypes. Other than effects of PAP on TC biotype, PAP did not affect carcass fat, REA or tenderness.

Key Words: Antibodies, Growth, Tenderness

W27 Evaluation of the acute phase response in the neonate bovine model following vaccination against bovine respiratory disease complex. W. J. Horne^{*1}, K. S. Barling², J. A. Carroll³, A. D. Herring¹, G. A. Holub¹, and J. E. Sawyer¹, ¹Texas A&M University, College Station, ²Novartis Animal Health US, Inc, Larchwood, IA, ³USDA-ARS, Lubbock, TX.

A study using 7-d old Holstein calves was conducted to determine the effects of viral vaccination on febrile and pro-inflammatory cytokine responses in the neonate. Calves were treated with a multi-valent modified live virus vaccine (Arsenal 4.1[®], n = 3; **ML**) or a multi-valent killed virus vaccine (ViraShield 6[®], n = 3; **KV**) within a week of birth at label dosage. Blood samples and rectal temperatures (**RT**) were collected 1 h before, hourly for 12 h, at 18, 24, 30, 36, 48, 60, and 72 h after vaccines were administered. Serum was analyzed for tumor necrosis factor- α (**TNF- α**), interferon- γ (**IFN- γ**), interleukin 1- β (**IL-1**), **IL-2**, **IL-4**, and **IL-6**. Responses were evaluated as difference from baseline within calf. Data were analyzed as repeated measures with calf as the subject. Time influenced ($P < 0.1$) all responses except serum IL-4 ($P = 0.18$). Peak increases in TNF- α , IL-6, and IFN- γ occurred at 24 h, with IFN- γ

falling below baseline at 48 h; IL-6 remained elevated through 60 h. Increased IL-2 was observed at 0, 30, 36, 60, and 72 h after vaccination. Treatment by time interactions occurred for RT ($P = 0.04$) and IL-1 ($P = 0.05$). After 6 h, all calves had elevated RT, but the magnitude of increase was greater for calves receiving ML than those receiving KV. Increase in IL-1 was of greater magnitude in the first 12 h for calves receiving KV, but returned to baseline after 24 h. For those receiving ML, IL-1 increased at 5 and 6 h, returned to baseline, then increased after 30 h. Animals receiving ML had greater increases ($P = 0.07$) in serum IL-4

concentrations than those receiving KV. However, KV induced greater ($P = 0.02$) increases in IL-6. While both vaccines stimulated cytokine production, the associated febrile response was not strongly correlated with the release of any specific cytokine. Our results demonstrate that different vaccines have differential effects on the magnitude and timing of release of various cytokines. Understanding these differences and immunological sequelae to cytokine release may enhance development of vaccination strategies.

Breeding and Genetics II

W28 Analysis of some environmental factors for growth parameters obtained from Gompertz nonlinear model in Kurdi sheep breed of Iran. H. Farhangfar^{*1}, D. A. Saghi², and M. H. Fathi Nasri¹, ¹*Birjand University, Birjand, Iran*, ²*Agricultural Research Centre, Mashhad, Iran*.

The main objective of the present research was to analyse some environmental factors for growth parameters in Kurdi sheep breed of Iran. The data consisted of 16949 weights recorded at different ages (0, 3, 6, 9 and 12 months) belonging to 4353 Kurdi sheep breed. The data were obtained from a large-size flock of Kurdi sheep (located at northern Khorasan province) during 1990-2005. All lambs were born in winter. Gompertz nonlinear model defined as $W = (z/b) \cdot \exp(-\exp(g_0 - b \cdot t))$ was initially fit to individual lambs to estimate corresponding parameters (z , b and g_0). Moreover, estimated parameters z/e ($e=2.71828$) and A (z/b) were also calculated for individual lambs. The estimated parameters z/e and A are associated with maximum daily growth rate and mature weight respectively. All estimated parameters were subsequently analysed by a general linear statistical model. In the model, fixed environmental factors of birth year, birth type, lamb sex, ewe lambing order, two way interactions between lamb sex and birth type, between lamb sex and ewe lambing, between birth type and ewe lambing and between birth year and lamb sex. The sire random effect was not considered in the analysis due to lack of sire identification in the data file. The analyses were carried out by SAS programme using nonlinear procedure. The results indicated that for all estimated parameters (z , b , g_0 , z/e and A) were significantly ($p < 0.05$) affected by year of birth, lamb sex and birth type. Ewe lambing had only a significant affect ($p < 0.05$) on estimated parameters z and z/e . The interaction between birth year and lamb sex was found to significantly ($p < 0.01$) affect on all estimated parameters. The results also revealed that the interactions between ewe lambing and birth type, between ewe lambing and lamb sex as well as between lamb sex and birth type had no significant ($p > 0.05$) influence on the estimated parameters.

Key Words: Kurdi Sheep, Growth, Gompertz

W29 Response surface regression analysis to locate optimal minimum age at sexual maturity based on body weights at weeks 8 and 12 for indigenous chicken in Khorasan province of Iran. H. Farhangfar^{*}, M. E. Hosseini, and S. M. Navidzadeh, *Birjand University, Birjand, Iran*.

An analysis using response surface regression statistical methods was carried out to locate optimal minimum age at sexual maturity (ASM) based on weight at weeks 8 (W8) and 12 (W12) for indigenous chicken in Khorasan province of Iran. The data used in this study consisted of 1617 weight and ASM records collected from 1617 indigenous chicken belonging to the same generation and sex (female) during year 2006. The arithmetic means W8, W12 and ASM were 513, 865 g and 162 days ($SD=10.45$ days) respectively. In the data file, the ASM ranged from 138 to 209 days. A response surface regression in which ASM was dependent and W8 and W12 were independent variables was fitted to the data set. In the model, linear, quadratic terms of the independent variables as well as interaction between W8 and W12 were included. The model was fitted using RSREG procedure of SAS programme. The results obtained in the present research indicated that except the intercept

term fitted in the model, all the independent variables (linear, quadratic and interaction terms) had no statistical significant ($p > 0.05$) effects on ASM variation suggesting that other possible environmental factors could affect sexual maturity age of the indigenous chicken studied in this research. However, the predicted value of the minimum ASM was found to be approximately 161 days (close to the simple average of ASM in the data set) as the chicken weight at W8 and W12 were 504 and 997 g respectively.

Key Words: Age at Sexual Maturity, Weight, Indigenous Chicken

W30 Estimates of genetic parameters for direct and maternal effects on growth traits and fleece weight of Angora goat (Markhoz) in Iran. M. B. Zandi^{*1}, S. R. Miraei Ashtiani¹, M. Moradi Shahrabak¹, and A. Rashidi², ¹*Tehran University, Karaj, Tehran, Iran*, ²*Kurdistan University, Sanandaj, Iran*.

The aim of the current study was to estimate additive and non-additive parameters for birth weight (BW), weaning weight (WW), 6-month weight (W6), 9-month weight (W9), yearling weight (YW), and fleece weight at first shearing (FW), which are essential to design a selection programme for Kurdish Angora goat (Markhoz). Data and pedigree information which were used in this study were collected at the Sanandaj and Saqez Animal Breeding Research Institute during 1993 to 2007. Data contains of 2950 to 4008 records for this traits and total number of sires and dams in the study was 364 and 1391 respectively. Genetic parameters were estimated using univariate and multivariate traits animal model analyses with restricted maximum likelihood (REML) method by ASREML software. Estimates of direct heritability were 0.25 for BW, 0.26 for WW, 0.30 for W6, 0.21 for W9, 0.14 for YW and 0.12 for FW. Estimates of maternal heritability were 0.120, 0.110, 0.034, 0.030, 0.036 and 0.046 for BW, WW, W6, W9, YW and FW, respectively. Estimates of direct genetic correlations among growth traits were positive and ranged from 0.28 to 0.89. FW had a moderate to high positive direct genetic correlation with BW, WW and YW but had a negative direct genetic correlation with W6 (-0.22) and W9 (-0.202). The results of this study showed that maternal heritability was higher for pre-weaning than for post-weaning traits and the magnitude of the heritability estimates for those traits indicate possibility of an effective selection.

Key Words: Markhoz Goat, Heritability, REML

W31 Comparison and estimation factors affected body weight traits in the Markhoz breed of goats. M. B. Zandi^{*1}, M. A. Syed Reza¹, M. Moradi Shahrabak¹, and R. Amir², ¹*Tehran University, Karaj, Tehran, Iran*, ²*Kurdistan University, Sanandaj, Iran*.

Data from 4008 Kids of the Markhoz breed were used to estimate genetic parameters. Traits analyzed were weights at birth (BW), 90 days (Ww), 6-month weight (W6), 9-month weight (W9), yearling weight (YW), and fleece weight at first shearing (FW). REML estimates of variance and covariance components were obtained assuming animal models that included the fixed effects of sex, age of dam, effect of year of birth and types of birth or rearing, and the animal random effects for the direct, maternal genetic and permanent environmental

effects. Results showed that an important direct additive and maternal genetic effects were observed. Estimates of the direct heritability, maternal and permanent environmental heritability with standard errors were respectively 0.32(0.046), 0.085(0.036), 0.085(0.028) for BW; .30(0.044), 0.15(0.034), 0.024(0.013) for WW; 0.35(0.046), 0.12(0.033), 0.014(0.012) for W6, 0.37(0.043), 0.12(0.026) 0.00(0.00) for W9, and 0.43(0.043), 0.10(0.024) 0.00(0.00) for YW. Estimates of additive direct-maternal correlations were important and negative ranged from -0.57 to -0.80 for pre-weaning weights, and from -0.80 to -0.89 for post- weaning weights. Results suggest that estimates of additive and maternal heritability were important but permanent environmental maternal effect had some influence on body weights at pre-weaning that we must selection goats for this trait. These results indicate that goats have maternal ability for single, twins and triple kids (litter size) and we must considering these traits in the selection programs.

Key Words: Markhoz Goats, Maternal Ability, Heritability

W32 Weaning results of Simmental beef calves. F. Szabó* and S. Bene, *University of Pannonia, Keszthely, Hungary.*

Weaning weight, preweaning daily gain and 205-day weight of Simmental calves (n = 8929, male = 4539, female = 4390) born from 232 sires between 1980-2003 were examined. Farm, age of cows, year of birth, season of birth and sex of calves as fixed, while sire as a random effect was treated. Data were analysed with Harvey (1990) Least Square Maximum Likelihood Computer Program, moreover two animal models were used for breeding value estimation. Variance, covariance components and heritability values and correlation coefficients and the effect of the maternal permanent environment on genetic parameters and breeding values were examined.

The overall mean value and standard error of weaning weight, preweaning daily gain and 205-day weight were 217±4.5 kg, 1009±19.8 g/day and 242±4.1 kg, respectively. Calving year and season, sire, age of dam and herd had significant (P<0.05) effect on the evaluated traits.

The direct heritability (h²_d) of weaning weight, preweaning daily gain and 205-day weight was between 0.37 and 0.42. The maternal heritability (h²_m) of these traits was 0.06 and 0.07. The direct-maternal correlations (rdm) were medium and negative -0.52 and -0.74. Contribution of the maternal heritability and maternal permanent environment to phenotype is smaller than that of direct heritabilities (h²_m + c² < h²_d). The proportion of the variance of maternal permanent environment in the phenotypic variance (c²) changed from 3 to 6 %. Estimated breeding values changed whether the permanent environmental effect of dam was not taken into consideration but the rank of the animals was not modified. The genetic value for weaning results of Simmental population has increased since 1997.

Key Words: Breeding Value, Heritability, Weaning Weight

W33 Genotype and environment interaction of weaning results of Simmental calves. A. Fördös and F. Szabó*, *University of Pannonia, Keszthely, Hungary.*

The interaction of sire and population in the Simmental breed of cattle was examined on data from the Hungarian Simmental Breeders Association. Data of 2345 progeny (1260 male and 1085 female), born between 1992-2003, of thirty five sires from two populations were

evaluated. Preweaning daily gain (PDG) and 205-day weight (205dW) were analysed. Population, age of cows, year of birth, season of birth and sex of calves were treated as fixed, while sire and sire x population were treated as random effects. Genetic (rg) and rank (rrank) correlations were calculated for sires represented in the two populations (A,B). Data were analysed according to Harvey (1990) Least Square Maximum Likelihood Computer Program and SPSS 9.0 for Windows. Results were as follows: rg= PDGA -PDGB: 0.31(P<0.01); 205dWA-205dWB: 0.22(P<0.01) and rrank= PDG: -0.04 (P>0.05); 205dW: 0.078 (P>0.05). According to the result of examination important and significant (P<0.001) sire x population interaction were found in case of the two traits in Simmental population.

Key Words: 205-Day Weight, Genetic Correlation, Rank Correlation

W34 Genetic association between age and litter traits at first farrowing in a commercial Pietrain-Large White population raised in an open-house system in Thailand. P. Pholsing¹, S. Koonawootrittriron¹, T. Suwanasopee¹, and M. A. Elzo*², ¹*Kasetsart University, Bangkok, Thailand,* ²*University of Florida, Gainesville.*

The Thai swine industry is becoming an increasingly competitive business. Producers are striving to increase productivity and decrease costs. A trait of interest is age at first farrowing. The goal is to reduce costs by lowering age at first farrowing without detrimental effects to economically relevant litter traits. The objective here was to evaluate genetic associations between age at first farrowing (AFF) and 3 litter traits: total born alive (TBA), still born and mummy (LOST), and total birth weight of live piglets (TBW), in a negative halothane gene swine commercial population composed of Pietrain (PT) and Large White (LW) pigs. Data consisted of pedigree, and first-farrowing traits (AFF, TBA, LOST, and TBW) from 1,777 PT and 450 LW sows gathered from 1999 to 2006. Pigs were raised in an open-house system and received the same nutrition, management, and health care. Restricted maximum likelihood estimates of variance and covariance components for AFF, TBA, LOST, and TBW were used to calculate heritabilities and genetic correlations. A 4-trait animal model (AFF-TBA-LOST-TBW) that accounted for contemporary group (year-month) and breed as fixed effects, and animal and residual as random effects was used. Computations were performed with the ASREML program. Large White had shorter AFF (10.00 ± 2.34 d; P < 0.01), higher TBA (1.20 ± 0.22 piglets; P < 0.01), lower LOST (0.20 ± 0.11 piglets; P < 0.01), and smaller TBW (1.11 ± 0.30 kg; P < 0.01) than PT. Heritability estimates were 0.07 ± 0.03 for AFF, 0.11 ± 0.04 for TBA, 0.08 ± 0.04 for LOST and 0.08 ± 0.03 for TBW. Genetic correlations between AFF and TBA (0.19 ± 0.26), LOST (-0.12 ± 0.33), and TBW (0.14 ± 0.32) were low and had high standard errors. These low correlation estimates indicate that selection for AFF may be carried out in this commercial swine population without severe undesirable effects on litter traits.

Key Words: Farrowing, Pig, Tropical

W35 Factors affecting plasma cholesterol, lipoproteins, and triglycerides in growing pigs of various breed compositions raised under Thai tropical conditions. S. Koonawootrittriron¹, T. Suwanasopee¹, and M. A. Elzo*², ¹*Kasetsart University, Bangkok, Thailand,* ²*University of Florida, Gainesville.*

Concentration of plasma cholesterol (CHOL), high density lipoproteins (HDL), low density lipoproteins (LDL), and triglycerides (TRIG) may vary in pigs of different breed composition under tropical conditions. Selection of pigs for low plasma CHOL, LDL, and TRIG, and high HDL could be beneficial for their health and for human consumption. The objective was to evaluate factors that may affect plasma CHOL, HDL, LDL, and TRIG in growing pigs from 5 breed groups: Pietrain (P), Large White (W), WP, Landrace-Pietrain (LP), and WLP, under tropical conditions in Western Thailand. Ten hogs and 10 gilts of the same age (85 d) and similar weight (30.03 ± 7.07 kg) from each breed group were assigned randomly to each cell of a 5×2 factorial design (5 breed groups \times 2 sexes). Pigs in each factorial group were kept in a 4.5 m by 7.5 m pen throughout the 90-d trial. All pigs were raised in an open barn, and received the same nutrition, management, and health care. Weights, ultrasound backfat thickness and lean percent were measured at 3 ages (89 d, 136 d and 178 d). Blood samples were drawn from the 3 fastest and the 3 slowest growing pigs within each factorial group at each age. Plasma was analyzed for concentration of CHOL, HDL, LDL, and TRIG by an enzymatic-colorimetric method. The statistical model considered breed group, sex, and age, the interactions breed group \times sex, breed group \times age, and sex \times age, and the covariates backfat thickness and lean percent, and residual. Computations were performed using the mixed procedure of SAS. Breed group was important for CHOL, HDL, and LDL ($P < 0.001$), but not for TRIG. Pietrain had the lowest least squares means (LSM) for CHOL (71.21 ± 3.04 mg/dL) and LDL (40.61 ± 2.45 mg/dL), WLP had the lowest LSM for TRIG (45.18 ± 4.24 mg/dL), and LP had the largest LSM for HDL (40.78 ± 1.29 mg/dL). Ultrasound lean percent was negatively associated with LDL ($P < 0.01$).

Key Words: Cholesterol, Lipoprotein, Pig

W36 Multibreed beef cattle breeding value estimation based on weaning results. Sz. Bene¹, I. Komlósi², Zs. Fekete¹, Z. Lengyel¹, and F. Szabó^{*1}, ¹University of Pannonia, Keszthely, Hungary, ²University of Debrecen, Debrecen, Hungary.

Weaning results of 603 calves (297 male and 306 female; 388 purebreed and 215 crossbreed) born from 9 dam breeds (Hungarian Fleckvieh, Hereford, Aberdeen Angus, Red Angus, Lincoln Red, Limousin, Charolais, Blonde d'Aquitaine, Shaver), kept among the same condition on peat-bog soil pasture at Keszthely were evaluated between 1997 - 2006. Variance, covariance components, heritability values and correlation coefficients were estimated. Three different animal model were used for the estimation.

Different models had different fixed effects of genotype: model 1 genotype of calf; model 2 genotype of calf and dam; model 3 genotype of sire and dam

The direct heritability of weaning weight, preweaning daily gain and 205-day weight was between 0.30 and 0.51, the maternal heritability of these traits was 0.07 and 0.15. The direct-maternal correlations in weaning weight and preweaning daily gain were -0.12 and -0.27. Contribution of the maternal heritability and maternal permanent environment to phenotype is smaller than that of direct heritabilities. The total heritability was between 0.37 and 0.47.

The results obtained with three different animal models were similar with very small difference. The rank-correlation between the three models was strong and positive ($r = 0.93 - 0.99$; $P < 0.01$), accordingly the simpler models adaptable successfully.

Key Words: Beef Cattle, Multibreed, Breeding Value

W37 Effect of breed composition, temperament, and ELISA scores for paratuberculosis on phenotypic residual feed intake and growth in an Angus-Brahman multibreed herd. M. A. Elzo^{*1}, D. G. Riley², G. R. Hansen³, D. D. Johnson¹, R. O. Myer⁴, D. O. Rae¹, J. G. Wasdin¹, and J. D. Driver¹, ¹University of Florida, Gainesville, ²USDA-ARS STARS, Brooksville, FL, ³North Carolina State University, Plymouth, ⁴North Florida Research and Education Center, Marianna, FL.

Breed composition, temperament, and subclinical paratuberculosis in dams are factors that may have an effect on growth and feed efficiency in beef cattle. The objective of this research was to assess the effect of breed group (Angus (A), Brahman (B), Brangus, 3/4 A 1/4 B, 1/2 A 1/2 B, and 1/4 A 3/4 B), chute score (CS), exit velocity (EV), and ELISA scores for paratuberculosis in dams of calves (ES) on 5 feed intake and growth traits in bulls, heifers, and steers ($n = 461$) ranging from 100% Angus to 100% Brahman. Traits were post-weaning phenotypic residual feed intake (RFI), daily feed intake (DFI), feed conversion ratio (FCR), average daily gain (ADG), and weight gain (WG). Calves were assigned to pens in a GrowSafe automated feeding facility by sire group and sex, and fed a concentrate diet (cottonseed hulls, corn, molasses, and a protein, vitamin, and mineral supplement). The pre-trial adjustment period lasted 21 d. Individual daily feed intake was collected during the 70 d feeding trial. Weights and temperament traits were recorded every 2 weeks. Phenotypic RFI was computed as the difference between actual and expected feed intakes. Traits were analyzed using mixed models. Fixed effects were contemporary group (year-pen), RFI group (except when trait was RFI), age of dam, sex of calf, age of calf, B fraction of calf, heterozygosity of calf, mean CS, mean EV, ES, and residual. The RFI groups were high (RFI $>$ mean + 0.5 SD), medium (RFI between mean \pm 0.5 SD), and low (RFI $<$ mean - 0.5 SD; SD = 5.4 kg). Random effects were sire and residual. Brahman had lower ($P < 0.01$) RFI, DFI, and WG than Angus. Calves with higher mean EV had lower ($P < 0.04$) DFI and ADG than calves with lower mean EV. Neither mean CS nor ES were important for RFI, DFI, FC, ADG, and WG.

Key Words: Cattle, Feed Intake, Temperament

W38 Association between breed composition, phenotypic residual feed intake, temperament, ELISA scores for paratuberculosis, and ultrasound carcass traits in an Angus-Brahman multibreed herd. M. A. Elzo^{*1}, D. G. Riley², G. R. Hansen³, D. D. Johnson¹, R. O. Myer⁴, D. O. Rae¹, J. G. Wasdin¹, and J. D. Driver¹, ¹University of Florida, Gainesville, ²USDA-ARS STARS, Brooksville, FL, ³North Carolina State University, Plymouth, ⁴North Florida Research and Education Center, Marianna, FL.

Ultrasound carcass measurements are an important tool for preliminary assessment of carcass worth in beef cattle. Breed composition, phenotypic residual feed intake (RFI), temperament, and subclinical paratuberculosis in dams may affect calf ultrasound traits. The objective was to evaluate the association between breed group (Angus (A), Brahman (B), Brangus, 3/4 A 1/4 B, 1/2 A 1/2 B, and 1/4 A 3/4 B), RFI, chute score (CS), exit velocity (EV), ELISA score for paratuberculosis (ES), and ultrasound longissimus muscle area (ULMA), subcutaneous fat thickness (UFT), percent intramuscular fat (UPIF), and tenderness score (UTS) in calves ($n = 461$) ranging from 100% Angus (A) to 100% Brahman (B). Calves were allotted to pens (by sire group and sex) in a GrowSafe automated feeding facility (adjustment period = 21 d; feeding trial = 70 d), and fed a ration of corn, cottonseed hulls, molasses, and

a protein, vitamin, and mineral supplement. Individual feed intake was recorded daily, CS and EV biweekly, and ultrasound measurements at the end of the feeding trial. Phenotypic RFI was estimated as actual minus expected feed intake. Statistical analyses used homoscedastic mixed models. Fixed effects were contemporary group (year-pen), age of dam, RFI group (high: RFI > mean + 0.5 SD; medium: RFI between mean \pm 0.5 SD; low: RFI < mean - 0.5 SD; SD = 5.4 kg), sex of calf, age of calf, B fraction of calf, calf heterozygosity, mean CS, mean EV, and ES. Sire and residual were random effects. Brahman had lower ($P < 0.001$) ULMA, UFT, UPIF, and higher ($P < 0.001$) UTS values than Angus. Low RFI calves had lower UPIF ($P < 0.001$) than high and medium RFI calves. High ULMA was associated with low mean EV ($P < 0.015$). Mean CS and ES were non-significant for all ultrasound traits.

Key Words: Cattle, Feed Intake, Ultrasound

W39 Relationship between carcass traits and phenotypic residual feed intake, breed composition, temperament, and ELISA scores for paratuberculosis in an Angus-Brahman multibreed herd. M. A. Elzo*¹, D. D. Johnson¹, D. G. Riley², G. R. Hansen³, R. O. Myer⁴, D. O. Rae¹, J. G. Wasdin¹, and J. D. Driver¹, ¹University of Florida, Gainesville, ²USDA-ARS STARS, Brooksville, FL, ³North Carolina State University, Plymouth, ⁴North Florida Research and Education Center, Marianna, FL.

Identification of factors that permit animals to grow quickly and efficiently, and have desirable carcass characteristics remains a primary goal in beef production. The objective was to evaluate the relationship between 7 carcass traits and breed group (Angus (A), Brahman (B), Brangus, 3/4 A 1/4 B, 1/2 A 1/2 B, and 1/4 A 3/4 B), residual feed intake (RFI) group (high: RFI > mean + 0.5 SD; medium: RFI between mean \pm 0.5 SD; low: RFI < mean - 0.5 SD), chute temperament score (CS), exit velocity (EV), and dam ELISA score for paratuberculosis (ES) in 84 steers ranging from 100% A to 100% B. Carcass traits were hot carcass weight (HCW), longissimus muscle area (LMA), fat thickness (FT), kidney, pelvic, and heart fat (KPH), marbling score (MS), Warner-Bratzler shear force (SF), and tenderness score (TS). Records of ES were taken preweaning, and CS, EV, and RFI (actual minus expected feed intake) were obtained post-weaning during a 70-d feeding trial at a GrowSafe automated feeding facility. Subsequently, animals were sent to a South Texas feedlot, and commercially slaughtered at approximately 14 mm of FT. Carcass traits were collected at the slaughter facility, and SF and TS were obtained at the Florida Meat Processing Lab. Traits were analyzed using mixed models. Fixed effects were pen, RFI group, age of dam, age of calf, B fraction of calf, calf heterozygosity, mean CS, mean EV, and ES. Random effects were sire and residual. Brahman had lighter HCW ($P < 0.05$), smaller LMA ($P < 0.001$), lower MS ($P < 0.02$), higher SF ($P < 0.03$), and lower TS ($P < 0.001$) than Angus. High KPH was associated with high mean EV ($P < 0.03$). Mean CS, RFI group, and ES were non-significant for all carcass traits.

Key Words: Carcass, Feed Intake, Multibreed

W40 Genotype x environmental interaction to Nelore cattle raised in two Brazilian regions. J. C. DeSouza*¹, L. O. C. DaSilva², J. A. DeFreitas¹, C. H. M. Malhado³, A. Gondo², P. B. Ferraz Filho⁴, R. L. Weaber⁵, and W. R. Lamberson⁵, ¹Parana Federal University, Palotina Campus, PR, Brazil, ²Embrapa Beef Cattle Research Company, CNPGC,

Campo Grande, MS, Brazil, ³South East of Bahia University, Jequeia, BA, Brazil, ⁴State University of Mato Grosso do Sul, Tres Lagoas, MS, Brazil, ⁵University of Missouri, Columbia.

The objective this paper was to estimate genotype \times environment interaction between progeny of Nelore bulls in two different regions and estimate correlations of traits. Records were from calves raised in two Brazilian regions, Pará State (Region one) in North of Brazil and Bolsão (Region two) in Mato Grosso do Sul State. The regions were characterized by ARRUDA and SUGAI (1994) and differed by one or more of the following: production system, technology level, and natural resources such as climate, rain, topography and quality of the soil. The data were provided by the Brazilian Zebu Breeders Association (ABCZ) and by the National Beef Cattle Research Center (CNPGC) of the Brazilian Agricultural Research Corporation (Embrapa). The traits analyzed were: gain between birth and 120 d (GBWT_WT120, kg); weight at 120 days of age (W120, kg); gain between 120 d and 205 d (GWT120_WT205, kg); weight at 205 d (WT205, kg); gain from birth to weaning (GBWWT205, kg); weight at 365 d (WY, kg); and gain between 205 d and 365 d (GWT205WY, kg). The G \times E interaction was calculated using an animal model in the MTDFREML program. The variation accounted for by G \times E was between 0.42 (GWT205WY) and 0.93 (GW120_205, WT205, GBWWT205). The change in environment calculated using MME solutions of fixed effects (contemporary group) were 17.4 kg, and 20.7 kg; 37.3 kg, 26.9 kg; 59.1 kg and 25.5 kg, respectively, for weight 120 d, WT205 and WT365, for Pará and Bolsão. For WT120 the better trend was in Bolsão, but for others weights, in Pará. The genotype \times environment interaction (co)variance components resulted in an improved fit of the model for all traits. However, the large genetic correlations between regions or management systems (greater than 0.80) provides evidence for combining the production data of Nelore cattle from different regions and management systems across Brazil. In this case, specifically using sires in both regions should yield similar results. The result of evaluation of the environments showed a positive trend.

Key Words: Gain, Weight, Zebu

W41 Comparison of different nonlinear functions to describe beef cattle growth. L. G. Albuquerque*^{1,7}, S. Forni¹, M. Piles², A. Blasco³, L. Varona⁴, H. N. Oliveira^{5,7}, and R. B. Lobo⁶, ¹Universidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil, ²IRTA, Unidad de Cunicultura, Caldes de Montbui, Spain, ³Universidad Politécnica de Valencia, Valencia, Spain, ⁴Centre UdL-IRTA, Lleida, Spain, ⁵Universidade Estadual Paulista, Botucatu, Sao Paulo, Brazil, ⁶Universidade de Sao Paulo, Ribeirao Preto, Sao Paulo, Brazil, ⁷National Counsel of Technological and Scientific Development - CNPq, Brasilia, DF, Brazil.

The aim of the present work was to compare different nonlinear models for the prediction of adult weight of Nelore females. The growth curve parameters, their (co)variance components and environmental and genetic effects acting on these parameters were estimated jointly in a Bayesian hierarchical model. In the first stage of the hierarchy, four nonlinear equations were employed: Brody, Von Bertalanffy, Gompertz and Logistic. The analyses were carried out using three different data files to determine the consequences of having animals with few records. Three approaches were considered to describe the fitting errors standard deviations: constancy throughout the trajectory, linear increasing until 3 years of age and constancy thereafter, and nonlinear variation following the same function applied in the first stage of hierarchy. Models were

compared using Akaike's Information Criterion, Bayesian Information Criterion and Deviance Information Criterion. The fit at different points of the growth curve were compared applying the Gelfand's check function. The mean estimates of adult weight ranged from 531.78 to 586.89 kg. The Brody model provided higher estimates of asymptotic weight than the other models. Considering the same growth function, higher adult weight mean estimates were obtained when the fitting error variance was constant along the trajectory. None of the models was suitable to describe the fitting errors standard deviations at the beginning of the growth curves. All functions provided less accurate predictions at the beginning and predictions were more accurate after 48 mo of age. An increase in the number of animals that did not reach maturity did not impair the prediction of adult weights since growth curve parameters and their (co)variance components were estimated jointly. The Gompertz, Von Bertalanffy and Brody models were adequate to establish mean growth patterns and to predict the adult weight of Nelore females. The Brody model was more accurate in predicting the birth weight of these animals and presented the best overall goodness of fit.

Key Words: Bayesian Analysis, Longitudinal Data, Model Choice

W42 Principal component analysis of body measurements of Hanwoo. J. J Lee* and N. S Kim, *Chungbuk National University, Republic of Korea.*

Unlike carcass traits, body size measurements are composed of more than ten traits that are highly phenotypically correlated. The technique of principal component analysis was used to reduce a large number of variables to a smaller number of new variables (PCs) and characterizing cattle according to body shape. The objective of this study was to estimate and identify the combination values of principal components calculated using body measurements of Hanwoo (Korean Cattle). During 2004 to 2007, ten body measurements were collected by Korean Animal Improvement Association using 744 cattle records at yearling (12 months of age) and 411 cattle records at the end of test (30 months of age). These measurements included wither height (WH), rump height (RH), body length (BL), chest depth, chest width, rump length, hip width, thurl width, pin bone width and chest girth (CG). Phenotypic correlations among body measurements were estimated ranging from 0.23 to 0.97 at 1 year of age and from 0.25 to 0.93 at the end of test. The first principal component (PC1) indicated a weighted average of overall body measurements, accounting for 71.3% and 55.7% of the total variation for yearling and end of test, respectively. The two first PC had positive coefficients for all body measurements. The major sources of PC1, such as CG, BL, RH and WH, were similar for both periods of test. The second principal component (PC2) included withers height, rump height and body length with chest girth for both periods of test. PC2 accounted for slightly less than 20% of total variation for both periods of test. Further studies are needed to estimate genetic principal components through the simple reparametrization for animal breeding purposes.

Key Words: Hanwoo, Principal Component Analysis, Body Measurement

W43 Analysis of growth trait in Brazilian Simmental. M. G. Dib*¹, F. R. Araujo Neto², L. F. A. Marques³, and H. N. de Oliveira¹, ¹*Faculdade de Medicina Veterinária e Zootecnia - UNESP, Botucatu,*

SP, Brazil, ²*Faculdade de Ciências Agrárias e Veterinárias - UNESP, Jaboticabal, SP, Brazil,* ³*Centro de Ciências Agrárias - UFESb, Alegre, ES, Brazil.*

Estimates of variance components were obtained from a sample of 22,000 records of weaning weight (WW) and weight gains from weaning to yearling (GWY), yearling to 550-day (GY5), and 550 to 730-day (G57) of Simmental cattle raised in Brazilian farms. Data were collected by Brazilian Simmental Breeders Association. The pedigree data included information from 60000 animals. Variance components were estimated within a Bayesian context considering a multiple trait animal model with the fixed effects of contemporaries groups and age of dam and random direct and maternal genetic effects of animal, and maternal permanent environmental effect. Maternal (genetic and permanent) effects were included in the model only for WW. Analysis was performed using GIBBS2F90 (Misztal, 2006). Flat priors were assumed for variance components and fixed effects. Marginal densities of the variance components and other genetic parameters were estimated from the Gibbs output. Graphical inspection and the Gibanal program (Van-Kaam, 1998) were used for assessing convergence to the equilibrium distribution, the joint posterior. A burn-in period of 20,000 iterations was adopted, followed by 550,000 iterations with a thinning interval of 100 iterations. Hence, nominal sample size for post-Gibbs analyses was 5,500. Posterior means of heritability estimates were low: 0.16 (WW); 0.12 (GWY); 0.11 (GY5) and 0.16 (G57) for the direct effects and 0.05 for maternal effect (WW). For the environmental correlations the posterior means were near to zero, except for the between GY5 and G57 (0.20). For the genetic correlations values were high and positive ranging from 0.39 (between GWY and GY5) to 0.72 (GWY and G57). For yearling, 550 days and 730 days heritabilities calculated from the estimates were, respectively, 0.21; 0.26 and 0.34. Results confirm that under Brazilian conditions, selection for growth on Simmental cattle should be effective. Although Simmental cattle are recognized among beef breeds by their good maternal ability, genetic variation among cows plays minor role on purebred calf growth in Brazil.

Key Words: Heritability, Correlations, Variance Components

W44 Relationship between ultrasonically-measured beef cow carcass traits and lifetime productivity. L. A. Pacheco*, J. R. Jaeger, D. W. Moser, and K. C. Olson, *Kansas State University, Manhattan.*

The objective of our study was to determine if ultrasonically-measured intramuscular fat (IMF) and longissimus muscle depth (LMD) of replacement heifers was related to lifetime cow productivity, cow longevity and progeny performance. Angus heifers (n=160) were managed as a contemporary group and developed in a dry lot until breeding at 14 months of age. Heifer IMF and LMD were measured at approximately 205 d of age. Each year females were mass-mated following estrus synchronization and exposed to bulls 10 days later for the remainder of the 45 d breeding season. Following first breeding, heifers were managed in a spring-calving, native range-based production system with a 12-mo calving interval for the duration of the study (2004-2007). Animals were examined for pregnancy during August each year. Following pregnancy determination, non-pregnant females were removed from the herd. Calves were weighed at birth; weaning weights were adjusted for age of calf, age of dam, and sex of calf. Pregnancy rate as heifers was not related to IMF or LMD (P=0.12 and P=0.18, respectively) measured at 205 d of age. As mature cows pregnancy rate was not related to IMF or LMD (P=0.12 and P=0.18, respectively). Similarly, calf birth weights

were not related to dam IMF; however, calf birth weights increased ($P < 0.06$) as dam LMD increased. A 1 mm increase in dam LMD was associated with an increase of 0.15 kg in calf birth weight. Calf adjusted weaning weights were not related ($P = 0.13$) to dam IMF. Conversely, calf adjusted weaning weights increased ($P < 0.04$) as dam LMD increased. A 1 mm increase in dam LMD was associated with an increase of 0.78 kg in calf adjusted weaning weight. Calving date was not related to dam IMF or LMD ($P = 0.3$ and $P = 0.08$, respectively). These data were interpreted to suggest that increases in cow LMD were associated with greater birth weights and weaning weights of progeny. In contrast, cow IMF measured at 205 d of age was not related to pregnancy rate, calf birth weights, calf weaning weights, or calving dates.

Key Words: Intramuscular Fat, Longissimus Muscle, Beef Cows

W45 Estimates of genetic parameters for reproductive traits in Nelore cattle females. M. J. Yokoo^{*1}, L. G. Albuquerque¹, C. U. Magnabosco², J. F. H. Rodrigues¹, R. B. Lobo³, L. A. F. Bezerra³, and G. J. M. Rosa⁴, ¹São Paulo State University, Jaboticabal, São Paulo, Brazil, ²Embrapa Cerrados, Planaltina-DF, Brazil, ³University of São Paulo, Ribeirão-Preto-SP, Brazil, ⁴University of Wisconsin, Madison.

This study aimed to estimate genetic parameters of female reproductive traits (RTs) in Nelore cattle, including age at first calving (AFC), first calving interval (FCI), average calving interval (ACI), gestation length (GL), and days to conception (DC). Data on 3,203 females were analyzed using univariate animal models, and Bayesian inference was utilized for inferring variance components (VC). The models included the fixed effect of contemporary groups and the random effect of animals. Permanent environment was also included in the models as a random effect, except for the traits AFC and FCI. The table below shows the means of the posterior distributions of VC and heritability. Heritability estimates were relatively low, indicating that these RTs will respond slowly to individual selection. Therefore, considering that these traits are highly influenced by environmental factors, improvements on females' management will probably enhance reproductive indices more effectively. In Zebu breeds selection has been made primarily for growth traits and the only RT widely used in the selection indexes is scrotal circumference. Female RTs are also highly influenced by the producer management decisions and, consequently, are difficult to select. However, these RTs present a significant impact in the production system profitability. As the gains obtained by selection are permanent, selection indexes including one or some of these female RTs could be developed. For that, further studies considering the genetic correlation between these RTs and other economic important traits are necessary.

Table 1. Posterior distributions of variance components and heritability for reproductive traits in Nelore cattle females

VC \ Trait	DC	GL	AFC	FCI	ACI
Direct additive genetic	657.4	2.1	372.8	691.0	555.3
Permanent environment	748.4	3.8	—	—	307.2
Residual	4749.8	56.9	3681.7	8410.2	7870.3
Heritability (SEM)	.11 (.02)	.03 (.02)	.09 (.05)	.08 (.02)	.08 (.02)

SEM = standard error of the mean

W46 An approach for considering genotype × environment interaction in the genetic evaluations of Zebu beef cattle in Brazil. L. O. C. Silva^{*2,3}, S. Tsuruta¹, J. K. Bertrand¹, A. Gondo², P. R. C. Nobre⁴, R. A. A. Torres, Jr.³, and C. H. C. Machado⁵, ¹University of Georgia, Athens, GA, ²EMBRAPA Beef Cattle, Campo Grande, Brazil, ³National Council for Scientific and Technological Development, Brasilia, Brazil, ⁴Foundation for Agric. and Environment Research, Campo Grande, Brazil, ⁵Brazilian Association of Zebu Breeders, Uberaba, Brazil.

The objective of this study was to evaluate the importance of genetic × environment interaction when doing genetic evaluations of Zebu beef breeds in Brazil. The data set of Tabapua breed included 72,331 actual weights at weaning (WW) and 43,567 at yearling (YW) from 94,612 animals in the pedigree file. These data were collected between 1979 and 2007 by the Brazilian Association of Zebu Breeders and sent to National Center for Research on Beef Cattle from EMBRAPA. The observed weights (WW and YW) were analyzed using AIREMLF90 under an animal model. Fixed effects included contemporary group (CG); difference of ages within the CG (linear covariable), performance group (PG), age group of cows (AGC: young and mature), age of cow at calving within AGC (fit as linear and quadratic), and the actual age of the animals at weighing were included in the model. CG, included a minimum of five animals, was defined by sex, farm, year, season, and feeding management. Random effects in the model were direct, maternal, maternal permanent environment, and sire × performance group interaction (SxPG). PG was created based on the average of CG for adjusted WW and YW. The population was divided in three performance groups (1-low; 2-medium; 3-high performance), each including 33% of the CG numbers. Preliminary results showed values of variance components for SxPG of 2.48 ± 0.66 (0.84% of residual variance-RV) for WW and 6.79 ± 1.84 (1.27% of RV) for YW. Correlations direct effect for sires with at least 20 progeny in high and low PG were 0.992 for WW and 0.978 for YW. Results are indication of no substantial reranking of sires in environments with different level of production.

Key Words: Zebu Beef Cattle, Growth Weight, GxE Interaction

W47 Phenotypic correlations between the ratio of body measurements and economic traits in Korean native beef cattle. S.-H. Oh^{*1}, T. White¹, and S.-D Kim², ¹North Carolina A&T State University, Greensboro, ²National Institute of Animal Science, South Korea.

The objective of this study is to investigate if there are any correlations between the ratio of body measurements and economic traits in the population of Korean native beef cattle. The data has been collected at the National Institute of Animal Science in South Korea. The body was measured every six months from 6 months of age to 24 months of age. The number of animals measured was 183 at 6, 12, and 24 months, and 663 at 18 months. The collected data included height at wither(BH), height at rump(RH), horizontal distance between top of shoulder and pins(BL), depth at chest(CHD), width of chest(CHW), horizontal distance between top of hips(HW), horizontal distance between projecting part of pelvises(TW), horizontal distance between pins(PW), distance in straight line between front of hipbone to pinbone(RL), and girth of chest(CHG) as body measurements. In the meantime, the number of animals having the economic traits was 2706. The economic traits consisted of body weight(BW), backfat(BF), carcass weight(CW), index of yield(YGI), and the percentage of dressing(DP), which were measured at slaughter. Pearson correlations in SAS 9.1.3 were used to analyze the data. Some of the ratio of body measurements showed

30-40% of phenotypic correlation with economic traits. The ratio of BH/CHD had negative correlations with BW, BF, CW, and DP, which were -0.29, 0.24, -0.31, and -0.20, respectively. The ratio of RH/CHD also showed negative correlations with BW, BF, CW, and DP, which were -0.35, -0.27, -0.38, and -0.22, respectively. As a result, there were phenotypic correlations between the ratio of body measurements and economic traits, which means that producers may use the ratios as a selection tool for better individuals. Further study will be needed to investigate if there are genetic correlations among them.

Key Words: Correlation, Body Measurement, Economic Trait

W48 Polymorphism of IGF-I gene and its association with growth traits in chicken. B. W. Wang^{*1}, X. X. Wei¹, M. A. Zhang¹, B. Yue¹, L. Wang¹, Z. G. Yang^{1,2}, S. H. Yu¹, Y. C. Wang¹, L. Z. Jing¹, and G. L. Liu¹, ¹Qingdao Nongye University, Qingdao, Shandong Province, China, ²Feed Research Institute of Chinese Academy of Agricultural Sciences, Beijing, China.

In order to study the polymorphism of 5' region of the insulin like growth factor I (IGF-I) gene in chicken and the association with growth traits, the genetic polymorphism of IGF-I gene in 372 Luxi game chicken (12 weeks) and 423 Langya Chicken (12 weeks) was detected by PCR-RFLP, the relationships between genotypes and meat traits, egg traits, belligerence were analyzed with linear model. Frequencies of IGF-I genotypes (AA, AB, BB) were 0.3688, 0.4965, 0.1348 in Langya Chicken and 0.4516, 0.3710, 0.1774 in Luxi game chicken respectively after PCR products had been cut by Pst I enzyme. The A to G transition was detected at the 5' region of IGF-I gene by sequencing the homozygotes (GenBank accession number: EF198877, EF488284). The observed genotype distribution was not different from the expected distribution under the assumption of the Hardy-Weinberg equilibrium for the IGF-I allele of two kinds (Langya Chicken, $\chi^2 = 0.359$, $P > 0.05$; Luxi game chicken: $\chi^2 = 2.422$, $P > 0.05$). For Langya Chicken, AA genotype had the highest least square means of meat traits indexes such as body weight (1080±34 g), eviscerated weight with giblet (761.1±10.5g), leg muscle weight (126.1±7.6g) and chest muscle weight (104.1±6.0g); AB genotype had the highest least square means of egg traits indexes. For Luxi game chicken, AA genotype had the highest least square means of stronger belligerence indexes such as neck length (17.93±1.82cm) and shank length (9.01±0.69cm); BB genotype had the highest least square means of meat traits index such as body weight (2.41±0.06kg). The results showed that the genetic polymorphism of the 5' region of IGF-I gene had different genetic effects in different breeds. The experiment provided theoretical foundation for IGF-I gene's distribution state and further utilization of local chicken breeds in China.

Key Words: Chicken, IGF-I Gene Polymorphism, Growth Traits

W49 Genetic and non-genetic factors affecting broiler chick weight at hatch in South West Nigeria. O. T. F. Abanikannda¹, A. O. Leigh¹, O. N. Coker³, O. T. Adeseko^{*1}, O. Orunmuyi⁴, A. L. Dare², I. S. Okoya¹, and I. O. Ola-Gbadamosi¹, ¹Lagos State University, Ojo, Lagos State, Nigeria, ²Obasanjo Farms Nigeria Limited, Igboora, Oyo State, Nigeria, ³S & D Farms Nigeria Limited, Odeda, Ogun State, Nigeria, ⁴Ahmadu Bello University, Zaria, Kaduna State, Nigeria.

Measurable productivity traits of animals are influenced by both genetic and non-genetic components. Most performance traits of broilers like

other animals are also quantitative in nature. The broiler breeds investigated were Anak, Marshall and Ross, and the eggs were sourced from reputable parent stock farms. The effects of the following factors on chick weight were investigated; chick sex (X), breed (B), hen's age (A), egg weight (E), egg length (L), egg width (W), egg weight at candling (C). The statistical model describing this study is given as $Y_{ijklmno} = \mu + X_i + B_j + A_k + L_l + W_m + C_n + \epsilon_{ijklmno}$. With the exception of chick sex, egg length and egg width which were not significant ($P > 0.05$), all other factors were highly significant ($P < 0.001$) on chick weight. All the factors studied exhibited similar trend across the three breeds, with Anak breed having the least and Ross breed the highest. Breed alone accounted for 48.32 percent of total variation explained, while egg weight and hen's age contributed 32.40 and 16.53 percent respectively. The Ross breed significantly had the highest values for all the measurements taken, while the Marshall breed was intermediate between the Ross and the Anak breeds. Considering the direct relationship that exist between the chick's initial weight, average daily gain and final weight, the Ross breed promises to be a better breed in terms of meat yield.

Table 1. Effect of breed on some egg measurements[†]

Breed	N	Egg Weight (g)	Egg Length (mm)	Egg width (mm)	[‡] Weight at Candling (g)	Chick Weight (g)
Anak	361	58.66±0.28 ^c	57.38±0.14 ^b	42.93±0.08 ^c	50.60±0.27 ^c	39.19±0.24 ^c
Marshall	361	60.33±0.34 ^b	57.40±0.17 ^b	43.62±0.09 ^b	52.56±0.31 ^b	41.29±0.26 ^b
Ross	282	66.02±0.30 ^a	59.65±0.15 ^a	45.41±0.10 ^a	58.27±0.30 ^a	45.45±0.30 ^a

W50 Boar fertility and semen quality characteristics in lines of pigs selected for component traits of female reproduction. B. A. Freking^{*1}, P. Purdy², C. Welsh², S. Spiller², and H. Blackburn², ¹USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, ²National Animal Germplasm Program, Fort Collins, CO.

Selection for 11 generations for ovulation rate (OR) or uterine capacity (UC) resulted in significant changes in component traits of litter size. Our objective was to characterize male fertility as a correlated response to selection compared to an unselected control line (CO). Each boar (n=60) from two replicate seasons was collected twice. The sperm-rich fraction was obtained and volume and concentration of sperm cells was measured to estimate total sperm production. Each ejaculate was extended 1:3 v/v with Androhep Plus (Minitube, Verona, WI) and packed for shipping to the NAGP lab for processing into frozen straws. Semen quality was measured by computer assisted semen analysis at three time points: fresh (F), 24 h after extender added (E), and post-thaw (PT). A mixed model analysis of variance was applied to the data. Fixed effects of replicate, line and two-way interactions were fitted. The random effect of boar within line × replicate was used to test line differences. Sperm concentration was not different ($P = 0.18$) among the lines (0.594, 0.691, and 0.676 *10⁹ cells/ml) for CO, OR, UC lines, respectively. Significance ($P < 0.05$) was detected for volume of the sperm-rich fraction, greatest for OR (86.4 ml), intermediate for UC (75.6 ml), and lowest for CO (70.2 ml). Line differences were thus detected ($P < 0.02$) for total sperm production, greatest for OR (54.9 *10⁹), intermediate for UC (48.7 *10⁹) and lowest for CO (40.5 *10⁹). A higher percentage of progressively motile sperm and also higher estimates of sperm velocity only at time point E ($P < 0.01$) were detected in favor of CO. Estimates of motility,

velocity, and activity measured on F and E time points were moderately and positively correlated with estimates obtained PT. Selection for component traits of female reproduction has had a favorable effect on total sperm production of boars.

Key Words: Fertility, Pigs, Semen Quality

W51 Association analysis of candidate SNPs on reproductive traits in swine. L. A. Rempel*, J. W. Holl, and G. A. Rohrer, *USDA, ARS, US Meat Animal Research Center, Clay Center, NE.*

Being able to identify young females with superior reproduction traits would have a large financial impact on commercial swine producers. Previous studies have discovered SNPs associated with economically important traits such as litter size, growth rate, fat deposition, and feed intake. The objective of this study was to test candidate SNPs for sow prolificacy production traits, including: age at puberty (AGEP, n = 963), ovulation rate (OR, n = 1,122), weaning to estrus interval (WEI, n = 744), total pigs born (TB, n = 1,924), number born alive (NBA, n = 1,924), number born dead (NBD, n = 1,924), and number mummified (MUM, n = 1,924) and determine association of these traits in gilts and sows of a Landrace-Duroc-Yorkshire composite population. Candidate SNPs included estrogen receptors (ESR) 1 and 2; prolactin receptor (PRLR); alpha-D-mannosidase (MAN); leptin (LEP); and melanocortin 4 receptor (MC4R). Genotypes were verified using GenoProb. Association analyses regressed additive (A), dominant (D), and imprinting (I) SNP effects on each trait. ESR2 A949G was associated with AGEP (A = 2.18 d; P < 0.025). PRLR T1528A was associated with AGEP (I = 3.62 d; P < 0.001). PRLR C1217T was associated with TB (A = -0.31 piglets; P < 0.017). An association was identified between MUM and PRLR G1439A (A = -0.09 piglets; P < 0.003). Age of puberty was also associated with MAN A1426G (A = -2.47 d; P < 0.008 and I = 1.99 d; P < 0.06). MC4R A1426G was associated with WEI (A = 0.86 d; P < 0.003) as well as MUM (D = -0.130 piglets; P < 0.001 and I = -0.06 piglets; P < 0.046). No significant associations were detected for ESR1 or LEP SNPs. These results indicate that SNPs previously linked to more traditional production and growth traits may also serve in the capacity to assist with selection of young females for superior reproductive performance.

Key Words: Pig, SNP, Reproductive Traits

W52 Analysis of founder-specific inbreeding depression on Landrace sow longevity. J. Casellas*, L. Varona, N. Ibáñez-Escriche, and J. L. Noguera, *Genética i Millora Animal, IRTA-Lleida, Lleida, Spain.*

Inbreeding depression is a biological aspect mainly related to the recessive genetic load carried by a population. When this genetic load is unevenly distributed among founder genomes, heterogeneity of founder-specific inbreeding depression (FSID) could be anticipated, although this phenomenon has never been evaluated on sow longevity (SL). The objective of this study was to ascertain whether FSID impairs SL. Longevity data of 4,226 hyperprolific Landrace sows (13.28 ± 0.06 piglets per litter) were recorded in a selection herd registered in the Pig Spanish Data Bank (BDporc) between years 1988 and 2006. Sow longevity was measured as the time interval between the first mating

until culling or death (complete records), whereas records from sows still alive at the end of data collection were considered as censored. Full pedigree included 1,082 founders and 5,273 descendants, and only 35 founders contributed inbred descendants. Sow longevity was analyzed under a Weibull piecewise proportional hazard model solved through Bayesian inference. Prior distribution for FSID effects was modeled as asymmetric Gaussian to allow for skew patterns. Modal (and highest posterior density region at 95%) estimates for ρ and λ baseline parameters were 0.927 (0.881 to 0.973) and 0.00008 (0.00006 to 0.00011), with three cut points placed at 296 d (289 to 300), 492 d (477 to 499) and 1,012 d (1,008 to 1,017). Additive genetic variance for SL was 0.312 (0.248 to 0.384; $h^2 = 0.159$), whereas the variance component for the FSID effects was 0.005 (0.001 to 0.009), revealing a substantial degree of between-founders heterogeneity. Posterior distribution for FSID effects was asymmetric with an over-expressed right-tail, where founder-specific modal estimates for FSID effects ranged between -0.006 (-0.084 to 0.076) and 0.076 (0.005 to 0.148) for each 1% inbreeding. These results corroborated a wide and skew distribution of FSID effects, with null or negative effects on SL.

Key Words: Asymmetry, Inbreeding Depression, Sow Longevity

W53 SNPs of LEP and FABP4 genes in *Bos indicus* and crosses: Segregation and association with meat traits. M. G. Dib*¹, R. A. Curi¹, L. A. L. Chardulo², A. C. Silveira¹, M. D. B. Arrigoni¹, and H. N. de Oliveira¹, ¹Faculdade de Medicina Veterinária e Zootecnia - UNESP, Botucatu, SP, Brazil, ²Instituto de Biociências - UNESP, Botucatu, SP, Brazil.

Fat deposition is one of the most important factors affecting carcass and meat quality in beef cattle. Leptin and fatty acid binding protein 4 play important roles on fat metabolism. The objectives of this study were to estimate, in beef cattle of different genetic groups, the allele and genotype frequencies of SNPs located in the Leptin (LEP) and the fatty acid binding protein 4 (FABP4) genes and to evaluate associations between the polymorphisms and meat traits. One hundred and forty seven animals (46 Nellore (*Bos indicus*), 41 Canchim (5/8 *Bos taurus* + 3/8 *B. indicus*), 26 Rubia Gallega x Nellore crossbred (1/2 *B. taurus* + 1/2 *B. indicus*), 19 three-way cross Brangus (9/16 *B. taurus* + 7/16 *B. indicus*) and 15 three-way cross Braunvieh (3/4 *B. taurus* + 1/4 *B. indicus*)) were genotyped by PCR-RFLP and recorded for backfat thickness, total lipids, marbling score, ribeye area and shear force. Data analyses were performed with a linear model that included combined effect of contemporary and genetic group and genotypes effect. The A and G alleles of the LEP/BsaAI polymorphism (Y11369.1: G1620A) presented homogeneous distribution in all of the genetic groups but no association with the phenotypes were found. The FABP4/MspAII locus (AAFC01136716.1: G7516C) was found to be fixed for the C allele in *B. indicus* and in the crossbreed animals the C allele was found in very high frequency. Besides not being informative in *B. indicus* animals, the FABP4/MspAII polymorphism didn't show relevant association with the studied traits in the crossbreed animals. In spite of the importance of the studied genes in fat metabolism, it was not possible to find evidences supporting association between the studied polymorphisms and meat traits.

W54 Markers on bovine chromosome 20 associated with fat related traits and incidence of contracting bovine respiratory disease. M. D. Garcia*¹, L. Matukumalli², T. L. Wheeler¹, S. D. Shackelford¹, M. Koohmaraie¹, T. P. L. Smith¹, and E. Casas¹, ¹USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE, ²USDA-ARS, Beltsville Animal Research Center, Beltsville, MD.

The objective of this study was to assess the association of single nucleotide polymorphism (SNP) markers with incidence of bovine respiratory disease (BRD) and fat related traits. Steers from the Cycle 7 of the Germplasm Evaluation Program (GPE7; n=565) were used. The GPE7 population comprises animals derived from 7 breeds: Angus, Charolais, Gelbvieh, Hereford, Limousin, Red Angus, and Simmental. Markers were located between centimorgan 14.5 and 20.3 on bovine chromosome 20 (BTA20). One SNP was associated with incidence of BRD and yield grade ($P < 0.008$). Animals inheriting the CT genotype had the lowest yield grade (2.82 ± 0.09), and the highest incidence of BRD (0.33 ± 0.04) when compared to those inheriting the CC genotype (3.12 ± 0.19 , and 0.17 ± 0.02 for yield grade and incidence of BRD, respectively). Animals inheriting the TT genotype were observed in low frequency (n=11) and were excluded from the analysis. A second SNP was associated ($P < 0.007$) with incidence of BRD, dressing percentage and estimated kidney, pelvic and heart fat percentage (KPH). Steers inheriting the AG genotype had the lowest incidence of BRD and KPH (0.15 ± 0.03 and 2.22 ± 0.05 , respectively) when compared to animals inheriting the AA genotype (0.28 ± 0.03 and 2.39 ± 0.05 , respectively). Animals inheriting the GG genotype had an intermediate incidence of BRD (0.21 ± 0.03), when compared to animals inheriting the AA and AG genotypes, and similar KPH as those inheriting the AA genotype (2.35 ± 0.05). Animals inheriting the AG and GG genotypes had lower dressing percentages (62.2 ± 0.13 and 62.2 ± 0.12 , respectively) when compared to animals inheriting the AA genotype (62.8 ± 0.13). Further evaluation of SNP markers in this region of BTA20 is needed to identify optimal marker combinations associated with BRD and fat related traits.

Key Words: Bovine Respiratory Disease, Carcass Traits, SNP

W55 Identification and comparison of a second stearoyl-CoA desaturase gene in pigs, sheep, and chickens. A. J. Lengi and B. A. Corl*, *Virginia Polytechnic Institute and State University, Blacksburg.*

Stearoyl-CoA desaturase (SCD) is an important enzyme of lipid metabolism controlling the ratio of monounsaturated to saturated fatty acids in body tissues. SCD catalyzes the addition of a *cis*-9 double bond to several saturated fatty acid substrates. Multiple isoforms have been described in some species, especially in mice which have four. Humans have two isoforms: SCD1 with homology to the SCD isoforms present in rodents, and SCD5 which appears to be a distinct gene not found in the mouse. We recently identified SCD5 in the cow. Here we report the identification of SCD5 in pigs, sheep, and chickens. We used 5' and 3' rapid amplification of cDNA ends to identify and sequence SCD5 transcripts. Sequencing revealed that the SCD5 gene has greater guanine and cytosine content than SCD1, especially in the 5' region. Aligning the amino acid sequences of human, cow, sheep, pig, and chicken SCD5 reveals high homology among the sequences, but less homology with SCD1 amino acid sequences. The amino acid sequence includes characteristic histidine motifs present in desaturase enzymes. Interestingly, the PEST-find algorithm showed that SCD5 lacks the PEST sequences present in the SCD1 protein that control its rapid degradation. We compared the

tissue specific mRNA expression of SCD1 and SCD5 by real-time PCR. Tissue expression of SCD1 was greatest in lipogenic tissues: adipose tissue of sheep and pigs and the liver of chickens. SCD5 had a different expression profile with consistently high expression in the brain of pigs, sheep, and chickens. This report expands the number of species known to have the SCD5 gene and is the first report of the SCD5 gene outside of mammals. These data tend to indicate that SCD1 and SCD5 are the result of a gene duplication event early in evolution.

W56 Differential expression of cyclic AMP-responsive element modulator (CREM) transcription factor isoforms during boar spermatogenesis and in transcriptionally silent boar spermatozoa. S. Green* and B. L. Sartini, *University of Rhode Island, Kingston.*

Identifying the origins of male fertility variation can lead to greater reproductive efficiency in livestock. Recent studies have demonstrated that temporal regulation of functional isoform expression by alternative splicing and polyadenylation is necessary for development of the male germ cell. Specifically, differential expression of the CREM (cAMP-responsive element modulator) transcription factor isoforms occurs in spermatogonia, spermatocytes and spermatids. Aberrant CREM isoform expression has been correlated with subfertility and infertility in humans, mice, and horses. Although species variation in developmental CREM isoform expression has been reported, CREM gene expression during boar spermatogenesis has not been investigated. Using RT-PCR and 3' rapid amplification of cDNA ends (RACE) primers designed from the reported human CREM sequence, we amplified CREM in boar testis from different developmental stages. The predicted full-length mRNA transcript size of adult boar CREM is 1090 bp while prepubertal boar testis contains a predominant CREM mRNA transcript that is 690 bp in length. From these results, alternative isoforms of CREM are expressed in boar testis at different developmental ages. Additionally, we have amplified a 690 bp CREM transcript from the pool of mRNA in transcriptionally silent boar spermatozoa. The boar spermatozoa CREM transcript contains a poly(A) tail and further analysis will determine if the spermatozoa CREM transcript is a remnant from spermatogenesis or translated at a further stage. Understanding the regulation of gene expression during boar spermatogenesis will identify sources of male fertility variation in livestock.

Key Words: Boar, Spermatogenesis, mRNA

W57 Molecular analysis of the Mexican hairless pig in the Yucatan Peninsula. F. Cetz-Solis², A. Sierra-Vasquez*¹, A. Da Silva-Mariante⁴, S. Rezende-Paiva⁴, C. Cruz-Vazquez², and C. Lemus-Flores³, ¹Instituto Tecnológico de Conkal, Conkal, Yucatan, Mexico, ²Instituto Tecnológico el Llano, Aguascalientes, Mexico, ³Universidad Autónoma de Nayarit, Tepic, Nayarit, Mexico, ⁴Embrapa Cenargen, Brasília, DF, Brasil.

Mexican hairless pig (MHP) is a descendant of introduced breeds from Spain about 500 years ago, and it is in danger of extinction at the present time. The objective of this study was to characterize at molecular level the genetic variability of MHP in the Peninsula of Yucatan. Ten loci microsatellites were used in 52 unrelated pigs from ten location distrib-

uted in three states, Yucatan (n=31), Campeche (n=10) and Quintana Roo (n=11). Genetic diversity for animals in each state was estimated by the unbiased average heterozygosity values (H_o and H_e) and the allele number. Polymorphic information content (PIC) was estimated based on allelic frequencies. Nei's standard genetic distances were used to reveal the genetic relationship among state populations. Campeche pigs presented the highest H_o and H_e values (0.59 ± 0.05 and 0.64 ± 0.17), whereas Yucatan pigs had the lowest values (0.50 ± 0.03 y 0.52 ± 0.26). Eight microsatellites loci (considering all animals) were polymorphic, ranging from 0.42 to 0.88; SO355 and SO227 had low polymorphic

values (0.15 and 0.29, respectively). The average PIC for animals in the Peninsula of Yucatan was 0.54. A genetic relation among pigs from the three states was found, with pigs from Yucatan and Quintana Roo being more closely related. This evaluation found a lower genetic diversity than other related studies in México. This work should be considered in order to design conservation programs for MHP; especially for pigs from the Campeche and Quintana Roo regions.

Key Words: Microsatellites, Mexican Hairless Pig, Genetic Diversity

Companion and Exotic Animal Biology

W58 *Ancylostoma* spp. in dogs of beaches and fishing villages of Navolato, Sinaloa, Mexico. M. C. Rubio Robles*, F. G. Torres N, I. Sánchez A, J. Gaxiola M, G. Estrada S, M. López V, G. Silva H, S. M. Gaxiola C, and N. Castro del C, *FMVZ Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico.*

Ancylostoma spp. represents a serious health problem for animals and humans. These blood-feeding parasites produce Larva migrans, also known as creeping eruptions or sandworm eruptions. These are characterized by tortuous migratory lesions of the skin and occur when the larvae of dog hookworm penetrate the intact exposed skin and migrate through the epidermis progressing at the rate of few millimeters to about 3 cm/day. It is seen in tropical and subtropical areas. International travel and increasingly exotic diets have resulted in an increase in cases of cutaneous larva migrans in industrialized countries.

The objective of this work was to determine the prevalence of *Ancylostoma* spp. in dogs of beaches and fishing villages of Navolato, Sinaloa, Mexico. This was determined for a representative sample (both sexes, breeds and sizes of dogs) described by the technique of Thrusfield (1995) : $n=[t*SD/L]^2$. Where n = sample size, t = value of the normal distribution (Student t) for a 95% confidence level (t = 1.96), L = accepted error or precision (5%), and SD = weighted disease prevalence (%). On the basis of the technique described, the total number of sample animals determined for random sampling was 134. For each, dog feces were collected rectally by digital stimulus into previously identified plastic bags. The samples were transported under refrigeration at 4°C to the unit Laboratories of the FMVZ-UAS, and processed by the flotation technique with sugar solution. The results indicate that of the 134 dogs analyzed 55 (41.04%) were positive for *Ancylostoma* spp. This is a considerable number and the proportion of animals testing positive continues to be an issue of importance in the community. Frequently these dogs roam in and around the town and can distribute parasites. Residents and visitors are not well informed or ignore the risk of diseases that dogs can transmit to them.

Key Words: *Ancylostoma*, Dogs, Prevalence

W59 The prevalence of fleas in dogs of beaches and fishing villages from Navolato, Sinaloa, Mexico. M. C. Rubio Robles*, J. Gaxiola M, G. Estrada S, M. López V, G. Silva H, I. Sánchez A, F. G. Torres N., S. M. Gaxiola C, and N. Castro del C, *FMVZ Universidad Autonoma de Sinaloa., Culiacan, Sinaloa, Mexico.*

Adult fleas are a nuisance to humans and their pets, and can cause medical problems including flea allergy dermatitis, secondary skin irritations and, in extreme cases, anemia. Although bites are rarely felt, it is the resulting irritation caused by the flea salivary secretions that varies among individuals. Some may witness a severe reaction (general rash or inflammation) resulting in secondary infections caused by scratching the irritated skin area. Also, fleas may transmit tapeworms (more common infection is *Dipylidium caninum*) which normally infest dogs and cats but may appear in children if parts of infested fleas are accidentally consumed. The objective of this work was to determine the prevalence of fleas in dogs of beaches and fishing villages of Navolato, Sinaloa, Mexico. This was determined for a representative sample (with both sexes, breeds and sizes of dogs) described by the technique of Thrusfield (1995) : $n=[t*SD/L]^2$. Where n = sample size, t = value

of the normal distribution (Student t) for a 95% confidence level (t = 1.96), L = accepted error or precision (5%), and SD = weighted disease prevalence (%). On the basis of the technique described, the total number of sample animals determined for random sampling was 264. For each dog, fleas were collected with cotton and placed into previously identified plastic bags. The samples were transported to the unit Laboratories of the FMVZ-UAS, and observed microscopically. The results indicate that of the 264 dogs analyzed 211 (79.92 %) were positive for fleas. It is concluded that this is a considerable number of positive animals and if the present condition continues, it can pose serious problems for the community since frequently these dogs are at different parts of the town and can pass the infection to other healthy animals, visitors and family members.

Key Words: Fleas, Dogs, Prevalence

W60 Diagnostic potential of serum proteomic patterns in canine *Fusarium* mycotoxicosis. M. C. K. Leung* and T. K. Smith, *University of Guelph, Guelph, ON, Canada.*

The clinical symptoms of canine *Fusarium* mycotoxicosis such as anorexia, growth inhibition, lethargy, and immunosuppression are often not specific enough for veterinarians to diagnose the mycotoxicosis. The low molecular mass range (1 - 10 kDa) of serum proteome holds great potential as a source of diagnostic biomarkers. Surface-enhanced laser desorption/ionization - time of flight - mass spectrometry (SELDI-TOF-MS) is a novel technique which generates a mass spectrum of a selected protein fraction in a biological sample. In the current experiment, SELDI-TOF-MS as well as conventional blood chemistry analyses were used to investigate the effects of a combination of foodborne *Fusarium* mycotoxins on the serum proteome of 12 beagle dogs. A control diet was prepared with corn, poultry by-product, and wheat as the main ingredients. A mycotoxin-contaminated diet was prepared by replacing control corn and wheat with naturally contaminated grains and contained deoxynivalenol (2.7 ppm), 15-acetyl deoxynivalenol (0.2 ppm), zearalenone (0.3 ppm), and fusaric acid (8.4 ppm). The animals was fed the experimental diets for a 14 day period and blood samples were taken. Blood chemistry analyses revealed an inhibitory effect of foodborne mycotoxins on serum concentration of fibrinogen and serum activities of alkaline phosphatase and amylase (P < 0.05%), but the other effects on blood hemoglobin concentration, serum protein concentrations, and serum enzymes activities were insignificant (P > 0.05). Serum samples were analyzed using cation exchange ProteinChip arrays and immobilized metal affinity capture ProteinChip arrays, producing 64 peaks at the mass range of 1 - 30 kDa. Intensities of 27 peaks were significantly down-regulated in response to the contaminated diet as compared to controls, while intensities of 11 peaks were up-regulated (P < 0.05). It was concluded that the foodborne *Fusarium* mycotoxins could affect the canine serum proteome. Further experiments are needed to identify, quantify, and validate these changes in order to discover applicable biomarkers of foodborne exposure to *Fusarium* mycotoxins.

Key Words: *Fusarium* Mycotoxins, Dog, Proteomics

W61 Dietary lysine: Calorie ratios and their influence on nitrogen metabolism and digestibility in overweight mature dogs. G. Hibbard*¹, K. R. McLeod¹, D. L. Harmon¹, R. Yamka², and K. G. Friesen², ¹University of Kentucky, Lexington, ²Hill's Pet Nutrition, Inc., Topeka, KS.

Two experiments were conducted to determine the effects of altering dietary lysine:calorie ratio on nitrogen metabolism and protein turnover in moderately overweight dogs. Exp. 1 used 8 moderately overweight female crossbred hounds fed four diets with varying lysine:calorie ratios (2.2, 3.0, 3.8, and 4.6 g lysine/Mcal ME) in a replicated 4x4 Latin square design experiment. Dietary lysine:calorie ratio was altered by adding crystalline lysine. Each of the four periods was 28 days in length, 14 days of which the dogs were fed ad libitum followed by 14 days of calorie restriction at 0.75 of maintenance for ideal weight. Collections took place the last seven days of each period, in which fecal, urine, and blood samples were acquired and protein metabolism was monitored using an oral dose (7.5 mg/kg) of 15N-glycine. Increasing the lysine:calorie ratio of the diet did not affect absorbed or retained nitrogen, however, plasma urea increased linearly ($P = 0.04$). Plasma total protein and creatinine concentrations were not affected by treatment. Protein synthesis, degradation and turnover were unaffected by treatment. Exp. 2 used 6 dogs in a design similar to above but they were fed at maintenance energy throughout either the 2.2 lysine:calorie diet from above (2.2), the 3.0 (3.0C) from above or a 3.0 lysine:calorie diet containing additional amino acids to provide an ideal amino acid profile based on published values (3.0I). Both 3.0 diets decreased ($P < 0.05$) urinary N, and N absorbed, and tended to increase N retained ($P = 0.11$), and % N retained ($P = 0.09$). These studies suggest that N metabolism can be altered by altering the lysine:calorie ratio of the diet but perhaps not during nutrient restriction.

Key Words: Lysine, Requirement, Amino acid

W62 Effect of added total sulfur amino acids and threonine on nitrogen balance in dogs. R. E. Bohaty*¹, M. R. C. de Godoy¹, K. R. McLeod¹, D L. Harmon¹, R. M. Yamka², N. Z. Frantz², and K. G. Friesen², ¹University of Kentucky, Lexington, ²Hill's Pet Nutrition, Inc., Topeka, KS.

Previously, we have shown that formulating foods to provide an optimal ratio of 3.0 g lysine/Mcal ME results in increased N retention in mature overweight dogs. Therefore, the objective of this study was to further investigate whether increased levels of essential amino acids in conjunction with a dietary lysine:calorie of 3.0 would further improve N metabolism in mature overweight dogs. Four isonitrogenous and isocaloric foods all with 3.0 lysine/Mcal ME ratios were formulated. The control food levels of all essential amino acids to provide an ideal profile based on literature values (EAA). Additional foods had increased concentrations of total sulfur amino acids (TSAA), or a combination of TSAA and threonine (TT). Foods were fed to eight overweight, mature, female crossbred hounds in a replicated 4 x 4 Latin Square design experiment. Experimental periods were 28 days in length. Dogs were fed to maintain their current body weight days 1-14 of each period then reduced to 75% of maintenance for their individual ideal weight for days 15-28 of each period. Total feces and urine were collected 2 times daily for the final 6 days of each period for N balance. Urine and feces were composited by dog within each period and analyzed for N. Daily food intakes were similar across treatments whereas nitrogen intake was higher ($P < 0.05$) for animals on the control and TSAA diet

than for animals on the TT diet. There was no difference in fecal DM output, DM digestibility, fecal N excretion, N retained or N digestibility. Based on the measurements made in the present study we see no benefit for additional TSAA, TT or formulation for additional EAA in foods formulated to provide a 3.0 lysine/Mcal ME ratio.

Key Words: Amino Acid, Dog, Nitrogen Metabolism

W63 Effect of dietary protein level on urea production and protein turnover in the adult cat (*Felis catus*). T. J. Wester*¹, K. Weidgraaf¹, C. E. Ugarte¹, and M. H. Tavendale², ¹Massey University, New Zealand, ²AgResearch Ltd., Palmerston North, New Zealand.

Cats are unique among domestic animals as they are obligate carnivores and have a high protein requirement. However, little is known about how they regulate amino acid (AA) metabolism. This study was undertaken to examine the effect of dietary protein level on urea production and AA metabolism in cats. Cats ($n = 18$) were allocated to three treatments (15, 40 or 65% ME intake as CP), fed at maintenance for 3 wk, and then fitted with saphanous and cephalic vein catheters. On the following day, they received primed continuous infusions of [¹³C]bicarbonate (to measure basal CO₂ production), [1-¹³C]Leu and [¹⁵N₂]urea from 0 to 120, 120 to 480 and 0 to 480 min, respectively. Cats were fed hourly during infusion and Leu entry rate from diet was calculated. Breath was sampled at 0, 100, 110, 120, 440, 460, and 480 min to measure ¹³CO₂, with blood sampled at 0, 440, 460, and 480 min to measure ¹³C enrichments in Leu and ketoisocaproate, and [¹⁵N₂]urea. Values for Leu flux, non-oxidative Leu disposal (NOLD, an indicator of protein synthesis), Leu rate of appearance in plasma (Ra, an indicator of protein degradation), Leu oxidation, and urea production rate (an indicator of net protein catabolism) are shown in Table 1. Cats fed the diet with 15% of ME intake as CP had the lowest rate of whole body AA catabolism and oxidation, whereas protein synthesis was only different between the highest and lowest CP diets. This study showed that cats modulated protein turnover mainly by altering rates of AA oxidation and catabolism. (Supported by the Massey University Research Fund)

W64 Microbiological and immunological effects of two yeast-based complex fermentation ingredients on adult dogs. D. C. Hernot*¹, G. C. Fahey, Jr.¹, S. Reeves², and M. Scott³, ¹University of Illinois, Urbana, ²Embria Health Sciences, Ankeny, IA, ³Diamond V Mills, Cedar Rapids, IA.

Nine female hound-mix dogs were used in a replicated 3x3 Latin square design to evaluate microbiological and immune responses of

two complex fermentation ingredients derived from a proprietary process consisting of *Saccharomyces cerevisiae* and the media on which they are grown. Dogs were given 400 g of food daily with one of 3 gelatin capsule treatments: 1) control (empty capsule), 2) 0.143 g yeast fermentate (Embria Health Sciences, Ankeny, IA), and 3) 1.0 g yeast culture (Diamond V Mills, Cedar Rapids, IA). Blood concentrations of lymphocytes positive for CD3, CD4, CD8 α , and CD21 cell surface markers and serum immunoglobulin concentrations were measured. Gene expression of cytokines TNF- α , IL-6, IFN- γ , and TGF- β also was determined by quantitative real-time PCR (qRT-PCR). Lactobacilli, bifidobacteria, *Escherichia coli*, and *Clostridium perfringens* populations were quantified in feces using qRT-PCR. Population changes within the predominant fecal microflora were evaluated using parallel DGGE. Immune indices measured in this study were not affected by treatment. No differences were found among treatments for any of the cell surface markers analyzed, or any of the serum immunoglobulins measured. Yeast fermentate decreased lymphocytes compared to the control. The two yeast-based complex fermentation ingredients decreased ($P < 0.05$) *Cl. perfringens* fecal populations compared to the control. Yeast culture had a more significant ($P < 0.05$) effect than yeast fermentate. In conclusion, the yeast-based complex fermentation ingredients had a beneficial effect on microbial ecology by reducing *Clostridium perfringens* populations.

W65 Nutrient levels in crop milk and plasma as an indicator of free-ranging American flamingo (*Phoenicopterus ruber ruber*) nutrient status. A. S. Hunt* and A. M. Ward, Fort Worth Zoo, Fort Worth, TX.

Crop milk and plasma samples were collected from six to eight week old juvenile American flamingos (*Phoenicopterus ruber ruber*) to evaluate nutrient availability and status in a free-ranging population. These samples were gathered with the goal to establish a database to assess the appropriateness of captive hand rearing formulas and nutrient status of captive and hand reared chicks. Samples were obtained in August

of 1999, 2000, 2001, 2003, and 2005 at the Ria Lagartos Biosphere Reserve (El Cuyo, Mexico) and analyzed for minerals, vitamins and carotenoids. The majority of the results were not normally distributed within and among years ($P < 0.05$, Shapiro-Wilkes), therefore coefficients of dispersion were calculated to describe the variability of medians across years. The dispersion coefficients were greater for crop milk than plasma ($P < 0.001$, paired t-test) for 11 of the 13 nutrients (Table 1). Minerals, vitamins, and carotenoids in crop milk samples collected at a single point during lactation are highly variable and therefore a poor indicator of nutrient requirements and status. Plasma nutrient parameters may present a more viable option for evaluating the status and requirements of growing flamingos.

Table 1: Nutrient median (M) levels (dry matter) and dispersion factor (DF) in *Phoenicopterus ruber ruber* crop milk (CM) and plasma (P) samples.

W66 Inactivation of *Clostridium botulinum* type A neurotoxin in milk by high pressure processing. J. E. Schlessner¹, R. Gerdes², G. E. Skinner¹, N. R. Reddy¹, and B. Parisi², ¹FDA, National Center for Food Safety, Summit, IL, ²Illinois Institute of Technology, National Center for Food Safety, Summit, IL.

The threat of terrorist attacks against the nation's food supplies has created the need to study food toxins that may be potential threats to the safety and security of the food supply. There is a need for the development of prevention and mitigation technologies/strategies to reduce this potential food defense threat. Non-thermal technologies such as high pressure processing have been proposed as a potential pasteurization method for milk. No data exist regarding the high pressure resistance of *C. botulinum* type A neurotoxin. The objective of the present work was to determine the high pressure resistance of *C. botulinum* type A neurotoxin in ultra-high temperature (UHT) 2% fat pasteurized milk. Samples of UHT 2% fat pasteurized milk were spiked with acid mud preparation of *C. botulinum* type A neurotoxin at a level of 10⁶ mouse lethal dose (MLD)/ ml. Spiked samples (10 ml each) were placed in high barrier film pouches, heat sealed, and pressure-treated in a Quintus Model QFP-6 High Pressure Food Processor at 400 or 600 MPa and an initial temperature of either 4 or 25°C for holding times of 3 min. After pressure treatment, samples were stored at 4°C until analysis. High pressure treated spiked samples were diluted with gel phosphate buffer and centrifuged. Supernatants were serially diluted with skim milk buffer and analyzed for presence of type A neurotoxin levels using the DIG-ELISA. Dilutions of 3:1, 1:3 and 3:37 of the last positive DIG-ELISA sample were further confirmed for type A neurotoxin by mouse bioassay. In general, the MLD determined by mouse bioassay was 10 times more sensitive than the MLD determined by DIG-ELISA. No inactivation of type A neurotoxin was observed in the untreated spiked samples by DIG-ELISA. A 3 log₁₀ MLD inactivation of type A neurotoxin was achieved in the UHT 2% fat milk samples when they were processed at a pressure of 600 MPa, initial temperature of 25°C for 3 min. High pressure denaturation of *C. botulinum* type A neurotoxin may result in a change of the structure and the toxin's activity.

Key Words: *Clostridium botulinum*, Type A Neurotoxin, High Pressure Processing

W67 Changes in fatty acid profiles of Awassi ewe and Damascus goat colostrums during ten days postpartum. Z. Guler¹, M. Keskin¹, S. Gül¹, and Y. W. Park², ¹Mustafa Kemal University, Antakya, Hatay, Turkey, ²Fort Valley State University, Fort Valley, GA.

Awassi sheep and Damascus goats are the most productive small ruminants in the Mediterranean countries including Turkey, Syria, Lebanon, and Israel. The study was conducted to characterize fatty acid profiles of colostrum milks during ten days postpartum from randomly selected 10 animals each (3-yr old) of Damascus (Shami) goat and Awassi sheep at Research Farm of Mustafa Kemal University, Hatay, Turkey. Fatty acids in colostrums were determined using GC-MS (Model 6890/5973N, Agilent, Palo Alto, CA, USA) equipped with fused silica capillary column coated with free fatty acid phase. The major fatty acids in the ewe and goat colostrums were C18:1, C16:0, C18:0, C14:0 and C10:0, which accounted for about 75 % total fatty acids. Anteiso-C15 and anteiso-C17 were the prominent branched chain fatty acids (BCFA) in both species.

C18:3 acid was found only in ewe colostrum, while trans-C18:1 was detected only in goat colostrum. For the last two days of experimental period, cis-9-octadecenoic acid was predominant in goat colostrum milk, while hexadecanoic acid was high in ewe milk. The relative concentrations of fatty acids in colostrum milks of both species were unchanged during the 8 days postpartum. The average percentages (%) of short, medium and long chain fatty acids in both species colostrums were 4.94, 15.5, and 79.4, respectively. However, for the last two days, short chain acids remained unchanged, medium chain acids decreased from 15.6 to 12.3%, and long chain acids increased from 79.4 to 83.3% in goat milk, whereas ewe milk increased in short chain acids from 4.45 to 5.86% and medium chain acids from 14.8 to 19.5%, but decreased in long chain acids from 80.7 to 74.2%. These changes in fatty acid profiles in colostrum milks during the 10 days postpartum may indicate that there are certain differences in metabolism and secretory processes between the two species.

Key Words: Damascus Goat, Colostrum, Fatty Acids Profile

W68 Interaction between β -lactoglobulin and dextran sulfate at near neutral pH and their effect on thermal stability. B. Vardhanabhuti¹, E. A. Foegeding¹, U. Yucel², and J. Coupland², ¹North Carolina State University, Raleigh, ²Pennsylvania State University, University Park.

Proteins and polysaccharide interactions play a major role in the structure and stability of many foods. Understanding their interactions and the effects on thermal stability could aid processors in product development. In this study, thermal stability of β -lactoglobulin (BLG) in the presence of dextran sulfate (DS) and their interactions were investigated. Samples containing 6% w/w BLG and DS (M_w 5k to 500k) at different biopolymer weight ratios, pH (5.6-6.2), and NaCl concentrations (0-30 mM) were heated at 85°C for 15 min. Thermal stability was evaluated by turbidity measurement. Protein stability was characterized by differential scanning calorimetry. Interactions between BLG and DS were characterized by size exclusion chromatography coupled with multi angle laser light scattering (SEC-MALLS) and zeta potential measurement. Turbidity results showed that the degree of BLG aggregation increased with decreasing pH. The presence of DS at appropriate molar ratios significantly lowered the turbidity of heated BLG (P ≤ 0.01). Low Mw DS had broader range of effective weight ratios in decreasing the turbidity than the highest Mw DS. Data showed that DS lowered the denaturation temperature of BLG. Interaction between BLG and DS was confirmed by SEC-MALLS. Higher amount of BLG-DS complex formation was found with increasing amount of DS. Addition of 30 mM NaCl inhibited complex formation and the effect of DS on inhibiting aggregation, suggesting that the interaction was electrostatic driven. Zeta potential results revealed that samples with DS were more negatively charged compared to the BLG control. These results indicated that electrostatic interactions between BLG and DS led to a decrease in denaturation temperature of BLG, formation of higher negatively charged complex, and a different type of aggregates after heating. At appropriate conditions, DS improves thermal stability of BLG. The results provide information that will facilitate the application of whey proteins and polysaccharides as functional ingredients in foods and beverages.

Key Words: β -Lactoglobulin, Thermal Stability, Dextran Sulfate

W69 Using lactic acid bacteria to detect chemical substances in milk. A. AbuGhazaleh*¹ and S. Ibrahim², ¹*Southern Illinois University, Carbondale*, ²*North Carolina A&T University, Greensboro*.

The U.S. food system—from farms to processing and distribution to retail food service presents an array of vulnerable targets for terrorist attack. Intentional contamination of agricultural or food products with biological, chemical, or radiological agents could lead to potentially devastating effects on human health, as well as major economic losses to a critical sector of the economy. Therefore, there is an urgent need to develop a practical and sensitive approach to monitor food supplies, in case of a bioterrorist attack. The objective of this work was to determine the effect of cadmium and sodium cyanide on the growth of lactic acid bacteria in MRS broth. A total of 12 lactic acid bacteria were used in this study. A stock solution of each chemical was prepared and added to fresh batches of 10 mL MRS broth tubes to obtain final concentrations within the LD50 concentration assuming a 200 mL consumption (cadmium, 0.64 mg/mL; cyanide 7.0 mg/mL). MRS tubes were inoculated with individual strains, mixed and incubated at 37°C. Bacterial growth was monitored by measuring the optical density. At the end of the incubation period; the pH values of each sample were measured. Our results showed that at concentrations of 0.5 mg/mL and 1.4 mg/mL, cadmium and cyanide respectively, completely inhibited the growth of all 12 strains. The pH of those cultures that had strong inhibition remained relatively unchanged during the incubation period. These preliminary results suggest that typical dairy cultures could be a useful indicator of the presence of these chemical compounds. Further work will continue to expand the diversity of potential bioterror substances

Key Words: Lactic Acid Bacteria, Milk, Safety

W70 Development of symbiotic low fat buffalo milk yogurt. X. Han*² and M. Guo¹, ¹*University of Vermont, Burlington*, ²*Harbin Institute of Technology, Harbin, China*.

Buffalo milk represents an important animal product in South and East of Asia. As a specialty product, buffalo milk yogurt has become popular and has its own niche market in the US. In present study, symbiotic (containing both prebiotics and probiotics) low fat buffalo milk yogurt prototypes (plain and blueberry) were manufactured using 1% fat natural buffalo milk, inulin (a prebiotic ingredient), and probiotic cultures including *Bifidobacterium spp.*, *L. casei*, and *L. acidophilus* in a local commercial factory. Samples were analyzed for physicochemical and microbiological properties, and the survivability of probiotics during ten week storage. Gross composition results were: total solids 11.60 ± 0.58% and 17.12 ± 0.36%, ash 0.82 ± 0.06% and 0.78 ± 0.02, protein 4.49 ± 0.31% and 4.16 ± 0.11%, fat 0.68 ± 0.03% and 0.55 ± 0.05%, carbohydrates 5.68% and 11.38% for plain and blueberry flavors, respectively. Mineral contents were: calcium 1.97 ± 0.20 and 1.72 ± 0.06, magnesium 1.63 ± 0.02 and 1.69 ± 0.01, zinc 0.07 ± 0.01 and 0.07 ± 0.003, sodium 0.87 ± 0.15 and 0.94 ± 0.12 mg/g for the plain and blueberry flavored yogurt, respectively. The values of pH, titratable acidity and viscosity ranged from 4.34-4.01 and 4.42-3.70, 0.96-1.13 and 0.94-1.30%, 1.395-1.665 and 2.146-1.564 Pa.s for the plain and blueberry flavored yogurts, respectively. The initial population of *Bifidobacterium spp.* and *L. casei* were above 10⁸ cfu/g for both of plain and blueberry flavored yogurts. Both *bifidobacterium spp* and *L. casei* remained stable during the 10 weeks of storage (>10⁶cfu/g). However, population of *L. acidophilus* decreased sharply during the first a few

weeks and then dropped below 10⁶cfu/g. The results indicated that low fat buffalo milk may be a good vehicle for developing symbiotic yogurt. Improvement of the survivability of *L. acidophilus* in this matrix needs to be further studied.

Key Words: Buffalo Milk, Symbiotics, Yogurt

W71 Presence of geraniol in bovine milk following topical application as a natural insecticide. D. M. Watson*, J. P. Evans, R. E. Miracle, M. A. Drake, S. P. Washburn, and D. W. Watson, *North Carolina State University, Raleigh*.

Geraniol is a plant derived monoterpene found naturally in many plants with demonstrated insect repellency properties. Geraniol is listed as a minimal risk active ingredient exempt from the Federal registration requirements and this “generally recognized as safe” (GRAS) repellent could benefit organic or other producers wishing to reduce or eliminate reliance on insecticides. However, the effect of geraniol on milk flavor was not known. This study was conducted to determine if topical application of geraniol influenced milk flavor. Dairy cows at the Center for Environmental Farming Systems in Goldsboro, NC were divided into 4 groups of 3 cows each in 2 replicates: a control group (no geraniol treatment), and 3 treatment groups of topically applied 30% geraniol (60 mL geraniol; 120 mL geraniol; 180 mL geraniol) for 6 treatments at 2-wk intervals. Milk was collected from each cow at 8 h, and at 1, 3, 7, 10, and 13 d after each treatment. Milk from cows within each treatment group at each sample period was combined into a composite sample. Milks were analyzed for total solids non-fat (w/w) and percent fat using the CEM Smart Trac System. Headspace solid phase micro-extraction with gas chromatography mass spectrometry (SPME GC-MS) was used to screen for the presence of geraniol in the milks. The sensory threshold for geraniol in whole milk was determined using an ascending forced choice (AFC) method with 35 consumers. A trained sensory panel evaluated the flavor profile of vat-pasteurized whole milks. The instrumental detection limit for geraniol was 125 ppb (signal to noise ratio of 8:1) while the orthonasal sensory threshold in milk was 333 ppb. Geraniol was not detected instrumentally in any milk samples throughout testing. Similarly, trained panel flavor profiles of milk from geraniol-treated cows were not different from milk from control cows. Geraniol did not affect milk flavor when used as a topical insect repellent and may be viable for use with organic milk production.

Key Words: Geraniol, Pesticide, Flavor

W72 Comparative study of freeze-dried milk powder to spray-dried milk powder in water adsorption and stability. M. H. Seo*, S. H. Kim, J. Ahn, and H. S. Kwak, *Sejong University, Seoul, Korea*.

The present study was carried out to compare the stability such as water adsorption isotherms and solubility between freeze-dried milk powder and the spray-dried milk powder. Water adsorption isotherm of both freeze-dried and spray-dried milk powder samples were measured at 20, 30 and 40°C using COST-90 (Cooperation in the Field of Scientific Technical System-90) modified method. Results showed that isotherm were sigmoidal in shape in both milk powders. The adsorption isotherm of moisture content (g water/100 g dry solids) increased slowly in early stage and then increased sharply thereafter at all temperatures when

water activity changed from 0 to 1. The difference of moisture content between freeze-dried and spray-dried milk powders increased with the increase of the water activity. Especially, the moisture content difference was enhanced when the temperature increased. Equilibrium monolayer moisture content was in the range of 3.0 to 3.7 g H₂O/100 g dry solids in freeze-dried milk powder, while 0.4 to 1.7 g H₂O/100 g dry solids in the spray-dried milk powder at all temperatures. The composition of the freeze-dried milk powder was 3.4% in moisture, 41.7% in fat, and 26.8% in protein, which was comparable to that of the spray-dried milk powder. The solubility index and acidity were 0.02 mL and 0.11% in freeze-dried milk powder, and 0.17 mL and 0.19% in spray-dried milk powder, respectively. There was no difference in non-casein nitrogen (NCN) and non-protein nitrogen (NPN) contents. These results showed that the adsorption isotherm of moisture content was higher in freeze-dried milk powder than that in spray-dried milk powder, which may indicate the high stability of freeze-dried milk powder.

Key Words: Adsorption Isotherm, Freeze-Dried Milk Powder, Spray-Dried Milk Powder

W73 Comparative study of reconstituted milk made by freeze-dried milk powder to control reconstituted milk. S. I. Ahn*, S. H. Kim, J. Ahn, and H. S. Kwak, *Sejong University, Seoul, Korea.*

The present study was performed to compare the physico-chemical properties and nutrients of reconstituted milk made by freeze-dried milk powder to the control or spray-dried milk powder. There were three groups as follows: 1) control, raw milk, 2) freeze-dried, the reconstituted milk made by freeze-dried milk powder and 3) spray-dried, the reconstituted milk made by spray-dried milk powder. The freeze-dried powder was produced at 85°f using PVTFD-100 and contained 13% solid. In milk composition, freeze-dried group showed the little higher fat content and little lower moisture compared with those of the control. Spray-dried group showed much less moisture content than the control and freeze-dried group. Significant difference in L-value was found between the control and both reconstituted milks at 0 day period, however, the change was decreased throughout the period times. In addition, b-value of freeze-dried milk was significantly higher than others at 0 day. Total concentration of short chain fatty acids of freeze-dried reconstituted milk was significantly higher than others at every storage period. The concentrations of most water-soluble vitamins were lower in reconstituted milk made by spray-dried milk powder than in reconstituted milk made by freeze-dried milk powder when compared with the control. The present study indicated that there was no profound difference in physico-chemical properties in reconstituted milks made by freeze-dried and spray-dried milk powders, therefore, there is possibility of the dairy product manufacture using freeze-dried milk powder.

Key Words: Reconstituted Milk, Freeze-Dried Milk Powder, Spray-Dried Milk Powder

W74 Hysteresis of buffer capacity curves of cow, goat and sheep milks. J. Li*, M. Corredig, and A. Hill, *University of Guelph, Guelph, ON, Canada.*

Acid titration and buffer capacity measurements are simple tools that may yield information about ionic equilibria in milk and associated

changes to the micelle structure with implications for dairy technology, cheese texture and melting properties. Acid and base titrations and counter titrations show buffer capacity maxima near pH 2, near pH 4, in the range of 5.0 to 6.3, and near pH 12 for all species of milk. The colloidal calcium phosphate (CCP) maximum occurred at pH 5.1 to 5.2 during acid titration from native pH. Base titration following acid titration revealed a hysteresis effect for CCP. For minimum pH values during acid titration ranging from 5.4 to 4.8, the pH values for the CCP during subsequent base titration ranged from pH 6.5- 6.2 for cow and goat milk and 6.3-5.8 for sheep milk. Because the targeted minimum pH for most rennet coagulated varieties of cheese is near pH 5.0, the CCP peak is important for process control. Similarly, the hysteresis effect during base titration subsequent to acid titration may be important to pH control during the early stages of cheese ripening.

Key Words: Buffering Capacity, Milk, Hysteresis Effect

W75 Effects of yogurt fermentation bacteria on milk-based bioactive peptides. M. Paul and G. Somkuti*, *USDA-ARS-ERRC, Wyndmoor, PA.*

The incorporation of bioactive materials to increase the nutraceutical value of yogurt requires that these compounds survive all of the production processes, including proteolysis by endogenous enzymes. Since strains of the yogurt starter cultures *Streptococcus thermophilus* (ST) and *Lactobacillus delbrueckii* subsp. *bulgaricus* (LB) are known to have cell-associated peptidases involved in breaking down proteins to peptides transportable across cell membranes, this research focused on the sensitivity of selected bioactive peptides to ST and LB cells. The 11mer antimicrobial and 12mer hypotensive milk-protein based peptides were incubated with mid-log ST and LB cells at pH 4.5 and 7.0 to monitor the extent of proteolysis by membrane-bound peptidases, the presence of which was demonstrated by PCR analysis. Samples were removed at various time points and analyzed by reverse phase-high performance liquid chromatography (RP-HPLC). Results showed that the peptides were rapidly and extensively degraded by LB strains at both pH 4.5 and 7.0, while they remained intact at pH 4.5 in the presence of ST strains. The results suggested that the optimum time for the addition of these bioactive peptides is near the end of the yogurt making process when pH levels have dropped to 4.5 or lower, thereby limiting the extent of peptide loss caused by peptidase digestion.

Key Words: Lactic Acid Bacteria, Bioactive Peptides, Bacterial Peptidases

W76 Simplified petrifilm assay for lactococcus phage. Y. C. Tseng* and C. L. Hicks, *University of Kentucky, Lexington.*

Simplified procedures were developed to determine lactococcal phage plaques on specially prepared Petrifilm. To test this system *Lactococcus lactis* ssp. *lactis* C2 and c2 phages were used as a test culture/phage system and all films were compared to top/bottom gels in Petri plates. Phage plaques were viewed after 6 to 8 h of incubation at 30°C. M17 medium containing 1.0% fast hydrating cold set gelling agent, 0.01% FD&C Blue #1 dye and 15 mM CaCO₃ was prepared and weighed into vials (2.8 ml in each vial). In another vial 0.1 ml of *Lactococcus lactis* culture was combined with the appropriate dilution of phage (0.1 ml).

The two vials were mixed together and glucono- δ -lactone was added (final conc. 30 mM). The mixture then was poured into the well of the Petrifilm. Two types of Petrifilm prepared by 3M Corporation were tested. The first film was prepared by securing a clear film flap onto a second film. A 45mm ID o-ring (3 mm thick) was laid on the first film, and the gelling mixture was poured into the center of the o-ring. The well of second Petrifilm was prepared by stacking two expanded styrene films (2 mm thick) onto a clear film. The expanded styrene contained a 50 mm hole that formed the well, thus the well was 4 mm deep. After the gelling mixture was poured into the well, the top plastic sheet was lowered to seal the well. The development of large defined plaques required the use of a gelling agent that would form a soft non-weeping gel adhered well to the plastic film similar to the qualities of top agar. Soft gels allowed phage movement within the gel and the development of large plaques. A head space of 0.5 mm above the gel surface was required to prevent the top film from resting on the gel. If the film rested on the gel and the phage diffused across the surface of the gel, the whole lawn on the gel would plaque out. The use of a dye enhanced the contrast between the bacterial lawn and the clear plaque. Plaque size and counts were comparable to those determined using a standard top/bottom M17 medium agars in a Petri dish system.

W77 Construction of an integrative vector for recombinant gene expression in *Streptococcus thermophilus*. J. A. Renye* and G. A. Somkuti, *USDA-ARS-ERRC*.

Streptococcus thermophilus (ST) is an essential starter culture in yogurt and cheese production. Its “generally recognized as safe” (GRAS) status makes this organism an attractive candidate for the expression of gene products to improve the safety and nutritional value of dairy foods. The antibiotic resistance marker genes traditionally used in plasmid vectors may be eliminated by inserting heterologous genes into the bacterial chromosome. This pINTRS integrative vector was constructed with a temperature sensitive origin of replication and an erythromycin resistance marker gene (Erm) for initial selection in *S. thermophilus*. The green fluorescent protein (GFP) gene was transcriptionally controlled by a plasmid borne hsp promoter and cloned into pINTRS. The GFP gene was flanked by sequences homologous to an inactive ST pseudogene to facilitate integration within the locus. The pINTRS-GFP vector in *E. coli* DH5 α showed strong GFP expression at 32°C. In *S. thermophilus* the plasmid was maintained at 32°C but a temperature shift to either 37°C or 42°C resulted in plasmid loss. Weak GFP fluorescence was observed microscopically in individual cells of cultures grown at both low and high temperatures. Plasmid from cells grown at 32°C was back-transformed into *E. coli* yielding strong fluorescing colonies, suggesting that limited GFP expression in *S. thermophilus* is caused by low gene copy number. PCR analysis showed the *hsp-gfp* construct in colonies grown at 32°C and 37°C, but cells grown at the high temperatures were negative for the Erm gene suggesting that proper integration had occurred. The vector is also useful in testing the biological activity of recombinant products when expressed from single copy of a gene on the chromosome.

Key Words: *Streptococcus thermophilus*, Integrative Vector, GFP

W78 Fresh style panela cheese as a vehicle for probiotics and resistant starch. M. C. Escobar-Ramirez*¹, S. L. Amaya-Llano¹, M. Singh², and M. J. Miller³, ¹*PROPAC, Universidad Autónoma de Querétaro, Querétaro, Qro, Mexico*, ²*National Center for Agricultural Utilization Research, Peoria, IL*, ³*University of Illinois, Urbana*.

The importance of probiotic-containing products for maintaining health and well-being is becoming a key factor affecting consumer choice. In particular, there is interest in developing new probiotic containing products. Panela cheese, a Mexican fresh cheese, is a staple food in Mexico yet it lacks any probiotic microorganisms. As a potential vehicle for probiotics, panela has several advantages over yogurt including: 1) higher pH; 2) higher fat content; and 3) solid matrix. In addition, Panela cheese may also be a vehicle for resistant starch (RS) addition due to the potential for RS to complement the texture of traditional Panela cheese. The aim of this investigation was to manufacture and evaluate a Mexican fresh cheese (Panela) made with probiotic bacteria and resistant starch (RS). *Lactobacillus* spp. and *Bifidobacteria* spp. from our culture collection were screened to identify strains that could ferment RS from faba beans (*Vicia Faba* L.). None of the twenty *Lactobacillus* spp. examined were able to ferment RS. Of the 8 *Bifidobacterium* spp. examined, only *B. breve* ATCC 15700 were able to ferment RS. *B. breve* ATCC 15700 and *L. rhamnosus* GG ATCC 53103 were selected for use as probiotics. Two types of fresh cheese (with and without 3% RS) were made. Four combinations of probiotics was added to each of these cheeses: 1) no added cultures; 2) *L. rhamnosus* GG only; 3) *B. breve* only; and 4) both *L. rhamnosus* and *B. breve*. Viability analysis during 4 weeks of storage at 4°C demonstrated that the addition of RS had minimal effect on the viability of either probiotic culture. Scanning electron microscopy revealed that Panela cheese with RS has a more closed structure than traditional panela cheese. The addition of RS produced a greater softness in penetration test for cheeses samples. Panela cheese is an effective vehicle for delivery of probiotic microorganisms.

Key Words: Panela, Resistant Starch, Probiotic

W79 α -Ketoglutarate biosynthesis in *Lactococcus lactis* strains isolated from specific natural niches. N. Gutiérrez-Méndez, E. Valenzuela-Soto, A. F. González-Córdova, and B. Vallejo-Cordoba*, *Centro de Investigación en Alimentación y Desarrollo, A.C. (CIAD, A.C.), Hermosillo, Sonora, México*.

There has been an increased interest in the exploration of new strains of *L. lactis*, particularly those isolated from artisanal raw milk dairy products or vegetables since wild strains may produce large amounts of flavor compounds in dairy products. These compounds produced by *L. lactis* mainly derive from the amino acid catabolism, where the limiting factor is the α -ketoglutarate (α -KG) required in the transamination step. There are two main pathways in α -KG biosynthesis. One is the citrate-isocitrate pathway which needs the action of two key enzymes, the aconitase (AS) and the isocitrate dehydrogenase (IDH). The second pathway requires the enzyme glutamate dehydrogenase (GDH). Thus, the objective of this work was to explore both pathways involved in the biosynthesis of α -KG in strains of *L. lactis* isolated from different natural niches previously characterized for their capacity to produce aroma. The enzymatic activities (IDH, AS and GDH) of eighteen strains of *Lactococcus lactis* isolated from raw-milk cheeses, vegetables and commercial dairy starter cultures (DSC) were studied. Strains did not

present isocitrate dehydrogenase (IDH) and aconitase (AS) activities. Thus, it was concluded that *L. lactis* strains were not able to biosynthesize α -KG by the citrate-isocitrate pathway. On the other hand, half of the strains confirmed glutamate dehydrogenase (GDH) activity. Thus, the ability of *L. lactis* to synthesize α -KG via GDH was confirmed. Additionally, NADP-GDH activity was mainly found in strains isolated from vegetables, whereas NAD-GDH activity was mainly found in strains isolated from dairy products. These enzymatic activities may be related to the flavor production capacity of the different strains.

Key Words: *L. lactis*, Flavor Production, α -Ketoglutarate Biosynthesis

W80 Characterization of *Streptococcus thermophilus* isolates from traditional Turkish yogurts. N. Altay^{*1,2}, G. C. Gurakan¹, and J. L. Steele³, ¹Middle East Technical University, Ankara, Turkey, ²Selcuk University, Konya, Turkey, ³University of Wisconsin, Madison.

The objective of this study was to phenotypically and genotypically characterize *S. thermophilus* isolates from traditionally produced Turkish yogurts. By plating on LM17 agar, sixty putative *S. thermophilus* isolates were obtained from ten yogurts. The species designations of the Turkish isolates and four commercial isolates were confirmed by 16S sequencing. Fifty-six out of sixty Turkish isolates and all 4 commercial isolates were identified as *S. thermophilus*. Technological properties of the isolates were screened in sterile reconstituted skim milk. To determine the rate and extent of acid production, acidification profiles were examined. The twenty-six isolates having acidification rates comparable to commercial isolates (Δ pH at 4h \geq 1.3) were also tested for their final pH after 24 h incubation, acetaldehyde production and proteolytic activity. The final pH after 24 h incubation at 42°C was within the range of 3.76-4.09, which was comparable to the commercial isolates. The acetaldehyde production by the Turkish isolates was also comparable to commercial isolates and measured between 3.96-7.02 μ g acetaldehyde/ml using an acetaldehyde determination kit. Proteolytic activities of the isolates were examined by an OPA-based colorimetric assay and Δ Abs at 340nm were between 0.042-0.065. For genotypic characterization, CRISPR 1 locus was amplified and both leader and trailer ends were sequenced. Sixteen distinct amplicons were identified based upon amplicon size within the Turkish isolates. Based upon the sequence of the leader and trailer ends of the CRISPR 1 locus, the Turkish isolates were divided into 10 and 9 groups according to the first three spacers, respectively. The results demonstrate that significant phenotypic and genotypic diversity is present within *S. thermophilus* isolates from traditional Turkish yogurts and that these isolates may have commercial potential.

Key Words: *S. thermophilus*, Technological Properties, CRISPR

W81 Influence of encapsulated probiotic bacteria on the characteristics of plain yogurt. E. Noland and K. Aryana^{*}, Louisiana State University, Baton Rouge.

Encapsulation is a method of providing probiotic living cells with a physical barrier against adverse environmental conditions. *Lactobacillus acidophilus* is one of the very effective forms of probiotic bacteria and

is commercially available as pure culture (non encapsulated) and in an encapsulated form. In an attempt to use yogurt as a vehicle to successfully deliver large number of viable cells of *L. acidophilus*, it is not clear whether the use of encapsulated *L. acidophilus* will result in yogurt of a better quality compared to *L. acidophilus* in pure (non-encapsulated) form. The objective was to determine whether encapsulated *Lactobacillus acidophilus* R0052 altered the physico-chemical, microbiological and sensory characteristics of plain yogurt. Yogurt mixes were pasteurized, cooled to 37°C and inoculated with *Streptococcus thermophilus*, *Lactobacillus delbrueckii* subsp. *bulgaricus* and encapsulated *L. acidophilus* R0052 or non encapsulated *L. acidophilus* R0052. Yogurt manufacture was replicated three times. Yogurts with encapsulated *L. acidophilus* R0052 had significantly ($p < 0.05$) higher flavor scores, significantly ($p < 0.05$) lower body and texture scores and significantly ($p < 0.05$) lower appearance scores compared to yogurts with non-encapsulated *L. acidophilus* R0052. Apparent viscosity, pH, syneresis, lactobacilli counts and L*, a* and b* values of the yogurts with encapsulated *L. acidophilus* R0052 were not significantly ($p < 0.05$) different from those of yogurts with non-encapsulated *L. acidophilus* R0052. Use of encapsulated *L. acidophilus* R0052 resulted in better tasting yogurts.

Key Words: Yogurt, Probiotic, Encapsulated

W82 Evaluation of buffering capacity of amino acid and milk protein ingredients in acidic conditions. V. Harrison^{*}, D Song, F. O. Uruakpa, C. W. Seo, and S. A. Ibrahim, North Carolina A&T State University, Greensboro.

The buffering capacity of amino acids and protein is an important physico-chemical characteristic that corresponds to the ability of the food products to be acidified or alkalinized. There is a considerable amount of data available concerning the buffering capacity (BC) of several substances, but very little pertaining to the BC of amino acids and milk protein ingredients. The objective of this study was to determine the BC of amino acids and various milk proteins ingredients in acidic conditions. Nineteen amino acids (asparagine, methionine, proline, cysteine, alanine, arginine, serine, glycine, valine, threonine, glutamic acid, isoleucine, tyrosine, leucine, phenylalanine, aspartic acid, tryptophan, and histidine) and seven different milk protein ingredients were tested for their ability to resist pH change when titrated with 0.1 M HCl. Testing solution was prepared by mixing 1.0 g of amino acid or milk protein ingredient powder in 100 ml deionized water. The pH of the solution was then adjusted to 7 using NaOH in solution. A standard solution of 0.1 M HCl was used to titrate the amino acid solution at 1.0 ml intervals using a bottle top burette until pH 2.0 was reached. The buffering capacity was calculated as the amount of acid required to reach pH 2.0 divided by the overall change in pH. Our results showed that protein ingredients such as hydrolyzed milk had high BC (>50). Glycine and aspartic acid had the highest BC values (33.3 and 34.5) while tyrosine had the lowest BC value of 5.0. It is evident that proteins and amino acids could be used in several food systems to maintain pH value. In addition, including such ingredients in food products with controlled buffering capacity would be desirable to maintain stable food characteristics.

Key Words: Buffering Capacity, Milk Proteins

W83 Use of beta-cyclodextrin to lower level of cholesterol in milk and its influence on activity of probiotic bacteria. L. Alonso^{1,2}, P. Cuesta^{*1}, J. Fontecha³, M. Juarez³, and S. E. Gilliland¹, ¹Oklahoma State University, Stillwater, ²Instituto de Productos Lacteos. CSIS, Asturias, Spain, ³Instituto del Frio. CSIC, Madrid, Spain.

While dairy products in general have the image of healthy foods, this image is often not perceived for products with a high fat content like butter, cream and certain type of cheeses. The World Health Organization, the American Heart Association and others have recommended that consumers reduce their consumption of saturated fatty acids and cholesterol as a deterrent to coronary heart disease. Thus there is a growing interest in the manufacture of cholesterol reduced dairy products. Currently, the most effective method for reducing cholesterol content in milk is by using beta-cyclodextrin (BCD). One objective of this study was to find the optimum conditions for cholesterol removal from raw milk at 4°C on an industrial scale by adding BCD in a specially designed bulk mixer tank for use in continuous recycling of the milk from a storage tank. Optimum conditions found for removing cholesterol was treating the milk with 0.6% BCD for 20 min followed by holding it 6 h. Profiles of triglycerides and fatty acids in control and treated milk did not show significant differences. Related experiments revealed the BCD does not adversely affect the growth of probiotic cultures of lactobacilli in a broth medium but did enhance their deconjugation of bile acid. Thus in addition to being able to remove cholesterol from milk the BCD may enhance control of serum cholesterol by consumption of a selected probiotic culture since bile salt deconjugation is one of the proposed mechanisms whereby the culture provides this benefit.

Key Words: Beta Cyclodextrin, Cholesterol, Lactobacilli

W84 Effect of prebiotics on probiotic growth curves and resulting pH changes in skim milk and a model system. D. Olson* and K. Aryana, Louisiana State University, Baton Rouge.

The effect of Raftiline[®] GR, Raftiline[®] HP-Gel, and Raftilose[®] P95 prebiotics on growth curves of the probiotics *Lactobacillus casei*-01 and *Lactobacillus acidophilus* LA-K and resulting pH changes in skim milk and a model system consisting of 0.1% peptone was investigated. Skim milk and 0.1% peptone each containing 1% Raftiline[®] GR, Raftiline[®] HP-Gel, or Raftilose[®] P95 prebiotics were autoclaved and then inoculated with 13.21 µL of either *Lactobacillus casei*-01 or *Lactobacillus acidophilus* LA-K per 100 mL of skim milk and 0.1% peptone. Controls containing the probiotics without the prebiotics and controls containing neither prebiotics nor probiotics were also prepared. Both the growth of each probiotic and the changes in pH were followed for 16 h at 37°C. The growth was determined by measuring the absorbance at 650 nm. The 0.1% peptone proved to be a more suitable medium than skim milk for preparing growth curves because of the high absorbance of the skim milk blanks. Absorbance readings for the 0.1% peptone controls containing neither prebiotics nor probiotics were very stable as they varied by less than 0.002 absorbance units in 16 h. The 0.1% peptone containing prebiotics had less change in absorbance over 16 h than their probiotic containing controls for *L. casei* but greater change than the corresponding controls for *L. acidophilus* suggesting that prebiotics stimulated growth of *L. acidophilus* but not *L. casei*. Skim milk was a better medium than 0.1% peptone for following pH changes due to greater buffering capacity of skim milk. The increase in the change in pH over 16 h for skim milk containing prebiotics compared with the

probiotic containing skim milk control was greater when using *L. acidophilus* instead of *L. casei* implying that prebiotics had a greater effect on *L. acidophilus* than on *L. casei*. Absorbance data obtained for 0.1% peptone and pH data obtained for skim milk implied that the prebiotics stimulated the growth of *L. acidophilus* more than *L. casei*.

Key Words: Prebiotics, Probiotic, Growth

W85 Evaluation of the effect of bovine colostrum on gene expression in *E. coli*. M. Worku*, Z. Liu, and S. Oh, North Carolina A&T State University, Greensboro.

Bovine colostrum-based immune milk products have proven efficacy in prophylaxis and treatment against various infectious diseases caused by pathogens such as *E. coli*. A proline-rich polypeptide (PRP) in colostrum has a regulatory effect on the immune response. The objective of this study was to determine the effect of commercial nutraceutical grade colostrum (high in PRP), on expression of *E. coli* K-12 heat shock protein genes using microarray analysis. Two *E. coli* K12 Starter V2 array chips, consisting of 2 identical grids, with a total of 192 spots (MWG Biotech, High Point) were used for expression profiling of *E. coli* and to conduct dye swap experiments. Data were acquired using Jaguar analysis software and preliminary analysis was conducted using the MicroArray Genome Imaging and Clustering Tool Version 1.0. Data were log transformed and the value for the negative control was subtracted. Expression ratios were used to evaluate the effect of colostrum treatment compared to a negative control on gene expression. The highest expressed genes on two slides have been selected for further characterization and validation. These genes are listed in the Kyoto Encyclopedia of Genes and Genomes, and include 1: Fused mannose-specific PTS enzymes: IIA component/IIB component[EC:2.7.1.69]; 2:50S ribosomal subunit protein L30 Signal Recognition Particle (SRP) component with 4.5S RNA (ffs); 3:F1 sector of membrane-bound ATP synthase, delta subunit[EC:3.6.3.14]; 4: conserved protein with nucleoside triphosphate hydrolase domain; 5: D-tagatose 1,6-bisphosphate aldolase 2, catalytic subunit [EC:4.1.2.40]; 6: NADH:ubiquinone oxidoreductase, membrane subunit L [EC:1.6.5.3]; 7:UDP-N-acetylmuramate:L-alanyl-gamma-D-glutamyl-meso-diaminopimelate ligase [EC:6.3.2.-]. Further validation and characterization of the effect of colostrum components on these genes may provide keys to understanding *E. coli* pathogenesis and control.

Key Words: Colostrum, *E. coli*, Gene Expression

W86 Binding characterization between lactic acid bacteria and milk fat globule membrane in different dairy products. G. Brisson* and R. Jimenez-Flores, California Polytechnic State University, San Luis Obispo.

We have developed a combination of methods to characterize the binding between four different strains of lactic acid bacteria (LAB) and four products with high content of milk fat globule membrane (MFGM). This binding is important because probiotic bacteria are mostly consumed in dairy products and because there is genomic evidence that the interactions between these bacteria and milk fat globules are essential for turning on some genes involved with preservation and delivery of benefit to humans. However, more objective methods are necessary for evaluation of processes and strains that can better describe the relation-

ship between genomics and function in our dairy products. The method we have developed allowed assessing different LAB phenotypes and their interaction with MFGM-containing dairy products by means of a sugar gradient ultracentrifugation (SGU) fractionation step, fluorescent microscopy observations, and protein profiles. The dairy products we tested include: raw and pasteurized creams, buttermilk, and buttermilk powder. The DPTC culture strains (NCFM *L. acidophilus*; 33199 *L. gallinarum*; 1063-S *L. reuteri* and 53103 *L. rhamnosus*) were grown in normal MRS media. Harvested cells were washed 3 times with PBS, then left to contact the dairy product for 5 minutes prior to loading them on top of the ultracentrifuge tube with the sugar gradient. The sugar gradient was optimized between 25 and 50% sugar (w/v), and the ultracentrifugation conditions were 54,000g for 4 hrs at 4 °C. Different fractions were taken for microscopic observations. Also, characterization of the LAB surface proteins was achieved after using a 5M LiCl treatment and the extracts were analyzed by SDS-PAGE. The results of these analysis and the combination of microscopic observations and SDS-PAGE analysis indicate that genes regulating S-layer protein components in the surface of the LAB are the major determinant in binding frequency with the MFGM related dairy product.

Key Words: Lactic Acid Bacteria, MFGM, Binding

W87 Biophysical analysis of the milk fat globule membrane.

C. Cabral, T. Nelson, D. Rios, D. Gragson, and R. Jimenez-Flores*, *California Polytechnic State University, San Luis Obispo.*

We have used several modern surface characterization techniques to elucidate physicochemical properties of monolayer films derived from the components of the milk fat globule membrane (MFGM). Our work to date has focused on comparing the physicochemical behavior of the whole lipid fraction (polar and non-polar) with the non-polar lipid fraction of the MFGM extracted from commercial bovine buttermilk powder. We have gained information about film stability and elasticity using a Langmuir-Blodgett film balance, about film morphology on widely varying length scales using fluorescence microscopy and atomic force microscopy (AFM), and most recently about the formation and stability of bilayers with a quartz crystal microbalance (QCM). Additionally we have obtained mass spectral data of the polar lipid fraction detailing composition at the level of fatty acid chain length and saturation. Our results indicate that lipid domains form under appropriate temperatures and film pressures in monolayer films composed of MFGM lipid components analogous to lipid rafts in cell membranes. Further, we find that sphingomyelin and phosphatidylcholine both play a crucial role in forming these lipid domains. Our analysis give us great insight into the spatial distribution of lipids in MFGM monolayers and thus provide insight into the role each component plays in the native MFGM.

Key Words: MFGM, Phospholipids, Sphingomyelin

W88 Methods for screening ropy milk producers in raw milk samples. A. Cano, A. Laubscher*, and R. Jimenez-Flores, *California Polytechnic State University, San Luis Obispo.*

A recent concern about the presence of bacteria that can cause “ropy” milk has caused the examination of old testing methods to detect milk that can develop “ropyness”. Ropy milk is characterized by its viscosity

and its tendency to adhere to surfaces and form a slimy thread when the surfaces to which it is attached are pulled apart. The viscous character of the milk is produced by a complex oligosaccharide normally present in the form of a capsule around the bacteria. The objectives of this study were to survey the commercial supply of milk presenting the ropy milk defect with various traditional and molecular microbiological methods, and to give information on which microorganism or population of microorganisms are responsible for this defect. Over 200 raw milk samples were received from plants throughout the southern states. Samples are plated on TPC agar and incubated at 25°C for 36 hours to identify 5 types and obtain isolates. Isolated strains are tested for RM production by inoculation in sterile and UHT milk, which was then incubated at 25°C for 36 hours. The API method was used for bacterial identification of isolated strains which is based on a series of tests for sugar utilization that discern the genus and species. The “ropy test” proved to be successful with ropy isolates producing 100% reproducibility ropy milk and non-ropy isolates producing 100% non-ropy milk. We have established a database that classifies the isolated bacteria from milk on the basis of their gram stain, morphology, and exopolysaccharide capsule. Identification based on detailed biochemical analysis has indicated that the strains isolated belong to the coliform group of bacteria, with genus *Klebsiella* (*Klebsiella pneumoniae* and *Klebsiella oxitoca*).

Key Words: Milk Quality

W89 Effect of pH and reconstitution methods on heat stability of milk protein concentrate. V. Sikand*, B. L. Golden, and P. S. Tong, *Dairy Products Technology Center, San Luis Obispo, CA.*

The objective of the research was to determine the effect of pH and reconstitution methods on heat stability (HS) of 80% milk protein concentrate (MPC80). In the first series of experiments, we determined the effects of solvent type (water or permeate) used to reconstitute MPC80 on HS. MPC80 was reconstituted (RC) to 3.5% protein content with either water or permeate powder (PP) from skim milk ultrafiltration. To study the impact of homogenization, a second series of experiments were conducted in a pilot plant as previously described and subjected to homogenization treatments at 2000 and 500 psi in the first and second stages, respectively. The pH of the RC MPC80 in either series of experiments was adjusted to a pH varying from 6.6 to 7.0 and samples were tested for HS. Each experimental unit was replicated three times. The HS, defined as the heat-coagulation time (HCT), was measured as the time required for visible coagulation of the sample immersed in a 140°C oil bath. In the first experiments, HCT for MPC80 RC with water showed a steady increase from pH 6.6 to 7.0. HCT for MPC80 RC with permeate did not change significantly from pH 6.6 to 7.0. The least squares mean of HCT for MPC80 RC containing 3.5% protein with water was 7.96(± 0.64) minutes and with permeate was 5.06(± 0.78) minutes. In the second experiment, HCT for MPC80 RC with water showed a steady increase from pH 6.6 to 7.0. MPC80 RC with permeate first increased with increase in pH from 6.6 to 6.8 and then decreased with increase in pH of 6.9 - 7.0. MPC80 homogenized with permeate showed a significant increase in HS ($p < .001$). The least squares mean of HCT for homogenized MPC80 containing 3.5% protein RC with water was 7.48 (± 0.55) minutes and with permeate was 13.82(± 0.64) minutes. It was observed that permeate RC homogenized MPC samples are very similar to HCT- pH curves of skim milk sample. We suggest that the milk permeate can be exploited to improve HS (compared to water) of beverages containing MPC80 between natural pH of 6.7–6.8 when milk

components can be dispersed effectively (i.e. use of homogenization).

Key Words: MPC, Permeate, pH

W90 The concentration of lactoferrin in the bovine colostrum and immune milk. J. B. Cheng¹, J. Q. Wang*¹, D. P. Bu¹, G. L. Liu¹, C. G. Zhang^{1,2}, X. L. Dong^{1,2}, H. Y. Wei¹, L. Y. Zhou¹, and K. L. Liu¹, ¹*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*, ²*College of Animal Science and Technology of Yangzhou University, Yangzhou, China*.

Lactoferrin (LF) is a key element in the host innate defense system, and the level of protection mainly depends on the concentration of LF in milk. In this study, changes of LF level in the immune milk were monitored and compared with that of colostrums. The colostrum from thirty-six Holstein cows was collected in this study. The concentration of LF in the milk was detected by Sandwich enzyme-linked immuno-

sorbent assay (ELISA). The relative concentration of them in colostrum was analyzed by Dodecyl sodium sulfate-gel electrophoresis of proteins (SDS-PAGE). The immune milk used in this study was made by implanted Antigen Release Devise. The data was analyzed with FIXED MODEL by SAS 9.0. It was indicated that the concentration of LF in colostrum had a dramatic change, especially in the first 24 hours after parturition, from 1.315 ± 1.086 mg/mL to 0.655 ± 0.377 mg/mL ($P < 0.05$), then another sharply decrease occurred on day 4, with the level of 0.264 ± 0.098 mg/mL, which had no difference to the LF concentration in the normal milk (0.209 ± 0.071 mg/mL, $P > 0.05$). SDS-PAGE results resembled the aforementioned trends. In addition, implanted Antigen Release Devise could increase the concentration of LF in the milk. On day 7 after implantation, the concentration of LF in the milk (0.313 ± 0.133 mg/mL) could be equal to the level of colostrum on day 3. This result might indicate that the concentration of LF in the colostrum and milk is influenced by parturition and immune stress, indicating LT might be an important part of bovine protection system.

Forages and Pastures II

W91 The influence of wilting on the quality of *Acacia mangium* silage. T. Clavero* and R. Razz, *Centro de Transferencia de Tecnología en Pastos y Forrajes. Universidad del Zulia, Maracaibo, Zulia, Venezuela.*

An experiment was conducted in the dryland farming area of northwest Venezuela to evaluate the ensiling properties of *Acacia mangium* using microsilage techniques. Factors studied were wilting for 0 and 3 h and ensiling time of 0, 5, 8 and 16 days. A 1:2 (w:v) ratio of legume:molasses was mixed and stored at 25°C. Data were analyzed as a randomized design with a 2X4 factorial of wilting time and ensiling time, respectively. Means were compared by Tukey test. Response variables were: dry matter (DM), cellulose (C), pH, total nitrogen (TN), ammonia (NH₃) and NH₃/TN. Increasing ensiling time of high moisture *Acacia* resulted in losses of DM and C in the silage. Ensiling *Acacia mangium* from 0 to 16 d resulted in decreased ($P \leq 0.05$) DM and C content of 12 and 10%, respectively for high moisture silage in contrast to 8.5 and 6% for wilted. This could have been due to the cumulative activity of plant cell respiration, enzymes cellulose and some facultative bacteria in the fresh ensiled forage. The pH increased ($P \leq 0.05$) while CP, NH₃ and NH₃/TN decreased ($P \leq 0.05$) with reduced moisture content of ensiled *Acacia*. The concentrations of fermentation end-product decreased with wilting, showing that low moisture restricted fermentation. Therefore, pH increased in wilted silage. The reduction in CP content in wilted silage was expected due to breakdown of true protein during sun-drying and ensiling process. Wilting resulted in a decrease ($P \leq 0.05$) in NH₃ and NH₃/TN when compared to high moisture silage. The concentrations of NH₃ and NH₃/TN in high moisture silage were 38 and 25.9% greater, respectively, than wilted silage. However, the levels of NH₃ were still within acceptable limits, with values less than 80-100 g/kg TN which is commonly used to represent well fermented silage. Although fermentation patterns were different ($P \leq 0.05$), all silages in the current experiment achieved satisfactory preservation.

Key Words: *Acacia mangium*, Silage, Wilting

W92 Mulberry (*Morus alba*) fodder response to increasing levels of organic nitrogen. J. A. Elizondo-Salazar* and C. Boschini-Figueroa, *Estación Experimental Alfredo Volio Mata. Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, Costa Rica.*

In some areas of Costa Rica and many other countries, the available grazing is sometimes not sufficient to meet the nutrient requirements of animals, at least for part of the year. Thus, the use of fodder from trees and shrubs is widely utilized as dietary supplements for ruminants. However, high fodder yields and adequate CP levels require application of large doses of chemical N, increasing production costs and pollution risk. In order to reduce cost, producers utilized organic fertilizers without knowledge of the right amounts to use in order to obtain high yields. For this reason, a study was conducted to evaluate the application of increasing levels of N from organic fertilizer consisting of green waste composted material. A 12-yr-old mulberry plantation planted at spacings 0.9 × 0.40 m (27,777 plants/ha) was utilized in a randomized block design with 4 treatments: 150, 300, and 450 kg of N/ha/yr, and a control (no fertilizer). All plots were uniformly pruned at 0.6 m from the ground at the beginning of the trial. Organic fertilizer was applied in 2

doses during the rainy season. For a 365-d period, plants were pruned consecutively every 90 d. Leaves and stems were separated and analyzed for DM and CP content. On average, 475 kg of N/ha/yr were removed. There was no significant difference in dry matter yield; suggesting that the amount of N mineralized from the organic fertilizer was low during the duration of the study. However, CP content was greater for the higher N applications, indicating that greater N quantities were available for uptake. In order to replenish the N being removed, at least 450 kg of N/ha/yr should be applied.

Table 1.

Variable	Treatment kg N/ha/yr				SEM	P
	0	150	300	450		
Dry matter, %						
Leaves	22.28	22.16	21.12	21.51	0.44	NS
Stalk	23.47	23.80	22.70	23.03	0.43	NS
Total	22.67 ^a	22.63 ^a	21.63 ^b	21.60 ^b	0.33	0.09
Dry matter, kg/ha/yr

W93 Effects of one-seed juniper on intake, rumen fermentation, and plasma amino acids in sheep and goats fed supplemental protein.

S. A. Utsumi¹, A. F. Cibils¹, R. E. Estell², S. Soto-Navarro¹, and D. M. Hallford¹, ¹New Mexico State University, Las Cruces, ²USDA/ARS Jornada Experimental Range, Las Cruces, NM.

We tested the effect of feeding one-seed juniper (*Juniperus monosperma*) on total intake, VFA profile, and plasma AA of 12 does and 12 ewes fed sudangrass (*Sorghum vulgare*) and a basal diet with no protein supplement (Control; 5% CP) or rumen degradable (SBM; RDP 15% CP) or undegradable (FM; RUP 15% CP) protein supplements. After 15 d of adaptation to sudangrass and basal diets (period 1), animals were individually fed one-seed juniper leaves in addition to the sudangrass and basal diets during a second 15-d period (period 2). Each food was fed separately during 3-h periods at 110% of previous day intake. Blood and ruminal fluid samples were collected on the last 2 d of each period to determine plasma AA, VFA, and rumen pH. Analyses followed a split-plot design with periods with or without juniper as a sub-plot factor. Juniper intake did not vary between species ($P = 0.54$) or supplement treatments ($P = 0.93$; 4.7 g/kg^{0.75}). Total intake (TI), basal diet intake (BDI), and sudangrass intake (SGI) were not affected by supplements ($P > 0.05$), were higher for sheep than goats ($P < 0.01$), and decreased with juniper feeding in period 2 ($P < 0.01$). Total intake, BDI, and SGI for periods 1 and 2 were 54.9 vs. 47.6, 36.7 vs. 31.5, and 18.2 vs. 11.5 g/kg^{0.75}, respectively. Total VFA, acetate (Ac), and propionate (Pr) increased with juniper in period 2 ($P < 0.01$; period 1 vs. 2, VFA:

63.9 vs. 79.4; Ac: 47.5 vs. 60.5; Pr: 9.3 vs. 11.7 mM). Rumen pH averaged 6.4 and did not differ between supplements, species, or periods. Total AA and some individual AA differed between supplements (RUP \ge RDP>Control), species (goats>sheep), and decreased with the feeding of juniper in period 2 ($P < 0.05$). Juniper intake in period 2 was associated with decreases in plasma ALA, GLY, THR, SER, ASP, MET, GLU, PHE, CYST, TYR, and TRP. These data suggest one-seed juniper in sheep and goat diets depresses intake, but may increase VFA and requirements for certain amino acids.

Key Words: Essential Oils, *Juniperus monosperma*, Protein Supplementation

W94 Effects of one-seed juniper and polyethylene glycol on intake, rumen fermentation, and plasma amino acids in sheep and goats fed supplemental protein and tannins. S. A. Utsumi¹, A. F. Cibils¹, R. E. Estell², S. Soto-Navarro¹, and D. M. Hallford¹, ¹New Mexico State University, Las Cruces, ²USDA/ARS Jornada Experimental Range, Las Cruces, NM.

We tested the effect of polyethylene glycol (PEG) on juniper (*Juniperus monosperma*) and total intake, rumen fermentation, and plasma AA of 12 does and 12 ewes fed sudangrass (*Sorghum vulgare*) and basal diets containing 10% quebracho (*Aspidosperma quebracho*) tannins with no protein supplement (Control; 5% CP) or high rumen degradable (RDP 15% CP) or undegradable (RUP 15% CP) protein supplement. After 15 days of exposure to non-restrictive amounts of juniper leaves, sudangrass, and basal diets (period 1), animals received an additional 50 g of PEG for a second 15-d period (period 2). Blood and ruminal fluid samples were collected on the last 2 d of each period to determine AA and VFA. Analyses followed a split-plot design with periods with or without PEG treated as sub-plot factor. Juniper intake did not differ between species ($P > 0.05$) or supplements ($P > 0.05$), but increased with addition of PEG in period 2 (Period 1 vs. 2: 4.3 vs. 10.8 g/kg^{0.75}; $P < 0.01$). Total intake and intake of sudangrass and basal diets were higher for sheep than goats ($P < 0.01$) and differed between supplements and periods (supplement x period, $P < 0.05$). Polyethylene glycol stimulated higher intakes of basal diet for Control and RDP, and of sudangrass for RUP. Total VFA was higher for sheep than goats ($P < 0.05$) and decreased from period 1 to period 2 with supplemental PEG in sheep (70.6 vs. 62.1 mM; species x period, $P < 0.05$) and with RDP (67.3 vs. 58.6 mM; supplement x period, $P < 0.05$). Acetate and propionate differed between periods with or without PEG in the same manner as total VFA. Total AA and some individual AA differed between species (sheep > goats), supplements (RUP \ge RDP > Control), and periods ($P < 0.05$). Increased juniper intake with PEG in period 2 was associated with lower plasma GLY, THR, SER, ASP, MET, GLU, PHE, CYST, GLN, ORN, LYS, HIS, and TRP. Polyethylene glycol increased juniper intake and decreased several plasma AA when tannin-rich foods with varying CP were fed.

Key Words: Essential Oils, *Juniperus monosperma*, Condensed Tannins

W95 Effect of essential oils on in vitro NDF digestion. M. D. Tassoul*, J. P. Goeser, R. D. Shaver, and D. K. Combs, *University of Wisconsin, Madison*.

Our objective was to determine the effect of essential oils on in vitro NDF digestibility (ivNDFD). Corn (35.6% NDF) and alfalfa (41.8% NDF) silage samples were dried, ground (1 mm), and treated in one of two ways; left unsupplemented (Control, C) or mixed with an essential oil blend (CRINA[®], EO) at a rate similar to supplementing EO at 1.2 g/cow/d and weighed (0.5 g) into Ankom F57 forage fiber bags. Samples were digested with Goering and Van Soest in vitro media in duplicate using a modified ivNDFD assay for 0, 7, 10, 14, 21, 24, 30, 36, 46, 54, 72, or 96 h. Rumen fluid was collected and pooled from two cannulated donor cows. Strained rumen fluid was mixed with buffer, reducing solution and primed with a mixture of carbohydrates and nitrogen, and allowed to produce 0.3 ml gas/ml of rumen fluid inoculum prior to inoculating feed samples. In vitro NDF digestibility was calculated as: ivNDFD (% of NDF) = 100 X [(NDF_{0h} - NDF_{residue})/(NDF_{0h})]. Results were analyzed with SAS Proc Mixed. The model included fixed effects of: feed, EO, time, and two way interactions between each. Means were compared with the lsmeans statement. Corn silage NDF was more digestible than alfalfa silage NDF (32.1 vs. 31.1% ivNDFD, $P = 0.04$). There was a tendency for a feed by EO interaction ($P = 0.08$), Corn silage mean ivNDFD was greater with EO compared to C (32.9 vs. 31.3%, $P < 0.05$), while alfalfa silage did not differ. A significant time effect and a time by feed interaction were both observed ($P < 0.05$). There was a trend for an EO by time interaction ($P = 0.13$). Mean 24 h ivNDFD was greater for EO than C (24.51 vs. 20.57%, $P < 0.05$). The increased ivNDFD for both feeds at 24 h with EO, and improved corn silage ivNDFD with EO observed in this research agrees with previous in vitro experiments, but the feed by EO interaction merits further study.

Key Words: Essential Oils, In Vitro, NDF

W96 Nutritive evaluation of three browse tree foliages during rain and dry seasons: Total tannins and in situ digestibility in cattle and goats. R. Rojo*¹, D. López¹, F. Vázquez¹, O. Vázquez¹, B. Albarrán¹, S. Rebollar¹, J. Hernández¹, D. Cardoso¹, F. González¹, E. Dorantes¹, F. Avilés¹, A. García¹, and C. Narciso², ¹Universidad Autónoma del Estado de México, Temascaltepec, Estado de México, México, ²Colegio de Postgraduados, Córdoba, Veracruz, México.

Foliages from three browse spp. (*Lysiloma acapulcensis*, *Quercus laeta* and *Pithecellobium dulce*), native to the southern subtropical region of the state of México, México, was harvested during the rain (2006) and dry (2007) seasons to evaluate chemical composition (CP, NDF, ADF), total tannin (TT) and *in situ* digestibility of DM (DMD), fiber fractions (NDFD, ADFD), and crude protein (CPD), using three different ruminal inoculums (bovine, BOV; goat unadapted, GUA; goat adapted, GA). Animals were equipped with ruminal cannula and received forage:concentrate (80:20) diets; where forage for BOV and GUA was a mixture of: alfalfa hay (30%), corn silage (30%) and corn straw (20%), for GA the forage was alfalfa hay (24%) and browse species (56%). Browse foliages, season, and ruminal inoculums were arranged in a 3 X 2 X 3 factorial design. The incubations period was

48 h. Crude protein and fiber fractions were affected ($P < 0.01$) by species and season. Total tannin content varied among species ($P < 0.01$) (*L. acapulcensis* rain: 187.77^a vs dry: 160.24^a; *Q. laeta* rain: 89.9^{bc} vs dry: 108.99^b; *P. dulce* rain: 62.55^c vs dry: 94.11^{bc} g kg⁻¹ DM). Inoculum and season affected ($P < 0.01$) DMD, NDFD, and CPD. During the dry season, DMD was highest for *P. dulce* ($P < 0.01$) and lowest for *L. acapulcensis* ($P < 0.01$). In the dry season, DMD was higher for goats than cattle (rainy: BOV: 54.43^c, GUA: 54.78^c, GA: 51.46^d vs dry: BOV: 59.69^b, GUA: 66.89^a, GA: 65.28^a). NDFD was higher for goats in the dry season ($P > 0.01$) and was higher for *P. dulce* (rain: BOV: 30.86^{bc}, GUA: 33.24^{ab}, GA: 27.38^c vs dry: BOV: 21.47^d, GUA: 36.62^a, GA: 33.62^a). A similar effect was observed for CPD ($P < 0.01$). Goats had more capacity to use browse species with tannins. *P. dulce* could be a forage species with potential of use as protein source in small ruminants.

Key Words: Browse Species, Tannin, Digestibility

W97 Effect of fodder tree species, season, and inoculum source on in vitro gas production from foliage. L. M. Camacho^{*1}, R. Rojo¹, G. D. Mendoza², F. Avilés¹, D. López¹, D. Cardoso¹, S. Rebollar¹, and N. Pescador¹, ¹Universidad Autónoma del Estado de México, Temascaltepec, Estado de México, México, ²Universidad Autónoma Metropolitana, Distrito Federal, México.

The *in vitro* gas production of *Lisyloma acapulcensis*, *Quercus laeta* and *Pithecellobium dulce* harvested during the rainy and dry seasons was measured, using three different ruminal inoculums bovine (BOV), unadapted goat (UAG), and adapted goat (AG). Animals were fitted with ruminal cannulae and received forage:concentrate (80:20) ratio diets, where forage for BOV and UAG was a mixture of alfalfa hay (40%), corn silage (40%) and corn stover (20%), and for AG the forage was alfalfa hay (24%) and browse species (56%). Browse foliage, season, and ruminal inoculums were arranged in a 3 X 2 X 3 factorial design. Chemical composition (CP, NDF) and total condensed tannin (TCT) were determined. The gas volume was recorded at 0, 2, 4, 6, 8, 12, 16, 20, 24, 48, 72 and 96 h and the data fitted to the model $P = a + b(1 - e^{-ct})$. *P. dulce* had the highest ($P < 0.05$) CP content (186 and 167 g kg⁻¹ DM) in rainy and dry season, respectively. *L. acapulcensis* had the highest NDF (554 and 559 g kg⁻¹ DM) in the rainy and dry season, respectively. The highest levels ($P < 0.05$) of TCT were detected in *L. acapulcensis*, (188 and 160 g kg⁻¹ DM), while the lowest were observed in *P. dulce* (63 and 94 g kg⁻¹ DM) in rainy and dry season, respectively. Cumulative gas release at 96 h was 181–183 mL g⁻¹ DM for *P. dulce* in dry season with inoculum from goats while *L. acapulcensis* produced 30–39 mL g⁻¹ DM with inoculum from BOV in both seasons. The highest gas volume from the b pool was found with *P. dulce* ($P < 0.05$; 182 and 179 mL g⁻¹ DM) in rainy season with inoculum of AG and UAG, respectively. The least quantity from this fraction was produced in both seasons (46 and 43 mL g⁻¹ DM) from *L. acapulcensis* with inoculum from BOV. The highest constant rate of gas production (c) was observed with *P. dulce* (5% h⁻¹) from the dry season using UAG and AG inoculum. The lowest constant rate (1% h⁻¹) was observed with *Q. laeta* from the rainy season with BOV inoculum. *P. dulce* showed highest nutritional value and could be used for grazing goats in semi-arid regions.

Key Words: *In Vitro* Gas Production, Browse Species, Inoculums

W98 Ozone and nitrogen deposition effects on nutritive quality of a species-rich subalpine grassland. M. K. Cline^{*1}, J. C. Lin¹, K. Nadarajah¹, M. Volk², R. B. Muntifering¹, S. Bassin², and J. Fuhrer², ¹Auburn University, Auburn, AL, ²Swiss Federal Research Station for Agroecology and Agriculture, Zurich, Switzerland.

Rising global levels of tropospheric ozone (O₃) and excessive rates of atmospheric N deposition represent major threats to productivity and sustainability of grasslands across the Northern Hemisphere. Effects of exposure to each of these on productivity and nutritive quality of intensively managed forages have been reported, but little is known about their combined effects or impacts on extensively managed grasslands. For these reasons, we conducted an experiment to determine effects of co-exposure to a range of current and projected levels of these air pollutants on productivity and nutritive quality of an extensively managed, species-rich (primarily *Festuca*, *Nardus* and *Carex*, numerous forb and few legume spp.) pasture located at Alp Flix, Switzerland. One hundred eighty plots (40 × 30 cm) representative of vegetation at the site were exposed during the April–October growing seasons in 2004–2006 to one of three levels of O₃ (1.0, 1.2 or 1.6 × ambient) in a free-air fumigation system that comprised 9 exposure rings (3 rings/O₃ level). Within each ring, 20 plots received biweekly applications of NH₄NO₃ solution that simulated five areal concentrations of atmospheric N deposition equivalent to 0, 5, 10, 25 or 50 kg/ha (4 plots/N concentration). Plots were harvested once each year in August by cutting forage at 2 cm above ground surface. Differences ($P < 0.0001$) were observed among years in forage concentrations of N, NDF, ADF and ADL, and in relative nutritive quality calculated from forage concentrations of NDF and ADF. Across all three growing seasons and levels of N input, there was no systematic effect of O₃ exposure level on grassland nutritive quality. However, there was an O₃ × N interaction ($P = 0.09$) such that positive responses in forage quality to N inputs of 25 and 50 kg/ha were abated by increased deposition and lignification of cell-wall constituents associated with accelerated foliar senescence in the elevated-O₃ treatments. Results indicate that excessive rates of N deposition may increase plant sensitivity to elevated O₃, presumably from increased stomatal uptake, and further compound the phytotoxic effects of O₃ on forage quality.

Key Words: Ozone, Nitrogen, Forage Quality

W99 Forage quality of native pasture in an alpine area for the production of Bitto cheese. S. Colombini^{*1}, A. Tamburini, A. Sandrucci, and L. Rapetti, University of Milan, Milan, Italy.

Bitto is an Italian traditional cheese produced in Valtellina by grazing cows on alpine pasture with a maximum inclusion of 3 kg concentrate/day. The objective of this research was to characterize the nutrient composition and the feed value of native alpine pasture during rotational grazing. Grass samples were collected in two experimental study areas located in Valtellina (1500 m o.s.l.) in 2006. Triplicate samples were collected every 15 days during the grazing season (June–September) and chemically analyzed. NRC 2001 equations were used to predict the nutritive value of grass. NDF digestibility at 48 h was determined by Ankom Daisy Incubator II. Results were used to predict energy and protein metabolism of the cows with CPM-Dairy model and NRC Dairy

Cattle Program. Data were analyzed by GLM procedures of SAS, with 2 pasture levels and 8 sampling data.

DM content increased in both experimental sites during the grazing season (from 43.6 to 58.0% in site 1 - $P < 0.05$, and from 34.9 to 43.9% in site 2 - $P < 0.05$). Average NDF contents (67.6 and 62.9% on DM in site 1 and 2, respectively) were higher than those reported for north Italy alpine pastures. The energy value (Mcal NE_l/kg DM) was generally low and decreased from 1.11 to 0.78 in site 1 ($P < 0.01$) and from 1.41 to 0.94 in site 2 ($P < 0.10$). CP content decreased during the grazing season from 12.9 to 9.2% ($P < 0.05$) and it was negatively correlated with the date of sampling ($y = -0.0484 + 1895.3; r^2 = 0.86$). At the beginning of the season, in the diet there was low energy/nitrogen ratio due to herbage characteristics. Simulation of energy and protein requirements showed a negative balance for ME during the entire grazing season even with the daily integration of 1 kg soybean meal and 2 kg corn meal. Metabolizable protein balance was positive. The results showed an average low energy value of pasture, with significant differences between the two sites due to different botanical composition. The energy value decreased from June to September suggesting the importance of providing, during the grazing season, a proper supplementation in order to meet the energy and protein requirements of the cows.

Key Words: Alpine Pasture, Energy Value

W100 Mineral profiles of selected grass and legume species as affected by liquid hog manure and inorganic fertilizer. G. N. Gozho¹, M. Undi², J. Sletmoen², F. Stewart³, J. C. Plaizier², and K. M. Wittenberg², ¹University of Saskatchewan, Saskatoon, Saskatchewan, Canada, ²University of Manitoba, Winnipeg, Manitoba, Canada, ³Manitoba Agriculture, Food and Rural Initiatives, Beausejour, Manitoba, Canada.

Mineral profiles of selected grass and legume forages grown on land receiving either liquid hog manure or inorganic urea fertilizer were determined. Two sources of N, liquid hog manure or urea, were used, with application rates of 112, 224 and 336 kg available N ha⁻¹. Urea-treated plots received 5.5 kg P₂O₅ ha⁻¹ and 5.5 kg K₂O ha⁻¹ each year. Manure ammonia-N was measured using a Nova meter (Agros Nova Nitrogen Meter, Kalby, Sweden) before application. Liquid hog manure in western Canada generally contains, DM basis, 74 to 146 g kg⁻¹ N, 19 to 49 g kg⁻¹ P and 99 to 117 g kg⁻¹ K. A control that received no liquid hog manure or inorganic fertilizer was included. Three legume forages namely, alfalfa (*Medicago sativa* L.), red clover (*Trifolium pratense* L.), and birdsfoot trefoil (*Lotus corniculatus* L.) and three grass forages, tall fescue (*Festuca arundinacea* Schreb.), reed canarygrass (*Phalaris arundinacea* L.), and quackgrass (*Elytrigia repens* [L.] Nevski) were evaluated. The two replicates were harvested on June 12 and 18 (cut 1) and on September 4 and 6, 2001 (cut 2). Urea application reduced ($P < 0.05$) the ash content of grass forages at first cut but not second cut relative to unfertilized and liquid hog manure treatments. Grasses harvested from the highest urea treatment had the highest Ca content, whereas those receiving the highest liquid hog manure application had the lowest Ca content, with other treatments being intermediate. A similar profile emerged for plant Mg response to fertility. Fertility reduced ($P < 0.05$) Ca content of legume forages but had no effect ($P > 0.05$) on P, Mg or S concentrations. Liquid hog manure application resulted in elevated ($P < 0.05$) K levels compared to urea treatment in all forages. The tetany ratio, K:(Ca + Mg), used to predict incidence of tetany in cattle, was highest in grass and legume forages for the highest liquid hog manure.

Results of this study demonstrate that forage mineral profiles can be impacted differently when liquid hog manure is applied as opposed to conventional inorganic fertilizer sources.

Key Words: Liquid Hog Manure, Grass, Minerals

W101 Split application of nitrogen on perennial grasses compared to manure applications. D. J. R. Cherney*, J. H. Cherney, Q. Ketterings, and M. Davis, Cornell University, Ithaca, NY.

Timing of N applications and the form of the nutrients applied can impact forage yield and quality. Split application of nitrogen fertilizer on four field replications (3 × 6.1 m) of orchardgrass, tall fescue and reed canarygrass was compared with dairy manure applications. Nitrogen fertilizer was applied at 90.8 kg N/acre at spring greenup, or 45.4 kg N fertilizer/acre at spring greenup followed by 45.4 kg N fertilizer after first cut, or 45.4 kg N fertilizer/acre at spring greenup followed by 22.7 kg N/acre after first cut and 22.7 kg N/acre after second cut. Commercial N treatments were compared to two applications of 44.8 metric tons/ha of semi-solid dairy manure applied at spring greenup and after first harvest. A combination treatment of 89.6 metric tons/ha of manure split applied and 68 kg N fertilizer/ha split applied at spring greenup and after first and second cuts was also used. Plots were harvested with a forage harvester (Carter Mfg. Co., Brookston, IN). There was about a 5% yield increase due to a split N application and about an 8% yield increase using a three-way split application. Nitrogen fertilizer recovery decreased ($P < 0.05$) with split application of N from 60% to 53%. The proportion of the total yield in the first two cuts decreased ($P < 0.05$) from 80% to 71% with split N application. Manure application resulted in 20% lower yield ($P < 0.05$) than commercial N application, while a combination of manure and N fertilizer increased yields 10% ($P < 0.05$) over commercial N application alone. Grasses reacted similarly to treatments for yield and N recovery; yield of tall fescue was distributed more uniformly over the three cuts compared to the other species. Reed canarygrass was consistently 30-40 g/kg higher in CP and averaged 50 g/kg lower NDF than the other species over all three harvests. NDF averaged 530, 560, and 530 g/kg for the 3 cuts and NDF digestibility averaged 760, 690, and 640 g/kg for the three cuts. Treatments did not significantly impact NDFD. There was a small yield advantage for split application of N fertilizer on perennial grasses, and it will take more than four years of manure application at a 89.6 metric tons/ha rate to produce yields comparable with commercial N fertilization.

Key Words: Perennial Forage, Manure

W102 In vitro dry matter digestibilities of perennial peanut, annual peanut, alfalfa, and bermudagrass forages in horses. J. V. Eckert*, R. O. Myer, L. K. Warren, J. L. Foster, and J. H. Brendemuhl, University of Florida, Gainesville.

In vitro dry matter digestibilities (IVDMD) of perennial peanut (PP, *Arachis glabrata*, 'Florigraze'), annual peanut (AP; *Arachis hypogea*) hays (grown in Marianna, FL, 2005, 2006) as well as dried fresh forage samples taken from the same fields (2006), alfalfa hay (A; Iowa, 2006), Tifton 85 (T85) and Coastal (CB) bermudagrass hays (*Cynodon dactylon*, both from Suwannee county, FL, fertilized fields), and six vari-

ies of PP were compared (Marianna, FL, 2006). All hays had no rain damage. Seven yearling horses fed their normal diet (grass pasture and concentrate) were used as the source of feces. Samples were incubated in a closed fermentation apparatus (Daisy^{II} incubator). Freshly voided feces were collected from all horses, mixed with buffers, and placed in four incubation vessels. Twenty-one filter bags (each containing 0.5 g of sample) were placed in each vessel. Jars were heated and rotated for 48 h. Data were analyzed using PROC MIXED of SAS. Least square means of IVDMD (%±SE) from samples of dried fresh AP were 80 and 78% (±2). The IVDMD of AP hay (65% ±2) was lower than fresh AP (P < 0.0001). Dried fresh AP samples were greater than dried fresh PP (P < 0.01). Alfalfa hay (71% ±2) and PP hay (68% ±2) had similar IVDMD (P > 0.2). The IVDMD of A was greater than AP hay (P < 0.01) while PP and AP hays did not differ (P > 0.2). Perennial peanut, T85, and CB hays from a previous digestion trial (abstract 38 in 2007 meeting of the Southern Section of ASAS) showed a greater IVDMD for PP than T85 or CB (P < 0.0001; comparable to the in vivo DMD) and no differences (P > 0.2) between T85 and CB from the first two periods of that trial. During period 3 of that same trial, CB IVDMD tended to be greater than T85 (P < 0.06). Numerically, the IVDMD of the grasses was lower than their in vivo DMD. Of the six varieties of PP, the two with the highest IVDMD were Elite Line (75.7% ±2) and Ecoturf (73.8% ±2), even though all varieties were highly digestible. Results indicate that PP and AP are highly digestible, but PP may be better suited for horses.

Key Words: Perennial Peanut, In Vitro Digestibility, Horse

W103 Forage management affects bermudagrass Forage yield and nutritive value. A. E. Lee*¹, A. V. Riojas¹, B. D. Lambert^{1,2}, and J. P. Muir², ¹Tarleton State University, Stephenville, TX, ²Texas AgriLife Research, Stephenville, TX.

Bermudagrass (*Cynodon dactylon*) cultivars are common forages in the southern USA. Coastal (CB) and Tifton 85 (T85) bermudagrass are widely cultivated in Texas. As fuel and labor costs rise, producers have opted to “stockpile” standing forages for winter grazing instead of using hay. Experiments compared the effects of stockpiling (Exp. 1) and hay cutting (Exp. 2) on CB and T85 forage yield and nutritive value. Sixteen 3 × 9 m plots were utilized, consisting of four plots of each species (CB or T85) per treatment. All plots received a single spring application of nitrogen (94 kg/ha). In Exp. 1, previously unharvested forage was sampled by hand clipping (1 m²) to ground level every 14 days to determine the effect of maturity on forage stockpiling. In Exp. 2, forage was sampled by hand clipping to ground level (1 m²) every 21 days and only regrowth was subsequently sampled, emulating well-managed hay production. Samples were analyzed for dry matter (DM), nitrogen (N), neutral detergent fiber (NDF), and acid detergent fiber (ADF) concentrations. Forage DM yield (kg ha⁻¹ year⁻¹) was calculated. In Exp. 1, CB had greater yield (P=0.02) as well as greater N (P<0.0001), NDF (P<0.0001) and ADF (P=0.006) concentration. In Exp. 2, T85 had higher N (P=0.007) and lower NDF (P=0.01) concentrations than CB. Preliminary results indicate that CB is better suited for stockpiling than T85 while the reverse is the case for hay.

Key Words: Stockpiling, Coastal Bermudagrass, Tifton 85 Bermuda-grass

W104 Forage nutritive value of crown rust resistant and susceptible oat cultivars in Northern Mexico. H. Bernal-Barragán*¹, R. Quintero-Martínez¹, J. A. Hernández-Aguilar¹, M. A. Cerrillo-Soto², A. S. Juárez-Reyes², E. Gutiérrez-Ornelas¹, J. E. Treviño-Ramírez¹, and F. Zavala-García¹, ¹Facultad de Agronomía UANL, Escobedo, N.L., México, ²Facultad de Medicina Veterinaria y Zootecnia UJED, Durango, Dgo., México.

Oat (*Avena sativa* L.) cultivated in Mexico is mainly utilized as green forage or hay for feeding ruminants in winter and early spring. Crown rust caused by *Puccinia coronata* is an important oat disease, especially when relative humidity is high during the growing season, and it can affect forage productivity and quality. This study was conducted with the aim to assess the nutritive value of four crown rust resistant oat cultivars (L-112, L-124, L-135 and L-164), which were released at the Facultad de Agronomía UANL in 2007, and two crown rust susceptible oat cultivars (Cocker and Cuauhtemoc). Crown rust was present during the experiment in 100% of the plots of susceptible cultivars, whereas resistant cultivars were not affected at all. Three random whole plant samples were collected from small plots at 92 and 103 days of growth, oven dried at 55° C, and ground to pass through 1 mm screen. Dry matter, ash, CP, NDF, ADF, and ADL, were determined and contents of cellulose, and hemicellulose were calculated. Further analyses were conducted using a Daisy^{II} Incubator and an adiabatic calorimeter to determine in vitro true digestibility of DM (IVTDMD) and digestible energy (DE) content, respectively. A 6 x 2 factorial arrangement (six oat cultivars x two cutting stages) was used in a complete randomized design, with three replicates per treatment. Ash contents were least (P < 0.05) for L-135 and greatest for Cuauhtemoc. Differences in CP, cellulose, hemicellulose, IVTDMD, and digestible energy content were found (P < 0.05) among oat cultivars (Table 1). There were no differences in ADL content. Ash and CP content of cultivars at 103 days were 16% less (P < 0.05) than at 92 days, whereas IVTDMD and digestible energy content were 5% less (P < 0.05) at 103 than at 92 days. In conclusion, the forage nutritive value of crown rust resistant cultivar L-112 was similar to those crown rust susceptible oat cultivars Cocker and Cuauhtemoc.

W105 In vitro gas production characteristics and metabolizable energy content in crown rust (*Puccinia coronata*) resistant and susceptible oat (*Avena sativa* L.) cultivars. M. A. Cerrillo-Soto*¹, A. S. Juárez-Reyes¹, H. Bernal-Barragán², R. Quintero-Martínez², J. A.

Hernández-Aguilar², E. Gutiérrez-Ornelas², J. E. Treviño-Ramírez², and F. Zavala-García², ¹Facultad de Medicina Veterinaria y Zootecnia UJED, Durango, Dgo, México, ²Facultad de Agronomía UANL, Escobedo, N.L. México.

This study was conducted to determine the kinetics of in vitro gas production and the metabolizable energy (ME) content of four crown rust resistant oat cultivars released in 2007 at the Facultad de Agronomía UANL, México (L-112, L-124, L-135, and L-164) and of two crown rust susceptible oat cultivars (Cocker and Cuauhtemoc). During the experiment crown rust affected 100 % of the plots of susceptible oat cultivars, but plots of resistant cultivars were not affected at all. Three random whole plant samples were collected from small plots at 92 days of growth. Samples were oven dried and ground through 1 mm screen. In vitro gas production in oat samples was performed by incubating in triplicate 200 mg DM in 100 ml calibrated glass syringes. A buffered solution was mixed with rumen fluid from three ruminal fistulated sheep fed alfalfa hay and commercial concentrate (75:25) in a ratio of 1:2 (v/v). Thirty ml of the mixture was added to the syringes and the gas production was recorded at 0, 3, 6, 9, 12, 24, 48, 72 and 96 h of incubation. The data were fitted to the exponential equation $p = a + b(1 - e^{-ct})$. The content of ME was calculated by: $ME (Mcal\ kg^{-1}\ DM) = (2.20 + 0.136\ Gas\ Prod_{24h} + 0.057\ Crude\ Protein + 0.0029\ Crude\ Fat^2)/4.184$. Data were analyzed using ANOVA for a completely randomized design. Data shown in Table 1 indicate that in vitro gas production allowed identification of a greater nutritional value for resistant crown rust oat cultivar L-112 compared to the crown rust susceptible cultivars.

Table 1. In vitro gas production (mL/200 mg DM) and ME (Mcal/kg DM)

Cultivar	b	c	a+b	ME
L-112	64.5 ^a	0.049 ^{ab}	55.7 ^a	2.02 ^a
L-124	60.1 ^b	0.045 ^b	51.9 ^c	1.84 ^b
L-135	59.7 ^b	0.047 ^b	54.6 ^{ab}	1.90 ^b
L-164	57.5 ^b	0.053 ^a	50.9 ^c	1.93 ^{ab}
Cocker	59.2 ^b	0.047 ^b	52.3 ^{bc}	1.84 ^b

W106 Chemical composition, metabolizable energy content and in vitro gas production of grasses from North Mexico. E. Herrera-Torres, M. Murillo-Ortiz, M. A. Cerrillo-Soto*, O. Reyes-Estrada, and A. S. Juárez-Reyes, *Universidad Juárez del Estado de Durango, Durango, Dgo., Mexico.*

The objective of this study was to determine the chemical composition, in vitro gas production characteristics and metabolizable energy content of grasses commonly selected by grazing cattle in the semiarid region of North México. Samples of Plateado (1) (*Bothriochloa barbinodis*), Navajita (2) (*Bouteloua gracilis*), Banderita (3) (*Bouteloua curtipendula*), Pata de gallo (4) (*Chloris submutica*), Rhodes (5) (*Chloris gayana*), Rosado (6) (*Rhynchelytrum roseum*) and Buffel (7) (*Cenchrus ciliaris*) were collected during the wet season in an open grassland in Durango, Mexico. The samples were dried and ground (1 mm). Chemical analyses for CP, NDF and ADF were performed. In addition, triplicate samples (200 mg DM) were incubated in calibrated 100 ml glass syringes, with 30 ml of a mixture of buffer:rumen fluid. The inoculum was collected from three sheep fed alfalfa hay and a commercial concentrate (75:25). Gas production was recorded at 0, 3, 6, 9, 12, 24, 48, 72 and 96h. Data were fitted to the equation: $p = a + b(1 - e^{-ct})$. The ME content (Mcal Kg⁻¹DM) of sample was calculated by: $ME: (2.20 + 0.136GP_{24h} + 0.057CP + 0.0029CF^2)/4.184$. Statistical analysis was performed using a completely randomized design. Differences (P<0.05) were observed for CP and NDF among grasses. The content of ME calculated from in vitro gas production as well as the gas produced from the insoluble but slowly degradable fraction of the feed **b** and the constant rate of gas production **c** were also different among grasses. Based on our results, *C. ciliaris* has potential to improve grazing for cattle in the semiarid region of North Mexico.

W107 Evaluation of African star grass– pastures grazed under the leaf stage concept on commercial dairy farms in the humid tropics of Costa Rica. J.M. I. Sánchez*^{1,2}, S. Salazar^{1,3}, and A. Martínez^{1,2}, ¹Universidad de Costa Rica, San José, Costa Rica, ²Centro de Investigación en Nutrición Animal, San José, Costa Rica, ³Escuela de Zootecnia, San José, Costa Rica.

African star grass (*Cynodon nlemfuensis*) is used widely on dairy and beef farms in tropical countries. In Costa Rica it grows from sea level to 1200 m in altitude and it is the most important grass in the humid tropics, where annual average precipitation is 4500 mm and annual average temperature is 23°C (minimum of 10°C; maximum of 27 °C). This grass is characterized by a high DM yield and good nutritional value; however grazing intervals are critical because nutritional value declines rapidly with advancing maturity. Thus dairy farmers have had to apply plant phenological concepts such as the leaf stage concept, to determine when to graze this pasture. The aim of this study was to analyze the DM yield, utilization of the pasture on offer, botanical composition of African star grass-based pastures and nutritional value according with NRC (2001) proposed methodologies, on three dairy farms located in the humid tropics of Costa Rica. Farms were selected at random from a

group of farms where the pasture is intensively managed with fertilization, weed control and well-established grazing systems. Measurements and samples were taken every two mo for 1 yr period. Cows grazed the African star grass when it had an average number of 7.9 leaves. Botanical composition analysis showed that 86.7 % of the biomass was African star grass, 2.4% other grasses, 2.9% weeds and 7.8% senescent material. Average DM yield was 26.25 t/ha/year, which is similar to values reported in the literature when this grass is intensively managed. Pastures on the three farms were established more than 20 years ago, indicating farmers use management practices that sustain the grass. On average, pasture contained 20.3% CP, 72.8% NDF, 37.9% ADF, 8.7% ash, 7.7% NFC, 5.6% lignin and 1.2 Mcal/kg NEL (3X). Agronomic and nutritional data strongly suggest African star grass should be grazed when it has 8 leaves. A grazing system based on the leaf stage concept is a good tool for managing African star grass in the humid tropics.

Table 1.

W108 Production of *Brachiaria brizantha* and *Panicum maximum* forages according to period of intercropping with corn and nitrogen fertilization. R. S. Barducci¹, C. Costa¹, T. C. Putarov¹, L. M. N. Sarti¹, E. S. Ogawa¹, D. D. Millen¹, R. D. L. Pacheco¹, J. P. S. T. Bastos¹, T. M. Mariani¹, T. C. B. da Silva², and S. R. Baldin¹, ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²Faculdade de Zootecnia/UNESP, Dracena, São Paulo, Brazil.

The objective was to evaluate forage dry matter production (FDMP) according to period of intercropping with corn and responses to nitrogen fertilization (NF) applied after harvesting of corn. This study, conducted at São Paulo State University (UNESP-Botucatu) farm, Brazil, was designed in a split plot 4x4 factorial arrangement: corn with *Brachiaria brizantha* intercropped in the sowing (BS), corn with *Brachiaria brizantha* intercropped in the coverage fertilization (BC), corn with *Panicum maximum* intercropped in the sowing (PS) and corn with *Panicum maximum* intercropped in the coverage fertilization (PC) and four rates of N (0, 30, 60, 120 kg/ha) and three periods of growth (1=07/20/2006, 2=09/29/2006, 3=11/09/2006). Corn hybrid 30F90 from Pioneer was utilized to establish 55,000 plants/ha while 20kg of seed/ha of each forage was sown. Corn and BS and PS forages were sown on 12/20/2005, but BC and PC forages were sown on 01/14/2006 with coverage fertilization. Forage coverage fertilization was made on 05/24/2006. In period 1 FDMP increased (P<0.01) for BS as rates of N increased, but no effects were found (P>0.05) for BC, PS and PC. BC had greater (P<0.01) FDMP as rate of N increased in period 2. In period 3 as N rate increased, FDMP for BS, BC and PC increased (P<0.01). Summing the three periods, PS did not show a response (P>0.05) to rates of N. Thus, the system of cultivation, forage species, daylength and temperature are important factors to determine FDMP in tropical forages.

W109 Production of corn grain with *Brachiaria brizantha* and *Panicum maximum* forages according to period of intercropping. R. S. Barducci¹, C. Costa¹, T. C. Putarov¹, L. M. N. Sarti¹, E. S. Ogawa¹, D. D. Millen¹, R. D. L. Pacheco¹, J. P. S. T. Bastos¹, T. M. Mariani¹, S. R. Baldin¹, and T. C. B. da Silva², ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²Faculdade de Zootecnia/UNESP, Dracena, São Paulo, Brazil.

The study evaluated the production of corn grain intercropped with *Brachiaria brizantha* and *Panicum maximum* forages in no tillage systems. This study, conducted at São Paulo State University (UNESP-Botucatu) farm, Brazil, examined 5 treatment systems of corn cultivation with tropical grasses replicated four times and randomly blocked: single corn crop (MS), corn with *Brachiaria brizantha* intercropped in the sowing (BS), corn with *Brachiaria brizantha* intercropped in the coverage fertilization (BC), corn with *Panicum maximum* intercropped in the sowing (PS) and corn with *Panicum maximum* intercropped in the coverage fertilization (PC). Corn hybrid 30F90 from Pioneer was utilized to establish 55,000 plants/ha and 20kg of seed/ha of each forage was used. T-tests were used to compare means at P<0.05. Corn and BS and PS forages were sowed on 12/20/2005, but BC and PC forages were sowed on 01/14/2006 with coverage fertilization. Corn grain was harvested on 05/18/2006 when more than 50% the grain grain was at black layer. Results are showed on a 100% DM basis. BS and PC produced more (P<0.05) corn grain compared to MS (MS= 0%, BS= 1.3%, BC= -7%, PS= -9.3%, PC= 11%). Corn production was greater (P<0.05) for PC than MS, BS, BC and PS (MS=10729, BS=10873, BC=10089, PS=9731, PC=11904 kg/ha). Less competition for nutrients may contributed increased production for PC. Thus, the system of cultivation may impair or enhance corn grain productivity, as observed for PS and PC, respectively. Other factors that affect corn grain productivity are related to forage species, as observed for BC and PC.

Key Words: Corn, Forage, Intercropping

W110 Use of a nutraceutical feed produced by solid state fermentation of apple pomace in lactating dairy cows diets. C. Rodríguez-Muela*, F. J. Gutiérrez-Piñ, M. A. Gallegos-Acevedo, H. Garcí-Nevarez, H. E. Rodríguez-Ramírez, O. Ruiz-Barrera, and J. Jiménez-Castro, Universidad Autónoma de Chihuahua, Chihuahua, Mexico.

Manzarina (MZ), a feed rich in phenol compounds and yeasts produced by Solid State Fermentation of apple pomace, was evaluated in lactating cow diets. Two groups of 11 mature lactating cows (93 days of lactation) were used in a 2X2 Latin Square with a switch back arrangement. Treatments were: a concentrate with 15% MZ (MT) and a concentrate without MZ (CT). Concentrates were offered in the parlor and hay (alfalfa and oat) was offered free choice in the bunk. A 12 d adaptation period was followed by a 12 d sample collection during the two periods of the Latin Square (P1 and P2). Milk production was measured and milk samples were collected from each cow daily at milking. Milk constituents were analyzed with a Milk Scan FT 120[®]. Two blood samples per cow were obtained at the beginning and the end of each period. The concentrate intakes were 11.77 kg cow⁻¹ d⁻¹ for CT and 13.25 kg cow⁻¹ d⁻¹ for MT; the forage intakes were 12.60 kg cow⁻¹ d⁻¹ for CT and 11.19 kg cow⁻¹ d⁻¹ for MT. Milk production was different (P<0.05) between treatments (CT= 22.06±0.23 kg cow⁻¹ d⁻¹, MT= 22.84±0.23 kg cow⁻¹ d⁻¹). Milk constituents were not different between treatments (P>0.05). A diet*period effect (P<0.05) occurred for somatic cell count (P1: MT= 6.44±0.20*10³ cells ml⁻¹, CT= 7.13±0.21*10³ cells ml⁻¹; P2: MT= 6.64±0.20*10³ cells ml⁻¹, CT= 5.60±0.20*10³ cells ml⁻¹). White blood cell count was higher for MT (P<0.05; MT= 7.12±0.75%, CT= 4.86±0.75%). Plasma antioxidant activity differed across periods (P<0.05; 18.65±0.53 mM Fe₂ in P1, 22.52±0.53 mM Fe₂ in P2). We conclude that MZ can be incorporated into lactating dairy cow diets during early lactation.

Key Words: Nutraceutical Feed, Oxidative Stress, Phenol Compounds

W111 Use of feed produced by solid state fermentation of apple pomace (manzarina) in lambs feedlot diets. C. Hernández-Gómez*, C. Rodríguez-Muela, J. A. Ortega-Gutiérrez, H. E. Rodríguez-Ramírez, F. Salvador-Torres, A. Flores-Mariñelarena, and G. Corral-Flores, *Universidad Autónoma de Chihuahua, Chihuahua, México*.

The productive behavior and carcass characteristics of lambs fed with manzarina (MZ) were evaluated in 24 males and females (Charolais×Dorper and Katahdin) with an initial body weight (BW) of 25.5±3.3 kg. Lambs were assigned to two treatments: MT (with 5% MZ) or CT (without MZ); diets were isonitrogenous and isocaloric; diet ingredients were alfalfa, corn, soybean meal, animal fat, sugar cane molasses, mineral premix and MZ. Lambs were confined in individual stalls and received water and feed *ad libitum*. Feed intake (FI) was measured daily. The BW increase was evaluated by period (PWG) and by day (DWG). Periods were of 14 d each. Carcasses were evaluated 24 h after the slaughter in order to determine carcass yield (CY), rib eye area (RA) and back fat (BF). Productive variables were analyzed with a mixed statistical model with diet, sex and their interactions as fixed effects, replicate as random effect and initial BW as covariate. Carcass data were analyzed in SAS GLM procedure. There was a linear increase (P<0.01) on BW during the experiment. Males with MT diet had greater PWG (4.76±0.19 kg) and DWG (0.349±0.019 kg) than those with CT diet (3.96±0.19 and 0.309±0.018 kg), with a final body weight (FBW) of 44.58±0.77 and 41.97±0.71 kg respectively. Females with MT diet had less PWG (3.65±0.27 kg) and DWG (0.246±0.019 kg) than those with CT diet (4.05±0.27 and 0.290±0.019 kg), with a FBW of 38.94±0.76 and 41.46±0.72 kg respectively. There was a linear increase (P<0.01) on the FI throughout the trial; the increase was 2.68 g d⁻¹ lamb⁻¹. There was a sex effect (P<0.05) for Feed:gain ratio (FG). Males had greater (P<0.05) FG than the females (5.4±0.21 and 4.5±0.21 respectively). There was a diet*sex effect (P<0.06) for CY. Males of MT had a CY value of 48.00±1.25% and the males of CT of 50.23±1.14%.

Females of MT had a CY value of 51.52±1.23% and the females of CT of 48.96±1.15%. There was not effect (P>0.05) for RA. The BF was greater (P<0.06) on females (4.5±0.81 mm) compared with males (2.5±0.81 mm). We conclude that the use of manzarina is feasible in lambs feedlot diets.

Key Words: Apple Pomace, Manzarina, Lambs

W112 Fermentation of apple waste products added with bakery residues. Y. Castillo-Castillo¹, O. Ruiz-Barrera*¹, D. Cruz-Guillen¹, A. Elias-Iglesias², C. Rodríguez-Muela¹, J. Ortega-Gutiérrez¹, O. La O-Leon², and C. Arzola-Alvarez¹, ¹Facultad de Zootecnia, Universidad Autónoma de Chihuahua, Chihuahua, Chih, Mexico, ²Instituto de Ciencia Animal, La Habana, Cuba.

Solid state fermentation (SSF) is a tool to improve nutritive value of agroindustrial by-products. By promoting growth of epiphytic microorganisms, SSF is one of the most efficient methods to breakdown lignocellulosic compounds, increase the quantity and quality of protein and reduce environmental impact. The study assessed the influence of adding bakery waste (0, 15, 30 and 45%) on an as-is basis to apple waste on changes of pH and yeast count across fermentation time. Bakery waste was a mix of salted and sweetened bread, cookies, dough, etc. We hypothesized that adding bakery waste would increase DM, reduce pH, and increase counts of useful microorganisms. A completely random design with 6 replications of treatments in a 4 x 3 factorial was used. The variables were four levels of bread inclusion and three incubation periods (0, 24 and 48 h). During fermentation, pH decreased linearly (P<0.001) across time for all four treatments. Only the pH at 48 h of the 45% inclusion level was higher than the control (4.6 vs 4.01; P<0.001). Yeast count (log 10) increased across time (quadratic effect; P<0.001) for all levels of bakery waste. Yeast count was higher (P<0.001) for the 30 and 45% treatments compared to the control and 15% treatments. As levels of bakery waste increased, texture of the mix was improved. Based on these results we conclude that 30% inclusion of bakery waste improves the SSF fermentative process of apple residues and enhances beneficial bacterial populations.

Key Words: Solid State Fermentation, Apple Waste, Bread

W113 Fiber degradation during solid state fermentation of apple pomace. H. E. Rodríguez-Ramírez*, C. Rodríguez-Muela, H. A. Castillo-Gonzalez, J. A. Ortega-Gutiérrez, O. Ruiz-Barrera, D. Villagran-Torres, C. Hernández-Gómez, S. Romero-Villalobos, and C. A. Arzola-Alvarez, *Universidad Autónoma de Chihuahua, Chihuahua, Mexico*.

This experiment was conducted to measure yeast growth (YG) and changes in the structural carbohydrates during solid state fermentation of apple pomace (AP). Treatments (T) were: T1 (n=36) 100%AP as substrate and T2 (n=36) mixture of 66.67%AP+33.33% non commercial apple as substrate to get different carbohydrates concentration. Both were amended with urea, ammonium sulfate and a mineral mixture (1.5, 0.4, 0.5%, wet basis); around 350 g of substrate were placed on plastic containers (n=72), stirred four times daily every 5 h at 30±1°C. Six samples of each T were taken on 0, 1, 2, 4, 8 and 16 days (D) during the experiment to determine YG (using malt extract agar cultures) and %DM

consumed during fermentation (DMc). Neutral detergent fiber (NDF), acid detergent fiber (ADF) and lignin (L) were determined on d0 and d8 following ANKOM™ procedures. Colony forming units (CFU) were converted to their natural logarithm prior to statistical analysis. Data were analyzed with the MIXED procedure of SAS, using T, D and their interaction (T*D) as fixed effects, and sample as random effect. There was T*D effect ($P<0.05$). YG on d8 was different ($P<0.05$) between T1 and T2; YG of T1 increased from 2.14×10^9 on d0 to 3.09×10^{10} CFU*g DM⁻¹ on d8. YG of T2 increased from 1.99×10^9 on d0 to 4.69×10^9 CFU*g DM⁻¹ on d8. DMc was lower ($P<0.05$) in T1 than T2 on d2 (+2.08 vs. -7.79%); DMc reached 40.73 and 49.92% on d8 and d16 respectively without T effect ($P>0.05$). NDF of T1 decreased ($P<0.05$) from 55.81

on d0 to 28.59% on d8 and NDF of T2 increased ($P<0.05$) from 45.07 on d0 to 61.45% on d8. ADF of T1 decreased ($P<0.05$) from 40.52 on d0 to 31.98% on d8. ADF of T2 increased from 31.98 on d0 to 48.82% on d8. L of T1 decreased ($P<0.05$) from 17.29 on d0 to 9.83 on d8. L of T2 increased ($P<0.05$) from 9.62 on d0 to 25.87% on d8. These results suggest that a higher yeasts concentration and species diversity on T1 can degrade structural carbohydrates more efficiently than in T2, probably due to higher rapidly fermentable carbohydrates content on T2. Therefore we recommend further work on microbial isolation and community characterization on apple pomace solid state fermentation.

Nonruminant Nutrition: Carbohydrate and Lipids

W114 Effect of xylanase supplementation to wheat-rye based diet on the energy availability and the performance of ducks. L. Babinszky^{*1}, J. Tossenberger¹, and I. Kühn², ¹Kaposvár University, Kaposvár, Hungary, ²AB Enzymes GmbH, Darmstadt, Germany.

The objective was to determine the effect of dietary xylanase (xyl) supplementation on energy availability (intake-excretion/intake*100) and duck performance. The availability trial used 6 birds/Treatment (Trt) (Cherry Valley, Super M-3 Heavy drakes, individual keeping). Availability of energy was determined on the 2nd & 5th weeks of age. The performance trial was conducted with a total number of 756 birds (same hybrid) (252 birds/Trt, 50% male & 50% female, 49 days of age). Diets were formulated on a wheat-rye-soybean basis for a 2-phase feeding program. Birds were fed starter diets (days 1-14: AME: 11.0 MJ/kg, CP:208 g/kg, LYS: 10.0 g/kg) in crumbled form and grower diets (days 15-49: AME: 11.0 MJ/kg, CP:162 g/kg, LYS: 7.6 g/kg) in pelleted form. The trials consisted of 3 Trts. Birds in Trt1 were fed diets without added xyl. Diets in Trts 2 and 3 were supplemented with 6000 BXU/kg and 16000 BXU/kg ECONASE[®] XT (thermostable xylanase produced by *Trichoderma reesei*), respectively. Data were analyzed by ANOVA (SAS, 2004). According to our data xyl added at 6000 BXU/kg significantly increased the availability of energy ($P \leq 0.05$) (Wk2: 75.5 vs 77.2%; Wk5: 72.6 vs 76.7%). Xyl added at 16000 BXU/kg resulted further improvement of energy availability on Wk5 only.

The live weight of the ducks (49 days) was increased significantly ($P \leq 0.05$) by xyl supplementation added at the rate of 6000 BXU/kg (2974 g vs 3101 g). The higher enzyme dosage (16000 BXU/kg) was not associated with any further increase of the final weight of the ducks ($P \geq 0.05$). The xyl supplementation of the diets at the rate of 6000 BXU/kg, however, improved the feed conversion ratio of the birds by 3.1 % (2.92 kg/kg vs 2.83 kg/kg) while xyl added at the rate of 16000 BXU/kg improved it by 4.8 % (2.93 vs. 2.78 kg/kg). Based on these results xylanase supplementation to wheat-rye based duck diets starting from an inclusion rate of 6000 BXU/kg can be recommended.

Key Words: Duck, Xylanase, Availability

W115 Effect of phytase supplementation of the diets on the digestibility and urinary excretion of phosphorous and calcium in weaned piglets. J. Tossenberger¹, I. Kühn², and L. Babinszky^{*1}, ¹Kaposvár University, Kaposvár, Hungary, ²AB Enzymes GmbH, Darmstadt, Germany.

Aim was to determine the effect of dietary phytase supplementation on P and Ca digestibility and urinary excretion in weaned piglets. The trials used 4 hybrid barrows per treatment (Trt) in 2 replicates (8 pigs/Trt, individual keeping, initial live weight: 13.1±1.1 kg). The corn-soy based diets contained P_i supplementation at 1 g/kg of diet. The trial consisted of 5 Trts. The control diet contained no phytase supplementation (Trt1). Diets of Trts 2, 3, 4, 5, were supplemented with phytase (6-phytase produced by *Trichoderma reesei*) at the rate of 125, 250, 500 and 750 PPU/kg, respectively. Measured phytase activity of the diets was 90, 337, 424, 672 and 968 PPU/kg. Data were analyzed by ANOVA and regression analysis (SAS, 2004). According to our data phosphorous (P) digestibility (%) already showed a 17.0% increase (from .433 to .603) due to 125 PPU/kg phytase supplementation of the diet ($P < 0.05$).

According to the regression analysis the end value of P digestibility was 67.5% – 95% of which (i.e. 64.1%) was reached at 183 PPU/kg added phytase activity of the diets. Due to the restrictive P supply urinary P excretion was at a minimum. Retention of P (%) improved by 16.8% (from .425 to .593) when supplementing phytase at 125 PPU/kg of diet ($P < 0.05$). The 95% of the end value of P retention is estimated to occur at 185 PPU/kg added phytase activity of the diets. The limited P supply (1 g inorganic P/kg) and phytase activity (90 PPU/kg) has a negative impact on the digestibility of calcium (Ca). Calcium digestibility (%) already showed a 12.1% increase (from .656 to .777) due to 125 PPU/kg phytase supplementation of the diet ($P \leq 0.05$). Urinary Ca excretion – irrespective of the Trt – was on average about nine times higher than the (physiological) value characteristic of weaned piglets, suggesting a P deficiency. The 95% of the end value of P digestibility (i.e. 64.1%) is estimated to occur at 183 PPU/kg added phytase activity of the diets.

Key Words: Piglet, Phosphorous, Digestibility

W116 Ileal and post-ileal digestibility of heat treated cereals in weaners. J. Tossenberger¹, L. Babinszky^{*1}, and S. Reischl², ¹Kaposvár University, Kaposvár, Hungary, ²Agrokomplex C.S. Zrt., Zichyújfalu, Hungary.

Our study was aimed at evaluating the ileal and post-ileal digestibility of energy (E) and crude protein (CP) in heat-treated corn (C), wheat (W) and barley (B), using hybrid weaned piglets (barrows) (4 pigs/treatment, 2 replicates, initial weight: 9.4±0.8 kg, individual keeping), fitted with a simple T-cannula prior to the start of the trials. Both ileal and post-ileal (ileal undigestible-faecal undigestible/ileal undigestible*100) digestibilities were determined on the same animal using a marker (Cr₂O₃). Animals were provided with trial diets in an amount corresponding to 2.6 times their maintenance energy requirement (458 KJ MEs/kg^{0.75}/d). Cereals (C, W and B) were flaked after steam conditioning (125 °C) for ten minutes. GE levels were 16.2(C), 16.2(W) and 16.4(B) MJ/kg, CP contents were 87.0(C), 131.0(W) and 119(B) g/kg, respectively. Data were analyzed by ANOVA (SAS, 2004).

According to our data ileal digestibility of GE in the cereals studied was 85.1%(C), 70.6%(W) and 63.2%(B) ($P \leq 0.05$). A further 35.7%(C), 61.6%(W) and 52.4%(B) of GE reaching the post-ileal gut section was digested there ($P \leq 0.05$). Of total GE absorbed, 94%(C), 79.4%(W) and 76.3%(B) was digested in the ileal section, and 6.0, 20.5 and 23.6% in the post-ileal section. Accordingly, total tract GE digestibilities were 90.4%(C), 88.7%(W), and 82.7%(B) ($P \leq 0.05$), while DEs values were 14.6(C), 14.3(W) and 13.5(B) MJ/kg. Ileal digestibility of CP was found to be 73.4%(C) 61.4%(W) and 74%(B) ($P \leq 0.05$), CP post-ileal digestibility was 42.4%(C), 55.4%(W) and 34.50%(B) ($P \leq 0.05$), while total tract digestibility was 84.7%(C), 82.8%(W) and 83.0%(B). Our data highlight the possibility of substantial differences in the location of E absorption of the cereals studied, which should be considered for a more balanced energy supply of young pigs. In the interest of optimal protein supply the differences in the ileal digestibility of CP in heat treated cereals should also be considered.

Key Words: Ileal, Postileal, Digestibility

W117 Digestible and metabolizable energy content of high-oil corn for growing pigs. Y. L. Ma^{*1}, G. L. Cromwell¹, M. D. Lindemann¹, and K. E. Nestor, Jr.², ¹University of Kentucky, Lexington, ²Mycogen Seed, Indianapolis, IN.

An experiment was conducted to determine the DE and ME content of a high-oil corn (Supercede HE hybrid; Mycogen Seeds, Indianapolis, IN) based on energy balance with growing pigs. The corn analyzed 86.9% DM, 3,959 kcal GE/kg, 7.81% CP, 5.26% fat, and 0.26% lysine on an "as is" basis. Twelve crossbred barrows averaging 58 kg were assigned to one of two diets, placed in metabolism crates designed for separation of feces and urine, and fed a standard diet for a 7-d adjustment period. Pigs were then fed their assigned experimental diet twice daily for an additional 4 d of diet adjustment followed by a 5-d total collection of feces and urine. The experimental diets consisted of a basal diet (high-oil corn + minerals and vitamins) or the basal + supplemental AA to meet the estimated AA requirements. Indigo carmine was included at 0.25% in the morning feed of day 1 and day 6 to mark the beginning and end of the fecal collection period. Urine collection began and ended 4 hr after feeding the marked diet. The energy content of the diets, feces, and urine was determined by bomb calorimetry. Feed intake averaged 1.81 and 1.90 kg/d and GE intake averaged 6,973 and 7,313 (7,212 adjusted for the GE in AA) kcal/d for the two treatments, respectively. Pigs fed the AA supplemented diet retained more N ($P < 0.05$) than those fed the basal diet (17.84 vs. 13.30 g/d; 68.2 vs. 56.4% of N intake; 79.4 vs. 66.8% of N absorbed). The DE and ME of the high-oil corn (DM basis) following adjustment for the energy provided by the AA were 4,062 and 4,138 kcal DE/kg and 3,995 and 4,075 kcal ME/kg for the two treatments, respectively, with estimates tending to be slightly higher for the AA supplemented diets ($P < 0.09$). When adjusted to 89% DM and averaged across treatments, the DE of the high-oil corn was $3,646 \pm 17$ and the ME was $3,588 \pm 18$ kcal/kg. These energy values are 3.4 and 4.9% higher, respectively, than the DE and ME of normal corn at 89% DM (3,525 and 3,420 kcal/kg) listed in the current NRC *Nutrient Requirements of Swine*.

Key Words: Pigs, High-Oil Corn, Metabolizable Energy

W118 Effects of heat processing of corn and rice on faecal digestibility of nutrients and adipose tissue fatty acid composition in young pigs. D. Menoyo, M. P. Serrano, D. G. Valencia, R. Lázaro, and G. G. Mateos*, *Universidad Politécnica de Madrid, Spain*.

Heat processing (HP) of cereals gelatinizes the starch portion of the grain, which may result in improved nutrient utilization. A 24-d trial was conducted to evaluate the effect of the main cereal of the diet (corn or rice) and heat processing of the cereal (HP) on coefficients of apparent total tract digestibility (CATTD) of nutrients in young pigs. Also, diet effect on fatty acid (FA) composition of the adipose tissue was assessed. The experimental design was completely randomized with four treatments and nine replicates (one pig) per treatment. Piglets were fed their respective experimental complex diets with 52% of corn or rice either raw or cooked from 23 to 48 d of age. Pigs were slaughtered at 49 d of age and samples (5g) of subcutaneous fat were analyzed for FA composition. The CATTD of GE, OM, EE, and CP was higher for piglets fed rice than for piglets fed corn ($P \leq 0.01$). Heat processing of the cereal improved GE, OM, EE, and CP digestibility ($P \leq 0.001$). Also, the improvement of CATTD of nutrients with HP was higher in the corn- than in the rice-diets (7.4 vs. 0.8% for GE, 5.9 vs. 0.5% for OM, 9.4 vs. 2.7% for EE, and 5.9 vs. 0.6% for CP; $P \leq 0.01$). The

proportion of saturated FA (SFA) in the adipose tissue of the pigs was higher with rice than with corn (35.4 vs. 33.6%; $P \leq 0.05$), but HP did not affect SFA content. Both cereal type and HP of the cereal affected 18:2n-6 concentration ($P \leq 0.01$). Also, 18:2n-6 concentration was decreased with HP of corn but was increased with HP of rice ($P \leq 0.01$ for the interaction). In conclusion, feeding rice instead of corn and HP of the cereal portion of the diet increases nutrient digestibility in piglets. A more saturated fat with lower 18:2n-6 concentration was obtained in pigs fed rice than in pigs fed corn, especially when rice was HP. This effect might have important implications on meat quality of pigs when HP cereals are fed at the end of the growth period.

Key Words: Piglets, Cereal, Heat Processing

W119 Evaluation of a dynamic in vitro model to simulate the porcine ileal digestion of diets differing in the carbohydrate composition. J. P. Meunier^{*1}, E. Manzanilla², M. Anguita², S. Denis³, J. F. Pérez², J. Gasa², J. P. Cardot³, F. Garcia², and M. Alric³, ¹Pancosma Research, Geneva, Switzerland, ²Universitat Autònoma de Barcelona, Spain, ³University of Auvergne, France.

The aim of the study was to assess the ability of a dynamic in vitro model to determine the digestibility of OM, CP, and starch as compared to in vivo ileal digestibility obtained from growing pigs fitted with a T-cannula. Five experimental diets with different carbohydrate types and level were assessed: a standard corn-based diet (ST) or the same diet with coarse ground corn (CC), 8% sugar-beet pulp (BP), 10% wheat bran (WB), or 8% sugar beet pulp and 10% wheat bran (HF). In the in vivo experiment, diets CC and HF reduced ileum digestibility of OM when compared to ST diet (65.0 and 65.1 vs. 70.8%, $P = 0.015$, respectively). The inclusion of sugar-beet pulp reduced (65.9 vs. 76.6%, $P = 0.049$) ileal CP digestibility in the BP diet. This reduction was not statistically significant when sugar beet pulp was combined with the wheat bran in the HF diet. No differences were found in the in vivo starch digestibility among diets. The dynamic in vitro model yielded OM and CP digestibility coefficients comparable to those obtained in vivo for the ST and CC diets. However, values were considerably affected by the incorporation of the fibrous ingredients. Diets BP, WB, and HF had lower OM digestibility (33.3 vs. 74.9, $P = 0.009$, 48.5 vs. 74.9%, $P = 0.058$, and 24.0 vs. 74.9%, $P = 0.004$, respectively) compared with ST diet. Protein digestibility was also lower (43.0 vs. 81.8%, $P < 0.001$, 64.9 vs. 81.9%, $P = 0.019$ and 56.0 vs. 81.8%, $P = 0.003$, respectively) with the BP, WB, and HF diets than with the ST diet. However, digestibility was reduced to a greater extent in the BP diet than in the WB and HF diets, both containing wheat bran. The R-square between the dynamic model and in vivo results for CP digestibility was 0.99 when CC diet was not considered. No differences were found in starch digestibility among the diets with the dynamic in vitro model.

Key Words: In Vitro Model, Pig, Digestibility

W120 Performance of weanling piglets offered low, medium or high lactose diets supplemented with a seaweed extract from *Laminaria* spp. D. A. Gahan¹, M. B. Lynch¹, J. J. Callan¹, J. T. O'Sullivan², and J. V. O'Doherty^{*1}, ¹University College Dublin, Ireland, ²Bioatlantis Ltd, Ireland.

A 3 × 4 factorial experiment was conducted to investigate the interaction between different levels of lactose (60 (low) vs. 150 (medium) vs. 250 (high) g/kg) and seaweed extract (0 vs. 1 vs. 2 vs. 4 g/kg) on growth performance and nutrient digestibility of weanling pigs. The seaweed extract contained only laminarin and fucoidan. Three hundred and eighty-four piglets (24 days of age, 7.5 kgs live weight) (96 pens containing 4 piglets) were blocked on the basis of live weight and were assigned to one of 12 dietary treatments (n=8). The pigs were offered the diets *ad libitum* for 21 days post weaning. There was a significant lactose × seaweed extract interaction (P<0.05) in average daily gain (ADG) and food conversion ratio (FCR) from day 0 to 21. At the low and medium level of lactose there was an increase in ADG as the level of seaweed extract increased to 2 g/kg (P<0.05). However, at the high level of lactose there was no further response in ADG as the level of seaweed extract increased above 1 g/kg (P<0.05). At the low level of lactose there was a significant improvement in FCR as the levels of seaweed extract increased to 4 g/kg (P<0.01). At the medium level of lactose there was a significant improvement in FCR as seaweed extract increased to 2 g/kg. However, there was no significant effect of seaweed extract on FCR at the high levels of lactose. There was a linear increase in average daily feed intake from day 0-21 (488 \hat{I} / \hat{s} . 514 \hat{I} / \hat{s} . 541 \hat{I} / \hat{s} . 518 g/day s.e 14.8; P<0.05) as levels of seaweed extract increased. There was a quadratic decrease (P<0.01) in nitrogen (84.41 \hat{I} / \hat{s} . 80.48 \hat{I} / \hat{s} . 79.78. s.e 0.469) and neutral-detergent fibre (36.01 \hat{I} / \hat{s} . 23.34 \hat{I} / \hat{s} . 25.89. s.e 1.883) digestibility as the levels of lactose increased. In conclusion, pigs responded differently to the inclusion levels of seaweed extract at each level of lactose supplementation. The inclusion of a laminarin-fucoidan extract in piglet diets may alleviate the use for high lactose diets and would also alleviate some of the common problems that occur post weaning.

Key Words: Lactose, Seaweed Extract, Pigs

W121 Development of feeding program for gestating gilts and its effects on reproductive performance and progeny. L. G. Piao*, H. F. Long, W. S. Ju, J. H. Lee, H. K. Oh, and Y. Y. Kim, *Seoul National University, Seoul, South Korea.*

Numerous feeding programs for gestating sows was introduced because high producing sows are reared in swine farm. This study was conducted to compare the effect of four different feeding programs for gestating gilts on reproductive performance and progeny. A total of 41 F1 gilts (Yorkshire×Landrace) were assigned to four treatments in a complete randomized design. For treatments, gestating period of gilts was divided for three trimesters (0~35, 36~90 and 91~farrowing) and treatments were Flat, Down-Up-Down, Up-Down-Up and Down-Up-Up feeding program. Gestating gilts body weight gain from d 0 to 110 was affected by feeding program (50.8 kg, 73.3 kg, 72.6 kg and 75.7 kg for Flat, DUD, UDU and DUU, respectively; P<0.05). However gilts consumed constant feed ration (flat feeding), less body weight loss tended to be observed in lactating sows (-0.9 kg, -6.7 kg, -9.2 kg and -7.8 kg for Flat, DUD, UDU and DUU, respectively, P=0.17) and desirable backfat thickness (average 19.5mm) can be acquired at 110 days of gestation. Feed intake of lactating sows tended to be higher (4.22 kg/d, 3.60 kg/d, 3.97 kg/d and 4.13 kg/d, P>0.05) when gilts had low backfat thickness during gestation. Low feed intake of lactating sows resulted in increasing weaning to estrus interval after weaning which may affect on reproductive performance of sows in next parity. When gilts were fed higher feed during midtrimester, higher stillborn (1.4 piglet/litter, P<0.05) and mummies (0.8 piglet/litter P=0.25) were observed compared to other treatments.

Various and complex feeding programs for gestating gilts had no effect on litter weight gain and individual pig weight during nursing period. These results suggested that changing of feed intake for gestating gilts resulted in detrimental effects on body condition and reproductive performance of sows. And flat feeding program for gestating gilts showed better reproductive performance and less body fat loss in lactating period because sows consumed more feed at this time.

Key Words: Feeding Program, Reproductive Performance, Gilts

W122 Dietary energy levels of gestating gilts on gestation parameters and reproductive performance. H. F. Long*, L. G. Piao, W. S. Ju, C. S. Chang, H. K. Oh, and Y. Y. Kim, *Seoul National University, Seoul, South Korea.*

This study was conducted to determine the effects of different energy intake for gestating gilts on gestation parameters and reproductive performance of sows. A total of 40 F1 gilts (Large White × Landrace) were allotted to 4 treatments in a completely randomized design (CRD). Dietary energy levels for gestating gilts were 3165, 3265, 3365 and 3465 kcal ME/kg and 2 kg of experimental diet was provided daily during gestating period. After farrowing, lactating sows were fed lactation diet *ad libitum* approximately 5 days post-farrowing. During the whole gestation period, body weight gain and backfat thickness gain of gilts were increased in proportion to dietary energy level (P<0.01). Fat mass gain was also increased when gilts were fed 3465Kcal ME/kg diet (P<0.01). But estimated protein mass gain of sows was not significantly affected by dietary energy level (P>0.27). At farrowing, litter size did not show any significant differences among all treatments (P>0.11). Litter weight at birth was improved as higher energy diet was provided (P=0.06), but litter weight gain during 21 day lactating period was not affected by dietary energy treatments (P>0.23). 3465Kcal ME/kg for gestating gilts didn't show positive responses on reproductive performance of sows. Lower feed consumption during lactating period was observed when higher dietary energy was provided during gestating period of gilts. These results demonstrated that higher dietary energy level were not required for high producing gilts and NRC requirement of energy (3265 kcal ME/kg) were adequate for gestating gilts when 2 kg of diet was provided daily.

Key Words: Energy Level, Body Weight, Gilt

W123 The effect of dietary starch sources on the performance, nutrients digestibility and blood biochemical parameters in growing pigs. Q. Z. Dai², Y. Yin^{*1}, R. Huang¹, and T. Li¹, ¹*Laboratory of Animal Nutrition and Health and Key Laboratory of Subtropical Agro-ecology, Institute of Subtropical Agriculture, Changsha, Hunan, P. R. China,* ²*Hunan Institute of Animal Science, Changsha, Hunan, P. R. China.*

A feeding trial covered 30 days and a 5 × 5 Latin square design metabolism experiment using 45 20 ± 0.642kg Duroc × Landrace × Yorkshire cross breed pigs were conducted to study the effect of dietary starch sources on the performance and nitrogen metabolism. 4 iso-nitrogen, iso-energy and iso-starch diet were formulated using Maize, Brown rice, Stick rice and Resistant starch (Hi-maize-1043) as starch sources, as well as a nitrogen free diet was also formulated to determine the endogenous nitrogen losses. The results showed that the body weight

gain of Maize group was 719.52g per day which was 14.69%, 11.92% and 3.03% higher than Resistant starch, Stick rice and Brown rice group respectively. While the feed conversion (feed consumption/ body weight gain) was 1.64%, 12.46 ($p < 0.05$) and 0.5% lower than Resistant starch, Stick rice and Brown rice group correspondingly. The lowest fecal crude protein apparent and true digestibility were found in Resistant starch group, which were 10.23%, 12.76%, 12.42% and 9.64%, 12.11%, 11.73% ($p < 0.05$) lower than Maize, Stick rice and Brown rice group, and also the digestibility of energy and dry matter of Resistant group were lower than other groups. When compared with other groups, Resistant starch group excreted the most fecal nitrogen ($p < 0.05$), while Stick rice had the highest urinary nitrogen excretion ($p < 0.05$), but the largest whole body nitrogen retention was found in Maize group. The results of blood biochemical parameters analysis indicated that, the change of post-prandial blood glucose, insulin concentration and insulin/ glucose in Resistant starch was stable, while other groups had larger fluctuation, 1h after the meal which reached the pinnacle, among them Stick rice group had the highest blood glucose, insulin concentration and insulin/ glucose in post-prandial 1h, they were 1.21mg/ml, 52.35(μ U/ml) and 43.27(μ U/ml) respectively, and were significantly higher than other groups ($p < 0.05$).

Key Words: Pig, Metabolism, Starch

W124 The effect of dietary starch sources on amino acids portal flux and balance in growing pigs. W. Wang, Y. Yin*, R. Huang, and T. Li, *Institute of Subtropical Agriculture, Changsha, Hunan, P. R. China.*

Four Duroc \times Landrace \times Yorkshire cross breed male pigs fitted with permanent catheters in the portal vein, mesenteric vein and in the carotid artery were used in a 4 \times 4 Latin square to measure the different effect of dietary starch sources on net portal absorption of blood glucose, volatile fatty acids (VFA), amino acids and lactate in growing pigs. When calculated as per 100g feed intake, 8h post-prandial maize group portal vein net absorbed 27.52g glucose, which was 54.26%, 7.88% and 1.55% higher than resistant starch, stick rice and brown rice respectively. Stick rice group absorbed 2.52g lactate and it was significantly higher than other groups ($P < 0.05$). In resistant starch group the portal vein absorbed blood ammonia was (5.36g) lower than other groups ($P < 0.05$), while the absorbed VFA (403.87mmol) was significantly higher than maize, brown rice and stick rice group. Portal vein net absorbed total amino acids of resistant starch, maize, brown rice and stick rice group were 5.93g, 8.89g, 8.77g and 7.83g, the lowest net portal vein absorption was found in resistant group. The proportion of net absorbed total amino acids in ileum apparent and true digested amino acids were 52.70% and 48.39%, which were lower than 67.66%, 65.83%, 63.62% and 63.76%, 61.80%, 59.18% of maize, brown rice and stick rice group ($P < 0.05$). The proportion of essential amino acids in absorbed total amino acids of resistant starch group was 50.0% it was also lower than 57.43%, 56.64%, 57.74% of maize, brown rice and stick rice respectively. Portal vein net absorbed Glu, Ser, His, Arg, Ala, Tyr, Meth, Val, Phe, Ile, Leu and Lys of resistant starch group and His, Arg, Tyr, Val, Meth, Lys and Leu of stick rice were lower than maize and brown rice group ($P < 0.05$). There are no significant difference between maize and brown rice group for most net absorbed amino acids, but His, Lys and Leu in maize group were higher ($P < 0.05$), while Arg was lower than brown rice group ($P < 0.05$). The balance pattern of portal vein net absorbed amino acids of maize group was better than other groups.

Key Words: Portal Flux, Amino Acid, Pig

W125 Intravenous glucose tolerance test in Ningxiang pigs. X. F. Kong¹, M. J. Bo¹, X. Y. Song¹, Y. L. Yin*¹, B. E. Tan¹, Z. Q. Liu¹, H. J. Xu¹, W. J. Tang¹, F. G. Yin¹, and G. Y. Wu^{1,2}, ¹*The Chinese Academy of Sciences, Changsha, Hunan, P. R. China,* ²*Texas A&M University, College Station.*

Intravenous glucose tolerance test was conducted with the Ningxiang pig (a Chinese swine breed), which has a relatively slow rate of growth and small body size. Four Ningxiang barrows (approximately 60 kg) with indwelling catheters in the hepatic vein and carotid artery were fasted for 12 h before use for the experiment. On d 1, at 10 min before saline infusion, as well as at 0, 5, 10, 20, 30, 60, 120, 180, and 240 min after saline infusion, blood samples (5 ml per barrow) were taken from the carotid artery into tubes containing sodium heparin. Meanwhile, urine samples from each of the animals were collected for glucose analysis. On d 2 and 3, saline and a 50% glucose solution were infused into the hepatic vein, respectively. Blood and urine samples were obtained as described above. Plasma was analyzed for glucose, insulin and glucagon. The insulin/glucose ratio was calculated for each sampling time. Results indicate that plasma concentrations of glucose at 5-10 min and those of insulin at 5-30 min post glucose infusion were greater ($P < 0.05$) than the values obtained after saline infusion. Intravenous glucose infusion increased ($P < 0.05$) the insulin/glucose ratio at 10-60 min but reduced ($P < 0.05$) plasma concentrations of glucagon at 30-60 min, when compared with saline infusion. Glucose was detected in urine beginning at 30 min after glucose infusion. These findings suggest that Ningxiang barrows may exhibit insulin resistance, which explains in part their relatively slow growth rate.

Key Words: Intravenous Glucose Tolerance Test, Indwelling Catheters, Ningxiang Barrows

W126 Evaluation of nutrient equivalency values of natuzyme for broiler chickens. M. Majdeddin*, M. Zaghari, and H. Moravej, *Tehran University, Karaj, Tehran, Iran.*

The experiment was conducted to determine the nutrient equivalency values of commercial multi enzyme (natuzyme) for broiler chickens. 480 day-old male commercial broiler chickens (Ross 308) were used from 1 to 28 days of age. The experimental design was completely randomized and the experimental units (pens) were allotted randomly to 8 treatments, each in 4 replicates. The dietary treatments 1 to 4 formulated without enzyme and contained graded levels of ME, CP and non-phytate phosphorus. The dietary treatments 5 to 8 have graded levels of multi enzyme 0.1 to 0.4 gr/kg diets respectively. Performance of chicks fed dietary treatments 1 to 4 and 5 to 8 compared with each other and calculated the total nutrient equivalency values of enzyme. Body weight, group feed consumption and viability was recorded weekly. Toe ash Ca, P and Ca, P and protein content of excreta were measured at day 28. Data was analyzed using the general Liner and non-liner model procedure of SAS software. Final body weight for treatments 1 to 4 was increased ($p < 0.05$). Addition of enzyme increased final body weight ($p < 0.05$). Liner relationship between ME, CP, non- phytate phosphorus, enzyme and body weight in 28 day-old was observed ($p < 0.05$). The result showed that added enzyme (0.4 gr/Kg diets), increased availability of energy, crude protein and phosphorus, 2.8, 3.1 and 19.8 % respectively. The effect of age on nutrient equivalency was not significant.

Key Words: Equivalency, Broiler, Natuzyme

W127 In vitro fermentation of diets incorporating different levels of carob pulp by rabbit cecal fluid. G.-B. Aziza^{*1}, B. Ridha¹, K. Abdelhamid², M.-L. Maria-Rosa³, and K. Abdeljabbar¹, ¹*INAT, Tunis, Tunisia*, ²*INGREF, Institut National des Recherches en Génie Rural, Eaux et Forêts, Tunis, Tunisia*, ³*Escuela Polytechnica Superior, Universidade de Santiago de Compostela, Lugo, Spain*.

Fermentation characteristics of diets incorporating 0% (D1), 10% (D2), 20% (D3) and 100% (D4) dry matter (DM) of carob pulp were determined in an in vitro experiment using cecal contents collected from 4 rabbits. Samples of diets were incubated in glass syringe for 72 h and various fermentation variables were determined. Diets varied in their crude protein and fermentable carbohydrates. Potential gas production ranged from 123 (D3) to 179 (carob pulp) ml/g DM and was similar ($P > 0.05$) for D1, D2 and D3. Low value of pH after 72 h fermentation was observed in D4 (carob pulp: 6.47), and the highest was in diet incorporating 10% of carob pulp (6.66). Of all diets, carob pulp was fermented the most rapidly and had higher ($P < 0.05$) organic matter digestibility (64.3%) than D1 (62%), D2 (60.3%) and D3 (58.6%). In vivo studies will be conducted to validate the in vitro results.

Key Words: Carob Pulp, Rabbit, Gas Production

W128 Dietary fiber decreases fecal nutrient digestibility and ammonia emission in growing swine, but increases odor emission and odor intensity in air. W. Zhang¹, E. van Heugten^{*1}, T. van Kempen², V. Fellner¹, and P. Kai³, ¹*North Carolina State University, Raleigh*, ²*Provimi RIC, St. Stevens Woluwe, Belgium*, ³*University of Aarhus, Horsens, Denmark*.

This study was designed to determine the effects of dietary fiber on nutrient digestibility and emission of ammonia and odor compounds in air. Diets consisted of a low fiber diet (degermed, dehulled corn and soy protein isolate), a semi-low fiber diet (corn and soy protein isolate), a typical commercial diet (corn and SBM), and a high fiber diet (corn and SBM with 10% soy hulls), containing 2.8, 8.9, 7.6, and 13.6% NDF, respectively. The study consisted of 4 replicates. For each replicate, 40 pigs (BW=20.3±0.98 kg) were allotted by weight into 4 groups of 10 pigs and were adjusted to the diets for 14 days. Pigs were then transferred into one of 4 identical air-flow controlled (316 m³ per h) odor chambers (3.0 × 2.4 × 2.0 m) with fully slatted floors and pit recharge. Pigs remained in the chambers for 6 days prior to measurements. Total reduced sulfur (TRS) in exhaust air was measured using a Jerome meter and ammonia was measured by trapping in sulfuric acid. Air samples were collected in 10 L Tedlar bags for odor detection threshold evaluation by 8 panelists. Odor compounds were adsorbed using SPME fibers and analyzed by GC/MS. Fecal digestibility of CP, ADF, NDF, and GE was reduced ($P < 0.05$) with increasing fiber. Ammonia emission decreased with increasing dietary fiber (1.35a, 0.63bc, 0.78b, 0.49c ppm; means without a common letter denote differences at $P < 0.05$). Peak area for acetic acid (6.42a, 6.61a, 6.78ab, 7.26b), propionic acid (6.49a, 6.85a, 7.23b, 7.39b), butyric acid (6.74a, 6.89a, 7.54b, 7.69b), phenol (5.78a, 5.96a, 6.14ab, 6.65b), concentration of TRS (4.21a, 4.88ab, 7.92c, 8.50cd ppb), and odor intensity (144a, 174ab, 208ab, 251b) increased ($P < 0.05$) with increasing dietary fiber, but p-cresol, indole, and skatole were not affected. In conclusion, increasing dietary fiber reduced nutrient digestibility, increased odorous compounds and odor intensity of air, but it reduced ammonia emission.

Key Words: Ammonia, Fiber, Odor

W129 Effects of different fiber level diets on normal microbiological floras in goose intestines. M. A. Zhang, B. W. Wang^{*}, B. Yue, F. Y. Long, X. P. Wu, and X. H. Jia, *Qingdao Nongye University, Qingdao, Shandong Province, China*.

Different levels (5% and 9%) of *Leymus Chinesis* were appended in the diets to study normal microflora in the intestine of adult geese. The quantitative method of diluted inoculability was used to study the effect of different proportion of *Leymus Chinesis* on normal microbiological flora in four parts (duodenum, jejunum, ileum and caecum) of goose intestines. The results showed that the number of dominant bacterial flora was relatively large, when the content of CF was 9% in the diet, pH of intestine chyme in CF 9% group was lower than CF 5% group ($P < 0.01$). It indicated that increasing the content of *Leymus Chinesis* power in the diets could decrease intestine pH, thus the acid environment was good for the fermentation of intestine microorganisms. It made sure that the dominant bacterial floras were *Bifidobacterium* (8.21±0.8cfu/g), *Clostridium* (7.98±0.4cfu/g) and *Lactobacillus* (7.33±0.4cfu/g). The isolation efficiency of *Staphylococcus* and *Bacteroides* was the lowest. The number of cecum bacteria was significantly larger than the other intestine bacteria ($P < 0.01$). The total number of intestine bacteria in crude fiber (CF) 9% group was larger than in CF 5% group ($P < 0.01$), and that of ganders was larger than that of geese ($P < 0.05$). In this trial, the number of bacteria in intestine secretion of geese was 10⁶ cfu/g~10⁸cfu/g. The results also showed that in the intestine of geese, fungi had the best ability to decompose crude fiber, the following was actinomycetes and the worst was bacterium ($P < 0.01$).

Key Words: Goose, Intestines, Cellulose

W130 Stabilized rice bran improves weaning pig growth performance when feed in an antibiotic-free diet. T. Herfel, S. Jacobi, X. Lin, and J. Odle^{*}, *North Carolina State University, Raleigh*.

Stabilized rice bran (SRB) is classified as a functional food because of its prebiotic characteristics. With increasing corn prices and the possible removal of antibiotics from swine diets due to concern over antibiotic resistance, SRB was investigated as a replacement for corn with and without the addition of antibiotics (ANT). Two hundred pigs were weaned at ~21 days of age, blocked by weight, and allotted to diets containing 0 or 10% SRB and (-) or (+) ANT according to a 2 × 2 factorial design. Five animals were housed per pen throughout a 28 day growth period. At the end of the trial, one pig from each pen was euthanized for measurement of intestinal parameters. Antibiotic supplementation improved average daily gain by 6.3% from day 14 to 28 ($P < 0.05$). Gain:feed improved by 22% in pigs fed the ANT-free + 10% SRB diet compared to pigs fed the ANT-free + 0% SRB diet ($P < 0.05$), but was similar to pigs fed diets containing antibiotics. Cumulatively, pigs fed the ANT-free + 10% SRB diet improved gain:feed by an average of 14% compared to all other treatments ($P < 0.05$). Ileal histology revealed a 28% decrease in crypt depth for pigs fed the ANT-free + 10% SRB and ANT + 0% SRB diets compared to the ANT + 10% SRB diet ($P < 0.05$). Villi length: crypt depth (V:C) decreased due to SRB (23%) and ANT (22%) supplementation ($P < 0.05$). Differences in ileal and cecal digesta short chain fatty acid concentrations were not detected. In conclusion, SRB appears to improve the efficiency of nutrient utilization with only modest alterations in ileal mucosal morphology. Further research is warranted to elucidate the underlying mechanism by which SRB effects are mediated.

Key Words: Stabilized Rice Bran, Antibiotics, Gastrointestinal

W131 Linseed oil addition alters swine adipose fatty acid composition. A. A. AbuGhazaleh*, G. Apgar, and W. Brown, *Southern Illinois University, Carbondale.*

Previous studies have shown that including linseed oil (LSO) in swine diets increase the omega-3 fatty acids (FA) content in adipose tissues. The objective of this study was to determine the effect of the duration of LSO supplementation on omega-3 FA content in adipose tissues. Ninety six pigs (48 barrows and 48 gilts) with an average weight of 30 kg ± 3.7 were used in this study. Pigs were allotted to four dietary treatments (4 barrows and 4 gilts per pen with 3 pens per treatment) on the basis of body weight using a randomized complete block design. The four dietary treatments were: 1) conventional corn-soybean meal diet + 3% saturated fatty acid source (DM basis; CONT), 2) conventional corn-soybean meal diet + LSO at 3% (LS), 3) CONT diet fed until pigs reached a target weight of 60 kg ± 2.5 then switched to the LSO diet (LSO1) and 4) CONT diet fed until pigs reached a target weight of 80 kg ± 2.5 then switched to the LSO diet (LSO2). Pigs feed intake and growth performance were measured every 2 weeks. Pigs were slaughtered once they reached a target weight of 100 ± 5 kg. Samples of adipose tissues were dissected at the 10th rib and analyzed for the concentration of FA. Treatment diets had no effects (P > 0.10) on weight gain, back fat, marbling or color. Pigs on the LS diet tended (P < 0.13) to have lower feed intake (2.26 kg/d) when compared with other treatment diets (2.61, 2.49, and 2.72 kg/d for the CONT, LSO1 and LSO2 diets, respectively). The concentrations of C16:0 and C18:0 were higher (P < 0.10) while the concentration of C18:2n6 was lower (P < 0.10) with the CONT and LSO2 diets when compared with the LS and LSO1 diets. The concentrations of C18:3n3 were higher (P < 0.10) with the LS (8.73% of total FA) and LSO1 (8.49%) diets when compared with the CONT (3.13%) and LSO2 (4.57%) diets. The n6/n3 FA ratios were lowered (P < 0.10) with the LSO supplementations averaging 3.68, 2.78, 1.76 and 1.63 with the CONT, LSO2, LSO1 and LS diets, respectively. In conclusion, LSO supplementation altered the FA profiles of adipose tissues without compromising pigs performance and such alteration is affected by the duration of LSO consumption.

Key Words: Linseed Oil, Fatty Acids

W132 Influence of glycerol and added fat on finishing pig performance. A. W. Duttlinger*, M. D. Tokach, S. S. Dritz, J. M. DeRouchey, J. L. Nelssen, and R. D. Goodband, *Kansas State University, Manhattan.*

A study was conducted to determine the effects of dietary glycerol and fat on finishing pig performance. The experiment was conducted at a commercial swine research facility in southwest MN in August, 2007. Glycerol was procured and stored in the feed mill for approximately 60 d before diets were mixed. A total of 1,093 pigs (PIC, initially 77.7 kg) were used in a 28-d study. Pigs were blocked by initial weight and randomly allotted to 1 of 6 dietary treatments with 7 replications per treatment. Pigs were fed corn-soybean meal-based diets arranged in a 2 × 3 factorial with main effects of glycerol (0, 2.5, or 5%) and added fat (0 or 6%). Overall (d 0 to 28), there was a fat × glycerol interaction (P < 0.04) for ADFI. As added glycerol increased, ADFI was not influenced in diets containing added fat; however, ADFI was reduced when increasing levels of glycerol were added to diets without fat. Pigs fed diets with added fat had improved (P < 0.01) ADG and G:F compared

with pigs fed diets with no added fat. Increasing glycerol decreased ADG (linear, P < 0.02) and ADFI (linear, P < 0.04) and tended (linear, P < 0.11) to decrease G:F which was due to the negative impact when added to diets without fat. In conclusion, 6% added fat improved ADG and G:F, but the glycerol used in this study decreased ADG and ADFI when added to diets without added fat. The storage of glycerol before use may have contributed to the negative impact on performance in this experiment.

Table 1.

Item	Added Fat, %:			Glycerol, %:			SE
	0	0	0	0	2.5	5	
ADG, kg	0.84	0.81	0.76	0.92	0.90	0.91	0.02
ADFI, kg	2.90	2.92	2.74	2.87	2.82	2.85	0.04
G:F	0.29	0.28	0.28	0.32	0.32	0.32	0.01

Key Words: Fat, Glycerol, Pigs

W133 Conjugated linoleic acid and tryptophan supplementation improve immune response of weaned piglets. J. Morales¹, R. Gatnau², and C. Pineiro*¹, ¹*PigCHAMP Pro Europa, SA, Segovia, Spain,* ²*Molimen, Barcelona, Spain.*

Conjugated linoleic acid (CLA) is a natural product that enhances immune function while decreasing the negative effects of inflammatory responses. This effect is especially interesting at weaning, when piglets are highly susceptible to enteric diseases. On the other hand, aminoacidic profile of proteins affecting the immune system is different than muscle proteins, especially higher Trp: Lys ratio. The aim of this study was to assess the effect of CLA in combination with two different Trp:Lys ratios in weaned piglets in a low-health status nursery unit. Therefore, there were four treatments arranged factorially with 2 CLA dietary contents (0 vs 1%) and 2 Trp:Lys dietary ratios (0.15 vs 0.22). For the experiment, 336 piglets were used (7.6 ± 1.78 kg BW) and allotted in 48 pens. Average daily gain (ADG), feed intake and feed efficiency were controlled. Fecal consistency was assessed at 56 d of age (scale 0-normal, 1-soft, 3-diarrhea). During the trial period an acute outbreak of diarrhea occurred but, under these special circumstances, CLA supplementation improved ADG 80% (P=0.0001) and FGR 44% (P<0.001). Consequently, CLA supplemented piglets reached significantly higher final BW (13.5 vs 10.9 kg; P<0.001) than control piglets. Higher dietary Trp: Lys ratio allowed expressing CLA improvements in performance (P interaction < 0.10 in ADG). On the other hand, Trp also improved ADG (170 vs 155 g/d; P=0.02). Mortality rate was not significantly affected, but in the total nursery period the highest risk group (0% CLA & low Trp content) showed the highest % of mortality (10.7%; P=0.02). Fecal consistency was only affected by CLA supplementation, which reduced the signs of diarrhea (0.9 vs 1.8; P=0.001). We conclude that 1 % of CLA supplementation improved ADG, clinical symptoms and decreased the number of animals that needed to be treated during an acute outbreak of diarrhea in the nursery period. Furthermore, higher dietary Trp content facilitates the expression of the CLA effect, demonstrating compatibility and certain synergy between both (CLA and Trp).

Key Words: Conjugated Linoleic Acid, Tryptophan, Piglet

W134 Effect of conjugated linoleic acid on immune function and nutrition composition of duck. B. W. Wang*, Y. C. Wang, M. A. Zhang, B. Yue, L. Z. Jing, X. X. Wei, and G. L. Liu, *Qingdao Nongye University, Qingdao, Shandong Province, China.*

The experiment was conducted to study the effects of different grades of dietary Conjugated linoleic acid (CLA) on immune function and nutrition composition of duck. Two hundred and forty healthy Cherry Valley Ducks of one day old with the similar body weight were selected ($P > 0.05$), and divided into four treatment groups according to one-factor completely random design, with six replications each group and ten ducks each replication. The proportion of CLA in the basal diets was 0%, 1%, 2% and 3% respectively. The whole trial period was 56 days. Sterile blood collecting from each 12 ducks in every group, centrifuging, separate loading, to determine the Cellular Immunity Index, the antibody titer of Avian influenza and the content of Cytokines IL-2. Then slaughter the animal to determine indexes of immune organs on the day of 14, 28, 42 and 56. On the day of 42 and 56 the nutrition related index was carried on. The results showed that 1% and 2% CLA diets increased the indexes of the thymus and Fabricius's gland in different period ($P < 0.05$); 2% CLA diets increased the antibody titer of Avian influenza significantly at the 6th weekend ($P < 0.05$), 1% and 2% CLA diets increased the rate of lymphocyte transformation and the number of E-rosette ring; increased the content of IL-2 significantly after 4 weeks ($P < 0.05$). CLA reduced the percentage of abdominal fat and Subcutaneous fat percentage ($P < 0.05$ or $P < 0.01$), and 2% CLA diets increased the breast muscle percentage significantly at the 6th weekend ($P < 0.05$); 1% and 2% CLA diets increased the content of fat and saturated fatty acids in fatty acids of CLA diets was increased significantly in breast muscle ($P < 0.05$), and reduced significantly that of unsaturated fatty acids ($P < 0.05$). The results indicate that, CLA did promotion on the development of immune organs, increased the function of Humoral immunity and Cellular Immunity, regulate the immunity of meat duck effectively; and CLA did definite function of nutrition redistribution. The proper percent of CLA in diets was 2%.

Key Words: CLA, Meat Duck, Immune Function

W135 Efficiency of retention and conversion of α -linolenic acid (ALA) to other n-3 fatty acids (FA) in the whole body of growing gilts is reduced over time. H. R. Martínez-Ramírez* and C. F. M. de Lange, *University of Guelph, Guelph, ON, Canada.*

Fifteen gilts were used in a serial slaughter study to determine the rate of ALA retention; ALA conversion to other n-3 FA, including eicosapentaenoic acid (EPA), docosapentaenoic acid (DPA) and docosahexaenoic (DHA); and ALA disappearance. A corn-barley-soybean meal based diet with 10% flaxseed, containing 2.0% ALA, was fed for 30 d to pigs between 27.7 ± 1.9 and 45.7 ± 2.2 kg BW. Feed intake was fixed at 70% of ad libitum intake according to NRC (1998). Body composition was determined at initial, intermediate (d 15; 39.2 ± 1.4 kg) and final BW in 4, 6 and 5 pigs, respectively. At slaughter on d 15 and 30 digesta was sampled for measurement of apparent ileal fat digestibility, which was used as an estimate of ALA availability. Disappearance of ALA was calculated as the difference between available ALA intake and the sum of ALA retention and ALA conversion to other n-3 FA. At the initial BW (2516 g of body fat), the content of ALA, C18:4n-3, C20:3n-3, C20:4n-3, EPA, DPA and DHA was 0.79, 0.09, 0.10, 0.02,

0.04, 0.09 and 0.14% of body fat, respectively. Whole body content of individual n-3 FA increased linearly from d 0 to 30 ($P < 0.01$), except for DHA. Expressed as a portion of ALA intake, ALA retention declined numerically from 64% (day 0 to 15) to 49.8% (day 15 to 30; $P = 0.11$). Similarly, conversion of ALA to C20:3n-3 (7.06 vs. 4.29%), C20:4n-3 (0.60 vs. 0.34%), and DHA (1.07 vs. 0.33%) was reduced over time ($P < 0.05$), while disappearance of ALA tended to increase over time (3.07 vs. 22.02%; $P = 0.074$). Conversion of ALA to EPA (1.14 vs. 1.51%) and DPA (2.36 vs. 2.04%) did not change over time ($P > 0.10$). The rate of conversion of ALA to C20:3n-3 was much higher in this experiment than reported in other animals and humans and should be explored further. The rate of whole body n-3 FA catabolism appears to increase over time. Based on this study, feeding ALA to pigs only leads to modest increases in contents of EPA, DPA and DHA in the pig's body.

Key Words: Omega 3 Fatty Acid, Elongation, Growing Pigs

W136 Effects of betaine, conjugated linoleic acid or both on nutrient digestibility of growing Iberian gilts. I. Fernandez-Figares*, L. Gonzalez Valero, J. M. Rodriguez-Lopez, R. Nieto, L. Manuel, and J. F. Aguilera, *CSIC (Spanish National Research Council), Granada, Spain.*

We have demonstrated that betaine and CLA show a synergistic effect on growth rate and protein deposition in growing Iberian gilts (Fernandez-Figares et al., 2008). No difference on protein digestibility was encountered between treatments but no information on amino acid digestibility was available. The aim of the present study was to assess if betaine or CLA had an effect on apparent faecal amino acid digestibility of Iberian gilts. Twenty gilts (20 kg BW) were individually penned and fed barley-soybean meal based diets (12% CP, 0.81% lysine and 14.8 MJ ME / kg DM) containing either no added betaine or CLA (control), 0.5% betaine, 1% CLA, or 0.5% betaine + 1% CLA, at 95% *ad libitum* energy intake. At 30 kg BW, a balance experiment was conducted where animals were individually housed in metabolic cages placed in a controlled environment room to allow for separate collection of faeces and urine. Pigs were moved to the cages 3 d before starting excreta collection and fit with a self-retaining urethral catheter for urine collection. Total collection of faeces and urine was performed daily for 4 d. Aliquot samples of faeces and urine representative of total daily faecal output and of total urine were stored at -20°C and was then freeze-dried and finely ground for further analysis. Total nitrogen was determined by the Kjeldahl procedure. Dry matter content and total ash were carried out by standard procedures. Gross energy determination was measured in an adiabatic bomb calorimeter. Amino acids were determined after protein hydrolysis in 6 M HCl plus 1% phenol in sealed tubes at 110°C for 24 h, by HPLC according to the Waters Pico Tag method. The treatment effect was assessed by ANOVA and treatment means were compared by Duncan's procedure. Significance was set at $P < 0.05$. Digestibilities of DM, OM, GE, total nitrogen, total amino acids and ME (0.819, 0.836, 0.808, 0.771, 0.809 and 0.793, average values, respectively) were not affected by dietary treatments ($P = 0.27$ to 0.51). The synergistic effect of betaine and CLA on protein deposition must be exerted at tissue level and not at digestive level.

Key Words: Betaine and CLA, Pig, Amino Acid Digestibility

W137 Effects of dietary coconut fat powder supplementation on performance, nutrient digestibility and blood and milk characteristics in lactating sow. W. T. Kim*¹, H. J. Kim¹, J. H. Cho¹, Y. J. Chen¹, J. S. Yoo¹, S. O. Shin¹, Y. Haung¹, J. D. Hancock², C. Y. Lee³, and I. H. Kim¹, ¹Dankook University, Cheonan, Chungnam, Korea, ²Kansas State University, Manhattan, ³Jinju National University, Gyeongnam, Korea.

A total of thirty sows (Landrace×Yorkshire) were used to determine the effects of dietary coconut fat powder supplementation on performance, nutrients digestibility and blood and milk characteristics. A feeding trial was conducted for 21 days from parturition to weaning. Experimental diets were supplied for 1 week before the parturition day and throughout the experimental period. Dietary treatments included: 1) CON (basal diet), 2) CFP (basal diet added 0.5% coconut fat powder) and 3) CFH (basal diet added 0.5% coconut fat powder containing husk). Average daily feed intake was significantly improved ($P < 0.05$) in CFP and CFH treatments compared with CON treatment. Backfat loss was significantly lower ($P < 0.05$) in CFP and CFH treatments than CON treatment. Compared with CON treatment, final body weight, weight gain and average daily gain in piglet were significantly increased ($P < 0.05$) in CFP and CFH treatments. Red blood cell was significantly increased ($P < 0.05$) in CFH treatment compared with others. White blood cell at the final period and lymphocyte at the final period were significantly increased ($P < 0.05$) in sows fed coconut fat powder diet. At the final period, milk fat concentration was significantly improved ($P < 0.05$) in CFP and CFH treatments compared with CON treatment. Milk protein concentration was significantly higher ($P < 0.05$) in CFP treatment than CFH treatment at the initial period and was significantly lower ($P < 0.05$) in CFP and CFH treatments than CON treatment at the final period. Milk lactose concentration at the initial period was significantly increased ($P < 0.05$) in CFH treatment compared with CON and CFP treatments. On diarrhea rate in piglet, three piglets presented diarrhea in CON treatment from 0 to 5 days. Explanation should be the intestines of newborn piglets were not developed yet. However, none diarrhea occurred in all treatment from 5 to 20 days. In conclusion, dietary fat source from coconut supplementation improved feed intake, backfat loss, RBC, WBC and lymphocyte in sow and weight gain in piglet.

Key Words: Coconut, Nutrient Digestibility, Sow

W138 Use of glycerol for glucose, glycogen and non-essential amino acid synthesis by embryos from small and large chicken eggs. N. E. Sunny, J. Moorefield, S. L. Owens, and B. J. Bequette*, *University of Maryland, College Park.*

The objective was to determine the contribution of glycerol to glucose, glycogen and non-essential amino acid (NEAA) synthesis by d 14 and d 19 chicken embryos derived from small (56.6 ± 0.88 g) and large eggs (71.7 ± 1.09 g). After setting the eggs, small and large eggs were each divided into 2 groups (d 14 and d 19, $n = 7$ per group), after which [¹³C₃]glycerol (14 mg in 75 μ L H₂O) was administered into the chorio-allantoic fluid for 4 consecutive days prior to tissue and blood collection on d 14 and 19 embryonic. Blood and tissues were analyzed by GC-MS for ¹³C-mass isotopomer enrichments in blood glycerol, glucose, and NEAA, and liver and muscle glycogen. At both embryonic ages, [¹³C₃]glycerol administration led to the synthesis of [M+1], [M+2] and [M+3] isotopomers in blood glucose and liver and muscle glycogen. In d 14 embryos, ¹³C-isotopomer enrichments (moles ¹³C-isotopomer/100 moles ¹²C-isotopomer) were higher ($P < 0.05$) in small vs. large egg embryos

for blood glucose ([M+1]; 3.6 vs. 2.1, [M+2]; 3.7 vs. 2.2, [M+3]; 2.6 vs. 1.4) with a similar trend for liver and muscle glycogen. Compared to d 14 embryos, blood glucose ¹³C-isotopomer enrichments from d 19 embryos were 2-fold higher ($P < 0.05$), suggesting a greater reliance on glycerol for gluconeogenesis. There was also synthesis of [M+1], [M+2] and [M+3] isotopomers of alanine, aspartate and glutamate, the latter two of which were more highly enriched ($P < 0.05$) in liver. This study provides unequivocal evidence that glycerol is a major precursor for glucose synthesis by chicken embryos and that the indirect pathway of glycogen synthesis is a major metabolic route in the liver and the muscle for glycogen synthesis.

Key Words: Embryo, Chicken, Metabolism

W139 The effect of feeding omega-3 fatty acids during the grower and early finisher phases on intramuscular fatty acid composition at market weight in pigs. S. A. Meers*, C. R. Dove, T. D. Pringle, and M. J. Azain, *University of Georgia, Athens.*

The objective of this study was to determine the effects of feeding a diet containing omega-3 fatty acids during the grower and/or early finish phases on intramuscular fat content and fatty acid composition of loin muscle. The study was designed as a 2 × 2 factorial arrangement, with main effects of fat (Control, C or Omega-3, O) and diet phase (Grower, G d0-35, or Early Finisher, EF d35-70). All pigs were fed a common Late Finisher (LF, d70-98) diet. Diets were corn-SBM based: G (17.9% CP, 1.0% lys), EF (17.0% CP, 0.9% lys), & LF (15.9% CP, 0.8% lys). Omega-3 fatty acids were supplemented by adding 2% fish oil (Virginia Prime Gold, Omega Protein, Houston, TX) to the G and EF diets. Soybean oil (2%) was used as the control in G, EF, and common LF diets. Pigs ($n=92$, initial BW 29.3 kg) were allotted by gender and weight to pens where C or O diet treatments were assigned at random. There were no effects of diet on overall growth performance. There was a trend for 19% greater lipid content in loin from pigs fed the O diet relative to the C diet (5.03 vs 4.23%, $P < 0.10$). Pigs fed the O diet had lower loin concentrations of linolenic acid (0.32%, $P < 0.01$) and greater concentrations of EPA (1.03%, $P < 0.0001$), DPA (0.62%, $P < 0.006$), and DHA (0.91%, $P < 0.0001$) when compared to C fed pigs (0.44%, 0.16%, 0.38%, and 0.05% respectively). The addition of fish oil to the diet decreased the n-6/n-3 ratio in loin muscle (C 17.7 vs O 3.4, $P < 0.0001$). A 100-g loin sample from pigs fed the O diet in G and EF contained greater amounts of total n-3 fatty acids (112 vs 31 mg, $P < 0.0001$) and greater EPA & DHA (64 vs 5.6 mg, $P < 0.0001$) relative to that found in loin from C fed pigs. It should also be noted that despite dietary differences, there were no diet effects on the percent of saturated fatty acids ($37.7\% \pm 1.11\%$) or the iodine value (77.86 ± 3.35) in the loin muscle. These results demonstrate that feeding diets with 2% fish oil during the G & EF phases, followed by a withdrawal period, results in an increase in the omega-3 content and a trend for greater intramuscular fat in loin muscle.

Key Words: Fish Oil, Omega-3 Fatty Acids, EPA

W140 Effect of different dietary protein levels on lipid metabolism of subcutaneous adipose tissue in lean-type and fat-type fattening pigs. W. T. Gu¹, T. L. Liu², P. W. Xu¹, M. J. Bo¹, H. J. Xu¹, Y. L. Yin^{*1}, X. F. Kong¹, T. J. Li¹, Z. Q. Liu¹, W. J. Tang¹, and R. L. Huang¹,

¹The Chinese Academy of Sciences, Changsha, Hunan, P.R.China,
²Wuhan Polytechnic University, Wuhan, China.

Thirty six Duroc × Landrace × Yorkshire hybrid (lean-type) and twenty seven Ninxiang breed (fat-type) fattening pig were individually housed in metabolic cages and randomly allocated into three groups, fed each of three diets for 46-day periods. The corn and soybean meal-based diets included 10%,13% and16% protein levels for Ninxiang breed, and 13%,16% and 19% protein levels for hybrid, respectively, and each diet were identical in calories as fat. The effects of those diets on serum lipoprotein, cholesterol, triglyceride and leptin levels, and subcutaneous adipose tissue lipogenesis and lipolytic gene mRNA expression in two breed pigs were detected. With the increasing protein levels, serum triglyceride and leptin levels in hybrid breed were increased (quadratic; $p < 0.05$), while in Ninxiang breed, 16% group (493.00 ± 37 pg/mL) had higher serum leptin levels than 10% group (117.00 ± 46 pg/mL) ($p < 0.05$), but serum triglyceride levels was not significantly effected. The abundance of Acetyl-CoA carboxylase (ACC) mRNA in subcutaneous adipose tissue of hybrid breed was increased (linear; $p < 0.05$) but was not significantly changed in Ninxiang breed with the increasing of protein levels. The subcutaneous adipose tissue leptin mRNA abundance of Ninxiang breed was reduced (quadratic; $p < 0.05$), and the expression of leptin mRNA was positive correlated with the abundance of liver × receptor LXR in both breed ($p < 0.05$). The abundance of sterol regulatory element-binding protein (SREBP-1) mRNA of two breed tend to increase. Our findings suggest that different dietary protein levels alters the energy homeostasis of fattening pig, thereby effect the expression of key enzymes and related genes of lipid metabolism (mainly ACC and leptin) in order to regulate the lipid synthesis and secretion in subcutaneous adipose tissue. Furthermore, different dietary protein may act on nuclear transcription factors LXR/SREBP-1 directly or indirectly via leptin signaling.

W141 Cloning and characterization of porcine adipose triglyceride lipase (pATGL) gene. T. Shan, Y. Wang*, T. Wu, J. Guo, G. Yao, J. Feng, and Z. Xu, Zhejiang University, Hangzhou, P. R.China.

Adipose triglyceride lipase was recently identified as a major novel triglyceride lipase in animals. In this study, we aimed to study the tissue- and development- specific expression of porcine adipose triglyceride lipase (pATGL) in pigs, and the effect of resveratrol on expression of pATGL in vitro. The full-length cDNA sequences of pATGL was 1958 bp (accession no: EF583921), with an Open Reading Frame (ORF) of 1458 bp encoding 486 amino acids protein (the predicated molecular mass of 53.2 kDa, accession no. ABS58651). Comparison of the deduced amino acid sequence with the bovine, mouse, rat, dog and human adipose triglyceride lipase showed 87%, 84%, 83%, 81% and 80% similarity, respectively. Furthermore, The pATGL was highly expressed in porcine adipose tissue, to a lesser degree in kidney, heart, and muscle, and lowest but detectable in brain. In subcutaneous adipose tissue, the pATGL mRNA was very low at birth (1 kg body weight), and kept increasing postnatal, reaching a maximal value ($P < 0.01$) at 20 kg body weight (about 7 weeks old). Similarly, in peritoneal and omental adipose tissue, the highest expression of pATGL was observed at 40 kg body weight (about 14 weeks postnatal). Finally, administration of 40 μ M resveratrol and 80 μ M resveratrol for 24 h increased ($P < 0.05$) the mRNA levels of pATGL in cultured adipocytes by 95.3% (mean value = 1.95) and 146.8% (mean value = 2.47), respectively. Accordingly, lipid accumulation was decreased ($P < 0.05$) by 25.7% (mean value = 0.051) and 60.8% (mean value = 0.027), respectively. When treated with resveratrol for 48 h, the mRNA levels of pATGL were increased ($P < 0.05$) by 104.1% (mean value = 2.04) and 163.1% (mean value = 2.63), respectively. And 80 μ M resveratrol treatment decreased ($P < 0.05$) the lipid accumulation by 29.0% (mean value = 0.055). These data would be helpful for manipulating fat deposition via controlling adipose triglyceride lipase expression, thus improving meat quality.

Key Words: Gene Expression, Porcine Adipose Triglyceride Lipase (pATGL), Resveratrol

W142 Mathematical simulation to assess the validity of Bonnier's equation for estimating the frequency of monozygous twinning in a population of Holstein cattle. N. Silva del Río*¹, G. A. Broderick², and P. M. Fricke¹, ¹University of Wisconsin, Madison, ²US Dairy Forage Research Center, Madison, WI.

Twin calving records (n = 96,069) were extracted from MN DHIA (1996 to 2004) to estimate the incidence of monozygous twinning (MZ) and to evaluate the impact of varying the twin sex ratio and frequency of same-sex twins (SST) on estimates of MZ calculated using Bonnier's equation. Bonnier's equation: $m = 2npq - n^2 / 2pq(n - n^2)$, estimates the proportion of MZ among SST (m) based on total opposite-sexed twin (OST) pairs (n₂) and the observed proportions of male (p) and female (q = 1 - p) calves among all twin births. Bonnier's equation assumes the sex of one twin is independent of the other, therefore, similar proportions of SST and OST would be expected in the absence of MZ. We hypothesized a dramatic decrease in Bonnier's estimate of MZ if SST comprised a smaller proportion of a population than reported. Based on our study, 56.4% of twin calves were SST, and 51.9% were male. The estimates of MZ were calculated by simulating a reduction of SST of 5% (54.2% SST) or 10% (52.0% SST), whereas the proportion of male calves born as twins was 51.9% (observed) or simulated to be 50% (Table 1). Estimates of MZ were greater than expected based on observed outcomes of MZ (Silva del Río et al., *Therio.* 66:1292; 2006). We conclude that slight changes in the percentage of SST dramatically affect MZ estimates using Bonnier's equation, whereas the percentage of male calves born as twins has a minimal impact. Thus, if factors other than MZ affect the proportion of SST, such as oocyte maturity, vaginal and uterine pH, or hormonal estrous synchronization, then Bonnier's equation will inaccurately estimate the frequency of MZ.

Table 1. Estimation of monozygous twinning as a percentage of all twins using Bonnier's equation for observed and simulated percentages of same-sex twins (SST) and proportion of male calves born as twins.

SST (%)	Male calves born as twins (%)	
	51.9 (observed)	50.0
56.4 (observed)	11.6	11.3
54.2	7.9	7.8
52.0	3.9	3.9

Key Words: Bonnier's Equation, Monozygous Twins, Holstein Cattle

W143 Activated caspase-3 activity in the bovine fetal ovary. N. M. Barkley*, M. F. Smith, and H. A. Garverick, *University of Missouri, Columbia.*

During early bovine fetal development there is a 170 fold increase in germ cells from d 50 to d 110 followed by a rapid decline of germ cells by d 170 and even fewer remaining germ cells by birth. The objective of this study was to determine if the decline in germ cell numbers in fetal bovine ovaries from d 110 to d 170 can be attributed to apoptosis by characterizing active caspase-3 (effector of apoptosis) positive cells in fetal bovine ovaries from d 60–260 of gestation. Ovaries were dis-

sected from fetuses upon slaughter and fetal age was estimated based on crown-rump length. Following dissection, ovaries from each animal were fixed in 4% paraformaldehyde (pH 7.6) and embedded in paraffin. Ovaries were sectioned at a thickness of 5 µm. Activated caspase-3 protein localization was characterized by immunohistochemistry. Two serial sections from each animal were stained and all positive cells on each section were counted, classified as either germ cells or non-germ cells, and averaged. The mean positive cells for each time period (d 60-80, 100-120, 130-150, 170-180, 190-210, and 240-260; n ≥ 4 animals per time period) were determined. Germ cells were distinguished based upon morphology, location within the tissue, and association with follicular cells. The mean values were transformed in SAS, due to heterogeneity in variance, to determine differences across the time periods of gestation. However, the reported values are the means prior to transformation. The mean numbers of active caspase-3 positive cells per section were 63^{ab}, 156^a, 38^{ab}, 16^b, 25^b, and 11^b for d 60-80, 100-120, 130-150, 170-180, 190-210, and 240-260, respectively (^{ab} $P < 0.05$). Analysis of only germ cells showed 18.3^{abc}, 50.4^a, 13.9^{ab}, 3.3^{cd}, 6.1^{bcd}, and 0.1^d positively stained cells per section for d 60-80, 100-120, 130-150, 170-180, 190-210, and 240-260, respectively (^{abcd} $P < 0.05$). The greatest amount of caspase-3 activity occurred prior to d 150 of gestation. Thus, the sharp decline in germ cell numbers from d 110 to d 170 can, in part, be attributed to apoptosis.

Key Words: Bovine, Fetal Ovary, Caspase

W144 Multiple fibroblast growth factors stimulate interferon-tau production in bovine trophectoderm. K. A. Pennington* and A. D. Ealy, *University of Florida, Gainesville.*

Maintenance of early pregnancy in bovids depends on interferon-tau (IFNT) secretion from trophectoderm. Fibroblast growth factor 2 (FGF2) stimulates IFNT production in bovine blastocysts and a trophectoderm cell line (CT1). Several FGF receptors (FGFR) exist in the bovine conceptus, including FGFR2IIIb, a receptor subtype implicated in regulating placental development in several species. Multiple ligands for this receptor, notably FGF1, 7 and 10, are produced in bovine and ovine endometrium during early pregnancy. The objective was to determine if these uterine FGFs increase IFNT production in bovine trophectoderm. In study 1, CT1 cultures were incubated in medium containing 0, 0.05, 0.5, 5, 50 and 500 ng/mL of recombinant (r) bovine (b) FGF1, r human (h) FGF7, or rhFGF10. All cultures contained carrier protein (500 µg/mL BSA). RNA was extracted 24 h later and quantitative RT-PCR was used to determine IFNT mRNA abundance relative to an internal control (18s RNA). Four replicate experiments were completed. IFNT mRNA concentrations increased ($P < .05$) at 50 ng/mL rbFGF1 (5.9 ± 0.9 fold induction over non-treated controls), 50 ng/mL rhFGF7 (5.4 ± 0.2 fold induction) and 500 ng/mL rhFGF10 (8.4 ± 0.5 fold induction). In study 2, CT1 cultures were supplemented with various amounts of rbFGF1 or rhFGF10. rhFGF7 was not included in this study. Media were collected 48 h later and antiviral assays were completed to quantify IFNT protein concentrations. Five replicate experiments were completed. IFNT concentrations in conditioned medium increased ($P < .05$) in cells exposed to 50 ng/mL FGF1 (766.8 ± 266.1 pg/mL) and 500 ng/mL FGF10 (389.0 ± 185.5 pg/mL) compared with controls (56.3 ± 5.3 pg/mL). In conclusion, various FGFs can act on bovine trophectoderm to regulate IFNT mRNA and protein production. Further work is required to address the functional implications of these findings. W145 Identification and characterization of three MX1 isoforms in sheep. D. S. Clark^{*1}, K Williams², and T. L. Ott¹, ¹*Pennsylvania State University, University Park*, ²*University of Idaho, Moscow*.

Ruminant conceptuses produce interferon tau (IFN tau) during early pregnancy which increases expression of the myxovirus resistance gene, MX1, in the uterus. The role of MX1 in pregnancy is not known, but its role in the immune response is well-characterized. Kojima, et al. (2003) showed MX1 isoforms existed in cattle. In this study we characterized MX1 isoform expression in the sheep uterus. Sequence analysis of amplicons generated using a common set of MX1 primers in ovine endometrial cell lines revealed three isoforms that differed in their 5' regions. Full-length sequences for each isoform were generated. Compared to the published sequence (Accession # X66093:MX1a) one isoform contained an 18 base deletion (MX1b) and the other an insertion of 186 bases (MX1c). Computer-assisted translation of MX1b resulted in a protein lacking 6 amino acids near the amino terminus. An early stop codon in MX1c caused a 27 amino acid exchange on the amino terminus. Sequence differences occurred at the boundary between putative exon 3 and exon 4, suggesting the isoforms may be splice variants. We developed a quantitative, real-time PCR assay to distinguish each isoform. All three isoforms were identified in ovine uterine luminal epithelial (oLE) and stromal (oSC) cell lines. Interestingly, only two of the isoforms, MX1a and MX1c, were detectable in glandular epithelial (oGE) cells and sheep endometrium. Levels of MX1c mRNA were roughly 1000-fold greater and did not change with the application of IFN tau in any cell line. However, levels of MX1a and MX1b strongly increased in response to IFN tau in oLE (> 300-fold at 6 hours). In endometrial RNA from pregnant ewes, MX1a mRNA levels increased approximately 17-fold, while MX1c levels did not change. We have yet to confirm the presence of proteins representing each putative splice variant *in vivo*, but those experiments are ongoing. Results suggest that three splice-variants of MX1 mRNA are present in sheep, and that, unlike MX1a and MX1b, MX1c is highly abundant and is not regulated by IFN tau.

Key Words: Sheep, Uterus, Interferon

W146 Effects of nutrient restriction during early gestation on postnatal calf growth. C. L. Bailey^{*}, N. M. Long, M. J. Prado-Cooper, E. C. Wright, and R. P. Wettemann, *Oklahoma Agricultural Experiment Station, Stillwater, OK*.

Effects of prenatal nutritional restriction on postnatal growth of calves were evaluated in Angus \pm Hereford heifers (15 mo). Heifers were AI with semen from a single Angus sire in each of 3 yr. At 32 \pm 0.5 d after insemination, pregnancy was verified and heifers were stratified by BW and BCS and allotted to low or moderate nutrition (L, n = 25, fed 55 %; M, n = 25, fed 100% NRC 1996 requirements). After 83 \pm 3 d of treatment (115 d of gestation) heifers were commingled and received a common diet (100% NRC). Bulls were castrated at birth and calves

were weaned at 229 \pm 8 d of age. Data were analyzed using PROC MIXED procedures of SAS. There were no year \times treatment effects. At treatment BW ($P = 0.16$) and BCS ($P = 0.21$) were similar for L and M heifers. After treatment, M heifers had greater BW ($P < 0.001$; 487 kg) and BCS ($P = 0.006$; 5.49) compared with L heifers (373 kg, SE = 10; 4.38, SE = 0.14). At calving, BCS did not differ ($P = 0.20$) for M and L heifers (5.05 vs. 4.64, SE = 0.24). Length of gestation was not influenced by treatment ($P = 0.50$; 274 and 275 d for L and M, respectively). Birth weights were similar ($P = 0.75$) for L and M calves (32 and 33 kg, respectively). Weight of calves at weaning (222 kg, SE = 5) was not influenced by treatment ($P = 0.81$). Glucose in plasma of calves at birth (80 and 79 mg/dL for L and M, respectively, SE = 7) was similar between treatments ($P = 0.93$). Cortisol in plasma of calves at birth (57 and 73 ng/mL for L and M, respectively, SE = 9) was not influenced by treatment ($P = 0.20$). Prenatal nutritional restriction of heifers that resulted in 1.1 BCS units difference at 115 d of gestation did not influence gestation length, birth weight, weaning weight, or plasma concentrations of glucose and cortisol in calves at birth.

Key Words: Prenatal Nutrition, Calves, Growth

W147 Effects of nutrient restriction during early gestation on carcass and organ weights of beef steers. N. M. Long^{*}, M. J. Prado-Cooper, C. R. Krehbiel, U. Desilva, and R. P. Wettemann, *Oklahoma State University, Stillwater*.

Angus \times Hereford heifers (15 mo of age) were used to evaluate the effect of prenatal nutritional restriction on tissues and organs of 22 mo old steers. At 32.0 \pm 0.5 d after AI with semen from one sire, pregnancy was verified and heifers were stratified by BW and BCS and allotted to low (L, fed 56 % of NRC requirements) or moderate (M, fed 100% NRC requirements) nutrition. After 83 d of treatment, heifers were commingled and received a common diet (100% of NRC requirements). Bull calves were castrated at birth and maintained as a group before and after weaning. At 16 mo of age, L (n = 5) and M (n = 5) steers were fed a high concentrate diet and gained 2.2 \pm 0.1 kg/d to an average BW of 550 kg. Steers were harvested and weights of the empty body, heart, lungs and trachea, spleen, kidney, liver, pancreas, and the gastrointestinal tract were recorded. Samples of organs, muscle (complexus), subcutaneous fat (SubQ), and KPH were stored at -80 $^{\circ}$ C and DNA in tissue was quantified using Hoechst H33258 dye. RT-PCR was utilized to evaluate abundance of mRNA for genes involved in fatty acid metabolism in SubQ and KPH. Low steers had greater (2.41 \pm 0.51 g; $P = 0.05$) total DNA in the pancreas compared with M steers (1.64 \pm 0.51 g) and KPH from L steers tended ($P = 0.09$) to have increased concentrations of DNA compared with M steers. Concentrations of DNA in the other organs and SubQ fat were not influenced by treatment. Muscle fiber area was increased ($P = 0.04$) in L steers compared with M steers (1824 \pm 76 vs 1336 \pm 44 μm^2 , respectively) and concentrations of DNA were greater ($P = 0.04$) in muscle from L steers than M steers. Abundance of RNA for fatty acid binding protein 4, fatty acid translocase and GLUT 4 was decreased in KPH from L steers compared with M steers. Nutritional restriction during early gestation increased muscle fiber area and decreased abundance of RNA for genes involved in fatty acid and glucose transport in KPH of steers at 22 mo of age.

Key Words: Steers, Organs, Gene Expression

W148 Effect of age at first calving on milk production and days open in first-parity Iranian Holstein dairy cows. A. Heravi Mous-savi*, M. Danesh Mesgaran, and R. Noorbakhsh, *Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran.*

Age at first calving (AFC) is one of the important factors contributing to economic return and is determined partially by farmer policy. The aim of this study was to evaluate the effect of age at first calving on milk production and days open in first-parity Iranian Holstein dairy cows. Calving data were collected during 1996 until 2006 in seven large commercial Holstein farms. During the period the median number of cows in the study herds was 500. Farms were located in northeastern Iran and were enrolled in the official milk-recording scheme. Each cow was characterized by demographic data (birth date, sire, first calving date), production data (cumulative first 60 and 200 days milk productions), and reproduction data (days open). The dependent variables analyzed were the cumulative first 60 and 200 days milk production, and days open. The AFC was included in the model with 23 levels (from 17 to 40 mo, one per month). Data were analyzed using General Linear Models using the statistical software package JMP. Age at calving averaged 27.23 ± 3.37 month. The median was 26 mo and 25% and 75% quartiles were 25 and 28 mo, respectively. Its distribution showed almost a bell shape. Age at first calving decreased from 1996 to 2006 ($P < 0.01$). The cumulative first 60 and 200 days milk production was impacted by AFC ($P < 0.001$) and the milk yields were increased in greater AFC. Days open was similar among different levels of AFC. The results of this study demonstrate that milk yields increased with increasing AFC, but the AFC had no apparent impact on the interval from calving to conception. The

results also demonstrated that mean AFC is higher than the optimum age at first calving and can be decreased by 4 months.

Key Words: Dairy Cows, Age at First Calving, Days Open

W149 Changes in muscle proteome of dairy cattle with onset of lactation. P. J. Tyler*, K. A. Cummins, D. M. Carpenter, and R. Sabharwal, *Auburn University, Auburn, AL.*

An experiment was conducted to evaluate changes in the muscle proteome of dairy cows before and after the onset of lactation. Samples ($n = 3$ cows) of semi-tendinosus muscle were taken under local anesthesia either 7 d before expected calving date (mean 7.2 d) or 10 d after calving. Samples were subjected to two-dimensional gel electrophoresis in triplicate and stained with Sypro Ruby (Bio-Rad). Gel images were captured on a Typhoon 9410 (Amersham, Piscataway, NJ) and were processed with PD Quest software (Bio-Rad, version 8.0.1) for spot detection and expression quantification. The data were imported into the SAS statistical software (Version 9.1) for statistical differential protein expression analysis. There were a total of 613 spots detected in the union from all gels. Of these, 206 spots were matched in all 9 pre-calving gels, 251 matched in all 9 post-calving gels and 183 were matched across all 18 gels. Of the 183 commonly expressed spots, twenty-eight showed statistically significant ($P < 0.05$) differential expression, with 9 down-regulated and 19 up-regulated between pre- and post-calving. Significant changes occur in the muscle proteome of lactating dairy cattle with the onset of lactation.

W150 Immunosterilization of bitches with an anti-LHRH vaccine using CpG ODN as an adjuvant. R. Zanella¹, M. Ragagnin de Lima^{*4}, J. J. Reeves¹, V. Conforti², D. DeAvila¹, A Ferreira Marques⁴, S. A. Messina¹, R Bogden³, and E. L. Zanella⁴, ¹Washington State University, Pullman, ²Cincinnati Zoo & Botanical Garden, Cincinnati, OH, ³Amplicon Express, Pullman, WA, ⁴Universidade de Passo Fundo, Passo Fundo, RS, Brazil.

There are around 400 million street dogs in the world (WSPA), generating serious sanitary and welfare problems. Currently, contraceptive methods used in dogs are surgical spaying or neutering procedures or hormone treatments. However, the surgical methods are irreversible, and hormone treatments can cause undesirable side effects. Immunosterilization using an anti-LHRH vaccine has been tested in cattle, goats, and sheep, resulting in reproductive sterilization. Luteinizing hormone-releasing hormone (LHRH) immunization causes reproductive sterilization by disrupting the hypothalamic-pituitary-gonadal axis through immunoneutralization of LHRH. The objective of this study was to evaluate the effect of LHRH immunization with cytosine guanine oligodeoxynucleotide (CpG ODN 2006) as an immunostimulant in female dogs. Fourteen (n = 14) healthy, adult female dogs were used. Animals were randomly assigned in two treatment groups (n = 7 dogs/group): A) two injections of ova-LHRH with CPG ODN, 50 d apart (1 mg total dose); B) two injections of CpG ODN, 50 d apart (negative control). The effect of the vaccine was evaluated by comparing the proportions of females that showed estrous behavior and became pregnant. Four months after immunization, all dogs in group A and B that presented estrous behavior were bred. In Group B, 4 dogs displayed estrous behavior and became pregnant delivering 20 puppies. In Group A, one dog (out of 2 that displayed estrous) became pregnant with 3 puppies. The t-test result showed a difference between puppies born/treatment ($P < 0.02$). Although this vaccine was not 100% efficient in preventing pregnancy, our results suggest that LHRH immunization with CpG ODN reduced estrous activity and fertility rates in female dogs.

Key Words: LHRH Vaccine, Immunosterilization in Dogs, CpG ODN

W151 Ovarian follicular dynamics during the interovulatory interval in Najdi goats. H. Kohram^{*1,2}, S. Gooraninejad², A. Motaghedi², G. Mohammadi², and E. Dirandeh¹, ¹Tehran University, Karaj, Tehran, Iran, ²Shahid Chamran University, Ahvaz, Khoozestan, Iran.

The purpose of the present study was to characterize follicular dynamics during the estrous cycle in najdi goats. Najdi goats (n = 5) were synchronized with 2 im injections of prostaglandin F2a given 11 d apart (estrus = d 0). Ovarian follicular development was monitored daily by real-time ultrasonography using a B-mode instrument with a 7 MHz linear-array transducer. The mean (\pm SEM) interovulatory interval for the five najdi goats was 20.6 ± 0.9 d. The follicular patterns included either four (n = 2) or five (n = 3) follicular waves per cycle and the mean number of follicular waves in najdi goats was 4.6 ± 0.5 . The mean (\pm SEM) diameters of the largest follicles were 5.6 ± 0.8 , 5.6 ± 0.5 , 6.0 ± 1.7 , 7.0 ± 1.8 , and 5.2 ± 0.4 for first through fifth follicular waves, respectively. The mean (\pm SEM) appearance day of follicular wave was -0.8 ± 1.1 (n = 5); 3.2 ± 0.4 (n = 5); 7.0 ± 0.6 (n = 5); 12.3 ± 1.7 (n = 5); and 13.0 ± 1.6 (n = 3) for first to fifth follicular waves, respectively (n = number

of goats). Dominant follicles reached their maximum diameter on d 2.9 ± 1.5 , 7.6 ± 0.6 , 12.2 ± 1.4 , 16.7 ± 2.1 , and 18.6 ± 0.5 of the estrous cycle and the intervals from follicular wave emergence to dominant follicle maximum diameter were 4.3 ± 1.6 , 4.2 ± 1.3 , 4.3 ± 1.4 , 4.3 ± 1.4 , and 4.4 ± 1.4 d for first through fifth follicular waves, respectively. During the fourth and fifth follicular waves the maximum diameters of the dominant follicles were 7.7 ± 0.8 and 5.2 ± 0.4 , respectively. Najdi goats ovulated in average 1.8 ± 0.4 follicles per estrous cycle. Our results suggest that follicular growth in najdi goats is a dynamic process, and the development of ≥ 2 mm follicles occurs in waves. However, during each wave a single follicle becomes dominant whereas other follicles in the same wave regress.

Key Words: Goats, Follicles, Real-Time Ultrasonography

W152 Alteration of ovarian follicular dynamics by GnRH in water buffaloes. H. Kohram^{*1,2}, G. Mohammadi², and E. Dirandeh¹, ¹Tehran University, Karaj, Tehran, Iran, ²Shahid Chamran University, Ahvaz, Khoozestan, Iran.

The objective of the present study was to evaluate the ovarian response of buffaloes to GnRH injections given at different moments of the estrous cycle. The estrous cycles of 15 buffaloes were synchronized with 2 im injections of prostaglandin F2a \pm given 11 d apart. The buffaloes were randomly assigned to 1 of 3 treatments. Buffaloes in the control treatment received no treatment, whereas G6 buffaloes received a GnRH injection between d 5 and 7 and G16 buffaloes received a GnRH injection between d 15 and 17 of the estrous cycle (estrus = d 0). Daily, from estrous cycle d 0 to the next estrous cycle d 23, cows had their ovaries scanned by ultrasound. All follicles were classified in to 4 to 6 mm, and ≥ 7 mm follicles. Data were analyzed using the GLM procedure of SAS. In the three treatments, the number of 4 to 6 mm follicles had a declining trend from d 1 and reached their smallest amount on d 4 and 5 ($P < 0.05$). Thereafter, the number of this class of follicles in the control, G6 and G16 treatments increased until d 8, 10 and 6, respectively ($P < 0.05$). In response to an injection of GnRH, the number of small follicles in treatment G6 and G16 increased on d 9 and 18, respectively. Again, the number of small follicles increased in the control and G6 treatments from d 15 and 19, respectively, to d 21 of the estrous cycle. The number of ≥ 7 mm follicles had an increase ($P < 0.05$) until d 3 in the control and d 5 in the G6 and G16 treatments. In the G6 treatment of buffaloes, GnRH injection on d 6 increased ($P < 0.05$) the number of large follicles on d 10. The number of ≥ 7 mm follicles in the two treatments (control and G6) increased between d 17 and 19 of the estrous cycle. An increase the number of small and medium sized follicles 2 d after GnRH injection showed that an injection of GnRH at the beginning or later days of the estrous cycle could promote the emergence of a new follicular wave in buffaloes.

Key Words: Buffaloes, Follicles, Real-Time Ultrasonography

W153 Effects of oral doses of colostrum on luteal regression and synchronization of estrus in dairy heifers. S. L. McKee^{*}, S. P. Washburn, and C. S. Whisnant, North Carolina State University, Raleigh.

A 1984 study indicated an effect of 900 ml of oral colostrum on lowering milk progesterone (P4) in cattle, presumably due to estrogens and prostaglandin metabolites in colostrum. The objective of this experiment was to examine responses of cyclic dairy heifers to oral colostrum in comparison to untreated heifers or those receiving prostaglandin F2 α (PGF). The pooled, frozen-thawed colostrum used was either high (\approx 6 L) or medium (\approx 18 L) quality based on a colostrometer (Biogenics-Mapleton, OR). Heifers (n = 29) were Holsteins, Jerseys, or crossbreds of both breeds with mean BW = 287 \pm 11 kg. A corpus luteum (CL) was identified for each heifer with use of ultrasound; average CL diameter = 2.9 \pm 0.1 cm. Heifers were assigned at random to 1 of 4 treatment groups: T1 -untreated control (n = 7); T2-positive control, 25 mg PGF i.m. (n = 7); T3-1 L oral colostrum (n = 7); or T4 -2 L oral colostrum (n = 8). Colostrum was administered using an esophageal tube and pump. Ultrasound measurements and blood samples were collected before treatment, and 1 and 4 d after treatment to determine changes in CL size and serum P4 concentrations. Heifers received tailhead paint and were observed for estrus twice daily. All 7 heifers receiving PGF (T2) came into estrus within 4 d after treatment (2.8 \pm 0.2 d) whereas only 3 heifers from T1, 2 heifers from T3, and 3 heifers from T4 were detected in estrus within 6 d after treatment. All heifers detected in estrus had P4 \geq 2.0 ng/ml at treatment which declined after treatment. In contrast, the 14 heifers not observed in estrus by 6 d had concentrations of P4 \geq 2.0 ng/ml at treatment and 1 and 4 d after treatment. All PGF-treated heifers responded with a decline in P4 and subsequent estrus whereas responses among the 15 heifers that received colostrum were similar to the 7 untreated heifers. This trial does not support the hypothesis that oral doses of 1 to 2 L of colostrum enhance luteal regression. It is not known whether use of colostrum of higher quality or at higher doses would be more effective.

Key Words: Colostrum, Synchronization, Heifers

W154 Plasma progesterone concentrations determined by commercial radioimmunoassay kit as puberty criteria for Brahman-crossbred heifers. R. F. Cooke^{*1,2}, B. R. Austin², and J. D. Arthington¹, ¹University of Florida - IFAS, Range Cattle Research and Education Center, Ona, ²University of Florida - IFAS, Animal Sciences, Gainesville.

Concentrations of plasma progesterone (P4) greater than 1.0 ng/mL are often used as puberty criteria for beef heifers. Prepubertal Brahman-crossbred heifers may have P4 concentrations above this level, decreasing the accuracy of puberty determination in heifer development studies. The objective of this experiment was to evaluate three different plasma P4 concentrations (1.0, 1.5 or 2.0 ng/mL) as puberty criteria for Brahman-crossbred heifers. A total of 960 blood samples were collected, concurrently with assessment of ovarian luteal tissue via trans-rectal ultrasonography, from 37 Braford and 43 Brahman \times Angus heifers. Plasma samples were analyzed for P4 concentrations using a Coat-A-Count Kit (DPC Diagnostic Products Inc., Los Angeles, CA) solid phase ¹²⁵I RIA. Puberty was determined by detection of ovarian luteal tissue and elevated plasma P4 concentrations. Only data from prepubertal heifers were evaluated (630 of 960). Data were analyzed using the GLM procedure of SAS. A puberty criteria \times breed interaction was detected ($P < 0.05$). Increasing puberty criteria from 1.0 to 1.5 ng/mL decreased ($P < 0.01$) the incidence of false positives in Brahman \times Angus heifers; approximately 15 % (41 of 265) of false positives were

detected for 1.0 ng/mL, 6% (17 of 265) of false positives were detected for 1.5 ng/mL, and 4% (10 of 265) of false positives were detected for 2.0 ng/mL. Increasing puberty criteria from 1.0 to 1.5 or 2.0 ng/mL decreased ($P < 0.01$) the incidence of false positives in Braford heifers; approximately 33% (121 of 365) of false positives were detected for 1.0 ng/mL, 18% (65 of 365) of false positives were detected for 1.5 ng/mL, and 10% (37 of 365) of false positives were detected for 2.0 ng/mL. In conclusion, the adoption of 1.5 and 2.0 ng/mL of plasma P4 concentrations as puberty criteria for Brahman \times Angus and Braford heifers, respectively, decreased the incidence of false positives and appear to be appropriate for assessment of puberty in heifer development studies using these types of cattle.

Key Words: Brahman-Crossbred Heifers, Progesterone, Puberty Criteria

W155 Progesterone concentration during follicular development affects follicular fluid composition and uterine release of PGF2 α in dairy cows. R. L. A. Cerri^{*1,2}, F. Rivera², C. D. Narciso², R. A. Oliveira², R. C. Chebel², M. A. Amstalden³, W. W. Thatcher¹, and J. E. P. Santos¹, ¹University of Florida, Gainesville, ²University of California, Tulare, ³Texas A&M University, College Station.

Two experiments evaluated the influence of progesterone (P4) concentrations on follicular fluid content and circulating prostaglandin (PG) F metabolite (PGFM). Cows were pre-synchronized and then assigned to 1 of 2 synchronization protocols on d 7 of the estrous cycle: high progesterone (HP): modified Ovsynch (GnRH+CIDR, 7 d PG+CIDR removal, 2 d GnRH); and low progesterone (LP), similar to HP, but with additional PG injections on d 2, 2.5 and 3 of estrous cycle preceding the Ovsynch, and on d 0, 2, 2.5 and 3 relative to the first GnRH of the Ovsynch. Ovaries were evaluated by ultrasonography, and blood analyzed for concentrations of P4 and estradiol (E2). In experiment 1 (Exp 1; n = 20), blood was analyzed for LH concentrations every 15 min for 3 h on d 5 of the Ovsynch. The dominant follicle (DF) was aspirated 48 h after PG and the follicular fluid (FF) analyzed for P4, E2, and free and total IGF-1. In experiment 2 (Exp 2; n = 26), follicular development, and P4 and E2 concentrations were measured until d 16 after the Ovsynch, when cows were challenged with estradiol/oxytocin and PGFM measured. In Exp 1 and Exp 2, HP cows had less plasma E2 and greater P4 ($P < 0.001$) and smaller ($P = 0.005$) DF diameter during the Ovsynch than LP. In Exp 1, concentration of LH tended ($P = 0.10$) to be less for HP than LP (0.79 vs. 0.93 ng/mL). Concentrations of P4 in the FF were similar, but HP had less ($P = 0.005$) E2 than LP (330.9 vs. 387.5 ng/mL). Free IGF-1 was similar ($P = 0.15$) for HP and LP (5.23 vs. 3.53 ng/mL), but total IGF-1 was greater ($P = 0.02$) for HP than LP (51.7 vs. 40.8 ng/mL). In Exp 2, plasma concentrations of E2 and P4 did not differ ($P = 0.34$) between treatments after the Ovsynch. Proportion of cows with a short luteal phase was less for HP (0%) than LP (25%). Concentrations of PGFM were less ($P < 0.05$) for HP than LP at 90 and 120 min after the oxytocin challenge. Reduced P4 concentrations during Ovsynch altered follicular dynamics, FF composition and E2 concentrations, and exacerbated PG release in the subsequent estrous cycle when plasma P4 and E2 were comparable between treatments.

Key Words: Dairy Cow, Progesterone, Prostaglandin

W156 Evidence that the diminished production of progesterone during estrous cycles of cattle with a low antral follicle count during follicular waves is repeatable and not caused by alterations in size of the corpus luteum. F. Jimenez-Krassel*¹, J. K. Folger¹, G. W. Smith¹, P. Lonergan², A. C. O. Evans², and J. J. Ireland¹, ¹Michigan State University, East Lansing, ²University College Dublin, Dublin, Ireland.

The mechanisms that regulate the variation in progesterone (P) production in animals, which may contribute to infertility, are poorly understood. Previous results demonstrate that cattle can be phenotyped reliably based on antral follicle count (AFC) during ovarian follicular waves, and that cattle of similar ages with low versus high AFC not only have a diminished ovarian reserve (number of healthy eggs) and higher FSH concentrations, but lower serum P concentrations during estrous cycles. Based on these observations, animals with a low AFC are hypothesized to have smaller corpora lutea (CL) which have a correspondingly reduced capacity to produce progesterone during consecutive estrous cycles. To test this hypothesis, beef heifers (10-12 mo; 392 ± 14 kg) with low (≤15 follicles > 3 mm in diameter) or high (>25 follicles) AFC during follicular waves were identified and synchronized with two injections of prostaglandin F2α (PG) spaced 11-d apart. After the second PG injection, blood samples were collected daily until 14 d after ovulation. This estrus synchronization and blood sampling regimen was repeated three times during three different estrous cycles. CL size was measured by daily ultrasonography during the second estrous cycle. Although P concentrations were similar within groups during each estrous cycle, P was much higher ($P < 0.05$) from Day 3 to 14 and increased at a greater rate ($P < 0.05$) after ovulation during each of three consecutive estrous cycles for animals with a high versus low AFC. However, CL size did not differ ($P > 0.1$) between groups. Taken together, these results indicate that despite similarity in CL size, the capacity of the CL to produce P is diminished during several different estrous cycles for animals with relatively low versus high AFC. Whether the low circulating progesterone concentrations cause or contribute to infertility in cattle with low AFC during follicular waves and correspondingly low ovarian reserve is unknown. Project supported by NRI Competitive Grant no. 2007-35203-18178 from the USDA-CSREES to JJI.

W157 Protocols using progesterone intravaginal device for lactating Holstein cows. R. M. Santos*¹, D. G. B. Demétrio², J. L. M. Vasconcelos², B. L. Cardoso², F. M. Abreu², L. H. Cruppe², and S. Soriano³, ¹EAFUDI, Uberlândia, ²FMVZ-UNESP, Botucatu, ³Fazenda Colorado, Araras, Brazil.

Studies in Brazil with dairy cows maintained on pasture, show that the protocol using an estradiol benzoate (EB) plus progesterone intravaginal device for 9 d results in a higher synchronization rate than the Heatsynch protocol. The objective of this study was to evaluate ovulation and conception of high producing cows maintained in a free stall barn treated with 2 different protocols. Lactating Holstein cows ($n = 637$) producing 37.9±9.64 kg milk/d and with 178.1±150 DIM, were randomly assigned to receive one of 3 treatments: Group 1 ($n = 270$): cows received AI 12 h after estrous detection; Group 2 (Heatsynch; $n = 248$): CIDR insertion (CIDR® 1.9 mg Pfizer) + GnRH (1 mL Fertagyl® Intervet) - 7 days - CIDR removed + PGF2α (5 mL Lutalyse® Pfizer) - 24h - Estradiol Cypionate (0.5 mL ECP® Pfizer), and Group 3 ($n = 119$):

CIDR insertion + EB (2 mL Estrogin® Farmavet) - 7 days - PGF2α (5 mL Lutalyse®) + 2 days - CIDR removed + Estradiol Cypionate (0.5 mL ECP®). Cows that showed heat received AI 12 h later and the remaining were TAI 48 h after the ECP injection. Presence of CL at d 7 (ovulation rate) and pregnancy 28 d after AI were evaluated by ultrasound. The variables ovulation, conception of all cows and ovulated cows were analyzed by the logistic model to evaluate the influence of the covariates (DIM, milk yield, parity, and treatment) on the probability of success. The ovulation rate was not affected by treatment ($G1=92.2$; $G2=92.7$; $G3=87.4\%$), but was negatively affected by parity ($P < 0.05$) and DIM ($P < 0.01$). The conception rate of all cows ($G1=22.6$; $G2=30.2$; $G3=19.3\%$) and ovulated cows ($G1=24.5$; $G2=32.6$; $G3=22.1\%$) was affected by treatment ($P < 0.05$) and DIM ($P < 0.05$). These results show that the protocol Heatsynch can increase conception in lactating dairy cows. This result is probably because the development of the ovulatory follicle occurs in higher progesterone concentration, due to formation of corpus luteum after GnRH injection, since no difference in ovulation rate was observed.

Key Words: Synchronization, Conception, Dairy Cows

W158 Effects of high vs. low progesterone concentrations during Ovsynch on double ovulation rate and pregnancies per AI in high producing dairy cows. A. P. Cunha*, J. N. Guenther, M. J. Maroney, J. O. Giordano, A. B. Nascimento, S. Bas, H. Ayres, and M. C. Wiltbank, University of Wisconsin, Madison.

The aim of this study was to evaluate if starting Ovsynch in a low progesterone (P4) environment (Short group) vs. a high P4 environment (Long group) would alter double/multiple ovulation rates (DOV) and pregnancies/AI (P/AI) in high producing dairy cows. Holstein cows ($n = 514$) from 2 different dairy farms were assigned to two groups in a CRD design. Cows were presynchronized before the breeding Ovsynch with an Ovsynch72 protocol (GnRH-7d-PGF-3d-GnRH) but no TAI was performed. This presynchronization Ovsynch allowed initiation of the breeding Ovsynch on a known day of the cycle. Cows then began Ovsynch immediately (the 2nd GnRH of the Ovsynch72 was the 1st GnRH of the breeding Ovsynch) (Short; $n = 259$) or cows received the 1st GnRH of the breeding Ovsynch 1 wk later (Long; $n = 255$). Ovarian ultrasound and blood samples were performed in order to assess ovulation, pregnancy diagnosis, and circulating P4 concentrations. As expected, cows in the Long had much higher P4 than cows in the Short at the 1st GnRH of the breeding Ovsynch (1.84ng/mL vs 0.28ng/mL) and higher P4 at the PGF treatment (4.40ng/mL vs 2.23ng/mL). Long and Short groups showed similar ovulation rate to the last GnRH of the breeding Ovsynch (94.5% vs 95.1%). The DOV was much greater in Short than Long (21.0% vs 7.1%; $P < 0.05$). Overall P/AI (at Day 29 pregnancy diagnosis) was much greater in Long than Short (48.2%, $n = 255$ vs 33.2%, $n = 259$; $P < 0.01$). Surprisingly, pregnancy loss (between d 29 to 57) was also less in Long than Short (4.3% vs 15.6%; $P < 0.05$). Thus, high P4 (Long protocol) during follicle development dramatically reduces selection of co-dominant follicles reducing double ovulation rate. In spite of ovulating fewer follicles, cows treated with the long protocol had better fertility than the Short providing strong evidence for the importance of high P4 during Ovsynch. Thus, the Long protocol may both reduce twinning rate and increase fertility during timed AI.

Key Words: Conception Rate, Fertility

W159 Effect of the third use of CIDRs on the pregnancy rate of beef cattle. W. A. Greene* and M. L. Borger, *The Ohio State University, Wooster, OH.*

The objective of this study was to determine the effect of the third use of intra-vaginal progesterone inserts (CIDRs), as a part of a synchronization program, on pregnancy rates (PR) in beef cattle. One hundred and twenty-two animals were allotted to two similar groups, new CIDR (N) and used CIDR (U), based upon breed, age, postpartum interval, and postpartum cyclicity (as determined by ultrasonography). All cattle received 100 µg GnRH im on d 0. Also on d 0, cattle in the N group received a new CIDR, containing 1.38 g progesterone, while U group cattle received a CIDR previously used for two 7 d periods. On d 7, jugular blood samples were collected for plasma progesterone (P₄) analyses, CIDRs were removed, and all animals received 25 mg PGF_{2α} im. Each removed CIDR was evaluated for signs of vaginal infection and scored from 1 to 5 (1 = clear, 5 = heavy pus). Animals were observed for estrus 0700 and 1900 and were bred by AI 11 - 13 h after estrus was observed. If estrus was not observed, animals were timed AI and received 100 µg GnRH im 70 - 72 h after PGF_{2α}. Following the synchronization period, repeat breedings were done until d 60. Cows were pregnancy diagnosed by ultrasonography on d 88. N and U groups had similar ($P > 0.05$) estrus detection rates [EDR] (59.0 and 62.3%). The N group had higher ($P < 0.05$) PR to synchronization (54.1 vs. 31.2%) and overall PR (91.8 vs. 73.8%) than the U group. Cycling ($n = 86$) and anestrus animals had similar ($P > 0.05$) EDR (66.3 and 47.2%), PR to synchronization (44.2 and 38.9%), and overall PR (87.2 and 72.2%). Cattle with high vaginal scores (4 & 5, $n = 90$) and low vaginal scores (1, 2, and 3) had similar ($P > 0.05$) PR to synchronization (43.3 and 38.7%) and overall PR (82.2 and 83.9%). The rates of high vaginal scores were similar ($P > 0.05$) for the N and U groups (78.3 and 70.5%). Mean P₄ levels (ng/ml) at CIDR removal were similar ($P > 0.05$) for N (1.1 ± 0.8) and U (1.1 ± 1.1) cattle. The third use of CIDRs in a beef cattle synchronization program resulted in lower pregnancy rates than the use of new CIDRs.

Key Words: Synchronization, CIDR Reuse, Progesterone

W160 Effect of the timing of CIDR insertion on the GnRH-induced LH surge and ovulatory response. G. A. Perry* and B. L. Perry, *South Dakota State University, Brookings.*

Elevated concentrations of progesterone have been reported to reduce the magnitude of a GnRH-induced LH surge, and GnRH is frequently used to induce ovulation and synchronize a follicular wave at the start of estrous synchronization protocols. Therefore, the objective of this study was to determine the effect of elevated concentrations of progesterone, from a CIDR, on the GnRH-induced LH surge and ovulatory response. Angus cross beef heifers ($n = 112$) were assigned to one of three treatments. Heifers received an injection of GnRH: 1) at CIDR insertion (CIDR-0), 2) 6 h before CIDR insertion (CIDR-6), or 3) 48 h after CIDR insertion (CIDR+48). Follicle size was determined prior to GnRH, and ovulatory response (follicle disappearance) was determined 2 d later. Blood samples were collected from a subset of heifers ($n = 60$) at 0, 30, 60, 90, 120, 150, 180, 210, 240, 300, and 360 min after GnRH. At time of GnRH, heifers that had initiated estrous cycles had greater ($P < 0.02$) concentrations of progesterone compared to periparturient heifers, and CIDR+48 (3.3 ± 0.6 ng/mL) had greater ($P < 0.01$) concentrations of progesterone compared to CIDR-0 (1.2 ± 0.6 ng/mL) and tended ($P = 0.1$) to be greater than CIDR-6 (1.9 ± 0.7 ng/mL) heifers.

There was no effect ($P = 0.2$) of cycling status on induction of ovulation (29/41 and 42/72 for periparturient and cycling). Ovulation was induced in more ($P < 0.05$) CIDR-0 (26/38) and CIDR-6 (28/37) heifers compared to CIDR+48 (17/38) heifers. There was no influence ($P = 0.19$) of treatment on concentrations of LH during the GnRH-induced LH surge, but there was an effect ($P < 0.01$) of progesterone. Heifers having elevated concentrations of progesterone at time of GnRH had a reduced LH surge compared to heifers with decreased concentrations of progesterone. However, there was no difference ($P = 0.11$) in the magnitude of the LH surge between heifers that did and did not ovulate. In summary, elevated concentrations of progesterone at time of GnRH decreased the GnRH-induced LH surge, but there was no difference in the magnitude of the LH surge between heifers that did or did not ovulate.

Key Words: Heifer, Ovulation, LH

W161 Ovarian activity and response to estrus synchronization with CIDR, β-estradiol and PGF_{2α} in Creole Rodeo compared to Hereford cows. J. A. Ramírez-Godínez*, J. P. Zárate-Martínez, F. A. Rodríguez-Almeida, and A. Flores Mariñelarena, *Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, Mexico.*

The objective was to compare ovarian activity, serum progesterone (P₄) concentrations and conception rates of Creole rodeo (Cr) and Hereford (HE) cows, synchronized and AI'ed 12 h after estrus initiation. The Cr ($n = 8$) and HE ($n = 10$) cows received a CIDR (1.9 g of P₄) and 1 mg of β-estradiol (d 0). On d 7, the CIDR was removed and 30 mg of PGF_{2α} was administered. On d 8, 1 mg of β-estradiol was injected. The anovulatory estrous rate (AOR), follicular waves number (FWN) and conception rate (CR) were analyzed with PROC FREQ of SAS. The time from CIDR removal to estrus (TE) was analyzed using PROC GLM, with breed (B) as a fixed effect. Diameter of the dominant follicle (DF) and corpus luteum (DCL), and P₄ were analyzed using PROC MIXED of SAS, with B, day (D) and their interaction as fixed effects and cow within B as a random effect. The Cr had a greater ($P < 0.05$) AOR (62.5%) compared to HE (30%) cows. The TE was greater ($P < 0.05$) in Cr (40.17 ± 1.06 h) than in HE (31.68 ± 0.95 h) cows. In both breeds a relationship between AOR and FWN was observed. At a greater FWN a greater AOR (44.4 %) was found ($P < 0.05$). A B by D interaction was observed ($P < 0.01$) for P₄. The Cr cows had increased P₄ (4.36 ± 0.30 ng/mL) during the synchronization period than HE (2.30 ± 0.31 ng/mL); however, during the luteal phase after the synchronized estrus, Cr had decreased ($P < 0.01$) P₄ (0.96 ± 0.13 ng/mL) than HE (1.8 ± 0.16 ng/mL) cows. The DF and DCL were smaller ($P < 0.01$) in Cr vs HE (1.32 ± 0.08 vs 1.67 ± 0.07 cm and 3.07 ± 0.17 cm vs 3.6 ± 0.15 cm, respectively). The conception rate was decreased ($P < 0.05$) in Cr (25%) vs HE (60%) cows. We concluded that Creole rodeo cows showed a greater incidence of anovulatory estrous than Hereford cows, which could be the cause of reduced fertility.

Key Words: Creole Cows, Synchronization, Ovarian Activity

W162 Effect of progestin treatment on formation of persistent follicles in postpartum beef cows. M. E. Risley*, J. A. Atkins, and M. F. Smith, *University of Missouri, Columbia.*

Progestins (melengestrol acetate [MGA] and Controlled Internal Drug Release [CIDR] inserts) are frequently used to effectively control estrus

and ovulation in beef cattle. Treatment of cycling cows with MGA for 14 d, in the absence of a corpus luteum, induces formation of persistent follicles and a corresponding reduction in fertility. The objective was to determine if the presence of a new or used CIDR in postpartum cows, without a corpus luteum, would induce the formation of persistent follicles and to compare serum concentrations of progesterone (P4) in cows treated with a new or used CIDR to luteal phase concentrations of P4 in non-treated cows. Normally cycling cows were blocked by days postpartum, age and body condition score and allocated into the following treatment groups: Control (n = 10), MGA (n = 11; 0.23 kg⁻¹hd⁻¹day), new CIDR (n = 9; 1.38 g P4), and used CIDR (n = 9; new CIDR previously inserted into cows for 7 d and subsequently stored for approximately six months). Groups were presynchronized with a CIDR for 7 d, prostaglandin F_{2α} (PGF) on d 6 and GnRH 48 hr after CIDR removal. Progestin treatment began on d 4 post-estrus and PGF_{2α} was injected on d 6 to induce luteolysis (d 0 = estrus). MGA or CIDR treatment continued for 14 d and length of a follicular wave was defined as the interval from follicular recruitment to ovulation or initiation of a new wave. Length of the first follicular wave (d) was 10.7^a, 15.6^b, 15.4^b, and 13.2^b (^{ab}P = 0.07) and maximum diameter (mm) of the dominant follicle was 14.1^a, 17.3^b, 16.7^b, and 16.1^b (^{ab}P < 0.08) in the Control, MGA, new CIDR, and used CIDR groups, respectively. Maximum diameter of the dominant follicle was similar (P > 0.1) in the used CIDR, new CIDR, and MGA groups. Serum concentrations of P4 in the new and used CIDR groups were similar (P > 0.1) throughout the 14 d treatment period but lower than in the control group. In summary, treatment with a new or used CIDR induced formation of persistent follicles in postpartum beef cows and serum concentrations of P4 were similar between the two CIDR groups.

Key Words: Progesterone, Persistent Follicle, Beef Cows

W163 Effect of duration of CIDR exposure on reproductive performance of beef heifers using a CIDR-based timed-AI protocol. A. Ahmadzadeh^{*1}, D. Gunn², and B. Glaze³, ¹University of Idaho, Moscow, ²University of Idaho Extension, Fort Hall, ³University of Idaho Extension, Twin Falls.

The objective of this experiment was to determine the effect of reducing the length of CIDR exposure in a CIDR-based timed-AI protocol (CIDR-PGF_{2α}-GnRH and AI) on conception and pregnancy rates in beef heifers. The experiment was conducted in two years using 152 heifers. In Year 1, British cross-bred heifers (n = 82) were stratified by body weight (BW), body condition score (BCS) and age; and were randomly subjected to one of the two Treatments: 1) heifers (n = 41) received CIDR (d -7) for 7 d, PGF_{2α}(25 mg) at CIDR removal (d 0), GnRH (75 ug) 56 h after CIDR removal and immediate AI (d 3; 7-d CPG); or 2) heifers (n = 41) received CIDR (d -5) for 5 d, PGF_{2α} (25 mg) at CIDR removal (d 0), GnRH (75 ug) 56 h after CIDR removal and immediate AI (d 3; 5-d CPG). In Year 2, 70 heifers were used. The experimental protocol was the same as in Year 1. Heifers were assigned to 7-d CPG (n = 35) or 5-d CPG (n = 35). Estrual behavior was monitored for three d following CIDR removal. Blood samples were collected on the day of CIDR insertion and at breeding (d 3). Heifers were exposed to bulls 14 d after AI. Pregnancy status was determined by ultrasonography at d 32 and 82 after AI. Data were analyzed by logistic regression. Percentage of heifers detected in estrus was different between Years (44% vs. 69 % for Year 1 and 2, respectively) but not different between treatments. Based on progesterone results, the synchronization rates were similar between treatments. However, at experiment initiation fewer animals

were cyclic in Year 1 compared with Year 2. There was a Treatment by Year interaction effect on conception to AI (P < 0.05). For 7-d CPG and 5-d CPG, in Year 1 conception to AI was 39% and 65.8 %; whereas in Year 2 conception to AI was 64.7% and 41%. Age tended to effect conception to AI (P = 0.07), whereas BW and BCS did not affect conception to AI. Overall pregnancy rate was not different between groups (93.4%). The yearly results from this study are inconsistent regarding the effect of reducing the length of CIDR treatment (5-d vs. 7-d) on conception to AI and thus, further research is warranted.

Key Words: Beef Heifers, CIDR, Timed-AI

W164 A field trial comparison of first service conception rates of Ovsynch-56 and CO-Synch-72 protocol in lactating dairy cattle. R. L. Nebel^{*1}, J. M. DeJarnette¹, M. R. Hershey², D. A. Whitlock², and C. E. Marshall¹, ¹Select Sires Inc., Plain City, OH, ²Select Sire Power, Rocky Mount, VA.

This study compared first service conception rates in 3 herds of lactating dairy cows (n = 739) after fixed time AI to one of 2 protocols. All cows received PGF (25 mg, i.m.) on treatment days -35, -21, and 0, GnRH (100 µg, i.m.) on d -7, and fixed time AI at +72 h after the last PGF injection. Within each herd, cows were randomly assigned to receive GnRH at +56 (Ovsynch-56) or +72 h (CO-Synch-72) after the last PGF injection. Data were analyzed in a least square means model including the effects of herd, treatment, parity and all two-way interactions. The mean days postpartum at AI (73 ± 0.1), parity (2.2 ± 0.05), and peak milk yield (kg) per cow (47 ± 0.34) did not differ by treatment. Conception rates were influenced (P < 0.05) by the parity by treatment interaction. Among multiparous cows, conception rates were greater (P < 0.05) among Ovsynch-56 (47%, n = 204) than CO-Synch-72 treated cows (25%, n = 253). Among primiparous cows, the numeric difference in conception rates favored the Ovsynch-56 treatment (37%, n = 134) but could not be confirmed as statistically different (P = 0.33) than those of the CO-Synch-72 (31%, n = 148) treated cows. No other main effects or interactions were determined to be significant. In conclusion, although difficult to implement in many large herds due to the necessity to handle or lock-up cows at an interval that is not divisible by 24 h, these data indicate that where facilities, labor and management allow for effective implementation the Ovsynch-56 protocol results in greater timed AI conception rates than does the CO-Synch-72 protocol.

W165 Effect of supplemental FSH during Ovsynch in high producing Holstein cows. H. Ayres^{1,2}, R. M. Ferreira^{1,2}, A. P. Cunha^{*1}, R. R. Araújo¹, and M. C. Wiltbank¹, ¹University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil, ²University of Wisconsin, Madison.

Programs that allow timed artificial insemination (TAI) have been used to improve reproductive efficiency in dairy herds; however, in many cases pregnancies per AI (P/AI) during these programs remain sub-optimal. Previous research indicated an increase in fertility when beef cattle were supplemented with low doses of FSH (10 or 20 mg) during the latter stages of a timed AI protocol. We hypothesized that treatment with FSH at the time of the prostaglandin F_{2α} (PGF_{2α}) treatment of Ovsynch would increase fertility to the timed AI in dairy cattle. This experiment

was done during the months of June through November 2007 on two commercial dairy farms in south-central Wisconsin. Weekly, a cohort of 35 to 65 cows at 120±73 DIM were stratified by parity and insemination number, and randomly assigned to 1 of 2 treatments: Ovsynch (n = 561) or Ovsynch+FSH (n = 571). All cows received the Ovsynch protocol (GnRH-7d-PGF_{2α}-56h-GnRH-18h-TAI) with prior presynchronization of first service cows and initiation of Resynch at 32d after previous TAI in cows at second or later services. Ovsynch+FSH cows received 20 mg of FSH at the same time as PGF_{2α}. Pregnancy diagnosis was performed 39 d after TAI. Statistical analyses were performed with logistic regression by PROC GLIMMIX of SAS. There were no interactions of treatment with days in milk, parity, insemination number, locomotion score, sire, batch, inseminator, or farm. Therefore, these variables were removed from the statistical model. The overall P/AI were not different between Ovsynch and Ovsynch+FSH [36.2% (203/561) vs. 39.1% (223/571); *P*>0.05]. Analysis of treatment effects by parity also indicated no difference between Ovsynch vs. Ovsynch+FSH on P/AI in primiparous [41.6% (96/231) vs. 42.0% (103/245); *P*>0.05] or multiparous [32.4% (107/330) vs. 36.8% (120/326); *P*>0.05] cows. Surprisingly, FSH tended to increase P/AI in cows with BCS that was greater than 2.5 [36.5% (148/406) vs. 42.7% (179/419); *P*=0.07] but not in cows with less than 2.5 BCS. Thus, these data do not indicate a major fertility-enhancing effect of a single FSH treatment during Ovsynch in high-producing dairy cows.

W166 Administering human chorionic gonadotropin (hCG) 7 d prior to initiating a CO-Synch protocol. C. R. Dahlen^{*1}, G. Marquezini², A. DiCostanzo², S. L. Bird³, and G. C. Lamb⁴, ¹University of Minnesota, Crookston, ²University of Minnesota, St. Paul, ³University of Minnesota, Grand Rapids, ⁴University of Florida, Marianna.

We determined the effects of administering human chorionic gonadotropin (hCG) 7 d prior to the CO-Synch estrous synchronization protocol on pregnancy rates and concentrations of progesterone in beef cows. Sixty-three suckled (n = 36) and non-suckled (n = 27) cows from 2 locations were stratified by body condition score or days post-partum and randomly assigned to receive one of two treatments: 1) CO-Synch protocol (100 µg injection of GnRH, followed in 7 d by a 25 mg injection of PGF_{2α}, followed in 48 hours by insemination and a 100 µg injection of GnRH); CONT, n = 32), or 2) pre-treatment with 1000 IU hCG 7 d prior to the initiation of the CO-Synch protocol (hCG: n = 31). Blood was collected on d -16, -9, -2, 0, 7, and 14 relative to insemination. On d 28 after insemination, transrectal ultrasonography was used to determine presence of a viable fetus. Days post-partum at the time of insemination was greater (*P* < 0.05) for suckled cows at Location 1 (65.8 ± 3.8) compared to Location 2 (23.9 ± 6.2). Pregnancy rates at Location 1 (65.1%; 23/35) were greater (*P* < 0.05) than Location 2 (28.6%; 8/28). However, no differences (*P* > 0.05) in pregnancy rates were detected between CONT (56.3%; 18/32) and hCG (41.9%; 13/31). On d -9, concentrations of progesterone were greater (*P* < 0.05) for cows in the hCG treatment compared to those in the CONT treatment (2.7 ± 0.46 vs 1.4 ± 0.43 ng/ml for hCG and CONT, respectively) No differences (*P* > 0.05) in concentrations of progesterone were present on d -2, 0, 7, or 14 among treatments. We concluded that while pre-treatment with hCG 7 days prior to a CO-Synch protocol appeared not

to alter pregnancy rates, it increased concentrations of progesterone at the time of the GnRH injection of the CO-Synch protocol.

Key Words: Human Chorionic Gonadotropin, Beef Cows, Progesterone

W167 Effect of human chorionic gonadotropin (hCG) on ovarian structure dynamics and concentrations of progesterone in cycling Holstein heifers. C. R. Dahlen^{*1} and G. C. Lamb², ¹University of Minnesota, Crookston, ²University of Florida, Marianna.

We determined the effects of administering hCG on subsequent ovarian structures and concentrations of progesterone in cycling Holstein heifers. In Exp 1, 20 heifers were assigned to receive one of two treatments: 1) 100 µg GnRH im (GnRH; n = 10); and 2) 1000 IU hCG im (hCG; n = 10). All heifers were given 25 mg PGF_{2α} im on d 6 after treatment. Blood collection and ovary examination via transrectal ultrasonography were conducted on d -9, 0, 2, 4, 6, 8, and 10 relative to treatment. In Exp 2, 21 heifers were given 100 µg GnRH im and a CIDR followed in 7 d by 25 mg PGF_{2α} im and CIDR removal. Heifers were scanned via transrectal ultrasonography 40 h after PGF_{2α}, stratified by size of dominant follicle, and randomly assigned to receive one of two treatments: 1) 100 µg GnRH im (GnRH; n = 10); and 2) 1000 IU hCG im (hCG; n = 11). Ovarian structures were evaluated and blood was collected on d -9, -2, 0, 7, and 14 relative to treatment. In Exp 1, a greater (*P* < 0.05) proportion of hCG heifers (9 of 10) ovulated in response to treatment compared to GnRH heifers (3 of 10). Subsequently, size of the largest follicle present on either ovary was smaller (*P* < 0.05) for hCG compared to GnRH heifers on d 2 (7.8 ± 1.2 vs 11.5 ± 1.2 mm, respectively), and tended to be smaller (*P* = 0.07) on d 4 (9.6 ± 0.7 vs 11.6 ± 0.7 mm, respectively) after treatment. In Exp 2, volume of luteal tissue on d 7 was greater (*P* < 0.05) in hCG heifers (5.4 ± 0.6 cm³) compared to GnRH heifers (3.4 ± 0.6 cm³). However, no differences were present on d 14 after treatment. No differences in concentrations of progesterone were present after treatment in either experiment. We conclude that hCG was superior to GnRH in its ability to ovulate follicles and increased volume of luteal tissue present 7 d after treatment in heifers previously synchronized, but had no effect on concentrations of progesterone.

Key Words: Human Chorionic Gonadotropin, Holstein Heifers, Ovulation

W168 Factors affecting ovulatory follicle size following follicular wave synchrony in beef heifers. J. A. Atkins, C. L. Johnson*, and M. F. Smith, University of Missouri, Columbia.

GnRH-induced ovulation of small dominant follicles (<11 mm) resulted in decreased pregnancy rates compared to larger follicles following the CO-Synch fixed-time insemination protocol (GnRH-1 on d -9, PGF_{2α} on d -2, and GnRH-2 plus insemination on d 0) in beef heifers. Factors contributing to the presence of small dominant follicles at insemination following the CO-Synch protocol have not been determined. Failure to synchronize a follicular wave following GnRH-1 seemed a likely hypothesis; however, ovulatory response to GnRH-1 had no effect on ovulatory follicle size at GnRH-2 in beef heifers (Atkins et al., 2008).

The objective was to examine the effect of day of the estrous cycle at GnRH-1 and growth rate of the dominant follicle (from d -5 or d -2 [PGF_{2α}] to GnRH-2 [d 0]) on ovulatory follicle size at GnRH-2. Pubertal beef heifers (n = 63) were allotted by age, weight, and breed to receive GnRH-1 on d 2 (no dominant follicle), 5 (first wave small dominant follicle), 10 (first wave large dominant follicle), 15 (second wave dominant follicle), or 18 (second or third wave large dominant follicle) after estrus (d 0 = estrus; n = 10 to 14 per group). Ovulatory response to GnRH-2 was greatest when GnRH-1 was administered on d 2, 5 or 10 compared to d 15 or 18, since many of the heifers in the d 15 and 18 groups were detected in estrus and ovulated on or before PGF_{2α} injection. There was no difference ($P > 0.1$) in follicle growth from d -5 to GnRH-2 among heifers given GnRH-1 injection on d 2, 5, or 10 of the cycle or based on ovulatory response to GnRH-1. Growth rate of the ovulatory follicle was less ($P < 0.01$) for ovulatory follicles that were < 11 mm compared to ovulatory follicles ≥ 11 mm (0.57 mm/d vs. 0.90 mm/d, respectively). Ovulatory follicle size and serum concentrations of estradiol at GnRH-2 were correlated ($r = 0.67$; $P < 0.01$). In summary, ovulatory follicle size was affected by growth rate from d -5 to GnRH-2 but not d of GnRH-1 injection or ovulatory response to GnRH-1.

Key Words: Estrus Synchronization, Ovulatory Follicle Size, Beef Heifers

W169 Early postpartum treatment of dairy cows with GnRH does not improve fertility. A. Ata and M. S. Gulay*, Mehmet Akif Ersoy University, Burdur, Turkey.

The objective of the current experiment was to determine the effect of early postpartum treatment with GnRH on reproductive performance of dairy cows. Two hundred thirty seven multiparous Holstein cows (3 to 10 yr old) averaging 13.1 d in milk at the start of the study were housed in a semi-open, freestall barn and were randomly assigned to GnRH (TRT; n = 126) and control (C; n = 111) groups. Cows in TRT group were given an iv injection of Receptal (5 mL; 0.0042 mg busserelin acetate) at assignment, whereas cows in C were not given Receptal. After assignment, estrus was confirmed based on secondary signs of estrus. Uterus and ovaries were checked by rectal palpation once a week. Grafian Follicles were confirmed and cyclic cows were inseminated. AI was performed according to the am-pm rule and pregnancies were confirmed by rectal palpation 45 - 60 d after AI. Open cows were re-inseminated until confirmed pregnant. Cows that did not cycle were injected with PGF_{2α}, whereas cows with metritis were treated with antibiotics. Mean number of AI for pregnancy was 2.5 and 2.4 for TRT and C, respectively. Percentages of cows injected with PGF_{2α} were 43.6 (TRT) and 51.3 (C). Days to first estrus were less for cows in TRT (TRT = 42.6 vs. C = 68.0 d; $P < 0.05$). The days open in cows that became pregnant did not differ between groups (TRT = 127.7 vs. C = 127.2 d). First (20.5 vs. 20.4%), second (41.1 vs. 39.7%), third (16.6 vs. 22.8%), fourth (10.7 vs. 10.8%), fifth (5.8 vs. 3.6%) and sixth (2.9 vs. 1.2%)-service conception rates also were similar for TRT and C. Overall, no significant effects of early postpartum injections of GnRH were detected on pregnancy rates (TRT = 80.9 vs. C = 74.7%). Number of cows with metritis was greater in TRT (13.4%) than C (5.4%) ($P < 0.05$). Results indicated that although early postpartum injections of GnRH decreased the days for first estrus, it did not improve fertility.

Key Words: GnRH, Dairy Cows, Conception Rates

W170 Factors associated with ovulatory follicle growth rate and diameter in postpartum beef cows. J. A. Atkins^{*1}, T. W. Geary², and M. F. Smith¹, ¹University of Missouri, Columbia, ²USDA ARS, Ft. Keogh, Miles City, MT.

Beef cows induced to ovulate small (≤ 11 mm) follicles had reduced establishment and maintenance of pregnancy compared to cows ovulating large (> 11 mm) follicles when bred after the CO-Synch protocol (GnRH1 on d -9, PGF_{2α} on d -2, and GnRH2 with timed AI on d 0). The reason for the presence of small ovulatory follicles is unknown but could be explained by failure to ovulate and synchronize a new follicular wave at GnRH1 or slower growth rate leading to GnRH2. Experiments were conducted in cycling (n = 60) or suckled, postpartum anestrus (n = 55) beef cows. Cycling cows were assigned to 1 of 5 treatments (n = 12 per treatment) based on day of the cycle at GnRH1 of the CO-Synch protocol (d 2, 5, 9, 13, and 18 [estrus = d 0]). The anestrus cow experiment was a 2x2 factorial design (n = 9 to 18 per treatment) based on ovulation (GnRH1+) or failure to ovulate (GnRH1-) to GnRH1 and presence (CIDR+) or absence (CIDR-) of a CIDR from GnRH1 to PGF_{2α}. Only cows ovulating to GnRH2 were used to analyze follicle growth. For the cycling cow experiment, follicle growth from d -5 to 0 was greatest in d 18 cows, followed by d 13, 5, 9, and 2 cows (1.1^a, 0.72^{ab}, 0.67^{ab}, 0.66^b, and 0.47^b mm/d, respectively; $^{ab}P < 0.05$). Cows that ovulated following GnRH1 had faster follicle growth from d -5 to d 0 than did the cows that did not ovulate (0.79 vs. 0.49 mm/d; $P < 0.05$). Follicle growth was slower in d 2 cows than d 9 cows from d -2 to 0 (0.339 vs. 1.29 mm/d, respectively; $P < 0.05$) but was similar among all other treatment groups (1.06, 1.13, and 1.28 mm/d in the d 5, 13, and 18 cows, respectively). In the anestrus cow experiment, GnRH1+ cows had greater follicle growth from d -5 to 0 ($P < 0.01$) compared to GnRH1- but similar growth rate from d -2 to 0 ($P > 0.10$), while CIDR+ cows had faster growth rate from d -2 to 0 ($P < 0.05$) compared to CIDR- cows but the growth rate was similar from d -5 to 0. In both experiments, follicle growth was faster ($P < 0.05$) from d -5 to d 0 in cows ovulating large (> 11 mm) compared to small follicles. Research supported by USDA 2006-35203-17284

Key Words: Beef Cows, Ovulatory Follicle Size

W171 Effect of reducing the period of follicle dominance in a timed AI protocol on reproduction of dairy cows. R. C. Chebel^{*1}, F. Rivera¹, C. Narciso¹, W. W. Thatcher², and J. E. P. Santos², ¹University of California, Davis, ²University of Florida, Gainesville.

Objectives were to determine the effect of reducing the period of follicle dominance in a timed AI protocol on pregnancy risk (PR) in dairy cows. In experiment 1 (Exp 1), 164 Holstein cows received 2 injections of prostaglandin F_{2α} (PGF, cloprostenol sodium) at 37 and 51 d in milk (DIM). At 61 DIM, cows were randomly assigned to: Cosynch 72 h (CoS72: d 61 GnRH, d 68 PGF, d 71 GnRH + timed AI) or 5 d-Cosynch 72 h with one (5dCoS1: d 61 GnRH, d 66 PGF, d 69 GnRH + timed AI) or two injections of PGF (5dCoS2: d 61 GnRH, d 66 and 67 PGF, d 69 GnRH + timed AI). Blood was sampled at the first GnRH, first PGF, and at timed AI and assayed for progesterone (P4). Ultrasound of the ovaries was performed to determine ovulatory responses to treatments. In experiment 2 (Exp 2), 933 cows were randomly assigned to CoS72 or 5dCoS2. Blood was sampled as described for Exp 1 and also 7 d after timed AI and assayed for P4. Ultrasound of the ovaries was performed as described for Exp 1. Pregnancy was diagnosed on d 38 and 66 after

timed AI. In Exp 1, CL regression differed ($P < 0.01$) and were 78.0, 58.7 and 95.8% for CoS72, 5dCoS1, and 5dCoS2, respectively. Cows that ovulated to the first GnRH of the Cosynch had less ($P < 0.01$) CL regression than cows that did not ovulate (68.6 vs. 90.8%). In Exp 2, CL regression (92.0 vs. 96.0%) was less ($P = 0.02$), but detection of estrus at timed AI (30.9 vs. 23.6%) was greater ($P < 0.01$) for CoS72 than 5dCoS2, respectively, and cows in estrus had increased ($P < 0.01$) PR (46.0 vs. 31.9%). Nevertheless, PR was greater ($P = 0.03$) for 5dCoS2 than CoS72 (37.7 vs. 31.1%). For cows with $P4 < 1$ ng/mL at timed AI, PR also were greater ($P < 0.01$) for 5dCoS2 than CoS72 (40.1 vs. 34.2%). Concentrations of P4 were similar between treatments and averaged 2.9 ng/mL 7 d after AI. Treatment with PGF on d 5 and 6 after GnRH resulted in high luteolysis and allowed for reducing the interval from GnRH to timed AI, which increased PR. Improvements in PR for 5dCoS2 were observed despite changes in luteolysis. This study reinforces the concept that reducing follicle dominance in timed AI protocols improves PR in dairy cows.

Key Words: Dairy Cow, Follicle Dominance, Reproduction

W172 Effects of an additional PGF_{2α} and estradiol-17β during Ovsynch in lactating dairy cows. D. J. Brusveen*, A. H. Souza, and M. C. Wiltbank, *University of Wisconsin, Madison*.

This study was designed to evaluate whether decreasing circulating progesterone (P4) and increasing circulating estradiol-17β (E2) near the

time of AI in an optimized Ovsynch protocol would increase pregnancies per AI (P/AI) in lactating dairy cows. Six hundred and nineteen lactating Holstein cows ($n = 782$ inseminations) received Ovsynch (GnRH-7d-PGF_{2α}-56h-GnRH-16h-timed AI). Cows were randomized in a 2 x 2 factorial design to receive or not receive: 25 mg PGF_{2α} 24h after the normal PGF_{2α} of Ovsynch and/or 0.5 mg of E2 at the time of the final GnRH. Blood samples were collected at 24h after the normal PGF_{2α} (BS1) and again at the time of the final GnRH (BS2) to evaluate circulating P4. Ovarian ultrasound was done at the time of the final GnRH to determine preovulatory follicle size and ovulation was confirmed by ultrasound 5 d after AI. Treatment with an additional PGF_{2α} increased the percentage of cows that regressed their CL (95.6%) compared to control cows (84.6%; $P < 0.001$). However, additional PGF_{2α} had no effect ($P > 0.1$) on overall P/AI (44.7; $n = 379$ vs. 41.5%; $n = 393$, treatment vs. control, respectively). Supplementation with E2 increased ($P < 0.001$) expression of estrus (84.4% vs. 37.2%), but had no effect ($P = 0.731$) on fertility (42.2%; $n = 393$ vs. 43.9%; $n = 379$). Thus, it appears that an additional PGF_{2α} treatment increases synchronization during Ovsynch; however, supplementation with 0.5 mg E2 at the time of the final GnRH did not improve fertility to Ovsynch.

Production, Management and the Environment: Nutrient and Animal Management

W173 A mass balance computer model of nutrient flow for a California dairy. H. A. Johnson*, E. J. DePeters, J. G. Fadel, P. L. Price, P. H. Robinson, and D. Meyer, *University of California, Davis.*

Estimating nitrogen (N) and phosphorus (P) output from a dairy production facility is essential to determining the land area necessary for environmentally sustainable nutrient recycling. To understand nutrient partitioning of N and P between liquid and solid waste streams from dairy farms, a dynamic computer model was created using acslXtreme v. 2.4 simulation software. The model consists of four parts: 1. Estimations of manure production and N, P content using regression equations based on milk production (Nennich et al., 2005), 2. Manure collection via scraping, flushing or vacuuming, 3. Manure storage and treatment including sand traps, solids separator, anaerobic digester, and holding ponds, and 4. Output composition of solid waste used for bedding or land application and liquid waste used as recycled flush water or land application i.e., irrigation. Simulations were run for 30 days for 1,500 milking cows at which time the amount and yield of N and P in recycled flush water reached steady state. Model predictions of yield of N and P in manure recycled flush water (N = 8,385 kg, P = 967 kg) were within ranges of data collected over 6 months at the test dairy (N = 8,458 kg, standard deviation (SD) = 1,032 kg; P = 972 kg, SD = 564 kg). Estimated yield of solid waste at 30 days was N = 2684 kg, P = 309 kg and liquid waste was N = 1509 kg and P = 174 kg. These comparisons indicate that this mass balance computer model is useful in predicting the yield of N and P in dairy waste output. However, more data are needed along the waste stream over a longer period of time to fully test the model. Data describing effects of storage and treatment on manure nutrient composition would increase the usefulness of the model by allowing addition of more manure handling technologies to simulate potential strategies to manipulate nutrient waste output.

Key Words: Manure, Waste Stream

W174 Bacteroidales PCR for universal, human, hog, and ruminant fecal pollution markers. B. R. Min*^{1,2}, G. Giovanni³, N. Garcia³, E. Casarez³, H. Y. Kim¹, M. K. Ho¹, J. Chang¹, L. Chang¹, C. Bae¹, and P. Dyer², ¹*Ichthus Education Center, La Trinitaria, Chiapas, Mexico*, ²*Texas AgriLife Research, Vernon, TX*, ³*Texas AgriLife Research, El Paso, TX.*

The overall objective is to quantify the effect of fecal contaminated drinking water on bacterial population in four Mayan villages. Raw water samples (7 to 25 ml) were collected from four villages (Comitan, Chiapas) in Mexico and analyzed for the presence of the fecal pollution indicator *Bacteroidales*. Samples were concentrated by membrane filtration and DNA was extracted from the concentrates by way of a commercial DNA kit (Qiagen DNA mini kit). DNA extracts were tested by PCR for the presence of *Bacteroidales* fecal bacteria in general using the universal marker, and *Bacteroidales* host-specific markers (nested PCR) for humans, ruminants, and hogs. Using a universal *Bacteroidales* marker, positive PCR products were detected for fecal contamination obtained from various samples in Mayan villages, indicating a presence of fecal pollution problems. However, *Bacteroidales* host-specific mark-

ers for humans, ruminants, and hogs shown that sample tested positive for the human marker, but negative for ruminants and hogs. This may have been due to the difference in PCR cycling conditions that have been optimized for the individual markers. It should be noted that nested PCR, with its increased sensitivity and detection levels, was able to confirm the presence of the human marker. In conclusion, the sources of the fecal contamination indicated by the universal markers in general shown that the most of Mayan villages have water pollution problem from animals or human. However, results in samples analyzed by host-specific markers shown that fecal contamination from humans, hogs and ruminants were identified with the limited markers available, and they may have originated from other animal (e.g. wildlife) or human sources. Further work to increase the sensitivity of the assays is underway. Additional samples are needed to confirm results and to determine if there is a trend in the sources of fecal pollution for the study sites.

Key Words: Water, Fecal Pollution, Bacterial Contamination

W175 Compost: A potential value-added product for dairy operations? E. M. Shane*¹, M. I. Endres¹, D. G. Johnson², and C. J. Rosen¹, ¹*University of Minnesota, St. Paul*, ²*University of Minnesota, Morris.*

The objective of this descriptive study was to evaluate the composting potential of various bedding materials that were previously used in experimental bedded packs. Each material was placed in windrows (1.83m height × 9.14m length × 2.29m width) from April 2007 to September 2007 and managed as needed to promote composting. Materials included: sawdust (SD), corn cobs (CC), woodchip/sawdust mix (WC/SD), soybean straw (SS), woodchip/soybean straw mix (WC/SS), and soybean straw/sawdust mix (SS/SD). Replicated samples were taken weekly and analyzed for DM, pH and C:N ratio. Temperature was measured twice weekly. Results for initial and final samples of the composting material (mean (SD)) are reported on Table 1. Number of days temperature stayed above 54.4°C (temperature needed to kill pathogens and weed seeds) were: SD, 35; CC, 109; WC/SD, 106; SS, 95; WC/SS, 92, and SS/SD, 95. Initial temperature across materials was 51#deg;C and final temperature was 39.2°C. Some of the observed C:N ratios were slightly below 20:1, but all materials still composted efficiently.

Table 1.

Item	Material					
	SD	CC	WC/SD	SS	WC/SS	SS/SD
DM (%)						
Initial	38.6 (2.4)	45.7 (4.0)	33.7 (1.6)	37.7 (2.4)	41.6 (0.5)	37.8 (0.8)
Final	51.5 (8.6)	73.9 (3.1)	42.9 (5.6)	63.0 (10.2)	68.1 (1.9)	54.4 (4.0)
pH						
Initial	8.25 (0.26)	8.36 (0.13)	8.69 (0.16)	8.75 (0.06)	8.55 (0.06)	8.78 (0.16)
Final	6.96 (0.22)	7.97 (0.31)	7.38 (0.22)	8.19 (0.31)	6.98 (0.16)	7.05 (0.12)
C:N Ratio						
Initial	34.7 (3.4)	18.2 (0.3)	39.8 (2.2)	17.5 (1.0)	32.0 (2.4)	18.7 (0.8)

W176 Associations between non-dietary factors and dairy herd performance. A. Bach*^{1,2}, N. Valls³, A. Solans³, and T. Torrent⁴, ¹ICREA, Barcelona, Spain, ²IRTA-Unitat de Remugants, Barcelona, Spain, ³CADI, Lleida, Spain, ⁴Pirenaica, Lleida, Spain.

Forty seven dairy herds (approximately 3,129 lactating cows) from northeast of Spain that were feeding exactly the same lactating ration were surveyed to determine the effect of non-dietary factors on herd performance. The survey collected information on the profile of the owners (their future intentions, the number of workers, and time devoted to the enterprise), information regarding the animals (reproductive performance, incidence of pathology, culling rate, etc...), information on the facilities (number of feeders, waters, stalls, cleanliness, etc...) and information on management practices (numbers of daily milkings, feed deliveries, feed push-ups, cleaning frequency, etc...). In addition, the chemical quality of drinking water from each dairy enterprise was determined. Also, amount of feed delivered to each herd, daily total milk production, and milk quality were obtained for each herd for a period of 8 months prior the fulfillment of the survey. Mortality rate of calves, tended to be lower in herds that weaned progressively than in those that weaned abruptly. Age at first calving (AFC) was negatively correlated with level of milk production (mainly due to the type of heifer rearing system used). Culling rate tended to be lower in herds that used a close-up ration than in those that did not. Using gloves and paper towels (instead of cloth towels) tended to reduce the somatic cell count in milk. Concentration of calcium in the drinking water tended to be negatively correlated with the number of days open and with the proportion of cows culled due to infertility problems. Despite that the 47 herds fed the same ration and shared a similar genetic base, average milk production per cow ranged from 20.6 to 33.8 kg/d. A positive relationship ($r = 0.57$; $P < 0.05$) between the number of stalls per cow and milk production was found. The most important non-dietary factors that affect milk production in these dairy herds were AFC, presence or absence of feed refusals, ratio of number of free stalls per lactating cow, and whether feed was pushed up in the feed bunk. These factors accounted for more than 50% of the observed variation, not attributable to the diet, in milk yield.

W177 Boric acid and borax treatment of stored swine manure to reduce ammonia and hydrogen sulfide emissions from swine facilities. M. Yokoyama*, S. Hengemuehle, and R. von Bernuth, *Michigan State University, East Lansing.*

The objective of this research was to evaluate the efficacy of boric acid and borax in reducing ammonia and hydrogen sulfide emissions from stored swine manure under in vitro and in vivo conditions. Boric acid was reagent grade (J.T.Baker Co.) and borax was commercial grade (20 Mule Team Borax). Swine manure was obtained from the MSU swine facility and incubated (200 ml) with 0.00, 0.0625, 0.125, 0.25, 0.25, 0.50 and 1.0% (w/v) of the borates in 2-L Erlenmeyer flasks for 7 days. Ammonia was measured daily in the headspace gases with Dräger ammonia tubes and hydrogen sulfide was measured using a Jerome analyzer. Increasing amounts of borates to swine manure in the incubations delayed hydrolysis of urea to ammonia by 48-144 hours (e.g. 2-6 days). Adding 1% borates almost completely inhibited (95%)

ammonia emissions. Borates at 1% almost completely inhibited (99%) hydrogen sulfide emissions. Shallow manure pits under nursery rooms at the MSU swine facility were treated with borax for 4 weeks. Air quality was continuously monitored with a Continuous Emission Photoacoustic Multi-Gas Monitor (CEM) with computer software program. Paired t-test comparisons of treatment means indicated that the control room had significantly higher hydrogen sulfide/carbon dioxide concentrations than the boron treated room. Hydrogen sulfide concentrations in the nursery room when pull plugs were opened, indicated that hydrogen sulfide levels were reduced by at least 80%. Paired t-test comparisons of treatment means indicated that the control room had significantly higher ammonia concentrations than the boron treated room. When normalizing the data for carbon dioxide concentrations, the boron treated room had higher ammonia concentrations than the control room. These results demonstrate that boric acid and borax are effective in controlling hydrogen sulfide emissions from stored swine manure. This project was supported by the National Pork Checkoff.

Key Words: Boric Acid, Ammonia, Stored Swine Manure

W178 Effect of different feed push-up schedule on milk production, feed intake and behavior in Holstein dairy cows. D. V. Armstrong*¹, T. R. Bilby¹, V. Wuthirornarith², W. Sathonghon², and S. Rungruang², ¹The University of Arizona, Tucson, ²Charoen Pokphand Foods Public Co. LTD, Bangkok, Thailand.

Primiparous and multiparous Holstein cows in early to mid lactation were divided into 2 groups of 43 based on milk production, days in milk and parity. Both groups were milked 2x daily and fed 3x daily (600, 1300 and 2200 hrs). Milk production and group feed weights and refusals were recorded daily. The feed area was empty for 2 hrs daily for both groups. Feed push-up schedule for the control group was once per hr, every 24 hrs, for a total of 22 push-ups daily. The treatment group was pushed-up every 30 min for the first 2 hrs after each feeding for an additional 9 push-ups totaling 31 push-ups daily. A crossover design was used with treatments being applied for one week then switching treatments between groups for another week with a 2 day interval between weeks. Cows were housed in a tunnel ventilated free stall barn with a feed line soaker. Milk production was increased in the treatment group versus the control (29.7 vs. 28.5 kg, respectively; $P < 0.01$). In addition, there was a significant interaction ($P < 0.05$) between treatment and parity with treatment moderately increasing milk production for primiparous cows (29.1 and 29.8 kg) but significantly increasing milk production in multiparous cows (27.8 and 29.6 kg). Daily dry matter intakes were not significantly different. Cow behavior was observed every 15 min for 24 hrs on the sixth day. Observations recorded were as follows: number of cows either (1) eating at the feed line, (2) standing at feed line, (3) lying at feed line, (4) standing in free stall, (5) lying in free stall, (6) at the water trough or (7) at the milking barn. Percent of cows at the water trough tended to be increased in treatment versus control groups (5.2 % vs. 4.2 %; $P < 0.10$). No significant differences between groups for all other behaviors. In conclusion, increasing feed push-ups at feeding increased milk production with little effects on dairy cow behavior.

Key Words: Feeding, Behavior, Dairy

W179 Hydrated lime bedding treatment for mastitis control. T. A. McCaskey*, R. S. Chettri, C. R. McCarthy, M. B. Brady, and L. I. Chiba, *Auburn University, Auburn, AL.*

Dairy cow mastitis is the inflammation of the mammary gland, usually caused by microbes, which is estimated to cost the dairy industry over \$1 billion annually. The principal remedy is antibiotic therapy, and the major preventive measure is good sanitary practices prior to, during, and after milking, and dry cow antibiotic treatment at time of dry-off. Most mastitis cases are associated with staph, strep and coliform bacteria which are acquired during the milking procedure due to improper milking practices, or acquired from the environment such as the bedding where the cows lie down. Earlier studies have evaluated alkalizing and acidifying agents to reduce microbial loads in cow bedding. Hydrated lime treatment of bedding has been reported to reduce bacterial counts by 100-fold, but the effect diminished in two days. A study was conducted to evaluate the daily application of hydrated lime to free-stall bedding, and to determine its effect on the incidence of mastitis for cows assigned to the stalls. Dairy cows with similar udder health status were allotted to two groups of 16 cows each. Both groups were bedded in free-stalls with peanut hull bedding. The control cow group received no lime, and the treatment group received daily applications of lime (~50grams) to the back 1/3 of the stalls. The assessment of the incidence of mastitis for both groups of cows was determined by the Wisconsin Mastitis Test (WMT) performed monthly for 12 months on quarter, foremilk collected from the cows in the milking parlor prior to milking. A somatic cell count (SCC) of 200,000/ml or more was used as the guideline to indicate an intramammary infection of the mammary quarter. Based on WMT data there was a 38% decrease in the incidence of mastitis for the cow group assigned to stalls with hydrated lime-treated bedding. SCC data taken from DHIA records indicated a 33% decrease in the incidence of mastitis for the lime treatment group. However, when the data for the cow groups were normalized for number of lactations and lactation period these differences were not significant ($P > 0.05$).

Key Words: Dairy Cow, Bedding Treatment, Mastitis

W180 Bedding options for an alternative housing system for dairy cows. E. M. Shane*¹, M. I. Endres¹, D. G. Johnson², and J. K. Reneau¹, ¹*University of Minnesota, St. Paul*, ²*University of Minnesota, Morris.*

Availability of bedding material for compost bedded pack barns is a concern for dairy producers who use this type of alternative housing system. The material most commonly used in these barns is sawdust. The objective of this descriptive study was to evaluate different types of material that could potentially work for these housing systems. The study was conducted at the West Central Research & Outreach Center in Morris, Minnesota from November 2006 to March 2007. Materials included: sawdust (control) (SD), corn cobs (CC), woodchips, and soybean straw (SS). Some of these materials were evaluated as mixtures on a 2:1 by volume ratio. These mixtures included: wood chips/sawdust (WC/SD), wood chips/soybean straw (WC/SS), and soybean straw/sawdust (SS/SD). Six bedded packs were used, each with one of six different materials, and 16 cows were placed on each pack for the specified time period. Replicated samples of the bedded pack material were collected biweekly and analyzed for dry matter. C:N ratios and pH were analyzed monthly. Temperatures of each pack were measured weekly at various depths (15.24, 30.48, 45.72, and 60.96 cm). Cows

were scored for hygiene (1=clean, 5=dirty) biweekly. Dry matter (mean \pm SD) of SD was 48.35 ± 21.16 ; CC, 53.78 ± 9.94 ; WC/SD, 47.60 ± 21.13 ; SS/SD, 41.77 ± 10.31 ; WC/SS, 60.45 ± 28.77 ; and SS, 63.31 ± 8.94 . SD pH was 8.69 ± 0.28 ; CC, 7.69 ± 0.73 ; WC/SD, 8.62 ± 0.28 ; SS/SD, 8.59 ± 0.20 ; WC/SS, 8.41 ± 0.37 ; and SS, 8.64 ± 0.15 . C:N ratio of SD was 36.61 ± 9.91 ; CC, 29.39 ± 6.05 ; WC/SD, 47.48 ± 11.81 ; SS/SD, 25.47 ± 4.92 ; WC/SS, 30.49 ± 4.95 ; and SS, 21.88 ± 3.11 . Temperatures (&DEG;C) were averaged across depths: SD, 31.00 ± 11.35 ; CC, 40.00 ± 12.22 ; WC/SD, 22.55 ± 13.93 ; SS/SD, 26.00 ± 8.83 ; WC/SS, 20.00 ± 10.54 ; and SS, 13.00 ± 11.14 . Hygiene score of cows on SD was 2.39 ± 0.74 ; CC, 2.71 ± 0.81 ; WC/SD, 2.46 ± 0.76 ; SS/SD, 2.90 ± 0.83 ; WC/SS, 2.63 ± 0.85 ; and SS, 2.84 ± 0.80 . Based on these results and our observations, it appears that any of the materials evaluated in this study would potentially work in this type of housing system if proper bedding management is applied on a consistent basis.

Key Words: Dairy Cow, Housing System, Bedding Material

W181 Effects of corn particle size and feeding management on dry matter intake, ruminal fermentation, chewing activity and nutrient digestibility in midlactation cows. Z. Cao*, S. Li, and M. Ma, *College of Animal Science & Technology, China Agricultural University, Beijing, China.*

The objective of the experiment was to estimate the effects of corn particle size and feeding management on dry matter intake, ruminal fermentation, chewing activity and nutrient digestibility in midlactation cows. Four multiparous Holstein cows with ruminal cannulas, averaged 625 kg (SD = 63) of BW and 195 DIM (SD = 21) were assigned randomly to a 4×4 Latin square design. Treatments were the effects of 1) corn silage particle size [100% short corn silage (SS, 6.3 mm), 50% short corn silage + 50% long corn silage (SL, 10.7 mm) and 100% long corn silage (LL, 16.4 mm)] in the TMR and 2) feeding TMR compared with SI. Dry matter intake and milk yield were similar for all diets. Cows fed SI spent more time ruminating (445 min/d vs 484 min/d, $P = 0.05$) and consumed less ADF (3.34 kg/d vs 2.89 kg/d, $P = 0.04$) than cows fed SS in the TMR. With the increasing of corn silage particle size, ruminating time ($P = 0.05$) and chewing time ($P = 0.03$) quadratic increased, and digestibility of dry matter ($P = 0.03$), organic matter ($P = 0.03$) and nitrogen ($P = 0.02$) linear increased.

Key Words: Corn Particle Size, Feeding Management

W182 Impact of simulated selection for feed efficiency and length of breeding season on beef life cycle performance. C. Williams* and T. Jenkins, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

The Decision Evaluator for the Cattle Industry (DECI) was used to simulate production for a base herd (BA), a herd in which genetically superior sires for feed efficiency were used (SA), and a herd in which genetically superior sires for feed efficiency and lower fertility were used (SB). Within each selection scenario, four breeding season lengths (BSL) were simulated, 90 d, 75 d, 60 d, and 45 d. Eight 15-yr-simulation runs were done for each selection by length of breeding season scenario. Animals were a composite of 50% Angus and 50% Simmental. Exposed females were palpated at weaning and open cows were culled at that

time and replaced with pregnant heifers to maintain herd size at 150 calving females. At weaning all open and excess pregnant heifers were sold, and all steers and non-replacement heifer calves were put on a stocker program for 150 d to gain 0.91 kg/day, then finished on a high-concentrate diet (3.258 Mcal ME/kg DM). In each 15-year simulation, yearly production and financial data were collected and averaged over yr 14 and 15 to measure selection response relative to the BA. Compared to BA, ADG increased by 0.04 kg ($P < 0.05$) and feed efficiency increased by 0.02 ($P < 0.05$) in both SA and SB. Decreasing BSL from 90 to 45 d, required an increase of 15 female replacements to maintain herd size, and resulted in a greater proportion of steers to heifers going into the finishing phase and heavier average slaughter weights. Except for the 90-d breeding season, the impact of lower fertility sires was to increase the number of replacement females needed to maintain herd size by 2 in SB herds. Income over feed costs (IOFC) for the combined cow/calf and post-weaning phases was significantly higher in SA and SB and decreased as BSL decreased. These results show that selection for feed efficiency would increase post-weaning feed efficiency and IOFC by about 10 and 12% respectively, and have a small positive impact on ADG. Shorter BSL increased replacement rate and decreased IOFC.

Key Words: Beef Model, Feed Efficiency, Selection

W183 Agricultural sustainability: The environmental impact of using recombinant bovine somatotropin (rbST) to improve the productive efficiency of one million lactating dairy cows. J. L. Capper*¹, R. A. Cady², and D. E. Bauman¹, ¹Cornell University, Ithaca, NY, ²Monsanto Company Animal Agriculture Group, St Louis, MO.

This study modeled the effects of supplementing one million lactating cows with rbST on the environmental impact of dairy production when compared to an equivalent milk production from unsupplemented cows. The model employed 2006 average milk yields (28.9 kg/d) and a 4.54 kg/d response to rbST, a 14 mo calving interval and a 60 d dry period. Use of rbST was assumed to begin at 57 DIM. Each population contained lactating cows, dry cows and replacement heifers, for which rations were formulated according to NRC. Resource inputs included feedstuffs, fertilizers and fossil fuels; waste outputs included manure, N and P excretion and greenhouse gas emissions. Supplementation of one million cows with rbST reduced the total population size required to produce 12.1 billion kg milk by 334,859 animals. In consequence, the quantity of nutrients required to maintain the population was decreased by 6.24×10^9 MJ metabolizable energy and 6.05×10^4 kg crude protein, and land required for feedstuff production was reduced by 2.19×10^5 ha. Total N and P excretion was considerably lower from the rbST-supplemented population, with annual reductions in greenhouse gas emissions of 8.2 million kg CO₂, 41 million kg CH₄ and 9,600 kg N₂O. Non-renewable resource (fossil fuel) requirements for feedstuff production were 7.28 million MJ/y lower in the rbST-supplemented population. Furthermore, both electricity (1.56 million kWh/y) and water (5.43 billion l/y) use were lower for the population supplemented with rbST. The carbon footprint, calculated as total CO₂-equivalents, was reduced by 1.77 billion kg/y. Reductions in resource inputs and waste outputs conferred by rbST use would considerably lessen the environmental impact of dairy production. Clearly rbST is a valuable dairy management tool that increases the efficiency of milk production, reduces the carbon footprint and improves agricultural sustainability.

Key Words: Recombinant Bovine Somatotropin, Biotechnology, Dairy

W184 Change in natural abundance of ¹⁵N and estimation of nitrogen losses from dairy manure during storage by mass balance and nitrogen to phosphorus ratio. M. J. Aguerre*¹, G. A. Broderick^{1,2}, and M. A. Wattiaux¹, ¹University of Wisconsin, Madison, ²US Dairy Forage Research Center, Madison, WI.

The main objective was to evaluate methodologies to estimate nitrogen (N) losses from stored dairy manure. Manure with high N (HN) and low N (LN) content was obtained from two groups of cows assigned diets of 17 and 15% CP (DM), respectively. Manure collected from the barn floor was diluted with water to 10% DM, loaded in 200 L barrels (186 kg) with or without addition of chopped straw (22 g/kg of undiluted manure) and stored in a partially temperature-controlled environment. Manure samples were collected on days 0 and 136 of storage and analyzed for N, phosphorus (P) and ¹⁵N natural abundance ($\delta^{15}N$). Nitrogen loss was estimated by mass balance and changes in N:P ratio. The study was conducted once in May and twice in October. There were no interactions for the reported measurements. Addition of straw had no effect on N loss measured by mass balance or N:P ratio. Nitrogen losses estimated by mass balance were reduced by 36 % on LN relative to HN (see table). Using the N:P ratio there was a trend for a reduction in N loss for LN relative to HN manure, however N loss measured using this technique was on average 44 % lower than estimated by mass balance. Average ¹⁵N abundance in manure increased during storage from 4.965 to 5.995‰, probably due to volatilization of ammonia depleted in ¹⁵N, but there was no difference in the magnitude of the increase between the LN and HN manures. Abundance in ¹⁵N at day 136 was lower when straw was added (5.603 vs. 6.398 ‰, $P < 0.01$), indicating that straw-containing manure may have lost less ammonia N. Results from this study suggested also that N loss was influenced by initial manure N content. Estimates of N losses were substantially lower using the change in N:P ratio compared with the values observed by mass balance.

Table 1.

Item	LN	HN	SEM	P-value
Total N Day 0, g	546	642	17.3	<0.01
Total N Day 136, g	447	490	13.8	0.06
N loss, g	98	153	16.3	0.04
N:P Day 0	6.03	6.98	0.5	0.23

N loss, g	54	85	10.0	0.07
$\delta^{15}N$ Day 0, ‰	4.95	4.98	0.4	0.96
$\delta^{15}N$ Day 136, ‰	6.01	5.98	0.2	0.93

Key Words: Nitrogen Loss, Manure

W185 Performance and selenium incorporation in beef heifers grazing pastures growing in saline soils containing high levels of trace minerals. S. O. Juchem*^{1,2}, S. E. Benes², P. H. Robinson¹, P. Vasquez², M. Brito², G. Getachew³, and P. Chilibruste⁴, ¹University of California, Davis, ²California State University, Fresno, CA, ³University of California, Davis, CA, ⁴Instituto Nacional de Investigaci3n Agropecuaria, Montevideo, Uruguay.

Salinification of soils in parts of the San Joaquin valley of California has led to the need to grow salt tolerant forages as a means of evapotranspiring water in order to concentrate salts in drainage water. Our objective

was to determine tissue selenium (Se) concentrations and performance of beef heifers grazing forages with high (>3 mg/kg DM) of Se, being 'Jose' tall wheatgrass (TWG) (*Thinopyrum ponticum* var. 'Jose') and creeping wildrye (CWR) (*Leymus triticoides* var. 'Rio'). Twenty 6 m old Angus heifers were allocated to two grazing areas, where each ~9 ha TWG or CWR area was divided into two subplots, with each subdivided into 4 paddocks that were rotationally grazed at 14 d intervals. Heifers grazed the TWG and CWR pastures for 190 d from May to November (2007). Blood and liver were sampled before grazing and at 190 d of grazing. At ~45 d intervals during grazing, additional samples of blood were collected and BW was recorded before grazing and at 135, 150 and 190 d of grazing. Concentrations of minerals in whole blood or serum, and in liver tissue, were determined. Data sampled over time were analyzed as repeated measures with the experimental unit (heifers) nested within subplots. Preliminary data (n=16) on chemical composition indicates that TWG had higher ME (7.7 vs. 6.6 MJ/kg DM) and CP (12.2 vs. 11.0% DM), whereas Se did not differ (4.7 vs. 3.9 mg/kg DM). Heifers grazing TWG gained more BW (0.59 vs. 0.27 kg/d; P<0.01), and these BW gains were higher than expected. Accumulation of Se in blood occurred quickly, with Se increasing by more than 300% by 45 d of grazing, with TWG heifers having higher concentrations of Se (0.67 vs. 0.48 ppm; P<0.05) at 45 d of grazing than did CWR heifers. However by 190 d, Se concentrations in blood were similar (0.87 vs. 0.94 ppm). Concentrations of Se in liver increased with time, but heifers grazing CWR had higher concentrations of Se (3.9 vs. 2.1 mg/kg) at 190 d of grazing than did TWG heifers. Use of TWG and CWR are viable options to increase the value to soils with low agronomic potential due to salinity, in spite of the high concentrations of Se in the plant tissue.

W186 Factors affecting milk component levels in Northern New York dairy herds. L. E. Chase*, W. C. Stone, C. M. Ryan, J. P. Tauzel, and T. R. Overton, *Cornell University, Ithaca, NY.*

Milk components are key determinants of the price received for milk on dairy farms. The objective of this field study was to investigate nutritional and management factors that may be related to differences in milk fat and true protein (TP) in cooperating dairy herds. Dairy herds (n=52) in 6 Northern NY counties were used in this study. All herds had to be on DHI test, feed total mixed rations and average > 29.5 kg/d of milk per cow. Milk fat percent was the main factor used to select herds. Visits were made to each herd and feed, forage, TMR, water and bulk tank milk samples were collected. Ration and grain mix composition was obtained from the feed representative. Regression analysis was used to identify factors that were related to variations in milk component levels across herds. Average milk production was 34.4 kg (SD ± 9.7). Average milk fat % was 3.47 (SD ± 0.29, range = 2.7 to 4.2%). Milk TP mean was 3.0 (SD ± 0.1, range = 2.8 to 3.3%). Seventeen herds were housed in tie-stall barns and 35 herds were housed in free-stall barns. Twenty-four herds milked twice a day and 28 herds milked 3 times per day. There were no significant relationships between number of cows per herd or herd average milk production and milk fat or TP percent in this study. There were only a few factors that had a significant (P<0.05) relationship with either milk fat or TP content. These were corn silage particle size, as determined using the Z-box, and milk fat %. Corn silage starch, NDF and nonfiber carbohydrate (NFC) levels also had significant relationships with milk fat %. The only significant relationships detected with milk TP % were ration starch and NFC levels. None of these factors accounted for > 10% of the variation observed in milk component levels. Herds with lower milk fat levels had significantly (P<0.05) higher levels of trans-10 C18:1 in bulk tank milk samples. The results of this study

identified some nutritional parameters that appear to be associated with milk component levels in these herds.

Key Words: Milk Fat, Milk Protein

W187 Survival curves and reproductive risk factors for culling in dairy herds. A. De Vries*¹ and J. Olson², ¹*University of Florida, Gainesville,* ²*Pfizer Animal Health, Fort Collins, Co.*

Objective of this study was to quantify dairy cow survival by stage of lactation and parity and reproductive risk factors for culling in Holstein herds. Data were DHI lactation records from 38 states primarily from the eastern US. After editing, the final data set contained 2.2 million records in 707 herds with at least 200 cows in each of the years from 2001 to 2006. For each herd-year, the breeding program was characterized as unlikely, possibly, probably or most likely synchronized. Synchronized breeding occurred mostly on Thursday (48%) or Friday (30%). Daily risk of culling was expressed per 100,000 days at risk. Daily risks of culling at 5, 30, 60, 120, 200, 300, 400, and 500 d after calving were 73, 124, 150, 145, 146, 275, 381, and 446 for open cows, respectively. For pregnant cows, daily risk of culling was -, -, 4, 35, 43, 46, 66, and 79. At day 5, the risk of culling was 132 for first parity cows, but increased from 32 to 64 for cows in parity 2 to 6 respectively. At day 30, cows in the second parity had the lowest risk. At day 60 and later, greater parity cows had higher daily risks of culling. At day 30, the primary reason for leaving the herd was death (35%) followed by injury/other (23%). By 400 DIM, primary reasons were repro problems (36%), followed by death (24%) and low production (15%). Hazard ratios of culling for parities 2 and 3+ were 2.2 and 4.2, respectively compared to parity 1. Breeding program did not affect the hazard of culling. The hazard ratio for cows with milk yields < 5 kg at 70 DIM compared to average herd mates was 3. For average cows it was 1.3 compared to cows with relative milk yields > 5 kg. Longer herd average days to first service only marginally increased the hazard ratio of culling. Herds with pregnancy rates < 12% had hazard ratios of 1.3 compared to herds with > 16% pregnancy rates. Of the first parity cows not pregnant at 150 DIM, 9% were culled by 365 DIM. For second and greater parity cows, results were 19 and 30%, respectively. Quantification of survival curves and reproductive risk factors for culling is useful for identification of opportunities to reduce forced culling losses.

Key Words: Culling, Reproduction, Hazard

W188 Effect of concentrations of progesterone during a timed AI protocol on fertility of lactating dairy cows. J. R. Lima¹, J. E. Santos², F. Rivera*¹, C. D. Narciso¹, R. A. Oliveira¹, and R. C. Chebel¹, ¹*University of California Davis, Tulare, CA,* ²*University of Florida, Gainesville, FL.*

Objective was to evaluate the effect of progesterone (P4) concentrations during a timed AI protocol on pregnancy risk (PR). Lactating dairy cows, from 2 dairy herds, were presynchronized with 2 injections of prostaglandin F2 α (PGF), 14 d apart (Presynch), and cows observed in estrus were inseminated (EST = 1,301). Cows not inseminated by 11 d after the end of the Presynch were submitted to the Heatsynch (d 0 GnRH, d 7 PGF2 α , d 8 estradiol cypionate, and d 10 TAI). At the beginning of the Heatsynch, cows were randomly assigned to receive

no exogenous P4 (CON = 432), one CIDR insert (CIDR1 = 440), or two CIDR inserts (CIDR2 = 440) from d 0 to 7. Blood was sampled at the end of the Presynch and at the beginning of the Heatsynch for determination of P4 concentrations. Cows with P4 concentration < 1.0 ng/mL in both samples were considered anovular and those with at least one sample > 1.0 ng/mL were considered cyclic. From a subgroup of cows, blood was sampled on d 3 and 7 of the Heatsynch. Pregnancy was diagnosed at 38 and 66 d after AI. Data were analyzed including all cows or only cows randomly assigned to treatments. During the Heatsynch, CIDR2 cows had the greatest ($P < 0.01$) P4 concentration (CON = 3.7 ± 0.3 , CIDR1 = 4.6 ± 0.3 , CIDR2 = 5.5 ± 0.3 g/mL). Proportion of cows classified as anovular was similar ($P = 0.67$) among treatments (CON = 20.2, CIDR1 = 17.8, CIDR2 = 19.3%), but it was different ($P < 0.01$) between sites (11.1 and 20.6%). When all cows were evaluated, treatment did not affect PR at 38 d (CON = 35.9, CIDR1 = 39.1, CIDR2 = 37.1, EST = 40.9%; $P = 0.43$) or 66 d (CON = 32.4, CIDR1 = 35.8, CIDR2 = 34.4, EST = 37.8; $P = 0.62$). When only cows randomly assigned to treatments were evaluated, treatment and the interaction between treatment and cyclicity did not affect PR at 38 ($P = 0.61$ and $P = 0.28$, respectively) and 62 ($P = 0.59$ and $P = 0.42$, respectively) d after AI. Anovular cows, however, tended to have smaller PR at 38 (31.2 and 38.9%; $P = 0.07$) and 62 (28.0 and 35.8%; $P = 0.06$) d. Treatment with 2 CIDR inserts increased P4 during a timed AI protocol but did not improve PR.

Key Words: Dairy Cow, Progesterone, Synchronization

W189 Effect of change in body condition score during the dry period on incidence of diseases and lactational and reproductive performance of Holstein cows. L. Lima¹, J. E. Santos², and R. C. Chebel^{*1}, ¹University of California Davis, Tulare, ²University of Florida, Gainesville.

Objectives were to evaluate the association between body condition score (BCS) change during the dry period and health, lactation, and reproductive performances of Holstein cows. Data from 2,089 multiparous cows and 3,451 lactations were collected. Cows received a BCS at dry off and at parturition and were classified according to change in BCS during the dry period as no change (NC), lost BCS (LB), and gained BCS (GB). Postparturient diseases were diagnosed by farm personnel. Milk yield and fat and true protein concentrations were recorded monthly. Productive and reproductive data were collected up to 305 d postpartum (DIM). The length of the dry period was longest ($P < 0.01$) for GB cows (NC = 63.9 ± 1.0 , LB = 64.6 ± 1.0 , GB = 67.5 ± 1.1 d). Change in BCS in the dry period tended ($P = 0.07$) to affect incidence of ketosis (NC = 2.3, LB = 4.3, GB = 2.5%). Milk yield (NC = 37.7 ± 0.4 , LB = 36.1 ± 0.4 , GB = 38.7 ± 0.4 Kg/d) and yield of 3.5%-fat corrected milk (NC = 40.2 ± 0.5 , LB = 38.6 ± 0.5 , GB = 41.4 ± 0.5 Kg/d) were ($P < 0.01$) greatest for GB cows. Milk fat concentration tended ($P = 0.06$) to be affected by BCS change (NC = 3.56 ± 0.03 , LB = 3.55 ± 0.03 , GB = $3.60 \pm 0.03\%$) and GB cows had ($P < 0.01$) the greatest yield of fat (NC = 1.41 ± 0.02 , LB = 1.35 ± 0.02 , GB = 1.45 ± 0.02 Kg/d). Change in BCS was not ($P = 0.71$) associated with true protein concentration, but it was associated ($P < 0.01$) with yield of true protein (NC = 1.18 ± 0.01 , LB = 1.14 ± 0.01 , GB = 1.20 ± 0.01 Kg/d). Interval from parturition to pregnancy (NC = 186.7 ± 2.8 , LB = 182.1 ± 2.7 , and GB = 175.6 ± 3.8 d) and from parturition to the time cows left the herd (NC = 256.5 ± 2.5 , LB = 255.6 ± 2.6 , and GB = 272.4 ± 3.0 d) were ($P < 0.01$) associated with BCS change. Greater ($P < 0.01$) proportion of GB cows remained in the herd after 305 DIM (NC = 73.9, LB = 72.9, and GB = 79.1%). Increase in BCS during the dry period was associ-

ated with improved health, reproductive, and productive performance of multiparous lactating dairy cows.

Key Words: Dairy Cow, Dry Period, Body Condition Score

W190 Comparison of pregnancy diagnosis strategies by stochastic simulation. A. H. Sanders* and A. De Vries, University of Florida, Gainesville.

Recent emphasis has been on earlier pregnancy diagnosis (PD) in dairy cattle. Combining earlier PD with an estrous control plan (SYNC, e.g. Ovsynch[®]) to minimize time to re-breeding, could decrease days open, but the success of a re-breeding plan is also influenced by pregnancy losses which occur after PD, accuracy of PD, and success in re-breeding. The economic efficiency of these strategies is less clear, being influenced by costs and returns from cows. Stochastic simulation is a useful way to compare different strategies while controlling influential factors over a long time span. In this study, PD by ultrasound (US) at 27 days post breeding was compared to PD by rectal palpation (RP) at 35 days post breeding. A 100 cow herd with production based culling for bred heifer replacements was modeled. Stochastic elements included gestation length, cyclicity, estrus detection (ED), fertilization, pregnancy loss, and milk production. Daily risk of resuming cyclicity was LogN~(19,11). Probability of ED were 0.30, 0.50, or 0.70. Probability of fertilization when breeding at estrus was 0.90, with daily risk of embryo loss before 42d Exp~(60) and fixed after 42d so overall probability of a late abortion was 0.03. Cows observed in estrus >60 days in milk (DIM) were bred by artificial insemination (AI). Open cows were bred by timed AI (TAI) at 75 DIM following SYNC. Cows open at PD were enrolled in SYNC for re-breeding. Cows open after 250 DIM were not rebred. Sample size was selected for >80% power using GLMPOWER (SAS[®]). Data were yearly milk yield (MY), live calves (LC), SYNC enrollments, AIs, PDs, and culls, in steady state, from 700 replicates of each PD x ED combination. Improving ED from 0.3 to 0.7 increased yearly MY (103.3kg) and LC (0.04), and decreased culls (0.04) and inputs (0.35, 0.28, and 0.14 for TAI, PD, and AI) per cow-slot. Yearly SYNC enrollments and PDs were 0.037 ± 0.003 and 0.177 ± 0.003 greater per slot with US than RP, and MY was 10.33 ± 3.09 kg less. Culls, LC and AI differed only slightly. This suggests that US may not be an efficient PD strategy because costs are generally greater than RP without improved returns from milk or cow turnover.

Key Words: Pregnancy Diagnosis, Simulation

W191 Supplementation of progesterone via CIDR inserts during ovulation synchronization protocols in lactating dairy cows. R. C. Chebel^{*1}, M. J. Al-Hassan², P. M. Fricke², J. E. Santos³, C. A. Martel⁴, J. S. Stevenson⁴, R. Garcia⁵, R. L. Ax⁵, and F. Moreira⁶, ¹University of California Davis, Tulare, ²University of Wisconsin, Madison, ³University of Florida, Gainesville, ⁴Kansas State University, Manhattan, ⁵University of Arizona, Tucson, ⁶Pfizer Animal Health, New York, NY.

Our objective was to determine the effect of exogenous progesterone (P4) during timed AI protocols on pregnancy risk (PR) in dairy cows not previously observed in estrus. Lactating cows, from 6 dairy herds, were submitted to a Presynch protocol (2 injections of PGF2 α [PGF] 14 d apart), and cows in estrus after the second PGF received AI (EDAI, n

= 1366). Cows not inseminated by 12-14 d after the end of the Presynch received a timed AI (TAI) protocol (GnRH [d 0], PGF [d 7], GnRH [48-72 h after PGF], TAI [0-24 h after GnRH]). At onset of the TAI protocol cows were blocked by parity and DIM and randomly assigned to receive no exogenous P₄ (CON, n = 721) or a CIDR insert (CIDR, n = 770). Blood was sampled at the second PGF injection of Presynch and at onset of the TAI protocol for P₄ determination. Cows with 2 samples in which P₄ < 1.0 ng/mL were classified as anovular and those with 1 or 2 samples in which P₄ > 1.0 ng/mL were classified as cyclic. Pregnancy was diagnosed at 38 and 62 d after AI. Data were analyzed including all cows or only cows randomly allocated into treatments. Proportion of cows inseminated following the Presynch was different among sites (P < 0.01). Proportion of anovular cows at the onset of the TAI protocol was affected (P < 0.01) by site (range 13.7 to 33.5%), but it was similar (P = 0.88) between treatments (CON = 25.7, CIDR = 26.0%). When all cows were considered, treatment did not (P = 0.12) affect PR at 38 d (CON = 33.7, CIDR = 37.9, EDAI = 38.5%), but it tended (P = 0.08) to affect PR at 62 d (CON = 30.0, CIDR = 34.9, EDAI = 34.9%). When only cows randomly assigned to treatments were considered (model 2), PR at 38 and 62 d tended to be (CON = 33.7, CIDR = 37.9%; P = 0.10) and was (CON = 30.0, CIDR = 34.9%; P = 0.05) improved by exogenous P₄, respectively. Cyclic cows had greater (P < 0.01) PR at 38 (38.4 vs. 29.1%) and 62 (34.9 vs. 25.7%) d than anovular cows, but PR did not differ (P > 0.15) among sites at 38 (range 31.9 to 42.4%) and 62 (range 28.6 to 37.5%) d. Use of exogenous P₄ during TAI protocols improved fertility of lactating dairy cows not previously observed in estrus.

Key Words: CIDR Insert, Dairy Cow, Synchronization

W192 Characterization of postpartum estrous behavior in lactating cows using radiotelemetry in a large dairy. C. R. Johnson^{*1}, M. W. Ayers², A. Ahmadzadeh³, S. Etter⁴, R. C. Chebel⁵, and J. C. Dalton¹, ¹Caldwell Research and Extension Center, Caldwell, ID, ²Caine Veterinary Teaching Center, Caldwell, ID, ³University of Idaho, Moscow, ⁴Canyon County Extension, Caldwell, ID, ⁵University of California, Tulare.

The objective of this study was to describe postpartum estrous behavior in lactating cows using radiotelemetry in a large dairy (n = 1,315 cows). Average annual milk production was 12,310 kg. Cows (n = 30) were continuously monitored for behavioral estrus by HeatWatch II (CowChips LLC, Denver, CO) from 14 to 49 d postpartum. Blood collection (for analysis of progesterone, P₄) and ovarian ultrasonography were performed once weekly. Based on increased concentration of P₄, 25 cows exhibited first ovulation without behavioral estrus. First ovulation was estimated to have occurred within four days before evidence of increased P₄ concentration (Appl. Anim. Behav. Sci. 66; 2000; 153-159). Estimated first ovulation occurred at 23.3±10.2 d (range 10-45 d) for 25 animals without evidence of behavioral estrus. A corpus luteum was visualized by ultrasonography in 22 of 25 cows. First ovulation was associated with behavioral estrus in 3 cows and occurred at 28±10.1 d (range 17-37 d). The average duration of estrus was 7.5±3.6 h (range 3-10.5 h), and average number of mounts were 19±1.7 (range 17-20). The interval postpartum to estimated first ovulation and first ovulation associated with behavioral estrus was not different. Cows that showed evidence of first ovulation with or without behavioral estrus (n = 28) were placed into two milk production groups, >47.3 kg (n = 12) and <47.3 kg (n = 16), based on first milk test weights. Level of milk production did not affect the interval to estimated first ovulation without estrus or first ovulation associated with estrus. The remaining two animals

did not show evidence of ovulation based on P₄ concentration. The majority of first ovulations (25/28; 89.3%) were not associated with behavioral estrus.

Key Words: Radiotelemetry, Estrous Behavior, Dairy Cattle

W193 Effect of overnight pasture on metritis and milk production of transition cows. C. Goldhawk^{*1}, N. Chapinal^{1,2}, D. M. Veira², J. Rushen², A. M. de Passillé², D. M. Weary¹, and M. A. G. von Keyserlingk¹, ¹University of British Columbia, Vancouver, BC, Canada, ²Pacific Agri-Food Research Centre, Agassiz, BC, Canada.

Transition dairy cows are highly susceptible to disease, and thus require management practices which reduce the occurrence of disease. Continuous access to pasture has shown improvements in udder health, however, it is unclear if this benefit can be extended to other health issues, such as metritis. This study tested the effect of housing transition cows on pasture overnight on dry matter intake, milk production and incidence of metritis. Forty-four multiparous and 26 primiparous Holstein dairy animals were monitored for 3wk prior to calving and 3wk post calving. All animals were housed in freestall pens (n=6) with 12 stalls at densities of 8-12 animals. Control cows (n=35) remained indoors 24 hr/d. Pasture cows (n=35) were housed in the same pens as controls but remained indoors from 0700-2000 and on pasture from 2000-0700. Detailed feeding behaviour of 20 pasture and 20 control cows was monitored from 2 wk pre to 3 wk post-calving in one pre-partum and two post-partum pens. After calving, body temperature and milk production were collected daily, and vaginal discharge was examined for detection of metritis at +3, +5, +7, +14 and +21 d. Following data collection, cows were classified as healthy (metritis score 0 or 1, no fever) or metritic (one metritis score ≥2). Cows with confounding health issues were removed, leaving 26 cows in the pasture group and 25 cows in the control group. We found no difference in the number of cases of metritis between treatment groups (11 pasture vs. 9 control, P>0.1). DMI of TMR, which was provided indoors, was similar between control and pasture cows for the duration of the transition period (12.8kg/d±0.95 vs. 11.62kg/d±0.67, P>0.1), except during week -2 when DMI was higher for control cows (13.7kg/d±0.73 vs. 11.8kg/d±0.60, P<0.05). Milk yields were also similar between groups (pasture=32.0kg/d±1.20, control=32.2kg/d±1.17) during the first 21 DIM. The results of this study indicate that overnight pasture access does not reduce TMR intake nor milk yield and has no effect on the prevalence of metritis.

Key Words: Transition, Pasture, Metritis

W194 Influence of hen's age on some productive indices of broilers in the hot humid southwestern Nigeria. O. T. F. Abanikannda¹, A. O. Leigh¹, O. Akinsola¹, I. S. Okoya^{*1}, O. N. Coker², I. O. Ola-Gbadamosi¹, and A. L. Dare³, ¹Lagos State University, Ojo, Lagos State, Nigeria, ²S & D Farms Nigeria Limited, Odeda, Ogun State, Nigeria, ³Obasanjo Farms Nigeria Limited, Igboora, Ogun State, Nigeria.

The relatively high meat yield and fast growth rate in broilers provides for an economical source of animal protein, which has been widely accepted by consumers. This study examined the effect of hen's age on some productivity indices (egg weight, fertility, hatchability, egg weight at candling and chick weight) within four flocks of the same breed that

originated from the same line, albeit at different ages. The hens were kept under similar management and environmental conditions and were all derived from the same line. The 607 hatchable eggs used in this study were sampled from the a single line of Anak broiler breeders at 39, 43, 66 and 106 weeks of age, comprising 34.60, 11.53, 34.10 and 19.77 percent respectively. Egg weight at 18 days consistently increased with age, aside from a slight drop observed at 43 weeks, which may have been attributed to a small sample size. However, the chick weight progressively increased as the hen's age increases. Fertility of the eggs was least at 66 weeks, while hatchability was least at 106 weeks. Hatchability after the initial rise at 43 weeks consistently decreased afterwards. A test of independence of fertility and hatchability of eggs on hen's age was highly significant ($P < 0.001$), with X^2 values of 24.79 and 29.53 respectively. It was observed that for a profitable and successful hatchery operations, breeder hens are better kept for optimal productivity up to about one year old and should be disposed thereafter.

Table 1. Some productive indices of Anak broiler breed at different ages

Age (Weeks)	N	Egg Weight (g)	Fertility (%)	Hatchability (%)	‡Weight at Candling (g)	Chick Weight (g)
39	210	56.94±0.33 ^b	88.10	79.46	49.28±0.33 ^b	37.72±0.33 ^c
43	70	56.17±0.59 ^b	90.00	82.54	48.36±0.58 ^b	37.79±0.59 ^{bc}
66	207	60.84±0.43 ^a	71.50	70.27	51.83±0.47 ^a	39.50±0.39 ^b

W195 Effect of two levels of diet density and milking frequency on performance of Holstein fresh lactating cow. N. Aghaziaraty*, H. Amanlou, D. Zahmatkesh, E. Mahjoubi, and S. Siari, *Zanjan University, Zanjan, Iran.*

The aim of this study was to investigate the effect of diet density and milking frequency on performance of fresh lactating cows. 20 fresh lactating cows (8 primiparous and 12 multiparous) arranged in a 2×2 factorial block design. The cows were fed two levels of diet density (high density (H) or low density (L) diet) and milked 3 time (3x) or 6 time (6x) daily. The four treatment combinations were L3, L6, H3 and H6, and experimental period comprised from day of 3 to 25 postpartum. The effect of milking frequency on DMI ($P<0/05$), milk production ($P<0/002$), and yield of milk fat ($P<0/003$) and milk protein ($P<0/002$) was significant and for 6x cows was higher, but on percentage of milk fat, milk protein, SNF, and blood metabolites was not significant. The NEFA concentration was affected by milking frequency ($P<0/01$). The effect of diet density on DMI, percentage of milk fat, milk protein, blood metabolites, and SNF was not significant, but on milk production ($P<0/035$), yield of milk fat ($P<0/02$) and milk protein ($P<0/01$) was significant and was higher for high density diet. The interaction of milking frequency and diet density was not significant for any measured parameters in this study. Final conclusion is that increasing milking frequency and diet density in early lactation can increase milk production.

Key Words: Fresh Cow, Milking Frequency, Diet Density

W196 Effect of applying bacterial inoculants to corn silage on the performance of dairy cattle. K. G. Arriola*, A. T. Adesogan, S. C. Kim, T. W. Kang, A. F. Pedroso, O. C. Queiroz, J. L. Foster, and C. R. Staples, *University of Florida, Gainesville.*

This study examined the effect of applying different bacterial inoculants to corn silage at the point of ensiling on the performance of lactating dairy cows. Corn plants were harvested at 35% DM, chopped and ensiled in Ag bags after application of 1) nothing (CON), 2) a homolactic inoculant (B2+) containing 3.63×10^{10} cfu/g of *Pediococcus pentasaceus* and *Propionibacteria freudenreichii* 3) a heterolactic inoculant (BUC) containing 4.95×10^{10} cfu/g *Lactobacillus buchneri*; and 4) a combo inoculant (500) containing 4.99×10^{10} cfu/g of *P. pentosaceus* and *L. buchneri*. Each of the 4 silages was mixed into separate total mixed rations consisting of 44% corn silage, 50% concentrate and 6% alfalfa hay (DM basis). Fifty two lactating Holstein cows were classified according to milk production and parity and randomly assigned at 22 DIM to the four dietary treatments. Cows were fed ad libitum and milked twice daily for 49 d. Dietary treatment did not affect intakes (kg/d) of DM (20.1), CP (3.65), NDF (5.72), or ADF (3.54), or digestibility (%) of DM (73.8) or CP (72.4). However, cows fed B2+ had lower NDF digestibility than those fed other diets (45.3 vs. 53.0%). Consequently, cows fed B2+ had lower digestible NDF intake (kg/d) than those fed other diets (2.5 vs. 3.1 kg/d). Nevertheless, dietary treatment did not affect milk yield (32.3 kg/d), efficiency of milk production (1.64), concentrations of milk fat (3.18%) and protein (2.78%), or yields of milk fat (1.02 kg/d) and protein (1.26 kg/d). Inoculant application to corn silage did not affect the milk yield or feed intake of the cows.

Key Words: Inoculants, Corn Silage, Cow

W197 Timing of herbage allocation on milk production and composition in mid-lactation dairy cows in winter. M. Vaccaro², F. Luparia^{1,2}, C. A. Cangiano¹, D. A. Garcarena¹, and G. A. Gagliostro*¹, ¹*Instituto Nacional de Tecnología Agropecuaria, INTA, Balcarce, Buenos Aires, Argentina,* ²*Facultad de Ciencias Agrarias, UNMDP, Balcarce, Buenos Aires, Argentina.*

The objectives were to evaluate milk yield and composition and dry matter intake (DMI) when the daily pasture strip was allocated each morning (M) or afternoon (A) in winter. Sixteen Holstein cows in mid-lactation (132 ± 11 DIM) were used in a cross over design. Cows were paired based on average milk production during early lactation and randomly assigned to one of two treatments: M: pasture was offered from 0530 to 1100 h and A: pasture was offered from 1100 to 1630 h. In both treatments cows grazed an oat (*Avena sativa*) sward at a daily herbage allowance of 13 kg DM/cow. During the rest of the day cows received 7.3 kg DM/d of maize silage, 2.7 kg DM/d sunflower meal and 6.2 kg DM/d of concentrate (TMR). Each experimental period lasted 20 d with the first 15 d for diet adaptation and the last 5 days for data collection. Data were analyzed as a cross-over design that included effects of treatment, period and sequence. Pasture DM (250 vs 275 g/kg) and soluble carbohydrate (229 vs 199 g/kg DM) contents were higher ($P<0.01$) during the afternoon. Milk production (22.1 kg/cow/d), 4%FCM (20.7 kg/cow/d) and milk fat content (35.9 g/kg) did not differ. Milk protein content was increased ($P<0.01$) in A (38.5 vs. 37.6 g/kg) and milk protein yield did not differ (0.80 kg/d). The efficiency of milk to yield cheese (kg cheese/100 kg of milk) resulted higher ($P<0.01$) in A (10.56) compared to M (10.31). Lactose content was increased ($P<0.01$) in A (51.4 vs 50.5 g/kg). Milk urea content (35 mg/dl) did not differ. Intakes (kg DM/cow/d) of pasture (3.94) and stall TMR diet (15.47) did not differ. The afternoon grazing management in winter improved milk protein content and the value of milk yield for cheese making. These results could probably be linked to a higher concentration of soluble carbohydrates in the afternoon grazed pasture.

Key Words: Morning or Afternoon Grazing, Pasture Water Soluble-Carbohydrates, Grazing Dairy Cows

W198 Effects of feed bunk competition on the feeding behavior of growing dairy heifers. T. J. DeVries*¹ and M. A. G. von Keyserlingk², ¹*University of Guelph, Kemptville, ON, Canada,* ²*The University of British Columbia, Vancouver, BC, Canada.*

Decreased feed bunk access for adult dairy cows increases competition and promotes feeding behavior patterns that increase the between-cow variation in the composition of ration consumed. To date, there is limited data on the effects of feed bunk competition on the behavior of growing dairy heifers. The objective of this study was to determine how feed bunk competition influences the feed sorting, feeding behavior, and feed intake of dairy heifers. Thirty-six prepubertal Holstein heifers, consuming a TMR diet, were assigned to one of 2 treatments: 1) noncompetitive (1 heifer/feed bin) or 2) competitive (2 heifers/feed bin). Dry matter intake and feeding behavior were monitored for 7 d for each animal. Fresh feed and orts were sampled on the last 3 d of the treatment period from each bin and were subjected to particle size analysis. The particle size separator consisted of three screens (18, 9, and 1.18 mm) and a bottom pan resulting in 4 fractions (long, medium, short and fine).

Sorting activity for each fraction was calculated as the actual intake expressed as a percentage of the predicted intake. To determine if sorting occurred, each fraction was tested for a difference from 100%. Overall, the heifers sorted against long particles (93.8%; $P \leq 0.01$), and sorted for medium (102.2%; $P \leq 0.005$) and short (102.7%; $P \leq 0.02$) particles. There was no difference in sorting behavior between the treatments. The competitively-fed heifers did not have lower daily DMI (6.3 vs 6.2 kg/d; SE=0.3, $P=0.8$), but did consume a higher proportion of their daily DMI in the later hours of the day. The competitively-fed heifers tended to have shorter feeding times (191.8 vs 212.5 min/d; SE=7.8, $P=0.08$), particularly during peak feeding times. These changes translated into a tendency for a higher intake rate (0.047 vs. 0.038 kg/min; SE=0.004, $P=0.15$) throughout the day for the competitively-fed heifers. These results suggest that increased competition at the feed bunk promotes feeding behavior patterns that will likely increase the between-heifer variation in composition of ration consumed.

Key Words: Heifers, Sorting, Competition

W199 Relationship between indices of energy status and plasma lipids, lipid-soluble vitamins and hepatic-derived export proteins in periparturient Holstein and Jersey cows. P. Rezamand*, T. A. Hoagland, R. M. Clark, and S. M. Andrew, *University of Connecticut, Storrs.*

In an observational study, the effect of breed on indices of energy status and plasma concentrations of lipid-energy metabolites, lipid-soluble vitamins, and hepatic-derived export proteins were investigated. Fifteen Holstein and 15 Jersey cows were monitored from cessation of lactation at wk -9 before expected calving date (ECD) through 8 wk of the subsequent lactation. Body condition scores (BCS) were measured at wk -9, -4, -2 and -1 (before ECD), and at wk 1, 3, 5, 7 and 8 postpartum (PP). Body weights (BW) were measured at wk -4 and -2 before ECD, and daily milk yield, weekly milk energy yield, and BW were measured for 8 weeks PP. Plasma metabolites were determined at wk -2 (before ECD) and at wk 1, 2, 4, and 8 PP. Data were analyzed using the mixed model of SAS with wk as a repeated measure. Although milk yield was greater for Holstein cows, there were no breed differences in milk energy yield adjusted to metabolic body size. Holstein cows lost more BW as compared with Jersey cows (128.1 vs. 89.1 \pm 11.6 kg). Although Holstein cows had greater BCS at wk -4 and wk -2 (before ECD), Jersey cows had a greater BCS at wk 8 PP ($P = 0.001$). Plasma non-esterified fatty acid and β -hydroxy butyrate (BHB) concentrations at wk 1 PP tended to be greater (+133 μ Eq/L and +170 μ mol/L) for Holstein than for Jersey cows. Holstein cows had reduced plasma concentrations of phospholipid (20 vs. 35.1 \pm 4.1 mg/dL; $P = 0.03$) and β -carotene (3.51 vs. 5.69 \pm 0.55 μ g/mL; $P = 0.03$) and greater plasma cholesterol concentrations PP compared with Jersey cows ($P = 0.001$). Holstein cows with high peak plasma BHB concentrations (>1000 μ mol/L) and no clinical signs of ketosis had reduced plasma apolipoprotein B (24.1 vs. 30.6 \pm 1.23 mg/dL), transthyretin (0.79 vs. 1.00 \pm 0.04), and retinol-binding protein (0.84 vs. 1.02 \pm 0.04) compared with Holstein cows with low peak BHB ($P < 0.003$). These findings suggest that the association between increased lipid mobilization and reduced synthesis or release of export proteins was greater for Holstein than for Jersey cows.

Key Words: Energy Status, Transition Period, Holstein and Jersey

W200 Effects of monensin and propylene-glycol on milk production and milk composition of Holstein lactating cows. H. Bahrami-Yekdangi, K. Rezayazdi, M. Dehghan-Banadaky*, A. Nejati-Javaremi, and F. Fatehi, *University of Tehran, Tehran, Iran.*

We evaluated the effects of Monensin and propylene glycol on feed intake, milk production and milk composition on 16 primiparous and multiparous Holstein lactating cows (60 \pm 30 DIM, Milk production 33 \pm 3 Kg/day) between September and November of 2007. Cows were used in a completely randomized design with 4 treatments (additives) and 4 replication (cows) and were fed a balanced total mixed ration (60% concentrate and 40% forages) with or without additives. Cows in group 1 were fed TMR without additive (control), Cows in group 2 were fed TMR with 335 mg/day monensin, Cows in group 3 were fed TMR with 400 ml/day propylene glycol, and cows in group 4 were fed TMR with 335 mg/day Monensin and 400 ml/day propylene glycol. Data were analyzed using mixed models for repeated measurement.

Experimental treatments did not affect feed intake and milk composition but propylene glycol significantly increased milk yield of cows (32.23, 34.53, 35.91 and 33.79 kg/day for groups 1-4 respectively). Monensin and/or propylene glycol significantly increased concentrations of plasma glucose (51.92, 56.15, 56.92 and 58.56 mg/dl for groups 1-4 respectively) and insulin (0.43, 0.65, 0.54 and 0.91 mg/dl for groups 1-4 respectively). Concentration of Plasma triglycerides (13.67, 11.97, 11.63 and 8.96 mg/dl for groups 1-4 respectively) were lower in Monensin and/or propylene glycol treated cows ($P < 0.05$). Treatments had not significantly effect on concentration of plasma calcium and phosphorus ($P > 0.05$).

Key Words: Monensin, Propylene-Glycol, Milk

W201 Feed sorting in growing dairy heifers: Effects of dietary dilution. A. M. Greter*¹, T. J. DeVries², and M. A. G. von Keyserlingk¹, ¹*The University of British Columbia, Vancouver, BC, Canada,* ²*University of Guelph, Kemptville, ON, Canada.*

An alternative to limit feeding of dairy heifers is to limit the nutrient density of a formulated diet fed ad libitum, primarily through the addition of a low-quality, inexpensive feedstuff to the ration. The objective of this study was to determine how adding straw to the TMR of growing dairy heifers affects their intake, feeding behavior, and feed sorting behavior. Six prepubertal Holstein heifers were subjected to 3 treatment diets in a replicated 3x3 Latin square design. The treatment diets were: 1) control (17.0% corn silage, 52.1% grass silage, 30.9% concentrate), 2) control diet with 10% straw, and 3) control diet with 20% straw. DMI and feeding behavior were monitored for 7 d for each animal on each treatment. Fresh feed andorts were sampled on the last 3 d of each treatment period for each heifer and were then subjected to particle size analysis. The particle size separator contained 3 screens (19, 8, and 1.18 mm) and a bottom pan, resulting in 4 fractions (long, medium, short, and fine). Sorting activity for each fraction was calculated as the actual intake expressed as a percentage of the predicted intake. To determine if sorting occurred, each fraction was tested for a difference from 100%. Heifers sorted against long particles (90.2%; $P \leq 0.07$) and for short particles (106.3%; $P < 0.05$) on all 3 diets. On the 10% and 20% straw diets heifers sorted for medium particles (102.9 and 105.5%; $P \leq 0.01$). Heifers also sorted for fine particles on the 20% straw diet (107.8%; $P = 0.02$). Feeding time increased (180.2, 193.3, and 199.2 min/d; SE=13.4, $P = 0.05$), whereas DMI decreased (8.1, 7.1, and 6.2 kg/d; SE=0.3, $P < 0.001$) with the addition of straw in the diet. Energy and nutrient requirements were

sufficiently met when the animals consumed the control and 10% straw diet. The results suggest that a moderate level of straw may be included in the diet to target nutrient intake without negatively affecting feeding behavior or growth potential. Furthermore, the ad libitum feeding of a diluted diet provides increased opportunity for these animals to express their natural foraging behavior.

Key Words: Sorting, Heifers, Straw

W202 Fenugreek as forage for dairy cows 2. Effect on rumen fermentation and turnover. A. W. Alemu* and L. Doepel, *University of Alberta, Edmonton, AB, Canada.*

Six multiparous Holstein cows fitted with ruminal cannula were used in a 3x3 replicated Latin square design to examine the effect of two varieties of fenugreek haylage, AAFC F70 and CDC Quatro, on rumen fermentation and turnover rate. Cows were fed isonitrogenous diets consisting of 50% concentrate, 10% barley silage, and 40% AAFC F70 haylage (F70), CDC Quatro haylage (QUAT), or alfalfa haylage (ALF) once daily. Periods were 18 d, with the last 7 d for sample collection. Rumen VFAs, lactate, and ammonia were measured over the last 24h of each period and rumen pH was monitored continuously using indwelling pH probes from d 12-15. Rumen digesta mass and kinetics of rumen neutral detergent fiber (NDF) were determined by complete ruminal evacuation. Data were analyzed using orthogonal contrast of alfalfa vs. fenugreek (FEN) and F70 vs. QUAT. Differences were considered significant at $P < 0.05$. Rumen pH was unaffected by treatment. Rumen ammonia nitrogen (NH_3N) was higher with FEN than with ALF ($P = 0.02$). Ruminal VFAs were not different between treatments except for total VFA, which was higher for ALF than FEN. Mean pool sizes of rumen digesta (84.4 kg) and rumen NDF pool (6.7 kg) were not affected by treatment. Rumen NDF passage rate (Kp), NDF intake rate (Ki) and NDF digestion rate (Kd) were higher for ALF than FEN, and Kp and Ki were higher for QUAT than F70. Rumen turnover time was higher for cows fed F70 than for those fed QUAT, which were both higher than for cows fed ALF. Overall, longer turnover times and slower NDF digestion rates likely contributed to the lower DMI of the FEN fed cows.

W203 Viability of commercial active dry yeast products decreases with high-temperature storage. J. Miranda* and B. J. Bradford, *Kansas State University, Manhattan.*

Active dry yeast (ADY) products are utilized as feed additives in the dairy industry, with the goal of modulating ruminal fermentation and improving productivity. Several proposed modes of action for ADY require that viable cells are fed; however, little information is available regarding viable cell count of commercial ADY products or the effects of summer storage conditions on viability. Samples of 6 ADY products were acquired through normal distribution channels to measure viable yeast cell count. Viable cells were quantified in 3 different samples of each product (from different lots) on receipt. In addition, 1 sample of each product was stored for 3 months at 40°C with ambient humidity, and viable cell count was assessed monthly. Viable yeast cells were quantified according to AOAC method 997.02, with the procedure modified to allow 5 minutes for sample homogenization in phosphate buffer. Colony forming units per gram (CFU/g) were log₁₀-transformed and analyzed by ANOVA to assess effects of storage on yeast viability. Across products, 44% of samples analyzed did not contain the minimum CFU/g guaranteed on the respective product labels, and mean viable cell counts were less than the label claim for 4 of the 6 products sampled, with only 1 product meeting the label claim on all 3 samples collected. Across products, high-temperature storage significantly decreased viable cell count ($P < 0.001$), with mean CFU/g decreasing by more than 85% with each month of storage at 40°C (9.88, 7.37, 6.28, and 5.43 log₁₀ CFU/g for 0, 1, 2, and 3 months of storage, respectively). Active dry yeast products provide highly variable numbers of viable yeast cells, and viability decreases substantially with high-temperature storage.

W204 Exogenous amylase enzymes for lactating dairy cows. C. M. Klingerman*, E. E. McDonell, W. Hu, M. C. Der Bedrosian, and L. Kung, Jr., *University of Delaware, Newark.*

An experimental (7B, Novozymes A/S, Bagsvaerd, Denmark and Dutch State Mines, Heerlen, Netherlands) and a commercial formulation (AMA, Alltech Biotechnology, Nicholasville, KY) of enzymes, with α -amylase activity, were evaluated for activity at various pH, stability in ruminal fluid, the potential to improve in vitro ruminal fermentations and the potential to improve production performance of lactating cows. When incubated (40°C) in buffer with a pH of 5.4, 7B had about 10-25 times more amylase activity than AMA. When the pH was increased to 6.0, enzyme activity increased by 100% for 7B but it decreased by about 26% for AMA. Both formulations maintained enzyme activity when they were incubated in in vitro ruminal fermentations over a 24 h period. After 6 h of ruminal in vitro fermentations, additions of 7B resulted in linear increases ($P < 0.05$) in apparent total VFA production for flint and dent corn but had no effect on floury corn. In a lactation trial, 28 Holstein cows (68 ± 31 days in milk, 46.9 ± 9.1 kg milk/d) were fed a TMR supplemented with nothing (CTRL), a low dose of 7B (7BL, 0.88 ml/kg TMR DM), a high dose of 7B (7BH, 4.4 ml/kg TMR DM), or AMA (0.4 g/kg TMR DM). The experiment was conducted as a 4 × 4 Latin square design with 21-d periods. Cows fed 7BL produced more (47.1 kg/d, $P < 0.05$) milk than cows fed CTRL (43.2 kg/d) and 7BH (44.2 kg/d) but produced similar amounts to cows fed AMA (45.4 kg/d). The production of 3.5% fat corrected milk was greater ($P < 0.05$) from cows fed 7BL and AMA when compared to CTRL. The percentage of milk fat and milk protein were unaffected by treatment. Cows fed

7BL, 7BH, and AMA ate similar amounts of DM (ave. of 28.5 kg/d) and cows fed the latter two diets consumed more ($P < 0.05$) DM than did cows fed CTRL (27 kg/d). Cows fed 7BL had a greater ($P < 0.05$) apparent total tract digestion of DM, OM, and NDF when compared to the CTRL and 7BH diets but digestion of these components were similar to cows fed AMA. The formulations of amylase enzymes evaluated in this study varied greatly in their activity, but were both stable in rumen fermentations and had the ability to increase animal performance.

Key Words: Amylase, Enzyme, Dairy

W205 Evaluation of nutritional management strategies for cows with a short (40-d) dry period. H. M. Dann*¹, M. P. Carter¹, H. M. Gauthier¹, K. W. Cotanch¹, P. D. Krawczel¹, C. S. Mooney¹, C. S. Ballard¹, R. J. Grant¹, T. Eguchi², and T. Nakao², ¹*William H. Miner Agricultural Research Institute, Chazy, NY*, ²*ZEN-NOH National Federation of Agricultural Co-operative Associations, Tokyo, Japan*.

Dairy producers are adopting the use of shorter dry periods for cows, but are unsure of the best nutritional strategy to use. The objective of this study was to evaluate the effect of two nutritional strategies for feeding dry cows with a 40-d dry period on periparturient metabolism and subsequent lactational performance. Holstein cows ($n = 101$) housed in pens with freestalls were used in a randomized design to test the effects of diet: 1) low-energy (1.4 Mcal NE_L/kg) for the entire dry period (LL; $n = 51$) and 2) low-energy for the far-off period and high-energy (1.6 Mcal NE_L/kg) for the close-up period (LH; $n = 50$). The far-off and close-up periods started at 40 ± 3 d and 21 ± 3 d from expected parturition, respectively. Body condition score (BCS) and body weight (BW) were recorded (dry-off and wk -3, -2, -1, 0, 2, 4, 8). Serum nonesterified fatty acids (NEFA) and β -hydroxybutyrate (BHBA) were analyzed (dry-off and every other day from d -7 to 13). Milk yield (daily from wk 1 to 8) and composition (weekly from wk 2 to 8) were measured. Health problems were recorded (entire study). Data were analyzed by ANOVA using the MIXED procedure (except health data) and Fisher's Exact Test using the FREQ procedure (health data) of SAS. Cows fed LL and LH had similar ($P > 0.10$) BCS (3.65) and BW (727 kg) during the far-off period. During the close-up period, cows fed LH had more BCS gain ($P \leq 0.05$; 0.16 vs. -0.07), more BW gain ($P \leq 0.05$; 28 vs. 9 kg), and lower serum NEFA ($P \leq 0.05$; 355 vs. 458 μ Eq/L) than cows fed LL. There was no carryover effect of treatment ($P > 0.10$) on postpartum serum NEFA (845 μ Eq/L) and BHBA (7.2 mg/dL), change in BCS (-0.32) and BW (39 kg), milk yield (44.1 kg), and health disorders. Cows fed LH tended ($P \leq 0.10$, treatment \times time) to have higher serum BHBA at d 5, 7, and 9 than cows fed LL. Milk fat content tended ($P \leq 0.10$) to be lower for cows fed LL than LH (3.54 vs. 3.76%). Both nutritional management strategies (LL and LH) are acceptable based on data collected during the first 8 wk postpartum. However, both strategies need to be evaluated based on performance during a complete lactation.

Key Words: Dry Period, Nutrition, Transition Cow

W206 Effect of dietary malic acid supplementation on rumen methanogenesis and performance of lactating dairy cows at pasture. P. A. Foley¹, D. A. Kenny¹, D.K. Lovett¹, T. M. Boland*¹, and F. P. O'Mara², ¹*University College, Dublin, Ireland*, ²*Teagasc, Oak Park, Ireland*.

It has been estimated that enteric fermentation from dairy cows which naturally results in methane production accounts for almost 14% of the total greenhouse gas emissions associated with agriculture in Ireland. There is evidence from in vitro studies that organic acids such as malic acid can inhibit ruminal methanogenesis. However, there is equivocation between published reports on the utility of this strategy in vivo. Furthermore, most of the limited in vivo work to-date has been conducted with small ruminants or beef cattle with little information on effects in lactating dairy cows, particularly under pasture based production systems. The objective of the current study, therefore, was to examine the effect of dietary malic acid supplementation on methane emissions from lactating dairy cows grazing pasture. Twenty-four mid lactation Holstein-Friesian cows with a pre trial mean (\pm s.e.) milk yield of 23.9 kg/d (\pm 4.3 kg) and a BW of 628.1 kg (\pm 36.5 kg) were blocked on days in milk, pre trial milk yield and live weight, and within block, randomly allocated to one of two diets over a six week period. Diets consisted of ad libitum grazed grass plus 6 kg concentrate containing either (1) 0 g (CON) or 480 g of malic acid (MA; 2.6% DMI). Cows were allowed a three-week acclimatisation period followed by a 5-day methane measurement period. Individual methane measurements were made using the SF6 tracer gas technique, while herbage intake was estimated for each animal using the n-alkane technique. Measurements for milk yield were taken daily for each animal using flow meters while samples for compositional analysis were collected on a weekly basis. The dietary inclusion of MA had no effect ($P > 0.05$) on DMI or on ruminal methane emissions ($P > 0.05$). Furthermore, supplementation had no effect ($P > 0.05$) on animal performance in terms of milk yield, milk composition and weight gain.

W207 The impact of a blend of synthetic antioxidants (AGRADO® Plus) on milk production and milk fat synthesis when fed a diet high in unsaturated fatty acids. C. L. Preseault*¹, M. Vázquez-Añón², G. R. Bowman², C. S. Ballard³, H. M. Dann³, and A. L. Lock¹, ¹*University of Vermont, Burlington*, ²*Novus International Inc., St. Louis, MO*, ³*William H. Miner Agricultural Research Institute, Chazy, NY*.

Dietary-induced milk fat depression (MFD) is a result of changes in rumen biohydrogenation (BH) of unsaturated fatty acids and the passage of specific BH intermediates out of the rumen that subsequently reduce milk fat synthesis in the mammary gland. The objective of this study was to examine the impact of a blend of synthetic antioxidants, AGRADO® Plus (Agrado), on milk fat synthesis and milk production when cows were fed a diet with a high unsaturated fatty acid load (UFAL). The experiment was designed as a crossover with two 21-d periods. Sixteen lactating Holstein cows (163 ± 47 days in milk) were fed 1 \times /d and milked 3 \times /d. Cows were assigned randomly to one of two treatments: 1) basal diet (Control) and 2) basal diet supplemented with 0.02% (DM basis) of Agrado. The basal diet was designed to induce MFD, primarily through feeding distillers' grains (15% DM) to induce a high rumen UFAL. Individual feed intake and milk yield were recorded daily and milk samples collected every 5 d for milk composition. Data were analyzed as a crossover design with model effects for diet, period, sequence, day, and treatment by day using the MIXED procedure of SAS. There was no effect of treatment ($P > 0.05$) on DMI (26.6 ± 0.5 kg/d) or milk yield (49.8 ± 1.7 kg/d). Compared with pre-treatment values, MFD was observed when cows were fed both the Control and Agrado treatments, but the extent of MFD was significantly less across both periods when cows were fed Agrado; milk fat content was 3.22 and 3.32% ($P < 0.01$) and milk fat yield was 1.58 and 1.64 kg/d ($P < 0.05$) for the Control and Agrado treatments, respectively. This resulted in a

trend for 3.5% fat-corrected milk to be higher for cows on the Agrado treatment ($P < 0.10$). No other milk components were different between the two treatments ($P > 0.05$). Overall, data demonstrate the potential for dietary antioxidants in improving milk fat content and yield. Further studies, however are required to verify and extend these results and to determine the mechanism by which antioxidants impact rumen lipid metabolism and milk fat synthesis.

Key Words: Antioxidants, Milk Fat, Biohydrogenation

W208 Response of lactating cows to the supplementation with live yeast. L. L. Bitencourt^{*1}, M. N. Pereira¹, B. M. L. de Oliveira¹, J. R. M. Silva², G. S. Dias Júnior¹, F. Lopes¹, R. C. M. de Melo¹, and S. Siécola Júnior¹, ¹Universidade Federal de Lavras, Lavras, MG, Brazil, ²Centro Federal de Educação Tecnológica, Januária, MG, Brazil.

Performance and nutrient utilization of dairy cows supplemented with *Saccharomyces cerevisiae* strain CNCM I-1077 (Lallemand SAS, France) was evaluated. Twenty Holsteins, averaging 143±49 days in lactation at the beginning of the trial, formed ten blocks based on milk yield and were randomly assigned to a sequence of two treatments, in a cross-over design, with 28-day periods. Measurements were performed on the fourth week of each period. Treatments were: 10 g of the product Natucell (Ouro Fino Saúde Animal, Brazil) capable of providing 1×10^{10} cfu of live yeast or the same amount of placebo. Treatments were fed daily by allocation to each cow over the individually fed TMR. Diet composition was (% of DM): Corn silage (43.9), tifton hay (2.0), steam-flaked corn (14.4), pelleted citrus pulp (16.9), and soybean meal (21.7). Diet crude protein content was 16.8%, NDF was 30.9%, and NFC was 41.0% of DM. Data was analyzed with a model containing the effects of block, cow within block, period and treatment. Yeast supplementation increased daily milk (29.4 vs. 28.5 kg, $P=0.11$), protein (0.919 vs. 0.884 kg, $P=0.05$) and lactose yields (1.265 vs. 1.212 kg, $P=0.06$), and had no effect on milk fat ($P=0.53$). Daily dry matter intake was 21.4 kg with yeast and 20.7 for the control ($P=0.11$). Total tract apparent digestibility of the NDF was 48.1% with yeast and 43.2% for the control ($P=0.08$). There was a tendency for increased intake of digestible organic matter with yeast supplementation ($P=0.07$). Rumen fermentation and microbial parameters did not change between treatments. The concentration of purine derivatives in urine was numerically increased by yeast supplementation ($P>0.20$). The positive performance response to live yeast supplementation may have been the result of better diet digestibility.

Key Words: Yeast, Digestibility, Fiber

W209 The effect of feed sorting on chewing behavior, production, and rumen fermentation in lactating dairy cows. D. D. Maulfair^{*}, M. Fustini, and A. J. Heinrichs, *The Pennsylvania State University, University Park.*

Ration sorting is thought to allow cows to effectively eat different rations throughout the day, causing fluctuations in rumen fermentation patterns that can be detrimental to production. The objective of this experiment was to study the effects of varying TMR particle size on the sorting behavior of lactating dairy cows and to evaluate effects on chewing behavior, milk yield, milk components and rumen fermentation. Eight multiparous (parity = 2.3 ± 0.5) Holstein cows (90 ± 32 DIM initially;

642 ± 82 kg BW) were randomly assigned to replicated 4×4 Latin Squares. During each of the 4 periods cows were fed diets that varied only in the chop length of dry grass hay. When sieved through the Penn State Particle Separator (PSPS), the percentage of hay on the top screen (19.0 mm) was 23.1, 65.7, 86.6, and 94.9% for the short (S), medium (M), long (L), and extra long (XL) hay respectively. This resulted in the TMR of each diet having 6.4 (S), 17.4 (M), 18.6 (L), and 23.1 (XL) % on the top screen of the PSPS. The diet consisted of 29.4% corn silage, 22.9% ground corn, 17.6% alfalfa haylage, and 11.8% grass hay on a DM basis (DM 53.8%, forage 58.8%, NDF 32.1%, starch 27.7%). Chewing behavior was monitored using the IGER Behavior Recording system. No differences ($P < 0.05$) in chewing behavior between diets were found. Ruminating time/d was 518.7 ± 15.8 (S), 524.5 ± 15.4 (M), 495.6 ± 15.4 (L), and 522.5 ± 15.4 (XL) min/d (mean \pm SE). Chewing time was 373.4 ± 19.4 (S), 383.9 ± 18.9 (M), 365.7 ± 18.9 (L), and 385.6 ± 18.9 (XL) min/d. Milk production and DMI were also similar between diets. Milk yield was 39.0 ± 1.7 (S), 38.5 ± 1.7 (M), 37.3 ± 1.7 (L), and 36.3 ± 1.7 (XL) kg/d. DMI was 25.6 ± 1.0 (S), 25.3 ± 1.0 (M), 23.6 ± 1.0 (L), and 23.9 ± 1.0 (XL) kg/d. In addition no differences were found in milk fat, milk protein, MUN, rumen pH, rumen VFA and boluses/d. Despite drastic differences in particle size between these diets, there were no changes in chewing behavior, production, and rumen fermentation found in this study.

Key Words: Sorting, Particle Size, Rumination

W210 Effect of feed sorting on fecal particle size. M. Fustini^{*2}, D. D. Maulfair¹, A. J. Heinrichs¹, and A. Formigoni², ¹The Pennsylvania State University, University Park, ²University of Bologna, Bologna, Italy.

Increasing forage particle size of a TMR increases sorting activity by cows. Under this condition cows eat different diets during the day, with a higher intake of more palatable particles during the first meals and poorer quality feed during the later meals. The amount and timing of peNDF consumption and the impact of NFC, largely determine the fluctuations in rumen environment. The purpose of this study was to evaluate the effect of feed sorting and different diets throughout the day on fecal particle size distribution during a 24-h period. Four multiparous Holstein cows (BW = 659 ± 88 kg; DIM = 104 ± 15 d) were used in a 4×4 Latin Square design (21 d). During each of the 4 periods, cows were fed a diet that differed in the chop length of the grass hay. The diet was formulated to contain 58.8% forage (DM basis) in which dry hay comprised 11.8% of DM (20% of the forage). When sieved through the Penn State Particle Separator (PSPS) the percentage of hay on the top screen (19.0 mm) was 23.1, 65.7, 86.6, and 94.9% for the short (S), medium (M), long (L), and extra long (EL) hay respectively. This resulted in the TMR of each diet having 6.4 (S), 17.4 (M), 18.6 (L), and 23.1% (EL) on the top screen of the PSPS. Fecal samples were collected by rectal sampling 1 d during the last wk of each period at 0, 1.5, 3.5, 5.5, 8.5, 11.5, 14.5, 18, 21.5, and 24.5 h after feeding. Each sample was wet sieved in duplicate with screen apertures of 6.7, 3.35, 1.18, 0.6, and 0.15 mm using a vibrational sieve shaker. All diets resulted in similar fecal particle size distributions: fecal mean particle lengths (mm) of the 4 diets were 1.14 ± 0.16 (S), 1.15 ± 0.14 (M), 1.12 ± 0.15 (L), 1.12 ± 0.15 (EL), suggesting a possible sorting behavior against long particles. Each diet showed a daily variation in fecal particle size distribution, possibly an indication of inconstant rumen activity or passage.

Key Words: Fecal Particle Size, TMR Particle Size

W211 Interaction between particle sizes of alfalfa hay and concentrate on lactation performance, chewing activity, and ruminal pH of dairy cows. M. A. Bal* and E. B. Buyukunal Bal, *Kahramanmaraş Sutcu Imam University, Turkey.*

The objectives of this study were to determine the interactions between alfalfa hay and concentrate particle sizes on intake, milk yield, milk composition, chewing activity, and ruminal pH of dairy cows. Alfalfa hay was chopped either at 4 cm (long; L) or 1 cm (short; S) TLC using a hay harvester mounted with 10 or 58 mm screens. Particle size of concentrate was obtained by grinding dry corn with a hammer mill either at 1 mm (coarse; C) or less than 1 mm (fine; F) mean particle size. Four lactating multiparous Holstein cows (averaging 70 DIM) were used in a 4x4 Latin Square design in a 2x2 factorial arrangement of treatments with 21-d periods. Treatment diets consisted of 33.5% alfalfa hay, 16.5% corn silage, 22.5% dry corn, 7% cottonseed meal, 6% soybean meal based concentrate (DM basis) which was formulated to contain 16% CP and 1.45 Mcal/kg NE_L, and were fed once daily as a TMR. Mean particle sizes of treatment alfalfa hays and concentrates were 4.9, 3.1, 0.9, and 0.5 mm for L, S, C, and F, respectively. Mean particle sizes of treatment TMRs were 4.0, 3.8, 3.0, and 2.6 mm for LC, LF, SC, and SF, respectively. Intake of DM was not different among treatments averaging 23.6 kg/d. Similarly, yields of milk and milk protein were not different among treatments averaging 22.8 and 0.75 kg/d, respectively. However milk fat yield tended to be higher (P= 0.07) for C (0.82 kg/d) than F (0.73 kg/d). There was an interaction trend (P= 0.1) for milk protein percentage of cows received SC (3.31%) compared to LC (3.24%). Although cows received LF (371 min/d) spent more time for eating than SF (332 min/d), cows received LC (325 min/d) spent less time for eating than SC (356 min/d; P< 0.05). Ruminal pH was higher at 9 h of post-feeding (P< 0.05; time-alfalfa hay particle size interaction) for both SF (6.50) and SC (6.36) compared to LF (6.06) and LC (6.17). The data indicate that cows received C had higher milk fat percentage and yield but particle size of alfalfa hay had no effect on lactation performance and ruminal pH possibly due to closest particle lengths.

Key Words: Particle Size, Lactation Performance, Ruminal pH

W212 Effects of live yeast supplementation on lactation performance and ruminal pH of dairy cows fed medium and high levels of dietary concentrate. M. A. Bal*¹, S. Goksu¹, and V. Akay², ¹*Kahramanmaraş Sutcu Imam University, Turkey*, ²*Global Nutritech Ltd., Kocaeli, Turkey.*

The objectives of this study were to determine the effect of live yeast supplementation (Global Nutritech Ltd., Kocaeli, Turkey) and dietary concentrate level interaction on DMI, milk yield, milk composition, and ruminal pH. Four multiparous Holstein cows (averaging 83 DIM) were assigned to one of four dietary treatments in a 4x4 Latin Square design in a 2x2 factorial arrangement with 21-d periods. The dietary treatments (DM basis) were: 1) 50% concentrate + 10 g/cow/d live yeast (50LY), 2) 50% concentrate + no live yeast (50NLY), 3) 70% concentrate + 10 g/cow/d live yeast (70LY), and 4) 70% concentrate + no live yeast (70NLY). Treatment 1 and 2 consisted of 43% corn silage, 7% alfalfa hay, 50% concentrate, and had 13.8% CP, whereas Treatment 3 and 4 consisted of 23% corn silage, 7% alfalfa hay, 70% concentrate, and had 15.7% CP. Diets were fed once daily as a TMR. Live yeast supplementation had only a numerical difference on DMI (18.0 vs. 17.5 kg/d), milk yield (20.2 vs. 19.1 kg/d), 3.5% FCM (19.4 vs. 18.8 kg/d) and ECM (20.0 vs. 19.2 kg/d) compared to no live yeast supplementation,

respectively. Live yeast supplementation tended to increase (P= 0.06) milk fat yield in 50LY (0.66 kg/d) compared to 50NLY (0.62 kg/d). Similarly live yeast supplementation tended to increase (P= 0.08) SNF percentage in 50LY (9.83%) compared to 50NLY (9.63%). Percentage of lactose tended to be higher (P= 0.07) for 50LY (4.52%) than 50NLY (4.41%). A more distinct effect of live yeast supplementation on ruminal pH was observed at 9 h of post-feeding (P= 0.05) and cows received 70NLY had the lowest ruminal pH (5.81) compared to cows received 70LY (6.40; P< 0.05). Although there were only numerical increases in DMI, milk yield, 3.5% FCM and ECM with the supplementation of live yeast, results indicated that live yeast supplementation at 50% dietary concentrate would increase milk protein, SNF, and lactose percentages. Ruminal pH reductions during the feeding of high dietary concentrate diets can be prevented with live yeast supplementation.

Key Words: Live Yeast, Lactation Performance, Ruminal pH

W213 Efficacy of SOLIS[®], NOVASIL[™]Plus, and MTB-100[®] to reduce aflatoxin M₁ levels in milk of dairy cows fed aflatoxin. R. Kutz*¹, J. Sampson¹, D. Ledoux¹, J. Spain¹, and M. Vázquez-Añón², ¹*University of Missouri, Columbia*, ²*Novus International, St. Charles, MO.*

An experiment was conducted to determine the efficacy of three adsorbents, SOLIS[®](SO; Novus International, Inc), NOVASIL[™]Plus(NOV), and MTB-100[®](MTB), in reducing aflatoxin M₁ (AFM₁) concentrations in milk of dairy cows fed an aflatoxin (AF)-contaminated diet. Twelve early to mid lactation dairy cows averaging 163 days in milk (DIM) were used in a 4 × 4 Latin Square Design (LSD) with 3 replications. Cows were blocked by parity, body weight, milk production, and were provided *ad libitum* access to feed and water. Within each replicate, cows were randomly assigned to the 4 dietary treatments for 4 consecutive 7 day periods. Diets included: AF (112 µg AFB₁/kg diet dry matter (DM)); AF plus 0.5% SO; AF plus 0.5% NOV; and AF plus 0.5% MTB. Milk samples were collected on days 6 and 7 of each of the 4 experimental periods. Feed intake, milk production, percent milk fat, percent milk protein, and somatic cell count scores were not affected (P > 0.05) by dietary treatments and averaged 22.29 kg/day DM, 33.87 kg/day, 3.78%, 2.95%, and 1.60, respectively across all treatments. Transfer rates of AF from feed to milk averaged 2.64, 1.48, 1.42, and 2.52% for cows fed AF, AF+SO, AF+NOV, and AF+MTB, respectively. Daily AFM₁ excretion in milk averaged 66, 37, 35, and 63 µg/day for cows fed AF, AF+SO, AF+NOV, and AF+MTB, respectively. The addition of SOLIS[®] and NOVASIL[™]Plus to the AF diet resulted in a significant (P < 0.05) reduction in milk AFM₁ concentrations (SO, 45%; NOV, 48%) and AFM₁ excretion (SO, 44%; NOV, 46%). In contrast, MTB-100[®] was not effective (P > 0.05) in reducing milk AFM₁ concentrations (4%), AFM₁ excretion (5%), or AF transfer from feed to milk (2.52%). Results indicate that SOLIS[®] and NOVASIL[™]Plus at 0.5% of the diet were effective in reducing milk AFM₁ concentrations in cows consuming a totally mixed ration containing 112 µg AFB₁/kg diet DM.

Key Words: Aflatoxin, Adsorbents, Lactating Dairy Cows

W214 Effect of an essential oil blend on performance of periparturient and early lactation dairy cows. M. D. Tassoul* and R. D. Shaver, *University of Wisconsin, Madison.*

Multiparous Holstein cows (n = 40) were used to examine effects of dietary supplementation with an essential oil blend (EO, CRINA®). Cows were randomly assigned to either control (C) or EO supplemented (1.2 g/cow/d) TMR. Treatments began three weeks prepartum and continued through 15 weeks in lactation. The dry cow TMR contained 70% forage comprised of 70% corn silage, 15% alfalfa silage and 15% wheat straw (DM basis). The lactation TMR contained 50% forage comprised of 60% corn silage, 33% alfalfa silage, 7% alfalfa hay (DM basis). Dry cow and lactation TMR were formulated to contain 12 and 17% CP (DM basis), respectively. There were no differences in plasma NEFA, BHBA, glucose, and urea-nitrogen concentrations measured on days -21, -7, -1, 1, 8, 15, 22, and 29 relative to calving. There was no difference in prepartum DMI, but lactation DMI was lower for EO than C (22.7 vs. 24.5 kg/d, P = 0.04). There were no differences in milk or FCM yields (P > 0.10). Milk true protein (TP) was 0.15%-units greater for C than EO (P = 0.03). Milk TP yield was greater for C than EO during weeks 1-5 (1.46 vs. 1.35 kg/d, P = 0.03). Energy balance tended to be lower for EO than C (-4.1 vs. -1.6 Mcal/day, P = 0.06), and was lower during weeks 6-10 and 11-15 (-1.8 vs. 0.8, P = 0.02; -1.0 vs. 3.3 Mcal/d, P = 0.006, respectively). Weekly body weights and condition scores were unaffected by treatment (P > 0.10). Feed efficiency (FE) tended to be greater for EO than C (2.15 vs. 1.99 kg milk/kg DMI, P = 0.06), and was greater during weeks 6-10 (2.18 vs. 1.97 kg milk/kg DMI, P = 0.04) and 11-15 (2.13 vs. 1.89 kg milk/kg DMI, P = 0.02). Fat-corrected milk FE tended to be greater for EO than C (1.98 vs. 1.83 kg FCM/kg DMI, P = 0.07). During weeks 6-10 FCM FE tended to be greater for EO than C (1.89 vs. 1.72 kg FCM/kg DMI, P = 0.08) and during weeks 11-15 was greater for EO (1.80 vs. 1.58 kg FCM/kg DMI, P = 0.03). Results suggest that dietary addition of EO improves feed efficiency in lactating dairy cows, but further research is needed to determine the mode of action.

Key Words: Essential Oils, Feed Efficiency

W215 Effects of essential oil combinations on in vitro rumen microbial fermentation of a high-concentrate diet for beef cattle. I. Fandiño¹, S. Calsamiglia¹, A. Ferret¹, D. Moya¹, J. Martin-Tereso², and H. ter Wijlen*², ¹Universitat Autònoma de Barcelona, Spain, ²Nutreco, The Netherlands.

Seven essential oils (*Tea Tree* TE, *Thyme* TH, *Oregano* OR, *Rosemary Moroc* RM, *Rosemary Tunes*, *Salvia* SA, *Clove* CL) and 13 different essential oil combinations were used in a 24 h batch fermentation study with a 10:90 forage:concentrate diet (16% CP, 32% NDF, 38 % starch) to study their effects on rumen microbial fermentation. Treatments were supplied at 10, 50, 200 and 400 mg/L of culture fluid and tested in triplicate in 2 consecutive periods (n = 6). Differences were declared at P < 0.05. Monensin reduced acetate (Ac) proportion, acetate to propionate (A:P) ratio, butyrate (Bu) proportion, branch-chained VFA (BCVFA) and NH₃-N concentration, and increased propionate (Pr) proportion, as expected. The TE and OR (50 and 200 mg/L) decreased Ac proportion and A:P ratio, and increased Pr and Bu proportions; TH (50 and 200 mg/L) decreased Ac proportion and A:P ratio, and increased Pr proportion; TH (200 mg/L) also decreased Bu proportion; SA (400 mg/L) increased Pr proportion, reduced A:P ratio and NH₃ N concentration, and tended to reduce total VFA concentration; TH and RM (400 mg/L) increased Ac and decreased Bu proportions, and total VFA concentration, and TH (400 mg/L) also decreased BCVFA and NH₃ N concentrations, suggesting that deamination was inhibited; CL (400 mg/L) decreased Pr proportion, and increased Bu proportion and A:P ratio. The combina-

tions 75%TE+25%TH (400 mg/L), 75%TE+25%CL (200 and 400 mg/L), 50%TE+50%CL (400 mg/L), 75%TE+25%OR (400 mg/L) and 50%TE+25%TH+25%OR (200 and 400 mg/L) decreased Ac proportion and A:P ratio and increased Pr proportion; 75%TE+25%CL (400 mg/L) tended to reduce pH, and 50%TE+25%TH+25%OR (400 mg/L) tended to reduce NH₃ N concentration. Careful selection and combination of these extracts may allow the manipulation of rumen microbial fermentation.

Key Words: Rumen Fermentation, Plant Extract

W216 Dose-response effects of Rumensin® supplementation on ruminal digestion kinetics of fiber and starch. M. S. Allen and Y. Ying*, Michigan State University, East Lansing.

Eight ruminally and duodenally cannulated multiparous Holstein cows were assigned randomly to replicated 4 x 4 Latin squares in a dose response arrangement of treatments. Treatments were Rumensin® supplementation at 0, 8, 16, and 24 ppm DM. Diets consisted of corn silage and alfalfa silage (2:1 ratio, DM basis), high moisture corn, distiller's grains (6.9% of diet DM), protein supplement, minerals and vitamins and contained 25% NDF, 18.5% forage NDF, 28.6 % starch and 16.5% crude protein. Treatment periods were 28 d with the final 11 d used for sample and data collection. Ruminal digestion kinetics were calculated using the pool and flux method. Rumensin® treatment increased dry matter intake (P = 0.02 cubic) but did not affect milk yield (mean = 39.8 kg/d, P = 0.77). Quadratic effects of treatment were detected for rates of digestion (P = 0.05) and passage (P = 0.02) of potentially digestible NDF; rate of digestion increased from 1.94 %/h for 0 ppm to 2.50 %/h for 8 ppm and then declined to 1.63 %/h for 24 ppm and rate of passage decreased from 2.56 %/h for 0 ppm to 2.06 %/h for 8 ppm and then increased to 3.09 %/h for 24 ppm. These resulted in quadratic effects of treatment on ruminal and total tract NDF digestibility (P < 0.08). Greater ruminal pool sizes of NDF, OM, and DM for 8 and 16 ppm compared to 0 and 24 ppm (all P < 0.06 for quadratic effect) were due primarily to greater dry matter intake because NDF turnover rate in the rumen was not affected by treatment (P > 0.80). Ruminal and total tract starch digestibility as well as starch digestion kinetics were not affected by treatment. Treatment tended (P = 0.09) to decrease ruminal pH linearly from 6.26 to 6.14. Treatment tended (P = 0.07 quadratic) to increase true ruminal OM digestibility for 8 and 16 ppm compared to 0 and 24 ppm but did not affect total tract OM digestibility. Lower concentrations of Rumensin® (8-16 ppm) might increase ruminal and total tract NDF digestibility without decreasing its filling effect in the rumen.

Key Words: Rate of Digestion, Rate of Passage, Rumen Fill

W217 Effect of feeding essential oils and monensin on fatty acid profiles of milk fat. M. L. He*¹, W. Z. Yang¹, C. Benchaar², A. V. Chaves¹, and T. A. McAllister¹, ¹Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada, ²Agriculture and Agri-Food Canada, Dairy and Swine R&D Centre, Sherbrooke, QC, Canada.

Essential oils (EO) from plant extracts have been reported to have an antibacterial activity against gram-negative and gram-positive bacteria. Several of the gram-positive bacteria are involved in ruminal biohydrogenation of fatty acids (FA), thus suggesting that feeding EO could

lower biohydrogenation of FA because of a decrease in the number of bacteria involved in that process. In addition, it has been reported that cows fed monensin produced milk with greater concentration of trans-10 18:1 and trans-11 18:1. The objectives of this study were to evaluate the effects of two EO (garlic and juniper berry oils) and monensin on FA profiles of milk fat. Four ruminally fistulated Holstein cows were used in a 4 × 4 Latin square experiment. Cows were fed for ad libitum intake a TMR without supplementation (control), or supplemented with monensin (330 mg/day), garlic oil (5 g/day), or juniper berry oil (2 g/day). The FA composition of saturated, monounsaturated or polyunsaturated was not affected ($P > 0.10$) by supplementation of EO and monensin. However, proportion of conjugated linoleic acid trans 10, cis 12 (CLA t10, c12) was higher ($P < 0.04$) for cows fed EO (0.11%) or monensin (0.12%) than for control cows (0.09%). Supplementation of monensin also increased ($P < 0.10$) the proportion of total trans FA compared with the control. The higher trans FA was primarily due to higher C18:1 trans 6-8 FA with monensin. These results indicate that supplementation of the dairy cow diet with garlic or juniper berry EO or monensin had the potential to increase the proportion of CLA t10,c12 in milk fat with minimal overall effects on FA of milk fat. The results also confirm the increase of trans-10 18:1 in milk fat by feeding monensin to dairy cows.

Key Words: Plant Essential Oil, Milk Fatty Acids, Dairy Cows

W218 Effect of abomasal infusion of formate on milk protein of cows fed a methionine deficient diet. J. A. A. Pires*, N. J. Benevenga, G. A. Broderick, and R. R. Grummer, *University of Wisconsin, Madison.*

Carbon from formate is transferred to the methyl group of Met in milk protein via the folate cycle. We hypothesized that post-ruminal formate infusion to dairy cows would partially compensate for dietary Met deficiency and enhance milk protein production. Six midlactation cows were used in a balanced replicated 3×3 Latin square design, with 7 d periods and sample collection during last 4 d of each period. Treatments were continuous abomasal infusions of L-Met (20 g/d; positive control), sodium formate (3× molar amount of L-Met; requirements for methyl groups may be 2 to 4× that for methionine in support of protein synthesis) or sodium acetate (1/2 molar amount of formate, to provide equal amount of carbon; negative control). Cows consumed a diet deficient in metabolizable Met and Lys (18 g/d and 25 g/d, respectively, for a cow producing 40 kg milk/d; estimated from NRC, 2001) ad libitum for at least 4 wk prior to treatment administration. One wk prior to initiation of abomasal infusions, feed was offered at a rate to meet requirements for milk produced the previous 7 d. L-Lys was mixed with each treatment (25 g/d), leading to an estimated total supply of 2.4% Met and 7.1% Lys (MP basis). As expected, Met infusion increased milk protein percent (Table 1), but protein yield was not different, probably due to greater variability in milk production. Formate did not differ from acetate for any of the measurements. The formate infusion rate may have been insufficient to elicit a production response. Formate may also have been catabolized by gastrointestinal tract, or it may have been diverted to other products of the folate cycle in the liver.

W219 Feeding rumen-protected choline reduces the risk of hepatic lipidosis in transition dairy cows. F. S. Lima¹, B. A. Barton*², and J. E. P. Santos¹, ¹*University of Florida, Gainesville,* ²*Balchem Co., New Hampton, NY.*

Objectives were to determine the effects of feeding rumen-protected choline (RPC) on hepatic tissue composition and hepatic lipidosis in dairy cows. Holstein cows, 46, 20 multiparous and 26 primiparous, were fed either 0 (n = 25) or 60 g of RPC to deliver 15 g/d of choline (n = 21; Reashure, Balchem) top dressed onto the diet once daily from 25 d prepartum to 80 d in milk (DIM). Blood was sampled at 1 and 14 d postpartum and analyzed for concentrations of 3-OH-butyrate (BHBA). Hepatic tissue collected by percutaneous biopsy at 9 DIM was analyzed for concentrations glycogen, triglycerides and dry matter (DM). Cows were categorized as having hepatic lipidosis if hepatic triacylglycerol concentration was > 5% on a wet basis. Data were analyzed using the Mixed and Logistic procedures of SAS and odds ratios (OR) and 95% confidence intervals (CI) were calculated. Concentrations of BHBA were similar ($P = 0.53$) for cows fed control and RPC at d 1 (1012.7 ± 137.5 vs. 836.6 ± 143.4 mMol) and d 14 (927.0 ± 137.5 vs. 926.3 ± 143.3 mMol) postpartum. Concentration of glycogen in hepatic tissue was similar ($P = 0.35$) for cows fed control and RPC (0.94 ± 0.15 vs. 1.14 ± 0.16 %). Similarly, concentration of triglycerides in the hepatic tissue did not differ ($P = 0.31$) for cows in the control and RPC diets (5.9 ± 1.2 vs. 4.1 ± 1.3 %); however concentrations of triglycerides on a DM basis tended ($P = 0.10$) to be greater for control than RPC cows (10.4 ± 1.7 vs. 6.0 ± 1.9 %). Feeding RPC reduced the risk (OR = 0.23; 95% CI = 0.05, 1.06) of cows to have hepatic lipidosis (40.0 vs. 14.3%; $P = 0.05$). Concentrations of glycogen in hepatic tissue declined as concentrations of triglycerides increased (glycogen % = $1.251 - 0.04451 \times$ triglycerides%; $r^2 = 0.11$, $P = 0.01$). Feeding rumen protected choline reduced triglyceride concentration in liver DM tissue and the risk of hepatic lipidosis in early lactation dairy cows.

Key Words: choline, dairy cow, fatty liver

W220 Effects of alcohol-fermented feedstuff on the feed intake, feed efficiency, milk quality and profitability of Holstein cows. J. K. Choi¹, B. W. Kim², and J. S. Shin*², ¹*Dae Han Feed, Incheon, Kyonggee, South Korea,* ²*Kangwon National University, Chuncheon, Kangwon, South Korea.*

This study was performed to determine the effects of alcohol-fermented feedstuff (AFF) on the milk yield, feed efficiency, milk composition, somatic cell count of Holstein cows and the earning per cow. Fifty percent corn meal was combined with 50% brewery meal to make AFF in addition with 5% molasses and 2% yeast for fermentation. Feeding trials were divided into control, T1, T2, and T3 groups which were supplied by 0, 5, 10, and 15% of AFF out of whole dairy feedstuff (50% corn meal and 50% sudangrass silage), respectively. The experiment was conducted from July to November in 2006. Forty Holstein cows were assigned using a completely randomized design. The groups fed AFF diets had a higher feed intake; control (19.40kg), T1 (20.64kg), T2 (21.89kg) and T3 (22.19kg). Especially, the feed intake in T3 group increased by 14.9% compared to control. The milk yields were lower in T1 and T2 groups than control, however the most yield was observed in T3 group, which was increased by 20.6% compared to control. The feed efficiency in control, T1, T2 and T3 groups were 1.04, 0.78, 0.87 and 1.09, respectively. The feed efficiency of 4% FCM production was improved in T2 and T3 groups, especially in T3 group in which it was improved by 19.8% compared to control. There was no significant difference in milk fat, milk protein, lactose, total solid, solid not fat, milk urea nitrogen, and citric acid between the groups. Somatic cell counts in control, T1, T2, and T3 groups were 457,810, 285,200, 254,860, and 73,310 cells/ml, respectively. Most earnings were resulted in T3 group (10.43 dollar per cow/day), least in T1 and T2 groups (8.56 and 8.49 dollar per cow/day), and intermediate in control (9.21 dollar per cow/day). These results indicate that the use of about 15% alcohol-fermented feedstuff with a conventional dairy feedstuff can ensure more profitable earnings as well as improved milk quality in the Holstein farm.

Key Words: Alcohol, Milk Quality, Holstein

W221 Effect of feeding polyphenols on growth, health, nutrient digestion, and immunocompetence of calves. R. A. Oliveira¹, C. D. Narciso¹, R. Bisinotto¹, M. A. Ballou*², and J. E. P. Santos¹, ¹University of Florida, Gainesville, ²Texas Tech University, Lubbock.

Objectives were to determine effects of feeding polyphenols from pomegranate extract (POMx) on growth, health, nutrient digestion, and immunocompetence of calves. Holstein calves (n = 67), at 3 ± 1 d of age (d 0 = birth day) were assigned to 0 (control), 5 (POMx5), or 10 g/d (POMx10) of POMx containing 10% gallic acid equivalent. Calves received colostrum in the first 24 h, pasteurized milk thereafter until 61 d of age, and grain was fed in the first 70 d of age. Grain intake, attitude and fecal scores, incidence and duration of health disorders were evaluated daily. Rectal temperature was measured for the first 21 d of age. Body weight was measured at 2, 30 and 70 d of age. Neutrophil phagocytic and killing activities and antibody response to immunization with ovalbumin were measured. Peripheral blood mononuclear cells (PBMC) were cultured and cytokine production measured. Concentrations of glucose and 3-hydroxybutyrate (BHBA) were measured in plasma. Nutrient digestion was measured using total fecal collection during a 3-d period. Feeding POMx tended to reduce (P=0.07) grain intake and the response was linear (847 vs 787 vs 754 g/d), with effects observed after 30 d of age. BW gain in the first 30 d was similar (P=0.98) and averaged 377 g/d, but BW gain after 30 d of age declined linearly (P=0.02) with feeding POMx (830 vs 784 vs 721 g/d). Plasma concentrations of glucose decreased and of BHBA increased with age, but treatments had no effect (P>0.55). Neutrophil phagocytic (61.3 vs 62.0 vs 64.6%) and killing percentages (54.8 vs 53.4 vs 58.2%) were similar (P>0.65) for control, POMx5 and POMx10, respectively. In

vitro production of tumor-necrosis factor-alpha was similar among treatments, but a linear increase (P=0.05) in PBMC production of interferon gamma (102 vs 200 vs 297 pg/mL) and interleukin-4 (271 vs 432 vs 497 pg/mL) was observed. Serum anti-ovalbumin IgG increased with immunizations, and response was enhanced (treatment x day, P=0.04) by feeding POMx. Results indicate that humoral immune response was enhanced by feeding polyphenols despite reduction in grain intake and BW gain after 30 d of age.

Key Words: Calf, Polyphenols, Immunity

W222 Changes in milk aflatoxin concentrations in response to investigational sequestering agents added to aflatoxin-contaminated diets fed to lactating Holstein cows. L. Waltman*, S. Davidson, B. A. Hopkins, G. W. Smith, and L. W. Whitlow, North Carolina State University, Raleigh.

Three experiments (EXP) were conducted to determine the effect of investigational sequestering agents, including clays or non-digestible yeast oligosaccharides (NYO), on milk aflatoxin concentrations in lactating Holstein cows consuming aflatoxin. All EXP included two periods in a randomized block design. Cows were fed an aflatoxin-contaminated total mixed ration (TMR) for both periods of all trials. During the first period, cows received no sequestering agents, but agents were included in the TMR for the second period. In EXP 1 and 2 there were two 7 d periods and 12 cows per treatment. Milk samples from d 5-7 and d 11-13 were analyzed for milk aflatoxin (AFM1) concentrations by HPLC. Two treatments in EXP 1 were: 1) control (no agent) and 2) 100g/d of a mixture of NYO-A and diatomite-montmorillonite (DMM). Four treatments in EXP 2 were: 1) control (no agent), 2) 10g/d NYO-B, 3) 10g/d NYO-C, and 4) 10g/d NYO-D. In EXP 3 there were two 8 d periods and 14 cows total. Milk samples from d 4-8 and d 11-16 were analyzed for AFM1 concentrations by ELISA. Three treatments in EXP 3 were: 1) control (no agent) (n=4), 2) 50g/d NYO-C (n=5), and 3) 227g/d bentonite (n=5). For all EXP, the percent differences in AFM1 concentrations between periods 1 and 2 were calculated. All percent differences were normalized using a correction factor that converted values for controls to zero. The changes from zero (%) due to sequestering agents were considered significant at P < 0.05. In EXP 1, the addition of a mixture of NYO-A and DMM resulted in a 5.2% numerical increase in AFM1 concentration. In EXP 2, investigational agents NYO-B, NYO-C, and NYO-D resulted in 8.0%, 6.2%, and 9.5% numerical increases in AFM1 concentrations respectively. In EXP 3, NYO-C resulted in a 5.1% numerical decrease in AFM1 concentrations, and the bentonite resulted in a 60.4% significant decrease in AFM1 concentrations. In summary, the bentonite in EXP 3 reduced AFM1 concentrations (P=0.01). There were no significant changes (P>0.25) in AFM1 concentrations in response to investigational sequestering agents other than bentonite.

Key Words: Aflatoxin, Milk, Binder

W223 Effect of monensin concentration on dry matter intake during the transition period of lactating dairy cows. M. A. Shah*¹, G. Schroeder¹, B. D. Strang¹, and H. B. Green², ¹Cargill Animal Nutrition, Elk River, MN, ²Elanco Animal Health, Greenfield, IN.

Feeding monensin to dairy cows is known to increase milk production efficiency (milk/unit energy intake). We analyzed data collected from

966 cows from nine randomized complete block design trials conducted in the US and Canada in which 4 doses of monensin (0, 7, 15, 22 g/ton of dry matter intake (DMI)) were fed for a complete lactation. The PROC MIXED and PROC NLIN procedures in SAS were used to analyze data. DMI and milk yield data were analyzed with monensin dose as fixed effect and location as a random variable. Location and cows were used as random factors and week in milk (WIM) as repeated measure in the model. Increased production efficiency (Milk/DMI) (1.51, 1.52, 1.56 and 1.59 ± 0.03 ; $P < 0.0001$) was a result of a linear reduction in DMI (20.4, 20.4, 19.8 and 19.6 ± 0.17 kg/d; $P = 0.003$) and similar milk yield (31.6 ± 0.4). When weekly DMI data for the first 12 WIM was analyzed using an exponential model ($DMI(t) = a - b \times \exp(-c \times t)$; where $DMI(t)$ = weekly DMI for corresponding WIM, a = asymptotic maximum DMI, b = potential increase in DMI, c = fractional rate of increase of DMI with WIM, and t = WIM) the rate of change in DMI was linearly increased as monensin dose increased (0.036, 0.047, 0.045, and $0.051 + 0.004$ % per d; $P = 0.007$). This also resulted in a linear increase in production efficiency (1.89, 1.92, 1.96, and 2.01 ± 0.04 ; $P < 0.0001$). These results may indicate that monensin may have a different effect on DMI depending on rumen dynamics or energy status of the cow. A faster intake recovery was associated with a reduction in the incidence of ketosis (12.7 % for control versus 6.2, 7.0 and 4.2 % for monensin treated, $P = 0.03$, 0.06 and 0.04, respectively), but there was no effect on reproductive efficiency (services per conception, days open, days to first service, calving interval and days open) except lower first service conception rate (37.5%) at 22 g/ton compared to the control group (49.6%). Feeding monensin to transition cows may help improve energy balance through a higher rate of DMI increase during early lactation.

Key Words: Monensin Concentration, Exponential Model, DMI

W224 Effect of malic acid on rumen fermentation *in vitro* with DHA diet. L. Liu, J. Q. Wang*, D. P. Bu, S. J. Liu, K. L. Liu, H. Y. Wei, and L. Y. Zhou, *Chinese Academy of Agricultural Sciences, Beijing, China*.

The objective of this study was to evaluate changes in rumen fermentation when different levels of malic acid were added in a DHA-enriched diet. The rumen-simulation technique (RUSITEC) apparatus containing eight vessels was employed in this experiment. Treatments were as follows: (1) base diet rich in DHA (CON); (2) base diet with 10 mM malic acid (Trt1) and (3) base diet with 20mM malic acid. This study was repeated at two-week intervals. Experimental period was 7 d including 6 d for adaptation and 1 d for sampling. Culture fluid was collected every 3 h over a 12 h period on the last day of each experimental period. The concentration of VFA was analyzed by gas chromatography (model 6890, Series II; Hewlett Packard Co., Avondale, PA). Data were analyzed with PROC MIXED procedure of SAS for a completely randomized design with repeated measures. The results showed that with the addition of malic acid, culture fluid pH numerically decreased ($P > 0.05$) from 6.17 to 6.14 and 6.09 for CON, Trt1 and Trt2, respectively. However, addition of malic acid in a DHA diet had no effect on acetate concentration in culture fluid ($P > 0.05$). Contrarily, propionate and butyrate concentration in culture fluid increased when malic acid was added. Compared to CON, concentration of propionate in Trt1 and Trt2 increased by 30.37% and 62.37%, respectively. Butyrate concentration increased by 21.76% and 24.85% for Trt1 and Trt2. The proportion of acetate to propionate decreased significantly ($P < 0.01$). Results suggest that malic acid supplementation in a DHA diet changes the rumen fermentation process.

W225 Effect of physical particle size on ruminal and post-ruminal disappearance of nutrients of a mixed concentrate in Holstein steers. H. Jahani-Azizabadi¹, M. Danesh Mesgaran*¹, and A. Rahmatimanesh², ¹*Ferdowsi University of Mashhad, Mashhad, Mashhad, Iran*, ²*Heram Talae Shargh Feed Mill Company, Nishabour, Iran*.

In situ ruminal and post-ruminal disappearance [dry matter (DM), crude protein (CP) and ether extract (EE)] of a mixed concentrate prepared as fine mesh (fm), fine pellets (fp) and coarse pellets (cp) were studied. All pellets were provided in a condition of 70°C with pressure of 3 bars in 7 seconds. Concentrate was composited of cereal grain, soybean meal, canola meal, fish meal, urea, wheat bran, beet pulp, bagasse, salt, sodium bicarbonate, mineral and vitamin premix, anionic salt, molasses, sugar, protected fatty acid and Mg oxide (318, 60, 150, 15, 3.6, 250, 33, 40, 6.7, 8.6, 8, 15, 55, 30, 5 and 2.1 g/kg DM, respectively). Four Holstein steers (430 ± 50 kg, BW) fitted with ruminal fistulae and T-shaped intestinal cannulae were used. Steers fed (DM basis) 2.5 kg of alfalfa hay, 2.1 kg of corn silage, 1.5 kg of straw and 2.5 kg of concentrate (170 g CP/kg of DM). Approximately 5 g of sample (DM) was placed in polyester bag (12x19 cm, pore size of 48 μ m, n=8), then incubated in the rumen for 12 h. After removal from the rumen, bags were washed and dried. Then, 1 g DM of un-ruminal disappeared sample was weighed into a mobile bag (3x6 cm, pore size of 48 μ m, n=8) and inserted in small intestine, then removed from the voided feces and rinsed in cold tap water. DM, EE and CP of intact and incubated samples were determined. Data were analyzed using completely randomized design. Ruminal DM, CP and EE disappearance of fm was significantly ($P < 0.01$) lower than fp and cp. Ruminal DM, CP and EE disappearance of fp was significantly ($P < 0.01$) higher than cp (0.71, 0.61 and 0.65 vs. 0.67, 0.58 and 0.59, respectively). Post-ruminal DM, CP and EE disappearance of fm concentrate (0.45, 0.50 and 0.80, respectively) was significantly ($P < 0.01$) higher compared with fp (0.35, 0.38 and 0.68, respectively) and cp (0.39, 0.38 and 0.57, respectively). Results of the present study indicated that the physical particle size of a mixed concentrate might impact on ruminal and post-ruminal disappearance of DM, CP and EE.

Key Words: Physical Processing, Disappearance, Mobil Nylon Bag

W226 Influence of an α -amylase on *in vitro* ruminal fermentation and starch degradation. W. Hu*¹, M. E. Persia², and L. Kung, Jr.¹, ¹*University of Delaware, Newark*, ²*Syngenta Animal Nutrition, Research Triangle Park, NC*.

A thermostable α -amylase was isolated and then expressed in corn grain. Although this amylase was specifically developed for use in ethanol production, because it has completed the FDA consultation process for food and feed, the utility of this amylase as a feed enzyme on rumen fermentation and starch degradation *in vitro* was explored. In experiment 1, pure corn grains were fermented individually with inoculums of rumen fluid and artificial saliva for 6 h at 40°C. Four corns were evaluated: flint, opaque and two corns with near identical nutrient profiles: one containing amylase (CA) and the other the isogenic control (IC).

Flint corn produced less ($P < 0.05$) total VFA (18.3 mM) than the other three corns (an average of 25.3 mM), validating the ability of the assay to detect differences in fermentation among hybrids. No difference ($P > 0.05$) was noted in total VFA production from CA when compared to IC, but there was a small but significant increase in starch degradation (90.6 vs. 89.7%, $P < 0.01$). In experiment 2, mixtures of the CA and IC corns (0, 25, 50, 75 and 100% CA grain concentrations) were fermented using the same *in vitro* model. Total VFA production was not different ($P > 0.05$) among treatments for any concentration of CA (0 to 100%). These data suggested that the amylase was not sufficiently active at the physiological temperature of the rumen. To test this hypothesis, CA and IC were incubated in water at 40 and 65°C for 24 h to determine starch degradation. Apparent starch degradation at 40°C was 1.99 and 1.60% for CA and IC, respectively. When both grains were incubated at 65°C, the apparent starch degradation was 10.56 and 0.85% for CA and IC, respectively. This >10-fold increase in starch degradation of the CA grain incubated at 65°C resulted in an interaction between corn variety and temperature. These data clearly demonstrate that amylase activity is expressed sufficiently in CA at a high temperature (65°C) but the amylase activity does not have any positive or negative effects at physiological temperature of the rumen (40°C) when used as a feed enzyme for ruminant production.

Key Words: Corn, Amylase, Starch

W227 N and energy synchronization of barley: Effect of variety and growth year. P. Yu* and K. Hart, *University of Saskatchewan, Saskatoon, SK, Canada.*

The objective of this study was to investigate N and energy synchronization of six barley varieties during three consecutive growth years of 2003, 2004 and 2005 in order to determine the magnitude of the differences between the varieties and growth years which affect optimizing rumen fermentation. The synchronization of N and energy was indicated by hourly effective degradation ratio between effectively degraded N and CHO. The difference in cumulative amounts degraded at successive hours was regarded as the amount of degraded each h. The experimental design was a RCBD and the data was analyzed using SAS Mixed Model procedure. The results showed less difference at the beginning of the incubations. However, with increasing incubation times, the difference was highly increasing among the varieties. At the beginning of the incubation, hourly effective degradation ratio of N/CHO was 3 to 5 g/kg. At 10 h incubation, the ratio ranged from 24 to 30 g/kg ($P < 0.05$). With further increasing times, the ratios were also increased ($P < 0.05$). However, the different varieties resulted in different magnitude of increments in ratio. The lowest increase was from 3 to 41 g/kg for CDC Trey. The highest increase was from 5 to 225 g/kg for Cowboy. The variations between the growth years were smaller at the beginning of incubations, but variations increased ($P < 0.05$) with increasing incubation times.

Key Words: Synchronization, Hourly Effective Degradation Ratio of N to CHO, Barley Variety

W228 Effects of fibrolytic enzymes on *in vitro* digestibility of destoned olive cake. D. Elia¹, P. P. Danieli¹, P. Bani², and U. Bernabucci*¹, ¹*Dipartimento di Produzioni Animali, Viterbo, Italy*, ²*Istituto di Zootecnica, Piacenza, Italy.*

Olive cake has a poor digestive utilization and can negatively interfere with the ruminal microflora activity. The use of exogenous enzymes can improve ruminal digestion of fibrous feedstuffs. Aim of the present study was to evaluate the effect of two different exogenous enzymes treatment (Natuzym S.F.[®] cellulase = CELL and an experimental impure macerage preparation = MAC) on *in vitro* feed utilization of destoned olive cake (DOC). CELL and MAC were added at the dose of 0.8 g/kg of DOC. *In vitro* evaluations were carried out using, as a substrate, the treated (CELL and MAC) or untreated (C) olive cakes alone or added (5 or 10%) to a TMR for dairy cattle. NDF digestibility (48 hours = NDFD) was measured according to the Ankom DaisyII procedure whereas *in vitro* gas production (GP) test was carried out for 72 hours in glass bottles by a pressure transducer method and measuring final AGV concentration in the fermentation liquor. Enzymatic treatment did not reduce NDF content of DOC. NDFD was numerically but not statistically lower in the treated samples (26.16, 23.55 and 22.56% for C, CELL and MAC, respectively). Enzymes reduced GP (0.26, 0.20 and 0.19 ml/mg of incubated sample, for C, CELL and MAC, respectively), but higher VFA concentration was measured for CELL. When added to the TMR substrate, olive cake increased GP and VFA concentration in a dose dependent manner. Enzymatic treatments significantly improved GP (+17%) but not VFA production. The additional amount of gas production due to addition of olive cake to TMR was not simply explained by the higher substrate available, suggesting an interference with the microbial activity. Adding olive cake had only minor influence on main VFA molar ratio, but total isoacids were significantly reduced. Enzymatic treatments did not improve DOC digestibility but had some positive effects when treated DOC was added to TMR. In general, olive cake showed positive effects on *in vitro* digestibility of TMR for dairy cattle.

Key Words: Destoned Olive Cake, *In Vitro* Digestibility, Exogenous Fibrolytic Enzymes

W229 The effect of alcohol fermented feedstuff made of byproduct on *in vitro* fermentation characteristics and NDF disappearance. J. S. Shin¹, G. Z. Lin², and B. W. Kim*¹, ¹*Kangwon National University, Chuncheon, Kangwon, South Korea*, ²*Linyi Normal University, Linyi, Shandong, China.*

An *in vitro* study was conducted to examine the influence of alcohol-fermented feedstuff formulated with byproduct on the fermentation characteristics and NDF disappearance. Dietary treatments were a commercial beef cattle feed-based sudan grass silage (Control) and soybean curd-based alcohol-fermented feedstuff (AFS). The control was composed of 70% commercial beef cattle feed and 30% sudangrass silage. Fifty percent commercial beef cattle feed and 50% soybean curd dreg were combined to make AFS with addition of 5% molasses and 0.5% yeast for fermentation. The ruminally cannulated Korean cattle were utilized to investigate the change of ammonia, pH, alcohol, volatile fatty acids, and NDF disappearance at 0, 2, 4, 8 and 12-h *in vitro* incubation. Ammonia concentrations and pH were similar for both dietary treatments during all incubation periods, although the decrease of pH was slightly less in AFS compared to control during later periods of incubation (pH 6.4 in control and pH 6.6 in AFS at 12-h incubation). The alcohol concentrations were significantly higher in AFS at all incubation times. Especially, the difference of alcohol concentrations between control and AFS was greatly increased with longer incubation time (0.5 mg/dl in control and 4 mg/dl in AFS at 2-h incubation vs 0.7 mg/dl in control and 7 mg/dl in AFS at 12-h incubation). The acetate concentration was

slowly decreased in AFS compared to control with longer incubation time. Lower concentrations of propionate and butyrate were observed in AFS at all incubation times ($p < 0.05$). The NDF disappearance did not differ between control and AFS, although AFS showed little higher NDF disappearance during initial periods of incubation (4% in control and 6% in AFS at 2-h incubation). It is concluded that an alcohol fermented feedstuff made of the industrial byproduct such as soybean curd dreg can be effective materials to substitute the conventional beef cattle feed and resulted in similar or better fermentation characteristics and NDF disappearance during *in vitro* incubation.

W230 Comparison of chemical composition and digestibility among wheat straws treated by white-rot fungi. O. D. Montañez-Valdez*¹, J. H. Avellaneda-Cevallos², E. O. Garcia-Flores³, J. M. Tapia-Gonzalez¹, G. Rocha-Chavez¹, I. E. Morales-Zambrano¹, and E.C. Guerra-Medina³, ¹Centro Universitario del Sur de la Universidad de Guadalajara, Ciudad Guzman, Jalisco, México, ²Universidad Técnica Estatal de Quevedo, Quevedo, Los Rios, Ecuador, ³Centro Universitario de la Costa Sur de la Universidad de Guadalajara, Aulán de la Grana, Jalisco, México.

A study was conducted to evaluate the effect of *Pleurotus pulmonarius* on chemical composition and *in situ* digestibility of DM, OM, ADF, NDF of wheat straw. Wheat straw treated and untreated with *Pleurotus pulmonarius*, were obtained from a commercial facility. Ten samples were obtained at random and combined to analyze dry matter (DM), organic matter (OM), crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF), hemicellulose (HC) and lignin (L) of each wheat straw. Data were analyzed by mean comparison using a T Student test. No differences ($P \geq 0.05$) between treatments were found for DM, CP and hemicellulose; however, treated straw ($P \leq 0.05$) showed higher percentages of OM, NDF, and ADF. There were no differences ($P \geq 0.05$) among treatments on *in situ* digestibility of DM, OM, ADF, NDF, CP or HC, but the highest coefficients of digestibility were observed in the treatment of treated straw. The growth of *Pleurotus pulmonarius* on wheat straw changes its chemical composition by increasing organic matter content and modifying cell wall components, this may improve the nutritional quality of agricultural byproducts. This process may allow using *Pleurotus pulmonarius*-treated straw for ruminant feeding.

W231 Effects of genetics and water management on corn plant NDF digestibility. I. Fusaro*¹, N. Brogna², A. Palmonari², G. Biagi², C. J. Sniffen³, and A. Formigoni², ¹Dipartimento di Scienze Degli Alimenti, Università di Teramo, Teramo, Italy, ²DIMORFIPA, Università di Bologna, Ozzano dell'Emilia, Bologna, Italy, ³Fencrest, LLC., Holderness, NH.

Objective of this study was to evaluate the NDF digestibility of three corn hybrids selected for silage: T (traditional), L and BMR (high digestibility hybrid provided by Long Island Cauliflower Association). The hybrids were grown in farms with different agronomic conditions in Northern Italy. Two farms had 55% gravel soil with a furrow irrigation system (F) while the other two had a sandy loam soil and a sprinkler system (S). The hybrids were seeded in March with a density of 7 plants/m². Nitrogen was applied as urea at 450 kg per ha, at the fifth leaf stage. The growing season had low rainfall (120 mm instead of 190 mm of the last thirty year); average and highest temperatures recorded were respectively 30.5 (May, June, July) and 38.6 °C (July). F irrigation system spread water 355 mm/m² for 6 times while 50 mm/m² for 5 times for S system. At the harvest time (last week of July) for each hybrid and from each farm 4 samples of chopped corn and 8 entire plants, randomly selected, were collected. The plants were separated into stalk, leaves and ear; the ears were then split into grain, cob and husk. The husks were analyzed with leaves, and grain has not been processed. All the samples were dried at 60°C and analyzed for chemical composition and *in vitro* NDF digestibility at 24h (IVNDFd), with Tilley&Terry technique. The results relative to irrigation system showed no statistical differences for IVNDFd in fresh corn samples and plant parts ($P > 0.05$). The IVNDFd was higher in BMR fresh corn samples than in T and L ($P < 0.05$), as L than T but without statistical differences. BMR cob and stalk showed the better results in IVNDFd than the L and T hybrids ($P < 0.05$). Cob IVNDFd was higher in L than in T hybrid ($P < 0.05$). Higher digestibility of L chopped corn than T one, could be a consequence of this characteristic. These results show that a proper choice of the corn hybrid is important to achieve a better corn silage digestibility over the irrigation strategy.

Ruminant Nutrition: Proteins and Amino Acids - Beef, Sheep and Misc Ruminants

W234 Effect of dietary CP level on visceral organ mass and the protein expression of ATP synthase and Na⁺/K⁺-ATPase in steers. Y. J. Wang*, S. Holligan, H. Salim, M. Z. Fan, B. W. McBride, and K. C. Swanson, *University of Guelph, Guelph, ON, Canada.*

Twenty-four beef steers (510 ± 6.7 kg BW) predominately of Angus breeding were used to determine the effect of dietary CP levels on visceral organ mass and the protein expression of ATP Synthase and Na⁺/K⁺-ATPase. Steers were allotted to 6 pens (4 steers per pen, 1 from each treatment) in a randomized block (pen; week of slaughter) arrangement of treatments consisting of high-moisture corn based diets containing 8.8, 12.1, 13.2 or 15.4% of dietary CP (DM basis), respectively. The starting date of the experiment was staggered so that all steers were on treatment for 28 d, and 4 steers from the same pen were slaughtered per week for 6 weeks and visceral organs were removed. Liver, kidney, rumen and jejunum were sampled. Wet tissue weight and intestinal length were recorded. The protein expression of ATP synthase and Na⁺/K⁺-ATPase in liver, kidney, rumen and jejunum was analyzed by Western blotting. Final BW and ADG increased linearly (kg; P < 0.008) as CP increased. Kidney, liver, lung, and rumen weights (g) increased linearly (P < 0.05) with increasing CP. Lung weight on a BW basis (g/kg BW) was also linearly increased (P < 0.05) with increasing CP. The protein expression of ATP Synthase in liver increased as CP level increased from 8.8 to 12.1% and decreased as CP level increased from 12.1 to 15.4% (P < 0.05). Kidney ATP Synthase increased linearly (P < 0.05) as CP increased. There was also a linear increase (P ≤ 0.05) in jejunum Na⁺/K⁺-ATPase with increasing CP. These results indicate that increasing dietary CP level increases ADG and the mass of kidney, liver, lung and rumen, and alters expression of proteins involved with ATP production and utilization in liver, kidney, and small intestine.

Key Words: Dietary CP, Expression of ATP Synthase and Na⁺/K⁺-ATPase, Steer

W235 Intake and total and partial digestibility of nutrients, ruminal pH and ammonia concentration in beef cattle fed diets containing soybean silage. J. P. Rigueira, O. G. Pereira*, M. I. Leão, S. C. Valadares Filho, and R. Garcia, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The intake and total apparent and partial digestibility of nutrients, ruminal pH and ammonia concentration were evaluated in beef cattle fed diets containing soybean silage (SS), SS with microbial inoculant (SSI), SSI with molasses (SSIM) and SS with molasses (SSM). Diets consisted of 40% soybean silage, 30% corn silage and 30% concentrate, being formulated to be isonitrogenous (13% CP, DM basis). The inoculant used was Sil All C4 (Altech, Brasil). Powder molasses was used in the ratio of 2.5% in natural basis. Four crossbred Holstein × Zebu steers, fistulated in the rumen and abomasum with 230 kg initial body weight, were assigned to a 4×4 Latin square design. Chromic oxide was used as a marker to estimate fecal and abomasal dry matter flows. The intakes (kg/day) and total, ruminal and intestinal apparent digestibilities of all nutrients were not influenced (P > 0.05) by diets. However, the intake of DM and NDF, as % BW, were affected (P < 0.05) by diets, where the animals fed the SSIM diet had higher intake than those fed SS diet. Mean values of 73.5 and 75.0; 70.4 and 44.0; 78.8 and 28.3; 73.3 and 86.2%, were calculated for the apparent total tract and ruminal digestibilities of DM, CP, EE and neutral detergent fiber correct

for ash and protein (NDFap), respectively. The ammonia concentration and ruminal pH were not influenced (P > 0.05) by diets and the mean values were 11.91mg/100ml and 6.45, respectively. Molasses, with or without microbial inoculant, in soybean silage did not affect intake and digestibility of nutrients, nor pH and ruminal ammonia concentration in beef cattle.

W236 Dry matter intake and performance of Nellore steers fed diets based on different proportions of soybean and corn silages. W. F. Souza¹, O. G. Pereira*¹, K. G. Ribeiro², S. C. Valadares Filho¹, A. S. Chaves¹, F. Zamuner¹, and G. A. Aguiar¹, ¹*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.* ²*Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Minas Gerais, Brazil.*

A trial was conducted with 30 Nellore steers (372 kg), castrated, and distributed in 6 randomized blocks to evaluate the effects of different proportions of soybean (SS) and corn silages (CS) on dry matter intake, ADG, carcass gain, feed conversion and carcass yield. The diets consisted of 60% silage and 40% concentrate (DM basis), and were formulated to contain 12.5% CP (DM basis). Treatments consisted of different proportions of soybean and corn silage: 100:0; 75:25; 50:50; 25:75 and 0:100, respectively (DM basis). The experiment was conducted for 84 d (15 d for diet adaptation, and 3 periods of 28 d for data collection). Steers were individually fed for ad libitum intake twice daily at 0700 and 1500. There were no differences (P > 0.05) in the daily intake of DM (kg/d or % BW) among treatments (Table 1). Similarly, no treatments effects were observed on ADG, carcass gain, and feed conversion, which were, on average 0.683 kg/day, 1.16 kg/day, and 7.66, respectively. Although animal performance was similar among the diets, an economic evaluation is necessary.

Financial support by CNPq and FAPEMIG

Table 1. Effect of different proportions of soybean and corn silages on dry matter intake (DMI), average daily gain (ADG), carcass gain (CG), and feed conversion (FC)

W237 Efficacy of condensed glutamic acid fermentation solubles as a nitrogen source in ruminant diets. A. I. Soria-Flores* and L. L. Berger, *University of Illinois, Urbana.*

The efficacy of feeding a new condensed extracted glutamic acid fermentation solubles (GAFS) with GAFS containing *Corynebacterium*

in feedlot cattle. Twenty-four dairy-beef steers (425.8 ± 0.9 kgs) were randomly assigned to 6 pens (4 steers/pen). Steers were fed one of three diets: The Control diet was 72.5% cracked corn, 20.0% chopped hay, 5.0% molasses, 1.3% urea. The Old GAFS and New GAFS replaced the molasses and urea. Diets were formulated to meet NRC nutrient requirements for growing steers. Blood samples were collected to determine differences in metabolic profile due to diet. Steer performance was similar across diets (table). Significant differences in kidney heart and pelvic fat (KHP) percentage, and USDA yield grade are not considered to be biologically important. Metabolic profile showed that most measurements were within the normal range for healthy animals. However, blood Na concentrations decreased ($P < 0.01$) for GAFS diets (140.7 mEq/L) vs. Control (142.0 mEq/L) steers. GGT production was increased ($P = 0.03$) in GAFS diets (24.3 U/L) vs. Control (17.5 U/L). In summary, based on animal performance, carcass traits and metabolic profile of steers, New GAFS is similar to Old GAFS, and supported feedlot performance similar to a typical control diet.

W238 *In vitro* gas production kinetics of protein sources used in sheep nutrition. A. S. Juarez-Reyes*¹, M. Murillo-Ortiz¹, M. A. Cerrillo-Soto¹, J. F. Obregon², and F. G. Rios², ¹FMVZ-Universidad Juarez del Estado de Durango, Durango, Durango Mexico, ²FMVZ-Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico.

A study was conducted to evaluate the *in vitro* gas production characteristics of protein sources commonly used in sheep nutrition practices in the dry tropics of northwest Mexico. Samples (200 mg DM) of cotton seed meal (CSM), corn distiller dried with solubles (CDD), overheated sesame meal (OSM), safflower meal (SM), canola meal (CM), and soybean meal (SBM), were placed in 100 ml calibrated glass syringes by triplicate. Buffered and mineral solutions were mixed in a 2:1 proportion with rumen fluid collected from three rumen cannulated sheep fed alfalfa hay and a commercial concentrate (75:25). Thirty ml of buffered rumen fluid was dispensed to each syringe at the time incubation started. The gas volume was recorded at 0, 3, 6, 9, 12, 24, 48, 72 and 96 h. Data obtained were fitted to the equation: $p = a + b(1 - e^{-ct})$ using PROC NLIN. Metabolizable energy content from *in vitro* gas production was determined by: ME (Mcal kg⁻¹ DM) = (2.20 + 0.136 Gas Prod_{24h} + 0.057 Crude Protein + 0.0029 Crude Fat²)/4.184. Data were then analyzed using ANOVA for a completely randomized design. The gas produced

from the soluble (a) fraction in CM was significantly ($P < 0.05$) higher than other feeds. Corn distillers dried, followed by SBM, registered the higher ($P < 0.05$) gas produced from the slowly degraded b fraction. The constant rate of gas production (c) was higher ($P < 0.05$) in CM. The potential gas production a + b was higher in CDD. The ME content was higher ($P < 0.05$) in SBM followed by CM. Variables such as constant rate of gas production c might indicate a good availability of nitrogen in the rumen, whereas the ME content of analysed feeds shows a non negligible energy content.

Table 1. *In vitro* gas production characteristics of sources of protein used in sheep nutrition practices in northwest of Mexico

Feed	Parameters				ME
	a	b	c	a+b	
CSM	5.53 ^b	39.09 ^c	0.053 ^d	44.63 ^d	2.22 ^d

W239 Effects of dried distillers grains with solubles as a replacement for soybean meal and corn in diets fed to Boer-cross feeder kids. R. Cox*, T. Hutchens, G. Rentfrow, and G. Anderson, *University of Kentucky, Lexington.*

One hundred sixty crossbred feeder kids were used to characterize the effects of replacing soybean meal (SBM) and whole corn (WC) energy with dried distillers grains with solubles (DDGS) on growth and carcass characteristics. Crossbred feeder kids were randomly assigned to 4 dietary treatments. All kids were given ad libitum access to water and a control diet (0%) containing WC, SBM, soybean hulls (SBH) and Kentucky 31 tall fescue hay (KY-31), or energy replaced with DDGS at 10, 15 and 25% of total diet. All kids were fed concentrates at 3% of live body weight. Each treatment had 2 replications with 20 kids per replication. Kids were allowed 14 d to acclimate to the diets prior to beginning of the trial. Kids in each treatment group were weighed at 0, 14, 28, 42 and 56 d. Feed concentrates were increased accordingly following each weight measurement in order to maintain the 3% of body weight feeding rate. Additionally, both leg and hock circumference was measured at 56d. A stratified random sample of 3 was taken from each pen for carcass evaluation. Energy replaced at 15% DDGS showed the highest average live weight value at 56 d (31.05 kg) as compared to energy replaced at 0%, 10% and 25% DDGS (27.86, 29.50 and 30.87 kg respectively). Values were not different for both leg circumference ($p = 0.35$) and hock circumference ($p = 0.34$) across all treatments. Additionally, there was no difference ($p = 0.41$) for hot carcass weight across all treatments in the harvest group. Average daily gain was highest for the 25% DDGS group (170g/d compared to 136, 159 and 163 g/d). Moreover, the 25% DDGS showed the highest percentage of gain on trial, gaining 7.56% more than the 0% DDGS treatment. These results

indicate that DDGS can be substituted for soybean meal and corn as an energy source with no detrimental effects on live animal weight gain or carcass weight.

Key Words: Distillers Grains, Boer-Cross

W240 Effect of substitution of canola meal by cotton seed meal on apparent digestibility of diets for hair sheep. J. F. Obregon*, L. E. Antonio, E. Vazquez, F. G. Rios, A. Estrada, and J. J. Portillo, *UASCA-205 FMVZ-Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico.*

With the objective of determinate the effect of substitution of canola meal for cotton seed meal on the apparent digestibility of isoproteic diets, a total faecal collection experiment was conducted. Four hair sheep (males; BW = 21.25 ± 0.96 kg), were used in a crossover design experiment, the sheep were assigned to consume one of two diets in that consisted the treatments: 1) Diet with 17.2 % of CP and 3.38 Mcal of DE/kg, containing (DM basis): canola meal 22.3%, corn 53 %, Sudan grass hay 15%, sugar cane molasses 7% and mineral premix 2.7% (CM); and 2) Diet similar to CM but containing 19.5% of cotton seed meal and 55.8% of corn (CSM). Diets were offered twice a day (0800 and 1600 h). Sheep were placed individually in metabolic crates (0.6 × 1.2 m). Experimental periods consist in six days adaptation period and four days for samples collection. From each diet treatment and period one kg of diet was sampled and the total faecal production was collected. DM and CP were assayed. DM intake was similar ($P = 0.69$) across the treatments (737.8 vs. 736.9 g/day) for CM and CSM. Cotton seed meal in diet increased ($P = 0.06$) DM excreted in faeces (158.4 vs. 139.1 g/day), and increased ($P = 0.02$) faecal excretion of crude protein (30.9 vs. 26 g/day). Apparent DM digestibility was reduced ($P = 0.06$) by CSM treatment (78.5 vs. 81.1 %), and diminished ($P = 0.02$) digestibility of dietary crude protein from 79.6 to 75.8 %. Digestible of the diets was decreased ($P = 0.07$) by CSM treatment (3.36 vs. 3.47 Mcal/kg). This data suggest that substituting canola meal for cotton seed meal, decrease the digestibility of dry matter and crude protein, and reduce energy content of diet for sheep.

Key Words: Apparent Digestibility, Protein Sources, Sheep

W241 Apparent digestibility of diets for hair sheep elaborated with cull chickpeas, cotton seed meal and overcooked sesame meal. J. F. Obregon*, S. Fernandez, E. Vazquez, F. G. Rios, J. M. Uriarte, and G. Contreras, *UASCA-205 FMVZ-Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico.*

To compare the apparent digestibility of isoproteic diets elaborated with cull chickpeas, cotton seed meal and overcooked sesame meal, were utilized four Katahdin-Pelibuey sheep, males (BW = 19.85 ± 0.208 kg), individually placed in metabolic crates (0.6 × 1.2 m), Agreement with a square of Jouden design experiment were assigned to consume one of three diets in that consist the treatments 1) Diet with 17% of CP and 3.5 Mcal of DE/kg, containing (DM basis): cull chickpeas 53.5%, corn 20%, Sudan grass hay 15%, sugar cane molasses 9% and mineral premix 2.5% (CHP), 2) Diet similar to CHP but containing 19.5% of cotton seed meal and 54% of corn (CSM), 3) Diet similar a CHP but with 17.7% of overcooked sesame meal and 55.8% of corn (OSM). Diets were offered twice a day (0800 and 1600 h), after six days of adapta-

tion period, samples of diets (1 kg) and the total faeces produced were collected during four continues days. Samples were dried and weighed. DM and CP were performed and apparent digestibility of DM and CP, as well DE content of diets was calculated. Apparent DM digestibility was higher ($P < 0.01$) for CHP vs. CSM and OSM with values of 83.96, 78.23 and 75.98% respectively. Similar situation was observed for apparent digestibility of CP ($P < 0.01$) with values of 75.1 vs. 64.73 and 64.67 % for CHP, CSM and OSM respectively. The content of DE of the diets was affected ($P < 0.01$) for treatments with values of 3.6 vs. 3.35 and 3.25 Mcal/kg for CHP vs. CSM and OSM respectively. It is concluded, that cull chickpeas can be included in isoproteic diets for sheep substituting sources of protein as cotton seed meal and overcooked sesame meal.

Key Words: Isoproteic Diets, Apparent Digestibility, Hair Sheep

W242 Oscillating dietary protein in finishing cattle rations to reduce nitrogen inputs, with or without subcutaneous implants does not affect performance or final carcass composition. C. R. Nightingale*, K. L. Swyers, H. Han, T. E. Engle, and S. L. Archibeque, *Colorado State University, Fort Collins.*

We hypothesized that oscillating dietary CP concentration would reduce total N inputs while yielding comparable performance in finishing beef steers, regardless of implant status. Angus steers (n = 118; 358 SEM 9 kg initial BW) were used in a completely randomized block design with a 2x2 factorial arrangement of treatments, and fed in 12 pens. The steers were fed either a 1) Control diet (11.7% CP; n = 6 pens), or 2) Control diet and a diet with no added urea (9.6% CP) oscillated on a 48-h interval for each feed (OSC, n = 6 pens). Additionally, steers received no implant (6 pens), or were implanted with Revalor S (n = 6 pens). Dry matter intake did not differ among dietary treatments ($P = 0.13$), but increased ($P = 0.003$) from 10.86 to 11.56 kg/d when cattle were implanted. By design, N intake was decreased ($P < 0.001$) from 0.276 to 0.249 kg/d when steers were fed the OSC diet instead of the Control diet. This equated to a total reduction ($P = 0.009$) in N intake from 32.01 to 28.86 kg/hd during the 116 d finishing period. There was no difference in final live weight due to diet ($P = 0.82$) or implant ($P = 0.16$). Implanted cattle had a greater ($P < 0.001$) ADG than non-implanted cattle, yet there was no diet x implant interaction ($P = 0.80$) or dietary ($P = 0.78$) effect on ADG. There was no diet x implant interaction ($P \geq 0.36$) on any measured carcass characteristics. There was no difference in corrected yield grade ($P = 0.44$), marbling ($P = 0.47$), fat thickness ($P = 0.10$), or rib eye area ($P = 0.43$), due to diet. Steers fed the OSC diet had no difference in premium value above base carcass value ($P = 0.17$), or total carcass value ($P = 0.93$) compared to steers fed the Control diet. Cattle that were implanted had a numerical increase ($P = 0.19$) in total carcass value from \$1099 to \$1157, even though there was a decrease ($P = 0.008$) in marbling score compared to non-implanted cattle. These data suggest that oscillating dietary protein will decrease N inputs without compromising productivity or quality of feedlot steers regardless of implant status.

Key Words: Beef Steer, Protein Oscillation, Feedlot

W243 Fractional protein synthesis rate (FSR) in intestinal mucosa of kids: Effect of a diet containing casein or soy protein. U. Schoenhusen¹, A. Floeter¹, S. Kuhla¹, P. Junghans¹, C. C. Metzges¹, K.

Huber², R. Zitnan³, and H. M. Hammon*¹, ¹*Research Institute for the Biology of Farm Animals (FBN), Dummerstorf, Germany*, ²*School of Veterinary Medicine Hanover, Hanover, Germany*, ³*Institute of Animal Production, Nitra, Slovakia*.

In pre-ruminants, feeding soy protein instead of milk protein leads to alteration in intestinal mucosal structure and absorption of digested nutrients, which is partially caused by a deficit of indispensable amino acids (AA). Supplementation of those AA to soy protein may stimulate epithelial growth and probably affect mucosal protein synthesis in the gut. The present study has investigated effects of feeding soy protein with or without AA supplementation on jejunal mucosa development and FSR in kids. Kids (14 d of age) were fed comparable milk protein-based diets, in which 50% of the crude protein was either casein (CA), soy protein isolate (SP) or soy protein isolate with supplementation of those AA known to be lower concentrated in soy protein than in casein (SPA) for 43 d (n=8/group). An oral dose of [1-¹³C]leucine (180 mg/kg BW, 99

atom% ¹³C) was administered 4 h after feeding the milk drink. Timed blood samples were collected between -15 and +45 min relative to the ¹³C-leucine administration for determination of plasma free AA and ¹³C ketoisocaproic acid. Kids were killed 5 h after feeding and mucosa was collected to measure protein-bound ¹³C-leucine and to calculate FSR. Data were analyzed by GLM of SAS with diet as fixed effect. In medial jejunum (MJ), villus height/crypt depth ratio was higher (P < 0.05) in CA than SP, and mucosal protein content and protein/RNA ratio were higher (P < 0.05) in CA than SP and SPA. The ¹³C-recovery in blood CO₂ tended to be lower (P < 0.1) in CA than SP. FSR of mucosal protein in MJ tended to be lower (P < 0.1) in CA than SP. Plasma concentrations of Met were lower in SP (P < 0.05) and of Thr were lower (P < 0.01) in SP and SPA than in CA. Feeding SPA does not ameliorate soy protein effects on intestinal mucosa in a significant manner. Supported by German Research Foundation (DFG: SCH 627/1-1).

W244 Lignocellulolytic activity of *Pleurotus ostreatus* solid culture on barley straw. L. Luna-Rodriguez¹, M. Meneses-Mayo¹, G. Mendoza-Martinez², C. Montalvo-Paquini³, S. S. Gonzalez-Muñoz^{*1}, and O. Loera-Corral⁴, ¹Colegio de Postgraduados, Montecillo, Edo. Mexico, Mexico, ²UAM Xochimilco, Mexico D.F., ³Universidad Politécnica de Puebla, Puebla, Mexico, ⁴UAM Iztapalapa, Mexico D.F.

The first objective of this study was to evaluate radial growth (Vr) of *Pleurotus ostreatus* (IE8 and CP50 strains) with N supplement (urea and ammonia sulfate) and 70 or 80% humidity, on barley straw. The experimental design was completely randomized, an analysis of variance was performed and means were compared with Tukey test ($P < 0.05$). The higher Vr were: 0.568 mm/h for CP50 control (80% humidity, distilled water only); 0.573 mm/h for IE8 and 80% humidity plus a saline solution (magnesium sulfate 25.0 g/L, ferrous sulfate 2.8 g/L, manganese sulfate 1.7 g/L, sodium chloride 1.6 g/L). For both strains, Vr was improved only by 80% humidity. Therefore, strain IE8 was selected to determine fibrolytic enzymes (xylanases, cellulases and laccases) activity and *in vitro* DM digestibility (IVDMD) for 30 d. Values were expressed in international units (IU): the amount of enzyme needed to release 1 μ mol product/min under the assay conditions. Activity was referred to initial substrate dry weight (IU/g dry wt). The higher activity was at 8 d for cellulases (15.95 IU/g dry wt) and at 12 d for xylanases (80.51 IU/g dry wt) and laccases (3.46 IU/g dry wt) which coincided with the maximum content of extracellular protein (0.12 IU/g dry wt). Further characterization of enzymatic activity (39°C; pH 6 and 7) showed the following: 1) higher stability at pH 6 with residual activity of 77.5, 49.1 and 27.5% for xylanases, cellulases and laccases; 2) at pH 7 residual activity was lower and similar (xylanases 41.1%; cellulases 36.8%; laccases 24.1%). After 30 d there was a significant decrease in the content of NDF (2.42%), hemicellulose (7.03%) and lignin (3.79%), whereas CP increased 0.86% and IVDMD also increased from 36.64% to 42.36%. It may be concluded that this rather simple biotechnological procedure improved IVDMD of barley straw.

Key Words: Fungi, Fibrolytic Enzymes, Crop Residues

W245 Feedlot performance, carcass characteristics and liver abscesses in heifers fed MGA, Rumensin and Tylan continuously or withdrawn the last 35 days on feed. G. E. Sides^{*1}, R. S. Swingle², R. C. Borg¹, and W. M. Moseley¹, ¹Pfizer Animal Health, Kalamazoo, MI, ²Cactus Feeders, Cactus, TX.

Experimental design: 2x2 factorial, randomized block, one location. Treatment groups: Rumensin, Tylan (RT), RT plus MGA (RTM), RT withdrawn 35 d pre-harvest (RTwd), and RTM withdrawn 35 d pre-harvest (RTMwd). Experimental unit: pen of heifers. Numbers per treatment group: 10 pens; 985, 997, 974, 1026 heifers in RT, RTM, RTwd, RTMwd, respectively. Diets: 30 g* t^{-1} (air dry basis) Rumensin; 90 mg*heifer⁻¹*day⁻¹ Tylan; 0.4 to 0.5 mg*heifer⁻¹*day⁻¹ MGA. Implants: Revalor-IH d 0; Revalor-200 d 60. Statistics: appropriate mixed model procedures including fixed effect of treatment and random effects of block and residual. Average days fed: 150.2 to 150.8. Percent died or removed: 2.7 to 3.9. Final BW (kg): greater ($P < 0.05$ to $P < 0.01$) for RTM (524) than RT (512), RTwd (511), RTMwd (516). DMI (kg): greater ($P < 0.01$) for RTM (8.1) and RTMwd (8.1) than RT (7.8), RTwd (7.9). ADG (kg): greater ($P < 0.01$) for RTM (1.45) than RT (1.39), RTwd

(1.38), RTMwd (1.40). ADG:DMI ratio (0.17 to 0.18). Dressing percent: groups ranged from 64.5% to 64.9%; greater ($P < 0.01$) for RTMwd than RTM and RT. RTM had greater ($P < 0.01$) HCW, marbling score, rib fat, calculated yield grade, and percent quality grade prime and choice but lesser ($P < 0.01$) color score, percent dark cutters, percent yield grade 1, 2, or 3, and rib eye area compared to RT, RTwd, and RTMwd. Withdrawal of RTM: significantly ($P < 0.05$ to $P < 0.01$) decreased HCW, marbling score, rib fat, calculated yield grade, and percent quality grade prime and choice; significantly ($P < 0.01$) increased color score, percent dark cutters, rib eye area and percent yield grade 1, 2, or 3 compared to continuous RTM. Liver abscesses: no difference among groups. MGA fed heifers: increased in both carcass weight and carcass quality traits of economic importance. Withdrawal of RT: no adverse affect on carcass weight or quality traits. Withdrawal of RTM: adversely affected economically important feedlot performance and carcass traits.

Key Words: Carcass, Feedlot, MGA

W246 Effects of feeding different dose levels of melengestrol acetate on feedlot performance, carcass characteristics and estrus activity of feedlot heifers. G. E. Sides^{*1}, O. A. Turgeon², W. C. Koers², M. S. Davis², K. Vander Pol², R. C. Borg¹, and D. J. Weigel¹, ¹Pfizer Animal Health, Kalamazoo, MI, ²Bos Technica Research Services, Inc., Salina, KS.

A randomized complete block design was used to compare the effects of feeding melengestrol acetate (MGA) at 0.4 mg*heifer⁻¹*d⁻¹ (0.4M) and 0.5 mg*heifer⁻¹*d⁻¹ (0.5M) on feedlot performance, health, and carcass characteristics of commercial beef heifers (n=1,418). Heifers were enrolled upon arrival at the feedlot (Bos Technica Research Inc., Syracuse, KS), randomly assigned to treatment, processed according to feedlot protocol and administered an abortifacient within 48 h of arrival. Enrollment date was used as the blocking factor with pen (n=10 per treatment) as the experimental unit. Heifers averaged 290.2 kg of BW at enrollment and were fed for an average of 176 d. Estrus activity was monitored twice daily and summarized as a count of heifers showing estrous within a pen over each 21 d interval throughout the feeding period. Linear mixed model procedures were used to compare treatment differences in feedlot performance parameters and all quantitative carcass measurements and included the fixed effect of treatment and the random effects of block and residual. A generalized mixed model was used to evaluate proportional measures of estrus activity (E), dark cutting carcasses (%DC), preliminary USDA Yield Grades ≤ 3 , and Quality Grades \geq Choice using the same model listed above. Repeated measures models for E also included fixed effects for time of measure and time by treatment and the random effect of block by treatment. Overall treatment effects were significant for E and %DC ($P < 0.05$ and $P < 0.10$, respectively). Least squares means of E were 3.2% and 2.1% in 0.4M and 0.5M, respectively, and for %DC were 3.0% and 1.7% in 0.4M and 0.5M, respectively. Dry matter intake, ADG, gain*feed⁻¹ and all other carcass measurements were not significantly different between treatments. The decrease in E and %DC may suggest an economic advantage of feeding a higher level of MGA to finishing heifers.

Key Words: Carcass Performance, Feedlot, MGA

W247 Effects of tannins supplementation on animal growth and in vivo ruminal bacterial populations associated with bloat in heifers grazing wheat forage. B. R. Min^{*1,4}, W. E. Pinchak¹, K. Hernandez², C. Hernandez³, M. E. Hume³, E. Valencia², and J. D. Fulford¹, ¹Texas AgriLife Research, Vernon, TX, ²University of Puerto Rico, Puerto Rico, ³USDA-ARS, Southern Plains Agricultural Research Center, Food & Safety Research Unit, College Station, TX, ⁴Ichthus Education Center, La Trinitaria, Chiapas, Mexico.

Two experiments were conducted to 1) enumerate the effect of tannins supplementation on bio-film production, in vitro gas and foam production, ADG, and bloat frequency; and 2) quantify the influence of tannins supplementation on ruminal bacterial populations of heifers grazing wheat forage. Molecular PCR enumeration was used to quantify 5 major ruminal bacterial strains in the rumen of heifers grazing wheat forage supplemented with tannins. Twenty-six heifers (286.1 ± 25.7 kg) were randomly allocated to 1 of 3 treatments that included a control (non-tannins group) and two types of tannins (mimosa, mainly condensed tannins vs. chestnut tannins, mainly hydrolysable tannins). Plant tannins (1.5% of DMI) were supplemented once daily (approximately 0800) mixed with a textured feed (500 g/animal). Heifers were visually monitored daily for bloat score (0 = no bloat, 3 = severe bloat). In Exp. 1, supplementation of tannins reduced the rate of frothy foam and biofilm production with chestnut being more efficacious than mimosa tannins. Chestnut tannin supplementation increased ADG. Mean bloat score and bloat day were greater ($P < 0.01$) for the control diet than for tannins treatment groups. In Exp. 2, phenotypic study shows that the dynamics of *Fibrobacter succinogenes*, *Streptococcus bovis*, and *Prevotella rumenicola* strains were relatively stable with time (d 0, 10, and 25) in the rumen of animals not receiving tannins supplementation. However, with supplementation of chestnut and mimosa tannins, populations of *P. rumenicola* and strains of both *F. succinogenes* and *Ruminococcus flavefaciencens* were increased, respectively. Conversely, populations of both *F. succinogenes* and *S. bovis* were decreased in chestnut tannins supplementation with time, indicating that different types of tannins have different mode of action on rumen bacterial population.

Key Words: Ruminal Bacterial Populations, Bloat, Plant Tannins

W248 Carcass traits of grazing young bulls. H. J. Fernandes^{*1,2}, A. G. Silva², J. Cavali², A. A. Rocha², M. F. Paulino², L. M. Paiva^{1,2}, and R. M. Paula², ¹State University of Mato Grosso do Sul / FUNDECT, Brazil, ²Federal University of Viçosa, Brazil.

The objective of this study was to evaluate the carcass measures of grazing young bulls in dry season, supplemented with concentrate rations with different urea levels. Twenty young bulls with initial weight of 220 kg were used, separated in four groups, housed in *Brachiaria decumbens* Stapf pastures and fed daily with one of the supplements: *ad libitum* mineral salt (control treatment); or 1.5 kg/animal of concentrated rations (32% of crude protein) formulated with corn, soybean meal and 0, 4 or 8% of urea. Two young bulls of each group were slaughtered after 90 days and the remaining after 180 days. After chilling, the carcasses were weighted. In the right half carcass, the lengths, and the loin eye areas (LEA) and the backfat thickness (BFT) in the 12th rib were measured. The effect of the supplementation with concentrate and the linear and quadratic effects of the urea level in the concentrate were evaluated by the partition of the sum of squares of treatment in orthogonal contrasts.

The significance level was 5%. The carcasses yields and lengths to the reference treatment and to the supplemented treatments (levels of 0, 4 e 8% of urea) were: 51.2, 51.8, 53.3 and 52.2 % (coefficient of variation - CV=3.9%); and 95.6, 101.3, 104.0 and 96.3 cm (CV= 6.7%). In the same way, the LEA and BFT were 38.3, 48.3, 51.4, 43.0 cm² (CV= 15.45%); and 0.70, 0.88, 0.87 and 1.15 mm (CV=46.2%). Only the LEA presented significant effect of the concentrate supplementation. The linear or quadratic effects of the urea levels in the supplement were not significant to none of the measures. Usually, grazing animals have low development in dry season because the low forage availability. This may explain these results. This study showed that the extra nutrients offered by the concentrate or the different urea levels in the supplement were not able to alter the carcass traits

Key Words: Carcass, Grazing, Supplementation

W249 Influence of feed restriction and oral vitamin D and E supplementation on meat quality of Canchim heifers. S. A. Matsuhara^{1,3}, M. Parrili¹, M. D. B. Arrigoni¹, C. L. Martins¹, D. D.s Millen¹, R. D. L. Pacheco^{*1}, M. V. Fossa¹, L. M. N. Sarti¹, J. P. S. T. Bastos¹, T. M. Mariani¹, H. N. de Oliveira¹, S. R. Baldin¹, T. C. B. da Silva², R. S. Barducci¹, R. d. O. Roça¹, ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²Faculdade de Zootecnia/UNESP, Dracena, São Paulo, Brazil, ³Apoio FAPESP.

This study, conducted at São Paulo State University (UNESP) feedlot, Botucatu Campus, Brazil, was designed to evaluate the influence of feed restriction (FR) and oral vitamin D and E supplementation (VIT) on meat quality of Canchim (5/8 Charolais, 3/8 Nellore) heifers. The experiment was designed as a 2x2 factorial arrangement, in which sixteen 7-mo-old heifers (227.4±23.7kg) were randomly assigned according to FR: Restricted (RT) and Non-Restricted (NR) fed one of two diets with (VDE) or without (WV) vitamins (D=7.5X10⁶ UI/head/d and E=1838 UI/head/d during 18 and 43 days prior to slaughter, respectively). During 48d RT heifers received 70% of amount fed to NR, but after this period all animals were fed 77 days ad libitum. Rib eye samples were harvested between 12th and 13th ribs for total lipids in % (TL), color (L*, a*, b*), vitamin concentration and tenderness analysis. Tenderness was evaluated by three methods: shear force (SF), miofibrillar fragmentation index (MFI) and sensory panel (using a scale from 1 (extremely tender) to 9 (extremely tough)). It was found a FR effect ($P < 0.05$) for meat tenderness, evaluated by sensory panel, where RT was more tender than NR (RT=2.9, NR=4.3), but no VIT effect ($P > 0.05$) was found (WV=4.0, VDE=4.2). Both FR and VIT did not affect ($P > 0.05$) TL (WV=1.99, VDE=2.07; RT=1.89, NR=2.18), meat tenderness evaluated by SF (WV=3.46, VDE=3.89; RT=3.60, NR=3.75) and MFI (WV=81.98, VDE=69.32; RT=77.50, NR=73.80). It was found ($P < 0.05$) VIT effect for L*, where WV heifers presented brighter meat than those VDE (WV=42.88, VDE=40.23), but no differences were observed ($P > 0.05$) for a* (WV=18.43, VDE=18.45) and b* (WV=10.60, VDE=10.30). There was not FR effect ($P > 0.05$) on color. No FR and VIT effects were observed ($P > 0.05$) on vitamin D (WV=0.07, VDE=0.07; RT=0.60, NR=0.80) and E (WV=4.27, VDE=5.91; RT=4.80, NR=5.38) concentration (%). No interactions were found ($P > 0.05$) between FR and VIT in this study. Thus, FR improved tenderness by sensory panel and VIT did not enhance meat quality of Canchim heifers.

Key Words: Feedlot, Feed Restriction, Heifers

W250 Influence of feed restriction on performance and carcass traits of Canchim heifers. M. Parrili^{1,3}, S. A. Matsuhara¹, M. D. B. Arrigoni¹, C. L. Martins¹, D. D. Millen^{*1}, R. D. L. Pacheco¹, H. N. de Oliveira¹, M. V. Fossa¹, L. M. N. Sarti¹, T. M. Mariani¹, J. P. S. T. Bastos¹, S. R. Baldin¹, R. S. Barducci¹, and T. C. B. da Silva², ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²Faculdade de Zootecnia/UNESP, Dracena, São Paulo, Brazil, ³Apoio FAPESP.

This study, conducted at São Paulo State University (UNESP-Botucatu) feedlot, Brazil, was designed to evaluate the influence of feed restriction (FR) on performance and carcass traits of Canchim (5/8 Charolais, 3/8 Nellore) heifers. Sixteen 7-mo-old (253.4±23.7 kg) Canchim heifers were randomly assigned according to treatments: Restricted (RT) and Non-Restricted (NR). Heifers were fed in feedlot for 125d. During the first 48d RT heifers received 70% of amount fed to NR, but after this period all animals were fed 77 days ad libitum. Initial and final rib eye areas in cm² (REA) and initial and final back fat thickness in mm (BFT) were measured by ultrasound. After slaughter, visceral fat (VF) and livers were weighed and rib eyes scored for marbling (MB) using a scale from 1 to 6. During FR, NR presented greater (P<0.05) average daily gain in kilos (ADG) than RT (NR=1.16, RT=0.74), but no differences (P>0.05) were found when heifers were re-fed *ad libitum* (NR=0.96, RT=1.12). There was not difference (P>0.05) for total ADG, considering 125d on feed (NR=1.03, RT=0.95). FR did not affect (P<0.05) REA, BFT, final live weight (FBW), hot carcass weight (HCW), dressing percentage (DP), MB and weights of VF and liver (Table 1). Treatment had a significant impact (P<0.05) for percent hindquarter (NR=50.3, RT=51.58), but it was not found effect (P>0.05) for percent forequarter (NR=37.12, RT=36.38). Feed costs were reduced by 4.31% for RT heifers. FR could be useful for Canchim heifers in feedlot for reducing feed costs and presenting heavier hindquarter without affecting performance and carcass traits.

Table 1. Influence of FR on carcass traits of Canchim heifers

Item	NR	RT	SEM
Initial Live Weight (kg)	250.60	256.38	18.53
Final Live Weight (kg)	381.10	377.13	30.58
Initial REA (cm ²)	40.05	44.32	3.01
Final REA (cm ²)	64.24	62.21	3.50

W251 Supplementation frequency effects on performance of steers grazing tropical grass. J. A. S. Morais¹, T. T. Berchielli^{*1}, M. F. S. Queiroz¹, R. A. Reis¹, M. A. Balsalobre², G. Fiorentini¹, S. F. Souza¹, and P. H. M. Dian¹, ¹Faculdade de Ciências Agrárias e Veterinárias - Campus de Jaboticabal/UNESP, ²Bellman Nutrição Animal.

The objective of this research was to determine the effect of reduction in supplementation frequency over the performance of Nellore steers grazing palisade grass (*Brachiaria brizantha* cv. Marandu) pasture.

Twenty seven castrated steers, 270 kg average initial body weight (BW) were distributed in nine palisade grass paddock of two ha each. Each paddock still received a variable number of regulators animals to maintain the forage allowance approximately 8 kg DM/100 kg of BW. The animals were supplemented with 0.5% of BW/day of a concentrate composed by 65% of corn gluten-60, 25% of dry sugarcane yeast and 15% of citric pulp. The supplement was offered in 3 different frequencies: daily, from Monday to Friday or Monday, Wednesday and Friday. There was no interaction time*frequency supplementation effect (P > 0.05). The supplementation frequency didn't affect (P > 0.05) the animals performance, weight gain was in average 0.890 kg/day. However, the experimental periods affect animals performance (P < 0.05), in the first period (from February to March) it was observed highest daily animal BW gain compared to the other period (from March to May). Based on the experimental results it can be concluded that the supplementation frequency reduction from 7 to 3 days of the week doesn't affect the performance of steers grazing palisade grass pasture, becoming a viable alternative for reduction in the costs with labour and equipments. The experimental period has important effect on the performance of the steers grazing tropical pasture.

Table 1. Effect of supplementation frequency on performance (kg/an/day) of Nellore steers grazing palisade grass pasture (São Paulo – Brazil).

W252 Comparative effects of virginiamycin supplementation on growth-performance and dietary energetics of calf-fed Holstein steers. E. Ponce^{*1,2}, J. Lenin^{1,2}, U. Sanchez^{1,2}, N. Torrentera¹, and R. Zinn², ¹UABC, Mexicali, BC, Mexico, ²University of California, Davis, CA.

One hundred forty-four Holstein steer calves (119 kg) were used in a 340-d trial. Treatments were: Control (no antibiotic); 2) 16 ppm virginiamycin; 3) 22.5 ppm virginiamycin; and 4) 28 ppm monensin. Calves received a steam-flaked corn-based growing diet, formulated to meet average nutrient requirements for the first 112 d, and thereafter were fed a finishing diet formulated to meet average nutrient requirements from d 112 until slaughter. Steers were divided into two weight groupings (light and heavy), and assigned within groupings to 24 pens (6 steers/pen). Fresh feed was provided twice daily. Virginiamycin supplementation did not affect (P > 0.10) ADG, but increased (linear component, P = .02) 340-d gain efficiency. Improvement in gain efficiency was attributable to enhanced energetic efficiency (linear component, P = 0.04). Improvements in dietary NE were most pronounced during the final 116 d of the feeding period (linear component, P = 0.04) that comprised the hot summer months (June through September). Mon-

ensin supplementation did not affect ($P > 0.10$) growth performance or dietary NE. There were no dietary treatment effects ($P > 0.10$) on carcass characteristics. Both virginiamycin (linear component, $P = 0.03$) and monensin ($P = 0.06$) supplementation reduced morbidity. There were no dietary treatment effects ($P > 0.10$) on mortality. Although average initial weight for the light and heavy groupings differed by only 4 kg, the heavy-weight grouping had greater carcass weight (13 kg, $P = 0.02$), LM area (5.4%, $P = 0.01$), ADG (4.3%, $P = 0.03$), and gain efficiency (2.3%, $P = 0.08$) than the light-weight grouping. Improvement in gain efficiency was due largely to increased (3.2%, $P = 0.01$) dietary NE. We concluded that virginiamycin supplementation can markedly enhance feedlot growth-performance and dietary energetic efficiency of calf-fed Holstein steers. Holstein calves that are lighter than group average for initial weight may have slightly slower growth rates as well as slightly reduced dietary energetic efficiency.

Key Words: Virginiamycin, Cattle, Performance

W253 The effects of dexamethasone and Revalor-S® on growth, carcass quality and visceral organ and fat mass of finishing beef steers fed cracked corn. S. E. Kitts*, S. W. El-Kadi, C. C. Taylor-Edwards, F. F. Korthaus, J. B. Cannon, A. F. Koontz, D. L. Harmon, E. S. Vanzant, and K. R. McLeod, *University of Kentucky, Lexington.*

Dexamethasone (DEX), a synthetic glucocorticoid, has been shown to alter site and rate of fat accretion in several mammalian species, including cattle. The current study was designed to investigate potential interactions between DEX and trenbolone acetate/estradiol (Revalor-S) administration on growth performance, carcass quality and visceral organ and fat mass of finishing beef steers fed cracked corn. Ninety-six crossbred steers (385 ± 1 kg) were assigned randomly to a 2×2 factorial arrangement of treatments consisting of either no implant or Revalor-S (d 1 and 56) and either no injection or i.m. injection of 0.09 mg/kg BW DEX (d 1, 28, 56 and 84). Steers received a 90:10 concentrate-forage diet ad libitum during the feeding period and were slaughtered ($n=60$) on d 113 for determination of carcass quality. A subset of steers (9/treatment) was slaughtered between d 106-119 for determination of visceral organ and fat wet mass and carcass quality. There were no interactions ($P \geq 0.05$) between implant and DEX for any variable measured. Over the feeding period, DMI was unaffected by treatment. However, ADG and efficiency of gain were both 13% greater ($P \leq 0.05$) with implant. Conversely, DEX lowered ADG by 10% ($P = 0.007$). Dexamethasone decreased ($P = 0.04$) and implant increased ($P = 0.04$) HCW. There were no effects ($P \geq 0.05$) of treatment on carcass quality. Implant resulted in greater ($P \leq 0.01$) digestive tract and liver weights which translated to greater ($P \leq 0.05$) small intestine (SI) and liver weights as a function of empty BW. Dexamethasone decreased ($P \leq 0.05$) digestive tract and liver weights and decreased ($P = 0.02$) SI weight as a function of empty BW. As expected, Revalor-S increased ADG and feed efficiency; however, DEX decreased ADG and had no effect on fat deposition. These results indicate that, in contrast to previous data, DEX does not alter site or amount of fat deposition in finishing beef cattle.

Key Words: Cattle, Fat, Dexamethasone

W254 Effect of feeding cinnamaldehyde essential oils and monensin on feedlot cattle performance. W. Z. Yang¹, C. Benchaar², M. L. He*¹, and K. A. Beauchemin¹, ¹*Agriculture and Agri-Food Canada,*

Research Centre, Lethbridge, AB, Canada, ²*Agriculture and Agri-Food Canada, Dairy and Swine R&D Centre, Sherbrooke, QC, Canada.*

A study was conducted to evaluate the effects of supplementing cinnamaldehyde essential oil (CIN) on growth performance of feedlot cattle. Seventy-five yearling steers (BW=390 kg) were assigned to a randomized complete block design with five treatments: control; 400; 800; 1600 mg/head/day CIN; or 330 mg monensin (MO)/head/day. At the start of the trial, steers were blocked according to BW and assigned to fifteen blocks of five cattle. The diets consisted of 9% barley silage, 86% dry-rolled barley grain, and 5% supplement (DM basis). Steers were housed in individual pens that allowed measuring feed intake individually, and weighed on days 0, 28, 56, 84 and 112. Cattle fed with CIN consumed more feed DM than the cattle fed control (7.7 vs 6.6 kg/d; $P < 0.01$) or MO diet (7.7 vs 7.1 kg/d; $P < 0.14$) in the first 28 days. However, feed intake (kg/d or % of BW) of cattle fed CIN was not different from those fed MO or control from day 29 to the end of the experiment even though a quadratic dose response to CIN was detected during the first 28 d ($P < 0.01$) and the overall experiment ($P < 0.11$). A general decrease in feed intake was observed the first week of the trial compared to the adaptation period, with the highest decrease for control (7.4 vs 5.3 kg/d), following by MO (7.4 vs 6.0 kg/d) and minimal decrease for CIN (7.2 vs 6.7 kg/d). The reduction of feed intake was likely due to the stress of weighing and bleeding on the day before starting the trial. The mean ADG (kg/d) overall ranged from 1.64 to 1.75 and was not affected by the treatments. In contrast, feed efficiency (gain/intake) tended ($P < 0.10$) to be lower for CIN (0.21) than for MO (0.22) with no difference between control and CIN. These results indicate that supplementation of a feedlot finishing diet with CIN improved feed intake of stressed beef cattle but had minimal effects on ADG or feed efficiency over the entire feedlot finishing period.

Key Words: Cinnamaldehyde Essential Oil, Intake and Growth, Feedlot Cattle

W255 Effect of a rumen buffer derived from calcified seaweed on ruminal disappearance and fermentation in steers. O. D. Montañez-Valdez*¹, J. M. Pinos-Rodriguez², J. H. Avellaneda-Cevallos³, E. O. Garcia-Flores⁴, and E. C. Guerra-Medina⁴, ¹*Centro Universitario del Sur de la Universidad de Guadalajara, Ciudad Guzmán, Jalisco, México,* ²*Universidad de San Luis Potosí, San Luis Potosí, México,* ³*Universidad Técnica Estatal de Quevedo, Ecuador, Quevedo, Los Ríos, Ecuador,* ⁴*Centro Universitario de la Costa Sur, Aulán de la Grana, Jalisco México.*

Effect of a rumen buffer derived from calcified seaweed on ruminal disappearance was evaluated in steers. Three ruminally cannulated steers (450 ± 15 kg body weight) with three treatments in a crossover design, were fed with a diet formulated with 30% forage (15% alfalfa hay and 15% corn silage) and 70% concentrate (47% ground sorghum, 8% soybean meal, 7% molasses cane, 6.8% corn gluten meal and 1.2% mineral premix). The treatments were: 1) control (without buffer); 2) 1% sodium bicarbonate; and 3) 0.5% rumen buffer derived from calcified seaweed. There were differences ($P \leq 0.05$) among treatments on ruminal pH; the values from steers fed diet without ruminal buffer were lower (5.98) than those fed buffer derived from calcified seaweed (6.34), but pH values from both treatments were similar than those fed sodium bicarbonate (6.14). This reduction of pH values induced by no addition of ruminal buffer did not affect ($P \geq 0.05$) ruminal disappearance of diet, ruminal volatile fatty acid (108.1 vs 97.8 vs 93.9), and N

ammonia (28.5 vs 33.3 vs 39.5) as compared to sodium bicarbonate or buffer derived from calcified seaweed. Buffer derived from calcified seaweed increase ruminal pH values in steer fed a diet with 30% forage and 70% concentrate, but did not changed the ruminal disappearance of diet, volatile fatty acid or N ammonia.

Key Words: pH, Ruminal Disappearance, Ruminal Buffer

W256 Net energy and protein requirements for maintenance and gain of Nellore steers estimated with deuterium oxide². G. Aferrri^{*1}, P. R. Leme¹, A. S. C. Pereira¹, R. R. P. S. Corte¹, M. Z. Moreira¹, and D. P. D. Lanna¹, ¹Universidade de São Paulo, Pirassununga, São Paulo, Brasil, ²FAPESP, São Paulo, São Paulo, Brasil.

Thirty six Nellore steers with a mean weight and age of 359 kg and 20 months at the beginning of the trial were individually fed to determine the energy and protein requirements for maintenance and gain. The steers were fed the same diet (76.43% TDN and 13.62% CP) in three levels of dry matter (DM) intake, *ad libitum*, 75 g DM/kg LW^{0.75} and 60 g DM/kg LW^{0.75}. The body composition was estimated with the marker deuterium oxide that allowed repeated water estimate in the same animal. Deuterium in blood samples was analyzed by mass spectrography. The empty body weigh (EBW) from shrunk body weigh (SBW), was obtained from equation: EBW(kg) = -15.74911+(0.98517×SBW), (R²=0.96, S_{y,x}=8.64). The following equations were used to estimate the empty body chemical composition: Water% = 65.9654+(0.0977×Deuterium Space)-(0.0909×SBW), (R²=0.83, S_{y,x}=1.33), Fat% = 93.92968-(1.27598×Water%), (R²=0.97, S_{y,x}=0.62). The relationships between protein and water and between ash and water in the empty body were 0.3009 and 0.0747, respectively. The net energy for maintenance (NEm) was calculated as the antilogarithm of the intercept of the linear regression of the logarithm of heat production on the metabolizable energy intake. The heat production of the steers was calculated by deducting energy retained from metabolizable energy intake. The net energy requirement for weight gain (NEg) was determined as the energy deposited in the gain. The net protein requirement for weight gain (NPg) was determined as the retained protein in the gain. The equations were calculated using the statistical program SAS. The NEm was 74 kcal/kg EBW^{0.75} or 70 kcal/kg LW^{0.75}. The NEg for steers with 450 kg weight was 4.47 Mcal. The net protein maintenance requirement was 186 g/kg LW and NPg was 133 g/kg LW gain.

W257 Venous blood gas in Holstein steers fed diets differing in concentrate to alfalfa hay ratios. M. Danesh Mesgaran^{*}, A. R. Vakili, and A. Heravi Mousavi, *Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran.*

The aim of the present experiment was to investigate the effect of diets providing different concentrate: lucerne hay ratios on venous blood gas in Holstein steers. Holstein steers (initial body weight= 261±15 kg, n=30) were adapted to experimental diets for one week. Then, for 120 days, steers were fed 10 kg of DM of diets differing in concentrate (155 g CP kg⁻¹ of DM; 30% maize, 34% barley, 8% soybean meal, 5% sugar beet pulp, 10% wheat bran, 12% cottonseed meal, 0.3% CaCO₃, 0.5% mineral and vitamin premix, 0.2% salt) to alfalfa hay ratios as 60:40 (C₆₀:A₄₀) and 80:20 (C₈₀:A₂₀) in a completely randomized design.

Animals were fed the experimental diets (ad lib) as total mixed ration twice daily at 0800 and 2000 h. At days 60 and 120 of the experimental period, blood samples were taken from jugular vein 4 h after the morning feeding. Samples were analyzed for venous blood gas by Automatic blood gas system (AVL 995, Switzerland). Data were analyzed as repeat measures using the PROMIX of SAS and the means compared by the Duncan test (P< 0.05). The results of the present study indicated that blood HCO₃⁻ and PaCO₂ were not significantly affected by time when steers were fed high concentrate diets. However, HCO₃⁻ was significantly affected by time (p< 0.05). Therefore it was concluded that the increasing of concentrate from 60 to 80 % could not cause a mixed metabolic acidosis in our condition.

W258 In vitro gas production kinetics of regional feedstuffs used in sheep diets in Northwest Mexico. A. S. Suarez-Reyes¹, G. Nevarez-Carrasco¹, M. A. Cerrillo-Soto^{*1}, J. F. Obregon², and F. G. Rios², ¹FMVZ-Universidad Juarez del Estado de Durango, Durango, Durango, Mexico, ²FMVZ-Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico.

Sheep production in Northwest Mexico represents an important potential. Agricultural products which are mainly produced for human consumption are also utilized for animal production. Thus, a study was carried out to determine the *in vitro* gas production (GP) characteristics of regional feedstuffs commonly used in sheep nutrition practices in the dry tropics of northwest Mexico. Samples (200 mg) of broom sorghum (BS), cull apple meal (CAM), cull raw chickpeas (CRC), cull cooked chickpeas (CCC), and cull cooked beans (CCB) were placed in 100 ml calibrated glass syringes by triplicate. Buffered and mineral solutions were mixed in a 2:1 proportion with rumen fluid collected from three rumen cannulated sheep fed alfalfa hay and a commercial concentrate (75:25). Thirty ml of buffered rumen fluid was dispensed to each syringe at the time incubation started. The gas volume was recorded at 0, 3, 6, 9, 12, 24, 48, 72 and 96h. Data obtained were fitted to the equation: p=a+b(1-e^{-ct}) using PROC NLIN. Metabolizable energy (ME) content from *in vitro* gas production was determined by: ME (Mcal kg⁻¹ DM) = (2.20 + 0.136 GP_{24h} + 0.057 Crude Protein + 0.0029 Crude Fat²)/4.184. Data were analyzed using ANOVA for a completely randomized design. Differences (P<0.05) were registered in the gas produced from the soluble (a) fraction of feeds. CRC registered the higher value while the lower was registered in BS. The higher (P<0.05) gas produced from the slowly

fermentable fraction (**b**) was accounted in CCB and the lower in CAM. The constant rate of gas production (**c**) was higher ($P < 0.05$) in CCC, CCB and CAM than in the other analyzed feeds. The higher values for the potential gas production (**a+b**) were registered in CCB, CRC, and CCC. The same pattern was observed for the ME content. *In vitro* gas production data supported the good potential of beans and chickpeas as feeds for sheep production in the subtropics of Northwest Mexico.

Table 1. *In vitro* gas production characteristics of regional feedstuffs used in sheep nutrition practices in northwest Mexico

Feed	Parameters				ME
	a	b	c	a+b

W259 Effect of two doses of zilpaterol clorhidrate on productive performance and carcass characteristics of hair sheep in the feedlot. F. G. Rios*, F. Leon, J. F. Obregon, J. A. Felix, D. C. Acosta, and J. J. Portillo, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico.*

To determinate the effect of two doses of beta-agonists zilpaterol clorhidrate (HCl-Z) on productive performance and carcass characteristics of hair sheep in the feedlot, 36 ram lambs (37.34 ± 0.570 kg) were used in a randomized complete block experiment where block was initial weight. The lambs were assigned to one of three diets fed ad libitum: 1) control diet with 17% CP and 3.62 Mcal of DE/kg consisting of 62% whole corn grain, 14% soybean meal, 11.9% Sudan grass hay, 5.0% molasses cane, 2.0% meat meal, 2.0% animal fat, 2.5% mineral premix and 0.6% sodium bicarbonate; 2) diet similar to control but with the addition of 12 ppm of HCl-Z; and 3) Diet similar to control but with the addition of 18 ppm of HCl-Z. Feed intake (FI), average daily gain (ADG), feed efficiency (FE), carcass traits, and primary cuts weight were recorded. The data were analyzed with ANOVA for randomized blocks design; Tukey test were utilized to examine the effect of treatment. The final weight was higher in 4.49% (46.54 vs. 44.50 kg; 0.623 SEM) ($P < 0.07$), and FE was improved 24.25% (5.760 vs. 4.635 ; 0.249 SEM) for lambs fed diets with HCl-Z, but ADG (0.285 kg/d) not was modified and feed intake was similar (1.386 kg/d). Diet with beta-agonist increased ($P < 0.05$) hot carcass weight was improved in 6.65% by HCl-Z (27.07 vs. 25.384 ; 0.329 SEM) and the dressing carcass percent in 3.0%. Rib eye area (15.71 cm²); fat thickness (2.67 mm); retail product yield (47.9%), mesenteric fat weight (1.160 kg), kidney fat weight (0.871 kg), and empty body weight (44.29 kg) not were modified by treatments. Diets with beta agonists increased ($P < 0.01$) the weight of primal cuts: shoulder (1.92 vs. 1.59 kg; 0.057 SEM), leg (3.05 vs. 2.73 kg; 0.039 SEM), and rack (1.83 vs. 1.68 kg; 0.039 SEM). Loin (1.82 kg), breast (1.37 kg) and flank (0.912 kg), was not affected by diets. Its concluded that addition of 12 or 18 ppm de HCl-Z to diets of hair sheep increased feed efficiency, final, hot carcass, shoulder, leg and rack weight.

Key Words: B-Agonists, Hair Sheep, Carcass Characteristics

W260 Effects of feeding a polyclonal antibody preparation against *Escherichia coli* O157:H7 on performance, carcass characteristics and *E. coli* O157:H7 fecal shedding of feedlot steers. N. DiLorenzo*, C. R. Dahlen, and A. DiCostanzo, *University of Minnesota, St. Paul.*

Oral doses of avian-derived polyclonal antibody preparations (PAP) against *Streptococcus bovis* or *Fusobacterium necrophorum* were effective at reducing ruminal counts of target bacteria, and improving feed efficiency of feedlot steers. The objective of this study was to determine the effects of feeding a PAP against *E. coli* O157:H7 (PAP-Ec) on performance, carcass characteristics and *E. coli* O157:H7 fecal shedding of feedlot steers. Eighty four Angus and Angus crossbred steers (258 kg initial BW ± 22) were randomly allocated to one of two treatments: PAP-Ec or CTL. Steers received a basal diet (1.39 Mcal NE_g/kg DM, 12.5% CP, 0.7% Ca, and 0.35% P) comprised of high-moisture corn and dry ground corn (50:50 mix, DM basis), corn silage, and a supplement containing laidlomycin propionate and were supplemented (PAP-Ec) or not (CTL) with 2.5 mL PAP-Ec/d. Individual fecal samples were collected every 28 d for *E. coli* O157:H7 analysis. Steers receiving PAP-Ec tended ($P = 0.06$) to have greater feed efficiency (live basis). Carcass-adjusted feed efficiency did not differ ($P = 0.10$) between treatments. Steers receiving PAP-Ec had greater ($P < 0.05$) fat thickness than CTL. No differences ($P > 0.10$) were observed in *E. coli* O157:H7 fecal shedding at 0, 28, 84 and 165 d on feed. After 56 d on feed, a greater ($P < 0.05$) prevalence of *E. coli* O157:H7 was observed in steers fed PAP-Ec. Steers fed PAP-Ec had a lower ($P < 0.05$) prevalence of *E. coli* O157:H7 after 112 d on feed and tended ($P = 0.06$) to have reduced *E. coli* O157:H7 prevalence after 140 d on feed. The use of an avian-derived polyclonal antibody preparation against *E. coli* O157:H7 in feedlot diets may be a valid intervention to enhance cattle performance and reduce *E. coli* O157:H7 fecal shedding.

Key Words: Steers, Antibodies, *E. coli* O157:H7

W261 Selenoprotein expression is induced during oxidative stress in beef cows. E. Terry, K. Brennan, J. Michal*, K. Johnson, and R. Kincaid, *Washington State University, Pullman.*

Oxidative stress is increased during fat mobilization during weight loss. Selenoproteins, including glutathione peroxidase (Gpx), thioredoxin reductase (TrxR), and selenoprotein W (Sel-W), are potent antioxidants that protect against cellular damage and may be particularly important at times when oxidative stress is acute. Therefore, a study was conducted to examine the expression of selenoprotein mRNA in skeletal muscle 18 Angus-cross cows during weight loss and weight maintenance. Cows were fed at maintenance for 60 days in early-lactation to allow weight loss. The weight maintenance period (60d) took place shortly after weaning. Cows had access to trace mineralized salt with added selenium at all times. Muscle biopsies were aseptically collected from the *Biceps femoris* at the end of each period and immersed in liquid nitrogen. Total RNA was later extracted and cDNA synthesized. Primers were designed based on available sequences for Gpx1 (Accession No. AF532927), TrxR1 (Accession No. NM174625) and Sel-W (Accession No. AF380118) and real-time quantitative PCR used to determine expression of mRNA relative to β -actin. During the 60-d period following parturition, cows lost an average of 72.2 ± 4.97 kg, whereas, in the 60-d after weaning, cows gained 5.18 ± 4.97 kg. Gpx1 mRNA expression in skeletal muscle during weight loss was not changed when compared to expression during weight maintenance. However, skeletal muscle TrxR1 mRNA

was 10 fold higher ($P < 0.05$) and expression Sel-W mRNA was almost 3-fold greater ($P < 0.05$) during weight loss when compared to weight maintenance. The mammalian antioxidant system has evolved to protect against reactive oxygen species and the subsequent oxidative stress that an animal experiences. Increased expression of these antioxidant genes indicate these cows responded to increased oxidative stress.

Key Words: Beef Cattle, Selenium, Oxidative Stress

W262 Validation of a continuous in vitro system modeling the jejuno-ileal ecosystem of veal calves. M. Champod^{2,1}, S. Blanquet-Diot¹, D. Bravo², J. P. Meunier^{*2}, and M. Alric¹, ¹University of Auvergne, France, ²Pancosma Research, Geneva, Switzerland.

Since the European prohibition of antibiotics used as growth promoters in 2006, it is necessary to develop new feed additives able to maintain the intestinal microflora equilibrium of the veal calves. The aim of this work is to validate an in vitro system that has been set up to reproduce the intestinal ecosystem of veal calves.

This fermentor reproduces the anaerobic, pH and temperature conditions found in the jejuno-ileum of calves. It is inoculated with the jejuno-ileal contents of three 20 weeks-old Prim'Holstein veal calves slaughtered after 6h fasting. The fermentative content is continuously homogenized and renewed by addition of fresh nutritive medium (composition established from biochemical analyses of in vivo intestinal content). The main bacterial groups were followed by regular counting on selective culture media during 1 week. Fermentative samples were collected for lactate and ammonia analyses. The results were compared with in vivo data by one-way analysis of variance.

The levels of total anaerobic microflora, Enterococci, Bifidobacteria and lactate utilizing bacteria were not statistically different from in vivo ones. The concentrations of *Bacteroides* and *Escherichia coli* were significantly ($P \leq 0.001$) higher in vivo than in vitro whereas *Lactobacilli* were stabilized at 8.1 log compared to 6.9 log in vivo ($P = 0.001$). In vivo and in vitro lactate concentrations were not different ($P > 0.05$), whereas ammonia reached concentrations significantly ($P < 0.001$) higher in vitro than in vivo (3.39 vs 0.14 g/L).

These results show that most of the bacterial groups enumerated were stabilized in the in vitro system at their in vivo levels and that their metabolic activities were maintained. This model will be used to screen new feed additives by studying their action on the intestinal microflora equilibrium of the veal calves.

Key Words: Veal Calf, Intestinal Microflora, In Vitro System

W263 Maternal natural source vitamin E supplementation on suckling calf performance and immune response. M. J. Richardson^{*1}, S. L. Lake¹, S. D. Eicher², R. Lemenager¹, M. Einstein¹, and N. Pyatt³, ¹Purdue University, West Lafayette, IN, ²USDA-ARS, West Lafayette, IN, ³ADM Animal Nutrition Research, Decatur, IN.

The objective of this study was to determine the effects of maternally supplemented natural-source vitamin E (NSVE) on suckling calf performance and immune response. In a two-year study, one hundred twenty-five Angus-cross beef cows ($n = 75$ in year one, 50 in year two; initial BW = 607 kg; initial BCS = 5.3) were randomly assigned to one of two isocaloric dietary treatments: 1) corn-based supplement (CON) or 2) corn-based supplement formulated to contain 1000 IU/d NSVE

(NAT). Maternal supplementation began 5 wk prepartum and continued through wk 8 of lactation. Blood was collected from calves at 24 h of age for analysis of IgG concentration as an indicator of passive transfer and circulating α -tocopherol concentration. At 19 d of age, blood was collected from calves to determine the presence of CD14 and CD18 receptors on leukocytes. At 21 and 35 d of age, calves were injected with hen egg albumin (20 mg; OVA) and bled weekly until d 63 of age to determine total antibodies produced to OVA. No differences were seen in calf birthweight ($P = 0.59$), ADG ($P = 0.93$), or weaning weight ($P = 0.39$). Circulating α -tocopherol concentrations were increased at both 24 h ($P < 0.001$) and at the day of initial OVA challenge ($P < 0.001$). There was no difference in IgG concentration ($P = 0.36$) at 24 h or presence of CD14 ($P = 0.83$) or CD18 ($P = 0.84$) receptors at d 19 of age. Calves suckling NAT cows tended ($P = 0.19$) to have a greater overall titer response than calves suckling CON cows, however there was no treatment \times day interaction ($P = 0.59$). In conclusion, calves suckling cows supplemented with NSVE had increased circulating concentrations of α -tocopherol at 24 h which appeared to continue throughout maternal supplementation. Furthermore, calves suckling NAT dams tended to have increased overall titer response when compared with CON calves; however, calf performance was not affected.

Key Words: Beef Calves, Immune Response, Vitamin E

W264 The relation between plasma vitamin C, leptin and fat accumulation during the fattening period in Japanese Black steers. K. Hodate^{*}, M. Hayashi, and K. Kido, National Institute of Livestock and Grassland Science, Tsukuba, Ibaraki, Japan.

In this study, changes of plasma vitamin A and C, leptin and insulin were observed and investigated in relation to fat accumulation in fattening Japanese Black steers. Nine Japanese Black steers (334 ± 18 kg) were fattened for 56 weeks (from 14 to 28 months of age) and divided into three groups: vitamin A supplemented S group was supplemented with 296.8 (42.4×7) IU/BW kg vitamin A weekly from week 1 to week 56, vitamin A restricted R group was restricted vitamin A, keeping the plasma vitamin A level above 30 IU/dL, and the RS group was restricted vitamin A and treated as the R group from week 1 to week 44 and then supplemented with vitamin A weekly and treated as the S group from week 45 to week 56. Blood plasma samples were drawn every 4 weeks before feeding. Leptin and insulin concentrations were measured by RIA kit. Vitamin A and C concentrations were determined using HPLC and a colorimetric method, respectively. Backfat thicknesses were measured by real ultrasonography every 4 weeks. At the start of the experiment, plasma vitamin A and C concentrations were 127 IU/dL and 6.2 mg/L, respectively. At the end of the experiment, plasma vitamin A and C concentrations of the supplemented (S and RS) groups and the R group were 120 and 37 IU/dL ($p < 0.01$), and 3.5 and 2.7 mg/L ($p = 0.10$), respectively. Backfat thickness of the S and the R groups was 17.0 and 15.0 mm and had no correlations with plasma vitamin A concentrations. Plasma leptin and insulin concentrations increased with fattening and showed a high correlation to backfat thickness during the experimental period ($r = 0.93$ and 0.81 , $p < 0.01$). Cross-correlation coefficient between backfat thickness and plasma leptin concentration was at its maximum with a 4 week delay. Backfat thickness was reflected in the circulating leptin concentration 4 weeks later. There was a reciprocal correlation between plasma leptin and vitamin C concentration ($r = -0.93$, $p < 0.01$). Fattening cattle for a long term with high energy feed has decreased plasma vitamin C concentrations.

Key Words: Vitamin C, Steer, Fat Accumulation

W265 Performance, carcass characteristics and IGF-I plasmatic concentrations of feedlot young cattle from different genetic groups. C. L. Martins¹, M.D. B. Arrigoni¹, A. C. Silveira¹, H. N. de Oliveira¹, R. d. C. Cervieri¹, L. A. L. Chardulo¹, D. D. Millen^{*1}, R. D. L. Pacheco¹, T. M. Mariani¹, J. P. S. T. Bastos¹, T. C. B. da Silva², S. R. Baldin¹, L. M. N. Sarti¹, and R. S. Barducci¹, ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²Faculdade de Zootecnia/UNESP, Dracena, São Paulo, Brazil.

This study was designed to evaluate performance, carcass characteristics, meat tenderness and IGF-I plasmatic concentration (IGFPC) of *Bos indicus*-based types (BT). The experiment was designed as a 5X2 factorial arrangement, in which 80 8-mo-old bullocks (302.4±28.5kg) and 80 8-mo-old heifers (260.8±26.4kg) of five BT: 40 CH (1/2 Charolais, 1/4 Nellore, 1/4 Simmental), 40 GE (1/2 Gelbvieh, 1/4 Nellore, 1/4 Simmental), 40 AN (1/2 Angus, 1/4 Nellore, 1/4 Simmental), 40 HE (1/2 Hereford, 1/4 Nellore, 1/4 Simmental) and 40 SI (3/4 Simmental, 1/4 Nellore) were fed in feedlot for 150 days. Rib eye area (REA) and back fat thickness (BFT) were taken after slaughter to evaluate muscle and fat deposition. Meat samples were harvested between 12th and 13th ribs for shear force (SF) and intramuscular fat (IMF) analysis. Rib eyes were scored for marbling (MB) using a scale of 1 to 6. CH, HE and SI presented greater (P<0.05) average daily gain in kilos (ADG) when compared to GE and AN (CH=1.07, HE=0.97, SI=1.13, GE=0.84, AN=0.86). Bullocks (BL) had greater (P<0.05) ADG (1.09 vs. 0.85) than heifers (HF). No differences were observed (P>0.05) for dressing percentage and hot carcass weight during the study. AN presented smaller (P<0.05) REA in cm² (56.70) than CH (64.34), SI (62.30), HE (65.85) and GE (63.99). In the other hand, AN showed in mm (P<0.05) greater BFT (AN=3.8, HE=2.9, SI=2.6, GE=2.5, CH=2.6), higher (P<0.05) MB scores (AN=4.4, HE=3.4, SI=3.1, GE=3.1, CH=3.2) and greater (P<0.05) IGFPC in ng/ml (AN=245.6, HE=177.1, SI=197.4, GE=184.8, CH=178.5) and IMF in % (AN=4.27, HE=3.20, SI=3.06, GE=2.78, CH=2.96) between BT. It was found (P<0.05) lower SF (kilograms) values for AN (AN=3.95, HE=5.12, SI=5.63, GE=5.38, CH=5.27). HF had smaller (P<0.05) REA (57.85 vs. 67.42), greater BFT (3.1 vs. 2.6) and lower IGFPC (137.8 vs. 260.1) when compared to BL. No differences were observed (P>0.05) in MB, IMF and SF for HF and BL. Even presenting lower ADG, AN showed better carcass and meat quality with higher MB scores, greater BFT and IMF and better tenderness. BL performed better than HF, but without impacting carcass and meat quality.

Key Words: Carcass, Cattle, Feedlot

W266 Influence of chromium methionine addition during last days in feedlot on performance and carcass characteristics of finishing bulls. R. Barajas^{*1}, B. J. Cervantes^{2,1}, J. A. Romo¹, P. J. Rojas³, and E. A. Velazquez¹, ¹FMVZ-Universidad Autonoma de Sinaloa, Culiacán, Sinaloa, Mexico, ²Ganadera Los Migueles SA de CV, Culiacán, Sinaloa, Mexico, ³Tecnología de Máxima Producción, S.A. de C.V., Culiacán, Sinaloa, Mexico.

With the objective of determine the effect of addition of chromium methionine during last days in feedlot on performance and carcass characteristics of bulls, sixty bull calves (455.95 ± 2.19 kg) Brahman cross were used. Bulls from a same fattening lot, in a complete randomized block design, were assigned to received one of two diets during last 34

days in feedlot: 1) Diet with 13.17 % CP and 2.048 Mcal of NEm/kg, containing 87% de concentrate corn-soybean meal-based (Control); 2) Diet similar to control added with 0.2 ppm of chromium from chromium methionine. Chromium improved (P = .09) ending weight, and augmented (P = 0.09) ADG in 14.6%. Dry matter intake was not affected (P = 0.84). Chromium enhanced (P = 0.09) in 12% feed conversion, 8% NE retained from the diet and 11% NEm retained from diet. Chromium did not affected (P = 0.20) hot carcass weight, and tended (P = 0.11) to improved carcass dressing. Chromium not modifies (P > 0.20) back fat thickness, rib eye area, marbling score, KPH fat neither meat pH. It is concluded, that addition of chromium methionine at low dosages during last days in feedlot, could contribute to improve performance of finishing bulls.

Key Words: Chromium, Feedlot Cattle, Growth-Performance

W267 Influence of chromium-methionine supplementation level during last 32 days on feedlot performance, carcass characteristics, and blood cortisol of finishing bulls. V. Monterrosa^{1,2}, R. Barajas^{*3}, J. A. Romo³, and B. J. Cervantes^{3,4}, ¹Técnica Mineral Pecuaria, Guadalajara, Jalisco, Mexico, ²CUCBA-Universidad de Guadalajara, Guadalajara, Jalisco, Mexico, ³FMVZ-Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico, ⁴Ganadera Los Migueles, S.A. de C.V., Culiacan, Sinaloa, Mexico.

Forty five finishing beef bulls (487.7 ± SE 2.49 kg) were involved in an experiment to determine the influence of chromium-methionine supplementation level during last 32 days on feedlot performance and carcass characteristics. Animals were blocked by weight, and in groups of five were placed in ground pens. Within each block pens were randomly assigned to one of three dietary treatments: 1) Finishing diet 13% CP; NEm 1.9 Mcal/kg without additional chromium (CTRL); 2) Diet similar to CTRL but with 0.2 mg/kg of chromium added during last 32 days in feedlot (Cr-0.2); and 3) Diet similar to CTRL but added with 0.4 mg/kg of chromium added during last 32 days in feedlot (Cr-0.4). Chromium-methionine premix (MiCroplex TM; Zinpro, Co, Eden Prairie, MN) was used as source for additional Cr. All cattle received 60 mg/head/d of zilpaterol hydrochloride from day 33 to day 3 prior to slaughter. Ending weight was not affected by treatments (P > .40). Cr-0.4 increased ADG 4.8% (P = .04) with respect to control, and a linear increase in ADG as Cr level increased was observed (P < .05) with values of 1.898, 1.920 and 1.898 by CTRL, Cr-0.2, and Cr-0.4, respectively. Dry matter intake was not influenced by treatments (P > .25). Feed/gain ratio was improved 4% by Cr-0.4 (P < .05) with respect to CTRL. Feed/gain ratio was linearly reduced supplementary Cr was increased (P < .05), with values of 6.023, 5.917, and 5.785 kg/kg for CTRL, Cr-0.2, and Cr-0.4, respectively. NEm and NEm observed/expected ratio was not altered by Cr-supplementation (P > .15). Carcass characteristics and meat-pH were not altered by treatments (P > .40). Blood cortisol at slaughter time was decreased 28% by Cr-0.2 and Cr-0.4, relative to unsupplemented-Cr cattle (4.53, 3.23, and 3.23 mg/dL by CTRL, Cr-0.2, and Cr-0.4, respectively). The results suggest that chromium methionine supplementation during last 32 days in feedlot, improves daily weight gain and feed/gain ratio of finishing bulls without affecting carcass characteristics.

Key Words: Beef Cattle, Chromium Methionine, Feedlot Performance

W268 Effects of essential oils on ruminal environment and performance of feedlot calves. J. I. Geraci¹, A. D. Garcarena¹, D. Colombatto^{2,3}, D. Bravo⁴, and J. C. Burges¹, ¹EEA Balcarce INTA, Argentina, ²University of Buenos Aires, Argentina, ³CONICET, Argentina, ⁴Pancosma SA, Switzerland.

Essential oils (EO) have the potential to modify the ruminal environment and to replace the use of antibiotics for specific markets. Twenty four Aberdeen angus calves (135.4 kg initial weight) were blocked by weight in four groups and randomly allocated to 8 pens of 3 animals each. Treatments were EO (800 mg Xtract 7065 animal⁻¹ d⁻¹) or monensin (430 mg Rumensin[®] kg DM⁻¹) added into a mineral mixture. Diets were fed twice a day and consisted (DM basis) of 70% coarsely ground corn, 28% pelleted sunflower meal and 2% mineral mixture, plus 200 g alfalfa hay animal⁻¹ d⁻¹. The experiment lasted for 85 days, and DM intake, average daily gain (ADG), feed conversion ratio (FCR) and rate of subcutaneous fat deposition (RFD) were determined throughout the study. In addition, two ruminally fistulated steers were also used in a cross over design in order to examine ruminal variables (pH and NH₃) as affected by EO or monensin. Compared to monensin, EO did not alter DM intake (6.50 vs. 6.45 kg, $p=0.79$), ADG (1.31 vs. 1.23 kg d⁻¹, $p=0.35$), FCR (4.96 vs. 4.99, $p=0.91$) or RFD (1.80 vs. 1.68 mm month⁻¹, $p=0.65$) for EO and monensin, respectively. In addition, feeding behaviour was not altered by EO compared to monensin, as animals visited the feeders a similar number of times and the length of each visit was also similar (11.2 vs. 10.74; and 9.55 vs. 9.72 min for EO and monensin, respectively). Ruminal pH was lower with EO than with monensin (5.58 vs. 6.09, $p=0.002$), and the same held true for NH₃ (10.78 vs. 20.05 mg dl⁻¹, $p=0.01$). Lower NH₃ concentrations with EO addition can be partially explained by the lower pH, conducive to lower protein degradation, and perhaps due to some EO action on specific, deaminative bacteria in the rumen. Overall, this study shows that EO can replace monensin in high grain diets without any alteration in the productive response of feedlot cattle.

Key Words: Essential Oils, Monensin, Feedlot

W269 Body and ultrasound measurements, muscularity scores, blood physiology and behaviour in growing beef heifers differing in phenotypic residual feed energy intake. M. McGee^{*1}, M. J. Drennan¹, D. A. Kenny², and B. Earley¹, ¹Teagasc, Grange Beef Research Centre, Dunsany, Co. Meath, Ireland, ²University College Dublin, Belfield, Dublin, Ireland.

The effect of residual feed energy intake (RFI), an alternative measure of feed efficiency, on growth, body and ultrasound measurements, blood physiology and behaviour was determined in growing purebred Simmental and Simmental x Friesian-Holstein heifers (n=85; mean (± SD) initial age 299 ± 47 d and weight 311 ± 48.8 kg). They were individually offered grass silage ad libitum and 2.0 kg of concentrate once daily over 84 d using a Calan gate system. Live weight (consecutive days), body (withers height, chest depth and girth, pelvis width and back length) and ultrasound fat (13th rib), and fat and muscle (3rd lumbar) depth measurements were taken at the beginning and end, and additionally, a visual muscularity score was recorded at the end, of the feeding period. Blood samples were obtained on four occasions for analysis of albumin, creatinine, beta-hydroxy butyrate, globulin, glucose, non-esterified fatty acids, total protein, triglycerides, urea, aspartateaminotransferase, alkaline phosphatase, creatine kinase, fibrinogen, haptoglobin, anti-

oxidant status and total bilirubin. Expected energy intake (EI) (UFL/d) was calculated by regressing average daily EI on average daily live weight gain (ADG) and mean live weight^{0.75}, with a model which included genotype. Within genotype, heifers were then ranked by RFI and assigned to low (efficient), medium and high RFI groups. At the end of the study, time spent lying and standing was determined using pedometers on nine heifers with the highest and lowest RFI. Overall mean (± SD), ADG (kg/d), DMI (kg/d), EI (UFL/d) and RFI (UFL/d) were, 0.52 ± 0.20, 5.81 ± 0.73, 5.17 ± 0.58 and -0.00 ± 0.35, respectively. The RFI groups did not differ ($P>0.05$) in live weight, ADG, body and ultrasound measurements, muscularity score, blood variables or lying and standing time.

Key Words: Beef Cattle, Residual Feed Intake, Feed Efficiency

W270 The effect of mineral supplement delivery system on frequency, duration, and timing of use by beef cows grazing topographically rugged native range. N. A. Sproul^{*}, K. C. Olson, J. S. Drouillard, J. R. Jaeger, L. A. Pacheco, J. W. Bolte, M. D. Thomas, and J. J. Higgins, Kansas State University, Manhattan.

The study was conducted on 4 pastures (average size = 101 ha) from June to September. The pastures were grazed by 188 lactating beef cows and their calves (30-70 pairs/pasture). Treatments were mineral provided in dry granular form (DRY) or mineral provided in a low-protein, cooked molasses-based block (BLOCK). Both supplements were available ad libitum. DRY was supplied to cattle via 1 covered mineral feeder. BLOCK was supplied via 4 open-topped barrels spaced within 3 m of one another. Both DRY and BLOCK were deployed in each pasture and pasture constituted the experimental unit. No additional NaCl was supplied to cattle. Forage use in the vicinity of each supplement and the frequency and duration of herd visits to each supplement were measured during 7 14-d periods. Supplements were moved to new locations at the beginning of each period. BLOCK consumption was greater ($P<0.01$) than DRY in periods 1, 3, 5, and 7 but was not different ($P>0.1$) from DRY during periods 2, 4, and 6. The frequency of herd visits to BLOCK and DRY sites were similar ($P>0.1$) for periods 1 through 5; however, herds visited BLOCK about twice as often as DRY during periods 6 and 7 ($P<0.01$). Herd visits to BLOCK sites were longer than those to DRY sites (84 vs. 51 min/herd visit; $P<0.01$). The total length of nighttime visits (1800 to 0600) to BLOCK was greater than that for DRY (57 vs. 49 min/d; $P<0.01$); however, the percentage of all herd visits that occurred at night was similar ($P=0.38$) between treatments. Forage disappearance around supplement deployment sites was not influenced by treatment ($P=0.81$). Forage disappearance over time generally decreased (main effect of period, $P<0.01$). BLOCK influenced the behavior of grazing cattle more strongly than DRY. Influences extended to the amount of supplement consumed as well as to the frequency, duration, and timing of use.

Key Words: Beef Cattle, Grazing Behavior, Native Range

W271 Effects of the dose of capsicum extract on intake, water consumption and rumen fermentation of beef heifers fed a high-concentrate diet. M. Rodriguez-Prado¹, S. Calsamiglia^{*1}, A. Ferret¹, J. Zwieter¹, L. Gonzalez¹, and D. Bravo², ¹Universitat Autònoma de Barcelona, Spain, ²Pancosma, Switzerland.

Four beef Holstein heifers (BW = 438 ± 71 kg) fitted with a 1-cm i.d. plastic ruminal trocars were used in a 4 × 4 Latin square design to evaluate the effect of 3 doses of capsicum extract on intake, water consumption and ruminal fermentation in heifers fed a high-concentrate diet. Animals were fed (DM basis) 10% barley straw and 90% concentrate (32.2% barley grain, 27.9% ground corn, 7.5% wheat bran, 10.7% soybean meal, 10.7% soybean hulls, 7.2% corn gluten feed, 3.1% mineal-vitamin mix; 16.6% CP, 18.3% NDF). Treatments were: no additive (CTR), 625 mg/d of capsicum extract (CAP625), 1250 mg/d of capsicum extract (CAP1250), and 2500 mg/d of capsicum extract (CAP2500). Each experimental period consisted of 25 d (15 d for adaptation, 5 d of continuous measurement of DM intake, and 3 d for rumen sample collection). Animals had ad libitum access to water and feed offered once daily at 0800. Data was analysed using PROC MIXED for repeated measures (SAS), and differences were declared at $P < 0.05$. Intake of water (30.3 and 29.4 vs 27.4 L/d) was higher in CAP625 and CAP2500 compared with CTR, respectively. Intake of concentrate was also higher in CAP2500 vs CTR (8.40 vs 7.64, respectively). As a result of the higher intake, total volatile fatty acids tended ($P < 0.07$) to be higher in CAP625 and CAP2500 compared with CTR (144.8 and 142.9 vs 134.1 mM, respectively). However, the concentration of acetate (59.2 mM), propionate (23.8 mM), butyrate (14.2 mM), lactate (0.28 mM) and ammonia N (14.9 mg N/dL) was not affected by treatments. In spite of the higher intake, pH was not affected by treatments. Capsicum extract can be used in beef cattle diets to stimulate DM intake and water consumption without reducing ruminal pH.

Key Words: Intake, Capsicum, Fermentation

W272 Blood metabolic profile of feedlot cattle supplemented with monensin or polyclonal antibodies preparations against lactate-producing rumen bacteria during diet step-up. D. D. Millen^{1,3}, R. D. L. Pacheco¹, M. D. B. Arrigoni¹, A. DiCostanzo², C. T. Marino¹, N. DiLorenzo², S. A. Matsuhara¹, M. Parrili¹, M. V. Fossa¹, L. M. N. Sarti¹, S. L. Beier¹, H. N. de Oliveira¹, C. L. Martins¹, T. M. Mariani¹, J. P. S. T. Bastos¹, ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²University of Minnesota, Saint Paul, ³Apoio FAPESP.

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to test polyclonal antibody preparation (PAP) against lactate-producing rumen bacteria on blood gas concentrations during diet transitions (58% to 85% concentrate; substituting corn silage and sugarcane bagasse for corn grain) of *Bos indicus*-based biotypes. The experiment was designed as a 3 X 2 factorial, replicated thrice (4 bullocks/pen), in which 24 8-mo-old bullocks (259.6±26.4kg) of each of three *Bos indicus*-based types: 3-way cross (1/2 Brangus, 1/4 Angus, 1/4 Nellore; TC), Canchim (5/8 Charolais, 3/8 Nellore; CC), or Nellore (NE) were fed one of two diets containing either monensin (MO) at 300 mg/head/d or RMT at 10 ml/head/d. Jugular venous whole blood was collected in 1 ml syringes and analyzed within 1 h. Over the step-up periods, greater ($P < 0.05$) O₂ pressure in mmHg (pO₂) and percentage O₂ saturation (O₂Sat) were observed in NE bullocks (33.5 and 63.8 vs. 30.2 and 57.6 and 31.1 and 58.7 for NE, CC, and TC, respectively). No differences ($P > 0.05$) were found in pH, bicarbonate concentration (BC) in mmol/l, CO₂ pressure in mmHg (pCO₂) and base excess in mmol/l (Beb) among biotypes. There were not differences ($P > 0.05$) in pH, BC, Beb, pCO₂ and O₂Sat when either PAP or MO was fed, but feeding MO led to greater ($P < 0.05$) pO₂ (32.2) than PAP (31.2). Within MO transitions, transition to 73% concentrate led to greater ($P < 0.05$) pCO₂ and a linear increase ($P < 0.05$) of O₂Sat during all diet transitions.

Lower ($P < 0.05$) pH, BC and Beb were observed during transition to 73% concentrate diet. Values for blood gas were in normal ranges (not representative of metabolic acidosis). Effects of diet transition were greater than those of biotype or feed additive.

Key Words: Blood Gas, Monensin, Antibodies

W273 Intake fluctuations of feedlot cattle supplemented with monensin or polyclonal antibodies preparations against lactate-producing rumen bacteria during diet step-up. D. D. Millen^{1,3}, R. D. L. Pacheco¹, M. D. B. Arrigoni¹, A. DiCostanzo², N. DiLorenzo², C. T. Marino¹, S. A. Matsuhara¹, M. Parrili¹, L. M. N. Sarti¹, M. V. Fossa¹, H. N. de Oliveira¹, S. L. Beier¹, C. L. Martins¹, T. M. Mariani¹, J. P. S. T. Bastos¹, ¹FMVZ/UNESP, Botucatu, São Paulo, Brazil, ²University of Minnesota, Saint Paul, ³Apoio FAPESP.

The adaptation response to high-concentrate diet step-up in bullocks of three distinct biotypes (Nellore, NE; Canchim cross, 5/8 Charolais, 3/8 Nellore, CC; or a 3-way cross, 1/2 Brangus, 1/4 Nellore and 1/4 Angus, TC) supplemented with a polyclonal antibody preparation (PAP) against lactate-producing bacteria (10 ml/head/d) or monensin (MON; 300 mg/head/d) was measured in a 2 × 3 factorial design. Seventy-two bullocks (24 of each biotype; 259.6±26.4 kg) were randomly allocated to each of 18 pens (one biotype within treatment) for a 135-d (TC and CC) or 175-d (NE) feeding period. On the first 4 d of each step-up period (from 58% to 85% concentrate), daily DMI (kg and as percent of BW) and daily DMI fluctuation (DMIF; kg and as percent of BW; the absolute value of the difference in DMI between consecutive days) were measured. During step-up, corn grain replaced proportions of corn silage and sugarcane bagasse. Over the step-up periods, bullocks fed PAP consumed more ($P < 0.05$) DM than those fed MON (2.34% vs. 2.24%), but no differences were detected for DMI kg or DMIF. *Bos taurus*-influenced biotypes consumed more ($P < 0.05$) DM than pure *Bos indicus* biotypes (9.65 and 9.15 vs. 7.14 for TC, CC, and NE, respectively), but no differences in DMI fluctuation were observed. During the transition from 58% to 73% concentrate, bullocks fed PAP consumed more DM (8.34 kg and 2.69% vs. 7.38 kg and 2.38%, respectively), but no differences were observed in subsequent diet transitions. When comparing across diet transitions, the transition from 58% to 73% concentrate resulted in greater ($P < 0.05$) DMI (as percent of BW) and DMIF. A day effect was observed, where day 1 showed greater ($P < 0.05$) DMIF kg (1=0.73, 2=0.52, 3=0.43, 4=0.49) and DMIF BW (1=0.20, 2=0.14, 3=0.11, 4=0.13) when compared to the days 2, 3 and 4. It was not found ($P > 0.05$) interaction between days and feed additives for DMIF. Diet transition effects were greater than those elicited by use of either feed additives.

Key Words: Dry Matter Fluctuation, Monensin, Antibodies

W274 Effects of supplemental cobalt on site and extent of digestion in beef heifers consuming chopped grass hay. E. J. Scholljegerdes¹ and W. J. Hill², ¹USDA-ARS, Northern Great Plains Research Laboratory, Mandan, ND, ²Ralco Nutrition, Inc., Marshall, MN.

The objectives of this study were to determine if a mineral supplement containing a high level of organic cobalt would improve site and extent of digestion in beef cattle consuming a forage-based diet. Six ruminally cannulated Angus heifers (BW 432 ± 6.6 kg) were utilized in a triplicated

2 × 2 Latin square. Animals were fed chopped (2.54 cm) native grass hay (9.19% CP, 67.5% NDF on an OM basis) ad libitum. Cattle also received twice daily, 42.5g of a Bullseye™ All Purpose mineral-vitamin premix plus Suppli-mix® formulated to provide either 109 mg of Co/ kg or 283 mg of Co/ kg. Experimental periods lasted 21 d (17 d of adaptation with 4 d of sampling). Total DM, OM, N, and NDF intake did not differ ($P = 0.80$ to 0.85) across treatment. Likewise, no differences ($P = 0.54$ to 0.99) were noted for fecal DM, OM, N, and NDF flow (g/d) between cattle fed 109 mg of Co/ kg of supplement or 283 mg of Co/ kg. Therefore, Total tract DM, OM, N, and NDF digested (g/d) was not different ($P = 0.75$ to 0.79) across treatments. Increasing supplemental cobalt from 109 mg of Co/ kg to 283 mg did not improve ($P = 0.68$ to 0.91) total tract digestibility of any of the nutrients examined when expressed as a percent of intake. Dietary treatment did not affect ruminal pH ($P = 0.99$) or ruminal NH_3 ($P = 0.18$). Likewise, additional cobalt had no effect ($P = 0.40$) on total VFA production. However, feeding 283 mg of Co/ kg of supplement did tend ($P = 0.08$) to increase ruminal molar proportions of butyrate from 9.9 to 10.2 mol/100mol but did not influence any other ruminal VFA ($P = 0.36$ to 0.87). Due to the lack of differences in ruminal molar proportions of acetate and propionate, the acetate:propionate ratio did not differ ($P = 0.77$) across treatments. Overall, increasing the concentration of cobalt from 109 mg of Co/ kg of supplement to 283 mg of Co / kg did not improve diet digestibility. Nevertheless, more work needs to be done to elucidate the potential of supplemental cobalt to improve forage digestibility.

Key Words: Cobalt, Digestibility, Forage

W275 Effect of added dietary tannins on animal performance, carcass traits, and methane producing activity in finishing calves. W. K. Krueger^{1,2}, H. G. Bañuelos¹, W. E. Pinchak³, B. R. Min³, R. C. Anderson^{4,2}, G. E. Carstens^{1,2}, R. R. Gomez¹, and N. A. Krueger⁴, ¹Texas A&M University, College Station, ²Intercollegiate Faculty of Nutrition, TAMU, College Station, TX, ³Texas AgriLife Research, Vernon, TX, ⁴USDA-ARS-Food and Feed Safety Research Unit, College Station, TX.

The objective of the study was to characterize the effect of added dietary tannins on animal performance, carcass traits, and methane producing activities in finishing cattle. Thirty-six crossbred steers (414 ± 40 kg) were stratified by initial BW (IBW) and randomly assigned to one of three treatments (n = 12): control (Cn), mimosa (M), and chestnut (Ch) tannin. Tannins were supplemented at 1.5% of the diet. Calves were fed for 42 d in a Calan gate™ system; intake and BW were measured weekly. Rumen fluid and feces were collected on d 0, 7, 21, and 42 for methane producing activity, ammonia, and pH. There was no effect ($P > 0.05$) of tannins on IBW, final BW, ADG, DMI, feed to gain ratio, and DMI %BW. IBW was used as a covariate in carcass trait analysis. There was no effect ($P > 0.05$) of tannin on HCW, 12th rib fat thickness, LMA, and YG; there tended ($P < 0.10$) to be a tannin effect on KPH and marbling score. There was an IBW*treatment interaction in dressing percent (DP) and internal fat (IF). Estimates of treatment differences in DP and IF were computed as the mean covariate IBW, and mean ± 1 SD. At mean IBW, M had lower ($P < 0.05$) DP compared to Cn while Ch was intermediate. At heavy IBW, Ch and M had lower ($P < 0.05$) DP than Cn. At light IBW, Cn had more ($P < 0.05$) IF as compared to Ch and M; at heavy IBW, Ch had the most ($P < 0.05$) IF, M the least ($P < 0.05$) with Cn intermediate. Methane, ammonia and pH data were analyzed using repeated measures; d 0 was used as a covariate. Tannins had no

effect on rumen fluid or feces methane producing activity, rumen or fecal ammonia and rumen pH ($P > 0.05$). There was a treatment*d0 interaction on fecal pH. In low initial fecal pH calves, Ch and M increased fecal pH versus Cn calves. The expected decrease in methane producing activity did not materialize, which is in contrast to our previous findings with cattle grazing winter wheat pasture. There appears to be no detrimental or positive effects of adding tannins in finishing diets; however, site of digestion may be altered in some calves, evidenced by treatment effect on fecal pH.

Key Words: Tannins, Carcass Traits, Methane Producing Activity

W276 Evaluation of feed efficiency and feeding behavior traits in Angus and Red Angus growing bulls. Z. D. Paddock^{*1}, G. E. Carstens¹, P. A. Lancaster¹, L. R. McDonald², and S. Williams², ¹Texas A&M University, College Station, ²Midland Bull Test, Columbus, MT.

Objectives of this study were to characterize feed efficiency traits and to examine phenotypic relationships with feeding behavior traits in growing bulls. Feed intake and feeding behavior traits were measured in Angus (n = 243, initial BW = 366 ± 47 kg) and Red Angus (n = 87, initial BW = 364 ± 43 kg) bulls for 70 d using a GrowSafe feeding system. Bulls were fed a corn silage based diet (ME = 2.42 Mcal/kg DM), and BW measured at 14-d intervals. Residual feed intake (RFI) was calculated as the residual from the linear regression of DMI on mid-test BW^{0.75} and ADG within breed. Daily meal duration (min/d) and meal frequency (events/d) were averaged over the 70-d study, and eating rate (g/d) computed as DMI divided by meal duration. Red Angus bulls had higher ($P < 0.05$) ADG (1.52 vs 1.45 ± 0.03), consumed more ($P < 0.05$) DMI (10.64 vs 10.35 ± 0.13) and tended ($P < 0.10$) to lower feed:gain ratios (7.36 vs 7.06 ± 0.14) than Angus bulls. Overall (mean ± SD) RFI of Angus and Red Angus bulls were 0.0 ± 0.62 and 0.0 ± 0.74, respectively. RFI was positively correlated ($P < 0.05$) with DMI (0.54) and feed:gain ratio (0.35), but not with ADG or initial BW. Angus bulls had longer ($P < 0.01$) meal durations (193.4 vs 211.3 ± 2.50 min/d) lower ($P < 0.01$) meal frequencies (10.92 vs 11.75 ± 0.23 events/d) and higher ($P < 0.01$) eating rates (54.20 vs 50.82 ± 0.87 g/min) than Red Angus bulls. Meal Duration was more positively correlated ($P < 0.05$) with ADG (0.35) than DMI (0.23), such that meal duration was negatively correlated with feed:gain ratio (-0.22). Eating rate was not correlated with ADG, but was positively correlated ($P < 0.05$) with DMI and feed:gain ratio (0.58, 0.35). RFI was positively correlated with meal duration and eating rate (0.23, 0.24), but not with meal frequency. These results suggest that feeding behavior traits may be useful indicator traits for early identification of bulls with favorable phenotypes for RFI.

Key Words: Feed Efficiency, Feeding Behavior, RFI

W277 Effects of fish oil and sunflower oil supplementation on trans-10, cis-12 CLA and cis-9, trans-11 CLA contents of ruminal bacteria from beef cattle. D. P. Bu, S. L. Liu, J. Q. Wang*, S. Liang, L. Liu, H. Y. Wei, and L. Y. Zhou, State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, P.R. China.

The objective of this study was to evaluate fatty acids profile of ruminal bacteria in beef cattle fed the mixture of fish oil and sunflower oil.

Four steers with ruminal cannulas were randomly assigned to control (C, without additional oil supplement) or C with 3% sunflower oil plus 1% fish oil (SF1), 2.5% sunflower oil plus 1.5% fish oil (SF2) and 2% sunflower oil plus 2% fish oil (SF3) in a 4 × 4 Latin square with 12-wk durational periods. All diets (forage to concentrate ratio was 65:35) were isonitrogenous (average of 12.6 %). Ruminal digesta was collected every 4 h over a 24 h period on d 20 and 21 of each experimental period and pooled for each animal. Pooled samples were prepared for bacteria separation and fatty acids analysis according to M. Sönnichsen. All data were analyzed using the MIXED procedure of SAS 8.2. Compared with CK, stearic acid in ruminal bacterium was obviously changed with fish oil increasing ($P < 0.001$), and reduced by 41.36%, 65.69%, 73.15% in SF1, SF2 and SF3 treatments, respectively. Cis-9, trans-11 CLA in ruminal bacterium was not affected with dietary sunflower and fish oil supplementation. Compared with C, trans-11 C18:1 in ruminal bacterium increased by 2.88, 4.26 and 3.99 times in SF1, SF2 and SF3 ($p < 0.01$). When fish oil was added to diets, trans-10, cis-12 CLA proportion of mixed ruminal bacterium reached to average 1.02% of total fatty acids, yet was not detected in C ($p > 0.05$). In bacterium fatty acid profiles, cis-9 C18:1 and cis-11 C18:1 content did not change with dietary unsaturated fatty acids addition. These results showed that CLA content of rumen bacteria was affected by the supplementation of fish oil and sunflower oil.

Key Words: Ruminal Bacteria, Fish Oil, Conjugated Linoleic Acids

W278 Different levels and combinations of fish oil and sunflower oil do not alter fiber digestion in China Nooxi steers. S. Liang, J. Q. Wang*, D. P. Bu, S. J. Liu, L. Liu, H. Y. Wei, L. Y. Zhou, and K.L. Liu, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Adding fish oil (FO) and sunflower oil (SFO) is one of the best established strategies to enhance conjugated linoleic acid content in ruminant products, while effect of combinations of fish oil and sunflower oil into diet on nutrient digestion was scarcely reported. Four rumen-cannulated China Nooxi steers, with initial weight of 600±20 kg, were used in a 4 × 4 Latin square study to determine the effects. Treatments were basal diet (forage to concentrate was 65:35, control), or basal diet with 3% SFO plus 1% FO (SF1), or basal diet with 2.5% SFO plus 1.5% FO (SF2), or basal diet with 2% SFO plus 2% FO (SF3). The steers were fed at maintenance level. Each experimental period lasted for 21 d. Ruminal fluid was collected every 2 h from 0730 to 1930 on d 15 of each experimental period. On d 20 and 21, duodenal digesta were collected every 4h over a 24-h period for a composited sample. All data were analyzed by MIXED procedure of SAS8.2. Statistical model included cow as random effect, and period and treatment as fixed effects. Ruminal acetic and butyric acid content decreased ($P < 0.05$), while propionic acid was remarkably enhanced ($P < 0.01$). DM, OM, ADF and NDF digestion across rumen was not affected statistically by treatments, averaged 43.94, 42.50, 47.72, 49.24%. Although SF3 tended to increase total tract digestion, the results from this study suggested fish oil inclusion did not decrease ($P > 0.05$) fiber digestion. It even seemed that dietary fish oil addition increased nutrient digestion of steers fed high forage diet. This result should be considered with caution, for steers used in this study have a relative lower DMI. Meanwhile, high forage in diets might be the main reason that masked the effect of combined oils.

W279 Different combinations of fish oil and sunflower oil alter fatty acids profile in rumen fluid and duodenal fatty acid flows in China Nooxi steers. S. Liang, J. Q. Wang*, D. P. Bu, S. J. Liu, L. Liu, K. L. Liu, H. Y. Wei, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Adding fish oil (FO) and sunflower oil (SFO) is one of the best ways to enhance milk CLA content, while effect was not clear to beef steers. This experiment was designed to evaluate influence of combination of fish oil and sunflower oil on fatty acid profile in rumen fluid and duodenal fatty acids flow. Four rumen-cannulated China Nooxi steers, with initial weight of 600±20 kg, were used in a 4 × 4 Latin square study. High forage (60%) diets were fed. Treatments were basal diet (forage to concentrate was 65:35, control), or basal diet with 3% SFO plus 1% FO (SF1), or basal diet with 2.5% SFO plus 1.5% FO (SF2), or basal diet with 2% SFO plus 2% FO (SF3). Each experimental period lasted for 21 d. Ruminal fluid was collected every 2 h from 0730 to 1930 on d 15 of each experimental period and composited. On d 20 and 21, duodenal digesta were collected every 4h over a 24-h period for a composited sample. All data were analyzed by MIXED procedure of SAS 8.2. Statistical model included cow as random effect, and period and treatment as fixed effects. Compared with control (3.36% of total fatty acid), TVA content in rumen fluid highly increased ($P < 0.01$) when FO and SFO were added, but there was no significant difference ($P > 0.05$) among SF1, SF2 and SF3 with an average of 6.56% of total fatty acid. RA content was also similar among three oil-added treatments. Duodenal flow of TVA markedly increased ($P < 0.01$) when SFO and FO was added while there was no significant difference among SF1, SF2 and SF3 averaged 35.67 g/d vs. 9.45 g/d for control. The results from this study suggest that providing only 1% FO in diet is enough to maximize RA and TVA production in rumen and duodenum of China Nooxi steers.

Key Words: Fatty Acid Profile, Fish Oil, Sunflower Oil

W280 Changes in rumen bacterial flora in beef cattle fed fish oil. Y. X. He, J. Q. Wang*, D. P. Bu, P. Yu, S. J. Liu, H. Y. Wei, L. Y. Zhou, and K. L. Liu, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Dietary cis-9, trans-11-conjugated linoleic acid (CLA) is generally thought to be beneficial for human health. Unsaturated fatty acid added to ruminant diets increases the CLA concentration of milk and meat. The aim of this study was to investigate the change of rumen bacterial floras after beef cattle were supplemented with 2% fish oil. Total genomic DNA was extracted from rumen fluid obtained before and after oil supplementation. 16S rDNAs were amplified with bacteria universal primer 27F/1492R and two 16S rDNA libraries were constructed. 384 clones were picked up randomly from each library and positive clones were evaluated by restriction fragment length polymorphism (RFLP) with *Hha*I. Representative clones in each RFLP class were sequenced. A phylogenetic tree was constructed to study the structural differences of rumen bacterial floras before and after oil supplementation. Cluster analysis identified 74 and 41 unique RFLP patterns in oil supplementation library and without oil supplementation library separately. It was indicated that CFB (*Cytophaga-Flexibacter-Bacteroides*) and LGCGPB (low G+C Gram positive bacteria) were the major taxa in both libraries.

The percent of LGCGPB declined and no *Fibrobacteres* were detected after oil supplementation. The sequencing results showed that the similarity of 50%-60% sequences obtained were ~97% to the 16S rRNA gene sequences reported in GenBank. Uncultured bacteria accounted for over 90%. The diversity of rumen bacteria flora was reduced after oil supplement. The percent of CFB in post-oil supplementation library was increased but the diversity decreased. Bacteria in LGCGPB and

Fibrobacteres phyla decreased. These results provided evidence for investigating mechanism of increasing the CLA concentration of milk and meat, controlling the fermentation of rumen and recognizing more uncultured bacteria.

W281 Effect of wheat bran and zinc oxide on the microbiota of weanling pigs. F. Molist*, A. Gómez de Segura, J. Gasa, R. G. Hermes, and J. F. Pérez, *Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

This experiment was conducted to evaluate the effects of an antimicrobial agent such as zinc oxide (ZnO) and an insoluble fiber source like wheat bran (WB), and its interaction (WB-ZnO) on the gastrointestinal ecosystem in newly weaned piglets. A total of 64 piglets (24±0.77 days) were assigned randomly to 1 of 4 experimental groups. The dietary treatments consisted on a basal diet (STD) based on corn, barley and soybean meal which was supplemented with 4% WB (WB), 0.3% ZnO (ZnO) or 4% WB and 0.3% ZnO (WB-ZnO). On day 3, 6, 9 and 12 after beginning the dietary treatments, animal weight and feed intake were controlled and feces samples were taken for quantifying enterococci and *E.coli* population in agar plates and lactobacilli counts by real time PCR. As compared to the STD diet, dietary supplementation with ZnO increased ($p<0.05$) body weight (7157.2, 7261.5, 7509.5, 7385.4 g for the STD, WB, ZnO, WB-ZnO, respectively) and feed intake (2121.6, 2219.4, 2783.5, 2381.1 g/animal for the STD, WB, ZnO, WB-ZnO, respectively, $p=0.08$). The inclusion of WB and ZnO in the diet diminished ($p<0.05$) *E.coli* counts (5.7, 4.8, 4.6, 5.6 log cfu/ g FM for STD, WB, ZnO, WB-ZnO, respectively) in the feces compared to the STD diet and to the WB-ZnO combination. Diet containing ZnO decreased also lactobacilli loads (11.9, 11.7, 11.1, 11.5 log 16S rDNA gene copies/ g FM for STD, WB, ZnO, WB-ZnO, respectively, $p<0.05$). However, these effects were not observed when WB and ZnO were included in the same diet. No significant differences were observed in the enterococci population. It can be concluded that ZnO increased feed intake and productive performance associated with a reduction on the major groups of bacteria, including lactobacilli. On the other hand, WB inhibited *E.coli* and promoted the stability of beneficial bacteria namely lactobacilli.

Key Words: Piglets, Wheat Bran, Zinc Oxide

W282 Effects of wheat bran level and particle size on the intestinal microbiota composition and activity of early weaned piglets. F. Molist*, A. Gómez de Segura, J. Gasa, R. G. Hermes, and J. F. Pérez, *Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

The incorporation of insoluble fiber in the piglet diets during the early weaning period was evaluated as a strategy to promote feed intake and digestive adaptation of the intestinal microbiota. Two different studies were conducted. In Exp 1, 90 early-weaned (24±0.77 days) pigs were allocated to three dietary treatments: a STD diet based on corn, barley and soybean protein, and two fibrous enriched diets including 4 and 8% of wheat bran (WB-4 and WB-8). Animals and feed were weighed and feces sampled on d 3, 6, 9, 12 and 15 for the microbial activity and composition analyses. Results indicated that WB-4 showed the highest feed intake ($p=0.02$), averaging 211.6, 226.7 and 189.6 g/animal and

day for the STD, WB-4 and WB-8, respectively. The same diet tended to decrease enterococci (6.1, 5.3, 6.1 log cfu/g FM; $p=0.06$) and coliforms (6.9, 6.3, 6.7 log cfu/g FM; $p=0.08$ for STD, WB-4 and WB-8, respectively). The inclusion of WB in the diet increased ($p=0.02$) the fecal SCFA concentration on day 15 (93.6, 145.5, 141.1 $\mu\text{mol/g}$ FM, respectively). In the Exp 2, it was studied the likely influence of the WB particle size on the above referred effects. A total of 48 early-weaned (22±0.66 days) pigs were fed with the STD diet and diets containing 4% of WB, either as coarse particle size (WBc, 1135 μm) or finely milled (WBf, 406 μm). WB increased the BW of pigs compared to the STD diet (7156.6, 7360.9, 7463.1 g; $p=0.02$ for STD, WBc, WBf, respectively). Diet containing WBc decreased ($p=0.05$) *E.coli* counts in feces, averaging 5.7, 4.8, 5.2 log cfu/g FM for the STD, WBc and WBf, respectively. Results suggest that WB included at 4% in the diet increases the microbial activity and improves the microbial composition of early weaned piglets. This effect was independent of the particle size.

W283 Effect of supplemental mixed *Saccharomyces cerevisiae* and *Lactobacillus acidophilus* 30SC on the growth performance of weaned pigs. J. P. Kim*¹, K. H. Kim¹, K. G. Kim², S. J. Oh¹, S. H. Kim², and K. Y. Whang², ¹Chonnam National University, Gwangju, Korea, ²Korea University, Seoul, Korea.

The objective of this study was to examine the effect of supplemental mixed *S. cerevisiae* and *L. acidophilus* 30SC (MSL) on the growth performance of weaned pigs. Forty-eight weaned barrows weighing about 10.78 kg were allotted to four dietary treatments with four replications. Experimental period was consisted of Phase I (14 days) and Phase II (14 days). The Phase I diet contained 3600 kcal/kg ME, 22.6 % CP, 1.56 % Lys, 0.54% Met, 0.82% Ca, and 0.75% P. The Phase II diet contained 3430 kcal/kg ME, 19.5 % CP, 1.30 % Lys, 0.47% Met, 0.80% Ca, and 0.55% P. Each diet was formulated to meet the NRC (1998) requirements. Dietary treatments were; 1) Basal diet (B, no antibiotics), 2) B + 0.2% antibiotics (AB), 3) B + 0.2% MSL, 4) B + 0.4% MSL. Pigs consumed feed and water *ad libitum*. Body weights and feed intakes of pig were measured at the end of each Phase, and average daily gain was calculated. The ADG of pigs was slightly increased by MSL supplementation, however, pigs in AB tended to grow slower than pigs in other treatments in Phase I. In Phase II, ADG was not affected by supplementation of MSL or antibiotics. The ADG of pigs tended to be higher in 0.2% and 0.4% MSL treatments at the end of experiment. Feed intake was not different among treatments through the experiment, but, slightly increased feed intake was found in 0.2% MSL treatment. AB and MSL were not effective to increase FE in whole experimental period, however, FE of basal diet and 0.4% MSL fed groups showed increased FE compared to that of AB fed group at Phase I. The results of this study indicated that supplementation of MSL could improve the growth and feed efficiency of weaned pigs in early phase; however, these beneficial effects of MSL were diminished as the pigs grew.

W284 Effect of supplemental mixed *Saccharomyces cerevisiae* and *Lactobacillus acidophilus* 30SC on the energy, nitrogen, Ca, and P digestibility of weaned pigs. K. H. Kim^{*1}, J. P. Kim¹, J. G. Kim², S. J. Oh¹, S. H. Kim², and K. Y. Whang², ¹Chonnam National University, Gwangju, Korea, ²Korea University, Seoul, Korea.

The effects of supplemental mixed *S. cerevisiae* and *L. acidophilus* 30SC (MSL) on the energy, nitrogen, Ca, and P digestibility were determined by using forty-eight weaned barrows (about 10.78 kg). The pigs were allotted to four dietary treatments with four replications. Experimental period was divided into Phase I (14 days) and Phase II (14 days). The Phase I diet contained 3600 kcal/kg ME, 22.6 % CP, 1.56 % Lys, 0.54% Met, 0.82% Ca, and 0.75% P. The Phase II diet contained 3430 kcal/kg ME, 19.5 % CP, 1.30 % Lys, 0.47% Met, 0.80% Ca, and 0.55% P. Each diet was formulated to meet the NRC (1998) requirements. Dietary treatments were; 1) Basal diet (B, no antibiotics), 2) B + 0.2% antibiotics (AB), 3) B + 0.2% MSL, 4) B + 0.4% MSL. Pigs consumed feed and water *ad libitum*. Cr₂O₃ (0.2%) included diets were supplied from day 12 and day 26 to day 14 and day 28, and feces was collected at the end of each Phase (day 14 and 28). Energy digestibility at day 14 was significantly increased by supplement of 0.4% MSL (p<.05), and AB supplementation had no effects on energy digestibility. There was no difference among treatments at day 28. Nitrogen digestibility at day 14 was increased by 0.4% MSL supplementation, but 0.2% supplementation was not effective to increase nitrogen digestibility. Nitrogen digestibility at day 28 was not changed by supplementation of MSL either AB. Ca and P digestibility was not affected by MSL or AB supplementation, however, MSL supplementation slightly increased Ca and P digestibility. The results of this study suggested that supplementation of MSL could improve the energy and nitrogen digestibility weaned pigs in early phase, however, these beneficial effects of MSL were diminished as the pigs grew

W285 Effect of supplemental mixed *Saccharomyces cerevisiae* and *Lactobacillus acidophilus* 30SC on the immunoglobulin G production of weaned pigs. S. J. Oh^{*1}, J. P. Kim¹, K. H. Kim¹, J. G. Kim², S. H. Kim², and K. Y. Whang², ¹Chonnam National University, Gwangju, Korea, ²Korea University, Seoul, Korea.

This study was done to investigate the effect of supplemental mixed *S. cerevisiae* and *L. acidophilus* 30SC (MSL) on the Ig G production of weaned barrows by vaccination. Forty-eight weaned pigs (about 10.78 kg) were used for a 28 days trial, and allotted to four dietary treatments with four replications. Experimental period was consisted of Phase I (14 days) and Phase II (14 days). The Phase I diet contained 3600 kcal/kg ME, 22.6 % CP, 1.56 % Lys, 0.54% Met, 0.82% Ca, and 0.75% P. The Phase II diet contained 3430 kcal/kg ME, 19.5 % CP, 1.30 % Lys, 0.47% Met, 0.80% Ca, and 0.55% P. Each diet was formulated to meet the NRC (1998) requirements. Dietary treatments were; 1) Basal diet (B, no antibiotics), 2) B + 0.2% antibiotics (AB), 3) B + 0.2% MSL, 4) B + 0.4% MSL. Pigs consumed feed and water *ad libitum*. Swine cholera vaccine was injected at day 7, and serum samples were taken from all individual pigs at the end of each Phase (day 14 and 28). ELISA was used to determine the total Ig G and cholera specific Ig G. AB supplementation reduced total Ig G production compared to no-AB fed groups at both day 14 and 28. Total Ig G of pigs fed 0.4% MSL was higher than other groups at both day 14 and 28 (p<.05), and supplementation of 0.2% MSL also increased total Ig G production, however, these effects was reduced at day 28. Cholera specific Ig G production was increased by MSL supplementation, and decreased by AB supplementation. At day 14, the cholera specific Ig G of 0.2% MSL fed group was similar to that of no-AB fed groups, but at day 28, 0.2% MSL fed group showed higher cholera specific Ig G than no-AB fed group (p<.05). These results indicated that supplementation of MSL could increase total Ig G and specific Ig G production, and this increased immune response might be helpful to increase the preventive effects of vaccination on specific disease.

W286 The effects of seaweed extract inclusion on gut microflora and immune status of the weaned pig. P. Reilly¹, T. Sweeney¹, K. M. Pierce^{*1}, J. J. Callan¹, A. Julka², and J. V. O'Doherty¹, ¹University College Dublin, Ireland, ²Bioatlantis Ltd, Ireland.

An experiment (complete randomised design) was conducted to investigate the effects of *Laminaria hyperborea* (LH) and *Laminaria digitata* (LD) seaweed extract inclusion on gastrointestinal health and immune status of the weaned pig. Twenty eight piglets (24 days of age, 6.5± 1.4 kg live weight) were assigned to one of four dietary treatments for 7 days and then sacrificed: T1) basal diet (control); T2) basal diet and 1.5kg /tonne LH; T3) basal diet and 1.5kg /tonne LD and T4) basal diet and 1.5kg /tonne of a combination of LH and LD. The SE contained both laminarin and fucoidan. Digesta samples were taken from the caecum and colon to measure the Enterobacteria, Bifidobacteria, and Lactobacilli populations. Blood samples were taken to determine the cytokine gene expression profile and to measure the phagocytotic capacity of the blood cells. Data was analysed by GLM procedure (SAS). A contrast statement was used to compare T1 vs. T2, T1 vs. T3 and T1 vs. T4. Pigs offered diets containing LH had a lower population of Bifidobacteria in the colon (P<0.05) and Lactobacilli in the caecum (P<0.05) and colon (P<0.001). The inclusion of LD resulted in lower populations of Enterobacteria in the caecum and colon (P<0.01), Bifidobacteria in the caecum (P<0.05), and Lactobacilli in the caecum (P<0.05) and colon (P<0.001). Pigs offered the combination of LH and LD had a reduction in Enterobacteria (P<0.05) and Lactobacilli (P<0.01) in the caecum and colon. An increase in the expression of Interleukin-8 (IL-8) mRNA was observed on day six with the supplementation of the combination of LH and LD (P<0.05). The inclusion of LH resulted in an increase in total monocyte number (P<0.05). In conclusion, the supplementation of LH and LD seaweed extract alone and in combination acted as a powerful antimicrobial in reducing the Enterobacteria, Bifidobacteria, and Lactobacilli populations in the caecum and colon, while only marginal effects on the immune response was observed.

W287 Yam on fermentation characteristics and immune function in pigs. M. J. Bo, Y. I. Yin*, X. F. Kong, Y. Z. Zhang, G. Y. Wu, and B. E. Tan, *Laboratory of Animal Nutrition and Human Health and Key Laboratory of Agro-ecology, Changsha, Hunan, P. R. China.*

The present study was conducted to determine in vitro fermentation characteristics and in vivo immune enhancement of the Chinese Yam

(CY) with the goal of developing a novel dietary additive for pigs. The terminal ileum digesta collected from fistula in Duroc × Landrace × Yorkshire barrows fed the corn- and soybean meal-based diet was used as inoculums, and CY served as a substrate for in vitro fermentation. The slurry was fermented for 48 h in an in vitro anaerobic system. Fermentation products were determined. The maximum volume of gas production in the CY-containing medium was higher (P < 0.05) compared with the non-supplemented and glucose-supplemented media. The rate of gas production in the CY-supplemented medium was lower (P < 0.05) than that in the glucose-supplemented medium but higher (P < 0.05) than the value for the non-supplemented medium. The pH and NH₃ concentration were higher (P < 0.05) in the CY-supplemented medium, compared with the glucose-supplemented medium but lower (P < 0.05) compared with the non-supplemented medium. Concentrations of acetate, propionate, and butyrate in the CY-supplemented medium were higher (P < 0.05) than those in compared with the glucose- and non-supplemented media. For the feeding trial, 4 barrows were fed the basal diet, supplemented with 0.1% CY powder for 8 d. On days 0, 4 and 8 after initiation of the treatment, total and differential counts of leucocytes, lymphocyte proliferating activity, and serum levels of antibodies were measured. Dietary supplementation with CY increased (P < 0.05) the numbers of leukocyte, lymphocytes, monocytes, and neutrophils in plasma on day 8 compared with days 0 and 4, as well as lymphocyte proliferation. In summary, CY may be a good source of carbon and energy for intestinal microbial metabolism, therefore contributing to enhancement of immune function in barrows.

Key Words: Fermentation Characteristics, Chinese Yam, Immune Function

W288 Effect of Chinese herbal ultra-fine powder as a dietary additive on digestion and absorption of amino acids in early-weaned piglets. X. F. Kong¹, Q. H. He¹, F. G. Yin¹, Y. L. Yin^{*1}, G. Y. Wu^{1,2}, B. E. Tan¹, and R. L. Huang¹, ¹Laboratory of Animal Nutrition and Human Health and Key Laboratory of Agro-ecology, Changsha, Hunan, P. R. China, ²Texas A&M University, College Station.

To study the effects of Chinese herbal ultra-fine powder (CHUP) as a dietary additive on digestion and absorption of amino acids, sixty piglets weaned at 21 days of age were randomly assigned to 3 treatment groups, representing supplementation with 0 or 2 g/kg of CHUP, or 0.2 g/kg of colistin to corn- and soybean meal-based diets (n = 20 per group). Blood samples were collected from 5 piglets per treatment group on days 7, 14 and 28 to determine serum concentrations of amino acids. Digesta at terminal ileum was collected to determine amino acids after piglets were sacrificed under anesthesia with intraperitoneal administration of sodium pentobarbital. The results showed that plasma concentrations of total amino acids in CHUP-supplemented pigs were higher (P < 0.05), compared with the control group on days 14 and 28. Concentrations of total amino acids at terminal ileum were lower (P < 0.05) in CHUP-supplemented pigs, when compared with the other two groups of pigs on day 28. These findings indicate that the Chinese herbal product could enhance digestion and absorption of protein or amino acids in early-weaned piglets.

Key Words: Dietary Additive, Herbal Product, Amino Acids

W289 Effects of dietary supplemental Chinese herbal formula on immune responses in weaned piglets. X. F. Kong, B. E. Tan, Y. L. Yin*, H. J. Liu, F. G. Yin, and M. J. Bo, *Laboratory of Animal Nutrition and Human Health and Key Laboratory of Agro-ecology, Changsha, Hunan, P.R. China.*

The study was conducted to evaluate the effects of dietary supplemental Chinese herbal formula (CHF) on immune responses in piglets. A total of 60 three-way crossbred piglets weaned at 21 days of age were randomly assigned to three treatments which were replicated twenty times with one piglet. Corn-soybean meal based diet was used in the control group, while CHF and colistin were used at 0.2 and 0.02 percent of the total diets in the other two groups to substitute for equal cornstarch, respectively. On days 7, 14 and 28 after initiation of the addition, the total and differential counts of leucocytes, and lymphocyte proliferation conversion efficiency, and serum concentrations of immunoglobulin and cytokines, as well as immune organ index, were determined. The results showed that dietary supplementation with the formula increased ($P < 0.05$) the ratio of middle cell to leukocyte and concentrations of serum IL-2 and IL-6 compared with the control groups after 7 days trial, and the concentrations of serum IL-2 was higher ($P < 0.05$) while of IL-6 and TNF were lower ($P < 0.05$) in the formula-supplemented piglets than those of the colistin groups. On day 14, the index of spleen and groin lymphonodues, and number of middle cell in piglets of the formula groups were higher ($P < 0.05$) compared with the control groups and leukocyte number was higher than that of the colistin group, and the concentration of serum IL-6 decreased ($P < 0.05$) compared with the other two groups. Dietary supplementation with the formula for 28 days decreased ($P < 0.05$) the numbers of the middle cell and granulocyte, while increased ($P < 0.05$) the ratio of lymphocleukocyte to leukocyte compared with the control groups. The concentrations of serum IgG and IgM in the CHF piglets increased ($P < 0.05$) compared with the others. The higher ($P < 0.05$) proliferation conversion efficiencies of peripheral lymphocytes in the CHF piglets were observed on days 14 and 28 compared with the other two groups. Collectively, these findings indicated that the CHF as dietary additive could be beneficial to immune responses in the weaned piglets.

Key Words: Chinese Herbal Formula, Weaned Piglet, Immune Responses

W290 Level of management affects finisher growth and pig composition. J. S. Fix* and M. T. See, *North Carolina State University, Raleigh.*

Differences in finisher growth and composition of pigs from three sire lines in a high management research facility (SES) compared to a commercial facility (COM) were evaluated. Pigs were farrowed over 2 wk at COM sow farm. At weaning 400 pigs were randomly selected across sire lines (B, G, R) and sex and placed in SES. Remaining pigs were transferred to COM nurseries. At 66 d of age SES pigs ($n = 336$) and COM pigs ($n = 538$) began finish phase. Pigs were randomly assigned within sire line and sex to pens of 4 pigs at SES and 20-22 at COM. Body wt, fat depth (BF) and loin muscle area (LMA), measured using real-time ultrasound, collected at 20 kg, 50 kg, 75 kg, 100 kg and 115 kg (178 d of age) on all SES pigs and 10 pigs from each COM pen. Feed allotment was recorded daily. Feed weigh back (SES) and feed estimate (COM) was done at BW measurement. Pigs raised at SES were heavier entering the finisher (21.0 vs. 19.2 kg; $P < 0.01$) and at off-test

(118.9 vs. 95.8 kg; $P < 0.01$). Sire line x management interaction was observed for G:F ($P < 0.05$) where pigs at COM did not differ between sire lines (0.418, 0.409, 0.401 ± 0.006) but SES pigs from sire line R had the poorest G:F (0.432, 0.427, 0.392 ± 0.004). This is supported by a sire line x management interaction ($P = 0.06$) for ADFI where SES pigs consumed more feed (2.16, 2.08, $2.36 \text{ kg/d} \pm 0.03$) than COM pigs (1.68, 1.73, 1.82 ± 0.05). Pigs raised at SES had greater ADG (0.87 vs. 0.68 kg/d; $P < 0.01$), ADFI (2.2 vs. 1.7 kg/d; $P < 0.01$), G:F (0.42 vs. 0.41; $P < 0.05$) and lean ADG (0.35 vs. 0.28 kg/d; $P < 0.01$) Pigs raised at SES had less ($P < 0.01$) BF depth and greater ($P < 0.01$) LMA at 20 kg (0.65 vs. 0.73 cm; 11.14 vs. 10.02 cm²), 50 kg (0.99 vs. 1.06 cm; 23.55 vs. 21.90 cm²) and 75 kg (1.33 vs. 1.47 cm; 33.08 vs. 31.39 cm²). At 100 and 115 kg BW SES pigs had greater ($P < 0.01$) LMA (43.26 vs. 36.93 cm²; 48.31 vs. 45.33 cm²). However, at 100 kg COM pigs had less BF (1.59 vs. 1.76 cm; $P < 0.01$) and did not differ at 115 kg. Raising pigs in a high management vs. commercial facility resulted in increased LMA, ADFI, ADG and G:F. However, higher management resulted in increased ADFI resulting in decreased efficiency for one sire line.

Key Words: Pigs, Growth, Management

W291 *In vivo* antioxidant activity of peptide fractions from porcine plasma albumin in rats. J. Z. Wang*^{1,2}, H. Zhang¹, S. S. Zeng², and F. Z. Ren¹, ¹*College of Food Science & Nutritional Engineering, China Agricultural University, Beijing, China,* ²*American Institute for Goat Research, Langston University, Langston, OK.*

Our previous research showed that porcine plasma peptide fractions (A5, MW < 3 KDa) had antioxidant effect *in vitro*. In the present study, the effect of A5 on antioxidant activity, lipid peroxidation, and total antioxidant capacity (TAOC) in rats was investigated *in vivo*. Thirty five male Sprague Dawley rats (3 month old, BW 366 ± 24 g) were randomly divided into five groups. The five feeding treatments were control, 100, 200, 400 mg of A5/kg BW, and 10 mg of vitamin E/kg BW (as positive control). Blood samples and organ tissues (liver, heart, spleen, thymus, and lung) were collected one month after daily treatments were started. TAOC, activities of superoxide dismutase (SOD) and glutathione peroxidase (GSH-Px), and level of malondialdehyde (MDA) in serum and organ tissues were determined. ANOVA was treated by GLM procedure using SAS software. $p < 0.05$ was considered as significant. The results showed that A5 treatments increased TAOC and the activities of SOD and GSH-Px ($p < 0.05$), and decreased the level of MDA in all the organ tissues tested ($p < 0.05$). It is concluded that the peptide fractions A5 can enhance the TAOC and antioxidant activities, reducing the risks of lipid peroxidation in rats.

Key Words: Porcine Plasma Peptide Fractions, Rats, Lipid Peroxidation

W292 Influence of weaning age and number of weaning per week on productive performance of sows and piglets. N. Simal¹, A. Fuentetaja², M. Nieto², M. P. Serrano¹, and G. G. Mateos*¹, ¹*Universidad Politécnic de Madrid, Spain,* ²*Copese, Segovia, Spain.*

A total of 320 crossbred sows (LW x LR) between the second and seventh lactation were used to study the influence of weaning age (21 vs. 28 d) and number of weanings per week (1 vs. 2) on productive performance

of sows and piglets. The 4 treatments arranged factorially and each treatment was replicated five times. The experimental unit was a room with 16 lactating sows. Number of weaning per week did not affect any of the productive traits studied. Age at weaning had little effect on productive performance of piglets during lactation. Sows weaned at 28 d tended to lose more weight (27.1 vs. 24.8 kg; $P \leq 0.10$) and lost more fat thickness (2.85 vs. 2.44 mm) during lactation than sows weaned at 21 d but daily BW losses were smaller ($P \leq 0.05$). Piglets weaned at 28 d were heavier (8.3 vs. 6.4 kg; $P \leq 0.05$) than piglets weaned at 21 d but the uniformity of the litters decreased with increases in weaning age. A positive relation was observed between fat thickness at farrowing and loss of fat during lactation. For sows with a fat thickness lower than 15 mm backfat, fat loss was less than for sows with a fat thickness higher than 18 mm (1.89 and 3.47 mm; $P \leq 0.05$). Also, piglet growth was higher in sows with a fat thickness lower than 20 mm at farrowing than in sows with fat thickness higher than 20 mm ($P \leq 0.05$). Sows with heavier litters at weaning lost more weight during lactation than sows with lighter litters ($P \leq 0.05$). In the next gestation, weaning to oestrus interval tended to be reduced (6.8 vs. 8.0 d) in those sows weaned at 28 d. Number of piglets born alive tended to increase (12.5 vs. 11.3; $P \leq 0.10$) in sows that were weaned at 21 d. It is concluded that weaning at 28 d had a positive effect on sow productivity but that number of weanings per week did not have any effect.

Key Words: Weaning Age, Weaning Number, Sow Productivity

W293 Sow parity and number born alive influence piglet birth weight along with subsequent growth, composition, mortality and endpoint value. J. S. Fix* and M. T. See, *North Carolina State University, Raleigh.*

Piglets ($n = 1472$) were weighed and identified within 24 h of birth to determine effect of parity and number born alive (NBA) on piglet birth weight (BWT), within litter variation, along with growth, composition, mortality and endpoint value. Sows ($n = 217$) were mated via AI with pooled semen from 3 sire lines, resulting in 163 litters. The commercial sow farm experienced a clinical PRRS outbreak during the trial and used a high level of cross fostering which may have contributed to the severity. Individual BWT along with mean litter BWT, BWT SD, and BWT CV were evaluated. At 18 d of age pigs were weaned and 421 were transported to the NCSU Swine Evaluation Station (SES) and BW was measured; remaining pigs were placed in 3 commercial nurseries. At approximately 66 d of age pigs at SES were placed in pens of 4 and pigs in commercial nurseries were placed in pens of 20-22 at a commercial finisher. Body weight, at placement and off-test, along with fat depth (BF) and loin muscle area (LMA), using real-time ultrasound at off-test, were collected on all pigs at SES and 10 pigs from each pen at commercial finisher. At time of final BW a value was given to all pigs (2 = dead; 1 = $BW < [\text{mean BW} - \text{one SD}]$; 0 = $BW > [\text{mean BW} - \text{one SD}]$). This was done to simulate levels where price discounts based on wt occur at local packing plants. A range 0.45 to 2.45 kg, with a mean of 1.28 kg was observed for BWT. Individual and mean litter BWT increased quadratically with increasing parity ($P = 0.07$, $P < 0.01$) to parity 5 and increasing NBA ($P < 0.01$) to 9 pigs. Pig wean wt decreased quadratically with increasing NBA ($P < 0.05$) to 6-7 pigs born alive. Increasing parity also had a quadratic effect on LMA ($P < 0.01$) and BF ($P = 0.07$) both reaching a minimum at parity 4. As NBA increased pigs had 1.09 ($P < 0.01$) and 1.12 ($P < 0.05$) times greater odds of being alive vs. dead at placement and full value vs. non-full value or dead at harvest. As parity increased pigs had 1.10 ($P < 0.01$) times greater odds

of being alive vs. dead at placement. These findings indicate parity and NBA affect birth weight, growth, composition and survival.

Key Words: Parity, NBA, Pigs

W294 Influence of a live yeast on the faecal microflora of gestating and lactating sows. N. Walker*¹, M. Cintora¹, H. Durand², and Y. le Treut², ¹*Lallemand Animal Nutrition, Montreal, Canada*, ²*Lallemand Animal Nutrition, Toulouse, France.*

Live yeast products have been shown to have significant effects on the health and performance of production farm animals, both ruminants and monogastrics. They may have this effect by stabilizing the beneficial gut microflora, particularly during periods of stress, leading to the competitive exclusion of opportunistic pathogens and reducing incidences of diarrhea. The use of *Saccharomyces cerevisiae* type *boulardii* (CNMC I-1079) as a feed additive for improving performance and health of animals has been well documented. The aim of the current work was to determine whether the inclusion of CNMC I-1079 in two different diets had any effect upon the faecal microflora and whether a stress event like farrowing altered the structure and composition of the gut microbial community. Faecal samples were collected from 80 animals which had been randomly assigned to 4 different treatment groups on d-21, d-3 and d+7 in relation to farrowing. Treatment 1, high corn-soy, no yeast; treatment 2, high corn-soy plus yeast; treatment 3, high fibre, no yeast; and treatment 4, high fibre plus yeast. Total DNA was extracted and PCR-TTGE was used to generate a DNA fingerprint of the faecal bacterial community for each treatment group. GelComparII with the DICE similarity indice and UPMGA was used to generate the dendrogram and determine the relatedness of each profile. Not surprisingly, 2 distinct clusters due to diet were observed, indicating an effect of diet on the microbial community. Within each diet, in the days before farrowing, control and yeast treated groups clustered together, indicating an effect of yeast on the composition of the microbial population. Farrowing caused a dramatic change in the fingerprint profile for each treatment indicating that this stress event had a direct effect on the microbial community. It should be noted however that the yeast treated animals tended to have a population which was more closely related to the original microflora, indicating a degree of stabilization. To conclude, several different factors eg diet, inclusion of yeast and stress events may influence the composition of the gut microflora and yeast may help to stabilize the normal microflora.

Key Words: Yeast, PCR-TTGE, Microflora

W295 Effect of lactation length of on herd-level performance of breeding sows. S. S. Anil*, L. Anil, and J. Deen, *University of Minnesota, Saint Paul.*

Reducing lactation length in sows results in an improvement in the number of litters farrowed per year. However, early weaning has been suggested to influence the subsequent reproductive performance of the sow along with the performance of its litter. At the herd level, the crucial point is to maintain a lactation length that does not reduce the reproductive performance of sows while enabling maximum utilization of farrowing facilities. However, most of the studies on this aspect have focused on sow-level performance. The present study evaluates the

effect of lactation length on the overall performance at the herd level. Data pertaining to the performance in 2006 of 493 US swine herds were collected from the Pigchamp datashare database. Based on the average lactation length (19.02 days), these herds were divided into 2 groups and compared in terms of performance and longevity variables (proc MEANS, SAS V 9.1). The average number of piglets per litter, average number of piglets born alive per litter and average litter weaning weight were higher ($P \leq 0.05$ for all) in the herds with average lactation length ≥ 19.02 days. However, these farms also had higher average stillborn piglets per litter and preweaning piglet mortality ($P \leq 0.05$ for both). The groups were similar in terms of farrowing rate, pigs weaned per mated female per year, culling and death rates. The results indicate that farrowing and post-partum management should be improved to make full benefit of an increased lactation length on herd performance.

Key Words: Sow, Lactation Length, Herd Performance

W296 Association between claw lesions and farrowing performance of sows. S. S. Anil*, L. Anil, and J. Deen, *University of Minnesota, St. Paul.*

Lameness is a major reason for reduced sow longevity in swine breeding herds. Claw lesions, especially severe white line and side wall lesions are reported to lead to lameness. Claw lesions are very common in pigs. Despite a high prevalence, studies focusing on claw lesions and their adverse effects sow performance are scanty in the US. At present, it is less clear whether claw lesions are linked to sow performance. The objective of the present study conducted at the University of Minnesota was to analyze the associations between claw lesions and performance variables such as number of piglets born alive (≤ 10 or greater), mummies, stillborn and preweaning piglet mortality (present or absent) and wean to service interval (≤ 5 or greater), along with parity (≤ 3 or greater). Claws of 257 sows were examined for lesions while the sows were in the farrowing crates prior to farrowing. Lesions included erosions, cracks, and overgrowths. Areas on the claw were categorized as side wall, heel, overgrown heel, sole, heel-sole junction and white line. The number of lesions in these areas was counted. The associations between number of lesions in different claw areas with performance variables and parity were analyzed using logistic regression analysis (Proc logistic, SAS V 9.1). Results indicated a positive association ($P \leq 0.05$) between piglets born alive and white line and side wall lesions (Odds ratios, OR 1.29 and 1.60 respectively). Heel-sole lesions were negatively associated ($P \leq 0.05$) with mummies (OR 0.62). White line lesions were negatively ($P \leq 0.05$) associated with stillbirth and preweaning piglet mortality (OR 0.74 and 0.79 respectively). Parity was positively associated ($P \leq 0.05$) with heel and heel-sole lesions (OR 1.26 and 1.40 respectively) and negatively ($P \leq 0.05$) associated with white line lesions (OR 0.72). The positive association between lesions and production performance may be indicative that high producing sows are more susceptible to lesions especially white line and side wall lesions.

Key Words: Sow, Claw Lesions, Performance

W297 Evaluation of welfare of gestating sows in conventional gestation stalls and in gestation stalls with widths defined by the sow height. L. Anil*, S. S. Anil, and J. Deen, *University of Minnesota, St. Paul.*

Sow welfare guidelines have indicated that pregnant sow in gestation stalls should have at least the minimum space to lie down without its teats extending into the adjacent stalls and its hind quarters not in contact with the back of the stall. Increasing the stall dimensions in relation to sow dimensions will increase the dynamic space available to the sow to make movements, thus minimizing injuries. A study was conducted to evaluate welfare of pregnant sows housed in conventional gestation stalls (control $n = 46$) and in stalls with width of the stall at least 75% of the height of the sow in it (treatment $n = 40$). Body measurements (length and height) of sows were taken before weaning and sows were allotted after weaning to either control or treatment group. Injury scores of all sows and behavior of focal sows (24 in control and 27 in treatment) were recorded on day 6 post-breeding and on days 70 and 105 of the gestation. Farrowing performances were also recorded. Data were analyzed using repeated measures ANOVA, two sample proportion tests and two sample test for means. Width of stalls had no significant effect on various postural behaviors studied except on the average duration of getting up (from either lying or from sitting posture) which showed a trend ($p = 0.061$) towards lower duration in the treatment group. Higher % of time lying in lateral recumbency and standing and lower % of sitting were noticed at day 105 than at other time periods. The groups did not differ significantly in terms of injuries. Farrowing performances were also similar among the treatments. The results indicate that ensuring the width of the stall at least 75% of the height of the sow may not be sufficient to improve welfare in terms of behavior and injury scores when compared to the existing conventional stalls.

Key Words: Sow, Welfare, Gestation Stall

W298 The relationship between distance of pig farms to roads and its seroprevalence to Aujeszky's disease. G. Rocha-Chavez¹, O. D. Montañez-Valadez¹, R. Santibañez-Escobar¹, J. G. Michel-Parra¹, and M. A. Pinto-Jacobo^{*2,3}, ¹CUSUR, Univ de Guadalajara, Cd Guzman, Jalisco. Mexico, ²Private practice, Zapotiltic, Jalisco. Mexico, ³URPJ, El Salto, Jalisco Mexico.

Aujeszky's disease is a viral infection of pigs transmitted through aerosols. Western Mexico is still struggling with this disease and there are a lot of small improvised farms rising up to 30% of pigs in that area. It is hypothesized that the closer the farms are to a busy road, the greater the possibility of acquiring this disease. The purpose of this study was to determine the relationship between the distance from the farm to an interstate highway and its level of prevalence of Aujeszky's disease. A total of 15919 blood samples from 297 small sow farms (20-100 sows) were analyzed for this disease. Farms were divided according to their location into four groups: (a) 35 farms located from 0 to 300 meters of a road; (b) 108 farms 300-1000 meters away; (c) 70 farms between 1 and 3 kilometers and (d) 83 farms with more than 3 km away from a road. Serology was done with the ELISA method and the prevalence was expressed as a percentage of positive sera of those sent for analysis. Pearson's correlation was used to compare distance and prevalence and Chi squared was used for comparison between means. Prevalence of 3.4 ± 5.9 , 7.21 ± 6.7 , 3.42 ± 2.29 and 8.4 ± 6.2 were found for Groups A, B, C, and D respectively with no significant difference between groups ($p > 0.05$). The correlation between distance and seropositivity was 0.07 indicating that there is no interaction between the two parameters studied. Contrary to what we were expecting, it was observed that under the conditions of this study, the distance from the farm to an interstate highway has no influence on their likelihood of acquiring this disease.

Key Words: Aujeszky's Disease, Interstate Roads, Prevalence

W299 Expression of Dicer and Ago-2 in Porcine Ovarian Tissue. H. M. Barton* and S. L. Pratt, *Clemson University, Clemson, SC.*

MicroRNA (miRNA) is hypothesized to have fundamental roles in mammalian embryonic development. miRNAs are short, non-coding RNA, processed by a ribonuclease enzyme known as Dicer and then loaded into the RNA-induced silencing complex (RISC), to be guided to its target. The argonaute gene family has been identified as key proteins in RISC, and Argonaute-2 (Ago-2) has been identified as the only member of this family possessing endonuclease activity. The nucleotide sequence for Dicer and Ago-2 has yet to be identified in pigs. Our objective is to identify the cDNA sequence for porcine Dicer and Ago-2, and verify their expression in reproductive tissue. Total cellular RNA was isolated from bovine and porcine ovaries using mirVana miRNA isolation kit (Ambion, Austin, TX). RNA was then subjected to endpoint RT-PCR using SuperScript™ III First-Strand Synthesis Super Mix for qRT-PCR (Invitrogen, Carlsbad, CA). The first strand reaction was utilized for PCR with GoTaq (Promega, Madison, WI). To generate PCR primers, the cDNA sequences for bovine, human and rodent Dicer (accession numbers XR027590, NM177438, and NM148948, respectively), and Ago-2 (BC151491, NM012154, and BC096465, respectively) were aligned. Primers were generated from highly conserved regions for each respective cDNA by using the Vector NTI program (Invitrogen, Carlsbad, CA). Reactions were subjected to non-denaturing slab gel electrophoresis and visualized using EtBr staining and UV-light exposure. PCR products were subcloned into pDrive Cloning Vector using Qiagen PCR Cloning Kit (Qiagen, Valencia, CA), transformed into *E. coli*, plasmid propagated, purified and subjected to dideoxy-sequencing at the Clemson University Genomics Institute. A 489 bp product and a 346 bp product were visible in both bovine and porcine samples. Sequencing verified the porcine products as Dicer and Ago-2, respectively, showing a 97.6% and 93.9% sequence identity to bovine Dicer and Ago-2, respectively. These data show that Dicer and Ago-2 are present in porcine ovary and that the sequences are highly similar to those reported for other species.

Key Words: Pigs, Argonaute, Dicer

W300 Association of gene markers affecting the principal components of skeletal design and feet and leg soundness in pigs. B. Fan, S. Onteru, B. Mote, T. Serenius, M. Nikkilä, K.J. Stalder, and M.F. Rothschild*, *Iowa State University, Ames.*

Identifying and culling the replacement gilts with poor skeletal and leg and feet conformation is helpful to reduce replacement and mortality rates in breeding stock. Recent replacement and mortality rates have averaged around 50% and 10% respectively in US commercial swine herds in 2007 according to PigCHAMP reports. Due to the low to moderate heritability of conformation and soundness traits, molecular markers would be useful selection aids. In our recent candidate genes studies, several promising significant associations between SNPs and 6 body conformation traits and 10 leg structure traits and overall leg action were observed. However, it was difficult to determine which SNPs were overall associated with total structural soundness. Using the PRINCOMP procedure of SAS, 6 body conformation traits could be primarily combined into two principal factors, each explaining greater than 20% of the total variation, and which accounted for body volume and side-view, respectively. The other 11 feet and leg traits were summarized into three principal factors, which generally described leg movement, leg defects and uneven toes, respectively. The subsequent

association analyses between the SNPs and the principal factors were implemented using the MIXED procedure of SAS. The raw P values were further adjusted using the false discovery rate (FDR) method from the MULTTEST package of the R program. SNPs in the following genes COL9A1, hDBP, APOE, DK, PPARGP and PAPPB were associated with body volume ($P < 0.05$). SNPs in COL1A2, CALCR, FBN1 and OXTR were associated with side-view. Leg movement was significantly associated with SNPs in COL1A2, CALCR, BMP8, OPG, PTHR and OXTR. Leg defects were significantly associated with SNPs in ALOX15, ALOX5, COL9A2 and WNT16. It appears that, genes involving cartilage development and fatness seem to function in skeletal structure, and genes relevant to cartilage and bone formation are likely to play important role for feet and leg soundness in pigs.

Key Words: Body Conformation, Feet and Leg Structure, Candidate Gene

W301 Effects of the sex and the halothane genotype on carcass and meat quality characteristics in Duroc and Landrace crossbred pigs. L. L. Lo*¹, C. C. Tsai¹, M. C. Huang², R. S. Lin³, and T. H. Huang⁴, ¹*Chinese Culture University, Taipei, Taiwan, ROC*, ²*National Chung-Hsing University, TaiChung, Taiwan, ROC*, ³*National ILan University, ILan, Taiwan, ROC*, ⁴*Taiwan Farm Industry Co., Ltd., Pingtung, Taiwan, ROC.*

Two hundred and thirty crossbred Duroc×Landrace pigs of two halothane genotypes (NN=185, Nn=45) of 107 kg live weight were slaughtered to detect the effects of sex (barrows=116, gilts=114) and halothane genotype on carcass and meat quality characteristics. All data were analysed using a linear model that included fixed effects of year, farm, sex, halothane genotype, and the important two way interactions ($P < 0.20$). Carcass weight was used as a covariable. Sex and halothane genotype were important sources of variation for most carcass and meat quality traits. Compared with barrows, gilts had larger 10th rib longissimus muscle area (LMA, $P < 0.01$), but lower marbling score ($P < 0.05$), higher protein percentage ($P < 0.01$), and lighter Hunter value ($P < 0.05$). For eating quality, LM from barrows had higher scores on juiciness, flavour, tenderness and overall acceptability ($P < 0.01$). Halothane genotype significantly affected the dressing percentage, carcass length, 10th rib backfat thickness, and the 10th rib LMA. Carcasses from Nn pigs had a higher dressing percentage ($P < 0.05$); longer carcass ($P < 0.01$); and larger LMA at the 10th rib ($P < 0.001$) than that of the NN pigs. Fat thickness and the lean percentage; however had no differences between the two halothane genotypes ($P > 0.10$). LM of Nn halothane genotype had lower ultimate pH ($P < 0.001$), higher drip loss ($P < 0.001$), and lighter Hunter L value ($P < 0.05$). As for sensory evaluation, LM from Nn genotype had lower scores on juiciness ($P < 0.01$) and tenderness ($P < 0.05$). These results suggest that LM from barrows had better meat quality and pigs from Nn halothane genotype had better carcass characteristics but poor quality with regard to ultimate pH, drip loss, reflectance values, and the eating quality of juiciness and tenderness.

Key Words: Halothane Genotype, Meat Quality, Crossbred Pigs

W302 Identification and quantification of miRNA expression in porcine sperm cells. E. Curry* and S. L. Pratt, *Clemson University, Clemson, SC.*

MicroRNAs (miRNA) are short, non-coding, single-stranded, ribonucleic acids which are transcribed by RNA polymerase and down-regulate or prevent RNA translation. miRNAs have been shown to play roles in diverse biological processes such as insulin secretion, regulation of adipocyte differentiation, B-cell development, and tumorigenesis. More importantly, it is theorized that miRNAs are important for embryonic development, but little information is known as to the identity of miRNA in porcine gametes or their potential involvement in reproductive failure. Previous investigations have demonstrated that sperm messenger RNA (mRNA) are introduced into the oocyte during fertilization and may play a role in early embryonic development, but the presence and/or identity of miRNA in porcine sperm cells has not been thoroughly investigated. The objective of this study was to determine the presence and identity of miRNA in porcine sperm cells. In this experiment, RNA was isolated from porcine sperm cells using TRIzol[®] Reagent (Invitrogen; Carlsbad, CA) and was used to hybridize to commercially available arrays (LC

Sciences, LLC; Houston, TX) to identify the known miRNA present. The arrays were constructed from 1260 known miRNA sequences from 19 different species and, because many miRNAs are highly conserved among species, allowed for efficient hybridization. Of the miRNAs probed, results showed that 73.7% (n= 929) were non-detectable, 12.4% (n= 154) had low detection, and 12.2% were moderately (7.4%; n= 93) to highly expressed (4.8%; n= 60) in porcine sperm cells. In particular, the majority of the let-7 family, a highly conserved group of heterochronic miRNAs shown to play critical roles in developmental timing in non-mammalian species, was present and highly expressed in porcine sperm cells. Results of this study suggest that sperm miRNAs may play a fundamental role in spermiogenesis. In addition, if delivered along with mRNA to the oocyte at fertilization, miRNAs may have a function in early embryonic development.

Key Words: microRNA, Sperm, Swine

SYMPOSIA AND ORAL SESSIONS

Animal Behavior and Well-Being: Swine

240 ASAS Centennial Presentation: Animal behavior and well-being: What does the future hold? A. K. Johnson*, *Department of Animal Science, Iowa State University, Ames.*

Compared to the more traditional sciences of nutrition, physiology and reproduction, farm animal behavior and well-being science is quite young. Seven colleagues who are considered to be the future generation of ethologists were asked several questions on the challenges and opportunities facing the field. The information collected was pooled for anonymity. The average time working in the field was 10 yr. Species that are regularly worked with were beef (5), swine (5), dairy (2), poultry (1), and sheep (1). Challenges identified by the group were (1) are we making progress and if so how can we define this? (2) the demand for information has outpaced the science (3) pressures from stakeholders (4) individuals in the field of research, teaching and extension are over-worked and (5) the need to address basic ethological questions has been lost. Solutions were (1) to continue providing sound science that has been validated, measured objectively and is reliable, (2) to separate behavior and well-being into their own research funding categories and for a percentage of this funding to be directed towards the basic science and (3) for animal science and veterinary medicine departments to continue to employ faculty trained in ethology. Highlights for the future are the willingness and acceptance for ethologists to work across disciplines within their department, across departments within the same institution, and across state lines. There is also interest in continuation and expansion of new teaching models that bring together a critical mass of experts and students and the innovative researchers who are discussing questions in regards to animal cognition, emotions and pain. In conclusion, new and innovative tools, personalities and dedication to the field of animal behavior and well-being will continue to provide scientific information and direction. ASAS has a critical role in bringing together scientists in this field to deliver new and invigorating findings to the scientific community and beyond.

Key Words: Behavior, Future, Well-Being

241 Effects of facility design on the stress response of market weight pigs during loading and unloading. A. Johnson*¹, L. Sadler¹, M. Faga², C. Feuerbach², H. Hill², R. Bailey³, and M. Ritter⁴, ¹*Department of Animal Science, Iowa State University, Ames,* ²*Iowa Select Farms, Iowa Falls, IA,* ³*Swift and Co., Marshalltown, IA,* ⁴*Elanco Animal Health, Greenfield, IN.*

Thirty three loads of market weight pigs (n = 5,901) were used in randomized complete block design to determine the effects of 2 different facility designs on stress responses and transport losses at the plant. The new (NEW) design had 192 pigs/pen and internal swing gates that were used to manually pre-sort market weight pigs on the day before loading. Traditional (TRAD) design had 32 pigs/pen; it was not feasible to pre-sort market weight pigs prior to loading. This design confounds the effects of facility design with pen size and pre-sorting, but this is how the 2 facility designs are being utilized under commercial conditions. Three sites were used in this study. Each site had 2 rooms and both facility designs were represented in each room. During loading, treatments were randomly assigned to trailer decks. Pigs were moved in groups using sort boards and prods, when necessary. Pigs were loaded onto straight deck trailers, mixed with unfamiliar pigs, provided with ~0.41 m²/pig and were transported ~1 h to a commercial plant. During loading and unloading, the number of pigs displaying open mouth breathing (OMB), skin discoloration (SD) and muscle tremors (MT) were recorded. At the plant, dead and non-ambulatory pigs were recorded during unloading, and total losses were defined as the sum of dead and non-ambulatory pigs at the plant. Data were analyzed by Proc Glimmix of SAS. NEW pigs had lower (P ≤ 0.05) percentages of OMB, SD and MT during loading and unloading compared to TRAD pigs. NEW pigs had fewer (P < 0.05) dead pigs (0.01 vs. 0.23 ± 0.05%), non-ambulatory pigs (0.29 vs. 0.66 ± 0.12%) and total losses (0.30 vs. 0.89 ± 0.14%) at the plant compared to TRAD pigs. In summary, utilizing large pens and pre-sorting prior to loading, reduced physical signs of stress during loading and unloading, and reduced total losses at the plant by 66% compared to pigs from traditional pens.

Key Words: Facility Design, Pig, Transportation Stress

242 Effect of trailer design on the behavior of market weight pigs during unloading and lairage. S. Torrey^{*1}, H. Gonyou^{2,3}, J. A. Correa⁴, R. Bergeron⁵, T. Widowski⁵, N. Lewis⁶, T. Crowe², C. Dewey⁵, and L. Faucitano¹, ¹Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, ²University of Saskatchewan, Saskatoon, SK, Canada, ³Prairie Swine Centre, Saskatoon, SK, Canada, ⁴Université Laval, Quebec City, QC, Canada, ⁵University of Guelph, Guelph, ON, Canada, ⁶University of Manitoba, Winnipeg, MB, Canada.

Trailer design has been implicated with influencing in-transit mortality and carcass quality in market weight pigs, although little is known about its effect on behavior during unloading or lairage. Therefore, the objective of this experiment was to determine if trailer design influenced behavior during unloading and lairage at a commercial facility. Over the course of 6 wk, 1,596 pigs (BW=118.4±0.4 kg) were transported on either a 3-deck pot-belly truck with internal ramps to upper and lower levels (PB; n=181 pigs per week in 8 experimental compartments; 0.40 m²/pig) or a double-decker hydraulic truck without internal ramps (DD; n=85 pigs per week in 4 compartments; 0.40 m²/pig) for 2 h to a commercial abattoir. Pigs were unloaded by compartment at the abattoir and driven into lairage pens segregated by truck compartment. Behavior during unloading (slips and falls), time to unload each compartment (adjusted for number of pigs per compartment), latency to rest (75% of pen lying) and total time lying during the first hour of lairage were observed. Behavior data were analyzed using the mixed model procedure in SAS. Accounting for the number of pigs, unloading from PB was significantly longer than from DD ($P<0.001$; PB: 2.9±0.1 sec/pig; DD: 2.1±0.2 sec/pig), although there was no difference in the number of slips and falls during unloading ($P=0.48$; PB: 0.04±0.01 incidence/pig; DD: 0.05±0.01 incidence/pig). During lairage, there was no difference between trucks in latency to rest after transportation ($P=0.96$; PB: 35.3±2.4 min; DD: 35.1±3.9 min), although pigs from DD tended to spend more time lying than PB pigs ($P=0.06$; PB: 45.2±2.0% of time lying; DD: 51.4±3.0% of time lying). Although trailer design did not influence latency to rest, pigs from PB took longer to unload and spent less time lying in lairage. Further analyses will determine the effect of location within truck on behavior and welfare.

Key Words: Pig, Transportation, Behavior

243 Space requirements of weaned pigs during transport in summer. M. A. Sutherland^{*1,2}, P. J. Bryer^{1,2}, B. L. Davis^{1,2}, and J. J. McGlone^{1,2}, ¹Pork Industry Institute, Lubbock, TX, ²Texas Tech University, Lubbock.

Currently there are no trucking quality assurance recommendations for space allowance of weaned pigs during transport. The objective of this research was to establish an estimate of the space requirements of weaned pigs during transport in summer based on measures of animal well-being. A commercial semi-trailer was fitted with compartments that provided 0.05, 0.06, and 0.07 m²/pig (on both upper and lower decks) with 100 pigs per compartment. Cameras were placed in each compartment to record behaviors and postures of the pigs during transport. The frequencies of standing, lying, sitting, standing on another pig, and lying or huddling on top of another pig were recorded using 1 min scan samples during the entire duration of transport. Blood samples were taken and weights and lesion scores recorded from 4 pigs (5.1 ± 0.10 kg) per compartment for performance and physiology measures before and after transport (n=8 pigs/treatment). Pigs were transported for 60 min to the wean-to-finishing site using the same route for each 4 replicates

during summer (28.4 ± 1.23 ° C and 59.8 ± 4.42% humidity). Data were analyzed by Proc MIXED of SAS. The trailer was the experimental unit. Cortisol, hematocrit, blood urea nitrogen, total protein, albumin, aspartate aminotransferase, creatine kinase, and gamma glutamyl transferase were increased ($P<0.05$) during transport regardless of space allowance. Glucose and body weight were decreased ($P<0.05$) during transport regardless of space allowance. The neutrophil to lymphocyte (N:L) ratio was greater ($P<0.005$) in pigs transported at 0.05 m²/pig compared with pigs transported at 0.06 and 0.07 m²/pig. Pigs transported at 0.05 m²/pig laid down less ($P<0.05$) than pigs transported at 0.06 and 0.07 m²/pig between 30 and 60 min of transport. In conclusion, increased N:L ratio and decreased lying behavior in pigs transported at 0.05 m²/pig suggest that space allowances of 0.06 or 0.07 m²/pig are preferable when transporting weaned pigs during summer.

Key Words: Animal Welfare, Pigs, Transport

244 The effect of 30-hour transport at two space allowances on physiological measures of stress in breeding gilts. P. J. Bryer^{*}, M. A. Sutherland, B. L. Davis, J. Smith, and J. J. McGlone, *Pork Industry Institute, Texas Tech University, Lubbock.*

Long duration transport is an important welfare issue. Little experimental work exists on the effects of long duration transport on breeding gilts. The goal of this study was to evaluate the effects of a 30-h transport on acute physiological measures in breeding aged gilts. Two space allowances were constructed 5 times in a commercial semi-trailer allowing 0.334 and 0.409 m²/pig. The experiment was repeated twice in October 2007 in Lubbock, TX, USA and included 120 pigs (91.4kg ± SE1.40). In addition to 4 gilts per experimental treatment on the trailer, 4 control gilts remained in the home pen. Control gilts had access to food and water within their 3.05 by 4.27 m pen. Every 6 h, pigs in one pair of compartments were sampled by removal from the trailer. Blood samples (10 mL via jugular venipuncture) and body weights were collected from gilts and their respective controls before and after transport (at -24, 6, 12, 18, 24, and 30 h). The MIXED procedure in SAS with repeated measures was used with individual gilts as the experimental unit. Weight loss was greater ($P<0.05$) among transported pigs relative to controls at the first 6-h measure, however after the initial weight loss, body weights were not different ($P>0.05$) in transported pigs from 12 through 30 h. Additionally, no differences ($P>0.05$) were observed in weight between space allowances. Transient changes were seen in glucose, total protein, albumin, lymphocytes, granulocytes, neutrophil:lymphocyte ratio, hematocrit, and platelets. Cortisol, creatine kinase, and aspartate aminotransferase did not differ between treatments. Transported gilts experienced only transient compromises of health or welfare based on the parameters evaluated. Overall, these data indicate that the 28-h law may be too conservative to be broadly applied to all classes of livestock as we found no negative health trends at 30 h in gilts transported 12 to 24 h vs. gilts not transported.

Key Words: Transportation, Animal Welfare, Pigs

245 Responses to weaning and transport in pigs: Influence of sex and weaning weight. T. A. Cooper^{*}, M. P. Roberts, C. J. Kojima, and H. G. Kattesh, *University of Tennessee, Knoxville.*

Pigs (n=64; 22±0.3 d of age) were blocked by sex and weight and allocated into transported (T) or non-transported (NT) groups at weaning (d 0). All NT pigs were weaned into 1.2 m² pens (4 pigs/pen, 2 pens/factorial group) while T pigs were transported as a group for 3 h in a small livestock trailer before being similarly placed in pens. Pigs were weighed and a blood sample collected on d 0 (pre-weaning), 1, and 7. Data were analyzed using a mixed model with a factorial design and repeated measures; fixed effects were transport, sex, and time. Weaning weight was used as a covariate. Plasma concentrations of corticosteroid-binding globulin (CBG) decreased (P<0.001) by d 1 and remained lower through d 7 in both T and NT pigs. A sex*time interaction occurred (P=0.003) such that while cortisol concentrations in males increased from d 0 to d 1 and then decreased to pre-weaning levels by d 7, females had higher preweaning cortisol levels which did not change on d 1 but decreased by d 7 to lower levels than in males (P<0.05). The free cortisol index (FCI; a ratio of cortisol to CBG) was elevated (P<0.001) on d 1 in all groups but returned to pre-treatment levels by d 7. Regardless of

treatment, lighter weight pigs had lower CBG concentrations (r=0.330; P=0.010) and higher FCI (r=-0.305; P=0.018) as measured on d 1. Total white blood cell number increased from d 0 to d 1, then decreased by d 7 (P<0.001). The percentage and absolute number of neutrophils followed a similar pattern, whereas lymphocyte percentage and number changed in an opposite manner. The number of neutrophils present on d 1 also varied by sex (P<0.05) such that females had higher numbers of neutrophils than males. Correlation analysis revealed that, regardless of treatment, lighter weight pigs had greater numbers of neutrophils (r=-0.304, P=0.025) and percentages of neutrophils (r=-0.403, P=0.002) in circulation than did the heavier pigs prior to weaning but not after. The process of weaning appears to uncouple the relationship between body weight and circulating immune cell populations. The physiological response due to weaning is greater, especially in lighter weight pigs, than is the response to transport.

Key Words: Swine, Stress, Weaning

Animal Health IV

246 Metabolic disorders and immune response in farm animals.

N. Lacetera*, U. Bernabucci, B. Ronchi, and A. Nardone, *Dipartimento di Produzioni Animali, Viterbo, Italy.*

Metabolic regulation and immune response are highly integrated systems and the proper function of each is dependent on the other. It is widely recognized that the immune system requires energy and substrates to maintain its function, and mounting an immune response likely requires using resources that could otherwise be allocated to other biological functions. Reproduction, lactation, growth, thermoregulation represent some of the energetically-demanding functions that in farm animals are likely to compete with immune system for resources. Studies carried out in different animal species revealed that activation of the immune response may cause perturbation of metabolic status, and suggested that understanding the cost of immune function in terms of energy or single nutrients is essential for more accurate characterization of nutrient budgets of animals and better understanding of the role of immunity in the evolution of life strategies. On the other hand, several papers described an association between disorders of energy, lipid, vitamins or minerals metabolism and perturbation of immune response. In particular, recent studies carried out in domestic ruminants revealed an association between energy deficit and related loss of body condition and increase of plasma non esterified fatty acids, impairment of immunoresponsiveness and increased susceptibility to infections. From a biochemical point of view, metabolic disorders and related deficiency or excess of nutrients or metabolites may regulate immunity by causing perturbation of both innate and adaptive immune pathways. From an ecological perspective, the immune system may be considered as an energetically costly system that may or may not have priority over other uses of energy available. The hypothesis of a trade-off between immune and other biological functions in farm animals would deserve to be investigated with particular emphasis for those physiological circumstances, as it is the case of the periparturient period, characterized by high demands, low feed intake, frequent occurrence of metabolic disorders and immunosuppression.

Key Words: Metabolism, Immunity, Farm Animals

247 Administration of a *Staphylococcus aureus* bacterin to dairy heifers reduces new infection rate and somatic cell counts at time of calving. S. C. Nickerson¹, E. Hovingh², C. Peterson³, S. Brannock³, E. Schaffer³, and P. W. Widel⁴, ¹University of Georgia, Athens, ²Pennsylvania State University, College Park, ³James River Correctional Facility, Goochland, VA, ⁴Boehringer Ingelheim Vetmedica, Inc., St. Joseph, MO.

Use of a *Staphylococcus aureus* bacterin as a means of preventing intramammary infections (IMI) in dairy heifers was evaluated. At approximately 6 to 18 months of age, Holstein heifers from the James River Correctional Center Dairy in Goochland, VA were processed for vaccination and to collect mammary secretions for microbiological analysis. Fifty-three heifers were immunized with a commercial bacterin (Lysigin, Boehringer Ingelheim Vetmedica, Inc.) using a 5-ml dose intramuscularly in the semimembranosus muscle of the rear leg; 53 heifers served as unimmunized controls. The vaccine was a lysed culture of polyvalent *S. aureus* somatic antigens of 5 phage types in an aluminum hydroxide base. Fourteen days after initial processing and at

6-month intervals until calving, vaccinates were processed for boosting. At 2-month intervals after trial initiation and through calving, mammary secretion samples were collected for bacteriological culture and somatic cell counts (SCC). Microbiological examination of mammary samples collected from bred heifers over gestation demonstrated that 19.8% of heifers (9.4% of quarters) were infected with *S. aureus*, 68.9% (34.3% of quarters) were infected with coagulase-negative staphylococci (CNS), 6.6% (2.3% of quarters) were infected with environmental streptococci, and 1% (0.3% of quarters) were infected with coliforms. Vaccine efficacy data showed that the percentage of heifers with *S. aureus* IMI at calving was lower in vaccinates (13.3%) compared with controls (34.0%). Likewise, IMI with CNS were lower in vaccinates (64.2%) compared with controls (69.8%). The SCC in samples collected during first week of lactation from uninfected heifers for vaccinates and controls were 66,095 and 132,754/ml; a 50.2% reduction; and for infected heifers, SCC were 441,764 and 892,176/ml; a 50.5% reduction. Results demonstrated that administration of a commercial bacterin to breeding age and pregnant Holstein heifers reduced the prevalence of *S. aureus* mastitis as well as the SCC at time of calving.

Key Words: *Staphylococcus aureus*, Mastitis, Vaccination

248 Serum non-esterified fatty acid and beta-hydroxybutyrate in the transition period and their associations with disease in dairy cows.

M. E. Carson¹, S. J. LeBlanc¹, S. M. Godden², M. B. Capel³, M. W. Overton⁴, J. Santos⁵, K. E. Leslie¹, and T. F. Duffield¹, ¹University of Guelph, Ontario, Canada, ²University of Minnesota, St. Paul, ³Perry Veterinary Clinic, Perry, NY, ⁴University of Georgia, Athens, ⁵University of California Davis, Tulare.

The objective of this study was to characterize the relationship of serum NEFA and BHB concentrations in the transition period with clinical disease in dairy cows across different regions of North America. A field study was conducted with 2316 Holstein cows in 56 dairy herds in 4 regions of Canada and the United States. Once weekly, after the morning feeding, blood was collected from cows in the week before their expected calving date, and again from the same cows in weeks 1, 2, and 3 postpartum. Serum was stored at -20°C within 8 hours of collection. NEFA, BHB and Ca were measured using a Hitachi 911 auto-analyzer. Considered alone and assuming equal weight on sensitivity and specificity, the optimal cut-points for prediction of displaced abomasum (DA) and retained placenta (RP) were calculated. The 23% of cows with NEFA ≥ 0.5 in week -1 were 2.8 times more likely to subsequently have DA than cows below this cut-point. Multivariable logistic regression models of the probability of DA were made using information available before and after calving. Accounting for the random herd effect and region, pre-calving NEFA ≥ 0.5 mmol/L (odds ratio (OR) = 1.8, P = 0.02), week 1 postpartum NEFA ≥ 1.0 (OR = 3.0, P < 0.001) and week 1 Ca ≤ 2.2 mmol/L (OR = 2.5, P = 0.0003) predicted risk of DA for serum data obtained at or prior to week 1 postpartum. BHB did not remain in the week 1 model when pre- and postpartum NEFA were included. Cows that did not have elevated NEFA pre- or postpartum or sub clinical ketosis (SCK) had the lowest risk of DA (0.8%). For serum obtained during the week prior to calving, multivariable logistic regression models accounting for the random herd effect found pre-calving NEFA ≥ 0.3 mmol/L (OR = 1.7, P = 0.0032), twins (OR = 5.9, P < 0.0001) and dystocia (OR = 2.3,

P=0.0002) to be important predictors of the risk of RP. These data confirm the associations of NEFA with health and support their use as tools for monitoring or investigation of transition dairy cows.

Key Words: Metabolic, NEFA, Transition

249 Intramammary pathogens from 3755 dairy goats and sheep and farm characteristics from New York State. D. J. Wilson*¹, R. N. Gonzalez², P. M. Sears³, L. H. Southwick⁴, H. F. Schulte², and G. J. Bennett², ¹Utah State University, Logan, ²Cornell University, Ithaca, NY, ³Michigan State University, East Lansing, ⁴Lee H. Southwick Consulting, Virgil, NY.

Prevalence of mastitis pathogens of dairy sheep and dairy goats and mean SCC in bulk milk are not the same as in bovines. Mastitis control practices used on small ruminant farms have limited documentation. Milk samples were aseptically collected for milk culture from 3164 dairy goats (36 herds) and 591 dairy sheep (6 flocks) from 1993-2004 in New York State. Lactating doe numbers averaged 88 (median 30.5); milking ewes averaged 99 (median 83.5). Most common goat breeds when specified were French Alpines and Saanens. Mean number of dry animals was 23 does and 258 ewes.

Mean bulk tank SCC was 425,000/ml for sheep, 835,258/ml for goats. Mean estimated milk production per 305 d was 1102 lb (500 kg) for sheep and 1856 lb (843 kg) for does. Pathogens were isolated from milk of 64 ewes (10.8%) and 864 does (27.3%). The most common pathogens were coagulase-negative staphylococci (CNS), from 6.8% of ewes and 23.0% of does, non-agalactiae streptococci (Strep spp.), from 3.2% and 0.8%, and *S. aureus* from 1.2% and 1.5%, respectively.

33 of the 36 goat farms (92%) used udder preparation; 50% predipped, most with 0.5% titratable iodine dip, 31% used udder wash, 11% dry wiped, and 69% stripped for abnormal milk. 89% broke vacuum and 83% postdipped, most with 0.5% iodine or 0.5% chlorhexidine. Teat end vacuum averaged 13.7 inches Hg. 78% infused antibiotics during lactation, 78% dry treated all does and 6% selectively dry treated.

2 of the 6 sheep farms did no udder preparation, the rest used various methods that usually included dry wipe. All broke vacuum before unit removal and used postdip. Mean teat end vacuum was 12.5 inches Hg. Milking system features and performance test results will be discussed further. The most common mammary pathogen isolated from both sheep and goats was CNS, accounting for 63% and 84% of isolates, respectively. The prevalence of mammary pathogens in goats was low compared with that for dairy cows, despite the fact that goats have markedly higher mean bulk milk SCC than cows. Adoption of mastitis control practices was similar to that for cow farms, except that sheep owners did minimal udder preparation before milking.

Key Words: Ovine, Caprine, Mastitis

250 Ability of an immunomodulatory feed additive to reduce infection of the murine mammary gland with *Streptococcus uberis*, *Escherichia coli* and *Staphylococcus aureus*. A. Rowson*¹, Y. Q. Wang¹, E. Aalseth², N. E. Forsberg¹, and S. B. Puntteney¹, ¹OmniGen Research, Corvallis, OR, ²Aalseth Consulting, Lake Stevens, WA.

Four experiments were completed to assess ability of OmniGen-AF to reduce the infection of the murine mammary gland with 3 bovine isolates: *S. uberis*, *E. coli* and *S. aureus*. Pregnant mice were received from Charles River and housed in pairs. Animals were assigned to either

a powdered control diet (Teklad 8604) or to the same diet supplemented with OmniGen-AF (Prince-Agri Products; 0.5% w/w). Animals consumed diets during gestation (from approximately Day 15) and into lactation (to approximately Day 10). On the day of the experiments, pups were removed and euthanized. Lactating mice were anesthetized with ketamine and xylazine and the abdomen sterilized. The terminal 0.5 mm of the L4 and R4 teats were removed via sterile technique after which pathogens in 50 ul of PBS were infused into the teat canals via 33 gauge needles. Control mice received infusion of PBS only. Experiment 1 consisted of infusing mice with 50 CFU of a bovine isolate of *S. uberis* and an infection period of 48 hr. Experiments 2 and 3 consisted of infection of glands with 100 and 25 CFU of a bovine isolate of *E. coli* and infection periods of 48 and 24 hrs, respectively. Experiment 4 consisted of infusion of glands with 50 CFU of a bovine isolate of *S. aureus* and an infection of 36 hrs. After progression of the infection, lactating mice were anesthetized, blood taken via cardiac puncture and euthanized. L4 and R4 mammary tissues were taken. DNA was extracted from mammary and blood (Qiagen) and concentrations of pathogen DNA determined using quantitative PCR. Genomic DNA from each pathogen was used to generate a standard curve for each pathogen. OmniGen-AF caused significant (P<0.05) reductions (>95%) in *S. uberis* and *S. aureus* DNA in mammary tissues. Further, OmniGen-AF reduced (P<0.05) *S. uberis* DNA concentration in blood by >95%. Feeding OmniGen-AF caused a numerical reduction in (P>0.05) in *E. coli* detection (60% reduction) in mammary tissue. *E. coli* and *S. aureus* DNA were not detectable in blood. In summary, feeding OmniGen-AF reduced infection of the murine mammary gland by bovine mastitic pathogens.

Key Words: Mastitis, OmniGen-AF, Murine Model

251 Evaluation of selective, chromogenic media in an on-farm culture kit. D. W. Rensburg*, B. I. Smith, and M. A. Kristula, *University of Pennsylvania, Kennett Square.*

Identification of mastitis causing organisms through microbiological culture has been suggested as a first step in successful mastitis treatment. This process is particularly important in mastitis caused by *Staphylococcus aureus* (SA), where rapid identification and segregation of infected animals is critical to an effective control program. The goal of this study was to evaluate the sensitivity and specificity of a commercially available culture media compared to culture performed in a diagnostic microbiology lab. HyLabs AP059 (marketed as IdentMast) is a commercially available mastitis culture paddle with two sides of selective chromogenic media. Chromogenic media differentiates between bacterial species by changing the color of the bacterial colony and surrounding media. In this project composite milk cultures were aseptically collected from 163 lactating Holstein dairy cows at University of Pennsylvania Veterinary School's dairy farm. The AP059 paddles were immersed into the milk sample and then incubated for 24 hours. The remaining milk was submitted to the University of Pennsylvania Veterinary Microbiological Laboratory (PVML) for routine aerobic bacterial culture. Results from the HyLabs AP059 paddle were compared to results from the microbiology lab to determine the sensitivity, specificity and accuracy. The sensitivity, specificity and accuracy of the HyLabs AP059 compared to the PVML results were 100%, 94% and 95%, respectively. The positive predictive value and negative predictive values of the HyLabs AP059 were 74% and 100%, respectively. These results are based on an interpretation of any pink colonies being described as SA. All false positive samples were cultured by the PVML as a coagulase negative Staph sp.(CNS). Additional CNS colonies were observed on the SA

selective media as clear and green colonies. The results demonstrate that the HyLabs AP059 mastitis culture paddle can be an effective screening tool for mastitis caused by SA but positive cultures should be confirmed through traditional laboratory culture.

Key Words: Mastitis, Culture, Dairy Cow

252 Evaluation of a novel chlorine dioxide teat dip on teat end and teat skin health. L. L. Timms*, Iowa State University, Ames.

The purpose of this study was to evaluate the teat end health and skin conditioning performance of an experimental chlorine dioxide teat dip vs. commercial dips and best management practices at the ISU Dairy. A teat dip trial was conducted from late August through early November 2007. An experimental teat dip utilizing a no mix chlorine dioxide germicidal mode and containing 15% emollients was evaluated (Boumatic, Madison, WI). Herd standard post-milking teat dip used was a 0.5% iodine, 10% emollient product (Quadraplex, IBA), while the pre milking teat dip was a 0.25% iodine, 2% skin conditioning product (BacStop, IBA). The trial used a split udder design. Left teats of 56 cows were pre and post dipped with current herd dips (control) while right side teats were dipped with the chlorine dioxide dip (treatment). Teat skin and teat end scoring were performed using a variation of the Goldberg and Timms methods, respectively, by trained graders. Scoring was performed twice per week. Results were compiled and analyzed using SAS. Teat end and skin scores were analyzed using a 2 sample t-test while proportion of rough/cracked teat ends were analyzed using a 2 sample test of equality of proportions. There were no significant differences in teat skin score between treated and control teats, and skin condition was excellent (mean near score 1). Within 3 days of dipping, average teat end score started to trend higher with significantly higher ($p < .01$) average teat end scores in treated vs. control quarters by 6 days post dipping through end of the trial. Average teat end scores and % rough teats were significantly higher in chlorine dioxide dipped teats, with this reaction occurring more on teats that had higher hyperkeratosis at the start. Marked changes in teat end scores were measured over time and periods as short as days in all groups signifying other factors besides teat dips also influence teat health.

Key Words: Chlorine Dioxide Teat Dips, Teat Skin, Teat End

253 Sodium chlorite lactic acid teat dip contaminated with *Serratia liquifaciens*. D. J. Wilson*, J. D. Trujillo, R. T. Skirpstunas, and K. B. Cavender, Utah State University, Logan.

This report describes bacterial contamination of sodium chlorite lactic acid (SCLA) teat dip, which has not been reported previously. A commercial dairy farm had two apparently healthy cows that died within 48 h following intramammary (IMM) infusion of dry cow treat-

ment at the end of lactation. Teat dip containing SCLA had been stored for 2 years on the farm, and was used only to dip teats following IMM infusion with dry cow treatment.

The original container storing the SCLA teat dip was visibly soiled externally. The dip was found culture-positive for *Serratia liquifaciens*. A plan for follow up milk cultures was recommended, but no samples were received. All remaining teat dip was discarded. Further herd history was lost to follow up.

Only when BHI rinse of the original teat dip container was incubated and then streaked for culture was *Serratia liquifaciens* isolated from the film on the inside of the container. In addition to previous reports of contamination of other types of teat dips, the risk of contamination with potential mastitis pathogens, especially *Serratia* spp. applies to SCLA teat dip. Soiled containers of teat dip should be cultured to monitor for contamination with bacteria, or preferably discarded.

Key Words: Teat Dip, Contamination, *Serratia marcescens*

254 Teat end and skin conditioning evaluation of two experimental heptanoic acid teat dips during winter. L. L. Timms*¹ and J. Morelli², ¹Iowa State University, Ames, ²Ecolab, Inc., St. Paul, MN.

The purpose of this study was to evaluate the teat end health and skin conditioning performance of two experimental heptanoic acid based teat dips vs the commercial product Remain Gold[®] using a split udder design during the winter season under best management winter milking practices. Two separate teat dip trials were conducted simultaneously at the Iowa State Dairy Farm from late October 2006 through March 2007. Experimental teat dips KX-6185 and KX-6186 were provided by Ecolab (St Paul MN). Both products contained 1% heptanoic acid and 10% skin conditioners. All trials used a split udder design. In trial 1 (Pen 1 Free Stalls), left teats of 56 cows were pre-dipped with 0.25% iodine teat dip (IBA) and post dipped with Remain Gold[®]. Right side teats were pre and post dipped with KX-6185. In trial 2 (Pen 2 Free Stalls) 56 cows had teats pre-dipped with a 0.25% iodine dip. Left teats were post-dipped with Remain Gold[®] and right teats were post-dipped with experimental teat dip KX-6186. Teat skin and teat end scoring were performed using a variation of the Goldberg and Timms methods, respectively, by trained graders. Scoring was performed twice per week. Results were compiled and analyzed using SAS. Teat end and skin scores were analyzed using a 2 sample t-test while proportion of rough/cracked teat ends were analyzed using a 2 sample test of equality of proportions. There were no significant differences in teat end and teat skin condition between udder halves for all products in all trials. However, there was significant teat changes within udder halves across time, signifying other factors beside teat dips contributing to teat condition issues. Marked changes in teat end scores were measured over time and periods as short as days. Product treatment comparisons frequently showed parallel trends in score averages. This illustrates the importance of a split udder design to evaluate skin conditioning performance.

Key Words: Teat Dipping, Teat Skin, Teat End

Symposium: Bioethics: How Do We Integrate Bioethics into Our Food Animal System?

255 ASAS Centennial Presentation: History and future perspectives of bioethics in food animal agriculture. W. R. Stricklin*, *University of Maryland, College Park.*

During the past 100 years, American animal agriculture has experienced a rapid transformation. Husbandry practices changed more dramatically than during the previous 15 thousand years of human-animal relationships. This transformation freed Americans from stoop-labor once needed for food production and made safe, healthful food available at relatively low costs. But modern confinement practices also brought forth ethically-based concerns about animal welfare, environmental impact, loss of the rural community, and the possible impact of new genetic technologies. Some persons contend that science and technology have been used in an ever striving effort for cheaper food, with the concepts of stewardship and shepherding having been given over to that of dominionism over animals and the environment. In short, some critics contend that ethical costs such as animal suffering, environmental pollution, etc. have been largely ignored by animal scientists who have instead tended to focus more on increased productivity per animal unit. A common response has been that such issues should be resolved by "science alone." Animal scientists can best serve American animal agriculture by acknowledging that ethical considerations are critical, and always included, in decisions about current and future practices in food animal systems. Ultimately, ethics is said to be about "doing the right thing" and from the time of Socrates it has argued that the right thing to do is that with the best reasons for doing. Thus, appropriate ethical decisions are consistent with scientific information but also extend appropriate consideration to animals, the environment, and to persons associated with animal agriculture at the farm level.

Key Words: Bioethics, Animal Welfare, Animal Science

256 Bioethics from 1995-2008: How far have we come? R. Anthony*, *University of Alaska, Anchorage.*

Three prominent varieties of bioethics (broadly construed), namely moral humanism, humane moralism and holism, inspired our moral imagination during the mid-nineties and the decade to follow. They continue to underpin much of how we think about the meaning and form of our obligations to others, including nonhuman animals, and how we perform the complex balancing of different moral concerns. In terms of animal agriculture, the meaning and moral structures of these varieties have had a significant impact on contemporary "animal liberation" ethic, agrarianism, pastoralism and environmental holism. As a way to assess just how far we have come in terms of our commitment towards a more just and compassionate animal food system two important questions remain:

- a. How should we address diffusion of moral responsibility, procrastination and bystanding in the food system, that is, the problem of moral denial?
- b. How should we respond to our current philosophy of technology? That is, how should we explore the epistemological and framing assumptions behind the relationship between ethics and technology in order to provide a just and humane policy response to technology's opportunities and challenges?

Key Words: Bioethics, Animal Ethics, Food Animal Welfare

257 Bridging the DVM and PhD Gap. P. Ruegg*, *University of Wisconsin, Madison.*

The objective of this paper is to discuss similarities and differences in attitudes about animal use between veterinarians and animal scientists. There is a shrinking pool of professionals that serve animal agriculture and their domains are increasingly overlapping. The interests of students that select careers as food animal veterinarians tend to be different from students that focus on research careers. While there are few differences in personality characteristics, students interested in becoming veterinarians tend to be more interested in clinical activities associated with individual animals and less interested in research. These differences can translate into significant differences in interpretation of welfare criteria and may create tension when evaluating animal well-being or research usage. Important welfare issues vary by species but overall attitudes of veterinarians and animal scientists tend to be fairly consistent when evaluating philosophical concepts. However, academic veterinarians seem to indicate that they are more concerned about welfare aspects of many common agricultural practices as compared to faculty in animal science departments. Many practicing veterinarians are uncomfortable discussing animal welfare issues with their clients because of perceived lack of interest or negative economic impact. The official welfare statement of the American Association of Bovine Practitioners states: "Bovine veterinarians are expected to simultaneously represent the individual and herd welfare, the economic and production interests of producers and consumer concerns." The tension produced by this statement is lived everyday by veterinarians and is probably not well appreciated by animal scientists. The American Association of Bovine Practitioners' statement on tail docking is representative of this tension as it minimizes a coherent body of existing research in favor of perceived client preferences. In general, increased communication and respect along with enhanced cooperative activities related to training of future food animal veterinarians & animal scientists should be pursued in order to fully optimize both professions and ultimately animal well-being.

Key Words: Bioethics, Animal Welfare, Animal Use

258 How to talk truthfully with the public regarding bioethical and animal welfare issues. W. Jamison*, *University of Florida, Gainesville.*

Agriculturalists should be truth-tellers who overcome the incongruence between the reality of animal production/processing and the perception of animals and their role in society. Conversely, many successes of animal protection groups derive from their prowess in illuminating this gap. Market capitalism and economic rationalism force animal producers to maximize economies and minimize costs in order to maintain competitive advantages, while consumers increasingly view animals as idealized repositories of human values. This creates centrifugal forces within animal agriculture, which must maximize production efficiencies while withdrawing images of production and processing that would cause cognitive dissonance among consumers. This 'legitimacy gap' is unsustainable, and therefore leaders in animal agriculture should use two-way symmetry to communicate the reality of modern animal production and processing.

Key Words: Incongruence, Bioethics, Alignment

259 Roles of surveys and foundation reports in policy decisions. F. B. Norwood* and J. L. Lusk, *Oklahoma State University, Stillwater*.

Farm animal welfare policy emerges from a complex mix of industry interests, interest group pressure, and consumer concerns. To some extent, the interests of industry and interest groups represent consumer concerns, but in other cases do not. This research discusses how industry

and interest group foundation reports and consumer surveys influence policy and set the tone for farm animal welfare debates.

The paper will discuss consumer survey results that have important implications for farm animal welfare policy, and how the results are used and misused by different industry and livestock groups.

Symposium: Breeding and Genetics: Genome Wide Selection

260 Genome wide selection: Potential and pitfalls. B. Hayes* and M. Goddard, *University of Melbourne, Attwood, Victoria, Australia.*

Genomic selection exploits dense marker information to calculate genomic breeding values (GEBV) as the sum of the effects of all quantitative trait loci (QTL) across the genome, thereby potentially exploiting all the genetic variance for a trait. The QTL effects, either inferred from haplotypes or individual single nucleotide polymorphism (SNP) markers, are first estimated in a large reference population with phenotypic information. In subsequent generations, only marker information is required to calculate GEBV. Computer simulation suggested that accuracies of GEBV calculated for animals with marker information only could be as high as 0.85. Results from analysis of real data from the Australian Holstein Friesian population suggest that to achieve this level of accuracy, particularly for young animals with no performance records, a number of challenges must be met. In order for single SNP or haplotype effects used in calculating the GEBV to persist across the population and across generations, the SNP or haplotypes must be in high linkage disequilibrium (LD) with the QTL. This requires adequate marker density and methods for estimating QTL effects which distinguish between contributions from LD as opposed to pedigree tracing or linkage. Another challenge is recent reports in both livestock and human whole genome association studies suggest even the largest QTL effects on some traits may only account for 1-2% of the phenotypic variance. The implications of such a distribution of QTL effects is that a large number animals will be required in the reference population. Finally, ensuring long term genetic gain with genomic selection will be challenging. Particularly if the marker density is not high enough to ensure all QTL are captured, long term gain from genomic selection may be less than from a traditional BLUP based breeding. One solution to this problem is to include a polygenic component in the GEBV. Breeding programs based on genomic selection do however offer the prospect of reducing the rate of inbreeding, as greater emphasis will be placed on individual selection as opposed to family selection, particularly for traits of low heritability.

Key Words: Genome Wide Selection, Genomic Breeding Values, GEBV Reliability

261 Reliability of genomic predictions for North American dairy bulls. P. M. VanRaden*¹, C. P. Van Tassell^{1,2}, G. R. Wiggans¹, T. S. Sonstegard², R. D. Schnabel³, and F. Schenkel⁴, ¹*USDA Animal Improvement Programs Laboratory, Beltsville, MD*, ²*Bovine Functional Genomics Laboratory, Beltsville, MD*, ³*University of Missouri, Columbia*, ⁴*University of Guelph, Guelph, ON Canada.*

Genetic progress will increase when breeders examine genotypes instead of only pedigrees and phenotypes. Genotypes for 39,835 markers and August 2003 genetic evaluations for 2609 Holstein bulls born before 1998 were used to predict January 2008 daughter deviations for 510 bulls born 2001-2. Genotypes were from the Illumina Bovine SNP50™ chip and semen contributed by U.S. and Canadian AI organizations to the Cooperative Dairy DNA Repository. Genomic predictions for 5 yield traits, 5 fitness traits, 16 conformation traits, and net merit were computed by a linear model with an assumed normal distribution for marker effects and also a nonlinear model with a heavier tailed prior to account for major genes. The official parent average from 2003 and a 2003 parent average computed from only the subset of genotyped

ancestors were combined with the genomic predictions by selection index. The combined predictions were significantly ($P < .0001$) more accurate than official parent averages for all 27 traits. Squared correlations were 0.03 to 0.22 higher with linear genomic predictions included than those from parent average alone. Nonlinear genomic predictions had R-square similar to linear except for a few traits such as fat percentage, with maximum additional increase of 0.08. Squared correlations were converted to realized reliabilities by dividing by the average reliability of 2008 daughter deviations and by adding the difference between published and observed reliabilities of the 2003 parent averages. When averaged across all traits, combined genomic predictions had realized reliabilities 18% higher than reliabilities of parent average (48% vs. 30%), and gains in information were equivalent to 9 daughter records. Reliability increased more by doubling the number of bulls genotyped than the number of markers genotyped. Genomic selection can decrease generation interval and greatly increase accuracy by tracing the inheritance of minor genes.

Key Words: Genotype, Genomic Selection, Marker Assisted Selection

262 Data optimization techniques for large phenotypic and molecular data sets. R. Rekaya*, *University of Georgia, Athens.*

Recent advances in high throughput technologies have lead to the generation of massive amounts of genomic/molecular data in addition to the already extensive phenotypic recording. Over the years several creative statistical and computational optimization techniques have been developed to successfully analyze phenotypic data; achieving some success in the area of quantitative genomics. However, for the ultimate objective of marker assisted or genomic selection to be realized, serious challenges must still be met in order to optimally combine these two sources of information. The complexity of this task stems in part from the huge imbalance of genomic and phenotypic information in selection candidates. In fact, genomic information, although extensive at an individual level, is only available on a small number of animals. By contrast, the phenotypic information is limited at the individual level, but it is extensively recorded on a large number of animals. This situation creates two major problems: 1) an NxP problem in which the number of parameters to be estimated is far greater than the degrees of freedom available to estimate them and 2) inferring the genotypes of untyped individuals and the selective sampling of animals to be genotyped. Theoretically both problems are simple to solve; however, they are computationally intractable. Consequently, some dimension reduction techniques and/or feature selection procedures need to be developed and implemented prior to analysis. In this study a machine learning procedure, often implemented to select optimal subsets of features, was developed to deal with both problems. Ant colony algorithm (ACA) was developed to efficiently search large sample spaces for optimal solutions, making it ideal for applications on high dimension data sets. This algorithm is based on the natural process of communication between real ants, and utilizes simple units to perform complex tasks. When used in applications to disease diagnosis, features identified by ACA yielded increases in prediction accuracy from 13.94 to 43.97% over filter methods. For optimal genotyping strategies, ACA yielded at least 5% superiority compared to any other method.

Key Words: Ant Colony, Feature Selection

263 The next steps in genomic selection: An industry perspective.

J. P. Chesnais*¹, F. Schenkel², and N. Caron¹, ¹*Semex Alliance, Guelph, ON, Canada*, ²*University of Guelph, Guelph, ON, Canada*.

Recent results from genomic selection projects indicate that significant increases in the accuracy of evaluation of young dairy animals can be obtained by combining genomic data from high-throughput SNP panels with traditional pedigree data. In a recent project based on a 50K SNP panel, the reliability of prediction increased by an average of 18 points over parent average across all traits. As expected, the increase is proportionally larger for traits with low heritability such as fertility or longevity. These results are still far from those of several simulation studies. In theory, the proportion of genetic variance explained by the SNP markers does not have to be very high to justify moving from a traditional progeny-testing scheme to one where animals are selected at a younger age based on their SNP genotype. The ensuing reduction in the generation interval more than compensates for the decrease in selection accuracy. In practice, however, dairy producers are accustomed to proven

bull reliabilities that are significantly higher than those currently obtained with genomic selection. Dairy cattle breeding companies are therefore likely to first use genomic selection to pre-select bull dams and young bulls rather than as a replacement for organized progeny testing. Over time, as the number of genotyped animals and SNP density increase, and methods of data analysis are refined, reliability may improve. An increasing number of young genotyped bulls will then be used as sires of sons and to commercially breed cows. The use of genomic selection is not necessarily synonymous with an increase in homozygosity. First, large SNP panels can be used to provide better estimates of homozygosity than current measures of inbreeding. Second, genomic selection may lead to the selection of more genetically diverse candidates than BLUP selection based only on phenotypes. Finally, the use of optimum genetic contribution methods may become more common among breeding companies, which would prevent the selection of only very few animals with top genomic breeding values as parents of future generations.

Symposium: Food Safety: Assuring Food Safety in a Globalized Market

264 Quality and safety concerns of outsourced foods. M. W. Griffiths*, *University of Guelph, Guelph, ON, Canada.*

The increased global trade in food commodities and ingredients requires a rethink in the way we approach ensuring the safety of these materials. Recent incidents involving feed ingredients produced in China and contaminated with melamine have triggered changes in the attitude of the U.S.A and Canada towards imported foods and have prompted both countries to propose new guidelines and legislation to address consumer concerns. The industry, in conjunction with Codex Alimentarius, also have proposed a new global standard, the ISO 22000 standard for managing food safety in processing plants; with the intent to make it easier for companies worldwide to implement the Codex HACCP system. This standard has been adopted by many companies, including Wal-Mart. Despite these initiatives, a movement has developed to promote locally grown food and this has been supported by the publication of books such as "The 100 Mile Diet" and "In Defense of Food". As well as involving safety and quality issues, eating local food is perceived to be more environmentally friendly. However, as climate changes affect agricultural production we shall be increasingly reliant on global markets which makes it even more important that the safety and quality of imported and exported foods are beyond reproach.

Key Words: Food Safety, Imported Foods, Control

265 Melamine contaminated animal feed recalls. M. G. Alewnse*, *U.S. Food and Drug Administration.*

Menu Pet Foods notified FDA on March 16, 2007 of a pending recall due to adverse events reported to the firm. Menu suspected wheat gluten was linked to the problem. Within 24 hours of the company's notification, FDA investigators were at the company's manufacturing sites. Investigators were sent to all involved pet food/ feed manufacturers and to many retailers. In addition, FDA monitored the effectiveness of the recalls. In late March, scientists discovered that the contaminant in the wheat gluten was melamine and related analogs. Later, melamine was also detected in rice protein concentrate. Melamine is an unapproved food additive causing animal foods that contain it to be adulterated. Adding to the complexity of FDA's investigation of the reported adverse events was that melamine by itself is not very toxic, but can cause some damage to the renal system in laboratory animals. By April, there was a strong association between melamine in the kidneys of cats and the contaminated pet foods. The likely toxicological mechanism is that melamine and its analogs are concentrated in the renal filtrate where melamine combines with one of its analogs (cyanuric acid) resulting in crystal formation in, and damage to, the renal tubule. Food producing animals were also exposed to melamine through pet food scraps, but at much lower levels. FDA laboratory specialists screened hundreds of samples of pet food and animal feed for melamine and its analogs. In late April, FDA issued an import alert that required the detention of 11 different vegetable protein supplement products from China. From March to May, FDA received more than 18,000 consumer calls. Protecting the safety of feed and food is becoming more difficult, as the melamine recalls demonstrated that an action taken by only a few protein supplement firms in China could create a nationwide problem. The Menu recall alone involved 60 million packages of pet food from approximately

100 companies. The contaminated rice protein concentrate necessitated the recall of 155 metric tons of pet food. Eventually, a total of 1,051 melamine-related product recalls were conducted.

Key Words: Melamine, Recalls, Feed Safety

266 FDA's food protection plan and import safety plan. S. A. Benz*, *Center for Veterinary Medicine, Food and Drug Administration, Rockville, MD.*

As global trade expands and the food and feed chain become more complex, protecting the safety of feed and food is becoming increasingly difficult. The contamination of pet food with melamine in 2007 demonstrated the impact that a few companies can have on the animal feed supply. An intergovernmental task force suggested strategies to improve import product safety that focus on prevention, intervention, and response. For prevention, the government must work with companies to build safety into the manufacturing and distribution processes to prevent harm. If a problem does occur, intervention needs to involve not only the FDA but state and local authorities and foreign governments. The response to an identified problem must be quick and effective to limit any further exposure to humans and animals to prevent additional harm. FDA has an ongoing effort to write process control regulations for animal feed manufacturers that will cover the procurement, receipt, manufacture, and distribution of all animal feed including pet food. Traceability of distributed feed is an important component of the process when an unsafe feed must be located and recalled, diverted, or destroyed.

Key Words: Food Safety, FDA, Imported Feed

267 The global threat of foreign animal diseases and their role in food safety. T. McKenna*¹ and A. Torres², ¹*Wisconsin Veterinary Diagnostic Laboratory, Madison, WI,* ²*Cornell University, Ithaca, NY.*

The term foreign animal diseases refers to a large number of known animal diseases, or new emerging animal diseases that are not present in our country. Many of these diseases have never been found in the US, while many others were eliminated from our nation after long and expensive eradication campaigns.

Globalization has resulted in increased travel and trade at an unprecedented rate. Animals and animal products are traded legally and illegally around the world at increasingly higher numbers and at a faster and faster pace. There are many reasons for the recent increase in frequency and severity of serious animal disease outbreaks: animal industry consolidation; increased density of animals per production unit; decreasing animal genetic variability; mixing of species; environmental degradation; and livestock-wildlife habitat encroachment. Many of these outbreaks have serious public health consequences.

This paper highlights a number of foreign animal diseases that pose a significant threat to human food safety. The most notable recent examples are the emergence of Bovine Spongiform Encephalopathy; of highly pathogenic avian influenza, particularly the Asian H5N1 strain; and of Rift Valley Fever. The increasing human consumption of bush meat harvested from sick or dead wildlife in many parts of the world

has resulted in a food safety crisis leading to outbreaks of anthrax, Ebola and other hemorrhagic diseases.

Key Words: Foreign Animal Diseases, Food Safety

268 BSE: Risk communication lessons learned in North America.

R. R. Ulmer*¹, W. D. Hueston², and A. Millner¹, ¹*University of Arkansas, Little Rock*, ²*University of Minnesota, St. Paul*.

The discovery of BSE in North America (Canada and later the US) presented the most powerful lesson in animal health risk communications seen in our lifetimes. From the initial Canadian case of BSE in 1993 in a cow imported from the United Kingdom through the identification of the first indigenous North American case in 2003 and the later “atypical” BSE cases, important lessons continue to be learned and risk communications strategies improved. The seminal lessons are:

1. Everyone eats, therefore food supply issues that involve diseases that affect both animal and human health, like BSE, will garner tremendous media attention for extended periods of time.

2. Making government officials readily accessible to media early and often decreases media skepticism and increases the dissemination of accurate information to the widest possible audience.

3. Multiple “publics” exist and different publics want and need different information, therefore no single set of messages and no single delivery format can ever address everyone’s needs.

4. Planning and practice are critical to successful risk communication strategies and plans must be regularly revised.

5. Outbreaks of disease in other countries offer the opportunity for “vicarious rehearsal” and improvement of risk communications plans

6. Acknowledging what is not known and what is being done to address those remaining questions is as important as sharing what is known.

7. “Never say never” – the progression of disease outbreaks can not be predicted with any certainty and the natural tendency of animal health officials and politicians to share a positive perspective on prevention and control activities will almost always underestimate the number of cases thereby creating mistrust.

8. New science will appear, therefore response strategies and answers to questions may change during the period of media interest. Preparing the media, and hence the public, for these changes will increase credibility of the government and industry officials.

Symposium: Forages and Pastures: Forage-Based Systems for Beef and Dairy Cattle Production: Regional Challenges and Opportunities

269 Northeast opportunities and challenges for forage-based beef and dairy production. K. J. Soder*, *USDA-ARS, Pasture Systems & Watershed Mgmt. Research Unit, University Park, PA.*

Forage-based livestock systems generate nearly two-thirds of current agricultural income in the northeastern U.S. Much of the agricultural land in this region is best suited for forage production due to soil, site, and climatic limitations for other agricultural practices. Many opportunities exist to promote forage-based dairy and beef systems. Research has shown that grazing systems require less grain and fuel inputs than those relying heavily on cropping and confinement feeding systems. Potential exists to utilize abandoned land for grazing enterprises which may present a low-cost option to lease or buy this land while maintaining a 'greenscape' desired by the general populace. The Northeast is situated among several high-population areas that are becoming more aware of food origin and are willing to pay more for actual or perceived benefits from locally- and forage-produced food. Specialty and direct markets exist in the Northeast, some growing at a rate of 20-40%/yr, including organic production, community-supported agriculture (CSA) and farmers markets where locally-produced products are marketed directly to the consumer. While opportunities are plentiful, there are also formidable challenges to Northeast agriculture. Even though abandoned land may be available for grazing, this land is often in very small parcels and surrounded by urban development. Urban pressure challenges animal agriculture, including inflated land prices, animal welfare/rights issues, and non-farm public concerns with inputs, nutrient management, and odors associated with farming practices. Lack of custom processing facilities is causing a bottleneck in the direct market trade, particularly for beef operations. Current consumer economic trends may be a concern if disposable income decreases, as the ability or desire to purchase value-added products may decrease. Sustainability of agriculture in the Northeast depends on keeping forage-based livestock systems competitive and profitable while protecting the environment. Final thoughts will include potential future directions for research and management improvements.

Key Words: Challenges, Forage-Based, Northeast

270 Forage-based systems for the Upper Midwest. W. K. Coblenz*, *US Dairy Forage Research Center, Marshfield, WI.*

Recently, the dynamics of agricultural production have changed, particularly as prices for cash-grain crops, such as corn (*Zea Mays* L.) increase with demand for ethanol production. Other changes likely will be needed to meet increasing public demands for environmentally responsible nutrient management, as well as expanding markets for grazing-based and/or organically produced milk and meat products. Our objectives are to discuss how these external pressures may affect forage systems throughout the region, and identify potential focus areas for future forage research. Excepting corn silage, potential focus areas for research can be divided into five areas: i) improving alfalfa (*Medicago sativa* L.) and other legumes; ii) improving grazing systems; iii) unique forage needs of specific livestock classes; iv) harvest and storage of forage crops; and v) strategies for improved nutrient management.

Within each of these broad areas, it is possible to identify specific needs that are both traditional, as well as new and unique. For alfalfa, new research may evaluate alfalfa varieties or management schemes that permit less-frequent harvests, harvest by plant part for multiple end uses (livestock and energy), improved grazing tolerance, and reduced proteolysis during silage fermentation. Grazing initiatives may include assessment of long-term health benefits of grazing, supplementation strategies for grazing dairy cows, strategies to supply adequate forage during the summer slump or gap, and forage options that extend the grazing season. Continued research will be required to assess proper agronomic management of low-cation grass forages for nonlactating dry cows, as well as viable low-energy forages to dilute replacement-heifer diets comprised primarily of corn silage or by-products of ethanol production. Finally, improving nutrient management will require increased opportunities for summer spreading, as well as evaluation of new application methods engineered to reduce volatilization and runoff. Addressing changing forage research needs will require creativity and diligence by scientists, but such efforts are essential for the long-term stability of the dairy and beef industries.

Key Words: Forage Systems

271 Opportunities and obstacles for forage-based dairy and beef production in the Southeastern U.S. J. Andrae*, *Clemson University, Clemson, SC.*

Increasing feed, fuel and fertilizer costs are pressuring dairy, cow-calf, and stocker producers to manage forages more efficiently. High rainfall and moderate winters in the southeastern U.S. are perhaps the regions biggest competitive advantage. These provide a long growing season with minimal stored feed requirements. High quality, productive forage species like novel endophyte-infected tall fescue and winter annuals are widely grown. Summer conditions are favorable for subtropical legumes and grasses which can support moderate animal performance with minimal input costs. The availability of dependable and relatively inexpensive irrigation in some areas has fueled recent foreign investments in grazing dairies. Regional metropolitan areas also provide direct marketing opportunities for both milk and meat products. Forage-based beef and dairy production also face several obstacles in the southeast. Acidic soils often limit legume production. The lack of a persistent, perennial cool season grass species for the Coastal Plain increases reliance on annual grasses and creates a severe forage gap from late October through December. Much of the forage produced across the region is inefficiently utilized due to a widespread ignorance of grazing management practices. However, the largest impediment to southeastern forage-based operations is a producer resistance to accept risk or modify traditional management practices. Most prior forage research in this region has focused upon the extensive management of traditional species. Integrated system-wide grazing research is needed to explore multiple forage species under intensively managed dryland and irrigated scenarios. The development and improved management of high quality complimentary forages (both grasses and legumes) could further extend the grazing season, minimize nitrogen inputs, decrease risk, and improve profitability of stocker and dairy operations in the southeastern U.S.

Economic and environmental impacts of these management practices also warrant investigation.

Key Words: Grazing, Forage, Southeast

272 Forage-based systems for beef and dairy cattle production: Challenges and opportunities in the South Central region. W. A. Phillips*¹, G. W. Horn², and B. K. Northup¹, ¹*USDA-ARS Grazinglands Research Laboratory, El Reno, OK*, ²*Oklahoma Agricultural Experiment Station, Stillwater, OK*.

The states of Kansas, Oklahoma, Texas, Missouri, Arkansas and Louisiana comprise the South Central Region (SCR) and contain 106 million ha of agricultural land, with roughly equal halves under crop and forage production. The region is also home to 33 million beef cows and calves and 0.7 million dairy cows. The SCR is a mosaic of eco-regions varying from sub-tropic to temperate and humid to dry domains, supporting a diverse range of plant communities. In the future, forage-based production systems in the SCR will have to compete with cropping enterprises for land, water and inorganic N, and utilize perennial forages more than annual species. Further, the region's most productive agricultural land will see increased use for grain production, to meet the increasing demands for ethanol as bio-fuel. Therefore, forage-based beef- and dairy-production systems will have to use marginal lands and employ limited amounts of expensive inorganic N. Forage-based systems have the potential to play important roles in agricultural production in the SCR. Opportunities for improving production in forage-based systems exist in utilizing bio-fuel byproducts as a feedstock, incorporating legumes as a renewable N source, extending the grazing season with combinations of cool- and warm-season swards, developing drought tolerant cultivars, increasing forage yields per unit of fossil fuel input, integrating management strategies to maximize revenue for sequestering carbon, and applying precision agricultural tools to production systems.

Key Words: Forages, Pasture, Grazing

273 Forage-based systems for beef production: Western regional challenges and opportunities. K. C. Olson*¹ and B. L. Waldron², ¹*South Dakota State University, Rapid City*, ²*USDA-ARS Forage and Range Research Laboratory, Logan, UT*.

There are two divergent forage-based production systems in the western U.S. based on land type and ownership. The first system is based on native rangeland. Much of this is public land but some is privately owned. The other system is based on tame pastures on privately-owned land, much of which is irrigated. These two land types lend themselves to extensive vs. intensive management systems, respectively. Public rangelands are managed based on multiple use, meaning that livestock grazing is only one of many uses and services this land must provide. Thus, management of the land and the forage base is not limited just to livestock production. These rangelands are spatially and temporally diverse. This lends grazing management to seasonal patterns of use based on the suitability of the forage as a nutrient resource. The most typical seasonal-suitability grazing pattern is based on the elevation gradient in the mountain west wherein cattle forage at lowest elevations (valley floors) in winter, middle elevations (foothills) in spring and fall, and upper elevations (mountains) in summer. This allows livestock to graze when forage nutritional value and vegetation tolerance of grazing are both high. Challenges to these systems include invasion by noxious, weedy species of limited or no forage value. Research opportunities include developing alternative forage species that not only contribute forage to overcome bottlenecks in seasonal suitability grazing, but also provide other ecological uses and services. On intensive-managed irrigated-pasture systems, forage productivity and nutrient density may exceed the requirements of a typical cow-calf enterprise. Opportunities exist to develop pasture-based growing and finishing systems that may focus on producing beef for natural and organic niche markets. An array of research questions need to be answered for these novel systems, including pasture, nutritional, breeding, and reproductive management, as well as production alternatives such as calving and weaning dates. Alternatives should be evaluated in a systems approach to ascertain overall system response and not just response of the specific alternative.

Growth and Development: Historical Perspective and Future Direction

274 ASAS Centennial Presentation: The history of growth biology research - A reflection on the episodic nature of science. T. Etherton*, *Penn State University, University Park.*

Evans and co-workers were the first to demonstrate the presence of a substance in the anterior pituitary that increased the growth rate of rats in the 1920's. Subsequent research established the active compound was growth hormone (somatotropin; ST). In the ensuing 80 years much has been learned about the endocrine system and how it regulates animal growth, and nutrient partitioning. Products of biotechnology, such as growth hormone and beta-agonists, have been developed and approved for commercial application. A "reflection over the past eight decades of research is telling. In the early days of recombinant DNA technology (late 1970's), numerous hypotheses could be tested that were not feasible with purified pituitary preparations of ST. Recombinant bovine ST (rbST) was approved for use by the FDA in 1993, with great excitement in the scientific community. A contemporary reflection on research is revealing. We have developed numerous and wondrous scientific breakthroughs, and the ability to manufacture recombinant proteins in large scale. Yet, the agricultural scientific community has not been actively involved in the "public discussion" about the need for and benefits of "biotechnology in the barnyard". Activist groups have attacked science and the application of science. A recent "episode" that illustrates this is the attack on rbST use in the dairy industry. The point of their misguided attacks being that rbST is a risk to consumers! We are standing at a point in time where the next pulse is not associated with the secretory profile of a circulating hormone, but rather a concerted "push" by the academic community to defend science and the freedom to use products of science.

Key Words: Growth Biology, Endocrine Regulation, Somatotropin

275 ASAS Centennial Presentation: Future needs and directions in animal growth and development research. M. A. Mirando*, *Cooperative State Research, Education, and Extension Service, United States Department of Agriculture, Washington, DC.*

As the 21st century progresses, the increased rate of societal, economic and environmental changes occurring at the global, national, regional and local levels will significantly impact animal agriculture and require even greater commitment to research to solve new problems that arise. Research in the area of animal growth and development, in particular, can yield solutions to many of those problems. A variety of needs and approaches will dictate future directions in animal growth and development research. Changes in land use and global climate will provide additional impetus for greater environmental stewardship, reduced nitrogen output and decreased carbon footprint of generating animal products. Research will continue to focus on increasing production efficiency, thereby reducing input of resources, while continuing to improve quality of animal products. Areas of research emphasis will include, but not be limited to, studying mechanisms regulating muscle growth, adiposity and marbling of meat, fetal programming of postnatal growth and development, and removal or replacement of dietary antimicrobial growth promotants. Future studies will take advantage of genome

sequences that have been or will be obtained for agricultural animals, and research will include transcriptional profiling and proteomic approaches. However, although the latter approaches are incredibly powerful, they only yield information on which genes are involved but not how those genes products act or are utilized in cellular or tissue responses. Thus, research will continue to include biochemical and physiological studies to elucidate specific actions and functions of individual gene products, as well as their roles in metabolic and signaling pathways. Finally, there will be continued need for a balance between basic and applied research. Because the private sector, including commodity groups, funds primarily applied research, the fundamental discoveries that lay the groundwork for future applied research will need to be supported by Federal funding sources.

Key Words: Development, Growth, Research

276 The role of microRNA on murine mammary epithelial cell and mammary gland. Q. Z. Li* and C. M. Wang, *Northeast Agricultural University, Harbin, Heilongjiang, China.*

MicroRNAs (miRNAs) are encoded small RNAs that hybridize with messenger RNAs, resulting in degradation or translational inhibition of targeted transcripts. The potential for miRNAs to regulate cell proliferation or differentiation from murine mammary epithelial cell or mammary gland is unknown, and the mechanism of miRNA on mammary development is also not clear. We used microarrays and qRT-PCR to evaluate miRNA expression in mammary tissue during development and functional states of the murine mammary gland. Physiological stages evaluated were that miRNAs was differentially expressed the different developmental stages of the mouse mammary gland. Bioinformatic programs were used to predict targets for miRNA that were identified as significant features of differential expression during developmental and functional cycles of the mammary gland. Antagomirs were used to assess the function and targets of miR-138, miR-292-5p and let-7g in vivo and in vitro. Stage-specific expression patterns on miRNA were evident. miRNAs such as miR-138 and miR-431 were downregulated ($P < 0.05$) some miRNAs such as miR-133, miR-133a, miR133b were upregulated ($P < 0.05$) during pregnancy and lactation compared with expression during mammary involution or expression tissue from virgin mice. It also displays that Prolactin-receptor, STAT5 protein, MAPK protein were up-regulated after treatment with miR-138 antagomir ($P < 0.05$), and PKC protein was (spell out up or down)-regulated by antagomirs for miRNA-292-5p and let-7g ($P < 0.05$). Treatment with antagomirs demonstrated that miR-138 inhibited viable and proliferation of mouse mammary epithelial cells ($P < 0.01$). Venous injections of antagomir for miR-138 into mice on the second day of lactation increased milk production at 12 h followed by a decrease at 48 h ($P < 0.01$). Finally, assembling miRNA networks helped to predict miRNA targets. In conclusion, we demonstrated that different networks of miRNA are expressed during development, lactation and involution of the mouse mammary gland, and that these miRNAs play important roles during these physiological states.

Key Words: MicroRNA, Mammary Pregnancy Cycle, Target

277 Effect of AMP-activated protein kinase (AMPK) and insulin-like growth factor-1 (IGF-1) on expression of muscle-specific ubiquitin ligases in C2C12 myotubes. J. F. Tong*, K. R. Underwood, X. Yan, M. J. Zhu, and M. Du, *University of Wyoming, Laramie.*

INTRODUCTION: AMP-activated protein kinase (AMPK) is a key cellular energy sensor. A mutation in AMPK leads to Rendement napole (RN) phenotype in pigs characterized by superior lean growth. AMPK regulates protein synthesis in skeletal muscle, but its role on myofibrillar protein degradation is unclear. Two newly identified muscle-specific ubiquitin ligases (UL), MAFbx and MuRF1, are crucial for myofibrillar protein breakdown. The insulin-like growth factor-1 (IGF-1) pathway induces muscle hypertrophy in part through inhibition of MAFbx and MuRF1 expression, mediated by protein kinase B (PKB). C2C12 myotubes are commonly used for studying skeletal muscle growth. **HYPOTHESIS:** AMPK interacts with IGF-1 to control the expression of UL in C2C12 myotubes. **METHODS:** C2C12 cells were incubated in DMEM medium with 10% fetal bovine serum. Fusion was induced by 2% horse serum. Myotubes were treated with 5-Aminoimidazole-4-carboxamide-1- β -D-ribo nucleoside (AICAR, 0, 0.1, 0.3 and 1 mM), and/or IGF-1 (100 ng/ml). After 4, 12 and 24 h treatments, myotubes were collected for real-time PCR and immunoblotting analyses. Four independent experiments were conducted (n=4). **RESULTS:** Activation of AMPK by AICAR, a specific AMPK activator, increased MAFbx and MuRF1 mRNA expression, accompanied by an increase in their protein levels. As expected, IGF-1 activated PKB and reduced the expression of UL ($P < 0.01$). Intriguingly, activation of AMPK synergized IGF-1-induced PKB activation; however, the expression of UL was not attenuated, but strengthened by AMPK activation. These data indicate that a PKB independent mechanism exists through which AMPK induces the expression of UL, surpassing the inhibitory effect of IGF-1/PKB pathway on UL expression. In addition to regulating IGF-1/PKB signaling pathway and protein synthesis in muscle cells, AMPK also mediates protein degradation through enhancing the expression of UL. These data indicate that AMPK may be an important molecular target for enhancing lean growth in livestock.

Key Words: Skeletal Muscle, AMPK, Degradation

278 Metabolic gene networks in longissimus muscle of early-weaned Angus and Angus \times Simmental steers fed high-grain or high-byproduct diets during the growing phase. D. E. Graunard*, P. Piantoni, M. Bionaz, L. L. Berger, D. B. Faulkner, and J. J. Loor, *University of Illinois, Urbana.*

mRNA abundance and expression profiles of lipogenic and intracellular energy metabolism gene networks were evaluated via quantitative PCR in longissimus muscle (LM) of early-weaned (~142 d age) Angus (n = 3/diet) and Angus \times Simmental steers (AxS; n = 3/diet) fed a high-grain (HiE) or high-byproduct (HiF) diet for 112 d. LM biopsies were collected at 0, 56, and 112 d of feeding. We evaluated 32 genes associated with lipogenesis (e.g., *G6PD*, *ACACA*, *FASN*), intracellular FA activation (*ACSL1*), esterification (*GPAM*, *DGAT1*, *DGAT2*), desaturation (*SCD*, *FADS2*), intracellular energy metabolism (AMPK subunits, *PRKAA1* and *PRKAA2*), TCA-cycle (*MDH2*), mitochondrial biogenesis (*PPARGC1A*), nuclear receptor signaling (*PPARG*, *PPARD*), transcriptional regulation of lipogenesis (*SREBF1*, *THRSP*, *INSIG1*),

as well as insulin-regulated glucose transport (*GLUT4*) and signaling (*INSR*, *IRS1*). *MDH2*, *SCD*, *GLUT4*, *IRS1*, *ACSL1*, *FASN*, and *PRKAA2* had the greatest relative mRNA abundance averaging 26, 16.5, 7.9, 6.9, 5.4, 5.3, and 4.8%, respectively, of total genes measured. Among those, there was a diet \times steer type \times time ($P < 0.05$) effect for *PRKAA2* whose expression was 2-fold greater in AxS steers namely on d 56. A similar response was observed for *THRSP* in AxS steers fed HiE during the first 56 d (~60-fold greater mRNA relative to d 0). A diet \times steer type effect was found for *SREBF1*, *PPARG*, and *PPARGC1A*, with HiE inducing greater expression in Angus and HiF in AxS steers. Angus steers had greater ($P < 0.05$) expression of lipogenic genes (*ACACA*, *FASN*, *G6PD*, *GLUT4*, *SREBF1*), which might have been associated with numerically greater marbling score (4.49 vs. 4.16, $P = 0.20$) during the 112 d feeding period. Feeding HiE resulted in greater ($P = 0.05$) *IRS1*, *PPARGC1A*, and *ACSL1*, as well as a tendency ($P < 0.15$) for greater *SREBF1*, *THRSP*, and *GLUT4*. Results indicate that lipogenic and intracellular energy metabolism gene networks have different temporal expression patterns in crossbred vs. purebred steers. Further, these patterns could be altered by level of dietary energy during the rapid-growth phase.

279 Enhanced skeletal muscle protein synthesis rates in pigs treated with somatotropin requires fed amino acids levels. F. A. Wilson*, A. Suryawan, R. A. Orellana, H. V. Nguyen, A. S. Jeyapalan, M. C. Gazzaneo, and T. A. Davis, *Baylor College of Medicine, Houston, TX.*

Chronic somatotropin (pST) treatment in pigs increases skeletal muscle protein synthesis and circulating insulin, a known promoter of protein synthesis. Previously, we showed that the pST-mediated rise in insulin alone could not account for the pST-induced increase in protein synthesis. This study aimed to determine whether the pST-induced increase in insulin promotes skeletal muscle protein synthesis when amino acids are not limiting and are provided at fed levels, and whether the response is associated with enhanced translation initiation factor activation. Growing pigs were treated with pST (180 μ g/kg/day, n=18) or saline (n=18) for 7 days, then pancreatic-glucose-amino acid clamps were performed to obtain plasma insulin levels equivalent to fasted or fed-pST treated pigs. Amino acids were raised to fed levels at both fasted and fed insulin concentrations; glucose was maintained at fasting levels throughout. Treatment with pST decreased plasma urea nitrogen and increased insulin-like growth factor⁻¹ levels ($P < 0.001$), confirming effectiveness of treatment. Skeletal muscle protein synthesis was increased by pST treatment and by insulin and/or amino acid infusion ($P < 0.001$). When amino acids were raised to fed levels, in the presence or absence of fed insulin concentrations, muscle protein synthesis rates were higher in pigs treated with pST than saline ($P < 0.02$). Fed amino acids, with or without raised insulin concentrations, increased the phosphorylation of S6K1 and 4EBP1, decreased the inactive 4EBP1•eIF4E complex association and increased active eIF4E•eIF4G complex formation ($P < 0.02$). However, treatment with pST did not alter translation initiation factor activation. We conclude that the pST-induced stimulation of muscle protein synthesis requires fed levels of amino acid, but this response is not mediated by mRNA binding to the ribosomal complex. (Supported by USDA NRI 2005-35206-15273).

280 Changes in the transcriptome of adipose tissue of the dairy heifer during late pregnancy and lactation as measured by gene array analysis: Global changes and cell control. J. Sumner*, C. Schachtschneider, and J. McNamara, *Washington State University, Pullman.*

Metabolic adaptations in adipose tissue are a critical part of establishment and maintenance of lactation in dairy cattle. Adipose tissue stores and releases energy and also secretes a number of metabolic regulators and cytokines. The objective was to obtain a more in-depth understanding of the transcriptomic adaptations in adipose tissue of Holstein heifers from 30 d prepartum to 14 DIM. Adipose tissue was obtained at 30 d prepartum and 14 DIM, extracted for RNA, and hybridized to the Affymetrix Genechip® Bovine Genome Array. There were 20 animals and of those 12 animals provided a quantity and quality of RNA for gene array analysis. Animals averaged 29.8 (SEM = 1.3 kg/d of milk for the first 60 DIM (range 18.6 to 44.8 kg/d). They lost 42.6 kg of BW (SEM 8.4, range +9.1 to -113.6) and 0.38 BCS units (SEM 0.10, range 0 to -1.0) from 0 to 14 DIM. Chip quality backgrounds averaged below 50 units, and 3/5 bias on control genes < 2.0. Correlations among replicates were > 0.85. Approximately 433 genes increased 100% or more, 3406 increased 25 to 100%; 1951 decreased 25 to 50 %, 337 decreased 75% or more. Genes expressed in greatest amounts (signal > 6000, average signal 125) included collagen, and ribosomal proteins, and FABP4. Lipoprotein lipase was expressed at 4261 (SEM 509), the most highly expressed gene regulating nutrient flux. Leptin receptor expressed at 734 (50) prepartum and fell 12 % at 14 DIM. Genes involved in cell synthesis, transcriptional control and inflammation increased 5-fold or more, including beta-defensin, 10-fold, cytokine inducible nuclear protein, 8-fold; chromosomal reading frame 4; 6-fold; sarcoplasmic Ca ATP-ase, 4-fold; leucine-rich repeat-containing 2, 3.5-fold; voltage-dependent calcium channel subunit, 3.5-fold. Bos taurus uncoupling protein 3 increased 3-fold, indicating possible proton uncoupling in white adipose tissue. These data provide some initial insight into the global transcriptomic response of adipose tissue to lactation.

Key Words: Lactation, Adipose, Transcriptome

281 Changes in the transcriptome of adipose tissue of the dairy heifer during late pregnancy and lactation as measured by gene array analysis: changes in specific metabolic control genes. J. Sumner*, C. Shachtschneider, J. Vierck, and J. McNamara, *Washington State University, Pullman.*

Metabolic adaptations in adipose tissue are a critical part of establishment and maintenance of lactation. Adipose tissue stores and releases energy and secretes a metabolic regulators and cytokines. Previous work determined that several enzymes and pathways are controlled gene transcription for enzyme synthesis, and hormonal and neurocrine regulation of enzyme activity. Our objective was to obtain a more in-depth understanding of the gene transcriptome changes underlying the adipose response to lactation. We tested the hypothesis that genes encoding for proteins regulating metabolism changed expression in adipose tissue of Holstein heifers from 30 d prepartum to 14 DIM. Adipose tissue biopsies were obtained, tissue extracted RNA, and hybridized to the Affymetrix Genechip® Bovine Genome Array. Animals averaged 29.8 (SEM = 1.3 kg/d of milk for the first 60 DIM (range 18.6 to 44.8 kg/d). They averaged 33.0 (1.6) kg/d for d 53-60 (range 25 to 46 kg/d). They lost 42.6 kg of BW (SEM 8.4, range +9.1 to -113.6) and 0.38 BCS units (SEM 0.10, range 0 to -1.0) from 0 to 14 DIM. Anabolic pathway genes decreased ($P < 0.05$), including (mean (% change), (SEM)): SREBP, -25.1, (6.2); GLUT1, -57.3 (14.1); THRSP14, -30.8 (7.4); LPL, -48.4 (7.7) and AcCoA Carboxylase, -60.6 (13.0). The regression of transcript change on milk production was 0.18 for AcCoA carb and 0.26 for ATP-CL ($P < 0.05$). Lipolytic control elements increased, with much variation among animals, including Ca channel subunit 338 % (203); B2AR 52.0 (8.8); PKC receptor 10.1 (2.6) and HSL mRNA 23.0 (17.9). The regression of transcript change on milk was 0.30 and 0.25 for B2AR and HSL mRNA. We now have a more complete picture of the adaptive mechanisms to lactation. Reductions in lipogenesis are primarily due to a systemic reduction in enzyme synthesis, while increases in lipolysis are a combination of increases in transcription and metabolic flux control through previously reported changes in hormonal and nervous system activity.

282 ASAS Centennial Presentation: Historical review and future outlook of equine reproductive technology. D. Sharp*, *University of Florida, Gainesville.*

The twentieth century was a rich and fascinating time for those with an interest in equine reproductive biology. The birth of equine reproductive research might properly be marked as the first Symposium on Equine Reproduction held at King's College, Cambridge, 1973. Seen as a summation of equine reproductive research up to that point, the symposium also provided moral support for those daring to venture into the sometimes unpopular field. In the more-than a quarter of a century elapsed since then, equine reproductive research has benefited and grown as a result of technological advances that touched all areas of biological research. Key to the growth of that research was the introduction and utilization of but five major technological advances; radioimmunoassay, novel surgical procedures, ultrasound, molecular biological approaches, and acquisition of the equine genome. The latter has yet to prove its worth, but likely will pass the test. The allotted space cannot serve to point out the many milestones and conceptual leaps accomplished in our understanding of equine reproduction. Nor can this short abstract list the players who contributed. The rate of knowledge gain has roughly paralleled that of other domestic species; sometimes lagging, sometimes ahead, but definitely advancing. Suffice it to say here, that horses deserve a place in the texts and in the universities of those who would understand the underlying mechanisms of reproductive biology. The many departures by horses from central scientific dogma provide perspective on the problems of reproduction, and often prove the rule by their exception. Often, the unique anatomical and physiological features of horses, mares especially, lend themselves to development of new approaches which return the investment manifold in knowledge. Certainly one cannot long work with these animals without a sense of awe at their invention. New technologies alone cannot guarantee progress. Those who employed new technologies in the study of equine reproduction, and those yet to do so have a responsibility to ask intelligent, pertinent, questions of the fundamental principles, and direct new technologies appropriately.

Key Words: Equine, Reproduction, Technology

283 Pituitary responsiveness to continuously-administered native GnRH at the winter solstice in anovulatory mares and mares with residual ovarian activity. I. C. Velez^{1,2}, M. Amstalden^{1,2}, J. D. Pack^{1,2}, and G. L. Williams^{1,2}, ¹Texas AgriLife Research, Beeville, TX, ²Texas A&M University, College Station.

Mares exhibit profound reproductive seasonality in North America, and varying strategies have been used to regulate this phenomenon in order to promote earlier foaling during the calendar year. Previous work in our laboratory has shown that low doses of continuously-administered, native GnRH (2.5-5 µg/h s.c.) are unable to prevent the development of or to reduce the length of winter anovulation. However, similar doses in April successfully induce follicular development and ovulation in approximately 80 % of persistently anovulatory mares, suggesting that the anterior pituitary may be less responsive before or near the winter solstice than after. Moreover, results of other studies in our laboratory have questioned whether GnRH secretion is limiting during the anovulatory season. Because of these limited and controversial findings, we examined dose-related effects of GnRH on anterior responsiveness just

before the winter solstice (December 6 through 20). Fifteen mares (5/grp) were used, with 12 of 15 confirmed anovulatory and assigned randomly to: 1) Control, saline; 2) GnRH-20, 20 µg/h GnRH; 3) GnRH-100, 100 µg/h GnRH. Three mares with residual ovarian activity were distributed equally across groups. Treatments were administered s.c. for 14 d using Alzet osmotic minipumps (model 2ML2; 5 µL/h). Repeated measures ANOVA was used to analyze data. Mean concentrations of serum LH (0.3 ± 0.08 ng/mL) did not differ among groups on d 0, but increased (P < 0.001) in a dose-dependent manner within 24 h. On d 14, least squares mean concentrations of LH averaged 0.1, 0.8, and 1.8 ng/mL (SEM = 0.14) for control, GnRH-20 and GnRH-100 groups, respectively (P < 0.001). Maximum follicle sizes did not exceed 25 mm in controls and ranged from 21 to 38 mm in GnRH groups. By d 14, 0/5 control, 1/5 GnRH-20 and 4/5 GnRH-100 had ovulated. Anterior pituitary responsiveness to GnRH at the winter solstice appeared adequate to support follicle development and ovulation.

Key Words: Equine, LH, Seasonality

284 Patterns of pituitary venous LH release in the luteal and follicular phase mare: Effects of continuous treatment with native GnRH. I. C. Velez^{1,2}, M. Amstalden^{1,2}, J. D. Pack^{1,2}, and G. L. Williams^{1,2}, ¹Texas AgriLife Research, Beeville, TX, ²Texas A&M University, College Station.

Continuous administration of high-dose GnRH to most mammals results in GnRH receptor down-regulation and reduced secretion of LH. However, in the horse, continuous GnRH exposure remains stimulatory. Little is known about the hypothalamic-pituitary interrelationships that subserves this unique phenomenon. Herein, we tested the hypothesis that endogenous circulating patterns of LH, as measured in pituitary venous effluent of the intercavernous sinus (ICS), retain their pulsatile character in the face of continuous GnRH exposure. Twelve cyclic mares were assigned randomly to one of two groups (n = 6/group): 1) Control, saline, and 2) GnRH, 100 µg/h. Between 3 and 6 d after ovulation (d 0 of expt.), Alzet osmotic minipumps (Model 2ML1) containing saline or GnRH were placed s.c. and connected to a jugular infusion catheter. On d 3, the ICS of 10 of 12 mares (5/group) were catheterized for 5-min sampling during 8 h on d 4, followed immediately by treatment with prostaglandin F₂-alpha to cause luteal regression. A similar intensive sampling period (6 h) was performed 36 h later (d 6). A pulse detection algorithm was used to identify pulses. Data were analyzed by one-way and repeated measures ANOVA. Mean jugular concentrations of LH on d 0 (2.2 ± 0.7 ng/mL; n=12) did not differ between groups; however, within 24 h, a 2.8-fold increase in mean LH was observed in GnRH-treated mares (P < 0.001). Values in treated mares remained greater (P < 0.001) than controls in both daily peripheral (4.1 vs 1.6 ng/mL; SEM = 0.3) and ICS plasma of luteal (6.9 vs 1.3 ± 0.1 ng/mL) and follicular phases (5.5 vs 1.2 ± 0.1 ng/mL). The luteal phase pattern of pituitary venous LH in 4/5 controls was characterized by infrequent (0.175 ± 0.07/h), secretory episodes of long-duration, punctuated by small secondary pulses. Continuous GnRH exposure eliminated this pattern, producing a chronically-elevated baseline of high-frequency, low-amplitude pulses. Moreover, follicular phase pulse frequency (1.2 ± 0.3 episodes/h) was accelerated (1.6 ± 0.3 episodes/h; P < 0.05) further by GnRH treatment. Results provide additional insight into unique mechanistic features of the equine hypothalamic-hypophyseal axis.

285 Effect of centrifugation technique on post storage characteristics of stallion spermatozoa. M. M. Dean and G. W. Webb*, *Missouri State University, Springfield.*

Three ejaculates were collected from each of 4 stallions and used to compare the effects of 3 centrifugation methods on motility, percent harvest and intact acrosomes following both storage at 5°C for 48 h and freezing in liquid nitrogen. Following collection 2 aliquots per treatment were diluted with skim milk-glucose (SKMG) extender to a final concentration of 50×10^6 , placed in 50 ml conical bottom tubes, and centrifuged at either $700 \times g$ for 15 minutes or $600 \times g$ for 12 minutes. A third aliquot was diluted 1:1 with SKMG, placed in 15 ml conical tubes and centrifuged at $400 \times g$ for 7 minutes. Following centrifugation aliquots were again split with subsamples from each stored at 5°C in Equine Express® shippers (Exodus Breeders Supply, York, PA) for evaluation after 24 and 48 h. Another aliquot of each centrifugation treatment was diluted with INRA 96® (IMV International) supplemented with 4% egg yolk and 4% glycerol, loaded into 0.5 ml straws and frozen. Following storage, aliquots were evaluated for motility using CASA (CEROS®, Hamilton Research Inc, Beverly, MA). Data were analyzed using a GLM procedure with a one-way ANOVA and Tukey's used to test differences between centrifuge treatments. Post storage percentages of intact acrosomes and detached heads were evaluated after staining with Spermac Stain™ (FertiPro, Beernem, Belgium). Percentage of spermatozoa harvested was determined by hemacytometer and was higher ($P \leq 0.05$) for aliquots centrifuged in 15 ml tubes at $400 \times g$ for 7 min vs. $600 \times g$ for 12 min in 50 ml tubes. Spermatozoal damage, measured by percentage of detached heads or intact acrosomes, was not different between treatments. Following cold storage total motility was higher ($P \leq 0.05$) for aliquots which were centrifuged in 15 ml tubes compared to those centrifuged in 50 ml tubes at higher speeds and longer amounts of time. Post thaw motility of frozen spermatozoa was not different between treatments. Use of 15 ml vs. 50 ml centrifugation tubes allows centrifugation at slower speeds and shorter times without affecting the % harvest of available spermatozoa. This may result in less damage to the spermatozoa due to centrifugation.

286 Effect of selenium supplementation and dietary energy manipulation on mares and their foals: Selenium concentrations and glutathione peroxidase activity. B. J. Karren*¹, J. F. Thorson², C. A. Cavinder¹, C. J. Hammer², and J. A. Coverdale¹, ¹Texas A&M University, College Station, ²North Dakota State University, Fargo.

To investigate maternal plane of nutrition and role of Se yeast on muscle Se concentration, plasma glutathione peroxidase (Gsh-Px) activity, and colostrum Se concentration in mares and their foals, 28 Quarter Horse mares were utilized in a randomized complete block design. Mares were blocked by expected foaling date and assigned randomly within block to dietary treatments. Dietary treatments were arranged as a 2x2 factorial with two levels of nutrition, pasture or pasture plus grain (fed at 0.75% BW) and two levels of Se supplementation (0 or 0.3 mg/kg BW) equaling four treatment groups: pasture (P), pasture + grain (PG), pasture + grain + Se (PGS), or pasture + Se (PS). P and PS mares received approximately 100% of calculated NRC DE requirements, while PG and PGS received 120%. Selenium supplementation began 110 d prior to estimated foaling (d 0) and all dietary treatments were terminated at

parturition. Plasma and muscle were collected on d 0 with plasma continuing every 14 d and muscle every 28 d until parturition. Additionally, BW, BCS, and rump fat measurements were observed every 14 d. At parturition colostrum, foal plasma and muscle samples were collected and continued every 14 d for plasma and 28 d for muscle until day 56. All data were analyzed using PROC MIXED of SAS. Mare BW, BCS, and rump fat was affected by nutrition ($P < 0.02$) but not Se ($P > 0.40$). Mares fed grain (PG and PGS) had greater BW, BCS, and rump fat measurements throughout the trial. Mare plasma, muscle, and colostrum Se concentrations were greater ($P < 0.01$) in mares fed Se (PS and PGS). Mares fed grain (PG and PGS) also had greater plasma Se ($P < 0.01$) than mares fed pasture. Mare and foal plasma Gsh-Px concentrations were unaffected by treatment ($P \geq 0.25$). Foal plasma and muscle Se concentrations were greater when dams were fed supplemental grain ($P = 0.03$, $P = 0.01$ respectively) and supplemental Se ($P = 0.0002$, $P < 0.0001$ respectively). Data indicate maternal plane of nutrition and Se supplementation influences mare and foal plasma, muscle, and colostrum Se concentrations but not Gsh-Px activity.

Key Words: Se, Maternal Nutrition

287 Effect of selenium supplementation and dietary energy manipulation on mares and their foals: Equine colostrum quality and passive transfer of IgG. J. F. Thorson*¹, B. J. Karren², M. L. Bauer¹, C. A. Cavinder², J. A. Coverdale², and C. J. Hammer¹, ¹North Dakota State University, Fargo, ²Texas A&M University, College Station.

To investigate maternal plane of nutrition and role of Se yeast on colostrum quality and passive transfer of Immunoglobulin G (IgG), 28 quarter horse mares were used in a randomized complete block design. Mares were blocked by expected foaling date and assigned randomly within block to dietary treatments. Dietary treatments were arranged as a 2x2 factorial with two levels of nutrition, pasture or pasture + grain (fed at 0.75% BW) and two levels of Se supplementation (0 or 0.3 mg/kg BW). This resulted in four treatments: pasture (P), pasture + Se (PS), pasture + grain (PG), and pasture + grain + Se (PGS). P and PS mares received approximately 100% of calculated NRC DE requirements, while PG and PGS received 120%. Selenium supplementation began 110 d prior to the estimated foaling (d 0) and all dietary treatments were terminated at parturition. Colostrum samples were obtained at parturition for fat, protein, milk urea nitrogen (MUN), somatic cell count (SCC) and IgG analysis. Foal serum samples were collected at 0, 6, 12, 18, and 24 h after parturition for IgG analysis. All data were analyzed using a mixed model of SAS. There was no effect ($P \geq 0.77$) of Se or level of nutrition on foal birth weight. There was also no effect ($P \geq 0.18$) of Se or level of nutrition on colostrum fat, protein, MUN, or SCC. Mares fed grain had lower ($P = 0.03$) colostrum IgG levels (76.46 mg/ml) compared to mares on pasture (126.64 mg/ml). Foals from mares fed grain tended ($P = 0.07$) to have lower serum IgG (13.66 mg/ml) compared to foals from mares on pasture (15.26 mg/ml). In summary, grain supplementation to mares during the last trimester of pregnancy resulted in decreased IgG concentrations in colostrum and tended to lower foal serum IgG. However, volume of colostrum was not measured and thus further studies are needed to determine if changes in colostrum IgG are due to alterations in colostrum volume.

Key Words: Equine, IgG, Passive Immunity

288 Differential mRNA expression of amino acid transporters in the equine small and large intestine. A. D. Woodward*, S. J. Holcombe, C. Colvin, J. Liesman, and N. L. Trottier, *Michigan State University, East Lansing.*

The role of cationic and neutral amino acid absorption in the large intestine of equids is unknown. The objective of this study was to determine the relative abundance of amino acid transporter mRNA in the proximal jejunal mucosa (JM) and left ventral colon mucosa (LVM) in the adult horse. It was hypothesized that transporters capable of cationic and neutral amino acid trans-membrane uptake are equally expressed in the JM and LVM of the adult horse. Tissue from the proximal jejunum and large ventral colon was obtained from three adult horses shortly following euthanasia. The mucosa was gently separated from the seromuscular layer, flash-frozen in liquid N, and stored at -80 °C for RNA isolation. Concentration and quality of RNA was determined, and Relative Quantitative Real Time-PCR (Q-RT-PCR) was conducted using amino acid transporter specific primers and the standard curve method. Primers were designed and complementary DNA was synthesized for amino acid transporters B^{0,+} (GenBank, XM001489968), CAT-1 (GenBank, XM001492839), and LAT-2 (GenBank, XM001493818); GAPDH (GenBank, XM001496020) was used as a housekeeping gene. Analysis of variance was done on cycles for the gene of interest adjusted by the cycles for the housekeeping gene. Abundance of the amino acid transporter B^{0,+} mRNA was similarly expressed in the JM compared to the LVM (P = 0.38). Compared to the LVM, amino transporter LAT-2 relative abundance was higher (P < 0.05) in the JM. The amino acid transporter CAT-1 was expressed in the JM but showed little expression in the LVM (P < 0.001). The data indicate both the JM and the LVM may be equally capable of sodium-dependent uptake of neutral amino acids through the B^{0,+} amino acid transporter. Sodium-independent uptake of neutral amino acids through the LAT-2 transporter occurs predominantly in the JM. However, uptake of cationic amino acids via the CAT-1 transporter may occur within the JM but not in the LVM. In conclusion, amino acid transporter mRNA expression will vary depending on location within the intestinal tract of adult horses.

Key Words: Horse, Amino Acid Transporter, PCR

289 Differential gene expression in two segments of the equine intestinal tract using a bovine long oligo microarray. A. D. Woodward*, S. S. Sipkovsky, S. J. Holcombe, J. Liesman, and N. L. Trottier, *Michigan State University, East Lansing.*

Gene expression profiling along the equine intestine is critical in order to identify genes related to nutrient digestion and gastrointestinal dysfunction. This study was conducted to 1) determine whether or not equine intestinal tissue hybridizes to a bovine long oligo microarray (BLO), and 2) determine whether or not genes are differentially expressed between the small and large intestinal tract. We hypothesized mRNA expression will be shown on the BLO, and genes of interest will differ in relative abundance between the small and the large intestine. Tissue from the proximal jejunum and large ventral colon was obtained from three adult horses shortly following euthanasia. The mucosa was gently separated from the seromuscular layer, flash-frozen in liquid N, and stored at -80 °C for RNA isolation. Dye-labeled cDNA was synthesized for hybridization to the BLO, which was comprised of 8400 oligos. Expression of mRNA was detected on all three microarrays, indicating equine mRNA hybridized to the BLO. Differences in expression intensity ratios of the jejunal mucosa (JM) compared to the left ventral colon mucosa (LVM) were found for 750 genes (P ≤ 0.05). Of those, 60 genes showed greater than a three-fold difference in intensity of mRNA expression in the JM compared to the LVM. In regards to genes known to be involved in amino acid transport, mRNA abundance for CAT-3 was higher in the JM compared to the LVM (P < 0.05), and tended to be higher for the excitatory amino acid transporter 1 (EAA1, P = 0.08). Several amino acid transporters showed similar mRNA expression in both the JM and the LVM. Among these were CAT-7 (P = 0.41), LAT-1 (P = 0.44), LAT-3 (P = 0.26), amino acid transport system N2 (P = 0.50) and solute carrier family 3 (P = 0.70). These results indicate cationic amino acid uptake may occur predominately in the JM compared to the LVM, while uptake of other amino acids may occur similarly in both the JM and LVM in the adult horse.

Meat Science and Muscle Biology: Measuring and Manipulating Pork Quality

290 Oxidation results in formation of an intramolecular disulfide bond in μ -calpain. R. Lametsch², E. Huff-Lonerger¹, and S. M. Lonergan^{*1}, ¹Iowa State University, Ames, ²University of Copenhagen, Copenhagen, Denmark.

Examination of mechanisms that regulate calcium dependent protein degradation in muscle continues to be a significant area of inquiry in muscle biology. The active site cysteine of calpain not only facilitates effective catalysis, it also makes the enzyme sensitive to oxidation as characterized by its decreased activity in the presence of an oxidant. It is hypothesized that oxidation of the active site cysteine residue of μ -calpain is responsible for the reversible inactivation of calpain that has been observed. Oxidation of cysteine is very complex and more than 10 different sulfur oxidation states are found *in vivo*. Porcine μ -calpain contains 11 cysteines, which are all likely to be subject to oxidation. This makes it clear that sulfur oxidation state may contribute to regulation of calpain proteolytic activity. These experiments utilized LC-MS/MS analysis to determine the specific consequence of the oxidation of porcine μ -calpain by hydrogen peroxide (H_2O_2). The effect of different oxidative and reducing conditions on μ -calpain activity was examined by incubating μ -calpain with either with 200 μ M H_2O_2 , 0.03%, 0.1%, or 0.2% 2-mercaptoethanol (MCE) or without H_2O_2 and MCE. Activity was determined in the presence (0.2%) or absence (0%) of MCE. Pre-incubation with H_2O_2 resulted in an inhibition of autolysis, activation and activity. However, when activity was evaluated under reducing conditions, the effects of incubation with H_2O_2 were reversed. The LC-MS/MS analysis of the oxidized μ -calpain revealed a peak at m/z 1032.5 that was not present in the control. The MS/MS data revealed that the peptide 105-133 likely contains a disulfide bond between Cys(108) and Cys(115). The disulfide bond was confirmed by reduction of the peptide. The finding that the active site cysteine in μ -calpain is able to form a disulfide bond has to our knowledge not been reported before. It is hypothesized that this is part of a unique mechanism for regulation of μ -calpain.

Key Words: Calpain, LC-MS/MS, Oxidation

291 Developmental changes in tissue skatole levels and hepatic activity of cytochrome P4502E1 and P4502A6 in local and exotic pigs. C. Y. Li*, C. Wu, T. Z. Shan, J. X. Liu, Y. Z. Wang, and J. K. Wang, Ministry of Education Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, P.R. China.

The objective of this study was to evaluate the developmental changes in tissue skatole levels and hepatic activity of cytochrome P4502E1 (CYP2E1) and P4502A6 (CYP2A6) in local Jinhua and exotic Landrace pigs. Eighteen intact male pigs (nine for each breed) were slaughtered at 30, 90 and 150 days of age, when samples were taken from blood, backfat, abdomen fat and liver and analyzed for skatole levels. CYP2E1 and CYP2A6 activities were evaluated for liver samples. For both breeds, tissue skatole contents elevated with the increasing age ($P < 0.01$), but the two breeds showed different developmental changes with age. Compared with Jinhua pigs, plasma skatole levels were significantly lower in Landrace, at all ages ($P < 0.05$). Skatole levels in liver and abdomen fat were lower in Landrace only at d 90 ($P < 0.05$) and d 150 ($P < 0.05$), respectively. No significant difference was found in backfat skatole levels between the two breeds ($P > 0.05$). There were significant breed \times age interactions ($P < 0.05$) in plasma and abdomen skatole levels, but not

in liver and backfat skatole content. The CYP2E1 activity was not different among d 30, 90 and 150 in Landrace, but decreased ($P < 0.05$) from d 90 to 150 in Jinhua pigs. At d 30, CYP2E1 activity in Landrace was significantly higher than that in Jinhua pigs ($P < 0.05$), while CYP2A6 activity was not different between the two breeds. For pigs at d 90, no significant difference existed in both CYP2E1 and CYP2A6. For pigs at d 150, CYP2E1 activity was not different between the two breeds, but CYP2A6 activity were significantly higher ($P < 0.05$) in Landrace than that in Jinhua pig. The lower tissue skatole levels in Landrace pigs appear to be associated with higher CYP2E1 or CYP2A6 activities. However, CYP2E1 or CYP2A6 was not involved in the mechanism of age-related increase in skatole levels of Landrace pigs. Factors other than CYP2E1 or CYP2A6 may play a role.

Key Words: Skatole, Pig, Breed

292 Objective and sensory measures of meat quality and fatty acid profile of *longissimus* intramuscular lipid from pigs fed crude glycerol. P. Lammers^{*1}, B. Kerr², T. Weber², K. Bregendahl¹, S. Lonergan¹, K. Prusa¹, D. Ahn¹, W. Stoffegen³, W. Dozier, III⁴, and M. Honeyman¹, ¹Iowa State University, Ames, ²Swine Odor and Manure Management Research Unit, USDA-ARS, Ames, IA, ³Bacterial Diseases of Livestock Research Unit, USDA-ARS, Ames, IA, ⁴Poultry Research Unit, USDA-ARS, Mississippi State, Mississippi.

The effect of inclusion of crude glycerol on pork loin quality and composition was examined. Barrows (48) and gilts (48) were fed corn-soybean meal based diets containing 0, 5, or 10% crude glycerol for 138-d. Crude glycerol was obtained from AG Processing Inc., Sergeant Bluff, IA and contained 84.51% glycerol, 11.95% water, 2.91% sodium chloride, and 0.32% methanol. Diets were fed in 5-phases with each diet within a phase formulated to be equal in ME, NaCl, and Lys with other AA balanced on an ideal AA basis. On d-138, all pigs were weighed (133 ± 6 kg BW) and on the morning of d-139, pigs were transported to a commercial abattoir. Loins from the left side of each carcass (87) was removed, vacuum packaged, placed on ice, transported to Iowa State University, and stored at 0°C until subsequent analysis. Loin marbling scores, color scores, purge loss, and drip loss were determined following 12 d of storage. Lipid was extracted and quantified from a sample of each loin (87), with fatty acid profile being determined using authentic standards. Two 2.54 cm thick loin chops were removed from the center of 48 loins (24 barrows, 24 gilts) for sensory and instrumental texture analysis. Data were analyzed using a regression model to test for effect of dietary treatment, pig gender, and diet \times gender interaction. Neither diet nor gender affected any meat quality or sensory evaluation measure of loin chops ($P \geq 0.10$). There was no diet \times gender interaction for any measure examined. There was a trend ($P = 0.06$) for loins from pigs fed 5 or 10% crude glycerol to have a greater ultimate pH than loins from control animals. Eicosapentaenoic acid increased with increasing crude glycerol supplementation ($P = 0.02$) and pigs fed 10% crude glycerol had lower levels of linoleic acid than the other dietary treatments ($P = 0.01$). The results of this study demonstrate that up to 10% crude glycerol can be fed to pigs with little to no effect on meat quality. The noted differences in fatty acid profile and trend in ultimate pH may warrant further examination.

293 Correlation of pork texture characteristics determined using different instrumental texture analysis methods. M. J. Anderson*, R. M. Smith, E. Huff-Lonergan, and S. M. Lonergan, *Iowa State University, Ames*.

Warner-Bratzler shear (WBS) force and star probe (SP) are two regularly used methods of instrumental texture analysis. Previously, little research has focused on the relationship of measurements made with these two methods. The objective of this study was to determine consistency of correlations between these instrumental texture methods and specific quality attributes. Forty pork loins aged 10-12 days postmortem were cut into chops from the blade end, center, and sirloin end. Quality attributes were measured on the longissimus dorsi at each location. Hunter L*, a*, and b* values as well as drip loss were measured in duplicate. Intact desmin and pH were also measured in each location. Correlations were run between instrumental methods and quality attributes. Linear regression between SP and WBS was also calculated. SP and WBS were positively correlated at $r = 0.67$ ($P < 0.01$). Drip loss tended to be positively correlated to SP ($r = 0.16$, $P = 0.08$) and WBS ($r = 0.17$, $P = 0.07$). L* values were negatively correlated to SP ($r = -0.47$, $P < 0.01$) and WBS ($r = -0.34$, $P < 0.01$). a* values were negatively correlated to SP ($r = -0.38$, $P < 0.01$) and WBS ($r = -0.22$, $P = 0.014$). b* values were negatively correlated to SP ($r = -0.47$, $P < 0.01$) and WBS ($r = -0.31$, $P < 0.01$). WBS tended to be positively correlated to the intensity of the intact desmin band ($P = 0.076$). SP was positively correlated with intact desmin ($r = 0.26$; $P = 0.02$). Linear regression between SP (kg) and WBS (kg) was used to calculate the model: $SP = 1.5 + 1.47(WBS)$. The data show that there was a very strong correlation between the two instrumental measures of texture. While not significant, there was a high consistency between the correlations of both SP and WBS to drip loss. For all color measurements, SP had a stronger correlation than WBS, and also had a correlation to the intensity of the intact desmin band whereas WBS did not. The linear regression between SP and WBS is the beginning of a prediction model of the two instrumental texture methods that will allow us to better interpret data from either source.

294 Effect of different dietary levels of natural-source vitamin E in grow-finish pigs on pork quality and shelf life. D. D. Boler*¹, S. R. Gabriel¹, H. Yang², R. Balsbaugh², D. C. Mahan³, M. S. Brewer¹, F. K. McKeith¹, and J. Killefer¹, ¹*University of Illinois, Urbana*, ²*ADM Alliance Nutrition, Inc., Quincy, IL*, ³*The Ohio State University, Columbus*.

Feeding high levels of DDGS in the diet will result in increased levels of poly-unsaturated fatty acids in adipose tissue which increases lipid oxidation. This project evaluated the effects of natural source vitamin E (NSVE; Nova-E) compared with synthetic vitamin E on pork quality, shelf life, and color stability. One hundred forty-three pigs were used in the experiment. Six diets were fed for 95 d prior to harvest at 120 kg BW in a complete randomized block design. Six pens per treatment with 4 pigs per pen were assigned to the following treatments: 10 mg/kg NSVE, 40 mg/kg NSVE, 70 mg/kg NSVE, 100 mg/kg NSVE, 200 mg/kg NSVE, and 200 mg/kg synthetic vitamin E. Carcass evaluations, objective color, and NPPC color, marbling, and firmness were recorded for all loins. One pig per pen was randomly selected for estimations of shelf life, color stability, and lipid oxidation. Thiobarbituric acid reactive substances (TBARS) was used to estimate amounts of lipid oxidation of fresh loin chops and ground pork packaged in high oxygen modified
