686 Comparison of the severity of Necrotic Enteritis caused by *Clostridium perfringens* in broiler chickens given either an attenuated or non-attenuated live coccidial vaccine. G. Mathis*[1] and C. Hofacre[2], [1]*Southern Poultry Research, Inc.*, *Athens, GA*, [2]*University of Georgia*, *Athens*.

Two studies were conducted to evaluate the degree of severity of Necrotic Enteritis in broiler chickens challenged or vaccinated with either an attenuated or non-attenuated live coccidial vaccine. The challenge study used battery cages. The treatments were no coccidia challenge, non-attenuated (NA) coccidia challenged, and attenuated (A) coccidia challenged. Both coccidial inoculums were mixtures of *E. acervulina, E. maxima*, and *E. tenella*. Birds were coccidia challenged on Day 14. All birds were dosed with *Clostridium perfringens* on Days 19, 20, and 21. The performance parameters measured were feed conversion and weight gain. The percent NE mortality for the A challenged birds was 2%, compared to 20% for the NA challenged birds. Significantly better performance and lower NE lesion scores were observed with the A challenged birds compared to the NA challenged birds. The vaccine study was conducted in a floor-pen facility. The treatments were non-vaccinated, non-challenged or challenged, coccidia vaccinated with attenuated or non-attenuated vaccine and challenged. Vaccination was performed on day of hatch, prior to placement. Challenged birds received *Clostridium perfringens*. Presence of litter oocysts in all vaccinated pens confirmed viability of both vaccines. The non-attenuated vaccinated birds had higher percent NE mortality and NE lesion scores and lower performance at Days 22 and 42 compared to attenuated vaccinated birds. The results demonstrate that the severity of Necrotic Enteritis was not as much in birds challenged with attenuated strains of coccidia than the non-attenuated coccidial strains.

Key Words: Necrotic Enteritis, Vaccine, Coccidia

687 Efficacy of CloSTAT™ direct-fed microbial for control of experimentally induced necrotic enteritis by *Clostridium perfringens* in broiler chickens. B. Boren*[1], G. F. Mathis[2], C. L. Hofacre[3], and S. Moore[1], [1]*Kemin AgriFoods North America*, *Des Moines, IA*, [2]*Southern Poultry Research*, *Athens, GA*, [3]*University of Georgia*, *Athens*.

An experiment was conducted to determine if CloSTAT™ could affect the severity of experimentally induced Necrotic Enteritis (NE) and lessen related production losses. Chicks were assigned to 1 of 6 treatments each replicated 8 times. Birds were reared 8 chicks per battery brooder pen. Three doses of CloSTAT: 1 x 10^{10}, 1 x 10^9 and 1 x 10^8 cfu/ton mash starter feed were tested in 384 male, Cobb x Cobb 500 broilers. The 3 control treatments were: an unmedicated, uninfected positive control; an unmedicated, infected negative control; and an infected, antibiotic control receiving 50g Bacitracin MD

(BMD)/ton feed. All birds were infected on day 14 with a mixed coccidial inoculum containing 25,000 oocysts of *E. acervulina*/bird and 5,000 oocysts of *E. maxima*/bird. On days 19, 20 and 21, all birds, with exception of positive controls, received a dose of 1 x 10^8 cfu of a *C. perfringens* strain proven to induce NE via cultured broth provided fresh daily. BW (0 to 22-day) of broilers fed CloSTAT at 1 x 10^{10} cfu/ton was higher vs. negative control (P<.05). By day 27, CloSTAT at all tested doses proved as efficacious (P<.05) in protecting against NE model as BMD and not significantly different (NSD) from uninfected positive controls. FCR of negative controls (0 to 27 days) was higher (P<.05) than those of all other treatment means and were NSD from one another. NE mortality of CloSTAT-treated chicks was lower (P<.05) for those receiving 1 x 10^9 cfu/ton (9.4%) than those fed 1 x 10^8 cfu/ton (20.3%); with both NSD from highest CloSTAT dose of 1 x 10^{10} cfu/ton (10.9%). Mortality due to NE of BMD was NSD from any CloSTAT treatment. Therefore, of the birds challenged with *C. perfringens*, those receiving CloSTAT lived as well as birds receiving BMD at 50g/ton. Based on the results of this study, CloSTAT proved effective in reducing NE mortality and related production losses.

Key Words: Clostridium, Chicken, Necrotic Enteritis

688 Immune interference of bacteriophage efficacy to treat colibacillosis in broiler chickens. W. E. Huff*, G. R. Huff, N. C. Rath, and A. M. Donoghue, *USDA/ARS Poultry Production and Product Safety Research Unit, University of Arkansas*, *Fayetteville, AR*.

Bacteriophage are viruses that kill bacteria, and may provide a natural and safe alternative to antibiotics. Colibacillosis is an important poultry disease caused by *Escherichia coli*. Previous work has indicated that bacteriophage could be used to both prevent and treat colibacillosis. However, bacteriophage may illicit an immune response in poultry, which could limit their effectiveness to treat bacterial diseases. The experimental design to investigate this possibility consisted of 5 treatments with 3 replicate floor pens of 20 birds per pen. The treatments were control, birds administered bacteriophage at 10 and 17 d of age, birds challenged with *E. coli* at 17 d of age, birds challenged with *E. coli* and administered bacteriophage at 17 d of age, and birds administered bacteriophage at 10 and 17 d of age and challenged with *E. coli* at 17 d of age. Five extra birds were placed in the pens of the control treatment and the treatment only administered bacteriophage. These extra birds were bled and euthanizied at 17 d of age for viral neutralization assay development. All remaining birds were necropsied at 31 d of age. Bacteriophage were administered into the thigh muscle providing 6.7 X 10^8 pfu. The birds were challenged with an airsac inoculation of *E. coli* delivering 1 X 10^6 cfu per bird. Mortality was significantly reduced by bacteriophage from 55% in the *E. coli* treatment to 8% in *E. coli* challenged bacteriophage treated birds, and reduced, but not significantly, to 33% in the birds that were administered bacteriophage 7 d prior to the *E. coli* challenge, and consequently treated with bacteriophage. The neutralization assays suggest that the activity of bacteriophage was compromised by the bird′s immune response. Although bacteriophage can be developed as an alternative to antibiotics for specific applications, bacteriophage efficacy to treat bacterial diseases may be affected by repeated intramuscular administration of bacteriophage due to immune interference.

Key Words: Bacteriophage, Colibacillosis, Poultry

689 Effect of lactic acid bacteria probioitc culture treatment timing on *Salmonella* in neonatal broilers. J. P. Higgins*, S. E. Higgins, V. Salvador, A. D. Wolfenden, G. Tellez, and B. M. Hargis, *University of Arkansas*, *Fayetteville*.

We evaluated the ability of a commercially available probiotic culture (FM-B11™ Ivesco LLC; LAB1) or a combination of 3 ATCC lactobacilli (LAB2) to reduce *Salmonella enterica* serovar Enteritidis (SE) in day-of-hatch broiler chicks. In Experiments 1 - 3, chicks were challenged with SE and then treated 1 h later with LAB1 or LAB2. Significantly less cecal SE was recovered from LAB1 treated chicks 24 h following treatment as compared to controls (48 - 76 % reduction) or LAB2 treated chicks (48 - 68 % reduction) in all three experiments ($P < 0.05$). LAB2 significantly reduced cecal SE recovery 24 h following treatment as compared to controls in Experiments 1 and 3 (24 - 29 % reduction) ($P < 0.05$), but not in Experiment 2. In Experiments 4 - 7, LAB1 was administered 24 h prior to SE challenge. LAB1 significantly reduced recovery of SE as compared to controls (60 - 78 % reduction) ($P < 0.05$) in Experiments 4 and 5, but not Experiments 6 and 7. In Experiments 8 - 10, chicks were first challenged with SE, then treated 24 h later with LAB1, and no reduction in cecal SE was observed. Together, these data demonstrate that the timing of probiotic treatment in relationship to SE challenge greatly affects the ability of LAB1 to reduce SE recovery. Furthermore, probiotic LAB1 significantly reduced cecal SE incidence as compared to LAB2 treatment, demonstrating that not all lactic acid bacteria are equally effective at reducing enteric pathogens in poultry.

690 Evaluation of methods for detecting influenza viruses in wild aquatic birds. T. V. Dormitorio*, J. J. Giambrone, K. Guo, and G. Hepp, *Auburn University*, *Auburn, AL*.

It is generally accepted that wild aquatic birds are the natural reservoirs of influenza viruses that infect other species including humans. There are a number of variables to consider when developing laboratory protocols for detecting avian influenza viruses (AIVs) in wild waterfowl. Egg embryo inoculation, hemagglutination, AC-ELISA and real-time RTPCR (RRT-PCR) were used to detect AIVs from cloacal swabs of wild ducks from Southeastern United States. No AIV was detected when cloacal samples (HA positives) were used directly for either RRT-PCR or AC-ELISA tests. AIV was detected 12 cycles earlier on allantoic fluid of egg inoculated on the 2nd passage. AC-ELISA detected influenza A only when the HA titer of the virus in the allantoic fluid sample was 256 or higher. Many factors such as inhibitors, RNA extraction, etc., could be responsible for the failure of the test to detect AIVs. The RRT-PCR appeared to be a more sensitive, cost-effective and rapid assay however, it still needed embryo inoculation, which is time-consuming and labor intensive.

Key Words: Real Time RT-PCR, Hemagglutination, ELISA

691 Evaluation of a novel recombinant salmonella vaccine vector for avian influenza. K. Cole*[1], S. L. Layton[1], M. M. Cox[1], Y.M. Kwon[1], L. R. Berghman[2], W. G. Bottje[1], and B. M. Hargis[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Texas A&M University*, *College Station*.

Avian influenza is a significant public health concern and serious economic threat to the commercial poultry industry worldwide. Previous research demonstrates that antibodies against M2e confer protection against influenza challenge. Using the Red recombinase system in combination with overlapping extension PCR, we recently developed several novel attenuated ΔSE)aroA Salmonella enteritidis strains (ΔSE) that express a protective M2e epitope alone or in combination with a potential immune-enhancing CD154 peptide sequence on the outer membrane protein lamB. These recombinant Salmonella strains (ΔSE, ΔSE-M2e, ΔSE-M2e-CD154, or ΔSE-M2eX4-CD154) were evaluated in chicken vaccination studies (challenge dose: 105-107 cfu/chick via oral gavage at day-of-hatch). Liver/spleen and ceca tonsils were aseptically removed at 7 d post-challenge for detection of ΔSE strain recovery, and blood samples were obtained for determination of M2e-specific IgG antibody response at 10 and 20 d post-challenge. Within challenge doses, no significant ($p>0.05$) differences were observed in ΔSE strain recovery from cecal tonsils (colonization) at d 7. However, marked differences in organ invasion were observed ($p<0.05$). Vaccinated chickens exhibited significantly increased M2e-specific IgG responses, which were further enhanced by simultaneous expression of CD154 ($p<0.05$). Virus neutralization assays using chicken embryos gave neutralizing indices of 7.5, 8.3 and 8.3 for ΔaroASE-M2e, ΔaroASE-M2e-CD154, and ΔaroASE-M2eX4-CD154, respectively, indicating effective neutralization of AI by serum IgG of vaccinated chickens. Continuing experiments are focused on duration of response, effect of booster vaccination, and protection against influenza challenge. Our preliminary data suggest that these Salmonella-vectored vaccines expressing M2e in association with CD154 are effective against AI.

692 Differential antibody response to AIV vaccination in chickens with different Mx genotypes. X. Y. Li, L. J. Qu, Z. H. Ning, G. Y. Xu, J. Y. Li, Z. C. Hou, and N. Yang*, *China Agricultural University*, *Beijing, China*.

The chicken Mx gene has been shown to be associated with the resistance to avian influenza virus (AIV). In this study, heterozygote (AG) parents with respect to the Mx gene S631N mutation were identified in a line of egg-type chickens and used to reproduce a segregation population. Chicks were divided into three groups based on the genotypes at the S631N site of the Mx protein: 58 chicks with AA, 56 with AG and 53 with GG genotypes, whereas A and G represent resistant and susceptible alleles to AIV, respectively. All experimental birds were vaccinated with 0.3 mL inactivated H5N2 AIV vaccine twice at 14 and 45 days of age. Blood samples were taken for each chicken before vaccination and at week 1, 2, 3, 4, 5, 7, 9 and 15 after the first vaccination, and the antibody titers to AIV measured using HI test. For the initial vaccination, the antibody levels were high with substantial maternal antibody, and there was no significant difference in antibody response among different genotypes. After the boosting vaccination, however, chickens with homozygous resistant allele (A) showed the lowest antibody response, whereas the heterozygous chickens (AG) presented the highest antibody level. The result implied that genetic background might interfere the effects of AIV vaccination.

Key Words: Avian Influenza, Mx Gene, Antibody

693 Impact of ergot infested sorghum on the reproductive performance of sows. G. M. AbdRahim*[1], R. C. Richardson[2], and A. Gueye[3], [1]*Alabama A&M University*, *Normal*, [2]*Texas State University*, *San Marcos*, [3]*Mt. Ida College*, *Newton, MA*.

Over two parities, the impact of three levels of sorghum infected with ergot alkaloids on the reproductive performance of sows was evaluated. The three levels of ergot alkaloids fed to sows were 0 ppm, 12 ppm, and 24 ppm. Eighteen sows similar in weight, age and breed were used in the experiment. Sows were selected randomly and assigned to the three treatments and fed 2.3 kg of DM/d of a diet based on ground grain sorghum during the gestation and lactation periods. With the exception of the control treatment, the same sows were used during the first and second parities. The number of pigs farrowed, and weights of pigs within 24 hours after birth and at 28 days of age were recorded for each litter. Lactation feed intake, interval to estrus, and weight at d-56, were determined throughout each parity. In the first parity, ADG at d- 28, and interval to estrus were affected by the level of ergot alkaloids in the diet. ADG at d-28 was greater ($P < 0.05$) for born pigs from sows fed the 24 ppm ergot alkaloids treatment than born pigs from sows fed the 12 ppm. In the same parity, the level of 12 ppm ergot alkaloids resulted in prolonged estrus interval ($P < 0.05$) over the 24 ppm treatment. In the second parity, variables that were affected by the level of ergot alkaloids were average weight of live pigs born and lactation feed intake. Average weight of live pigs born was greater ($P < 0.05$) in sows fed the 24 ppm and 12 ppm ergot alkaloids treatment than in sows fed the for 0 ppm treatment. The lactation feed intake was greater ($P < 0.05$) for sows fed the 0 ppm than for sows fed the 12 ppm. Statistical analysis of the combined results from parity one and parity two showed that the only variable affected by the treatments was ADG at d-28. ADG at d-28 was greater ($P < 0.05$) for born pigs from sows fed the 0 ppm and 24 ppm ergot alkaloids than for born pigs from sows fed the 12 ppm. Overall, variables that were affected by the infestation of grain sorghum by the ergot alkaloids were pigs gain to d-28, lactation feed intake, and interval to next estrus.

Key Words: Alkaloids Ergot, Sorghum, Sows

694 The effect of dam parity on circulating immunoglobulins (Ig) in neonatal swine. T. E. Burkey*, R. K. Johnson, P. S. Miller, D. E. Reese, and R. Moreno, *University of Nebraska*, *Lincoln*.

The belief that dam parity can affect progeny performance and survival has contributed to the establishment of parity-segregated management systems in the pork industry. To date, little experimental evidence exists that directly challenges the idea that dam parity affects progeny health statues and performance. The objective of this experiment was to evaluate and compare concentrations of IgA and IgG in serum obtained from the progeny of first parity (P1) and third parity (P3) females in order to gain insight into parameters that may be affected by dam parity. Neonatal piglets ($n = 9$) were selected from the progeny of either P1 or P3 females ($n = 4$ each from the P1 or P3 population) for inclusion in the study. Whole blood was collected via jugular venipuncture from piglets at 1, 8, 15, 20 (weaning), 29, and 37 d following parturition and concentrations of IgA and IgG were determined via swine-specific enzyme-linked immunosorbent assays (ELISA). Serum samples were diluted 1:2000 for IgG determination and 1:100,000 for IgA determination. Individual BW were recorded at similar time points. A significant parity by time interaction existed for circulating IgA. Within time point (d), P3 progeny had greater ($P < 0.05$) concentrations of IgA than P1 progeny on d 1, 8, and 37.

A similar interaction was not observed for IgG. Averaged across all time points, P3 progeny had greater ($P < 0.009$) concentrations of circulating IgG than P1 progeny. Piglet BW did not differ between parities. These results suggest that circulating Ig concentrations in neonatal pigs may be affected by dam parity. It remains to be determined whether the increase in circulating Ig observed in P3 progeny occurred because P3 females had greater capacity to provide passive transfer of Ig during lactation. Additional work is needed to determine whether these effects afford the progeny of dams of increasing parity advantages in health and performance during subsequent growth phases.

695 Impact of ochratoxin A and zearalenone on weaning piglets and counteracting. V. H. Starkl*[1] and M. Forat[2], [1]*Biomin GmbH*, *Herzogenburg, Lower Austria, Austria*, [2]*Instituto Internacional de Investigacion Animal*, *Queretaro, Mexico*.

Mycotoxins are ubiquitously present, secondary metabolites of different fungal species. Ochratoxin A (OTA) is nefro- and hepatotoxic, carcinogenic and immunesuppressive at low concentrations. Zearalenone (ZON) is known to mimick estrogene and thus leading to hyperestrogenism. A trial was performed to evaluate the effects of 500ppb OTA and 250ppb ZON on health and performance of weaned piglets. The trial started at day 21 and ended on day 63. 96 piglets were randomly separated into 4 treatments. As both, OTA and ZON, are only partly adsorbable, Mycofix® Plus (MP) a product based on biotranformation was tested. The product consists of two microorganisms, *BBSH 797* and *Trichosporon mycotoxinivorans*, that produce specific enzymes to biotransform trichothecenes, ZON and OTA. The following four treatments were applied: T-1 Control diet; T-2 500ppb OTA + 250ppb ZON, no MP; T-3 500ppb OTA + 250ppb ZON, 500g MP/ton of feed; T-4 500ppb OTA + 250ppb ZON, 1000g MP/ton of feed. Non-purified toxins provided by Biomin® were used. ANOVA was used for statistical evaluation. Measured parameters included performance parameters (feed consumption, body weight, mortality) and histopathology of liver, kidneys and uterus. Daily weight gain over trial period and subsequently final bodyweight were significantly lower in T-2, whereas both treated groups T-3 and T-4 did not show any difference to the control group in performance parameters. No clinical signs were diagnosed in treatment T-1. In treatment T-2 swollen vulva (41,6%), swollen prepuce (50,0%), rectum prolapse (25,0%), vomiting (4,1%) diarrhea (4,1%) and frequent urination (50,0%) were diagnosed. Symptoms in MP-treated groups T-3, T-4 were significantly reduced or completely overcome. Histopathology showed clear impact of ochratoxin A as kidney- and liver-toxin. Remarkable was the effect of 250ppb zearalenone on the epithelia of uterus of piglets of 63 days of age: Focal squamous cells and mitotic cells were observed in epithelia of uterus of piglets in T-2. As a conclusion can be stated that OTA and ZON strongly affected weaning piglets and that Mycofix® Plus was able to overcome the negative impact.

Key Words: Ochratoxin A, zearalenone, Piglet

696 Dietary supplementation with *acanthopanax senticosus* extracts beneficially modulates the gut microflora in weaned pigs. X. F. Kong*[1], Y. L. Yin[1], W. Y. Chu[2], F. G. Yin[1], H. J. Liu[1], F. F. Xing[1], Q. H. He[1], T. J. Li[1], R. L. Huang[1], P. Zhang[1], S. W. Kim[3,4], and G. Y. Wu[1,4], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Nanjing Agricultural University*, *Nanjing, Jiangshu, China*, [3]*Texas Tech University*, *Lubbock*, [4]*Texas A&M University*, *College Station*.

This study was conducted to investigate the effects of *acanthopanax senticosus* extracts (ASE) as a dietary additive on gut microflora in weaned pigs. Sixty pigs weaned at 21 d of age were randomly assigned to one of the three 3 treatments (20 pigs/treatment), representing supplementation with 0 or 0.1% ASE, or 0.02% colistin (an antibiotic) to a corn- and soybean meal-based diet. On d 0, 7, 14 and 28 after initiation of the supplementation, five 5 pigs from each treatment were euthanizedsacrificed to obtain the luminal contents of the ileum, jejunum, and cecum. The intestinal luminal samples were analyzed for the gut microflora using the polymerase chain reaction-denaturing gradient gel electrophoresis technique. The concentrations of lactobacillus and E. coli were determined using the in vitro culture methodology. The results indicated that the gut microflora of ASE-supplemented piglets was more diverse than the other 2two groups of piglets ($P < 0.05$). Particularly, the number of lactobacillus was higher ($P < 0.05$) and the number of E. coli was lower ($P < 0.05$) in ASE-supplemented pigs, compared with the other 2two groups of pigs. These findings suggest that dietary supplementation with ASE beneficially modulates the development of the gut microflora, suppresses the number of bacterial pathogens, and promotes a healthy intestinal environment in weaned pigs. We suggest that ASE is an effective alternative to a feed antibiotic for young pigs. (Supported by NSFC and CAS)

Key Words: *Acanthopanax senticosus* Extracts, Weaned Pigs, Gut Microflora

Nonruminant Nutrition: Poultry Nutrition - Ingredient and Mineral Nutrition

697 Investigation of antagonism and absorption of zinc and copper when different forms of minerals were fed to chicks. T. Ao*, J. L. Pierce, R. Power, A. J. Pescatore, K. A. Dawson, A. H. Cantor, M. J. Ford, and B. L. Shafer, *Alltech-University of Kentucky Nutrition Research Alliance*, *Lexington, KY*.

The aim of this study was to investigate the antagonism of Zn and Cu when organic or inorganic forms of these minerals were fed to chicks. A practical corn-soybean meal diet without Cu and Zn supplementation, containing 31 mg Zn /kg diet and 5.4 mg Cu /kg diet, was used as a basal diet. Bioplex Zn® (a chelated Zn proteinate) and Bioplex Cu® (a chelated Cu proteinate) were used as the organic sources. Reagent grade sulfate salts provided the inorganic sources of Zn and Cu. Supplements provided 20 ppm Zn and 8 ppm Cu. Ten groups of six day-old male broilers were assigned to each of seven treatments. Tap water with no detectable Zn and Cu (<0.001 ppm) and feed were supplied on an *ad libitum* basis during the 3 wk trial. Treatments consisted of the following dietary supplementation: 1) none, 2)

inorganic Cu, 3) inorganic Zn, 4) inorganic Zn + inorganic Cu, 5) inorganic Zn + Bioplex Cu, 6) Bioplex Zn + inorganic Cu, and 7) Bioplex Zn + Bioplex Cu. The luminal mucus layer of the chick's duodenum was separated from the mucosa by filling the lumen with agar to observe the Zn and Cu uptake of mucus in the agar cast and the mucosa. Weight gain and feed intake were increased by Cu ($P<0.01$) and were further increased by Zn or Zn + Cu ($P<0.01$). Gain to feed ratio was decreased ($P<0.01$) by Zn + Cu provided as inorganic forms but not as the organic forms, compared with Zn alone. Zinc supplementation increased ($P<0.01$) tibia and plasma Zn concentrations. Tibia Zn and Cu levels were higher ($P<0.01$) for the organic Zn + Cu treatment than for the inorganic Zn + Cu treatment. The Cu content in the mucosa of chicks fed both organic Zn and Cu was significantly higher ($P<0.01$) than that of chicks given no supplementation or both inorganic Zn and Cu. This suggests that the Bioplex form of Cu is more efficiently absorbed from the lumen and that the antagonism between Zn and Cu can be avoided through using proteinated forms of these minerals.

Key Words: Zinc, Copper, Antagonism

698 Body weight, carcass yield and intestinal clearance of broilers having Na and K salts in the drinking water during pre slaughter feed removal. H. A. Gomes, S. L. Vieira*, D. M. Freitas, and C. A. Torres, *Universidade Federal do Rio Grande do Sul*, *Porto Alegre, RS, Brazil*.

Ideally, pre slaughter feed removal in broilers should take between 8 and 12 hours. This time allow the intestinal contents to be cleared out, however body and carcass weight are reduced. In this study, Na and K salts were added to the drinking water and given to 46 d old broilers during a 24 hour pre slaughter period. From these, the last 12 hours corresponded to the feed removal period. Six hundred and forty eight Cobb X Cobb 500 broilers were placed in drinking water treatments having tap water or graded increases of 0.15, 0.30, and 0.45% sodium bicarbonate or potassium chloride. In a last treatment, birds were not allowed access to water. The 8 treatments had 9 replications of 9 birds each and were placed in 2.8 m2 floor pens at start. Each pen had one feeder and 3 nipple drinkers connected to a 20 L water tank with a volume scale, full at the beginning. Since one d old placement o 46 d all birds were on a ad libitum feed and water program. They were then kept out of feed for 3 hours and then allowed one hour access to feed after which the feed withdrawal period started. All birds were weighed at this time and one bird per pen was randomly sacrificed, eviscerated and had its entire gastro intestinal system weighed. Intestinal contents were collected from the crop through proventriculus and from the duodenum through the cloacae. Followed a standard carcass and cut up processing. This procedure was repeated every 2 hours until a total of 12 hours was attained and 7 birds per pen were sacrificed. Water intake was estimated at 2 hour intervals by checking the amount left in the tank compared to the amount in the immediately former period. At the end of the study, water intake demonstrated to be linearly increased with the use of salts in the water ($P<0.05$), regardless of the salt type. Body weight loss increased linearly through the feed removal period, however, it was higher with birds without access to water ($P<0.0001$). There were no effect of treatments on carcass and cut up yields as well as on the intestinal dry matter mass at any evaluated moment.

Key Words: Broiler, Feed Withdrawal, Drinking Water

699 The effect of dietary glycine and *Clostridium perfringens* challenge on whole blood chemiluminescence responses in broiler chickens. Z. Papp, J. P. Dahiya, G. Widyaratne, J. E. G. Smits, and M. D. Drew*, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

Whole blood chemiluminescence (WBCL) is a simple and rapid method of measuring the production of reactive oxygen species by circulating polymorphonuclear leukocytes. WBCL was used as a method of assessing innate immune function in broiler chickens fed ideal-protein balanced diets with different protein and glycine concentrations and orally challenged with *Clostridium perfringens*. In Experiment 1, one-day-old male broiler chicks (Ross 308; N=144) were housed in two separate rooms with 12 cages of 6 birds per room. On day 14, four cages of birds in each room were randomly assigned to one of 4 diets containing 16 or 18% digestible crude protein and 0.98 or 1.75% glycine (gly) in a 2 x 2 factorial arrangement. All diets contained 9.80 MJ/kg net energy and 1.11% digestible lysine with all other essential amino acids at ideal protein levels. Birds in one room were challenged with 1 ml of an overnight culture of *C. perfringens* on days 14-21 and in the other room, birds were challenged with sterile PBS. On day 28, blood samples were collected for measurement of WBCL. Challenged birds had significantly higher WCBL responses than unchallenged birds (36,640 vs 26,370 cpm) and those receiving the 1.75% gly diets had significantly higher WCBL responses than birds fed the 0.98% gly diets (34,400 vs 28,374 cpm; $P < 0.05$). Digestible protein level had no significant effect on WCBL responses. In Experiment 2, two cages of 6 birds each were fed 1 of 4 diets containing 0.76, 2.10, 3.43 or 4.77% of gly. Net energy, amino acid levels and oral challenge with *C. perfringens* were as described for Experiment 1. On day 28 blood samples were collected for measurement of WBCL. The birds fed the 0.76% gly diet had significantly lower WCBL responses compared to birds fed the other 3 diets. The results demonstrate that dietary gly level and challenge of birds with *C. perfringens* significantly alters innate immune status of broiler chickens measured using WBCL.

Key Words: Glycine, Clostridium perfringens, Chemiluminescence

700 Live performance of broilers fed diets supplemented with the plant extract Sangrovit or a blend of organic and inorganic acids. S. L. Vieira*[1], D. M. Freitas[1], J. L. B. Coneglian[1], A. F. Klein[1], P. X. Silva[1], and O. Figueiró[2], [1]*Universidade Federal do Rio Grande do Sul*, *Porto Alegre, RS, Brazil*, [2]*Phytobiotics*, *Londrina, PR, Brazil*.

Quaternary benzo[c]phenanthridine alkaloids (QBA) sanguinarine and chelerythrine are plant extracts which have antimicrobial and anti-inflammatory properties usually present in the ratio of 3 to 1. Blends of organic and inorganic acids are used due to their antimicrobial properties in animal feeds. This study evaluated broiler performance when fed Sangrovit, a commercial extract marketed in several countries (1.5% sanguinarine) or a Blend of Acids (40% lactic, 7% acetic, 5% phosphoric and 1% butyric). One thousand five hundred and forty Cobb X Cobb 500 one day old male broiler chicks were placed in 44 floor pens, 35 per pen. All birds were fed corn-soybean meal feeds w/o traditional antibiotic growth promoters or anticoccidials. Feeds were provided as follow: 1 to 7 d, 8 to 21 d, 22 to 35 d and 36 to 42 d with 4 treatments and 11 replications in a RBD as follow: T1: Control Treatment w/o any additive; T2: Sangrovit 50 ppm added from 1 to 21 d and then 25 ppm to 42 d; T3: a Blend of Acids at 8 kg/ton from 0 to 7 d, 6 kg/ton from 8 to 21 d, 4 kg/ton from 22 to 35 d, and 2 kg/ton

from 36 to 42 d; T4: Sangrovit as in T2 + a Blend of Acids at 6 kg/ton from 0 to 7 d, 4.5 kg/ton from 8 to 21 d, 2 kg/ ton from 22 to 35 d, 1 kg/ton from 36 to 42 d. Birds were vaccinated for coccidiosis at placement with Paracox. All diets had nutrients and ME to meet or exceed NRC (1994). Body weight, feed intake and feed conversion were weekly evaluated. One bird per pen was sacrificed for evaluation of intestinal lesion scores as well as villi height and crypt depth at 7, 14 and 21 d, whereas 6 birds per pen were processed at 42 d. When compared to the Control Treatment, body weight was improved at 21 d when Sangrovit or the Blend of Acids was used ($P < 0.05$). Improvements in feed conversion were shown weekly and also in the overall period when using Sangrovit alone as well as when a combination with the Blend of Acids ($P < 0.05$). No differences due to the treatments were observed in terms of intestinal lesion scores or villi height and crypt depth at 7, 14 and 21 d, or for the yield of carcass and commercial cuts at 42 d.

Key Words: Broiler, Sanguinarine, Sangrovit

701 Effects of tannin concentration on nutritional value of sorghum grain in broiler chicks. C. R. Monge*[1], J. D. Hancock[1], C. Feoli[1], R. C. Kaufman[1,2], M. R. Tuinstra[1], S. R. Bean[1,2], S. Beyer[1], and B. P. Ioerger[2], [1]*Kansas State University*, *Manhattan*, [2]*USDA/ARS*, *Manhattan*.

A total of 192 broiler chicks (Cobb x Cobb, 7 d of age, and average initial body weight of 131 g) was used in a 7-d metabolism experiment to determine the effects of tannin concentration on nutrient utilization. A reference diet with 50% cornstarch was formulated to meet or exceed the nutrient concentrations recommended in the 1994 NRC for poultry. Sorghum grain was then substituted for cornstarch in the reference diet. The sorghum treatments were created by mixing 60% endosperm from non-tannin sorghum (Mycogen 627) with blends of pericarp from the non-tannin sorghum and a tannin sorghum (Sumac) as 40% of the composite. The pericarps were blended so the sorghum composites had none, 0.34, 0.68, 1.36, 2.72, and 5.44 mg of catechin equivalents/100 mg of DM (i.e., % CE). The birds were adjusted to treatment for 4 d followed by 3 d collection of excreta. The excreta were dried, ground, and analyzed for DM, N, and GE with Cr2O3 used as an indigestible marker. There was a linear decrease ($P < 0.03$) in average daily gain (ADG) and a trend (quadratic effect, $P < 0.08$) for decreased gain to feed ratio (G:F) as tannin in the sorghum was increased from none to 5.44% CE. The trend in G:F was consistent with quadratic responses ($P < 0.001$) in percentage retention of DM, N, and GE with concentration of tannins greater than 1.35% CE resulting in decrease nutrient utilization. For the none, 0.34, 0.68, 1.36, 2.72, and 5.44% CE treatments, ADG was 27.9, 26.7, 26.9, 26.8, 25.4, and 25.7 g/d, G:F was 811, 804, 854, 812, 786, and 757 g/kg, retention of DM was 72.8, 73.0, 74.3, 73.4, 68.9, and 65.2%, retention of N was 59.3, 57.3, 60.7, 58.7, 52.2, and 48.5%, and retention of GE was 78.8, 77.4, 79.9, 78.2, 74.6, and 70.6%, respectively. In conclusion, our experiment suggests that some tannin (up to 1.35% CE) is tolerated by growing broiler chicks without loss in nutrient utilization.

Key Words: Poultry, Sorghum, Tannin

702 Effects of tannins from different sorghums on nutrient utilization in broiler chicks. C. R. Monge*[1], J. D. Hancock[1], C. Feoli[1], R. C. Kaufman[1,2], M. R. Tuinstra[1], S. R. Bean[1,2], S. Beyer[1], and B. P. Ioerger[2], [1]*Kansas State University*, *Manhattan*, [2]*USDA/ARS*, *Manhattan, KS*.

A total of 96 broiler chicks (Cobb x Cobb, 7 d of age, and initial body weight of 128 g) was used in a 7-d metabolism experiment to determine the effects of tannin source on nutrient utilization. A reference diet with 50% cornstarch was formulated to meet or exceed the nutrient concentrations recommended in the 1994 NRC for poultry. Sorghum treatments were created by mixing endosperm (60% of the composite) from non-tannin sorghum (Mycogen 627) with blends of pericarp (40% of the composite) from the non-tannin and tannin sorghums (Koro Kollo, Sumac, and SC599). The pericarps were blended to provide 0.6 mg catechin equivalents/100 mg DM from each sorghum source. The sorghum treatments were substituted for cornstarch in the reference diet on a wt/wt basis. The birds were adjusted to treatment for 4 d followed by 3 d collection of excreta. The excreta were dried, ground, and analyzed for DM, N, and GE with Cr2O3 used as an indigestible marker. Compared to birds fed pericarp from Mycogen, birds fed the Koro Kollo treatment had less ($P < 0.05$) average daily gain (ADG). Birds fed pericarp from Mycogen had greater retention of DM ($P < 0.03$), N ($P < 0.02$), and GE ($P < 0.01$) compared to birds fed pericarp from Sumac and SC599. However, retention of DM, N, and GE were similar among birds fed pericarp from the different tannin sorghums with only a trend ($P < 0.09$) for greater GE retention in birds fed Koro Kollo rather than SC599. Means for Mycogen, Koro Kollo, Sumac, and SC599 were 27, 23, 27, and 26 g/d for ADG, 804, 779, 798, and 793 g/kg for G:F, 82, 78, 77, and 76% for retention of DM, 71, 67, 63, and 63% for retention of N, and 86, 82, 81, and 79% for retention of GE. In conclusion, pericarp from the various sorghums having tannins reduced nutrient utilization with only minor indication of differences in biological activity of the tannins from different sorghums.

Key Words: Sorghum, Tannins, Poultry

703 Quality characteristics of newly developed flaxseed: Chemical evaluation. B. A. Slominski*[1], T. Davie[1], A. Rogiewicz[1], W. Jia[1], C. M. Nyachoti[1], O. Jones[2], J. Dean[3], and P. Dribnenki[3], [1]*University of Manitoba*, *Winnipeg, Canada*, [2]*Canadian Bio-Systems*, *Calgary, Canada*, [3]*Agricore United*, *Winnipeg, Canada*.

Flaxseed is being widely used in laying hen nutrition for omega-3 enriched egg production and is currently being considered as a valuable source of fatty acids in swine and broiler chicken finishing rations. A comprehensive evaluation of the nutritive profiles of two newly developed yellow-seeded lines NuLin™ CR12 and NuLin™ CR50 in comparison with the conventional brown-seeded flax var. CBC Bethune was undertaken. On average, more oil ($P \leq 0.01$) was found in NuLin CR12 (47.8% DM) and NuLin CR50 (47.1% DM) than in the conventional flaxseed (43.9% DM). Even a higher magnitude of difference was noted for linolenic acid (omega-3) which, on seed basis, averaged 31.4 and 29.7% for NuLin CR12 and NuLin CR50, respectively, and was higher by 9-10 percentage points than that of Bethune (21.3% DM). Similar amounts of crude protein (23.5 and 21.6 vs 21.6% DM), sucrose (2.1 and 1.8 vs 1.9% DM), oligosaccharides (1.7 and 1.4 vs 1.8% DM), and phytate (1.3 and 1.0 vs 1.0% DM) were observed for NuLin CR12 and NuLin CR50 in comparison to Bethune. The yellow-seeded characteristic was reflected in the lower fiber content only for NuLin CR12 showing the mean total fiber value of 25.8% which differed significantly ($P \leq 0.001$) from that of NuLin

CR50 (32.0%) and Bethune (32.3%). On a fat free and DM basis, the total fiber content of NuLin CR12 and NuLin CR50 averaged 51.0 and 62.6%, respectively, and was followed by the same magnitude of difference (P≤0.001) in the content of lignin and polyphenols (9.2 vs 12.7%), glycoprotein (10.4 vs 16.1%) and ash (1.3 vs 2.8%). There was no difference in the non-starch polysaccharide (NSP) content between the two lines (30.2 vs 31.0%), although NuLin CR12 was lower (P≤0.001) in water-insoluble (15.8 vs 18.15%) and higher in water-soluble (i.e., mucilage) NSP (14.5 vs 12.9%). No major differences in essential amino acids and phytate and non-phytate P contents were observed among the samples.

Key Words: Yellow-seeded Flax, Chemical Composition, Omega-3

704 Evaluation of a dynamic model of calcium and phosphorus metabolism in layers. E. Kebreab*[1], J. Dijkstra[2], R. P. Kwakkel[2], and J. France[1], [1]*University of Guelph*, *Guelph, ON, Canada*, [2]*Wageningen University*, *Wageningen, The Netherlands*.

Phosphorus (P) is an essential nutrient involved in most metabolic processes of the body. Most of the interest in calcium (Ca) metabolism relates to eggshell formation. Although the eggshell is composed of calcium carbonate, metabolism of both Ca and P are closely related such that a deficiency in one can interfere with proper utilization of the other. Depending on time and availability, P can be mobilized in excess amounts in the laying hen which ends up being excreted in urine and contributes to build-up of P in the soil and water. Reduction and timing of P availability can mitigate pollution. To understand Ca and P metabolism properly, modeling can be of paramount importance. A new dynamic model of P and Ca metabolism in layers has been developed using ACSL to simulate diurnal changes in Ca and P and the layer's hourly requirement for those minerals. The model consists of 8 state variables representing Ca and P pools in the crop, stomachs, plasma and bone. The duodenum is represented as a zero pool in the model. An experiment that measured Ca and P uptake in layers fed different Ca levels during shell-forming days was used to compare with model simulations. The experiment showed that the percentage of Ca retained in body and egg decreased from 62.5 to 50.5% when the Ca in diet was increased. The model simulations were in agreement with the trend. Predictions were 63.2, 56.1 and 55.3% for low, medium and high Ca levels in the diet. The experimental results showed that P retention increased significantly from 11.5% at the lowest Ca inclusion level to 24.1% at the highest. The model also predicted an increase in P retention from 8.4 to 25.4% at lowest and highest level of Ca inclusions, respectively. The advantage of the model is that absorption and utilization (or excretion in urine) can be monitored on hourly basis and adjustments to the diet can be made based on the times where Ca is mobilized for eggshell formation. The model successfully showed how the availability of one mineral affects the utilization of the other and is a useful tool to evaluate feeding strategies aimed at reducing P excretion to the environment in poultry manure.

Key Words: Phosphorus, Pollution, Model

705 Impact of dietary available phosphorus levels on growth and tibia ash of male broilers to 21 d. L. A. Oden*[1], S. D. Frankenbach[2], N. Augspurger[2], and J. B. Carey[1], [1]*Texas A&M University*, *College Station, TX*, [2]*JBS United, Inc.*, *Sheridan, IN*.

An experiment was conducted to evaluate the available phosphorus requirement of contemporary male broilers through 21 days of age. The basal diet was estimated to have 0.15% available phosphorus. Six additional diets were formulated with incremental 0.05% increases in available phosphorus with 0.45% the highest level of available phosphorus. Supplemental available phosphorus was provided in the form of Potassium phosphate. Eight replicate pens of each of the seven diets were arranged in a randomized block design with fifteen birds per battery pen for a total of 840 birds. Pens of birds were group weighed on day 1. Feed and water were provided ad libitum. Mortalities were removed, weighed and recorded twice per day. At 21 days, individual bird weights were recorded and the right tibia was removed, weighed and frozen until analyzed for ash content. There were no differences in 21d body weight, feed consumption, mortality, feed:gain, tibia weight or tibia as a % of body weight among birds fed 0.35, 0.40 and 0.45% available phosphorus. Lower levels of phosphorus resulted in significant decreases in feed consumption, body weight, and tibia weight. Level of phosphorus below 0.35% resulted in significant increases in mortality and feed:gain. The lowest level of phosphorus did not support normal growth performance. Based on these data dietary levels of 0.35% available phosphorus appear adequate for 21d male broilers reared in battery pens.

Key Words: Available Phosphorus, Broilers, Tibia Ash

706 Apparent calcium and phosphorus retention with different levels and source of vitamin D. J. A. G. Brito[1], A. G. Bertechini[1], J. C. C. Carvalho[1], A. Geraldo[1], J. O. B. Sorbara*[2], and F. J. Piraces[2], [1]*Universidade Federal de Lavras, DZO*, *Lavras, MG, Brazil*, [2]*DSM Nutritional Products*, *Sao Paulo, SP, Brazil*.

Vitamin D is high related with calcium and phosphorus retention. A metabolism trial was performed with four levels of vitamin D (800; 1500; 3500 and 5500 IU/ton feed) provided by two source of vitamin D and an additional two treatments with 2000 IU of vitamin D3 plus 37,5 mg of 25(OH)D3/ton feed and 2000 IU of vitamin D3 plus 70 mg of 25(OH)D3/ton feed fed to 18-d-old broiler chicken. The feed was based on corn soybean meal with 500 FTU/ton feed. Three days of total excrete collection was performed on wire cage. The treatments had five replications with 15 birds per replications in a complete randomized design. Calcium and phosphorus intake and calcium and phosphorus excreted were determined. The apparent calcium and phosphorus retention was calculated (intake - excreted / intake x 100). No interaction was observed (P>.05) between vitamin D supplementation levels and vitamin source to apparent calcium retention (ACaR), apparent phosphorus retention (APR) and phosphorus excreted (PE). Comparing the treatments that received just one source of vitamin D with the treatments with both source of vitamin D showed a better apparent calcium and phosphorus retention for the treatments that received both source of vitamin D. And comparing the two treatments with both source of vitamin D showed a better apparent calcium retention and calcium excreted to the treatment with higher level of 25(OH)D3 .

Table 1. Apparent Ca and P retention and total Ca and P excreted.

Source	Level	ACaR	APR	CaE	PE

707 Differences in amino acid digestibility in soybeans processed by different methods. T. Shi[1,2], H. M. Edwards, Jr.[2], G. M. Pesti*[2], and R. I. Bakalli[2], [1]*Shandong Academy of Agricultural Sciences*, *Jinan, Shandong, China*, [2]*University of Georgia*, *Athens, GA, USA*.

Three samples were obtained to investigate the influence of soybean processing method on the chicks' response to phytase supplementation. Corn (53.61%), soybean meal (37.47%), & soybean oil (5.49%) based diets (with 0.1 % Cr2O3) were fed to 3 replicate pens of 10 broiler chicks each in battery brooders for 16 days. Solvent extracted, expeller or extruded soybean meals were substituted for 50% of the entire diet. On day 16, ileal contents were gently removed from the posterior two-thirds of the ileum. The samples were freeze dried and assayed for amino acids. Only LYS, MET, CYS, THR, TRP & ARG were included in these analyses. If the amino acids were considered separately (11 error degrees of freedom), only LYS digestibility appeared to be affected by phytase (p<0.006), and there was no significant source by phytase interaction (p>0.20). However, if the amino acids were considered together in one ANOVA (66 error degrees of freedom), there were clear differences in amino acid digestibilities (ARG=88.2±1.5, CYS=57.0±4.0, LYS=87.2±2.0, MET=82.0±2.9, THR=73.7±3.0, TRP=84.5±1.9, p<0.013) and a very significant source by phytase interaction (p<0.002). There were no significant differences in chick growth or feed utilization between chicks fed the three soybean meals.

Table 1. Avg. amino acid digestibility in 3 SBM's (LYS, MET, CYS, THR, TRP & ARG)

Phytase	Solvent	Expeller	Extruded
0	84.5±3.4	72.1±5.0	75.8±3.8
1200	74.3±5.3	82.0±5.3	81.6±4.6
Avg	79.4±2.6	78.1±3.2	78.7±2.3

Key Words: Amino Acids, Digestibility, Phytase

708 Evaluation of hydrated lime as a litter treatment at three application rates for broiler chickens. J. P. Blake*, J. B. Hess, K. S. Macklin, and C. A. Wilson, *Auburn University*, *Auburn, AL*.

A total of 1120 commercial broiler chicks (Cobb X Ross) were randomized with 70 birds assigned to each of 16 environmental chambers (2.44 × 2.44 × 2.44 m). Birds were fed a corn-soybean meal starter (1.5 lbs/bird; 22% CP, 3087 kcal/kg), grower (3.0 lbs/bird; 20% CP, 3131 kcal/kg), finisher (4.0 lbs/bird; 17.5% CP, 3197 kcal/kg) and withdrawal (c.a. 3.0 lbs/bird; 16.5% CP, 3219 kcal/kg). Treatments comprised a control (CON) with no litter treatment and hydrated lime (HL) at a commercial application rate equivalent to 50, 100, or 150 lbs/1,000 ft2 of floor space with each treatment assigned to four chambers. New pine shavings (54.42 kg) were placed in each pen. Feed and water were provided ad libitum under 24 hrs continuous light. Birds and feed were weighed at 21, 42 and 49 d to determine growth and feed performance. Litter and air quality samples were obtained for analysis initially and on day 7, 14, 21, 28, 35, 42 and 49 of the experiment. Ammonia measurements were conducted using a closed container of specified dimension inverted over the litter bed and determined using a Drager CMS Analyzer equipped with a remote air sampling pump. No differences (P>0.05) in growth performance (body weight, feed consumption, or feed efficiency) occurred during the 49-d experimental period due to treatment. Litter pH for the HL treatments was significantly higher (P<0.05) through day 21 as compared to the CON. Initial pH of the litter on day 0 for CON and HL at the 50, 100, or 150 rates were 6.35, 12.45, 12.82, and 12.82, respectively. By day 21 pH measurements were 7.25, 8.92, 9.38, and 9.45 for the CON and HL at the 50, 100, and 150 rates, respectively. Afterwards, there were no differences in pH due to treatment. Results indicated no significant (P>0.05) changes in ammonia levels due to the HL treatments. Results indicate that the application of HL on clean shavings resulted in an initial increase in litter pH (c.a. 50% higher) that continued through day 21 (c.a. 21% higher). HL failed to support any reduction in ammonia volatilization. Litter sample analysis did not indicate an increase in the amount of nutrients retained due to treatment. Litter moisture increased from a low of 8.9% to 26.4% by day 49 with no differences between treatments.

Key Words: Hydrated Lime, Litter Treatment, Ammonia

709 Evaluation of Poultry Guard™ litter treatment at three application rates for broiler chickens. J. P. Blake*, J. B. Hess, K. S. Macklin, and C. A. Wilson, *Auburn University*, *Auburn, AL*.

For each of two experiments a total of 1120 commercial broiler chicks (Cobb × Ross) were randomized with 70 birds assigned to each of 16 environmental chambers (2.44 × 2.44 × 2.44 m). Birds were fed a corn-soybean meal starter (1.5 lbs/bird; 22% CP, 3087 kcal/kg), grower (3.0 lbs/bird; 20% CP, 3131 kcal/kg), finisher (4.0 lbs/bird; 17.5% CP, 3197 kcal/kg) and withdrawal (c.a. 3.0 lbs/bird; 16.5% CP, 3219 kcal/kg). Treatments comprised a control (CON) with no litter

treatment and Poultry Guard™ (PG) at a commercial application rate equivalent to 50, 100, or 150 lbs/1,000 ft^2 of floor space with each treatment assigned to four chambers. New pine shavings (54.42 kg) were placed in each pen. Feed and water were provided ad libitum under 24 hrs continuous light. Birds and feed were weighed at 21, 42 and 49 d to determine growth and feed performance. Litter and air quality samples were obtained for analysis initially and on day 7, 14, 21, 28, 35, 42 and 49 of the experiment. Ammonia measurements were conducted using a closed container of specified dimension inverted over the litter bed and determined using a Drager CMS Analyzer equipped with a remote air sampling pump. No differences ($P>0.05$) in growth performance (body weight, feed consumption, or feed efficiency) occurred during the 49-d experimental periods due to treatment. Litter pH was significantly lower ($P<0.05$) for PG treated pens as compared to CON and this effect continued at the 100 and 150 rates until termination of the experiments at 49-d. Overall reduction in pH as compared to the control ranged from approximately 5 to 65% and was dependant on level of application, bird age and other environmental influences. Results indicated that the PG treatments did not elicit a significant ($P>0.05$) reduction in ammonia in either experiment.

Key Words: Poultry Guard, Litter Treatment, Ammonia

710 Litter bacterial levels associated Poultry Guard™. K. S. Macklin*, J. P. Blake, J. B. Hess, and R. A. Norton, *Auburn University*, *Auburn, AL*.

Litter treatments are commonly applied to litter to reduce ammonia and bacterial levels. Two trials were performed in which the effects of Poultry Guard™ (PG) on litter bacterial counts, percent moisture and pH were measured. Both trials were performed using clean pine shaving litter that was placed into 16 environmental chambers (2.44 x 2.44 × 2.44 m). Chicks were placed at a density of 70 chicks/pen. In both experiments there were four treatments, with each treatment getting four pens. The treatments comprised of a control (CON) and (PG) being applied at 50, 100 and 150 lbs/1000ft^2. Both experiments had litter collected weekly from three areas within each pen for 7-weeks. Bacteriologically total aerobic, anaerobic, Staphylococcus, and C. perfringens levels (cfu/g) were determined. Also the presence or absence of Campylobacter and Salmonella was determined. Bacterial counts (CFU/g) and percent moisture data were transformed using log10 and arcsine transformations, respectively. The data was analyzed using GLM with $P<0.05$ and significant means were separated using Tukey's HSD. The results for the two trials showed that both the 100 and 150 lb application rates kept the pH lower then the CON and 50 lb rate until day 49. There was differences ($P<0.05$) in the moisture level between the treatments. The bacterial numbers between the two trials showed that there was no reduction in any of the numbers between the four treatments over the 7 weeks in which they were measured ($P<0.05$).

Key Words: Poultry Guard™, Litter, Bacteria

711 Pasteurization of chicken litter with steam and calcium oxide to reduce colonization and incidence of *Salmonella typhimurium*. M. Farnell*[1], A. Byrd[2], L. Sunkara[1], K. Stringfellow[1], P. Anderson[1], J. McReynolds[2], J. Carey[1], A. Bell[2], R. Stipanovic[2], and D. Caldwell[1], [1]*Texas A & M University*, *College Station*, [2]*USDA-ARS*, *College Station, TX*.

Commercial poultry are raised on absorbent bedding materials such as wood shavings or rice hulls. These materials are costly to remove and replace in an environmentally sound manner. Therefore, multiple flocks of chickens often are raised on the same bedding material for as long as 1 ½ to 10 years. Good management practices and decaking machines considerably extend the useful life of the bedding material. However, down time between flocks is only 5-14 days which does not allow a desired degree of pathogen reduction residual of the previous flock. As a consequence, day of hatch chicks with naïve immune systems are placed onto contaminated litter. These practices often result in costly infections from coccidia and other opportunistic pathogens. Additionally, foodborne pathogens such as *Salmonella* and *Campylobacter* survive in the litter to be transmitted from bird to bird and flock to flock via coprophagy or fomites. The nursery industry pasteurizes soil with steam to reduce plant pathogens. Another method adds calcium oxide to nursery soils to capitalize on the resulting exothermic reaction that occurs when the chemical interacts with water. These techniques are likely to reduce pathogens if used in commercial poultry houses. In this study, a steam sterilization cart simulated conditions used by the nursery industry to treat Salmonella typhimurium inoculated litter. Homogenized litter was exposed to steam for 0, 5, 30 or 120 minutes. Calcium oxide was used at concentrations of 0, 2.5, 5 or 10 %. Results showed that all treatments significantly reduced Salmonella typhimurium colonization by at least 3 orders of magnitude. However, most treatments reduced colonization levels to undetectable levels even when samples were enriched. These data demonstrate two novel techniques for reducing bacterial pathogens in poultry litter. Soil pasteurization potentially offers an environmentally sound means to reduce the pathogenic load and output of poultry waste.

Key Words: Chicken, Litter, Pasteurization

712 Evaluation of Envirobed® litter product for broiler production. R. M. Hulet* and T. L. Cravener, *The Pennsylvania State University*, *University Park*.

High quality litter products are essential for optimizing broiler efficiency and good health. Litter products must be able to absorb moisture, have low levels of mold and bacteria, allow efficient growth and development, and not damage skin or foot pads. Envirobed® is a "recycled-fiber" product made from chipped cardboard tubes with dust and fine particles removed. Broilers (864) were placed at a density of 14.35 birds/square meter into twenty-four pens containing either pine wood shavings (PS) or Envirobed® litter (E) at a depth of 5 cm. Birds were weighed at 0, 14, 28, and 42 days of age and feed consumption, conversion and percent mortality evaluated. At the end of the study, litter moisture and condition was evaluated. No statistical difference in body weight was found between birds grown on the PS (2.74 Kg) or E (2.70 Kg) litter by 42 days of age. PS reared birds at 14 and 28 d had greater body weight than the E reared birds. Overall feed intake was significantly less for birds on the E litter (4.78 kg) than for PS reared birds (4.93 kg). Therefore, feed conversion was significantly improved for the E reared birds (1.775) when compared to the PS reared birds (1.801) at the $P<0.054$ level. At forty-two days, percentage moisture for PS litter was significantly greater ($P<0.06$ level) than for the E litter (48 vs 43%, respectively). In Summary, Envirobed® was found

to be an acceptable litter product when compared to PS for rearing broilers to 42 days of age.

Key Words: Broiler, Litter, Growth

713 Use of ferric sulfate for ammonia reduction in commercial broiler houses. C. W. Ritz*[1], L. A. Harper[1], B. D. Fairchild[1], M. Czarick[1], J. Pavlicek[2], and V. Johnson[2], [1]*The University of Georgia*, [2]*Kemira Water Solutions*.

Ammonia concentration in poultry houses is a production issue of concern. Previous work has correlated negative bird performance with poor indoor air quality due to ammonia. Ventilation has been the key means of removing ammonia from poultry houses but the use of litter treatment products that lower pH are also commonly applied. Acid-based products, though effective for short-term ammonia reduction, have not proven to be long-term solutions to ammonia reduction due to the amount of product required to chemically bind ammonia, problems of application when birds are present, and the corrosiveness of the material. Consequently, new types of litter treatment are needed along with other mechanisms to reduce in-house ammonia concentrations and subsequent house emissions. The purpose of this study was to evaluate the effectiveness of a new litter amendment containing ferric sulfate compared to an alum-based litter amendment. Since alum is a commonly-used litter amendment in the broiler industry and at the request of the participating poultry company, in this study the alum treatment product was used as the Control and the ferric sulfate as the Treatment. Both Treatment and Control were applied at the same time and rate of 100 lbs per 1000 ft^2. Litter analyses for total nitrogen, ammonium nitrogen, nitrate nitrogen, percent moisture, pH, dry matter content, and soluble salts were taken throughout the study. Aerial ammonia concentrations were measured using time weighted detection tubes and gas-washing bottles. The ferric sulfate amendment was, on average, superior to the aluminum sulfate amendment in reducing ammonia concentrations in the houses during the first 10 to 12 days after bird placement, with mean ammonia concentrations for the ferric sulfate and alum at 13-19 ppm and 21-26 ppm, respectively. The ferric sulfate product improved retention of nitrogen in the litter over the control. No differences were noted in mortality, body weight, or feed efficiency between the two treatments.

Key Words: Ferric Sulfate, Ammonia, Broiler

714 Egg yolk and serum antibody titers, and manure nutrients of broiler breeder hens immunized with uricase or urease. Adrizal*[1], P. Patterson[2], and T. Cravener[2], [1]*University of Jambi*, *Jambi, Indonesia*, [2]*The Pennsylvania State University*, *University Park*.

This study evaluated if broiler breeder hens immunized with uricase, urease, or uricase+urease would develop IgY titers against these antigens to prevent manure-N degradation and NH_3 release. Hens (76, 43-wk, Ross × Arbor Acre) kept in individual cage were randomly assigned to PBS control, uricase, urease, or uricase+urease antigen. Hens were immunized with the antigens in the breast muscle i.m. on d 0, 7, and 14. Blood samples were drawn via the wing vein of 7 hens/treatment on d 0 (before injection), 4, 9, 12, 17, 21, and 24 for serum IgY titer analysis. Eggs were collected for 28 d for yolk IgY titer analysis. Manure samples were taken on d 0, 7, 14, 22, and 29 for solids, total-N, NH_4-N, organic-N, P, K, pH, and NH_3 measurements. Elevated egg yolk uricase-IgY titers were observed after the 2nd injection ($P \leq 0.0001$) and remained significantly higher than the PBS or urease treatment from d 9 to 24. An egg yolk urease-IgY titer was noticed after the 1st injection ($P \leq 0.01$), then undetectable for 13 d, and elevated again on d 17, 21, and 24 ($P \leq 0.0001$) beyond the control and uricase treatments. Serum uricase-IgY response was obvious ($P \leq 0.01$) after the 1st injection, highly significant by d 9, and remained greater than the PBS or urease treatment until d 28. The serum urease-IgY titer response lingered later in comparison with uricase-IgY. Only at 24 and 28 d were urease titers significantly greater than the PBS or uricase group. Hens immunized with uricase or urease responded well with both egg yolk and serum titers. Combination antigens were also significantly greater than the PBS controls, but less than the individual uricase or the urease. Manure NH_3 volatilization showed no clear relationship with the IgY titers. Only manure total-N concentration indicated greater N retention on d 29 from the uricase+urease combination (63.5 g/kg, DM basis) compared to the others ($P = 0.07$).

Key Words: Antibody Titer, Manure Nutrient, Broiler Breeder Hen

715 Dietary sodium bisulfate, humate and zeolite for broiler chickens: Impact on performance, litter nutrients and ammonia flux. P. Patterson*[1], T. Cravener[1], E. Wheeler[2], P. Topper[2], and D. Topper[2], [1]*Department of Poultry Science*, [2]*Department of Agricultural and Biological Engineering, The Pennsylvania State University*, *University Park*.

A broiler feeding trial was conducted to evaluate the effects of dietary Sodium bisulfate (S), Humate and Zeolite on growth performance, litter nutrients and litter ammonia flux. Cobb chicks (1728) were placed in 48 pens (0.0699 m^2/bird) with new pine shavings, and fed a commercial control diet from 0-14d. Six dietary treatments were fed from 14-44 days including a control, 0.75% S (S75), 0.50% S+0.75% Humate (S50H75), 0.50% S+1.0% Zeolite (S50Z100), 0.75% S+0.75% Humate (S75H75) and 0.75% S+1.0% Zeolite (S75Z100). Body weight (44d) was significantly higher for birds fed S75 (3.01 kg) vs. control (2.94 kg) or S50H75 (2.94 kg) diets. Feed intake to 44d was greatest for the S75Z100 vs. the other treatments, except S75H75 (P=0.0015). Overall FC was lowest for S75, highest for S50Z100 and S75Z100, and intermediate for the control and other treatments (P=0.0076). Mortality was unaffected by the dietary treatments and averaged 4.11%. Ammonia flux measures from the 23d litter (mg NH_3/m^2/min) were highest from the control litter, but linearly reduced by increasing levels of dietary S (P≤0.0001). The same trend was observed at 41d with S75 treatments averaging 4-fold less NH3 than the controls, and S50 treatments 35% less (P=0.0019). Litter pH was significantly reduced by dietary 0.75% S treatments compared to the control. Litter solids at 42d were significantly less (46.6%) for the S75 dietary treatments vs. the control and S50 treatments (mean 53.6%, P≤0.0001). On a DM basis litter Na (P≤0.0001), K (P=0.0004) and P (P=0.0286) were greater from dietary treatments with 0.75% S, and less from the control and 0.5% S treatment birds. Litter sulfur levels showed a linear trend with greater concentrations tied to greater dietary S levels (P≤0.0001). Overall, improvements in growth performance, and litter ammonia flux with the 0.75% S diet suggest promise for commercial application.

Key Words: Litter, Ammonia Flux, Broiler Performance

716 The potential for plants to trap emissions from farms with laying hens: 1. Ammonia. P. H. Patterson*[1], Adrizal[4], R. M. Hulet[1], and R. M. Bates[2], [1]*Department of Poultry Science*, [2]*Department of Horticulture*, [3]*Department of Agricultural and Biological Engineering, The Pennsylvania State University*, *University Park*, [4]*University of Jambi*, *Jambi, Indonesia*.

The potential of plant vegetation to trap ammonia (NH_3) discharged from a layer house through the exhaust fans was evaluated at the Pennsylvania State University Education Research Center in September 2005. Five tree species were planted in pot-in-pot containers in five rows downwind of the house fans, and in two control rows upwind of the hen house. Each row included one plant (upwind) or two plants (downwind) per species per row. When measured with a photoacoustic NH_3 detector at the same elevation as the fan (1.5 m), NH_3 concentration decreased sharply with greater distance, from 51.54 ppm at 0 m (at the fan) to 1.89 ppm at 5.5 m (between row 2 and 3), 0.27 ppm at 10 m (after row 5), and 0 ppm at 50 m (control). This trend was also observed with the dosi-tubes and photoacoustic detector at the 0.3 and 3.0 m elevations. Significantly lower NH_3 concentrations were recorded when the trees were present downwind of the fans compared to when the trees were removed (16.45^b vs. 19.35^a ppm) suggesting a portion of the atmospheric NH_3 was being held by the plants. This was further supported by a marked decrease in foliar N status of the plants with greater distance from the source. Plant species also differed with willow appearing to be the most responsive species and effective as an NH_3 trap.

Key Words: Plant, Ammonia, Foliage Nitrogen

717 The potential for plants to trap emissions from farms with laying hens: 2. Ammonia and dust. Adrizal*[1], P. Patterson[2], and M. Hulet[2], [1]*University of Jambi*, *Jambi, Indonesia*, [2]*Department of Poultry Science*, [3]*Department of Horticulture*, [4]*Department of Agricultural and Biololgical Engineering, The Pennsylvania State University*, *University Park*, [5]*Department of Natural Resource Ecology and Management, Iowa State University*, *Ames*.

The potential of plant vegetation to trap ammonia (NH_3) and dust (particulate matter [PM]) discharged from a layer house through the exhaust fans was evaluated at the PSU Poultry Education and Research Center in July 2006. Poultry and livestock NH_3 emissions are a concern for air quality, surface deposition, and animal and human health. PM is a human health concern as well and regulated by the US-EPA in non-attainment areas. Five tree species were planted in pot-in-pot containers in five rows downwind of four hen house fans and in two control rows upwind of the fans. When measured with a photoacoustic NH_3 detector at fan elevation (1.5 m), NH_3 concentrations decreased sharply ($P \leq 0.0001$) with greater distance, from 71.11 ppm at 0 m (at the fan) to 2.07 at 5.5 m (between row 2 and 3), 0.32 at 10 m (after row 5), and 0.07 ppm at 50 m (control). This trend was also observed with dosi-tubes and the photoacoustic detector at 0.3 and 3.0 m elevations. Significantly lower NH_3 concentrations were recorded in the presence of the trees compared to when the trees were removed at both 0.3 and 3.0 m elevations, suggesting a portion of the atmospheric NH_3 was being trapped by the plants. This was further supported by greater foliar N concentrations in plants when downwind of the fans ($P \leq 0.0001$). Dust concentrations sampled downwind of the fans were greatest at 2.5 m and decreased linearly to 50 m ($P \leq 0.0001$). Plant PM-2.5, 10 µm, and PM-total washed from the foliage showed the sample significant linear trend with greater distance from the fans. Plants also showed unique species differences in their capacity to trap and hold NH_3 and PM that can be applied in practical recommendations. In conclusion, these findings indicated vegetative buffers are capable of trapping NH_3 and PM fan emissions from poultry facilities.

Key Words: Plant, Ammonia, Dust

718 Vegetative buffers for fan emissions from poultry farms: ammonia, dust, and foliar nitrogen. R. M. Hulet*[1], Adrizal[1], P. H. Patterson[1], and C. A. B. Myers[2], [1]*The Pennsylvania State University*, *University Park*, [2]*Berks County Extension*, *Lebanon, PA*, [3]*Capital Region Extension*, *Lancaster, PA*, [4]*USDA-NRCS*, *Harrisburg, PA*, [5]*USDA-NRCS*, *Corning, NY*, [6]*Iowa State University*, *Ames*.

A study evaluated the potential of trees planted around commercial PA poultry farms to trap ammonia (NH3) and dust particulate matter (PM). Hybrid poplar (HP), hybrid willow (HW), Norway spruce (NS) and Streamco willow (SW) were planted in several rows downwind of the exhaust fans of one turkey, two layer, and two broiler farms (2003 to 2004) and sampled in 2006 for DM, nitrogen (N), and PM analysis. Concentrations of ammonia were passively measured downwind of exhaust fans (eight hours). Plant N levels did not differ among farms, but were significantly affected by distance from the fan ($P<0.001$), especially when comparing ammonia (ppm) at 0 m (12.01) with 11.4 m (2.59), 15 m (2.03), and 30 m (0.31). Farm type affected foliar DM ($P< 0.0001$) but not N. Both foliar DM and N were influenced by species ($P<0.0005$), where HP, HW and SW showed a greater response than NS. Location also affected foliar N with significantly higher values noted nearer the fans than the controls (3.19 vs. 2.71 %). Plant species had no effect on foliar PM at greater than PM10µm, but NS and HW trapped PM2.5µm, PM10µm and total PM significantly better than the other two species. The effect of location was seen only in PM >10µm, where the plants nearer fans held more total PM than controls (0.021 vs. 0.0005 mg cm-2). The capacity of plants to trap and benefit from ambient ammonia around commercial poultry farms and their potential as dust traps were observed in the present study and suggested the buffer's function to reduce farm emissions. HP, HW, and SW seemed to be appropriate plants to absorb aerial ammonia nitrogen whereas NS and HW appeared to be more effective dust traps.

ARPAS Symposium: Current and Future On-Farm Auditing & Assessment

719 Animal welfare assessment and auditing. S. E. Curtis*, *University of Illinois*, *Urbana*.

The assessment and the auditing of animal welfare are related but distinct processes. An assessment protocol prescribes how the assessment will be accomplished in terms of indicators of animal state of being and their measurable goals. The auditing process aims to determine whether or not those goals have been achieved. Of course, an auditor must first assess, following the assessment protocol, to be able to determine that. The auditing process is the topic of another presentation in this symposium. Here the focus will be on the rational development of an assessment protocol. Several preliminary decisions have to be made as an approach to establishing an assessment protocol is set. In this author's opinion, the following guidelines should be followed: (1) The concept of animal welfare should be followed, not animal rights; (2) Objective criteria of evaluation should be employed, not subjective criteria; (3) An approach based on animal performance, not animal feelings, is favored; (4) The performance axiom, not the feelings axiom, is favored; (5) Animal-performance standards, not environmental-design standards, should rule; (6) Different goals for assessment —e. g., inter-herd comparison or intra-herd improvement—dictate different approaches; (7) Theoretical constructs often will still serve better than intuition (often flawed) or empirical data (not enough at hand); (8) Respective evaluation criteria should be subjected to weighting schemes as the final composite index of state of being is formulated (although developing such strategies is proving to be a difficult task); and (9) the mixed model of motivation should serve as the guide when developing a variable-weighting scheme.

Key Words: Assessing Animal Welfare

720 Auditing and assessing nutrient management for water quality. A. L. Sutton*, *Purdue University*, *West Lafayette, IN*.

Concentrated animal feeding operations (CAFO) and many mid-sized animal feeding operations (AFO) are required to comply with state and federal environmental regulations specifically related to the protection of water quality. Most current regulations are based on the need to account for and control nutrient flow on-farm to minimize buildup, leaching and runoff of nutrients that may pose a risk to surface and ground water quality. In addition, there is pressure for producers to control pathogens, antibiotics, hormones and endocrine disruptors in the waste stream, soils and water. Attempts to encourage best management practices to control nutrient flow include the requirements for nutrient management plans, comprehensive nutrient management plans, conservation practice plans, storm water pollution prevention plans, chemical and fuel handling, animal mortality management, and emergency action plans. The overall goal of the nutrient management plan on a livestock and poultry farm is to sustain as much as possible a whole farm nutrient mass balance while producing animal products efficiently and profitably. An extensive auditing and assessment program evaluates the status of nutrient management on-farm and develops an action plan specific for CAFO and AFO to minimize water pollution and sustain water quality standards. An annual audit and review checks the performance of the CAFO and AFO on environmental stewardship and identifies areas needing improvement. Critical control points that need to be audited and assessed for each farm are 1) nutrients imported on-farm, 2) nutrients exported off-farm, 3) nutrient status of soils and water, 4) manure handling and storage facilities, 5) conservation practices, 6) runoff waste water control, 7) land application practices, 8) animal mortality practices, 9) record keeping system, 10) operation and maintenance plan, and 11) alternative treatment systems, if applicable. Professionals involved currently and in the future that audit and assess nutrient management on-farm will be discussed including the role of animal scientists in this process.

Key Words: Nutrient Mass Balance, Animal Feeding Operations

721 Auditing and assessing nutrient management for air quality. N. A. Cole*[1], R. W. Todd[1], B. Auvermann[2], and D. B. Parker[3], [1]*USDA-ARS-CPRL*, *Bushland, TX*, [2]*Texas Agricultural Experiment Station*, *Amarillo*, [3]*West Texas A&M University*, *Canyon*.

The potential adverse effects of concentrated animal feeding operations (CAFO) on the environment are a growing concern. The air quality concerns of CAFO vary with the location, type of operation, and other factors. In general, those of most concern include ammonia, hydrogen sulfide, particulate matter (PM), volatile organic compounds (VOC), green house gases (GHG), and odors/odorants. Some states have initiated their own air quality regulations, in part because only PM and VOC are regulated under the Clean Air Act. However, in the future, ammonia and hydrogen sulfide may be regulated under the Superfund (CERCLA) and(or) "Right-to-Know" (EPCRA) Acts. The U.S. EPA and poultry, swine, and dairy industries recently agreed to the National Air Emissions Monitoring Study (Consent Agreement) to fund research on emissions of ammonia, hydrogen sulfide, PM, and VOC from U.S. production farms. Air quality regulations may be based on actual emissions, atmospheric concentrations, human perception (odors) or via limiting the size or location of CAFO. Measuring the concentrations or emissions of most air pollutants is expensive, complex, and labor intensive. Because of large spatial and temporal variability, concentrations and emissions must be measured continuously over an extended period of time. Because different methods/models can give widely varying results with the same data set, it is preferable to use a multitude of methods simultaneously and a mass balance should be run to assure emissions estimates are plausible. In the future, requirements for monitoring of air emissions from CAFO will probably vary from state to state and among different types of operations. Most likely, producers, and not the government, will be responsible for the costs of any air quality monitoring program. Processed-based and empirical models need to be developed so that emissions and(or) concentrations of air pollutants can be estimated from readily obtainable diet, animal, facility, and environmental variables. Auditors will need to be trained in a variety of disciplines including animal sciences, chemistry, engineering, micrometeorology, instrumentation, mathematical modeling, and logic.

Key Words: Air Quality, Regulation, CAFO

722 Training and certification of animal auditors. A. K. Baysinger*, *Farmland Foods*, *Bruning, NE*.

Animal auditing as a profession is in its infancy. Oversight of a profession that can and will have a significant impact to animal agriculture was the motivation to create the Professional Animal Auditor Certification Organization (PAACO). PAACO is an organization of

five animal industry organizations with extensive expertise on best management practices and current science in animal agriculture. The organization's purpose is to promote the humane treatment of animals through education and certification of animal auditors and to promote the profession of animal auditors. Founding and current organizations are the Federation of Animal Science Societies (FASS), American Registry of Professional Animal Scientists (ARPAS), American Association of Swine Veterinarians (AASV), American Association of Bovine Practitioners (AABP) and American Association of Avian Pathologists (AAAP). Website: www.animalauditor.org. PAACO does not create audits nor determine protocols within animal agriculture. Its role is to work with the species organization to train and certify auditors to the industry determined standards.

PAACO, Inc. Background

Successful livestock, dairy and poultry producers and their related industry partners provide sound animal care on commercial farms and harvest plants. Most animal and meat producer organizations have guidelines that are consistent with sound science and a consideration of economic realities. The process by which auditors are qualified, trained and certified continues to be developed by PAACO. Many groups require auditors and audit firms to have specific qualifications, experience and abilities. FASS, ARPAS, AABP, AAAP and AASV are professional, independent, science-based groups that have come together to initiate training and certification for on-farm and harvest plant auditors. PAACO has anticipated the need to evaluate, train and qualify candidates that want to pursue animal auditing as a career. Animal welfare is only the first of many aspects of livestock production to be audited at the farm level. It is in agricultures best interest to verify the qualifications of the potential auditors.

Key Words: PAACO, Audit, Welfare

Breeding and Genetics - Livestock and Poultry: Dairy Cattle III

723 Analysis of calving ease trait in Canadian Holsteins. A. Sewalem*[1,2], F. Miglior[1,2], G. Kistemaker[2], P. Sullvian[2], and B. Doormaal[2], [1]*Agriculture and Agri-Food Cananda*, *Guelph, Ontario, Canada*, [2]*Canadian Dairy Network*, *Guelph, Ontario, Canada*.

The aim of this study was to examine the level of calving ease trait across parities and to estimate genetic parameters in Canadian Holsteins. Data consisted of 271,789 cows from 11,283 herds sired by 2,276 sires. At time of calving the calving ease was recorded as unassisted or unobserved, easy pull, hard pull and surgery. The distribution of each score across parities was 61.38, 31.15, 7.21 and 0.26% for unassisted or unobserved, easy pull, hard pull and surgery, respectively. The statistical model included the fixed effects of herd-year-season, age at calving, sex of calf and the random effects of service sire and animal. A single trait animal model was used. The distribution of each category in the first parity were 49.16, 37.70, 12.84 and 0.30 % for unassisted or unobserved, easy pull, hard pull and surgery, respectively. The corresponding figures in the second parity are 64.53, 30.54, 4.81 and 0.13% and in the third parity 65.18, 29.92, 4.74 and 0.17%. The phenotypic correlations of calving ease trait for parity 1 and 2 was 0.21, for parity 1 and 3 0.17 and for parity 2 and 3 is 0.24. Heritability values from a single trait analysis (as trait of the dam) for parity 1, 2 and 3 were 0.096, 0.132 and 0.129, respectively. Estimation of genetic parameters using a multiple trait animal model is under progress.

Key Words: Calving Ease, Genetic Parameters, Canadian Dairy Breeds

724 Genetics of grass dry matter intake, energy balance and digestibility in Irish grazing dairy cows. D. P. Berry*, M. O'Donovan, and P. Dillon, *Moorepark Dairy Production Research Center*, *Fermoy, Co. Cork, Ireland*.

The objective of this study was to estimate genetic parameters for grass dry matter intake (DMI), energy balance (EB) and cow internal digestibility (ID) in grazing Holstein-Friesian dairy cows. Grass DMI was estimated up to four times per lactation on 1,588 lactations from 755 cows on two research farms in southern Ireland. Simultaneously measured milk production and body weight records were used to calculate EB. Cow ID, measured as the ratio of feed and faecal concentrations of the natural odd carbon-chain n-alkane pentatriacontane, was available on 583 lactations from 238 cows. Random regression and multi-trait animal models were used to estimate residual, additive genetic and permanent environmental (co)variances across lactation. Results were similar for both models. Heritability for DMI, EB, and ID across lactation varied from 0.10 (8 days in milk; DIM) to 0.30 (169 DIM), from 0.06 (29 DIM) to 0.29 (305 DIM), and from 0.08 (50 DIM) to 0.45 (305 DIM), respectively when estimated using the random regression model. Genetic correlations within each trait tended to decrease as the interval between time periods compared increased for DMI and EB while the correlations with ID in early lactation were weakest when measured mid-lactation. The lowest correlation between any two time periods was 0.10, -0.36 and -0.04 for DMI, EB and ID, respectively suggesting the impact of different genes at different stages of lactations which has repercussions for genetic selection. Eigenvalues and associated eigenfunctions of the additive genetic covariance matrix revealed considerable genetic variation among animals in the shape of the lactation profiles for DMI, EB and ID which may be exploited in breeding programs. Genetic parameters presented are the first estimates from dairy cows fed predominantly grazed grass and imply that genetic improvement in DMI, EB and ID in Holstein-Friesian cows fed predominantly grazed grass is possible.

Key Words: Grass Dry Matter Intake, Energy Balance, Genetics

725 Principal components approach for estimating heritability of mid-infrared spectrum in bovine milk. H. Soyeurt*[1,2], S. Tsuruta[3], I. Misztal[3], and N. Gengler[1,4], [1]*Gembloux Agricultural University*, *Gembloux, Belgium*, [2]*FRIA*, *Brussels, Belgium*, [3]*University of Georgia*, *Athens*, [4]*FNRS*, *Brussels, Belgium*.

Mid-Infrared spectrometry predicts the milk components (e.g., %fat, %protein) from spectral data reflecting the milk composition. The data included 9,663 test days on 1,937 cows in 1 to 12 parity recorded from April 2005 to May 2006. Each sample was scanned by MilkoScan FT6000 into 1,060 points. Due to the high dimension, principal components approach (PCA) was done to reduce the traits and indicated

that 48 principal components (PC) described 99.02% of information. These PC were analyzed by multi-trait REML using the canonical transformation. This analysis considered 2,850 first lactation records for 738 cows in 7 breeds from 26 herds. Effects included in the multi-trait model were herd*test date, lactation stage, permanent environmental and animal random effects. The estimates of the variances were back transformed to the initial scales. Heritabilities varied from 0.005% to 57.20% for the different pin numbers. Spectral regions with heritability greater than 5% were located between 1 to 181; 194 to 558 and 709 to 1,060 pin numbers. PCA involving points in those regions demonstrated that only 9 PC explained 99.23% of information. Mid-Infrared spectrum contains specific regions with substantial genetic information potentially useful for selecting improved milk quality directly on spectral data.

Key Words: Mid-Infrared, Milk, Heritability

726 Associations between body size, body condition score and fertility parameters in pasture-based seasonally calving commercial dairy herds in Australia. T. E. Stirling*[1], C. R. Stockdale[2], and K. L. Macmillan[1], [1]*The University of Melbourne*, *Werribee, Victoria, Australia*, [2]*Primary Industries Research Victoria*, *Kyabram, Victoria, Australia*.

The objective of this study was to evaluate the associations between body size parameters (hip height and hip width) with changes in body condition score (BCS), and the association with fertility parameters. A total of 1850 cows from 5 commercial pasture-based seasonally calving herds were monitored over a 12-month production cycle, with BCS assessed pre-calving, start of the artificial insemination period (SAIP), mid lactation and late lactation. Little variation was observed in height and width parameters; 140.0 ± 0.11cm and 43.0 ± 0.09cm respectively (mean ± standard error); but associations with BCS and fertility could be drawn. Taller cows tended to be thinner throughout the production cycle ($P<0.05$ pre-calving, SAIP and late lactation) while wider cows were fatter ($P<0.05$). Height was not related to the likelihood to become pregnant nor the interval between SAIP and conception (INT); however, width was positively correlated to the INT ($P<0.01$) meaning wider cows took longer to conceive. Body frame size (HxW) was not significantly related to BCS per se, apart from at SAIP when larger cows were fatter ($P<0.01$). Despite this, larger cows lost more condition in early lactation, were less likely to become pregnant, and those that did become pregnant had a longer INT. Cows with a greater height to width ratio (H:W) were thinner throughout the production cycle and did not have significant losses in condition in early lactation. These cows were more likely to become pregnant and those that did become pregnant had a shorter INT. The experiment was conducted during drought conditions when nutritional intake was limited and fertility compromised. Under these conditions, large cows were unable to maintain enough condition to optimise fertility. Despite being thinner overall, cows with greater H:W were able to maintain a more consistent BCS and had a better reproductive performance.

Key Words: Body Size, Body Condition Score, Fertility

727 Comparison of yield in Holsteins, Jerseys, and reciprocal crosses in the Virginia Polytechnic Institute and State University - Kentucky crossbreeding trial. B. G. Cassell*[1], K. M. Olson[1], and A. J. McAllister[2], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*University of Kentucky*, *Lexington*.

Purebred Holstein and Jersey cows at Virginia Polytechnic Institute and State University and Kentucky were bred to four Holstein and four Jersey bulls in AI in a diallele scheme. First calvings to project animals were in June 2005 at Virginia Polytechnic Institute and State University and January 2006 at Kentucky. Here we summarize summit and peak yields and projected 305 day actual production from animals with at least 150 days in milk in first parity. Data include 33 HH (breed of sire first), 19 HJ, 17 JH, and 12 JJ animals. Breed comparisons were from a fixed model including four breed groups, seven herd-seasons of calving groups (five four-mo groups at Virginia Polytechnic Institute and State University and two at Kentucky), and regression of response variable on age at calving in mo. The three degrees of freedom for breed groups were also partitioned into additive effects of Holstein versus Jersey genes, maternal effects, and heterosis and fit with herd-season and regression on age at freshening. Limited JJ animals and unequal sire progeny distribution may affect results. We found significant ($P<0.05$ for all comparisons) effects for additive gene action and heterosis for summit milk, peak milk, and projected actual 305 day yields of milk, protein, and fat, but no significant maternal effects for any trait. Heterosis ranged from 8% for summit to 13% for peak yields, and exceeded 10% for 305d projected yields. Fixed effects were significant for all traits except age for summit yield and herd-season for protein yield. Summit yield differed only for Jerseys, while peak yield differed for Jerseys and JH vs. HH. Milk yields were higher for HH than HJ, JH, or JJ, but were not different from HJ or JH for protein. Milk, protein, and fat yields for Jerseys were lower than other breed groups, while HJ fat was higher than HH or JH. Entries in the table are in kg. Summit and peak refer to milk production while milk, protein, and fat refer projected 305d yields in kg.

Table 1. Breed group least squares means (kg) for summit and peak milk and for projected 305d yields of milk, protein, and fat

Breed	Summit	Peak	Milk	Protein	Fat
HH	34	37	9642	291	350
HJ	31	36	8915	293	383
JH	32	34	8963	288	360
JJ	24	25	6596	228	322

728 Quantitative Trait Loci affecting IgG serum protein levels, birth weight and gestation length in a Holstein x (Holstein x Jersey) backcross population. C. Maltecca*, K. A. Weigel, H. Khatib, and V. R. Schutzkus, *University of Wisconsin*, *Madison*.

Aim of the study was to identify QTL associated with stillbirth and calf survival, using data from a crossbred HOL x JER. experimental population consisting of 172 backcross calves created via backcross matings. Stillbirth is defined as a calf that dies just prior to, during, or within 24 to 48 h of parturition. The cost of stillbirths to the US dairy industry has been estimated to be ~$132 million per year. Nonetheless its binary nature and low frequency make it difficult to investigate. In the study three indicators of general health were utilized instead. The first, calf birth size, was considered in relation with the ability of the calf to survive and later perform. The second, Calf IgG absorption during the first 72h of life, is a strong indicator of passive immunization

attainment and it's associated with long-term calf performance. Finally, studies by Meyer et al. ranked gestation length as the third most important factor affecting stillbirth rates in primiparous cows with dystocia scores of 3+ and third for multiparous cows for any level of dystocia. The same author also reported a significant decrease in stillbirth for longer gestations. This trait was then chosen in connection with its influence on newborn survival. Calves were measured for weight after birth. Immune function was evaluated through serum IgG levels between 24 and 78h of age. Serum IgG levels were determined by radial immuno-diffusion assay. Gestation lengths were recorded as part of the routine data collection. Results from a genome scan, are discussed. 182 microsatellites were chosen among 270 after sires genotyping. Spacing between markers ranged from 3.4 to 32.85 cM with an average of 15.93 cM. Interval mapping analysis was performed for all traits considered. Evidences for suggestive QTL ($P<0.05$) for IgG levels were found in at least one of the families at CHR2 (~72 cM) and CHR5 (~88 cM). Evidence for a significant QTL (~$P<0.01$) for IgG level were found in CHR6 (~68 cM) in one family. Evidence for suggestive QTL ($P<0.05$) for birth weight were found in CHR2 (~24 cM) and CHR6 (~90 cM) in at least one family. Evidences for a suggestive QTL ($P<0.05$) affecting gestation length, were found in CHR9 (~100cM).

Key Words: QTL, Cattle, Health

729 Stearoyl-CoA desaturase gene polymorphism and milk production traits in Italian Holsteins. N. P. P. Macciotta*[1], M. Mele[2], G. Pagnacco[3], M. Cassandro[4], G. Conte[2], A. Cappio-Borlino[1], and P. L. Secchiari[2], [1]*Dipartimento di Scienze Zootecniche, Università di Sassari*, *Sassari, Italia*, [2]*Dipartimento di Agronomia e Gestione dell'Agro-Ecosistema, Università di Pisa*, *Pisa, Italia*, [3]*Dipartimento di Scienze e Tecnologie Veterinarie per la Sicurezza Alimentare, Università di Milano*, *Milano, Italia*, [4]*Dipartimento di Scienze Animali, Università di Padova*, *Padova, Italia*.

The Stearoyl-CoA desaturase (SCD) is a key enzyme for the lipid metabolism of ruminants, being able to introduce a double bond at the ÃƒÅ½Ã¢â‚¬Â9-position in a large spectrum of fatty acids. A polymorphism with two alleles (A and V) has been reported for the SCD locus in cattle, due to three single nucleotide polymorphisms that are in linkage disequilibrium. In this work, possible associations between SCD genotype and milk production traits in Italian Holsteins are investigated. Data were 5,097 test day records for milk, fat and protein yields, fat and protein contents, measured on 313 Italian Holsteins (2,2 lactations per cow). Data were analysed with a mixed linear model that included the fixed effects of herd, test date, genotype at the SCD locus, parity, lactation stage nested within SCD genotype and the random effect of the animal plus the random residual. Parity, test date, herd and lactation stage affected significantly milk production traits, except for parity on fat content. A statistically significant effect of the SCD genotype was observed for milk yield, fat content and protein yield. In particular, VV cows had an average daily milk yield higher than AV and AA cows (kg/day 35.95, 34.59, 33.71, respectively; $P<0.01$), a lower fat content (gr. fat/100 gr milk 3.39, 3.51, 3.55, respectively; $P<0.05$) and a higher protein yield (kg/day 35.95, 34.59, 33.71, respectively; $P<0.01$). Differences observed among the three different genotypes tend to remain constant throughout the whole lactation. Although observed in a limited sample of cows, these results, together with the recently reported influence of the SCD polymorphism on fatty acid composition of carcass and milk fat in cattle, seem to suggest a possible role of the SCD locus as a candidate gene to be used in the genetic improvement of milk production traits in cattle via schemes of Marker Assisted Selection.

Key Words: Stearoyl-CoA Desaturase, Polymorphism, Milk Production Traits

730 Effect of pregnancy on milk yield of Canadian dairy cattle. S. Loker*[1], J. Bohmanova[1], F. Miglior[2,3], M. Kelly[1], and G. Kistemaker[3], [1]*University of Guelph*, *Guelph, ON, Canada*, [2]*Agriculture and Agri-Food Canada*, *Sherbrooke, QC, Canada*, [3]*Canadian Dairy Network*, *Guelph, ON, Canada*.

Pregnancy has been reported to have a negative impact on milk production in dairy cattle. A suitable method for estimating the effects of pregnancy is required before pregnancy can be properly accounted for in genetic evaluations. In this study, two models were used to account for pregnancy in seven Canadian dairy breeds. The first model represented pregnancy effects with days open, studying the impact of increased days open on the shape of the lactation curve. The second model measured the impact of the stage of pregnancy on milk production. Milk production for cows with short days open tended to drop significantly in the last part of lactation, while cows with longer days open had proportionally higher milk yield. Using the second model, milk yield declined in all breeds in the study after 4 months of pregnancy (from -0.5 kg/d in first parity Jerseys to -1.3 kg/d in third parity Holsteins). While the pattern of decline in milk yield using both models generally followed the results of other studies, the effect of days open from the first model seemed to be confounded with the production level of the cows. Stage of pregnancy provided a more realistic estimate of the effect of pregnancy on milk production, especially when adjusted for stage of lactation.

731 Kinetics and properties of plant β-galactosidase extracted from durian seeds *(Durio zibethinus)* and its utilization on ice milk production. E. E. El Tanboly*, *National Research Center*, *Dokki, Cairo, Egypt*.

β-galactosidase (β-gal) was partially purified 2.16-fold with a total yield of 21.32% of the original activity by sequential use of ammonium sulfate precipitation and gel filtration through Sephadex G-200 from durian seeds *(Durio zibethinus)*. The β-gal activity was linear with time up to 20 min and still constant thereafter. A progressive increase in activity of the purified β-gal was observed up to 60°C accompanied by a decrease thereafter. An energy of activation of 3.04 Kcal/mole for the enzyme activity was derived from the Arrhenius plot. The purified β-gal started loosing activity above 40°C when incubated at different temperatures for 10 min and became completely inactivated at 80°C. The optimum pH was 3.0. Michaelis-constant (Km) value of 1.42 mM and a maximum velocity (Vmax) of 3.3 μmoles/ml/min. Fe+++, Zn++ and Cu++ strongly inhibited the enzyme. However, the enzyme was partially inhibited by Mg++, Ca++ and Mn++. The use of a plant β-gal in ice milk production was studied. Different concentrations of β-gal;

11.2 (TI), 22.4 (TII) and 33.6 (TIII) units/ml were added to fresh pasteurized milk., and a control with no β-gal. The results indicated that there is a direct of the increase of proportional of the increase of plant β-gal activity level to the level units to the hydrolyzed lactose, specific gravity and weight per gallon of ice milk. On the other hand, increasing β-gal decreased the overrun values. This can be attributed to the decrease in the amount of incorporation air. Organoleptic tests showed the highest value is recorded with TI (85.6%) this may be due to the increase in the sweet taste based on the hydrolysis of lactose by the β-gal, it could be said that the addition of β-gal to ice milk mixes increased the sweetness but properties of body and texture and appearance of the resultant ice milk slightly decrease.

Key Words: Durian fruit *(Durio zibethinus)*, β-galactosidase (β-gal), Ice Milk

732 Selenium supplementation of lactating dairy cows: effects on total selenium content and speciation in blood, milk and cheese. R. H. Phipps*[1], A. S. Grandison[1], A. K. Jones[1], D. T. Juniper[1], and G. Bertin[2], [1]*University of Reading*, *Reading*, [2]*Alltech (France)*, *Paris, France*.

Forty-multiparous Holstein cows were used in a 16-wk continuous design study to explore the effects of two selenium (Se) sources, (selenized yeast from *Saccharomyces cerevisiae* CNCM I-3060 Sel-Plex® and sodium selenite (Na_2SeO_3)) and inclusion rate of selenized yeast on Se concentration and speciation in blood, milk and cheese. Cows received ad libitum a TMR with 1:1 forage to concentrate ratio. The four diets (T1-T4) differed only in source and dose of Se additive. Estimated total dietary Se for T1 (no supplement), T2 (Na_2SeO_3) and T3 and T4 (selenized yeast) was 0.16, 0.30, 0.30 and 0.45 mg/kg DM, respectively. Whole blood and milk samples were measured at 28-d intervals. At each time point there were linear effects ($P < 0.001$) of selenized yeast on whole blood and milk Se concentration. At day 112 the whole blood and milk Se values for T1-T4 were 177, 208, 248, 279 ± 9.4 and 24, 38, 57, 72 ± 3.7 ng/g fresh material, respectively. Furthermore comparable doses of selenite and selenized yeast indicate improved Se bioavailability (T2: 38 vs. T3: 57 ng/g fresh material) from selenized yeast. In blood, selenocysteine (SeCys) was the main species and was not markedly effected by treatment, while in contrast, the inclusion of selenized yeast resulted in a marked increase in selenomethionine (SeMet) concentration. In milk, Se speciation showed that there were no marked treatment effects on SeCys content, while Se source had a marked effect on SeMet. At day 112 the SeMet content of milk from T3 was approximately three times higher (111 vs. 36 ng Se/g) than T2, and the level increased further to 157 ng Se/g for T4. At study end, milk from T1, T2 T3 was made into cheese (Caerphilly). Se source had a marked effect on total Se, SeMet and SeCys content of cheese. Replacing Na_2Se0_3 (T2) with selenized yeast (T3) increased the total Se, SeMet and SeCys content from 180 to 340 ng Se/g, 57 to 153 ng Se/g and 52 to 92 ng Se/g, respectively.

Key Words: Dairy Cows, Milk and Cheese, Selenium Speciation

733 Effects of temperature and membrane pore size on fractionation of caprine milk proteins in developing infant formula analogs. C. O. Maduko[1] and Y. W. Park*[2,1], [1]*University of Georgia*, *Athens*, [2]*Fort Valley State University*, *Fort Valley, GA*.

Denaturation of milk proteins during temperature treatment may cause a simultaneous change in permeate flux during subsequent membrane processing of the milk. Few studies have been reported on the modification of caprine milk proteins by membrane fractionation based on molecular size and temperature treatment to eliminate β-lactoglobulin (Lg) while retaining α-lactalbumin (La) for infant feeding. The study was conducted to examine effects of temperature treatment and membrane pore size on the elimination of β-Lg and retention of α-La, and subsequently determine these effects on the optimum permeate fractionation. Four batches (18.9 L each) of raw goat milk were collected, and 2 batches were pasteurized and immediately cooled to 4°C, and the other 2 batches were treated as raw milk. One batch of raw and pasteurized milks were frozen stored at -35°C for 2 days and the other batches were left at refrigeration (4°C). After separation of cream, all treated milk groups were underwent a two-step-cascade membrane separation by ultrafiltration to eliminate β-Lg from the whey fraction. The results showed that the frozen goat milk groups, either raw or pasteurized, showed the best membrane separation performance. The infant milk formula analog produced using the casein and optimum permeate (800/30kDa) fraction of these milk samples had the closest similarity to human milk with respect to the total protein content (1.3 g/100g), β-Lg content (1-2 %), and casein-lactalbumin ratio (0.6-0.7). Complete elimination of β-Lg in most permeate fractions of all 4 milk groups was observed, although the 800/30 kDa permeate fractions of frozen groups had small β-Lg content. It was concluded that membrane performance during ultrafiltration of caprine milk were affected by temperature treatment of the milk prior to membrane separation.

Key Words: Goat Milk Infant Formula, Ultrafiltration, β-lacto-globulin

734 The effect of dry period duration and dietary energy density in early lactation on the rennet gelation properties of milk. S. T. Butler*, M. de Feu, B. O' Brien, and J. J. Murphy, *Teagasc Moorepark DPRC*, *Co Cork, Ireland*.

This study was carried out to examine the effects of omitting the dry period and altering the energy density of the diet during early lactation on the rheological characteristics of milk. Forty mature Holstein-Friesian cows were used in a completely randomized design with a 2×2 factorial arrangement of treatments. Cows were randomly assigned to one of two dry period treatments (no planned dry period or standard 8 week dry period) and one of two nutritional treatments in early lactation (standard energy TMR or high energy TMR). Milk samples were collected at 2, 6 and 10 weeks postpartum. The concentration of fat, protein and lactose was determined in each sample. The rennet gelation properties were measured at 31° C using dynamic low-amplitude strain oscillatory rheometry. The elastic shear modulus, G′, was used as an index of gel firmness. Gelation time (GT; time taken for G′ to reach a value ≥ 0.2 Pa), maximum curd firming rate (CFR_{max}; maximum slope of the G′-time curve), and gel strength (GS; G′ value at 50 minutes) were calculated. Data were analysed as a factorial design using the MIXED procedure of SAS. Protein concentration was increased by omitting the dry period (31.8 vs. 34.7 g/kg; $P < 0.001$), but not by increasing diet energy density (32.9 vs. 33.7 g/kg; $P = 0.2$). Fat concentration was not affected by duration of the dry period (39.3 vs. 41.5 g/kg; $P = 0.1$), but was significantly reduced by increasing dietary energy density (43.1 vs. 37.7 g/kg; $P < 0.001$). GT was not affected by either dry period duration or diet. Omitting the dry period increased CFR_{max} (2.58 vs. 3.60 Pa/min;

P < 0.001) and GS (69.4 vs. 90.5 Pa; P = 0.003), whereas dietary energy density did not have an effect on either measurement. GS was correlated with CFR_{max} (r = 0.98; P < 0.001), and both variables were correlated with milk protein concentration (r = 0.71; P < 0.001, and r = 0.73; P < 0.001, respectively). The results indicate that omission of the dry period significantly increased milk protein concentration and improved the rennet gelation properties of milk, but that dietary energy density had little effect.

Key Words: Milk Processability, Dry Period, Rheology

735 Rheological properties of rennet gels prepared with milk protein concentrates. M. A. Ferrer*[1,2], A. R. Hill[2], and M. Corredig[2], [1]*University of Zulia*, *Maracaibo, Venezuela*, [2]*University of Guelph*, *Ontario, Canada*.

Milk protein concentrates (**MPC**) are value-added ingredients prepared by membrane filtration commonly employed in dairy processing. To understand the factors affecting the rheological behaviour of rennet-induced gels containing MPC, MPC (56%, 70% and 90% protein) dispersions were prepared in water at a final concentration of 5% protein and their gelation behaviour was tested using a controlled stress rheometer. The calcium to protein ratio and the soluble calcium were inversely proportional ($p<0.05$) to the amount of protein present in the MPC powders. The amount of casein-macropeptide (**CMP**) released during the enzymatic reaction was determined by RP-HPLC. The maximum amount of CMP released from the micelles was lower in MPC 90 and MPC 70 compared to MPC 56 and skim milk powder. These results can be explained by SDS-PAGE data that showed more κ-casein in the soluble phase of MPC90, and therefore less remaining in association with the micelles, relative to MPC 56 and skim milk. Because calcium plays a major role in rennet-induced gelation of casein micelles, we also studied gelation behaviour of MPC dispersions equilibrated to their original environment by extensive dialysis against milk. In all cases, when more free calcium was present in the dispersions, dialysis dramatically extended the gelation time and decreased the stiffness of the gels. It was also shown that dialysis of MPC dispersions against milk significantly increased the amount of non-micellar casein in the dispersions. These results indicate that the equilibrium between the soluble and insoluble ions is the determining factor affecting the renneting functionality of casein particles present in MPC.

Key Words: Milk Protein Concentrate, Rennet Gel, Ionic Equilibrium

736 Rheological properties of whey protein dispersions in the presence of exopolysaccharides from *Lactococcus lactis* ssp. *cremoris*. I. Ayala Hernandez*[1], A. N. Hassan[2], and M. Corredig[1], [1]*University of Guelph*, *Ontario, Canada*, [2]*South Dakota State University*, *Brookings*.

Exopolysaccharides (EPS) produced by some strains of lactic acid bacteria improve textural properties and increase water retention in fermented dairy products. The aim of this research was to study the characteristics of EPS produced by *Lactococcus lactis* ssp. *cremoris*, and to better understand how those polysaccharides interact with proteins in milk under different conditions. A highly ropy strain of *Lactococcus lactis* ssp. *cremoris*. (JFR1) was selected for this research, and fermentations were conducted in ultrafiltation (UF) permeate with and without added whey proteins at 30°C under controlled pH and different fermentation times. The highest degree of ropiness and viscosity increase was obtained at pH values between 5.8 and 5.5 after 22 hrs of fermentation, and a significant loss of ropiness was observed after prolonged incubation. Rheological tests performed on the different fermented permeates confirmed the increase of viscosity correlated with the observed increase in ropiness. The molecular weights of the EPS obtained (determined by HPLC-MALS) are affected by the pH and the duration of the fermentation. A novel scanning electron microscopy technique confirmed whey protein-EPS interactions. This method covalently links milk proteins to the observation surface so that any non-interacting material can be washed out, and only interacting components are observed. Comparisons of fermentations performed with non-EPS producing strains on media with the same protein content helped to confirm the importance of the interaction of the polysaccharide with the protein to generate the viscosity increase. The results of this work suggest that the impact of EPS on the textural properties (ropiness and increased viscosity) of fermented products is determined not only by its molecular weight but also by its ability to interact with milk proteins.

Key Words: Whey Proteins, *Lactococcus lactis*, Exopolysaccharides

737 The impact of preacidification of milk and fermentation time on the properties of yogurt type gel. Y. Peng*[1], D. S. Horne[2], and J. A. Lucey[1], [1]*University of Wisconsin*, *Madison*, [2]*Formerly of Hannah Research Institute*, *Ayr, Scotland*.

The textural properties of yogurt are determined by the nature and type of casein interactions. To understand how the amount of insoluble Ca (CCP) associated with casein particles and fermentation time influence yogurt gels, we used a central composite experimental design and varied the initial milk pH and fermentation time (from the initial milk pH to 4.6). We hypothesized that varying the initial milk pH altered the amount of CCP and varying the fermentation time influenced the rate and extent of solubilization of CCP during the gelation process. Both of these factors could influence casein interactions and thereby alter gel properties. Milks were preacidified to pH values from 6.55 to 5.65 using glucono-δ-lactone and equilibrated for 4 h at 40°C before inoculation. Fermentation time was varied from 250 to 500 min by adding various amount of culture at 40°C. Gelation properties were monitored using dynamic oscillatory rheology. Microstructure was studied using fluorescence microscopy. Whey separation was analyzed at pH 4.6. The initial pH value of preacidification strongly affected the solubilization of CCP ($P<0.0001$). Storage modulus values at pH 4.6 were positively influenced by initial pH and negatively affected by fermentation time. Loss tangent maximum during gelation was positively affected by initial milk pH. Fermentation time positively affected whey separation ($P<0.0001$). Fermentation time significantly influenced the rate of CCP dissolution during fermentation as CCP dissolution was a slow process. Longer time resulted in greater loss of CCP at the pH of gelation. At the end of fermentation (pH ~4.6) virtually all CCP was dissolved. Preacidification of milk increased the solubilization of CCP, increased the loss of CCP crosslinks, and produced weak gels that had low storage modulus values. Long fermentation time allowed more time for solubilization of CCP during the critical gelation stage of the process and increased the possibility of greater casein rearrangements; both could have contributed to the increase in whey separation.

Key Words: Yogurt, Gelation, Whey Separation

738 The role of functional ingredients in marinated meat and poultry. B. S. Smith*, *John R. White Company, Inc.*, *Birmingham, AL*.

Traditionally, meat and poultry marinades have been used to convey a mixture of ingredients, through soaking, massaging, tumbling or injecting, in an effort to influence flavor, texture or other sensory attributes. Adding functional ingredients to a marinade can further influence product yield, cook loss, oxidative and microbial stability, and operational efficiency. Functional ingredient classes may include salts, sweeteners, phosphates, starches, gums and other hydrocolloids, and non-meat proteins. Many ingredients perform multiple functions when properly selected and incorporated through marinating. For example, aside from their contribution to flavor, ingredients like sodium chloride, sugars, and sodium or potassium lactate chemically bind water and effectively reduce water activity, which may positively influence shelf life. The combination of sodium chloride with phosphate enhances water holding capacity of the meat system by aiding muscle protein extraction, positively impacting yield and product texture, and minimizing package purge and cooking losses. Phosphates also have chelating properties that effectively reduce oxidation and warmed over flavor. Certain sweeteners participate in maillard browning to enhance product flavor and appearance. Starches, gums and other hydrocolloids effectively manage moisture to improve yield, manipulate texture, and minimize purge. Non-meat proteins also control moisture, but often are formulated to replace meat for economic purposes. Certain non-meat proteins may also contribute to marinade viscosity, which can influence absorption and retention. Freeze-thaw stability can be manipulated by the addition of certain sugars and modified starches. Water, while typically the transport medium for other ingredients in a marinade, can impact the efficacy of certain other functional ingredients. Chilling and softening source water for marinades can provide significant benefits in minimizing oxidation and improving protein extraction. In conclusion, proper ingredient selection, inclusion level, order of addition, and an understanding of functional properties and limitations are critical to success of the finished product.

739 Maximizing carcass characteristics of grass- and grain-fed Bonsmara steers using electrical stimulation. K. R. Hawks*[1], R. K. Miller[1], T. D. A. Forbes[2], F. M. Rouquette, Jr.[3], J. W. Holloway[2], and B. G. Warrington[2], [1]*Texas A&M University*, *College Station*, [2]*Texas Agricultural Experiment Station Uvalde*, *Uvalde*, [3]*Texas Agricultural Experiment Station Overton*, *Overton*.

Grass-based beef production systems have increased as market alternatives for beef. The effects of location, forage type, supplementation, limited grain feeding and electrical stimulation (ES) on subsequent carcass characteristics and fatty acid composition have not been fully elucidated. Our objectives were to identify the effects of location, forage type (warm v cool season), supplementation (S), harvesting steers immediately off forage or after 90 d on a high grain feedlot ration, and ES on USDA Quality and Yield grade characteristics, fat and lean color, pH and fatty acid composition in Bonsmara steers. Steers (n=48) were randomly assigned to pasture at Overton or Uvalde, TX. Eight steers were assigned to one of six treatments: Cool-season forage (CSF) at Uvalde and harvested off grass; CSF at Uvalde and harvested after 90 d on a feedlot ration; CSF at Overton and harvested off grass; CSF at Overton and harvested after 90 d on a feedlot ration; warm season forage (WSF) at Overton and harvested off grass; and WSF at Overton and harvested after 90 d on a feedlot ration. Within a treatment, four steers were given S (corn at 0.8% of BW/d) during forage feeding. After harvest, steers were ES (300 V for 30s, 350 V for 30s, 350V for 30s with 10s rest cycles) and chilled for 48 h. USDA Quality and Yield grade factors, meat and fat color, pH and fatty acid composition were determined. Steers harvested off grass had younger bone maturity, higher lean maturity, less marbling, higher pH, darker colored lean and fat, softer, coarser lean, lighter hot carcass weights and lower yield grades than steers harvested after 90 d on a feedlot ration regardless of location ($P>0.01$). Treatment by S interactions for lean firmness ($P=0.046$) and fat thickness ($P>0.01$) were observed. Lean maturity, heat ring, lean color and marbling were improved by ES ($P>0.05$). ES carcasses from S steers had lighter subjective lean color than carcasses from non-supplemented non-ES steers (5.0 v 4.5) ($P>0.05$). Fatty acid composition was influenced by treatment ($P>0.05$).

740 A novel technique to assess internal body fat using real–time ultrasound. F. R. B. Ribeiro*[1], L. O. Tedeschi[1], J. Stoffer[2], and G. E. Carstens[1], [1]*Texas A&M University*, *College Station*, [2]*Cornell University*, *Ithaca, NY*.

The objective of this study was to develop a method to quantify internal fat composition of growing calves using real–time ultrasound (**RTU**) of KPH fat depth or linear measurement of KPH fat depth at. Data for this study were obtained from 56 animals (24 steers, 16 heifers, and 16 bulls) from two trials. Trial 1 was composed of Angus steers (n = 24) and Trial 2 had Angus bulls (n = 16) and Heifers (n = 16). Ultrasound KPH images were collected between the first lumbar and the 13th rib and KPH depth was measured between the ventral part of the *Psosa major* muscle and the end of the KPH fat 7 days pre-slaughter to measure the depth of KPH (**uKPHd**). Whole KPH and gastrointestinal tract (**GIT**) were removed from the hot carcass. Whole GIT was dissected and total internal fat (**IF**) was physically separated. Bulls were heavier than heifers and steers (479.87, 354.02, and 392.7 kg, respectively). Heifers had more KPH and total IF than bulls and steers (8.7 and 33.27, 7.18 and 28.35, and 7.50 and 28.94 kg, respectively). Carcass KPH depth (**cKPHd**) was predicted from uKPH with an R^2 of 0.87. Predictions of KPH weight using uKPHd had an R^2 of 0.81. Predictions of total IF using uKPHd had an R^2 of 0.81 whereas using cKPHd had an R^2 of 0.89. Our results showed that cKPHd can be predicted from uKPHd. Results also indicated that cKPHd can precisely predict total IF and that uKPH is a measurement just as precise as cKPHd to predict IF. The ability to measure total IF with a non–invasive and cheaper technique could greatly increase our ability to measure this trait in live animals at different points of the growing and finishing phase. More research is needed to evaluate the system for different diets, stages of growth, and breeds.

Key Words: Ultrasound, Internal Fat, Non-Invasive

741 Proteomic analysis of whole muscle fingerprints from yellow perch, (*Perca flavescens*), and identification of proteins associated with body weight and length. J. M. Reddish*, K. B. Green-Church, A. D. Nichols, N. S. St-Pierre, and M. Wick, *The Ohio State University*, *Columbus*.

A challenge of commercial aquaculture is to accelerate growth and increase muscle mass by genetic selection which will lead to higher harvest yields and increased profitability. Increased growth rate of yellow perch can be achieved through genetic selection; however, the concomitant changes in gene expression related to increased muscle growth in fish are not fully understood. Gaining an understanding of the molecular mechanisms of muscle development in fish species will have considerable economic value and may prevent meat quality problems due to selection in fish that have occurred in other animals of agricultural importance such as PSE in swine and poultry. Our hypothesis is that altered gene expression in muscle results in variability in body weight and length in fish and that the differential protein expression associated with the growth of fish muscle can be identified using electrophoretic, statistical and protein sequencing technologies. Our objective is to apply this proteomic technology to identify the gene products unique to enhanced muscle growth in pond-cultured yellow perch. Yellow perch muscle was sampled (n = 70) and body weight and length were recorded. Proteins were resolved by SDS-PAGE on 5 to 20 % gradient gels, stained with SYPRO Ruby® and analyzed using TotalLab™ image analysis software. Individual band percentages were independently analyzed using stepwise linear regression in SAS v.9.1 against body weight and length. Eight bands were associated with body weight (R^2 = 0.84) and nine bands were associated with length (R^2 = 0.85); four bands were common to body weight and length. Detection by MALDI-TOF-MS of peptides significantly associated with body weight and length identified forty-eight individual proteins or protein isoforms This information will be used to help identify genes which are uniquely associated with enhanced muscle growth in pond-cultured yellow perch.

Key Words: Yellow Perch, Muscle, Proteomics

742 Production and evaluation of a value-added turkey product using mechanically separated turkey meat. S. Williams*, N. Djeri, M. Balaban, and A. Ruiz, *University of Florida*, *Gainesville*.

The objectives of this research were to 1) manufacture a turkey product utilizing mechanically separated turkey meat (MSTM) as the chief ingredient, 2) determine the appropriate thermal processing conditions for cooking the canned product and 3) determine sensory and chemical characteristics, and microbial content of the finished product. Frozen 18.2 kg blocks of MSTM were purchased from a Virginia turkey processor and used to manufacture the product. The MSTM (83%) was blended with 17 % nonmeat ingredients (soy protein concentrate, water and seasonings). The meat mixture was stuffed into fibrous casings and cooked to an internal temperature of 71.1°C. The cooked sausage was cut into 681 gram portions, packaged in 0.91 kg capacity metal cans and retorted at 123.0°C for 2 hours or 112.8°C for 3.2 hours. The average protein and fat contents of the finished products were 15.0% and 19.4%, respectively. Sensory evaluation of the product revealed no significant differences (P > 0.05) in texture and flavor. However, 20% of the panelists commented that the product processed at 123.0°C for 2 hours had a "slightly softer texture" than the product processed at 112.8°C for 3 hours. The color of the product processed at 123.0°C was rated lower (P < 0.05) than the product processed at 112.8°C. The product yield, proximate composition and pH values were similar (P > 0.05) for both cooking processes. No microbial growth was detected in the finished canned products. As a result of this study, the canned turkey product is currently being shipped to Jeremie, Haiti for evaluation by the Haitian Health Foundation for utilization in their feeding program for children ages 6 months to 3 years old living in remote villages.

Key Words: Mechanically Separated Turkey Meat, Product Development, Turkey Product

743 Impact of early deboning and portioning on tenderness of vertically portioned broiler breast fillets. C. M. Owens*, S. C. Purcell, A. Saha, and J. F. Meullenet, *University of Arkansas*, *Fayetteville*.

Uniformity of boneless breast fillets is a highly desired aspect in the food service industry. In order to accommodate the demand for uniform product, poultry producers portion breast fillets to achieve the perfect size and shape. Tenderness is also an important consumer issue and early deboning can often result in decreased tenderness. Portioning fillets early postmortem may also negatively impact meat tenderness. The purpose of this study was to determine the effect of time of portioning and genetic strain on tenderness of vertically portioned breast fillets. One hundred twenty, six-week-old broilers from two commercial high yielding broiler strains were processed via an in-line system and then chilled with a two-stage method in 3 replications. Broiler carcasses were deboned at 2h or 4h postmortem (PM). Boneless breast fillets were vertically portioned at time of deboning (2h or 4h PM) or at 24h PM (i.e., after aging of deboned breast fillet) using a heart-shaped standard template removing cranial and caudal fractions. All fillets were cooked 48h PM to an internal temperature of 76°C and sheared using the MORS method, recording total energy (TE). Whole fillets used in this study were similar in weight (approximately 315 g) and all were portioned to approximately 75% of the original weight. Fillets deboned at 2h PM had significantly higher TE than those deboned at 4 h PM, indicating decreased tenderness as a result of early deboning. Portioning with a vertical cut further impacted meat tenderness as indicated by significantly higher TE in those portioned at time of deboning compared to those portioned at 24h PM (P<0.05). However, this effect was predominantly observed in those fillets deboned at 2h rather than at 4 h. Strain had little impact (Strain, P=0.1016; Strain × Debone, P=0.0570) on meat tenderness of portioned fillets. The results of this study suggest portioning with vertical cuts early postmortem can decrease meat tenderness to a greater degree than deboning alone. Processing procedures (e.g., deboning and portioning) had a greater impact on tenderness than the effect of commercial strain.

Key Words: Tenderness, Portioning, Broiler

744 Carcass and meat quality traits of Angus-cross steers finished on three different winter annual forages. C. R. Kerth*, K. W. Braden, and B. S. Wilborn, *Auburn University*, *Auburn, AL*.

Angus-cross steers (n = 18) were randomly assigned to one of three forages during an 84-d finishing phase. Ryegrass (*Lolium perenne*), rye (*Secale cereale*) and oats (*Avena sativa*) were compared with replicate 1.42-ha paddocks (2 paddocks per forage) established and stocked

with three steers (374 kg ± 6.43 initial BW) per paddock. All steers had access to salt and minerals free-choice. Grazing was initiated on Jan 19, 2006, when average forage mass reached 1000kg ha^{-1} as the first of two replicate years. When forage quality could no longer sustain growth, cattle were transported 50 km to the Auburn University Lambert-Powell Meat Laboratory and humanely harvested. Carcass data, pH, lean and fat color was measured 48 h postmortem and a boneless ribeye roll was removed from each carcass, vacuum-packaged, and stored (4C) until 21 d postmortem. Steaks were removed from the posterior end of the ribeye roll, overwrapped in PVC film and stored under simulated retail conditions for 7 d. Lean color was measured daily on each steak to monitor L*, a*, and b* values. Average daily gain was not affected (P > 0.10) by forage treatment. Type of forage did not affect (P > 0.50) HCW, preliminary yield grade, KPH fat%, LM area, maturity, marbling, final yield grade or final quality grade. Carcasses from steers finished on rye tended (P = 0.08) to have lighter (higher L* values) subcutaneous fat color compared to carcass from steers finished on either ryegrass or oats. Subcutaneous fat redness and yellowness and lean lightness, redness, and yellowness did not differ (P > 0.24) among the three forage treatments. Lean lightness (L*) and redness (a*) decreased (P < 0.05) with increasing days of retail display. The type of forage used to finish steers did not (P > 0.05) affect color traits of steaks under retail display. Type of forage used to finish Angus-cross steers does not affect carcass or meat color traits.

Key Words: Forage-Fed, Beef, Carcass

745 Impact of litter size and birth weight on growth performance, carcass characteristics, and meat quality in pigs. J. Bérard[1], M. Kreuzer[2], and G. Bee*[1], [1]*Agroscope Liebefeld-Posieux, Research Station ALP*, *Posieux, Switzerland*, [2]*ETH Zurich, Institute of Animal Science*, *Zurich, Switzerland*.

There is some evidence that within litter low birth weight (**Btw**) pigs not only grow slower and have fatter carcasses but also meat quality traits are impaired compared to their high Btw siblings. Because the variability of the Btw is greater in large compared to small litters, the aim of this study was to test the hypothesis that effects of Btw on growth performance, carcass characteristics, and meat quality in the LM and the light portion of the semitendinosus muscle (**ST**) are different when pigs originate from small or large litters. The 60 Swiss Large White barrows used originated from 20 litters with either less than 10 (**S**) or more than 14 (**L**) piglets born per litter. Within each litter, the lightest (**L-Btw**), the heaviest (**H-Btw**), and the barrows with a Btw nearest to the average Btw of the litter (**M-Btw**) were selected. At weaning the barrows were individually penned and had free access to the diet until slaughter at 105 kg BW. The Btw of L- as compared to S-litters were lower in L-Btw (1.2 vs. 1.6 kg) and M-Btw barrows (1.6 vs. 1.9 kg) and similar in H-Btw barrows (1.9 vs. 2.0 kg) (litter size × Btw interaction; $P < 0.01$). The L-Btw barrows grew slower (0.81 vs. 0.90 kg; $P < 0.01$), ingested less feed (2.30 vs. 2.42 kg; $P = 0.03$), and were still less efficient (2.84 vs. 2.71 kg feed/kg gain; $P < 0.01$) than H-Btw- and M-Btw barrows, regardless whether they originated from S- or L-litters. The carcass yield was higher (81 vs. 82%; $P < 0.01$), the liver (1.58 vs. 1.74 kg), and kidney (0.31 vs. 0.34 kg) were lighter ($P \leq 0.01$) in L-Btw barrows in the S- and L-litters. Drip loss and shear force was neither affected by litter size nor by Btw. The LM of L-Btw was less red (6.1 vs. 6.9; $P = 0.02$) than the LM of H-Btw barrows and b*-values of the ST was lower (3.4 vs. 3.8; $P = 0.03$) in barrows originating from L- than from S-litters. The present results confirm the marked effect of Btw on growth performance whereas the hypothesized impact on carcass characteristics and meat quality could not be demonstrated. Although the litter size affected average Btw its impact on growth performance, carcass and meat quality was minor.

Key Words: Birth Weight, Litter Size, Meat Quality

Extension Education - Livestock and Poultry: Extension Dairy Session

746 A Net Present Value Dashboard of the dairy cow in a commercial setting. D. T. Galligan*, J. Ferguson, R. Munson, and D. Remsburg, *University of Pennsylvania, School of Veterinary Medicine*, *Kennett Square*.

An economic model of the production life of a modern dairy cow was created in a dashboard environment. The user enters information that characterizes the production life of a cow using sliders arranged in a menu driven series of screens: Milk and Feed $, Reproduction, BST, Heifer, Finance, Other Cost, Labor, Longevity. Over 30 input variables (management factors, production parameters, economic values) are controlled by the user. Based on entered values, an economic model of annual cash flows is created and discounted to reflect the opportunity of value money. Several gauges show: the cow net present value, annuity value per year, internal rate of return estimate, time in the herd and the resulting cull rate. These gauges respond to user changes of inputs instantly demonstrating the magnitude of impact. Lactation yields are shown in a graph format and are changed by altering first lactation yields. For example a cow having 3 lactations and culled at 100 DIM in the last lactation, with a first lactation yield of 22,000 (305 milk) valued at $13/cwt, with debt/cow at $2000 financed at 7% over ten years will have a NPV of $662 and an annuity value of $160. Use of BST starting at 100 DIM in all lactations, will increase the NPV to $925 and the annuity value to $226, assuming a 10 lb daily response and a start DIM at 100 for each lactation. Other investment strategies can be explored with the model.

Key Words: Net Present Value, Economics, Dashboard

747 Accuracy of prediction of future uniform milk prices in Florida from Class III and IV futures markets. S. Feleke* and A. De Vries, *University of Florida*, *Gainesville*.

The objective of this study was to evaluate the accuracy of a method to predict the future uniform milk price in Florida from the Class III (cheese) and Class IV (butter) futures markets. Milk futures contracts are traded at the Chicago Mercantile Exchange for delivery 1 to 18 months in the future. Futures market theory holds that futures prices may be unbiased predictors of spot prices. The uniform milk price in Florida is a function of the announced Class III and IV prices, butter price, and the utilization of Class I, II, III, and IV skim milk and butterfat prices. To accurately predict future uniform milk prices, unbiased estimates of these factors are needed. Therefore, future butter prices were predicted from the future Class IV price and the ratio of the most recently announced butter price and the Class IV price. Future

utilizations of skim milk and butterfat prices were predicted from the most recently announced utilizations. Daily traded Class III and IV futures prices from 2003 to 2006 (48 mo) were obtained and were averaged per month. The monthly average milk futures prices were taken as unbiased predictors of the actual Class III and IV prices that are announced every month by USDA. The predictions of uniform milk prices for 1 to 6 months in the future from 2003 to 2006 were used to assess the accuracy of our method of prediction. Average uniform milk price in Florida in this period was $16.53 ± 2.20 / cwt. The mean and standard deviation of the prediction error for 1-month-ahead forecast were $0.11 ± 1.01 / cwt. For 2, 3, 4, 5, and 6-month-ahead forecasts, prediction errors were $0.26 ± 0.97, $0.43 ± 1.42, $0.53 ± 1.87, $0.52 ± 2.14, $0.47 ± 2.29 $/cwt. Thus, the actual uniform milk price was typically overestimated. The majority of the prediction error was due to the inefficiency of the futures market to predict the announced Class III and IV prices by USDA. The implication of the study is that the uniform milk price in Florida for more than a few months into the future cannot be accurately estimated from the Class III and Class IV futures market prices.

Key Words: Futures Market, Milk Price, Prediction

748 Economic evaluation of decision choices facing dairy producers in Sicily, additional milk or additional cows? D. T. Galligan*[1], G. Azzaro[2], and G. Licitra[2,3], [1]*University of Pennsylvania, School of Veterinary Medicine*, *Kennett Sqaure*, [2]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [3]*2DACP University of Catania*, *Catania, Italy*.

Thirty one dairy herds in Sicily, subscribing to the Corfilac dairy herd record collection system, were visited during 2006 and interviewed regarding basic herd characteristics (cow demographics, production levels, culling rates, calving interval) and economic factors (milk price, cow purchase price, calf value, variable production cost, quota cost, financing options) associated with their herd. Under the quota system, additional milk either from existing cows or by adding cows must have quota purchased and financed (mean rate 5.1%/year and terms 5 years). Of the herd reporting their purchased quota, eight herds were producing below their purchased quota, while 10 herds were at quota and 11 over. Milk price per kg averaged .37 Eur/kg (range .30 -.40) and the average herd size was 84 (range 20 to 340) with cows producing an average of 6721 kg/yr (range 1,100 to 25,500). The herds would increase marginal profits per/cow/year by increasing milk yield by 1 kg/day (average 107 Eur) and with the purchase of quota (average 77 Eur/cow/year). Twenty two herds were estimated to see a positive profit by adding an additional cow averaging 966 Eur/cow/yr without quota purchase. Fifteen herds were estimated to see a positive profit by adding an additional cow and purchasing the necessary quota averaging 357 Eur/cow/year. If the additional cow can be added to the herd without additional labor, then the marginal increases per cow are 1454 Eur/cow/year without quota purchase and 846 Eur/cow/year with quota purchase. Economic analysis of existing farm situation can help producers make more informed decisions concerning cow numbers and quota purchase.

Key Words: Economics, Quota, Marginal

749 Spartan Dairy Ration Evaluator/Balancer Version 3: A user-friendly, windows-based software program for dairy nutrition management. M. J. VandeHaar*, H. F. Bucholtz, D. K. Beede, M. S. Allen, and R. D. Kriegel, *Michigan State University*, *East Lansing*.

Version 2 of the Spartan Dairy Ration Evaluator/Balancer software program was used widely because it was user-friendly and enabled formulation of reasonable diets relatively quickly. Our goal with version 3 was to retain those aspects of version 2 that made it successful, while also incorporating the latest scientific findings related to diet formulation and completely redesigning the program as a MS Windows application. The nutrition model largely is based on the 2001 version of the Nutrient Requirements of Dairy Cattle by the National Research Council (NRC). The 2001 NRC made fundamental changes in the sub-models for almost all nutrients. The NRC model was designed as an evaluation tool and created some challenges for routine use in formulating diets on farms. Version 3 of Spartan Dairy incorporates modifications of the 2001 NRC system, but energy and protein values based on the 1989 and 2001 NRC systems can be monitored simultaneously. Some of the most notable changes in Spartan version 3 compared with version 2 are that the predicted feed intake is greater, energy values of diets are calculated based on nutrient composition and depend upon rate of feed intake, the % CP required is typically lower, mineral adequacy can be assessed on an absorbed basis, concentrations of met and lys can be tracked, and N and P excretion are predicted. Many of these changes are based on the 2001 NRC. Spartan Dairy 3 is a stand-alone Windows application written in Delphi that stores data in MS Access database files. Like Spartan Dairy 2, the application features a ration worksheet at its center. It also includes the ability to open multiple rations and feed libraries simultaneously, and graphics to display nutrient adequacy. It features movable columns, feed characteristics organized by tabs, the ability to copy and paste feeds to and from MS Excel, previews of printed reports, and, of course, you can now use your mouse! The program works best with computers running Windows XP or later. Spartan Dairy 3 should prove to be a useful tool for use in formulating diets for commercial farms as well as for teaching.

Key Words: Dairy Cattle, Nutrition, Software

750 Nitrogen and phosphorus in by-product feeds and dairy diets in central Texas. T. D. Nennich*[1], N. M. Cherry[1], R. A. Whitney[2], R. J. Scott[3], and W. H. Weems[4], [1]*Texas A&M University*, *Stephenville*, [2]*Texas Cooperative Extension*, *Comanche*, [3]*Texas Cooperative Extension*, *Stephenville*, [4]*Texas Cooperative Extension*, *Hamilton*.

Environmental concerns associated with N and P in surface and ground waters have encouraged efforts to improve management of these nutrients on dairy operations. Understanding the nutrient variation in feeds provides an opportunity to fine tune the nutrient content of the diet and decrease the overfeeding of nutrients. A study was conducted to determine the amount of N and P in dairy diets and by-product feedstuffs in Central Texas. Samples were collected from 50 dairy operations, representing over 40,000 cows, in central Texas. Producers were asked to complete a survey on their knowledge and the importance of P in their dairy rations. Samples of total mixed rations (TMR) were collected from each dairy operation, along with individual by-product feeds whenever they were available. Samples were collected by taking approximately 10 grab samples, compositing and mixing the sample,

and taking a sub-sample. By-product feed samples were collected from commodity barns, and TMR samples were collected at several places along the feed lane. A total of 12 by-product feeds were collected, including dried distillers grains, wet brewers grains, canola pellets, corn gluten pellets, and wheat midds. Diet and feed samples were analyzed to determine crude protein (CP) and P concentration. Overall, 54 TMR samples and 52 individual by-product feed samples from 50 dairy operations were collected. The CP and P contents of the TMR samples collected averaged 18.7% and 0.44% on a dry matter basis, respectively. The phosphorus contents of by-product feeds were greatly variable and often differed from average book values. For example, corn gluten feed samples (n = 8) averaged 22.3% CP and 0.67% P as compared to 2001 Dairy NRC book values of 23.8% CP and 1.00% P. Reducing the concentrations of N and P in dairy diets to recommended levels reduces nutrient excretion and improves the overall balance of these nutrients on dairy operations.

Key Words: Dairy, Nitrogen, Phosphorus

751 An evaluation of family farm transfer in Vermont. S. Purchase[1], C. Ballard*[2], and D. Maynard[1], [1]*University of Vermont*, *Burlington*, [2]*W.H. Miner Agricultural Research Institute*, *Chazy, NY*.

One of the most significant challenges to a family farm operation is the transfer of ownership to the next generation. Two surveys were developed to identify obstacles to farm transfers as determined by professionals who work with farmers during the transfer process and by farmers themselves. A total of 6 farm transfer professionals and 42 farmers throughout the state of Vermont completed a 4-page survey. The respondents from non-dairy farms, small dairy (<100 milking cows), medium (100-300 cows), and large farms (>300 cows) were 7.1, 40.5, 31, and 21.4 %, respectively. Thirty-four percent of the farms had been in operation for over 50 years and 53.7% were sole proprietorships. Ninety-eight percent of the farms had 2 or more family members involved with the day-to-day operation of the farm. Nearly half of the respondents indicated their plans for bringing additional family members into the business as owners. Half of the farms surveyed had been family-owned for at least one generation. These farmers were asked to rank obstacles experienced during the process of transferring farm ownership (1=most, 5=least significant). Both interpersonal relations with farm family members and the business plan were ranked 1 or 2 for 62% of respondents. The farmers who experienced difficulties with family members during the transfer process identified personal temperaments as contributing more to these conflicts than money, time commitment or work responsibilities. Although the business plan was considered an obstacle during past farm transfers, less than 10% of the farms surveyed had a 5-10 year business plan for their farm. In looking ahead to the future farm transfer, 72% felt the business plan would be the primary obstacle, ranking 1 or 2. Interpersonal relations with farm family members was predicted to be a substantial obstacle for 53% with personal temperaments and time commitment being the primary contributor to the conflict. Five of six professionals surveyed find a 5-10 year written plan is beneficial during a farm transfer. However, all professionals identified interpersonal relations with farm family members as being the most significant obstacle as farm ownership is conveyed to the next generation.

Key Words: Family Farm, Transfer

752 A survey of AABP-L members concerning training of farm personnel. D. W. Remsburg*, D. T. Galligan, and J. D. Ferguson, *University of Pennsylvania School of Veterinary Medicine*, *Kennett Square*.

A survey regarding the frequency of veterinary tasks, issues facing the dairy industry, skills desired in a herd manager, and disadvantages of working with a herd manager was conducted as part of a pilot herd manager project. An internet link to 21 questions was distributed to the American Association of Bovine Practitioners Listserv in December 2006. Eighty-seven veterinarians from 30 states and 6 countries participated. On average, respondents worked in practices containing 3.93 vets and 1.61 veterinary technicians. The mean practiced allocated its services as follows: 67.2% Dairy, 18.6% Small Animal, 9.6% Beef, and 4.6% other. The most frequent tasks performed by veterinarians were pregnancy exams, surgery, and postpartum reproductive exams. The least frequent services performed were milking system evaluation, ration formulation, and labor management consulting. Veterinarians principally serving herds of greater than 1200 cows performed postpartum checks and surgery less often than did their colleagues. When asked about issues facing the dairy industry, implementing, learning and client adoption of new technologies were respondents' largest concerns. However, when characterized by region and principle herd size served the concern regarding decreasing number of farms, biosecurity, time available for family and recreational activities, income from veterinary service, foreign animal disease outbreak and animal welfare differed. In regards to desired herd manager skills, veterinarians thought management of fresh cows, record keeping and diagnosis and treatment of sick cows were the most important tasks a herd manager should be trained to accomplish. Milking instruction and labor management were rated of higher importance by veterinarians working with medium (301-600 cows) and large (>1200 cows) farms, while fresh cow management was less important to large farm vets. These results demonstrate the difference in frequency of veterinary tasks, concerns about the dairy industry and skills expected of herd managers, and the need to account for these demographic and regional variations when offering training to on-farm personnel.

Key Words: Veterinary Service, Staff Rraining, Management

753 The "Summer to Winter performance ratio" as a tool for evaluating heat stress relief efficiency of dairy herds. I. Flamenbaum*[1] and E. Ezra[2], [1]*Ministry of Agriculture, Extension Service*, *Beit-Dagan, Israel*, [2]*Israel Cattle Breeders Association*, *Caesarea, Israel*.

Summer conditions in Israel make heat stress relief from cows an important tool for efficient milk production. New cooling methods have been developed and introduced to dairy farms all over the country. The Extension Service of the Israeli Ministry of Agriculture in cooperation with the Israel Cattle Breeders Association (ICBA) have developed a computerized report, based on the "Israeli Herd book" data, that evaluates the effectiveness of farmer's activities in reducing the impact of summer on cow's performance. The "Summer to Winter (S:W) performance ratio" report includes S:W Economical Corrected Milk (ECM), fat, protein, Somatic Cells Count (SCC) and Conception Rate in the first five inseminations (C.R.). The higher the ratio is (close or above 1.0) for production and fertility data and the lower ratio is for SCC data, the better the farm is dealing with summer heat-stress. The calculation includes the estimation of L.S.M for milk yield (ECM-kg/day) fat and protein percent, SCC (000/ml) and conception rate

percent for each season, followed by calculation of S:W ratios. During 2005, S:W ECM ratios above 0.96, 0.90 to 0.96 and below 0.90 were recorded in 40, 38 and 22% of the dairy farms in Israel respectively. S:W - ECM, fat, protein, SCC and C.R. ratios were 0.93, 0.94, 0.96. 1.2 and 0.4, in 495 family farms averaging 50 cows and 0.93, 0.95, 0.96, 1.05 and 0.51, in 191 cooperative farms averaging 300 cows, respectively. High, middle and low producing herds (mean winter ECM yields of 35.2, 33.1 and 30.2 kg/d respectively), had S:W ratios of 1.03, 0.93, 0.82 and 0.63, 0.51, 0.38 for ECM and C.R. respectively. S:W production ratio was above 0.96 in 70% of the farms located in cool regions, compared to only 30% of the farms located in extremely hot regions. The computerized report described here, enables the detection of farms that need improvement of summer performance and allows the provision of necessary consultancy and follow up by extension agents.

Key Words: Heat Stress, Milk Production, Conception Rate

Lactation Biology: Applied Lactation Biology

754 Induced lactation in nulliparous dairy goats with or without prolactin secretion enhancement. A. A. K. Salama*, G. Caja, E. Albanell, S. Carné, R. Casals, and X. Such, *Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

Fourteen Murciano-Granadina nulliparous goats were used to evaluate the effects of a standard protocol for inducing lactation with or without using a prolactin releasing agent (reserpine). Goats were submitted to a hormonal challenge consisting of daily s.c. injections of estradiol-17β and progesterone (0.5 and 1.25 mg/kg BW, respectively) for 7 d (d 1 to 7). Goats were divided into 2 groups and i.m. injected with 1 mg/d of reserpine (n = 7) or vehicle as control (n = 7) on d 12, 14, 16, 18 and 20. Lactation was triggered by i.m. injections of dexamethasone (10 mg/d) during d 18 to 20. Goats were machine-milked once daily from d 21 to 120 when goats were mated jointly with the rest of the herd after the buck effect. Goats initiated lactation on d 21 (100%) and milk yield increased logarithmically ($R^2 = 0.95$) thereafter. Difference in milk yield between control and reserpine goats increased as lactation advanced, peaking at wk 10 of lactation when reserpine goats yielded more milk than control goats (1,079 vs. 850 mL/d, respectively; $P = 0.08$). However, milk yield at the peak averaged only 55% of peak milk yield observed in primiparous goats from the same herd. Composition of initial milk (d 21) was lower than the expected for colostrums ($P < 0.001$). Milk composition steadied after d 3 of lactation. Teat length increased in control goats during mammogenesis (d –2 to 35; $P < 0.05$) but steadied in reserpine goats. Distance between teats, and volume and depth of the udder increased ($P < 0.05$) similarly in both goat groups during mammogenesis and lactation. After mating, 82% of the contemporaneous goats in the herd became pregnant, whereas only 21% of the experimental goats conceived (1 reserpine and 2 control goats), revealing the occurrence of side effects after the lactation induction treatment. In conclusion, lactation induction was effective and reserpine improved milk yield in nulliparous goats, but it seems that neither the obtained milk yield nor the side effects on fertility support its recommendation in practice.

Key Words: Lactation Induction, Prolactin, Dairy Goat

755 Effects of shortening the dry period from 60 to 40 days on milk yield and composition during the subsequent lactation. D. J. Grusenmeyer*, C. M. Ryan, R. W. Everett, D. M. Galton, and T. R. Overton, *Cornell University*, *Ithaca, NY*.

Holstein cows (n = 306) at the end of first (n = 158) or greater (n = 148) lactation on three commercial farms were used to determine effects of dry period length on subsequent milk yield and composition. Cows producing 22 kg/d of milk or more at 60 d before expected calving were assigned randomly to receive either a 60 d (actual mean = 58.5 d; n = 150) or 40 d (actual mean = 40.6 d; n = 156) dry period. Milk yield and composition data were collected for the first 10 monthly test days of the subsequent lactation; previous 305-d mature equivalent milk yield for each cow was used as a covariate during data analysis. Shortening the dry period from 60 to 40 d decreased milk yield (39.2 vs. 37.7 kg/d; $P < 0.004$); however, the difference was attributable largely to effects on one farm (40.4 vs. 40.3; 40.8 vs. 37.4; 36.3 vs. 35.4 kg/d; farm by treatment, $P < 0.02$) for 60 vs. 40 d dry on the three farms, respectively, and to cows at the end of their first lactation (39.6 vs. 37.1 and 38.8 vs. 38.4; treatment by parity, $P < 0.04$). Shortening the dry period tended to increase subsequent milk fat content (3.63 vs. 3.70; $P < 0.11$) and increased true protein content (2.98 vs. 3.05; $P < 0.001$); therefore, overall effects of dry period length on yields of milk fat (1.41 vs. 1.38 kg/d; $P = 0.18$) and true protein (1.15 vs. 1.13 kg/d; $P = 0.29$) were not significant. Farm by treatment interactions ($P < 0.04$) for yields of milk fat and true protein followed the same pattern as those described for milk yield. Somatic cell linear score was not affected by dry period length (2.76 vs. 2.79; $P < 0.81$), athough effects varied by farm (farm by treatment, $P < 0.04$). Results from data analysis following Test Day Model adjustment were consistent with those reported above. Overall, results support the concept that shortening the dry period of multiparous cows from 60 to 40 d results in minimal impact on subsequent production, and that shortening the dry period of primiparous cows from 60 to 40 d may decrease subsequent production.

Key Words: Dry Period, Transition Cow

756 Effects of altered timing and duration of unilateral frequent milking during early lactation on milk production of dairy cows. E. H. Wall* and T. B. McFadden, *Lactation and Mammary Gland Biology Group, Department of Animal Science, University of Vermont*, *Burlington*.

Several studies have reported that increased milking frequency during early lactation can elicit immediate and long-lasting increases in milk yield, however the timing and duration of frequent milking has not been optimized. Our objective was to utilize a half-udder model to determine milk yield response to 2 wk of frequent milking imposed at two different times in early lactation. Multiparous Holstein cows were assigned at parturition to unilateral frequent milking (UFM), which entailed twice-daily milking (2X) of the left udder half and four-times daily milking (4X) of the right udder half on d 1 to 14 (UFM-1-14) or 7 to 21 (UFM-7-21) of lactation (n = 10 cows per treatment). Before

and after UFM, cows were milked 2X. Half-udder milk weights were measured at 1, 3, 7, 14, 21, 28 and 35 DIM, then once every 3 mo for the remainder of lactation. For both treatments, the 4X udder halves produced more milk than the 2X udder halves during UFM (P's < 0.001), resulting in an average difference of 3.7 ± 0.7 kg/d in UFM-1-14 cows and 2.9 ± 0.9 kg/d in UFM-7-21 cows. After cessation of UFM, milk production of the 4X udder halves decreased in both treatments (P < 0.01). However, throughout the remainder of lactation, UFM-7-21 cows produced 1.5 ± 0.6 kg/d more milk from the 4X side than the 2X side (P < 0.05), whereas in UFM-1-14 cows the difference was 1.2 ± 0.7 kg/d, which was not significant (P=0.16). The mean difference in milk yield between 4X and 2X udder halves over the entire lactation was not different between UFM-1-14 and UFM-7-21 cows (P > 0.50). Moreover, the total milk yield response to UFM observed in the current study did not differ from that observed in a previous study in which cows were assigned to UFM for days 1 to 21 of lactation (P > 0.60). We conclude that UFM during days 7 to 21 of lactation elicited a persistent increase in milk production of the frequently-milked udder half. In addition, the overall milk yield responses observed for UFM-1-14 or UFM-7-21 were not significantly different than that previously observed for UFM on days 1 to 21 of lactation.

Key Words: Frequent Milking, Local Regulation, Mammary Gland

757 Use of milking frequency for alleviating milk depression in Holstein dairy cows under heat stress conditions. R. Ben Younes[1], M. Ayadi[2], T. Najar[1], M. Zouari[3], A. A. K. Salama[4], X. Such[4], M. Ben M'Rad[1], and G. Caja*[4], [1]*Institut National Agronomique de Tunisie*, *Tunis, Tunisia*, [2]*Institut Superieur de Biologie Appliquée de Medenine*, *Tunisia*, [3]*Office des Terres Domaniales*, *Tunis, Tunisa*, [4]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

Forty-eight Holstein Friesian cows raised in North Tunisia were used to study the effects of increasing milking frequency during summer heat stress. Twice daily milked cows (170 DIM, 18.0 L/d, 3.43% fat, 3.09% protein) were grouped in early July according to udder cistern size (large-cisterned, 44.5 cm^2; small-cisterned, 20.6 cm^2) and randomly allocated to a milking frequency treatment (×2 or ×3) for 70 d. Average temperature, relative humidity and thermohygrometric index (THI) during the experiment ranged between 20.9-30.2°C, 49-78% and 67-81. Lactational performance and physiological traits were recorded fortnightly and monthly, respectively. Initial milk yield was used as covariate. Respiratory rate and rectal temperature showed the highest correlations (r > 0.9) with temperature on test-days. Heat stress symptoms on rectal temperature, and respiratory and heart rates were detected when THI was greater than 64, 75 and 78, respectively. Increases per THI unit were 0.2°C, 5 breaths/min and 1 beat/min, respectively. Milk yield was decreased by effects of heat stress and lactation stage during the experiment (P < 0.001) but milk losses reported in ×3 cows were half those of ×2 cows (–2.3 vs –4.7 L/d; P = 0.08). Decrease in milk yield was accompanied by a marked increase in milk fat (16%; P < 0.01) but no effect on milk protein was found (P = 0.39). As a result, only 5% loss in energy corrected milk was observed in ×3 cows at the end of the experiment. Milk urea decreased 22% on average during the experiment (P < 0.001). No interaction between cistern size and milking frequency was detected for milk yield (P = 0.70) or milk losses (P = 0.25). In conclusion, temperatures above 25ºC induced heat stress symptoms in Holstein cows raised in Tunisia, which was observed when THI was greater than 64. Best external indicator for detecting heat stress was respiratory rate which markedly increased when THI > 75. Milk yield depression due to heat stress was partially alleviated by ×3 milking which may be a useful short-term strategy for Tunisian dairies.

Key Words: Heat Stress, Milking Frequency, Dairy Cows

758 Comparison of manual and automatic milk flow recording in dairy goats. G. Caja[1], M. Rovai*[2], S. Carné[1], A. A. K. Salama[1], X. Such[1], and R. M. Bruckmaier[3], [1]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*, [2]*E (Kika) de la Garza American Institute for Goat Research*, *Langston, OK*, [3]*Veterinary Physiology, University of Bern*, *Switzerland*.

A total of 24 multiparous Murciano-Granadina dairy goats milked once-daily were used at wk 12 of lactation to compare manual and automatic methods for milk flow recording during routine milking. Goats were machine milked in a 2 x 12 parallel milking parlor with low milk pipeline at 42 kPa vacuum, 90 pulses/min and 66% pulsation rate. At least 3 replicates for each method and each goat were randomly done during consecutive days (169 milk flow curves in a total of 10 d). Manual flow (MF) recording was done by udder half using millimetric paper strips in conical milk jars of 2 L (Westfalia-Surge Ibérica, Granollers, Spain) with manual marks done every 5 s. Automatic flow (AF) recording was done in whole udder using a Lactocorder (WMB, Balgach, Switzerland) specially calibrated for cow quarter milking. Both milk recording devices were placed at the same height under the milking platform. Milk flow curves were classified into 4 groups according to curve shape and maximum peak flow (sharp and >1.5 L/min; plateau and >1.0 L/min; interrupted plateau; flat and <1.0 L/min). Five MF and 5 AF curves were discarded. Percentages of curves by group were 24:35:12:29 (n = 61) and 44:23:8:25 (n = 98) for MF and AF respectively. Repeatability within (R > 0.9) and correlation between methods (R^2 = 0.80) were high. Sixty percent of goats (MF, 62.5%; AF, 58.3%) were included in the 2 first curve groups considered more favorable for milkability. Total milk yield was similar for both methods (MF, 2.08 ± 0.06 L; AF, 2.01 ± 0.05 L; P = 0.48), but milking time before machine stripping (2.00 vs. 2.56 min; P =0.05) and maximum milk flow in the 1st min (1.78 vs. 1.16 L/min; P = 0.11) were 28 and 54% higher for MF vs. AF. On the contrary, recorded values for milk amount collected in 2 min (1.61 vs. 1.78 L; P = 0.23) and in 3 min (1.77 vs. 2.47 L; P <0.001) were overestimated by AF in regard to MF. In conclusion, milk yield, shape and class of milk flow curves were adequately recorded by both methods. Nevertheless, large differences were found on most milk flow traits, the automatic method requiring more accurate calibration for low flow conditions.

Key Words: Milking Ability, Dairy Goats, Milk Flow

759 Comparisons of teat structure changes after milking between farms with high and low bulk somatic cell counts. P. Vinitchaikul* and W. Suriyasathaporn, *Faculty of Veterinary Medicine, Chiang Mai University*, *Muang, Chiang Mai, Thailand*.

Objectives of this study were to evaluate the changes in teat structures after milking between farms with high and low bulk somatic cell counts. Thirty-nine lactating cows from 10 small-holder dairy farms in Chiang Mai and Lamphun provinces, Thailand, were selected. Milk samples were collected from all quarters to measure somatic

cell counts (QSCC). The teat structures were examined using the ultrasound machine model ALOKA SSD 500 with 5 MHz linear probe. The teat structures consist of teat-canal length (TCL), teat-width (TW) at the top of the teat canal, teat-wall thickness (TWT) at 1 cm above the end of the teat canal and teat-cistern width (TCW) at the same level. On each teat, all structures were scanned before and after the evening milking period. Data on the averages of bulk milk somatic cell counts (BSCC) for the month of experiment were collected from their farm's cooperatives. Farms with BSCC more than 300,000 cells/ml were defined as high BSCC (HBSCC). Student's T Tests were used to compare the changing of teat structures after milking and log of QSCC between quarters from farms with high and low BSCC. Results show that average BSCC of farms with high and low BSCC was 372 ± 25.5 (n=5) and 197 ± 41.6 (n=5) x1,000 cells/ml, respectively. The QSCC and percent changes in TWT and TCW were different between farms with high and low BSCC ($P < 0.05$). Percentage of changes in TWT and TCW of HBSCC farms (9.75% and -18.42%, respectively) were significantly different from farms with low BSCC (2.42% and -8.38%, respectively). In conclusion, the changes in teat structures after milking are associated with BSCC.

Production, Management & the Environment - Livestock and Poultry: Livestock Production and Management

760 Effects of winter feeding systems on cow performance, soil nutrients, and crop biomass. B. M. Kelln*[1], H. A. Lardner[1,2], J. Schoenau[1], and K. Lang[1], [1]*University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*, [2]*Western Beef Development Centre*, *Lanigan, Saskatchewan, Canada*.

Two experiments were conducted to determine the effects of winter feeding systems on beef cow performance, soil nitrogen (N), and crop yield (DMY) the following year. The research site was a 40 hectare field seeded to barley (*Hordeum vulgare*) (cv. Ranger), located on Orthic Black soil. At the site, experiment one consisted of 36 hectares that was used for a winter feeding trial, while experiment two consisted of a 4 hectare paddock that was used for compost vs. fresh manure trial. In experiment one, crossbred pregnant beef cows (n=180) (range 626 to 634 kg) were allocated to one of four replicate (n=3) winter feeding systems. Feeding systems included (1) field bale grazing (BG), round barley greenfeed bales fed *ad libitum*; (2) field straw & chaff grazing (ST/CH), barley straw/chaff piles fed *ad libitum*; (3) field swath grazing (SG), barley swaths fed in windrows *ad libitum*; and (4) drylot feeding (DL), round barley greenfeed bales fed *ad libitum* in bunk. Cows were weighed at start, every 21 d and end of feed period. Ultrasound measurements (rib and rump fat) and body condition scores [5-point scale (1=thin, 5=fat)] were taken at the start and end of feed period. In experiment two, fresh (FM) and composted (CM) manure from the DL system was applied mechanically in the fall on replicated plot areas (n=4). Spring soil samples were taken from high, mid, and low slope positions (n=3), at the 15 cm soil levels for both experiments. DMY was estimated for both experiments by sampling (n=5) using meter quadrats. In experiment one, manure distribution of each treatment was mapped using a 32 point grid and computer analysis programming. Cow body weight ($P<0.01$), was minimally affected by the swath graze treatment. Soil N levels were not significantly different ($P>0.10$) between slope positions or treatments. Results indicate that extensive winter feeding systems on annual cropped fields have minimal effects on cow performance, DMY and soil N levels.

Key Words: Dry Matter Yield, Straw/Chaff Grazing, Swath Grazing

761 Incorporating condensed corn distillers solubles into an integrated pasture and drylot finishing system for feedlot steers. T. Purevjav*, M. P. Hoffman, and W. B. Roush, *Iowa State University*, *Ames*.

The objectives of this experiment were to evaluate the use of condensed corn distillers solubles (CCDS) mixed with chopped corn stalks on a pasture and drylot growing-finishing program. A three-year study was conducted, using 112 Angus and Angus crossbred steer calves each year. Calves were weighed and assigned to four treatment groups by weight and color pattern, with 4 replications, and 7 cattle per replication in each year respectively. Treatments one (TRT 1) and two (TRT 2) were fed in the feedlot from May until harvested. TRT 1 included chopped alfalfa hay and corn, and TRT 2 included chopped corn stalks and CCDS. Treatments three (TRT 3) and four (TRT 4) utilized rotational bromegrass pasture grazing (May-September) with TRT 4 also receiving chopped corn stalks and CCDS. Following pasture, chopped alfalfa hay and corn (TRT 3) or chopped corn stalks and CCDS (TRT 4) were provided during the feedlot finishing period. Steers were weighed every 28 days and daily feed intake was recorded to obtain feed consumption and feed conversion among the treatments during drylot feeding. The bromegrass pasture consisted of 24 paddocks, each .69 ha in size. Cattle were fed on average to 591 kg and harvested to obtain carcass measurements. Comparing TRT 1 vs. TRT 2 and TRT 3 vs. TRT 4, TRT 1 and TRT 3 had greater daily DMI and ADG ($P<0.05$) than TRT 2 and TRT 4, respectively. Feed conversion during the drylot feeding period favored TRT 1 over TRT 2 and TRT 3 over TRT 4 ($P<0.05$), and overall TRT 1 and 2 over TRT 3 and 4 ($P<0.05$). When TRT 3 and TRT 4 were removed from pasture, TRT 4 had gained well over .23 kg/day better than TRT 3. Though this advantage did not carry over into drylot feeding, this might be a function of daily energy intake while on pasture. Average carcass weights and liver abscesses were not significantly different across treatments, but differences were found among treatments ($P<0.05$) for loineye area, backfat thickness and kidney, pelvic and heart fat. The finding resulted in a sligthly higher quality grade for cattle fed in the feedlot and on hay for the duration of the feeding period. Overall treatment responses for yield and quality grades were similar.

Key Words: Feedlot Cattle, Pasture, Condensed Corn Distiller Solubles

762 Effects of pre-breeding target weight and progestin on reproduction, calving parameters, and rebreeding in beef heifers. J. L. Martin*, K. W. Creighton, J. A. Musgrave, D. C. Adams, and R. N. Funston, *University of Nebraska West Central Research and Extension Center*, *North Platte*.

Two experiments evaluated pre-breeding target weight or progestin exposure for heifers developed lighter than traditional recommendations. Exp. 1 evaluated effects of system on heifer performance through subsequent calving and re-breeding over 3 yr. Heifers (229 kg) were assigned randomly to be developed to 55% mature BW (MBW; 299kg) before a 45-d breeding season (Intensive, INT; n = 119) or 50% MBW (272 kg) before a 60-d breeding season (Relaxed, RLX; n = 142). Pre-breeding and pregnancy diagnosis BW were greater (P < 0.001) for INT than RLX. Overall pregnancy rate did not differ (88.5%; P = 0.51), but RLX heifers had lower conception rate the first 30 d of the breeding season (67.9% vs. 81.8%; P = 0.03), later calving dates (9 d; P < 0.001), and lighter calf weaning BW (190 vs. 197 kg; P < 0.001) compared to INT. Calf birth BW (P = 0.61), calving difficulty (P = 0.30), weaning rate (P = 0.67), second-calf conception rates (P = 0.70), and 2-yr old retention rate (73.4%; P = 0.82) did not differ between systems. Of heifers that failed to become pregnant, more (P = 0.07) RLX than INT heifers were pre-pubertal when the breeding season began. Therefore, a second 2 yr experiment evaluated melengesterol acetate (MGA, 0.5 mg/d) as a means of hastening puberty in heifers developed to 50% MBW. Heifers were assigned randomly to receive CON (n = 103) or MGA (n = 81) for 14 d and placed with bulls 13 d later for 45 d. Pre-breeding and pregnancy diagnosis BW were similar (280 kg and 380 kg, respectively; P > 0.10) for CON and MGA. Proportion of heifers pubertal prior to breeding (74%), pregnancy rate (90%), calving date, calf weaning BW, and second breeding season pregnancy rate (92%), were similar (P > 0.10) between treatments. Developing heifers to 50 or 55% MBW resulted in similar overall pregnancy rates and supplementing heifers developed to 50% MBW with MGA prior to breeding did not improve reproductive performance.

Key Words: Heifer Development, Progestin, Target Weight

763 Simulation model of fat deposition and distribution in beef steers: 3. Model description and development. M. J. McPhee*[1,2], J. W. Oltjen[1], J. G. Fadel[1], and R. D. Sainz[1], [1]*University of California*, *Davis*, [2]*NSW DPI*, *Armidale, Australia*.

The 1st objective of this study was to describe the first-order differential equations of intermuscular (INTER), intramuscular (INTRA), subcutaneous (SUB), and visceral (VIS) fat (kg) depots in the Davis Growth Model of fat deposition and distribution. The 2nd objective, using acslXtreme (Hunstville, Alabama USA, Xcellon), was to (a) estimate the parameters for protein synthesis ($kg^{0.27}$) and maintenance ($Mcal.kg^{-0.75}.day^{-1}$) and (b) estimate parameters for the 4 fat depots (1/kg DNA). The data used are from a meta-analysis study of implanted and nonimplanted steers across a range of frame sizes. The 3rd objective was to test the hypothesis that different fat depots are metabolically different. Parameter estimates for protein synthesis ($kg^{0.27}$) were 0.0487 ± 0.0001 and 0.0467 ± 0.0001 for implanted (n = 94) and nonimplanted (n = 44) steers, respectively and parameter estimates for maintenance ($Mcal.kg^{-0.75}.day^{-1}$) were 0.1133 ± 0.0014 and 0.1035 ± 0.0026, for implanted (n = 94) and nonimplanted (n = 42) steers, respectively. A 4.1% increase in the protein synthesis parameter was detected between implanted and nonimplanted steers. Fat depot parameters (1/kg DNA) were estimated and no differences between implant status and frame size were detected. The mean (n = 129) of the 4 fat depot parameter coefficients were 0.1596 ± 0.0061, 0.3447 ± 0.0049, 0.2715 ± 0.0061, and 0.2242 ± 0.0063 for INTER, INTRA, SUB, and VIS, respectively. This study suggests that fat depots are not metabolically different between frame sizes and implant status at the level of aggregation used to simulate fat deposition in beef steers. Therefore the mean of the 4 fat depot parameter coefficients would be used in the first-order differential equations in the Davis Growth Model.

Key Words: Fat Depots, First-order Differential, Parameter Estimation

764 Simulation model of fat deposition and distribution in beef steers: 4. Model evaluation. M. J. McPhee*[1,2], J. W. Oltjen[1], J. G. Fadel[1], and R. D. Sainz[1], [1]*University of California*, *Davis*, [2]*NSW DPI*, *Armidale, Australia*.

The first-order differential equations for intermuscular (INTER), intramuscular (INTRA), subcutaneous (SUB), and visceral (VIS) fat depots (kg) in the Davis Growth Model of fat deposition and distribution in beef steers were evaluated. The models were challenged with an independent data set (ad libitum and limit fed finishing steers, frame size=5.6, no implants; n=107; BW=288 to 557 kg; ADG=0.55 to 2.45 kg/d; body fat=20 to 153 kg; backfat=0.51 to 17.78 mm; IMF=0.47 to 8.09 %; KPH=0.5 to 3.5 %) that looked at compensatory growth in steers that had been subjected to different forms of restriction in the growing phase. Carcass characteristics were converted to their respective kg of fat. Several techniques were used to evaluate the model: (a) mean bias (MB, observed – model-predicted); (b) modeling efficiency (MEF, values close to 1 indicate a perfect model and values < 0 indicate a very poor model); (c) Kolmogorov-Smirnov (KS) 2-sample test; and (d) linear regression. The KS was a test of the hypothesis that the observed and model-predictions have the same parent distribution. The linear regression evaluated slope=1, intercept=0 and bias using the simultaneous F-statistic for both slope=1 and intercept=0. The results were: MB of 1.95, -0.33, -0.07, and -1.15 kg; MEF of 0.75, 0.63, 0.64, and 0.56, for INTER, INTRA, SUB, and VIS, respectively; the KS test (P=0.01) indicated that the observed and model-predicted values were from the same parent distribution for all fat depots and the linear regression indicated there was no bias P=0.19, P=0.33, for INTRA and SUB, respectively and some bias P=0.02, P<0.01 for INTER and VIS, respectively. The results from this study show a reasonable degree of precision (MEF) although differences do exist between treatments. On the average (MB) the model over predicts for INTRA, SUB, and VIS however the model tends to under-predict fat as fat increases in the carcass. This under-prediction as fat increases in all 4 fat depots could possibly be due to a secondary phase of hyperplasia that is not currently represented. Additional data sets to challenge the model are required to confirm this phenomenon.

Key Words: Carcass Characteristics, Fat Depots, First-order Differential

765 Use of neonatal blood parameters to predict weaning weight in Brahman cattle. J. P. Banta*[1], N. C. Burdick[1], J. C. White[1], R. C. Vann[2], D. A. Neuendorff[1], A. W. Lewis[1], J. C. Laurenz[1], T.

H. Welsh, Jr.[1], and R. D. Randel[1], [1]*Texas A&M University System*, *Overton, College Station, Kingsville*, [2]*Mississippi State University*, *Raymond*.

An experiment was conducted to determine the utility of various blood parameters obtained approximately 24 h after birth to predict future performance of beef calves. Plasma and serum samples were collected from 111 calves and analyzed for plasma protein, serum protein, IgA, IgM, and IgG concentration. Calf BW were obtained at birth and weaning (average age = 172 d); weaning BW were adjusted to 172 d of age. Based on blood concentration of each parameter, calves were assigned to low, medium, and high groups. For example, calves with plasma protein concentrations less than 1 SD below the mean were assigned to the low group (n = 23), those with concentrations greater than 1 SD above the mean were assigned to the high group (n = 21), and all remaining calves were assigned to the medium group (n = 67). This procedure was repeated for serum protein (n = 22, 69, and 20; low, medium, high, respectively), IgA (n = 8, 92, and 11), IgM (n = 0, 96, and 15), and IgG (n = 22, 73, and 16). The statistical model included the blood parameter being tested, calf sex, calf temperament, and cow temperament. Of the five blood parameters only serum protein classification had a significant effect on calf weaning BW (Table 1). Correlation coefficients were determined for each blood parameter and weaning BW; plasma protein (r=0.11; P=0.26), serum protein (r=0.11; P=0.27), IgA (r=0.14; P=0.14), IgM (r=0.19; P=0.04), and IgG (r=0.13; P=0.17). The results of this experiment suggest that of the blood parameters evaluated, serum protein concentration may be the most appropriate measure for predicting future performance of suckling calves.

Table 1. Effect of blood parameter classification on adjusted 172 d weaning BW, kg

	Low	Medium	High	SE	P =
Plasma protein	163	173	173	5.5	0.13
Serum protein	162^{x}	171^{y}	180^{z}	5.6	0.03
IgA	174	169	178	7.8	0.32
IgM	-	170	174	6.2	0.46
IgG	167	170	176	5.7	0.48

^{x,y,z}Within a row, means lacking a common superscript differ (P < 0.10).

Key Words: Serum Protein, Performance

766 Effects of pre-shipping management on measures of performance and inflammation in beef calves entering a receiving feedlot. J. D. Arthington*[1], X. Qiu[1], R. F. Cooke[1], D. B. Araujo[1], C. C. Chase[2], and S. W. Coleman[2], [1]*University of Florida-IFAS, Range Cattle Research and Education Center*, *Ona*, [2]*USDA-ARS*, *Brooksville, FL*.

Our objectives were to evaluate the effects of pre-shipping management on performance of calves subjected to a 24-h transport. The study was conducted over two consecutive years using a total of 96 crossbred steers. Steers were randomly allocated to one of four pre-shipping management strategies: 1) Control; weaned immediately prior to transport, 2) Creep-fed; free-choice access to grain for 45 d prior to weaning, 3) Pre-weaned; weaned 45 d prior to shipping, and 4) Early-weaned; weaned at 80 d of age. On d 0, calves were loaded onto a commercial truck, hauled for 24 h, and delivered into a feedlot (d 1). Calves were penned within treatment (4 pens per treatment) and provided free-choice access to hay and grain. Calf BW and blood samples were obtained on d 0, 1, 4, 8, 15, 22, 29 and 30. Concentrations of haptoglobin and ceruloplasmin were measured in blood samples. Overall calf ADG was greater for early-weaned vs. control calves. In wk 1, early-weaned calves consumed more grain and less hay compared to control calves and pre-weaned calves consumed more grain, but a similar amount of hay compared to creep-fed calves. Overall DMI intake was greatest for early-weaned compared to control, and pre-weaned compared to creep-fed calves. Feed efficiency of early-weaned calves was greater than control, but similar among pre-weaned and creep-fed calves. Haptoglobin concentrations were less in creep-fed vs. pre-weaned calves on d 0, but increased sharply after shipping and were greater than pre-weaned on d 1 and 4. In Yr. 1, control calves experienced a sharp increase in ceruloplasmin concentrations, resulting in concentrations greater than early-weaned on d 15, 22, and 29. Creep-fed calves also experienced greater ceruloplasmin concentrations than pre-weaned calves on d 29 (Yr. 1) and d 4 (Yr. 2). These data suggest that early-weaned calves (80 d of age) have improved performance in the receiving yard compared to calves weaned directly prior to transport and feedlot entry. Differences in pre-shipping management appear to significantly impact measures of the acute phase response in calves.

Key Words: Weaning, Calves, Stress

767 Water solubility of phosphorus in feedlot cattle feces and manure. V. R. Bremer*, C. D. Buckner, G. E. Erickson, and T. J. Klopfenstein, *University of Nebraska*, *Lincoln*.

Runoff from manure is a concern with elevated concentrations of phosphorus (P) in surface waters. The water solubility of P can have a dramatic impact on the runoff potential of feedlot cattle feces and manure. Two hundred fifty-four fecal samples and 158 manure samples from 15 University of Nebraska feedlot nutrient mass balance studies were analyzed to evaluate the effect of level of P intake on water extractable P (WEP). Samples were from diets ranging from 0.10 to 0.49% P. Total P (TP) of each sample was analyzed in duplicate by ashing one g of sample at 600 degrees C for six hours, refluxing with 10 mL of 3 N HCl for 5 min., standardizing to 100 mL volume with double distilled water, and filtering through Whatmann 42 filter paper. Water extractable P was analyzed in duplicate by shaking 0.5 g DM of each sample with 100 mL double distilled water at 150 rpm for one h, a 50 mL aliquot was then centrifuged at 1500 g for 10 min, 125 µL of concentrated HCl was added to a subsequent 14 mL aliquot of supernate. All samples were stored at 4 degrees C prior to colorimetric analysis with the molybdovanadate method on a spectrophotometer (400 nm) calibrated with standards developed in a matrix similar to each analytical procedure. There was a linear increase (P < 0.01) in concentration of fecal TP as dietary P level increased. Changing from a 0.30% P diet to a 0.50% P diet increased fecal P concentration 67%. Fecal WEP (% of TP) did not change as fecal TP concentration increased (P = 0.55) and averaged 40% WEP. Dietary P concentration was not related to manure WEP (P = 0.43) and averaged 23% WEP. Manure WEP increased as manure TP concentration increased (P < 0.01) but not disproportionately. Changing manure TP from 0.25% to 0.50% increased manure WEP 38%, although, there is considerable trial to trial variation. These data suggest that pen surface conditions impact the water solubility of P in feedlot cattle manure. One factor influencing P solubility is OM content of manure from open lots.

Key Words: Feedlot Cattle, Phosphorus, Solubility

768 Practices and perceptions of cow-calf producers regarding the National Animal Identification System. S. J. Breiner*[1], D. A. Blasi[1], K. M. Boone[1], T. C. Schroeder[1], and S. A. Grau[2], [1]*Kansas State University*, [2]*Beef Magazine*.

The proposed U.S. National Animal Identification System (US-NAIS) has generated many concerns among beef cattle producers. The goal of the NAIS is to utilize 48-hour traceback in the event of an animal disease outbreak. The traceback would identify all animals that have had contact with the diseased animal, while linking an animal to its premise of origin. According to the Diffusion of Innovation theory, getting a new idea adopted, even when it has clear advantages, is often very difficult. However, by adopting innovations relatively sooner than others in their system, the theory shows marked benefits for innovators and early adopters, as well as a widening of the socioeconomic gap. A national study was conducted at Kansas State University to gauge beef producer acceptance and adaptability to implement the US-NAIS. Participants were selected in the spring of 2006, from a mailing list of cow-calf producers with more than 100 head of cows. *BEEF*® Magazine provided the mailing list and a random sample of 1,000 producers was selected. The results show a knowledge gap between the proposed system and producer understanding. Producers were also divided on support for the proposed system. When ranking their level of support on a scale of 1 to 6, with 1 being strongly supportive and 6 being strongly opposed, 49% of producers showed some level of support and 48% showed some level of opposition. Data shows a mean of 3.53 with a standard deviation of 1.672. Data also highlights a lack of understanding of the regulations and implementation procedures among producers. The results of this study brought considerable insight into the current practices and perceptions of beef cattle producers, and will be used to develop educational materials to improve their understanding of this proposed program.

Key Words: Animal Identification, Beef Cattle Producers, Radio Frequency Identification

Production, Management & the Environment - Livestock and Poultry: Livestock Production, Management, and Environment

769 Effect of littered systems on pollutant emissions into the air in gestating sows. C. Pineiro*[1], G. Montalvo[2], P. Illescas[2], and M. Bigeriego[3], [1]*PigCHAMP Pro Europa, SA*, *Spain*, [2]*Tragsega*, *Spain*, [3]*Spanish Ministry of Agriculture*, *Spain*.

During the last decade, the approach to environmental issues related to animal production is changing, including concepts such as emissions to soil, water, air and proper use of energy and water. In the EU Reference Document (BREF, 2003) on Best Available Techniques (BAT) for Intensive Rearing of Poultry and Pigs several techniques were proposed for emissions abatement. In Spain, a project financed by the Spanish Ministry of Agriculture, Fisheries and Food was planned to evaluate the BAT proposed by the BREF under Spanish conditions. The aim of the present work was to assess one of the BAT proposed for gestating sows, the littered systems (straw based) using good practices (enough straw, changing the straw frequently, functional areas) on gas emissions. The study was performed in a commercial farm using 60 gestating sows housed in two different rooms during four weeks. In the first room, the reference system was implanted (total-slated floor over deep manure channel and monthly removal); whereas in the second room, concrete floor was applied and 360 kg of straw were scattered over the floor (3 kg per sow and week). The concentration of the NH_3, N_2O and CH_4 (by means of semi-continuosly monitoring using an Innova 1312 multi-gas monitor; SIR, SA, Spain) in each room were measured. The solid concrete floor system with straw reduced the average NH_3 (11%, $P<0.05$), and CH_4 (66%; $P<0.01$) in comparison with the reference system. However, N_2O emissions increased by 190% ($P<0.001$) in the littered system. From these results, we conclude that despite ammonia emissions are reduced, an important greenhouse gas (N_2O) is hugely increased. Moreover, associated costs were extremely high (extra costs was 47.6 - 55.4 euros/place and year for new installations, and 72.7 - 80.5 euros/place and year for existing installations) because of the cost of straw and the required extra labour. Hence, harmonization of this directive with others affecting animal husbandry (Council Directive 98/58 CE) should be carefully performed to avoid the impairment of environmental performance.

Key Words: Gestating Sows, Ammonia, Littered Systems

770 Effect of different dietary strategies on productive performance and gas emissions in post-weaned piglets. G. Montalvo[1], C. Pineiro*[2], J. Morales[2], S. Godbout[3], S. P. Lemay[3], M. Belzile[3], J. Feddes[4], P. Illescas[1], M. Bigeriego[5], and C. de Blas[6], [1]*Tragsega*, *Spain*, [2]*PigCHAMP Pro Europa SA*, *Spain*, [3]*IRDA*, *Canada*, [4]*U. Alberta*, *Canada*, [5]*Spanish Ministry of Agriculture*, *Spain*, [6]*UP Madrid*, *Spain*.

The objective of this study was to assess the effects of different dietary strategies on post-weaned piglets performance and gas emissions. Dietary strategies assessed were low-protein content (LP, 16.6%CP), soluble fibre through sugar beet pulp inclusion (SBP, 10%) and acidification adding benzoic acid (BA, 5%). A total of 80 piglets were fed on five different isoenergetic diets: control diet, LP, SBP, BA, and the combination of all (LP+SBP+BA) during four weeks. Ten environmentally-controlled chambers, each housing eight piglets (13.1 kg initial BW, F1 cross (Yorkshire × Landrace) × Duroc) were used to monitor: average daily gain, ADG; average daily feed intake, ADFI; gain:feed ratio, G:F, airflow rate, NH_3, CH_4, and N_2O concentrations. G:F differed among treatments, being higher in LP+SBP+BA groups (0.46 vs 0.55 kg/kg in LP+SBP+BA and control groups, respectively; $P<0.05$). This effect was due to both a lower ADG compared with SBP and BA groups (532 vs 628 as average g/d; $P<0.05$), and higher ADFI compared with that of the control group (1.16 vs 1.05 kg/d; $P<0.05$). Also showed higher ADFI than control group (1.15 as average vs 1.05 kg/d; $P<0.05$), but no differences were found in G:F or ADG among any individual dietary strategy and the control group. Ammonia emissions from the control diet where 0.9 mg/h/kg pig, and similar to the BA diet, but the LP, SBP and LP+SBP+BA diets had emission rates about 50% lower with respect to control diet ($P<0.05$). For CH_4, the control diet showed an emission of 0.851 mg/h/kg pig, whereas the LP diet decreased emission rates about 40% ($P<0.05$). Other treatments had not effect on the emission rates of this gas. Nitrous oxide emissions were similar for all treatments (around 0.017 mg/h/kg pig), except for LP+SBP+BA diets where emissions reached 0.028 mg/h/kg pig. These results show that changes in nutrition may help to control emissions to the atmosphere, without affecting animal performance.

Key Words: Piglet, Nutrition, Gas Emissions

771 Cost of ammonia emissions abatement techniques in Spain. C. Pineiro*[1], G. Montalvo[2], P. Illescas[2], and M. Bigeriego[3], [1]*PigCHAMP Pro Europa, SA*, *Spain*, [2]*Tragsega*, *Spain*, [3]*Spanish Ministry of Agriculture*, *Spain*.

The Integrated Pollution Prevention and Control Directive is mandatory in the EU from the first of January of 2007. The implementation of the best available technicques (BAT) to control emissions is a key concept to be implemented at farm scale. The objective of this study was to present a calculation on cost of every BAT under Spanish conditions. The information provided will allow defining the most cost-effective methods for reducing ammonia emission from Spanish farms. The calculation was carried out according to the methodology set out in the Reference Document on Best Available Techniques for Intensive Rearing of Poultry and Pigs, taking into account the economic life of the investment, deducting grants and including changes in performance. The costs were calculated for feeding techniques, animal housing, slurry storage and spreading techniques. Units used for assessing costs were \$/place per year for feed and housing techniques, and \$/m^3 or tonnes per year for manure or slurry storage and manure or slurry spreading categories. All these costs have been expressed also as \$/kg pig produced, because in the pig sector it is more easily understood, and it is easier to calculate the cost for all of the production process. The basis for this calculation was 20 marketed pigs of 100 kg per sow per year. Further adjustments can easily be undertaken to reflect local conditions. Extra costs calculated for abatement techniques are listed next table. The standard concepts used and the transparency of the proposed methodology allows its implementation in other countries just using the appropriate figures for local conditions.

Table 1.

Techniques		\$/place/year	\$/t pig prod./year
Feeding	Low protein diet + amino acids	0.5 - 3.4	1.7 - 11.6
Housing			
Gestating sows	Reduced manure pit	7.5 - 8.9	2.8 - 3.9
	Littered system	62.5 - 105.7	23.5 - 39.7
Lactating sows	Manure pan underneath	23.0 - 48.9	2.9 - 6.0
Growers-finishers	Sloped manure channel	0.9 - 10.1	3.3 - 34.6
	Partially slatted floor	0 - 5.6	0 - 19.3
		\$/m^3/year	
Spreading (pig slurry)	Trailing shoe	1.2 - 1.8	15.1 - 23.1
	Band spreader	1.1 - 1.6	13.0 - 19.8
	Incorporation	0.3 - 0.8	3.8 - 10.0

Key Words: Cost, Ammonia Abatement, Pig

772 Influence of diet and genotype on performance of weanling pigs destined for natural label or commodity pork markets. A. F. Harper* and M. J. Estienne, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Diet formulation and pig genotype are important factors in the production of pork for niche markets. Weanling pigs (n = 60; 9.71 ± 0.03 kg BW) were used to assess diet and sire breed effects on performance. Diet treatments were a 2-phase series of diets acceptable for natural pork labeling (no antibiotics or blood or meat products) or a 2-phase series of conventional nursery diets (contained blood and meat products in phase 1 and medicated with 27 ppm carbadox throughout). The factorial treatments were: the natural diet fed to Berkshire-sired pigs, the natural diet fed to terminal Hampshire-sired pigs, the conventional diet fed to Berkshire-sired pigs, and the conventional diet fed to terminal Hampshire-sired pigs. There were 5 pens of 3 pigs per pen for each treatment. Feed and water were provided ad libitum. Pig BW and feed intake were determined at d 9 (phase 1) and d 34 (phase 2). During phase 1 pigs fed the natural diet had lower ($P < 0.01$) ADFI (201 vs. 280 ± 15 g) and ADG (156 vs. 204 ± 9 g) than pigs fed the conventional diet. Over the 34-d trial there was no main effect difference ($P > 0.24$) in ADFI (803 vs. 844 ± 25 g), ADG (436 vs. 453 ± 10 g) or G:F (0.55 vs. 0.54 ± 0.01) for the pigs fed the natural or conventional diets, respectively. During phase 1 performance traits were not different ($P > 0.19$) between Berkshire- and Hampshire-sired pigs, but for the entire trial ADG tended be greater for Berkshire-sired pigs (472 vs. 418 ± 17 g; $P = 0.11$). An interaction ($P < 0.05$) between diet and genotype was observed for ADG during phase 1. Hampshire-sired pigs fed the natural diet had lower ADG (123 ± 17 g) relative to Berkshire-sired pigs fed the natural diet (188 ± 17 g) or Berkshire-sired (208 ± 17 g) or Hampshire-sired (199 ± 17 g) pigs fed the conventional diet. Conventional diets produced superior growth performance during phase 1 but this advantage was not maintained for the entire 34-d nursery period. The interaction in ADG suggests that Berkshire-sired pigs may have greater potential to maintain a high level of performance than certain terminal-line sired pigs when less complex, antibiotic-free starter diets are fed.

773 Loading gantry versus traditional chute for the finisher pig: Effect on transportation and packing plant losses. N. Berry*, A. Johnson, K. Stalder, T. Baas, and L. Karriker, *Iowa State University*, *Ames*.

Pig mortalities from the farm to the harvest facility have been estimated to cost the U.S. swine industry over 55 million dollars annually. The objective of this study was to determine if chute design affects the incidence of dead, injured or stressed pigs upon arrival at the packing plant. A total of 456 semi loads of crossbred finisher pigs (117.43 kg) from a single finishing site were collected. A two by two factorial arrangement of treatments was compared, with loading systems (prototype loading gantry [P] vs. traditional chute [T]) and pull (first pigs marketed or first pull [FP] vs. last pigs marketed or closeout [CO]). Pigs were loaded using standard procedures for pig handling and transportation. Performance measures evaluated were dead on arrival (DOA), stressed on arrival (SOA), crippled on arrival (COA), dead in plant (DIP), stressed in plant (SIP) and crippled in plant (CIP). Data were analyzed using PROC Glimmix of SAS where dependent traits were evaluated with a full model including load chute, load crew, barn, pull, load time per pig, travel time, hauler, average live weight, kill date, week, and month fixed effects and a harvest day random effect. All non-significant sources of variation were removed from the final analyses models. For all performance measures there was no loading systems (P vs. T) effect (P>0.05). A pull effect (P<0.01) for SOA's with more occurring at closeout than first pull (0.30 vs. 0.16) was identified. Month of marketing was a source of variation (P<0.05) for SOA, DIP and SIP. Pull by load chute was a source of variation (P<0.01) for DIP's with CO pulls from the P chute having fewer DIP's when compared to CO pulls from the T chute. Fewer DIP's were

observed in CO pulls from the T chute when compared to FP from the T chute. A trend (P=0.06) for DOA's was seen between loading systems and pull. Additional work is needed to further characterize the role that loading system plays in the incidence of both the fatigued and dead pig during transportation and at the packing plant.

Key Words: Finisher Pig, Loading Gantry

774 Effect of autosort technology on pork production measures. J. M. Suchomel*, A. E. DeDecker, and J. L. Salak-Johnson, *University of Illinois*, *Urbana*.

Limited data exist about the impact autosort technology, a relatively new management tool, has on pig performance measures. The objective of this study was to determine the effects that 3 different pen layouts incorporating autosort technology had on wean-to-finish performance. This experiment was replicated twice with 622 ±13 cross-bred pigs per treatment in trial 1 and 615 pigs per treatment in trial 2. Treatments were food court (FC), water court (WC) and fast lane (FL) autosort floor layouts or conventional large pen (CV; control). Resources were zoned off in autosort treatments with 40% of total floor space zoned for food and water in (FC) and 20% zoned for water in (WC), respectively. For the (FL), food and water were distributed equally between 8 zones with 12.5% floor space per zone. Weights from automated scale units were recorded on a regular basis and production data was collected at slaughter. Performance measures included: mortality, average daily gain (ADG), days to market (DTM), and hot carcass weight (HCW) at market for the first two sorts from each treatment. In trial 1, carcass lean % data was also recorded from the first sort. Data were analyzed with Proc GLM procedure and Chi-Square in SAS. Pig ADG and DTM were similar among treatment groups. Pig HCW was similar across sorts. However, HCW overall (P< 0.0001) was less for the FC and WC pigs compared with the CV pigs. Pig HCW was greater for the FL pigs (P= 0.0002) than CV in trial 1, but the WC, FL, and FC (P< 0.001) were less than the CV pigs in trial 2. Percentage of pigs that died prior to shipping was greater in the FC (P = 0.01) and FL (P< 0.0001) treatments than CV pens. Percent carcass lean was similar among treatments. These data indicate that pig performance is similar among these specific autosort layouts when compared to large conventional pens but it seems possible that these systems can be improved to achieve the potential benefits of autosort technology. The food court, at this point, may be the best layout to attempt to modify in order to realize those potential benefits.

Key Words: Pig, Autosort, Production

775 Characterization of the acute-phase protein response following vaccination and weaning in beef steers. R. F. Cooke*[1], D. B. Araujo[1], G. L. Stokka[2], and J. D. Arthington[1], [1]*University of Florida - RCREC*, *Ona*, [2]*Pfizer Animal Health*, *New York, NY*.

The objectives of this study were to assess the acute-phase protein response of beef steers following vaccination with two different vaccines and to determine if this response is additive to the weaning process. On d 0, 48 steers (Brahman × British; avg. age = 7 mo) were randomly assigned to one of six treatments in a 2 × 3 factorial arrangement, including: weaning (WN) vs. no weaning (NW), and vaccination with One Shot® (1S; 2 mL s.c), UltraBac® 7 (U7; 5 mL s.c.), or saline control (Control; 5 mL s.c.). Blood samples were collected on d 0, 1, 3, 5, 7, 10, 14, and 21, relative to weaning and vaccination, for determination of plasma fibrinogen, ceruloplasmin, haptoglobin, and acid-soluble protein (ASP) concentrations. During the course of the study, free-choice hay and a grain-based supplement (< 4.5 kg/d) were offered to WN steers, while NW steers remained with their dams. Compared to NW, WN had greater (P<0.05) ceruloplasmin concentrations on d 3, and greater haptoglobin concentrations on d 3 (P<0.01) and 5 (P<0.05) (weaning treatment × day interactions; P<0.01). Among WN steers, average ceruloplasmin concentration was greater (P<0.05) for 1S vs. Control and U7. Vaccination treatment × day interactions were detected (P<0.01) for fibrinogen, ASP, and haptoglobin. Fibrinogen concentrations were greater (P<0.01) on d 1, 3, and 5, and tended (P<0.10) to be greater on d 7 for 1S vs. Control and U7. Concentrations of ASP were greater (P<0.01) on d 3 and tended (P<0.10) to be greater on d 5 for 1S vs. Control and U7. Haptoglobin concentrations were greater (P<0.01) for 1S vs. Control and U7 on d 1 and 3, but greater (P<0.05) for U7 vs. Control and 1S on d 5. Data from this study imply that animals vaccinated with One Shot® experience a greater inflammatory response compared to animals vaccinated with UltraBac® 7 and saline control, and this response mainly occurs during the 5 d following vaccination. In addition, additive effects of vaccination on weaning were only observed for plasma ceruloplasmin concentrations.

Key Words: Acute-Phase Proteins, Steers, Vaccination

776 Efficacy of chlorate against *E. coli* O157:H7 and *Salmonella* Typhimurium in bovine feedlot soil mixture. C. E. Oliver*[1], B. K. Magelky[2], M. L. Bauer[1], J. S. Caton[1], H. Hakk[2], G. L. Larsen[2], R. C. Anderson[3], and D. J. Smith[2], [1]*North Dakota State University*, *Fargo*, [2]*USDA/ARS Biosciences Research Laboratory*, *Fargo, ND*, [3]*USDA/ARS Food & Feed Safety Research Unit, Southern Plains Agricultural Research Center*, *College Station, TX*.

Our aim was to determine if chlorate, temperature, or atmosphere affected pathogen viability in feedlot soil. Aliquots (1 g) of dried bovine feces/soil mixture (75:25 w:w) and 1 mL bovine urine were incubated in 10 or 20 mL glass serum vials with chlorate (0, 17, 33, or 67 ppm), at 6, 20, or 30°C, under aerobic or anaerobic conditions. Each vial was inoculated with 1 mL of a fresh bovine fecal supernatant mixed with overnight cultures of *E. coli* O157:H7 strain 933 (EC) and *Salmonella enterica* Typhimurium DT104 (ST) in an 8:1:1 ratio. Aerobic vials were weighed daily and evaporative loss replaced with distilled water. Anaerobic vials were capped with a butyl stopper and aluminum seal. Samples were collected on d 0, 0.5, 1, 3, 7, 14, 21, and 28; serially diluted in phosphate buffered saline; and plated on MacConkey and XLT-4 agars. Plates were incubated at 39°C for 24 h and pathogens were counted. A second study was performed using sterile feedlot soil and fecal supernatant, so that added EC and ST were the only live bacteria present in the cultures. In the first study, EC was not detected in any aerobic cultures by d 3 at 20°C and by d 1 at 30°C. At 6°C, EC was not detected at 67 ppm chlorate by d 21, but persisted through d 28 in the remaining cultures at $\log_{10}$ 4 to 5.5 bacteria/mL culture. Aerobic cultures at all temperatures had no detectable ST by d 21 to 28. Pathogens in anaerobic cultures were detected in nearly all cultures at d 28, however, bacterial counts declined over time. In sterilized feedlot soil, results were similar. In both studies, there was no effect of chlorate on pathogen viability at the higher temperatures, but at 6°C there was an apparent chlorate dose–dependent decline in EC

counts. Chlorate may be effective in preventing pathogen persistence in feedlot soils at ~6°C temperatures.

777 Effects of maternal nutrition and selenium supply on postnatal organ mass: Evidence for developmental programming in lambs. J. S. Caton*[1], J. J. Reed[1], T. L. Neville[1], K. A. Vonnahme[1], P. P. Borowicz[1], J. B. Taylor[2], D. A. Redmer[1], J. S. Luther[1], C. J. Hammer[1], K. R. Carlin[1], and L. P. Reynolds[1], [1]*Center for Nutrition and Pregnancy, Animal and Range Sciences Department, North Dakota State University*, *Fargo*, [2]*USDA-ARS, U. S. Sheep Experiment Station*, *Dubois, ID*.

To examine effects of maternal nutrient restriction or excess and dietary Se on postnatal organ mass in the lamb, 82 pregnant Rambouillet ewe lambs (52.2 ± 0.8 kg) were allotted randomly to one of 6 treatments in a 3 x 2 factorial design. Groups included plane of nutrition (60% [RES], 100% [CON], and 140% [HIGH] of requirements) and dietary levels of Se (adequate Se [7.4 µg/kg BW] vs. high Se [85 µg/kg BW]; from Se enriched yeast). Selenium treatments were initiated at breeding and nutritional treatments on d 40 of gestation. Pelleted diets were fed once daily (36.5% beet pulp, 22.3% alfalfa meal, 16.2% corn, 18% soybean hulls, and 7.0% soybean meal; 14.4 % CP, 2.63 Mcal ME/kg; DM basis). At parturition, lambs were removed from the ewes before nursing and provided artificial colostrum for the first 20 h and were maintained on common management and diets until necropsy at approximately 5 mo of age. Live BW, hot carcass weight, and dressing percent were not affected ($P > 0.26$). Lamb pancreatic mass (g) was reduced ($P = 0.06$) in RES and HIGH compared with CON, as was blood mass (g and g/kg of empty BW; $P < 0.08$). Mass of the reticulum (g) was also reduced ($P = 0.10$) by in lambs from the RES and HIGH compared with CON ewes. In the lambs, maternal Se supplementation increased ($P < 0.01$) mass (g and g/kg empty BW) of the ovaries, decreased ($P < 0.09$) mass of heart and kidney (g/kg empty BW), and increased ($P = 0.04$) total visceral adiposity compared with adequate Se. Maternal nutrition by Se interactions were observed ($P < 0.06$) for omasum, small intestine, ileum and lungs. These data provide strong evidence for developmental programming of internal organ mass in offspring from pregnant ewes receiving various nutritional levels and supplemental Se.

Key Words: Maternal Nutrition, Selenium, Fetal Programming

778 Effects of maternal nutrition and selenium supply on ewe and lamb performance. T. L. Neville*[1], J. J. Reed[1], K. A. Vonnahme[1], P. P. Borowicz[1], J. B. Taylor[2], D. A. Redmer[1], J. S. Luther[1], C. J. Hammer[1], G. P. Lardy[1], L. P. Reynolds[1], and J. S. Caton[1], [1]*Center for Nutrition and Pregnancy, Animal and Range Sciences Department, North Dakota State University*, *Fargo*, [2]*USDA-ARS, U. S. Sheep Experiment Station*, *Dubois, ID*.

To examine effects of maternal nutrient restriction or excess and dietary Se on ewe and lamb performance, 82 pregnant Rambouillet ewe lambs of equivalent BW (52.2 ± 0.8 kg) and condition score (BCS; 3.0 ± 0.05) were allotted randomly to one of 6 treatments in a 3 × 2 factorial design. Groups included plane of nutrition (60% [RES], 100% [CON], and 140% [HIGH] of requirements for gestating ewes) and dietary levels of Se (adequate Se [7.4 µg/kg BW] vs. high Se [85 µg/kg BW]; from Se enriched yeast). Selenium treatments were initiated at breeding and nutritional treatments on d 40 of gestation. All diets were fed once daily in a complete pelleted form (36.5% beet pulp, 22.3% alfalfa meal, 16.2% corn, 18% soybean hulls, and 7.0% soybean meal; 14.4 % CP, 2.63 Mcal ME/kg; DM basis). At parturition, lambs were removed from the ewes before nursing and provided artificial colostrum for the first 20 h, after which they were fed milk replacer. At parturition, ewe BW and BCS were least ($P < 0.01$) in RES, intermediate in CON, and greatest in HIGH (53.9, 67.3, and 76.5 ± 1.4 kg and 1.60, 2.53, and 3.61 ± 0.10, respectively), as were ewe ADG and efficiency ($P < 0.01$). Ewe BW, BCS, ADG, gain efficiency, and gestation length were not altered by Se supplementation. Gestation length was reduced ($P < 0.01$) in HIGH compared with CON and RES. At birth, lamb BW, curved crown rump length, and heart girth were lower ($P = 0.01$) in RES and HIGH compared with CON. Weaning weight 8 weeks postpartum was less ($P = 0.01$) in lambs from RES ewes compared with those from CON and HIGH. Birth and weaning weight were unaffected by Se supplementation. These data indicate that maternal plane of nutrition but not supplemental Se affects the BW, BCS, and gestation length of the ewes and the birth and weaning weights of the resulting lambs.

Key Words: Birth Weight, Maternal Nutrition, Selenium

779 First-lactation milk production for cows fed control or intensified milk replacer programs as calves. J. K. Drackley*, B. C. Pollard, H. M. Dann, and J. A. Stamey, *University of Illinois*, *Urbana*.

Potential long-term effects of early-life plane of nutrition were quantified in 2 trials. Female Holstein calves housed in individual hutches were fed milk replacers in either conventional limit-fed (C: 22% CP, 20% fat; 1.25% of birth BW) or intensified programs (I: 28% CP, 20% fat). The 2 trials differed only in how I was increased after wk 1. Calves were weaned at 5 wk (C) or 6 wk (I). Calves were housed in groups by treatment from wk 9 to 12, then combined under common group management. Growth results were reported previously (Pollard et al., 2003, J. Dairy Sci. 86(Suppl. 1):174). Calves fed I had greater (P<0.001) ADG to wk 4 (Trial 1: 0.30 vs. 0.71 kg/d; Trial 2: 0.36 vs. 0.72 kg/d for C and I, respectively) and wk 8 (Trial 1: 0.56 vs. 0.69 kg/d, P<0.01; Trial 2: 0.59 vs. 0.67 kg/d, P=0.08). However, because growth slumped around weaning for I calves, BW at wk 12 did not differ (Trial 1: 103.7 vs. 104.2 kg, P=0.93; Trial 2: 103.9 vs. 97.2 kg, P=0.11). Lactation data from the 2 trials were pooled and analyzed using the Mixed procedure (SAS) with a model containing month of calving, age at calving, and lactation length as covariates; diet, trial, and the interaction were fixed effects. Age at first calving differed (P<0.01) between trials (Trial 1=25.9 mo; Trial 2= 24.1 mo) but was not affected by diet. Post-calving BW did not differ between trials or diets (mean 568 kg). A total of 10, 10, 18, and 14 heifers completed lactation records for C and I diets in Trials 1 and 2, respectively. Actual 305-d milk was greater (P<0.01) for I calves (Trial 1: 9,245 vs. 10,577 kg; Trial 2: 8,796 vs. 9,138 kg). Protein yield (305 d) was greater (P<0.001) for I calves but milk fat yield did not differ. Lactation length tended to be greater (P=0.07) for I calves (358 vs, 407 d). Total lactation milk yield was greater (P<0.01) for I calves (Trial 1: 11,232 vs. 12,917 kg; Trial 2: 10,824 vs. 11,243 kg; trial x diet, P=0.08). Intensified early nutrition increased early growth rates but greater BW was not sustained through wk 12; nevertheless, first-lactation milk yield was increased.

Key Words: Calf Nutrition, Lactation, Calves

780 Effect of mineral supplementation with MIN-AD during the transition period on cow health and production performance. J. E. Nocek*[1], R. G. Hinders[2], C. J. Sniffen[3], G. A. Nunnery[4], and M. B. Crombie[4], [1]*Spruce Haven Farm and Research Ctr*, *Auburn, NY*, [2]*Hinders Nutritional Consulting*, *Acampo, CA*, [3]*Fencrest*, *Holderness, NH*, [4]*MIN-AD, Inc.*, *Amarillo, TX*.

The objective of this study was to determine the effect of partial replacement of MgO and sodium bicarbonate with MIN-AD in the ration of early lactation cows on milk yield, composition and health. One hundred and four multiparous cows were group housed pre- and postpartum in separate pens containing approximately 70cows/group. They were assigned to the following treatments based on parity and previous lactation 305ME: Control: Cows received sodium bicarbonate at 1.0% of DM upon calving, MIN-AD: Cows received MIN-AD (MIN-AD, Inc., Amarillo, TX) at 0.5% DM for the entire study. At calving, these cows also received sodium bicarbonate at 0.5% of ration DM. Cows started the experimental period 21d prior to expected calving and remained on treatment for 10 wk during the subsequent lactation. There was no significant effect of MIN-AD on health incidence measured. However, there was a tendency for reduced displaced abomasums (P = 0.16, 7.7 and 1.9%) and clinical milk fever (P=0.15, from 3.8 % and 0%) for cows supplemented with MIN-AD. Group dry matter intakes were similar between treatments during the pre- and postpartum periods. Milk yield was higher (P = 0.001) for cows supplemented with MIN-AD as compared to control cows (42.4 and 44.1 kg/d for control and supplemented respectively). There was no treatment effect on milk fat percentage, yield or protein percentage. Protein yield and MUN were higher (P=0.03 and 0.02 respectively) for cows supplemented with MIN-AD, and lactose was higher (P=0.01) for control cows. Body condition scores were not affected by MIN-AD supplementation. Partial replacement of MgO and sodium bicarbonate with MIN-AD during the transition period did not influence health but increased milk production and protein yield.

Key Words: Dairy cattle, Transition, MIN-AD

781 Effects of twin pregnancy and dry period feeding strategy on milk production, energy balance and metabolic profiles in Holstein cows. N. Silva del Río*, R. R. Grummer, and P. M. Fricke, *University of Wisconsin*, *Madison*.

To evaluate the interaction of pregnancy type [singleton (S) vs. twin (T)], and dry period feeding management [transition diet (NEL=1.54 Mcal/kg) for 3 (3TR) vs. 8 (8TR) wk before expected calving date (ECD)], multiparous (n=39) and primiparous (n=8) Holstein cows were used in a 2x2 factorial randomized complete block design. Our hypothesis was that 8TR would improve metabolic status and lactation performance for T but not S cows. All cows were feed a late lactation diet (NEL=1.58 Mcal/kg) 90 to 60 d before ECD and the same early lactation diet (NEL=1.71Mcal/kg) after calving. At dry-off, cows were randomly assigned to 8TR or a far-off diet (NEL=1.32 Mcal/kg) for 5 wk followed by 3TR. DMI was measured daily, milk components were analyzed weekly, and blood samples were collected weekly from 90 d before ECD to calving. Postpartum, blood was collected from wk 1 to 5, and wk 7 and 10. Liver biopsies were performed about 3 wk before ECD and 1 and 35 d after calving. All data were covariately adjusted and statistically analyzed in a repeated measures design using the MIXED procedure of SAS. The least square means for main effects and their significances are described in the table below. Contrary to our hypothesis, no interaction (P>0.05) of dry period feeding management and pregnancy type was detected either prepartum or postpartum; however, feeding a diet moderate in energy throughout the dry period was associated with increased milk production. Supported by USDA NRI grant number 2002-35204-12351

782 Effect of botanical extracts (Queen of Calves) on the growth, development and weaning age of calves. J. K. Margersion* and R. W. Reynolds, *Massey University*, *Palmerston North, New Zealand*.

This research assessed the effect of feeding botanical extracts (Queen of Calves) with milk on; calf growth, development, feed intake and weaning age. Sixty calves were selected at random and allocated (48 h) according to sex, breed and live weight to one of three treatments; 4 l /h/d of whole milk (M); 4 l/h/d whole milk 4 l, plus 200 g botanical extracts (M+B); 2 l/h/d whole milk, plus 200 g botanical extracts (0.5M+B). Calves offered M+B had significantly higher live weight gain (g/h/d): M; 648^{b}, M+B; 755^{a}, 0.5M+B: 729^{ab} (sem 31.3), hip height (m): M; 1.81^{b}, M+B; 1.83^{a}, 0.5M+B; 1.82^{ab} (0.43) compared with M, there was no difference between calves offered 0.5M+B and M. All calves offered botanical extracts had higher hip width (mm): M; 18.7^{b}, M+B; 19.5^{a}, 0.5M+B; 19.0^{b} (0.17) compared with M. Days to weaning from milk (M; 79.2^{a}, M+B; 70.6^{b}, 0.5M+B; 74.7^{a} (1.97) and weaning from concentrated feed (M; 87.3^{a}, M+B; 79.0^{b}, 0.5M+B; 82.5^{a} (1.10) were significantly lower for calves offered M+B and were not significantly different for calves offered 0.5 M+B with 4 l milk. Concentrated feed intake was not significantly different (kg/h): M; 103.8, M+B; 97.3, 0.5M+B; 110.3 (4.34). Calves offered milk with botanical extracts had significantly higher growth rates, hip height and width, and weaned significantly sooner. Calves offered 2 l/h/d milk with botanical extracts had similar growth rates compared with calves offered 4 l/h/d milk.

Key Words: Calves, Growth, Development

783 Impacts on growth of beef cattle due to long-term copper deficiency are further exacerbated in the presence of high dietary manganese. S. L. Hansen*, L. R. Legleiter, R. S. Fry, K. E. Lloyd, and J. W. Spears, *North Carolina State University*, *Raleigh*.

A study was conducted to evaluate the effects of long-term copper (Cu) deficiency, either alone or in the presence of high manganese (Mn), on the performance of beef calves. Twenty-one Angus calves were born to cows that had been on one of the following treatments for at least 410 days by calving: 1)10 mg Cu/kg DM from tribasic copper chloride in addition to the basal diet (analyzed 7 mg Cu/kg DM; +Cu), 2) no supplemental Cu and 2 mg molybdenum (Mo)/kg DM (-Cu), and 3) no supplemental Cu, 2 mg Mo/kg DM and 500 mg Mn/kg DM from manganese sulfate (-Cu+Mn). After weaning, calves remained on the same treatments as their dams and were group fed by treatment for a period of 33 days before being individually fed via Calan gate feeders through a 136 day growing phase. The average calf age at weaning was 180 days. Liver biopsies taken when calves were approximately 160 days of age indicated that calves fed low-Cu diets were below the threshold for Cu deficiency (7 and 4 mg Cu/kg DM for -Cu and -Cu+Mn, respectively). Copper adequate calves were heavier (237 kg; $P < 0.05$) at weaning than those fed -Cu (199 kg) or -Cu+Mn (186 kg) diets. Daily gains from birth to weaning were greater ($P < 0.01$) for +Cu calves (1.09 kg) than for -Cu (0.88 kg) and -Cu+Mn (0.82 kg) calves. During the growing phase, ADG was not different between +Cu (1.08 kg) and -Cu (1.05 kg) calves, but was lower (0.86 kg; $P < 0.05$) in -Cu+Mn calves. Dry matter intake during the growing phase did not differ among +Cu (7.36 kg) and -Cu (7.08 kg) calves. However, DMI was lower ($P < 0.01$) in -Cu+Mn calves (5.39 kg) when compared to -Cu calves. Feed efficiency during the growing phase did not differ among treatments. Findings from this study indicate that a low-Cu diet fed to calves prior to weaning adversely affects performance. In addition, the presence of high Mn in diets of Cu-deficient calves further exacerbates the effects of low Cu on growth.

784 Effects of high B-vitamin supplementation on measures of health and performance of veal calves. D. Wood*[1], J. Sowinski[1], and N. Keith[2], [1]*Animix*, *Juneau, WI*, [2]*Keith Associates*, *Springfield, MO*.

An experiment was conducted to determine effects of enhanced B-vitamin fortification on calf health and performance. Auction sourced Holstein bull calves (n = 110; initial BW = 46 kg; ~1 wk of age) were transferred to the facility, and randomly placed into individual raised, slatted veal stalls. All calves were provided starter formula (22% CP and 16% fat) composed of liquid fat, whey, skim milk, & spray dried plasma, and transitioned to a veal finisher (19.5% CP and 17% fat) at ~40 days. Formulas were fortified with a typical B-vitamin containing, dispersible premix. Calves were randomly assigned to receive one of two treatments, 1) Increased B-vitamin fortification: 9 × B1, B2 and B6; 8 X pant. acid, 6X B12, 7× biotin, 3× folic acid, 2× choline and 4× niacin (B-vit; n = 55), 2) no added supplement, only basal formula (Control; n = 55). Individual calf BW was determined on d 11 and d 62 and individual hanging carcass weights were determined at slaughter. Calf ADG from day 11 – 62 did not differ (P = 0.50) among treatments (0.95 and 0.97 kg/d for Control and B-vit.-Fortified, respectively). Calf ADG from day 11 – 143 (market) did not differ (P=0.75). Individual antibiotic treatments day 11 – 63 were reduced from 1.52 / calf in control to 0.63 / calf in B-vit. (P = 0.101). Incidence of feed refusals day 11 – 63 reduced 23% (P = 0.35) and percentage of calves treated was reduced from 41.8% in control to 25.5% in B-vit (P=0.07). Incidence of re-treatment day 11 – 63 was reduced from 29% in control to 12.7% in B-vit (P=0.035). Mortality and culls to 9 weeks was 1.8% B-vit and 5.3% Control. Weeks 10 – 23 reported no diff. in ADG (1.49 and 1.50 kg/d for Control and B-vit, respectively, P=0.93) or feed refusals (P=0.91). 4 calves (7.2%) died of disease in both treatments during week 10 - 23. Individual antibiotic treatments week 10 – 23 were reduced from 1.79 / calf in B-vit to 1.22 in control (P=0.254). No difference was noted in carcass color or confirmation (P=0.36). Under the conditions reported in this study, additional B-vitamin supplementation improved measures of calf health to week 9 but did not improve health parameters week 10 – 23.

Ruminant Nutrition: Protein and Fiber Digestion

785 Protein requirements of Nellore bulls, steers and heifers in Brazil. P. V. R. Paulino*[1], S. de C. Valadares Filho[1], M. A. Fonseca[1], K. A. Magalhães[1], M. I. Marcondes[1], M A. de Souza[1], E. Detmann[1], R. F. D. Valadares[1], and R. D. Sainz[2], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [2]*University of California*, *Davis*.

The objective in this trial was to determine the protein requirements of Nellore bulls, steers and heifers, reared under the same experimental conditions. Forty–seven animals were used (16 bulls, 15 steers and 16 heifers), being fed in individual pens for 112 days, and slaughtered at the end of this period. Eleven animals (4 bulls, 3 steers and 4 heifers) were slaughtered at the beginning of the trial, composing the reference group, which was used to estimate the initial body composition of the animals. The remaining animals were randomly assigned to 6 treatments, in a factorial design, 3 × 2 (3 sexual classes and 2 concentrate allowance levels), with four replicates per treatment. Four animals of each sexual class were designated to the maintenance group. The concentrate allowance levels used corresponded to the allowance of 0.6 or 1.2% of the body weight. The diets were formulated to be isoproteic, with corn silage as the source of roughage. The protein content retained in the body was estimated by a regression equation of the logarithm of the body content of protein on the logarithm of the empty body weight (EBW). The net requirements of protein for 1 kg of empty body gain (EBG) were estimated as the derivative of the regression equation described above. The net protein requirements of EBG decreased as the live weighted increased, being greater for the bulls, intermediate for the steers and lower for the heifers. The retained protein (RP) can be estimated by the equations: RP = 14,78 + 175,86 * EBG – 2,95 * RE (bulls), RP = 25,62 + 139,81 * EBG – 7,43 * RE (steers); RP = 18,13 + 177,27 * EBG – 16,57 * RE (heifers). Bulls had higher net requirements of protein for empty body gain in relation to the steers and heifers, being lower for the heifers in relation to the steers, reflecting the differences observed in the body composition among the three sexual classes. The estimated total requirements of crude protein, for finishing of Nellore cattle, were 12.92; 11.14 and 10.08% of the total dry matter of the diet, for bulls, steers and heifers, respectively.

786 Digestibility of cottonseed with Tifton 85 hay fed free-choice to beef steers. G. M. Hill*[1], M. H. Poore[2], and B. G. Mullinix, Jr.[1], [1]*University of Georgia*, *Tifton*, [2]*North Carolina State University*, *Raleigh*.

Whole cottonseed (WCS) is a supplement for wintering beef cows, but few reports indicate effects of free-choice feeding of WCS. Large beef steers (n=28; 417.2 ± 36.1 kg initial BW) were ranked by BW, randomly assigned to four treatments (7 steers each), and individually-fed diets for 17 d. Dietary treatments included free-choice hay (Tifton 85 bermudagrass; 12.4% CP, 42.6% ADF, 76.8% NDF) and minerals. Dietary treatments included hay with Control supplement [C; 75% ground corn, 25% cottonseed meal (19.9% CP, 14.2% NDF), fed at 2.5 kg/steer daily], or WCS (DM basis: 22.4% CP, 39.2% ADF, 54.7 % NDF, 18.0% crude fat) fed at three levels (LCS, WCS at 0.25 % initial BW; MCS, WCS at 0.5 % initial BW; and FCS, WCS fed free-choice). Chromic oxide (10 g/steer daily; d 8 to d 17) was fed as an indigestible marker, mixed with C supplement, or fed in a carrier (corn=0.25 kg/steer daily) for CS treatments. Fecal samples (11/steer, d 13 to d 17) were analyzed to determine apparent digestion of dietary nutrients. Dietary CP and crude fat (% of DM) based on DMI for C, LCS, MCS and FCS, respectively, were: 14.4, 2.1; 13.6, 3.7; 14.8, 5.7; and 14.5, 5.2. Breed type (BT) of steers [BT1, Angus (n=7) and Angus crossbred (n=8); BT2, Angus x Hereford (n=8); BT3, Hereford steers (n=5)] was used as a covariate ($P > 0.20$; Table). Hay DMI (Table) was reduced for MCS and FCS, and dietary DMI was similar for LCS and FCS, both lower than C or MCS. Inconsistent WCS intake by FCS steers resulted in lower WCS intake and dietary DMI than for MCS. Digestibility of OM was lowest for FCS, intermediate for LCS and MCS; and, ADF and NDF digestibility declined with increasing dietary WCS. The short duration of the trial contributed to DMI adjustment to WCS in MCS and FCS diets.

Table 1.

Item	Control	LCS	MCS	FCS	SE	*P* <
Hay DMI, kg	6.61^{a}	6.49^{a}	5.89^{ab}	5.47^{b}	0.29	0.04

787 Performance of beef heifers and digestibility of steers fed whole cotton seed, corn gluten feed and pigeon peas. V. A. Corriher*, G. M. Hill, S.C. Phatak, and B.G. Mullinix, Jr., *University of Georgia*, *Tifton*.

Exp.1: Yearling beef heifers were fed supplements including whole cotton seed [WCS; 1.36 kg/d; 92.6% DM, 22.5% CP, 18.1% crude fat], corn gluten feed [CGF; 1.59 kg/d; 88.2% DM, 22.1% CP], pigeon peas [PP; 1.59 kg/d; 88.9% DM, 21.5% CP], corn/soybean meal as a control [(70% corn, 30% SBM) C/SBM; 1.59 kg/d; 89.9% DM, 30.8% CP], and free-choice corn silage [28.6% DM, 8.3% CP, 39.1% NDF] in feedlot. Supplements contained Rumensin® (200 mg/animal daily) in both experiments. Heifers (n=56) were of Breed Type 1 (BT1, Angus=19, Angus × P. Hereford= 8) or Breed Type 2 (BT2, Brangus=13, Braford= 16). Heifers were ranked by BW (initial BW=249.27 ± 23.72 kg) within BT, and randomly assigned to dietary treatments for 57d. Initial and final BW were means of consecutive daily unshrunk BW. The ADG for heifers tended to be higher for pigeon peas (Table). However, DMI/gain tended to be higher for corn gluten feed compared with other supplements.

Exp.2: Yearling beef steers were fed the same supplements (C/SBM: 2.00 kg/d; WCS: 2.30 kg/d; CGF: 2.30 kg/d; PP: 2.00 kg/d) as in experiment 1, and free-choice bermudagrass hay [92.5% DM, 12.4% CP, 76.8% NDF]. Steers (n=28) were of Breed Type 1 (BT1, Angus=7, Angus X=8), Breed Type 2 (BT2, Angus × P. Hereford= 7, Simmental X=1) or Breed Type 3 (BT3, P. Hereford= 4, Hereford X=1). Steers were ranked by BW (initial BW=450.55 ± 28.21kg) within BT, and randomly assigned to dietary treatments for 14d. Initial and final BW were means of consecutive daily unshrunk BW. Chromic oxide (10g/steer daily, d 5 to d 14) was fed as an indigestible marker and mixed with supplement. Total DMI was higher for whole cottonseed. Crude protein, ADF and OM digestibility were higher for corn gluten feed. Higher digestibility, suggests greater nutrient availability of corn gluten feed for cattle.

Key Words: Steer, Pigeon Peas, Digestibility

788 The rumen passage rate of forage NDF is highly associated only to the level of intake of dietary NDF. A. Cannas*[1], F. Boe[1], V. Giovanetti[2], E. Zerbini[3], and G. Molle[2], [1]*Dipartimento di Scienze Zootecniche, University of Sassari*, *Sassari, Sardinia, Italy*, [2]*Istituto Zootecnico e Caseario della Sardegna*, *Olmedo, Sardinia, Italy*, [3]*Cargill Animal Nutrition*, *Spessa, Italy*.

Cannas and Van Soest (2000) published a prediction equation in which the level of intake of dietary NDF was used to predict the rumen passage rate (Kp) of forages. The two variables were associated curvilinearly. Their prediction model included a second variable (dietary CP concentration) to account for the negative effect of rumen N shortage on Kp. However, in the literature many other independent variables have been used to predict Kp of dietary forages in ruminants. Thus, to elucidate which dietary and animal variables affects the rumen passage rate of forages, 40 dairy ewes (BW 46.8 kg ± 2.9 kg of s.d.) in mid-lactation (5 per treatment kept in metabolic cages) were fed ad libitum 8 different pelleted diets with a large range of variation in NDF concentration (23.9%-45.8%, DM basis). CP concentration was sufficiently high (on average 18.4 % DM) to rule out rumen shortages of nitrogen. Four of the 8 diets (range of NDF= 28.5%-45.8%, DM basis) were also given in rationed amounts (1.19% of BW, DM basis) to dry ewes. Rumen Kp passage rate was estimated supplying a single dose of dehydrated alfalfa, the common and only forage ingredient of all diets, marked with Yb.

Overall, DMI ranged from 489 to 2634 g/d (1.09%-5.77% of BW) and NDF intake from 117 to 1367 g/d (0.29%-2.87% of BW). The best predictor of rumen passage rate of forage NDF was the level of intake of dietary NDF. This predictor was both linearly and curvilinearly associated to forage NDF Kp with equally good statistics: Kp (%/h) = 1.82 × NDFI (% of BW) +2.27; r^2 = 0.76, P< 0.001; or Kp (%/h) = 4.23 $NDFI^{0.50}$ (% of BW), r^2 = 0.76, P< 0.001. The distribution of the residuals and the regressions based on the treatment means (Kp = 1.84 NDFI + 2.27, r^2 = 0.93, P< 0.001; or Kp = 4.29 $NDFI^{0.49}$, r^2 = 0.95, P< 0.001) seemed to slightly favour the curvilinear model. No other dietary or animal variables seemed to affect rumen Kp.

Key Words: Passage Rate, Prediction, Sheep

789 Meta analysis of rumen fill of cattle in relation to NDF intake and digestibility. D. J. Sauvant*[1] and D. R. Mertens[2], [1]*AgroParisTech*, *Paris, France*, [2]*US Dairy Forage Research Center*, *Madison, WI*.

Rumen fill is related to intake and ruminal digestion. Our objective was to explore if NDF relationships could be used to establish a rumen fill unit system. A database was compiled from 41 published experiments (n=164 treatments) where weights of dry matter (DMru) and NDF (NDFru) in the rumen were measured on various types of cattle. On a live weight (LW) basis, DMru averaged 1.76±0.30%LW and NDFru 0.99±0.22%LW. Dietary NDF averaged 36.0±9.7% of DM and NDF intake (NDFI) averaged 1.10±0.25%LW. As several experimental objectives were included in the database, only global regressions were evaluated. NDFru was related to the ruminal weight of total contents (TWru = 7.68 + 3.44 NDFru, n=156, rmse=1.51 %LW) or DM (DMru = 0.843 + 0.918 NDFru, n=164, rmse=0.22). The major variable related to NDFru was NDFI (NDFru = 0.461 + 0.484 NDFI, n=164, rmse=0.18). The residual variations of this equation (RESNDFru) were compared to variables other than NDFI, which might influence rumen fill. The ratio NDFru/NDFI, which is sometimes used as an index of rumen fill, was closely related with RESNDFru (RESNDFru = -0.76 + 0.83 NDFru/NDFI, n=159, rmse=0.08). There were no relationships between RESNDFru and DM intake; milk yield or composition; dietary NDF, CP, or starch; percentage of concentrate; mean particle size; chewing time or index; rumen fermentations; or fractional outflow rates of particles and liquid. In contrast, NDF digestibility (NDFD = 0.53±0.12) in the whole gut was negatively related with RESNDFru (RESNDFru = 0.988 NDFD - 1.67 NDFD2, n=121, rmse=0.16). Organic matter digestibility, which is correlated to NDFD, was also negatively linked with RESNDFru. For 43 treatments, in situ degradation of NDF of the forage was measured (NDFDis = 0.71±0.21). For these data a curvilinear regression was observed between RESNDFru and NDFDis (RESNDFru = - 1.08 + 4.90 NDFDis - 4.44 NDFDis2, n=43, rmse=0.13), the maximum value being achieved for NDFDis = 0.55. In conclusion, rumen fill is related primarily to NDF intake and secondly to its digestibility.

Key Words: NDF, Digestibility, Rumen Fill

790 Predicting ruminal passage rates of fiber fractions and starch in dairy cattle. J. A. Voelker Linton* and M. S. Allen, *Michigan State University*, *East Lansing*.

Passage rates of fiber fractions and starch are important factors determining ruminal nutrient digestion, microbial protein production, efficiency, and flow to the duodenum, and physical and metabolic satiety effects of a diet. Data obtained in our laboratory from 11 experiments utilizing the pool and flux method for estimating passage rates of digesta fractions were used to develop new regression equations predicting passage rates of indigestible NDF (iNDF), potentially digestible NDF (pdNDF), and starch. The data set included 254 animal-periods from multiparous lactating cows, 29 animal-periods from primiparous lactating cows, and 32 animal-periods from pregnant heifers. For passage rates, 95% confidence intervals were 1.23 to 5.31 h^{-1} for iNDF, 0.19 to 4.26 h^{-1} for pdNDF, and 3.44 to 33.9 h^{-1} for starch. Data were divided into two sets by randomly selecting 2/3 of the animal-periods from each study (210 records) for a database used to develop potential models, then assigning the remaining 1/3 of the animal-periods from each study (105 records) to a database used to validate potential models. Equations were developed using predictor variables that are available on farms. Predictors used in the regression equations included dietary concentrations of NDF, forage NDF (forNDF), and starch; 30-h in vitro NDF digestibility of forages; DIM and BW; intake of DM, NDF, and starch; and MY, milk fat concentration, and 3.5% fat-corrected MY (FCMY). The best predictions explained 68% (RMSE = 0.69), 53% (RMSE = 0.71), and 42% (RMSE = 5.87) of variation in passage rates of iNDF, pdNDF, and starch, respectively. Equations developed indicate that important predictors of passage rate include proportions of starch, NDF, and forNDF in the diet, intake of DM and starch, forage NDF digestibility, and MY or FCMY. Improving accuracy of predictions of passage rates will increase our ability to optimize ruminal fermentation, which can aid in optimizing DMI and nutrient utilization, thus reducing nutrient waste and increasing efficiency of milk production.

Key Words: Passage Rate, Fiber Fractions, Starch

791 Evaluation of counts of ruminal fibrolytic bacteria and enzyme activities in response to corn silage particle size in high-yielding dairy cows. Q. Zebeli*[1], V. Ölschläger[1], M. Tafaj[1], W. Vahjen[2], B. Junck[1], O. Simon[2], and W. Drochner[1], [1]*University of Hohenheim*, *Stuttgart, Germany*, [2]*Free University of Berlin*, *Berlin, Germany*.

This study examined the effects of particle size (PS) of corn silage (CS) on counts of selected fibrolytic bacteria and related enzyme activities in particulate or fluid ruminal digesta as well as on ruminal or total digestive tract fiber degradation in dairy cows fed TMR (40% CS, 10% hay and 50% cereal-based concentrate; DM basis) ad libitum. Four early-lactating (67 ± 8 DIM), rumen-fistulated Holstein cows were randomly assigned to incomplete block switch-back design in four 23-d periods to 1 of 3 diets (in average: 6.9 MJ NEL/kg of DM, 15% CP and 35% NDF in DM) differing in PS of CS: 14, 8.1 and 5.5mm (n=5/treatment). After a 12-d diet adaptation, digesta samples were collected from dorsal (particulate) and ventral (fluid) rumen sac, 1h before and 3h after morning feeding, and analyzed for pH, VFA, fibrolytic enzyme activities (by an agar-diffusion assay) and counts of fibrolytic bacteria using 16S rDNA quantification by real-time PCR. In general, the counts of total eubacterial cells, R. albus and R. flavefaciens were not affected by dietary PS (P>0.10), but the activities of CMCase, Glucanase, Galactanase and Xylanase quadratically increased with reducing PS (P<0.05). This was reflected in quadratically increased ruminal (in situ; P=0.07) or total tract (P<0.05) fiber degradation. Decreasing dietary PS did not affect ruminal pH (P>0.10), but increased ruminal C2/C3 ratio and C4 proportion (P<0.05).

Compared to fluids, the particulate digesta showed higher counts of fibrolytic bacteria and enzyme activities (P<0.05), whereas the latter were stronger enhanced by reducing dietary PS (P<0.05). Results of this study indicate that reducing PS of CS in a TMR has the capacity to increase fiber degradation in the rumen of dairy cows, particularly by stimulating the activities of fibrolytic enzymes rather than increasing the total count of fibrolytic bacteria.

792 Nutrient digestibility and utilization in non-lactating fistulated cows fed diets containing ratios of untreated corn silage and Silo-King®treated alfalfa haylage. G. A. Ayangbile*, D. Spangler, D. Jones, and K. Thompson, *Agri-King, Inc.*, *Fulton, IL.*

It is a common practice in most dairy operations to feed diets consisting of two or more types of forages. On some farms, choices are made to ensile corn silage (CS) with or without any additive. However, it is of greater risk to ensile alfalfa without any additive. This study evaluates nutrient digestibility and utilization in non-lactating fistulated cows fed a TMR containing varing ratios of untreated CS and Silo-King® treated alfalfa haylage. Cows were arranged in a 4 × 4 latin square design. Diets consisted of a) 80% untreated CS and 20%, treated alfalfa haylage (80:20, CS/Hlg), b) 60:40, CS/Hlg, c) 40:60, CS/Hlg, and d) 20:80, CS/Hlg. Each period consisted of 16 d adaptation to diets, and 5-d collection. Total fecal collection was obtained per cow, and random spot urine samples were collected before (0 h) and after (4 h) feeding. Rumen fluid and blood samples were collected at 0 h and 4 h. The amino acids composition expressed as percentage of insoluble crude protein were higher for the TMR containing lowest inclusion of haylage. DMI ranged from 31.2 lb DM to 33.5 lb DM. Total DM fecal output (14.5 lb) was highest (P<.05) for 80:20, CS/Hlg and lowest (11.1 lb) for the 20:80, CS/Hlg. Digestibilities for DM, NDF, ADF, and starch were greater (P<.05) for 40:60 and 20:80, CS/Hlg TMR. Blood glucose (P<.05), ammonia, rumen valeric and isoacids were increased (P<.05) with higher haylage ratios in TMR. Results indicate the benefits of replacing portion of a diet containing an untreated corn silage with a higher level of treated alfalfa haylage. There were greater digestibility and utilization of organic and inorganic nutrients.

793 Effects of a ground raw soybean diet on reproductive performance in gilts. D. Sykes*, K. Necaise, W. Brookshire, P. Gerard, F. Cunningham, M. Crenshaw, and P. Ryan, *Mississippi State University*, *Mississippi State*.

Raw soybeans contain high levels of phytoestrogens (i.e., genistein), which are bioactive compounds known to enhance ovarian function in sows, but little is known about the use of raw soybean diets on reproductive performance in gilts. Thus, the objective of this study was to examine the effects of a raw soybean diet on pregnancy outcome and weaning performance of gilts. To this end, prepubertal Yorkshire x Landrace gilts (n=20; BW 73.6 ± 1.1 kg; age 140 d) were assigned to balanced isonitrogenous (CP 14%) and isocaloric diets using either soybean meal (SBM; n=10) or ground raw soybean (RSB; n=10) as the protein (100%) supplement source. Gilts were housed in covered outdoor pens with ad libitum access to feed and water and monitored daily (from 160 d of age) for estrus using a teaser boar then bred by AI on the third standing estrus using the AM/PM rule. After breeding, gilts were penned individually indoors and restricted to their respective diets (2.23 kg/day) through to d 111 of gestation when they were placed in farrowing crates and maintained on a lactation diet until weaning. There was no difference (P > 0.10) with respect to diets on age of gilts at time of first estrus (RSB 193.2 d ± 6.86; SBM 188.4 d ± 5.97) or breeding (RSB 235.6 d ± 7.51; SBM 230.1 d ± 6.82). All but three gilts in the RSB group conceived on first AI. There was no difference in the average number of pigs born to gilts (RSB, 13.2 ± 1.29; SBM, 13.8 ± 0.59 pigs) or on the number of mummified fetuses and stillborns. Mean litter birth weights (RSB, 1.34 ± 0.08; SBM, 1.41 ± 0.05 kg) and placenta weights (RSB, 3.35 ± 0.41; SBM, 3.75 ± 0.22 kg) were not different. While there was a difference (P < 0.05) in the mean number of pigs weaned per litter (RSB, 8.90 ± .80; SBM, 11.80 ± 0.59 pigs) there were no differences in the average weaning weight of pigs (RSB, 7.90 ± 0.45; SBM, 7.50 kg ± 0.31 kg). There was an observed but not significant difference in time to return to estrus post-weaning of sows (RSB, 18.0 ± 4.59; SBM, 13.9 ± 4.79 d). These studies indicate that feeding raw soybeans as a protein dietary supplement source is not detrimental to reproductive performance in gilts.

Key Words: Raw Soybeans, Gilts, Reproduction

794 Effect of feeding Luctarom "S" 55972Z® on sow reproductive performance. D. Towey[1], J. Sonderman[2], D. Reese*[1], D. Travnicek[1], and K. Eskridge[1], [1]*University of Nebraska, Lincoln*, *Lincoln, NE*, [2]*Danbred North America*, *Columbus, NE*.

The objective of this study was to determine the effects of feeding Luctarom "S" 55972Z® (Lucta S.A., Barcelona, Spain) and maternal line on sow reproductive performance. Luctarom is a product with a milky flavor and strong cured cheese and vanilla bottom notes. Treatments were arranged as a 2 x 2 factorial with diet and maternal line as factors. Diets were corn-soybean meal based containing 1.2% total lysine, 3,260 kcal of ME/kg and 3% added fat, with or without Luctarom. Parity two to nine line 241 and 482 Danbred N.A. females (n=176) were used at a parity-segregated commercial farm. Control or Luctarom feed (containing 0.075% Luctarom) was introduced to sows when they were moved into the farrowing quarters 4d before farrowing. Sows remained on their respective dietary treatment until weaning (average 16.8 d of lactation). Prior to farrowing, sows were limit-fed, but after farrowing they were allowed ad libitum access to feed until weaning. Each sow's allotment of feed was weighed prior to dispersal. Feed disappearance was calculated the next morning by weighing any feed that remained in the feeder. All data were analyzed using analysis of covariance with parity as a covariate. In addition, day was treated as a repeated measure for the feed disappearance data. Feed disappearance before (2.36 vs. 2.52 kg/d; P = 0.222) and following farrowing (6.79 vs. 6.79 kg/d; P = 0.989) was similar for control and Luctarom fed sows, respectively. During the prefarrowing

phase, line 482 sows made more feed disappear than line 241 sows (2.67 vs. 2.19 kg/d; P = 0.010). However, during lactation feed disappearance was not different between the lines (P = 0.865). Total number of pigs born/litter (13.35 vs. 13.90; P = 0.353) and number born alive (12.21 vs. 12.66; P = 0.429) were similar for control and Luctarom fed sows, respectively. Luctarom did not improve sow feed disappearance or reproductive performance.

795 Supplemental microbial phytase effects the expression of intestinal and liver mineral transporters in the iron/zinc deficient pig. E Tako*, R. P Glahn, R. M Welch, X Lei, and D. D Miller, *Cornell University*, *Ithaca, NY*.

Over 50% of phosphorous in beans is in the form of phytate that is poorly available. Phytases, catalyze the stepwise removal of inorganic orthophosphate from phytate. Since bioavailability of iron and zinc in foods of plant origin is a function of phytate concentration, we hypothesized that enhanced dietary phytate phosphorus utilization by supplemental microbial phytase might also produce simultaneous improvements in the bioavailabity of zinc and iron in red and white beans based diets, and by that means effect iron/zinc related transport protein gene expression in the iron/zinc deficient pig. Iron deficient piglets at age 4 wks were divided into 5 treatment groups (n=4): 1. Standard corn-soy diet (control); 2. 50% white bean diet ; 3. 50% red bean diet ; 4. 50% white bean diet + 1000 units phytase/kg diet; 5. 50% red bean diet + 1000 units phytase/kg diet. Diets 2-5 had no supplemental iron/zinc. After 30 days, animals were killed and sections of tissue from the duodenum and liver were collected for analysis of expression of iron transport genes. Semi quantitative RT-PCR used to evaluate relative expression of DMT1, Dcytb, ZnT1, mucin, ferritin and ferroportin. In the duodenum, DMT1 and Dcytb expressions were higher ($P \leq 0.05$) in the controls compared to all other groups. ZnT1 and mucin expressions were higher ($P \leq 0.05$) in groups 2, 4 compared to other groups. Ferritin and ferroportin expressions did not differ between treatments. As for the liver, ZnT1 and ferritin expressions were increased ($P \leq 0.05$) in treatment 4 compared to other treatments. These results suggest that supplemental dietary phytase may affect genes encoding for iron and zinc transporters and in this way enhance iron and zinc absorption by enterocytes. Support- HarvestPlus.

796 Effects of dried distillers grains and NCKP soybean meal on growth performance and fat quality characteristics of growing/finishing pigs. J. M. Benz*, M. D. Tokach, S. S. Dritz, J. L. Nelssen, J. M. DeRouchey, and R. D. Goodband, *Kansas State University*, *Manhattan*.

A total of 111 barrows (maternal line PIC 1050) with an initial BW of 47.9 kg were used in an 83-d trial to study the effects of dried distillers grains (DDGS) and extruded expelled soybean meal (EESM) on growth performance and fat quality. Pigs were blocked by weight and randomly allotted to one of six treatments with two pigs per pen and nine pens per treatment. Diets were: a corn-soybean meal control diet with no added fat; corn-EESM diet with no added fat; corn-EESM diet with 15% DDGS; corn-soybean meal diet with 15% DDGS and 1.55% choice white grease (CWG): corn-soybean meal diet with 3.25% CWG; and corn-soybean meal diet with 4.7% CWG. Diets were formulated to have three dietary iodine value (IV) levels (42, 55, and 62) to compare the impact of fat source within dietary IV levels. On d 83, jowl and backfat samples were collected. Pigs fed 4.7% CWG had increased ADG compared with pigs fed either diet containing 15% DDGS. Pigs fed EESM with 15% DDGS or the diets with 3.25 or 4.7% CWG had increased G:F compared with pigs fed the control. Pigs fed either of the diets with 15% DDGS had increased backfat IV compared with pigs fed diets without DDGS. Pigs fed EESM had increased backfat IV when compared with the control diet or diets with 3.25 or 4.7% CWG. Adding DDGS to the diet or using EESM increased IV of jowl fat. Adding CWG to the control diet also increased IV of jowl fat. Feeding ingredients with higher levels of unsaturated fat, such as EESM and DDGS, had a greater impact on fat IV than CWG even when diets were formulated to similar IV levels.

Table 1.

Item	Control	EESM	EESM + DDGS	1.55% CWG + DDGS	3.25% CWG	4.7% CWG
Calculated Diet IV	42	55	62	55	55	62
ADG, kg	0.95^{ab}	0.95^{ab}	0.91^{a}	0.92^{a}	0.94^{ab}	1.00^{b}
ADFI, kg	2.88^{c}	2.74^{bc}	2.56^{a}	2.68^{ab}	2.61^{ab}	2.67^{ab}

797 Effects of a commercial sequestering agent on performances of fattening pigs fed diet artificially contaminated by aflatoxin B1 and ochratoxin A. G. Battacone*[1], G. A. Carboni[2], P. Nicolussi[2], C. Patta[2], and G. Pulina[1], [1]*Dipartimento di Scienze Zootecniche - University of Sassari*, *Sassari, Italy*, [2]*Istituto Zooprofilattico Sperimentale per la Sardegna*, *Sassari, Italy*.

The use of feed additives with mycotoxin adsorption capacity is a common strategy for controlling negative effects of mycotoxins in swine production systems. However, adsorbents that may results very effective under experimental conditions, i.e. when feed contamination level is rather high, do not necessarily retain their efficacy when tested under field conditions feed with generally low mycotoxin contamination. In this study the effects of diets artificially contaminated with aflatoxin B1 or ochratoxin A on fattening performance and serum chemistry of fattening pigs are investigated. Moreover, the ability of a commercial glucomannan polymer (Gm polimer) to reduce or eliminate the effects of the contaminated feeds is tested. Thirty heavy pigs (BW = 110±10.6 kg) were fed 6 diets (n = 5 pigs/diet) for 4 weeks until slaughtering. Diets were: control without toxin added (C); added with 0.02 ppm of aflatoxin B1 (AFB1); added with 0.05 ppm of ochratoxin A (OTA); other three diets as the previous but the addition of 2.0 g/kg of Gm polymer (C-Gm, AFB1-Gm, OTA-Gm). Daily weight gain (ADG) and feed efficiency ratio were taken every two weeks. Data were analyzed with two-way ANOVA that included the fixed effect of diet, time and their interaction. After the first 2 weeks the ADG did not differ significantly between the diets, even if the ADG of AFB1 diet was about 20% lower than AFB1-Gm or C. In

the last 2 weeks the ADG of AFB1 diet was significantly lover than the other diets (P<0.01) and was about one-half of the values reported for the same group in the first period. The contamination with ochratoxin A did not affect fattening performance of pigs during the whole experimental period. No damages were found in kidneys of all diets. Moreover, no evidence of association between observed liver damages and different diets. Finally, no differences between experimental diets were evidenced for the haematological parameters. The research was supported by the project *Sicurezza e qualita' nella filiera suinicola regionale* funded by the Regional Authorities

798 Ghrelin secretion is more closely aligned to the energy balance than with feeding behaviour in the grower pig. P. C. Wynn*, K. Scrimgeour, M. J. Gresham, P. Thomson, and R. E Newman, *Faculty of Veterinary Science University of Sydney*, *Sydney, NSW, Australia*.

Ghrelin secreted from the gastric fundus is thought to act as an initiator of feeding behaviour in the arcuate neurocircuitary of the hypothalamus across species. Thus this hormone has the potential to stimulate feed intake and therefore animal productivity. In our study we have evaluated changes in the circulating total ghrelin activity in response to different patterns of meal feeding over a 24h period and related these to insulin and metabolite status in grower pigs. Male Large White × Landrace pigs (57.5 kg) maintained at 22oC in a 12:12 light:dark lighting regime were offered a commercial pelletted ration (13MJ DE and 6.2g Lysine per kg) ad libitum for 7 days. Blood samples were collected hourly for 24h from indwelling ear vein catheters without restraint. Animals were then offered 95% of ad libitum feed intake in 2 meals (1 hour each) at 0900 and 1600h daily for 2 days. Animals were then bled hourly for 12 hours over the 2 feeding periods. The same protocol was repeated on the subsequent day with the exception that feed was provided only at 1600h. The 12h bleeding protocol was repeated on this day. During ad libitum feeding ghrelin status (Phoenix kit) remained constant for the 24h and was not related to either insulin, glucose or free fatty acid profiles. Similarly ghrelin status did not change when animals were offered their feed as 2 meals nor as a single meal. However it was associated with a gradual rise in FFA status during meal feeding. In contrast insulin status changed in line with the increased glucose following each meal. Our results suggest that ghrelin is not an acute regulator of feeding in grower pigs.

Teaching/Undergraduate & Graduate Education: From Choosing a Graduate Program to Embarking on a Successful Career: A Guide for Livestock and Poultry Science Students

799 Choosing a graduate program. D. R. Notter*, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Interest in graduate education in the animal sciences is widespread among both new graduates and midcareer professionals, and graduate training opportunities in the field are becoming more diverse. Students therefore need to develop a clear understanding of their training goals and be proactive in identifying opportunities consistent with those goals. Most land-grant universities provide excellent educational opportunities for motivated undergraduates, but the choice of an individual to act as graduate advisor is critical. Consultation with faculty at the student's home institution is usually the first step in choosing a graduate program. Departments can facilitate these discussions in seminar classes and workshops. On-line resources are useful, but students should also initiate communication with prospective advisors early in the application process. Few things warm the heart of a prospective major professor more than a well-composed, grammatically correct message from a prospective student expressing enthusiasm and understanding regarding an area of study. Students should likewise expect clear signals about deadlines, funding options, and potential research areas. In most cases, if a message to a prospective advisor does not elicit a reply, look elsewhere. Recent trends in graduate education include increasing emphasis at many universities on retention of their own undergraduates and growing preferences for doctoral students. Yet we often advise students to change institutions and to complete an M.S. before embarking on the Ph.D. A critical aspect in comparing graduates program involves visiting the campus to meet prospective advisors and current students. The objective is to find out if students in the program are doing things that you aspire to do. Strong programs have students that are engaged, enthused, and mentored, with clear understanding of the expectations of their program and the relevance of their research. A campus visit provides opportunity to ask existing students about their relationship to the department and assess the extent to which they feel respected and valued.

Key Words: Advising, Graduate education, Teaching

800 Research and teaching: what else? The unwritten guide to graduate school. C. C. Taylor-Edwards*, *University of Kentucky*, *Lexington*.

What makes a successful graduate student? Graduate school is all about taking classes, teaching, and research, so these must make you successful, right? Many employers may disagree. Several of the skills that employers desire in a new hire are lacking in graduate students. Graduate students often have poor communication skills, the tendency to avoid risk, a lack of vision, and a failure to understand the value of time. However, with the awareness and willingness of the graduate student, the process of graduate school can develop a core set of competencies that can be transferred successfully to a multitude of careers. This set of skills includes time management, effective presentation communication, interpersonal relationship building, goal-setting and prioritizing, organization, and independence. These

are skills that will make an employer take notice; furthermore, they can be achieved via a variety of venues. Teaching and taking classes and conducting research certainly all lend themselves to improving these skills. However, to become an exceptional graduate student, extra effort is needed. Become involved with your department, guest lecture in classes, participate on panels about graduate school, and be involved in departmental or university-wide committees and programs. Be engaged in professional organizations; not only are they a great place to network and raise your visibility to future employers, but often offer opportunities for professional development, such as symposia, workshops, and leadership opportunities. Strive to become a well-rounded individual. In a world of increasing specialization, graduate students and faculty are often isolated in their department or discipline. This specialization isolates us socially and intellectually, and creates an environment in which it is difficult to "think outside the box". Finally, remember that with the stress and long hours of graduate school, the importance of family, friends, good health, and sleep is often underestimated. Keeping these a priority can improve productivity in the classroom or lab and lead to the formation of a highly successful graduate student, valued by future employers.

801 Opportunities outside of the lab, international experience, networking, and professional societies? J. S. Radcliffe*, *Purdue University*, *West Lafayette, IN*.

Obtaining a graduate degree in Animal Sciences requires a significant amount of laboratory, animal, and course work. However, often opportunities outside of these traditional settings may be most beneficial to the student and to the advisor's research program. Individuals seeking a laboratory to complete a graduate degree in are often instructed not to get all of their degrees from one institution. The rationale behind such advice is that it is good to gain different experiences and perspectives by attending more than one University. While this advice seems reasonable, it still usually limits the student's exposure to labs conducting similar research within the United States. As the globalization of agriculture continues, it is becoming increasingly important for individuals in Animal Sciences to have a global rather than a national perspective of agriculture. International opportunities for graduate students during their degree program are invaluable in helping students to obtain a broader perspective of agriculture and how their research may impact animal agriculture. Providing graduate students with an international opportunity can be as simple as letting them attend an international meeting or as complex as allowing them to complete a portion of their research in a lab based outside of the United States. The advantages and disadvantageous of such opportunities will be discussed based on personal experience as a student and advisor.

Key Words: Graduate Education, International Experience

Bio Ethics - Livestock and Poultry

802 Why it is important to understand bioethical concepts. R. D. Reynnells*[1], C. C. Croney[2], and D. J. R. Cherney[3], [1]*USDA/CSREES/PAS, Washington, DC*, [2]*Oregon State University*, *Corvallis*, [3]*Cornell University*, *Ithaca, NY*.

Understanding bioethics helps us discern how food animals ought to be treated, and is basic to our views of animal welfare and animal rights. Few of us were trained in philosophy or ethics. Our ethical training primarily is based on religious concepts or societal expectations. Bioethics, ethics applied to biological systems, increasingly influences decisions by stakeholders and officials. Philosophical attacks on food animal production may first eliminate Judeo-Christian religious concepts, and then dissect secular ethics based on rules of logic. Change is promoted based on these chains of logic that discard current norms for animal use in favor of new found "truths". Organizations are changed by decision makers' understanding of issues, structural requirements and goals, desires, political pressure, etc. Agricultural firms are no different. Decision makers may include consumers who make purchasing decisions (drive market demand), voters, government officials, and producers. Historically, cheap food demand has been a major change agent for agriculture, as has the desire of farmers to avoid undesirable situations. It is increasingly difficult, and yet imperative, to balance ethical considerations with economic and practical aspects of animal agriculture. This balance is complicated if production changes are not market driven but imposed by persons apparently attempting de facto management, absent the risks, of farmer's resources. New standards for change are not restricted to questions about how to efficiently raise food animals, but include concepts of refinement, reduction, and replacement of animal management and care practices. Consideration of whether or not we should use animals for food is a crucial ethical concept. Several bioethical concepts will be discussed. Should bioethical and animal welfare science considerations be the basis of our management and regulatory decisions? Should a person's or organization's vision of ethical behavior be forced on an industry and society, or should changes in agriculture come through true market demand? Also to be discussed is how our awareness of bioethical concepts facilitates our ability to properly address animal welfare issues.

Key Words: Animal Welfare, Bioethics, Societal Expectations

803 The ethical landscape of non surgical embryo-transfer in pigs: An explorative study of public concerns. F. R. Stafleu[2], D. W. B. Ducro-Steverink[1], and J. W. M. Merks*[1], [1]*IPG, Institute for Pig Genetics B.V.*, *Beuningen, the Netherlands*, [2]*Ethics Institute, Utrecht University*, *Utrecht, the Netherlands*.

Non surgical embryo transfer (nsET) focuses on the development of a technique in pig production to improve genetic preservation and international trade. In modern society however, the public is concerned about ethical aspects of animal production. To get an impression of these "public concerns", an opinion about the nsET technique was asked of four groups: agricultural professionals involved in nsET, professionals of the Eurogroup for Animal Welfare, volunteers of the Dutch Society for the Protection of Animals and a group of members of the public. An ethical analytical tool (the ethical Matrix) was used to collect these opinions in a standardized way. Rooted in these opinions, an ethical analysis of moral problems possibly connected

with the technique was made, resulting in a description of the "ethical landscape" of the technique. From the results it emerges that, seen from inside the practice of pig breeding, it is a skillful technique with clear economic and animal welfare advantages. But many of the contra arguments come from an outside perspective and are concerned mostly with the "unnaturalness" of the procedure and the negative impact that the technique may have on biodiversity. Also the technique is often associated with intensive farming which has for many a negative connotation. It is concluded that moral criticism is possible. Whether this criticism leads to an overall negative moral judgment remains to be seen; an overall judgment falls outside the scope of this study. It is stressed that in a pluralistic democratic society it is very important that agricultural professionals discuss these issues with the rest of society, each on the basis of their own ethical convictions. In such a discussion the strong and the weak points will emerge and a judgment can be made.

Key Words: Ethics, Non Surgical Embryo Transfer, Pigs

804 Animal welfare and the ethics of care: Towards a sustainable practice. R. Anthony*, *University of Alaska*, *Anchorage*.

Recently, the ethics of care has become part of the vocabulary in animal welfare ethics. It has gained momentum in animal welfare circles because the orientation that it takes best suits the apparent progress we've made in understanding animals' capabilities and how they are harmed, and because of its genuine desire to converge toward appropriate and sustainable ethical norms by appreciating the set of cultural and technological practices involved in farming. The ethics of care approach, in contrast with formal rule theories like utilitarian and rights-based approaches, begins not with the "what, if anything, do we owe animals" question, but instead with the context sensitive question of "how can we better meet our care responsibilities, to those who rely on us". After a brief consideration of the moral, political and technological contexts of agriculture, I attempt to show what it might take for an ethics of care to occupy a central role in our animal farming practices. Following scholars in this area, four key elements of an ethic of care will be delineated (i.e., attentiveness, responsibility, competence, and responsiveness) and applied to farmed animal welfare ethics.

Key Words: Animal Ethics, Animal Well-Being, Ethics of Care

805 Animal biotechnology: where to from here? A. L. Van Eenennaam*, *University of California*, *Davis*.

Biotechnology is defined as the application of science and engineering to living organisms. From this definition it is obvious that livestock breeders have been practicing animal biotechnology for many years. However, in recent years this term has been increasing associated with the technologies of cloning and genetic engineering. Products of these controversial technologies are slowly starting to move towards commercialization with the first human therapeutic compound derived from the milk of a genetically engineered animal being approved by the European Commission in 2006. The global market for recombinant proteins from domestic animals is predicted to reach US$18.6 billion in 2013. Similarly, the entry of products from cloned animals into the food supply also moved a step forward with the release of the FDA's draft risk assessment which found that edible products derived from marketable clones posed no additional food consumption risks relative to corresponding products from sexually-derived animals. However, the animal biotechnology industry still faces a variety of scientific, regulatory, ethical, and public acceptance issues. Many polls have concluded that the majority of people are opposed to 'animal biotechnology'. Closer examination reveals opinions are technology-dependent, with most people being favorably disposed towards the concept of genomics, and less supportive of genetic engineering and cloning. The industry is also faced with uncertainty arising from whether governmental agencies intend to consider moral and ethical factors, in addition to scientific evaluation of risks and benefits, when making regulatory decisions about cloned or genetically modified animals. Perhaps in response to public opposition or decreased funding support, the previously increasing numbers of published papers on cloning and genetic engineering have leveled off in recent years. Additionally, relatively few scientists have actively participated in the public discourse by articulating the science-based risks and benefits, in addition to the ethical issues, occasioned by these potentially-compelling technologies. It is currently unclear what role publicly-funded animal scientists will play in arriving at a societal consensus on the acceptable uses of animal biotechnology.

ADSA Production Division Symposium

806 Feeding programs that meet the challenges of heat stress. J. N. Spain* and D.E. Spiers, *University of Missouri*, *Columbia*.

Increased levels of milk production has increased the metabolic heat load lactating dairy cows must transfer to the environment to maintain thermal balance. As a result of this advanced genetic base, the incidence and severity of heat stress has increased. Heat stressed dairy cattle experience significant adverse responses including decreased milk production, increased incidence of mastitis, decreased fertility and lower reproductive success. Management strategies focus on reducing the thermal stress by decreasing heat load while concurrently increasing heat loss. Nutritional management strategies have been developed to support heat stressed dairy cows. Increased nutrient density and diets with a lower heat increment have been designed to decrease the heat load. Heat stressed cows have increased nutrient demands associated with higher requirement of electrolytes. Heat stress also alters rumen function. Decreased rumination, lower saliva secretion and lower buffering capacity of saliva increase the incidence of ruminal acidosis. Use of feed additives to help maintain a higher ruminal pH can provide important therapeutic support of the heat stressed cows. In addition, the lower rate of passage also decreases microbial efficiency and flow of microbial protein from the forestomachs. Therefore, the adjustment of protein supplementation can be made to maintain optimal amino acid flow to the small intestine. Therefore, seasonal adjustments of nutritional management strategies can be implemented to help mitigate the negative impact of elevated temperature and humidity on high producing dairy cattle.

Key Words: Dairy, Heat Stress, Nutrition

807 Environmental modifications to address heat stress. M. J. Brouk*[1], J. P. Harner, III[1], J. F. Smith[1], and D. V. Armstrong[2], [1]*Kansas State University*, *Manhattan*, [2]*University of Arizona*, *Tucson*.

Heat stress results in significant economic and production losses for dairy operations throughout the world each summer. Due to the continuous nature of dairy production, losses in the current lactation often result in losses in subsequent lactations or premature culling of animals. Reduction of losses due to heat stress represent an opportunity for dairy producers to gain a competitive edge. As a result, many producers have utilized different methods of heat abatement. In general these methods can be divided into two groups, those which enhance heat exchange between the cow and the environment or those which modify the environment to prevent or limit the degree of heat stress to which the animals are exposed. Increased heat exchange generally involves increasing heat loss from the body surface by enhancing heat loss mechanisms. The most common methods involve the addition of water to the hair coat and supplemental airflow to increase the rate of evaporation of the additional water and sweat enhancing heat exchange which reduces body temperature. Heat stress abatement with these systems is generally achieved by cooling heat stressed cattle. Environmental modifications attempt to reduce the potential for heat stress by lowering the temperature of the air around the cow. Evaporation of water into warm air reduces the temperature while increasing the relative humidity. Water evaporation can be achieved by high pressure fogging systems or by drawing warm air through evaporative pads. The challenge is to maintain an environment in which the temperature-humidity index is below the heat stress threshold for lactating dairy cattle. Critical factors for consideration when evaluating these systems is the air temperature and relative humidity of the environment. An inadequate or improperly designed system may actually increase the THI above the unmodified environment. When selecting a heat abatement system, one should consider production goals, facilities, environment, heat stress potential, water supply, and economic factors. In some very stressful environments, application of both environmental modifications and surface heat exchange may be beneficial.

Key Words: Cooling, Facilities, Environmental Stress

808 What we have learned about the genes involved in the response to heat stress. R. J. Collier* and R. P. Rhoads, *University of Arizona*.

Climate has profound effects on animal performance (i.e. growth, reproduction and lactation) and understanding the interaction between thermal environment and animal production has been the subject of intense research. Traditionally, examination of heat stress effects have focused on physiological and phenotypic changes, however, the development of molecular tools is allowing animal scientists to characterize transcriptional alterations across the genome and identify key cellular responses to heat stress. Gene expression changes associated with thermal environment may be grouped into 3 categories; acute, acclimatory and adaptive. Acute and acclimatory responses occur on a physiological and cellular level and decay with removal of the stress while adaptive responses involve short and long-term genetic alterations. At the systemic level, gene families associated with homeorhetic regulation of metabolism (growth hormone, prolactin, thyroxine, glucocorticoids) play an important role in heat stress acclimation. At the cellular level, thermal tolerance is maintained as long as heat shock family proteins are elevated and lost when expression of these genes declines in the face of continued stress. Cellular expression of heat shock proteins during thermal stress is altered by prolactin, IGF-I and prostaglandins E2 and A1. indicating that considerable opportunity may exist to improve thermotolerance. Evolutionary adaptation to heat stress involves genotypic differences associated with coat color, hair quality and density and sweat gland function which are related to inter-breed variation in heat gain and loss. Short-term genetic alterations involving epigenetic regulation of gene expression and thermal imprinting of the genome represent potentially promising but relatively unexplored areas in animal agriculture. Opportunities exist to improve thermal tolerance of animals by selection for specific hair coat characteristics, homeorhetic responses to thermal stress and improved heat shock response. The heat shock response opportunity is greatest during early embryonic development.

Key Words: Heat Stress, Gene Expression, Acclimation

Breeding and Genetics - Livestock and Poultry: Swine

809 Genetic factors affecting growth traits of Nili-Ravi Buffalo calves in Pakistan. P. Akhtar*, U. Kalsoom, S. Ali, M. Yaqoob, M. I. Mustafa, and J. I. Sultan, *Faculty of Animal Husbandry, University of Agriculture*, *Faisalabad, Punjan, Pakistan*.

Records on body weights at different ages of 624 Nili Ravi buffalo calves (from 1989 to 2002) kept at LES, Bahadurnagar, (Pakistan), were analyzed by computer programs LSMLMW and DFREML. Average weights at birth , weaning and yearling were 35.86±4.30, 66.12±9.16 and 145.82±19.50 kg. Pre-weaning average daily gain was 316 ± 88 gm, while post-weaning average daily gain was 301±29 gm. The ANOVA indicated that year and season of birth, age and weight of dam significantly effected the traits. Maximum weights were observed in spring season, while minimum gains were obtained in other seasons. Maximum heritability was 0.25±0.14 for birth weight, while minimum heritability was observed for weight at nine months of age that was 0.11±0.12 which indicates that growth traits were moderate to highly heritable suggesting that selection will be a best criteria for improvement. Among phenotypic correlations maximum correlation was 0.90 that was between weaning weight and weight at six months of age whereas minimum correlation was observed in birth weight. Environmental, phenotypic and genetic correlations were fairly large and positive indicating that selection for the improvement of one trait will positively affect the other trait.

Key Words: Genetic Factors, Growth, Buffalo Calves

810 Genetic analysis of ewe stayability and its association with lamb growth and adult body weight. R. C. Borg[1], D. R. Notter*[1], and R. W. Kott[2], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*Montana State University*, *Bozeman*.

Records from 2,525 adult Targhee ewes and 10,099 lambs were used to estimate genetic parameters in an animal model for ewe stayability (STAY), weaning weight (WW), adult weight (AW), and number of lamb born (NB). Weaning weights were recorded at approximately 120

d of age. Annual NB and AW were recorded at lambing and weaning, respectively. Stayability were analyzed as overall stayability (STAYn|2) which indicated presence or absence of a ewe at n yr of age, given the ewe was present at 2 yr of age, or marginal stayability (STAYn|n-1) recording the presences of a ewe at n yr of age, given the ewe was present in the previous year. Adjustments were made to WW for effects of age, type of birth and rearing, age of dam, and sex, and NB was adjusted for ewe age effects. Birth year was included as a fixed effect on all traits; additional fixed effects of management group on WW and ewe age and type of birth and rearing on AW were also included. Models for all traits included random direct additive genetic and residual effects. Uncorrelated random effects of the ewe were also included for AW and NB, and additive maternal and dam permanent environmental effects were included for WW. Additive variance in STAY was only present after 5 yr of age ($P < 0.05$), so only STAY5|4 and STAY6|2, with heritability estimates of 0.08 and 0.10, respectively, were used in multiple-trait analyses. All phenotypic correlations involving STAY were near zero, ranging from -0.04 to 0.03. Estimates of direct additive-maternal correlations of STAY5|4 and STAY6|2 with WW were positive (both 0.46; $P < 0.05$), suggesting that STAY and maternal effects on WW may both reflect genetic variation in ewe fitness characteristics. Genetic correlations between STAY6|2 and WW, AW, and NB were all negative, with values of -0.17, -0.32 ($P < 0.05$) and -0.03, respectively, indicating a possible small antagonism between STAY and additive effects on body size.

Key Words: Sheep, Heritability, Stayability

811 Gene regulation in liver of cattle exposed to heat stress. E. Antoniou*, J. Robertson, and D. Spiers, *University of Missouri*, *Columbia*.

Summer heat stress results annually in hundreds of million of dollars of lost productivity and impaired animal health. Cattle have reduced feed intake, lower growth and conception rates, panting activity, increased peripheral blood flow and sweating. Although these effects are well documented, the changes in cellular function and gene regulation are poorly understood. Liver is one of the major organs involved in the regulation of metabolism and heat production. The goal of this study is to investigate the changes in gene regulation in liver of cattle under long term mild heat stress. Angus steers (n=5) from the University of Missouri herd were housed in the Brody Environmental Center. Steers were maintained for 7 days at a temperature of 19.07 ± 0.06°C after which liver biopsies were obtained. Heat stress consisted of a 14 day exposure to a cycle of 27.39 ± 0.15°C nighttime low to 36.21 ± 0.14°C daytime high temperatures. Biopsies were again performed at the end of the heat stress period. RNA was extracted, labeled and hybridized to our cDNA bovine cDNA array. The microarrays were printed using PCR products amplified from 17,692 bovine cDNA clones. Normalization was accomplished by using a two-stage ANOVA analysis and a list of differentially expressed genes was obtained using the Fs statistic. A total of 100 differentially expressed genes were identified with at least a 40% up- or down-regulation and a false discovery rate of less than 0.05% (adjusted for multiple testing using permutations). Some genes involved in oxidative stress were down-regulated, such as Metallothionein 1, 2, and 3 (80%) and glutathione peroxidase (40%), while glutathione S-transferase was up-regulated by heat stress (240%). Insulin-like growth factor binding proteins 2 and 5 were up-regulated 200% and 160 %, respectively. Heat shock 70-kD protein 2 was up-regulated by 160%. Several genes involved in energy metabolism were differentially expressed, such as cytochrome c oxidase subunit I and III, ATP synthase F0 subunit 8, and NADH dehydrogenase subunit 4L and 5. A number of genes involved in immune functions were also differentially expressed under heat stress.

Key Words: Heat Stress, Microarray, Liver

812 Differential gene expression profiling of malignant melanoma in Sinclair swine. M. A. Okomo-Adhiambo[1], A. Rink[2], W. Rauw[1], C. W. Beattie[3], and L. Gomez-Raya*[1], [1]*University of Nevada*, *Reno*, [2]*Animal Disease and Food Safety Laboratory*, *Reno, NV*, [3]*University of Illinois*, *Chicago*.

The miniature strain of Sinclair swine develops an aggressive form of malignant melanoma, which in many cases spontaneously regresses after a complete metastatic phase. We used Affymetrix GeneChip® Porcine Genome Array consisting of 24,123 transcripts to compare gene expression profiles of blood and visceral tissues harvested from a Sinclair piglet afflicted by melanoma at birth and exhibiting metastatic lesions at weaning (6 weeks), with those from a full sibling piglet that showed no incidence of melanoma at birth and at weaning. Between 2% (in spleen) to 14% (in liver) of analyzed transcripts were significantly up-regulated (fold change in gene expression ≥ 2.0 and t-test p-values ≤ 0.05) in tissues sampled from the melanoma pig compared to those sampled from the normal pig, while 3% (in blood) to 15% (in inguinal lymph node) were significantly down-regulated. Among the modulated transcripts were genes directly involved in melanoma development and progression, as well as genes generally associated with cancer pathogenesis including oncogenes, transcription factors, cell cycle regulators and apoptosis related genes. These results suggest that significant changes in gene expression occur during the progression and metastasis of malignant melanoma in the Sinclair pig model, facilitating further analysis for discovery of candidate genes and transcriptional pathways that can be utilized in the development of novel intervention and diagnostic strategies for malignant melanoma.

813 Genetic parameter estimates for growth, carcass composition, and meat quality traits in Duroc swine. C. R. Schwab*, R. Tait, and T. J. Baas, *Iowa State University*, *Ames*.

The objective of this study was to estimate genetic parameters for growth, carcass composition, and meat quality traits in Duroc swine. Five generations of data from a project involving selection for increased intramuscular fat (IMF) using real-time ultrasound were analyzed. Within each generation, off-test ultrasonic measures (n = 3885) were collected on all three genders. Loin samples from all available barrows and randomly selected gilts (n = 847) were collected at a commercial abattoir for carcass composition and further meat quality assessment. Genetic parameters were estimated using MTDFREML procedures applied to a two-trait animal model that included fixed effects of sex and contemporary group along with a random effect for permanent environment of the litter. A covariate of BW was included for traits measured at off-test, and a covariate of carcass weight was included for composition traits measured on the carcass. Average heritability values across all two-trait analyses for IMF and ultrasonically predicted

intramuscular fat (PFAT) were 0.56 and 0.30, respectively, and their mutual genetic correlation was 0.87. The table shows estimated heritabilities and genetic correlations of IMF and PFAT with selected growth, carcass composition, and meat quality traits. The estimated genetic parameters further validate the use of ultrasound measurements in breeding programs aimed at meat quality improvement.

Table 1. Heritability and genetic correlation estimates of growth, carcass composition, and meat quality traits in Duroc swine

Trait	h^2	Genetic Correlation IMF	PFAT
Weight per day of age	0.32	-0.08	0.18
Ultrasonic 10th rib backfat	0.57	0.46	0.52
Ultrasonic loin muscle area	0.55	-0.25	-0.30
Carcass 10th rib backfat	0.41	0.52	0.42
Carcass loin muscle area	0.59	-0.71	-0.45
24 hr pH	0.32	-0.04	-0.05
24 hr Minolta reflectance	0.26	0.72	0.54
Percent cooking loss	0.06	0.01	0.08
Instron tenderness	0.16	-0.30	-0.10

Key Words: Genetic Parameters, Heritability, Swine

814 Doe reproductive and fitness traits among three meat goat breeds semi-intensively managed in the southeastern US. R. Browning, Jr.*, M. L. Leite-Browning, B. Donnelly, and M. Byars, *Tennessee State University*, *Nashville*.

In the fall of 2003-2005, Boer (BR; n = 81), Kiko (KK; n = 64), and Spanish (SP; n = 59) straightbred does were exposed to Boer, Kiko, and Spanish bucks in a complete 3-breed diallel mating scheme to assess doe reproductive performance on southeastern US pastures. Does were managed together in a semi-intensive manner. This 3-yr dataset represents 157 BR, 152 KK, and 150 SP doe exposures. The proportion of exposed does delivering at least one live kid was lower ($P < 0.01$) for BR (82%) than for SP (93%) and KK (96 ± 3%). Litter size (1.9 kids) and litter weight (6.03 kg) at birth were not affected by breed of dam. By weaning at 3 mo, the proportion of exposed does weaning at least one kid was lower ($P < 0.01$) for BR (72%) than for KK and SP does (88 ± 4% each). Litter size at weaning was smaller ($P < 0.01$) for BR (1.55 kids) than for SP dams (1.8 ± 0.06 kids); KK were intermediate with 1.65 kids. Litter weight at weaning was lightest ($P < 0.01$) for BR (25.7 kg) than for KK dams (29.5 ± 1 kg); SP dams were intermediate (28.2 kg). The efficiency ratio of litter weight to dam weight at weaning was greater ($P < 0.01$) for SP and KK (67 and 61 ± 2%, respectively) compared to BR dams (52 ± 2%), SP and KK tended to differ ($P = 0.1$). As measures of whole herd performance based on all does exposed to bucks, BR does weaned a lower ($P < 0.01$) kid crop percent and litter weight (112%, 18.5 kg) compared to KK (144%, 25.8 kg) and SP (157 ± 9%, 24.5 ± 1.5 kg). Annual doe treatment rates for lameness and internal parasitism and attrition rates were higher ($P < 0.01$) for BR (71, 50, and 21%) than for SP (39, 24, and 8%) and KK does (31 ± 5%, 17 ± 5%, and 7 ± 4%). Fecal parasite egg counts differed ($P < 0.01$) among each of the three dam breeds: BR = 523, KK = 331, and SP = 233 ± 45 eggs/g. Results at this point of the study indicate that significant differences exist among meat goat breeds for doe performance on southeastern pastures.

Key Words: Meat Goat, Breed, Reproduction

815 Measures of libido and their relation to testicular hypertrophy and fertilizing competence in boars. D. O. Umesiobi*, *Central University of Technology*, *Bloemfontein, Free State, South Africa*.

The aim of this study was to determine whether the testicular hypertrophy and reproductive competence in boars could be evaluated by selected measures of libido. Twenty-four (12 months old) Large White boars were randomly selected using standard tests for libido: reaction time (RT). Eight boars were assigned to each of the three treatment combinations involving 0, 5 and 10 minutes of sexual restraint (R). Semen was collected using gloved hand device following sexual stimulation and analyzed for quantitative and qualitative parameter using standard methodology. Sperm cells from each boar were used to artificially inseminate (AI) 10 oestrus-synchronized gilts (twice), 12 and 24 hours after the onset of oestrus. Boars were hemi-orchidectomised after 16 weeks of the experimental period. Sexual excitement of boars at 5 and 10R caused the weight of the testis to hypertrophise by 220.2% and 501.6%, respectively, as compared to the unexcited control (38.5%) boars. Total daily sperm production per testis (TDSP) increased to 160.3% and 328%, respectively, with this increase being dramatic (328%) in the 10R boars. Sexual excitement of boars at 10R resulted in the highest testicular traits, number of mounts (10.4 ± 1.6 per 30 min), ejaculation rates (4.1 ± 0.9 per 30 min, total sperm count (92.1 ± 3.1x10^9), sperm motility (89.7 ± 1.4%) and normal acrosome morphology (94.4 ± 2.6%), with the shortest RT (1.5 ± 0.5 min). Gilts artificially inseminated with sperm cells from 10R boars exhibited significant improvements than the 5R boars, in NRR (91.5 ± 6.7 vs. 50.8 ± 13.3%), farrowing rate (88.3 ± 5.5 vs. 53.1 ± 9.2%), total piglets born (12.0 ± 0.4 vs. 5.5 ± 0.8) and live piglets (11.4 ± 0.2 vs. 3.5 ± 0.6). Results suggest that sexual excitement of boars induces testicular hypertrophy, leading to significant improvement in the fertilizing competence of boars.

Key Words: Boar Sexual Drive, Testicular Traits, Sow Fertility

816 Comparison of pure Berkshire, Landrace, and the reciprocal crosses at two market endpoints. K. M. Brueggemeier*, A. C. Naber, S. J. Moeller, H. N. Zerby, and K. M. Irvin, *The Ohio State University*, *Columbus*.

The objective of the study was to assess differences of two divergent breeds, using pure Berkshire (BB), Landrace (LL) and their reciprocal crosses (BL and LB; sire represented as the first letter) for carcass and pork quality traits at two market endpoints. The study was conducted in two seasons (n = 74 and 79) with approximately equal representation of the four combinations in each season. Pigs of each combination were harvested at two end-points: harvest 1 (H1; average weight 105 kg, 151 d) and harvest 2 (H2; average weight 123 kg, 178 d). Tenth rib backfat (BF), loin muscle area (LMA), Minolta L* (L), visual marbling score (MARB), and pH were assessed at 24 h postmortem with Warner-Bratzler Shear force assessed after aging for 7 d. Data were analyzed using a mixed model within a harvest endpoint. Fixed effects were breed combination, sex, and breed x sex interaction, with a random sire within breed combination effect, and live weight was included as a linear covariate for carcass traits. The only differences observed for BF occurred in H1 with BB pigs being significantly fatter ($P < 0.01$) than LL. For LMA in H1 and H2, BB pigs had less LMA than LL ($P < 0.05$) and LB pigs ($P < 0.07$); however, LB and LL pigs did not differ. Differences ($P < 0.01$) in pH were observed across breed combinations in both H1 and H2 and BB pigs had greater

(P < 0.05) pH when compared with all other combinations. For L within H1 and H2, loins from LL pigs were paler (P < 0.05) than all other combinations. In addition, loins from BB pigs had greater MARB at H1 and H2, with no differences among other combinations. Shear force followed a similar trend, with loins from BB pigs requiring less (P < 0.05) force than those from BL at H1 and les force than those of LL at both H1 and H2. The data suggest that F1 crosses of Berkshire and Landrace were not different in carcass composition, but were poorer in pork quality attributes than pure Berkshire contemporaries and for many quality attributes the LL pig produced inferior quality.

Key Words: Swine, Pork Quality, Carcass

817 Correlated response in fatty acid composition from five generations of selection for intramuscular fat in Duroc pigs. J. L. Burkett*, T. J. Baas, D. C. Beitz, C. R. Schwab, N. L. Berry, and S. Zhang, *Iowa State University*, *Ames*.

The objective of this study was to evaluate differences in fatty acid composition differences among Duroc pigs selected for increased intramuscular fat (IMF) for five generations. Selection was based on EBV for IMF estimated by fitting a two-trait animal model and the full relationship matrix in MATVEC. In the select line (SL), the top 10 boars and top 50% of gilts were used to produce the next generation. One boar from each sire family and 50 gilts representing all sire families were selected randomly to maintain the control (CL). Longissimus muscle samples (n=175, 136 barrows, and 39 gilts) collected from generation 5 pigs in the CL (n=102) and SL (n=73) were used to determine the fatty acid profiles of IMF. Total lipids were extracted from the trimmed longissimus samples and methylated directly with acetyl chloride and methanol. Methyl esters were quantified by using a gas chromatograph with a 100 m column and flame ionization detector. Data were analyzed using a fixed linear model containing main effects of line and gender, and covariates of carcass contemporary group and total lipid within line. Select line pigs had more (P < 0.01) total lipid (5.15% vs. 3.07%) than did control line pigs. There were no differences (P > 0.05) in SFA, MUFA, MUFA:SFA, and atherogenic index (AI) between CL and SL pigs. A significant decrease (P < 0.01), however, was detected in total essential fatty acid composition (18:2+18:3n3) and PUFA:SFA in the SL when compared to CL pigs. This difference could be the result of greater de novo synthesis of fatty acids in the SL resulting in a dilution effect of the essential fatty acids as based on more total lipid. These results suggest that selection for increased intramuscular fat could lead to improved meat quality without affecting nutritional value.

Key Words: Fatty Acid Composition, Intramuscular Fat, Pigs

818 Analysis of incidence of Porcine Circovirus Associated Disease (PCVAD) in a landrace/large white composite population. J. S. Bates*, A. R. Doster, and R. K. Johnson, *University of Nebraska*, *Lincoln*.

The objective was to determine the importance of genetic and environmental effects on the incidence of Porcine Circovirus Associated Disease (PCVAD) in pigs. 1,905 pigs from Generations 24 and 25 of two lines selected for increased reproduction and growth and two control lines were scored for symptoms of PCVAD. From 60 d of age pigs were grown in confined buildings or outside lots containing straw-bedded hoop structures. Scoring was on a scale of 0 (no symptoms), 1 (suspect), or 2 (positive) for symptoms including muscle wasting, growth retardation, rough hair coat, diarrhea, and skin lesions, and was done weekly from 70 to 180 d of age. 16.3% of the pigs received a score of 2. A sample of 37 pigs with a score of 2 were necropsied and lung, lymph node, tonsil, liver, kidney, thymus, spleen, ileum, and colon tissue was microscopically examined for lesions suggestive of PCVAD. Immunohistochemistry and RT-PCR were used to detect the presence of PCV-2 in collected tissues. All 37 pigs scored as a 2 were positive for PCV-2. PCVAD score was analyzed with ASREML using the Binomial and Probit functions to estimate genetic and environmental effects. Pigs receiving at least one score of 2 were considered positive for PCVAD; all pigs scored with a 0 or 1 were considered negative. Direct and maternal birth dam heritabilities were 0.02 ± 0.001 and 0.12 ± 0.006, respectively. The proportion of variance due to common birth litter and common nurse litter effects were 0.13 ± 0.04 and 0.01 ± 0.001, respectively. The proportion of variance due to pen effects was 0.05 ± 0.03. Differences between select and control lines were not significant. Significant differences (P<0.05) in weight between negative and positive pigs, estimated in MTDFREML, were 0.09 kg at birth, 0.57 kg at weaning, 4.77 kg at 70 d, and 23.74 kg at 180 d. Probability of score 2 was greatest in pigs placed outside and least for pigs in temperature-regulated buildings (P<0.01). Maternal genetic, common birth litter, and environmental variation affect incidence of PCVAD.

Key Words: Genetic Variation, PCVAD, Immunity

819 Breeding for robust pigs across the year in heat stress affected areas. B. Zumbach[1], I. Misztal[1], S. Tsuruta[1], J. P. Sanchez*[1], M. J. Azain[1], W. Herring[2], J. Holl[2], and T. Long[2], [1]*University of Georgia*, *Athens*, [2]*Smithfield Premium Genetics Group*, *Rose Hill, NC*.

The aim of this study was to describe genetic variability of pig carcass weight as a function of heat stress. Data included carcass weights of 21,653 crossbred pigs (Duroc x [Landrace x Large White]) raised on two farms in North Carolina, and harvested from May 2005 through September 2006. Weather data were obtained from a nearby weather station. Monthly heat loads were calculated as degrees of average temperature-humidity index (THI) in °C over 23. Assumed heat load (H) was a sum of heat loads 4 months prior to harvest. The H was the greatest for pigs harvested in August-October 2005 (4.3-4.5) and 2006 (3.3), respectively, intermediate in July and November, lowest in June 2005, and none for the remaining months. Variance components were estimated with 3 models: univariate - not accounting for heat stress, 2-trait and random regression using linear splines (RRMS). Effects included in all the models were contemporary group, sex, and age at slaughter, sire, and litter. The 2-trait model treated observations July/August-October ("hot") and December-June ("cold") as separate traits. RRMS added a random regression on heat load for the sire effect with 3 knots at H=0, 2.2, and 4.5, respectively. The heritability estimate ± SE in the univariate model was 0.17±0.01. In the 2-trait model the estimates were 0.15±0.01 for "cold" and 0.34 for "hot"; the genetic correlation (0.08±0.15) was not significant. The heritability estimates with RRMS were 0.15±0.08, 0.27±0.11, and 0.59±0.16 for H=0, 2.2, and 4.5, respectively. The genetic correlations between H=0/H=4.5, H=0/H=2.2, and H=2.2/H=4.5 were -0.45±0.14, 0.30±0.16, and 0.50±0.13, respectively. This study supports the existence of genotype by environment interaction in growth traits of pigs across commercial environments.

Key Words: Pig, Carcass Weight, Heat Stress

820 Addition of probiotic microorganisms to improve proteolysis, sensory evaluation and the release of antihypertensive peptides in Cheddar cheeses ripened at 4 and 8ºC. L. Ong[1], N. P. Shah*[1], and A. Henriksson[2], [1]*Victoria University*, *Werribee, Victoria, Australia*, [2]*DSM Food Specialties*, *Moorebank, NSW, Australia*.

Our objectives were to assess the influence of probiotic microorganisms and ripening conditions on proteolysis, organic acid production and sensory evaluation of Cheddar cheeses, and to examine the release of angiotensin-converting enzyme (ACE)-inhibitory peptides during ripening. Cheddar cheeses were made using starter culture and probiotic microorganisms and ripened at 4 and 8°C for 24 wk. Proteolytic patterns were examined using SDS-PAGE and by monitoring water soluble nitrogen, PTA-soluble nitrogen and TCA soluble nitrogen. Organic acids were analysed using HPLC. Semi-trained panellists (n=15) were used in sensory evaluation. ACE-inhibitory activity was measured using spectrophotometric method. Peptides were purified using RP-HPLC and identified using MALDI-TOF. Addition of probiotic organisms and higher ripening temperature increased proteolysis and the concentration of lactic, acetic and propionic acids in Cheddar cheeses ($P< 0.05$). Acceptability of probiotic cheeses during sensory evaluation was not affected by the increased proteolysis and organic acids concentration. The ACE-inhibition of the cheeses stored at 8°C was not significantly different to those stored at 4°C. The ACE-inhibitory activity of the probiotic cheeses (IC_{50}, 0.15-0.20 mg/mL) was higher compared to the cheeses without probiotic (IC_{50}, 0.22 mg/mL) after 24 wk of ripening. The lowest value of the IC_{50} (0.15 mg/mL), and therefore the highest ACE-inhibitory activity, corresponded to cheeses made with the addition of *Lb. acidophilus* LAFTI® L10 ripened at 8°C. Various ACE-inhibitory peptides from the water-soluble extract of the cheeses corresponding to α_{s1} -casein [(f1-6), (f1-7), (f1-9), (f24-32) and (f102-110)], and β-casein [(f 47-52) and (f193-209)] were identified. Probiotic organisms used in this study can be added successfully in Cheddar cheeses for their health benefits while simultaneously producing bioactive peptides for further health attributes.

Key Words: Probiotic, Cheese, Angiotensin Converting Enzyme

821 Ras cheesemaking using starter cultures and nonstarter lactic acid bacteria isolated from the Pharos land. M. El Soda*, S. Awad, and N. Ahmed, *Faculty of Agriculture, University of Alexandria*, *Alexandria, Egypt*.

Consumers make their choice of cheeses primarily based on flavor characteristics. Cheese flavor results mainly from the biochemical activities of the starter and nonstarter lactic acid bacteria. Ras cheese is the main hard cheese made in Egypt; it is also appreciate in many neighbor countries. The cheese has been manufactured for a long time from raw milk. Nowadays Egyptian regulations require the cheese to be made from pasteurized milk for hygienic reasons and for consistency purposes. The aim of the present communication was to develop cheese culture mixtures for Ras cheesemaking. Cultures isolated, identified and selected in the Laboratory of Biochemistry of Dairy Microorganisms were evaluated during Ras cheesemaking. The cheese was made according to the conventional method and analyzed for chemical composition. Free fatty acids (FFA) and free amino acids (FAA) were determined to follow the ripening process. The resultant cheese was also evaluated for organoleptic properties. The variations were statistically analyzed during cheesemaking and ripening. Starter or non-lactic acid bacteria did not influence cheese composition during manufacture or ripening. On the other hand, levels of FFA, FAA correlated well with the rate of ripening and flavor intensity of Ras cheese. Several of the tested mixtures produced the typical flavor and texture of Ras cheese. The highest overall score of flavor intensity, flavor and texture acceptability was detected in the cheese made using a commercial starter in addition to an adjunct mixture isolated from the Egyptian dairy environment composed of several lactobacilli in addition to *Enterococcus faecium*.

Key Words: Ras Cheese, Starter Culture, Lactobacilli

822 Microbiological evaluation of commercial cream cheese. A. Losambe* and P. S. Kindstedt, *University of Vermont*, *Burlington*.

Currently, the literature contains very little information relating to the microbiological characteristics of commercial Cream cheese. Furthermore, little is known about the potential for microbial-induced syneresis in commercial Cream cheese. The objective of this research was to evaluate microbiological characteristics of commercial Cream cheese samples during refrigerated storage and under temperature abuse conditions. Retail samples of Cream cheese representing three different brands were obtained from local sources. Three retail samples of each brand, each with a different expiration date, were obtained and stored at 4°C. Split samples were evaluated for aerobic plate count (APC) and aerobic spore count (ASC) immediately upon receipt (≥60 d before expiration) and again on the expiration date printed on the package. Also, split samples were subjected to temperature abuse at 20°C for 14 d and then enumerated for APC and ASC. Effects of storage time (at receipt v. at expiration) and temperature abuse on microbial counts were evaluated ANOVA using a repeated measures design. Upon receipt, all 3 brands of Cream cheese had very low APC values (1.70±1.56 log CFU/g) which did not differ significantly among the 3 brands. Similarly, initial ASC values were also very low (1.50±1.47 CFU/g) and did not differ among brands. APC and ASC values at the expiration date did not differ significantly from their initial values, indicating little or no microbial growth during storage at 4°C for ≥60 d. Similarly, APC and ASC values after temperature abuse at 20°C for 14 d did not differ significantly from the initial values. None of the samples displayed any visible syneresis at the expiration date or after temperature abuse. In summary, all of the samples resisted syneresis and had very low microbial counts, comprised mostly of aerobic spore formers, which remained low throughout product shelf life and during temperature abuse.

Key Words: Cream Cheese, Microbiology, Syneresis

823 Microbiological and sensory characteristics of Prato cheese obtained from milk with different levels of somatic cells. P. C. B. Vianna[1], G. Mazal[1], M. V. Santos*[2], H. M. A. Bolini[1], and M. L. Gigante[1], [1]*State University of Campinas*, *Campinas, São Paulo, Brazil*, [2]*University of São Paulo*, *Pirassununga, São Paulo, Brazil*.

Mastitis, an inflammatory reaction of the mammary gland, is characterized by increased somatic cell count (SCC) and by the higher concentrations of antimicrobial substances in milk. Antimicrobial

substances, originating from blood or secreted by somatic cells, may influence the growth and metabolism of starter bacteria used in cheese production. The objective of this research was to evaluate the effect of two levels of raw milk SCC on microbiological and sensory characteristics of Prato cheese, during ripening. Two groups of animals were selected to obtain milk with low (≤200,000 cells/ml) and high (≥700,000 cells/ml) SCC. Prato cheese was manufactured by traditional method and evaluated after 3, 9, 16, 32 and 51 days of storage for lactic bacteria, psychrotrophs, and yeasts and moulds counts. A 2x5 factorial design with four replications was performed. The sensory evaluation of cheeses with low and high SCC was carried out for firmness and taste attributes using nine points just right scale and for general acceptance using hedonic scale of nine points after 8, 22, 35, 50 and 63 days of storage. The SCC level only affected the lactic bacteria count of the cheeses. Cheeses produced with the low-SCC milk presented, in average, higher lactic bacteria count than cheeses produced with the high-SCC milk. A negative effect of time of storage was observed in lactic bacteria and psychrotrophic counts, while yeast and moulds counts were increased during storage time. Interaction of SCC x storage time significantly affected the lactic bacteria count. The presence of antimicrobial factors may be responsible for lower counts and the behavior of the lactic bacteria in cheeses produced with high SCC milk. Cheeses produced with the low-SCC milk had better overall acceptance in sensory evaluation by panelists, which may be explained by differences in firmness and flavor of the cheeses during storage time.

Key Words: Somatic Cell, Prato Cheese, Microbiological Characteristics

824 Effect of temperature abuse on water-holding capacity and microbiological characteristics of commercial cream cheese and cream cheese spread. A. Losambe* and P. S. Kindstedt, *University of Vermont*, *Burlington*.

Previous laboratory-scale studies have suggested that microbial growth in Cream cheese during refrigerated storage or as a result of temperature abuse may contribute to the development of syneresis defect, a costly problem for the industry. Cream cheese spread is higher in moisture than Cream cheese and typically has sorbic acid added as a preservative. Little is known about the potential for microbial-induced syneresis in commercial Cream cheese and Cream cheese spread. The objective of this research was to evaluate the water-holding capacity and microbiological characteristics of commercial Cream cheese and Cream cheese spread samples before and after temperature abuse. Three retail samples of Cream cheese and Cream cheese spread representing 3 different brands were obtained from local supermarkets. All samples had ≥60 d remaining before expiration. Split samples were stored at 20°C for 14 d and evaluated before and after storage for aerobic plate count (APC), aerobic spore count (ASC), and expressible serum (ES), obtained by centrifugation at 12,500 x g for 75 min at 25°C. Typical colonies were picked from APC and ASC and identified using the RiboPrinter® system. Effects of cheese type (Cream cheese v. Cream cheese spread) and temperature abuse on ES and microbial counts were evaluated by ANOVA using a repeated measures design. Upon receipt, Cream cheese and Cream cheese spread samples had very low APC (1.80±1.49, 1.66±.32 log CFU/g) and ASC (1.53±1.0, 1.43±0.9 log CFU/g) values, which did not differ significantly. APC, ASC and ES values before and after temperature abuse did not differ significantly. Colonies picked from APC and ASC were identified as Bacillus pumilus, Bacillus cereus, Bacillus subtilis and Bacillus lichenformans. In summary, all of the samples had very low microbial counts, comprised mostly of aerobic spore formers, which remained low despite temperature abuse. Temperature abuse did not cause a loss of water-holding capacity in these microbiologically stable samples.

Key Words: Cream Cheese, Microbiology, Syneresis

825 New alternative approaches to study cheese microstructure. M. Caccamo*[1], G. Impoco[2], F. Zanini[3], G. Tromba[3], P. Campo[1], S. Carpino[1], and G. Licitra[1,4], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*IPLAB, University of Catania*, *Italy*, [3]*Sincrotrone Trieste S.C.p.A.*, *Trieste, Italy*, [4]*D.A.C.P.A. University of Catania*, *Italy*.

Scanning Electron Microscopy (SEM) is nowadays widely used to study and characterize cheese microstructure. SEM imagery offers the advantage of high resolution digital scanning. Several recent studies have applied computerized systems of image analysis to SEM images in order to obtain quantitatively valuable features of cheese microstructure. Nevertheless SEM maps a 3D structure of the scanned surface to a 2D. It does not allow therefore direct in-depth measurements. Two alternative approaches are proposed to overcome the problem of lack of information and creation of artifacts due to sample preparing techniques for SEM analysis. The microstructures of 9 Sicilian cheeses (5 pressed and 4 pasta filata) were analyzed using stereoscopy applied to SEM images and X-ray microtomography techniques. Stereoscopy mimics the characteristics of the human visual system by reconstructing 3D information from 2D images that are required to partially overlap. Two images of the same sample were taken with a small displacement (3mm vertically, 4mm horizontally). These scans are accurately aligned such that the structures in small overlapping areas match between different images. 3D models of the scanned cheese surface were generated using a software system that mimics human binocular vision. X-ray microtomography does not require a special sample preparation. This technique allows to obtain a 3D representation of the inner structure of a sample from a set of projection measurements recorded from a certain number of points of view. In the common case of X-ray absorption tomography, the structure of the object under study is represented by the linear attenuation coefficient, which is proportional to the mass density. The microtomographic investigations were carried out using the SYRMEP beamline of the Elettra Laboratory in Trieste, Italy. The samples, mounted on a rotation stage, were illuminated by monochromatic radiation (E = 16 KeV). For each tomographic set 1440 projections of the sample were acquired for equally spaced rotation angles and measurement times of 1 s over a total rotation of 180 degrees. The final result was visualized by 3D rendering by 2D slices using the ImageJ software.

826 Enhancement of flavour profile of cheddar cheese using microencapsulated enzymes. K. Kailasapathy* and S. Seneweera, *University of Western Sydney*, *NSW, AUSTRALIA*.

To accelerate cheese ripening and to improve cheese flavour, exogenous enzymes are used in the cheese industry. Direct addition of free enzymes however, leads to premature proteolysis, glycolysis, and

lipolysis. The aim of our study was to develop an efficient hydro-gel enzyme encapsulation process for the controlled release of flavour-enhancing enzymes into the cheese matrix, and to study proteolysis during cheese ripening using a reverse-phase HPLC. Flavourzyme (commercial protease-peptidase enzyme mixture from Novozymes Pty. Ltd) when encapsulated using 1.8% (w/v) alginate and polymerised in 0.1M calcium chloride solution and 0.1% (w/v) chitosan solution, produced 72% encapsulation efficiency. When the hydro-gel capsules containing enzymes were incorporated during cheese manufacture, the enzymes were released and accelerated cheese ripening. Four batches of cheddar cheese were prepared without enzyme (control) and with encapsulated enzyme. Sampling was carried out during various stages of cheese ripening (0, 1, 7 and 10 weeks) to assess ripening. Free amino acid, water soluble and insoluble fractions of nitrogenous compounds in the ripening cheese were separately analysed by RP-HPLC and SDS-PAGE. Addition of encapsulated enzyme accelerated the cheese proteolysis by producing a large number of low to medium size molecular mass peptides in the water soluble nitrogenous fraction, some of which were unique for the enzyme treated cheese. In contrast, analysis of water insoluble nitrogenous fraction showed that hydrolysis of casein after 70 days of maturity was greater in enzyme treated cheese. Particularly, beta-casein degradation was rapid compared to alpha-casein and kappa-casein in the enzyme treated cheese. This study showed that alginate microcapsules can be effectively used to release flavour enhancing enzymes into cheese matrix to accelerate ripening and improve the flavour profile of cheddar cheese

827 Recent developments in proteomics: Implications for dairy protein research. P. Qi*, *USDA-ARS-ERRC*, *Wyndmoor, PA*.

Proteomics, the systematic study of the identities, quantities, structures, and biochemical and cellular functions of all proteins in a cell, tissue or organism, promised a rapid transformation for biological and medical research in the post-genomic era. Tremendous progress has been made over the past decade in this highly mass spectrometry dependent discipline of systems biology. Proteomics is regarded as a comprehensive research tool not only capable of identifying and quantifying large sets of proteins but also can be used to determine their localization, interactions, modifications, activities, and functions. Recent developments in proteomics research that include protein separation methods, mass spectrometric instrumentation, computational analysis, and integrative databases will be reviewed with the focus on post-translational modifications. In light of the current status and the perspectives of proteomics applications, we will discuss the implications for future dairy protein research suc as structural and functional studies of milk fat globule membrane proteins and other low abundance yet biologically important proteins in milk and dairy products.

Key Words: Proteomics, Post-translational Modification, Milk Proteins

828 Quantitative proteomic analysis of bacterial enzymes released in cheese during ripening. V. Gagnaire, D. Molle, J. Jardin, and S. Lortal*, *INRA*, *Rennes, France*.

Bacterial ecosystems contribute to the cheese ripening not only during their growth but also after their lysis, through the release of numerous proteins in the cheese curd, including enzymes. A prefractionation method allowing the isolation of bacterial proteins from cheese extracts was previously developed as well as a proteomic qualitative survey during Swiss cheese ripening (Gagnaire et al., 2004. Int. J. Food Microbiol.,94,185). Numerous peptidases coming from the lactic starters were identified on 2D-gel electrophoresis as well as many glycolytic enzymes and stress proteins. This new insight even if very informative provided only qualitative data. The aim of this work, using new iTRAQ technique (isobaric tagging reagent for quantitative proteomic analysis), was to provide quantitative proteomic data about the bacterial proteins released at different stages of ripening. This technique is based upon chemically tagging the N-terminus of peptides generated from protein digests, which are then fractionated by nanoLC and directly analysed by tandem mass spectrometry.

Experimental Swiss cheeses were performed in our laboratory using microfiltered milk in order to remove the initial bacterial raw milk contamination. Thermophilic lactic acid bacteria (L. helveticus LH1 and S. thermophilus ST20) and propionibacteria (P. freudenreichii P23) were used as starters. At four times of the ripening (day one, entrance, middle and end of the warm room ripening), cheese aqueous extracts were prepared and fractionated to separate bacterial proteins. To standardize the protein content of each sample before proteomic analysis, a total amino acid analysis was performed. The standardized samples were i) analysed by 2D-electrophoresis for qualitative analysis and ii) submitted to trypsinolysis. Each tryptic hydrolysate was labelled with a specific iTRAQ tag (one tag per ripening time) and submitted to a LC-ESI-MS/MS analysis. This technique provided the identification of the bacterial proteins released and their respective abundance at different times of the ripening.

Key Words: Proteomic, Cheese, Enzyme

829 Animal Science Image Gallery – A Source for poultry images. J. B. Hess* and W. D. Berry, *Auburn University*, *Auburn, AL*.

The Animal Science Image Gallery was created to provide images to middle school, high school and university teachers wishing to include images of animal agriculture in their courses. With limited expertise in poultry at the university level in some regions, a reference site of poultry and/or poultry industry images would be a useful teaching tool nationally. The Animal Science Image Gallery was designed to fill this role. Each image on the site comes with a limited description so that educators can select correct images for the course content. Subject editors review each image and the corresponding text for accuracy and appropriateness. Within the poultry portion of the Image Gallery, subcategories include; anatomy and physiology, disease and pathology, housing and equipment, poultry processing and poultry species and breeds. To date, the poultry site does not have a wide range of images available to offer coverage of the many types of poultry operations in the U.S. In addition, little has been uploaded regarding poultry physiology and disease. Please consider uploading images to the site commensurate with your area of expertise. Access the Animal Science Image Gallery at http://cygnet.richmond.edu/image_gallery to browse or upload images. Contributing to the Image Gallery will ensure that agricultural and science instructors will have quality poultry science materials to draw from in organizing lectures on poultry related topics.

830 National training program on depopulation and disposal procedures for avian influenza infected poultry flocks: An extension success story. G. Malone*[1] and N. Tablante[2], [1]*University of Delaware*, *Georgetown*, [2]*University of Maryland*, *College Park*.

Following an outbreak of low pathogenic H7N2 avian influenza (AI) on the Delmarva Peninsula in 2004, it became apparent that others could benefit from our successful response and the knowledge gained in the depopulation and disposal of these flocks. With support from the USDA-CSREES, a comprehensive training program was developed based on lessons-learned from our experience and others who have dealt with an AI outbreak. This half-day program was offered from 2005-2007 and was continually updated as new information became available. Information discussed in this training included a historic and current review of the AI situation, human health requirements for responders, and the various options and procedures for mass depopulation and carcass disposal for infected breeder, broiler, turkey and cage layer flocks. A total of 33 sessions were held in 26 different USA poultry producing states with ~2000 key poultry industry, agencies, university and private industry personnel in attendance. With the recent heightened awareness to AI and the need for developing response plans for a potential outbreak, the feedback from this training was highly favorable and very timely. Areas identified as most helpful were an understanding of the intricacy of responding to an AI outbreak based on real-world experiences, mass depopulation techniques with a particular interest in water-base foam as an emerging technology, and in-house composting as one of the most viable disposal options. This training has made participants aware of the need and complexity of being prepared to rapidly respond to an AI outbreak in order to effectively and quickly eradicate the disease. As a measure of success, this extension program has provided direction and help shape how we respond to AI in the USA using the most appropriate mass depopulation and disposal methods for the different situations that might be encountered.

Key Words: Avian Influenza, Mass Depopulation, Carcass Disposal

831 Educating livestock producers on the impacts of temporary feeding sites by the use of a novel mobile rain fall demonstration trailer. K. W. Harborth*, J. M. DeRouchey, T. T. Marston, and J. P. Harner, *Kansas State University*, *Manhattan*.

The use of temporary winter feeding sites is very common during the late winter and early spring months to supply feed and/or water to livestock. While most small producers do not feel environmental deterioration can occur from these sites, improper placement or management in fact can impact the surrounding environmental quality. In order to educate livestock producers on the impact that feeding sites can have on feed utilization, animal health and performance, stable fly production and environmental quality, a mobile demonstration trailer was designed and constructed in 2005. The demonstration equipment was designed and constructed on a 16' bump hitch trailer. The demonstration involves a rainfall event (up to 3" in 15 min) on a mixture of forage and manure to illustrate typical combinations at a feeding site. Excess moisture from the rain fall event is collected both from seepage (6" deep mixture) and from surface runoff. Once the water is collected, visual observation as well as rapid analysis for nitrates, ammonia, pH, turbidity, total solids and bacteria using quick test procedures can be performed. This demonstration has impacted over 3,000 producers from 80 Kansas counties as well as 5 different states in 2005 and 2006. For ease of use, table top demonstration units have been developed in 2007. These units will improve the ease of use for indoor events and new educational opportunities for small acreage educational events. In conclusion, the mobile rain fall demonstration trailer provides a means to practically and interactively educate producers on the implications of using winter feeding sites by providing an educational opportunity to recommend best management practices for their use.

Key Words: Water Quality, Winter Feeding sites, Extension

832 The effect of tillage practice and corn stalk grazing on crop yields. W. A. Griffin*[1], T. J. Klopfenstein[1], G. E. Erickson[1], W. Luedtke[2], and M. A. Schroeder[2], [1]*Universtiy of Nebraska*, *Lincoln*, [2]*Agricultural Research and Development Center*, *Ithaca, NE*.

A nine year study was conducted to determine the effect of four different tillage practices and spring grazing of corn stalk residue on crop yields in a corn-soybean crop rotation. The fields used were a combination of fine sandy loam and silty clay loam soil types. The four tillage practices used were: 1) pre-corn till (soybean residue tilled in the fall prior to the planting of corn; PCT), 2) ridge till (RT), 3) no-till (NT), and 4) spring till (corn residue tilled prior to planting of soybeans; ST). Additionally, steers were allowed to graze half of the corn stalks at a 2.5 times stocking rate for 60 d (Normal stocking rate = 0.32 hectares/steer for 60 d) and yields were compared to determine

the effects of corn stalk grazing on corn and soybean yields. Corn yields for NT (13,720 kg/ha), ST (13,635 kg/ha), and RT (13,823 kg/ha) were similar (P = 0.30); however, PCT had a negative impact on corn yield (11,832 kg/ha; P < 0.01). Soybean yields were similar (P = 0.06) for NT (3907 kg/ha), ST (3880 kg/ha), and RT (4005 kg/ha); however, PCT (4332 kg/ha) had a positive effect on soybean yields (P = 0.05). Spring grazing corn stalks did not have any effect on corn yields (13,250 vs. 13,275 kg/ha; P = 0.72). Additionally, soybean yields (4081 vs. 3987 kg/ha) were not different (P = 0.12) for grazed plots compared to ungrazed plots. In this study, utilizing pre-corn till had a negative impact on corn yield (13,726 vs. 11832 kg/ha; P = 0.05), and a positive impact on soybean yield (3931 vs. 4332 kg/ha; P < 0.01). However, grazing corn stalk residue at a 2.5 times stocking rate in the spring had no impact on corn or soybean yield. additionally, in this study, muddy conditions in the field that arise from spring grazing corn stalks had no effect on corn yield.

Key Words: Corn Stalk Grazing, Crop Yields, Tillage

833 Evaluation of storage methods for wet distillers grains plus solubles with forages and byproducts in silo bags and bunker silos. D. R. Adams*, T. J. Klopfenstein, and G. E. Erickson, *University of Nebraska*, *Lincoln*.

Two different experiments were conducted to determine methods to store traditional wet distillers grains plus solubles (35% DM; WDGS), because WDGS will not store in silo bags under pressure or pack into a bunker. The first experiment evaluated 3 forage sources as well as wet corn gluten feed (WCGF) or dry distillers grains mixed with WDGS. The product was mixed using feed trucks and was placed into a 2.74 meter diameter silo bag. During bagging, the bagger was set at a constant pressure of 21.09 kg/cm2. The height of the silo bag was a determining factor of storability. While continuing to bag the product, adjustments to the inclusion level of the feedstuffs were made based on the shape of the bag. Inclusion levels ranged from 7.5% to 25% forages and 40% to 60% corn byproducts. The silo bag split open at the 7.5% grass hay: 92.5% WDGS and 10% grass hay: 90% WDGS levels and also at the 40% WCGF: 60% WDGS and 50% WCGF: 50% WDGS (DM basis). The recommended levels for bagging are 15% grass hay: 85% WDGS, 22.5% alfalfa hay: 77.5% WDGS, 12.5% wheat straw: 87.5% WDGS, and 50% dry distillers grains: 50% WDGS (DM basis). The second experiment was conducted by mixing grass hay with WDGS stored in a concrete bunker. Two ratios were evaluated including 30:70 and 40:60 grass hay: WDGS (DM basis). Both levels packed into the bunker with the skid loader. A skid loader with tracks, which was used in this experiment, may require less hay compared to commercial conditions using heavier equipment. In both experiments, the product was stored over 45 days and the apparent quality didn't change. Forages should be compared based on the fiber content, with lower amounts of forage needed for more fibrous feeds. Appropriate conversions to an as-is basis is important because WDGS contains 65% water, meaning the percentage of WDGS on an as-is basis will be even greater. In conclusion, WDGS can be stored in a silo bag or bunker silo when mixed with drier or bulkier feedstuffs.

Key Words: Forages, Storage, Wet Distillers Grains

834 Evaluating the Alabama beef quality assurance program. W. F. Owsley*, H. D. Dorough, and J. D. Gladney, *Auburn University*, *Auburn*.

The Alabama Beef Quality Assurance program reached 1100 beef producers in 2005 to 2006. To evaluate the educational component of the program, all participants were asked to complete a pre-test and a post-test. Three questions on the test were designed to further evaluate the understanding of the veterinarians' role in production. Each examination contained the same 20 questions. All questions were taken from the 2 hour Beef Quality Assurance oral presentation. The average score on the pre-test was 13.8 correct. On the post-test, producers averaged 18 correct answers. The most frequently missed question on the pre-test related to the ideal yield grade. Sixty percent of producers missed the question on the pre-test. Only 3 percent missed the same question on the post-test. Three questions asked about veterinarian-client-patient relationships and prescriptions. Fifty percent of the responses on the pre-test were incorrect, while only 21 percent of the responses to the post-test questions were incorrect. Based on the changes in test scores, beef producers appeared to have a better understanding of Beef Quality Assurance following the oral presentation. However, over 20 percent did not have a good understanding of the veterinarians' role and/or responsibilities.

Key Words: Beef Quality Assurance, Evaluation, Producers

835 Evaluation of a total ranch management workshop as an educational tool to transfer technology in Mexico. R. Teliz-Triujeque*[1,2], R. H. Williams[2], J. A. Ortega-Santos[2], C. W. Hanselka[3], E. A. Gonzalez-Valenzuela[1], J. A. Hinojosa[2], and R. L. Stanko[2], [1]*INIFAP*, *Mexico*, [2]*Texas A&M University*, *Kingsville*, [3]*Texas Cooperative Extension*, *Corpus Christi*.

The total ranch management (TRM) planning process is an approach to help ranchers maintain better control of the ranch and its future, and is based on the idea of management achievements rather than specific management practices. The objectives of this study were to 1) evaluate the effect of a TRM workshop as a method of technology transfer, 2) determine impressions of participants, 3) determine extent of learning, and 4) determine comprehension and utilization of information. Mexican ranchers (n=20) interested in technology transfer attended a 6-d workshop taught by 6 U.S. instructors in 2 sessions. The information was divided into 8 themes and adapted from Texas Cooperative Extension's Total Ranch Management program. Participants were asked to complete a confidential 45-question survey to identify demographics and background knowledge of TRM issues and elements, a 9-question evaluation of each session and instructor, and a 13-question evaluation of the entire workshop. Eleven mo. after the workshop, ranchers were revisited to apply a 26-question, post evaluation survey. Workshop evaluations were analyzed using descriptive statistics and t-Test. Major enterprises of workshop participants included: cow/calf (63%), stockers (13%), registered cattle (57%), and wildlife (40%). Level of understanding of all topics was greater (P<0.01) after as compared to before the workshop. Total mean change in understanding concepts of strategic planning, ranch resources, economics, livestock production, wildlife management, and grazing management were 65, 48, 39, 54, 63, and 54%, respectively. TRM as a program has proved to be both a platform to convey and continue education and improve

decision making processes in ranch management. Mexican ranchers are welcoming through TRM a technology transfer mechanism that was not in place.

Key Words: Technology Transfer, Total Ranch Management, Mexico

836 Summary of the 2004 – 2005 University of Georgia Master Cattlemen's Programs. T. W. Wilson*[1], J. E. Rossi[1], R. C. Lacy[1], M. E. Pence[1], J. Andrea[2], R. E. Silcox[1], D. Ensley[1], R. L. Stewart[1], J. W. Worley[1], N. C. Hinkle[1], and J. C. McKissick[1], [1]*The University of Georgia*, *Tifton*, [2]*Clemson University*, *Clemson, SC*.

One hundred and seventy-six participants attended the four Master Cattlemen's programs offered during 2004 and 2005 by The University of Georgia's Beef Team. These programs incorporated speakers from six departments within two colleges. One multi-county program was offered during each six month period and was rotated within the four Extension Districts in Georgia. Each program met for a total of seven sessions that included either one or two speakers for a total of two hours. Program topics were customized by season and location. Participants received a notebook complete with materials from speakers, and those that attended five of the seven sessions received a program hat and a certificate of completion. Evaluations were collected after the completion of three of the four programs, and a one year post-meeting survey was conducted with all four programs to determine impact. Across the three that were evaluated, the overall program was rated 4.5 (scale 1 to 5; 5 = best; n=80) and the average speaker evaluation was rated 4.2. The one year post-meeting survey (n=60) indicated that 95% of the respondents were commercial, while 5% were purebred operators. Sixty-eight percent of participants surveyed indicated that they derived 0 to 25% of their gross income from their beef operations; 27% received 26 to 50%; the remaining 5% received between 51 to 100%. Fifty-two percent of participants indicated they had an impact in revenue ranging from $0 to $5,000; 5% indicated they received from $5,001 to $10,000; 17% indicated no change in revenue from this program. When asked which of the management strategies they incorporated or made improvements in, 42% indicated improvements in record-keeping; 12% EPDs; 27% vaccinations; 27% feeding options; 38% pasture management; 35% reproduction; 22% fly control; 17% facilities; 20% hay storage; and 60% general herd management. Of the participants that returned the survey, 98% indicated that the information they received from this program improved their ability to successfully raise beef cattle, and 100% indicated that they would recommend this program to other beef producers.

Forages and Pastures - Livestock and Poultry: Grazing

837 Copper and Cu/Zn superoxide dismutase status in steers grazing three fescue types. R. L. Stewart, Jr*, G. Scaglia, W. S. Swecker, Jr., J. P. Fontenot, A. O. Abaye, J. H. Fike, M. A. McCann, and E. A. Wong, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

During two consecutive grazing seasons, a study was conducted to measure Cu status of steers grazing three tall fescue (*Festuca arundinacea*) types: 'Kentucky-31' endophyte-infected (E+) and endophyte free (E-) tall fescues, and Q4508-AR542 non-ergot alkaloid-producing endophyte-infected tall fescue (Q). In 2004, forage Cu concentration was greater ($P < 0.05$) in E-. No differences in forage Cu were observed among treatments in 2005 ($P = 0.19$). In 2004, Cu intake was highest ($P < 0.001$) for steers grazing E- and lowest for E+ but was similar across treatments in 2005. Serum Cu was not different among treatments in 2004 ($P = 0.81$), but in 2005, serum Cu of steers grazing E- and Q was higher than E+ ($P < 0.05$). In 2004, liver Cu levels of cattle grazing E- were higher ($P < 0.05$) than for those grazing E+, while liver Cu levels of steers grazing Q were intermediate. No differences were detected among treatments in 2005 ($P = 0.86$). Enzymatic activity of Cu/Zn superoxide dismutase (SOD) did not differ among treatments in 2004 or 2005 ($P = 0.79$ and 0.80, respectively). In 2004 and 2005, no difference in relative Cu/Zn SOD mRNA abundance was observed among treatments ($P = 0.33$ and 0.92, respectively). These results suggest that lower Cu intake of steers grazing E+ and Q was related to lower DMI on these pastures. The lower Cu intakes likely contributed to differences in liver Cu. Endophyte status of forage did not affect Cu/Zn SOD enzymatic activity or relative mRNA abundance.

Key Words: Beef Cattle, Copper, *Festuca arundinacea*

838 Effects of clipping and implants on rates of hair growth and sweating, and rectal temperature of steers grazing endophyte-infected tall fescue. L. K. McClanahan*[1] and G. E. Aiken[2], [1]*University of Kentucky*, *Lexington*, [2]*USDA-ARS, Forage-Animal Production Research Unit*, *Lexington, KY*.

The effects of hair coat clipping and steroidal implants on rectal temperatures, rates of sweating and hair growth of beef steers grazing endophyte infected tall fescue [Schedonorus arundinaceus (Schreb.) Dumort; Soreng et al., 2001] were determined. Steers were stratified by body weight and hair coat color before initiation of grazing on six, 3.0-ha pastures of endophyte-infected 'Kentucky 31' tall fescue on 3 May, 2006. Ten clipped and 10 unclipped steers were assigned to pastures as the two main plot treatments. Five steers in each pasture were implanted with Synovex-S (200 mg progesterone-20 mg estradiol) and five were implanted with Compudose (25 mg estradiol) and handled as sub-plots. Thirty to 40% of body surface of clipped steers was shaved with surgical clippers. A small area over the shoulder of all steers also was clipped to measure hair length growth rate and sweating rate (g/m2/h). These variables and rectal temperature were measured at 28, 56, 84, and 104 days of grazing. Rectal temperatures for clipped steers were not lower ($P > 0.10$) than for unclipped steers, except at 84 days when the highest mean ambient temperature (33°C) was recorded (clipped = 39.5°C, unclipped = 39.3°C; $P < 0.05$). Sweating rate declined ($P < 0.001$) as ambient temperatures increased. Sweating rates tended ($P > 0.10$) to be higher with the estradiol than the progesterone-estradiol implant. Hair growth rates averaged 0.28 mm/d and were unaffected ($P > 0.10$) by the treatments. Results indicated that retention of rough hair coats, continuous growth of hair, and a reduction in sweating rate at higher ambient temperatures are factors that contribute to the vulnerability of fescue cattle to heat stress during the summer.

Key Words: Tall Fescue, Fescue Toxicosis, Heat Stress

839 Comparison of novel endophyte tall fescues for stocker cattle in southern Arkansas. P. A. Beck*[1], C. B. Stewart[1], D. Singh[2], and S. A. Gunter[1], [1]*University of Arkansas SWREC*, *Hope*, [2]*Barenbrug USA*, *Tangent, OR*.

Calves grazing Kentucky-31 (KY-31) tall fescue often exhibit signs of fescue toxicosis caused by ergot alkaloids produced by fungal endophytes. These fungal ergot alkaloids enable the tall fescue to be highly persistent in harsh conditions. Performance of calves grazing Endophyte-free (EF) tall fescue is improved but plant persistence is reduced. Novel endophyte (NE) tall fescues combine the advantages of plant persistence with the increased animal performance of fescues not containing the endophytes. Eleven 0.81-ha pastures (Una silty clay loam) were sprayed with 4.7 L glyphosate/ha 2 times at a 6-wk interval and no-till seeded with EF (Barcel®, Barenbrug USA, Tangent, OR), NE (Jessup AR542, MaxQ®, Pennington Seed, Madison, GA; and BAR FA BE 9301A, Barenbrug USA), and KY-31 tall fescues in the fall of 2005 to evaluate plant persistence, forage production, and animal performance. Calves (BW = 227 ± 6.7 kg, n = 3/pasture) grazed pastures from 4 January 2005 until 24 May (EF) or 21 June (KY-31 and NE). Calf BW at the end of grazing was 14% greater ($P < 0.01$) EF or NE than KY-31. Average daily gains were least ($P < 0.01$) for KY-31 (0.59 kg). Daily gains of calves grazing EF were greater ($P = 0.05$) than Jessup AR542 and tended ($P= 0.07$) to be greater than BAR FA BE 9301A, averaging 1.05, 0.83, and 0.88 ± 0.06, respectively. Total BW gain per calf and gain per ha were 33 and 34%, respectively, less ($P \leq 0.02$) for KY-31 than EF or NE tall fescues which did not differ ($P \geq 0.62$). Stand counts conducted during the grazing study indicate stand losses were already occurring for EF (32%) and were heavily contaminated with annual ryegrass, but stand counts of Jessup AR542, BAR FA BE 9301A, and Kentucky-31 were 75, 69, and 86%, respectively. The results of this experiment indicate that NE tall fescue pastures can improve animal performance compared to toxic endophyte tall fescue without the reduction in persistence observed for EF.

Key Words: Beef Cattle, Endophytes, Festuca arundinacea

840 Supplementation of digestible fiber and glucomannan to tall fescue pastures: performance, forage availability, and prolactin response. R. L. Mills*[1,2], C. J. Richards[2], F. N. Schrick[1], and J. C. Waller[1], [1]*The University of Tennessee*, *Knoxville*, [2]*Oklahoma State University*, *Stillwater*.

An 84 d randomized block design utilizing 96 weaned beef calves (238.8 ± 20.1 kg) in each of two consecutive years was used to assess the efficacy of digestible fiber and glucomannan (MTB-100®, Alltech, Nicholasville, KY) supplementation. Groups of four test calves were randomly assigned to 24 endophyte-infected tall fescue spring pastures (1.23 ± 0.06 ha) with additional grazer calves used in a put-and-take system. Pastures, blocked by previous productivity, were randomly assigned to one of five treatments: 1) no supplementation (CON); 2) supplemented with soybean hulls (SH) at 0.33% BW (DM basis; LO); 3) supplemented with SH at 0.66% BW (DM basis; HI); 4) LO plus 20 g•hd^{-1}•d^{-1} MTB-100®; and 5) HI plus 20 g•hd^{-1}•d^{-1} MTB-100®. Calves had free-choice access to water and a loose vitamin/mineral mix. Every 21 days, calves were weighed, serum was collected, and forage clip samples taken to estimate forage availability. Data were analyzed using the MIXED procedure in SAS with contrasts of main effects of SH level (LO vs. HI), MTB, SH level x MTB, and CON vs. supplemented (SUPP). No interaction between SH level and MTB was observed ($P > 0.10$). ADG increased by 0.24 kg/d with SUPP ($P < 0.01$). HI SH increased ADG by 0.13 kg/d ($P < 0.01$) over LO SH, but MTB had no effect ($P > 0.10$). Forage availability was only affected by day of collection ($P < 0.01$). HI SH had greater total gains per hectare than LO SH ($P < 0.01$). Serum prolactin differed on days 63 and 84 ($P < 0.01$) with concentration increasing by 52% due to SUPP ($P < 0.01$) and 34% by increasing from LO to HI SH ($P < 0.05$). Results indicate that digestible fiber supplementation can improve animal performance and endocrine function on endophyte-infected tall fescue. MTB showed no effect when included with SH supplementation.

Key Words: Tall Fescue, Soybean Hulls, Glucomannan

841 Performance of primiparous beef cows grazing bahiagrass pastures with three rates of soybean hull supplementation. J. M. B. Vendramini* and J. D. Arthington, *Range Cattle Research and Education Center - University of Florida*, *Ona*.

The objective of this study was to evaluate the performance and milk production of primiparous beef cows grazing bahiagrass (Paspalum notatum Flugge) pastures with three rates of soybean hull supplementation. The experiment was conducted at the Range Cattle Research and Education Center –Ona, FL from Aug. 14 2006 to Jan. 5 2007. The treatments were three rates of soybean hulls (0, 1.6, and 3.2 kg/head/d), in addition to a base supplement of 1.6 kg of molasses and 0.8 kg of cottonseed meal per head daily. Treatments were evaluated in a completely randomized design with four replications. Three Brangus-crossbred and one Braford cow were assigned to each experimental unit. The experimental units were 1.2 ha pastures. Heifer BW and body condition score (BCS) were recorded every 28-d. Calf BW and cow milk production were evaluated on Dec. 4 2006 and Jan. 1 2007. Milk production was measured using the weigh-suckle-weigh method. Herbage mass was measured every 14-d using the disk plate meter methodology. There was a treatment by time interaction on herbage mass ($P<0.05$). The control treatment had a greater decline in herbage mass (1400 to 950 kg DM/ha) than treatments receiving soybean hulls (1500 to 1200 kg DM/ha) from Aug. to Jan. Heifer ADG (-0.12 to 0.22 kg/d), BCS change (-0.65 to 0), milk production (4.2 to 6.6 kg/d), and calf ADG (0.60 to 0.88 kg/d) increased linearly ($P<0.05$) as rate of soybean hull supplementation increased. The Increased energy and protein supplementation of primiparous cows with soybean hulls increased BW of calves and BCS of cows; however, the economic feasibility of this management practice will depend upon soybean hull cost and calf prices.

Key Words: Milk Production, Soybean Hulls, Primiparous Cows

842 Grazing efficiency in free range Merino sheep. W. M. Rauw*[1], H. A. Glimp[1], W. Jesko[2], M. Sandstrom[1], and L. Gomez-Raya[1], [1]*Department of Animal Biotechnology, University of Nevada Reno*, *Reno*, [2]*Rafter 7 Ranch*, *Yerington, NV*.

Although the importance of grazing efficiency has been recognized, no practical method is available today to record grazing efficiency in grazing animals that can be used in a selection program. We propose a new method to measure grazing efficiency that can be selected for. Grazing efficiency as defined by our model is an estimate of the individual ability to graze at resource limiting rangelands and is

estimated from changes in body weight during a grazing period. The model was applied to a free range Merino and Merino × Rambouillet sheep herd with a total of 905 ewes. Body weights were measured before and after the ewes were allowed to graze freely on the rangelands for 75 days. The model is based on the expected metabolizable energy that they need for production, maintenance and reproduction in that period. The ewes grazed on average 2861 ME (kcal/d) with a standard deviation of 325 ME (kcal/d). Tests for normality (Shapiro-Wilk and Anderson-Darling) of the distribution of grazing efficiency indicated that this trait is normally distributed. The effect of the ewe's age was highly significant ($P < 0.001$) with younger ewes having the lowest grazing efficiency. Results showed that this is a size effect (older animals having higher requirements), but this may have a behavioral component as well with older animals having more grazing experience. The effect of sire was significant also ($P < 0.001$). Estimates of heritabilities for grazing efficiency and number of lambs were 0.340 (± 0.056) and 0.056 (± 0.046), respectively. The genetic and phenotypic correlations between grazing efficiency and number of lambs weaned were 0.168 (± 0.269) and 0.468 (± 0.027), respectively. Therefore, selection for grazing efficiency may result in a correlated response to number of lambs. The model of grazing efficiency may have a range of applications such as comparing grazing efficiency of different ruminant species, and providing information on the potential for grazing of different range ecosystems. It also has implications for animal welfare.

Key Words: Sheep, Grazing Efficiency, Selection

843 Glycerol as a supplemental energy source for meat goats.
K. R. Hampy*, K. P. Coffey, D. W. Kellogg, E. B. Kegley, J. D. Caldwell, M. S. Lee, M. S. Akins, J. L. Reynolds, J. C. Moore, and K. D. Southern, *University of Arkansas*, *Fayetteville*.

Glycerol, a by-product of the manufacture of bio-diesel, has potential for use as a feedstuff for cattle, sheep, and goats. Limited research reported that glycerol was fermented rapidly in the rumen and increased proportions of propionate, but decreased DM intake. Our objective was to determine the impact of adding different levels of glycerol on intake and digestibility of a medium quality crabgrass (Digitaria ciliaris (Retz.) Koel.)/ goosegrass (Eleusine indica (L.) Gaertn.) hay basal diet by meat goats. Twenty wether meat goats (23.5 ± 0.74 kg BW) were housed in individual pens (1.1 by 1.5 M) with expanded metal floors and offered one of four treatments (five goats each). Treatments consisted of a basal diet of medium quality crabgrass/goosegrass hay offered for free-choice consumption with no supplement (C), or with either 1) glycerol at 5% of the total diet (G5), 2) glycerol at 10% of the total diet (G10), or 3) liquid molasses at 10% of the total diet (M10). Diets were offered twice daily at 0800 and 1400h and liquid supplements were top-dressed onto the hay and mixed by hand at each feeding. Trace mineralized salt was provided at 0.5% of the total diet daily. Hay samples were collected at each feeding, and refused feed was removed daily at 0800h, weighed, and dried at 50 C for DM determination. Following a 10-d dietary adaptation period four goats per treatment were fitted with fecal collection bags and total feces were collected for 5 d. Feces were removed twice daily, weighed, then dried at 50 C. Total DM intake did not differ ($P > 0.33$) among treatments (11.5, 15.5, 11.4, and 12.6 g/kg BW for C, G5, G10, and M10, respectively). Digestibility of DM tended ($P = 0.10$) to be lower for C compared with G5, but other treatments did not differ (60.1, 66.2, 62.2, and 63.2% for C, G5, G10, and M10, respectively). Therefore, lower levels of glycerol may be used to increase digestibility of medium-quality forages without negatively impacting forage intake.

Key Words: Glycerol, Meat Goats, Crabgrass

844 Effects of level of concentrate supplementation on nutrient digestion of lactating dairy cows grazing at two pasture allowances.
T. H. Garmo, H. Volden, S. J. Krizsan*, and S. K. Nes, *Norwegian University of Life Sciences*, *Ås, Norway*.

The impact of low vs. high pasture allowance (PA) (12 vs. 24 kg DM/cow per d) within 2 levels of concentrate supplementation (C), 3 vs. 7 kg/d (C3 vs. C7) on digestion and rumen fermentation was evaluated in lactating cows grazing a white clover dominated pasture (percent coverage>60%). Four ruminally cannulated cows averaging 107±51 DIM and producing 36±10 kg milk/d pretrial were used in a change over experiment with four 15-d periods. The concentrate mix provided 190 g NDF and 334 g starch per kg of DM. Pasture CP and NDF were: 193 and 345 g/kg of DM. During the last 5 days of each period fecal, omasal digesta, rumen fluid and rumen evacuation samples were collected. Additionally, ruminal pH was measured continuously for 24 h. Pasture DMI was calculated from C31 and C32 alkane content. No significant interactions between PA and C were detected for any trait. Apparent digestibility of CP and NDF was higher for cows on low PA and cows fed C3, respectively. Ruminal NDF digestibility (RNDFD) decreased and ruminal K_pNDF, omasal OM and AA flow to the small intestine increased for cows fed C7 compared with C3. There were no treatment effects on total or individual VFA concentrations, but rumen NH_3 was lower for cows fed C7 than for cows fed C3. Ruminal pH was below 6 for 11 h compared to 1 h for cows fed C7 and C3 diets, respectively. Results indicate that energy is the first limiting nutrient for lactating cows grazing high quality pasture.

Key Words: Concentrate Level, Nutrient Digestion, Pasture Allowance

845 Effect of daily herbage allowance and concentrate level, offered at different stages of lactation, on milk production, dry matter intake, blood metabolites, bodyweight and body condition score. E. Kennedy*[1,2], M. O'Donovan[1], F. O'Mara[2], and L. Delaby[3], [1]*Teagasc, Dairy Production Research Centre, Moorepark, Fermoy, Co. Cork, Ireland*, [2]*School of Agriculture, Food Science and Veterinary Medicine, UCD, Belfield, Dublin 4, Ireland*, [3]*INRA, UMR, Production du Lait 35590 St. Gilles, France*.

The objective of this study was to establish the influence of daily herbage allowance (DHA) and concentrate supplementation on milk production, dry matter intake (DMI), blood metabolites, bodyweight and body condition score (BCS) of spring calving dairy cows at approximately 40, 80 and 120 days in milk (DIM). Sixty-six (30 primiparous and 36 multiparous) Holstein Friesian dairy cows (mean calving date – 7 Feb) were randomly assigned to a 6 treatment (n=11) grazing study. Animals were offered one of 3 DHA′s (13, 16 and 19kg DM/cow/day >4cm; *Lolium perenne*) and either 0 or 4kg DM/day concentrate supplementation at 40 and 80 DIM. All animals were offered 20kg DM/cow/day of herbage and no concentrate at 120 DIM. Milk yield was recorded daily; milk composition, BW and BCS were determined weekly. Blood metabolites and DMI were measured at 40, 80 and 120 DIM. The experiment was a randomised block design and was analysed using covariate analysis. There was no effect of DHA on milk production at 40 DIM, however BW (P<0.01) and DMI (P<0.05) were lower when a low DHA was offered while plasma NEFA, BHB and urea concentrations were higher. DHA tended to influence animal performance at 80 DIM. A low DHA reduced BW (-21 kg) when compared to a medium and high DHA at 80 DIM but there was no effect of treatment at 120 DIM. Concentrate significantly increased milk production at 40, 80 and 120 DIM (+ 4.1, 5.9 and 1.2 kg/cow, respectively). It also increased total DMI but decreased grass DMI and plasma NEFA at 40 and 80 DIM. These results indicate that a low DHA in early lactation does not adversely affect animal performance however DHA needs to be increased as lactation progresses. Including concentrate in the diet increased animal performance throughout early lactation.

Key Words: Daily Herbage Allowance, Concentrate, Days in milk

846 Timing of herbage and fasting allocation in strip grazed cattle: Effects on patterns of ingestive behavior, herbage intake, and nutrient supply. P. Gregorini*[1], S. A. Gunter[2], and P. A. Beck[2], [1]*USDA–ARS, University Park, PA*, [2]*University of Arkansas SWREC, Hope*.

Afternoon herbage allocations have shown to improve animal performance due to an increase in intake at dusk, when herbage quality is higher. However, this trend might not yet be maximized. This work aimed to assess the impact of timing of herbage and fasting allocations on patterns of ingestive behavior, herbage intake, and ruminal fermentation, plus nutrient flow to the duodenum. Treatments were daily herbage allocation in the afternoon (1500, AHA), morning (0800, MHA), AHA plus 20 h of previous fasting (AHAF), and MHA plus 20 h of previous fasting (MHAF). Four ruminal and duodenal fistulated heifers (279 kg ± 99 kg BW) individually strip-grazed wheat (Ttriticum aestivum L.) pastures in a 4 × 4 Latin square design. Eating behavior was recorded every 2 min, and bite rate was measured every hour while heifers were in the strips (12 h MHA and AHA; 4 h MHAF and AHAF). Ruminal DM pools were measured 4 times daily (0800, 1200, 1500, and 1900) to determine daily herbage DMI and its pattern. Ruminal fluid was sampled at the same times plus at 2300. Duodenal digesta was sampled over 2 d. Samples were collected at intervals of 4 h for the first 24 hr. The second day collection times were advanced 2 h. Treatments did not affect daily herbage DMI (16.5 g/kg BW, SE 0.0025; P > 0.05). However, eating pattern was altered; evening grazing bout of AHA and AHAF was longer (P < 0.05) and more intense (P < 0.05; bite rate, bite mass and intake rate). Ruminal fermentation patterns followed the pattern of herbage intake. Non-glucogenic/glucogenic VFA ratio and ruminal pH were lower (P < 0.05) for AHA and AHAF during the evening. The flow of OM, N, microbial protein and non-microbial OM to the duodenum did not vary (P >0.05) among MHA, MHAF and AHAF; however, it was in average 970, 40, 300 and 540 g/d respectively greater (P < 0.05) for AHA. These results demonstrate that at the same level of resource allocation and herbage intake, nutrient supply to grazing cattle can be modified through simple grazing management.

Key Words: Eating Pattern of Cattle, Fasting and Herbage Allocation, Nutrient Supply

847 Frequent reallocation of strip grazing cows improves productivity. P. A. Abrahamse*, J. Dijkstra, and S. Tamminga, *Animal Nutrition Group, Wageningen University, Wageningen, The Netherlands*.

Twenty Holstein cows were split into two equal groups to test the effect of allocation frequency to new strip grazing plots on dry matter intake (DMI), grazing behaviour, rumen characteristics and milk production using a repeated measurements design with two periods of 12d. Treatments were daily allocation to 0.125 ha plots (1D) and every four days allocation to 0.5 ha plots (4D) of Lolium perenne L. Cows were fed 2.7 kg DM/d concentrates as a supplement. There were no differences in chemical composition of grass between 1D and 4D, but between offer and turnout leaf fractions decreased from 70.7% to 53.0% of grass DM, causing decreased CP and increased NDF grass contents. DMI determined using the n-alkane technique did not differ (p>0.05) between 1D and 4D but there was a significant (p=0.0253) treatment*period interaction (period 1: 1D 18.3 vs. 4D 16.5; period 2: 1D 14.7 vs. 4D 15.0 kg DM grass/cow/day), due to limited DM on offer in period 2. Grazing behaviour, observed using IGER graze recorders, showed no difference in eating time per day (561.8 min/day, p=0.5834), but bite mass was numerically higher in 1D than in 4D (490.7 vs. 440.2 mg/bite, p=0.2601). Between offer and turnout in 4D, eating time increased (548.2 to 572.3 min/d) and rumination time decreased (468.5 to 452.4 min/d). Ruminal ammonia concentration (NH_3) was significantly lower in 1D than in 4D (93.7 vs. 120.1 mg/L, p=0.0256), NH_3 decreased from 171.5 to 77.5 mg/L from d1 to d4 in 4D. There was no difference in milk urea between treatments, but milk urea decreased from 26.5 to 20.6 mg/dL from d1 to d4 in 4D. Fat and protein corrected milk (FPCM) was significantly higher in 1D than in 4D (24.0 vs. 21.9 kg/cow/day, p=0.0068), mainly due to a difference in milk production (25.0 vs. 23.0 kg/cow/day). The results show that more frequent reallocation of cows increases FPCM. DMI was higher in 1D when grass DM on offer was high, probably due to less variation in grazing behaviour between days. The difference in grass composition between days in 4D had major effects on NH_3 in rumen fluid and excretion of N with milk urea.

Key Words: Grazing Behaviour, Rumen Fermentation, Milk Production

848 Effect of sulphite salts on the aerobic stability and intake levels of whole crop wheat by grazing of dairy cattle. J. K. Margerison*[1] and R. R. Edwards[2], [1]*Massey University*, *Palmerston North, New Zealand*, [2]*University of Plymouth*, *Plymouth, UK*.

Two experiments were completed to measure the effect sulphite salts on the aerobic stability and intake levels of whole crop wheat (WSW) offered to grazing dairy cattle. In experiment 1: 40 cows (60 days postpartum), were allocated into matched pairs according to milk yield and composition: 20 received WSW with no additive (NoSS), 20 received WSW with added sulphite salts (SS) for 42 days, with a 28 day measurement period using pre-treatment milk yield and composition as covariates. In experiment 2: 1.5 kg of WSW from each treatment in experiment 1 was used for laboratory aerobic stability studies and plate yeast culture. WSW intake levels (kg DM/d) were significantly lower in SS 6.9, NoSS 5.9 (SE 0.19), grazing time (min/d) SS - 263.5, NoSS 296.0 (SE 6.911), ruminating time (min /d), SS 546.6, NoSS 530.8, 3.353 was significantly greater with NoSS. Diet had no significant effect on milk yield (kg/d), SS 33.3, NoSS 32.9, (SE 0.52), milk fat (g/kg), SS 40.5, NoSS 42.1, 0.07 or protein (g/kg), SS 33.6, NoSS 33.6 (SE 0.03) content. Mean live weight (kg) was significantly greater in SS cows, SS 666.81, NoSS 660.14 (0.823). Time to peak temperature (h), SS 128.64, NoSS 82.89 (SE 1.547), maximum temperature (°C), SS 6.76, NoSS 10.90 (0.372) heat generated (°C), SS 39744.0, NoSS 54938.0 (1171.00) and yeast numbers (NoSS 4.951, NSS 4.156 (SE 0.62) log cfu/ml) were greater with NoSS. In conclusion, silage quality, live weight gain and aerobic stability of WCW was increased by the addition of sulphite salts, but had no significant effect on milk yield.

Growth and Development - Livestock and Poultry: Transcriptional Factors and Cell Mechanisms for Regulation of Growth and Development with Application to Animal Agriculture

849 Defining the transcriptional signature of skeletal muscle stem cells. Z. Yablonka-Reuveni*, I. Kirillova, G. Shefer, K. Rider, R. Almuly, A. Vine, B. Kwiatkowski, and K. Day, *University of Washington*.

Skeletal muscle myofibers are supplied with new nuclei by satellite cells, myogenic progenitors located between the plasma membrane and the basal lamina of the myofiber. During postnatal growth, satellite cells proliferate and contribute myoblasts that fuse with the enlarging myofibers. In mature muscles, satellite cells are mitotically quiescent, but they can enter the cell cycle and produce myoblasts in response to stimuli generated by muscle damage. Quiescent satellite cells commonly express the paired-homeobox transcription factor Pax7, while their proliferating progeny co-express Pax7 and the muscle-specific transcription factor MyoD. Upregulation of FGFR4, along with the induction of the muscle-specific transcription factor myogenin and a concomitant decline in Pax7, marks the transition of satellite cell progeny into the differentiation phase. These cells rapidly withdraw from the cell cycle, terminally differentiate and fuse into myotubes. We identified expression of green fluorescent protein (GFP) driven by regulatory elements of the nestin gene within satellite cells of different muscles in mice. This GFP expression establishes a novel means for characterizing satellite cells in their niche. Sorted GFP+ cells exclusively acquired a myogenic fate, even when supplemented with media supporting non-myogenic development. Common and unique gene expression patterns were identified in satellite cells from different muscle groups. GFP+ sorted cells from hindlimb, diaphragm and extraocular muscles expressed relatively high levels of Pax7 and Myf5. Only the diaphragm cells exhibited a distinctly greater expression of Pax3. GFP expression declined following satellite cell activation and was reacquired in late stage myogenic cultures by non-proliferating Pax7+ progeny. The dynamics of this expression pattern reflect the cycle of satellite cell self-renewal. The nestin-GFP model reveals unique transcriptional activity within quiescent satellite cells and permits novel insight into the heterogeneity of their molecular signatures. Supported by USDA and NIH.

Key Words: Satellite Cells, Pax7, Skeletal Muscle

850 The role of microRNAs in muscle development. T. P. L. Smith*[1], T. G. McDaneld[1], M. E. Doumit[2], L. K. Matukumalli[3], T. S. Sonstegard[3], L. L. Coutinho[4], and R. T. Wiedmann[1], [1]*USDA, ARS, U.S. Meat Animal Research Center*, *Clay Center, NE*, [2]*Michigan State University*, *East Lansing*, [3]*USDA, ARS, Bovine Functional Genomics Laboratory*, *Beltsville, MD*, [4]*University of Sao Paulo*, *Brazil*.

The genomes of multicellular eukaryotic organisms encode numerous non-coding RNA (ncRNA) species with a variety of known functions, as well as many whose functions are currently unknown. One class of ncRNA genes produce transcripts that are processed by specific cellular machinery to result in small ~18-22 nucleotide-long micro-RNAs (miRs) that provide a targeting mechanism to direct RNA-protein complexes (RISC) to cognate mRNAs. Association of the RISC complex with mRNA has been shown to control gene expression by inhibiting translation or targeting messenger RNA for degradation. The data on miR expression and activity suggests that a major role for this level of regulation is to provide a mechanism for switching the physiological state of the cell in a rapid fashion, as a single miR may have numerous target genes and may act more rapidly than transcriptional control by silencing mRNA already present in the cell. Tissue-specific miRs have been implicated in control of development, homeostasis, and immune response. Studies in mouse myoblast cell lines have defined significant responses of miR populations during differentiation. Our studies of miR profiles in porcine and bovine satellite cell and fetal muscle samples demonstrate marked similarity, but also significant differences, to the murine system. In addition, miR profiles in fast-growing neonatal muscle and fully mature muscle indicate potential roles for regulation of gene expression throughout the life cycle. Analysis of mRNA coexpression through these developmental stages of muscle growth and maturity begins to provide a picture of the interplay between protein-coding gene expression and regulation at the post-transcriptional level via miRs. The data suggest potentially critical roles for miRs in the switch from proliferation to differentiation, in regulating muscle growth in early life, and in maintaining tissue homeostasis in mature muscle.

Key Words: Muscle Development, Non-coding RNA, Gene Regulation

851 Cellular and molecular regulation of muscle growth and development in meat animals. W. R. Dayton*, M. E. White, and M. R. Hathaway, *University of Minnesota*, *St Paul*.

Insulin-like growth factor (IGF)-I and IGF binding proteins (IGFBP) play a significant role in mediating the actions of myostatin, TGF- β and anabolic steroids on muscle cells at the cellular and molecular level. Both myostatin and TGF-β suppress proliferation in porcine embryonic myogenic cell (PEMC) cultures. Treatment with myostatin or TGF-β also increases production and secretion of IGFBP-3 and IGFBP-5 by PEMC cultures. Immunoneutralization of IGFBP-3 and IGFBP-5 in the culture media of TGF-β or myostatin-treated PEMC cultures returns proliferation rate to 90% of levels observed in control cultures that were not treated with myostatin or TGF-β. Consequently, it appears that IGFBP-3 and IGFBP-5 play a crucial role in mediating the proliferation-suppressing actions of myostatin and TGF-β in PEMC cultures. Furthermore, the mechanisms by which IGFBP-3 and IGFBP-5 facilitate the proliferation-suppressing activity of myostatin and TGF-β appear to be IGF-independent and do not involve reduced phosphorylation of Smad2 or Smad3 by the TGF-β or myostatin receptors. The IGF/IGFBP system also plays a significant role in mediating the muscle-growth-enhancing actions of anabolic steroids. Steers implanted with a combined trenbolone acetate/estradiol (TBA/E) implant have increased circulating IGF-I levels and increased IGF-I mRNA levels in muscle tissue. Treatment of cultured bovine satellite cells (BSC) with E or trenbolone (TB) results in increased levels of IGF-I mRNA in these cells. Additionally, treatment of cultured BSC with either TB or E results in increased proliferation rate. Although, these data suggest that TBA/E-induced increases in muscle IGF-I levels may mediate the enhanced muscle growth observed in feedlot steers implanted with these steroids, studies utilizing the IGF-I receptor blocker JB1 indicate that the proliferation-promoting effects of TB and E in BSC cultures may not result solely from increased IGF-I levels.

852 Application of cellular mechanisms to growth and development of food producing animals. B. J. Johnson*, *Kansas State University*, *Manhattan*.

Postnatal skeletal muscle growth is a result of hypertrophy of existing skeletal muscle fibers in food producing animals. Accumulation of additional nuclei, as a source of DNA, to the multinucleated skeletal muscle fiber aids in fiber hypertrophy during periods of rapid skeletal muscle growth. Muscle satellite cells are recognized as the source of nuclei to support muscle hypertrophy. Exogenous growth enhancing compounds have been used to modulate growth rate and efficiency in meat animals for over a half century. In cattle, these compounds enhance efficiency of growth by preferentially stimulating skeletal muscle growth compared to adipose tissue. There are two main classes of compounds approved for use in cattle in the United States: anabolic steroids and β-adrenergic agonists (β-AA). Administration of both trenbolone acetate (TBA) and estradiol (E) as implants increased carcass protein accumulation 8 to 10% in yearling steers. Muscle satellite cells isolated from steers implanted with TBA/E had a shorter lag phase in culture compared to satellite cells isolated from control steers. Collectively, these data indicate that activation, increased proliferation, and subsequent fusion of satellite cells in muscles of implanted cattle may be an important mechanism by which anabolic steroids enhance muscle hypertrophy. Oral administration of β-AA to ruminants does not alter DNA accumulation in skeletal muscle over a typical feeding period. The enhanced muscle hypertrophy observed due to β-AA feeding occurs by direct, receptor-mediated changes in protein synthesis and degradation rates of skeletal muscle tissue. Often, the muscle is unable to sustain this level of hypertrophy due to no additional accumulation of nuclei to support the increased protein accretion. Proper timing of anabolic steroid administration when coupled with β-AA feeding could result in a synergistic response in skeletal muscle growth due to the effects of anabolic steroids at increasing satellite cell activity which then can support the rapid hypertrophic changes of the muscle fiber when exposed to β-AA.

Key Words: Anabolic Steroid, β-Adrenergic Agonist, Skeletal Muscle

International Animal Agriculture - Livestock and Poultry: Global Livestock and Poultry Issues

853 Factors affecting milk price and revenues of dairy farms in the central region of Thailand. J. A. Rhone*[1], R Ward[1], S Koonawootrittriron[2], and M. A. Elzo[1], [1]*Univeristy of Florida*, *Gainesville*, [2]*Kasetsart University*, *Bangkok, Thailand*.

Milk prices in Thailand are based on a base price set by the government as well as premiums and deductions, based on milk quality and components, given by dairy cooperatives. The objectives of this study were 1) to determine month and year, farm location, and farm size effects on milk price, and 2) to calculate farm milk revenues across time, farm location, and farm size. There were a total of 967,110 farm milk yield and 58,575 milk price records from 1034 farms collected from 2003 to 2006. Farm milk revenues were calculated as the product of farm milk yield and milk price. Milk price was analyzed using a linear model. Fixed effects were 1) pricing system (1 = price based on milk fat and bacterial score, and 2 = price based on milk fat, bacterial score, and bulk tank somatic cell count, 2) interaction of pricing system by month nested within year, 3) interaction of pricing system by farm size (number of cows milked per day); small: < 10 cows; medium: 10 to 19 cows; and large: > 20 cows, and farm location (4 districts: Kaeng Khoi, Muaklek, Pak Chong, and Wang Muang). All fixed effects were important ($P < 0.05$) sources of variation for milk price. Milk prices in system 1 were higher (11.54 vs. 11.71 Thai bhat, $P < 0.05$) than in system 2. Under pricing system 1, large farms had the lowest milk price ($P < 0.05$) in all districts except Kaeng Khoi. Under pricing system 2, small farms had higher ($P < 0.05$) milk prices than medium and large farms across all districts. Farms in Kaeng Khoi had the least loss of revenue due to milk price, whereas farms in Wang Muang had the greatest. Higher bacterial scores and (or) bulk tank somatic cell counts in large and medium farms made them lose more revenue than small farms. Improvements in farm management and sanitary conditions would need to be implemented if milk revenues are to be increased.

Key Words: Milk Price, Milk Revenue, Thailand

854 Factors affecting bacterial score and bulk tank somatic cell count of dairy farms in the central region of Thailand. J. A. Rhone*[1], S. Koonawootrittriron[2], and M. A. Elzo[1], [1]*University of Florida*, *Gainesville*, [2]*Kasetsart University*, *Bangkok, Thailand*.

The objectives of the study were to determine the effects of year-season, farm location, and farm size on bacterial score and bulk tank somatic cell count (BTSCC). Collection of data was at the farm level; individual animal records were unavailable. There were a total of 58,575 bacterial score and 24,109 BTSCC count records from 1,034 farms. The BTSCC data was transformed using natural logarithms. The BTSCC and bacterial score traits were analyzed as single trait mixed and log linear models, respectively. Fixed effects were: 1) year-season, where year = 2004 to 2006, and season = winter (November to February), summer (March to June), and rainy (July to October), 2) farm size (number of cows milked per day of farms), small: < 10 cows; medium: 10 to 19 cows; and large: > 20 cows, and 3) farm locations (4 districts: Kaeng Khoi, Muaklek, Pak Chong, and Wang Muang). Random effects were farm and residual effects. Farm effects were assumed to be uncorrelated. Important effects were year-season, farm district by farm size interaction for log bacterial score (LBS), and month nested within year and farm district by farm size interaction for log BTSCC. The 2006 summer was lower ($P < 0.05$) than all other seasons and the rainy season was higher ($P < 0.05$) than either adjacent season for LBS. Small size farms in Muaklek and Pak Chong had lower ($P < 0.05$) LBS values than medium and large farms. There were no differences among farm sizes in Kaeng Khoi and Wang Muang for LBS. Small size farms in Muaklek, Pak Chong, and Wang Muang had lower ($P < 0.05$) log BTSCC values than both medium and large size farms. There was no difference ($P < 0.05$) among farm sizes for log BTSCC in Kaeng Khoi. The lower values of LBS and log BTSCC in most small size farms suggests they had better health and sanitary management than medium and large size farms.

Key Words: Bacterial Score, Bulk Tank Somatic Cell Count, Thailand

855 Effects of supplementing finger millet straw with concentrates differing in partitioning factor on microbial biomass synthesis in crossbred dairy cows. W. Jackson*[1], S. Sudha[2], U. Krishnamoorthy[2], R. Bhaskaran[2], and P. Robinson[1], [1]*University of California*, *Davis*, [2]*Karnataka Veterinary, Animal & Fisheries Sciences University*, *Bangalore, Karnataka, India*.

Improving utilization of crop residues by obtaining maximum microbial biomass from ruminally digestible organic matter (OM) is beneficial to lactating cows. The 'Partitioning Factor' (PF) is an index of distribution of truly degraded substrate between microbial biomass and fermentation waste products as measured by in vitro digestion, where a high PF indicates more efficient microbial biomass synthesis. In this study, effects of supplementing finger millet straw (FMS) with concentrates differing in PF on DM intake, nutrient digestibility and N metabolism were studied in mid-lactation cows. A high PF concentrate (HPFC) and a low PF concentrate (LPFC) were formulated to be iso-metabolizable energy and iso-N, but to differ in PF. Six crossbred cows were divided into 2 groups based on BW in a switchover design consisting of 2 periods of 4 weeks. A 5 day metabolism study was conducted at the end of each period. Diets consisted of ad libitum FMS as the sole source of forage, and concentrate supplements to meet requirements (ARC, 1984). FMS was fed daily at 8:30 h and concentrate was fed in 2 portions at 5:30 h and 14:00 h. The ME (MJ/kg DM) and CP content (g/kg DM) of the HPFC and LPFC concentrates were 12.7, 168 and 13.4, 188, respectively, and the PF was 3.78 and 3.65. Intake (kg/d) of DM, OM and CP for the HPFC and LPFC groups were 12.72, 11.61, 0.54 and 12.40, 11.59 and 0.53, respectively, but they did not differ between treatments. OM digestibility (g/kg DM consumed) of 624 vs. 659, as well as the N retained (8.0 g/d) was also similar. Urinary allantoin excretion (UAe, mmol/d) in HPFC was higher (P=0.05) than in LPFC (170 vs. 131), but calculated microbial N supply to the duodenum was similar between groups (125 and 112 g/d). Total N content (g/d) in urine was higher (P=0.0003) in the HPFC (57.0) vs. the LPFC (43.0) group, and BW gain (g/d) for the groups was 320 and 30 (P=0.09). A concentrate with a higher PF tended to have a higher efficiency of microbial biomass synthesis in an FMS based high forage diet.

Key Words: Efficiency of Microbial Biomass Synthesis, Allantoin, Microbial Nitrogen

Nonruminant Nutrition: General Topics

856 Temporal changes in biochemical indices of sulfur amino acid (SAA) metabolism in the folate deficient piglet. Z. Zhang* and J. D. House, *University of Manitoba*, *Winnipeg, MB, Canada*.

The impact of folate deficiency on temporal changes in markers of SAA metabolism was determined in weanling pigs. Pigs (5.3 kg; n=6/treatment) were fed a basal semi-purified diet (20.5% casein; 3474 kcal ME/kg) containing either 0 (folate deficiency, FD) or 0.6 (folate control, FC) mg/kg folate, using a pair-feeding design. Feed intake was measured daily, and body weight and plasma were collected weekly for 6 weeks. Animals were killed at the end of 6 weeks, and tissue samples harvested. Plasma folate and vitamin B-12 were determined by Quantaphase ? Folate/B12 Radioassay. Total homocysteine (Hcy) and cysteine (Cys) were quantified by reverse-phase HPLC. Hepatic serine hydroxymethyltransferase (SHMT) was measured by a binding assay using radioactive isotope L-[^{14}C(U)]-Serine. SHMT was statistically analyzed by PROC GLM with randomized complete block design. The mixed model was applied to analyze all the other parameters with repeated observations. In addition to average daily feed intake, average daily gain and feed efficiency were not affected by folate deficiency throughout the experiment. Plasma folate in FD pigs was decreased from the end of the second week (FC=72.7 nM; FD=29.1 nM; SE=8.4; p<0.001) till the sixth week (FC=67.2 nM; FD=15.1 nM; SE=9.1; p<0.001). Plasma vitamin B-12 in FD pigs tended to increase over the depletion. At 6 weeks, plasma vitamin B-12 was significantly elevated by folate deficiency (FC=229 pM; FD=1074 pM; SE =198; p<0.01). Increases in plasma Hcy in FD pigs were detected on the fifth (FC=16.6 μM; FD=37.0 μM; SE=5.9; p<0.05) and the sixth (FC=16.6 μM; FD=71.3 μM; SE=5.9; p<0.0001) weeks. By contrast, decreases in plasma Cys in FD pigs were found on the fifth (FC=187.0 μM; FD=146.5 μM; SE=9.3; p<0.01) and the sixth (FC=226.6 μM; FD=159.6 μM; SE=5.9; p<0.0001) weeks. SHMT was not affected by folate deficiency (p>0.05). These results provide evidence that folate depletion perturbs vitamin B-12 and SAA metabolism in the young pig.

Key Words: Folate, Homocysteine, Pig

857 Effects of diet conditioning (steam at low and high temperatures, expanding, and extruding) prior to pelleting on growth performance in nursery pigs. K. K. Lundblad*[1,2], S. Issa[2], J.D. Hancock[2], M. Sørensen[3,4], K. C. Behnke[2], E. Prestløkken[1], L. J. McKinney[2], and S. Alavi[2], [1]*Felleskjøpet Fôrutvikling*, *Trondheim, Norway*, [2]*Kansas State University*, *Manhattan*, [3]*University of Life Sciences*, *Aas, Norway*, [4]*AKVAFORSK*, *Aas, Norway*.

A total of 180 weanling pigs (avg BW of 5.6 kg) was used in a 36-d experiment to determine the effects of diet conditioning on growth performance. The diets were wheat-fishmeal-soybean meal-based and formulated to 1.6% lysine for d 0 to 13 and 1.35% lysine for d 13 to 36. Treatments were: 1) a control diet fed in mash form; 2) low-temperature steam conditioning (50°C for 20 sec before pelleting); 3) high-temperature steam conditioning (90°C for 20 s before pelleting); 4) expander conditioning (75°C for approximately 20 s in a preconditioner and 105°C for 20 s in the expander barrel before pelleting); and 5) extrusion processing (92°C for 150 s in a preconditioner and 120°C for approximately 50 s in the extruder barrel). The diets were fed to six pigs/pen and six pens/treatment with feed and water consumed on an ad libitum basis. For d 0 to 13, G:F of pigs fed the hydro-thermally processed treatments was greater than for pigs fed the mash control (P< 0.01) and ADG was greater for pigs fed diets that were extruder vs expander conditioned (P<0.06). Overall (d 0 to 36), ADG was not different among pigs fed the dietary treatments (P>0.40). However, G:F was greater for pigs fed hydro-thermally processed diets vs the mash control (P<0.01) and for pigs fed extruder vs expander conditioned diets (P<0.03). Means for pigs fed the dietary treatments (1 to 5 as stated above) were 287, 289, 288, 287, and 328 g/d for d 0 to 13 ADG and 945, 1,038, 1,104, 1,067, and 1,169 g/kg for d 0 to 13 G:F, respectively. Overall means were 425, 439, 429, 430, and 445 g/d for ADG and 760, 810, 802, 802, and 860 g/kg for G:F, respectively. In conclusion, hydro-thermal processing (and especially extrusion) of diets improved growth performance of weanling pigs.

Key Words: Pelleting, Expanding/Extrusion, Pig

858 Effects of diet conditioning (steam at low and high temperatures, expanding, and extruding) prior to pelleting on growth performance in broiler chicks. K. K. Lundblad*[1,2], S. Issa[2], J. D. Hancock[2], M. Sørensen[3,4], K. C. Behnke[2], E. Prestløkken[1], L. J. McKinney[2], and S. Alavi[2], [1]*Felleskjøpet Fôrutvikling*, *Trondheim, Norway*, [2]*Kansas State University*, *Manhattan*, [3]*University of Life Sciences*, *Aas, Norway*, [4]*AKVAFORSK*, *Aas, Norway*.

A total of 150 broiler chicks (1 d old and average BW of 41 g) was used in a 21-d experiment to determine the effects of diet conditioning on growth performance. The diets were wheat-fishmeal-soybean meal-based and formulated to 1.35% lysine. Treatments were: 1) a control diet fed in mash form; 2) low-temperature steam conditioning (50°C for 20 sec before pelleting); 3) high-temperature steam conditioning (90°C for 20 s before pelleting); 4) expander conditioning (75°C for approximately 20 s in a preconditioner and 105°C for 20 s in the expander barrel before pelleting); and 5) extrusion processing (92°C for 150 s in a preconditioner and 120°C for approximately 50 s in the extruder barrel). The diets were fed to five chicks/cage and six cages/treatment with feed and water consumed on an ad libitum basis. Average daily gain (ADG) and average daily feed intake (ADFI) were greater for chicks fed diets that were simply steam conditioned vs expander and extruder conditioned. Also, expander conditioning resulted in greater ADG and ADFI than extruder conditioning (P<0.004). Gain to feed ratio (G:F) was not different among chicks fed the various treatments (P>0.21). Means for chicks fed the dietary treatments (1 to 5 as stated above) were 32, 34, 37, 32, and 28 g/d for ADG, 47, 47, 52, 47, and 38 g/d for ADFI, and 681, 723, 712, 681, and 737 g/kg for G:F. In conclusion, there was no advantage to using elaborate conditioning technologies (expanding and extrusion) vs. steam conditioning prior to pelleting diets for broiler chicks.

Key Words: Pelleting, Expanding/Extrusion, Chicks

859 Effects of feed form and fiber inclusion in the diet on nutrient utilization in twenty one–day–old broilers. E. Jiménez-Moreno[1], J. M. González-Alvarado[1,2], A. de Coca-Sinova[1], R. Lázaro[1], and G. G. Mateos*[1], [1]*Universidad Politécnica de Madrid*, *Spain*, [2]*Universidad Autónoma de Tlaxcala*, *México*.

We evaluated the effects of feed form and the inclusion of fiber in the diet on total tract apparent retention of nutrients (TTAR) and AME_n of diets in 21–d–old chicks fed low–fiber diets. The experimental design was completely at random with twelve treatments arranged factorially with two feed forms (mash and pelleted) and six diets that consisted in a combination of three sources of fiber (OH; oat hulls, RH; rice hulls, and SFH; sunflower hulls) and two levels of fiber source inclusion (2.5 and 5%). In addition, a control diet based on rice (57.7%), soy protein concentrate (24%), fish meal (7.6%), fat (5.05%), and celite (2%) that contained 3,200 kcal AME_n /kg, 1.4% total lysine, and 1.6% crude fiber was formulated and offered either in mash or pellet form. The diameter of the pellet was 2–mm. The fiber source was included (wt/wt) at expenses of the whole diet. Each treatment was replicated six times (12 chicks caged together). At 21 d of age TTAR of DM, organic matter (OM), soluble ash, and nitrogen (N), and AME_n of the diets were determined. Fiber inclusion increased TTAR of all dietary components studied ($P \leq 0.001$). However, pelleting of the diet did not improve digestibility of any dietary component ($P \geq 0.10$). Chicks fed SFH had lower TTAR of DM, OM, and N than chicks fed OH, with chicks fed RH intermediate ($P \leq 0.05$). The TTAR of soluble ash was greater with SFH than with RH ($P \leq 0.01$). An interaction fiber source x level of fiber inclusion in the diet was observed for TTAR of DM ($P \leq 0.05$) and AME_n ($P \leq 0.001$); an increase in RH from 2.5 to 5% decreased TTAR of DM and AMEn, but no effect was observed with OH or SFH. We conclude that feed form has not effect on digestibility but that the inclusion of a fiber sources improves utilization of nutrients. Therefore, young broilers fed low–fiber diets might benefit with the inclusion of additional fiber in the diet.

Key Words: Pellet, Hulls, Nutrient Digestibility

860 Effects of inclusion of several fiber sources on digesta pH of broilers. E. Jiménez-Moreno*[1], J. M. González-Alvarado[1,2], A. González-Serrano[1], R. Lázaro[1], and G. G. Mateos[1], [1]*Universidad Politécnica de Madrid*, *Spain*, [2]*Universidad Autónoma de Tlaxcala*, *México*.

A trial was conducted to evaluate the effect of the inclusion of 3% of a fiber source in the diet on pH of the digesta in the gastrointestinal tract (GIT). The experimental design was completely at random with four dietary treatments. The control diet contained 58% rice, 7% fish meal, 22% soy protein concentrate, and 3% sepiolite, and contained 3,095 kcal AME_n/kg, 1.31% total lysine and, 1.53% crude fiber. The three additional experimental diets were similar to the control diet but

sepiolite was substituted (wt/wt) by oat hulls (OH; insoluble and high in lignin fiber source), sugar beet pulp (SBP; soluble and low in lignin fiber source), or microcrystalline cellulose (CEL; insoluble fiber source with no lignin). Each treatment was replicated five times (1 chick per cage). The mean particle size of the diets was 472, 567, 771, and 682 µm for control, CEL, OH, and SBP diets, respectively. The pH of the crop, proventriculus, gizzard, duodenum, jejunum, ileum, ceca, and rectum digesta was recorded at 25 d of age. Fiber inclusion modified the pH of all the organs and segments of the GIT but the effects varied with the GIT segment considered and the fiber source used ($P \leq 0.05$). Inclusion of OH reduced pH of gizzard digesta but not crop or proventriculus pH. Inclusion of SBP increased pH of crop digesta but reduced proventriculus and gizzard pH. The inclusion of CEL had little influence on digesta pH of proximal GIT (from crop to gizzard). Also, the inclusion of fiber had little effect on pH of distal GIT (beyond the gizzard). The only effect of interest observed was that SBP tended to increase the pH in this part of the GIT whereas CEL inclusion had the opposite effect. We conclude that the inclusion of OH or SBP in low–fiber diet for broilers reduces digesta pH in the gizzard but that CEL had no effect. Therefore, the inclusion of OH or SBP to low–fiber diet might improve motility and health of the GIT.

Key Words: Digesta pH, Fibers Sources, Broiler

861 Adhesion ability of probiotic lactobacillus strains and their effect on piglet performance. S. Qiao*, X. Li, and H. Yu, *National Key Lab of Animal Nutrition, China Agricultural University*, *Beijing, China*.

Four Lactobacillus strains, Lactobacillus gasseri S1031, Lactobacillus reuteri I2021, Lactobacillus acidophilus I021 and Lactobacillus fermentum I5007 were isolated from mucosa of stomach, duodenum, jejunum and colon, respectively, of healthy weaning pigs and screened by in vitro selection from over 7000 native Lactobacilli colonoes according to probiotic bacteria criteria including resistance to heat, low pH, copper and bile salts in addition to antagonism to pathogenic agents. A complex Lactobacilli preparation made of the four Lactobacillus strains with approximately 2.0 X 108 CFU per ml was fed to 36 piglets weaded at 28±2 d (7.65 ± 1.09 kg BW). The piglets fed complex Lactobacilli preparation showed better ADG (P<0.05) than that fed carbadox. Earlier studies have shown that adhesion is a prerequisite for the colonization of bacteria and strains with the highest adhesion ability have the greatest effect on the health and performance of the host. Therefore, the adhesion ability of the four Lactobacillus strains on Caco-2 cells was observed by light and electron microscope, and that on the porcine intestinal mucus was examined by the scintillation counter using [methyl-3H] thymidine labeled bacteria. Lactobacillus fermentum I5007 displayed the best adhesion ability among the four strains. In competitive exclusion assay using Salm. typhimurium and E. coli K88ac, Lactobacillus fermentum I5007 showed an excellent probiotic ability. Futhermore, 288 piglets weaned at 28±2 d (7.65 ± 1.09 kg BW) were uesd to compare the effects of Lactobacillus fermentum I5007 preparation and complex Lactobacilli preparation on the piglet performance. The complex Lactobacilli preparation was prepared using the four lactobacillus strains with approximately 2.0 X 108 CFU per ml. While, Lactobacillus fermentum I5007 preparation was prepared with approximately 2.0 X 108 CFU per ml. The piglets fed Lactobacillus fermentum I5007 preparation showed better ADG (P<0.05) than that fed the complex Lactobacilli preparation.

Key Words: Lactobacillus, Probiotic, Adhesion Ability

862 Supplementing rice protein concentrate to a milk-based diet enhances growth performance in weaned pigs. Z. P. Hou[1], Y. L. Yin*[1,2], R. L. Huang[1], T. J. Li[1], P. Zhang[1], X. Wu[1], and G. Y. Wu[1,3], [1]*Key Laboratory of Subtropical Agro-ecology, Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Nanchang University*, *Nanchang, Jiangxi, China*, [3]*Texas A&M University*, *College Station*.

Milk products, including dried skim milk and dried whey, are typical feed ingredients for young pigs because of their high palatability and digestibility values. However, these protein sources are currently expensive and, therefore, their use is limited. The objective of this study was to determine whether rice protein concentrate (RPC) can replace milk protein without affecting piglet growth performance. The basal milk replacer powder used in the present study consisted of 60% dried whey, 26% skimmed milk, 6.2% a-casein, 3.6% lactose, 1.65% glucose, 1% calcium lactate, 1% dihydrocalcium phosphate, 0.1% vitamin premix, 0.2% mineral premix, 0.1% lysine, 0.1% methionine, and 0.05% antibiotic. Forty-four piglets weaned at 7 d of age (BW 2.83±0.22 kg) were assigned randomly to one of the four treatments, representing the substitution of 0 (control), 5, 10, and 15% dried whey with RPC in milk replacer powder. Piglets had free access to their respective diets for 3 wk. The results indicate that there was no difference (P<0.05) in ADG, ADFI or feed/gain ratio among the treatment groups in wks 1 and 2. During wk 3, feed intake and ADG by piglets fed the 10% RPC diet were 13% and 22% higher (P<0.05), respectively, than those for control piglets, whereas growth performance did not differ (P>0.05) between piglets fed the 5 and 10% RPC diets. Growth performance of piglets fed the 15% RPC diet tended to be lower than that of piglets fed the 10% RPC diet (P>0.05). These results indicate that an optimal replacement of 10% dried whey with RCP in the diet for weaned piglets did not compromise their growth performance.

Key Words: Weaned Pigs, Rice Protein Concentrate, Piglet Growth

863 Effects of different carbohydrates on the growth performance of weaned pigs. X. G. He*[1,2], H. J. Xu[1,2], X. F. Kong[1,2], W. Y. Chu[2], R. L. Huang[2], Z. Y. Deng[1], S. W. Kim[3,4], G. Y. Wu[1,4], and Y. L. Yin[1,4], [1]*Nanchang University*, *Nanchang, Jiangxi, China*, [2]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Hunan, Changsha, China*, [3]*Texas Tech University*, *Lubbock*, [4]*Texas A&M University*, *College Station*.

This experiment was conducted to evaluate the effects of different carbohydrates on the growth performance of weaned pigs, with the goal of choosing appropriate carbohydrates to formulate diets for weaned piglets. One hundred twenty Duroc x Landrace x Yorkshire pigs weaned at 28 d of age were randomly assigned to one of the five treatments (24 pigs/treatment), representing supplementation with 6% corn (control), lactose, sucrose, glucose, or cornstarch to a maize-soybean meal-based diet. Pigs had free access to their respective diets and drinking water. At the end of a 28-d experimental period, blood samples were collected from pigs before they were euthanized to obtain the duodenum and jejunum. The results indicate that the ADG of pigs fed the glucose diet was higher (P<0.05) than that for the sucrose group. The feed:gain ratio of pigs fed the lactose group was lower (P<0.05) than that for the other four groups. The activities of lactase in the duodenum and jejunum of pigs fed the lactose diet were higher (P<0.05) than that for the control, sucrose, glucose, and cornstarch groups. Intestinal maltase activities in the lactose and

cornstarch groups were similar (P>0.05) but were higher (P<0.05) than those for the other 3 groups of piglets. Intestinal sucrase activities in the control, sucrose and cornstarch groups were higher (P < 0.05) than those for the glucose and lactose groups. Serum concentrations of glucose and calcium were higher (P<0.05) in the sucrose group than that in the cornstarch group. In conclusion, glucose could be used to substitute lactose completely or partly in the diet for weaned pigs but sucrose or cornstarch cannot be used effectively as a single source of carbohydrate.

Key Words: Carbohydrate, Weaned Pigs, GrowthPerformance

864 *Pediococcus pentosaceus* FBB61 reduces oxidative damage by ochratoxin A in rats. A. Piva[1], V. Pizzamiglio*[1], E. Grilli[1], M. R. Messina[1], P. P. Gatta[1], G. Casadei[2], M. Bognanno[3], and F. Galvano[3], [1]*DIMORFIPA, University of Bologna*, *Bologna, Italy*, [2]*Northeastern University*, *Boston, MA*, [3]*STAFA Department, Mediterranean University of Reggio Calabria*, *Reggio Calabria, Italy*.

Ochratoxin A carcinogenicity and cytotoxicity are associated with free radical mediated oxidative cell damage. Aim of the present study was to investigate the effects of a chronic in-feed supplementation of *Pediococcus pentosaceus* FBB61 to counteract the toxic effects induced by chronic exposure to ochratoxin A contaminated diet in rats. Sprague Dawley male rats (initial body weight 83.9±8.2 g) were divided in 4 dietary treatments (10 animals/group, individually housed) fed a commercial standard pellet diet (control, CTRL) supplemented with *P. pentosaceus* FBB61 (10^6 CFU/g of feed, PP) or ochratoxin A (200 ppb, OTA) or both the previous treatments (PP+OTA). After 4 weeks rats were sacrificed by an over-dose of ether. Liver, kidneys and brain of each rat were rapidly removed, plasma samples were collected and immediately frozen (-80 °C). Aliquots of tissue homogenate were used to evaluate non-proteic thiol groups (RSH) and lipid hydroperoxide (LOOH) levels, as markers of oxidative damage. Data were analyzed with one-way ANOVA. No differences (P > 0.05) were observed in growth performance. PP-fed rats showed higher (P < 0.001) RSH value in liver and brain and lower (P < 0.001) LOOH values in liver and kidney than all other treatments. PP-fed rats improve oxidative status of liver than control group. Higher levels of RSH and lower levels of LOOH in liver of PP+OTA-fed rats than of OTA-fed rats suggest that supplementation of PP was able to reduce OTA induced oxidative damage.

Table 1.

	CTRL	SD	PP	SD	OTA	SD	PP+OTA	SD
RSH (nmol/mg of protein)								
Liver	111.9	2.2^c	129.6	3.8^d	74.2	2.2^a	94.4	0.9^b
Kidney	106.8	2.1^c	109.4	4.3^c	85.2	2.6^a	102.8	2.2^b
Brain	88.7	1.8^b	90.8	2.5^c	82.9	1.7^a	84.8	2.5^a
LOOH (µmol/mg of protein)								
Liver	0.34	0.01^b	0.29	0.01^a	0.54	0.01^d	0.37	0.01^c
Kidney	0.34	0.01^b	0.33	0.01^a	0.51	0.02^d	0.39	0.01^c
Brain	0.24	0.01^a	0.24	0.01^a	0.52	0.01^c	0.32	0.01^b

CTRL: standard diet; PP: *P. pentosaceus* FBB61; OTA: ochratoxin A; PP+OTA: both PP and OTA; SD: standard deviation. n=10 Different letters in row indicate P< 0.05

865 Apparent ileal digestibility of nitrogen, amino acids and energy of soybean meals from different origins in twenty one-day-old broilers. A. Coca-Sinova, D. G. Valencia, E. Jiménez-Moreno, J. M. González-Alvarado, R. Lázaro, and G. G. Mateos*, *Universidad Politécnica de Madrid*, *Spain*.

An experiment was conducted to compare the apparent ileal digestibility (AID) of nitrogen (N), amino acids (AA), and energy (E) of five different soybean meals (SBM) in 21 d old broiler chicks. Four of the SBM samples were collected from local traders, and had a chemical composition within the range accepted by the feed compound industry. Three of them were from Brazil (45.2 to 47.2% CP) and the other was from Argentina (46.1% CP). The fifth batch of SBM was obtained from Owensboro crushing plant (KY, USA). It was a high protein SBM (48.8% CP) obtained after dehulling by using a proprietary processing method (SoyMAX tradermark) that reduced to a minimum the trypsin inhibitors content of the meal, without damaging AA digestibility. The experimental design was completely randomized with 5 treatments and 6 replicates (6 chicks each) per treatment. The experimental diets were based on sucrose, corn starch, and oil and the only source of protein was the SBM tested. All the diets contained approximately 3,100 kcal ME/kg, 20% CP, and 1.24% total lysine. Celite (2%) was included in the diets as an additional source of acid–insoluble ash. All chicks were fed a commercial diet from 1 to 16 d of age and then their respective experimental diets from 17 to 21 d of age. At 21 d of age, digesta was collected from the distal ileum (2 cm anterior to the ileocaecal junction) and N, AA, and E digestibilities were determined. Treatment means were compared using a protected t–test. SoyMAX inclusion increased AID of DM, N, Met, and Cys ($P \leq 0.001$), as compared to the average of the remaining SBM samples. The AIDE was higher for the diet with SoyMAX than for the average of the remaining diets (3,156 vs. 3,012; $P \leq 0.001$). We conclude that SoyMAX had higher N, AA, and E digestibility than the commercial batches of South American SBM tested. Therefore, the inclusion of SoyMAX in prestarter diets might benefit poultry efficiency.

Key Words: Ileal Digestibility, Amino Acids, Soybean Meal Origin

866 Fecal near-infrared reflectance spectroscopy (NIRS) calibrations for predicting intake of donkeys. N. Kidane*, J. Stuth, and D. Tolleson, *Texas A&M University*, *College Station*.

Fecal-near infrared reflectance (fecal-NIRS) has been used as a method for predicting of DMI, and organic matter intake (OMI) of ruminants. Information about the capability of NIRS method for predicting intake of equines (donkeys) is lacking. The objective of the study was to determine the potential of fecal-NIRS calibration for predicting the DMI and OMI of donkeys. One hundred diet-fecal pair samples were generated from in vivo feeding trials conducted for 10 weeks (plus 1 wk adaptation) in the Horse Center, at Texas A & M University. Ten female donkeys (Equus asinus), with an average body weight of 196.3±50.6 kg, were fed 100 different diets blended from 13 natural forage and crop residues. Donkeys were fed twice a day (0700-1900 hr), and daily feed intake, refusal, and fecal output were measured for each diet. Ground fecal samples were scanned in reflectance mode (400-2500 nm) using a Pacific Scientific model 6500 monochromator. Calibrations were developed using modified partial least square regression (MPL) model. The SE of calibration (SEC) for the DMI and OMI were 3.45 g/kgw$^{0.75}$ and 3.21 g/kgw $^{0.75}$, with R^2 values of 0.89, and 0.84, respectively. Independent sample set (n=50) was used to validate the performance of each equation. The SE of prediction

for DMI and OMI were 4.36 g/kgw$^{0.75}$ and 3.28 g/kgw$^{0.75}$ with corresponding r^2 values of 0.84 and 0.87, respectively. Both calibration and validation results indicated that NIRS equations were successfully developed, and could be a used as a tool for predicting the intake of donkeys.

Nonruminant Nutrition: Natural Phytobiotics for Health of Young Animals: Applications and Mechanisms

867 Natural phytobiotics for health of young piglets and poultry: Mechanisms and application. W. Windisch*[1] and A. Kroismayr[2], [1]*University of Natural Ressources and Applied Life Sciences*, *Vienna, Austria*, [2]*BIOMIN GmbH*, *Herzogenburg, Austria*.

In order to establish alternatives to antibiotic growth promoters (AGPs), phytogenic substances, especially essential oils, are of increasing interest actually. Herbs, spices, plant extracts and essential oils may have positive effects on performance of animals. For example, phytogenic substances derived from Oregano (Origanum vulgare), especially the major active substances thymol and carvacrol, are known to exert antimicrobial and bactericidal actions in vitro. Phytogenic substances can also lead to higher secretion of digestive enzymes and mucus, thus presumably stimulating transport rates of nutrients from intestinal lumen towards blood. As an additional effect phytogenic substances may protect intestinal tissue from microbial attack. In order to gather more information about mode of action of phytogenic feed additives, especially with respect to similarity to AGPs, a commercial essential oils bled was tested with a negative control group as well as a standard AGP (Avilamycin) in a 50days model study employing 120 weaner piglets. A subgroup of 3 x 12 animals was sacrificed at trial day 22 to collect chyme and tissue samples for analysis of chyme microbiology including microbial products, gut morphology, and mRNA expression of apoptotic and inflammatory markers in gut tissues. The study showed that the impact of essential oils on performance and aforementioned parameters was very similar to those of the antibiotic growth promoter (Avilamycin). Essential oils enhanced immune status of piglets and improved nutrient digestibility. Generally speaking, phytogenic feed additives can be considered to act similarly to other substances with growth promoting action (e.g. antibiotics, probiotics, organic acids) with the overall effect of promoted zootechnical performance.

Key Words: Phytobiotics, Essential Oils, Piglets

868 The use of bioactive herbal saccharides in China. X. Piao*[1], S. Yuan[1], S. W. Kim[2], D. Li[1], and D. Ou[1], [1]*China Agriculture University*, *Beijing, China*, [2]*Texas Tech University*, *Lubbock*.

Immune disorders are common phenomena in human and animals due to immature immune system and stress, and thus they might be more susceptible to infection when exposed to a variety of micro-organisms. Bioactive saccharides like polysaccharide and/or oligosaccharide found in herbs are considered to be important components playing roles in immunomodulatory action and antioxidant activity. The structure and bio-activity of saccharides is, however, not fully understood. In this review, immune and antioxidant activities of the saccharides from Chinese herbs are introduced, including polysaccharids (astragalus, ganoderma lucidum, phoma herbarum, lycium barbarum, lentinus edodes, angelica Sinensis, coriolus versicolor, misgurnus anguillicaudatus, spirulina platensis, cladonia furcata, pumpkin polysaccharide) and oligosaccharide (mannan-, galacto-mannan-, isomalto-, fructo-, and xylo-oligosaccharide). Growing interests in herbal saccharides mainly arise from the emerging knowledge about their roles in: 1) enhancing T-cell mediated immune response and humoral immune response; 2) inhibiting the growth of tumour; 3) scavenging effects on active oxygen; 4) protective effects on the acute hepatic injury; 5) promoting wound healing and proliferation of endothelial cells in vitro; 6) decreasing total cholesterol and triglyceride; and 7) improving the impaired glucose tolerance. Considering these possible benefits but without drug residues and low side effects, the bioactive herbal saccharides can be a potential immunmodulating agent to improve health and immune function for life.

Key Words: Saccharide, Immunity, Antioxidant

869 Effect of a phytogenic feed additive on reproduction performance of sows. A. Kroismayr*[1,4], C. Hsun[2], M. Racousier[3], and T. Steiner[4], [1]*University of Natural Resources and Applied Life Sciences*, *Vienna, Austria*, [2]*BIOMIN America Inc*, *San Antonio, Texas*, [3]*Universidad Mayor*, *Santiago, Chile*, [4]*BIOMIN GmbH*, *Herzogenburg, Austria*.

Growing concern about antibiotic growth promoters in animal nutrition has created efforts to use different plant compounds as possible natural alternatives. Phytogenics are a heterogeneous group of feed additives originating from fruits, herbs, spices or other plants. The aim of this study was to evaluate the effect of a defined phytogenic feed additive (Biomin® P.E.P. 1000), which contains essential oils derived from oregano, anise and citrus peels, on reproductive performance of sows. A feeding trial was conducted under guidance of Universidad Mayor, Santiago, Chile. In this study, eighty cross-bred (PIC 337× Camborough 22) sows were assigned to two dietary treatments with 40 sows per treatment. A gestation diet was fed restrictively (3 kg/d) from day 15 to day 3 before farrowing. Subsequently, a lactation diet was offered ad libitum until weaning. Diets based on corn, soybean meal and wheat by-products were either supplemented or not supplemented (Control) with a phytogenic feed additive (Biomin® P.E.P. 1000, 2 kg/t). Addition of phytogenics to the diets substantially increased feed intake in the lactation period. The average feed intake in lactation amounted to 7.070 and 7.238 kg ($P>0.05$) for the control and trial group, respectively. It is generally accepted that a higher feed intake in lactation together with improved digestion results in an increased supply of nutrients and energy for the piglets in the milk. Inclusion of phytogenics in diets of sows positively affected litter performance as well. Compared to the control group, phytogenics improved growth performance of piglets, resulting in higher body weights of piglets at weaning (6.15 vs. 5.90 kg, $P>0.05$). Average daily gain was 220 and 230 g ($P>0.05$) in the control and trial group, respectively. Compared to the control group, piglets in the trial group were 4 and 6% heavier at birth (15.52 vs. 14.93 kg, $P>0.05$) and weaning (65.81 vs. 61.83, $P>0.05$), respectively.

Key Words: Sows, Phytogenics, Essential Oils

870 Effects of phytobiotics on nursery pig performance. R. C. Sulabo*[1], J. Y. Jacela[1], J. M. DeRouchey[1], M. D. Tokach[1], F. Neher[2], R. D. Goodband[1], S. S. Dritz[1], and J. L. Nelssen[1], [1]*Kansas State University*, *Manhattan*, [2]*Biomin Inc.*, *San Antonio, TX*.

A total of 192 weanling pigs (initially weighing 5.85 kg and 22 ± 2 d of age, PIC) were used in a 42-d growth assay to determine the effects of phytobiotics (Biomin® P.E.P. 125 and 125T) on post-weaning growth performance. Pigs were blocked by initial weight and randomly allotted to one of four treatments: 1) negative control (feed containing no antibiotic or phytobiotic); 2) negative control + phytobiotic 1 (125 g/ton of Biomin® P.E.P. 125); 2) negative control + phytobiotic 2 (125 g/ton of Biomin® P.E.P. 125T), and 4) positive control (feed containing 140 g/ton of neomycin sulfate and 140 g/ton of oxytetracycline HCl; Neo/OTC). Each treatment had six pigs per pen and eight replications (pens). Phase 1 and 2 diets were fed from d 0 to 14 and d 14 to 42, respectively. Overall (d 0 to 42), ADG (g), ADFI (g), and G:F was 453, 642, and 0.71 for pigs fed the negative control; 481, 658, and 0.73 for pigs fed phytobiotic 1; 477, 649, and 0.74 for pigs fed phytobiotic 2; and 502, 705, and 0.71 for pigs fed the positive control. Pigs fed Neo/OTC had greater (P<0.03) ADG and ADFI than pigs fed the negative control diet and pigs fed diets with phytobiotics. Addition of phytobiotics to the nursery diet also increased (P<0.03) ADG and G:F compared to pigs fed diets without antibiotics and improved (P<0.01) G:F compared to pigs fed the positive control diet. No differences (P>0.38) were observed in ADFI between pigs fed the negative control diet and pigs fed either phytobiotic. Pigs fed diets with Neo/OTC had similar (P>0.28) G:F compared to pigs fed diets without antibiotics. No differences (P>0.52) were observed in ADG, ADFI, and G:F between pigs fed diets with phytobiotic 1 and 2. In conclusion, phytobiotics in nursery diets improved post-weaning growth performance when added to diets without antibiotics. Further research is needed to elucidate specific modes of action that caused positive effects in post-weaning growth and efficiency.

Key Words: Phytobiotics, Antibiotics, Nursery Pig

871 Dietary supplementation with *Acanthopanax Senticosus* extracts enhances the digestion and absorption of dietary protein and amino acids in weaned pigs. F. G. Yin*[1], X. F. Kong[1], Y. L. Yin[1], H. J. Liu[1], F. F. Xing[1], Q. H. He[1], T. J. Li[1], R. L. Huang[1], P. Zhang[1], and G. Y. Wu[1,2], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Texas A&M University*, *College Station*.

This study was conducted to determine the effects of dietary supplementation with *Acanthopanax senticosus* extracts (ASE) on the digestion and absorption of protein and amino acids in weaned pigs. Sixty piglets weaned at 21 d of age were randomly assigned to one of the three treatment groups, representing supplementation with 0 (control) or 0.1% ASE or 0.02% colistin (an antibiotic) to a corn- and soybean meal-based diets for 28 d (n=20 pigs/group). On d 0, 7, 14 and 28 post the initiation of ASE supplementation, venous blood samples were obtained from 5 pigs per group and sera were analyzed for amino acids. On d 28, pigs were euthanized to obtain digesta from the terminal ileum for determining total amino acids. The results indicated that serum concentrations of total amino acids in all groups of pigs were gradually increased (P<0.05) with increasing age. On d 28, serum concentrations of His and Lys in ASE-supplemented pigs were higher (P<0.05) than those in the other two groups, whereas serum concentrations of Thr in ASE-supplemented pigs were higher (P<0.05) than those in colistin-supplemented pigs. Serum concentrations of Phe, Tyr, Leu, Ile and Ala in ASE-supplemented pigs were higher (P<0.05) than those in the control group. Concentrations of Phe, Tyr, Leu, Ile, Ala, Gly, Asp, Glu, His, Lys and Ser in the digesta of in ASE-supplemented pigs were lower (P<0.05) than those in the other two groups. Further, concentrations of Val, Arg and Thr Ser were lower (P<0.05) in ASE-supplemented pigs than those in colistin-treated pigs. Collectively, these findings suggest that dietary supplementation with ASE enhances the digestion and absorption of protein or amino acids in weaned pigs.

Key Words: Herbal Extracts, Amino Acids, Weaned Pigs

Nonruminant Nutrition: Weanling Pig Nutrition

872 Effect of organic acids and antibiotic growth promoters on growth performance, gastrointestinal pH, intestinal microbial populations and immune responses of weaned pigs. Z. Li[1], D. Li[1], G. Yi*[2], J. Yin[1], and P. Sun[1], [1]*China Agricultural University*, *Beijing, P.R. China*, [2]*DaChan NorthEast Asia Corp*, *Beijing, P. R. China*.

Two experiments compared the effects of feeding organic acids and antibiotic growth promoters (AGP) in weaned pigs. Nursery pigs (N=96, 7.80 ± 0.07 kg) were allotted to a control or supplemented with AGP (200 ppm chlortetracycline plus 60 ppm Lincospectin), 0.5% potassium diformate, or 0.5% dry organic acid blend ACTIVATE Starter DA. During 4 weeks postweaning, pigs fed AGP or ACTIVATE had better ADG (P<0.03) and GF (P<0.04) than controls. On d 14 postweaning, control pigs had the lowest fecal lactobacilli counts among all treatments (P<0.02), whereas pigs fed AGP or ACTIVATE tended to have lower fecal E. coli counts compared to the controls (P<0.08). Serum IGF-1 levels of pigs fed AGP was greater than control pigs (P<0.03). Weaned pigs (N=24, 5.94 ± 0.33 kg) were used to evaluate AGP and ACTIVATE on performance, gastrointestinal measurements, and immune response of E. coli K88+ challenged pigs. Pigs were fed a control, or supplemented with AGP (100 ppm colistin sulfate, 50 ppm Kitasamycin plus 60 ppm Olaquindox), 0.5, or 1% ACTIVATE. During d 5 to 14 after E. coli K88+ challenge, pigs fed AGP, 0.5, or 1% ACTIVATE had higher gain than controls (P<0.01). Furthermore, control pigs had the worst GF among all treatments (P<0.03). On d 14, compared to the control pigs, pigs fed 0.5% ACTIVATE had higher lactobacilli in the duodenum, and pigs fed AGP and 1% ACTIVATE tended to have higher lactobacilli in the ileum (P<0.08). Pigs fed AGP, 0.5% or 1% ACTIVATE diets tended to have lower ileal E. coli counts compared to the controls (P<0.08). Serum interleukin-6, cortisol, or digesta pH values were not affected by treatment (P=0.11). These results indicate that AGP and organic acid blend ACTIVATE can improve growth performance of weaned pigs, mainly via modulating intestinal microflora populations or somatotrophic axis.

Key Words: Antibiotics, Growth Performance, Organic Acid

873 Dietary supplementation with glycyrrhetinic acid (GA) increases endogenous arginine provision and growth performance in milk-fed piglets. Z. S. He[1], Y. L. Hu[2], Y. L. Yin*[1,3], R. L. Huang[1], X. F. Kong[1], T. J. Li[1], F. W. Li[1], and G. Y. Wu[1,3], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Nanjing Agricultural University*, *Nanjing, Jiangsu, China*, [3]*Texas A&M University*, *College Station*.

Physiological levels of cortisol stimulate intestinal arginine synthesis in piglets. Interestingly, some herbal extracts contain GA (a pentacyclic triterpenoid derivative of the β-type amyrin), which has a chemical structure similar to cortisol. This study was conducted to test the hypothesis that dietary GA supplementation may increase arginine availability and growth performance in young pigs. In Experiment 1, 20 piglets (Landrace x Yorkshire) with similar BW (2.92 ± 0.10 kg) were obtained from 5 sows (4 piglets/sow) and weaned at 7 d of age to a liquid milk-replacer diet. After a 2-d period of adaptation, piglets were assigned randomly to one of the 4 treatments, representing supplementation with 0, 0.01, 0.02 or 0.04% GA to the milk powder for 12 d (1 piglet/pen; 5 pigs/treatment). Dietary supplementation with 0.02% GA resulted in highest ADG among all the treatment groups (P<0.05). Experiment 2 was conducted as Experiment 1, except that 9-d-old pigs were fed a liquid milk diet supplemented with 0 or 0.02% GA for 12 d (n=15 pigs/group). On d 0, 5, and 12, BW was measured and venous blood samples were obtained for the analysis of hematology and amino acids. Compared with the control, dietary supplementation with 0.02% GA increased feed intake by 27%, ADG by 47%, and the gain:feed ratio by 17%, while reducing scour frequency by 40% (P<0.05); increased the ratio of lymphocytes to leukocytes by 12-13% and reduced the ratio of neutrophils to leukocytes by 20-27%, while elevating mean corpuscular hemoglobin concentrations by 5% (P<0.05); and increased plasma arginine concentrations by 25% (P<0.05). These results suggest that GA enhances the endogenous provision of arginine and growth performance of milk-fed piglets.

Key Words: Glycyrrhetinic Acid, Pigs, Arginine

874 Dietary arginine supplementation enhances the immune status of piglets. B. E. Tan[1], Y. L. Yin*[1], X. F. Kong[1], T. J. Li[1], R. L. Huang[1], P. Zhang[1], F. G. Yin[1], I. Shinzato[2], S. W. Kim[3,4], and G. Y. Wu[1,4], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Ajinomoto*, *Tokyo, Japan*, [3]*Texas Tech University*, *Lubbock*, [4]*Texas A&M University*, *College Station*.

The study was conducted to determine effects of dietary L-arginine (Arg) supplementation on the immune status of 7- to 21-d-old pigs fed a milk replacer diet, which consisted of 60% dried whey, 26% dried skim milk, 6.2% a-casein, 3.6% lactose, 1.65% glucose, 1% calcium lactate, 1% dihydrocalcium phosphate, 0.1% vitamin premix, 0.2% mineral premix, 0.1% lysine, 0.1% methionine, and 0.05% antibiotic. Seventy piglets (Landrace×Yorkshire) were weaned at 7 d of age and assigned randomly to one of the five treatments (14 piglets/treatment), representing supplementation with 0% (control), 0.2%, 0.4%, 0.6% or 0.8% Arg to the milk replacer powder. Milk powder was dissolved in water to obtain 18% DM, and the resultant liquid milk was fed to piglets every 4 h for 14 d. On d 7, the ratio of spleen weight to BW and serum concentrations of immunoglobulin (Ig) M were higher and serum concentrations of interleukin (IL)-8 were lower in Arg-supplemented piglets compared with control piglets (P<0.05). On d 14, the ratio of thymus weight to BW in piglets supplemented with 0.6% dietary Arg and the numbers of white blood cells (WBC) and blood lymphocytes in piglets supplemented with 0.8% dietary Arg were higher than those in control piglets (P<0.05). On d 14, the numbers of WBC and blood granulocytes as well as serum concentrations of IL-1Ã*f*Å½Ã‚Â² were higher in piglets supplemented with 0.4% dietary Arg, compared with control piglets (P<0.05). Dietary supplementation with 0.6% and 0.8% Arg enhanced lymphocyte proliferation in response to phytohaemagglutinin and increased serum concentrations of IgG and tumor necrosis factor, compared with control piglets (P<0.05). Collectively, these findings suggest that dietary Arg supplementation is beneficial for improving immune function in piglets.

Key Words: Arginine, Immune-function, Piglets

875 Evaluation of different additives in weaned pigs raised in a commercial setting. K. J. Touchette[1], M. D. Newcomb[1], J. A. Cuaron[2], G. Lanz-Arias[2], and D. W. Giesting*[1], [1]*Cargill Animal Nutrition*, *Elk River, MN*, [2]*INIFIAP/PAIPEME*, *Queretaro, Qro., Mexico*.

A trial was conducted with 244 weaned pigs (19.6 d, 6.15 ± .34 kg) to evaluate the effect of additives alone or in combination with antibiotics on nursery performance. The pigs were weaned and assigned to one of 6 treatments in a 2x3 factorial arrangement in a RCBD with 2 levels of antibiotics (AB, none or added) and 3 levels of additives (none, ADD3, or ADD4). The antibiotic used in this study was carbadox fed at 55 mg/kg. The additives used in this study were combinations of enzymes, sweetener, a *Bacillus* DFM, and a plant extract. The ADD3 trt contained the first 3 additives, and the ADD4 trt contained all 4 additives. Pigs were fed a 3-phase, 28 d nursery program with diet changes on d 7 and 21. For phase 1, there were no effects of treatment on animal performance. For phase 2, treatment did not affect feed intake, while pigs fed either ADD3 or ADD4 had improved ADG ($p < 0.001$) and G/F ($p < 0.004$) versus the diets with no additives, while AB did not affect ADG or G/F. For phase 3, AB improved ADFI ($p < 0.02$) compared to no AB, and both ADD3 and ADD4 treatments improved ADFI ($p < 0.04$) compared to the diet with no additives. For both ADG and G/F, there were AB x additive interactions ($p < 0.03$), with no effect of either additive when in diets without, but an improvement in ADG in diets with AB. Adding additives to diets without AB decreased G/F, while adding additives to diets with AB increased G/F. For the entire 28 d trial, AB improved ADFI ($p < 0.04$), while there were interactions for ADG and G/F ($p < 0.003$). Both additives had no effect on ADG or G/F in diets without AB, while they improved ADG and G/F in diets with AB. This study demonstrates that both additives and antibiotics improved nursery performance.

Key Words: Swine, Antibiotics, Additives

876 The interaction of dietary energy and an *E. coli* phytase enzyme on the performance of weanling pigs. A. D. Beaulieu*[1], J. F. Patience[1], T. M. Parr[2], C. L. Wyatt[2], and M. R. Bedford[2], [1]*Prairie Swine Centre, Inc.*, *Saskatoon, SK, Canada*, [2]*Syngenta Animal Nutrition*, *RTP, NC*.

Supplementation of swine diets with phytase enzyme improves the digestibility and retention of phytate-bound P. Phytate complexes other nutrients; however, the data demonstrating an improvement in the utilization of these nutrients is equivocal. The objective of this experiment was to examine the interaction of dietary energy and an

E. coli derived phytase (Quantum™) on weanling pig performance. A total of 406 pigs (9.30 ± 0.51 kg) were utilized in a 42-d experiment. Pelleted phase 1 and 2 diets were fed for 2 and 4 wks, respectively. Treatments consisted of a positive control (PC: 3.48 and 3.52 Mcal DE/kg in phases 1 and 2, respectively) and 6 additional treatments arranged as a 3 x 2 factorial (3 DE levels [HI: 3.45 and 3.49, MED: 3.41 and 3.45, LO: 3.37 and 3.40 Mcal DE/kg for phases 1 and 2, respectively]; 0, 500 FTU phytase/kg). The PC contained 0.32 and 0.23% aP and 0.70 and 0.60% Ca in phases 1 and 2, respectively. Treatment diets contained 0.18 and 0.09% aP and 0.58 and 0.48% Ca in phases 1 and 2. To exploit the factorial arrangement, the initial statistical analysis excluded the PC. Overall ADG improved from 500 to 560 g/d (P<0.001), ADFI from 900 to 950 g/d (P<0.01) and FCE from 0.58 to 0.62 (P<0.05) with 500 FTU/kg phytase. Phytase by energy interactions were non-significant (P>0.05); thus, the analysis examining the effect of energy also excluded the phytase treatments. Increasing DE improved ADG, FCE (linear, P<0.02) and ADFI (quadratic, P<0.05). The ADG and FCE of the PC were similar to HI (P>0.15) regardless of phytase supplementation, but similar to MED and LO only when 500 FTU/kg phytase was included (P>0.20). The ADG and FCE of the PC were improved (P<0.02) relative to the MED and LO treatments when no enzyme was added. Regardless of the diet DE content, phytase improved ADG and FCE in weanling pigs. Based on ADG and FCE, 500 FTU/kg of an *E. coli* derived phytase provided approximately 100 kcal DE/kg when added to the diets of weanling pigs.

Key Words: Weanling Pigs, Phytase, Dietary Energy

877 Bioavailability of iron in an organic iron source for young pigs. G. L. Cromwell*, M. D. Lindemann, and H. J. Monegue, *University of Kentucky*, *Lexington*.

An experiment involving 96 pigs was conducted to determine the bioavailablity of Fe in an organic Fe source (Bioplex®Fe, Alltech, Nicholasville, KY) (OrgFe) relative to the bioavailability of Fe in an inorganic Fe source ($FeSO_4 \bullet H_2O$) (FeSul). Pigs not injected with Fe at birth were weaned at 17-22 d of age and fed a low-Fe diet for 4-5 d, resulting in low hemoglobin (Hb, 4.1 g/dl) and hematocrit (Hct, 17.9%) levels. The pigs (n=84, intial BW=5.5 kg) were allotted to 7 treatments with 6 replications of 2 pigs/pen. Treatments were a low-Fe basal diet (35 ppm Fe) and the basal with 14, 28, or 42 ppm added Fe from OrgFe or the basal with 14, 28, or 42 ppm added Fe from FeSul. An 8th treatment consisted of 12 positive control (PC) pigs injected with 150 mg Fe at birth and fed the basal diet with 150 ppm added Fe as FeSul during the study. These pigs had initial Hb of 10.4 g/dl and Hct of 36.8%. Diets were fed on an ad libitum basis and pigs were on plastic coated floors. At the end of the 28-d study, 4 pigs/treatment were killed and liver, heart, spleen, and kidneys were collected for Fe determination. Increasing the Fe level from either Fe source resulted in linear (P<0.001) increases in ADG (257, 339, 430, 438, 372, 424, 452 g for treatments 1 to 7, respectively). ADG for the PC pigs was 565 g. Hb and Hct also responded to added Fe from the 2 sources (4.82, 6.51, 7.28, 8.73, 7.14, 8.00, 9.95 g/dl; 20.8, 24.9, 28.3, 31.1, 27.1, 29.5, 35.2%). Levels of Hb and Hct for the PC pigs were 12.33 g/dl and 40.5%. Liver Fe (ppm of DM) was 15.3, 18.8, 25.5, 29.0, 28.8, 31.3, 43.5, 99.0 and total liver Fe was 1.31, 1.77, 2.93, 3.65, 3.16, 3.37, 4.97, 14.13 mg for the 8 treatments. Hb, Hct, and liver Fe responded linearly (P<0.001) to added Fe from either source, and the responses were greater for FeSul than for OrgFe (P<0.001). Hb, Hct, and liver Fe were regressed on Fe intake for each Fe source with the basal included in both regressions. Based on slope ratios, the bioavailability of Fe in the organic Fe source was 80 to 85% of the bioavailability of Fe in FeSul. Based on this study, the Fe in Bioplex®Fe seems to be less available to pigs than the Fe in $FeSO_4 \bullet H_2O$.

Key Words: Pigs, Iron, Bioavailability

878 A comparison of water delivered direct fed microbials or organic acids with in-feed antibiotics on weanling pig growth performance, intestinal morphology, gut microbiota and immune status following a *Salmonella typhimurium* challenge. M. C. Walsh*[1], D. M. Sholly[1], K. L. Saddoris[1], B. E. Aldridge[1], A. L. Sutton[1], M. H. Rostagno[2], B. T. Richert[1], and J. S. Radcliffe[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*USDA Livestock Behaviour Unit*, *West Lafayette, IN*.

Pigs (n=88) weaned at ~19 d of age were used in a 14 d experiment to compare the effects of water delivered direct fed microbials (DFM) or a propionic acid based blend with in-feed antibiotics on growth performance, intestinal morphology, gut microbiota and immune status following a *Salmonella typhimurium* challenge. Treatments were: 1) negative control (NC), 2) Trt. 1 + water supplied DFM (*Enterococcus faecium, Bacillus subtillis, Bacillus licheniformis*, Chr Hansen, Inc.), 3) Trt. 1 + water supplied propionic acid based blend (PA blend, 2.58 mL/L; Kem San®)and 4) Trt. 1 + in feed antibiotics (carbadox, 55 ppm). Pigs were challenged intra-nasally with *Salmonella typhimurium* on d 6 post-weaning, and harvested (22 pigs/d) on d 6 (prior to challenge), 8, 10 and 14 post-weaning. Water delivered DFM or PA blend or in feed antibiotics improved ADG (P<0.05) on d 2-4 post-challenge compared to NC pigs. Water supplied DFM tended (P<0.10) to increase G:F from d 0-5 pre-challenge compared to NC pigs. Water supplied DFM increased (P<0.05) duodenal villus height on d 4 post-challenge compared to pigs receiving carbadox or NC pigs. Water delivered PA blend tended (P<0.10) to decrease Enterobacteriaeace counts in the cecum on d 0 and 2 post-challenge compared to the DFM treatment. Salmonella presence in the ileum, cecum and mesenteric lymph nodes was not different among treatments at any time point post-challenge. However, the proportion of pigs shedding salmonella in the feces was decreased 100 and 50% by DFM and PA blend treatments, respectively, on d 5 post-challenge. There were no treatment differences in TNFα concentrations in serum, duodenal, jejunal, or ileal tissue at any time point post-challenge. However, serum TNFα linearly increased (P<0.04) through d 4 post-challenge for all treatments. Treatments had no effect on microbial presence and/or concentrations in the gastrointestinal tract, but did improve growth performance and intestinal morphology following a salmonella challenge.

Key Words: Pig, Direct Fed Microbials, Water Acidification

879 Influence of diet and manure management on growth performance and carcass characteristics of wean-finish pigs. D. M. Sholly*, R. B. Hinson, K. L. Saddoris, M. C. Walsh, A. L. Sutton, B. T. Richert, and J. S. Radcliffe, *Purdue University*, *West Lafayette, IN*.

A total of 1,920 pigs (initial BW=5.8 kg) were used in a 2 x 2 factorial, 153 d wean-finish experiment to determine the effects of diet (CTL or LNE) and manure management (deep pit, DP vs. monthly pull

plug-recharge, PP) on growth performance, live ultrasound scans, and carcass characteristics. The CTL and LNE diets were corn-SBM based and had equal Lys:calorie. The LNE diets had reduced CP and P, increased synthetic amino acids, contained a non-sulfur trace mineral premix and added fat. Pigs were housed in a 12 room environmental building, with 30 barrows and 30 gilts per room. Split-sex and phase feeding (9 phases) were used to meet or exceed the nutrient requirements of pigs (NRC, 1998) at different stages of growth. Nursery ADFI was greater for pigs fed the CTL diet compared to LNE fed pigs (1.00 vs. 0.96 kg/d; P<0.05), but ADG and d 56 BW (avg BW=37.0 kg) were not different (P>0.05). The LNE diet tended to improve nursery G:F over the CTL diet (0.45 vs. 0.42; P=0.06). Grow-finish ADG, G:F, and market BW were greater (0.97 vs. 0.94 kg/d, 0.39 vs. 0.35, and 130.1 vs. 125.4 kg, respectively; P<0.05) for LNE fed pigs compared to CTL fed pigs. Market BW pigs fed LNE diets had a greater loin eye area (LEA) and backfat compared to CTL fed pigs (40.7 vs. 38.9 cm2 and 20.9 vs. 17.9 mm, respectively; P<0.05). Pigs housed under the DP manure management had greater market BW live scan LEA (40.3 vs. 39.3 cm2; P<0.05) compared to PP manure management. Pigs fed the CTL diet had greater (P<0.05) carcass % lean, however LNE fed pigs had greater carcass % yield, fat depth, and hot carcass wt (P<0.05). Deep pit manure management increased carcass yield (74.83 vs. 73.82%; P<0.05) compared to PP manure strategy. All other carcass characteristics and nursery and grow-finish growth performance were unaffected by manure management. Diet formulation can impact pig performance to a greater extent than either a deep pit or pull plug-recharge manure management system.

Key Words: Pigs, Diet Manipulation, Manure Management

880 Relationship of isoprostanes, biomarker of oxidative stress, and pig productivity. T. S. Stahl*, J. B. Zamzow, D. Wang, and A. E. Atwood, *Iowa State University*, *Ames*.

Variation in a urinary isoprostanes, a biomarker of systemic oxidative stress status, was determined in pigs and its relationship to pig productivity was quantified. An imbalance between oxidative and antioxidative processes within cells results in excess production of reactive oxidative species which in turn create oxidized lipids and potential cell dysfunction. These cell dysfunctions include a greater loss of cellular energy and a potential redirection of energetic pathways. Four female pigs from each of 27 litters were selected from a single sow strain and herd and reared in a common environment. Pigs were individually penned, self-fed a nutritionally adequate diet and weighed weekly from weaning to 126 kg BW. Freshly voided urine was collected and the isoprostane/creatinine (IC, ng/mg) content determined at BW (±3) of 6, 18, 54, 90 and 126 kg. Urinary IC varied (P<.01) among litters and stage of growth. Urinary IC were elevated in young pigs and declined as the pigs grew, averaging 28.8, 18.3, 5.1, 2.9 and 1.6 ng/mg at 6, 18, 54, 90 and 126 kg BW, respectively. Urinary IC was elevated in small birth weight pigs initially (at 6, 18 kg BW) but not at later stages of growth. Urinary IC at 54 and 90 kg BW was negatively associated (P<.02) with efficiency of feed utilization from BW of 36-72 and 72-108 kg, respectively, but not daily BW gain. Each 1 ng increase in urinary IC at 54 and 90 kg BW was associated with an additional .02 and .04 kg of feed per unit BW gain. From the last 75 pigs to reach 126 kg BW, pigs (11 pigs/group) with mean urinary IC at 54-90 kg BW in the highest and lowest 15% of the sample population were killed at 135 kg BW and their carcass traits evaluated. The high urinary IC pigs possessed greater subcutaneous backfat (20.8 vs. 16.6 mm, tenth rib) and leaf fat (1.94 vs. 1.31 kg). Based on these data, greater oxidative stress in pigs is associated with less efficient feed utilization and the accumulation of body fat.

Key Words: Isoprostanes, Energetic Efficiency, Pigs

881 The impact of coating on thermostability and bioefficacy of phytase in weaned pigs fed corn-soybean meal based diets. A. Owusu-Asiedu[1], P. H. Simmins[1], J. L. Landero[2,3], and R. T. Zijlstra*[3], [1]*Danisco Animal Nutrition*, *Marlborough, UK*, [2]*Universidad Autónoma de Baja California*, *Mexicali, México*, [3]*University of Alberta*, *Edmonton, AB, Canada*.

A study evaluated the effects of a new coating on thermal tolerance and bioefficacy of a bacteria-derived, phytase product Phyzyme XP (6-phytase, EC 3.1.3.26; U-phytase) against the same phytase with a thermo-protective coating (Phyzyme XP-TPT; C-phytase) in weaned pigs fed corn-soybean meal-based diets. Individually-housed 28-day-old pigs weaned at 21 d with average initial BW of 8.20 kg (8 pigs per treatment) were randomly allotted to 7 dietary treatments based on corn-soybean meal for a 21 d. The treatments were: 1, Positive Control (PC) mash; 2, Negative Control (NC) mash; 3, NC pelleted at 90°C; 4, NC + 500 U/kg U-phytase; 5, NC + 500 U/kg C-phytase; 6, NC + 500 U/kg C-phytase pelleted at 80°C; and 7, NC + 500 U/kg C-phytase pelleted at 90°C. The PC and NC diets were formulated to be isocaloric and isonitrogenous. Calcium content was 1.01 and 0.83% and available P content was 0.40 and 0.22% in the PC and NC diets, respectively. Pig BW and feed intake were measured on d 7, 14, and 21. Data were analyzed as a CRD using ANOVA. Pigs fed the PC performed better than those fed the NC (P<0.05). Both the U-phytase and C-phytase increased ADG and improved G:F (P<0.05) but not ADFI in mash diets compared with the negative control. Compared to NC diets pelleted at 90°C, G:F for C-phytase diet pelleted at 90°C improved (P<0.05) by 16%. Other performance variables were not significantly different (P>0.05) in pigs fed C-phytase in mash diets or diets pelleted at 80 and 90°C diets compared with U-phytase diet. In conclusion, in diets limiting in Ca and P, a coated phytase product in mash or diets pelleted at 90°C improved performance of weaner pigs indicating that phytase bioefficacy remained intact.

Key Words: Phytase, Pelleting, Weaned pig

882 Enzymatic comparisons of *Aspergillus niger* PhyA and *Escherichia coli* AppA2 phytases. A. H. J. Ullah[2], J. D. Weaver*[1], K. Sethumadhavan[2], E. J. Mullaney[2], and X. G. Lei[1], [1]*Cornell University*, *Ithaca, NY*, [2]*SRRC, ARS, USDA*, *New Orleans, LA*.

Both *Aspergillus niger* PhyA and bacterial *Escherichia coli* AppA2 have been used to increase phosphorus bioavailability and decrease excreta phosphorus content in simple-stomached animals. Although different feeding efficiencies have been observed with these two phytases, it remains unclear whether or not this difference is due to inherent enzymatic properties of these proteins. The objective of our study was to compare the kinetic properties of these two enzymes at the commonly observed stomach pH 3.5. Both PhyA and AppA2 were expressed in the same *Pichia pastoris* host using a constitutive expression system, and purified to >95% homogeneity using two steps of ion-exchange chromatography. While AppA2 had a lower affinity

to phytate with a higher K_m (74 vs. 34 μM, P < 0.01) than PhyA, this bacterial enzyme displayed a greater (P < 0.01) V_{max} (1,070 vs. 120 μmol min^{-1} mg^{-1}), k_{cat} (840 vs. 170 sec^{-1}) and k_{cat}/K_m ($1.1x10^7$ vs. $0.5x10^7$ M^{-1} sec^{-1}) than that of PhyA. PhyA and AppA2 had optimal temperatures of 65°C (pH 5.0) and 58°C (pH 3.5), respectively. Both enzymes had two pH optima at 37°C: PhyA with a peak at 2.0 and a greater peak at 5.5, while AppA2 had a peak at 3.4 and a greater peak at 5.0. PhyA was nearly twenty times more resistant to competitive inhibition by myo-inositol hexasulfate than AppA2 (K_i = 3.9 vs. 0.2 μM). Likewise, 4 times more (1.4 vs. 0.3 M) guanidine hydrochloride was required to produce the same 50% inhibition of enzyme activity for PhyA than AppA2. Overall, AppA2 possesses superior kinetic properties compared to PhyA at pH 3.5, which helps in catalyzing phytate hydrolysis at commonly observed gastric conditions of simple-stomached animals.

Key Words: Phytase, Kinetics, Enzymology

883 Effects of dietary electrolyte balance and molasses in diets with corn-based distillers dried grains with solubles on growth performance in nursery and finishing pigs. C. Feoli*[1], J. D. Hancock[1], S. M. Williams[1], T. L. Gugle[1], S. D. Carter[2], and N. A. Cole[3], [1]*Kansas State University*, *Manhattan*, [2]*Oklahoma State University*, *Stillwater*, [3]*USDA/ARS*, *Bushland, TX*.

Two assays were conducted to determine the effects of dietary electrolyte balance (dEB) and molasses in diets with corn-based distillers dried grains with solubles (DDGS, Sioux River Ethanol, Hudson, SD) on growth performance of nursery and finishing pigs. For the first experiment, 126 nursery pigs (35 d old and avg BW of 10.2 kg) were assigned with six pigs/pen and seven pens/treatment. Treatments were a corn-soybean meal-based control and diets with DDGS as 30% of the formula without and with 0.93% sodium bicarbonate to bring dEB to 64 meq/kg [(Na + K) × (Cl + S)] as in the control. Diets were formulated to 1.4% Lys, 0.75% Ca, and 0.35% available P. Pigs fed the control diet had greater ADG (P < 0.03) and ADFI (P < 0.08) but did not differ in G:F (P > 0.6) compared to those fed diets with DDGS. Addition of sodium bicarbonate did not improve growth performance (P > 0.3). For the second experiment, a total of 70 gilts (avg BW of 60.5 kg) were assigned with two pigs/pen and five pens/treatment. The pigs were fed the experimental diets for 26 d, fed a common diet for 6 d, and then reassigned to a different treatment for an additional 26-d assay. The end result was 10 pens per treatment. Treatments were a corn-soybean meal-based control and diets with DDGS as 40% of the formula without and with 5% molasses and sodium bicarbonate (none, 1, and 2%) arranged as a 2 x 3 factorial plus control. Diets were formulated to 0.9% Lys, 0.6% Ca, and 0.22% available P. Pigs fed the control diet had greater ADG and ADFI (P < 0.001) but did not differ in G:F (P > 0.4) compared to those fed diets with DDGS. Adding molasses and(or) sodium bicarbonate did not affect ADG (P > 0.5) or ADFI (P > 0.14) and adding molasses actually decreased (P < 0.03) G:F. In conclusion, adding sodium bicarbonate and(or) molasses to diets with DDGS did not improve growth performance in nursery or finishing pigs.

Key Words: Distillers Dried Grains, dEB, Pig

Physiology & Endocrinology - Livestock and Poultry: Reproductive Physiology

884 Emerging concepts regarding the integration of neuroendocrine signals that regulate gonadotropin secretion in domestic livestock. C. A. Lents*[1] and C. R. Barb[2], [1]*The University of Georgia*, *Athens*, [2]*USDA-ARS, Russell Research Center*, *Athens, GA*.

The pulsatile discharge of GnRH from hypothalamic neurons is obligatory for the synthesis and release of the pituitary gonadotropins. Many conditions have been characterized that reduce gondadotropin secretion and result in anovulatory states which contribute to inefficiencies in livestock production. Nutrient intake, body energy reserves, suckling, and season are all major regulators of gonadotropin secretion in mammals. Lack of adequate gonadotropin secretion during the pre-pubertal and postpartum periods adversely impact the reproductive efficiency of domestic herds and flocks. These various anovulatory states typically have one fundamental similarity; a lack of hypothalamic release of GnRH. For the most part, pituitary function remains intact, as indicated by the release of gonadotropin from the anterior pituitary gland in response to exogenous GnRH. Identifying the hormonal and metabolic factors that mediate the central effects of these factors on the GnRH neuronal network in the brain has been an intensely studied area. Additionally, season and metabolic status seems to enhance the central mechanism of estradiol negative feedback on LH secretion. Despite much progress, identifying the mechanisms that directly mediate these actions on GnRH neurons in a consistent and well regulated fashion has proven difficult. For example, GnRH neurons appear to lack estrogen receptors, suggesting that feedback effects of estrogen are mediated through interneuronal systems. A role for the peptide hormone kisspeptin as a major regulator of gonadotropin secretion has recently emerged. Recent reports have demonstrated a potential role of kisspeptin in regulating the onset of puberty as well as mediating metabolic and photoperiodic control of reproduction in rodents. The purpose of this review is to summarize what is currently known regarding kisspeptin in domestic livestock and postulate the role it may have in regulating reproductive function of these larger mammalian species.

Key Words: Kisspeptin, Gonadotropin, Reproduction

885 Effects of human chorionic gonadotropin (hCG) and gonadotropin releasing hormone (GnRH) on follicle and corpus luteum dynamics and concentrations of progesterone in pre-pubertal Angus heifers. C. R. Dahlen*[2], J. E. Larson[1], G. Marquezini[1], and G. C. Lamb[1], [1]*North Central Research and Outreach Center, University of Minnesota*, *Grand Rapids*, [2]*Northwest Research and Outreach Center, University of Minnesota*, *Crookston*.

We determined the effects of administering human chorionic gonadotropin (hCG) on subsequent follicle and corpus luteum dynamics and concentrations of progesterone in pre-pubertal heifers. Forty-seven purebred, pre-pubertal Angus heifers were stratified by age and weight and assigned randomly to one of three treatments: 1) heifers received a 100 μg injection of GnRH (GnRH; n = 16); 2) heifers received a 1,000 IU injection of hCG (H1000; n = 16); and 3) heifers received a 500 IU

injection of hCG (H500; n = 15). From d -1 to 9 relative to treatment daily blood samples were collected to determine concentrations of progesterone and ovaries of each heifer were examined daily by transrectal ultrasonography using a 7.5Mhz transducer. Diameter of all follicles larger than 5 mm and all corpora lutea (CL) were measured and recorded. A greater percentage ($P < 0.05$) of heifers in the H1000 treatment (87.5%) ovulated compared with GnRH heifers (43.8%), whereas H500 heifers (73.7%) were intermediate. A greater percentage ($P < 0.05$) of H1000 (87.5%) and H500 (73.3%) heifers developed a CL compared with GnRH heifers (18.8%). The largest follicle present on ovaries of H1000 and H500 heifers was smaller ($P < 0.05$) from d 2 to 5 than that of GnRH heifers. Concentrations of progesterone peaked on d 6 for all treatments. Heifers treated with H1000 (1.72 ng/ml) had peak concentrations of progesterone that were greater ($P < 0.05$) than H500 heifers (1.34 ng/ml), which were greater ($P < 0.05$) than heifers treated with GnRH (0.31 ng/ml). Mean volume of luteal tissue was greater ($P < 0.05$) in H1000 heifers (1.54 cm^3) than in H500 heifers (1.15 cm^3), which was greater ($P < 0.05$) than in heifers treated with GnRH (0.23 cm^3). We concluded that hCG was more effective than GnRH in its ability to ovulate follicles, increase volume of luteal tissue in the subsequent developing CL, and concentrations of progesterone in pre-pubertal heifers. In addition, hCG appears to be more effective when administered at 1,000 IU than 500 IU.

Key Words: Human Chorionic Gonadotropin, Estrous Synchronization, Beef Heifers

886 Increasing ovulation rate reduced follicle size and increased blood progesterone concentrations but had no effect on fertility in cattle selected for twins. S. E. Echternkamp*, R. A. Cushman, and M. F. Allan, *USDA, ARS, U.S. Meat Animal Research Center*, *Clay Center, NE*.

Smaller ovulatory follicles (F) and lower progesterone concentrations during the luteal phase after breeding reportedly decrease fertility and embryonic survival in cattle. Diameter of individual F and corpora lutea (CL), blood progesterone concentrations, and conception to AI were compared among cows with ovulation rate (OR) records of one (n = 74), two (n = 253), three (n = 88), or four (n = 6) CL in 2004 to 2006; herd mean for OR was 2.09. Number and diameter of F and subsequent CL were determined by ultrasonography at 12 h after onset of estrus and 8 to 15 d after AI, respectively, and number of fetuses at 60 d after AI. Progesterone was quantified by RIA in a single blood sample collected at CL diagnosis. Data were analyzed by SAS PROC MIXED procedures; main effects in the models were OR, day, fetal status, and year. Follicle diameter was smaller ($P < 0.01$) in 2006. Follicle and CL diameter were correlated ($r = 0.53$; $P < 0.01$) and decreased ($P < 0.01$) with increasing OR (1 CL = 17.1 ± 0.3 and 23.3 ± 0.4 mm, 2 CL = 14.0 ± 0.1 and 20.2 ± 0.4 mm, 3 CL = 12.6 ± 0.2 and 18.1 ± 0.3 mm, 4 CL = 11.7 ± 0.5 and 16.7 ± 0.7 mm, respectively), but diameter were similar for fertile (fetus) and infertile ovulations (13.9 ± 0.1 and 19.8 ± 0.4 mm vs. 13.8 ± 0.1 and 19.4 ± 0.4 mm, respectively). Fetal number per female increased ($P < 0.01$) with OR (0.56 ± 0.11, 1.04 ± 0.06, 1.47 ± 0.10, and 1.80 ± 0.26 for 1, 2, 3, and 4 CL, respectively), but the fetus:ovulation ratio (0.52 ± 0.3) was unaffected. OR did not affect pregnancy rate (65.6 ± 0.3%) at 60 d after AI. Progesterone concentrations increased ($P < 0.01$) with OR (1 CL = 7.1 ± 0.3, 2 CL = 8.9 ± 0.2, 3 CL = 9.7 ± 0.3, 4 CL = 8.5 ± 0.7 ng/ml) and from d 8 (6.3 ± 0.5 ng/ml) to 14 (10.6 ± 0.5 ng/ml). Progesterone concentrations did not differ between pregnant and nonpregnant cows (8.8 ± 0.3 vs. 8.2 ± 0.3 ng/ml). Decreased follicle size and increased progesterone in cows with natural multiple ovulations did not affect conception.

Key Words: Cattle, Fertility, Ovulation Rate

887 Altered liver gene expression and reproductive function in postpartum suckled beef cows on different planes of nutrition. M. Bionaz*[1], F. Samadi[2], M. J. D'Occhio[2,3], and J. J. Loor[1], [1]*University of Illinois*, *Urbana*, [2]*The University of Queensland*, *Gatton Campus, Australia*, [3]*CRC for Beef Genetic Technologies*, *Gatton Campus, Australia*.

The effect of caloric restriction on long-term liver gene expression was evaluated using Droughtmaster cows (n = 5/diet) assigned to improved (IP) or moderate pasture (MP) from 6 mo of gestation through 14 wk of lactation. Ovarian follicular status and blood IGF-1, insulin, and glucose postpartum were determined weekly. Liver was biopsied at 1, 6, and 14 wk postpartum and RNA used to measure expression of genes (qPCR) with key functions in fatty acid metabolism (*PPARA*, *CPT1A*, *ACOX1*, *ADIPOR2*, *HNF4A*, *SREBF1*), cholesterol metabolism (*APOB*, *HMGCR*, *PPARD*, *SREBF2*), insulin signaling (*IRS1*, *FRAP1*), gluconeogenesis (*PCK1*, *FBP1*, *PC*), reproductive function (*IGF1*, *GHR*, *SHBG*, *SIRT1*), signal transduction (*IGFBP1*), regulation of cell growth (*IGFBP2*), and oxidative stress (*SOD1*). Cows on IP had greater ($P < 0.05$) BW (+57 kg) and BCS (3.7 vs. 2.3) at parturition, and greater plasma concentrations of insulin (5.9 vs. 3.8 μIU), glucose (3.9 vs 3.4 mmol/L), and IGF-1 (191 vs. 145 ng/mL) postpartum. All IP cows resumed ovulation between 12-15 wk postpartum compared with only one MP cow. Effects of caloric restriction on liver gene expression were most evident at wk 6 when IP cows had greater ($P < 0.05$) expression (1.5 to 2.9-fold) of *ACOX1*, *ADIPOR2*, *CPT1A*, *FRAP1*, *GHR*, *HNF4A*, *IRS1*, *PPARA*, *PPARD*, *SCD*, *SHBG*, *SREBF1*, and *SREBF2*. Temporal effects of diets on gluconeogenesis, cholesterol synthesis/metabolism, and oxidative stress were most apparent between wk 1 and 6, with MP resulting in lower (time × diet $P < 0.06$) mRNA (-1.4 to -2.3-fold) of *HMGCR*, *PC*, *APOB*, *PPARD*, and *SOD1* at wk 6. *IGFBP1* increased between wk 1 and 14 with both IP and MP. However, on wk 6, *IGFBP1* was 3.7-fold greater with MP vs. IP (time × diet $P < 0.05$). *IGFBP2* was greater with MP vs. IP at wk 1 (2-fold), but decreased linearly through wk 14 compared with IP. *SCD* and *SREBF1* expression was lower with MP throughout lactation, suggesting reduced desaturation and fatty acid synthesis in liver. Delayed resumption of ovulation with caloric restriction might be linked to altered metabolic homeostasis driven at least in part by liver genomic adaptations.

Key Words: Liver, Reproduction, Caloric Restriction

888 Luteal function at day 30 of pregnancy in relation to serum progesterone in dairy cows at risk for late embryonic or early fetal mortality. J. D. Rhinehart*[1], J. A. Flores[1], R. A. Milvae[2], and E. K. Inskeep[1], [1]*West Virginia University*, *Morgantown*, [2]*University of Connecticut*, *Storrs*.

Pregnancy failures during placentation have been associated with low concentrations of peripheral serum progesterone (P_4) in lactating dairy cows. Experiments were done to determine if luteal function and/or metabolic clearance rate of injected P_4 differed for cows with high or

low concentrations of serum P_4 on approximately d 30 of gestation. Luteal tissue was removed from pregnant cows with ≥ 4.0 ng/mL (H) or ≤ 2.5 ng/mL (L) serum P_4 during d 28 to 34 post-insemination. Luteal tissue was analyzed for P4 by radioimmunoassay and mRNA expression of preproendothelins 1 and 3, endothelin converting enzyme, endothelin receptors A and B, cyclooxygenase-2, aldoketoreductase 1B5, 15-hydroxyprostaglandin dehydrogenase, and prostaglandin E synthase by real-time RT-PCR. Dispersed luteal cells were incubated for 2 h with bovine luteinizing hormone (bLH) or arachidonic acid (AA), increasing (10^{-10} to 10^{-7}) concentrations of endothelin-1 (ET-1), and combinations of ET-1 and bLH or AA. Neither luteal content of P_4 (mean 106.0 ± 3.3 µg) nor mRNA for genes investigated were correlated with serum P_4 at lutectomy. Both basal and LH-stimulated P_4 secretion from dispersed luteal cells were inhibited ($P < 0.05$) by ET-1 in a dose dependent manner. This inhibition was greater ($P < 0.05$) for luteal cells from L vs. H cows cultured with ET-1 and AA. To evaluate P_4 catabolism, cows were injected s.c. with 150 mg P_4 every 12 h beginning at lutectomy. In jugular blood collected every 4 h until h 48, serum P_4 was maintained at lower ($P < 0.05$) concentrations for L vs. H cows. Area under the curve was less ($P < 0.05$) for L (49.6 ± 6.2) vs. H (83.6 ± 12.5) cows. Metabolic clearance was more important in regulating peripheral concentrations of P than luteal production. However, luteal sensitivity to co-culture with ET-1 and AA was enhanced for cows with low serum P_4. Management practices that reduce metabolic clearance rate of P_4 might decrease late embryonic or early fetal mortality as efficiently as supplementation with exogenous progestogens. Supported by USDA-CSREES-NRI 2002-35203-12230.

Key Words: Embryonic and Fetal Mortality, Progesterone, Lactating Dairy Cow

889 Effect of seminal plasma and transforming growth factor (TGF)-β1 treatment on pregnancy outcome in beef cattle. J. F. Odhiambo*[1], I Holásková[1], J. D. Rhinehart[1], D. H. Poole[2], J. M. DeJarnette[3], E. K. Inskeep[1], and R. A. Dailey[1], [1]*West Virginia University*, *Morgantown*, [2]*Ohio State University*, *Colombus*, [3]*Select Sires Inc*, *Plains City, OH*.

The role of post-mating inflammatory response on pregnancy outcome has been described in rodents, pigs and humans. Transforming growth factor (TGF)-β1 was identified as the active inflammatory-inducing moiety derived from seminal vesicles (Tremellen et al., 1998). The present studies tried to examine in beef cattle the significance of pre-sensitization of the uterus before or at breeding with seminal antigens on pregnancy outcome. Spring calving beef cows (n = 1083) were synchronized for estrus and assigned randomly to treatments during 2003 to 2006. In Trial 1, treatments included 0.5 ml seminal plasma (SP), 80 ng/ml rhTGF-β1 suspended in bovine serum albumin (BSA) and 0.5 ml BSA (control). In Trial 2, two treatments SP and BSA were examined. Trial 3 compared treatment with SP or no treatment (control). Treatments were infused at onset of estrus (12 h before insemination) in Trial 1 or at inseminations (Trial 2 and 3). Pregnancy data were examined by contingency analysis and least squares analysis of variance using the GLM procedures of SAS for effects of treatment, time of treatment, age of cow, year, and their second and third order interactions. Differences were considered significant at $\alpha = 0.05$. In Trial 1, pregnancy rates did not differ (53.1, 54.7 and 54.8 % for BSA, SP and TGF-β1 respectively). In Trial 2, TGF-β1 tended to improve pregnancy outcome compared to SP or BSA in 2005 (49.2 vs. 33.1 and 38.4 %, respectively). In a separate 2005 study, pregnancy rates were 59.4 and 67.0 % for BSA and SP, respectively and tended to be affected by time of insemination. In Trial 3, pregnancy outcome was not different between SP or control, 61.4 and 52.4 % respectively. However, interactions of farm by treatment existed. The data obtained from these studies did not provide any conclusive evidence for the effect TGF-β1 or seminal plasma on pregnancy outcome in beef cattle, although TGF-β1 might improve pregnancy rates when fertility is compromised.

Key Words: Seminal Plasma, TGF-β1, Pregnancy

890 Prolactin and luteinizing hormone profiles during the reproductive cycle in the native Thai chicken. S. Kosonsiriluk[1], N. Sartsoongnoen[1], N. Prakobsaeng[1], I. Rozenboim[2], M. E. El Halawani[3], and Y. Chaiseha*[1], [1]*Suranaree University of Technology*, *Nakhon Ratchasima, Thailand*, [2]*The Hebrew University of Jerusalem*, *Rehovot, Israel*, [3]*University of Minnesota*, *Saint Paul*.

Unlike Gallinacous-temperate zone birds, the reproductive cycle of the native Thai chicken, an equatorial non-photoperiodic continuous breeder consists of three reproductive stages including laying (LAY), incubating (INC) and rearing of young (R). In temperate zone birds, luteinizing hormone (LH) and prolactin (PRL) levels vary during the four reproductive stages with the high PRL levels observed during the incubation phase are responsible for the suppression of gonadotropic hormones and ovarian steroids, follicular atresia, termination of egg laying activity and induction of incubation behavior. PRL action on the reproductive neuroendocrine system has been shown to be mediated by its feedback effects on the hypothalamus, pituitary and ovary. The objective of this study was to establish baseline information on the neuroendocrine changes (LH and PRL levels) associated with reproductive stages of the native Thai hens. Chickens were classified into three stages: LAY, INC and R (n=10). Blood samples were collected for determining plasma PRL and LH levels by Enzyme-Linked immunoSorbent Assay. Daily records were kept of egg production and nesting activity during the reproductive cycle. The results revealed that PRL levels (ng/ml) were low in R (24.1±1.9), intermediate in LAY (40.4±12.6) and highest in INC (351.9±37.1, $P<0.05$). There were no changes ($P>0.05$) in LH levels across the reproductive stages. Levels were 3.4±0.3, 3.7±0.4 and 3.2±0.1 ng/ml, whereas ovarian weights were ($P<0.05$), 35.9±0.9, 3.1±1.2 and 1.9±0.9 gm for LAY, INC and R, respectively. The finding that ovarian regression occurred in INC and R hens in the absence of a decline in LH levels is interpreted as an adaptive mechanism(s) allowing for reinitiating egg laying activity in case of nest destruction at any time and irrespective of the season. The finding further suggest the antigonadotropic effect of PRL is limited to its effect on the ovary.

Key Words: Bird, Luteinizing Hormone, Prolactin

891 The effect of active immunization against vasoactive intestinal peptide and inhibin on semen production of young and aged roosters. I. Rozenboim* and N. Avital, *Hebrew University of Jerusalem, Faculty of Agriculture, Department of Animal Science*, *Rehovot, Israel*.

Low levels of fertility are causing major economic losses in poultry breeder farms. The objective of this study was to investigate the effect of active immunization against VIP and inhibin on semen production and quality of roosters at different ages. Exp. 1. Sixty WL roosters at 19 wk of age were divided to 4 groups (n=15): 1) control, 2) VIP immunized, 3) Inhibin immunized and 4) immunized against VIP and inhibin. Semen quality was measured every 2 wks, blood samples were collected every other week for plasma steroid levels. At 41 wks of age roosters were killed, hypothalamai pituitaries and testicular tissue were removed and stored for mRNA analysis of GnRH, VIP and LH, FSH, prolactin and LH and prolactin receptors respectively. Exp. 2. Sixty WL roosters at 67 wk of age were treated similarly as in exp 1. All measurements conducted in exp. 1 were similarly conducted. Exp. 3. Twenty eight WL roosters at 97 wk of age were divided to 4 groups (n=7): 1) control, 2) VIP immunized, 3) control + prolactin (1mg/day/bird for 7 days) and 4) VIP immunized + prolactin (1mg/day/bird for 7 days). Results: combined immunization (VIP+inhibin) in young roosters significantly ($P<0.05$) increased semen quality compare to control birds (volume: 0.78 ± 0.01 ml vs. 0.6 ± 0.01 ml, concentration: 3.7×109 vs. 3.5×109 (cells/ml) and mobility 0.6 vs. 0.2 O.D.). In elderly birds VIP immunization significantly ($P<0.05$) reduced semen concentration, volume, motility and mobility compare to all other treatment groups. In addition active immunization against inhibin significantly increased mobility value compare to control group (1.4 vs. 0.9 O.D.) and semen motility (8 vs. 7.2) Prolactin administration (Exp. 3) to old roosters previously actively immunized against VIP significantly improved semen quality manifested by increase in concentration from $2.1 \times 109 \pm 0.1$ to 3.1×109 (cells/ml), mobility from 0.9 to 1.15 and motility from 6 to 7.5. As in mammalian species, prolactin was found to be involved in semen production of old roosters. The mechanism of this phenomenon involves testicular prolactin and LH receptors, since prolactin significantly elevated testicular LH receptors mRNA in this study.

Key Words: Rooster, Semen, Prolactin

892 Chicken epiregulin (ER) gene: cDNA cloning, genomic organization, and regulation of its mRNA expression in ovarian granulosa cells. Y. Wang*, J. Li, and F. C. Leung, *The University of Hong Kong*, *Hong Kong, HK-SAR, China*.

Growing evidence suggests that epiregulin (ER), a ligand of epidermal growth factor receptor (EGFR), is involved in controlling follicular development in mammals. However, there is no information on its expression in the ovary of non-mammalian species including chicken. In this study, we first cloned the full-length cDNA of chicken epiregulin gene from ovary. The cloned cDNA is 948 bp in length and encodes a membrane-anchored precursor of 153 amino aicds, which shares high sequence identity (~59%) with its mammalian counterpart. Genomic structural analysis shows that chicken epiregulin gene spans approximately 8 kb on chromosome 4 and consists of 5 exons. Using RT-PCR assay, ER mRNA was detected to be expressed in embryonic (embryonic day 20), sexually immature (3 week), and mature ovaries (6 chickens used at each stage), suggesting a role of ER in ovarian development. Compared with the other six EGFR ligands, epiregulin appeared to be expressed at a low level. However, using semi-quantitative RT-PCR assay, epidermal growth factor (EGF), transforming growth factor-α (TGF-α) and heparin-binding epidermal growth factor-like growth factor (HB-EGF) have been demonstrated to be capable of inducing ER mRNA expression significantly in cultured ovarian granulosa cells from preovulatory follicle (F1) in a time-dependent manner. The expression of epiregulin reached the maximum at 4 h and was sustained at 24 h post-treatment. Moreover, phorbol 12-myristate 13-acetate (PMA), a potent protein kinase C (PKC) activator, could also significantly induce epiregulin mRNA expression in a dose-dependent manner, suggesting that PKC (or PKC-activated) signaling pathway may be involved in controlling ER expression in the chicken ovary. These findings suggest that ER is a potential paracrine/autocrine factor involved in controlling ovarian development and its expression is regulated by local ovarian factors including EGFR ligands from chicken ovary.

Key Words: Epiregulin, Chicken, Ovary

893 Effects of different cryopreservation methods on the glyocalyx of chicken spermatozoa. J. Pelaez and J. A. Long*, *Beltsville Agricultural Research Center*, *Beltsville*.

The carbohydrate-rich zone on the sperm surface is essential for inmunoprotection in the female tract and early gamete interactions. We recently have shown the glycocalyx of chicken sperm to be extensively sialylated and contain residues of mannose, glucose, galactose, fucose, N-acetyl-galactosamine, N-acetyl-glucosamine and N-acetyl-lactosamine. Our objective here was to evaluate the effects of cryopreservation on the sperm glycocalyx. Semen was pooled from 6 roosters, diluted 1:1 (Lakes pre-freeze diluent), cooled to 5°C and aliquoted for cryopreservation using 6% DMA, 11% DMSO or 11% glycerol. For the DMA method, semen was equilibrated for 1 min with DMA and rapidly frozen by dropping 25 µl aliquots into liquid nitrogen. For the DMSO and glycerol methods, semen was equilibrated for either 1 min (DMSO) or 20 min (glycerol), loaded into 0.25 ml straws and frozen (5 to -35°C, 7°C/min; -35 to -140°C, 20°C/min; nitrogen plunge). Thawed (rapid, DMA; moderate, DMSO, glycerol) semen was stained with 1 of 12 FITC-conjugated lectins (100 µg/mL; 30 min; 25°C; $100x10^6$ cells/mL). Samples counterstained with PI were assessed by flow cytometry. On the day of cryopreservation, aliquots of fresh semen were stained with the panel of lectins and PI. For each lectin, the Mean Fluorescence Intensity (MnFI) of live sperm was compared among fresh and frozen/thawed (fr/th) treatments (n=5 replicates). For the majority of lectins (10/12), the MnFI was higher ($P<0.05$) for fr/th than fresh sperm. Exceptions included lectins specific for sialic acid and α-fucose, where DMSO and glycerol treatments, respectively, had MnFI similar ($P>0.05$) to fresh sperm. Among the fr/th treatments, the MnFI of sperm cryopreserved with DMSO was higher ($P<0.05$) for 4/10 lectins, including those specific for N-acetyl-lactosamine and N-acetyl-glucosamine. These data indicate that surface carbohydrates are altered during cryopreservation, and that cryoprotectant type and fr/th rates affect the degree of modification. While the specific functions of these glycoconjugates are not known, it is likely that the observed differences in fr/th sperm contribute to the reduced fertility of cryopreserved chicken semen.

894 Testicular development in meishan and commercial crossbred prepubertal boars. J. J. Ford*, *U.S. Meat Animal Research Center*, *Clay Center, NE*.

Total daily sperm production and testicular size of adult boars increase in proportion to the number of Sertoli cells within the testis. Meishan

(MS) boars experience puberty at a younger age than commercial crossbred (CB) boars in association with earlier cessation of Sertoli cell proliferation and smaller postpubertal testicular size. The objectives of the current study were 1) to define changes in the production of anti-Mullerian hormone (AMH) and p27kip1, markers of Sertoli cell differentiation, in prepubertal MS and CB boars (n > 3/breed/d), and 2) to relate these changes with the pubertal expansion of the seminiferous tubules. Presence of AMH and p27kip1 were assessed by immunohistochemistry and densitometric analyses using a Bioquant Nova color imaging system. Testicular weights were similar (P>0.10) in MS and CB boars at 7, 28 and 49 d of age although CB boars had greater (P<0.01) body weight at these ages. Testes weights of MS increased more rapidly than in CB after 49 d of age and were greater (p<0.02) at 70, 91 and 112 d of age. Diameter of seminiferous tubules increased (P<0.01) at a younger age and to a greater extent in MS than in CB boars. Relative amount of AMH, a product of less mature Sertoli cells, increased in both breeds from 7 to 28 d. AMH then declined thereafter at a more rapid rate (P<0.001) in MS than in CB boars and was nearly absent at 70 d in MS and at 112 d in CB boars. Seminiferous tubules containing p27kip1 were first detected at 28 d in some MS and at 70 d in some CB boars (P<0.01) and increased in both breeds through 112 d. The earlier onset of pubertal development in MS boars was characterized by expansion of seminiferous tubules at a younger age in association with a more rapid decline in AMH production and an earlier increase in p27kip1, indicative of an earlier onset of Sertoli cell differentiation in MS relative to CB boars.

895 Transcript profiling of testes from boars divergently selected for testosterone production. M. S. Ashwell*, S. Druyan, C. M. Ashwell, and J. P. Cassady, *North Carolina State University*, *Raleigh*.

The objective of this research is to identify changes at the gene level associated with 10 generations of divergent selection for testosterone production in response to a GnRH challenge. After ten generations of selection, average testosterone levels were 75 and 200 ng/ml for the low and high lines, respectively. Lines were subsequently maintained using random selection. Testicles from five boars from each line in generation 21 were collected at 1, 30, and 120 days of age. Tissues were snap frozen in liquid nitrogen and stored at -80°C for transcript profiling using a 13,297-oligonucleotide swine microarray. RNA was extracted from all boars from both lines, pooled by age and line, fluorescently labeled with either Cy3 or Cy5, and hybridized to the arrays. Hybridization intensity data were LOWESS-normalized within and across the arrays and analyzed using ANOVA. In total, 25 genes showed differential expression with a false discovery rate of 8%. Ten of these 25 genes have no known function or characterization. Most of these 25 genes were found to be differentially expressed across ages and by the interaction of age and line. The ability to detect differences in gene expression between the lines that are related to the observed differences in testosterone level is in part a result of the degree of replication in the array. Two genes associated with steroid biosynthesis, steroidogenic acute regulatory protein and aromatase type II, were shown to be differentially expressed. Validation of these findings is underway using real-time PCR methods.

Production, Management & the Environment - Livestock and Poultry: The Evolving National Animal Identification System

896 The Canadian Livestock Traceability System. J. M. Stitt*, *Canadian Cattle Identification Agency*, *Calgary, Alberta, Canada*.

The Canadian Cattle Identification Agency (CCIA) is a not-for-profit National Agency, incorporated in 1998, and led by a Board of Directors, representing all sectors of the livestock industry. The mandate of CCIA is to establish and maintain an efficient Animal Health and Food Safety Identification and Traceability system. With the program fully implemented on July 1, 2002, CCIA has been successfully established as a leader in Animal Identification and Traceability. Guided by National Standards and operating Under the ID Regulations within the Federal Health of Animals Act, the CCIA, in partnership with the Canadian Food Inspection Agency (CFIA), has achieved 98-100% compliance nationally. The CCIA system provides multi-species services and currently houses the beef, dairy, bison and sheep trace back data and is offering services to pork and poultry. In 2003, the Canadian cattle industry committed to the transition from barcode dangle tags to Radio Frequency Identification Devices (RFID). The program is industry supported, sustainable and has proven invaluable through the recent BSE investigations. The Canadian System incorporates the 3 Key Pillars for Traceability; Animal Identification, Premises Identification and Animal Movement. Additionally, it offers Value-Added services, as required by industry. Age Verification is one example of a Value-Added service assisting in assuring market access. The program implementation was not easy and as we expand on the national infrastructure we continue to face challenges. The successful implementation and commitment to ongoing development of the National Livestock Traceability System can be attributed to:

- support from all sectors of the cattle industry across Canada

- national communications strategy

- shared industry/government partnership

- commitment for industry to lead the program

- commitment to keep the program user-friendly, cost-effective and scaleable

- the unfortunate but timely global Animal Health and Food Safety issues.

CCIA is committed to ensuring that all program components continue to meet and exceed evolving Domestic and International requirements.

Key Words: Traceability, Identification, CCIA

897 Issues surrounding existing and potentially disruptive RFID technologies for the identification of food producing animals. D. A. Blasi*, *Kansas State University*, *Manhattan*.

The primary objective of a voluntary US National Animal Identification System (NAIS) when fully operational is the integration of the

regulatory capacity of animal health. Several species working groups (bison, cattle and equine) initially recommended the implementation of low frequency (LF) radio-frequency identification (RFID) technology based on internationally recognized ISO 11784/11785 standards in order to achieve the goal of a 48-hour trace back when the system is fully operational. LF technology has been manufactured, on an industrial basis, since the mid 1990s and is used in multiple animal identification systems worldwide. The subsequent adoption of a technology-neutral position by USDA to ensure a level playing field for all types of technologies has created a surge of startup companies promising new technologies that are readily available off the shelf and capable of offering improved solutions to existing LF technology at a fraction of the cost. Emerging technologies have not been validated under a variety of livestock environments for transponder retention and read range performance. Moreover, performance standards do not exist for any existing technology at the present time. The USDA has recognized the importance of standardization within NAIS for ensuring compatibility across vendors and international recognition of identification technologies used within the system. The USDA has subsequently endorsed the use of ISO 11784/11785 standards for livestock producers who elect to use RFID in the NAIS with the proviso for establishment of voluntary consensus standards for emerging technologies in the US through the American National Standards Institute (ANSI). This institute could facilitate the acceptance of standards for emerging technologies at the international level. All technologies must be fairly and consistently evaluated in transparent testing environments. The development of this process is essential for ensuring that NAIS– approved technologies can achieve the primary objective while providing the most economical means of individual identification for the livestock producer.

Ruminant Nutrition: Intake Behavior/Acidosis/Metabolism - Dairy

898 Feed sorting in dairy cattle: Effects of repeated acidosis challenges. T. J. DeVries*[1], F. Dohme[2], and K. A. Beauchemin[1], [1]*Agriculture and Agri-Food Canada*, *Lethbridge, AB*, [2]*Agroscope Liebefeld-Posieux*, *Posieux, Switzerland*.

An experiment was conducted to determine if dietary forage content influences feed sorting by dairy cattle and whether this changes during acidosis. Eight ruminally cannulated cows were assigned to either a high (HF, 60% forage) or low forage (LF, 45% forage) diet (DM basis). Following a 2 wk adaptation, cows were exposed to 2 repeated acidosis challenges (2 periods) separated by 14 d. The challenge consisted of restricting feed to 50% of ad libitum intake for 24 h, followed by a meal of 4 kg of ground barley/wheat before ad libitum allocation of TMR (challenge day). Ruminal pH was measured continuously. Feed and orts were sampled for 2 baseline days, on the challenge day, and 1, 2 and 5 d after the challenge day for each animal and subjected to particle size analysis. The separator contained three screens (18, 9, and 1.18 mm) and a bottom pan to determine the proportion of long, medium, short and fine particles, respectively. Sorting activity was calculated as actual intake as a percentage of predicted intake. To determine if sorting occurred, each fraction was tested for a difference from 100%. The bout of acidosis following the challenge was more severe ($P<0.05$) in period 2 and was greatest ($P<0.05$) for cows fed LF. Cows fed LF sorted ($P<0.01$) for medium particles (107%), but against long (92%), short (98%), and fine particles (90%). Cows fed HF sorted ($P<0.01$) for medium (103%) and short particles (102%), but against long particles (89%). Overall, sorting for medium particles and against fine particles were greater ($P<0.01$) on the LF diet. Diet × period × day interactions ($P<0.01$) indicated that during period 2, LF cows decreased their sorting against long particles and increased sorting against short and fine particles on the day after the challenge when acidosis was most severe. These results suggest that the proportion of forage in the diet affects how dairy cows sort their feed. Furthermore, cows experiencing severe acidosis preferentially sort their feed to attenuate the effects of this disease.

Key Words: Acidosis, Sorting, Forage

899 Severity of ruminal acidosis increases with repeated bouts particularly when cows are fed low forage diets. F. Dohme*[1], T. J. DeVries[2], K. A. Beauchemin[2], K. M. Krause[3], and K. S. Schwartzkopf-Genswein[2], [1]*Agroscope Liebefeld-Posieux, Research Station ALP*, *Posieux, Switzerland*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, AB*, [3]*West Virginia University*, *Morgantown*.

An experiment was conducted to determine the response of cows to repeated acidosis challenges. Eight lactating ruminally cannulated cows were assigned to one of 2 diets (DM basis): high fiber (HF, 60% forage) or low fiber (LF, 45% forage). Following a 2-wk adaptation, cows were exposed to 3 acidosis challenges (3 periods), each separated by 14 d. The challenge consisted of restricting feed to 50% of *ad libitum* intake for 24 h, followed by a meal of 4 kg of ground barley/wheat before *ad libitum* allocation of TMR (challenge day). Ruminal pH was measured continuously. Total acidosis was defined as pH < 5.8, moderate acidosis as pH < 5.5, and severe acidosis as pH < 5.2. The entire grain allotment was consumed by all cows in Period 1, 6 cows in Period 2, and only 3 cows in Period 3. Despite reduced grain intake in each period, the severity of acidosis increased ($P < 0.05$) in each period: mean pH dropped by 0.13 pH units, minimum pH dropped by 0.20 units, and duration of total acidosis increased by 2 h/d. Furthermore, the severity of acidosis following the challenge was greater for cows fed LF compared to HF, as evidenced by diet × period interactions ($P < 0.05$) for area under the total acidosis threshold, area under the moderate acidosis threshold, and duration of acute acidosis. Those variables indicated that the severity of acidosis increased from Period 1 to 3 by 3 to 6-fold for cows fed LF and by 2 to 4-fold for cows fed HF. This study indicates that cows become more prone to acidosis over time even though they alter feed intake to avoid acidosis. The severity of each subsequent bout of acidosis increases, especially when cows are fed diets low in physically effective fiber. Therefore, a bout of acidosis that occurs due to improper feed delivery or poor diet formulation can have long-term consequences on cow health and productivity.

Key Words: Acidosis, Ruminal pH, Physically Effective Fiber

900 Grain-induced subacute ruminal acidosis (SARA) stimulates translocation of lipopolysaccharide (LPS) into the blood, and increases acute phase proteins in bovine plasma and milk. E. Khafipoor*, D. O. Krause, and J. C. Plaizier, *University of Manitoba*, *Winnipeg, MB, Canada*.

The effects of grain-induced subacute ruminal acidosis (SARA) on translocation of lipopolysaccharide (LPS) into the blood, and acute phase proteins in plasma and milk were determined in lactating Holstein cows. Between wk 1 and 5 of two successive 6 wk periods, cows received total mixed ration (TMR) ad-libitum with a forage-to-concentrate (F:C) ratio of 50:50. In wk 6 of both periods, SARA was induced by replacing, on average, 21% of DM of the TMR with pellets containing 50% wheat and 50% barley, resulting in a F:C ratio of 29:71. Rumen pH was monitored continuously using in-dwelling pH probes. Rumen fluid and peripheral blood samples were collected 15 min before feeding and 6 and 12 h after feeding for two days during wk 5 (control) and 6 (SARA). Induction of SARA significantly reduced average daily pH from 6.17 to 5.97 and increased the duration of rumen pH below pH 5.6 to above 180 min/d, which was taken as the threshold for SARA. SARA also reduced dry matter intake (16.5 vs. 19 kg/d), milk yield (28 vs. 31.2 kg/d), and milk fat (2.82 vs. 3.41%, 0.79 vs. 0.99 kg/d), but increased milk protein percentage (3.58 vs. 3.28 %) without affecting milk protein yield (0.94 vs. 0.98 kg/d). Concentrations of free-LPS in rumen fluid and blood plasma were also increased by SARA. In response to plasma LPS, blood concentrations of the acute phase proteins serum amyloid-A (SAA), haptoglobin (Hp), and LPS-binding protein (LBP) were increased during SARA. The data suggest that grain-induced SARA increases lysis of Gram-negative bacteria and translocation of LPS into the peripheral blood, and that this triggers an immune response.

Table 1. Rumen LPS, plasma LPS and acute phase proteins during SARA

Item	Control	SARA	P-value
Rumen LPS, EU/ml	28,400	107,700	0.005
Plasma LPS, EU/ml	<0.05	0.52	0.004
LBP in plasma, µg/ml	18.0	53.0	0.018
LBP in milk, µg/ml	3.00	6.94	0.02
Hp in plasma, µg/ml	0.0	484.0	0.001
SAA in plasma, µg/ml	77.6	218.6	0.01

Key Words: Subacute Ruminal Acidosis, Plasma LPS, Acute Phase Response

901 Induction of subacute ruminal acidosis (SARA) by replacing alfalfa hay with alfalfa pellets does not stimulate inflammatory response in lactating dairy cows. E. Khafipoor*, D. O. Krause, and J. C. Plaizier, *University of Manitoba*, *Winnipeg, MB, Canada*.

To determine if SARA induced by feeding diets with a short particle length results in similar increases in free bacterial lipopolysaccharide endotoxin (LPS) in rumen fluid and peripheral blood than grain-induced SARA, four rumen fistulated and four non-rumen fistulated dairy cows were used in a 6 wk study. During wk 1, cows received a diet containing 50% DM as concentrate and 50% DM chopped alfalfa hay. Between wk 2 and wk 6, alfalfa hay was gradually replaced with alfalfa pellets. Rumen fluid and peripheral blood were sampled before and 8 h after feeding. Rumen pH was monitored continuously in the rumen fistulated cows. Replacing alfalfa hay with alfalfa pellets reduced average daily pH (6.35 vs. 5.78), milk yield (35.9 vs. 32.7 kg/d) and milk fat (3.22 vs. 2.32%) and increased milk protein (3.04 to 3.80 %) and rumen VFA (90 to 122 mM). SARA was induced from wk 3 onwards when the rumen pH was lower than 5.6 for more than 180 min/d. Similar to grain-induced SARA, in this study SARA increased rumen LPS. However, this increase was not accompanied by feed intake depression, and increases in LPS and in the acute phase proteins serum amyloid-A (SAA), haptoglobin (Hp), and LPS-binding protein (LBP), in peripheral blood. This suggests that factors other than low rumen pH and increased free rumen LPS are responsible for the inflammatory response seen during grain-induced SARA. These factors might include rumen bypass starch, which has potential to alter microbiota and LPS release in the hind gut.

Table 1.

Item	Wk 1	2	3	4	5	6	P-value

902 Particle analysis of swallowed hay boluses varying in chop length. I. Schadt*[1], M. Caccamo[1], J. D. Ferguson[2], G. Azzaro[1], R. Petriglieri[1], P. Van Soest[3], and G. Licitra[1,4], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*University of Pennsylvania, School of Veterinary Medicine*, *Kennett Square*, [3]*Cornell University*, *Ithaca, NY*, [4]*D.A.C.P.A. University of Catania*, *Catania, Italy*.

Sufficient long fiber is critical in dairy rations to maintain normal rumen function. Effective NDF has been defined as material retained on a 1.18 mm sieve. Mertens further refined this to describe physically effective NDF as material that maintains acceptable rumination and milk fat content. Dietary particle size is altered as a cow chews to process feed material for swallowing. This project examined the long particle distribution in a swallowed bolus from hay of variable lengths. Three nonlactating, rumen fistulated cows, adapted to Loietto grass hay, were held off feed for 12 hours, rumens evacuated, and offered 0.25 kg of long or chopped hay. Swallowed boli were manually retrieved from the reticulo-rumen at the esophageal orifice. Treatments were as follows: 1) long hay, 2) hay cut to 5 cm lengths, 3) chopped hay retained on a 1.91 cm screen, 4) chopped hay which passed a 1.91 cm screen but retained on a .787 cm screen, and 5) chopped hay passing a .787 cm screen but retained on a .127 cm screen. Long particles in hay treatments and boli were defined as those retained on a 1.6 mm screen. Mean long particle size and distribution in hay treatments and boli were defined after Licitra et. al. (J. Anim. Sci. 83:supplement 1, 252). Mean long particle sizes (mm, (sd)) for treatments were as follows (superscripts differ by p<.05): 1) long hay, not determined, 2) 46.2^{a} (.6), 3) 51.0^{b} (.9), 4) 25.8^{c} (.3), and 5) 9.8^{d} (.1). Mean long particle

bolus sizes (mm, (sd)) by treatments were as follows (superscripts differ by p<.05):1) 9.1[a] (.1), 2) 9.1[a] (.1), 3) 9.5[b] (.1), 4) 9.0[a] (.1), and 5) 7.8[c] (.1). Chewing altered particle distribution so hay particles which were retained above a screen size of .787 cm were rather similar in mean size and distribution when swallowed. Dietary hay particles smaller than .787 cm were smaller in the swallowed bolus.

Key Words: Hay Particles, Bolus Particles, Dairy Cattle

903 Rumen function and lameness in pasture based dairy cows of the South Island of New Zealand. J. Gibbs*, J. Laporte-Uribe, C. Trotter, and J. Noel, *Dairy Science Group, Agriculture and Life Sciences, Lincoln University*, *Canterbury, New Zealand*.

Dairying in the South Island (SI) of New Zealand is pasture based, commonly with large herds (>600) and intensive pasture management with high feed quality across the lactation season. Lameness in this system is a dominant health and welfare concern, and a common industry explanation is sub-clinical laminitis due to the high sugar and low fibre of the pastures. This project sought to establish the incidence and profile of lameness in SI herds, and the characteristics of rumen function and any role it has in lameness, in SI systems. All lameness on 43 representative SI farms (>32000 cows) in 2005/06 was recorded. All cases had affected claw, diagnosis, and treatment recorded in a diary. Monthly pasture samples were obtained. Detailed ancillary information on farm management, infrastructure, nutrition, production, reproduction and lameness reduction strategies was obtained. Five cows in one herd were rumenally fistulated. For 96 h periods across the season, rumen pH and temperature were logged every 15s via indwelling probes. Rumen samples were obtained twice weekly for metabolite and microbiota assessment. The mean lameness incidence recorded was >22%. Pasture quality was very high with little variation across the season. Lameness was positively associated with herd size and pasture quality, but not infertility. Recorded pH values were low: up to 80, 20 and 10% of some trial periods were <6.0, <5.5, and <5.0, respectively. A daily pH trough of 5.0-5.5 was recorded in most cows across the season. Lactic acid was absent or <1 mmol/L, while volatile fatty acid profiles were typical of grass fed ruminants. Microbial profiles suggested major sub-populations changed little across the season. No clinical or production observations suggested rumen dysfunction. Conclusions: The incidence of lameness in 2005/06 in the SI appears higher than previously reported in similar systems in NZ and Australia. Several potential regional influences are suggested: large herd size, nutrition, and management. Rumen function in high production SI cows appears atypical, with marked diurnal pH trough and flux, yet stable metabolite production and microbiota.

Key Words: Dairy Pasture, Lameness, Rumen pH

904 Effect of lifecycle stage of dairy cattle on serum mineral concentrations. D. R. Bremmer[1], R. H. Schulte[2], and M. T. Socha*[3], [1]*Vita Plus Corporation*, *Madison, WI*, [2]*Modified Genetics*, *Marshfield, WI*, [3]*Zinpro Corporation*, *Eden Prairie, MN*.

Blood samples were obtained from Holstein cows on a commercial dairy to determine lifecycle stage effect on serum mineral concentrations. Samples, collected on 2 d, approximately 8 wk apart, were obtained from 40 cows in first 2 wk of dry period (Dry), 43 cows less than 2 wk prior to calving (Prefresh) and 40 cows in first wk of lactation (Postfresh). Effects included in data analysis model were sampling time and lifecycle stage, with significant period effects noted at P≤0.05. Serum concentrations of non-heme Fe and Mg were lower, Postfresh than in Dry and Prefresh periods (121.0 vs. 156.9, 158.0 µg/dL; 21.7 vs. 23.3, 23.5 µg/mL), while serum concentrations of Mo and Cu were higher, Postfresh than in Dry and Prefresh periods (24.9 vs. 4.9, 4.8 ng/mL; 0.84 vs. 0.70, 0.66 µg/mL). More Postfresh cows had less than adequate serum concentrations of non-heme Fe and Mg than Dry and Prefresh cows (42.5 vs. 2.5, 2.3%; 37.5 vs. 7.5, 7.0%), while more Prefresh and Dry Cows had less than adequate serum concentrations of Mo and Cu than Postfresh cows (100, 100 vs. 7.5%; 22.5, 32.6 vs. 2.5%). Serum Mn concentrations were higher in the Prefresh period than in the Dry period (1.48 vs. 1.20 ng/mL, P<0.05), with 82.5, 58.1 and 75.0% of Dry, Prefresh and Postfresh Cows having less than adequate Mn serum concentrations. Serum Co concentrations were highest, Prefresh, followed by Dry and Postfresh periods (1.18, 0.91 and 0.74 ng/mL). More Dry and Postfresh cows had less than adequate serum Co concentrations than Prefresh cows (15.0, 15.0 vs. 0.0%). Serum Zn concentrations were highest in Dry period, followed by Prefresh and Postfresh periods (1.77 vs. 1.65 vs. 1.34 µg/mL) while serum Se concentrations were highest, Postfresh, followed by Dry and Prefresh periods (103.7 vs. 91.8 vs. 82.4 ng/mL). All cows had adequate serum Se concentrations and only 2.5% of Postfresh cows had less than adequate serum Zn concentrations. Results of this survey indicate that cows on this dairy are most prone to Fe and Mg deficiencies, Postfresh, Cu and Mo deficiencies in Dry and Prefresh periods and Mn deficiencies in Dry, Prefresh and Postfresh periods.

Key Words: Serum, Dairy Cattle, Minerals

905 Phosphorus balance in dairy cows during lactation. J. A. Elizondo Salazar*[1], D. B. Beegle[1], J. D. Ferguson[2], and Z. Wu[2], [1]*Pennsylvania State University*, *University Park*, [2]*University of Pennsylvania*, *Kennett Square*.

Phosphorus balance in lactating cows was determined. Thirty multiparous Holsteins were fed 0.32% P during the dry period and assigned to one of the following three dietary treatments for the subsequent lactation: 0.36% P throughout the lactation (0.36-0.36-0.36), 0.36% P for 30 wk followed by 0.29% P for 14 wk (0.36-0.36-0.29), and 0.43% P for the first 10 wk, 0.36% P for the second 10 wk, and 0.29% P for the last 14 wk (0.43-0.36-0.29). Phosphorus balance was determined during wk -4 to -1, 9 to 13, 19 to 23, and 38 to 42 of lactation as intake P - fecal P - urinary P - milk P, when appropriate. While not different among treatment groups, the balance was negative for wk -4 to -1 and 9 to 13, became positive by wk 19 to 23, and showed a clear deposition during wk 38 to 42 for all groups. Consistent with the changes in P balance, plasma osteocalcin, a bone formation maker, increased during most of lactation, averaging 6.9, 9.4, 12.0, and 5.9 ng/ml for all groups, and plasma pyridinolin, a bone resorption marker, decreased, averaging 3.1, 2.8, 2.6 and 2.4 pg/ml, for wk -4 to -1, 9 to 13, 19 to 23, and 38 to 42, respectively. Rib bone P averaged 10.7 and 12.3% for all groups during wk -4 to -1 and 38 to 42, respectively, also consistent with the P balance data. Results suggest that cows mobilized P from bone during the dry period toward parturition and during early lactation, and restored P toward the end of lactation; this pattern of P metabolism did not differ when different amounts of P were fed. (Partially funded by Pennsylvania Department of Agriculture)

Table 1. Phosphorus balance (g/d)

Week	0.36-0.36-0.36	0.36-0.36-0.29	0.43-0.36-0.29	SEM	*P* Constant vs. varied P[1]	P changed once vs. twice[2]
-1 to -4[4]	-7.9	-7.9	-7.9	...	...	...
9 to 13	-3.0	-4.4	-0.5	4.3	0.55	0.82

Key Words: Dairy Cows, Phosphorus Requirement, Bone Phosphorus

906 Effect of 2-hydroxy-4-(methylthio) butanoic acid isopropyl ester on milk production and composition of high yielding lactating Holstein dairy cows. R. H. Phipps*[1], A. K. Jones[1], C. K. Reynolds[1], D. I. Givens[1], P-A. Geraert[2], and C. Richard[2], [1]*University of Reading*, *Reading, UK*, [2]*Adisseo*, *Commentary, France.*

Sixteen-multiparous, high yielding Holstein cows (72 ± 16 DIM; 45.0 ± 2.96 kg milk/d) were used, in a 4 × 4 Latin square design to determine the effect of 2-hydroxy-4-(methylthio) butanoic acid isopropyl ester (Metasmart®; 4.2 g/kg concentrate DM) and dietary crude protein (CP) content (low: 14.7 % vs. standard: 16.9 %, DM fed) on milk yield and composition in a 2 × 2 factorial design. All cows received ad libitum a TMR with a 1:1 forage to concentrate ratio (DM basis) and diets contained an estimated metabolizable lysine and methionine content of 6.7 and 1.8 % of metabolisable protein, respectively. Data for DM intake (DMI), milk yield and composition were obtained in wk 4 of each period. No significant treatment effects on DMI (24.7 ± 0.52 kg/d) were noted. There was a significant interaction between dietary CP and Metasmart® for milk yield, 3.5% fat-corrected milk (FCM) yield and yield of milk protein. Metasmart® increased milk yield by 0.5 kg/d (P < 0.05), 3.5% FCM yield by 1.3 kg/d (P < 0.05) and milk protein yield by 65 g/cow/d (P < 0.001) with 16.9 % dietary CP, but had no effect in the 14.7 % CP diet. Feeding Metasmart® increased milk protein content by 1.1 g protein/kg (P < 0.001), with values of 1.3 and 0.8 g/kg noted for standard and low CP diets, respectively. Although numerically higher at both levels of dietary CP, there was no significant effect of Metasmart® on milk fat concentration. In conclusion, feeding Metasmart® increased 3.5 % FCM yield and milk protein content after only 3 wks of supplementation. In addition, the effect of Metasmart® on milk protein and 3.5 %FCM yield was only observed at the standard level of dietary CP, suggesting other factors limited the response to Metasmart® when dietary protein supply was restricted.

Key Words: Dairy Cows, Milk Production, Amino Acid Supplement

907 Transport of 2-hydroxy-4-methyl-thio-butanoic isopropyl ester (HMBi) across rumen epithelium *in vitro*. W. Heimbeck*[1] and G. Breves[2], [1]*Degussa GmbH*, *Hanau, Germany*, [2]*Institute for Physiology, School of Veterinary Medicine*, *Hannover, Germany*.

Objective was to evaluate the potential of rumen epithelium to transport HMBi using Ussing chambers. Rumen tissues were obtained from a nearby slaughter house, stripped from the muscle layer, placed in buffer and gassed with 95:5 O2:CO2 before mounting. Two levels of HMBi (0.78 and 1.56 mg per ml) and 2 incubation times (120 and 180 min) were used in 12 chambers with 3 replicates with an exposed surface of 2 cm2. Four separate experiments were conducted (n= 48). Concentrations of HMBi and methionine hydroxy analog (HMB) were measured by HPLC in mucosal and serosal buffers. Data are expressed as % of added HMBi. Differences were assessed with GLM of SAS. Model included terms for experimental day, HMBi level, incubation time, sampling side and interactions. Adding the HMBi-buffer mixture to the mucosal side caused an immediate release of HMB (mean = 6.3%). Breakdown of HMBi to HMB at 0 time may be due to hydrolysis reactions in buffer or reactions at epithelial surface. A small but consistent amount of HMBi (mean 0.58%) was transferred to serosal buffer. A larger amount of HMB (8.94%, P<.01) was also isolated (about 0.06% per minute). Evidence of HMB in serosal buffer may indicate HMBi transfer and subsequent hydrolysis. Increasing dose elevated quantity but decreased % of dose appearing as HMB on the serosal side (10.54% and 7.33%, P<.01). Increasing incubation time increased the amount of HMB in the mucosal side buffer (34.0% at 120 min versus 43.4% at 180 min, P<.01) and decreased the amount of HMBi (37.9% at 120 min versus 28.1% at 180 min, P<.01). Small differences among experiments for recovery of HMB and HMBi were observed (MSD= 4.18 and 1.84 mucosal; 4.29 and 0.28 serosal). These data indicate that, if HMBi is transported actively, the system may be readily saturated. Alternatively, HMBi may move across the epithelium by diffusion. From these *in vitro* experiments, there is no evidence that rapid increases in blood HMB in response to HMBi intake are due to ruminal absorption.

Key Words: HMBi, Rumen Epithelium

908 Responses of rumen and blood metabolites of Holstein dairy cows to propylene glycol during frequent feeding. Y.-H. Chung*, C. M. Martinez, N. E. Brown, T. W. Cassidy, and G. A. Varga, *Dairy and Animal Science, Pennsylvania State University*, *University Park*.

The objective of the present experiment was to study the metabolic adaptation of Holstein dairy cows in response to propylene glycol (PG) when provided under different methods of delivery. By providing the same amount of pure PG, methods of delivery of PG assessed were: (1) control: no PG, (2) oral-drench: 226.8 ml (8 oz) of liquid PG (100% purity) oral drenched, (3) rumen-drench: 348.9g of dry PG (65% purity) drenched via rumen cannula, and (4) mixed: 348.9g of dry PG mixed into the TMR. Eight multiparous rumen cannulated Holstein dairy cows (DIM = 204 ± 104 SD) were fed PG for 4 d in a replicated 4 × 4 Latin square design with 14-d periods. On the last day of each period, cows were fed every 2 h to minimize postprandial effects. Blood was serially sampled from the jugular vein immediately before and for 4 h after PG administration. Rumen contents were serially sampled hourly for 4 h via the rumen cannula. Feed intake and milk yield were not affected by PG. Percentage of milk lactose was significantly increased by PG, across all methods tested in this experiment. The concentration of acetate was significantly decreased and propionate was significantly increased by PG (21.9 vs. 24.4 mol/100mol for control vs. PG treatments), regardless of delivery method. Concentration of butyrate was significantly decreased by PG

drench, either via oral or ruminal drench. Production of total VFA however was not statistically altered by PG. Serum insulin peaked significantly higher and more rapidly for cows receiving PG via drenching but not as a part of the TMR. Plasma glucose, however, tended to peak higher and more rapidly for cows receiving PG, regardless of delivery method. Results showed that rumen and blood metabolites responded similarly to liquid or dry PG drench indicating that top dressing dry PG is as effective as oral drenching liquid PG. Feeding dry PG as a part of the TMR during frequent feeding significantly altered the rumen profile toward a more glucogenic environment without stimulation of insulin.

909 Glucose minimal modeling in lactating dairy cows. R. C. Boston*[1], J. R. Roche[2], and P. J. Moate[1], [1]*University of Pennsylvania*, *Kennett Square*, [2]*University of Tasmania*, *Burnie, Tas, Australia*.

Quantification of the kinetics of glucose metabolism in lactating dairy cows may have application in elucidating the factors that control milk production or are involved in the etiology of metabolic diseases such as ketosis, fatty liver disease and downer-cow syndrome. For more than twenty years, researchers in the field of diabetes have used the Intravenous Glucose Tolerance Test (IVGTT) in humans, coupled with Bergman's non-linear "minimal model" (MinMod) to derive a rich set of parameters to describe the interaction between blood glucose and insulin. These parameters include: Glucose effectiveness (S_g), a first order rate constant describing its disappearance from blood, and Insulin sensitivity (S_I), which represents the capacity of insulin to promote the disposal of glucose from blood. Although more than 700 publications in human research have used the well-documented and carefully standardized IVGTT protocol and minimal modeling methodology, few studies in ruminant nutrition have used this approach. This investigation examined the capability of the standard (no insulin injection) IVGTT coupled with minimal modeling to obtain identified estimates of S_g and S_I in lactating cows. Ten lactating cows of diverse genetic origin and fed a wide range of diets, underwent a standard IVGTT with blood sampled at 0, 2, 4, 6, 8, 10, 12, 15, 18, 20, 23, 26, 30, 35, 40, 50, 60, 90, 120, 150, 180, 210, and 240 minutes. Plasma was measured for glucose and insulin. Minimal model analysis was conducted using MINMOD Millennium. The median, minimum and maximum estimates for S_g [% min^{-1}] were: 2.25, 1.12 and 3.44 and for S_I [10^{-4}(mU/L)$^{-1}$.min^{-1}], the corresponding estimates were 12.9, 8.7 and 17.1. In all individual cows, S_g and S_I were well identified with coefficients of variations less than 5%. The median estimate 2.25 for S_g is similar to the value of 2.2 reported for humans, but the median value of 12.9 for S_I in cows is surprisingly substantially higher than the value of 2.0 in humans. These findings suggest that glucose minimal modeling has great potential application in ruminant nutrition research.

Key Words: Glucose Effectiveness, Insulin Sensitivity, Minimal Model

Ruminant Nutrition: Lipid Supplementation

910 A decade of research developments in ruminant nutrition at the University of Wyoming. B. W. Hess*, *University of Wyoming*, *Laramie*.

Research efforts have focused on nutritional management practices to improve production efficiency of forage–fed ruminant animals, with primary emphasis on strategic supplementation regimens and secondary interest in alternative forage systems. The research program consists of three primary foci: 1) dietary lipids for ruminant animals; 2) protein nutrition of ruminant animals; and 3) the use of alternative forage crops and cropping methods in ruminant animal production systems. Interest in dietary lipids stems from the potential to alter fatty acid composition of food products derived from ruminants and the possibility to increase reproductive performance of ruminants through provision of supplemental vegetable oil. Investigations span from evaluating effects of supplemental lipids on site and extent of digestion to characterizing fate of fatty acids during metabolism and subsequent responses within various tissues and by the whole animal. Results of those endeavors suggest that vegetable oil may be added to forage–based diets at 3% of total DMI, tissue composition of fatty acids generally reflect fatty acids made available to the animal after ruminal biohydrogenation, and feeding cracked high–linoleate safflower seeds to beef cows during early lactation may have deleterious effects on reproduction and immune response by the suckling calf. The likelihood of livestock experiencing limited DMI in many range production systems has led to exploration of range management practices to enhance rangeland forage productivity and quality. Additionally, an interest in identifying specific nutrients involved with mediating various physiological responses within the animal has led to investigations centered on assessing essential AA status in ruminants fed limited amounts of roughage. An animal protein–based supplement has been developed to balance intestinal supply of essential AA in ruminants fed limited amounts of roughage. The research program is becoming more integrated as nutritional evaluations of rangeland forages indicate that strategic supplementation with lipids or protein may be warranted.

Key Words: Forages, Ruminants, Supplementation

911 Effect of dietary fish and soyoil supplementation on muscle fatty acid concentrations and oxidative lipid stability in beef cattle. D. A. Kenny*[1], J. P. Kelly[1], F. J. Monahan[1], and A. P. Moloney[2], [1]*University College Dublin*, *Dublin 4, Ireland*, [2]*Teagasc Grange Research Centre*, *Co. Meath, Ireland*.

The objective of this study was to examine level and duration of soyoil (SO) and fishoil (FO) supplementation on muscle fatty acid (FA) concentration and lipid oxidative stability in beef cattle. Young beef bulls (n=48) were blocked on age, bodyweight, and breed and individually offered ad libitum one of four isolipid and isonitrogenous diets for 100 days. All diets consisted of 10:90 (DM basis) straw:concentrate. The concentrates contained one of: (i) 6% SO (CON); (ii) 6% SO + 1% FO (FO1); (iii) 6% SO + 2% FO (FO2) or (iv) 8% palmitic acid for first 50 days and 6% SO + 2% FO for latter 50 days (FO2(50)). Palmitic acid was added to CON and FO1 to give 8% added lipid. The SO had 53% linoleic acid while the FO had 39%

EPA and 24% DHA. All diets were fortified with vitamin E. Following slaughter steaks were recovered from the M. longissimus dorsi (LD) and FA were analysed by GC. Lipid oxidative stability of LD was measured at 0, 24, and 72 h post cooking. The data were analysed using mixed models ANOVA with repeated measures as appropriate. Muscle concentrations of EPA and DHA were not different within FO treatments but were higher ($P < 0.001$) in all FO treatments compared with CON. Vaccenic acid (VA) the substrate for Δ-9 desaturase catalysed synthesis of c9, t11 CLA was higher in FO1 and FO2 compared with CON ($P < 0.01$) or FO2(50) ($P< 0.05$) but there was no difference ($P > 0.05$) between FO2(50) and CON. There was no effect ($P > 0.05$) of treatment on the concentration of c9, t11 CLA. The t10 c12 CLA isomer was higher in FO2 compared with the other treatments ($P < 0.05$). After 24 and 72 h post cooking, malondialdehyde (MDA) concentrations in CON were lower compared with the three fishoil treatments ($P < 0.01$). There was a tendency towards higher MDA in FO2 compared with FO1 at both 24 and 72h ($P = 0.08$). The lack of enhancement in c9, t11 CLA despite increases in tissue VA, suggest a possible direct inhibitory effect of ω-3 PUFA on Δ-9 desaturase activity. Furthermore, increasing ω-3 PUFA in the animals diet tended to reduce the oxidative stability of beef post cooking.

Key Words: Beef Cattle, CLA, Fatty Acids

912 Effects of feeding fresh and oxidized fat in the presence and absence of dietary antioxidant on lactation performance. M. Vazquez-Anon[1], G. Bowman*[1], T Hampton[1], P. Vazquez[2], T. Jenkins[3], and J. Nocek[4], [1]*Novus International*, *St Charles, MO*, [2]*Universidad de Santiago*, *Lugo, Spain*, [3]*Clemson University*, *Clemson, SC*, [4]*Spruce Haven Research*, *Union Springs, NY*.

The objective of the study was to evaluate the effect of feeding the dietary antioxidant AGRADO Plus® (AO; Novus International) in diets that contained 2 % fresh (FF) or oxidized (OF) soybean oil on milk production and composition and plasma antioxidant status of cows. Forty-four mid-late lactating primiparous cows were housed in a tie-stall barn and fed a diet that contained 2% FF for 15 days as adaptation period and them randomly allocated to the four dietary treatments (FF, FF+AO, OF, OF +AO) for six weeks. Feeding AO improved dry matter intake 3% ($P = 0.007$), milk yield 2.7% ($P = 0.08$), fat corrected milk 3.8% ($P = 0.01$), and milk fat yield 5.3% ($P = 0.01$). Feeding OF reduced dry matter intake 2.2% ($P = 0.04$) and BW at the end of the trial ($P = 0.05$) and increased milk fat yield 5.3% ($P = 0.02$). Feeding AO improved plasma total antioxidant status (TAS; $P = 0.002$) and the activity of antioxidant enzyme glutathione peroxidase ($P = 0.009$), whereas, feeding OF reduced TAS ($P = 0.003$) and increased accumulation of end products of oxidation in plasma ($P = 0.003$) at the end of the trial. It can be concluded that feeding OF reduced dry matter intake, BW, and the antioxidant status of the cow but improved milk fat yield. Feeding AO improved dry matter intake, milk yield and fat and the antioxidant capacity of the animal, independently of the degree of oxidation of the dietary fat.

Key Words: Antioxidants, Oxidized Fat, Agrado

913 The energetic and non–energetic effects of supplemental fish oil during the peripartum period on the metabolic status of multiparous Holstein cows. M. A. Ballou*, M. K. Yelle, R. C. Gomes, D. W. Kim, and E. J. DePeters, *University of California*, *Davis*.

The etiology of ketoacidosis and hepatic lipidosis during the peripartum period is complex. Increased energy demands and shifts in the hormonal and cytokine milieu play a role. In addition to its energy component, fish oil was shown to repress inflammation and alter gene expression profiles. The objectives were to evaluate the energetic and non–energetic effects of supplemental fish oil during the peripartum period on the metabolic status of multiparous cows. 42 Holstein cows were completely randomized to one of three treatments at 3 wk prepartum. Treatments were no supplemental lipid or supplemental lipid at either 250 g (prepartum) or 1% of the previous day's intake (postpartum), from either Energy Booster®(EB) or fish oil (FO). Supplemental lipid was fed as a bolus prior to the AM feeding. DMI was recorded daily; BW and BCS were measured at d -21, +1, +10, and +21. Peripheral blood samples were collected 3X weekly until 21 DIM. On d -21, -10, +1, and +14 a liver biopsy was performed to determine the FA, triglyceride, and glycogen concentration in the liver. Feed intake during the pre- and postpartum periods was not affected by either supplementing the diet with lipid or the source of lipid. Cows fed either lipid source lost similar BW and BCS during the peripartum period. Supplemental lipid had no effect on prepartum serum glucose concentrations, but postpartum glucose was higher for EB and FO compared with control (49.7, 50.7, 47.3 mg/dl; $P<0.05$) respectively. Serum NEFA concentration was lower in EB and FO both prepartum (0.28, 0.25, 0.50 mM; $P<0.02$) and postpartum (1.04, 0.88, 1.17 mM; $P<0.05$). Serum BHBA concentration was unchanged prepartum, but was lower in lipid supplemented cows postpartum (1.30, 1.25, 1.88 mM; $P<0.001$). There was no effect of either lipid or source on liver glycogen composition. Supplementing FO did not adversely affect intake; subsequently these cows had metabolic profiles that indicated better energy status. However, the effects of FO appear to be predominately due to the direct effects on energy intake rather than any non-energetic effects.

Key Words: Transition, Fish Oil, Metabolism

914 Lactation response and milk α-linolenic acid concentration in dairy goats fed different forage species supplemented with extruded linseed. A. Doyon*[1], G. F. Tremblay[2], D. Cinq–Mars[3], and P. Y. Chouinard[1], [1]*Nutraceuticals and Functional Foods Institute (INAF), Laval University*, *Quebec, QC, Canada*, [2]*Agriculture and Agri-Food Canada, Soils and Crops Research and Development Center*, *Quebec, QC, Canada*, [3]*Ministère de l'Agriculture, des Pêcheries et de l'Alimentation du Québec, Direction de l'innovation scientifique et technologique*, *Quebec, QC, Canada*.

Forages and linseed are two important sources of lipids in the diets of ruminant animals. The objective of this study was to evaluate the effect of forage species and extruded linseed supplementation on milk production and composition in dairy goats. Thirty six primiparous Alpine dairy goats (90 days in milk; 48 kg body weight) were randomly assigned to 6 dietary treatments within a 3×2 factorial arrangement in a 4 week experiment. Treatments were three forage species (corn, alfalfa, and annual ryegrass silages) fed at 60% of dry matter in a TMR supplemented with 0 or 17% extruded linseed (EL). Diets were

formulated to be isonitrogenous, and goats were allowed ad libitum consumption. Treatment differences were compared at week 4 with data from week 0 used as covariates. Alpha-linolenic acid (*cis*-9, *cis*-12, *cis*-15 C18:3) concentration in TMR was 2.0, 8.8, 16.0, 43.8, 56.8, and 60.6 mg/g DM for corn, alfalfa, ryegrass, corn+EL, alfalfa+EL, and ryegrass+EL, respectively. Dry matter intake, milk yield, protein yield, true protein yield, and casein yield were lower, and milk fat content was higher when goats were EL supplemented as compared to nonsupplemented rations ($P<0.01$). Goats fed alfalfa had a higher milk fat content compared to those fed corn or ryegrass ($P<0.01$), and a higher milk fat yield compared to goats fed corn silage ($P<0.01$). The milk fat concentration (mg/g of FA) of α-linolenic acid was increased by the EL supplement ($P<0.01$), and this increase was more pronounced ($P<0.05$) with corn (3.4^{d} vs. 17.2^{a}), intermediate with alfalfa (8.8^{c} vs. 16.4^{a}), and lower with ryegrass (11.1^{b} vs. 17.2^{a}) silage. In conclusion, the concentration of omega-3 fatty acids in milk of dairy goats can be increased by feeding forage species rich in α-linolenic acid and it can be further increased by supplementation with EL.

915 Predicting production of de novo fatty acids in milk. P. J. Moate*[1], W. Chalupa[1], R. C. Boston[1], and I. J. Lean[2], [1]*University of Pennsylvania*, *Kennett Square, PA*, [2]*Sydney University*, *Sydney, NSW, Australia*.

We have developed a model to describe effects of diet and cow factors on milk fat concentration and concentrations of individual long chain fatty acids (LCFA) in milk. We collated data on milk from 120 treatment groups of cows described in 29 published dietary experiments. The diets included a wide variety of fat supplements and wide range in fatty acid intakes (258 - 1794 g/d). Mixed effects modeling was used to relate dietary and cow factors to total production of C4-C15 fatty acids (TPdenovo) [g/d]. The regression equation which best described TPdenovo was:

$$TPdenovo = 190 \pm 41 + 24.8 \pm 4.42^{*} IFCHO - 1.01 \pm 0.163^{*}ATuFA + 0.0018 \pm 0.0004^{*}ATuFA^{2} - 0.25 \pm 0.029^{*}IFishFA - 21.2 \pm 10.7^{*}Diet - 6.46 \pm 2.20^{*}DIM^{0.5}$$

Where IFCHO (kgDM/d) represents intake of fermentable carbohydrate, ATuFA (g/d) is the estimated (by CPM-Dairy) amount of unsaturated fatty acids absorbed from the diet, IFishFA (g/d) is the intake of fish-oil fatty acids, Diet is a categorical variable (0 = Pasture diet, 1 = TMR) and DIM is days in milk. The R^2 for this regression was 0.76 and the RMSE was 37.4 (g/d). Milk fatty acids containing 4 to 15 carbon atoms and approximately half of the C16 fatty acids are generally considered to be synthesized de novo in the udder. Univariate regressions revealed strong linear relationships between the total production of de novo fatty acids and production of individual de novo fatty acids. The slope coefficients for these regressions indicate that each of the individual fatty acids constitute a fairly fixed proportion of the total production of de novo fatty acids. The estimated coefficients (± SE) were: C4:0 0.12 ± 0.01; C6:0 0.082 ± 0.004 ; C8:0 0.052 ± 0.003 ; C10:0 0.111 ± 0.003; C12:0 0.134 ± 0.004; C14:0 0.441 ± 0.007; C14:1 0.046 ± 0.002; and for C15:0 0.043 ± 0.002. These findings present a simple method to predict daily production of individual de novo fatty acids.

Key Words: Model, Predict, de Novo Fatty Acids

916 Effect of in vitro DHA supplementation to adapted and non-adapted rumen inoculum on the biohydrogenation of linolenic and linoleic acid. B. Vlaeminck[1], G Mengistu[2], J. Dijkstra[2], and V. Fievez*[1], [1]*Laboratory for Animal Nutrition and Animal Product Quality*, *Ghent University, Belgium*, [2]*Animal Nutrition Group*, *Wageningen University, The Netherlands*.

The objective was to examine the ruminal biohydrogenation of linoleic (C18:2 n-6) and linolenic (C18:3 n-3) acid during in vitro incubations with rumen inoculum from dairy cattle adapted or not to DHA and either with or without additional DHA supplementation in vitro. Treatments were incubated in 100 ml flasks containing 400 mg freeze dried grass, 5 ml strained ruminal fluid and 20 ml phosphate buffer. Ruminal fluid was collected just before the morning feeding from three cows receiving a control diet (49% ryegrass silage, 39% corn silage, 1% straw and 11% concentrate, fresh weight basis) supplemented with marine algae for 21d (DHA-adapted population, Adapt) or from the same cows receiving the control diet only (non-adapted population, non-Adapt). In half of the incubation flasks, pure DHA (5mg) was added as an oil-ethanol solution (100 µl). Incubations were carried out during 0, 0.5, 1, 2, 4, 6 and 24h. After 24h, in vitro addition of DHA resulted in higher amounts (mg/incubation) of C18:3 n-3 (0.23, 0.43, 0.26 and 0.34 for Adapt, Adapt+DHA, non-Adapt and non-Adapt+DHA, respectively, SEM=0.047), C18:2 n-6 (0.14, 0.22, 0.15 and 0.20, SEM=0.071) and trans-11, cis-15 C18:2 (0.27, 2.40, 0.06 and 2.20, SEM=0.220) whereas no effect of inoculum source was observed. Trans-11 C18:1 accumulated after 24h when Adapt was incubated irrespective of DHA supplementation, whereas in incubations with non-Adapt, accumulation of trans-11 C18:1 only occurred when DHA was added (6.40, 4.35, 1.06 and 3.91, SEM=0.047). The increased amounts of trans-11 C18:1 was due to the strong inhibition of the reduction to C18:0. Indeed, after 24h, the amount of C18:0 was significantly different from 0h for the non-Adapt treatment without in vitro DHA only (0.49, 0.34, 8.95 and 2.14, SEM=0.369). The results show the DHA-adapted microbial population is able to convert trans-11, cis-15 C18:2 but not trans-11 C18:1 whereas DHA inhibits the conversion of both trans-11, cis-15 C18:2 and trans-11 C18:1.

Key Words: Biohydrogenation, DHA, Rumen

917 Identification of enriched conjugated linoleic acid isomers in cultures of ruminal microorganisms after dosing with 1-^{13}C-linoleic acid. Y-J. Lee*[1], J. T. Brenna[2], P. Lawrence[2], S. K. Duckett[1], G. L Powell[1], W. C. Bridges, Jr.[1], and T. C. Jenkins[1], [1]*Clemson University*, *Clemson, SC*, [2]*Cornell University*, *Ithaca, NY*.

Most accounts of linoleic acid biohydrogenation depict its conversion to only a single conjugated linoleic acid (CLA) isomer (c9t11). A multitude of other CLA isomers have been identified in ruminal contents, raising questions that the pathway of linoleic acid biohydrogenation is more complex. The objective of this experiment was to identify CLA isomers that arise from ruminal biohydrogenation of linoleic acid. Six rumen in vitro cultures were run that contained ground dairy feed (with 5% added unsaturated fatty acids), buffer, and strained rumen fluid from a ruminally-fistulated dairy cow. Half of the cultures received an additional 50 mg of unlabelled linoleic acid in 1 mL of ethanol and the other half received a mixture of 15 mg 1-^{13}C-linoleic acid and 35 mg unlabelled linoleic acid in ethanol injected at the start of incubation. Samples were taken from each flask at 0, 24, and 48 hours. Methyl esters of fatty acids were separated on a 100-m CP-Sil 88 column and abundances of the quasimolecular ion (M) and M+1 ion were

determined by mass spectroscopy in positive chemical ionization mode using methane reagent gas. Geometry and double bond position of CLA isomers was verified by acetonitrile chemical ionization tandem mass spectrometry. Enrichment for each peak was calculated as [(M+1/M) * 100] in labeled minus unlabelled cultures and tested for their difference from zero by t-test ($P < 0.05$). At 48 h of incubation, enrichment was observed in t11 18:1 (14.2%), 18:0 (2.7%), and seven CLA isomers (range from 18.1 to 30.7%). The c9t11 isomer had the highest enrichment (30.7%), followed by enrichments from 20.8 to 23.4% for t10c12, c10t12, t9t11, and t10t12. The remaining two CLA isomers (c9c11 and c10c12) had enrichments of 18.1 and 19.2%, respectively. The results of this study verified the formation of c9t11 and t10c12 CLA isomers from linoleic acid biohydrogenation. An additional five CLA isomers also contained carbons that originated from linoleic acid indicating that pathways of linoleic acid biohydrogenation are more complex than usually depicted.

Key Words: Linoleic Acid, Biohydrogenation, Conjugated Linoleic Acid

918 Octadeca-carbon fatty acids affect microbial fermentation, methanogenesis and microbial flora in vitro. C. M. Zhang*[1], J. X. Liu[1], Y. Q. Guo[1], Z. P. Yuan[1], J. K. Wang[1], and W. Y. Zhu[2], [1]*College of Animal Sciences, Ministry of Education Key Laboratory of Molecular Animal Nutrition, Zhejiang University*, *Hangzhou, Zhejiang, P.R. China*, [2]*College of Animal Science and Technology, Nanjing Agricultural University*, *Nanjing, Jiangsu, P.R. China*.

The effects of type and level of C18-fatty acids on rumen fermentation, methane emission and microbial community structure were examined using an in vitro gas production technique (Reading Pressure Technique). Three levels (0, 3.5 and 7.0% of substrate DM) were evaluated for four types of C18-fatty acids: stearic acid, oleic acid, linoleic acid and linolenic acid. The 24 h gas production and methane emission were significantly decreased by type, level and their interactions ($P<0.001$). Methane suppressing effect of unsaturated C18-fatty acids was more profound than on gas production. Compared to the control, addition of C18-fatty acids had little effect on pH, concentration of ammonia-N and total volatile fatty acids. However, the fermentation patterns were significantly changed ($P<0.001$), with lower proportion of acetate and higher propionate with increasing levels and unsaturation of C18-fatty acids. Methanogens and protozoa population relative to total bacteria were decreased by linoleic and linolenic acids, with the linolenic acid being more effective. However, addition of these unsaturated C18-fatty acids also inhibited growth of fibrolytic microbes including fungi, *F. succnogens* and *R. flavefaciens*. From the present study, it is demonstrated that there is a significant effect of unsaturated C18-fatty acids on suppressing methanogenesis, mediated probably by a direct action against the rumen microbes involved in methane formation and by a decreased hydrogen supply.

Key Words: C18-Fatty Acids, Methane Emission, Microbial flora

919 Effect of feeding rate of a 26% CP calf milk replacer. T. M. Hill*, H. G. Bateman, II, J. M. Aldrich, and R. L. Schotterbeck, *Akey*, *Lewisburg, OH*.

The objective was to determine the effect of feeding rate of a 26% CP, 17% fat milk replacer (MR) on calf ADG, starter intake, and efficiency. Single source Holstein calves (d 0 = 42 ± 2 kg, 3-4 d old) were fed different amounts of the MR and weaned on d 42. They were offered free-choice water and 18% CP starter in individual pens within a naturally ventilated barn with no supplemental heat. In Trial 1, MR (16 calves/MR) were fed at A) 681 g/d, B) increased to 795 g/d by day 8, or C) increased to 908 g/d by d 15. In Trial 2, MR (24 calves/MR) were fed at A) 681 g/d or C) increased to 908 g/d by d 14. In Trials 1 and 2, calves were weaned by feeding half of the MR amount on d 39-42. In Trial 3, the MR (24 calves/MR) were fed at A) 681 g/d or D) increased to 1,135 g/d by day 22. Calves were weaned by feeding half of MR A on d 39-42 or half of MR D on d 36-42, in Trial 3. In Trials 1-3, post-weaning measurements were made in the individual pens until d 56 and no calf rejected any MR fed. Each trial was analyzed as a randomized block design. In each trial, calves fed MR A grew the slowest ($P < 0.05$) during d 1-21. In Trial 1, starter intake and efficiency from 0-42 d declined linearly as MR increased ($P < 0.05$), while ADG did not differ from 0-42, 42-56, and 0-56 d. In Trial 2, calves fed MR A had the slowest ADG, were least efficient, and consumed the most starter from 0-42 d and had the fastest ADG, were most efficient, and consumed the most starter from 42-56 d ($P < 0.05$). The ADG from 0-56 d did not differ between MR. In Trial 3, calves fed MR A had the slowest ADG, were least efficient, and consumed the most starter from 0-42 d and had the fastest ADG, were most efficient, and consumed the most starter from 42-56 ($P < 0.05$). The ADG from 0-56 d did not differ between MR. In summary, calf ADG from 0-56 d was not improved when the 26% CP MR was fed at more than 681 g/d because starter intake and efficiency was decreased at higher feeding rates.

Key Words: Calves, Milk Replacer

920 Effect of CP concentration in a post-weaning calf grower. T. M. Hill*, H. G. Bateman, II, J. M. Aldrich, and R. L. Schotterbeck, *Akey*, *Lewisburg, OH*.

The objective was to determine to the effect of CP concentration in the diet for weaned calves. The four treatments were A) 13.5, B) 15.0, C) 16.5, and D) 18.0% CP (as-fed basis). Each feed contained 3% molasses, 12.5% pellet (34% CP, minerals, vitamins), and 25% whole oats. Rolled corn and a 40% CP pellet (77.7% soybean meal, 12.8% wheat midds, 5% alfalfa meal, 3% binder, 1.5% fat) were varied to achieve the targeted CP concentration. The feeds (blended with 5% chopped grass hay, 14% CP as-fed) and water were fed free-choice. Single source Holstein steers (d 0 = 81 ± 2 kg, 59-60 d old) that had been weaned 28 d from a 26% CP, 17% fat MR fed at 0.68 kg/d were used. Calves were fed for 28 d in pens (4 pens/treatment, 6 calves/pen). Calves were weighed, hip widths and body condition were measured on d 0 and 28. Feed offered and refused was measured daily. Venous blood of calves from 2 pens/treatment) were also sampled on d 0 (baseline values), 7 and 28 and analyzed for several constituents. The change in blood constituent from d 0 was calculated. Performance measures (as a randomized block design) and blood measures (as a completely randomized design) were analyzed with pen being the experimental unit using polynomial contrast statements to characterize the treatments. Body weight gain (A= 0.99, B= 1.09, C= 1.11, D= 1.11, SEM= 0.02 kg/d), efficiency (A= 0.33, B= 0.36, C= 0.36, D= 0.35, SEM= 0.009 gain/feed), and change in hip width (A= 2.0, B= 2.2, C= 2.2, D= 2.2, SEM= 0.07 cm) increased quadratically ($P < 0.05$) to concentration of CP in the diet with calves fed A being lowest. The change in serum urea nitrogen (A= -2.7, B= -1.3, C= -0.8, D=

-0.6, SEM= 0.2 mmol/L) and creatinine (A= +11.3, B= -7.3, C= -5.8, D= -7.2, SEM= 3.5 umol/L) concentration from d 0-28 increased in a quadratic ($P < 0.05$) manner as CP concentration of the diet increased. These results indicated that 13.5% CP diets were deficient, 15% CP diets were marginal, and 16.5 and 18% CP diets were adequate for calves 2-3 months of age.

Sheep Species: Sheep Production and Management

921 Cobalt supplementation to the pregnant ewe reduces vitamin E levels in the newborn lamb. T. M. Boland*, L. Hayes, J. J. Murphy, T. Sweeney, J. J. Callan, and T. F. Crosby, *University College Dublin*, *Belfield, Dublin 4, Ireland*.

The objective of this experiment was to determine the effects of offering supplementary iodine or cobalt during late pregnancy on lamb serum vitamin E and IgG concentrations at 24 and 72 h *post partum*. Sixty twin-bearing ewes were individually penned and offered grass silage *ad libitum* supplemented with 800g/ewe daily of a 190g/kg crude protein concentrate, with or without supplemental cobalt or iodine, from day 126 of gestation until parturition. Ewes were allocated to one of the following treatments: **C:** no mineral supplement; **I-3:** 26.6 mg iodine from day 126 – parturition; **I-1:** 26.6 mg iodine from day 138 – parturition; **Co-3:** 20 mg cobalt from day 126 – parturition. Colostrum yield was measured following hand milking at 1, 10 and 18 h *post partum*, after which the lambs were fed measured quantities of colostrum, via stomach tube. A 10 ml blood sample was taken from lambs at 24 and 72 h *post partum* for IgG and vitamin E determination. The efficiency of IgG absorption at 24 h *post partum* was lower in the progeny of ewes offered supplementary iodine for either one or three weeks (I-3; 0.08, I-1; 0.18) than in the progeny of the ewes not offered supplementary iodine (C; 0.26, Co-3; 0.28; $P < 0.001$) resulting in reduced IgG concentrations at both 24 and 72 h *post partum* ($P < 0.001$) in the lamb's serum. Lamb serum vitamin E concentration was lower for both of the iodine supplemented treatments than for Co-3 at 24 h *post partum* (2.02, 2.06 v. 2.48; sem 0.137), while at 72 h *post partum* the lamb serum for all mineral supplemented treatments (I-3, I-1 and Co-3) had lower vitamin E levels than in the control (C) lambs ($P < 0.01$). We conclude that not only do excessively high levels of dietary iodine in late pregnancy lead to a reduction in IgG and vitamin E transfer but that excessively high dietary cobalt in late pregnancy (20 mg per ewe per day) also leads to a breakdown in the transfer of vitamin E from colostrum to the serum of the newborn lamb.

Key Words: Cobalt, Iodine, Vitamin E

922 Evaluation of alternative small ruminant finishing systems for the tropics. S. A. Weiss*, R. C. Ketring, and R. W. Godfrey, *University of the Virgin Islands, St. Croix*, *Kingshill*.

The objective of the experiment was to evaluate the growth and carcass characteristics of Dorper $/times; St. Croix White lambs managed in two types of post-weaning alternative pasture finishing systems in the tropics. After weaning and background grazing on native pasture for eight months, lambs (n = 37) were stratified by weight and sex into two treatments consisting of native pasture (NP) and improved pasture (IP), with energy supplement. Native pasture consisted of a mix of guinea grass (Panicum maximum) and hurricane grass (Boithrocloa pertusa), while IP consisted of a mix of seeded tropical legumes (Desmanthus vergatus, clitoria ternetea, and Lablab purpureus) and volunteer guinea grass. All lambs were supplemented with crushed corn daily at 1% of BW for 100 d and slaughtered at approximately 365 d of age. During the finishing trial, IP lambs had greater total weight gain ($P < 0.0001$) than NP lambs (10.8 vs. 6.8 ± 0.6 kg, respectively). In addition, IP lambs had higher ADG ($P < 0.0001$) than NP lambs (112.2 vs. 66.5 ± 5.9 g/d, respectively). Compared to NP lambs, IP lambs were heavier at slaughter ($P < 0.0001$; 37.8 vs. 32.4 ± 0.9 kg, respectively), had heavier carcasses ($P <0.0001$; 18.7 vs. 15.1 ± 0.6 kg, respectively), and greater dressing percentages ($P = 0.0633$; 49.5 vs. 46.7 ± 1.1%, respectively). Further, IP lambs had greater leg circumference ($P < 0.0005$; 43.4 vs. 40.1 ± 0.6 cm, respectively), body wall thickness ($P < 0.0001$; 14.8 vs. 9.6 ± 0.7, mm, respectively), and rib eye area ($P <0.0001$; 12.9 vs. 10.1 ± 0.4 cm^2, respectively) than NP lambs. Back fat thickness for IP and NP lambs was 3.1 and 2.1 ± 0.3 mm, respectively ($P < 0.02$). The IP lambs had greater percent KPH ($P < 0.02$) than NP lambs (3.8 vs. 3.1 ± 0.2%, respectively). In this study, crossbred hair sheep lambs grown under tropical conditions responded with improved growth rate and carcass muscularity to mixed legume improved pasture but had similar yield grades compared to lambs grown on native pasture.

Key Words: Sheep, Legumes, Pasture Finishing

923 Potential for onions to reduce bitterweed toxicity in sheep. E. S. Campbell*[1], T. R. Whitney[2], C. A. Taylor[1], and N. Garza[1], [1]*Texas Agricultural Experiment Station*, *Sonora, TX*, [2]*Texas Agricultural Experiment Station*, *San Angelo, TX*.

Bitterweed (*Hymenoxys odorata*) toxicity is a major cause of death losses in sheep. Supplements high in sulfhydryl groups (i.e. L-cysteine) can be used to prevent bitterweed intoxication. Cull onions (*Allium cepa*) are an inexpensive and commercially available feed source that also contain high levels of naturally occurring disulfide compounds. Yearling Rambouillet (n = 12; 22.9 kg BW) and Dorper $/times; Barbado (Dorpado) ram lambs (n = 12; 22.5 kg BW) were used to evaluate whether onions have the potential to reduce bitterweed toxicity in sheep. Each breed was randomly assigned to one of four groups: no onions, 25% onions, 50% onions, and 75% onions (DM basis). The remainder of the isonitrogenous diet consisted of alfalfa pellets to provide 43 g DM/kg BW per d. The study was divided into three periods. Period 1 represented control data, prior to onion and bitterweed challenge. In period 2, lambs were incrementally adapted to respective onion diets for 14 d. In period 3 lambs were dosed with an aqueous slurry of dried bitterweed (0.25% live weight) for five days. At the end of each period blood samples were analyzed for serum chemistry measurements. Hematocrits, overall DMI and feed refusals were also measured. The statistical model included breed, onion level, and the two-way interaction. Following period 3 there was a breed effect ($P < 0.05$) for serum measurements reflective of bitterweed

toxicity; GGT and AST levels were higher ($P < 0.001$) for Dorpados (465.6 U/l and 877.0 U/L) than for Rambouillets (117.1 U/L and 186.5 U/L), indicating greater susceptibility to hepatic insult by bitterweed. Bilirubin, though numerically greater for Dorpados (0.542 mg/dL) than Rambouillets (0.400 mg/dL) did not vary by breed ($P > 0.10$). For period 3 there was an inverse correlation (-0.42, $P < 0.05$) between level of onions in the diet and levels of serum GGT after bitterweed dosing. Results indicate that further study is required to confirm the benefit of onions as a prophylactic feed during periods of bitterweed consumption.

Key Words: Bitterweed, Sheep, Onions

924 Effectiveness of allopathic and homeopathic dewormers on gastrointestinal nematodes and gain in ewes. A. Baños L, E. Cortés D*, S. Vázquez, J. L. Zaragoza, P. A. Martínez, and T. González, *UACh-Chapingo*, *Mexico*.

The objective was to evaluate the effectiveness of 4 allopathic (Albendazole, Levamisole, Closantel, Avermectin) and 5 homeopathic (*Aconitum napellus L, Antimonium crudum, Azadirachta indica, Artemisia cina, Chenopodium ambrosoides*) dewormers on gastrointestinal nematode control and gain of hair sheep from two communities in Tepalcingo, Morelos, Mexico. Ten treatments were compared: the 9 dewormers and a control group. Treatments were assigned at random to ewes, 12 ewes per treatment. Fecal samples were taken directly from the rectum before deworming and every month from February 2005 to March 2006. Nematode egg count in feces was by McMaster and nematode identification by Coproculture. Ewes were weighed at the beginning of the study and every month thereafter. Allopathic dewormers were administered every 3 mo and homeopathic dewormers were administered at 2 wk intervals. Data were analyzed as a completely randomized split-plot design. The main plot was the dewormer and the sub plot was the sampling date. Nematode egg count was different ($P < 0.01$) among sampling dates and treatments. There were two peaks (April to May and November to January); both considered as a reflection of the nematode life-cycle in a tropical range and both occurred at the same time as lambing. Allopathic and homeopathic dewormers showed similar ($P > 0.05$) nematode-egg counts which were lower than in control ewes (872 eggs/g feces). Monthly live-weight change was not different ($P > 0.05$) among treatments. The average monthly live-weight change per ewe ranged from 2348 to -474 g. Nematodes found were *Trychostrongylus, Bunostomum* and *Haemonchus*. This study shows that gastrointestinal nematode load in hair sheep can be controlled either by allopathic or homeopathic dewormers.

Key Words: Internal Parasites, Sheep, Dewormer

925 Influence of feeding tanniniferous sainfoin on the nitrogen balance of lambs artificially infected with the abomasal nematode *Haemonchus contortus*. A. Scharenberg[1], Y. Arrigo[1], F. Heckendorn[2], H. Hertzberg[2], A. Gutzwiller[1], H. D. Hess[1], M. Kreuzer[3], and F. Dohme*[1], [1]*Agroscope Liebefeld-Posieux, Research Station ALP*, *Posieux, Switzerland*, [2]*Research Institute for Organic Farming (FiBL)*, *Frick, Switzerland*, [3]*ETH Zurich, Institute of Animal Science*, *Zurich, Switzerland*.

Condensed tannins (CT) have the potential to suppress gastrointestinal nematodes in sheep. However, it is unclear, if the anthelmintic effect results from a direct impact of CT on the nematodes or from counterbalancing the nematode-caused higher protein requirements of the host by ruminal protection of dietary protein. To evaluate the effects of CT on infected lambs, 24 lambs, 18 of which were infected with the blood sucking abomasal nematode *H. contortus*, were subjected to 4 treatments (n = 6). After 4 wk, when the infection was established, 12 infected lambs were fed for 3 wk either dried sainfoin or dried sainfoin treated with polyethylene glycol (PEG) which inactivates CT. The third infected group and the uninfected group remained on a grass-clover hay diet. The lambs were offered 66 g/d forage OM per kg $BW^{0.75}$. To monitor the infection, egg count in fecal DM (FEC) and packed cell volume in the blood (PCV) were determined weekly throughout the experiment. During the third experimental wk, feed refusals were recorded daily, and feces and urine were collected quantitatively and results expressed per d and per kg $BW^{0.75}$. While the DM intake was not affected by treatments, the nitrogen (N) intake was higher in lambs fed PEG-treated sainfoin instead of grass-clover (2.29 vs. 1.51 g; $P < 0.001$) which resulted in a higher total N-excretion (1.64 vs. 1.22 g; $P < 0.001$) and a higher N-retention (0.65 vs. 0.29 g; $P < 0.001$). Lambs fed PEG-treated sainfoin excreted less fecal N than lambs fed sainfoin without PEG (0.66 vs. 0.75 g; $P < 0.01$). The proportion of urinary N (g/g N excreted) was higher with PEG-treated sainfoin than with untreated sainfoin ($P < 0.05$). The nematode infection had no influence on the N-balance. The PCV was lower in infected compared to uninfected lambs ($P < 0.001$). The FEC was not different among the 3 infected groups and averaged $10.5 \pm 8.21 \times 10^3$ eggs/g fecal DM at the end of the experiment. In conclusion, neither the CT of sainfoin nor the higher N-intake with sainfoin compared to grass clover increased the resilience of lambs infected with *H. contortus*.

926 Prediction of carcass measures and wholesale product weights in sheep using B-mode ultrasound. T. D. Leeds*[1], M. R. Mousel[1], D. R. Notter[2], and G. S. Lewis[1], [1]*USDA-ARS, U. S. Sheep Experiment Station*, *Dubois, ID*, [2]*Virginia Polytechnic Institute and State University*, *Blacksburg*.

Widespread use of ultrasound (US) in the sheep industry to predict carcass traits requires knowledge of its reliability. Our objectives were to 1) evaluate US estimates of carcass measures in live sheep via correlations (r) and other statistical measures (prediction SE [SEP]; repeatability SE [SER]; and bias [TB]) established for beef and swine; and 2) compare US estimates of loin muscle area (LMA), depth (LMD), width (LMW), and an elliptical interpretation (LME) as single predictors of roast ready rack (RRR) and trimmed loin (TL) weights. Wethers (n = 172) from four sire breeds were reared in an extensive production system, weaned at approximately 130 d, finished on a concentrated diet, and harvested at a mean weight of 62.9 kg (SD = 9.5 kg). Before harvest, $12^{th}/13^{th}$ rib transverse US images were captured using an ALOKA SSD-500V US device with a 3.5-MHz, 14.5-cm linear transducer and standoff. Images were interpreted using ImageJ software (v1.36b). After a 24-h chill, carcasses were ribbed, measured for LMA and backfat (BF), and fabricated. Weights of RRR and TL were described using linear models with LMA, LMD, LMW, and LME as single predictors. Predictors were evaluated via model R^2 and root

mean square error (RMSE) statistics. For Objective 1, SEP, SER, and TB for BF were 0.14, 0.08, and 0.07 cm, respectively, and r was 0.81. The SEP, SER, and TB for LMA were 1.55, 1.31, and -0.004 cm^2, respectively, and r was 0.75. For Objective 2, single-prediction models for RRR had R^2 of 0.46, 0.09, 0.40, and 0.37 and RMSE of 0.22, 0.28, 0.23, and 0.24 for LMA, LMW, LMD, and LME, respectively. Single-prediction models for TL had R^2 of 0.46, 0.11, 0.39, and 0.38 and RMSE of 0.31, 0.39, 0.33, and 0.33 for LMA, LMW, LMD, and LME, respectively. Based on these data, the best single predictor for RRR and TL was LMA; LMW and LME should not be used to predict RRR or TL. Ultrasound can be used to reliably predict corresponding carcass measures in sheep.

Key Words: Sheep, Ultrasound, Carcass

927 Prediction of lamb carcass leg and loin weights using leg score and leg width measurements. M. R. Mousel*[1], T. D. Leeds[1], D. R. Notter[2], and H. N. Zerby[3], [1]*USDA-ARS U.S. Sheep Experiment Station*, *Dubois, ID*, [2]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [3]*The Ohio State University*, *Columbus*.

Lamb carcass leg score (LS; 1 = low cull to 15 = high prime) is considered a subjective estimate of carcass muscling. We compared the predictive value of LS, live leg width (LLW), and carcass leg width (CLW), individually, and in combination with live (LWT) or carcass weight (CWT), of various leg and trimmed loin (TL) weights. Wether lambs (n = 170) from four sire breeds were weaned at approximately 130 d, finished in a feedlot, and harvested at a mean weight of 62.9 (SD = 9.5) kg. Before harvest, LLW was measured at the widest point between hip and stifle. The CLW was measured on hanging carcasses at the dorsal tip of the visible gluteus and a trained evaluator assessed LS. As single-predictors of leg weights or TL, R^2 values ranged from 0.16 to 0.32 for LS, 0.31 to 0.48 for LLW, 0.60 to 0.83 for CLW, 0.70 to 0.88 for LWT, and 0.75 to 0.95 for CWT (Table 1). Based on the data, CWT was the best single-predictor of leg and TL weights. When comparing LS, LLW, and CLW as single-predictors, CLW was consistently best. No additional leg weight ($P > 0.5$) and very little TL weight ($P < 0.08$) variation was explained when LLW was added to LWT model. The R^2 improved slightly for boneless leg weight when LS or CLW ($P < 0.01$) was added to CWT model. However, after accounting for CWT, LS and CLW explained a significant ($P < 0.01$) portion of leg weight variation.

Table 1. Model R^2 and root mean square error (RMSE) for predicting weights from live and carcass measurements.

Cut		LLW	LS	CLW	LWT	CWT	LLW + LWT	LS + CWT	CLW + CWT
Whole Leg	R^2	0.48	0.27	0.83	0.88	0.95	0.88	0.95*	0.96*
	RMSE, kg	1.16	1.37	0.66	0.57	0.35	0.57	0.35	0.34
Bone-in Leg	R^2	0.42	0.29	0.78	0.82	0.90	0.82	0.90*	0.90*
	RMSE, kg	0.76	0.84	0.46	0.42	0.32	0.42	0.31	0.31
Boneless Leg	R^2	0.39	0.32	0.78	0.70	0.79	0.70	0.81*	0.83*
	RMSE, kg	0.50	0.53	0.30	0.35	0.29	0.35	0.28	0.27
TL	R^2	0.31	0.16	0.60	0.70	0.75	0.71+	0.75	0.75
	RMSE, kg	0.35	038	0.27	0.23	0.21	0.23	0.21	0.21

928 Influence of body weight and body condition score at breeding on conception and prolificacy of Merino and Composite Coopworth, East Friesian, Romney and Texel sheep in Tasmania, Australia. A. E. O. Malau-Aduli*[1], G. H. Bond[1], and M. Dunbabin[2], [1]*University of Tasmania*, *Hobart, Tasmania, Australia*, [2]*Bangor, Dunalley*, *Tasmania, Australia*.

We evaluated ewe conception and prolificacy in six flocks on three sheep farms with similar commercial management conditions in the Australian State of Tasmania. The aim was to investigate the effects of BW and BCS at mating, age group, and breed on reproductive traits. 1759 Merino, Composite Merino/Coopworth (M/Coop), Composite East Friesian/Romney (EF/Rom), and Composite Coopworth/East Friesian/Texel (Coop/EF/Tex) ewes of maiden (7 mo) and mature (18 to 30 mo) age groups were evaluated. Body weight and BCS of ewes were recorded before rams were introduced to the breeding mob. Ultrasound scanning 90 d after ram removal was carried out. Results demonstrated that ewes that conceived were consistently of greater BW and BCS than barren ewes. The average BW of non-pregnant, single, and multiple-bearing ewes were 41.3, 43.7, and 54.6 kg respectively, while their corresponding BCS were 2.77, 2.80, and 2.85. However, highly significant ($P < 0.0001$) breed, age group, and flock variations were observed: 7 mo-old maiden ewes had a significantly lower conception rate than 18 mo-old ewes at the same BW at breeding. Within the 18-mo age groups, percentages of non-pregnant ewes were 16.7, 3.0, and 2.4% and percentages of multiple fetus-bearing ewes were 1.4, 53.6, and 74.2% for Merino, Coop/EF/Tex, and M/Coop, respectively. The Coop/EF/Tex flocks were consistently more prolific than other breeds with 74.2, and 77.5% of ewes scanned as multiple fetus-carrying at ages 18 and 30 mo, respectively. Above BW of approximately 55 kg, the probability of multiple conceptions began to increase at a greater rate at the expense of single conceptions. The study shows that nutritional management prior to joining in commercial Tasmanian sheep flocks has the potential to increase reproductive performance in ewes. This is of particular importance when ewes are bred as lambs or from breeds with characteristically low fertility levels.

Key Words: Conception, Prolificacy, Sheep Bodyweight

929 Body weight changes and subsequent lambing rates of western white-faced ewes grazing winter range. J. B. Taylor*, C. A. Moffet, and T. D. Leeds, *USDA, ARS, U. S. Sheep Experiment Station*, *Dubois, ID*.

To describe BW change (BWC) and subsequent lambing rates of western white-faced ewes grazing on sagebrush steppe of the northwest United States, Columbia (1,174 records), Polypay (910 records), Rambouillet (1,280 records), and Targhee (868 records) ewe BW and lambing-rate records for 1989, 1990, and 1991 were extracted from the USDA, ARS, U. S. Sheep Experiment Station breed database. In December, after breeding each year (October to December), ewes were moved to winter range. Depending upon severity of climatic conditions and vegetation accessibility, ewes grazed winter range for 30 to 60 d. The BW that were analyzed were collected 2 d before winter-grazing commenced and 2 to 7 d after ewes were transported off winter range. Only data from litters with at least one live lamb were included in these analyses. Because initial BW may influence BWC during grazing, daily BWC was calculated as a proportion of initial BW: BWC, g•kg BW^{-1}/d = ([exit BW – initial BW] / initial BW) / d of grazing. Data were analyzed within each breed, with age as the fixed effect and

management year as the random effect. For all breeds, 2-yr-old ewes were lightest going on to winter range and had the lowest lambing rate. Ewes lost weight while grazing winter range, but mature BW, once achieved, was restored annually, with the exception of the 7-yr-old Targhee ewes. Regardless of breed or age, ewes were able to achieve acceptable lambing rates following early-gestational weight loss. Compared to younger ewes, lambing rates were similar or greater in older ewes, even though they generally lost more BW during winter grazing.

Key Words: Sheep, Winter Grazing, Reproduction

930 Changes in metabolic and endocrine measurements during feed restriction in dairy ewes with different BCS. G. Pulina*[1], G. C. Bomboi[2], A. Mazzette[1], B. Floris[2], C. Dimauro[1], S. P. G. Rassu[1], and A. Nudda[1], [1]*Dipartimento di Scienze Zootecniche - Università di Sassari*, *Sassari, Italy*, [2]*Dipartimento di Biologia Animale - Università di Sassari*, *Sassari, Italy*.

The effects of feed restriction on metabolic and endocrine measurements of Sarda lactating ewes were evaluated. Ten ewes, divided into two groups according to the level of BCS (low: BCS < 2.75; high: BCS > 2.75), were fed 2.5 kg of a complete pelleted diet (CPD) for 7 d (preliminary period, PRE), followed by 3 d (treatment period, RESTR) of feed restriction (1.25 kg/head per day of CPD, i.e. 50% of the intake of the PRE period) and 3 days of recovery (REC). Blood samples were collected at -24, -12, 0 (beginning of RESTR), 6, 14, 24, 36, 52, 76, and 126 h during the trial. Blood concentrations of NEFA, urea, glucose, insulin, leptin, and IGF-I were measured. Data were analyzed by a mixed model with BCS, period and their interaction as fixed factors and ewe within BCS as a random factor (Table 1). BCS did not show significant effects on any blood measurement. Period influenced almost all measurements, except glucose concentration. Blood IGF-I and insulin concentrations showed a rapid response to feed restriction whereas the effect of feed restriction on NEFA, urea and leptin concentrations was observed in the REC period. The expected increase in NEFA during the RESTR period was observed only in low BCS ewes, whereas this measurement tended to slightly decrease in the high BCS group. Low BCS ewes had lower insulin concentrations during the PRE and RESTR periods than high BCS, whereas the opposite happened during the REC period. The results suggest that feed restriction of 50% for only a 3-d period is enough to cause metabolic changes in lactating dairy ewes. Moreover the differences found between the two BCS groups suggest an important role of the capability of body reserve mobilization when feed restriction occurs. *Funded by MIPAF project on Small Ruminant Welfare.*

SYMPOSIA AND ORAL SESSIONS

Beef Species II: Feed Intake and Efficiency

931 Energy cost of cows' grazing activity: Estimation in large plots. A. Brosh*, Z. Henkin, E. D. Ungar, A. Dolev, A. Orlov, Y. Shabtay, Y. Yehuda, and Y. Aharoni, *Beef Cattle Section, Newe Yaar Research Center*, *ARO, Israel*.

This study of 17 grazing beef cows on the herbage range was designed to compare previously published data of total daily energy expenditure (EE) and the energy cost of various activities measured in medium-size plots of 28 ha to those determined in larger plots of 145.8 and of 78 ha. Data were obtained by continuously monitoring EE using the heart-rate method and simultaneously monitoring the cows' location and activity with Global Positioning System (GPS) collars with motion sensors. The cows were monitored through March (lactating cows on high quality herbage), May (non-lactating cows on low quality herbage), and September (non-lactating cows on low quality herbage supplemented with poultry manure). These data were compared to previously published data that were determined on smaller plots. Three statistical models were evaluated, including one which was designated as a stepwise model. Across seasons the cows total daily EE (kJ•kgBW$^{-0.75}$•d^{-1}) ranged from 644 in September up to 1014 in March, and all activities together (grazing, standing and walking) ranged respectively from 58 to 66. The cows` daily vertical and horizontal locomotion ranged from 85 to 124 m and from 2.51 to 3.44 km, respectively. The time spent standing and grazing ranged from 6.6 to 9.0 h and from 7.4 to 11.7 h respectively; horizontal distance traveled while grazing ranged from 1551 to 2327 m/d. These data ranges and effect of month were similar to those measured in comparable months in medium plots. Plot size did not directly affect the duration of time the cows spent on each activity and consequently the energy cost of these activities. However, when the herbage was dry, cows in larger plots grazed longer and expended more energy on grazing activity, and probably consumed more herbage of significantly better quality than in medium plots, as was expressed by the greater daily energy expenditure.

Key Words: Grazing Cows, Energy Cost, Global Positioning System

932 Relationships among exit velocity, cortisol, and carcass characteristics of beef heifers. R. R. Reuter[1,2], J. D. Dailey*[2], J. A. Carroll[2], M. S. Brown[3], and M. L. Galyean[1], [1]*Texas Tech University*, *Lubbock*, [2]*USDA-ARS Livestock Issues Research Unit*, *Lubbock, TX*, [3]*West Texas A&M University*, *Canyon*.

One hundred ninety-nine crossbred beef heifer calves (205 ± 7.9 kg initial BW) were used in a 44-d receiving trial with 2 dietary treatments (9 pens/treatment) in a completely randomized design. Heifers were weighed and bled on d 0, 16, 30, and 44 after arrival. Blood was collected by jugular venipuncture, and serum was analyzed for cortisol, several cytokines, and 2 acute-phase proteins. Exit velocity was recorded by an electronic infrared timer system each time heifers were weighed. Animals were brought to the processing facility in pen groups of 10 to 12, and no effort was made to control processing sequence of individual animals. Exit velocity was not related ($P = 0.71$) to processing sequence. Repeatability of exit velocity was 77%. A trend was evident for a negative linear relationship between average exit velocity and 44-d ADG ($P = 0.08$) and for positive linear relationships between exit velocity and serum cortisol ($P = 0.10$) and interferon-gamma concentrations ($P = 0.13$). At d 44, the heifers were transported to a commercial feedlot, fed for 200 d, and individual carcass data were collected at slaughter. After controlling for treatment and pen effects, exit velocity, averaged over the 4 measurement times, was not related to carcass characteristics ($P > 0.23$) nor to ADG over the entire 240-d trial ($P = 0.92$). Although exit velocity measured during the receiving period seemed to be associated with increased serum cortisol and decreased ADG during the receiving period, it was not associated with ADG or carcass measurements after an extended feeding period. Thus, further research is needed to determine whether extended feeding periods during which cattle are not handled might mitigate deleterious effects of exit velocity on cattle performance.

933 Evaluation of a mathematical model to estimate total feed required for pen-fed animals based on performance and diet information. B. M. Bourg*[1], L. O. Tedeschi[1], and M. S. Brown[2], [1]*Texas A&M University*, *College Station*, [2]*West Texas A&M University*, *Canyon*.

The Cattle Value Discovery System (CVDS) was developed to predict growth and body composition based on animal, diet, and environment information, and to allocate feed to individual cattle fed in pens. The objective of this study was to evaluate the adequacy of CVDS in predicting total DM required (DMR) of pen-fed steers, based on either mean BW method (MBWM) or using the dynamic iterative growth

model (DIM). Steers (N= 1,314) used in this evaluation were fed in 173 pens for an average of 133 days on test, across 8 studies conducted at West Texas A&M University. Diet ME values ranged from 2.78 to 3.13 Mcal/kg DM. The CVDS model was used to predict individual DMR and to estimate total DMR of each pen. Model adequacy was analyzed using the Model Evaluation System (MES). The mean of observed DM allocated to pens was 10,258 kg and the mean pen DMR predicted by the CVDS was 10,630 and 10,267 kg for MBWM and DIM methods, respectively. The regression of observed on predicted values indicated a high precision of both methods (r^2 of 0.97) and no outliers were identified. The intercept and slopes of the regressions differed from zero and one simultaneously. Both methods had great accuracy based on the Cb value of 0.98 and 0.99 for MBWM and DIM methods, respectively. The mean biases were -3.5% ($P < 0.01$) and -0.08% (P=0.83) for MBWM and DIM methods, respectively. The balance analysis revealed that both methods tended to overpredict DMR for pens with greater than average DMI. The mean square error of prediction (MSEP) for the MBWM indicated that 26% of the error was attributed to mean bias, 30% to systematic bias, and only 44% to random error. For the DIM method, these values were 0.025%, 23%, and 77%, respectively. These results suggested that the CVDS model using either MBWM or DIM was highly precise and accurate in predicting DMR for pen-fed steers, but further work is needed to decrease mean and systematic biases when using the MBWM method and account for more of the random variation for the DIM method.

Key Words: Modeling, Feed Intake, Simulation

934 Genetic trends for feed intake, average daily gain, mid-test weight and residual feed intake in a population of Angus cattle selected for feed efficiency. D. P. Kirschten*[1], E. J. Pollak[1], D. R. Strohbehn[2], and D. Warden[3], [1]*Cornell University*, *Ithaca, NY*, [2]*Iowa State University*, *Ames*, [3]*Wardens Farm*, *Council Bluffs, IA*.

Wardens Farm of Council Bluffs, IA provides Angus bulls to area purebred and commercial breeders and AI companies. In business since 1964, Wardens Farm has tested yearling bulls for feed efficiency (FE) since 1981, accumulating feed intake (FI) records on over 450 animals. Wardens Farm uses a multiple trait approach to yearling bull evaluation with independent culling levels. Selection criteria are: weight per day of age (off test): > 1.36 kg, frame score: < 6.5, Ultrasound (US) fat thickness: < 1.02 cm, US intramuscular fat: > 3.0%, US ribeye area: > 80.6 cm2, FE ratio: > 100, birth weight: < 43 kg, and scrotal circumference: > 36 cm. Genetic parameters for FI, average daily gain (ADG), mid-test weight (MW) and residual feed intake (RFI) were estimated using records from 309 bulls with a pedigree population of 782 animals. Animals born before 1991 were not included in the genetic trend charts. Genetic trends for FI and RFI were variable until key sires were identified through progeny testing that were favorable for FE, while at the same time several sires were identified that were unfavorable for FE and were culled which allowed genetic trends to become evident. Also, increased capacity to measure FI in recent years has resulted in rapidly decreasing trends for FI and RFI. Selection has resulted in animals with increased genetic merit for ADG and MW with increased genetic merit (decreasing trends) for FI and RFI.

Table 1. Genetic Trends for Feed Intake, Residual Feed Intake, Average Daily Gain and Mid-test Weight, kg

Year	FI	RFI	ADG	MW
1991	-0.054	-0.008	0.002	0.09
1992	-0.057	-0.055	0.00	-1.15
1993	-0.143	-0.105	0.006	1.71
1994	-0.055	-0.064	0.01	1.16
1995	0.017	0.031	0.009	4.41
1996

2004	-0.182	-0.313	0.057	10.31

Records previous to 1991 and for the years 1996 and 1998 were not available for analysis.

Key Words: Feed Intake, Feed Efficiency, Beef Cattle

935 Relationship between residual feed intake and ultrasonic measures of body composition in yearling performance tested bulls. T. L. Perkins*, J. L. Drury, and A. Rimal, *Missouri State University*, *Springfield*.

Feed input is the greatest cost in livestock production. Residual feed intake is a measure of growth that can be used to select breeding animals, to reduce feed cost. Residual feed intake compares actual consumption and estimated feed consumption. Low or negative RFI values are present in animals that are efficient feed converters. The objectives of this study were to examine the relationship between residual feed intake (RFI) and ultrasound measurements taken at yearling weigh off period in performance tested bulls. One hundred forty-four registered bulls (n=144) were scanned ultrasonically for ribeye area (REAU), fat thickness (FTU), and percent fat (%FatU) at the conclusion of a 112 d feed test. The cattle used in this study were from the Greensprings Bull Test Station in Nevada, Missouri. Ultrasound measurements were taken at approximately one year of age at the end of the 112 d weigh off. All ultrasound measurements were taken by an Ultrasound Guidelines Council (UGC) field and laboratory certified technician using the Beef Image Analysis (BIA) image capturing software. All captured images were sent to and interpreted by the National CUP Lab in Ames, Iowa. Means and standard deviations for 112 d measures for on test weight (ONWT), off test weight (OFFWT), RFI, REAU, FTU, and %FatU were 384.95 ± 57.36 kg, 577.95 ± 63.30 kg, -0.20 ± 2.14, 93.87 ± 12.21 cm^2, 0.76 ± 0.26 cm, and 4.07 ± .87 %, respectively. Pearson correlations between RFI and OFFWT, REAU, FTU and %FatU 0.03, 0.08, 0.22 and 0.18, respectively; whereas, the correlation between RFI and feed consumption (KG FEED) was higher and more significant at 0.55. These coefficients indicate that RFI is a better indicator of yearling fat measures (FTU and %FatU) than muscle (REAU).

Key Words: Ultrasound, Residual Feed Intake, Bulls

936 Characterization of residual feed intake and relationships with serum insulin-like growth factor-I in growing Brangus heifers. P. A. Lancaster*[1], G. E. Carstesn[1], J. G. Lyons[1], T. H. Welsh, Jr.[1], R. D. Randel[2], and T. D. A. Forbes[3], [1]*Texas Agricultural Experiment Station*, *College Station*, [2]*Texas Agricultural Experiment Station*, *Overton*, [3]*Texas Agricultural Experiment Station*, *Uvalde*.

The objective of this study was to characterize residual feed intake (RFI) and examine phenotypic correlations with serum insulin-like growth factor-I (IGF-I) in growing heifers. Average (± SD) initial age and BW of Brangus heifers (Camp Cooley Ranch) were 225.8 ± 9.1, 236.0 ± 10.7 and 235.6 ± 14.6 d, and 285.1 ± 28.0, 268.5 ± 23.8 and 267.8 ± 25.8 kg for year 1 (N=114), 2 (N = 115) and 3 (N = 119), respectively. Heifers were individually fed a roughage based diet (ME = 2.1 Mcal/kg DM) using Calan gate feeders for 70 d. Weekly BW were measured and ultrasound measures of 12th rib fat thickness (BF) and longissimus muscle area (LMA) obtained at d 0 and 70. Whole blood was collected at weaning, and at d 0 and 70 of the intake measurement period, and serum assayed in duplicate aliquots for IGF-I by EIA procedures (IDS, Inc., Fountain Hills, AZ). RFI was computed as actual minus predicted DMI, with predicted DMI determined by linear regression of DMI on mid-test BW$^{.75}$ and ADG with year as a random effect using a variance component covariance structure (R2 = 0.57). Overall ADG, DMI and RFI were 0.90 ± 0.15, 1.06 ± 0.16 and 1.00 ± 0.13 kg/d, 9.10 ± 1.11, 9.47 ± 1.04 and 9.92 ± 1.06 kg/d, and 0.00 ± 0.75, 0.00 ± 0.68 and 0.00 ± 0.70 kg/d for year 1, 2 and 3, respectively. ADG was strongly correlated with FCR (-0.67), but not with RFI, whereas, DMI was correlated with both RFI (0.67) and FCR (0.17). In addition, RFI was strongly correlated with FCR (0.60). Heifers with low RFI (< 0.5 SD; n = 112) consumed 16% less (P < 0.01) DMI and had 15% lower (P < 0.01) FCR than heifers with high RFI (> 0.5 SD; n = 98), even though ADG and final BW were similar. Overall IGF-I concentrations were 113.3 ± 27.4, 121.0 ± 29.6 and 116.6 ± 28.7 ng/ml for weaning, d 0 and d 70 sampling times. RFI was not correlated with IGF-I concentration at any of the sampling times. However, weaning IGF-I concentration was weakly correlated (P < 0.05) with ADG (-0.11) and final BF (0.11) and LMA (0.17), but not with DMI or FCR. These data suggest serum IGF-I concentration may be indicative of growth, but not feed intake or efficiency in Brangus heifers.

Key Words: Residual Feed Intake, IGF-I

937 Feed efficiency and residual feed intake of Nelore young bulls selected for yearling weight. R. Almeida*[1], R. F. Nardon[2], A. G. Razook[2], L. A. Figueiredo[2], and D. P. D. Lanna[3], [1]*Universidade Federal do Paraná*, *Paraná, Brazil*, [2]*Instituto de Zootecnia*, *São Paulo, Brazil*, [3]*ESALQ/USP*, *São Paulo, Brazil*.

A Nelore herd at the Sertãozinho Experimental Station, São Paulo, Brazil has been selected for yearling weight for more than 25 years. The feedlot test used 72 young bulls from the 12-13-14th progenies of the Selection Program for Zebu Breeds. Thirty-six intact males from the Selected Nelore (NeS) line and 36 from the Control Nelore (NeC) line, with the same initial age of 13 months, were transferred to the feedlot and fed a high roughage diet and slaughtered at a similar age (19 months). Predicted DM intake and residual feed intake (RFI) were calculated from average intakes regressed on metabolic mid-test body weight, average daily gain and 9-11th rib fat content. RFI mean was 0.00 ± 0.41 kg/d, with minimum and maximum of -0.73 and +0.95 kg/d. Results confirm there is considerable variability for this trait in *Bos indicus*. NeS young bulls were heavier (P<0.01) at the beginning and at the end of the trial and grew faster (P<0.01) than NeC. NeS bulls had greater (P<0.01) DM intakes than NeC bulls: 8.18 vs 7.03 kg/d and 92.5 vs 87.5 g/kg BW$^{0.75}$. DMI expressed as a % of BW was not different (P>0.10) between NeS and NeC lines (2.08 vs 2.03% BW). When efficiency was analyzed as feed conversion, there were no (P>0.10) differences between the two lines. However, for RFI the NeS young bulls were less eficient and ate 0.263 kg/d more (P<0.05) than NeC. There were no (P>0.10) differences for EBW fat content between the two lines, compared at the same age, but NeC were much lighter than NeS (428 and 481 kg, respectively). Consequently, the estimated energy retained was similar (P>0.05): 5.23 and 5.27 Mcal/kg EBWG, respectively for NeC and NeS. While NeS young bulls retained 11.7% more energy per day, their heat production was 17.9% larger than NeC. Thus, NeS bulls had greater (P<0.10) maintenance requirements than the control line: 78.6 and 68.0 kcal/kg BW$^{0.75}$, respectively. In conclusion, results suggest that selection for yearling weight may increase heat production and maintenance requirement. Is is also shown that selection changes RFI, but it does not change feed conversion efficiency, when animals are fed to the same fat endpoint.

938 Genetic parameters estimation for Test Day Model evaluation in Italy. F. Canavesi* and S. Biffani, *ANAFI*, *Cremona, Italy*.

In November 2004 the first Italian genetic evaluation based on Test day random regression model (TDRRM) was published. The model is a Multiple-Trait-Multiple-Lactation model including four traits and three lactations for each trait. The four traits evaluated are milk, fat and protein kg and somatic cell counts. Genetic parameters used in the current model were estimated in 2003 (Muir et al, 2007). The estimated parameters were close to the parameters estimated for the same model in Canada. Heritability was close to the one used for the Lactation Repeatability model used in the past for official evaluations. Genetic correlations within trait and across traits were very similar to the parameters estimated for the same model in Canada. Research is ongoing in order to improve the stability of proofs over time and the predictive ability of the model. Pre adjustment of test day for number of days of pregnancy and the inclusion of the effect of single years in the fixed effect structure showed better results in residual analysis and a slight reduction in proof variability. The new model with pre-adjusted data was used to estimate genetic parameters with a four and three traits analysis. The three trait analysis did not consider somatic cell count. Estimations of genetic parameters of variances and covariances for the two models were achieved by Bayesian methods using the Gibbs sampler as described by Jamrozik and Schaeffer (2003). The four traits analysis resulted in very similar correlation within and across traits and a lower heritability (0.25) than the current used (0.30). The three traits analysis resulted in a higher correlations within traits across lactations very similar to correlations from single trait analysis (Muir, 2004) which may lead to a decrease in variability of proofs from run to run. Correlations between first and second lactation increased by about 0.06 and correlations between first and third lactation increased by 0.10. The new parameters are under test to verify their impact on stability of proofs.

939 Use of a mathematical computer model to predict feed intake in Angus cattle: Genetic parameters between observed and predicted values, and relationships with other traits. D. P. Kirschten*, E. J. Pollak, and D. G. Fox, *Cornell University*, *Ithaca, NY*.

The objectives of this study were to investigate the suitability of using dry matter required (DMR) as predicted by the Cornell Value Discovery System (CVDS) in genetic evaluations and to determine relationships between model predicted and individual DMI and other traits. Group 1 (659 finishing steers) and group 2 (309 yearling bulls) had observed feed intake (FI) records. Group 3 (1586 yearling bulls and heifers) had pedigree ties to the other datasets, but did not have FI data. The data also contained records of ADG and body weight (BW). Two predictions of DMR were made with the CVDS model iterating on BW (DMR-W) and ADG (DMR-G). For purposes of parameter estimation, CVDS DMR predictions were considered surrogates for FI. Genetic parameters were estimated with MTDFREML, using an animal model with fixed effects of weaning weight contemporary group and pen. Phenotypic correlations between FI and DMR-W and DMR-G were 0.69 and 0.71. The phenotypic correlation between DMR-W and DMR-G was 0.98. Genotypic correlations between FI and DMR-W and DMR-G were 0.79 and 0.85. The genetic correlation between DMR-W and DMR-G was 0.97. Heritabilities for FI, DMR-W and DMR-G were 0.42, 0.31 and 0.33, respectively. Genetic correlations between ADG and FI, DMR-W and DMR-G were 0.45, 0.80, and 0.83, respectively. Genetic correlations between mean body weight (MW) and FI, DMR-W, and DMR-G were 0.50, 0.64 and 0.58, respectively. Residual feed intake (RFI) was calculated using FI, metabolic MW ($MW^{0.75}$) and ADG. The heritability of RFI was 0.36. The phenotypic correlation between RFI and FI was 0.57. Phenotypic correlations between RFI and MW and ADG were not estimated. Genetic correlations between RFI and FI, MW, and ADG were 0.77, 0.09, and 0.01, respectively. Heritabilities of ADG and MW were 0.27 and 0.48. Standard errors for all genetic correlations were less than 0.06. The genetic relationships between FI, DMR-W and DMR-G suggest that CVDS predictions of FI may be used as surrogates for actual FI in genetic evaluations.

940 Computing options for genetic evaluation with a large number of genetic markers. S. Tsuruta, I. Misztal*, and J. K. Bertrand, *University of Georgia*, *Athens*.

Test data set included records on about 110,000 animals for 11 growth, reproduction and other traits. Also available were marker genotypes or marker probabilities on 78 markers. The model included the effects usually fitted for these traits plus two covariables per marker; only selected markers were fit for each trait. Computing was by program blup90iod, which uses iteration on data using a preconditioned conjugate gradient algorithm with a diagonal preconditioner. Without the markers in the model, the evaluation finished in 421 rounds and 2.5 h. With the markers included, the evaluation took one week of computing and 797 rounds of iteration. Modifications included the algorithm by Strandén and M. Lidauer (SL) to reduce the number of operations for each record, a block preconditioner for traits (BT), and a block preconditioner for all markers (BM). With the markers included in the model, the number of rounds (computing time) were 797 (7.8 h.) for SL, 544 (6.2 h) for SL+BM, 459 (4.3 h) for SL+BT, and 431 (5.2 h) for SL+BT+BM. The memory requirements for all methods except BT were around 60 Mbytes; with BT, the memory requirements increased 10 times. The most important modification to decrease the computing time was the SL algorithm. Setting up BM was computationally demanding, and would be very expensive if the number of markers is increased. BT would show greater advantage with higher genetic correlations among traits. With careful programming, adding markers fitted as covariables to a genetic evaluation increases the computing time only a few times.

941 Sampling genotype configurations in large complex pedigree. M. Szydlowski*[1] and N. Gengler[1,2], [1]*Gembloux Agricultural University*, *Gembloux, Belgium*, [2]*National Fund for Scientific Research*, *Brussels, Belgium*.

Efficient genotype samplers are needed for Bayesian and maximum-likelihood analysis of complex genetic problems implemented via Markov Chain Monte Carlo (MCMC) algorithms. The examples of such analysis include polygene mapping in complex pedigrees and prediction of total genetic value using genome-wise dense marker maps. For large complex pedigree sampling from desired probability is impossible. We present a simple method to sample genotype configurations for large pedigree from approximate probability. The sampler uses combination of exact (simple peeling) and iterative methods (iterative peeling) to approximate target probability. Two techniques were applied to reduce computational burden: genotype elimination and set-recoding of alleles. The new sampler was evaluated on a large complex pedigree using simulated data sets for various experimental designs and degree of marker polymorphism. The pedigree used in simulation was real bovine pedigree of 907 903 animals born between 1960 and 2005 derived from Belgian dairy and dual-purpose cattle database. Four types of experimental designs were considered: (i) genotyping sires only, (ii) genotyping dams only, (iii) genotyping half of the dams but no sires, and (iv) genotyping half of the sires and half of the dams. For hypothetical single nucleotide polymorphism the new sampler reached 100%, 100%, 44% and 89% of maximum efficiency for the four experimental designs respectively. For microsatellite polymorphism the efficiency of the sampler reached 100%, 100%, 32% and 76%, respectively. To exemplify the use of the new sampler it was applied to estimate genes shared identical by descent (IBD). The calculation of genes shared IBD among relatives is an important component of gene mapping in complex diseases and quantitative traits. The convergence diagnostic methods gave indirect evidence of irreducibility of the new sampler and showed its good mixing performance.

Key Words: MCMC Sampler, Genotype Estimation, IBD

942 Comparisons of single and multiple trait random regression models for analyses of multi-parity test-days. S. Tsuruta* and I. Misztal, *University of Georgia*, *Athens*.

The objective of this study was to compare a single-trait (ST) test day model with combined covariance functions for DIM within lactation

and for across parities with a multiple-trait (MT) test day model with random regressions on DIM treating each parity as a separate trait. Analyses involved records on 50,494 Holstein cows calved from 1993 to 2003 in Georgia. The data contained 495,455 test day records from first to third parities. The number of animals in the pedigree file was 118,281. The MT model for each trait (parity) included herd-test-date, age × month of calving group, milking frequency and cubic regressions on DIM using Legendre polynomials as fixed effects, and random effects of additive genetic, permanent environmental with cubic random regressions on DIM and residual. The ST model included the same fixed and random effects as the MT model except for additive genetic and permanent environmental effects with cubic random regressions on DIM within lactation and quadratic random regressions on parities. The MT model required 288 parameters and the ST model required 72 parameters. Variance components were estimated using an MCMC approach. Breeding values were obtained using the preconditioned conjugate gradient algorithm with iteration on data. With the MT model, heritability estimates were 0.22, 0.19 and 0.23 on average for first, second and third parities, respectively. With the ST model, those estimates were 0.21, 0.17 and 0.21, respectively. Correlations of EBV between MT and ST models at 65 (245) DIM were 0.99 (0.98) for first parity, 0.98 (0.97) for second parity and 0.94 (0.96) for third parity. Correlations of EBV between MT and ST models averaged over 5-305 d were 0.99, 0.99 and 0.98 for first, second and third parities, respectively. The MT model required 2 times of computing time and memory for the ST model. Results of tests with larger data sets will be presented. The ST test day model as presented may be a cost-effective alternative to the MT test day model.

Key Words: Test Day Model, Random Regressions

943 Investigation of genetic differences in feed efficiency through comparison of observed versus model predicted feed intake in *Bos indicus – Bos taurus* F_2 full sib steers. T. S. Amen*, J. E. Sawyer, A. D. Herring, J. O. Sanders, D. K. Lunt, and C. A. Gill, *Texas A&M University*, *College Station*.

Individual feed intake (DMI) and body weight were measured on 149 F_2 Nellore-Angus steers born and raised at the Texas A&M University Experiment Station at McGregor. Steers belonged to 12 full sib embryo transfer families sired by 4 bulls and from 11 dams born in the spring and fall of 2003 to 2005. At approximately 12 months of age, steers were placed on feed for an average of 140 d with individual intake measured using Calan gates. Using the NRC (2000) model, daily feed intake was predicted based on observed weight gain for each animal and standardized input for animal type, age, sex, condition, and breed. This model predicted intake (MDMI) was then subtracted from observed DMI and the difference defined as model predicted residual consumption (MPRC) such that those animals that consumed less than predicted (and thus, were more efficient) had negative MPRC. This method was utilized instead of traditional residual feed intake in order to make simultaneous use of data from multiple contemporary groups. Mixed procedures of SAS were then used to analyze MPRC with fixed factors of sire and family nested within sire. Initial analysis also included contemporary group; however, substantial imbalance existed with sire and family, so it was subsequently omitted. Sire ($P = 0.016$) and family(sire) ($P < 0.001$) both accounted for variation in MPRC. Least squares means for MPRC by sire ranged from a low of -0.51 ± 0.22 kg day $^{-1}$ to a high of 0.65 ± 0.36 kg day $^{-1}$. Least squares means for MPRC by family(sire) ranged from -2.13 ± 0.48 kg day $^{-1}$ to 1.45 ± 0.60 kg day $^{-1}$ across families. Variation between sires and families for MPRC indicates that genes affecting this trait are segregating in this population and presents future opportunities for QTL analysis, and subsequent gene discovery; further, MPRC holds promise as a model derived method of evaluating efficiency across contemporary groups.

Key Words: Predicted Intake, NRC Model, *Bos indicus*

944 First screening of QTL using a segment mapping approach. M. Sargolzaei*[1], F. Schenkel[1], and H. D. Daetwyler[2], [1]*University of Guelph*, *Guelph, Ontario, Canada*, [2]*Roslin Institute*, *Roslin, Midlothian, Scotland, UK*.

Panels of SNP markers are rapidly increasing in size and are being used for fine mapping. The first step in fine mapping is to identify potential regions which are more likely to harbor QTL. The objective of this study was to evaluate a modified version of the segment mapping method (SM) for a first screening of QTL using simulated SNP data. The SM included the polygenic effect, the putative QTL effect and the whole chromosome effect excluding the putative QTL. The SM was compared to the point identity by descent (IBD) method (PM), in which only the polygenic effect and the putative QTL effect were fitted, using 4 simulated generations of randomly mated sires (15) and dams (300; 1 progeny per dam). A trait with heritability of 0.3 was considered. A 1-Morgan chromosome with 100 evenly spaced SNPs was simulated. Two bi-allelic QTL with additive effects were symmetrically located at 20, 15, 10 and 5 cM from the centre of chromosome. Each QTL explained 16.6% of total additive genetic variance. In every generation, 50% of the oldest sires and dams were randomly replaced. The software Loki was used to compute IBD at every cM. For SM, the average of 99 point IBDs was used as an approximation of IBD for the rest of chromosome. The full models, with putative QTL included, were tested against the corresponding models with no putative QTL, using the software ASReml. The likelihood ratio peaks for the QTL positions given by SM were always narrower and clearer than PM. However, when the two QTL were located less than 20 cM apart, both SM and PM revealed a single peak. The SM seemed to separate loosely linked QTL better than PM. Thus, SM might be useful for first screening of QTL, but the number of QTL, their precise positions and effects should be estimated by fine mapping methods in a second step.

Key Words: First Screening, QTL, Segment Mapping

945 Evaluating the feasibility of fitting haplotype effects as random: Variance component estimation. L. A. Kuehn*, R. M. Thallman, and K. A. Leymaster, *USDA-ARS U.S. Meat Animal Research Center*, *Clay Center, NE*.

Fitting haplotypes as random effects in association studies may prevent overestimation of haplotypic effects with low frequencies. The objective was to determine whether haplotypic variance could be accurately estimated. Using simulation, haplotypic effects were deterministically assigned to either 2 or 16 haplotypes with variances of haplotypic effects set at 2, 4, or 16.67 units^2. Haplotypes were

assigned stochastically to base animals in frequencies such that the 3 haplotypic variance scenarios accounted for 3, 6, and 25 units^2 of genetic variance, respectively. Polygenic additive effects were assigned from a normal distribution so that a total of 25 units^2 of the phenotypic variance was genetic. Residual effects were sampled from a normal distribution with a variance of 75 units^2. Either 250 or 1,000 progeny (5 or 15 per sire) with performance records were simulated. With varying levels of haplotype number, haplotypic variance, numbers of progeny, and numbers of progeny per sire, there were a total of 24 different simulation scenarios. Each simulation scenario was replicated 100 times and analyzed using MTDFREML with a model that included a random independent regression for the number of copies of each haplotype (0, 1, or 2), a random polygenic effect, and error. Estimates of polygenic and residual variance were accurate for all scenarios. Standard errors of the mean estimates for both variance components were greater with 250 than 1,000 progeny and with 5 than 15 progeny per sire. When 16 haplotypes were simulated, the variances of haplotypic effects were accurately estimated when the pedigree contained 1,000 progeny and underestimated with 250 progeny. Haplotypic variance was consistently overestimated when only 2 haplotypes were simulated, possibly due to the small number of classes for the haplotypic regression. Large, phenotyped pedigrees are important when estimating haplotypic variance for association studies.

946 Interval mapping of deleterious recessive loci in half-sib families. L. Gomez-Raya* and W. M. Rauw, *University of Nevada*, *Reno*.

Deleterious recessive genes in farm species with a half-sib structure are difficult to eliminate by breeding. However, their frequency can be increased by the widespread use of semen of carriers with high genetic value. In this study, we developed maximum likelihood interval mapping methods to detect deleterious recessive genes. The methods were developed for recessive genes that are lethal in homozygotes before birth, and also in homozygotes that are born with a disease. The available DNA marker data in the first situation is that one fragment in one of the two chromosomes is inherited in a lower number of offspring than the other chromosomal fragment. For this situation, we carried out a Monte Carlo computer simulation modeling a heterozygous sire with one copy of the recessive allele and a varying number of progeny and frequency of the recessive allele among the progeny. The simulated chromosomal fragment was bracketed by DNA markers separated 20cM, with the recessive locus equally distant from each of the two markers. The percentage among 10,000 replicates with a lod score greater than 2 for 100 tested offspring were 2.69, 8.56, 23.65, and 51.05% for a frequency of the recessive allele of 0.20, 0.30, 0.40 and 0.50, respectively. The percentage of replicates with a lod score greater than 2 for a progeny size of 2000 was 21.44, 60.83, and 92.65% for allele frequencies of 0.10, 0.15, and 0.20, respectively. The average estimate of the position of the recessive locus was 0.5cM or less in all simulations. Estimates of the allele frequency of the deleterious locus were unbiased except when the frequency or the progeny group was small. The percentage of replicates that located the locus within 1cM of the simulated position was 16.9% for a progeny size of 2,000 and allele frequency of the recessive allele of 0.20. The results illustrate that large progeny groups are required to detect recessive alleles at low frequency. Mapping strategies, including selective genotyping of offspring of dams genetically related to the sire, are discussed.

947 Investigating the role of genetics on bovine respiratory disease incidence. M. J. Schneider*, J. R. Tait, M. V. Ruble, and J. M. Reecy, *Iowa State University*, *Ames*.

Bovine Respiratory Disease (BRD) is one of the most costly diseases facing the cattle industry. Therefore, the objective of this study was to examine the role genetics has on susceptibility and resistance to bovine respiratory disease. Calving, pedigree, and health treatment records were collected on 1400 cattle born from 1997 through 2006 at the Iowa State University beef teaching farm with majority of cattle sired by Angus or Simmental bulls. Calves were born in both the Spring and Fall seasons for each year with the exception of 2006 where only Spring calves were used. The number of treatments for BRD varied with 80% of cattle never being treated for respiratory symptoms, 16% treated once, 3% treated twice, and 1% treated three to five times. The highest incidence of BRD treatment occurred in calves born in the Spring of 2001 when 74.8% of calves were treated at least once, whereas the lowest incidence of treatment occurred in calves born in the Fall of 2003 (1.5%). Statistical analysis was performed using general linear models to estimate significance level and effects. Traits showing significant effects ($P<0.05$) on the number of times an animal was treated for BRD included sire nested within breed, calving season group, and birth weight these accounted for 28.4% of the variation in number of BRD treatments. Calving ease score and sex did not have a significant effect on the number of treatments for BRD ($P>0.10$). LSMeans estimates of sire effect for number of respiratory treatments within Angus ranged from -0.22 to 1.96 and in Simmental ranged from -0.06 to 1.77. The results from this study show a significant effect on number of treatments for BRD among sires within breeds. Thus, further investigation into the genetic control of BRD is warranted.

948 Simulation study controlling inbreeding in litter size. S.-H. Oh*[1], G.-M. Kim[1], and Y.-C. Jung[2], [1]*North Carolina A&T State University*, *Greensboro*, [2]*Jung P&C Institute*, *Seongnam, Gyeonggi, South Korea*.

Inbreeding is the mating of relatives that produces progeny having more homogenous alleles than non-inbred animals. Inbreeding causes an increase of recessive alleles, which is often associated with a decrease in performance, known as inbreeding depression. The magnitude of inbreeding depression depends on the level of inbreeding expressed by coefficients. Litter size is a quantitative trait compound of effects from two generations. The number of pigs born in a litter depends partly on the dam and partly on the offspring of the dam. Therefore both the dam's fertility and the litter's viability influence litter size at the same time. The fact that the inbreeding rate of young in the litter is always one step ahead of that of the dam seems to be more of an influence of the litter on reduction of litter size. One of breeding goal in livestock is uniform productivity which means uniform progeny from homogenous

parents, maintaining optimal inbreeding level, especially keeping inbreeding lower than 20%. The concept of the theory of optimum genetic contribution (OGC) uses the relationships between individuals as weights. The objective of this study was to compare simulated results of the OGC algorithm in different conditions for 30 generations. Results showed this algorithm could effectively control inbreeding maintaining a consistent increase in selection responses. The difference of breeding values between selection based on the OGC algorithm compared with with EBV was only 13%, but the rate of inbreeding could be controlled as much as ~67% after 30 generations, indicating that the OGC algorithm can be effectively used for long-term selection programs.

Contemporary & Emerging Issues - Livestock and Poultry: Contemporary and Emerging Issues

949 Avian H5N1: Still an animal virus? F. C. Leung*, *The University of Hong Kong*, *Hong Kong, HK-SAR, China*.

As of Feb 6, 2007, the cumulative number of confirmed human cases of avian influenza A/(H5N1) reported to World Health Organization (WHO) is 272 with 166 deaths. Avian influenza including H5N1 refers to a large group of different influenza viruses of which the primary host is birds. Only on rare occasions do these viruses cross over and infect other species including pigs and humans. Pandemic influenza happens when a new subtype emerges that has not previously circulated in humans. Since H5N1 is a strain of such potential, WHO and other health experts, for this reason, have been priming the world to prepare for this threat along with OIE and FAO calling for culling million of poultry world-wide. During my presentation, I will present a model based on the most recent event of an animal virus 'crossing over' to become a human virus, SARS, and argue that the scale of the warnings appears to outstrip the magnitude of the real threat. Culling millions of chicken may not have actually lowered the actual risk and efforts and resources should be directed to research in understanding the molecular and genetic mechanisms underlying the virus-crossing species event. Only then can effective barriers be set up to limit the direct contact of susceptible species; to lower the transmission rate; and avoid establishing/adaptation to a new host. In addition, I shall review recent scientific findings that avian H5N1 remains as an animal virus and the probability and possibility for H5N1 successfully adapting to humans as a new host remains low at this particular moment!

i**Key Words:** Avian Influenza, H5N1, Virus

950 Bovine spongiform encephalopathy in the United States. J. A. Richt*, *National Animal Disease Center-ARS-USDA*, *Ames, IA*.

Transmissible spongiform encephalopathy (TSE) agents or prions induce fatal neurodegenerative diseases in humans and in other mammalian species. They are transmissible among their species of origin, but they can also cross the species barrier and induce infection with or without disease in other species. In animals, four distinct TSE diseases are recognized: scrapie in sheep and goats, transmissible mink encephalopathy (TME) in mink, chronic wasting disease (CWD) in cervids, and bovine spongiform encephalopathy (BSE) in cattle. BSE was first identified as a TSE of cattle in the mid 1980s in the U.K. and more than 180,000 positive cases have been diagnosed in the U.K. to date. Using epidemiological surveillance programs, many European and non-European countries have discovered BSE-positive animals within the last decade. In the U.S., the first BSE case (case 1) was identified in December 2003; this animal was determined to be imported from Canada. After this animal was identified, the USDA began its enhanced BSE surveillance program in June 2004. Since then, two additional animals (cases 2 and 3) have been identified as being positive for BSE. Both animals were born and raised in the U.S. Case 1 showed molecular features similar to typical BSE isolates, whereas cases 2 and 3 revealed unusual features referred to as atypical BSE isolates. Unusual cases of BSE are an unexpected finding since it was previously believed that BSE disease in cattle is caused by a single strain of infectious agent, which has been shown to be very consistent and uniform in appearance, even after transmission to other species. The appearance of unusual phenotypes of BSE in cattle suggests that different BSE strains exist in cattle.

Key Words: Prion Diseases, U.S BSE Cases, BSE Strains

951 Scenario and economic analysis of a hypothetical link between MAP and Crohn's disease. H. Groenendaal* and F. Z. Zagmutt, *Vose Consulting*, *Boulder, CO*.

Johne's disease (JD) is an infectious disease of cattle caused by the agent Mycobacterium avium subspecies paratuberculosis (MAP). Crohn's disease is a disease of unknown etiology that causes chronic bowel inflammation in humans. No causal link between MAP and Crohn's disease in humans has been scientifically established but given the potential for such discovery, it is important to understand its possible impacts on society. In this presentation, we will show the implications and the possible economic impacts on the dairy industry and to provide a framework for further discussion among stakeholders. Three scenarios were developed based on the effectiveness of possibly risk mitigation strategies. In the first scenario, it was assumed that an effective strategy would exist, resulting in negligible demand effects. In the second scenario it was assumed that new risk mitigation would need to be implemented, in which case a small milk demand was expected, with the potential of being large. The third scenario assumes that no fully effective risk mitigation would be available, which more likely results in a considerable demand decrease and a reduction in milk supply as a result of government regulations. With milk demand of 1% or 5%, a reduction in consumer surplus of $600 million and $2.9 billion and a reduction in dairy farm income of $270 million and $1.3 billion respectively was found. The true shift in demand is however impossible to predict. An decrease in milk supply would slightly increase total losses, but would cause great losses to MAP positive dairy farms. Given the current scientific knowledge about the link between MAP and Crohn's and the effectiveness of risk mitigation methods, it is concluded that in case a link would be established, it is most likely that the first scenario or potentially the second scenario could occur. Consumer response and economic consequences to discovery of such link are therefore expected to be limited, but could

be large if the consumer's perception of risk turns out to be large or if risk mitigation strategies appear not fully effective.

Key Words: Mycobacterium Avium Subspecies Paratuberculosis, Crohn's Disease, Economic Analysis

952 Tuberculosis: A re-emerging disease at the interface of domestic animals and wildlife. M. V. Palmer*, *National Animal Disease Center, ARS, USDA*, *Ames, IA*.

In the early twentieth century there were large numbers of tuberculous cattle in many countries. An association was made between the number of *Mycobacterium bovis* infected humans and the prevalence of tuberculosis in cattle. Mandatory pasteurization of milk and advances in public health caused the prevalence of human tuberculosis due to *M. bovis* to decline dramatically in developed countries. However, in some countries eradication has been prevented by several factors not least of which is the presence of a wildlife reservoir of *M. bovis*. In Great Britain evidence suggests that *M. bovis* is endemic among badgers (*Meles meles*), and that tuberculous badgers are the source of infection for cattle. In New Zealand, brushtail possums (*Trichosurus vulpecula*), first taken to New Zealand from Australia in the mid-nineteenth century now occupy over 90% of New Zealand's land mass and serve as a source of *M. bovis* for domestic livestock. In Michigan, USA free-ranging white-tailed deer (*Odocoileus virginianus*) represent the first known reservoir of *M. bovis* in free-living wildlife in the United States. Deer to cattle transmission of *M. bovis* has been documented. Wildlife reservoirs of *M. bovis* represent a serious challenge to the eradication of *M. bovis*. The presence of wildlife reservoirs is the direct result of spill-over of *M. bovis* from domestic livestock and efforts to eradicate *M. bovis* from domestic livestock are impeded by spill-back from wildlife reservoirs. The test and slaughter policies of tuberculosis control, effectively used with domestic livestock, are insufficient in areas where wildlife reservoirs exist. Complete removal of wildlife is impractical, and often impossible. It will not be possible to eradicate *M. bovis* from livestock until transmission between wildlife and domestic animals is halted. Such an endeavor will require a collaborative effort between agricultural, wildlife, environmental and political interests.

Nonruminant Nutrition: Poultry Nutrition - Phosphorus and Phytase

953 Early response of young breeder source broilers to combined xylanase-amylase-protease-phytase supplementation of a high performance feed and when both ME-available phosphorus (AP) are reduced. E. T. Moran* and R. Lehman, *Auburn University*, *Auburn University, AL*.

Reserve body fat and calcium-phosphorus of chicks at hatch suffer when from small eggs of young breeders. Supplemental enzymes that focused on energy and AP recovery were examined as a means to relieve early inadequacies of these source broilers. Chicks (1600; 64 pens) originating from a 26 week old R X 708 flock were either directly placed (34g/bird) in litter pens or delayed 24 hours (30 g), respective of sex. Corn-soybean meal feed for next 3 weeks was crumbed and either high performance (23% CP, 1.38% lysine, 0.98% TSAA, 3.19 Kcal ME/g, 0.44% AP, 0.99% Ca) or low ME-AP (omission of 2% fat and 0.25% dicalcium phosphate for corn: 3.11 Kcal/g, 0.34% AP, 0.87% Ca) formulations were used. Crumbed feeds were either fed "as is" or supplemented "on top" to provide units/kg of xylanase, 300; amylase, 400; protease, 4000; phytase, 5000 (0.05% Avizyme 1502 + 0.01% Phyzyme XP). The enzyme mixture did not improve gain during the subsequent 3 weeks of birds given high performance feed as much as improve F/G ($P<.05$). Low ME-AP feed adverse affected live performance that was rectified by supplemental enzymes to the same level as those receiving high performance feed with enzymes ($P<.05$). Adding enzymes also reduced within pen standard deviation of body weights, regardless of feed ($P<.05$). Delayed placement decreased body weight when placed in pens and accentuated the loss in performance from low ME-AP and benefit from enzyme supplementation. Most advantages from added enzymes were exhibited similarly by both sexes, but improved F/G was more apparent with males than females. Supplementation with feed enzymes that improve recovery of energy and phosphorus was of distinct advantage to chicks derived from young breeder hens.

954 The effects of supplemental Quantum Phytase on second cycle Hyline W-36 hens. M. Lilburn[1] and C. Wyatt*[2], [1]*Ohio State University*, *Wooster*, [2]*Syngenta Animal Nutrition*, *Research Triangle Park, NC*.

A flock of Hyline W-36 hens was molted using the non-feed withdrawal program developed by the University of Illinois. During the molt period, all hens were fed a diet containing primarily ground corn (23%) and wheat midds (71.1%) and the hens never completely ceased production. At the onset of second cycle production, 7 replicate blocks of hens (n=4 cages per block; 2 hens per cage) were fed one of 5 diets. The diets were a positive control containing 0.50 total phosphorus (TP), a negative control diet (NC) containing 0.28% TP and the NC diet with either 200 , 400 , or 600 units of QuantumTM phytase. All hens were limit fed 95 g/hen/d. Hen-day egg production was measured over four consecutive 28-day periods and egg weight and shell weight were determined on all eggs collected on two consecutive days during the second and last 28-d production periods. Only the data from the second 28-d period will be reported. The NC diet was numerically lower in hen-day egg production during the first 28-d compared with the mean of the PC and Quantum treatments (47.9 vs. 51.0) but the variability precluded any significant treatment differences. Over the subsequent three production periods, however, hen-day production in the NC treatment was significantly lower than the PC and Quantum supplemented treatments (Pd 2, 68.5 vs 82.0; Pd 3, 67.4 vs 79.7; Pd 4, 70.2 vs 77.3). There were no significant differences between the PC and Quantum treatments during any of the four production periods. Egg weight (63.7 vs 66.4 g) and shell weight (5.89 vs 6.08 g) were both significantly lower in the NC compared with the PC and Quantum supplemented treatments. In summary, a diet containing 0.28% TP resulted in a significant reduction in both hen-day egg production, egg weight, and shell weight compared with a diet containing 0.50% TP or the NC diet supplemented with as little as 200 units of Quantum phytase.

955 Influence of dietary calcium and phytase source on broiler performance. T. M. Parr*, M. R. Bedford, and C. L. Wyatt, *Syngenta Animal Nutrition*, *Research Triangle Park, NC*.

Previous research has shown that bird response to fungal phytases may be linked to the level of calcium in the diet relative to phosphorus. An experiment was conducted to determine the effect of incremental doses (500 and 1000 FTU/kg diet) of a coated fungal phytase (CFP) compared with similar doses of Quantum phytase (QP; an evolved E.coli-derived phytase) on bird performance to 49d, when added to diets containing different levels of calcium. A four-phase (0-18d, 19-30d, 30-39d, and 39-49d) feeding program utilized two positive control (PC) basal diets containing either high (HPC; 1.0, 1.0, 0.95, 0.90) or low (LPC; 0.90, 0.85, 0.78, 0.72) levels of Ca, respectively. The PC diets supplied all nutrients at or above NRC requirements, with the exception of Ca in the LPC treatments. The respective negative control (HNC and LNC) diets contained 0.10% less Ca than the PC. Additionally, all NC diets were reduced by 0.13% available P, 0.029% Thr, 0.018% TSAA, 0.01% Lys, and 45kcal ME. To each negative control diet, 500 or 1000 FTU/kg of either QP or CFP was added to give 12 diets in total. Each diet was fed to 11 pens of 17 birds per pen with both feed and water being offered ad libitum. At 49 days of age, both HPC and LPC-fed birds were heavier than their NC-fed counterparts. There was a significant Ca x enzyme interaction, with birds fed QP weighing more than CFP-treated birds, as well as PC-fed birds. The addition of 500 FTU/kg QP increased intake to PC levels whereas CFP-fed birds required 1000 FTU/kg phytase. Weight corrected feed conversion (WcFCR) showed a significant interaction for Ca level x dose as well as Ca level x enzyme, indicating QP was more effective in restoring FCR than was CFP at either Ca level. When feeding high Ca levels, 1000 FTU/kg of phytase was more effective, whereas at the low Ca levels, 500 FTU/kg of either phytase had a more beneficial effect. These results indicate all phytases are more effective when Ca is not over supplied in the diet, but that QP is more efficient at restoring performance than CFP whether Ca levels in the diet are high or low.

Key Words: Calcium, Phytase, Broiler

956 Influence of dietary calcium and phytase source on litter moisture and mineral content. M. R. Bedford*[1], T. Parr[1], M. E. Persia[1], A. Batal[2], and C. L. Wyatt[1], [1]*Syngenta Animal Nutrition*, *Research Triangle Park, NC*, [2]*University of Georgia*, *Athens*.

The effects of incremental doses (500 and 1000 FTU/kg diet) of a fungal phytase (FP) was compared with that of Quantum phytase (an evolved E.coli-derived phytase; QP) on litter moisture (LM) and mineral content in a 49d grow out study utilizing a four-phase (0-18d, 19-30d, 30-39d, and 39-49d) feeding program. Birds were offered a positive control, that met or exceeded all NRC requirements (HCaPC) or a reduced Ca positive control that met or exceeded NRC requirements with the exception of Ca (LCaPC). Negative controls (HCaNC and LCaNC were generated by removing 0.13% available P, 0.1% Ca, 0.029% Thr, 0.018% TSAA, 0.01% Lys, and 45 kcal ME from the respective positive control diets. To each negative control diet, 500 or 1000 FTU of either QP or FP were added to give 12 diets in total. Each diet was fed to 11 pens of 17 birds with feed and water being offered ad libitum. At approximately day 25, it became apparent that litter quality had deteriorated in many pens. Grab samples of litter were taken immediately from each of 132 pens and analysed for moisture and mineral content. The data were analysed by ANOVA and means separated by the pdiff option of the LS means procedure. Feeding the negative control diets without phytase increased LM (30%) compared with the positive control diets. Although, feeding the LCaPC resulted in similar LM to the HCaPC (31.5 v. 33.5%), feeding the LCaNC diet resulted in significantly less LM than that of the HCaNC diet (43.5 v. 49.2%). Addition of phytase reduced LM in the HCaNC diets, but never reached the level of the HCaPC. Supplementation of the LCaNC diets with 500 and 1000 FTU of QP and 1000 FTU of FP reduced LM to the level of the LCaPC. Mineral analysis of the litter, when correlated with moisture, suggested that Zn, Ca and Na were associated with high LM whereas Mn and Cl were associated with low LM. The results suggest that LM may be influenced by feeding diets adjusted for phytase inclusion. These effects may be mitigated by manipulation of dietary mineral content.

Key Words: Phytase, Litter Moisture, Litter Minerals

957 A holo-analysis of trials investigating the gain and feed conversion ratio benefits of Quantum™ phytase supplementation to broilers under a variety of managerial, environmental and dietary conditions. M. R. Bedford*, C. Murphy, and M. E. Persia, *Syngenta Animal Nutrition*, *Research Triangle Park, NC*.

Data from a total of 77 broiler trials executed over a period of 6 years in which Quantum™ phytase (QP) and several other phytase sources were employed at dosages ranging from 25 FTU/kg to 62,500 FTU/kg were collected and collated in a database that was used to construct a comprehensive multifactorial model to describe the effect of phytase on broiler gain and FCR. Management and environmental factors, dietary ingredients and nutrient contents along with enzyme type and dosage were offered in a stepwise regression analysis ($p<0.20$ in $p>0.10$ out) of the 1032 tests available. Each test represented a response to a given dose of enzyme in any particular trial. Models for gain and FCR were generated which explained 54 and 48% of the variation, respectively. Factors which significantly influenced the FCR response to phytase included the source of the phytase (QP performing significantly better then fungal phytases), sex (females responding moreso than males), and the presence of a coccidiostat (in most cases being significant and positive). Factors influencing the gain response included the age at which the experiment started (effect being greater if the trial starts at day of age), lighting (effects diminish as lighting time increases) and the duration of the trial (longer trial gives a larger effect). Responses in both gain and FCR were best described by the logarithm of the dose of the enzyme employed rather than linear or quadratic dose terms, which suggests that phytase, unlike most other enzymes and nutrients, does not pose a risk to performance if overdosed. Indeed it suggests that technologically optimum dose for performance is considerably higher than current commercial practice. The implications of the significant factors in each model need further investigation.

Key Words: Holo-analysis, Phytase, Broiler

958 A novel rapid method for determining Quantum™ phytase activity levels in animal feeds. R. Upton*, C. Wyatt, M. Yarnall, A. Bruton, and T. Parr, *Syngenta Animal Nutrition*, *Research Triangle Park, NC*.

A new phytase (Quantum Phytase™; QP) has been selected and modified to withstand a desired thermo-tolerance range through the

feed processing system while maintaining high bio-activity in the animal. One method to demonstrate thermo-tolerance is to measure the phytase activity in the feed post-pellet to determine the critical limits in temperature tolerance. The standard method to measure phytase activity in feed is the colorimetric assay which is based on the release of P and calibrated against a P standard curve. Although it is accurate and robust, this technique is laboratory based and labor intensive. The objective of this research was to develop a rapid and reliable method to accurately determine phytase activity in complete feed samples in the field. Several methods were evaluated and an ELISA based method was determined to meet the initial requirements of being quick and reliable. The new ELISA method is based on a monoclonal antibody developed directly against the intact QP protein. Multiple studies were conducted to evaluate the thermo-tolerance of this phytase and results have shown it can survive the rigors of normal feed pelleting conditions. Further studies were performed to determine that the ELISA measures the active phytase protein levels by using levels of phytase heated at different temperatures in feed. Results of this work demonstrated a significant positive correlation (r^2= 0.92) between the phytase activity and ELISA protein levels. These results indicate that the monoclonal is able to detect the active form of the phytase and not denatured protein. Thus, additional evaluation was completed on the ELISA method in commercial feed samples which were collected from several countries and submitted to the laboratory for activity and protein determination. Results have shown a positive linear relationship between the standard colorimetric assay and the new ELISA method (r^2 = 0.825). These data support the use of this new field based method to rapidly (less than 2 hrs) and reliably measure QP in feed samples at the feed mill laboratory.

Key Words: Phytase, ELISA, Rapid Detection

959 The interaction between dietary electrolyte balance and microbial phytase on the performance and nutrient utilization of broiler chickens. V. Ravindran*[1], A. J. Cowieson[2], and P. H. Selle[3], [1]*Massey University*, *Palmerston North, New Zealand*, [2]*Danisco Animal Nutrition*, *Marlborough, United Kingdom*, [3]*University of Sydney*, *Camden, Australia*.

The possible interaction between dietary electrolyte balance (DEB = Na + K + Cl meq/kg diet) and microbial phytase on the performance and nutrient utilization of broiler starters was examined in this study. A 4 x 2 factorial treatment structure was used with four levels of DEB (150, 225, 300 and 375 meq/kg diet) with two levels of phytase (0 and 500 U/kg; Phyzyme XP). Experimental diets were based on corn and soybean meal, and formulated to contain a non-phytate P level of 0.30%. The DEB levels were altered by the use of sodium bicarbonate and ammonium chloride. Each diet was offered to 6 replicates of 8 birds each from d 1 to 21. Increasing the DEB values from 150 to 300 meq/kg had no effect on weight gains ($P<0.05$) and feed per gain ($P<0.001$), but the gains were lowered and the feed per gain was increased at 375 meq/kg. Feed intake was unaffected ($P>0.05$) by DEB levels. Supplemental phytase improved the weight gains ($P<0.001$) and feed intake ($P<0.05$) at all DEB levels. Feed per gain was lowered ($P<0.05$) by phytase addition, but a tendency for DEB x phytate interaction ($P=0.06$) was also observed, indicating that the responses to phytase were affected by DEB level. The responses in feed per gain were greater at the lowest DEB level and phytase addition had no effect on feed per gain at the highest DEB level. DEB levels had no effect on the AMEn and ileal N digestibility to 300 meq/kg, but lowered ($P<0.001$) both parameters at 375 meq/kg. Phytase addition improved ($P<0.05$) the AME and N digestibility, but responses were observed only at the first three DEB levels and none at 375 meq/kg. The improvements in AME with 500 U/kg phytase addition in 150, 225 and 275 meq/kg DEB were 0.22, 0.25 and 0.16 MJ/ kg dry matter, respectively. The present data suggest that phytase responses are influenced by DEB levels.

Key Words: Dietary Electrolyte Balance, Phytase, Broiler Chickens

960 Energetic implications of endogenous amino acid flow at the terminal ileum of broilers as influenced by phytate and phytase. A. J. Cowieson*[1] and V. Ravindran[2], [1]*Danisco Animal Nutrition*, *Marlborough, United Kingdom*, [2]*Massey University*, *Palmerston North, New Zealand*.

The enzyme-hydrolyzed casein (EHC) method was employed to determine the effect of the ingestion of different concentrations of phytic acid, without or with microbial phytase, on the flow and composition of endogenous protein at the terminal ileum of broiler chickens. Phytic acid (fed as the sodium salt) was included in a dextrose-EHC based synthetic diet at 0.85, 1.15 and 1.45 % (or 0.24, 0.32 and 0.40% phytate-phosphorus) and each diet was fed without or with an Escherichia coli-derived microbial phytase (Phyzyme XP) at 500 FTU/kg diet. A control diet containing no phytic acid was also fed as a comparison to estimate basal endogenous flows. Ingestion of phytic acid increased ($P<0.05$) the flow of endogenous amino acids and nitrogen by an average of 47% at the lowest phytic acid concentration and 87% at the highest. The addition of microbial phytase reduced ($P<0.05$) the inimical effects of phytic acid on endogenous amino acid flow at all dietary phytic acid concentrations. The energetic implications of the changes in endogenous amino acid flow were calculated using reported gross energy values for individual amino acids. The ingestion of phytic acid increased endogenous energy loss associated with protein flow by 44kcal/kg DM intake and supplemental phytase reduced this by around 15kcal/kg DM intake. It can be concluded that phytic acid is an antinutrient capable of increasing endogenous amino acid loss and as a consequence impairing the caloric value of the diet. Further, the reported effects of phytase on amino acid and energy retention may be partially explained via a reduction in endogenous investment.

Key Words: Phytic Acid, Phytase, Endogenous Energy Loss

961 The response of chicks fed 5 corn cultivars to phytase supplementation. G. M. Pesti*, H. M. Edwards, Jr., and R. I. Bakalli, *University of Georgia*, *Athens*.

Five hybrid “non-transgenic” identity preserved corn cultivar samples from the 2002 growing season with a variety of genetic backgrounds were obtained to test the hypothesis that variation in corn may be responsible for variation in the responses to phytase supplementation observed in broiler chickens. The cultivars were grown in 3 different locations, to provide a good geographical range. The cultivars ranged from 6.6 to 7.9 % crude protein. In both experiments chicks (10 per replicate) in battery brooders were fed corn, soybean meal and soybean oil based feeds for 16 days. In Experiment 1, 3 pens per treatment were fed each of 5 cultivars with 0.46 or 0.68% total phosphorus (tP) or 0 or 12000 FTU of phytase. There were significant phytase by cultivar

interactions for the incidence of P-deficiency rickets and % tibia ash. In Experiment 2, the cultivars giving the highest and lowest growth responses to phytase when fed 0.46% tP were fed to 4 replicate pens with 18 or 23% crude protein, 0.46 or 0.68% tP and 0 or 12000 FTU of phytase. Chicks fed the 18% protein feed grew slower and had much lower incidences of P-deficiency rickets (21 vs. 14%) and improved % tibia ash (39.4 vs. 37.8%). Again, the phytase x corn interactions for P-deficiency rickets and % tibia ash were significant, but the magnitude of the differences was very small. The corn x phytase interactions could be attributed to differences in the magnitude of p-deficiency rickets between cultivars (for instance, for two cultivars chicks had 97.2 vs. 59.2 % P-deficiency rickets when fed 0.46% tP and 0 FTU phytase). When phytase supplementation reduced both values to zero, the magnitude of the reductions was different. It is concluded that there were no large differences in the responses to phytase supplementation in the 5 corn samples tested.

Key Words: Broiler Chickens, Corn Cultivars, Phytase

962 Performance and nutrient utilization in broilers fed corn-soybean based diets supplemented with coated phytase. I. A. Emiola*[1], T. A. Woyengo[1], A. Owusu-Asiedu[2], P. H. Simmins[2], W. Guenter[1], and C. M. Nyachoti[1], [1]*University of Manitoba*, *Winnipeg, MB, Canada*, [2]*Danisco Animal Nutrition*, *Marlborough, United Kingdom*.

A study evaluated the effects of a new coating (c) on the bioefficacy and nutrient utilisation of a bacterially-derived phytase product (Phyzyme XP; 6-phytase, EC 3.1.3.26) in broilers fed corn-soybean meal-based diets. Two hundred and eighty-eight day-old Ross broiler chicks, balanced for initial bodyweight (BW), were fed one of 6 dietary treatments (6 replicate cages/diet; 8 birds/cage) to 21 days of age. Diets were formulated to be isonitrogenous and isoenergetic, and Ca and available P content in the PC and NC diet were reduced from 0.78 to 0.58% and 0.41 to 0.22%, respectively. The NC diet was fed without or with supplemental phytase as follows: uncoated (u) Phytase at 500 FTU/kg; cPhytase at 500, 600 or 700 FTU/kg feed. Titanium dioxide was used as an indigestible marker. Birds fed the PC diet had higher ($P < 0.05$) feed intake (FI), BW gain (BWG), and tibia ash than those fed the NC diet. Supplementing phytase, irrespective of coating, to the NC diet increased BWG and FI ($P < 0.05$) but had no effect on FCR ($P > 0.10$). No differences in response to the two phytases tested were detected. Increasing the level of cPhytase from 0 to 700 FTU/kg linearly increased FI ($P < 0.05$), BWG ($P < 0.001$), and tibia ash ($P < 0.004$). Compared to NC diet, apparent ileal digestibility of P improved ($P < 0.05$) by 19.4 percentage units with phytase supplementation at 500 FTU/kg. Growth performance, tibia ash content, P and Ca digestibilities were not different ($P > 0.05$) for cPhytase and uPhytase, however, better ($P < 0.05$) than chicks fed the NC diet. In conclusion, the efficacy of a new coated phytase based on chick performance and nutrient utilization was similar to that of the same phytase in uncoated form indicating that the coated phytase is effectively released in vivo.

Key Words: Broiler, Phytase, Coating

963 Phytase recovery test after pelleting process in different commercial feed mills in Brazil. J. O. B. Sorbara*[1,2], J. L. Lecznieski[1], C. Arakaki[1], and F.J. Piraces[1], [1]*DSM Nutritional Products*, *Sao Paulo, SP, Brazil*, [2]*Universidade Estadual de Maringa*, *Maringa, PR, Brazil*.

Several commercial phytase products are available today. For a long time just one phytase originate from Peniophora lycii (Ronozyme™ P 5000 CT) which had thermostable characteristics based on its advanced formulation technologies. During the year of 2006, four hundred feed samples with Ronozyme™ P 5000 (CT) were collected in twenty commercial feed mills in Brazil. All those samples was collected under the same methodology and phytase recovering test was run at DSM lab in Sao Paulo. Ten feed samples with Ronozyme™ P 5000 (CT) were collected after the normal mixing time. Samples were collected as the mash emptied from the mixer, and were collected in a manner to permit samples to be equally spread based on time to empty. Pellet samples were taken as they emptied from the cooler in a manner that spread samples over the batch for equal distribution. Temperature of the pelleted feed was determined immediately at the die, time of conditioning and the amount of Ronozyme™ P 5000 (CT) added to the feed were recorded. Based on these results we can conclude that Ronozyme™ P 5000 (CT) is a very stable phytase. In additional, it is important to monitor the phytase level in pellet feed due to be affected by several factors.

Table 1. Phytase recovering test in 20 feed mill in Brazil

	Phytase Recovering (%)	Temperature (°C)	Conditioning Time (sec)
Mean	89.8	79.1	25.7
SD	10.5	5.7	10.3
CV	11.7	7.2	40.0
Min	68.8	67	13
Max	107.2	90	45

Key Words: Enzymes, Pellet, Thermostability

964 Influence of feed phosphates and phytase supplementation on broiler performance. T. Mushtaq*[1], M. Sarwar[1], G. Ahmad[1,2], M. A. Mirza[1], and M. M. H. Mushtaq[1], [1]*University of Agriculture*, *Faisalabad, Pakistan*, [2]*Shamim Feed Industries*, *Bahawalpur, Pakistan*.

The study was conducted to compare dicalcium phosphate (DCP) as phosphorus (P) source with three other phosphates i.e., bone ash, bone meal and triple-super phosphate (TSP). A low DCP diet was prepared by reducing the available P by 0.10%. The low DCP diet was divided into two portions. One portion was fed as such whereas the other portion was supplemented with phytase at 500 phytase units per kg of finished feed. Each of the 6 dietary treatment was offered to 3 replicates having 500 straight-run Hubbard broiler chicks (n = 9000). The experiment diets having 2650 kcal ME/kg and 19.7% CP were offered for 35 d. The three DCP diets depressed the BW gain during 1 to 14 ($P \leq 0.001$), 1 to 21 ($P \leq 0.001$) and 1 to 28 d ($P \leq 0.012$). Feed intake was lowered by the three DCP diets during 1 to 21 ($P \leq 0.016$), 1 to 28 ($P \leq 0.021$) and 1 to 35 d ($P \leq 0.001$). The feed:gain data revealed a depression due to the three DCP diets during 1 to 21 ($P \leq 0.001$), 1

to 28 (P≤0.01) and 1 to 35 d (P≤0.031). The BW gain, feed:gain, feed intake, mortality and foot ash were unaffected when available P was reduced by 0.10% or phytase supplementation in low DCP diets. The results of the present study demonstrated bone ash, bone meal and TSP a superior source than that of DCP. Lowering of available P by 0.10% and addition of phytase in low available P diets did not affect the growth performance or foot ash of the broilers raised on low ME and CP diets.

Physiology & Endocrinology - Livestock and Poultry: Metabolic Physiology

965 Plane of nutrition by tick burden interaction in cattle: Effect on metabolic indicators in plasma. D. Tolleson*, G. Carstens, T. Welsh, P. Teel, O. Strey, S. Prince, K. Dean, and L. Slay, *Texas A&M University*.

Previous studies concerning the effect of external parasites on intake, performance, and metabolism in cattle utilized a single moderate quality (14% CP, 60% TDN) diet. The effects of an external parasite burden may be exacerbated in cattle grazing low quality forage. The objective of this study was to examine the interaction between plane of nutrition and a Lone Star (Amblyomma americanum) tick burden as expressed by metabolic indicators in cattle. Twenty eight growing beef steers (194 ± 3.0 kg) were randomly assigned to one of four treatments in a 2 × 2 factorial arrangement: moderate (M; 14.0 ± 1.0% CP, 60 ± 1.5% TDN) vs low (L; 7.0 ± 1.0% CP, 58 ± 1.5% TDN) plane of nutrition (PON), and control (no tick) vs tick treatment (300 pair of adult A. americanum per treated animal). Steers were individually fed M and L diets ad libitum for 35 d prior to and 21 d following the start of tick infestation (day 0), with peak tick feeding occurring on d 10 to 14. Animal weight and BCS were obtained on d -35, 0, and 21. Blood was sampled on d -7, 0, 7, 8, 9, 10, 11, 12, 13, 17 and 21. Plasma was harvested and analyzed for urea nitrogen (BUN), glucose (GLU), non-esterified fatty acids (NEFA), and beta-hydroxy-butyrate (BHBA). PON affected (P < 0.01) BUN and GLU but not (P > 0.1) BHBA and NEFA. The effect of day was significant (P < 0.01) for BUN, BHBA and NEFA but not (P > 0.1) GLU. Across PON, tick burden did not affect (P > 0.1) any constituent. A model containing BUN, GLU, and NEFA at d 12 and 21 described 54.9, 66.4, and 75.5 % of the variation in d 21 BCS, d 21 weight and d 0 to d 21 average daily gain (P < 0.01). PON but not tick burden affected metabolism of growing beef steers.

Table 1. Effect of tick treatment and plane of nutrition on metabolic indicators in cattle (mean, SE).

Constituent	Tick		Control		Moderate		Low	
BUN	4.91	0.20	5.05	0.22	7.01	0.15	2.89	0.08
GLU	95.24	1.23	96.72	1.04	101.42	1.13	90.38	0.95
BHBA	473.39	15.03	426.49	12.97	455.37	14.13	444.36	14.20
NEFA	0.27	0.01	0.24	0.01	0.25	0.01	0.26	0.01
	MT		MC		LT		LC	
BUN	6.83	0.21	7.19	0.21	2.97	0.12	2.82	0.12
GLU	102.85	1.25	100.01	1.87	87.52	1.71	93.28	0.68
BHBA	482.45	19.65	428.65	19.93	464.21	22.87	424.24	16.57

966 Using serum components and ultrasound measurements at weaning to predict feedlot gain and carcass merit. J. S. Thurlow*[1], T. L. Perkins[2], S. T. Reiter[1], A. H. Brown Jr.[1], and C. F. Rosenkrans Jr.[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Missouri State University*, *Springfield*.

The objective of this study was to determine if weaning characteristics could be used to predict subsequent feedlot gain and carcass composition. The following items were collected at weaning and used as predictor variables: lactate dehydrogenase (LDH) activities, lactate, cortisol, insulin-like growth factor I (IGF-I), and prolactin concentrations and ultrasound measurements. Forty-six crossbred steers (203 ± 1.7 kg) were weaned (216 ± 2.6 d) and blood samples collected. Calves were weighed every 21 d and ADG calculated. Longissimus dorsi muscle area (REAU and REAU2), rib fat thickness (FTU and FTU2), intramuscular fat (IMFATU and IMFATU2), and rump fat (RUMP) were determined using ultrasonic measurements at weaning and at d 57 of the feedlot phase. Hot carcass weight (HCW), rib fat thickness (RF), longissimus dorsi muscle area (REA), marbling score (MARB), yield grade (YG), and quality grade (QG) were determined at harvest. Weaning FTU correlated with YG (r = 0.28; $P < 0.05$), and weaning REAU correlated with HCW and REA (r = 0.55 and 0.60; $P < 0.01$). Lactate concentrations at weaning tended ($P < 0.10$) to be negatively correlated with YG (r = -0.27). Serum activity of LDH tended ($P < 0.10$) to be negatively correlated (r = -0.25) with MARB. Serum IGF-I concentration correlated with REAU2 and FTU2 during the feedlot phase (r = 0.29 and 0.41 respectively; $P < 0.05$), and HCW, REA, and RF at harvest (r = 0.40, 0.38, and 0.39; $P < 0.01$). Serum components and ultrasound measurements at weaning did not accurately predict feedlot gain. However, weaning measurements of lactate concentration, serum LDH activity, and ultrasound measurements may be useful in predicting carcass composition.

Key Words: Feedlot, Carcass Composition, Ultrasound

967 Use of infrared thermal imaging to measure changes in body temperature following lipopolysaccharide (LPS) administration in hair sheep ewes. R. W. Godfrey*[1], R. C. Ketring[1], and S. T. Willard[2], [1]*University of the Virgin Islands, Agricultural Experiment Station*, *St. Croix, US Virgin Islands*, [2]*Mississippi State University*, *Mississippi State*.

Previous work in our lab has shown a high correlation of rectal and vaginal temperature (RT and VT, respectively) with maximum eye temperature (MAX) measured using digital infrared thermal imaging in hair sheep ewes. The objective of this study was to evaluate the relationship of VT, RT and MAX in hair sheep ewes after the administration of LPS to induce a febrile state. Rectal temperatures

and infrared images of the right and left eyes of each ewe were taken at -12, -1, 0, 1, 2, 3, 4, 6, 12, 24, 36 and 48 hr. Temperature data loggers, programmed to record at 5-min intervals, were inserted into the vagina of each ewe at -12 hr and removed after the 48 hr sample collection. At 0 hr ewes were administered saline (CONT; n = 7; 0.5 mL i.v.) or LPS (n = 7; 0.2 ug/kg BW i.v.). Infrared images of the right and left eye were analyzed to obtain an average MAX for each ewe at each time point. Analysis consisted of measuring the change in RT, VT and MAX over time and determining the correlation among RT, VT and MAX. Ewes given LPS had higher ($P < 0.008$) RT and VT than CONT ewes from 1 hr after treatment through 12 hr. Ewes given LPS had higher ($P < 0.01$) MAX than CONT ewes from 1 hr after treatment through 6 hr. Within ewes given LPS, MAX was lower than VT ($P < 0.02$) during the entire sampling period and lower than RT ($P < 0.03$) from 3 hr through 48 hr after treatment. Within CONT ewes, MAX was lower than RT and VT ($P < 0.01$) during the sampling period. There was no difference ($P > 0.10$) between RT and VT within either the CONT or LPS ewes. Overall, VT and RT were highly correlated ($r = 0.96$, $P < 0.0001$) and MAX was highly correlated with RT ($r = 0.82$, $P < 0.001$) and VT ($r = 0.93$, $P < 0.0001$). In agreement with our previous work, these results suggest that thermography of eye, using maximum eye temperature, may have application as a non-invasive method to measure elevated body temperatures in the ewe.

Key Words: Thermography, Eye, Sheep

968 Effects of plane of nutrition and selenium on colostrum quality and mammary development in ewes. T. J. Swanson*[1], C. J. Hammer[1], J. B. Taylor[2], D. A. Redmer[1], K. A. Vonnahme[1], J. S. Luther[1], T. L. Neville[1], J. J. Reed[1], J. S. Caton[1], and L. P. Reynolds[1], [1]*North Dakota State University*, *Fargo*, [2]*USDA-ARS, U.S. Sheep Experiment Station*, *Dubois, ID*.

To examine the effects of plane of nutrition and selenium supplementation on colostrum quality and mammary development in pregnant ewe lambs, 82 Rambouillet ewe lambs were allotted randomly to one of six treatments in a 3 × 2 factorial design. Groups included dietary levels of Se [adequate Se (ASe, 7.4 µg/kg BW) vs. high Se (HSe, 85 µg/kg BW)], and plane of nutrition [60% (RES), 100% (CON), and 140% (HIGH) of NRC requirements for ewe lambs]. Basal diets were fed once daily in complete pelleted form and HSe ewes received a Se pellet to meet the required Se level. Upon parturition lambs were immediately separated from their dams. Three hours post lambing colostrum was stripped from the udder. Colostrum yield was measured and samples obtained for milk component and IgG analysis. Ewes were slaughtered within 24 h of parturition and mammary tissues collected for RNA, DNA, and protein analysis. Plane of nutrition decreased ($P<0.05$) mammary gland weight in RES (670.1 g) compared to CON (838.9 g) and HIGH (815.3 g). In contrast, Se had no effect on ewe mammary weight. Colostrum weight and volume were lower ($P<0.01$) in RES (343.8 g and 325.9 mL respectively) and HIGH (364.0 g and 364.0 mL respectively) compared to CON (585.7 g and 575.1 mL respectively). Total IgG was lower ($P<0.02$) in RES (32 g/L) and tended ($P<0.06$) to be lower in HIGH (34 g/L) compared with CON (43 g/L). Plane of nutrition decreased ($P<0.02$) butter fat, lactose, and nonfat solids in colostrum of RES and HIGH compared to CON. Milk urea nitrogen increased ($P<0.02$) with increasing plane of nutrition. There was no effect of Se on any colostrum components measured. Total DNA and RNA in mammary tissue was lower ($P<0.03$) in RES (1.52 g and 2.21 g respectively) compared to CON (2.18 g and 3.42 g respectively). Total RNA in RES was also lower ($P<0.01$) compared to HIGH. Results indicate plane of nutrition plays a fundamental role in both colostrum formation and mammary gland development in pregnant ewe lambs.

Key Words: Colostrum, Selenium

969 Evaluating nutritional status of Dorper and Rambouillet ewes in a range sheep production system. T. R. Whitney*, D. F. Waldron, T. D. Willingham, and B. O. Payne, *Texas A&M Agricultural Experiment Station*, *San Angelo*.

Nutritional status of Dorper and Rambouillet ewes, originating from multiple flocks and grazing a common pasture was investigated. Forty-six Dorper and 33 Rambouillet ewes that lambed within the first 45 days of the lambing season (January 12 to February 26) were used. Data were analyzed with a model that included breed and age of ewe as fixed effects, BW at the start of the breeding season as a linear covariate, and flock of origin of the ewe as a random effect. Blood samples were collected from ewes at the start of the breeding season (August 9 and 16), mid-gestation (October 28 and November 9), and late gestation (December 13 and 20). Dorper ewes had greater insulin-like growth factor-1 (IGF-1; $P < 0.05$) concentrations except on August 16, and had greater non-esterified fatty acid concentrations than Rambouillet ewes on August 9 and 16 and November 9. Since IGF-1 has been shown to be directly related to performance and reproduction efficiency, these results suggest that Dorper ewes could possibly have greater production efficiency than Rambouillet ewes on rangelands. In contrast, higher NEFA concentrations suggest that Dorper ewes were at times, catabolizing more fat than Rambouillet ewes. Dorper ewes had greater body condition (BC; $P < 0.05$) than Rambouillet ewes at the beginning of the study. Thus, either Dorpers were more capable of using stored energy reserves (e.g. fat) during periods of poor nutrition, or they have higher NEFA concentrations than Rambouillets due to genetics. Results are not conclusive since serum metabolite and hormone concentrations must be analyzed over longer periods of time and interpreted along with other measures. Data from the second year of this study need to be analyzed to make better inferences.

Key Words: Insulin-like Growth Factor-1, Sheep, Physiology

970 Variation in metabolic parameters in dairy cattle kept in a constant environment. K. L. Ingvartsen*, T. Larsen, P. Berg, and N. C. Friggens, *University of Aarhus, Faculty of Agricultural Sciences*, *Tjele, Denmark*.

The aim of this study was to describe normal changes in selected physiological variables dependent on breed, lactation number and time in lactation in a constant environment and describe phenotypic and genetic variation in physiological variables. The experimental design has been published earlier (Nielsen et al., 2003, LPS 79, 119-133) as has the blood sampling and univariate analysis (Ingvartsen & Friggens, 2005, DAE 29, 294-304). In short, a total of 317 cows (Danish Red (RD), Danish Holstein (DH) and Jersey (DJ)) and 634 lactations (parity 1, 2, ≥3) were included. Blood samples collected weekly from -28 d to 298 d relative to calving, a total of 10809 samples, were analyzed for selected hormones, metabolites, and minerals (only non-esterified fatty acids (NEFA), β-hydroxybutyrate (BHBA) and glucose included here). Mixed models using random regression techniques (LeGendre

polynomials) were set up to analyze the systematic effects comprising combinations of breed, line, feeding, parity and time in lactation using the MIXED procedure in SAS. Variance components were estimated across breeds using a package for multivariate mixed models (DMU-program, Madsen & Jensen, 2000). A significant interaction between breed and parity was observed for NEFA, these were higher concentration ($P<0.05$) in DH compared to DJ for parity 2 and 3. RD had generally lower NEFA compared to DH. While DH and DR showed marked differences in BHBA profiles due to parity DJ did not, causing an interaction ($P<0.05$). Also for glucose an interaction between breed and lactation was found. In general glucose was lowest in DJ, particularly for primiparous cows, and the concentration did not increase as quick after nadir as in DH and DR. For both NEFA, BHBA and glucose the between cow variation was highest in early lactation. The intra-class (intra-cow) correlation during the first 4 weeks declined from 0.71 to 0.46 for NEFA, 0.44 to 0.36 for BHBA and 0.44 to 0.27 for glucose. The large between cow variation and relatively high intra-class correlation indicates that these parameters may be of use to describe animal status.

971 Uncovering adaptive hepatic gene networks due to prepartum plane of dietary energy and physiological state in periparturient Holstein cows. M. Bionaz*, J. K. Drackley, S. L. Rodriguez-Zas, H. M. Dann, N. A. Janovick Guretzky, R. E. Everts, R. Oliveira, H. A. Lewin, and J. J. Loor, *University of Illinois*, *Urbana*.

Gene network assembly from bovine tissue microarray studies could advance our understanding of function and molecular events underlying complex traits (e.g., fatty liver, ketosis). Joint ANOVA using MIXED was conducted on liver microarray data (174 arrays) from 2 of our published studies (Physiol. Genomics 23:217-226, 27:29-41) using a platform with 7,872 bovine cDNA inserts. Liver microarray data were generated from Holstein cows fed control (100% of NRC), ad libitum (ca. 150% of NRC; AA), or restricted (ca. 80% of NRC; RR) energy diets and biopsied at -65, -30, -14, 1, 14, 28, and 49 d relative to parturition. The statistical model included cow as random effect and time, diet, and time × diet as fixed effects. A total of 1,555 genes showed a time × diet interaction ($P < 0.0001$). Ingenuity Pathways Analysis software recognized and mapped 798 genes. A cut-off of ≥1.5-fold change in expression on d -14, 1, 14, 28, and 49 relative to -30 was used. Analysis showed that on d -14, 1, and 14, cell-to-cell signaling (20-28 genes) molecular transport (10-13 genes), and tissue development (16-24 genes) were among the most affected molecular functions in cows fed AA. In cows fed RR gene transcription (12-76 genes), protein synthesis (8-30 genes), and immune response (17-23 genes) were among the most enriched molecular/physiological functions. Fewer genes changed by ≥1.5-fold relative to d -30 in control liver. Several canonical pathways enriched in the data set also were observed, e.g. Integrin and Actin cytoskeleton signaling (AA primarily), protein ubiquitination and complement cascade (RR primarily), and ERK/MAPK and IGF-1 signaling (control primarily). Results confirmed that RR and AA prepartum affected liver genomic adaptations differently. However, one of the most striking observations from this analysis was the marked effect of prepartum dietary energy on expression of genes associated with functions (e.g. transport, gene transcription) supporting tissue remodeling.

Key Words: Microarray, Liver, Genomics

972 Liver fatty acid binding protein (FABP) and acyl-CoA synthase (ACSL) isoform gene expression due to plane of dietary energy prepartum in dairy cows. M. Bionaz*, J. K. Drackley, H. M. Dann, and J. J. Loor, *University of Illinois*, *Urbana*.

Specific isoforms of FABP and ACSL may work in concert to partition fatty acids towards discrete metabolic pathways in liver, particularly after parturition when NEFA influx increases dramatically. The main objective of this study was to examine mRNA expression by qPCR of FABP (1, 3, 4, 5, 6) and ACSL (1, 2, 3, 4, 5, 6) family members in liver from Holstein cows fed control (100% of NRC) or ad libitum (ca. 150% of NRC; AA) energy diets and biopsied at -14, 1, and 14 d relative to parturition. Expression of 14 genes with key functions in fatty acid oxidation (LPIN1, ACOX1, CPT1A, PPARA, PPARGC1A, CYP4A11), lipid synthesis and desaturation (DGAT1, SCD, HMGCR), fatty acid transport (CD36), lipid droplet synthesis (S3-12, LSDP5, ADFP), and RP9 (reference gene) also were analyzed. ANOVA using MIXED was used for statistical analysis. All ACSL isoforms and the 1, 4, and 6 FABP isoforms were affected by day relative to parturition ($P \leq 0.10$). Relative to d -14, ACSL1 increased on d 1 whereas ACSL isoforms 2 through 6 decreased. Similarly, FABP4 and FAPB6 increased on d 1 whereas FABP1 decreased relative to d -14. A significant interaction effect was observed for ACSL3, ACSL4, FABP4, and FABP5. Expression of FABP isoforms was 4 to 11-fold greater with AA vs. control on d 1. Cows fed control had greater overall expression of ACSL3 and FABP3. Among other genes examined, expression of HMGCR and SCD in cows fed control vs. AA experienced a marked decrease by d 1 and then increased by d 14 resulting in an interaction effect. The opposite response was observed for CD36 expression. Expression of PPARA on d 14 was higher in cows fed control vs. AA. ADFP and PPARGC1A expression increased over time, reaching peak values on d 1. Results indicate that prepartum plane of dietary energy affects expression of FABP and ACSL family members to different extents primarily on d -14 and 1. The fate of exogenous fatty acids (e.g., fatty acid oxidation vs. esterification) in the liver could be dictated at least in part by the expression pattern of specific ACSL and FABP isoforms.

Key Words: Liver, Gene Expression, Dairy Cows

973 The use of nicotinic acid as antilipolytic agent to induce sustained low plasma NEFA concentrations in feed restricted Holstein cows. J. A. A. Pires* and R. R. Grummer, *University of Wisconsin*, *Madison*.

The objectives were to determine the effects of nicotinic acid (NA) on blood metabolites (experiment 1) and whether successive doses of NA can induce sustained reductions of plasma nonesterified fatty acid (NEFA; experiment 2) in feed restricted non-lactating Holstein cows. Experiment 1 was a 4 × 4 Latin Square with 1 wk periods. Each period consisted of 2.5 d of feed restriction to increase plasma NEFA and 4.5 d of ad libitum feeding. Treatments were abomasal administration of 0, 6, 30 or 60 mg/kg BW of NA, given as a single bolus 48 h after initiation of feed restriction. Plasma NEFA concentration decreased (treatment and treatment × time: $P < 0.001$) from 546 uEq/L to 208 uEq/L at 1 h after the infusion of 6 mg NA/kg BW, and to less than 100 uEq/L at 3 h after the abomasal infusion of the two highest doses of NA. A rebound occurred after the initial decrease of plasma NEFA concentration during which NEFA increased transiently above 1,200 uEq/L. The rebound lasted up to 9 h for 30 mg NA/kg BW dose, and up to 6 h for 6 mg NA/kg BW dose. Experiment 2 was a randomized

complete block design with 3 treatments and 6 cows. Starting at 48 h of feed restriction, cows received nine hourly abomasal infusions of 0, 6 or 10 mg/kg BW of NA. Plasma NEFA concentrations was 553 uEq/L immediately before the initiation of treatments, and decreased to less than 100 uEq/L during infusions of 6 or 10 mg NA/h per kg BW (treatment × time: $P < 0.001$). Data suggest that the maximal antilipolytic response was achieved with the lowest dose of NA. NEFA concentrations rebounded to over 2,100 uEq/L 4 h after termination of NA infusions. The profile of insulin and glucose concentration suggests a state of insulin resistance during NEFA rebound in both experiments. This model for altering plasma NEFA concentration by abomasal infusions of NA can be used to study the metabolic ramifications of elevated vs. reduced NEFA concentrations. The data demonstrate potential benefits and pitfalls of using NA to regulate plasma NEFA and prevent lipid related metabolic disorders.

Key Words: Nicotinic Acid, NEFA, Bovine

974 Reduction of plasma NEFA concentration by nicotinic acid enhances the response to insulin in feed restricted Holstein cows. J. A. A. Pires*, J. B. Pescara, and R. R. Grummer, *University of Wisconsin*, *Madison*.

The objective was to study the effects of lowering plasma nonesterified fatty acid (NEFA) concentration, using supraphysiologic doses of nicotinic acid (NA) as an antilipolytic agent, on the responses to intravenous glucose tolerance test (IVGTT) in feed restricted Holstein cows. Six non-lactating, non-gestating, ruminally cannulated Holstein cows were blocked by body condition score, and randomly assigned to a sequence of two treatments in a cross-over design. Cows were offered legume/grass hay ad libitum, supplemented with minerals and vitamins and allowed free access to water and trace mineralized salt block. Mobilization of body reserves was stimulated by withdrawing forage for 48 h before initiation of treatments. Treatments consisted of eleven hourly abomasal infusions of water (control) or NA (6 mg/h per kg BW). Intravenous glucose tolerance test (0.25g glucose/kg BW) was performed 8 h after initiation of treatments and was followed by 3 h of blood sampling. Infusions of NA decreased ($P < 0.001$) plasma NEFA concentration from 545 µEq/L to around 100 µEq/L within 2 h after initiation of treatments and significant differences were maintained throughout infusions. The reduction of plasma NEFA concentration led to significantly greater glucose clearance rate (1.9 vs. 1.2 %/min, $P = 0.002$) and to decreased glucose half life (37 vs. 58 min; $P < 0.001$), time to reach basal concentration (81 vs. 114 min; $P < 0.001$) and glucose response area under the curve during 180 min of sampling (AUC180; 6942 vs. 10085 (µIU/mL)*180 min; $P < 0.001$). Enhanced glucose clearance was achieved despite lower ($P = 0.05$) insulin concentration (70.0 vs. 97.9 ± 13.4 µIU/mL) and a tendency ($P = 0.11$) for smaller AUC180 (7646 vs. 12104 ± 2587 (µIU/mL)*180 min) when plasma NEFA was reduced by NA, reflecting increased response to endogenous insulin. Based on literature, we do not expect NA to have altered glucose metabolism directly. Therefore, this experiment demonstrates a cause-effect relationship between elevated NEFA and insulin resistance in Holstein cows.

Key Words: NEFA, Insulin Resistance, Nicotinic Acid

975 Effect of short-term feeding of a plant botanical during late-gestation on temperature and physiological responses of piglets challenged with LPS. J. L. Salak-Johnson*[1], J. M. Suchomel[1], S. R. Niekamp[1], S. Block[2], and R. Balsbaugh[3], [1]*University of Illinois at Urbana-Champaign*, *Urbana*, [2]*ADM Animal Nutrition Research*, *Decatur, IN*, [3]*ADM Alliance Nutrition, Inc.*, *Quincy, IL*.

Crossbred sows were fed a control (n = 10) or treated (n = 15 ; control + plant botanical) diet for 14 d prior to farrowing to determine the impact of feeding a gestation diet supplemented with a plant botanical on piglet temperature and physiological responses to lipopolysaccharide (LPS). At birth, piglets were weighed and rectal temperatures were recorded. Eight piglets/litter were randomly chosen to receive a saline (n = 90) or LPS (n = 90); 25 µg/kg of BW) challenge at 24-h or 72-h of age with 2 pigs assigned per challenge category. Rectal temperature was recorded frequently and blood samples were collected 2 h post-challenge. Data were analyzed with the MIXED procedure of SAS. Diet×LPS×age interaction was observed for piglet rectal temperature. Piglets from sows fed treated diet had greater ($P < 0.05$) temperature response to LPS than did pigs from control sows at 24 h. Piglets farrowed by treated sows had greater ($P < 0.05$) temperature at 72 h than did 24 h piglets regardless of challenge. Piglets farrowed by control sows and challenged at 72 h with LPS had greater ($P < 0.05$) temperature than did piglets from sows fed treated diet. Diet or LPS had an affect on interleukin (IL)-10 and -12, but not IL-6. Piglets farrowed by treated sows had greater ($P < 0.05$) IL-10 than did control diet×LPS piglets. Plasma IL-12 was less ($P < 0.05$) in piglets from sows fed treated diet than control and IL-10 was greater ($P < 0.001$) in LPS pigs than in saline pigs. Cortisol was greater in LPS piglets than saline regardless of diet or age ($P < 0.001$). But, 24 h pigs had greater ($P < 0.05$) cortisol in response to LPS than did 72 h pigs. Piglets from sows on control diet had greater ($P = 0.14$) cortisol response to LPS than did piglets from sows fed treated diet. These data indicate that feeding sows a gestation diet supplemented with plant botanical has modulatory affects on the physiological responses of piglets, but no affect on piglet thermoregulatory processes.

Key Words: Piglet, Immune, Plant Botanical

976 Effects of multiple concurrent stressors on rectal temperature, blood acid-base status, and loin muscle glycolytic potential in market weight pigs. M. J. Ritter*[1], M. Ellis[2], D. B. Anderson[3], S. E. Curtis[2], K. K. Keffaber[1], J. Killefer[2], F. K. McKeith[2], C. M. Murphy[2], and B. A. Peterson[2], [1]*Elanco Animal Health*, *Greenfield, IN*, [2]*University of Illinois*, *Urbana*, [3]*Colorado State University*, *Fort Collins*.

Sixty four market weight (130.0±0.65 kg) barrows (n=16) and gilts (n=48) were used in a split-plot design with a 2×2×2 factorial arrangement of treatments: 1) handling intensity (gentle vs. aggressive); 2) transport floor space (0.39 vs. 0.49 m^2/pig); and 3) distance moved during handling (25 vs. 125 m) to determine the effects of multiple concurrent stressors on the stress responses of pigs. Pigs were moved ~50 m through a course with 0 (gentle) or 8 (aggressive) shocks from an electric goad. Next, pigs were loaded onto a trailer and transported for ~1 h at floor spaces of 0.39 or 0.49 m^2/pig. After transport, pigs were unloaded and moved 25 or 125 m through a course using livestock paddles. Rectal temperature was measured and blood samples were collected 2 h before handling procedures and immediately after

distance moved treatments. Longissimus glycolytic potential was also measured after the distance moved treatments on a subset of 32 pigs. Data were analyzed using PROC MIXED and PROC REG of SAS. Handling intensity × distance moved interactions existed (P<0.05) for several blood acid-base measurements. In general, there was no effect of distance moved on these traits when pigs were previously handled gently. However, when pigs were previously handled aggressively, pigs moved 125 compared to 25 m had higher (P<0.05) blood lactate and lower (P<0.05) blood pH, bicarbonate, and base-excess. Pigs transported at 0.39 compared to 0.49 m^2/pig had larger (P<0.01) increases in creatine kinase values, however, transport floor space did not affect any other measurements. Data were also analyzed by the number of stressors (aggressive handling, restricted transport floor space, and moved 125 m during handling) experienced by each pig (0, 1, 2, or 3). As stressor number increased, there was a linear increase (P≤0.01) in rectal temperature, blood lactate, and longissimus lactate and a linear decrease (P<0.01) in blood pH, bicarbonate, and base-excess. These data suggest that the stressors evaluated had additive effects on rectal temperature, longissimus lactate values, and blood acid-base balance.

Key Words: Pig, Handling, Pre-slaughter Stress

977 Neonatal Fc receptor mRNA expression in fetal pigs and in gastrointestinal tissues from pigs fed diets of varying form with or without irradiated and non-irradiated spay-dried animal plasma. C. N. Groesbeck*[1], T. E. Burkey[2], J. E. Minton[1], S. S. Dritz[1], R. D. Goodband[1], M. D Tokach[1], J. M. DeRouchey[1], and J. L. Nelssen[1], [1]*Kansas State University*, *Manhattan*, [2]*University of Nebraska*, *Lincoln*.

The neonatal Fc receptor (FcRn) participates in intracellular trafficking of IgG and the maintenance of circulating IgG. Also, the relationship between the FcRn and IgG may augment host defense immunosurveillance. The current studies evaluated FcRn mRNA from intestinal tissues in fetal pigs and weaned pigs fed meal or pelleted diets with or without irradiated or non-irradiated spray-dried animal plasma. In Exp. 1, fetal pigs were obtained at d 55 and d 70 of gestation (n = 5 fetuses/gestational age) and total RNA was isolated from intestinal tissues for quantitative real-time PCR (qPCR) to determine mRNA for FcRn. FcRn transcripts were observed in all samples, and greater levels of FcRn mRNA were observed in d 55 fetuses compared to d 70 fetuses (P < 0.02). In Exp. 2, weaned pigs were used in an 11-d growth assay to determine the effects of feeding meal and pelleted diets with irradiated or non-irradiated spray-dried animal plasma (AP 920) on FcRn expression in intestinal tissues. Pigs were blocked by weight and randomly allotted in a 2 × 2 factorial to one of four dietary treatments. Main effects were diet form (meal or pellet) and either irradiated or non-irradiated spray-dried animal plasma. Jejunal, ileal, and cecal tissues were collected from 24 pigs at the conclusion of the growth assay. Total RNA was isolated to quantify relative mRNA expression of FcRn. FcRn transcripts were again observed in all samples. FcRn mRNA was more abundant in pigs fed diets containing non-irradiated plasma compared with pigs fed the irradiated plasma (P < 0.02, 1.01 vs 0.57). FcRn mRNA was also more abundant in the pigs fed meal diets than pelleted diets (P < 0.05, 0.98 vs 0.59). The results suggest FcRn varies with gestational age in pigs and with factors affecting dietary bacterial load.

Key Words: FcRn Receptor, Irradiation, Pig

Poultry-Breeding and Hatchery Symposium: Semen Evaulation and Fertility Determination in Poultry

978 Using sperm penetration values to evaluate broiler breeder performance and reproductive efficiency. R. K. Bramwell*, *University of Arkansas*, *Fayetteville*.

The sperm penetration assay is a technique developed to quantitatively assess sperm-egg binding and penetration of the perivitelline layer (PL) enveloping the ovum of the avian egg. The process of sperm-egg binding and penetration represents one of the final steps in fertilization sperm must accomplish in order access the female pronucleus for syngamy. Sperm penetration (SP) values have proven to be beneficial for both research and industry applications as these values are based on a sliding scale as opposed to a binary scale for fertility values. As a research tool, male and or female contribution to infertility can be evaluated with much greater accuracy than using fertility values alone. As an industry tool, SP values are used to evaluate broiler breeder flocks experiencing poor hatchability. From identified broiler breeder flocks, each egg from a 50-egg sample is subjected to the SP assay. Holes in the PL overlying the germinal disc caused by sperm-egg binding and the subsequent acrosome reaction are counted and the values recorded in one of five groups (0-10, 11-30, 31-60, 61-100, over 100 holes). Data is expressed as a percentage of the egg samples that produced values in one of the five groups previously reported. For each age group of broiler breeder flocks, an ideal standard has been determined and each flock can be compared to that standard to determine their reproductive efficiency. From this data, the cause of poor performance can be determined and recommendations made improve breeder flock performance.

Key Words: Sperm Penetration, Sperm-Egg Binding, Fertility

979 Advances in sperm cell biology stemming from the analysis of sperm mobility. D. Froman*, *Oregon State University*, *Corvallis*.

Sperm mobility is a quantitative trait discovered in the mid-1990s. The term *sperm mobility* denotes the net movement of a sperm cell population against resistance at body temperature. The trait was discovered after development of a test based upon sperm penetration of 6% (wt/vol) Accudenz from an overlaid sperm suspension. This test was proven to be simple, objective, and suitable for semen analysis in the field as well as the laboratory. When applied to populations of males, extreme variation was observed among males. Sperm mobility phenotype was independent of age. The relationship between in vitro sperm mobility and male fecundity warranted a systematic analysis. Sperm mobility was proven to be a primary determinant of fertility based upon competitive and non-competitive fertilization. In fact, fertility was a *function* of sperm mobility phenotype. Heritability (h^2)

was estimated to be 0.30 using a random bred population. Thereafter, distinct lines were produced by genetic selection. Phenotypic variation evaluated with computer-assisted sperm motion analysis, which described motile properties of individual sperm within populations. Motile concentration and straight line velocity (VSL) were used to predict sperm mobility. Specifically, phenotype was a function of the area within the upper tail of a male's VSL distribution. Consequently, the predictive power of the sperm mobility assay depends on a context in which the *consequences* of variation in VSL become manifest in time. The shape of VSL distributions was explicable in terms of mitochondrial function. In this regard, mobile sperm were rendered immobile by a reagent used to induce the mitochondrial permeability transition pore. Consequently phenotypic variation may be related to Ca^{2+} overloading while sperm pass through excurrent ducts of the testis. As such, a sperm mobility measurement may reflect the proportion of disabled sperm within an ejaculate. Three unexpected experimental outcomes included: (1) a model explaining in vivo sperm storage, (2) the relationship between mitochondrial Ca^{2+} cycling and sperm motility, and (3) a new paradigm for artificial semen storage.

Key Words: Sperm Mobility, Sperm Motility, Semen Storage

980 Using the Sperm Quality Analyzer Vt for dosimetry of turkey semen in commercial turkey operations; the potential impact on fertility, and the economic implications of better utilization of sires with superior growth potential. K. K. Krueger*, *Diamond K Research*, *Marshville, NC*.

The Sperm Quality Analyzer Vt (SQA Vt) estimates total (TSC) and motile sperm cell (MSC) concentration in either neat or diluted turkey semen. The device is simple to use and results are returned within 3 minutes. No special calibration, operator training, or sensitive reagents are required. Bench trials have confirmed SQA Vt accuracy and repeatability matches or exceeds other methodologies (i.e., hemocytometer, conventional photo spectroscopy, subjective microscopy). Several field trials and ongoing use in properly managed and supervised commercial turkey operations have shown that when dosimetry is based on motile sperm cell number that ~150 million motile sperm per insemination had no adverse effect on fertility. When insemination doses were prepared on motile sperm cell number, fertility was found to be more stable and often improved during the latter weeks of egg production. Dosimetry based on motile sperm cell numbers has been shown to have a positive impact on fertility, but more importantly it allows sires with superior growth characteristics to be used more efficiently and effectively. Unlike the swine and cattle industries where better superior sire utilization is a primary concern, the commercial turkey industry has failed to recognize the potential impact this concept can have on profitability. Identifying males with superior growth and carcass characteristics, managing them for optimum motile sperm cell production, maximum harvest, and motile sperm cell based dosimetry can have a significant impact on genetic progress and economics in the turkey industry.

Key Words: Sperm, Motility, Fertility

981 Using egg breakout to estimate flock fertility. J. L. Wilson*, *University of Georgia*, *Athens*.

Egg breakout is an excellent tool to estimate flock fertility. This information is used in determining the number of eggs to incubate to meet broiler placements. In addition, egg breakout is a powerful diagnostic tool when flocks are not hatching as expected. It is important to candle eggs between 10-14 days of incubation and open the eggs to determine percentage fertility and early dead embryos. While the end results of low fertility or high numbers of early dead embryos are both low hatchability the causes are distinctly different. Valuable time can be gained in quickly identifying fertility issues and making managerial changes such as spiking the flock to increase fertility. High early embryonic mortality is usually related to egg handling, flock health or chemical exposure. During the candling process other important information can be gathered like the number of eggs in the incubator flat upside down and number of eggs with hairline cracks. Gathering and using egg breakout data to correct low fertility, high embryo mortality, upside down egg placement or loss due to high cracked egg numbers is critical in maximizing chick production.

Ruminant Nutrition: Nitrogen Digestion/Metabolism

982 Development and establishment of an enzymatic in vitro procedure for estimating intestinal protein digestibility of feedstuffs for ruminants. R. Irshaid[1,2] and K.-H. Suedekum*[2], [1]*University of Kiel*, *Kiel, Germany*, [2]*University of Bonn*, *Bonn, Germany*.

This study utilized forty-nine feed samples to develop and establish a completely laboratory-based, enzymatic in vitro procedure (EIVP) for estimating the intestinal protein digestibility (IPD) of rumen-undegradable protein (RUP) of forages and concentrates. Feed samples encompassed forages with varying crude protein (CP) contents, unprotected or rumen-protected protein supplements and cereal grains representing energy-rich feeds of low to medium CP concentration. The EIVP involved the subsequent digestion of samples with a protease from *Streptomyces griseus*, pepsin-HCl, and pancreatin. The concentration of the *S. griseus* enzyme was related to the true protein content of the feed sample. Briefly, the EIVP started with determination of true protein. Feeds were incubated for 18 h in a buffer solution at a constant ratio (41 U/g) of *S. griseus* protease activity to feed true protein. The dried residues were incubated in pepsin-HCl solution for 1 h and residues from this step were incubated with pancreatin solution for 24 h. Samples had previously been used for IPD estimates using a three-step in situ-in vitro procedure (ISIVP) and mobile-bag technique (MBT). The relationships between IPD values estimated by EIVP and ISIVP or MBT were best described by linear regression equations: IPD_{MBT} (g/kg true protein) = 1.221 IPD_{EIVP} (g/kg true protein) - 165.95 ($n = 38$, $r^2 = 0.666$, $P < 0.0001$) and IPD_{ISIVP} (g/kg true protein) = 1.053 IPD_{EIVP} (g/kg true protein) - 28.14 ($n = 49$, $r^2 = 0.985$, $P < 0.0001$). Results from the EIVP closely resembled those obtained with the ISIVP and thus, the completely laboratory-based, standardized EIVP can replace the more invasive ISIVP for estimating IPD of a wide range of feedstuffs for ruminants.

Key Words: Protein, Digestibility, Small Intestine

983 Evaluation of lysine digestibility in rumen undegraded protein using the precision-fed rooster assay and two *in vitro* methods. S. E. Boucher*[1], C. Pedersen[2], H. H. Stein[3], C. M. Parsons[3], and C. G. Schwab[1], [1]*University of New Hampshire*, *Durham*, [2]*Danisco Animal Nutrition*, *Marlborough, UK*, [3]*University of Illinois*, *Urbana*.

Sixteen feed samples were obtained from the Feed Analysis Consortium, Inc. to evaluate furosine and homoarginine (HA) methods for determining the availability of Lys in rumen undegraded protein (RUP-Lys). Furosine is a secondary product of the initial stages of the Maillard reaction, and HA is formed by the reaction of reactive Lys with O-methylisourea (guanidination reaction). Three samples of soybean meal (SBM), 3 samples of SoyPlus®, 5 samples of dried distillers grains with solubles (DDGS), and 5 samples of fishmeal (FM) were used. Samples were incubated for 16 h *in situ* in the rumen of 4 lactating Holstein cows, averaging (mean ± SD) 48 ± 4 days in milk, fed a 55% forage, 45% concentrate diet. Residues were collected and pooled by feed sample, and portions were crop-intubated to cecectomized roosters. Four birds per sample were intubated with the residue, and endogenous AA excretion was estimated from fasted roosters. Total excreta was collected for 48 h post-intubation and analyzed for Lys content. True digestibility (TD) of RUP-Lys was calculated. In the furosine method, all residues were analyzed for furosine and Lys content; however, only 9 of the 16 samples contained furosine. Percent blocked Lys was calculated. In the HA method all residues were guanidinated for 72 h and analyzed for Lys and HA content. The percent Lys converted to HA was calculated. The results of the experiment showed that percent furosine (n=9), blocked Lys (n=9), and Lys converted to HA (n=16) were correlated to TD of RUP-Lys (R^2 = 0.86 0.94, and 0.90, respectively). In conclusion, it appears that measurements of furosine or HA in rumen digesta residues of SBM, SoyPlus®, DDGS, and FM can be used to predict RUP-Lys digestibility.

Key Words: Lysine Digestibility, Rumen Undegraded Protein, Cecectomized Roosters

984 Amino acid digestibility in rumen undegraded protein estimated in cecectomized roosters and the immobilized digestive enzyme assay (IDEA™). S. E. Boucher*[1], M. Vázquez-Añán[2], J. Wu[2], C. M. Parsons[3], and C. G. Schwab[1], [1]*University of New Hampshire*, *Durham*, [2]*Novus International*, *St. Louis, MO*, [3]*University of Illinois*, *Urbana*.

Sixteen feed samples were obtained from the Feed Analysis Consortium, Inc. to evaluate the immobilized digestive enzyme assay (IDEA™; Novus International, Inc.) as an *in vitro* method to estimate the digestibility of amino acids (AA) in rumen undegraded protein (RUP-AA). Three soybean meal (SBM), 3 SoyPlus®, 5 dried distillers grains with solubles (DDGS), and 5 fishmeal (FM) samples were used. Each sample was incubated for 16 h *in situ* in the rumen of 4 lactating Holstein cows averaging (mean ± SD) 48 ± 4 days in milk, fed a 55% forage, 45% concentrate diet. Residues were collected and pooled by feed sample, and portions analyzed for AA content, crop-intubated to cecectomized roosters, and analyzed via IDEA™. Four birds per sample were used, and endogenous AA excretion was estimated from fasted roosters. Total excreta was collected for 48 h post-intubation and analyzed for AA content. True digestibility (TD) of RUP-AA was calculated. The IDEA™ consisted of 4 steps; sample preparation, dissolution, digestion, and *o*-phthaldialdehyde (OPA) analysis. An IDEA™ value was calculated for each sample based on absorption of the product after the OPA reaction. The IDEA™ values were correlated to TD of RUP-AA measured in the roosters. The IDEA™ values were good predictors of the digestibility of RUP-AA in SBM and SoyPlus® (R^2 = 0.91 and 0.83 for Lys and Met, respectively) and DDGS (R^2 = 0.95 and 0.95 for Lys and Met, respectively). However, the IDEA™ values were not as good predictors of RUP-AA digestibility in FM (R^2 = 0.53 and 0.46 for Lys and Met, respectively) which may be due to a lack of variability in digestibility of RUP-AA among the FM samples. In conclusion, IDEA™ may be a good approach for predicting the digestibility of RUP-AA in SBM and DDGS, and further evaluation of IDEA™ for predicting digestibility of RUP-AA in FM is warranted.

Key Words: Amino Acid Digestibility, Immobilized Digestive Enzyme Assay™, Rumen Undegraded Protein

985 Influence of level of intake upon rumen degradability of protein sources. I. Schadt*[1], G. Azzaro[1], R. Petriglieri[1], P. J. Van Soest[2], K.-H. Südekum[3], and G. Licitra[1,4], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*Cornell University*, *Ithaca, NY*, [3]*University of Bonn*, *Bonn, Germany*, [4]*D.A.C.P.A. University of Catania*, *Catania, Italy*.

Increasing intake pushes rumen turnover, passage and protein escape. The objective of this study was to investigate the effect of turnover on rates of protein degradation. Five protein sources: herring meal, soy flakes, soybean meal, sunflower and brewers grains were incubated in situ for 4, 8, 12, 24, 36, 48 and 72 hours and residual nitrogen measured with six cows, two dry, two midlactation and two at high level of intake and milk production. The TMR′s fed to respective cows were also incubated in situ. The level of DMI (level 1, 2, 3, respectively, range: 9,9 to 25,4 kg DM/d) significantly reduced rates of rumen degradability rates for all protein sources, varying from 12-50% from the lowest to the highest intake, depending on the protein source. Rumen escape protein was calculated using estimated Turnover time (T_{DM}) according to Cannas (PhD thesis, Cornell University, 2000). Kp= $1/T_{DM}$ where T_{DM} = 19.89 - 12.82 * LN (dietary Neutral Detergent Solubles intake as % of body weight). Protein degradabilities were also measured with S. griseus protease at the respective times. Average time required for the S. griseus (1 U/ml) to achieve the extents observed in the in situ bags at predicted T_{DM} were 47h at level 1, 11h at level 2, and 5h at level 3. Ratios of these times with T_{DM} estimate rumen enzymatic activities: 1,9U/ml at level 1, 0,9U/ml at level 2 and 0,5U/ml for level 3. Regression of enzyme time on T_{DM} was y = 2.84 - 23.4x, R^2=0.94, n 6. This is evidence that the differences in the respective digestion of the protein sources with intake are due to varying proteolytic activity in the rumen.

Key Words: Rumen Protein Degradability

986 Balancing diets for rumen microbial protein requirements: 1) effects on animal performance under a deficient rumen available protein scenario. P. J. Guiroy*, D. H. Theuninck, C. B. Calk, and J. N. Pike, *Cargill Inc*, *Minnetonka, MN*.

The objective was to evaluate feedlot performance in diets that provided the same percentage of rumen fermentable carbohydrates but differing in the supply of rumen available protein (**RAP**, sum of degradable intake CP and recycled nitrogen). Diets were formulated

with the Cargill MAX™ system, which utilizes a model to estimate microbial CP (**MCP**) based on type and amount of dietary carbohydrates fermented in the rumen. The trial was conducted with 1806 steers with 3 treatments and 6 pen replications per treatment for 166 d. All diets were isocaloric, and isonitrogenous at 13.3% CP. Diets contained the same inclusion of flaked corn, alfalfa hay, corn silage, fat, and supplement. Treatment supplements contained different sources of protein to meet diet objectives: **Low RAP** diet (RAP deficient by 10% compared to MCP with NPN at 2.50%), **Balanced RAP** diet (compared to MCP with NPN at 3.25%), and **Balanced RAP-High NPN** diet (compared to MCP with NPN at 3.60%). Balanced treatments improved ADG and feed to gain ratio in comparison to Low RAP. Only the Balanced RAP diet resulted in heavier HCW and larger LM in comparison to the Low RAP diet, indicating an advantage in limiting concentration of NPN. DMI was higher during the first 60 d (P< 0.01) when diets were balanced for RAP with a tendency for DMI to be higher for the entire feeding period (P=0.11). Results indicated that meeting MCP requirements with RAP improved DMI and performance. We hypothesize that improved DMI may be due to increasing MCP yield, which results in improved rumen health conditions.

Table 1.

Item	Treatments[1] Low RAP	Balanced RAP	Balanced RAP–High NPN	SEM	P–value
Initial BW, kg	342	343	343	1.54	0.71
Final BW, kg	606[b]	617[a]	613[ab]	2.50	0.02
ADG, kg	1.59[b]	1.65[a]	1.63[a]	0.01	0.01
Daily DMI, kg	9.30	9.52	9.36	0.07	0.11
Feed to Gain ratio	5.85[b]	5.77[a]	5.75[a]	0.019	0.01
HCW, kg	386[b]	394[a]	390[ab]	1.59	0.02

987 Balancing diets for rumen microbial protein requirements: 2) effects on animal performance under an excess rumen available protein scenario. J. N. Pike*, P. J. Guiroy, D. H. Theuninck, and C. B. Calk, *Cargill Inc*, *Minnetonka, MN*.

A trial was conducted to evaluate the effect of rumen available protein (**RAP**) relative to microbial CP (**MCP**). The Cargill MAX™ system was used to formulate diets. RAP is the sum of degradable intake protein (**DIP**) and recycled nitrogen while MCP potential is estimated from type and amount of dietary carbohydrate fermented in the rumen. The trial was a 2 x 3 factorial (2 management systems and 3 protein formulations) using mixed breed steers (n=2400, 4 replications). There were no important interactions and only effects of protein formulation will be discussed. Treatments were: **Control**, (13.8% CP, 1.6% NPN, RAP in excess of MCP by 11%); **Balanced** (12.8% CP, .77% NPN, RAP equal MCP), **Hi-Soluble DIP** (13.8% CP, 1.9% NPN, RAP in excess of MCP by 13%). Rations contained 33% steam-flaked corn, 21.5% high-moisture corn, 24% Sweet Bran, 9.5% corn silage, 4.6% tallow and 7.4 % supplement designed to provide desired levels of CP, DIP and NPN. There was a difference in feed conversion (P<0.10) among treatments and a trend for improved ADG for the Balanced diet. There were no differences among treatment groups in HCW or quality grade. The Balanced treatment resulted in lower fat thickness and larger LM than excess RAP diets. Formulating rations to balance RAP with MCP, with no minimum CP, had no negative effects on performance compared with formulating to more typical feedlot crude protein levels. In this trial, balancing RAP with MCP lowered total CP, resulting in reduced feed cost of US$2.81 and US$1.40 per head compared to the Control and Hi-Soluble DIP, respectively.

Table 1.

Item	Treatments[1] Control	Balanced	Hi–Soluble DIP	SEM	P–value
Initial BW, kg[2]	346	343	345	0.94	0.06
Final BW, kg	611	610	610	2.22	0.85
ADG, kg	1.54	1.56	1.51	0.02	0.16
Daily DMI, kg	8.85	8.82	8.84	0.07	0.96
Feed to Gain ratio	5.76[cd]	5.66[c]	5.85[d]	0.06	0.10
HCW, kg	388	387	386	1.24	0.54

988 Effect of level of metabolizable protein on milk production and nitrogen utilization in lactating dairy cows. C. Wang*[1], J. X. Liu[1], Z. P. Yuan[1], Y. M. Wu[1], S. W. Zhai[1], and H. W. Ye[2], [1]*Institute of Dairy Sciences, Ministry of Education Key Laboratory of Molecular Animal Nutrition, Zhejiang University*, *Hangzhou 310029, China*, [2]*Hangzhou Zhengxing Animal Industry Company*, *Hangzhou 311301, China*.

The objective of this study was to investigate the effects of levels of metabolizable protein (MP) on milk production and nitrogen utilization in Chinese Holstein dairy cows. Forty multiparous dairy cows (body weigh (BW) =590 kg; days in milk=135; average milk yield=30.2 kg/d) were assigned to treatments randomly within groups based on DIM and milk production. Animals were offered diets with different levels of MP: 8.3 (Diet A), 8.9 (Diet B), 9.7 (Diet C), and 10.4 (Diet D) % of DM. The MP level in Diet A was designed to meet the requirement according to current CNSAPH, while that in Diet D was based on NRC-2001 model. The experiment lasted for seven weeks. Milk yield and milk compositions (fat, protein, and lactose) were recorded, and urea nitrogen concentration in serum, urine, and milk were measured during the experiment. Milk yield and milk protein percentage increased as the MP increased up to 9.7 % of DM, and then leveled off. Concentrations of nitrogen in urine, serum, and milk increased lineally as the MP amount was increased, indicating decreased efficiency of N utilization. Milk lactose percentage and total solid percentage showed no significant differences among four diets. It is concluded that the optimal dietary MP level was at 9.6 % of DM for Chinese Holstein dairy cows producing 30 kg milk per day.

Key Words: Metabolizable Protein, Milk Production, Lactating Cows

989 Nutrient demand affects nitrogen utilization responses to diets containing alfalfa or orchardgrass. J. A. Voelker Linton* and M. S. Allen, *Michigan State University*, *East Lansing*.

Effects of feed intake on relative responses of N intake, digestion, and utilization to alfalfa silage versus orchardgrass silage were evaluated. Eight ruminally and duodenally cannulated Holstein cows were utilized in a crossover design experiment with a 14-d preliminary period and two 15-d treatment periods. Cows were 139 ± 83 (mean ± SD) DIM at the beginning of the preliminary period. During the preliminary period, milk yield ranged from 24.5 to 46.0 kg/d and preliminary voluntary DMI (pVDMI) ranged from 11.4 to 21.0 kg/d. Treatments were a diet with alfalfa silage as the sole forage (AL) and a diet with orchardgrass silage as the sole forage (OG). Alfalfa silage contained 20.5% CP (DM basis) and orchardgrass silage contained 20.4% CP; AL contained 18.3% CP and 5.6% estimated RUP, and OG contained 18.8% CP and 6.3% estimated RUP. Alfalfa silage contained 43% NDF (DM basis) and orchardgrass silage contained 48% NDF; both diets contained 23% forage NDF. Mean N intake was similar between treatments ($P = 0.95$), ruminal N digestibility was greater ($P = 0.03$) for AL than for OG, and whole-tract N digestibility did not differ between treatments ($P = 0.50$). The ability of linear and quadratic factors of pVDMI to predict the difference in responses of individual cows to treatments ($Y_{AL} - Y_{OG}$) was tested by analysis of variance, with treatment sequence as a covariate. With increasing pVDMI, intake and duodenal flow of N increased more for AL than for OG (N intake: $P = 0.01$; duodenal N flow: $P = 0.01$) because of increasingly greater DMI for AL compared to OG as pVDMI increased ($P < 0.01$). However, as pVDMI increased, whole-tract N digestibility tended to decrease for AL relative to OG ($P = 0.07$). When feeding less-filling diets to high-producing cows, reducing dietary N concentration could increase the efficiency of N utilization and reduce the extent to which greater DMI leads to greater N excretion.

Key Words: Grass, Legume, Nitrogen Utilization

990 A comparative review of the flow of nitrogen fractions at the omasal canal and duodenum of dairy cows. I. R. Ipharraguerre*[1], S. M. Reynal[2], P. Huhtanen[3], J. H. Clark[4], G. A. Broderick[2], and S. Ahvenjärvi[5], [1]*Lucta S.A.*, *Barcelona, Spain*, [2]*US Dairy Forage Research Center*, *Madison*, [3]*Cornell University*, *Ithaca*, [4]*University of Illinois*, *Urbana*, [5]*MTT Agrifood Research Finland*, *Jokioinen*.

The objective of this paper was to review and compare published data for the flow of N fractions to the omasal canal and duodenum of lactating dairy cows. Two data sets were created; one with data from 14 studies in which digesta was sampled from the omasal canal (57 means) and the other with data from 67 studies in which digesta was taken from the duodenum (264 means). Mean intakes of DM (DMI 19.7±3.4 kg/d) and N (NI 537±117 g/d) were similar between data sets. Flows (g/d) of nonammonia N (NAN), microbial N (MN), and NAN-non-MN (NANMN), and the ratio NAN/DMI averaged, respectively, 516±128, 342±100, 173±48, and 24.7±3.2 at the omasum; and 508±113, 271±84, 236±87, and 25.9±3.9 at the duodenum. Despite similar mean NAN flows and NAN/DMI between sampling sites (SS), 65% of the reported MN flows to omasum exceeded 300 g/d whereas only 32% of the reported MN flows to duodenum were greater than 300 g/d. As a result, MN represented more than 55% of the postruminal NAN flow in 90% of the cases in which samples were taken from the omasum compared with 39% of the cases in which samples were obtained from the duodenum. Both data sets were combined and subjected to regression analysis using a mixed model approach that included study as a random variable. Dependent variables were NAN, MN, and NANMN flow. Independent variables were SS, NI or DMI and dietary CP %, and all possible two-way interactions. The effect of SS and its interaction with other variables was not significant ($P > 0.25$) for all NAN-flow models. Conversely, the interactions SS x DMI and SS x NI were significant for the MN-flow ($P < 0.06$) and NANMN-flow ($P < 0.01$) models, respectively. These findings suggest that omasal canal and duodenal sampling may result in different estimates of the flow of MN and NANMN. More research is needed to determine the relative accuracy of these estimates and origin of these differences.

991 Essential oil supplementation of a corn silage based diet deficient in rumen undegraded protein fed to lactating Holstein dairy cows. C. A. Crawford, C. G. Schwab, A. B. Conroy, P. S. Erickson, N. L. Whitehouse*, and S. E. Boucher, *University of New Hampshire*, *Durham*.

Thirty multiparous Holstein cows in early lactation were used in a randomized complete block design to determine the efficacy of adding VERTAN, a specific blend of essential oils (EO), at 0 or 0.8% of diet dry matter (DM) to a corn silage based diet on DM intake, milk yield (MY), milk composition, and ruminal N metabolism. The basal diet contained (DM basis) 29.8% corn silage, 14.9% grass silage, 7.2% alfalfa hay, 0.11% grass hay, 21.5% finely-ground corn, 1.6% beet pulp, 1.6% citrus pulp, 4.3% soy hulls, 0.79% molasses, 11.9% soybean meal, 0.43% urea, 0.06% Smartamine M™, 2.5% Megalac™, and 3.4% vitamin and mineral premix. Animals were on treatment from 21 through 105 days in milk. Diets were formulated to meet NRC (2001) requirements for energy and all nutrients except rumen undegraded protein. Cows were fed and milked 3 × daily. Milk and blood samples were collected during wk 4-15 of lactation. There was no effect of VERTAN supplementation on DM intake, MY, milk composition, or blood urea N concentrations. To evaluate the effects of VERTAN on ruminal N metabolism, 2 rumen cannulated multiparous Holstein cows were used in a switchback design (each cow received each treatment twice). Experimental periods were 4 wk; 16 rumen fluid samples were collected during wk 4 of each period. Samples were collected during 2 consecutive days to represent every 2 h in a 24-h period. There was no effect of treatment on ruminal pH. A significant hour by treatment effect was observed for ruminal ammonia-N concentrations; VERTAN supplementation lowered ruminal ammonia-N concentrations at 2, 3, and 4 h post-feeding. These results support the work of others indicating that EO decrease amino acid (AA) deamination in the rumen. More research is needed to determine the interactions of supplementation levels of EO, diet composition, and rumen ammonia-N and free AA concentrations in lactating cows.

Key Words: Lactating Cows, Essential Oils, Corn Silage

992 The effect of rumen undegradable and rumen degradable protein concentration on urea recycling in mid-lactation cows. S. K. Ivan*[1], R. L. Baldwin, VI[2], and R. A. Kohn[1], [1]*University of Maryland*, *College Park*, [2]*USDA-ARS*, *Beltsville, MD*.

This study investigates potential mechanisms for control of urea recycling. We assigned 8 mid-lactation Holstein cows to a repeated 4

× 4 latin square, balanced for carryover effects. The isoenergetic diets contained 16.0, 17.3, 18.8, and 19.5% CP as a percent of DM, and the rumen degradable (RDP) and rumen undegradable protein (RUP) concentrations were arranged in a factorial design (10.0 and 12.5% RDP and 5.6 and 8.1% RUP as a percent of DM). There was no effect (P>0.05) of CP concentration on rate (g/d) of urea recycling, urea transferred to the GIT, or urea returning to the blood from the GIT. Of the urea transferred to the GIT, the proportion utilized by the microbes was also unaffected by CP concentration. Analysis of the RUP and RDP factorial identified tendencies for greater urea transfer (g/d) to the GIT with the low RDP diets (P=0.08), and for greater return of recycled urea to the blood (g/d; P=0.10). The blood urea N (BUN; mg/dL) was lowest for the low RDP diets but low BUN did not decrease transfer of urea to the GIT. As a proportion of urea transferred to the GIT there was more returned to the blood (P=0.05) with the high RUP diets, and a tendency (P=0.11) for more urea utilization by the rumen microbes with the low RUP diets. There was no difference in the liters of blood cleared of urea by the kidney per day per kg body weight indicating that any regulation of recycling is not at the kidney. We did not observe ruminal urea transporter (bUT-B2) expression changes. The rate of transfer of urea across the rumen wall appeared to be independent of rumen and blood urea concentrations, thereby increasing the proportion of BUN and rumen ammonia N (RAN) transferred when low protein diets decrease the BUN and RAN concentrations.

Key Words: Urea Recycling, Rumen Degradable Protein, Rumen Undegradable Protein

993 Nitrogen excretion and utilization efficiency in dairy sheep fed diets with different dietary energy contents. V. Giovanetti[1], M. Decandia[1], F. Boe[2], E. Zerbini[3], A. Cannas[2], and G. Molle*[1], [1]*Istituto Zootecnico e Caseario della Sardegna*, *Olmedo, Sardinia, Italy*, [2]*Dipartimento di Scienze Zootecniche, Università di Sassari*, *Sassari, Sardinia, Italy*, [3]*Cargill Animal Nutrition*, *Spessa, Italy*.

The aim of this study was to evaluate a) the effect of different dietary energy content on fecal N excretion (FNE), urinary N excretion (UNE) and N utilization efficiency (NUE), and b) the relationships between milk urea N (MUN) and the above variables in Sarda dairy ewes. Two experiments were carried out using mid lactating (E1) and late lactating (E2) dairy ewes (n=5 per treatment), kept in metabolic cages and fed 8 pelleted diets with different main ingredients: Corn Meal (CM), Wheat Middlings (WM), Corn Flaked (CF), Barley Meal (BM), Corn Cobs (CC), Beet Pulp (BP), Alfalfa (AA) and Soybean Hulls (SH). The diets ranged from low (1.26-1.53 Mcal/kg DM) to high (1.72-1.84 Mcal/kg DM) NEL contents, and had high CP concentration (on average 18.4 % DM). The lowest energy diet (AA) showed a trend to higher N excretion and MUN and lower NUE (Table 1). Pooling all data, a close positive relationship was found between UNE and MUN (R^2=0.94), while FNE was positively related to NDF and negatively to NFC (R^2=0.82 for both). A negative relationship between MUN and NUE was also found (R^2=0.58). It is concluded that diets with s high energy content can reduce overall N excretion and increase NUE in dairy sheep. In addition, MUN can be effectively used to predict urinary nitrogen excretion and NUE.

Teaching/Undergraduate & Graduate Education: Swine Teaching

994 Enrollment in swine classes at 49 four-year institutions during academic years 1998-99 to 2005-06. D. E. Reese*, K. M. Eskridge, and D. A. Travnicek, *University of Nebraska*, *Lincoln*.

Concern over enrollment decline in swine classes (SC) at some institutions was discussed at a North Central Region Animal Science department head meeting in 2003. The lack of quantifiable nation-wide enrollment information prompted an effort to collect SC enrollment data from 49, four-year US institutions. Enrollment data was obtained for each institute's SC beginning with the 1998-1999 academic year (AY) though 2005-2006. If no enrollment was reported, follow-up contact was made to discern whether 1) the SC was offered but not taught due to low enrollment (LE), 2) the SC was not offered (NO), 3) the SC was scheduled not to be offered (SNO), or 4) no SC existed. Regression analyses were performed with AY as the independent variable to test if the slope was zero for number of students enrolled, percent of SC that were taught (SCT), percent of institutions experiencing LE, percent of institutions experiencing NO, percent of institutions experiencing SNO, and percent of institutions teaching a SC with < 10 students enrolled. Forty-one institutions had a SC during 1998-99 to 2002-03; forty had a SC from 2003-04. The number of SC ranged from 43 to 46 depending on the AY. Enrollment in SC and the percent of SC that were taught decreased from 1998-99 to 2005-06 (see table). More institutions that had a SC did not offer their SC in 2005-06 vs. 1998-99, while those teaching their SC with < 10 students was stable. These results demonstrate that low enrollment and course offering issues exist with SC at many institutions.

Table 1. Swine class enrollment and offerings

995 Regionalization of teaching efforts? - Midwest Poultry Consortium experience. M. M. Beck*[1] and B. C. Wentworth[2], [1]*Clemson University*, *Clemson, SC*, [2]*University of Wisconsin*, *Madison*.

In 1993, faced with declining poultry programs at Midwestern universities and decreasing numbers of graduates with training in poultry science, a group of poultry producers, processors, and allied industry executives formed the Midwest Poultry Consortium (MPC) for the express purpose of supporting a regional teaching program. Faculty and administrators at the University of Wisconsin were instrumental in the development and implementation of the Midwest Poultry Science Undergraduate Center of Excellence (COE), to which initially 13 universities contributed funds and committed faculty time. With a representative of each university in attendance (the Coordinating Council) in 1995, a two-summer, six-course academic program was developed. Industry members of the MPC pledged their assistance and assurance in securing internships for students before and/or after the classes. Funding obtained from MPC members provides student travel to and from Madison, dorm room costs, in-state tuition, and course supplies and materials; and travel, a per diem, and accommodations in the UW Extension hotel for faculty. Faculty salary is not covered. Credits transfer back to home institutions. Nineteen students attended the 1st COE in Madison, WI, in 1996; ten years later, some 188 students have attended COE classes. A 2005 survey of students through 2004, with a response rate of 58%, showed that ~58% of respondents had completed all six courses; 64% had had at least one internship. Of those 1996-2000 COE participants currently employed in the poultry industry, the average salary is $46K (range $20K-$95K) in contrast to $39K (range $15K-$75K) for those not employed in the industry. Faculty participation has been remarkably constant and industry support has not wavered. A strength of the program is the very tight camaraderie that develops among the students and that continues as they move into industry positions in the poultry industry. In 2001, the Midwest Poultry Research Program was initiated to address issues of importance to the Midwest poultry industry.

Key Words: Regionalization, Teaching, Midwest Poultry Consortium

996 Regionalizaton of swine teaching efforts. D. J. Meisinger*, *US Pork Center of Excellence*, *Ames, IA*.

The mission of the US Pork Center of Excellence (USPCE) is to add value to the pork industry by facilitating research and learning for U.S. pork producers through national collaboration. The USPCE is bringing states together in a collaborative mode to accomplish many things in research, teaching and extension. Regionalizing swine teaching is definitely within the purview of the USPCE strategy. The first tool of the Center is the Pork Information Gateway (PIG), a virtual library of resources for pork producers and educators. Another tool available only to educators is PIGMAP or the PIG media asset portal which contains a large number of images. PIG will provide a convenient repository for all teaching materials allowing educators involved in teaching swine classes an opportunity to draw upon a wealth of material as they prepare lesson plans. The images would be a great addition to this body of material as well. Another related program being proposed by the USPCE is the concept of regional swine schools. These schools would provide for specific student centered instruction in pork production at central locations allowing the students to return to their respective universities to conclude their education. Much of the curricula developed for these schools would be made available to all swine class instructors through the PIG website to enhance their ability to teach modern pork industry practices, strategies and philosophies. The USPCE is poised to offer swine class instructors an opportunity to draw upon many resources as they prepare their lesson plans and build their curricula. This concept of assembling all the materials critical to preparing young people for future careers in the pork industry is sound and should be supported.

Key Words: Swine Teaching, Swine Curricula, Swine Instruction

997 Student perceptions of and enrollment in swine management courses at North Carolina State University. W. L. Flowers*, *North Carolina State University*, *Raleigh*.

The Department of Animal Science has surveyed incoming freshmen and graduating seniors for the past 10 years. None of the incoming freshmen (n=140 per year) have an interest in swine. In contrast, 10 to 15% of the graduating seniors (n=100) list swine as their primary species of interest or indicate they have accepted a position in the swine industry. Exposure to pigs early during a student′s academic program and a senior-level management course that focuses on problem-solving appear to be two factors that foster this change. Both courses are taught by the same instructor. All freshmen are required to take the introductory animal science course. This course has two laboratories that focus on swine. One is a behavior laboratory, which is the first scheduled laboratory. Students participate in quantifying behavioral interactions between sows and piglets. During a subsequent laboratory, students assist sows during farrowing and obtain blood samples from weaned pigs. Course evaluations indicate that the laboratories dealing with swine are the student's favorite. Access to sows and piglets and participating in events in which students felt they contributed to the animal′s well being are the two common reasons given. The senior-level management course is a departmental elective with enrollment capped at 30 students. Examinations require students to work in groups to solve simulated problems. Students have to analyze production records and identify problems. For each problem, they are required to gather information that will help them explain its cause(s). They have to rely on their own observations of the farm; data that they collect such as ventilation efficiency, feed intake, or semen quality; data that

they can request such as feed analyses, necropsy reports, or serology profiles; and questions they can ask of the employees. Previous exposure to swine in the introductory course and the interactive nature of the examinations consistently rank as the main reasons students enroll in the senior-level swine management course.

Key Words: Swine, Teaching

998 A survey of student demographics enrolled in a distance education swine production class. R. D. Goodband* and B. C. Minshal, *Kansas State University*, *Manhattan*.

Kansas State University is one of the few universities where enrollment in its swine production class, Swine Science, ASI 535, has gradually increased over the past 5 years. While enrollment in the on-campus class has remained steady at approximately 22 students in both fall and spring semesters, the gradual increase in student numbers has been a result of the introduction of a distance education, internet-based class. The on-campus and distance education classes are virtually identical in course content, with the exception that the distance class does not have a laboratory. As a substitute for laboratories, a DVD with video footage of some of the on-farm activities is distributed. Also, the distance education class is designed for students to work at their own paceSince spring of 2002, there have been 221 students who have taken the on-campus class (57% of students in the fall semester and 43% in the spring), whereas 64 students have taken the distance education class which is offered in fall (25%), spring (45%) and summer (30%) semesters. Of these distance education students, 37% are male and 63% female. Sixty seven percent are KS residents and 33% from other states. Of students enrolled, 56% are also full-time KSU students concurrently enrolled in on-campus classes. The other 44% are only taking classes from KSU via distance education (not enrolled in any on-campus classes). In the spring and fall semesters, 44% are on-campus students and 54% are not. However in the summer semester, 84% are full time KSU students. This suggests that on-campus students want to take classes during the summer semester when traditional animal science classes are typically not offered. It may also suggest a trend in more students wanting to take classes year round compared with the traditional fall/spring semester system. Distance education classes appear to offer scheduling flexibility, especially during the summer semester for students to complete their degree programs.

Key Words: Distance Education, Swine Production, Teaching

999 Teaching swine production as a capstone experience in the writing intensive curriculum. T. J. Safranski*, *University of Missouri*, *Columbia*.

From 1998-2006 the senior level Swine Production course at the University of Missouri was taught by the same instructor as a Capstone Experience in the Writing Intensive (WI) curriculum. For WI status assignments are reviewed and meet guidelines set by the Campus Writing Board to ensure rigor and include revision and critical thinking. Writing skills are learned using the ′writing across the curriculum′ concept, with students required to take one lower level WI class and one upper level WI class within their major. One writing class is required. Completion of one Capstone Experience is also required. Departmental guidelines require students complete two production courses choosing among Swine, Beef, Dairy, Poultry and Horse; four of the five are WI; all are Capstone. Swine Production was cancelled once with enrollment of six (1999). Otherwise enrollment ranged from 11 (2001) to 46 (2004) and averaged 26.1 students. Although assignments evolve, in 2006 there were 14 assignments, seven of which involved multiple drafts. Four of these seven involved developing a five year plan for a commercial farm working in instructor-assigned teams. Papers total a minimum of 33 pages of writing; most students write more. Many papers are short and used to force students to consider issues prior to class discussion. Normally less than 15% of students are enrolled specifically to meet the WI requirement. Student evaluations indicate the writing is not perceived as excessive. The most common complaint is coordinating teams, although the Farm Plan is also normally rated among the two best assignments of the class. Besides writing, other activities students often praise include the required one or two day field trips to commercial farms and an optional job shadowing experience. Rarely have more than 20% of students been to a swine farm. Teams prepare a 10 minute seminar on their field trip experience and present to the rest of the class. Incorporation of writing into a senior level Swine Production course may enhance student learning. It requires significant time investment for grading by the instructor.

SYMPOSIA AND ORAL SESSIONS

Monday, January 22
Physiology and Pathology
Room: B312

M1 Comparison of delayed type hypersensitivity reaction induced in chickens, turkeys and ducks by killed *Staphylococcus aureus*. O. A. Oladele*, A. A. Owoade, and T. O. Jolaoso, *University of Ibadan*, *Ibadan, Oyo State, Nigeria*.

Differentials in susceptibility of poultry species to a number of avian pathogens prompted the comparison of innate cellular immune response of chickens, turkeys and ducks via the assessment of delayed type hypersensitivity (DTH) reaction in these species. Delayed footpad reaction (DFR) to killed *Staphylococcus aureus* was adopted for this study.

Twelve broiler chickens, 16 turkeys and 8 ducks were sensitized twice via subcutaneous injection in the neck of *S. aureus* antigen (150µ/g) mixed 1:1 with Complete Freund Adjuvant (CFA) at 3 and 4 weeks of age. Control birds were injected with CFA only. At 6 weeks of age the birds were challenged intradermally with *S. aureus* antigen (75µg/bird) in Phosphate Buffered Saline (PBS) in the right footpads while the left footpads were injected with PBS only. The thickness of the footpads was measured at 0, 5, 12, 24, 48 and 72 hours (hrs) post challenge (pc) to evaluate DFR. At 72 hrs pc birds were euthanized and both footpads were excised for histopathology. In a second experiment spleens from both sensitized and non-sensitized broilers were separately harvested aseptically; splenic lymphocytes (SL) were prepared and injected intravenously into 2 groups of recipient broilers.

Average DFR values obtained in sensitized birds were generally higher than in non-sensitized birds and was statistically significant (P≤×0.5)between 24 and 72 hrs pc in chickens and at 12 hrs pc in turkeys. While maximum DFR response was at 24 hrs pc in broilers it was at 12 hrs in both turkeys and ducks. At histopathology the killed *S. aureus* injected footpads were characterized by dermal oedema, congestion of blood vessels and perivascular infiltration of lymphocytes and macrophages. Broiler chickens that received sensitized SL had a significantly pronounced DFR following challenge with *S. aureus* antigen in comparison with those that received non-sensitized SL.

This study has shown that while turkeys and ducks have innate ability to elicit faster cellular immune response to *S. aureus* antigen than chickens, chickens have the innate ability to respond more intensely.

Key Words: Innate cellular immunity, DTH reaction, Chickens, Turkeys, Ducks

M2 Effects of luteinizing hormone, follicle stimulating hormone, 17 β-estradiol or testosterone upon ghrelin receptor mRNA expression in cultured granulosa cells. M. E. Freeman* and A. J. Davis, *University of Georgia*, *Athens*.

Nutritional status and reproductive function are intricately connected. However, the complex hormonal interactions defining how nutrition effects reproduction have yet to be clarified. Ghrelin is a novel polypeptide hormone produced predominantly in the proventriculus of chickens that effects feed intake and energy metabolism. There is increasing evidence that ghrelin also directly affects reproduction in mammalian species. Previously we reported that ghrelin receptor (GHSR) mRNA was expressed in both the theca and granulosa cells of developing follicles of the ovary and that theca mRNA expression of GHSR increased significantly in fasted hens. In the current research the gonadotropin and steriod hormone regulation of GHSR mRNA expression was examined. For each replicate experiment granulosa cells were isolated from the F_1 and F_3 follicles and small yellow follicles (SYF) from three hens. The isolated and dispersed granulosa cells were then cultured for 24 hours in the absence or presence of 50 ng/mL of LH or FSH (5 replicate experiments) or in the presence or absence of 1 x 10^{-6} M of testosterone or 17 β-estradiol (4 replicate experiments). For each experiment, total RNA was extracted from the freshly dispersed granulosa cells and the cultured granulosa cells from each follicle size for two step real-time PCR analysis of GHSR. Untreated, cultured granulosa cells from all follicle sizes had significantly greater expression of GHSR than freshly dispersed granulosa cells. In the cultured granulosa cells isolated from the F_1 and F_3 follicles the addition of LH, FSH and testosterone, but not 17 β-estradiol, significantly decreased the mRNA expression of GHSR. In the granulosa cells isolated from SYF, expression of GHSR was

equal in the untreated control cells and the cells cultured with any of the hormones. The lower expression of GHSR in the presence of gonadotropins and testosterone indicate that these hormones may play a vital role in down-regulating GHSR expression in the granulosa cells of hierarchal preovulatory follicles.

Key Words: Ghrelin receptor, Granulosa, Gonadotropin, Steriod

M3 Compensatory changes to induced anemia in broilers. L. L. Hale-McWilliams*, Z. Williams, M. Putsakum, S. W. Anderson, and J. P. Thaxton, *Mississippi State University*, *Mississippi State*.

Experiments were conducted to evaluate compensatory changes to induced anemia in broilers in 4 wk-old broilers. Five treatments were used and these were non-bled and bled controls plus bled controls that received iv injections of saline (SAL), chick embryo extract (CEE) or anemic chick serum (ACS). The CEE extract was prepared by pooling 200, 10 d broiler embryos in 10 mL of PBS, homogenizing the embryos using a Stomacher blender, and then filtering the homogenate at 0.4 mmic. The ACS was prepared by collecting serum from 4 wk old chicks that were subjected to severe anemia by multiple bleedings. Additions of 7 mL (iv) of SAL, CEE, and ACS were made immediately after a 10% blood loss (v/BW basis). Thereafter, birds were bled at 5 min, 2 h, 24 h and 72 h to assess pH, pCO2, pO2, hematocrit, hemoglobin, electrolytes (Na+, K+, Ca+2, Cl-, and HCO3-), anion gap, and plasma corticosterone . The spleen and bone marrow samples were also evaluated for relative weight and hemoglobin levels. Results suggest that homeostatic regulation of acid-base balance were achieved within 72 h; however, physiological compensations of the induced-anemic condition had not been completed within 72 h.

Key Words: Anemia, Broilers, Hematocrit, Hemoglobin, Erythropoietin

M4 Evaluation of novel bacterial species on intestinal development and microflora. B. S. Lumpkins*, Y-J. Cho, A. B. Batal, and M. D. Lee, *University of Georgia*, *Athens*.

The growing concern of feeding antibiotics to poultry has lead researchers and animal health companies to investigate alternatives. An experiment was conducted to evaluate the effects of an oral inoculation with novel intestinal anaerobes on the development of the intestine. At 0d of age, 500 Cobb male chicks were separated into 4 treatments: a control and 3 test treatments that were orally inoculated with a novel species of *Bacteroidaceae, Clostridiaceae*, or a combination of the two. Throughout the experiment all birds were fed a corn-soybean meal diet. At 0, 1, 2, 3, 7, 16, and 42d of age performance parameters were measured and samples were taken for morphological and bacterial community analysis. At 42d of age, birds were randomly selected and processed for carcass yield. For bacterial community analysis, community DNA isolated from small intestinal contents were amplified with universal 16s primers. Diversity and compositional changes were assessed using denaturing gradient gel electrophoresis (DGGE) and terminal restriction fragment length polymorphism (T-RFLP). The performance parameters were similar among all 4 treatments from 0 to 16d of age. At the end of the 42d period the overall weight gain of the birds inoculated with *Clostridiaceae* was significantly lower than the control birds and the *Bacteroidaceae* inoculated birds. The birds inoculated with the combination of *Bacteroidaceae* and *Clostridiaceae* had increased villi height and goblet cell concentration during the first 3d of age, but after 7d of age there was no overall difference in morphological response between treatments. There was no difference in the carcass yield between treatments. Based on the DGGE analysis, the microbiota populations clustered based on age rather than treatment. Birds inoculated with either *Bacteroides* or *Clostridiaceae* had a higher proportion of lactobacilli in the ileum compared to the control birds, based on T-RFLP analysis at 42d of age. The combination of *Bacteroidaceae* and *Clostridiaceae* improved intestinal development at young ages, but *Clostridiaceae* may have negative effects on weight gain during the latter stages of growth.

Key Words: Microbiota, Morphological, Anaerobes, Bacterial community, DNA

M5 Effect of age on intestinal pH of broiler chickens. J. M. Rynsburger* and H. L. Classen, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

Protein digestion has been shown to be relatively poor in young birds therefore it is of interest to identify limiting factors. Initial protein digestion involves hydrochloric acid denaturation of protein and conversion of pepsinogen to its active form in the proventriculus and gizzard. If the production of hydrochloric acid is limited in young broilers, protein digestion may be hampered. A one-way ANOVA was used to study the effect of age on intestinal pH of broiler chickens fed a broiler starter diet. Ross x Ross 308 broilers (150 males) were randomly assigned to 10 battery cages. Using one bird per cage per sample age, the pH of the crop, proventriculus, gizzard, duodenum, jejunum and ileum was measured at 2, 3, 4, 5, 6, 7, 8, 9, 10 and 15 days of age. As the birds got older the crop pH increased (2d-5.01, 3d-5.51, 4d-5.64, 5d-5.54, 6d-5.42, 7d-6.13, 8d-5.08, 9d-5.56, 10d-6.29, 15d-6.02) while the pH of the proventricular proventriculus and gizzard decreased (proventriculus: 2d-5.20, 3d-5.12, 4d-4.78, 5d-4.58, 6d-3.33, 7d-4.85, 8d-4.16, 9d-3.48, 10d-3.56, 15d-3.37; gizzard 2d-3.49, 3d-3.47, 4d-3.43, 5d-3.50, 6d-3.24, 7d-3.48, 8d-3.30, 9d-3.42, 10d-3.27, 15d-3.27). The relationship between age and intestinal pH for the duodenum, jejunum and ileum was quadratic (duodenum: 2d-6.57, 3d-6.37, 4d-6.30, 5d-6.45, 6d-6.42, 7d-6.07, 8d-6.23, 9d-6.35, 10d-6.47, 15d-6.40; jejunum: 2d-6.82, 3d-6.66, 4d-6.44, 5d-6.5, 6d-6.38, 7d-6.3, 8d-6.26, 9d-6.34, 10d-6.42, 15d-6.5; ileum: 2d-7.74, 3d-7.07, 4d-7.26, 5d-7.1, 6d-6.74, 7d-7.08, 8d-6.9, 9d-7.05, 10d-7.43, 15d-8.15). In conclusion, during the first week of age the pH of the proventriculus and gizzard decreases indicating that the production of hydrochloric acid may not reach optimal levels until some time after hatch. As a result, protein digestion may be hampered during the first week post-hatch.

Key Words: Intestinal pH, Broiler, Chick, Protein, Digestibility

M6 Gonadotropin and steroid hormone regulation of zona pellucida proteins C and D messenger RNA in chicken granulosa cells. A. P. Benson*, M. E. Freeman, J. B. Hoffman, and A. J. Davis, *University of Georgia*, *Athens*.

The freshly ovulated ovum in avian species is surrounded by a protein layer called the inner perivitelline layer (IPVL), which is equivalent to the zona pellucida in mammals. For successful fertilization, sperm must attach and penetrate the IPVL. Previous research has established that

two of the IPVL protein components, ZPC and ZPD, are synthesized by the granulosa cells of the hierarchical follicles of the chicken ovary. In the current research, gonadotropin (LH and FSH) and steroid hormone (estrogen and testosterone) regulation of both ZPC and ZPD mRNA expression was investigated in cultured granulosa cells, which were isolated from the F1, F3, or small yellow follicles (SYF) from three broiler breeder hens for each replicate experiment. Isolated and dispersed granulosa cells from each follicular size were cultured for 24 hours in the absence or presence of 50 ng/ml of culture media of LH or FSH (4 replicate experiments), or in the presence or absence of 1 x 10^{-6} M testosterone or 17 β-estradiol (4 replicate experiments). For each experiment, total RNA was extracted from freshly dispersed granulosa cells and the cultured granulosa cells from each follicle size for subsequent Northern blot analysis of ZPC and ZPD. Neither ZPC nor ZPD mRNA were detected in freshly isolated granulosa cells from (SYF), however, both ZPC and ZPD mRNA expression was detected in untreated SYF granulosa cells cultured for 24 hours. ZPC and ZPD mRNA expression was also further up-regulated in SYF granulosa cells cultured in the presence of LH or testosterone. FSH increased ZPD mRNA expression in SYF granulosa cells. F3 granulosa cells cultured with FSH had higher ZPC and ZPD mRNA expression levels than untreated control cells. The mRNA expression of ZPD was higher in F3 granulosa cells cultured with testosterone and estrogen. The addition of LH to F1 granulosa cells lowered the mRNA expression of ZPC but not ZPD. These results indicate that gonadotropins and steroid hormones may play vital roles in regulating the expression of the mRNA for ZPC and ZPD in the granulosa cells of developing preovulatory follicles in the hen.

Key Words: Zona pellucida, Hormones, Granulosa

M7 Hormonal regulation of the activin type IA and IB receptors during follicular development in broiler breeder hens. J. B. Hoffman*, M. E. Freeman, A. P. Benson, and A. J. Davis, *University of Georgia*, *Athens*.

Increasing research evidence suggests that the activin and inhibin family of proteins have regulatory roles in chicken follicular development. Activin's cell surface receptor complex consists of an activin type I (ActRI) receptor and an activin type II receptor. Previously, we detected and profiled the expression pattern of the mRNA for two forms (ActRIA and ActRIB) of the ActRI receptor in the theca and granulosa cells of preovulatory hen follicles. In the current research, gonadotropin (LH and FSH) and steroid hormone (estrogen and testosterone) regulation of ActRIA and ActRIB mRNA expression was investigated in cultured granulosa cells, which were isolated from the F1, F3, or small yellow (SY) follicles from three broiler breeder hens for each replicate experiment. Isolated and dispersed granulosa cells from each follicular size were cultured for 24 hours in the absence or presence of 50 ng/mL of culture media of LH or FSH (5 replicate experiments), or in the absence or presence of 1 x 10-6 M testosterone or 17 -β estradiol (4 replicate experiments). Total RNA was extracted from all the cultured granulosa cell samples for subsequent real-time RT-PCR analyses of ActRIA, ActRIB and GAPDH (endogenous control) mRNA expression using gene specific primer pairs and a Taqman minor groove binding probe for each message. Granulosa cells obtained from F1 or F3 follicles and treated with LH had significantly lower mRNA levels of ActRIA and ActRIB than untreated granulosa cells. Similar results were obtained for FSH, except FSH did not significantly depress the mRNA expression of ActRIA or ActRIB in F1 granulosa cells. The expression of the mRNA for ActRIA and ActRIB in granulosa cells cultured from SYF was unaffected by the gonadotropins. Estrogen had no effect on the mRNA expression of ActRIA and ActRIB. The addition of testosterone to the granulosa cell cultures decreased the mRNA expression of ActRIA in F1 granulosa cells. The results suggest that the presence of LH and FSH in vivo may decrease the sensitivity of granulosa cells in hierarchical follicles to activin.

Key Words: Activin receptor type I, Broiler breeder hens, Follicular development

M8 Parthenogenesis discovered in unfertilized eggs of *Coturnix chinensis*, the Chinese painted quail. C. D. McDaniel* and H. M. Parker, *Mississippi State University*, *Mississippi State*.

Parthenogenesis, embryonic development of an unfertilized egg, has been studied for many years in turkeys. In fact, as many as 49% of unfertilized Beltsville Small White turkey eggs develop embryos. However, virtually no research exists on parthenogenesis in quail. The Chinese painted quail is a close relative of the more common Japanese quail and, unlike turkeys or chickens, the small Chinese painted quail reaches sexual maturity rapidly, making it a great candidate for further research on parthenogenesis. Obviously, a better understanding of avian parthenogenesis will increase our knowledge of avian fertilization and early embryonic development. Therefore we determined if unfertilized Chinese painted quail hens produce embryos. Secondly, we explored the possibility that position of the egg within the clutch influenced the rate of parthenogenesis. When initial secondary sexual plumage was apparent at 4 wk of age, male chicks were separated from females to prevent fertilization. Hens were placed in individual cages near sexual maturity, at approximately 8 wk of age. Individual eggs were collected daily and labeled with the hen number and date. Eggs were stored for 0 to 3 days at 20 C prior to incubation at 37.5 C. After 10 days of incubation, approximately 8,000 eggs from 308 laying hens were examined for embryonic development under a magnifying lamp. On average, 4% of the unfertilized eggs contained embryonic development consisting solely of unorganized membranes. About 37% of the laying hens produced at least one parthenogenetic embryo. However, about 9% of the hens exhibited a predisposition for parthenogenesis by producing 4 or more unfertilized eggs with embryos. One hen even produced 8 embryos from 25 unfertilized eggs laid. Additionally, the first egg laid in a clutch was most likely to produce an embryo, with a steady decline in the percentage of eggs developing embryos as position in the clutch increased. In conclusion, the Chinese painted quail does exhibit parthenogenesis and appears to be an excellent animal model for studying parthenogenesis.

Key Words: Chinese painted quail, Parthenogenesis, Fertility, Embryo, Quail

M9 Effects of chronic administration of NOS inhibitors on cardiopulmonary function and ascites parameters in broiler chickens. C. A. Ruiz-Feria*, N. Rougiere, and S. Kawthekar, *McGill University*, *Ste. Anne de Bellevue, QC, Canada*.

Endothelial dysfunction and inability to produce nitric oxide (NO) has been associated with the development of pulmonary hypertension (PH). Two experiments were conducted to investigate the effects of

chronic administration (14 d) of aminoguanidine (AG, 50 mg / kg BW / day) a specific inhibitor of the inducible form of nitric oxide synthase (NOS); N-Nitro-L-Arginine Methyl Esther (L-NAME, 15mg /kg BW /day), a non-specific NOS inhibitor; and a control (CTL, tap water) on cardiopulmonary function and parameters related to PH. Pulmonary arterial pressure (PAP) and mean systemic arterial pressure (MAP) after an acute challenge of epinephrine (EPI, 0,5mg/kg BW) were evaluated in birds raised in a thermoneutral environment (Experiment 1). Starting at day 28, 8 clinically healthy birds per treatment were anesthetised, cannulated, and after 10 min of equilibration, EPI was injected. The PAP and MAP were continuously recorded. In Experiment 2 we measured hematocrit and electrocardiogram parameters in chickens raised in a cold environment starting at d 14. Basal levels of PAP were highest in the L-NAME group. The PAP increased 30 s after EPI in all groups, but the increase was lower in the CTL group than in the AG and L-NAME group. The increase in PAP after EPI was similar for the AG and L-NAME birds. The basal and peak MAP after challenge was higher in L-NAME group and lowest in the CTL group. Both NOS inhibitors increased the hematocrit percentage and reduced the RS wave amplitude compared with the CTL group, but AG and L-NAME had comparable effects. Those results suggest that iNOS is an important source of NO in chronic pulmonary hypertension

Key Words: Ascites, Nitric oxide, iNOS, eNOS

M10 Effects of pre-lay 6/85 strain *Mycoplasma gallisepticum* inoculation on the internal egg and egg shell characteristics of commercial laying hens when given alone or in conjunction with F-strain *Mycoplasma gallisepticum* inoculations during lay. K. A. Viscione*[1], E. D. Peebles[1], S. L. Branton[2], A. M. Vance[2], S. K. Whitmarsh[1], R. W. Keirs[1], and P. D. Gerard[1], [1]*Mississippi State University*, *Mississippi State*, [2]*USDA, ARS, Poultry Research Unit*, *Mississippi State, MS*.

Alterations in egg production in commercial layers in response to an F-strain *Mycoplasma gallisepticum* (FMG) infection at 12 wk of age have been shown to be associated with changes in yolk composition. Two trials were conducted to examine the effects of age of inoculation, a pre-lay 6/85 strain of *Mycoplasma gallisepticum* (6/85MG) inoculation, and FMG inoculation overlays during egg production on internal egg and eggshell characteristics of commercial laying hens. Inoculation treatments included: sham inoculation at 10 wk of age, 6/85MG at 10 wk of age, 6/85MG at 10 wk overlaid by a subsequent FMG inoculation at 22 wk, and 6/85MG at 10 wk overlaid by a subsequent FMG inoculation at 45 wk. Parameters assessed in each trial included egg weight; percent yolk, albumen, and eggshell weights; percent yolk moisture and lipid concentrations; yolk fatty acid profiles; eggshell weight per unit of surface area (SWUSA); egg shape index (width/length); and relative eggshell conductance (RG). Determinations of egg shape index, SWUSA, RG, and percent yolk moisture, yolk lipid, eggshell weight, albumen weight, and yolk weight were at various time periods between 24 and 59 wk, egg weight was weekly from 23 through 55 wk, and yolk fatty acid profiles at 59 wk. Parameters investigated before 45 wk were analyzed separately from those investigated after 45 wk. Egg shape index was higher at 49 wk compared to that at 53 wk. FMG overlays at 22 and 45 wk increased yolk moisture content. An FMG overlay at 22 wk increased yolk palmitic acid, and FMG overlays at 22 and 45 wk decreased yolk linolenic acid concentration. However, the 6/85MG inoculation at 10 wk alone increased yolk oleic acid concentration. In conclusion, a pre-lay inoculation of 6/85MG may increase yolk oleic acid concentration, whereas, FMG inoculations overlaid on a pre-lay 6/85 MG inoculation may further decrease yolk linolenic acid and increase yolk moisture palmitic acid concentrations.

Key Words: Albumen, Egg, *Mycoplasma gallisepticum* , Shell, Yolk

M11 Effects of supplemental dietary phytase and 25-hydroxycholecalciferol on the blood characteristics of cCommercial layers inoculated before or at the onset of lay with the F-Strain of *Mycoplasma gallisepticum*. E. D. Peebles*[1], S. L. Branton[2], M. R. Burnham[1], S. K. Whitmarsh[1], and P. D. Gerard[1], [1]*Mississippi State University*, *Mississippi State*, [2]*Poultry Research Unit,ARS, USDA*, *Mississippi State, MS*.

In 3 trials, the effects of dietary supplementation with phytase and 25-hydroxycholecalciferol on BW and the blood characteristics of commercial layers that were inoculated pre-lay (12 wk of age) or at the onset of lay (22 wk of age) with F-strain *Mycoplasma gallisepticum* (FMG) were assessed at 34, 50, and 58 wk of age. Experimental layer diets which included either a basal control diet or the same diet supplemented with 0.025 % phytase (600 FTU / kg of diet) and 0.025 % 25-hydroxycholecalciferol (250 ppm) were fed from 20 through 58 wk of age. The supplemented diet decreased blood hematocrit values across bird age, inoculation type (sham versus FMG), and age of inoculation (pre-lay versus onset of lay). Phytase and 25-hydroxycholecalciferol supplemented diets reduced bird BW in sham-inoculated control birds across bird age and age of inoculation. This effect was not observed in FMG-inoculated birds. Across inoculation type and age of inoculation, supplemented diets also reduced serum triglyceride levels in birds that were 34 wk of age. Furthermore, across diet (control versus supplemented) and inoculation type, total plasma protein concentration at 34 wk of age was higher in birds that were inoculated at the onset of lay compared to those inoculated pre-lay. Diet, inoculation type, and inoculation age had no effect on mortality, reproductive organ histopathological lesion scores, or serum cholesterol and calcium concentrations. In conclusion, throughout lay, the supplementation of commercial layer diets with phytase may lower hematocrit, and inoculation with FMG pre-lay or at the onset of lay may ameliorate the depressing effects of dietary phytase and 25-hydroxycholecalciferol supplementation on hen BW.

Key Words: FMG, Inoculation, *Mycoplasma gallisepticum*, Phytase, 25-hydroxycholecalciferol

M12 A comparison of performance of coccidia vaccinated broilers fed RepaXol®, AciXol™, or Bacitracin Methylene Disalicylate. G. Mathis*[1] and N. Scicutella[2], [1]*Southern Poultry Research, Inc.*, *Athens, GA*, [2]*SODA Feed Ingredients*, *Monaco*.

The objective of the study was to determine if RepaXol®, an homogeneus blend of double coated essential oils, AciXol™ a blend of organic and inorganic acids (citric, fumaric, malic and ortho-phosphoric) along with the protected essential oils (as in RepaXol® encapsulated in the same MICROPEARLS®, or Bacitracin Methylene Disalicylate (BMD), an antibiotic, in conjunction with a coccidiosis vaccine improves performance of broiler chickens grown to 42 days of age. The experiment consisted of 32 pens of 45 male broiler chickens. Floor space was 0.77 sq. ft. per bird. All chicks were spray vaccinated

with the label recommended dosage of Coccivac-B (coccidial vaccine) on day of hatch. The treatments were replicated in eight blocks, randomized within blocks of four pens each. The test treatments were nonmedicated (NM), RepaXol® 100 ppm, AciXol™ 500 ppm, or BMD 55 ppm, from Day 0 to 42. To confirm Coccivac-B viability and cycling, on Day 21 oocysts per gram litter were determined for all pens. Expected levels of oocysts were detected confirming viability of vaccine. There was a significant improvement in Day 42 feed conversion with all feed additives. The feed conversion of the NM birds was 1.842, RepaXol® 1.785, AciXol™ 1.792, and BMD 1.762. Average live weight gain showed a significant improvement with both RepaXol® and BMD. The weight gains of the NM birds was 2.123 kg, RepaXol® 2.210 kg, AciXol™ 2.165 kg, and BMD 2.230. The feed conversion and weight gain for RepaXol® and BMD were not significantly different. To evaluate the level of coccidiosis immunity, on Day 28, five representative birds were removed from each pen, given nonmedicated feed, and challenged with a mixture of E. acervulina, E. maxima, and E. tenella. Six days post inoculation, all birds were coccidiosis lesion scored. No interference with development of coccidial immunity was shown with any of the feed additives. RepaXol® 100 ppm, AciXol™ 500 ppm, and Bacitracin Methylene Disalicylate 55 ppm, in conjunction with a coccidiosis vaccine improved performance of broiler chickens.

Key Words: Coccidiosis, RepaXol™, AciXol™, BMD, Coccivac B

M13 Selenium sources influence small intestinal characteristics and morphology in reovirus infected broiler chickens. S. Burgos*[1], F. W. Edens[1], J. Read-Snyder[1], A. Cantor[2], and S. A. Burgos[3], [1]*North Carolina State University*, *Raleigh*, [2]*University of Kentucky*, *Lexington*, [3]*University of Guelph*, *Guelph, ON, Canada*.

Avian reovirus (ARV) infections have been associated with malabsorption syndrome causing lower weight gains in broiler chickens. The aim of this investigation was to determine if ARV infection with and without selenium -organic and inorganic- affected small intestinal characteristics and morphology. Eggs were obtained from Cobb breeders that had been maintained on isocaloric Torula yeast diets containing either no supplemental selenium, sodium selenite at 0.3 ppm, or organic selenium (SelPlex, Alltech, Inc., Nicholasville, KY, USA) at 0.3 ppm. Chicks hatched from those eggs were placed on Torula yeast broiler diets containing no supplemental selenium, 0.3 ppm sodium selenite, or 0.3 ppm organic selenium similar to their respective parents' diets. On the day of hatch, 60 chicks per dietary selenium treatment were placed into either control or ARV-infected groups in heated metal-growing batteries in separate isolation rooms. Chicks in the ARV-infected groups were given each an oral gavage of 0.2 mcL of ARV-CU98 ($10^{4.2}$ pfu/chick), and control chicks were given the medium only. At 23 d of age, the chicks were weighed, killed by carbon dioxide asphyxiation, and their intestinal tracts were dissected for total and segmental weight and length, with tissue collections for histomorphotography. Data from this 2 X 3 factorially arranged completely randomized experimental design were analyzed using the GLM procedure of SAS. The ARV-CU98 challenge caused more than 15% reduction ($p< 0.0003$) in body weight and caused 18.4% mortality compared with 6% in controls. ARV-CU98 infection did not affect intestinal length, but infected chicks had more distended and heavier intestines than did controls. Selenium reduced the average intestinal weight in both control and infected birds ($P<0.05$). Microscopic analysis revealed longer microvilli in selenium-fed control and infected birds, and goblet cell numbers were increased in selenium-fed birds. It was concluded that selenium is necessary to maintain the integrity of the small intestine of both control and ARV-CU98 infected chickens.

Key Words: Reovirus, Selenium, Broilers, Small intestine, Morphology

M14 Specificity of antibody to detection of reticuloendoteliosis virus in imunohistochemistry and in situ hybridization assay. V. Santos*, S. Williams, C. Brown, and J. Zhang, *University of Georgia*, *Athens*.

To assist the differential diagnosis of virus induced tumors in poultry, reticuloendotelisis virus (REV), Marekâ€™ disease virus (MDV) and avian leukosis virus (ALV), immunohistochemistry and an in situ hybridization assays for REV were developed. A collection of blocks that represent natural and induced cases of REV as well MDV and ALV were tested for specificity and sensitivity of the REV antibody and probe. The REV positive and negative controls were obtained by paraffin-embedded cells extracted from cell culture.

Key Words: Reticuloendoteliosis, Immunohistochemistry, In situ hybridization, Paraffin-embedded tissues, Natural and induced cases

M15 Comparative study on quality of eggs from laying hens fed cocoa podhusk-based and farmers layer's mashes. R. A. Hamzat*[1], E. O. Uwagboe[1], M. A. Olumide[2], and M. T. Adeoti[3], [1]*Cocoa Research Institute of Nigeria*, *Ibadan, Oyo State, Nigeria*, [2]*Cocoa Research Institute of Nigeria*, *Ibadan, Oyo State, Nigeria*, [3]*Kolmart Farms*, *Ibadan , Oyo State, Nigeria*, [4]*Quadbis Farms*, *Ibadan, Oyo State, Nigeria*.

Cocoa podhusk (CPH) is a waste, constituting serious disposal problems on all cocoa farms in Nigeria. The use of CPH in feeding poultry, may alleviate the problem of high cost of feed ingredients which has occasioned the reduction in the rate of expansion of the poultry industry in Nigeria, as revealed by previous station trials. Hence, this study focused on the comparison of the effect of CPH based and farmers layers' mashes on the egg quality of laying hens.

A total of four hundred and ninety five, 3-month-in-lay birds were used for this on-farm trial. The birds were randomly distributed into 5 treatments replicated thrice with each treatment containing 99 layers, in a completely randomized design. These treatments were: 000 (Eggs from Control diet), 00A (Eggs from Farmer's feed 1), 00B (Eggs from Farmer's feed 2), 00C (Eggs from Farmer's feed 3), 00D (Eggs from Farmer's feed 4), 00E (Eggs from Farmer's feed 5). Each feed was fed adlibitum to the laying chickens. This trial lasted eight weeks. The

parameters measured included: egg weight, EW; egg length, EL; shell thickness, ST; shell weight, SW; yolk height, YH; yolk width, YW; albumin weight, AW; yolk colour score, YCS; yolk index, YI; and shell surface area, SSA. Eggs on layers mash OOB, was not significantly different (p<.O5) from OOA in all parameters studied, whereas significant differences (p<.05) occurred in other treatments as compared to the control. The overall ranking of the assessed feeds as revealed by the egg quality parameters studied was: OOA>OOB>OOD>OOF>OOE>OOC. The results revealed that feeding cocoa podhusk-based layer's mash considerably improved egg quality of laying hens.

Key Words: Comparison, Cocoa feed, Farmers' feeds, Egg quality, Laying hens

M16 Hemolytic and antimicrobial activity of guar meal extracts. S. M. Hassan*[1], O. Gutierrez[1], A. Haq[1], J. A. Byrd[2], C. A. Bailey[1], and A. L. Cartwright[1], [1]*Texas A&M University*, *College Station*, [2]*USDA-ARS Food and Feed Safety Research Unit*, *College Station, TX*.

Saponins extracted from guar meal were evaluated for hemolytic and antimicrobial activities. Saponin rich extracts were prepared by refluxing approximately 25 g guar meal with 250 mL ethanol:H_2O (1:1) for 3 hr, filtering and distilling the ethanol using roto-evaporation at 50 C. Resulting aqueous fractions were partitioned three times with equal volumes of n-butanol to yield saponin rich fractions of 4.8±0.6% of the original material. Ethanol extracted n-butanol fractions were further purified by reversed phase flash column chromatography on a C-18 preparatory column eluting 2 fractions with 20, and 1 each with 60, and 100% methanol (MeOH). Fractions were collected, roto-evaporated and freeze-dried with yields averaging 1.72±0.47, 0.88±0.16, 0.91±0.16 and 1.55±0.15 % of the original material, respectively. Freeze dried fractions were dissolved in PBS and filtered using 0.2 micrometer filters before use in two 96-well plate assays for hemolytic and antimicrobial activities. The hemolytic assay measured blood cell lysis of serial dilutions of the extracts (66.66 to 0.52 µgram/mL) using negative and 100% lysis control wells. Antimicrobial activity was measured as minimum inhibitory concentration (MIC) using serial dilution of the extracts (1 mg to 7.8 µgram extract/mL) in 96-well plates with negative and ampicillin or novobicin positive controls. A gram positive bacterium (Staphylococcus aureus) and two gram negative bacteria (*E. coli* and *Salmonella* Typhimurium) were surveyed. Hemolytic activity was observed in 100 % MeOH guar fractions (P<0.05) but not in 20 or 60% fractions. Antimicrobial activity was detected upon exposure of 100% MeOH fractions to Staphylococcus aureus but not to E. coli and *Salmonella* Typhimurium. Positive correlation of hemolytic and antimicrobial activity was only observed with 100% MeOH extracts and Staphylococcus aureus.

Key Words: Saponin, Guar meal, Hemolysis, Antimicrobial

M17 Evaluation of pearl millet in combination with different levels of flaxseed and natural pigment in laying hen diets. K. Amini* and C. Ruiz-Feria, *McGill University*, *Ste-Anne-de-Bellevue,QC, Canada*.

Two experiments were carried out to evaluate the effects of Canadian Pearl Millet (PM) in combination with different levels of flaxseed (FS) and natural pigment (Oro glo 15) on egg fatty acid(FA) profile and laying performance. In a six week experiment, six treatments were used (8 cage replicates, 3 birds per cage): a control diet (corn-soybean meal based diet) and diets in which corn was totally replaced by PM and supplemented with 0, 2, 4, 8 and 12% FS. In a 12 wk experiment, six diet treatments were used (6 cage replicates, 3 birds per cage) with diets based on PM with three inclusion levels of FS (4%, 6% and 8%) and two levels of natural pigment (0.1% and 0.2%). The diets were formulated to be isocaloric and isonitrogenous and to meet NRC requirements. Three eggs were randomly collected from each cage by the end of each week. Body weight, feed consumption, and egg production were recorded weekly. Yolk pigmentation was determined using the Roche® color fan. At the end of the experiments, all the hens were euthanized to determine liver integrity. Data were analyzed by one-way analyses of variance using the general linear models procedure of SAS. Egg characteristics and flock performance parameters were not different among treatments in both experiments. Yolk pigmentation score was lower for the diets containing PM compared with the control diet, but 0.1% inclusion of pigment was enough to restore pigmentation. No difference was observed among diets in regard to liver hemorrhage. We found that hens fed a diet based on pearl millet and 8% FS produced eggs with an average n-3 FA content of 447 mg , which was higher than n-3 FA content of eggs from hens consuming the control diet, or the PM based diets with lower FS supplementation. Diets based on PM and 8% FS can be used to produce n-3 FA enriched eggs, while maintaining flock productivity and health.

Key Words: Laying hens, Pearl millet, Flaxseed, Natural pigment, Flock performance

M18 Evaluation of Louisiana-produced extruded-expelled soybean meal for chickens. S. Powell[1], V. Naranjo[1], D. Lauzon*[1], L. Southern[1], T. Bidner[1], and C. Parsons[2], [1]*Louisiana State University Agricultural Center*, *Baton Rouge*, [2]*University of Illinois*, *Urbana*.

Soybean meal (SBM) can be produced either by solvent extraction or expeller-extrusion. Expeller-extruded SBM (EE-SBM) contains more oil but less CP than solvent extracted SBM (SE-SBM). The purpose of this research project was to evaluate the energy and protein content of EE-SBM compared with SE-SBM. True digestibility of the amino acids in EE-SBM was determined using the precision-fed cecectomized rooster assay (values are combined samples from 4 roosters). Digestibility values for the amino acids are as follows: Lys 86.8%, Met 87.4%, Cys 81.5%, Arg 92.2%, Thr 83.5%, Val 85.5%, Ile 86.5%, Leu 86.7%, His 86.4%, and Phe 88.9%. A growth experiment was conducted to evaluate the energy and protein content of the SBM. Ross x Ross 708 broilers (0 to 18 d of age) were used in 3 identical trials. Chicks were housed in starter batteries. Each trial had 8 replicates with 6 chicks per pen for a total of 24 replicates per treatment. Dietary treatments were: Diets 1 and 2) Corn-SE-SBM or corn-EE-SBM at 1% total dietary Lys and an ME of 3,300; Diets 3 and 4) Corn-SE-SBM or corn-EE-SBM at 1.3 % total dietary Lys and a ME of 3,000 kcal/kg; and Diets 5 and 6) Corn-SE-SBM or corn-EE-SBM at 1.3% Lys and a ME of 3,300 kcal/kg. The data will be presented and analyzed as 2 2x2 factorially arranged sets of treatments (one analysis will evaluate SBM source by Lys level and the second will evaluate SBM source by ME level). In the Lys component, daily gain (ADG), daily feed intake (ADFI), and gain:feed (GF) were decreased ($P < 0.04$) by the reduced Lys level but not affected ($P > 0.10$) by SBM source or the source by Lys level interaction. In the ME component, ADG and GF were

decreased and ADFI increased ($P < 0.01$) by the reduced ME level. Also, ADG and ADFI were decreased ($P < 0.06$) by EE-SBM, but there was no interaction ($P > 0.10$). The results of these experiments indicate that EE-SBM has similar feeding value to SE-SBM when the differences in nutrient values are considered in diet formulation.

Key Words: Broiler, Soybean meal, Extruded

M19 Intestinal enzymes gene expression of late term turkey embryos. J. E. de Oliveira*[1], P. R. Ferket[1], C. M. Ashwell[1], and Z. Uni[2], [1]*North Carolina State University*, *Raleigh*, [2]*Hebrew University of Jerusalem*, *Rehovot, Israel*.

The developing poultry embryo must go through an adaptive process of switching from lipid-based metabolism, associated with fat, absorbed by the yolk sac membrane, to a carbohydrate-based metabolism, associated with intestinal digestion and absorption. The intestine must develop sufficiently to receive exogenous substrates by the time of hatching. However, turkey poults have a limited ability to digest feed containing carbohydrates (CHO) and protein at hatch and they are susceptible to malabsorption problems of early survival. The objective was to study enteric development prior to hatch by measuring the sequence of gene expression of intestinal enzymes and nutrient transporters using microarray technology. Twenty-five Nicholas turkey eggs were sampled at 20, 22, 24, 26 and 28 d of incubation (E) to collect duodenum for RNA extraction. Fluorescent dyes were incorporated to cDNA produced from the extracted RNA and hybridized on array printed with 90 different 70 bp oligonucleotides. The intestinal genes studied were maltase/glucoamylase (MG), sucrase/isomaltase (SI), aminopeptidase (AP), peptide transporter 1 (PepT1) and sodium/glucose transporter 1 (GLUT-1). Cluster analysis revealed MG and SI mRNA was first expressed at E24, while PepT1 gene was expressed only at E28. Gene expression of AP was specifically evident at E22 and again at E26. GLUT-1 gene expression decreased from E20 until E26 and then was up regulated at E28. Enzymes and transporters responded to presence of substrate (amnion) until E26, but were independently highly expressed at hatch (E28) as in preparation for feeding.

Key Words: Turkey, Turkey embryo, Intestinal enzymes, Microarrays, Gene expression

M20 Effects of vitamin U on broiler performance and intestinal tract integrity. A. L. Shaw*, K. S. Macklin, and J. P. Blake, *Auburn University*, *Auburn, AL*.

Vitamin U (DL-methionine methylsulfonium chloride) has been found to modulate the immune system and protect the intestinal membrane in humans and swine. It has also improved weight gain and feed efficiency in cattle and hogs. Two trials were conducted to determine the effects of Vitamin U on growth performance, feed efficiency, and gut integrity of broilers. For each trial, day-old commercial broiler chicks were randomly allotted to one of 6 dietary treatments with 8 replicate pens each. Both trials employed a corn-soy starter diet from 0-28 d (21.5% CP, 3142 kcal/kg) and a grower diet from 28-42 d (19.5% CP, 3153 kcal/kg).

In Trial 1, 480 chicks (10 birds/pen) were fed the basal diet with 0, 200, 400, 600, 800, or 1000 ppm of Vitamin U. Birds were challenged with 1 ml of *Salmonella* Kentucky (10^6 cfu/ml) via oral gavage on day of placement and then re-dosed on day 14. Cecal samples of 4 birds/trt were collected and enriched weekly from days 7 to 28 to determine presence of *Salmonella*. Bird and feed weights were obtained on days 0, 7, 14, 21, 28, and 42. There was no effect on growth or feed efficiency due to Vitamin U addition. Significant differences ($p<0.05$) were present among the treatment levels for villi length, villi width, and crypt depth of the duodenum, jejunum, and ileum obtained on day 21.

In Trial 2, 384 chicks (8 birds/pen) were fed the basal diet with Vitamin U substituted for DL-methionine on a molecular weight equivalent at a rate of 0, 20, 40, 60, 80, or 100%. Feed and bird weights were obtained bi-weekly through 42 days of age. Vitamin U caused a slight decrease ($p<0.05$) in body weight gain between 0 and 14 days, with no differences detected in performance thereafter.

Vitamin U was not effective in improving growth or feed performance when fed to broilers challenged with *Salmonella*, nor did it provide advantages in performance as a substitute for DL-methionine. It did have an effect on duodenal villi characteristics, which may suggest an ability to aid in intestinal integrity improvement.

Key Words: Vitamin U, DL-methionine, *Salmonella* Kentucky, Broilers

M21 Response of broiler chickens to supplementation of xylanase or phytase in wheat-based diet. O. A. Olukosi* and O. Adeola, *Purdue University*, *West Lafayette, IN*.

Three-hundred broiler chicks were used for a 21-d study of growth response, bone ash, digestibility and carcass energy retention as influenced by supplementation of phytase or xylanase alone or in combination. Carcass retained energy was determined by comparative-slaughter. At day old, 20 broiler chicks were asphyxiated and frozen for determination of initial body energy content of the chicks. Two-hundred eighty chicks were assigned at 1-d old to 5 dietary treatments in a randomized complete block design. The treatments were: positive control (PC), negative control (NC) diet marginally deficient in ME and P, NC + phytase added at 1,000 FTU/kg, NC + xylanase added at 4,000 U/kg, and NC + phytase and xylanase added at the rates indicated above. Each treatment had 8 replicate cages of 7 birds each. Growth performance and feed intake data were collected weekly. On d 21, 1 bird with body weight closest to the average for the replicate cage was used for final body energy content determination. Excreta were collected at d 18 to 21 for determination of ME and total tract retention. Tibia was defatted and ashed for determination of bone ash. Phytase alone ($P < 0.01$) or in combination with xylanase ($P < 0.05$) improved final body weight of the broiler chicks whereas xylanase alone did. The treatments had no effect on either feed intake or gain:feed. Bone ash was not different between PC and NC; phytase alone or in combination with xylanase improved ($P < 0.01$) bone ash. Xylanase alone improved ileal digestible energy ($P < 0.01$). Combination of phytase and xylanase improved total tract DM retention ($P < 0.01$). Phytase alone or in combination with xylanase improved ($P < 0.01$) ME. Supplementation with phytase alone improved P retention ($P < 0.05$). Body retained energy was improved ($P < 0.01$) in the presence of phytase alone. In conclusion, supplementation of wheat-based diet with combination of phytase and xylanase improved growth performance of broiler chickens up to 21 d, however phytase by itself improved most of the response criteria whereas xylanase when used alone did not.

Key Words: Broilers, Performance, Phytase, Xylanase, Wheat

M22 Effect of dietary organic acids on phytate phosphorus disappearance. A. Liem*, H. M. Edwards, Jr., and G. M. Pesti, *University of Georgia*, *Athens*.

Supplementation of some organic acids to a phosphorus deficient diet has been shown to improve bone ash content in broilers. Two experiments were conducted from 0 to 16 d in battery pens to determine the effect of various organic acids supplementation on phytate P utilization, indicated by bone ash data, and phytate P disappearance. In both experiments, birds were fed a P deficient, corn and soybean meal based diet. In Expt. 1, citric acid, malic acid, fumaric acid, and ethylenediaminetetraacetic acid (EDTA) were supplemented at 3.23, 2.90, 2.90, and 3.65 % respectively. In Expt. 2, a 2 x 2 factorial design was utilized. Two sources of methinonine, 2-hydroxy-4methylthio butanoic acid (HMB), an organic acid, and DL-methionine (DLM) were added at 0.20% to the diets, with or without 500 U of phytase / kg diet. In Expt. 1, the addition of citric, malic and fumaric acid increased percent bone ash, but only the effect of citric acid was significant ($p<0.05$). The addition of citric acid and malic acid also increased the disappearance of P and phytate P ($p<0.05$). In Expt. 2, the addition of phytase to the diet significantly increased 16 d body weight gain, feed intake, percent bone ash, mg bone ash, phytate P disappearance, and decreased the incidence of P rickets. Methionine source did not affect 16d body weight gain, feed intake, feed efficiency, mg bone ash, and P rickets incidence. However, the birds fed HMB had higher percent bone ash and phytate P disappearance compared to birds fed DLM. The percent bone ash for the following treatments: DLM, HMB, DLM + phytase, and HMB + phytase were 28.5, 29.0, 31.2, and 33.2 %, respectively. The phytate P disappearance for the treatments above are 36.7, 39.5, 51.0, and 59.9%, respectively. With added phytase, HMB-fed chicks had higher percent bone ash and phytate P disappearance ($p= .005$ and $p= .026$ respectively), but not without added phytase ($p=.390$ and $p= .463$, respectively). In conclusion, some organic acids in our experiment, citric acid, malic acid and HMB, improved phytate P utilization, indicated by bone ash and phytate P disappearance data. HMB and phytase improves phytate P utilization by broiler chicks.

Key Words: Phytate, Phosphorus, Methionine, Broiler, Organic acid

M23 Effect of incremental levels of L-Lysine•HCl in low crude protein corn-soybean meal diets on growth performance of broiler chicks. A. Waguespack*, S. Powell, T. Bidner, and L. Southern, *Louisiana State University Agricultural Center*, *Baton Rouge*.

Three experiments (Exp.) were conducted to determine the level of L-Lys that can be included in corn-soybean meal (C-SBM) diets for broilers without an amino acid (AA) other than Met, Lys, Thr, or Gly becoming limiting. Ross x Ross 708 broilers (0 to 18 d of age) were used in brooder batteries. Treatments contained 7 or 8 replicates with 6 birds per pen. In all Exp., a control C-SBM diet containing no L-Lys•HCl was used. Also, a similar diet (PC+Gly) with supplemental Gly was fed to provide a total dietary Gly + Ser level of 2.32%, a level which previously has been shown to maximize growth performance of broilers fed AA-supplemented low CP diets. All diets were formulated to contain 1.26% total Lys and to maintain a ratio of TSAA:Lys of 0.72 and Thr:Lys of 0.70. Diets with added L-Lys•HCl contained supplemental Gly to provide a total dietary level of Gly + Ser of 2.32%. Also, when Lys was added, the dietary CP content was decreased by changing the ratio of corn to soybean meal. In Exp. 1, L-Lys•HCl was added to the diets at 0.02% increments from 0.15 to 0.27%. Compared with the PC+Gly diet, gain (ADG), feed intake (ADFI), and gain:feed (GF) were not affected ($P > 0.10$) by Lys addition to the diet. In Exp. 2, L-Lys•HCl was added to the diets at 0.05% increments from 0.25 to 0.60%. Compared with the PC+Gly diet, ADG and GF were decreased ($P < 0.03$) in diets containing greater than 0.30% L-Lys•HCl, but not ($P > 0.05$) in the diet containing 0.25% L-Lys•HCl. In Exp. 3, L-Lys•HCl was added to the diets at 0.05% increments from 0.20 to 0.30%. Daily gain was decreased ($P < 0.02$) in broilers fed 0.30% L-Lys•HCl but not in those fed 0.20 or 0.25% L-Lys•HCl. Feed intake and GF were not affected by L-Lys•HCl. The results of these Exp. indicate that 0.25% L-Lys•HCl (which results in a dietary CP level of 19.7%) can be added to C-SBM diets supplemented with Met, Thr, and Gly with no negative effects on growth performance, and that at 0.30% added L-Lys•HCl an AA other than these 4 becomes limiting.

Key Words: Broiler, Amino acid, Growth, Low crude protein

M24 Determination of the limiting amino acid other than methionine, threonine, lysine, and glycine in low crude protein corn-soybean meal diets for broiler chicks. A. Waguespack*, S. Powell, T. Bidner, and L. Southern, *Louisiana State University Agricultural Center*, *Baton Rouge*.

Two experiments (Exp.) were conducted to determine the order of limiting amino acids (AA) in low CP corn-soybean meal (C-SBM) diets for Ross x Ross 708 broilers (0 to 18 d of age) in brooder batteries. Treatments contained 7 or 8 replicates with 6 birds per pen. In both Exp., a control C-SBM diet (PC) and a similar diet (PC+Gly) with added Gly to provide a total dietary Gly + Ser level of 2.32% was fed. All diets in both Exp. were formulated to contain 1.26% total Lys and to maintain a ratio of TSAA:Lys of 0.72 and Thr:Lys of 0.70. In Exp. 1, the order of limiting AA was determined in a C-SBM diet containing 0.45% L-Lys•HCl and 17.8% CP. In addition to the PC and PC+Gly treatments, the treatments consisted of a negative control (NC), NC + 0.247% Ile, NC + 0.484% Arg•HCl, NC + 0.249% Val, and all possible two and three-way combinations of all 3 AA. Diets with added AA and the NC diet contained supplemental Gly to provide a total dietary level of Gly + Ser of 2.32%. Compared to the NC diet, addition of L-Arg•HCl and the combination of L-Arg•HCl and the other AA increased daily gain (ADG) and feed intake (ADFI) but not gain:feed (GF), indicating that Arg was the limiting AA in this diet. It is possible that the order of limiting AA (other than Thr, Lys, Met, and Gly) changes in a diet with different levels of supplemental Lys because of the change in ratio of corn to soybean meal. Therefore, Exp. 2 was conducted in an identical manner to Exp. 1 except the diets with the added AA contained the same ratio of corn to SBM that is found in a diet with 0.25% L-Lys•HCl, which was achieved by dilution with cornstarch. The results of Exp. 2 suggest that Arg and Val are equaling limiting in a diet with 0.25% L-Lys•HCl. In the diet with all 3 AA, ADG and ADFI were different ($P < 0.10$) from the PC and PC+Gly diet but GF was not different ($P > 0.10$). These results suggest that Arg and Val are equaling limiting (after Met, Thr, Lys, and Gly) in a diet containing 0.25% L-Lys•HCl.

Key Words: Broiler, Glycine, Low crude protein

M25 Dietary methionine sources affect intestinal microbial growth in broiler chickens. J. P. Dahiya*[1], D. Hoehler[2], A. G. Van Kessel[1], and M. D. Drew[1], [1]*University of Saskatchewan*, *Saskatoon SK, Canada*, [2]*Degussa Corporation*, *Kennesaw, GA*.

Previous work in our laboratory showed that methionine hydroxy-analogue (MHA-FA) is more available to gut bacteria than DL-methionine (DL-Met) and may stimulate the growth of intestinal bacterial populations including *C. perfringens*. An experiment was conducted to study the effect of various levels of DL-Met or MHA-FA on *C. perfringens* and other intestinal bacteria in broiler chickens. Two cages of 6 birds (14 d post-hatch) were assigned to one of 7 different diets containing no added Met (control); 2.0, 4.0 or 8.0 g/kg DL-Met or 2.27, 4.54 and 9.08 g/kg MHA-FA, thus providing 3 equimolar levels (0.2, 0.4 and 0.8%) of each methionine source. Birds were challenged with *C. perfringens* type A on d 1 and d 14 to 20, and killed on d 28. Intestinal populations of *C. perfringens*, lactobacilli, *Streptococcus* D and coli forms were enumerated and necrotic enteritis lesions were scored. There were no significant differences in the growth of various bacterial species in intestinal tract of broiler chickens fed two different methionine sources. However, we observed significantly reduced ($P < 0.05$) *C. perfringens* populations in ileum and cecum of birds fed 8 g/kg DL-Met and 9.08 g/kg MHA-FA supplemented diets vs. control. Also there was a significant interaction ($P < 0.05$) between methionine source and level for *C. perfringens* growth. The coli forms and *Streptococcus* D in ileum were significantly lower ($P < 0.05$) whereas lactobacilli in ceca were significantly higher in birds given highest levels of either DL-Met or MHA-FA than the other dietary treatments. There were no significant differences in necrotic enteritis intestinal lesion scores and performance of birds fed different methionine sources or concentrations. The results suggest that the use of low protein diets supplemented with relatively high levels of synthetic amino acids may reduce the risk of clostridial enteritis in broiler chickens.

Key Words: Methionine sources, Necrotic enteritis, Broiler chickens

M26 Standardized ileal amino acid digestibility of plant source ingredients in broiler chicks and turkey poults using a nitrogen-free or casein diet. S. A. Adedokun*[1], C. M. Parsons[2], M. S. Lilburn[3], O. Adeola[1], and T. J. Applegate[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*University of Illinois*, *Urbana/Champaign*, [3]*The Ohio State University/OARDC*, *Wooster*.

The aim of this study was to determine the apparent and standardized ileal amino acid digestibility (SIAAD), total amino acid (TAA), and N digestibility of 5 feed ingredients in 5- and 21-d old broiler chicks and turkey poults. Two methods of endogenous standardization were used, a nitrogen-free diet (NFD) and a completely digestible protein (CDP, 10% casein). The feed ingredients were two samples of corn distillers′ dried grains with solubles (light, L and dark, D DDGS), canola meal, corn, and soybean meal. These ingredients were the sole source of amino acids in the diets (20% CP). Each diet was fed to six replicates pens containing 30 and 8 birds which were sampled on d 5 and d 21, respectively. Age had a significant effect on apparent ileal amino acid and N digestibility in broilers. Both standardization methods in chicks resulted in higher values relative to the apparent digestibility values. Standardization using CDP in chicks resulted in higher ($P < 0.05$) standardized ileal digestibility for TAA, N, and some of the amino acids on d 21 for L DDGS, canola meal, corn, and SBM relative to the NFD method. The effect of poult age on ileal amino acid digestibility was significant for L DDGS, corn, and SBM. In poults, both standardization methods resulted in higher SIAAD compared to apparent digestibility, however, there was no significant difference in SIAAD values between the two methods at any particular age except for corn where SIAAD on d 21 was higher ($P < 0.05$) using a NFD method. Both the apparent and SIAAD values were higher for the L DDGS than the D DDGS in both species. The SIAAD for canola meal, corn, and SBM were higher than for DDGS in both species on d 5. These results show that correcting for ileal endogenous amino acid resulted in higher digestibility values and both methods of standardization produced similar results in poults at d 5 and d 21 whereas SIAAD in broiler chicks was higher on d 21 (3.8% TAA) using a CDP method.

Key Words: Casein, Chick, Ileal endogenous amino acid, Poult, Standardized ileal amino acid digestibility

M27 Utilization of low protein diets by large high yield Ross-708 broilers. J. Small*[1], E. O. Oviedo-Rondón[1], P. Tillman[3], D. Hoëhler[4], J. Grimes[1], C. M. Ashwell[1], and S. Shah[2], [1]*North Carolina State University*, *Raleigh*, [2]*North Carolina State University*, *Raleigh*, [3]*Ajinomoto Heartland Lysine*, *Chicago, IL*, [4]*Degussa Corporation*, *Kennesaw, GA*.

The US broiler industry currently has a tendency to grow large, high yield broilers. Commercial broiler diets are formulated to guarantee that these flocks receive all amino acids (AA) needed for high meat yield. Historically, relatively high protein diets (HP) have been used. In contrast, environmental regulations for nitrogen and ammonia are becoming more stringent. Low protein diets (LP) with AA supplementation are the logical alternative to reduce N waste. This project aimed to evaluate the effects of LP on high yield Ross-708 broilers raised to 56 d on live performance, carcass traits, flock uniformity, body chemical composition and blood metabolites. 240 day-old chicks of each sex were individually tagged and placed in 16 floor pens of 30 birds. Diets were formulated to contain equal amounts of digestible AA by adding crystalline Lys, Met, and Thr. Crude protein levels were 21 or 24% for starter (1-14 d), 20 or 23% for grower (15-34 d), 18 or 21% for finisher (35-56d) for LP and HP diets, respectively. Blood was drawn at 35 d from one male chicken per pen. Three birds of each gender from each pen (24/trt/sex) were processed at 56 d to determine carcass and parts yield. A 2X2 factorial design was used for data analyses. Final average body weights for males were 4292 and 4340 g, and females were 3366 and 3379 g when fed LP and HP diets, respectively. Gender differences were apparent for all variables evaluated. No significant differences ($P>0.05$) due to diets were observed for body weight, feed intake, or feed conversion in any feeding period or for the entire grow out. Flock uniformity as coefficient of variance was 6.7 and 7.1% for males, and 8.3 and 5.7% for females fed LP and HP diets, respectively. No significant differences ($P>0.05$) were observed for dressing, individual parts, abdominal fat or organ percentages. Body chemical composition was affected ($P<0.01$) by diet treatment in males only. Blood level of Val, Leu, Ile, and HyPro were lower in male chickens fed LP. In conclusion, LP diets supplemented with crystalline AA did not affect performance or meat yield of large broilers while N efficiency was increased.

Key Words: Large broilers, Low protein diets, Amino acids, Meat yield, Body composition

M28 Reducing dietary crude protein while maintaining performance and improving economics in Ross 708 broilers. E. A. Guaiume*[1], J. D. Firman[1], D. Hoehler[2], P. B. Tillman[3], D.

Burnham[4], J. Parcell[1], L. B. Linares[1], and P. Butkeraitis[1], [1]*University of Missouri*, *Columbia*, [2]*Degussa Corporation*, *Kennesaw, GA*, [3]*Ajinomoto Heartland LLC*, *Chicago, IL*, [4]*Aviagen Inc.*, *Huntsville, AL*.

A study was conducted to determine the effects of reduced dietary crude protein (CP) on performance and economics of Ross708 broilers from hatch to week 8. 1440 straight-run broiler chicks were randomly assigned to 4 treatments with 12 replicate pens containing 30 birds each. Diets were formulated to be isocaloric and to have the minimum digestible level for lysine , and the same minimum ideal amino acid ratios to lysine for Met+Cys, threonine, valine, isoleucine, arginine, and tryptophan across the four phases [starter (0-2wks), grower (2-4wks), finisher (4-6½wks), and withdraw (6½-8wks)]. An industry standard diet served as the control (A) and the benchmark for performance. The remainder of the treatments (A-0.5%, A-1.0%, and A-1.5%) had CP reduced in 0.5% increments. Birds were weighed at 2, 4, 6½, and 8 weeks of age for feed to gain calculation. At week 8, 4 birds per pen (48/trt) were sacrificed and had fat pad and carcass weighed, and carcass and meat yield determined. Feed cost savings (FCS) per metric ton (MT) of live body weight (BW), FCS/MT carcass, FCS/MT breast meat, income over feed cost/MT carcass, and income over feed cost/MT breast meat, were calculated. Treatments had no effect (P>.05) on performance throughout the 8-week period. At week 8, birds fed A-1.5% had a higher (P<.05) percentage of fat pad when compared to A (3.11% versus 2.77%, respectively for A-1.5% and A). The remainder of the treatments did not differ from the control. In addition, treatments had no effect (P>.05) on carcass and breast meat yield at 8 weeks of age (A: 33.82%; A-0.5%: 33.37%; A-1.0%: 33.13%; A-1.5%: 33.08%). For BW, relative to A, FCS were $3.90/MT when A-1.5% was fed; for carcass, $5.46/MT; and for breast meat, $16.37. Therefore, birds fed A-1.5% CP resulted in an increased income over feed costs of $5.46/MT carcass and $16.37/MT breast when compared to A. Overall, these results suggest that a decrease of CP by 1.5%, as compared with industry standards, did not affect performance, carcass, and meat yield, and resulted in significantly higher revenues.

Key Words: Low crude protein, Broilers, Performance, Meat yield, Economics

M29 Nutritional value of yeast extract Nupro® in male broiler chicks and turkey poults. R. L. Nanney*[1], P. R. Ferket[1], A. A. Santos Jr.[1], E. O. Oviedo[1], J. L. Grimes[1], and C. Parsons[2], [1]*North Carolina State University*, *Raleigh*, [2]*University of Illinois*, *Champaign*.

Yeast extract is a potentially valuable nutrient source of amino acids, peptides, nucleotides, vitamins, minerals and inositol for neonatal poultry, but feeding value must be estimated to facilitate least-cost feed formulation. Our objective was to determine metabolizable energy (ME) and true amino acid digestibility (TAAD) of the yeast extract Nupro® (NP, Alltech, KY). In experiment 1, true Me (TME) and TAAD of NP were determined in cecectomized roosters by precision feeding method. In experiments 2 and 3, 6 replicate groups of 15 male chicks and poults were fed diets containing 0, 5, 10 and 15% NP at the expense of a corn-soy diet that met NRC recommendations for 1-21d. Body weight (BW) and feed/gain (FCR) was determined at 7, 14, 21d and AMEn was determined from fecal collections from 12-14 and 19-21d. Average TAAD and TME of NP were determined to be 86.79% and 3,611 kcal/kg DM, respectively, which agree with the AME values determined for both trials. The chicks fed the 5 and 15% NP in the diet had heavier BW than those fed 0 and 10% NP throughout the trial (21d BW: 938, 932 vs 900, 891g, respectively, P<.05). Likewise, 1-21d FCR of chicks fed 5 and 15% NP was better than those fed 0 and 10% NP (1.264 and 1.262 vs 1.306 and 1.326, respectively, P<.05). Poults fed 10 and 15% NP had significantly greater 21d BW than those fed 0 and 5% NP (634 and 609 vs 498 and 567g, respectively, P<.05). However, 1-21d FCR was better for poults fed 0 and 5% NP than those fed 10 and 15% NP (1.160 and 1.199 vs 1.257 and 1.255, respectively, P<.05). Mortality rate was not significantly affected by dietary treatment in either experiment. The effect of dietary NP supplementation on the performance appears to be dependent upon the dose and species. Nupro® can be fed as high as 15% of the diet without adverse effects on feed intake and BW; however the benefit of NP may differ in chicks and poults.

Key Words: Nucleotide, Chicks, Poults, Performance, TME

M30 Utilization of cocoa pod husk (CPH) as substitute for maize in layers mash and poultry farmers' perception in Nigeria. E. O. Uwagboe*[1], R. A Hamzat[1], and M. Olumide[2], [1]*Cocoa Research Institute of Nigeria*, *Ibadan, Oyo State, Nigeria*, [2]*Kolmart Farms*, *Ibadan, Oyo State, Nigeria*.

Developing processing technique for efficient use of crop by–products such as cocoa pod husk (CPH) is very important in order to promote poultry feeding in the rural communities in Nigeria. Oluyole and Egbeda Local Government Areas (LGAs) of Oyo state, Nigeria were purposively selected out of the nineteen L.G.As producing cocoa in the state while one hundred and twenty respondents were selected from the list of eight hundred registered poultry farmers with simple random sampling technique. The farmers used the Cocoa Pod Husk (CPH) for a period of eight weeks January through February 2006 after which they were interviewed with interview guide. The data were presented using frequencies, percentages and charts while chi–square was used for the analysis.

The result revealed that 85 percent of the farmers are educated and 95 percent were willing to use CPH in feed production for layers. The result also revealed that there is a significant relationship between constraints of inadequate energy source of ingredients(X^2=6•242, p≤0•05) method of processing (X^2=5•895, p≤0•05), inadequate labour (X^2=9•196, p≤0•05) and perception of poultry farmers towards use of Cocoa pod husk as substitute for maize in layers mash. Five Points Likert Scale result revealed that 85 percent of the respondents had positive perception towards the use of CPH as substitute for maize in layers mash and 75 percent had negative perception towards the processing method of CPH.

In conclusion, poultry farmers are willing to use CPH as a substitute for maize in layers mash if there is an improved method of processing. Hence, there is need for modern processing technique of CPH using hygienic method and at commercial level to enhance increase in the use of waste cocoa by-products and reduction in feed production cost in Nigeria.

Key Words: Cocoa pod husk, Processing, Utilization, Farmers, Perception

M31 Isolation and evaluation of *Salmonella*-lytic bacteriophages from commercial broiler houses. J. P. Higgins*[1], R. L. Andreatti Filho[2], S. E. Higgins[1], G. Gaona[1], S. N. Henderson[1], A. D. Wolfenden[1], G. Tellez[1], W.G. Bottje[1], and B. M. Hargis[1], [1]*University of Arkansas*, *Fayetteville*, [2]*College of Veterinary Medicine and Animal Science (FMVZ) Sao Paulo State University (UNESP)*, *Botucatu, SP, Brazil*.

Bacteriophages (Ø) represent a group of viruses that specifically infect and replicate in bacteria, and could potentially be used to reduce recovery of *Salmonella* (*S*) from poultry. For experiments 1 – 3 environmental drag swab samples were collected from 5 – 6 broiler houses, each located on different farms for isolation of *S* and Ø. In experiment 1, *S* was isolated from 3 of the 6 houses. Six drag swab samples were individually screened against a panel of 9 endemic *S* isolates of 5 serotypes and no Ø was isolated. In experiment 2, *S* was isolated from all 6 houses. Six drag swab samples were individually screened as above and Ø were isolated from 4 out of 6. Interestingly, none of the Ø isolated were able to initially lyse the *S* isolated from that same house. However, once the Ø were amplified in a different *S* host these Ø were then able to lyse the *S* that was isolated from the original source environment. In experiment 3, *S* was isolated from 3 of the 5 houses. Five drag swabs were individually screened against a panel of 12 endemic *S* isolates and Ø were isolated from 2 out of 5 houses. Again, none of the Ø isolated were able to initially infect the *S* isolated from the same environment. However, in experiment 3, none of the Ø were able to infect the *S* from the same house following amplification in an alternate *S* host. Based upon unique Ø host susceptibility profiles and plaque morphologies, at least 9 unique Ø isolates against *S* were identified. In all cases Ø were only isolated from houses positive for *S* with one exception in experiment 3. In summary, *S* Ø isolations were successful almost exclusively from poultry environments where *S* was also isolated. Interestingly, Ø from given environments were not able to lyse *S* recovered from those environments. Based upon these observations, the presence of Ø against S does not immediately explain the absence of S in some poultry environments.

Key Words: *Salmonella*, Bacteriophage, Poultry, Environment, Drag Swab

M32 Effect of broiler litter on growth of campylobacter. Z. T. Williams*[1], K. Christensen[2], M. Putsakum[1], Y. Vizzier-Thaxton[1], and S. W. Anderson[1], [1]*Mississippi State University*, *Mississippi State*, [2]*OK Foods, Inc.*, *Ft. Smith, AR*.

Campylobacter is one of the leading causes of food born illness in the United States with poultry frequently sited as a reservoir of the organism. While there are many possible sources of broiler flock contamination, litter has been implicated numerous times as not only a primary source of infection but as a mode of transmission between consecutive flocks.

This experiment was conducted to determine if the type of litter or specific characteristic of the litter such as pH or moisture content, could influence whether or not Campylobacter was able to colonize the litter and subsequently the birds .

Litter Samples were taken using a zig-zag pattern throughout the broiler house. The pattern insured that samples from under or near feeders and waterers as well as areas approaching the sides and ends of the house were represented. In addition to measuring pH and moisture content, each sample was cultured in Campylobacter enrichment broth and then inoculated onto 10 Campylobacter Cefex plates. After 48-hour incubation plates were examined for the presence of generic Campylobacter. The data indicates that litter condition and type does influence the colonization of Campylobacter.

Key Words: Litter, Campylobacter, Broilers

M33 Effect of organic acids and probiotics on *Salmonella enteritidis* (SE) infection in broiler chicks. A. D. Wolfenden*[1], R. L. Andreatti Filho[2], J. P. Higgins[1], S. E. Higgins[1], G. Goana[1], G. Tellez[1], and B. M. Hargis[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Sao Paulo State University*, *Botucatu, SP. Brazil*.

A commercially-available (IVESCO LLC) water treatment PerforMax Optimizer II (PMO) and probiotic (FM-B11) have independently been reported to have anti-*Salmonella* effects. In exp. 1, 80 day-of-hatch chicks were challenged by oral gavage with 2.8 x 10^4 cfu SE, held in chick boxes for 2 h, and randomly assigned to either untreated control or continuous PMO treatment in the drinking water(dw; 1:128 product dilution for all exps.) in brooder batteries. Crop and cecal tonsils were cultured at 48 h and 5 d post-challenge for recovery of SE after enrichment. SE recovery in the crop and cecal tonsils at 48 h was significantly ($p<0.05$) lower in the PMO treated group as compared to control (crop: 75% vs 100%; cecal tonsil: 55% vs 100%, respectively) but not different at 5 d. In exps.2 and 3, 160 day-of-hatch chicks were SE challenged (2.4 x 10^4 cfu), held in chick boxes for 2 h, and randomly assigned to either untreated control, FM-B11 (1.8 x 10^7 cfu by oral gavage 1 h prior to placement), PMO, or FM-B11+PMO (n=40 per group). After 24 or 48 h in the brooder battery, crop and cecal tonsils were cultured for the presence or absence of SE recovery after enrichment. After 24 h, FM-B11 or FM-B11+PMO significantly ($p<0.05$) reduced SE recovery from the crop as compared to controls (75, 40 and 100%, respectively). All treatments reduced ($p<0.05$) SE recovery from the cecal tonsils at 24 h (control: 60%, FM-B11: 25%, PMO: 45%, FM-B11+PMO: 13%). While no significant differences were observed in SE recovery from crop at 48 h, SE recovery from FM-B11 and FM-B11+PMO groups was significantly lower than the controls in the cecal tonsils (20, 20 and 100%, respectively). In exp. 3, FM-B11 or FM-B11+PMO caused reduced cecal tonsil SE recovery as compared to controls at 24 h (5, 15 and 75%, respectively), and at 48 h (40, 21 and 100%, respectively) and FM-B11+PMO again reduced SE recovery incidence in crops at 48 h as compared to controls (42% vs 100%, respectively). These data suggest that combination treatment with FM-B11 and PMO are more effective than individual treatment for *Salmonella* reduction in chicks.

Key Words: *Salmonella*, Organic acids, Probiotic

M34 The effect of feed additive antimicrobials on antibiotic resistance activity of gram negative microbes indigenous to poultry. D. Cork[1], A. Gupta*[1], and J. Mathers[2], [1]*Illinois Institute of Technology*, *Chicago, IL*, [2]*Alpharma Animal Health*, *Chicago Heights, IL*.

Bacitracin, monesin, salinomycin, lasalocid and bambermycin are important feed additives used in the poultry industry due to their

antimicrobial activities and use as dietary production enhancers. The antimicrobial activity is generally limited to gram-positive, with minimal inhibition of gram-negative microorganisms. Initial studies have suggested resistance or plasmid loss effects in some bacterial classes. Six selected gram-negative poultry strains (3 *E.coli* & 3 *Salmonella typhimurium*) with phenotypic resistance to tetracycline and ampicillin (determined by antibiotic susceptibility testing) were screened for the presence of plasmid-borne tetR and ampR genes. Plasmid DNA profiling on agarose gel electrophoresis indicated sizes ranging from 3 to 50 kilobases in the selected strains. The plasmids were further evaluated for curing or decrease in copy number following *in vitro* exposure to various concentrations of the aforementioned feed additives. The compounds sodium dodecyl sulfate and acridine orange were additionally applied as known curing agents. Effective levels of some of these feed additive antimicrobials were found to affect losses or reductions of plasmids in certain strains. Plasmid band reductions in liquid test cultures were correlated with the percentage of isolates in the test system demonstrating phenotypic sensitivity to tetracycline and ampicillin. Such data may be important inputs in setting prudent standards for the use of feed additive antimicrobials in the poultry industry.

M35 Performance comparison between the use and non-use of an enteric health antibiotic program in commercial broiler flocks. J. Bray*[1,2], T. Cherry[1], J. Carey[2], and C. Smith[1,2], [1]*Stephen F. Austin State University*, *Nacogdoches, TX*, [2]*Texas A&M University*, *College Station*.

In the US, current trends show that enteric health antibiotics are being removed from broiler diets. The use of these antibiotics in broiler production is a contentious issue. An experiment was conducted to compare the differences in performance parameters between broilers that were fed enteric health antibiotics in the diets and broilers that were not fed enteric health antibiotics in the diets. This is the preliminary report from three flocks of a five flock trial. Broilers were reared under commercial settings in solid-side wall, tunnel ventilated broilers houses. The four-house farm was divided into two separate farms with two houses being fed the enteric antibiotic program and the other two were fed a naïve feed. Initially, 27,600 broilers were placed per house and reared for 49 days. All birds were fed commercially produced starter, grower and withdrawal rations. Individual body weights of 100 birds per house were collected at 18, 35, and 49 days of age. Feed conversion and adjusted feed conversion were calculated for each these days. Coccidiosis lesion scores using the Johnson and Reid Method were collected at 14, 21, 28, 35, and 42 days of age. At the conclusion of each flock 140 birds from both treatments were selected and processed in a yield study. The nature of the differences in bird performance between the treatments varied from flock to flock. In general the data indicates a slight improvement in performance and gut health among flocks receiving antibiotics.

Key Words: Broilers, Antibiotics, Performance, Enteric

M36 Effects of water treatment products on broiler performance. J. G. Hughes*, J. M. Cornelison, A. G. Hancock, L. B. Davis, and S. E. Watkins, *University of Arkansas*, *Fayetteville*.

The poultry industry continues to search for ways to improve bird performance with water additives. Two water acidifiers Kem San®, a proprionic acid blend and SYNTRx, a proprietary acid blend and one sanitizer, PronTech™, a cationic salt, were evaluated for their impact on broiler performance. Each product was added to the water according to manufacturer's recommendations and given to 6 pens of 55 birds on a continuous basis. Plain tap water served as the control. Average pH for each treatment was 4.49, 2.73, and 7.65 respectively, with the control pH averaging 7.98. Birds were group weighed by pen at days 14, 28, 42, and individually weighed at day 49. Feed consumption was measured for each period. There were no significant differences in body weights, feed conversion or mortality throughout the trial. Average weights, in grams, for the control, Kem San®, SYNTRx and PronTech™ for days 14 and 49 were 358, 357, 367 and 379 and 3508, 3488, 3493, and 3556. The feed conversion for the control, Kem San®, SYNTRx and PronTech™ for day 14 were 1.219, 1.189, 1.180, and 1.224. Feed conversions for day 49 were 1.684, 1.675, 1.702, and 1.688.

Key Words: Water acidifiers, Water treatments, Broiler performance, pH

M37 Evaluation of different products used for cleaning drinking water systems. A. G. Hancock*, J. G. Hughes, and S. E. Watkins, *University of Arkansas*, *Fayetteville*.

Clean water systems are essential for providing good water quality to poultry. Several products were evaluated for their effectiveness as water sanitizers in water that had an abundance of algae growth. The different products evaluated were: Proxy-Clean™, CID 2000®, Pro-Clean which are all concentrated stabilized hydrogen peroxide products; 35 % hydrogen peroxide, Citric Acid, 6% Sodium hypochlorite or household bleach, and Poultry PronTech™ which is a cationic salt. Each product was added to 2- 50 ml aliquots of water and untreated water served as the control. The Proxy-Clean™ and 35 % hydrogen peroxide were added at a rate of three percent. The CID 2000® was added at a rate of 2 %. The citric acid was prepared in a stock solution of two packets per one gallon of water, and the stock solution then used at a rate of 1:128. The household bleach was added at a rate of one ounce of bleach per gallon of water or 0.78% concentration. Also a stock solution was prepared using twelve ounces of bleach per gallon of water; the stock was then metered at 1:128. The product Pro-Clean was added at the standard medicator rate of one ounce per gallon and also at a rate of three percent. Poultry PronTech™ was added at a rate of one gram per liter or 400 ppm, and also at a rate of one gram per four liters or a rate of 100 ppm. The aerobic bacteria loads along with yeast and mold counts were tested initially and four hours and twenty-four hours after treatment. The ORP and pH for each sample was tested.

Microbial loads prior to treatment were within a six log range. Four hours after treatment the product CID 2000® had the greatest reduction in microbial presence, with the household bleach at .78%, Proxy-Clean™, and Pro-Clean products at the 3% rate had the next lowest levels of microbial presence. The remainder of the products only showed a one log reduction in microbial presence.

Key Words: Water sanitation, Chlorine, Hydrogen peroxide

M38 Effect of ventilation, basket capacity, and machine temperature during the last 5 days of incubation on broiler hatching egg temperature and embryonic development. J. T. Brake, P. W Plumstead, K. E Brannon*, N. Leksrisompong, J. H Small, and E. O. Oviedo, *North Carolina State University*, *Raleigh*.

It was hypothesized that altering hatching basket ventilation and capacity would ameliorate the adverse effects of high egg temperatures on embryonic development and broiler performance. Ross 344 x 708 SF broiler eggs were incubated at an egg temperature of 37.2-37.8°C until E17 when eggs were distributed into four combinations of basket ventilation and basket capacity in either a ″Hot″machine (38.2°C) or a ″Cool″ machine (36.1°C). The normal ventilation treatment (CN) utilized standard hatching baskets. The top-taped (TT) treatment did not permit air to flow through the top of each basket. Low and high basket capacity comprised either 95 or 190 eggs per basket, respectively. There were two replicate baskets per combination per machine. Egg temperatures and basket exit air velocities were measured daily from E17 to hatching. At hatching, BW and relative weights of the yolk, heart, liver, proventriculus, gizzard, and small intestines were determined. In the Cool machine, a significantly larger BW, and yolk and heart weights were observed in the CN-190 interaction, as well as a significantly smaller liver. In the same Cool machine, the TT-190 interaction displayed a significantly reduced BW, and yolk and heart weights in addition to a significantly larger liver. However, in the Hot machine, significant differences between the interactions were apparently obscured by increased egg temperature. Chicks were grown to 21 d and BW, adjusted FCR, and mortality were determined. At 7, 14, and 21 d of age the largest BW was observed in the CN-Hot interaction while the lowest was observed in the TT-Hot interaction with no major differences observed for adjusted FCR. The most notable difference in mortality was for the main effect of capacity, where the 95 treatment gave 0% mortality while the 190 treatment gave 3.13%.

Key Words: Ventilation, Capacity, Machine temperature, Egg temperature, Embryonic development

M39 Embryonic development when eggs are turned different angles during incubation. H. R. Cutchin*, S. L. Funderburk, M. J. Wineland, V. L. Christensen, and K. M. Mann, *North Carolina State University*, *Raleigh*.

Failure to turn eggs during incubation has been demonstrated to cause improper development of extra embryonic components necessary for embryonic growth. These include reduced development of the area vasculosa (AV), chorioallantoic membrane (CAM), an increased amount of residual albumen (RA) and reduced volume of sub embryonic fluid (SEF). The purpose of this trial was to evaluate the effects of different turning angles upon development. Eggs stored for 1 day from 48 week old broiler breeder hens were used in three incubators set at 15°, 30° and 45° turning angles with 720 eggs per treatment. The profiles for each incubator were kept the same. At days 3, 6, 8, 13, 18 and 20 samples were collected and evaluated for various aspects of embryonic growth such as: size of AV, amount of SEF, embryo size (ES), CAM development and amount of RA. Eggs were weighed, volume was determined, and moisture loss was calculated at designated sampling times. Hatch of fertile was significantly different (45°>30°>15°). 15° angle demonstrated significantly reduced 6d SEF volume but not CAM or AV. At hatch the residual yolk sac was removed from 20 chicks per treatment and all dried down at 70°C for determination of moisture content. Hatched chicks from eggs turned 45° weighed significantly more and had less dry matter in the residual yolk. Examination of hatch residue demonstrated significantly greater pipped chicks as well as embryonic dead 4-10d and 17-21d in the group turned 15°. Additionally, these embryos exhibited increased malpositions, hemorrhages and residual albumen. Turning eggs 15° causes multiple embryonic maladies while reduced hatch was noted in eggs turned 15° and 30°.

Key Words: Turning, Incubation, Malposition, Sub embryonic fluid, Chorioallantoic membrane

M40 Influence of a twice a day versus once a day feeding program after photostimulation on the reproductive performance of broiler breeder hens. J. M. Spradley*, M. E. Freeman, J. L. Wilson, and A. J. Davis, *University of Georgia*, *Athens*.

Previously we reported that extending skip-a-day feeding past photostimulation until five percent egg production decreased total egg production by more than 15 eggs per broiler breeder hen through 65 weeks of age. Those results suggested that broiler breeder hens' reproductive performance was very sensitive to periods of food deprivation. Therefore in the current research the effect of feeding hens twice a day versus once a day after photostimulation on egg production was investigated. Pullets were reared using a skip a day feeding program from 2-21 weeks of age. All pullets were weighed at 20 weeks of age and then segregated into 30 laying pens (35 hens and 4 roosters per pen) such that each pen had a similar distribution of body weights. At 21 weeks of age 15 laying pens were placed on once a day feeding while the other 15 pens were placed on twice a day feeding. The total amount of feed provided per day to the laying pens was the same for both treatments, however, the once a day birds received all of their feed at 6:30AM, while the twice a day birds received 60% of their total feed allotment at 6:30 AM and the other 40% at 3:00PM. Although egg production commenced for both treatments at the end of 23 weeks of age, total egg production through 29 weeks of age is significantly greater for the birds provided feed twice a day. Weekly hen-day egg production was significantly greater for the hens fed twice a day for the entire period from 24 – 29 weeks of age. In addition, although the body weight profile for the two treatments was equal at the start of the experiment, the coefficient of variation for body weight was also significantly smaller for the twice a day fed hens at 29 weeks of age. The results provide further support that once pullets are photostimulated it is essential to limit fasting periods with regard to dietary intake for maximum egg production in broiler breeder hens.

Key Words: Broiler breeder hen, Twice a day feeding, Egg production

M41 Broiler breeder feeding program during rearing and early lay affects reproductive and progeny performance. N. Leksrisompong*, P. W Plumstead, H. Romero-Sanchez, K. E. Brannan, and J. Brake, *North Carolina State University*, *Raleigh*.

Twelve replicate pens of 190 females each were randomly assigned to two rearing feeding program treatments (sigmoid or line) from 1

to 21 wk of age and two feed increase treatments (slow or fast) from photostimulation to peak egg production in a 2 x 2 factorial design with three replicate pens each. The flock was photostimulated at 21 wk of age when Ross 344 males and Ross 308SF females were housed and mixed in the production facility. Females from the sigmoid rearing program weighed more at 4, 6, 8, 10, and 12 wk but less at 18, 40, 48, and 56 wk. There were no differences in rate of lay but females that had been reared on the sigmoid feeding program exhibited reduced mortality during the laying period that resulted in an increased number of eggs per hen housed. Fertility was not affected but fertile hatchability was improved by the sigmoid rearing program as well. No differences due to the two different feed increase programs were found other than that the slow program produced a heavier egg weight at 28 wk. Eggs produced by these hens at 28 wk were incubated under standard conditions and the carryover effects on the broiler progeny evaluated. Fifteen male and 15 female broiler chicks were randomly assigned across 72 pens to create a 2 x 2 x 2 design with 9 replicates per interaction cell with sex added as the third main effect. Body weight, feed consumption, adjusted feed conversion ratio, and mortality were measured to 42 d. Male broilers were heavier and exhibited higher mortality than females, as expected. Mortality was significantly affected by the broiler sex by breeder feed increase rate from photostimulation to peak egg production interaction in that male broilers from the slow feed increase program exhibited the highest mortality. This was thought to be due to an increased egg temperature in the larger eggs of the slow feed increase group that adversely affected embryonic development, specifically the heart.

Key Words: Broiler breeder, Broiler progeny, Feeding program

M42 Measurements of growth and sexual maturity of commercial broiler-breeder pullets fed on varying growth curves. R. S. Harper*[1], B. Harvey[1], D. E. Yoho[1], J. R. Moyle[1], P. Sbanotto[2], and R. K. Bramwell[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Cobb-Vantress, Inc.*, *Siloam Springs, AR*.

Finding ways to measure pullet development and maturity is an important concept in the commercial broiler-breeder industry. Measurements are routinely taken to gather a sense of the uniformity of the flock. Body weight has long been the main measuring tool to check this uniformity. This study examines some new techniques in order to gauge pullet growth and sexual development. Cobb 500FF pullets were reared in four treatment groups, consisting of two separate growth curves. Two of the curves were a standard pullet growth curve and the other two a modified curve. The modified curve held the birds' growth back early in the rearing stage and then accelerated the growth towards lighting. Each curve had a high calorie feed treatment and low calorie feed treatment. Thirty birds from each treatment group were randomly selected for this trial. Measurements taken include: pelvic bone spread, body weight, fat pad score, fleshing score, comb and wattle development, and primary wing feather molt. Each bird was banded and measured to obtain the appropriate data previously mentioned. Birds were evaluated every two wks beginning at 12 wks and ending at 24 wks of age. At 20 wks the birds were moved from the pullet house into a production hen house. Data indicates that pullets that were gaining weight the fastest before being lit (modified curve) had the largest response to lighting. These birds had the largest increases in pelvic width and comb and wattle development. This data indicates that birds gaining aggressively before lighting at 21 wks are the most ready to become sexually mature and respond to light stimulation. Additionally, results of this experiment indicate that there are other factors besides body weight that can be utilized to assess a pullets readiness for their response to light stimulation.

Key Words: Pullet management,, Pullet sexual maturation,, Pullet development

M43 Evaluating external physical characteristics of commercial broiler breeder males and testes weight and volume. A. D. Swaffar*, D. E. Yoho, J. R. Moyle, R. S. Harper, and R. K. Bramwell, *University of Arkansas*, *Fayetteville*.

Commercial breeder managers often attempt to assess the reproductive potential of broiler breeder males by their physical characteristics. When evaluating the physical characteristics of commercially reared broiler breeder males the assumption is often that the more predominate the physical characteristics of the male, the larger the testes. This study was designed to determine if several physical characteristics had an effect on testicular weight and volume. Commercially raised broiler breeder males varying in age from 16-65 weeks of age were obtained from commercial broiler breeder farms and were brought to the University of Arkansas for evaluation. Males were weighed live, shank and spur length measured, the comb length, height and circumference determined, and wattle length was measured. Males were euthanized and the comb and wattles removed to obtain weights for each. The testes of each male were harvested and weighed in pairs with the weight and volume recorded for each male. Data were analyzed using JMP statistical software package. Paired testes weight ranged from 4 g to 63 g with live weight ranging from 3.443 kg to 6.485 kg. Analysis of the data indicated no significant correlation between physical characteristics and testes weight or volume. In summary, data from this research indicates that selecting or culling males based upon external physical characteristics is not an effective method for evaluating broiler breeder males for physiologically reproductive traits.

Key Words: Testes,, Sexual maturation,, Male management

M44 Effects of age on nitrogen mass balance of broilers. C. Smith*[1,2], J. Carey[2], J. Bray[1,2], and T. Cherry[1], [1]*Stephen F. Austin State University*, *Nacogdoches, TX*, [2]*Texas A&M University*, *College Station*.

A current important issue facing broiler producers involves the amount of nitrogen produced and subsequently released into the atmosphere from broiler production facilities. At the end of each growout caked litter must be removed from broiler facilities. A large percentage of broiler growers utilize pine shavings as litter in broiler houses and recycle litter from flock to flock. Thus, a study was conducted under simulated commercial broiler production conditions to more accurately measure litter and caked litter production, as well as perform a nitrogen mass balance for different ages during normal broiler production. Broiler chicks and feed were obtained from a commercial integrator and one flock was reared on recycled litter upon which two flocks had previously been reared. Birds were housed in twenty-four 10' X 10' pens with 134 broilers placed per pen, such that at 49 days of age 0.75 square foot per bird was allowed. Broilers were feed a commercially produced starter, finisher, withdrawl-1, withdrawl-2, and withdrawl-3.

To determine the nitrogen mass balance at varying flock age, all incoming and outgoing sources of nitrogen were sampled. Incoming sources of nitrogen include broiler chicks and feed. Outgoing sources of nitrogen include litter, cake, carcasses, mortality, and loss in the form of dust and ammonia. Samples and broiler weights were taken at Day 0, 21, 35, and 49 of age. All samples were analyzed for moisture and total nitrogen content and mass balance was calculated on a dry matter basis. Litter production, nitrogen content of the litter, and nitrogen loss was greater among older birds. This experiment aids in determining the impact of age on litter characteristics and nitrogen loss.

Key Words: Broiler, Nitrogen mass balance, Moisture, Litter, Age

M45 Effects of low refrigeration temperature storage on quality characteristics of shell eggs. M. A. Sartor*[1], J. Regenstein[2], and M. X. Sánchez-Plata[1], [1]*Texas A&M University*, *College Station*, [2]*Cornell University*, *Ithaca, NY*.

The egg processing industry reports that storage of shell eggs at low refrigeration temperatures (close to 0°C (32°F)) during retail display may be associated with quality deterioration. Typical problems reported include ″running whites″ and ″flaccid yolks″. Standard quality parameters and functional properties of shell-eggs stored at -1.1, 0.6, 2.2, 3.9, 5.6 and 7.2°C were evaluated at days 0, 2, 7, 14, 21 and 28 under simulated retail conditions. Quality parameters evaluated included yolk and white color (Minolta), yolk index, Haugh units, pH and vitelline membrane strength. Additionally, foaming properties (cake density) and coagulation properties of the egg products (yolks and whites) were also determined. As expected, the pH of the albumen increased over the time of storage at all storage temperatures tested. The vitelline membrane strength was the lowest when the eggs were stored at -1.1ºC. No significant differences associated with the temperature of storage were observed. However, significant differences in pH, Haugh units and yolk index were evident when comparing samples tested at the beginning of the experiment (day 0 and day 2, compared to day 28). Storage of shell eggs at temperatures below 1ºC may affect some of the quality parameters and functionality of egg products, especially the albumen. Shell eggs need to be maintained at temperatures below 7 ºC as recommended by the USDA guidelines; however, storage temperatures should be kept above 1ºC to minimize these changes.

Key Words: Egg storage, Vitelline membrane strength, White color, Yolk index, Haugh units

M46 Effect of immersion or dry air chilling on bacteria recovery from broiler carcasses. R. Huezo*[1], J. K. Northcutt[2], D. P. Smith[1], D. L. Fletcher[3], and R. J. Buhr[1], [1]*University of Georgia*, *Athens*, [2]*USDA-ARS*, *Athens, Georgia*, [3]*University of Connecticut*, *Storrs*.

A study was conducted to investigate the effect of chilling method (air and immersion) on *Escherichia coli*, coliforms, *Campylobacter*, and *Salmonella* counts and prevalence recovered from broiler carcasses. During each of four replications, 60 broilers were inoculated orally and intra-cloacally with 1 mL of a suspension containing approximately 10^8 cells/mL of *Campylobacter*. After one day, broilers were inoculated with 1 mL of a suspension containing approximately 10^8 cells/mL of *Salmonella*. Broilers were processed and carcasses were cooled by dry air (3.5 m/s, -1.1 C, 150 min) or immersion chilling in ice water (0.6 C, 50 min). Pre-chill counts recovered from carcasses averaged 3.5, 3.7, 3.4, and 1.4 $\log_{10}$ cfu/mL of rinse for *E. coli*, coliforms, *Campylobacter*, and *Salmonella*, respectively. Overall, both chilling methods significantly reduced bacteria levels on the carcasses, and no difference in the bacteria counts was observed between the two chilling methods ($P < 0.05$). Both chilling methods reduced *E. coli* and coliforms levels by 0.9 to 1.0 log units. Chilling reduced *Campylobacter* levels by 1.4 log (air) and 1.0 log (immersion), while *Salmonella* reductions were 1.0 log and 0.6 log units for air and immersion chilling, respectively. Chilling method had no effect on the prevalence of *Campylobacter* and *Salmonella* recovered form carcasses. These results demonstrate that air and immersion chilled carcasses, without any chemical intervention, are microbiologically comparable, and a 90% reduction in counts of *E. coli*, coliforms, and *Campylobacter* can be obtained after chilling.

Key Words: Broilers, Immersion chilling, Air chilling, Cross contamination, Carcass microbiology

M47 *Enterobacteriaceae* isolated from packer head brushes in commercial shell egg processing plants. J. D. Shaw*[1], M. T. Musgrove[2], and D. R. Jones[2], [1]*University of Georgia*, *Athens*, [2]*Egg Safety and Quality Research Unit, ARS, USDA*, *Athens, GA*.

Plant sanitation is an integral component of process control and is crucial to ensuring a wholesome product. This study is an extension of previous work designed to evaluate the status of egg contact surface sanitation in commercial shell egg processing plants. Packer head brushes are placed after the washers and are one of the last pieces of equipment to come in contact with the egg, and therefore may have an important effect on egg cleanliness. In the current study, two egg processing plants were sampled three times each: an offline plant (OL) and a mixed operation plant (MO). While in operation, one packer head brush at each packer head lane was sampled by running a moistened sterile gauze pad across the length of the brush. The gauze pads were then aseptically packaged and transported to the laboratory at refrigerated temperature. *Enterobacteriaceae* were enumerated by plating 1 ml of diluent on violet red bile glucose agar with overlay and incubated at 37 C for 24h. A larger number of *Enterobacteriaceae* were recovered from the MO plant packer head brushes than from those sampled at the OL plant (1.7 log cfu/ml and 0.069 log cfu/ml, respectively). From each positive plate, up to five typical colonies were picked at random, streaked for purity, and subjected to biochemical testing for identification to genus or species. A total of 121 isolates were

identified: 13 from OL and 108 from MO. Genera recovered included *Citrobacter*, *Enterobacter*, *Escherichia*, *Klebsiella*, *Moellerella*, and *Providencia*. At the OL plant, 84.6% of the isolates were identified as *Enterobacter*; of the isolates identified from the MO plant, 68% were *Escherichia*. These genera are the two most commonly isolated from the shells of washed eggs. Five non-*Enterobacteriaceae* genera were found: *Acinetobacter*, *Burkholderia*, *Comomonas*, *Pasteurella*, and *Sphingobacterium*. Identifying bacteria from packer head brushes can assist researchers in developing more effective sanitation practices for the shell egg industry. This is the first report to describe genera associated with packer head brushes in commercial shell egg processing plants.

Key Words: Sanitation, Packer head brush, Enterobacteriaceae, Shell egg

M48 Effect of chilling method and post-mortem aging time on broiler breast fillet quality. R. Huezo*[1], J. K. Northcutt[2], D. P. Smith[2], and D. L. Fletcher[3], [1]*University of Georgia*, *Athens*, [2]*USDA-ARS*, *Athens, GA*, [3]*University Connecticut*, *Storrs*.

A study was conducted to determine the effects of chilling method (dry air or immersion) and post-mortem aging time on broiler breast fillet quality (raw fillet color, raw fillet pH, cook yield and Allo-Kramer shear). One hundred fifty eviscerated broiler carcasses were removed from a commercial processing line prior to chilling and transported to the laboratory. Half of the carcasses were chilled by dry air (3.5 m/s, -1.1 C, 150 min), while the other half were chilled by water immersion (0.6 C, 50 min). Immersion chilled (IC) carcasses were divided into 3 groups (0, 1.67 and 24 h) that corresponded to post-mortem fillet aging time on the carcass after chilling. Air chilled (AC) carcasses were divided into two groups (0 and 24 h). Because AC requires more time, AC fillets deboned immediately after chilling were aged for the same length of time as the 1.67 h IC fillets. One fillet from each carcass was used for raw pH and color (L*, a* and b*), while the other fillet was cooked (steam cooker, 95 C, 15 min) and used to determine yield and texture. The pH of IC and AC fillets was similar when fillets were aged for the same length of time post-mortem. Method of chilling has no effect on raw breast fillet color ($P < 0.05$); however, post-mortem aging time had a significant, but slight affect on lightness. Tenderness of IC fillets removed 0 and 1.67 h after chilling was similar and corresponded to the texture previously designated as slightly tough to tough by sensory panels (Allo-Kramer shear > 8 kg/g). Force to shear AC fillets deboned immediately after chilling (8.4 kg/g) was significantly lower than IC fillets (10.3 kg/g) aged for the same length of time (1.67 h). After 24 h aging, shear values for IC and AC fillets were < 8 kg/g and values were in the range considered to be tender to very tender by sensory panels. Cook yield of AC fillets was significantly higher than IC fillets for all deboning times. Results show that rigor may develop at a faster rate during AC as compared to IC; however, post mortem aging is still required to maximize tenderness.

Key Words: Poultry chilling, Air chilling, Immersion chilling, Poultry texture

M49 Effect of immersion or dry air chilling on broiler carcass moisture retention and breast fillet functionality. R Huezo*[1], D. P. Smith[2], J. K. Northcutt[2], and D. L. Fletcher[3], [1]*University of Georgia*, *Athens*, [2]*USDA, ARS, Russell Research Center*, *Athens, GA*, [3]*University of Connecticut*, *Storrs*.

A study was conducted to investigate the effect of chilling method on broiler carcass skin color, carcass moisture retention, and breast fillet quality and functionality. One hundred fifty eviscerated broilers carcasses were removed from a commercial processing line prior to chilling, transported to the laboratory, weighed and chilled by dry air (3.5 m/s, -1.1 C, 150 min) or immersion in ice water (0.6 C, 50 min). Post-chill carcasses were weighed for moisture uptake, individually bagged and held at 4 C for 24 h. Fillets were deboned, marinated (20% wt:wt, 20 min, 3% salt: 2% STTP) and cooked (steam cooker, 95 C, 15 min), with weights taken at each step. Carcass skin color was measured immediately after chilling and after 24 h. Fillet color was measured on the medial surface before marination and after cooking. Cooked fillets shear values were determined using an Allo-Kramer multiple blade. After 150 min of air chilling, carcasses lost 2.5% of pre-chill weight, and weight loss ranged from 3.5% to 2.2%. Water absorption during immersion averaged 9.3% of the pre-chill weight, but varied widely with a range of 3.4% to 14.7%. Immediately after chilling, Immersion chilled (IC) carcasses were significantly lighter (higher L*), less red (lower a*), and less yellow (lower b*) than air chilled (AC) carcasses. Storage time improved appearance of AC carcasses, but skin color after 24 h of storage was still significantly different for the two chilling methods ($P<0.05$). Raw and cooked fillet color, fillet marination pick-up, and cooked fillet tenderness were not affected by chilling method. Cook yield for fillets deboned from IC carcasses was significantly lower than fillets deboned from AC carcasses. Results suggest that immersion chilling is better for whole birds and skin-on parts; however, air chilling is acceptable for deboned and further processed items as fillet color, marination yield and tenderness is not affected, while cook yield is improved.

Key Words: Broilers, Immersion chilling, Air chilling, Marination, Poultry meat color

M50 Validation of a chlorine dioxide product applied pre- and post- chilling to reduce bacterial levels in broilers. V. Molina*, M. Davis, and M. Sánchez-Plata, *Texas A&M University*, *College Station*.

Selectrocide™, a chlorine dioxide (CD) generating product, was validated as an antimicrobial intervention applied before and/ or after chilling in a commercial broiler processing facility. Five different scenarios were simulated during each of three independent plant visits. A control plant scenario consisted in sampling 10 different carcasses at each of three different stages including after evisceration, after a chlorine rinse (50ppm), and after a 1h static chilling in icy-water (2ppm chlorine). Interventions tested in this experiment created 4 additional plant scenarios. The second scenario featured pre-chill carcasses sprayed with an acidified sodium chlorite (ASC), Sanova™, solution (1,200ppm) with samples taken after the intervention and after chilling. The third scenario featured pre-chill samples submerged for up to 30s in a 10ppm CD solution and sampled 1 minute after treatment application, and after chilling. A fourth scenario consisted of samples subjected to the intervention post-chill; while the fifth scenario featured post-chill samples subjected to the CD intervention before and after chilling. Standard sampling methods were used to evaluate aerobic plate, coliform, generic *E. coli* and psychrotrophic

counts, as well as the incidence of *Salmonella* spp. Significant variability in *Salmonella* spp. incidence was observed between replications. In general, similar bacterial reductions were achieved by the pre-chill application of acidified sodium chlorite and the chlorine dioxide product. Coliform counts in final carcasses for each of the five scenarios were 3.38, 2.58, 2.04, 2.10 and 2.19 log CFU coliforms/ ml of rinse, respectively. Generic *E. coli* levels in final carcasses for each plant scenario were 2.50, 2.10, 2.00, 1.65, 1.57 log CFU/ ml of rinse, respectively. Final psychrotrophic counts for each scenario were 3.42, 3.52, 3.51, 2.66, 2.27 log CFU/ ml of rinse, respectively. Post-chill application (last two scenarios) of the chlorine dioxide product significantly reduces bacterial populations, especially generic *E coli* and spoilage organisms.

Key Words: Chlorine dioxide, Pre-chill, Post-chill intervention, Acidified sodium chlorite, *Salmonella*

M51 Ultra-violet light treatment lowers numbers of *Listeria monocytogenes* on raw chicken fillets without changing antibiotic resistance or meat color. S. A. Lyon*[1], M. E. Berrang[1], D. L. Fletcher[2], and P. J. Fedorka-Cray[1], [1]*USDA-ARS-Russell Research Center*, *Athens, GA*, [2]*University of Connecticut*, *Storrs*.

Listeria monocytogenes is an important foodborne pathogen and raw poultry meat has been shown to be a vector for its entrance into a poultry further-processing plant. Reduction of *L. monocytogenes* in these plants is a high priority for the industry. Ultra-violet (UV) light at a wavelength of 254 nm is called germicidal UV and can kill bacteria. This study was designed to test germicidal UV light as a means to lower *L. monocytogenes* counts on raw chicken meat prior to shipment from a slaughter plant to a further processing plant. Raw chicken breast fillets were inoculated with one of four subtypes of *L. monocytogenes* each with a different antibiotic resistance profile. Inoculated fillets were exposed to UV irradiation at 1,000 $\mu W/cm^2$ for 5 min. Untreated control samples were maintained for comparison. All fillets were rinsed in PBS and L. monocytogenes were enumerated by plating serial dilutions on modified oxford medium. UV treatment resulted in a 2 Log reduction in viable *L. monocytogenes*recovered from fillets. Antibiotic resistance profiles were determined using the broth micro-dilution method. UV irradiation did not alter the antibiotic resistance profiles of any of the 4 *L. monocytogenes* strains as compared to those isolated from non irradiated fillets. Likewise, UV treatment had no effect on meat color (lightness, redness, and yellowness) on the day of treatment or after 7 days of storage at 4°C. This study suggests that UV irradiation of raw breast fillets at a slaughter plant can significantly reduce *L. monocytogenes* without negatively affecting meat color or changing antibiotic resistance among the surviving population. UV treatment may be useful to reduce the negative impact of *L. monocytogenes* introduction into a poultry further-processing plant on raw poultry meat.

Key Words: Ultraviolet irradiation, Poultry processing, *L. monocytogenes*, Antibiotic resistance, Meat color

M52 The effects of paraffin wax and a wax antimicrobial product to reduce microbial levels in processed chicken broilers. M. X. Sánchez-Plata*, *Texas A&M University*, *College Station*.

The suspension of approved antimicrobial treatments into a molten paraffin wax matrix was evaluated as a potential intervention in commercially processed broilers. Bacterial reductions on carcass surfaces were expected after submersion in a hot coating wax product, followed by physical removal of attached bacteria to the solidified residue, and the antimicrobial effects of a chemical intervention suspended in the wax matrix. A total of 420 market age broilers, were processed in a pilot plant research facility and were subjected to four different processing scenarios. Control samples were humanely slaughtered, scalded in a water tank at 58ºC, picked using a pilot scale picker, manually eviscerated and chilled in a static icy-water tank (2ppm chlorine). For treatment 1, a separate set of carcasses were submerged in a molten paraffin wax product kept at 60ºC for 1 second, followed with immediate submersion in icy water to allow the manual removal of the solidified wax coating. For treatment 2, carcasses were submerged in molten wax for 15 seconds, followed with immediate submersion in ice water. For treatment 3, carcasses were treated with molten wax that had a suspended chlorine dioxide (CD) generating product. Samples taken after bleeding, scalding, picking, waxing, evisceration, and chilling were tested for total aerobic, coliform and generic *E. coli* counts as well as *Salmonella* spp. incidence using standard methodologies. The immediate submersion in the wax product was responsible for a 0.3 to 0.5 log CFU/ ml of rinse reduction in total aerobic, coliform and generic *E. coli* counts. No significant reductions in the incidence of *Salmonella* spp. were observed. Reductions of 0.5 to 0.9 CFU/ ml of rinse in all the parameters tested were observed by the 15 s submersion in the wax product and the submersion in the wax product suspended with the CD product. Results indicate that the thermal, physical and chemical potential of paraffin wax as an antimicrobial intervention could assist processors in reducing overall bacterial levels in processed broilers.

Key Words: Paraffin wax, Intervention, Antimicrobial, Microbial levels, *Salmonella*

M53 The effect of tasker blue applied at various intervention steps on aerobic plate counts and *Escherichia coli* counts on fresh broiler chicken carcasses. S. M. Russell*, *University of Georgia*, *Athens*.

A study was conducted to evaluate the effect of Tasker Blue (TB-sulfuric acid, ammonium sulfate, and copper sulfate) applied at various locations in a commercial processing facility on aerobic plate counts (APC) and *Escherichia coli* (*E. coli*) counts on fresh broiler chicken carcasses. TB was applied in the scalder (pH 2, Cu 3 ppm), as a New York Dressed (NYD) spray, as an online reprocessing (OLR) treatment (10 second dip was used offline to mimic a 10 second spray treatment), and as a post-chill dip (TB treated offline at pH 3.5, Cu 3 ppm) for 10 s. Ten carcasses were sampled after scalding (PS), after NYD spraying (PNYD), pre-online reprocessing (Pre-OLR), post-online reprocessing (Post-OLR), and post-chill (PC) for controls or PC dip (PCD) for TB carcasses at each of these locations using the whole carcass rinse procedure. Likewise, 10 carcasses were selected from the adjacent processing line and sampled as controls. After collecting from the lines or dip tanks, the carcasses were allowed to drip for 1 min, individually placed into sterile bags, packed on ice in coolers, transported to the laboratory, and evaluated for APC and *E. coli* counts. Log_{10} APC results for the control line were 5.44, 4.18, 5.50, 4.60, and 3.43 for PS, PNYD, Pre-OLR, Post-OLR, and PC, respectively. Log_{10} APC results for the TB treated line were 2.95, 3.29, 3.76, 0.97, and 0.00 for

PS, PNYD, Pre-OLR, Post-OLR, and PCD, respectively. Log_{10} *E. coli* results for the control line were 3.20, 2.65, 4.66, 3.73, and 0.43 for PS, PNYD, Pre-OLR, Post-OLR, and PC, respectively. Log_{10} *E. coli* results for the TB treated line were 2.27, 1.50, 2.60, 0.00, and 0.00 for PS, PNYD, Pre-OLR, Post-OLR, and PCD, respectively. Tasker Blue, applied at various locations throughout the processing operation, dramatically and significantly ($P \leq 0.05$) lowered APC and *E. coli* on broiler carcasses when compared to a commercial poultry processing line.

Key Words: APC, *E. coli* count, Tasker Blue, Chicken

M54 Effect of washing broiler carcasses in potassium hydroxide and lauric acid on native bacterial flora. A. Hinton Jr*, J. K. Northcutt, J. Cason, D. P. Smith, and K. D. Ingram, *Russell Research Center*, *Athens, GA*.

Experiments were conducted to examine the bactericidal effect of potassium hydroxide (KOH) and lauric acid (LA) on the native microflora of broiler carcasses. Eviscerated carcasses were placed in solutions of 1.0% KOH and 2.0 % LA or in distilled water (control) and washed by shaking for 1 min on a mechanical shaker. Whole-carcass-rinses (WCR) were performed to recover bacteria from the carcasses following each of 3 successive washes in KOH-LA or water. Bacterial populations of WCR rinsates were enumerated by plating serial dilutions of rinsates on bacteriological media. Total plate count bacteria (TPC), *Campylobacter*, and *Escherichia coli* in the native bacterial flora were enumerated by culturing rinsates on Plate Count Agar, *Campylobacter* Agar, and Petrifilm, respectively. Results indicated that significantly fewer TPC bacteria were recovered from carcasses washed in KOH-LA than from carcasses washed in water; however, there was no significant difference in the number of TPC bacteria recovered from carcasses washed 1, 2, or 3 times in KOH-LA. Additionally, significantly fewer TPC bacteria were recovered from carcasses washed once in water than from carcasses washed 3 times in water. No *Campylobacter* or *E. coli* were recovered from carcasses following the first KOH-LA wash, although log_{10} 2.71 *Campylobacter*/ml and log_{10} 0.95 *E. coli*/ml were recovered from carcasses following the first wash in water. Repeated washing in water did not significantly reduce the number of *Campylobacter* recovered from the carcasses, but no *E. coli* were recovered from carcasses after the third wash in water. Findings indicate that the antibacterial activity of KOH-LA can significantly reduce populations of native bacterial flora of broiler carcasses washed in the mixture. Reduction of the number of pathogenic and spoilage bacteria on processed carcasses washed in KOH-LA might reduce the number of foodborne illnesses associated with processed poultry products and extend the shelf life of fresh poultry.

Key Words: Lauric acid, Potassium hydroxide, Antimicrobial, Broilers, Carcasses

M55 Assessment of wing damage during catching and processing as a measure of animal welfare performance. K. N. Opengart*, R. Williams, W. Hammack, and A. Atencio, *Keystone Foods*, *Huntsville, AL*.

Meeting current animal welfare standards for wing disarticulation and breakage during catching and processing has proven to be one of the most difficult parameters to consistently achieve. In most audit systems, an acceptable level of wing damage is 1% for broilers <4.5 pounds, 3% for broilers 4.5 to 7 pounds and 5% for broilers greater than 7 pounds when measured prior to defeathering. These arbitrarily assigned targets are sometimes difficult to attain. Therefore, systematic and scheduled evaluation of the process is necessary to quickly identify when and where deficiencies may be occurring that will ultimately lead to damaged wings which may put a plant out of tolerance. Evaluation of wing breakage measured in the cage once the birds arrived at the plant (a measure of catching and hauling) has shown catch crew related wing damage to be 1.0-1.5%. An additional 1-4.5% wing damage was associated with unloading, conveying and shackling when measured prior to defeathering. Areas of opportunity that have been identified as potential causes of excessive wing damage include human:animal interfaces (catching, unloading, shackling), shackling systems (height, shackle spacing), stunning systems, conveyance systems (turns, drops) and factors which may increase bird activity.

Key Words: Wing, Breakage, Disarticulation, Welfare

M56 Non-feed withdrawal broiler processing. Y. Vizzier-Thaxton*[1], A. Corzo[1], M. Putsakum[1], Z. Williams[1], S. W. Anderson[1], K. Christensen[2], and J. P. Thaxton[1], [1]*Mississippi State University*, *Mississippi State*, [2]*OK Foods, Inc.*, *Ft. Smith, AR*.

To minimize fecal contamination in the processing plant, a feed withdrawal period has been considered necessary. With the modern high meat yield broiler there have been reports of excessive yard shrink as a result of holding time and feed withdrawal. At the same time, feed withdrawal has been singled out as a time when broilers are most likely to eat litter and thus arrive at the processing plant with *Salmonella* in the crop. The feeding of organic acids in the water has been practiced in an effort to control the pH of the crop and thus inhibit *Salmonella* attachment or colonization. This study was designed to determine if a feed could be formulated that would allow birds to eat until immediately prior to catching to minimize shrink and at the same time acidify the crop. A total of 600 birds were divided into 2 treatment groups and placed in mini-pens with 10 birds per pen. Twelve hours prior to catching, one group received the experimental diet while feed was removed from the other group. At catching birds were bled for plasma corticosterone analysis. Birds were immediately euthanized. The crops were aseptically removed for pH and coliform counts. The intestinal content and condition was observed and photographed. Shrink was reduced by 44% with no apparent difference in fecal content between treatments. Crop pH was lowered. This work indicates that it may be possible to keep birds on feed up to catching time.

Key Words: Feed withdrawal, Shrink, Crop acidification, *Salmonella*

M57 Tylosin applied at a sub-therapeutic level in broiler feed affects *Campylobacter* recovered from carcasses during processing. M. E. Berrang*, S. R. Ladely, R. J. Meinersmann, and P. J. Fedorka-Cray, *USDA-ARS-Russell Research Center*, *Athens, GA*.

Tylosin is an antimicrobial drug approved for use in broiler feed at sub-therapeutic levels for purposes of growth promotion. There is controversy about whether such use of antimicrobials could lead to the development of drug resistant pathogenic bacteria. Erythromycin is

often the drug of choice for treating humans with campylobacteriosis. Both tylosin and erythromycin are classified as macrolide drugs and cross resistance between these antimicrobials may occur if either is used. Commercial broiler chicks were placed in isolation grow-out chambers and colonized with *Campylobacter jejuni*. At 14 days of age broilers began to receive a diet including 20 g tylosin phosphate per ton which was continued ad libitim for the rest of grow-out. Control broilers received the same diet with no added drugs. At 42 days of age, broilers were processed in a pilot plant with equipment which very closely models commercial conditions. Carcass rinses were collected after feather removal, after inside/outside washing and after immersion chilling. *Campylobacter* numbers after feather removal were not different according to feed type (3.53 log cfu per ml rinse for control carcasses and 3.60 for those fed medicated feed). Likewise, medicated feed did not affect *Campylobacter* numbers on carcasses after inside/outside washing (3.11 and 3.07 log cfu per ml rinse). Carcasses of broilers fed medicated feed had lower numbers of Campylobacter after chilling (1.45 log cfu/ml rinse) compared to control carcasses (2.31 log cfu/ml rinse). No *Campylobacter* isolated from control carcasses were resistant to erythromycin. However, all *Campylobacter* recovered from carcasses fed medicated feed were resistant to erythromycin (minimum inhibitory concentration of greater than 8 Î¼g/ml). Application of tylosin in feed can act to promote growth and results in lower *Campylobacter* numbers on chilled carcasses; however, the *Campylobacter* that do remain are resistant to erythromycin.

Key Words: *Campylobacter*, Tylosin, Processing, Feed, Antimicrobial

M58 Animal rghts and eoterrorism - Current and emerging threats to animal researchers and commercial poultry. R. A. Norton*, G. S. Weaver, and N. R. Morrow, *Auburn University*, *Auburn, AL*.

Animal Rights extremism is one of the top domestic terrorist issues for the FBI. Originally confined to targeting animal research laboratories, some groups have developed extensive campaigns aimed at animal agribusiness and retail food operations. Legal challenges have also been mounted to dramatically alter animal production systems. The U.S. has experienced an escalation in direct action violence and calls for further violence. Recently a number of splinter groups have openly called for violence against people they feel harm animals.

Currently, there is no open source intelligence indicating animal rights groups are attempting to develop biological or chemical weapons to use against animal agriculture. Although counterintuitive, several activist leaders have openly wished U.S. animal production systems would experience foreign animal diseases (FAD). Potential threats that could cause catastrophic impacts include Highly Pathogenic Avian Influenza or Velogenic Newcastle Disease. Since many animal rights organizations have world-wide reach, infectious materials could be diverted from endemic disease areas and introduced into susceptible animal populations.

Significant changes are needed to harden poultry production facilities. Locked gates are not the answer. Growers need to be trained to recognize when animal rights groups or “lone wolves” are active in the community or conducting surveillance. Veterinarians and animal scientists also need to be trained to distinguish between naturally occurring diseases and those which are intentionally introduced. Combined, better defenses can lessen the probability of attack and better assure the continuation of a safe and secure food supply.

Key Words: Animal rights extremism, Current and emerging threats

M59 Performance improvement with feed additives RepaXol®, AciXol™, and Virginiamycin in broilers challenged with clostridium perfringens. G. Mathis*[1], C. Hofacre[2], and N. Scicutella[3], [1]*Southern Poultry Research, Inc.*, *Athens, GA*, [2]*University of Georgia*, *Athens*, [3]*SODA Feed Ingredients*, *Monaco*.

The objective was to evaluate the anticlostridial efficacy of feed additives RepaXol®, an homogeneus blend of double coated essential oils, AciXol™, a blend of organic and inorganic acids (citric, fumaric, malic and ortho-phosphoric) along with the protected essential oils (as in RepaXol®, encapsulated in the same MICROPEARLS®, and Virginiamycin, an antibiotic. Groups of 10 birds were weighed and placed into cages on day of hatch. The treatments were nonmedicated, non-challenged (NMNC), nonmedicated, challenged (NMC), RepaXol® 100 ppm, challenged, AciXol™ 500 ppm, challenged, and Virginiamycin (VIR) 20 ppm, challenged. Birds were challenged at 14 days of age with E. acervulina and E. maxima and on Days 19, 20, and 21 with Clostridium perfringens. Each treatment consisted of 6 replications in a complete randomized block design. Feed in mash form was fed ad libitum throughout the test period. The parameters measured were feed conversion and weight gain (Days 0 to 28 and Day 14 to 28), Necrotic Enteritis (NE) mortality and NE lesion scores. On Day 22, five birds per pen were NE lesion scored. There was a significant improvement of feed conversions and weight gains for both measurement periods with all feed additives compared to the NMC birds. The feed conversions (Day 0-28) of the NMNC was 1.461g, NMC, 1.726, RepaXol® 1.586, AciXol™ 1.577g, and VIR 1.519. The average live weight gains (Day 0-28) of the NMNC was 0.963 kg, NMC 0.774 kg, RepaXol® 0.915 kg, AciXol® 0.901 kg, and VIR 0.935 kg. Percent NE mortality was significantly less for the VIR 12 % compared to NMC 33 %. There was no significant difference in percent NE mortality between RepaXol® 23 %, AciXol™ 22 % and VIR. All feed additive treatments had significantly lower NE lesion scores compared to NMC. This study demonstrated the benefits of adding RepaXol® 100 ppm, AciXol™ 500 ppm, or Virginiamycin 20 ppm into the feeds of broiler chickens exposed to Clostridium perfringens.

Key Words: Clostridium perfringens, RepaXol, AciXol, Virginiamycin, Necrotic Enteritis

M60 Understanding *Salmonella* transmission on chicken pullet, broiler-breeder, and broiler farms in Georgia. K. Zamperini*[1], D. Cole[3], C. Hofacre[1], and J. Maurer[1,2], [1]*University of Georgia*, *Athens*, [2]*University of Georgia*, *Griffin*, [3]*Georgia Division of Public Health*, *Atlanta, GA*.

The prevalence of *Salmonella* within the various levels of the integrated poultry production system has not been fully elucidated, but vertical transmission is believed to be a significant contributor to carcass contamination by *Salmonella*. To investigate vertical transmission of *Salmonella*, we sampled two levels of poultry production for *Salmonella*: 1) select, paired pullet and broiler-breeder farms, and 2) broiler farms supplied with chicks from said broiler-breeder farms. Chick box liners were collected at the time of placement of the pullets and broilers in order to detect *Salmonella* strains present in the birds at placement. Of pullet farms surveyed, 26% of environmental samples were positive for *Salmonella*. Chick box liners were sporadically positive for *Salmonella*. Pullet farm houses have also been sporadically positive when sampled the day of placement. *Salmonella* prevalence varied within pullet farms, where *Salmonella* isolation rates ranged between 5 to 42%, for houses sampled on at least one-half of the pullet farms surveyed. While the initial *Salmonella* isolation rate from pullet farms was low at 2%, the number of houses and environmental samples positive for *Salmonella* increased with the age of the birds (chi-squared test, $p<0.05$). There was also a statistically significant difference between poultry integrators when comparing peak in prevalence with pullets' age (chi-squared test, $p<0.05$). No statistically significant differences were observed in *Salmonella* prevalence between poultry integrators (chi-squared test, $p=0.608063$) or pullet farms (chi-squared test, $p=0.780716$ and 0.155915 for companies A and C, respectively) despite differences in farm management practices evident with these the two integrators. Pulsed-field gel electrophoresis was used to identify strain types. Using this molecular typing tool, we were able to observe introduction and spread of *Salmonella* strains on poultry farms. Both vertical and horizon transmission appears to be involved in the spread of *Salmonella* within poultry integrator.

Key Words: *Salmonella*, Poultry, Vertical transmission

M61 Cationic peptides decrease susceptibility of young chickens to *Salmonella* enterica serovar enteritdis infection by up-regulation of the innate immune response. M. H. Kogut*[1], K. J. Genovese[1], H. He[1], and Y. W. Jiang[2], [1]*USDA-ARS*, *College Station, TX*, [2]*USDA-ARS*, *College Station, TX*, [3]*USDA-ARS*, *College Station, TX*, [4]*Texas A&M University*, *College Station*.

The TAMUS cationic peptides are a group of related cationic peptides produced by a Gram-positive bacterium. Cationic amphiphilic peptides have been found to stimulate or prime the innate immune responses in mammals. The innate immune system of poultry is functionally inefficient during the first week posthatch enabling pathogens such as *Salmonella* enterica serovar Enteritidis (SE) to invade and colonize the visceral organs of these immature birds. The objective of the present study was to evaluate the effect of TAMUS as an immunostimulator of the innate immune response of young chickens. TAMUS was provided as a feed additive at three different concentrations (12, 24, or 48 ppm) for 4 days post-hatch significantly increased protection against SE organ invasion in a concentration-dependent manner. The functional efficiency of heterophils isolated from chickens fed the TAMUS rations at the three concentrations was significantly up-regulated when compared to heterophils isolated from chickens fed a control starter ration as determined with an array of functional assays. Phagocytosis, oxidative burst, and degranulation were all significantly increased in a concentration-dependent manner in heterophils isolated from chickens fed the TAMUS diets. This is the first report of bacterial cationic peptides inducing the up-regulation of the avian innate immune response that provides protection against extraintestinal *Salmonella* infections. The significance of these data is that the orally delivered cationic peptides stimulate the innate response at a time of immunologic inefficiency and increased susceptibility to bacterial infections (first week posthatch). Because of the non-specific nature of the innate response, we speculate that TAMUS given as a feed additive during the first week posthatch could provide increased protection against a variety of bacterial pathogens.

Key Words: Cationic peptides, *Salmonella*, Innate immunity, Heterophils

M62 Herbal products for control of histomoniasis (blackhead disease) in turkeys. R. Hauck*, P. L. Armstrong, L. Fuller, and L. R. McDougald, *University of Georgia*, *Athens*.

In the absence of approved products for treatment of blackhead disease there is increased interest in the evaluation or use of natural products. Such products are used for other purposes in the feed industry and have good acceptance by producers and consumers. In this study we evaluated the effects of 3 such products which are used for odor management in feed. These products are extracts or essential oils from commonly used herbs. Tests of the products *in vitro* showed positive results against *Histomonas* and other protozoa. The test model in turkeys consisted of directly and indirectly exposed birds in battery cages. The products offered little protection against the severe direct infections. However, product 2 alone or in a combination with product 3 had beneficial effects on lesions in the liver and ceca. These results suggest that these products could have benefit in helping birds to resist the spread of histomoniasis within a flock.

Key Words: Histomoniasis, Turkeys, Treatment, Essential oils

M63 Comparison of *Mycoplasma gallisepticum* vaccine strain 6/85 dosage rates in layers subsequently challenged with virulent *Mycoplasma gallisepticum*: Serological response, vaccine persistence, and egg production. J. D. Evans*, S. A. Leigh, S. D. Collier, and S. L. Branton, *USDA-ARS South Central Poultry Research Unit*, *Mississippi State, MS*.

Commercially available attenuated strains of *Mycoplasma gallisepticum* (MG) are commonly used within the layer industry to control MG-induced mycoplasmosis. MG strain 6/85 is a commonly utilized vaccine strain which has been demonstrated to be safe due to reduced pathogenicity and transmissibility. Research has indicated that increased dosage rates or vaccination loads corresponded with an enhanced serological response and increased vaccine strain persistence within the host. In an effort to maximize protection associated with MG live vaccines and to further examine the effects of enhanced 6/85 dosage rates, Hyline W36 layers (n=160) were housed in biological isolations units (10 birds per unit) through 55 wks of age. The layers

were divided among 6 treatment groups: (1) subjects vaccinated with 6/85 at the recommended dosage (1X); (2) subjects vaccinated with 6/85 at 1X and challenged with virulent MG at 22 wks; (3) subjects vaccinated with 6/85 at 1X and challenged with virulent MG at 45 wks; (4) subjects vaccinated with 6/85 at the recommended dosage (15X); (5) subjects vaccinated with 6/85 at 15X and challenged with virulent MG at 22 wks; and (6) subjects vaccinated with 6/85 at 15X and challenged with virulent MG at 45 wks. Vaccinations occurred at 10 wks of age and were applied via fine spray. Throughout the study, eggs were collected and weekly hen production was determined. The *in vivo* persistence of 6/85 was determined via choanal cleft swabs/strain-specific PCR and the serological response was determined via serum plate agglutination (SPA). Preliminary results indicate that the seroconversion rates (measured at 50 wks) were not impacted by differing dosage rates of 6/85. Following virulent MG challenge at 45 wks, however, the 15X 6/85 treatment negated production losses readily evident with the similarly challenged 1X treatment group.

Key Words: Poultry, *Mycoplasma gallisepticum*, Attenuated vaccine, Mycoplasmosis

M64 The effects of stress and concurrent *Escherichia coli* infection on the isolation of *Listeria monocytogenes* from synovial tissue of turkey poults. V. Dutta*[1], G. R. Huff[2], W. E. Huff[2], N. C. Rath[2], M. G. Johnson[3], and R. Nannapaneni[3], [1]*University of Arkansas*, *Fayetteville*, [2]*USDA, ARS, PPPSRU*, *Fayetteville, AR, USA*, [3]*University of Arkansas*, *Fayetteville*.

The objective of this study was to determine if *Listeria monocytogenes* (Lm) infection of stressed turkey poults would result in colonization of synovial tissues. Male turkey poults, housed in floor pens, were subjected to cold stress from d 4 through 12 and were exposed to an aerosol challenge of either the Scott A strain of Lm, *Escherichia coli* (Ec), or the combination (Lm+Ec). All challenged birds were housed in the same building, while non-challenged controls were housed in a separate, biosecure building. At seven wks, poults were given an immunosuppressive dose of dexamethasone (Dex) and the same bacterial challenges were added to their drinking water. One wk post-challenge 4-6 birds per group were weighed, necropsied, and knee synovial tissues were cultured for Lm using pre-enrichment in University of Vermont medium (UVM) and Fraser broth, isolation of Lm on Listeria selective agar plates, and confirmation using biochemical tests. LM was isolated from knee synovial tissue of 75% of cold stressed poults challenged with Dex+Ec+Lm, 43% of cold-stressed poults challenged with Dex+Ec alone, and 20% of cold stressed poults challenged with Dex+Lm alone. Lm was not isolated from non-cold stressed birds challenged with either Dex+Lm or Dex+Ec+Lm, but was isolated from 25% of non-cold stressed birds challenged with Dex+Ec. Lm was not isolated from synovial tissues of any of the non-challenged controls. There were no differences in body weight due to early cold stress, however Dex treatment itself and Dex + all bacterial challenges significantly decreased body weight at 8 wks. These data suggest that Lm colonization of turkey synovial tissue can be enhanced by early cold stress and by concurrent infection of Dex-treated poults with Ec.

Key Words: Turkeys, Cold stress, *Listeria monocytogenes*, *Escherichia coli*

M65 Effects of vaccine stabilizer Spray-Vac™ on *Mycoplasma gallisepticum* vaccines FVAX-MG™ and Mycovac-L™ survival in solution. S. A. Leigh*, J. D. Evans, S. L. Branton, and S. D. Collier, *USDA-ARS South Central Poultry Research Unit*, *Mississippi State, MS*.

Infection of layer chickens with *Mycoplasma gallisepticum* (MG) can result in decreased egg production compared to uninfected hens. Live MG vaccines are available; however, the methods used to administer these vaccines by the end user vary, resulting in the potential for marked differences in vaccine efficacy. In order to help poultry growers obtain uniform results using the live vaccines, various conditions for vaccine delivery are being investigated. One area of investigation is the ability to use tap water for rehydration of lyophilized vaccines. However, the presence of chlorine or other oxidizing compounds in the water rapidly decreases vaccine viability. The use of a vaccine stabilizer (Spray-Vac™) that removes chlorine and other oxidizing compounds was investigated. Tap water for this experiment was simulated by adding chlorine (sodium hypochlorite) to distilled water to a final concentration of 4ppm. MG vaccines FVAX-MG™ and Mycovac-L™ were rehydrated with 10 ml distilled water and then diluted to a usable concentration in either tap water, or tap water containing vaccine stabilizer, or stabilizer with 0.1X or 1.0X PBS from concentrate added. 1.0X PBS concentrate in distilled water was used as a control. Samples were removed at 15, 30, and 60 min., and numbers of viable mycoplasmas were determined by measuring color-change units (CCU_{50}) per milliliter. The results show that chlorine rapidly decreases vaccine survival. The addition of the vaccine stabilizer removes the effects of the chlorine, yielding vaccine survival results similar to that obtained previously for distilled water. The best results were obtained when PBS concentrate was added to a concentration of 1.0X (physiological). These results show that vaccine stabilizer has no detrimental effects on vaccine survival, and can be used to remove the deleterious effects of chlorine from tap water.

M66 Effects of arginine, vitamin E and vitamin C on cardiopulmonary function and ascites parameters in broilers exposed to cold temperature. S. B. Kawthekar*, N. Rougiere, and C. Ruiz-Feria, *McGill University*, *Montreal, QC, Canada*.

One experiment was conducted to evaluate the combined effects of Arginine (AR), Vitamin E and Vitamin C on cardiopulmonary performance and ascites parameters of broilers reared under cold environmental temperature starting on d 16. One d old male broilers were fed with corn-soybean meal diet (CTL, 1.2 % AR and 40 IU vitamin E). The birds were assigned to four dietary treatments: CTL, control supplemented with 1% AR and either 200 IU vitamin E (AE), or 500 mg of vitamin C (AC), or a combination of vitamin E and C at the same levels (AEC) per kg of feed. Pulmonary Arterial Pressure (PAP) and Mean Arterial Pressure (MAP) were measured in anesthetized birds (n = 7 per group). Birds were challenged with epinephrine (EPI, 0.5 mg/kg BW i.v.), 20 min later with Amino- guanidine hemisulphate (AG, 100 mg / kg BW i.v.) and 20 min later with L-NAME (50 mg / kg BW, i.v.). PAP and MAP were recorded continuously after each challenge. Data were analyzed with the repeated measures ANOVA and the Student Newman-Keuls test was used to separate means within groups. The PAP values were lower ($P < 0.05$) in the AEC group as compared to all other groups after 30 s of EPI challenge. Within 120 s of EPI challenge, PAP were significantly decreased ($P < 0.05$) in the AEC birds compared to the CTL birds. The PAP returned to pre-EPI challenge levels within 300 s in all groups. The PAP increased ($P < 0.05$) 60 s after the AG and L_NAME challenge in all groups, but no differences were found among groups. The right to total ventricular weight was lower ($P < 0.05$) in the AEC birds as compare to the other groups. Hematocrit values ($P < 0.05$) were lower in the AEC group as compared to all other groups at 5 and 6 wks. EPI had a less severe effect on the cardio-pulmonary function of AEC birds, probably due to a better endothelial integrity and higher capacity to generate nitric oxide. In general AEC birds appeared to have a better pulmonary vasculature, and this may be explained by the extracellular and intracellular protection against oxidative stress provided by the combination of lipid and water soluble antioxidants.

Key Words: Arginine, Vitamin E, Vitamin C, Ascites, Nitric oxide

M67 Estimation of the relative bioavailability of copper sources for broiler chicks. P. Butkeraitis*[1], D. R. Ledoux[1], L. B. Linares[1], A. J. Bermudez[1], A. Dakovic[2], S. Matijasevic[2], and Z. Sekulic[2], [1]*University of Missouri*, *Columbia*, [2]*Institute for Technology of Nuclear and Other Mineral Raw Materials*, *Belgrade, Serbia*.

An experiment was conducted with 250 day-old male broiler chicks to estimate the biological availability of two sources of Cu, Cu-montmorillonite (Cu-MONT) and Mintrex®Cu. Copper sulfate ($CuSO_4$) was used as the standard source in the bioavailability assay. Chicks were allotted randomly to dietary treatments that included an unsupplemented basal corn-soybean meal, or the basal supplemented with 75, 150 or 225 mg Cu/kg diet as either $CuSO_4$ (25.1% Cu), Cu-MONT (2.65% Cu), or Mintrex®Cu (15% Cu). Chicks were housed in stainless steel chick batteries and allowed access to feed and water *ad libitum* for 21 d. Dietary Cu level or source had no effect ($P > 0.05$) on feed intake, body weight gain or feed conversion of chicks, which averaged 847 g, 696 g, and 1.22 g:g, respectively. A source x level interaction ($P < 0.05$) was observed for liver Cu. Liver Cu of chicks fed $CuSO_4$ and Mintrex®Cu increased with increasing Cu concentrations, whereas liver Cu in chicks fed Cu-MONT only increased at 225 mg Cu/kg diet. Bile Cu increased ($P < 0.0001$) with increasing dietary Cu and was higher ($P < 0.05$) for Mintrex® Cu (24.6 mg/L) compared with Cu-MONT (18.4 mg/L) and $CuSO_4$ (20.0 mg/L). Using the slope-ratio technique from regression of bile Cu on Cu intake with Cu from $CuSO_4$ set at 100%, the relative biological availability values and associated confidence intervals (CI) were estimated to be 93.8% (CI: 77.6 - 113.3%) and 115.5% (CI: 97.3 - 139.3%) for Cu-MONT and Mintrex®Cu, respectively. Data indicate that Cu from Mintrex®Cu was more available to broiler chicks than Cu from Cu-MONT.

Key Words: Copper, Bioavailability, Bile, Mintrex® Cu, Cu-MONT

M68 Effects of lignin and Bio-Mos on broiler performance and gut microbiology after *E. coli* and *Salmonella* challenge. B. Baurhoo*, C. A. Ruiz-Feria, and L. Phillip, *McGill University*, *Ste Anne de Bellevue, QC, Canada*.

Three experiments were conducted to evaluate the effects of virginiamycin, Bio-Mos and Alcell lignin using antibiotic-free diets on growth performance, feed efficiency, and cecal loads of Lactobacilli and Bifidobacteria (Exp. 1); cecal *E. coli* load after gavage (O2 and O88, Exp. 2); *Salmonella* internalization into jejunum after an in vivo challenge with S. enteritidis (PT4, Exp. 3). Dietary treatments for the 3 studies were: 1) antibiotic free (CTL-), 2) positive control (CTL+, 11 mg/kg virginiamycin), 3) MOS (diet 1 + 0.1% Bio-Mos), 4) LL (diet 1 + 1.25% Alcell lignin), and 5) HL (diet 1 + 2.5% Alcell lignin). 1040 day-old male Cobb 500 broilers were randomly assigned to the treatments (4 pen replicates). BW and feed intake did not differ among treatments. However, at d 35, feed conversion ratio was higher ($P < 0.05$) in birds fed CTL+ than CTL- fed birds. The cecal Lactobacilli load was highest ($P < 0.05$) in birds fed MOS or CTL- at d 28, and, at d 38, in MOS fed birds. At d 28 and 38, cecal Bifidobacteria loads were highest ($P < 0.05$) in birds fed MOS or CTL-, whereas Lactobacilli and Bifidobacteria loads were lowest ($P < 0.05$) in birds fed CTL+ or HL. At d 21, birds were transferred to cages for the *E. coli* challenge. At d 3 and 9 after *E. coli* challenge (n = 12), birds fed HL had lower ($P < 0.05$) cecal E. coli loads than CTL- or CTL+ fed birds. At d 9 after challenge, MOS fed birds had lower ($P < 0.05$) *E .coli* load than birds fed CTL- or CTL+. The *E. coli* loads did not differ in birds fed MOS, LL or HL. In *Salmonella* challenge study, at d 31, birds fed MOS or HL had lower ($P < 0.05$) internalized *Salmonella* in the jejunum than CTL- fed birds. Moreover, *Salmonella* load was lower ($P < 0.05$) in HL fed birds than those fed CTL+; but not different in birds fed CTL+, CTL- or LL. Therefore, as compared to birds fed CTL+, birds fed MOS and lignin had increased cecal Lactobacilli and Bifidobacteria loads, and, in the challenge studies, lower cecal E. coli and internalized *Salmonella* loads. MOS and lignin could potentially replace antibiotic growth promoters in poultry production.

Key Words: Broilers, Gut health, Antibiotic, Bio-Mos, Lignin

M69 Bioefficacy of an exogenous protease from *Bacillus amyloliquefaciens* in corn/soy-based diets for broilers. A. J. Cowieson[1], E. E. M. Pierson*[3], and J. M. McNab[2], [1]*Danisco Animal Nutrition*, *Marlborough, Wiltshire, United Kingdom*, [2]*Roslin Nutrition*, *Roslin, Midlothian, United Kingdom*, [3]*Danisco Animal Nutrition*, *St Louis, MO*.

The efficacy of an exogenous protease was examined using a total of 200 male Ross broiler chickens in a 5 treatment and 8 replicate 21d growth study. A maize/soy-based control diet was formulated to contain adequate concentrations of digestible P, Ca and energy (0.40%, 0.90% and 3070kcal/kg respectively) but to be marginal in Lys and TSAA (approx 85% NRC). This control diet was then supplemented with a bacterial protease at 3,000-40,000 U/kg. Weight gain was improved (P<0.05) by around 10% and FCR by around 3 points by supplementation of the diet with protease. Furthermore, the ileal digestibility of energy was improved (P<0.05) by around 90kcal/kg. Most of the beneficial responses were noted at 3,000-6,000 U/kg, with little additional benefit of supra-doses (up to 40,000 U/kg). Interestingly the ileal digestibility of N was not significantly improved with protease. The effect of protease on performance was assumed to be associated with an improvement in the retention of the limiting nutrients in this study (lys and SAA), however the measured responses were more apparent for energy than for amino acids. It is possible that the presence of exogenous protease in the GIT was detected via the CCK feedback mechanism, reducing pancreatic protease secretion and so lowering amino acid requirements of the animal. These net effects are interesting and require further elucidation. It can be concluded that protease is effective in improving performance of broilers fed corn/soy-based diets but the mechanisms are not fully understood.

Key Words: Enzymes, Protease, Corn, Soybean meal, Broiler

M70 Rapid and dramatic improvement in color intensity of brown egg shells from caged laying hens fed dietary CALSPORIN® (*Bacillus subtilis* C-3102 spores) in a commercial field trial in China. H. Miyazaki[1], S. Chou[2], M. Kato[3], and D. M. Hooge*[4], [1]*Calpis Co. Ltd*, *Tokyo, Japan*, [2]*Shanghai Naseco Ltd*, *Shanghai, China*, [3]*Calpis USA, Inc.*, *Elgin, IL*, [4]*Hooge Consulting Service, Inc.*, *Eagle Mountain, UT*.

China has a population of over 1.3 billion people with about 1.3 billion laying hens of which ~80% are brown egg strains. Uniformity and intensity of brown egg color are important marketing considerations because excellent brown egg color (and shell quality, as reported previously) can extend production, bring a premium price (Japan and Korea), or enhance marketing of natural and organic eggs (U.S.). Brown egg color becomes lighter as hens age. An investigation was conducted using dietary CALSPORIN®, a commercial direct-fed microbial product containing *Bacillus subtilis* C-3102 spores, to demonstrate the brown egg color enhancing effect of CALSPORIN® already observed in other situations. Lohmann brown hens, 65 wk 4 d (459 d), at Xiazhuang Egg Farm, Beijing, China and caged in 10 houses of 9,000 birds each, were fed CALSPORIN® for 13 d. Inclusion levels were 1 x10^6 CFU/g feed (3.33x) for 7 d (459 to 465 d) and 6 x 10^5 CFU/g feed for 6 d (466 to 471 d). Shell color was determined daily before and during CALSPORIN® feeding, except 1 d (446 d), from 63 wk 3 d (444 d) to 67 wk 1 d (471 d) from ~150 hens designated for the trial (84-125 eggs/d; collection d=26, 13 before and 13 during) using an egg color fan (1=light to 10=dark brown; Ghen Corp.). Daily weighted mean egg shell color scores were: before -- 6.02, 5.46, 5.15, 5.72, 5.68, 5.78, 5.83, 5.75, 5.56, 5.82, 5.60, 6.30, 5.92 (5.74, 13 d, n=1,393 eggs); during -- 6.12, 5.75, 5.87, 6.20, 6.10, 6.46, 6.60, 6.35, 6.50, 6.22, 6.47, 6.33, 6.84 (6.29, 13 d, n=1,321 eggs, vs 5.74 $P < 0.001$ by 1-way ANOVA). Compared to the period before, CALSPORIN® feeding increased egg counts in fan color score categories #7 (23.60% vs 14.11%, $P < 0.001$) and #8 (22.78% vs 17.98%, $P < 0.001$), and this shift was associated with a decreased egg count in #3 (5.03% vs 13.16%, $P < 0.001$). Dietary CALSPORIN® rapidly and significantly ($P < 0.001$) improved brown egg shell color.

Key Words: Bacillus subtilis C-3102, Brown egg, CALSPORIN, Color fan, Shell color

M71 Dose titration and safety margin of fumaric acid in broiler. A Schumacher[1], K Bafundo[2], K. M. S Islam*[3], H Aupperle[4], and J. M Gropp[1], [1]*Leipzig University*, *Leipzig, Germany*, [2]*Phibro Animal Health,Ridgefield Park*, *Ridgefield Park, NJ*, [3]*Bangladesh Agricultural University*, *Mymensingh, Bangladesh*, [4]*Leipzig University*, *Leipzig, Germany*.

Six isonitrogenous (22.8 % CP) and isocaloric diets (13 MJ ME kg-1) containing 0, 1.25, 2.50, 3.75, 5.0, and 7.5 % fumaric acid (FA), respectively, were fed for 26 days to 12 (replicates) x 8 (chicks per replicate) Lohmann-Hybrid newly hatched male chicks (48 g body weight) per treatment. The diets consisted mainly of wheat and soybean meal. Mortality ranged between 0 and 4 %. Final body weight (feed efficiency) amounted to 1,506 (756), 1,597 (767), 1,532 (754), 1,485 (759), 1,342 (738), and 1,378 g (747 g gain kg-1 feed) for the groups with 0, 1.25, 2.50, 3.75, 5.0, and 7.5 % FA, respectively. The 1.25 % FA group showed significantly (p<0.05) better weight gain than all other groups and better feed efficiency than the groups with 5.0 and 7.5 % FA. Higher gain was associated with higher feed intake. It is concluded that 1.25 % FA may promote growth of broilers, but the effect disappears with further increasing doses. Body weight of the 5.0 and 7.5 % FA groups was significantly lower than that of all other groups. The relative weight of heart, liver and spleen was not affected by the treatment. Pathological findings summarized to 5/10 in the 7.5 % FA group, to 1/10 in the control and to 2-3/10 in the other groups. The 7.5 % FA grouped showed also the highest incidence of kidney alterations. From the findings the margin of safety is concluded to be about 3 (3.75/1.25) considering 1.25 % FA in the diet as the optimally effective concentration.

Key Words: Fumaric acid, Performance, Safety, Broiler

M72 Effect of plane of rearing nutrition of broiler breeder females on body weight, egg production, fertility, and progeny performance. H Romero-Sanchez*[1], P. W. Plumstead[2], N. Leksri-sompong[2], K. E. Brannan[2], and J. Brake[2], [1]*Universidad de Antioquia*, *Medellin, Colombia*, [2]*North Carolina State University*, *Raleigh*.

An experiment was conducted to evaluate the effects of two levels of cumulative nutrient intake during the rearing period to 21 wk of age on female broiler breeder performance. A total of 1,120 day old Ross 308 female broiler breeders were reared in 16 floor pens in a blackout facility. From 0-2 wk all birds received a starter feed after which four

pens of pullets were randomly assigned to each of the experimental diets. Two diets were formulated and a single feeding program was used to achieve either a high or a low cumulative nutrient intake. The high cumulative nutrition program (HiDiet; 16.7% CP, 3.25 kcal ME/g) supplied 26.6 Mcal ME and 1,370 g CP, while the low cumulative nutrition program (LoDiet; 14% CP, 2.85 kcal ME/g) supplied 23.5 Mcal ME and 1,160 g CP to photostimulation at 21 wk of age. From 22 to 24 wk the two diets were blended to provide a gradual transition to a single common breeder diet (2,925 kcal/kg ME and 15% CP) that was then amended with calcium and fed throughout the production period. The HiDiet plane of nutrition increased female BW during the rearing period and the differences were maintained until 58 wk of age. The LoDiet plane group exhibited better egg production but no significant differences were observed for fertility, hatchability, or broiler progeny performance. The data showed that a cumulative nutrient intake during the rearing period of 23.5 Mcal ME and 1,160 g CP resulted in a bird of adequate BW at 21 wk of age that produced more eggs and was able to maintain good fertility without significant effects on progeny performance.

Key Words: Broiler breeder, Rearing nutrition, Growth, Fertility, Broiler performance

M73 Performance and health of broiler due to dietary humic acid. K. M. S Islam*[1], A Schuhmacher[2], C Ellenberger[3], H. -A Schoon[3], and J. M Gropp[2], [1]*Bangladesh Agricultural University,*, *Mymensingh, Bangladesh*, [2]*University of Leipzig*, *Leipzig, Germany*, [3]*University of Leipzig*, *Leipzig, Germany*.

Six diets containing 0, 0.3, 0.6, 1.2, 2.4, and 4.8 g Huminfeed® (74 % humic acid in DM) /kg were offered to 480 (6 treatmentsX10 replicatesX8 birds/replicate) Lohmann-Hybrid newly hatched male chicks to know the performance and health status. The diets formulated based on wheat and soybean meal (25.3 % CP, 12.8 MJ ME /kg). After 35 days feeding trial 60 birds (1 per replicate) were killed for necropsy. Initially HA depressed weight gain, but recovery started in the third week, so that at the end no significant differences could be observed (2,408, 2,369, 2,335, 2,355, 2,310 and 2,301 g for the groups with 0, 0.3, 0.6, 1.2, 2.4, and 4.8 g Huminfeed®/kg respectively). Feed intake was not affected by the treatment. Feed efficiency of the 4.8 g Huminfeed®/kg group was significantly lower (689) than control (723 g gain /kg feed) at the end of trial. Mortality ranged between 1.25 and 8.75 %, being highest in the control. The relative weight of liver, spleen, Bursa Fabricii and thyroid gland did not differ among the groups. Morphometric parameters (number and diameter of follicle, epithelial height, length and width of nucleus, number of hyperplasia and follicular epithelial index) of thyroid gland demonstrated absence of any dose related response of HA. So, the inclusion of HA at the level of 8 % (2.4/0.3) is possible without hampering performance and without causing any clinical condition in broiler.

M74 Effect of a hatchery nutrition supplement on broiler placement body weight and growth rate. S. Henderson*, J. Vicente-Salvador, C. Pixley, G. Tellez, and B. Hargis, *University of Arkansas*, *Fayetteville*.

Previously we have reported that administration of the perinatal nutrition supplement EarlyBird™ (EB; Ivesco, LLC) at a dose of 2 g/chick in chick boxes reduced body weight loss during 24-h simulated shipping conditions. Recently, we observed higher body weights at placement ($p<0.05$) in leghorn chicks (4.5%; 1.52 g) and broiler chicks (2.1%; 0.78 g) when chicks were weighed and treated (3 g EB/chick) prior to leaving the commercial hatchery and re-weighed upon arrival at the farm. To examine the effect of this conservation of weight on broiler chick performance, three experiments were conducted comparing the use of EB to no supplementation (NS). For each experiment, broiler chicks from a commercial hatchery were neck-tagged, individually weighed, and randomly placed in chick boxes (n=100/box). In all experiments, treated chicks received 2 g EB/chick in plastic chick boxes, covered boxes were immediately stacked, and held under ambient light (~42 FC). Following the 24-h simulated shipping period, chicks were individually weighed and randomly assigned to replicate pens. Body weights (BW) and BW gain (BWG) were determined at placement, 7, and 21 d (exps. 1-3), as well as 28 and 42 d (exp. 3 only). Weight loss prior to placement was reduced ($p<0.05$) by EB treatment in exp. 1 (1.86 g), exp.2 (0.92 g), and exp. 3 (1.63 g). EB treatment caused increased ($p<0.05$) BWG at 7 d in exp. 1 (11 %; 9.0 g), and exp. 3 (4.0 %; 3.6 g) and at 21 d in exp. 1 (2.7%; 16.1 g) and exp. 3 (2.1%; 14 g), with no difference in exp 2. Chicks in exp. 2 were unusually large at placement (49 g), but were 14% or 23% smaller at 7 d as compared to control chicks in exp. 1 and 3, respectively, suggesting suboptimal conditions for exp. 2. In exp. 3, EB-treatment increased ($p<0.05$) BWG at 28 d (3.1%; 34.7 g) and at 42 d (2.7%; 57.7 g). Hatchery application of EB reduced weight loss during chick transportation prior to placement in all experiments. Furthermore, in 2 of 3 experiments, hatchery treatment with EB resulted in continued segregation of BW and BWG during growth.

Key Words: Perinatal nutrition, Chick supplement, Performance, Early bird, Holding

M75 Brooding light intensity effects on broiler performance. A. J. Brown*[1], B. D. Fairchild[1], R. J. Buhr[2], and A. B. Webster[1], [1]*University of Georgia*, *Athens*, [2]*Russell Research Center, USDA-ARS*, *Athens, GA*.

Light intensity is an environmental factor which is used with a high degree of variation throughout the US Broiler Industry. Light intensity influences bird activity, immune response, growth rate and has been used to alleviate mortality issues related to metabolic disease (spiking mortality). The objective of the current study was to determine the effect of light intensity during the 10 days of brooding on bird performance. Two trials were conducted utilizing three light intensities

(15, 25, 45 lux). Each light intensity treatment was applied to chicks from day 1 through day 10. After day 10, the light intensity was reduced to 5 lux in each room. Each light treatment was applied to two rooms with six pens in each room. A bird density of 0.7 ft2 was used resulting in 40 birds per pen. Water and a standard broiler diet were provided ad libitum. Broiler management protocols followed the breeder company recommended guidelines.

In Trial 1, 25 lux resulted in significantly greater BW gain and gain to feed ratio but lower feed consumption at 7 days while 45 lux resulted in significantly greater BW gain at 21d. In Trial 2, BW gain and gain to feed were significantly greater for 25 and 45 lux when compared to 15 lux. No significant differences were noted among the treatments at 42 days of age in either trial. While there were differences in the results between the two trials, similar trends were apparent with the broilers provided 15 lux having the poorest performance. The results of the current study suggest that having light intensity too low (15 lux) during the brooding period will have negative results on broiler performance. The data from Trial 2 suggests that higher intensity light may be beneficial to broiler performance, but due to differences between the two trials the effects of intensities above 25 lux are inconclusive at this time.

Key Words: Broiler, Light intensity, Feed conversion, Lighting programs

M76 Effect of varying brooding management practices on broiler performance parameters and processing yield. A. H. Nilipour*[1], E. Robles[1], C. Rosales[1], F. Mora[2], and G. D. Butcher[3], [1]*Empresas Melo, S.A.,*, *Panama City, Rep of Panama*, [2]*Universidad de Panamá*, *Panama City, Rep of Panama*, [3]*University of Florida*, *Gainesville*.

With the advancing of genetics, health care and nutrition, the time period allotted for broilers to achieve optimal market body weight and meat characteristics is decreasing. The first two weeks of life comprise more than 30% of the broiler lifespan. A broiler from setting lives about 1500 hours (500 hrs incubating, 336 brooding, and 700 hrs growing). Management during the first 336 hrs (2 wks) affects final performance. A study was conducted at the Empresas Melo Experimental station where a total of 1692 Cobb X Cobb female and male broilers were sexed and randomly allocated into 36 pens of 47 chicks each. Feed and water were provided ad libitum, and commercial feeds were utilized. Two brooding management treatments were utilized each containing 18 replicates of 9 female and 9 male pens with total of 846 birds. Treatments were 1- Normal Management (NM) and 2- Modified Management (MM). Both trts had 23 hrs light for 7 days, MM had 20 hrs light till 14 days. Heat brooding extended from 9 to 14 days and chicks had access to an extra feed tray. Birds were individually weighed on arrival at DOA and weekly, thereafter. Feed consumption per pen was weighed to calculate the weekly and accumulative feed conversions (FC). Percent mortality and culls were calculated. At 43 DOA a total of 56 birds (14 per sex and trt) were randomly selected and eviscerated, and all parts collected and weighed. Weekly body weights and index were in favor of MM. However, at 42 DOA, weights were equal. Throughout the study MM % uniformity was consistently higher (3-6%), conversions (-2-3 points). Total carcass yield were 68.93, 67.48%, respectively, in favor of MM. Front halves were 37.47, 36.93, with % breast being 31.46, and 30.55%. When all meats (breast, thigh and muscle) were considered, 35.10 vs. 34.28% of the chicken is meat. MM improved total production costs by 0.25 cents per pound. Applying MM improved broiler performance parameters such as FC, uniformity while at the same time improved the salable part of the chickens, especially of breast meat.

Key Words: Broilers, Yield, Management, Chicks, Brooding

M77 Evaluation of drinking water or post-pelleting probiotic administration alone or in combination with a phytogenic product on broiler performance. D. J. Caldwell*[1], N. H. Eckert[1], J. T. Lee[1], S. M. Stevens[1], R. Beltran[2], M. Mohnl[2], and G. Schatzmayr[2], [1]*Texas A&M University*, *College Station*, [2]*Biomin GmbH*, *Herzogenburg, Austria*.

The present trial was conducted to evaluate the effects of either drinking water or post-pelleting feed application of a commercially available probiotic, Biomin® PoultryStar, alone or in combination with a phytogenic product, Biomin® P.E.P. 125 Poultry, on broiler performance during a 48 day pen study. Probiotic was administered to broilers either through the drinking water or by post-pelleting feed application. Phytogenic product was administered by inclusion within the starter and grower diets during grow-out. Experimental groups included a non-treated control group, a probiotic group with intermittent drinking water administration, a post-crumble or post-pelleting probiotic application by feed group, and a phytogenic product administration by feed group. On day of placement, 1,880 straight-run broiler chicks were randomly distributed to 40 pens allowing for 10 replicate pens per group. Broilers were reared on litter consisting of half used litter from a commercial broiler house and half fresh pine shavings. Feed and water were provided to all broilers ab libitum. The ration fed to broilers in both trials was a standard corn-soy ration fed in a four diet feeding program (starter, grower, finisher, and withdrawal). Drinking water application of probiotic was by a medicator system in place within the grow-out house. Across experimental groups, broilers receiving intermittent administration of probiotic by the drinking water performed better in terms of body weight gain and feed conversion. Specifically, body weights were higher ($P<.05$) on days 15, 30, and 40 of grow-out in broilers in the drinking water probiotic group. Similarly, feed conversion was improved ($P<.05$) in broilers receiving probiotic by drinking water application between days 1 and 40 of grow-out. Phytogenic product administration within the starter and grower phases of grow-out was not associated with increased body weight gain but was associated with improved ($P<.05$) feed conversion between days 1 and 40 of this trial.

Key Words: Probiotic, Phytogenic product, Drinking water, Post-pelleting, Broiler performance

M78 Drinking and eating as related to type of drinking fountain in broilers. J. P. Thaxton* and Z. T. Williams, *Mississippi State University*, *Mississippi State*.

Two separate trials were conducted, one during spring and the other during summer. In both trials 5 wk-old broilers were reared in pens (1.84 x 3.68 M) possessing fresh pine shavings litter in a curtain-sided grow-out facility. This facility was power ventilated and natural lighting prevailed. Ten chicks were maintained in each pen and each

bird was marked with paint so that individuals could be identified. Each pen possessed a centrally located hanging-type feeder and either a single Plasson drinking fountain or a nipple fountain that consisted of six nipples each of which was calibrated to deliver between 35 and 40 mL/min. In both trials, on d 36 through 40 two pens of birds were observed for 60 min starting at 0800 h. The observer recorded numbers of drinking and eating actions, as well as the time duration of each action on an individual bird basis. Results show that incidences of drinking and eating actions, as well as the durations of these actions, were not different among individual birds. However, seasonal differences in numbers of drinking and eating actions were found. Specifically, in spring birds averaged 2.46 drinks/h and 2.36 eating actions/ h and in summer these averages increased to 6.58 drinks/h and 4.36 eating actions/ h. Durations of drinking and eating times were also influenced by season. Average duration of a drink in spring was 45.6 sec and 73.1 sec in summer, while average eating time in spring was 169.6 sec and 113 sec in summer. The type of drinking fountain also influenced both numbers of drinking actions, as well as average duration of each drink. The number of drinks for birds over both seasons with nipple drinkers was 6.08 and 2.96 for those with a Plasson fountain. The average drinking time over both seasons from nipple drinkers was 80.3 sec and 38.5 for the Plasson drinker. Average eating time for birds drinking from nipples was 125.9 sec and those drinking from a Plasson fountain were 156.8 sec.

Key Words: Drinking, Season, Eating, Broiler

M79 Water consumption as a broiler management tool. B. D. Fairchild*[1] and M. Czarick[2], [1]*University of Georgia*, *Athens*, [2]*University of Georgia*, *Athens*.

Many broiler farms have water meters to monitor bird water consumption and most modern house environmental controllers are able to accept inputs from water meters and log the daily consumption. Water consumption is a parameter that while monitored is not utilized extensively in broiler house management however, it is a useful tool that when utilized, can provide timely information about bird performance and health status. The recent models of many of the computer controllers common in broiler houses are now accepting multiple digital inputs that allow several water meters to be used per house. So in theory a water meter could be used to monitor water in the front of the house, the back of the house, the evaporative cooling system, etc. A field evaluation of bird water consumption on several commercial broiler farms has been conducted utilizing two water meters per house for several years. Monitoring bird density in the front and back of houses has proven to be effective in determining the effects uneven bird distribution has in broiler houses. Observations have been made when bird distribution in houses differed as much as 40% between the front and back. Using digital photographs of the birds allowed estimates of bird density to be made in different areas of the houses. Comparing water consumption within the houe and using those comparisons to determine flock distribution between front and back of the house has resulted in bird distributions within 1 to 2 percent on subsequent flocks.

Individual water lines in the houses have also been monitored for the last six months with the objective of examining water use among the different lines in the house as well as various management factors that might influence water consumption. Most houses have four to five drinker lines in each end of the house. These studies have shown the inner water lines are used 25% more than the outer water lines. The difference in water consumption between the inner and outer lines appeared to decline as the birds get older. The results of this evaluation indicate that water consumption can be a useful tool in day to day broiler house management.

Key Words: Broiler, Drinking water, Management

M80 Growth performance of Rock Partridge (Alectoris graeca) under intensive conditions. S. Dikmen*, F. Alpay, and M. Petek, *University of Uludag*, *Bursa, Turkey*.

Partridge′s are game birds in the wild and there are four major markets: hunting preserves, gourmet food markets (mostly restaurants), individuals who buy live birds for custom slaughter and individuals who want to restock birds in the wild. And also recently it has been shown that partridge, especially the rock partridge, can also be raised for meat production. A trial was conducted to determine the growth performance and survival rate of rock partridge under intensive conditions. Seventy eight 1-day-old chicks were used. Chicks were weighed at hatching and fortnightly and recorded. Feed consumption was determined at the same time and the feed conversion ratio (kg feed / kg gain) was calculated. The experimental period was 16 weeks with the first 8 weeks as the starter period and the last 8 weeks as the grower period. Liveweight of partridge′s (g) at hatching, 1 mo, 2 mo, 3 mo and 4 mo of age were found 14.64±0.19, 73.27±1.94, 251.66±3.99, 390.72±7.23 and 457.82±8.33, respectively. Cumulative feed consumption (g) and feed conversion ratio (kg feed / kg gain) were found 2883 and 6.51, respectively, at the end of the study. Survival rate at 1 mo, 2 mo, 3 mo and 4 mo of age were found 84.2, 82.4, 70.1 and 63.1% respectively. In conclusion, under intensive conditions partridge′s perform a good growth performance but survival rate is low for mature age. According to the results of this study, further studies can be done for improving partridge performance and survival rate.

Key Words: Rock partridge, Growth performance, Survival rate

M81 Evaluate performance parameters and evisceration yield when incorporating two US Corn (before and after Katrina) vs. Argentinean corn. A. H. Nilipour*[1], R. Fabrega[1], E Robles[1], F Mora[2], and G. D. Butcher[3], [1]*Empresas Melo, S.A.*, *Panama City, Rep of Panama*, [2]*Universidad de Panama*, *Panama City, Rep of Panama*, [3]*University of Florida*, *Gainesville*.

Corn is a major imported grain used in poultry feed in Panama. Its quality can greatly influence production parameters and intestinal health. Due to hurricane Katrina, imports from the US were halted, thus Argentinean corn and fresh US corn, when imports were reestablished, were utilized. A study was conducted at the Empresas Melo Experimental station where a total of 1692 Cobb X Cobb female and male broilers were sexed and randomly allocated into 36 pens of 47 chicks each. Standard management practices were applied and commercial feeds with different corns utilized. Three treatments were utilized each containing 12 replicates of 6 female and 6 male pens with total of 564 birds. Treatments were 1- Control. US corn A (USCA), 2- Corn B (USCB), and 3- Argentine Corn (ARGC). Birds were individually weighed on placement, at DOA, and weekly, thereafter. Feed consumption per pen was weighed to calculate the weekly and accumulative feed conversions. Percent mortality and culls were also calculated. At 50 DOA a total of 18 birds (9 per sex) per treatment were randomly selected and eviscerated. The final body weights USCA vs. ARGC (+74 grams), conversions (-2 points) and performance index (6 points) were improved when CARG was used. There was 0.42 cents reduction in production cost utilizing Katrina corn. Total carcass yields were 71.31, 70.60 and 71.01%, respectively. Front halves of the breast % being 31.71, 31.06 and 31.25%. When all meats (breast, thigh and muscle) added, 37.48, 37.46, and 38.48% of the chicken is meat. ARGC inclusion improved total meat yield 1%, over US corn diets. Older US corn consistently had lower performance parameters, while ARGC improved body weight, feed conversion, and saleable part of the chickens, especially of breast meat.

Key Words: US corn, Argentinean Corn, Broilers, Yield

M82 The impact of two incubator systems upon moisture content in eggs and chicks. S. L. Funderburk*[1], M. J. Wineland[1], J. Beavers[2], J. Shepard[2], H. R. Cutchin[1], K. M. Mann[1], V. L. Christensen[1], and E. O. Oviedo-Rondon[1], [1]*North Carolina State University*, *Raleigh*, [2]*Mountaire Farms*, *Siler City, NC*.

Understanding how the environment within both single stage (SS) and multi-stage (MS) systems affects chick quality is needed by the industry in order to produce optimal quality chicks. Once an understanding of each system type is established, management of the systems can be done in order to have a significant impact on the economic return to both the integrator and the grower. The objective of this project is to compare the effects of SS and MS systems on chicks at hatching. Experiments were conducted to evaluate egg and chick characteristics between the incubator systems. Eggs of prime Ross 708 flocks were weighed and incubated, using SS and MS systems. At D18 eggs were reweighed and moisture loss was calculated. At hatch chicks were randomly sampled from each treatment. Sampling was done by carefully separating the chick and residual yolk and weighing to the nearest 0.01g. Yolk and chick samples were dried down in a 70°C oven in order to remove all moisture. Moisture content of the chick and residual yolk were calculated. SS and MS incubation systems affected the moisture loss among eggs and chicks differently. MS systems consistently lead to approximately a 2% higher moisture loss among eggs throughout incubation. Among chicks more moisture was found in the yolk of chicks hatching from SS systems, while the amount of dry yolk matter was less compared to the MS system. Yolk weights of chicks hatching from MS systems were higher, where chick weights were lower compared to the SS systems. Therefore, a higher percentage of chick to initial egg weight was found among SS systems. The incubation environment can affect the amount of moisture that is lost from the eggs and the moisture present in the chick at hatching. Additionally, the incubation system may have an effect on the ability of the embryo to utilize nutrients during incubation and impact the quality of the chick at hatching.

Key Words: Single stage, Multi-stage, Moisture loss

M83 Turkey embryo muscle growth and physiology is affected by incubator temperature and oxygen concentrations. V. L. Chrisensen*, M. J. Wineland, J. L. Grimes, D. Ort, S. Funderburk, P. E. Mozdziak, E. de Oviedo, and K. M. Mann, *North Carolina State University*, *Raleigh, NC*.

Incubator temperature and oxygen concentration may affect embryonic muscle development. Randomly selected turkey eggs were set in the same incubator for the initial 24 days of incubation. At that time, the eggs containing viable embryos were randomly divided into groups and placed in four experimental cabinets until hatching. Each cabinet was operated at temperatures (T) and oxygen concentrations (Ox) in a 2 T (36° and 39°C) x 2 Ox (17 and 23%) factorial arrangement. At 27 and 28 days of incubation, 10 embryos or poults were sampled from each cabinet. Blood was obtained following decapitation. The pipping (musculus complexus), breast (pectoralis thoracicus) and thigh muscles (gastrocnemus) were collected from each embryo, and each muscle was placed in cold 7% perchloric acid (5 mL/g of muscle) for glycogen and lactate analysis. An additional 5 embryos were sampled for histological analyses of muscle fibers. Blood plasma creatine kinase (CK) and lactate dehydrogenase (LDH) activities were measured. T and Ox affected muscle growth differently. Pipping muscle weights at day 27 were higher ($P<0.05$) for 23% Ox compared to 17% Ox, and T and Ox exhibited a significant interaction at hatching to affect the pipping muscle weight. Breast muscle weights increased at 27 days for 39°C compared to 36°C but the reverse was noted at hatching. The thigh muscle weight was affected only at hatching as 23% Ox weights were higher compared to 17% and 36°C weights were higher compared to 39°C, but the two factors did not interact. The CK and LDH activities were also affected at 27 days because 39°C incubation was associated with elevated CK and LDH activities, compared to 36°C. At 28 days, only CK was affected as 39°C elevated CK activity in the 23% oxygen environment, but not in the 17% environment. Thus, incubator conditions affect muscle development and function in poults.

Key Words: Embryo, Muscle grow and function, Incubation

M84 A new technique for measuring core temperatures of commercial broilers. K. D. Christensen*[1,2] and J. P. Thaxton[1], [1]*Mississippi State University*, *Mississippi State*, [2]*O.K. Industries, Inc.*, *Fort Smith, AR*.

Understanding core temperatures of commercial broilers should allow the identification of exact temperature profiles to maximize performance and bird welfare. Three trials were conducted to determine the feasibility of using Radio Frequency Identification microchips (RFID) with temperature-sensing capability to monitor deep core temperatures of broilers compared to rectal temperatures taken with a digital thermometer. In Trial 1, Day-old commercial broiler chicks were implanted with an RFID subcutaneously in the area between the wings or gavaged with an RFID. Temperatures collected from the RFIDs were compared to rectal temperatures. Implanted RFIDs provided temperatures throughout the 49 day trial period. RFIDs in the gizzard remained in the gizzard for up to 10 days but were either damaged by the muscular contractions of the gizzard or expelled. In Trial 2, commercial broilers were implanted with an RFID, or gavaged with an RFID. An antenna and microprocessor installed in the pen was used to collect and store the temperature data over time. In addition, rectal temperatures were taken and compared to RFID temperatures recorded at the same time. In Trial 3, an RFID was attached to the probe of a digital thermometer. Rectal temperatures of random birds were taken daily until Day 10 and then weekly through Day 49 from two commercial houses with two temperature profiles. Rectal temperatures and RFID temperatures were taken simultaneously using the modified probe. Results of these trials indicate that RFID can be a useful tool to monitor body temperature of commercial broilers. Using this information to improve the growing environment of commercial broilers should result in improvements in performance. Many advances in bird welfare can be made with a thorough understanding of the response of deep core temperatures to management practices.

Key Words: Body temperature, Commercial broilers, Microchip, Welfare, New technique

M85 Dietary calcium, phytate, and phytase control water soluble P excretion from broilers. A. B. Leytem*[1], P. W. Plumstead[2], R. O. Maguire[3], P. Kwanyuen[4], and J. Brake[2], [1]*USDA-ARS*, *Kimberly, ID*, [2]*North Carolina State University*, *Raleigh*, [3]*Virginia Tech*, *Blacksburg*, [4]*USDA-ARS*, *Raleigh, NC*.

Soluble phosphorus (P) in broiler litter and manure is important from an environmental perspective as it is related to potential off site P losses following land application. The effects of altering dietary P, calcium (Ca), phytate P, and the addition of phytase on litter and manure P excretion in broilers were investigated. Study I consisted of a 3 x 3 x 2 factorial treatment structure that was applied from 14 to 42 d of age with 3 levels of available P (AvP) of 0.35%, 0.30%, and 0.25% combined with 3 levels of Ca of 0.80%, 0.69%, and 0.57% with phytase applied at either 0 or 600 FTU/kg. Study II consisted of a 3 x 4 factorial treatment structure that was applied from 16 to 20 d of age with 3 levels of dietary phytate P (0.10%, 0.23%, and 0.27%) combined with 4 levels of dietary Ca (0.47%, 0.70%, 0.93%, 1.16%). To assess treatment effects on P excretion, fresh litter was collected when the broilers were 41 d of age in Study I, and fresh manure was collected when broilers were 20 d of age in Study II. Litter and manure were analyzed for total P, soluble P, and phytate P. Results indicated that the inclusion of phytase at the expense of inorganic P, reductions in AvP, or reductions in dietary phytate P decreased total P excretion. The ratio of Ca:AvP in the diets was negatively correlated with the solubility of P in the litter and manure. The effect of Ca on decreasing soluble P was greater in diets having a greater phytate P concentration. The ratio of litter soluble P:total P increased with phytase additions at all ratios of Ca:AvP. These data indicated that a decrease in litter or manure total P could be obtained by feeding diets with reduced AvP and phytase or by reducing phytate P in diets. However, the ratio of Ca:AvP in the diet was primarily responsible for effects on soluble P and was more pronounced in diets containing higher levels of phytate P.

M86 Influence of early light intensity on broiler performance and yield. J. B. Hess*[1], S. F. Bilgili[1], and E. R. Miller[2], [1]*Auburn University*, *Auburn, AL*, [2]*Mountaire Farms*, *Siler City, NC*.

Broiler strain responses to lighting programs continue to evolve as commercial strains change over time. The current trial examines the effects of light intensity during the first 9 d on Aviagen 708 broilers. Light intensities of 1, 2, 4 or 8 footcandles (fc) (23 h light; 1 h dark) were used on mixed-sex broilers (25 male and 25 females placed/pen) fed diets suggested by Aviagen (4 treatments, 4 light-controlled chambers/trt). At 9 d, all pens were switched to 20 h light and 0.25 fc. Light duration was returned to 23 h (0.25 fc) from 50 to 55 d. Body wt, uniformity and adjusted feed conversion ratio (FCR) were measured at 9 and 54 d. Mortality was monitored weekly and was summarized at 54 d. All birds were processed at 55 d to assess chilled carcass, abdominal fat, front half and parts yields.

Body wt were similar for 1, 2 and 4 foot candles at 9 d (236, 231, 234g respectively), while wt for birds given 8 fc was significantly ($p < 0.05$) lower (226g). No differences were seen in CV at 9 d, 54 d wt (although birds started on 8 fc had the lowest body wt numerically, 3839 vs 3870, 3859 and 3864g), FCR or mortality. Carcass yield of birds given 8 fc to 9 d was lower than that of birds given 4 fc (74.6 vs 75.7 %). Lean carcass yield showed similar results. No differences were seen in abdominal fat, front half yield or leg quarter yield. Fillet yield was lower in birds given 8 fc to 9 d than in those given 1 or 4 fc (19.5 vs 19.8 and 19.7% respectively). No differences in wing, tender or total breast yield were recorded. Early light intensity appeared to influence growth in Aviagen 708 broilers, with intensities up to 4 fc showing no growth reduction.

Key Words: Light intensity, Broiler, Yield

M87 Effects of three lighting programs during grow on performance of commercial egg laying varieties. 1. Growing period. N. P. O'Sullivan*, P. Settar, J. Arango, S. Saxena, and J. Arthur, *Hy-Line International*, *Dallas Center, IA*.

An experiment was set to compare the effect of slow (SL), moderate (ML) and rapid (RL) step down light programs (LP) during the growing period of commercial layers. Experiments were carried out in two phases: PH1 (Spring 2005) compared W36 and W98, and PH2 (Fall

2005) included one white (W98) and one brown (HYB) egg variety. A total of 500 pullets per variety were individually wing banded at hatching, and moved to the grow house by variety with 20 h of light during the first week. Three replicates were kept in separate pens by variety-LP during the rest of the growing period. The LP differed in the rate of step down duration of artificial light exposure. All groups started with 20 h light at week one; thereafter, the light exposure decreased 1h/2wk (SL), 1h/wk (ML) and 4h/wk (RL), to 13, 9 and 12 h at weeks 15, 12 and 3 for SL, ML and RL, respectively. Thereafter, SL plateaued at 13 h of light ML and RL plateaued at 9 h till week 17 when all treatments received 10 h of light. Weekly individual body weights (BW) were collected in the grow house up to 17 weeks of age, when the birds were transferred to the layer house. Body weight records were analyzed by variety using least square means procedures. Model included the effect of LP and pen within LP, age (wk) and its interaction with LP and residual. The models' R-squares were over 0.93 for both lines and phases. There were significant differences in growth due to LP. In general, BW was highest for SL and smallest for RL, being intermediate for ML. In PH1 SL birds were, relative to ML and RL, respectively, +18 and +52 g for W36, and -4 and +20 g for W98. In PH2 these figures were +23 and +36 g for W98, and +24 and +45 g for HYB. The SL treatment resulted in heaviest pullets. Final conclusions are pending results of the residual effect of LP during laying on production and egg quality.

Key Words: Laying hens, Growing, Body weight, Light programs, Lighting

M88 Effects of three lighting programs during grow on performance of commercial egg laying varieties. 2. Laying period egg production. J. Arango*, P. Settar, S. Saxena, J. Arthur, and N. P. O'Sullivan, *Hy-Line International*, *Dallas Center, IA*.

An experiment was set to compare laying period effects of slow (SL), moderate (ML) and rapid (RL) growing light programs (LP). The experiments were carried out in two phases: PH1 compared W36 and W98, while PH2 included one white (W98) and one brown (HYB) egg variety. A total of 500 pullets per variety were wing banded, and grown by variety with 20 h of light during the first week. Three replicates were kept in separate pens by variety-LP during the rest of the growing period. All groups started with 20 h light at week one; thereafter, the light exposure decreased 1h/2wk (SL), 1h/wk (ML) and 4h/wk (RL), to 13, 9 and 12 h at weeks 15, 12 and 3 for SL, ML and RL, respectively. Thereafter, SL plateaued at 13 h of light and ML and RL plateaued at 9 h till week 17 when all treatments received 10 h of light. Afterwards, 2h/wk light increase was applied to 16 h, and then kept constant during the whole laying period. Data were collected on sexual maturity (SM), daily production (PD), and individual weekly body weights (BW). Production records were analyzed by variety using least square means procedures. Model included the effects of LP, week of production and their interaction. Data were analyzed as daily hen housed production pooled by week of production. Additional models treated week of production as a regressor variable at different degree polynomial. Significant PD differences occurred among LP, especially during the pre-peak period. The RL excelled in PH1 due to an earlier SM and higher peak of production. On average, SL birds were 44 and 87 g heavier than ML and RL for W36 and 38 and 83 g forW98. In PH2, LP was not significant for PD in HYB but SL birds were 24 and 45 g heavier than ML and RL. For W98, PD trend was similar to that in PH1, and SL birds were 12 and 51 g heavier than ML and RL. Final conclusions are pending analysis of egg quality and bone density traits.

SCAD II (Avian Diseases)
Room: B312

T89 Development and initial evaluation of a candidate M2e-based avian influenza vaccine utilizing recombinant *Salmonella* as a vaccine vector. S. L. Layton*[1], K. Cole[1], M. M. Cox[1], J. L. Gallagher[1], T. Jiang[1], Y. M. Kwon[1], L. R. Berghman[2], W. J. Bottje[1], and B. M. Hargis[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Texas A&M University*, *College Station*.

The M2 ion transport protein extracellular domain (M2e) is highly conserved among influenza A viruses. Antibodies against M2e have conferred protection against influenza challenge in previously-reported research. We have recently developed several novel attenuated ΔaroA *Salmonella enteritidis* strains (ΔSE) that express a protective epitope of M2e with or without linkage to a potential immune-enhancing 10 aa CD154 sequence (CD154). These avirulent *Salmonella* mutants were evaluated as live vaccine candidates (~10^5 or 10^7 cfu/chick by oral gavage at day-of-hatch) for invasiveness and M2e seroconversion. Constructs evaluated included ΔSE, ΔSE containing M2e (ΔSEM2e), ΔSEM2e linked to CD154 (ΔSEM2eCD154), or ΔSE containing multiple copies of M2e linked to CD154 (ΔSEHM). At 7 d, liver+spleen and ceca tonsils were aseptically removed for detection of ΔSE mutant recovery (enrichment), and blood samples were obtained for M2e-specific IgG antibody response against M2e at 10 and 20 d. Within doses, no significant ($p>.05$) differences were observed in ΔSE construct recovery from cecal tonsils at d 7. However, marked differences in organ invasion were observed (ΔSE: 7/10, ΔSEM2e(10^5): 1/10, ΔSEM2e(10^7): 10/10, ΔSEM2eCD154(10^5): 4/10, ΔSEM2eCD154(10^7): 9/10, ΔSEHM(10^5):1/10, ΔSEHM(10^7): 5/10, $p<.05$). M2e-containing ΔSE constructs elicited M2e seroconversion

(S/P-ratio; p<.05) with higher responses from higher vaccination doses at d 20. ΔSEM2e produced higher M2e seroconversion at d 20 than the ΔSEHM, but seroconversion was not detectable in any group at d 10. When SP-ratios 2 STD higher than ΔSE-only controls were considered as positive responses, 70% (14/20) ΔSEM2e and 85% (17/20) ΔSEM2eCD154 responded by d 20. Ongoing experiments are focused on duration of response and effect of booster vaccination. These early data suggest that effective M2e seroconversion is possible with this *Salmonella*-vectored vaccine. Such a vaccine could offer advantages relating to stability of epitope and cost of amplification and administration.

T90 Development and initial evaluation of a biosensor for in field screening of avian influenza virus. Y. Li*[1,2], R. Wang[1,2], L. Lassiter[1,2], B. Hargis[1], S. Tung[2], L. Berghman[1], and W. Bottje[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Texas A&M University*, *College Station*.

An important step in controlling the spread of avian influenza is rapid and sensitive detection of the virus in the field. Thus, a biosensor, originally developed for microbial detection, has recently been modified to enable detection of avian influenza virus. The biosensor consists of a sampler, a microfluidic chip, and impedance detector attached to a microprocessor. In preliminary studies, magnetic nanobeads were coated with specific antibodies to targeted H5N1 (killed) avian influenza virus and used in the automatic sampler to separate target viruses from a poultry swab sample. Red blood cells were mixed with the captured target viruses to form an antibody coated nanobead-virus-red blood cell complex as a result of hemaglutination with the H5N1 virus. The complexes were then sent to a microfluidic chip that was designed and fabricated as a flow-through device with an embedded interdigitated array microelectrode for impedance measurement. The change in impedances of the antibody coated nanobead-virus-red cell complex was correlated to the concentration of avian influenza virus H5N1 in a poultry sample. Results of these studies indicate that the biosensor was very sensitive (102 EID50/ml) in detection of killed H5N1 virus in buffer and when the virus was added to cloacal and tracheal swab samples. No false positives were observed when unknowns were tested with various combinations of killed viruses consisting of H5N1, infectious bronchitis, and exotic newcastle disease. The total amount of time required for in-field detection would be 20 to 30 min. Thus, the biosensor could be potentially used both in detection of H5N1 in commercial poultry, but also in wild bird populations and backyard chickens or village chickens found throughout the world.

T91 Molecular and antigenic characterization of recent H5N1 avian influenza isolates from Vietnam. J. Pfeiffer* and D. L. Suarez, *Southeast Poultry Research Laboratory*, *Athens, GA*.

A recent sequence comparison of the hemagglutinin (HA) gene of Asian H5N1 avian influenza viruses isolated over the past 10 years demonstrated separation into three clades with recent isolates separating into two clades. Most reported viruses from Vietnam from 2001-2005 clustered in Clade 1, but 19 viruses isolated from the northern part of Vietnam from December 2005 all were clade 2 viruses. These viruses clustered into two sublineages, with no apparent clustering based on origin of the viruses. Genetic relatedness for the other genes also showed two unique clusters that correlated with the HA gene. Additionally, we evaluated the antigenic relatedness between these Vietnamese viruses by cross hemagglutination inhibition (HI) tests using antisera generated with DNA vaccines in chickens. Hemagglutinin-specific sera collected was to be used against either homologous antigen or antigen from the other Asian viruses against which antibodies to their HA genes were produced. We also wanted to evaluate the effectiveness of various vaccines using two Vietnamese challenge viruses that represented each genetic sublineage. Two-week old white leghorn chickens were vaccinated with one of five oil emulsion vaccines, two of which are currently used in Vietnam. Three weeks later, these birds were challenged with 10^6 EID_{50} virus. Clinical protection was seen with four of the vaccines, and real-time RT-PCR was used to evaluate levels of shedding among the groups. By compiling the data from these various analyses of the recently isolated Vietnam highly pathogenic H5N1 viruses, we will gain knowledge which can be applied to selecting vaccine seed strain viruses in the future.

T92 Isolation and characterization of an avian influenza virus from a wild waterfowl. T. Dormitorio*, J. Giambrone, K. Guo, and G. Hepp, *Auburn University*, *Auburn, AL*.

Wild aquatic birds form the natural reservoir of avian influenza viruses, and have been implicated as a continuous source of virus for domestic birds as well as other animal species including humans. Through surveillance of wild birds, prevalence of avian influenza viruses (AIVs) can be monitored and the pathogenic and antigenic properties of the circulating viruses can be determined. Cloacal swabs were obtained from various species of wild, hunter killed or trap nested waterfowl on the Eufaula Wild Life Refuge in Southern Alabama. The samples were brought to the laboratory where they were processed for embryonated egg inoculation, hemagglutination, Directigen™ AC-ELISA, and real-time RT-PCR (RRT-PCR) tests. Samples positive for AIV, using all tests, were submitted to NVSL, Ames, Iowa for subtyping. Only one sample, S10706-26, which came from a Northern shoveler was positive for presence of AIV by all tests. It had an HA titer of 64 and allantoic fluid from a second, but not the first, egg passage produced a positive result by Directigen™ test. RRT-PCR showed that allantoic fluid from the inoculated egg was positive (Cp=24) for the matrix gene of AIV, but negative for the H5 and H7 genes. Allantoic fluid containing the positive AIV was sent to the NVSL and was determined to be of the H10N7 subtype. Additional molecular characterization of this H10N7 isolate is being conducted using cloning and sequencing of the H10 gene.

Key Words: Avian influenza, Waterfowl, Real-time RTPCR, AC-ELISA, Hemagglutination

T93 Protection against exotic Newcastle Disease virus (NDV) challenge of chickens vaccinated with NDV vaccines made from different genetic lineages. P. J. Miller*, C. Estevez, Q. Yu, D. L. Suarez, and D. J. King, *Southeast Poultry Research Laboratory*, *Athens, GA*.

Vaccines for control of Newcastle Disease (ND) have been used for over fifty years in the United States. The available ND vaccines, both live and killed have been shown to prevent mortality and symptoms of disease. However, they typically do not prevent vaccinated birds from becoming infected and shedding virus that may infect susceptible birds. The purpose of this study was to determine if vaccination with Newcastle Disease virus (NDV) strains that are genetically more similar to the challenge strain reduce the shedding of challenge virus. Two experiments were conducted using four-week-old specific pathogen-free Leghorn chickens. In the first experiment chickens were subcutaneously vaccinated with inactivated vaccines utilizing strains B1, Ulster, CA 2002, Pigeon 84, Alaska 196, or uninfected allantoic fluid as control. In the second experiment chickens were vaccinated with either live or inactivated vaccines using a recombinant Anhinga 1993 NDV with either its own hemagglutinin neuraminidase (HN) gene or with a HN substitution from CA 2002, a live B1 commercial vaccine, an inactivated challenge virus (CA 2002) vaccine, or appropriate control vaccines. Three weeks post-vaccination seroconversion was assessed by ELISA and hemagglutination inhibition (HI) assays performed against each of the vaccine antigens. After challenge with virulent CA2002, birds were examined daily and monitored at selected intervals for virus shedding. All treatments except for the sham vaccinated controls induced greater than 83% protection from clinical disease and mortality. More importantly, the vaccines homologous with the challenge virus reduced oral shedding significantly more than the antigenically heterologous vaccines. Consequently, vaccines formulated to be antigenically closer to circulating virulent viruses can provide better Newcastle Disease control by reducing virus transmission from vaccinated birds.

Key Words: Exotic Newcastle Disease, NDV, Inactivated vaccine, Live vaccine, Viral shed

T94 Infectious bursal disease viruses identified in Colombia, South America. L. Purvis*, P. Villegas, and F. Perozo, *University of Georgia*, *Athens*.

During 2005-2006, inactivated bursal imprints in FTA cards were obtained from Colombia for molecular identification of infectious bursal disease virus (IBDV) using RT-PCR and sequencing. Molecular analysis of the hypervariable region of VP2 containing amino acids 206 through 310 was conducted in order to determine the strain of IBDV. The samples were submitted from farms in Colombia experiencing problems with IBDV. Over half of the samples analyzed were classified as very virulent IBDV (vvIBDV), and the second largest group of samples corresponded to variant strains. The finding of the presence of vvIBDV and variant strains in Colombia is important to establish procedures to control these field strains.

Key Words: Infectious Bursal Disease, South America

T95 Characterization of infectious bursal disease virus RNA-dependent RNA-polymerase leads to higher viral titres in cell culture. T. Letzel[1], A. E. Gorbalenya[2], and E. Mundt*[3], [1]*Institute of Molecular Biology*, *Insel Riems, Germany*, [2]*Leiden University Medical Center*, *RC Leiden, The Netherlands*, [3]*University of Georgia, PDRC*, *Athens*.

Infectious bursal disease virus (IBDV) as a member of the family Birnaviridae contains a bisegmented genome of double-stranded RNA. The larger segment A encodes a polyprotein [viral proteins (VP) 2-4-3] and the viral protein VP 5. The smaller segment B encodes VP1 which represents the RNA-dependent RNA-polymerase (RdRp) of IBDV. VP1 was expressed fused to a His-tag employing a baculovirus system for investigation of the functionality of this protein. After purification by affinity chromatography VP1 was used in an in vitro RdRp assay using a mutated VP1 as control. VP1 showed in vitro RdRP activity whereas the mutant did not indicating that the RdRp activity was indeed caused by the presence of VP1. Further investigations using different divalent cations were performed to characterize the reaction conditions in vitro. It was observed that in presence of 5 mM Co2+ the efficiency of the reaction was 20-fold higher than in the presence of 5 mM Mg2+. To apply this finding to the improvement of virus production in cell culture appropriate experiments were performed. After optimization of the cell culturing conditions IBDV infection experiments were performed. The obtained results showed a significant increase of IBDV titres in the presence of 50 µM Co2+. This phenotype was observed independent from the used cell culture since in further experiments using a different bird cell line a signifcant increase of the viral titre was detected. This effect was observed to be IBDV specific since for the avian reovirus strain 1133 no significant differences were detected. This finding could help establishing a more efficient vaccine production of IBDV in cell culture.

SCAD III (Avian Diseases)
Room B312

T96 Efficacy study of a live attenuated reovirus vaccine given by the *in ovo* route to SPF and commercial broilers. K. C. Cookson*[1] and J. J. Giambrone[2], [1]*Fort Dodge Animal Health*, *Overland Park, KS*, [2]*Auburn University*, *Auburn, AL*.

The efficacy of an attenuated reovirus vaccine was measured using a previously established reovirus challenge model. **Study design:** Broilers from a commercial flock (COM, breed A) and an SPF flock (breed B) were vaccinated *in ovo* with a full dose of HVT/SB-1 with or without a 1/5 dose of V.A. ChickVac (VAChVac). 20 chicks per flock were bled for reovirus Idexx ELISA. 120 chicks per flock were then housed 20 per Horsfall isolator. At 3 days of age (D3) a set of birds were challenged intratracheally (IT) with 4.0 logs10 (chick ID50) of malabsorption strain 2408. Another set were challenged at 5 days of age. At 16 days of age all groups were weighed. **Results:** Non-vaccinated COM broilers (NoVax rows, table below) were significantly lighter from challenge at 3 days (8.5%) and 5 days (25.7%). SPF-NoVax were lighter only after D3 challenge. V.A. ChickVac caused no weight suppression (NC columns). V.A. ChickVac completely protected both SPF challenge groups against weight suppression (D3 and D5 columns). The commercial flock was fully protected from the D3 challenge but there was only partial, but significant protection from D5 challenge. **Discussion:** The commercial flock was selected for its marginal levels of reovirus maternal antibodies (MAB). Previous challenge studies using this model have shown flocks near 1,800 geometric mean titer (GMT) are susceptible to D3 reovirus challenge. In this study, the D5 challenge resulted in even greater weight suppression, perhaps because there was less MAB protection at the time of challenge. The SPF flock had a similar level of weight suppression from D3 challenge; however, it was resistant to the D5 challenge. The MAB-negative SPF flock was expected to be more susceptible to early reovirus challenge. Perhaps the breed difference is responsible for the discrepancy seen here. **Summary:** The live attenuated reovirus vaccine was safely given *in ovo*, resulting in full protection in 3 of the 4 challenge groups and partial protection in the 4th, most heavily stunted group.

Table 1. 16-day body weights of broilers intratracheally challenged with reovirus strain 2408

Flock description	Hatch GMT	No-Reo BW	Challenge BW suppression	Challenge BW	at 3D BW suppression	Challenge BW	at 5D BW suppression
COM-NoVax	1,793	561a	NA	513b	8.5%	417d	25.7%
COM-VAChVac		588a		560a		474c	15.5%
SPF- NoVax	192	462b	NA	432c	6.5%	452b	02.2%
SPF-VAChVac		498b		470b		530a	

Challenge groups within a flock (i.e., COM) having a different letter are significantly different, based on Tuke's multiple range test ($P<0.05$).

T97 Multiplex RT-PCR for the detection of astroviruses and rotaviruses in poultry. C. Stephens*, M. J. Pantin-Jackwood, and E. Spackman, *University of Georgia*, *Athens*.

Viral enteric diseases cause substantial economic loss to the US poultry industry because they lead to decreased weight gain, increased morbidity, increased mortality, and increased production costs from poor feed conversions and increased use of therapeutic anti-microbial treatments. Astroviruses and rotaviruses are among the most commonly detected viruses found in chicken and turkey intestinal samples. Two multiplex RT-PCR tests for the simultaneous detection and differentiation of four avian astrovirus types and avian rotaviruses from feces and intestinal samples from poultry were developed and validated. The multiplex RT-PCR for chicken samples detects Avian Nephritis Virus (ANV), Chicken Astrovirus (CAstV) and Rotavirus. The multiplex RT-PCR for turkey samples detects Turkey Astrovirus 1 (TAstV-1), Turkey Astrovirus 2 (TAstV-2), Avian Nephritis Virus (ANV) and Rotavirus. Assay detection limits for each virus were determined. An evaluation of different sampling times and types for each virus was performed with experimentally infected chickens and poults. The multiplex RT-PCR's developed were successfully used in a survey on enteric viruses circulating in poultry in the United States.

Key Words: Astrovirus, Rotavirus, Chicken, Turkey, Multiplex RT-PCR

T98 Ecology of reticuloendotheliosis virus (REV) in a closed population of captive endangered prairie chickens. T. M. C. Barbosa*, G. Zavala, and S. Cheng, *University of Georgia*, *Athens*.

Reticuloendotheliosis (RE) is a neoplastic and immunosuppressive disease of poultry. RE virus (REV) can be a contaminant of vaccines. Attwater's Prairie Chicken (APC) is an endangered avian species, partly due to enzootic REV infection. REVs were isolated from APCs housed at the Fossil Rim Wildlife Center (TX). In a previous study, one isolate (REV APC-566) experimentally induced delayed growth, mortality, and decreased egg production and hatchability in Japanese quail. It also caused tumors at early ages and the majority of tumors were classified as CD3+ Lymphosarcomas. Nucleotide and amino acid alignments of full genome showed that REV APC-566 is closely related to REV inserted into Fowlpox virus. In this study we examined the nucleotide and amino acid sequences of several APC REV isolates. REVs were isolated and propagated in DF-1 cells from whole blood or tumors from APCs. The proviral DNA was amplified with specific primes for the *env* gene and the LTR. These regions were aligned with REV sequences available at GenBank and other REV sequences also resolved in our laboratory. All APC REV LTR sequences showed highly conserved deletions and insertions in the U3 region. All known promoters and enhancers are also highly conserved. The *env* gene is well conserved, in contrast with other avian retroviruses. Similar to REV APC-566, other APC isolates from the same APC colony display high similarity with REV inserted into Fowlpox virus. An immunosuppressive peptide coding region within the transmembrane

region of env is highly conserved in all REV sequences examined. This immunosuppressive peptide is well described in mammalian in vitro systems and has been detected in mouse, feline, monkey and other retroviruses. Thus, REVs circulating in a closed colony of APCs are genetically stable. REV APC-566 caused impairment of immune responses in experimentally inoculated SPF turkeys. Functional assays are still needed to confirm the immunosuppressive properties of the putative REV immunosuppressive peptide.

Key Words: Reticuloendotheliosis virus, Attwater′s Prairie chicken, Sequencing, Immunosuppressive peptide, Fowlpox

T99 Effects of chicken anemia virus (CAV), infectious bursal disease virus (IBDV) and reovirus on cellulitis development in chickens. K. S. Macklin*[1], J. J. Giambrone[1], K. Cookson[2], and H. Toro[1], [1]*Auburn University*, *Auburn, AL*, [2]*Fort Dodge Animal Health*, *Lawrence, GA*.

E. coli derived cellulitis is a major problem in the broiler industry that costs the industry millions of dollars annually. In this experiment 72 broiler chickens were obtained from a commercial hatchery and randomly assigned into 6 Horsfall isolator units. Six treatments were used with no replication per pen. All birds had maternal antibody against all 3 viruses used in this study. The treatment 1 was the negative control (CON). In treatment 2 (VIR), the birds were administered CAV and reovirus at 3 days of age, and IBDV at 7 days of age. Treatment 3 (VHI) consisted of the 3 viruses mentioned in VIR and 0.1 ml of 4.7x108 *E. coli* administered subcutaneously in the breast at 25 days of age. Treatment 4 (VLO) was similar to treatment 3, except *E. coli* was administered at 4.7x105. Treatments 5 (LO) and 6 (HI) were not given a viral challenge, but were challenged at 25 days of age with *E. coli* at 4.7x105 and 4.7x108, respectively.

Of the 3 groups that received CAV, histopathology showed that there was atrophy of the thymus in 18% of VLO, 25% of VHO, but no signs of the virus were detected in VIR. CAV-PCR results show that the virus was present in some of the birds from all three viral challenge groups. All birds that were administered reovirus showed a 9% suppression in body weight compared to the non-reovirus challenged birds. All 3 of the IBDV challenged treatments had approximately 90% bursal atrophy. None of the non-viral challenged treatments showed thymic or bursal atrophy and their body weights were similar to CON. Among the *E. coli* challenged treatments, the 2 high dose groups had 91% and 75% incidence of cellulitis in the HI and VHI groups, respectively. Of the two low dose groups only VLO had positives at 36%. As was observed with the viruses, there were no cellulitis lesions in non-*E. coli* challenged birds. The addition of immunosuppressive viruses did not effect the development of cellulitis lesions in the high dosed birds; however in the low dosed birds the addition of the viruses increased the likelihood of cellulitis development.

Key Words: Cellulitis, *E. coli*, CAV, IBDV, Reovirus

T100 Evaluation of the tissue tropism and transmission of the tissue culture origin (TCO) live-attenuated vaccine of infectious laryngotracheitis virus. A. Rodriguez* and M. Garcia, *University of Georgia*, *Athens*.

The protection ability and safety of the ILTV TCO live-attenuated vaccine has been widely studied, however the tropism and transmission of the TCO vaccine has not been well documented. The aim of this study was to determine the target organs where the vaccine replicates, and the ability of the vaccine to transmit to unvaccinated birds in close proximity. Four weeks old specific pathogen free (SPF) chickens were vaccinated by eyedrop with the TCO vaccine. Unvaccinated SPF chickens were housed in direct contact to vaccinated chickens since first day of vaccination. Virus isolation and real time PCR were used to detect the presence of live virus and viral DNA, respectively, in the trachea, trigeminal ganglia, eyelids swabs, cecal tonsils, and cloacal swabs at interval days postvaccination (2, 4, 5, 6, 7, 8, 9, 10, 14, 18, 21, 24, and 28) from vaccinated and contact-exposed birds. The virus was isolated from trachea at day 9 post vaccination from both vaccinated and unvaccinated birds, and from eyelid swabs at 4, 6, 7, and 9 from vaccinated birds, and at 7 and 9 days from unvaccinated birds. Virus was not isolated from the trigeminal ganglia, cloacal swabs, and/or cecal tonsils at any of the time points. Viral DNA was detected from eyelid swabs from day 2 to 14, from trachea at days 4, 5, 6, 9, and 10, and from trigeminal ganglia at days 5, 6, 7, and 9. Real time PCR analysis of cecal tonsils, cloacal swabs and other samples collected at 18, 21, 24, and 28 days post vaccination is ongoing. Replication of the TCO vaccine in the eyelid and the trachea, as well as the transmission from vaccinated to unvaccinated birds was demonstrated.

Key Words: Infectious laryngotracheitis, Tropism, Transmission, Real time PCR, Virus isolation

T101 A natural challenge model for ILTV laboratory studies. J. Giambrone*, S. Fagbohun, and K. Macklin, *Auburn University*, *Auburn, AL*.

Infectious laryngotracheitis virus (ILTV) is an economic problem in broilers reared in concentrated areas. A natural exposure (challenge) model was needed to test the efficacy of commercial litter treatments, which are used to reduce ILTV exposure. The ILTV challenge model was developed by seeding pine shavings with commercial ILTV vaccine. This was done by serial back passage of vaccine virus in SPF chickens. The back passage was started by vaccination of four, 3-week-old broilers with 10 doses each of live vaccine by eye and nasal instillation. Birds were placed on litter in Horsfall-Bauer units. At 1 week later birds showed slight respiratory signs (sneezing and conjunctivitis) typical of silent or vaccine induced ILTV. Three more 4-week-old sentinel birds were added to the same units. At 1 week later contact exposed birds showed minor respiratory signs. At this time the initially vaccinated birds were killed and examined post-mortem. Their trachea were taken for microscopic observation and tested for ITLV DNA using a newly developed nested PCR. Another group of 3, 3-week-old sentinel birds were added to the contaminated unit, containing the remaining infected birds. At a week later, these birds also developed minor clinical respiratory signs. At this time all birds were killed and examined. All birds had slight congestion in the trachea or conjunctivitis, and mild microscopic lesions in the trachea suggestive of respiratory distress. A piece of each trachea was pooled from all groups and all were positive for ILTV DNA by the nested PCR test. This contaminated litter was taken to an isolated block house, to be exposed to various litter treatments for 5 days. After this treatment, the litter was returned to the units and 9, day-old birds were again placed on the litter to see if the became infected with ILTV at 3, 4 or 5 weeks of age. Three, SPF birds placed on the positive non-treated

litter were negative for ILTV DNA at 3 weeks of age. However, the additional birds placed in the same unit at day of age, which were tested at 4 or 5 weeks of age, were positive for ILTV DNA. This ILTV challenge model has proved useful for testing the efficacy of litter treatments.

Room: 313

T102 Effect of a new coating on the thermotolerance and bioefficacy of a phytase product in broilers fed corn-soybean meal-based diets. A. Owusu-Asiedu[1], J. C. Remus*[1], P. H. Simmins[1], and R. Croxall[4], [1]*Danisco Animal Nutrition*, *Marlborough, Wiltshire, United Kingdom*, [2]*Danisco Animal Nutrition*, *St. Louis, MO*, [3]*Danisco Animal Nutrition, Marlborough*, *Marlborough, Wiltshire, United Kingdom*, [4]*ADAS, Gleadthorpe*, *Mansfield, Nottinghamshire, United Kingdom*.

A study evaluated the effects of a new coating (C) on thermal tolerance and bioefficacy of a bacterially-derived, phytase product (Phyzyme XP; 6-phytase, EC 3.1.3.26) in broilers fed corn-soybean meal-based diets. 1440 male Ross 308 chicks were assigned to six dietary treatments (1-6) with eight replicates pens each (30 chicks/pen). The treatments were: 1. Positive control (PC), 2. Negative control (NC), 3. NC + 500 U/kg phytase, 4. NC + 500 U/kg C phytase, 5. NC + 500 U/kg C phytase pelleted at 80°C, and 6. NC + 500 U/kg C phytase pelleted at 90°C. All the diets were formulated to be isocaloric and isonitrogenous. The Ca and available P levels were 0.90% and 0.37% in PC and 0.78% and 0.26% in NC diets, respectively. Birds were weighed on days 0 and 21, and two birds from each pen were randomly selected and sacrificed on day 21. The left tibia was removed and dry defatted ash determined. Birds fed PC diet and diets supplemented with phytase were heavier (P<0.05) at day 21 than birds fed NC diet. Birds fed C phytase supplemented diets and pelleted at 80°C and 90°C were heavier (P < 0.05) at day 21 and had a better FCR (P<0.05) than birds fed the PC diet. Birds fed the NC diet consumed less (P<0.05) feed than birds fed the PC or phytase supplemented diets. Tibia ash was lower (P<0.05) for birds fed the NC diet compared to all other treatments. In conclusion, a new coating applied to the phytase achieved thermostability up to 90°C while demonstrating similar bioefficacy to the uncoated phytase.

Key Words: Enzymes, Phytase, Pelleting, Broiler, Thermostability

T103 Coating for pellet stability does not adversely affect the phosphorus-releasing efficacy of an *E. coli*-derived phytase in young chickens. N. R. Augspurger[1], S. D. Frankenbach*[1], T. J. Applegate[2], J. S. Moritz[3], F. Ruch[1], and D. M. Webel[1], [1]*JBS United, Inc.*, *Sheridan, IN*, [2]*Purdue University*, *West Lafayette, IN*, [3]*West Virginia University*, *Morgantown*.

The phytase enzyme is highly susceptible to inactivation by heat and moisture, conditions encountered during pelleting. Alternatively, phytase can be applied as a liquid to the pellet, by-passing the high heat and moisture, or the dry phytase can be stabilized to retain a high proportion of activity and added prior to pelleting. A series of trials was done with an *E. coli*-derived phytase (OptiPhos™, JBS United, Inc.) to determine the effect of adding a lipid coating to the phytase particle on the pellet-stability, as well as its *in vivo* phosphorus (P)-releasing efficacy in chickens. For each of the pelleting trials, corn-SBM diets containing 1,000 FTU/kg phytase, from either uncoated or coated preparations, were pelleted at 85°C following 60 s of mixing with steam. Samples of feed were taken pre- and post-pelleting and analyzed for phytase activity; retention values were then calculated. Three chick assays utilized standard-curve methodology to compare the P-releasing efficacy of both uncoated and coated phytase. In each assay, four pens of four or six male broilers were fed P-deficient experimental diets supplemented with inorganic P or phytase from either uncoated or coated preparations for 11-14 d, after which tibia were collected for determination of bone ash (mg and %). The first chick assay showed no effect ($P > 0.10$) of the coating on the P-releasing efficacy of an *E. coli*-derived phytase at 500 FTU/kg (0.14% P); the coated phytase retained 76 ± 6 (SD)% of its activity after pelleting at 85°C (32 ± 10% for uncoated). The addition of the coating to the phytase in the second chick trial did not affect ($P > 0.10$) the P-releasing efficacy, and resulted in a phytase retention value of 82 ± 13% after pelleting at 85°C. The third assay revealed P-releasing efficacy estimates of 0.128 and 0.133% for 500 FTU/kg of the uncoated and coated phytases, respectively ($P > 0.09$). These data show that adding a lipid-based coating to phytase is efficacious for stabilizing the phytase in the pelleting process at 85°C, and does not adversely affect the quantitative efficacy in chickens.

T104 Quantum™ phytase exhibits high specific activity and high substrate affinity over the full gastric pH range. A. Nelson*[1,2], S. S. Basu[1,2], and S. Betts[1,2], [1]*Syngenta Biotechnology, Inc.*, *Research Triangle Park, NC*, [2]*Syngenta Animal Nutrition*, *Research Triangle Park, NC*.

Phytin in bird feed is solubilized in the acidic environment of the upper gastrointestinal tract, releasing phytate and mineral cations. However the release of phytate is reversible such that as the pH increases, for example as feed digesta move from the gizzard into the small intestine, phytate can again chelate soluble cations to form insoluble phytin. For this reason phytases used to supplement bird feed must be active in the acidic pH range where phytate is soluble and biologically available. The region of highest phytate solubility - and hence susceptibility to enzymatic hydrolysis - is therefore the upper digestive tract from the crop to the duodenum.

In this in vitro study the catalytic properties of an Escherichia coli-derived phytase, Quantum™ phytase, were examined side-by-side with two commercially available fungal phytases at a series of

physiologically relevant pH conditions. The plot of specific activities (μ mol phosphate released/min/mg protein measured at 37°C) vs. reaction pH showed that compared to fungal phytases Quantum phytase catalyzes phytate hydrolysis at a very fast rate over a broad range of acidic pH-conditions (as low as pH 1.5). By contrast, the fungal phytases exhibited much lower specific activities and were more sensitive to acidic pH conditions. The substrate affinity (apparent Km values) of each phytase was also determined from double-reciprocal plots of the reaction rate at varying phytate-substrate concentrations. Quantum phytase was found to have comparable Km values at all physiologically relevant pH conditions tested (pH 2.5, 4.5 & 5.5). These results demonstrate that Quantum phytase is a highly efficient catalyst for phytate-phosphate hydrolysis and an attractive candidate for use as a feed additive enzyme.

T105 Effects of buffer types and concentrations on phytase product analysis. S . Dalsgaard*[1], C. Gilbert[2], and R. Lorentsen[1], [1]*Danisco Innovations*, *Brabrand, Denmark*, [2]*Danisco Animal Nutrition*, *Marlborough, Wiltshire, United Kingdom*.

Phytase is used in feed to improve phytate phosphorus digestibility. Commercial phytases are either fungal or bacterial in origin. The feed industry needs a robust assay to measure phytase in products, in premixes and in feed. Ideally, this assay needs to be appropriate for all commercial phytases. To get a better understanding of phytase functionality, a study of two commercially available bacterial origin phytases was carried out to assess how each phytase reacted under different assay buffer conditions. Phytase is described based on the phytase unit (FTU) wherein 1 unit is defined as the amount of enzyme needed to liberate 1 micromole of inorganic phosphate from sodium phytate per minute at pH 5.5 and 37°C. The buffer system used to achieve this pH can vary and potentially could influence the number of phytase units measured. This study used different molarities of acetate and citrate buffers, both of which have been used in published assay methods for phytase. Also, two different colour reagents used in phytase assays were compared to assess their impact on the activity measured. Phytase activity was measured at pH 5.5 and 37°C as per the standard definition of a phytase unit (FTU). The colour reagents did not affect measured activity in the phytases. Changing the buffer from a 0.25M acetate buffer to a 0.2M citrate buffer reduced the assayed activity by approximately 50%. Use of a 0.1M citrate buffer increased the activity measured compared to the 0.2M citrate buffer, but the activity was still 15-20% less than with acetate buffer. Measured activity (FTU) is therefore significantly influenced by assay buffer within the same unit definition. In conclusion, this study shows that it is incorrect to assume that products containing a specified number of phytase units (FTU) are directly equivalent without seeing detail of the assay methodology. For this reason it is always necessary to standardise phytase units using one method before running, or interpreting, comparative bioefficacy studies.

T106 Kinetics of phytase-catalyzed sequential hydrolysis of inositol phosphates: Can this be a criterion to differentiate among phytases used in poultry diet? R. Prata*[1,2], C. Batie[1,2], S. Betts[1,2], and S. S. Basu[1,2], [1]*Syngenta Biotechnology, Inc.*, *Research Triangle Park, NC*, [2]*Syngenta Animal Nutrition*, *Research Triangle Park, NC*.

Supplementation of poultry feed with exogenous phytase is viewed as essential to liberate trapped phosphate from phytate (inositol hexakisphosphate; IP_6). In addition, phytases have indirect nutritional benefits. Phytate is an anti-nutrient: its metal chelating activity decreases the bioavailability of minerals as well as the digestibility of starch and protein. Thus, phytase also reduces the anti-nutritive effects of phytate. It has also been proposed that the chelating power and capacity of phytate markedly decreases upon removal of two phosphates to form inositol tetrakisphosphate (IP_4).

Studies were conducted to investigate the kinetics of the phytase-catalyzed sequential conversion of IP6 to inositol phosphate reaction intermediates, IP_5 and IP_4, using the E. coli derived Quantum™ phytase (a 6-phytase) and two commercial fungal phytases (one 6-phytase & one 3-phytase). The objective of these experiments was to identify possible differences in the rates of IP_6 and IP_5 depletion by these phytases. Experiment set 1, all phytase reactions were performed using equal doses of enzyme activity measured in standard unit (FTU, assayed at pH 5.5 & 37°C). The concentrations of IP_6, IP_5 and IP_4 were measured over time in reactions carried out at pH 2.5 and 3.5 with 100% IP_6 as the substrate. Under these conditions Quantum phytase depleted the anti-nutrients IP_6 & IP_5 at a significantly faster rate than the two fungal phytases. In experiment set 2 similar reactions were performed but using equal phytase activity, this time measured at the pH of the reaction (pH 2.5 & 3.5). Development of kinetic models and comparison of the rate constants of IP_6, IP_5 and IP_4 hydrolysis catalyzed by these phytases show that Quantum phytase is more efficient in converting IP_6 to IP_4 over the full range of physiologically relevant pH conditions. Based on the above described catalytic properties of phytases, it may be predicted that Quantum phytase can be highly effective in neutralizing the anti-nutritive properties of phyate in poultry diet.

Key Words: 6-phytase, 3-phytase, Reaction mechanism, Inositol phosphate, Rreaction intermediates

T107 The effect of exogenous phytase on performance, dietary energy, mineral metabolism and endogenous losses when different protein sources are fed to chicks. V. Pirgozliev*[1], T. Acamovic[1], S. Sarwar[1], M. Allymehr[1,2], and M. R. Bedford[3], [1]*Scottish Agricultural College, ASRC*, *Edinburgh, United Kingdom*, [2]*Urmia University, FVM*, *Urmia, Iran*, [3]*Syngenta Animal Nutrition Inc.*, *Marlborough, Wiltshire, United Kingdom*.

An experiment (5*3 factorial) was designed to investigate the effects of different concentrations of an evolved E. coli derived phytase (Quantum, Syngenta Animal Nutrition) and three different protein sources on performance, dietary energy, N and mineral metabolism when fed to young chickens (from 7 to 21d of age). Four hundred and fifty male Ross 308 chicks were allocated in a randomised block design to one of the six replicate cages (5 birds per cage) and fifteen experimental diets (positive control (PC), negative control (NC), NC + 250, + 500, + 12500 FTU (phytase units/kg feed). The diets included rapeseed meal (RSM), soybean meal (SBM) or sunflower meal (SM) as the main protein source. Birds fed enzyme supplemented diets

had improved performance (P<0.05) compared to those fed negative control diets. Chicks had higher feed intake, gain and gain:feed ratio (P<0.001) when the protein source in the diet was either SBM or SM, compared to the RSE. Although phytase did not affect (P>0.05) dietary metabolisable energy (ME) and dry matter digestibility (DMD), SBM supplemented diets had higher ME (P=0.042), metabolisability of gross energy and DMD coefficients (P<0.001) compared to the two other protein sources. Birds fed RSM had higher (P<0.001) endogenous losses, measured as sialic acid. Birds fed RSM also had lower Ca, P (P<0.001) and Mg (P<0.05) metabolisability coefficients compared to SBM and AM. The lower coefficient (P<0.001) of S metabolisability of RSM indicates that the S-containing amino acids were also less available compared to those from SBM and SM. The data from the present study suggests that the phytate in rapeseed may be less susceptible to phytase degradation compared to phytate in the other two sources and indicates that phytase supplementation of diets needs to be adjusted depending on the ingredients used in the diets.

Key Words: Phytase, Rapeseed solvent extract, Soybean, Sunflower, Chicks performance

T108 Assessment of the efficacy of quantum phytase and a fungal phytase on the performance of broilers fed a maize-based diet deficient in available phosphorus. T. C. Murphy* and M. R. Bedford, *Syngenta Animal Nutrition*, *Research Triangle Park, NC*.

A 42d pen trial consisting of 8 replicates of 30 male Ross broilers, randomly assigned to 1 of 9 dietary treatments, was conducted to study the effects of various levels of a bacterial phytase, Quantum™ 2500D (QP) on the performance of broilers compared to a constant level of a fungal phytase (FP). The treatments were: a corn/soybean meal positive control (PC) formulated to meet or exceed NRC requirements, a negative control (NC) with 0.12% and 0.16% less non-phytate phosphorus in the starter (0-21d) and finisher (21-42d) respectively, NC plus QP added at a rate of 125, 250, 500, 750, 1000 or 2000U/kg and NC plus FP added at a rate of 500U/kg. Gain, intake and FCR were analysed by ANOVA with mean separation using the LSD method at the 5% level. The reduction in dietary phosphorous significantly depressed gain and intake at both 21 and 42d but did not alter FCR. All doses of QP significantly improved gain at 21 and 42d. During the 0-21d period the 2000U/kg dose of QP was the only inclusion rate that was capable of increasing gain to levels not significantly different from the PC. By 42d birds fed diets supplemented with QP doses of 750U/kg and above had weight gains equivalent to that of the PC. The FP failed to show any positive effect on gain during either period, in fact it appeared to suppress gain from 0-21d. Supplementation of the NC with 250U/kg or above of QP increased intake. Whilst the lowest dose of QP was unable to offer any benefit upon addition to the NC in terms of intake, it still resulted in birds consuming significantly more than that observed for the 500U/kg of FP. No dose of QP restored intakes to that of the PC; however, since weight gain achieved parity at 750U/kg this meant that FCR was better for treatments having at least 750U/kg, relative to the PC. No difference was noted between 500U/kg of QP and the same dose of FP for FCR. This study further validates that QP, a bacterial derived phytase, can support performance when dietary phosphorus is limiting, in contrast to the FP source.

Key Words: Phytase, Quantum, Performance, Maize, Broiler

T109 Effects of dietary calcium and phytate on phosphorus retention and the optimal ratio of calcium to non phytate phosphorus in broiler diets. P. W. Plumstead*[1], A. B. Leytem[2], J. W. Spears[3], R. O. Maguire[4], P. Kwanyuen[5], and J. Brake[1], [1]*North Carolina State University*, *Raleigh*, [2]*USDA-ARS*, *Kimberly, ID*, [3]*North Carolina State University*, *Raleigh*, [4]*Virginia Tech*, *Blacksburg*, [5]*USDA-ARS*, *Raleigh, NC*.

The effect of reduced dietary phytate phosphorus (P) from soybean meal (SBM) on the ratio of calcium (Ca) to non phytate P (NPP) required for optimal retention of phosphorus (P) was investigated. Ross 508 broiler chicks were reared in battery cages to 14 d of age and fed one of 12 experimental diets from 15 to 20 d. Excreta or ileal digesta were collected from 18-19 d and at 20 d of age, respectively, and apparent ileal digestibility coefficients and overall retention of Ca and P and excretion of Ca, P, and phytate P calculated. A 4 x 3 factorial treatment structure was used with 4 levels of dietary Ca from 0.47% to 1.16% and 3 levels of phytate P of 0.27%, 0.23%, and 0.10% that were obtained by including either High, Conventional, or Low phytate SBM in diets. Apparent prececal P digestibility decreased when dietary Ca was increased and was higher when diets contained Low phytate SBM. The percentage phytate disappearance from the distal ileum decreased at high inclusions of Ca but was not different between diets containing High or Low phytate SBM. Inclusion of Low phytate SBM reduced excreta P output by 42% and 62% compared to broilers that had been fed either conventional or High phytate SBM, respectively. The ratio of Ca:NPP that resulted in the highest P retention and lowest P excretion was 2.53:1, 2.40:1, and 2.34:1 for diets with 0.27%, 0.23%, and 0.10% phytate P. This suggested that while increased dietary Ca reduced the extent of phytate hydrolysis, the optimum Ca:NPP ratio at which P retention was maximized was not greatly altered when Low phytate SBM replaced High phytate or Conventional sources of SBM in broiler diets.

Key Words: Broiler, Phosphorus, Soybean meal, Phytate, Environment

T110 The requirement of Zn provided as organic Zn for broiler chicks fed corn-soy based diet with or without supplementation of phytase. T. Ao*, J. L. Pierce, A. J. Pescatore, A. H. Cantor, K. A. Dawson, M. J. Ford, and B. L. Shafer, *Alltech-University of Kentucky Nutrition Research Alliance*, *Lexington, KY*.

A study was conducted to investigate the requirement of Zn when provided as Bioplex Zn® (a chelated Zn proteinate) for broiler chicks fed a practical corn soybean meal diet (25 mg/kg Zn content) with or without supplementation of phytase. One-day-old male broiler chicks were housed in starter cages with plastic covered feeders in an environmentally controlled room for 3wk. Birds were given *ad libitium* access to feed and regular tap water with no detectable Zn (<0.001 ppm). A 2 x 6 factorial treatment structure was used with two levels of phytase (0 or 500 U/kg) and six levels of Bioplex Zn® providing 0, 2, 4, 8, 16 and 32 mg Zn/kg. A total of 864 chicks was randomly assigned to each of twelve dietary treatments with six replicate cages of 12 chicks. Dietary inclusion of phytase increased (P<0.01) the feed intake, weight gain, plasma Zn and tibia Zn content. Dietary supplementation of Bioplex Zn® linearly (P<0.01) increased the feed intake, weight gain, plasma Zn concentration, liver Zn concentration and tibia Zn content. Significant interaction effects (P<0.05) of phytase and Bioplex Zn® on the feed intake and weight

gain were found. When the supplemental level of Zn was below 8 mg/kg, the dietary inclusion of phytase increased (P<0.05) feed intake and weight gain of the chicks. One slope, straight broken-line analysis of weight gain regressed on the supplemental Zn level provided as Bioplex Zn® indicated that 12 mg/kg supplemental Zn without phytase and 7.4 mg/kg supplemental Zn with phytase were required for the maximal weight gain of chicks.

Key Words: Chick, Zinc, Organic zinc, Phytase, Requirement

T111 Influence of betaine supplementation at different levels of dietary protein in diets on performance, blood composition and hepatic amino acid concentration in laying hens. K. S. Ryu* and J. H. Park, *Chonbuk National University*, *Chonju, South Korea*.

The effects of betaine intake on performance, internal egg quality, blood component and hepatic amino acid concentration were examined in laying hens fed diets at different levels of protein. A total of 540 Hy-Line Brown laying hens were allotted to six treatments with five replications for twenty four weeks. Treatments were factorially designed with three levels of CP (14, 16 and 18%) and two levels of betaine (0 and 600ppm). Egg production, egg mass and feed conversion improved as increase dietary protein level (p<0.05), but different from betaine supplementation. Eggshell breaking strength, eggshell thickness and haugh unit were not influenced by either supplementary betaine or the level of protein. Serum albumin concentration was significantly elevated in 18% protein-fed groups compared to those fed on the other protein-fed groups (p<0.05). Supplemental betaine did not affect serum total protein, albumin and BUN concentration, whereas uric acid concentration significantly increased in betaine supplemental groups (p<0.05). Concentrations of hepatic amino acids were influenced by increased protein-fed groups and dietary betaine supplementation. These results suggest that betaine does not increase in laying henÃ¢â‚¬â„¢s performance, but may affect protein metabolism by change in serum uric acid and hepatic amino acids.

Key Words: Betaine, Performance, Hepatic amino acid, Blood composition, Laying hens

T112 Versazyme additive improved growth performance, amino acid digestibility, and intestinal proteolytic activity in broiler chickens. H. Y. Wang[1,3], W. C. Huang[1], J. J. Wang[2], Y. M. Guo[3], and J. C. H. Shih*[1], [1]*North Carolina State University*, *Raleigh*, [2]*BioResource International*, *Morrisville, NC*, [3]*China Agricultural University*, *Beijing, China*.

Effects of dietary supplementation of Versazyme, a keratinase based feed additive, on growth performance, ileal amino acid digestibility and intestinal proteolytic activity were studied in broiler chicks fed corn-soy diets for 3 wks from d 1 to d 21. A total of 144 male broiler chicks were randomized to 2 treatments with 9 replicate pens per treatment. Digesta samples from different gastrointestinal segments (crop, gizzard, duodenum, jejunum, ileum) were collected at d 12 and d 21. Keratinase identity was analyzed by immunoblot and total proteolytic activity based on substrates specific for trypsin, chymotrypsin and keratinase was determined respectively. The amino acid digestibility was determined amino acid analysis in the digesta collected from the terminal ileum with celite as the undigested marker. Versazyme at 0.1% supplementation rate significantly improved average daily gain (ADG) (44.40 vs. 42.35 g, P<0.01) and feed conversion ratio (FCR) (1.24 vs. 1.28, P<0.01). It also significantly increased ileal amino acid digestibility. In addition, intestinal proteolytic activity was increased by 60% as measured by trypsin substrate (40 vs. 25 u/g protein) and by 66% as measured by the chymotrysin substrate (5 vs. 3 u/g protein). The 60-66% increase of activity could be contributed by the additional keratinase activity in the Versazyme in feed and in the intestine, because keratinase is active on a wide range of substrates including the trypsin- and chymotrypsin-specific substrates. The results of this study confirmed that dietary supplementation of Versazyme improved the growth of broiler chicks. Its beneficial effect is believed to be due to the improved protein digestibility as evidenced by the increased amino acid digestibility, proteolytic activity and the presence of keratinase in the intestine.

Key Words: Versazyme, Keratinase, Ileal amino acid digestibility, Proteolytic Activity, Immunoblot

T113 Efficacy of dietary clay adsorbents for broiler chicks fed aflatoxin (AFB1). R. B. Shirley*, F. A. Uraizee, C. D. Knight, and J. J. Dibner, *Novus International, Inc.*, *St. Louis, MO*.

The objective of this study was to determine the efficacy of the adsorbents SOLIS™-Base (SB) and MTB-100® (MTB) in ameliorating the toxic effects of aflatoxin (AFB1) in broiler chicks. Two hundred seventy five day-old male broiler chicks were assigned to one of eleven treatments (5 chicks/pen; 5 pens/treatment): 1) Control (no binder or AFB1); 2) 1 ppm AFB1; 3) 2 ppm AFB1; 4) 1 ppm AFB1 + 0.1% SB; 5) 1 ppm AFB1 + 0.2% SB; 6) 1 ppm AFB1 + 0.1% MTB; 7) 1 ppm AFB1 + 0.2% MTB; 8) 2 ppm AFB1 + 0.1% SB; 9) 2 ppm AFB1 + 0.2% SB; 10) 2 ppm AFB1 + 0.1% MTB; 11) 2 ppm AFB1 + 0.2% MTB. Body weight gain (BWG, ± sd) was reduced from 817 ± 26 to 732 ± 93 and 642 ± 92 g/chick, feed intake (FI, ± sd) was reduced from 1,045 ± 62 to 919 ± 100 and 753 ± 116 g/chick, and liver weight also increased from 2.71 ± 0.21 to 3.20 ± 0.36 and 4.45 ± 0.81 g/100 g BW with the addition of 0, 1 and 2 ppm AFB1, respectively (p ≤ 0.0001). Marked differences in the response of broilers to SB and MTB were apparent at the two levels of aflatoxin, as there was an interaction between binder type and AFB1 level. Though there was no difference in the average BWG among broilers consuming 0.1 and 0.2% SB or MTB at 1 ppm AFB1, there was an improvement in the average BWG of broilers consuming 0.1 and 0.2% SB at 2 ppm AFB1 (p ≤ 0.05). A similar interaction was also observed for average liver weight of broilers for the two binders at the two AFB1 concentrations (p ≤ 0.02). Increasing levels of AFB1 depressed plasma albumin, protein, calcium, phosphorus, and alkaline phosphatase (p ≤ 0.01). Despite the use of SB and MTB, only a numerical improvement in the concentration for many of the latter biomarkers was noted. In the present study, these data indicate that SB is more efficacious than MTB in mitigating the negative effects of high dietary AFB1.

Key Words: Aflatoxin, Adsorbent, Broiler Chick, SOLIS™-Base, MTB-100®

T114 Impact of ochratoxin A and deoxynivalenol on selected immune parameters in broiler chicken and possible counteracting. V. Starkl*[1] and H. Sarandan[2], [1]*Biomin GmbH*, *Herzogenburg, Austria*, [2]*Faculty of Veterinary Medicine*, *Timisoara, Romania*.

This trial was performed to evaluate the impact of a combination of 500ppb ochratoxin A and 1000ppb deoxynivalenol on selected immune parameters and the effect of Mycofix® Plus counteracting immune suppression via enzymes and specific immune supportive substances.

216 day old chickens (males and females) were randomly chosen and divided into 4 treatments. Birds in treatment 1 (T1) were fed a mycotoxin free diet. Treatment 2 (T2) consisted of a diet contaminated with 500ppb ochratoxin A and 1000ppb deoxynivalenol. Diet of treatment 3 (T3) was equally contaminated as T2 but additionally treated with 1 kg of Mycofix® Plus. Treatment 4 (T4) only contained 1 kg of Mycofix® Plus. After 42 days blood samples were taken from 3 males and 3 females per treatment for hematological and immunological examination. Levels of lysozime and properdin were selected as humoral factors. Levels of neutrophils, monocytes and eosinophils as well as the activity of macrophages as phagocytic index represent the cellular factors. Properdin and lysozime concentration in blood serum and the phagocytic index can be characterized as indicators for the level of natural immunological reactivity. Levels of lysozime were significantly lower in T2 in both females and males compared to T1 and T4. In females the use of 1,0 kg of Mycofix® Plus (T3) brought the levels back to normal. Properdin levels in T2 are significantly lower than those of treatments 1, 3 and 4, both for females and males. Natural cellular defense expressed, as phagocytic index was significantly lower in T2 compared to the other treatments 1, 3 and 4. Additionally, levels in T4 (sole product) were significantly higher than in the control T1, indicating the capacity of the product to stimulate the activity of macrophages. Levels of hematological parameters were inconclusive.

As a conclusion it can be stated that the selected contamination had a significant impact on levels of lysozyme, properdin and phagocytic index which was overcome by the inclusion of Mycofix® Plus.

Key Words: Ochratoxin A, Deoxynivalenol, Immune systeme, Broiler, Deactivation

T115 High *in vivo* mycotoxin binding efficacy of anti-caking aid restores immune function and improves broiler performance. V. J. H. Sewalt, A. Lamptey, P. Maheswari, S. Wilson*, and C. N. Ramchand, *Kemin Industries, Inc.*, *Des Moines, IA*.

A 35-day dose response performance trial was conducted to evaluate the impact of graded levels (1, 2, 3, and 4 kg/ton) of TXN-86™ $_{brand}$ Dry Anti-Caking Aid (Kemin AgriFoods North America, Inc.) on weight gain and feed conversion of VenCobb broiler birds fed a corn-soy-fishmeal diet containing a mycotoxin cocktail consisting of aflatoxin, ochratoxin, citrinin, and T-2 toxin. Weight gain and feed conversion were negatively impacted by the exposure to mycotoxins ($P \leq 0.001$). Addition of TXN-86 reversed ($P \leq 0.001$) the negative effects of mycotoxins in a linear dose response, returning performance to levels achieved by birds in the positive control group (no toxin) with the 3-4 kg/ton application rates.

Relative organ weight was increased by ingestion of mycotoxin, which, again, was overcome with the inclusion of the Anti-Caking Aid TXN-86 ($P \leq 0.001$). While no discernible relationship was evident for mycotoxins and serum biochemistry parameters, NCD virus-specific immune response depression in birds receiving mycotoxins was reduced with increasing doses of TXN-86, with birds receiving the highest dose having HI titer values equivalent to those of positive control birds ($P \leq 0.001$). Fecal excretion data indicated increased excretion of all toxins in birds receiving increasing doses of TXN-86 ($P \leq 0.001$) in a linear or quadratic manner, along with highly positive correlations between the amounts of mycotoxin excreted and weight gain. Hence, the improved performance and immune response closely reflects the *in vivo* mycotoxin binding capacity of TXN-86 Anti-Caking Aid and also validates the *in vitro* assay results previously presented at this forum.

Key Words: TXN-86, Mycotoxins, Toxin binder, Performance, Excretion

T116 Preliminary assessments of flo-bond as toxins inhibitor and preservative in animal feeds. A. M. Raji*, R. A. Salako, A. O. Owosibo, and J. A. A. Sansi, *Federal College of Animal Health and Production Technology*, *Ibadan, Nigeria*.

Mycotoxins and other forms of anti-nutritional factors are major limitations in the production of quality animal feeds in the humid tropics of the world, Nigeria inclusive.

Four different poultry feed of 1kg each was used for the investigations; the samples of the feeds were commercially purchased from four different feed mills in and around Ibadan, Oyo State, Nigeria. The samples were properly prepared and labeled A to H with each part containing 250g. 0.025g of Flo-bond powder was added to categories A, B, C and D that served as treatment samples, while categories E, F, G and H served as control samples (without Flo-bond). The feed samples were sealed in cellophane bags and then observed for the period of 3 weeks as ripening period.

Microbial analysis was conducted and monitored over the ripening period, on the different feed categories to determine the bacteria as well as fungal counts of the samples. Sample F had the highest bacterial count; while C had the least bacteria count. For the fungal count, sample A had the highest, while samples C, E and H recorded no fungal count.

There was no significant difference in fungal count ($P>0.05$) but a significant difference in bacteria count ($P<0.05$). Those samples with Flo-Bond had growth of fungi which capable of producing toxins, unlike those that are without Flo-bond powder. Thus, Flo-bond can be regarded as an effective feed preservative as well as toxin binder in animal feeds. A further study on the actual utilization of Flo-bond in on farm trial is hereby recommended.

Key Words: Mycotoxins, Feeds, Flo-bond, Bacteria, Fungus

T117 Laboratory evaluation of advance bio-pro concentrate (ABPC) in odor and ammonia reduction in poultry droppings. A. M. Raji*, R. A. Salako, A. O. Owosibo, and J. A. A. Sansi, *Federal College of Animal Health and Production Technology*, *Ibadan, Nigeria*.

Poultry odor and emission of ammonia is a major problem in the industry in Nigeria. As a result of this many poultry farms are being forced to stop operation due to urbanization of their locations.

The investigation was conducted to evaluate the efficacy of Advance Bio Pro Concentrate in controlling poultry odor. The experiment consists of treatment and a control sample in triplicate. Poultry droppings already generating odor were collected from the poultry farm of the College. Equal amount of poultry manure was evenly spread out into different transparent rectangular basins, improvising the dip vat under battery cage system of production.

The solution of Advance Bio-Pro Concentrate (ABPC) was prepared with dilution rate of its one part to nine (9) parts of non-chlorinated water. Hence, the diluted mixture of the ABPC was applied by spraying on the surface area of the manure in the basin via a thoroughly cleaned small flitting cylinder. The other basins with the control were not treated.

Visual and smell evaluation was conducted on the treated and the untreated samples for odor reduction at 30 minutes, 12, 24, 48 and 72hrs respectively. Finally, samples of the treated and untreated were analyzed for ammonia phosphates and chemical oxygen demand content (COD).

Initial observation (visuals and smell panel evaluation) indicated a significant reduction in odor reduction from the treated than the untreated within 30 minutes of application. After about 3hours of application, there was sharp reduction in odor formation and further laboratory analysis revealed a mean value of 52.8% reduction in ammonia and 47.6% reduction in oxygen content of the treated samples compared to the untreated samples measuring up to 93.8% and 96.9% for ammonia and oxygen respectively. Another significant observation was gradual drying of the droppings and drastic reduction in maggots production.

These encouraging results indicate the relevance of ABPC in ensuring biosecurity, odor and ammonia control; and waste management in the livestock industry

Key Words: Poultry, Odor, ABPC, Ammonia, COD

T118 Initial laboratory evaluation of SEPTROL SA 102 in digestion of human and poultry waste (Sewage). A. M. Raji*, R. A. Salako, A. O. Owosibo, and J. A. A. Sansi, *Federal College of Animal Health and Production Technology*, *Ibadan, Nigeria*.

Sewage systems in Nigeria are not well developed for the ease of managing effectively human waste and other forms of wastes. Sewage lines are prone to blockage due to non-availability of digesting agent to degrade, digest and reduce odor formation from sewage collection systems.

Preliminary laboratory investigations were conducted to assess the effectiveness and efficiency of Septrol SA 102, in the degradation and odor/ smell reduction of sewage samples collected from pit latrine and dropping from a deep litter poultry system. Two treatment samples were set up in duplicates containing the same amount of waste samples, to one treatment; 0.22g of the septrol was administered according to the directives of the manufacturer. The treated and untreated samples were subjected to the same environmental conditions in the laboratory, and were left for 72hours for the initial inoculations to take place. After the expiration of the ripening period, the following observations were measured; rate of decomposition, odor reduction, intensity of color and volume reduction of the experimental samples. The results from the treated samples clearly showed that inclusion of Septrol reduced the volume, degraded the waste to watery substance, to almost clear solution. Also the odor was significantly reduced compared to the untreated wastes that continue to degenerate and producing maggots. The color of the waste changed from the initial dark brown to almost clear solution. From this initial evaluation, it was observed that Septrol is very effective in managing human and animal waste (sewage) in terms of digestion and odor control, most especially in pit latrine and soak away pits. With the instruction of monthly applications, Septrol is therefore recommended for sewage digestion and odor reduction.

Key Words: Septrol, Sewage, Odor control, Digestion

T119 Evaluation of poultry litter treatment (PLT) at three application rates for broiler chickens. J. P. Blake*, J. B. Hess, K. S. Macklin, and C. A. Wilson, *Auburn University*, *Auburn, AL*.

A total of 1120 commercial broiler chicks (Cobb X Ross) were randomized with 70 birds assigned to each of 16 environmental chambers (2.44 X 2.44 X 2.44 m). Birds were fed a corn-soybean meal starter (1.5 lbs/bird; 22% CP, 3087 kcal/kg), grower (3.0 lbs/bird; 20% CP, 3131 kcal/kg), finisher (4.0 lbs/bird; 17.5% CP, 3197 kcal/kg) and withdrawal (c.a. 3.0 lbs/bird; 16.5% CP, 3219 kcal/kg). Treatments comprised a control (CON) with no litter treatment and PLT at a commercial application rate equivalent to 50, 100, or 150 lbs/1,000 ft2 of floor space with each treatment assigned to four chambers. New pine shavings (54.42 kg) were placed in each pen. Feed and water were provided ad libitum under 24 hrs continuous light. Birds and feed were weighed at 21, 42 and 49 d to determine growth and feed performance. Litter and air quality samples were obtained for analysis initially and on day 7, 14, 21, 28, 35, 42 and 49 of the experiment. Ammonia measurements were conducted using a closed container of specified dimension inverted over the litter bed and determined using a Drager CMS Analyzer equipped with a remote air sampling pump.

The 49-d bodyweight for the 150lb PLT treatment group was greatest as compared to other treatments. Litter pH was significantly lower (P<0.05) for PLT treated pens as compared to CON (6.35 vs. 2.35). However by day 49 there were no differences in pH due to treatment. Results indicated that by day 35 detectable levels of ammonia could be measured and significantly lower (P<0.05) ammonia levels were encountered on days 35 (c.a. 50% lower) and 42 (c.a. 46% lower) for the PLT treatments, but any influence imposed by PLT disappeared by day 49 (P>0.05). Results from pH and ammonia measurements indicate that PLT remained effective on clean shavings through day 42. Litter sample analysis did not indicate an increase in the amount of nitrogen retained due to treatment. Litter moisture increased from a low of 8.9% initially to 24.4% by day 49 with no differences between treatments.

Key Words: Poultry litter treatment, PLT, Ammonia, Broiler

T120 Evaluation of aluminum sulfate (Alum) at three application rates for broiler chickens. J. P. Blake*, J. B. Hess, K. S. Macklin, and C. A. Wilson, *Auburn University*, *Auburn, AL*.

A total of 1120 commercial broiler chicks (Cobb X Ross) were randomized with 70 birds assigned to each of 16 environmental chambers (2.44 X 2.44 X 2.44 m). Birds were fed a corn-soybean meal starter (1.5 lbs/bird; 22% CP, 3087 kcal/kg), grower (3.0 lbs/bird; 20% CP, 3131 kcal/kg), finisher (4.0 lbs/bird; 17.5% CP, 3197 kcal/kg) and withdrawal (c.a. 3.0 lbs/bird; 16.5% CP, 3219 kcal/kg). Treatment comprised a control (CON) with no litter treatment and ALUM at a commercial application rate equivalent to 50, 100, or 150 lbs/1,000 ft2 of floor space with each treatment assigned to four chambers. New pine shavings (54.42 kg) were placed in each pen. Feed and water were provided ad libitum under 24 hrs continuous light. Birds and feed were weighed at 21, 42 and 49 d to determine growth and feed performance. Litter and air quality samples were obtained for analysis initially and on day 7, 14, 21, 28, 35, 42 and 49 of the experiment. Ammonia measurements were conducted using a closed container of specified dimension inverted over the litter bed and determined using a Drager CMS Analyzer equipped with a remote air sampling pump.

No differences (P>0.05) in growth performance were observed during the experimental period. Litter pH was variable among treatments where the highest level of ALUM maintained a significantly lower (P<0.05) pH through day 42 (9.23 vs. 9.68 for CON), while other levels of ALUM were intermediate or similar to CON. By day 49 there were no differences in pH due to treatment. By day 28 detectable levels of ammonia could be measured and significantly lower (P<0.05) ammonia levels were encountered on day 28 (c.a. 35% lower) and 35 (c.a. 59% lower for 100 and 150 lb application) for the ALUM treatments, but any effect due to ALUM treatment dissipated by day 42 (P>0.05). Results from pH and ammonia measurements indicate that ALUM retained its effectiveness on clean shavings through day 35. Litter sample analysis did not indicate an increase in the amount of nitrogen retained due to treatment. Litter moisture increased from a low of 8.9% to 32.4% by day 49 with no differences between treatments.

Key Words: Aluminum sulfate, Alum, Ammonia, Broiler

T121 Evaluation of ferric sulfate for ammonia control in commercial broiler production. C. W. Ritz*[1], L. A. Harper[1], B. D. Fairchild[1], M. Czarick, III[1], and J. Pavlicek[2], [1]*The University of Georgia*, *Athens*, [2]*Kemiron, Inc.*

In-house air quality is a major concern in poultry production. Growers spend much of their time and investment in maintaining good air quality to maximize poultry growth and performance. Previous work has correlated negative bird performance with poor indoor air quality due to ammonia (NH3). Ventilation has been the key means of removing NH3 from poultry houses but the use of litter treatment products that lower pH are also commonly applied. Acid-based litter treatments, though effective for short-term NH3 reduction, may not be viable for long-term ammonia control due to the amount of product required to chemically bind NH3, problems of application when birds are present, and the corrosiveness of the material. New products are needed that can address these issues. The purpose of this study was to evaluate the effectiveness of a new litter amendment containing ferric sulfate compared to an alum-based litter amendment. Since alum is commonly used within the broiler industry and at the request of the participating poultry company, in this study alum was used as the Control and the ferric sulfate product as the Treatment. Both Treatment and Control were applied at the same time and at the same rate of 100 lbs per 1000 ft2. Litter moisture, pH, mineral content, and soluble salts were recorded throughout the study. Ammonia was measured using time weighted detection tubes and gas-washing bottles. The ferric sulfate amendment was, on average, superior to the control in reducing NH3 concentrations during the first 15 days after bird placement with mean NH3 concentrations for the ferric sulfate and alum at 13-19 ppm and 21-26 ppm, respectively. No significant differences were noted in mortality, body weight or feed efficiency. The ferric sulfate product is applicator-friendly with noticeably reduced dust generation upon product application and improved retention of nitrogen in the litter.

Key Words: Ferric sulfate, Ammonia, Broiler, Alum

T122 Reduced ammonia emission diets: Implementation costs and production effects. E. C. Hale III*, *EcoCal Products, LLC*, *Brownstown, IN*.

The effect of a manure ammonia emission reducing diet on egg production and costs at a commercial egg production facility was determined.

A total of 6 hen houses comprised the trial group. Each house had an initial population of 125,000 hens, for a total population of 750,000 hens. The houses were separated into 3 pairs, matching hen age and production status as closely as possible within each pair of houses; however, exact age/production matches were not achieved.

Each house was fed an industry standard diet appropriate to the age and production status of the hens. Production factors, feed costs, and production costs were monitored for 9 weeks prior to introducing the test diet. This data was used to determine the innate differences in feed cost/ton, total egg production, mortality, feed consumption, egg grade, and per-dozen production costs between paired houses. The averaged difference for each parameter was used to correct observed data skewing caused by differences in hen age and production status between paired houses.

Once background performance data was collected, a test diet containing 1.0% clinoptilolite zeolite and 2.5% gypsum by weight was introduced to one house selected from each pair. Production factors and costs were monitored for a total of 14 weeks after introduction of the test diet.

Data from each pair of houses was handled separately from each other pair of houses for the purposes of determining production differences caused by the test diet and its effect on production costs. Once the average differences were determined for each of the 3 pairs, the average differences in production and costs across the 3 pairs were determined.

For the entire population in the study, averaged comparative data indicates that the test diet achieved a 5.9% improvement in total egg production, a 34.6% reduction in mortality, an increase of 3.0% in feed cost/ton, an increase of 3.5% in feed consumed/week, a reduction of 24.7% in undergrade eggs, and an increase of 5.3% in Grade A large + eggs. The comparative difference in the cost to produce one dozen eggs was -3.3%.

Key Words: Dietary manipulation, Production effects, Implementation costs, Ammonia emissions, Hen performance

T123 Efficacy of Elector® PSP (spinosad) for the control of the lesser mealworm (*Alphitobius diaperinus* Panzer) in heavy broilers. S. M. Stringham*[1], D. W. Watson[1], S. Denning[1], K. A. Baker[2], and G. Balme[1], [1]*North Carolina State University*, *Raleigh*, [2]*Elanco Animal Health*, *Greenfield, IN*.

The study evaluated the efficacy of Elector® PSP (spinosad) at two rates applied as banded or broadcast sprays against a broadcast application of Tempo® 1% Dust (cyfluthrin) and an untreated control. Production houses at two farms were randomly assigned as treatments and sampled through two nine-week flock cycles. All treatments were applied within a week of bird removal, immediately after cake-out and routine cleaning. A 0.08% spinosad spray was applied as a banded treatment under feeders, drinkers and along walls. Spinosad treatments (0.16%) were banded as described or applied as a broadcast treatment over the entire floor. Cyfluthrin dust treatments consisted of a single broadcast application at label rates using a power duster. Fifty gallons of water was applied as broadcast spray to control houses. Experimental houses were sampled using modified tube traps placed at twenty locations distributed between wall, feeder and center floor locations within the front three quarters of the houses. Traps were left in place for one week during each sampling period. Pre-treatment samples were taken one week prior to removal of the preceding flock. Subsequent samples were taken at weekly intervals for five weeks following treatment, and again at 7 weeks after treatment. Results demonstrated that, for the most part, spinosad sprays effectively suppressed larval numbers, often by a significant margin over cyfluthrin in comparisons with control houses. Cyfluthrin was more effective against beetle adults at the outset of the trial but was no more effective than spinosad beyond three weeks post treatment.

The study demonstrates that spinosyns are an effective class of insecticides for lesser mealworm control in broiler and other poultry production. It is a welcome addition to the limited array of insecticides currently available. As such, spinosad adds greater flexibility to the insecticide rotations now necessary to manage resistance in lesser mealworms.

Key Words: Spinosad, *Alphitobius diaperinus*, Lesser mealworm, Resistance management, Broilers

T124 Management strategies for utilizing hardwood sawdust as a poultry bedding. G. Malone*[1], S. Collier[1], and D. Rider[2], [1]*University of Delaware*, *Georgetown*, [2]*Department of Natural Resources*, *Annapolis, MD*.

Many concentrated poultry-producing areas of the USA including the Delmarva Peninsula have shortages of quality pine-base bedding materials. Yet, there are often ample supplies of cost-effective hardwood sawdust (HW) that could supplement this deficit. However, the poultry industry has been reluctant to use HW due to periodic mold-induced respiratory health concerns. A demonstration was implemented to evaluate management strategies for utilizing HW as poultry bedding. On a commercial farm growing roaster chickens; loblolly pine (LP), yellow poplar (YP) and white oak sawdust (WO) were each placed in 2 houses. For each bedding type, 1 house received fresh-cut sawdust (SD) directly from sawmills or SD that had been held in storage for 3 months. One half of each house also received a peracetic acid-base mold inhibitor prior to chick placement. The average moisture content of SD for all species at placement in Flock 1 was 31%. Moisture content of SD obtained directly from sawmills was higher (40%) compared to SD held in storage for 3 months (23%). While in storage the temperature of the SD averaged 137 F. Storage and the use of the mold inhibitor had little influence on bedding mold populations. However, there was a two-log reduction in mold populations in Flock 2 compared to Flock 1, and a one-log reduction in LP compared to the HW species. Two-week mortalities were less in Flock 2 for all bedding types. Based on the weight and content of the gizzards there were indications chick prefer consuming the WO. In Flock 1 the incidence of foot pad dermatitis was less with fresh compared to stored bedding and less with YP compared to the other bedding types for both flocks. Based on the physical, chemical and biological observations in this field demonstration, the data is suggestive that YP may be a viable alternative to LP in regions having a bedding shortage. Under conditions of this demonstration, using a mold inhibitor or placing bedding materials in storage had no distinct advantage.

Key Words: Hardwood bedding, Litter, Poultry

T125 The impact of litter type, depth and management on broiler foot pad lesions: Welfare and economic considerations. A. Atencio* and K. Opengart, *Keystone Foods LLC*, *Huntsville, AL*.

Each of sixteen houses on a commercial broiler farm was populated with 22,500 one-day-old Ross x Hubbard Ultra-Yield chicks. The farm was divided into 4, four house units with each house within a replicate having a different litter treatment: 1) one load of peanut hulls, 2) two loads of peanut hulls, 3) one load of pine shavings, or 3) one-half load of pine shavings on top of peanut hulls built-up litter. Birds were randomly placed and were grown using identical management and feed formulation. Foot pad lesions were scored using a scale of 0-2 (0 = no lesion, 1 = mild lesion, 2 = severe lesion) at 43 and 50 days of

age by examining the left and right foot pads of 100 birds per house at each age. At processing, foot pads from 66,080 fifty-six day old birds (19% of each house) were scored using a + or - scale to indicate the presence or absence of lesions, respectively. A highly significant treatment effect was observed. Chicks raised on pine shavings had a lower incidence and less severe paw lesions than chicks raised on peanut hulls. Lesion incidence scored in the house was 12.9^{a} ; 8.4^{a} ; 4.9^{b} and 0.9^{c} and at the processing plant was 9.7^{a}, 10.1^{a}, 1.96^{b} and 1.22^{b} % for the birds raised on one load of peanut hulls, two loads of peanut hulls, one load of pine shavings, or a half load of pine shavings on top of built up litter, respectively (means were compared using the Studen-Newman-Keuls test at 5% probability). It appears that a combination of litter depth and litter source may impact incidence and severity of paw lesions. Improving paw quality has significant welfare and economic implications.

Key Words: Paw lesion, Foot pad podermatitis, Bedding type, Animal welfare

T126 Heat recovery system: Attic ventilation. B. D. Lott*[1] and J. L. Purswell[2], [1]*Mississippi State University*, *Mississippi State*, [2]*USDA*, *Mississippi State, MS*.

Fuel cost has increased to dramatic levels for the poultry farmer. In an attempt to help alleviate some of the burden of increased fuel cost, a system was developed to take advantage of attic heat. With the attic ventilation system, an additional set of ventilation boxes are installed in the middle of the house to pull air out of the attic. On sunny days, the temperature may range from 5° to 20° C higher in the attic than outside temperatures. In summer when the temperatures are hot, the inside temperature of the house can be increased to over 50° C without any fossil fuel usage. A vent box system in the center of the ceiling, independent of the sidewall vent boxes, was installed. Minimum ventilation was used to ventilate the brood area with attic air, rather than outside air.

The system was developed to assist normal brooder operations and reduce the brooder runtime by using the preheated air in the attic. On a sunny day, the system can save as much as 20 percent on fuel cost.

Key Words: Broiler, Attic ventilation, Fuel cost

T127 Why understanding bioethical issues is important. R. D. Reynnells*[1], C. C. Croney[2], and D. J. R. Cherney[3], [1]*US Department of Agriculture, Cooperative State, Research and Extension Service*, *Washington, DC*, [2]*Oregon State University*, *Corvallis*, [3]*Cornell University*, *Ithaca, NY*.

Organizations are changed by decision makers' understanding of issues, organizational requirements and goals, and available options. Agricultural systems are no different. Decision makers may be consumers who make purchasing decisions (thus driving market demands), voters, government officials, animal producers, or company executives. Historically, cheap food demand has been a major change agent for agriculture, as has the desire of farmers to avoid dangerous, repetitive, dirty tasks. Change has often been straight forward in the form of mechanization, consolidation of production (e.g., feed mills serve many farms), vertical integration, or use of chemicals to control diseases or insects. Today, it is increasingly difficult, and yet imperative, to balance ethical considerations with economic and pragmatic factors relative to animal agriculture. This balance is complicated by a perception that some production changes may not be truly market driven but imposed by persons apparently attempting de facto management of producer's resources.

New standards for change are not restricted to questions about how to efficiently raise food animals. Rather, they include concepts of refinement, reduction, and replacement of certain animal management and care practices, and considerations of whether or not we should use animals for food. Should science alone be the basis of our management and regulatory decisions, or should bio-ethical considerations be used in framing housing, genetics, management and disease control decisions? Should a personal or organizational vision of ethical behavior reflecting specific religious or cultural values not held by all members of society be imposed on others or should changes in agriculture come through market demand? What if consumer demand does not reflect an informed or pragmatic decision regarding animal health or welfare? Bioethics increasingly influences decisions by consumers, voters, and regulatory officials. Bioethical concepts should therefore be understood by everyone involved in agriculture in order to properly address the issues presented to society and to inform decisions made in daily practice.

Key Words: Animal welfare, Bioethics, Cheap food, Management, Standards

T128 Share poultry images with others through the animal science image gallery. J. B. Hess* and W. D. Berry, *Auburn University*, *Auburn, AL*.

As the number of faculty dedicated to teaching poultry science in the U.S. continues to decline, the need for poultry-related teaching aids for those with limited access to the poultry industry increases. The Animal Science Image Gallery was created to provide images to middle school, high school and university teachers wishing to include information on animal agriculture in their courses. With the dwindling expertise in poultry at the university level, a reference site of poultry and/or poultry industry images would be a useful teaching tool nationally. The Animal Science Image Gallery was designed to fill this role. Each image on the site comes with a limited description, making it possible for educators to collect images that fit with the portion of the industry that is being discussed. Editors review each image and the corresponding text for accuracy.

Categories exist for most types of agricultural animals, including poultry. Within the poultry site, subcategories include; anatomy and physiology, disease and pathology, housing and equipment, poultry processing and poultry species and breeds. To date, the poultry site does not have a wide range of images available to offer coverage of the many types of poultry operations in the U.S. Please consider uploading images to the site commensurate with your area of expertise. Access

the Animal Science Image Gallery at http://cygnet.richmond.edu/image_gallery to browse or upload images. Contributing to the Image Gallery will ensure that high school and university instructors will have quality poultry science materials to draw from in organizing lectures on poultry science and the poultry industry.

Key Words: Images, Poultry, Pictures

T129 Development of macrolide resistant *Campylobacter* in broilers administered subtherapeutic or therapeutic levels of tylosin. S. R. Ladely*[1], M. A. Harrison[2], P. J. Fedorka-Cray[1], M. E. Berrang[1], M. D. Englen[1], and R. J. Meinersmann[1], [1]*USDA-ARS-Russell Research Center*, *Athens, GA*, [2]*UGA-Food Science and Technololgy*, *Athens, GA*.

The use of antimicrobials in food animal production, particularly those commonly used to treat infections in humans, has become a source of controversy in recent years. However, limited data are available regarding the development of resistance from subtherapeutic or therapeutic administration of antimicrobials in animal production. The objective of this study was to evaluate the effect of FDA approved levels of tylosin administration on susceptibility of *Campylobacter jejuni* and *C. coli* isolated from ceca of treated broilers. In each of three replicate studies, day-of-hatch chicks were exposed to macrolide susceptible *C. jejuni* or *C. coli*. At two weeks of age, tylosin was administered at subtherapeutic (22 ppm, continuously in the diet) or therapeutic levels (529 ppm in drinking water for 5 days). Weekly, 5 broilers per group were sacrificed. Total and resistant *Campylobacter* were enumerated from individual ceca with contents. Macrolide resistance was observed at a higher frequency ($P<0.01$) among *C. coli* isolates 70.8% (17 /24) compared to *C. jejuni* isolates 36.8% (35/95). Resistance was observed at a significantly higher frequency ($P<0.001$) when tylosin was administered at subtherapeutic levels (62.7 %, 47/75), compared to administration of therapeutic levels (11.4 %, 5/44). Subtherapeutic administration resulted in recovery of 83.3 % (15/18) and 56.1 % (32/57) macrolide resistant isolates compared to only 33.3 % (2/6) and 7.9 % (3/38) of the isolates expressing macrolide resistance following administration of therapeutic levels, for *C. coli* and *C. jejuni*, respectively. Further studies are needed to determine the factors involved in the apparent difference in the acquisition of macrolide resistance in *C. coli* compared to *C. jejuni*.

Key Words: Tylosin, Macrolide resistance, *Campylobacter*

T130 Effect of a pelleted experimental chlorate product (ECP) on Salmonella in the ceca of market-age broilers. J. A. Byrd*, J. L. McReynolds, L. F. Kubena, and D. J. Nisbet, *USDA-ARS-Food and Feed Safety Research Unit*, *College Station, TX*.

Previously, our laboratory demonstrated that ECP can be administered in drinking water to reduce *Salmonella, E. coli, and Clostridium* in bovine, porcine and poultry. The objective of this study was to evaluate the effectiveness of a feed grade pelleted ECP and to determine if nitrate pre-adaptation will increase the bactericidal activity of ECP to control *Salmonella* Typhimurium(ST) in market-age broilers. In three trials, at 6 wk-of-age, one hundred and forty broilers were randomly assigned to seven groups of twenty birds and placed in floor pens containing pine litter. Two days prior to slaughter, broilers in group 1 were fed a control finisher diet , groups 2 and 3 were fed either a 1.0% ECP-carrier or salt control, and groups 4 and 5 were provide either 1% or 5% ECP. Groups six and seven were fed a pelleted sodium nitrate diet 4 d prior to termination and then changed to either a 1% or 5% pelleted ECP diet two days prior to termination of the experiment. Prior to placement, each bird was orally challenged with 10^9 ST. Cecal contents were aseptically collected and spread on XLT4 plates to enumerate ST, respectively. Litter was collected from each group to determine moisture content. In the groups fed the salt control diet and 5.0% ECP diets, litter moisture was significantly increased when compared to all other treatments. Mortality was not significant. Pre-nitrate adaptation-5% ECP (0.92 $\log_{10}$ cfu ST) significantly reduced the number of ST recovered from the ceca when compared to the control fed broilers (1.87 $\log_{10}$ cfu ST). These results indicate that pelleted ECP feed prior to slaughter can effectively reduce ST in broilers, and may potentially reduce the risk of contaminating poultry products.

Key Words: Broilers, Experimental chlorate product, *Salmonella* typhimurium, Sodium nitrate

T131 Temperature and oxygen conditions during the plateau stage of incubation affect long bone development in broilers and turkeys. E. O. Oviedo-Rondón*, J. Small, M. J. Wineland, V. L. Christensen, D. T. Ort, K. M. Mann, and S. L. Funderburk, *North Carolina State University*, *Raleigh*.

Previous research suggested that several organs and bone development at hatch could be altered by high temperatures (T) during the plateau stage of incubation. Trials were designed to evaluate the effects of oxygen (O_2) concentrations and the interactions between O_2 and T on bone development in both Ch and turkeys (TU). Two strains of CH with low (LG) and high (HG) eggshell conductance, and one TU strain of LG were used. The first 2 trials O_2 concentrations (17, 19, 21 or 23%) were evaluated. The CH trial was analyzed as a 2x2 factorial design with O_2 concentrations and genetic strain as main effects. The TU trials data was analyzed as a completely randomized design. In the subsequent 2 trials, T (36 and 39 °C) and O_2 concentrations (17 and 23%) were evaluated in a 2x2 factorial design. At day of hatch, 15 CH or poults per strain were selected, both legs were dissected, parts weighed and relative asymmetry (RA) of each leg section calculated. The LG CH strain had heavier ($P<0.01$) body, legs, muscles and bone weights in both trials. CH at the lowest O_2 concentrations had ($P<0.05$) lighter and shorter tibias, lighter shanks, and increased RA of femur length compared to CH in the 23% O_2. Poult body and part weights were not affected ($P>0.05$) by O_2 concentrations, but poults at 23% O_2 had larger shanks and heavier tibias than TU at 17% O_2. High T depressed BW of LG CH, but no significant effect of treatments was observed on BW of HG CH. Nevertheless, in the HG CH, high T caused lighter ($P<0.01$) thighs and shanks; both high T and low O_2 independently caused ($P<0.001$) shorter shanks and lighter drums. Low O_2 reduced femur and tibia weight, length, and increased RA of drums. In the LG CH, high T decreased ($P<0.001$) shank weight and thickness; low O_2 caused shorter shanks, and both low O_2 and high T together increased ($P<0.05$) RA in shank weight. In trial 4 with TU, high T depressed ($P<0.01$) BW, leg muscle weights, and shank length. Low O_2 reduced ($P<0.05$) tibia and shank %. Incubation conditions affect long bone development in CH and TU and may have an impact in leg health.

Key Words: Broilers, Turkeys, Incubation, Bone development, Leg health

T132 Meta Analysis of dietary amino acid responses of broiler chickens. W. A. Dozier, III*[1], M. T. Kidd[2], and A. Corzo[2], [1]*USDA-ARS Poultry Research Unit*, *Mississippi State, MS*, [2]*Mississippi State University*, *Mississippi State*.

Defining the optimal balance of critical amino acids for diet formulation is of utmost importance to practicing nutritionists. This study summarized six peer-reviewed manuscripts that evaluated dietary amino acid density regimens that were published during 2003 to 2006 from USDA-ARS or Mississippi State University. Diets providing optimal growth responses during starter, grower, finisher, and withdrawal periods from the six manuscripts were used. Regression analyses were conducted with respect to bird age to generate prediction equations for dietary amino acid percentages, daily amino acid consumption, and daily amino acid consumption per unit of BW gain. Actual analysis of amino acids was used instead of calculated values. Regression equations for dietary Lys percentage, Lys consumption (mg/d), and daily Lys consumption per unit of BW gain (mg/g/d) had R^2 values of 0.93, 0.99, and 0.90, respectively. Predicted dietary Lys percentages were 1.36, 1.26, 1.19, 1.12, 1.06, 1.01, and 0.97 and dietary Lys consumption (mg/d) was 464, 861, 1,195, 1,466, 1,675, 1,821, and 1,904 for 7, 14, 21, 28, 35, 42, and 49 d, respectively. The R^2 values for dietary TSAA percentages, TSAA consumption (mg/d), and daily TSAA consumption per unit of BW gain (mg/g/d) were 0.86, 0.99, and 0.93, respectively. Predicted dietary TSAA percentages were 0.94, 0.90, 0.85, 0.81, 0.77, 0.74, and 0.70 and dietary TSAA consumption (mg/d) was 324, 623, 873, 1,074, 1,228, 1,333, and 1,390 for 7, 14, 21, 28, 35, 42, and 49 d, respectively. Dietary Thr percentage, Thr consumption (mg/d), and daily Thr consumption per unit of BW gain (mg/g/d) had R^2 values for 0.86, 0.99, and 0.92. Predicted dietary Thr percentages were 0.84, 0.81, 0.77, 0.74, 0.71, 0.69, and 0.67 and dietary Thr consumption (mg/d) was 290, 555, 779, 962, 1,104, 1,207, and 1,268 for 7, 14, 21, 28, 35, 42, and 49 d, respectively. These results provide dietary amino acid estimates for formulating diets throughout a 7 wk production period; however, these values are based upon dietary amino acid density research and not on minimum requirements.

Key Words: Amino acid, Broiler, Lysine, Mmethionine, Threonine

T133 Practical dietary L-threonine inclusion and resultant impact on broiler growth, yield, and nitrogen excretion. M. T. Kidd*[1], A. Corzo[1], W. A. Dozier, III[2], C. D. Coufal[1], B. J. Kerr[3], and D. Hoehler[4], [1]*Mississippi State University*, *Mississippi State*, [2]*USDA*, *Mississippi State, MS*, [3]*USDA*, *Ames, IA*, [4]*Degussa Corporation*, *Kennesaw, GA*.

The dietary inclusion of L-Thr has necessitated accurate knowledge of nutrient amino acid needs beyond Thr. Research delineating the former has been forthcoming, but remains sparse. As a result, many commercial nutritionists have included L-Thr using company historical data on CP fluctuations and bird performance. In this experiment, practical inclusions of L-Thr were used which resulted in a 1.3% decrease in CP. Cobb x 500 (fast feathering) broilers were reared in floor pens. At d 25, male broilers were selected, tagged, and placed across 24 pens (6 birds/pen). Three dietary treatments were fed from 25 to 43 d: 19.88% CP with no L-Thr; 19.25% CP with 0.023% L-Thr; and 18.62% CP with 0.045% L-Thr (8 replications/treatment). The highest and lowest CP pelleted treatments were blended to get the middle CP level. In addition to obtaining live performance and processing data on all birds, plastic was lined in the pens to obtain a 24 h collection of feces at d 32. All pens were positioned whereby the adjacent pen contained no birds to minimize fecal contamination. Protein efficiency ratio did not differ among treatments. Other live performance parameters did not differ ($P > 0.05$). Percentage abdominal fat increased ($P = 0.07$) as L-Thr increased, but other carcass measurements did not differ. Nitrogen excretion was highest ($P = 0.13$) in birds fed no L-Thr. Results indicate that Cobb male broiler live performance and processing traits can be maintained in reduced CP-L-Thr containing diets, and nitrogen excretion benefits may be realized.

Key Words: Amino acid, Threonine, Broiler, Protein efficiency ratio, Nitrogen excretion

T134 Impact of feeding reduced protein diets on performance, breast yields and nitrogen emissions in broiler chickens. R. Angel*[1], W. Powers[2], S. Zamzow[2], T. Applegate[3], and D. Hoehler[4], [1]*University of Maryland*, *College Park, MD*, [2]*Iowa State University*, *Ames*, [3]*Purdue University*, *Lafayette, IN*, [4]*Degussa Corporation*, *Kenessaw, GA*.

The impact of feeding reduced protein (RP) and industry (C) corn-soy diets on broiler performance, breast yield and litter nitrogen (N) content was determined. Ross 308 male broilers were allocated to 8 chambers and grown from hatch to 42 d. Five sequential Exp were conducted. C treatment (Trt) broilers were fed a 4 phase feeding program: starter (St), grower (Gr), finisher (Fn), and withdrawal (Wd) diets. RP Trt broilers were fed a 6 phase feeding program: prestarter (PrSt), St, Gr1, Gr2, Fn, and Wd diets. Protein concentrations were 22.1, 20.0, 17.2, and 16.6% for the C Trt St, Gr, Fn, and Wd diets, while those for the RP Trt PrSt, St, Gr1, Gr2, Fn, and Wd diets were 22.0, 18.6, 18.1, 17.3, 15.8, and 15.0%. Minimum amino acid (AA) requirements as well amino acid to lysine ratios were maintained for diets in both Trt. Synthetic Lys, Met, Ile, Thr, Arg, Trp, and Val were used to meet AA minimums in RP diets while only Met and Lys were used to meet the same minimums in C diets. Total concentrations of Lys, Met+Cys, Ile, Thr, Trp, Arg, and Val, in the St, Gr1, Gr2, Fn, and Wd RP diets were: 1.22, 0.91, 0.85, 0.82, 0.24, 1.40, 0.90%; 1.14, 0.83, 0.82, 0.68, 0.23, 1.25, 0.90%; 1.06, 0.80, 0.75, 0.74, 0.22, 0.83%; 1.01, 0.75, 0.71, 0.68, 0.20, 0.80%; and 0.96, 0.73, 0.70, 0.68, 0.19, 0.76%, respectively. Performance was determined at the end of each phase and litter was analyzed for DM, N and minerals. Ammonia (NH3) emissions were calculated by sampling incoming air followed by sequential sampling

of each chamber. Broilers on the C Trt weighed more ($P < 0.05$) at 42 d over the five F (2.74 kg) than those fed the RP Trt (2.66 kg) but feed/gain ratio was similar (1.88 vs. 190 for C and RP). Twenty broilers per chamber were sampled for yield determination in F 3 and 4. Dress percent, breast weight and breast yields were not affected by Trt. Based on analyzed diet, litter and air concentrations over the 5 F, N consumed was 9.2% less, litter N 20.6% less, and mean NH3 emissions were 16% lower in RP vs. C chambers. The study demonstrates that N emissions can be reduced substantially by feeding low-protein diets in broilers.

Key Words: Broiler, Protein, Nitrogen, Emissions

T135 Carcass defects with broilers fed requirement EAA levels from 6 to 8 weeks of age while CP and ME varied at practical extremes. E. T. Moran* and J. Galobart, *Auburn University*, *Auburn, AL*.

Formulating feed using commercial EAA reduces associated CP, and performance suffers when fully implemented. Experimentation examined incidence of carcass defects when CP was maximally decreased with the final feed, and if reducing ME to increase consumption of CP would provide relief. Ross X Ross 308 broilers were reared sexes-separate in floor pens from 0 to 6 weeks of age on common feeds. During the subsequent 6 to 8 weeks (25 C and 80% RH), feeds having CP at either 18.0 or 16.5% while ME was either 3250 or 3090 kcal / kg were given to 4 replicate pens of 25 chicks. All feeds employed corn, soybean meal, poultry fat, and purified essential amino acids as the central ingredients. AA analyses confirmed NRC(1994) requirement levels. Reducing CP adversely affected both live weight gain and F/G of both sexes between 6 and 8 weeks of age while reduction in ME independently increased F/G without altering growth. After on-line processing, static slush-ice carcasses were evaluated for the incidence of wings having dislocated joints, bruising, broken bones, and brachial veins having prominent blood; drumsticks with broken bones and bruising; breast bruising and broken clavicles; and back-thigh area having bruising, skin tear and scratching, ANOVA evaluated transformed percentages from each pen. Wing bruising was the defect having the greatest incidence (19.0%) and breast bruising the least (0.4%). No significant effects were detected that could be attributed to level of CP, ME or their interaction ($P>.05$). Males exhibited a greater vascular disruption of blood in the wing veins, broken drumsticks and bruising of the back than females while the converse occurred for drumstick bruising and skin tearing of back-thigh ($P<.05$). Absence of carcass defects associated with wide levels of feed CP and ME suggest infers that a minimal adverse effect on welfare audit and consumer quality exists in a practical context.

Key Words: Carcass quality, Feed formulation, Metabolizable energy, Protein nutrition, Welfare audit

T136 Dietary amino acid responses of broiler chickens from 36 to 47 d on subsequent 60 d performance. W. A. Dozier, III*[1], M. T. Kidd[2], A. Corzo[2], J. Anderson[3], and S. L. Branton[1], [1]*USDA-ARS Poultry Research Unit*, *Mississippi State, MS*, [2]*Mississippi State University*, *Mississippi State*, [3]*Mississippi State University*, *Mississippi State*.

Dietary amino acid responses of broilers from 5 to 9 wk of age have not been well defined. This study examined growth responses and meat yield of broilers provided diets varying in amino acid density from 36 to 47 d of age on 60 d performance. Sixteen hundred and sixty-four Ross × Ross 708 chicks were randomly distributed into 32 floor pens (26 males and 26 females; 0.08 m^2/bird) at one-d of age. All birds were fed common starter (0 to 17 d) and grower (18 to 35 d) diets. Broilers were provided diets characterized as being high (H), moderate (M), or low (L) in amino acid density from 36 to 47 and 48 to 60 d of age. The diets were formulated to contain: H (19.0% CP, 0.75% digestible (d) TSAA, and 0.92% dLys), M (18.0% CP, 0.73% dTSAA, and 0.85% dLys) , and L (16.8% CP, 0.70% dTSAA, and 0.78% dLys) amino acid density from 36 to 47 d, and H (17.6% CP, 0.70% dTSAA, and 0.88% dLys) and L (16.1% CP, 0.63% dTSAA, and 0.75% dLys) amino acid density from 48 to 60 d. Dietary treatments were HH, HL, ML, and LL from 36 to 60 d of age.

Broilers provided the HH regimen had lower ($P\leq0.05$) final feed conversion and less ($P\leq0.05$) abdominal fat percentage than ML and LL fed broilers. Decreasing dietary amino acid density from HH to LL regimen reduced ($P\leq0.05$) total breast meat weight and yield. Dietary treatments did not influence final BW, cumulative feed intake, cumulative mortality, or carcass weight and yield. These results indicate that reducing dietary amino acid density from H to L during 36 to 47 d negatively impacted 60 d feed conversion and breast meat yield under these experimental conditions.

Key Words: Amino acid, Broiler, Lysine, Methionine, Theonine

T137 Dietary amino acid responses of broiler chickens from 48 to 60 d on growth and carcass traits. W. A. Dozier, III*[1], M. T. Kidd[2], A. Corzo[1], J. Anderson[3], and S. L. Branton[1], [1]*USDA-ARS Poultry Research Unit*, *Mississippi State, MS*, [2]*Mississippi State University*, *Mississippi State*, [3]*Mississippi State University*, *Mississippi State*.

Dietary amino acid responses of broiler chickens from 7 to 9 wk of age are sparse. This study examined growth responses and meat yield of broilers provided diets varying in amino acid density from 48 to 60 d of age. Sixteen hundred Ross × Ross 708 chicks were randomly distributed into 32 floor pens (25 males and 25 females; 0.08 m^2/bird) at one-d of age. All birds were fed common starter and grower diets until 35 d of age. Broilers were provided diets characterized as being high (H), moderate (M), low (L), or sub-optimum (S) in amino acid density from 48 to 60 d of age. The diets were formulated to contain: H (17.9% CP, 0.70% digestible (d) TSAA, and 0.87% dLys), M (16.9% CP, 0.65% dTSAA, and 0.81% dLys), L (15.8% CP, 0.60% dTSAA, and 0.75% dLys), or S (14.8% CP, 0.55% dTSAA, and 0.69% dLys).

Broilers provided the H regimen had improved ($P\leq0.05$) cumulative feed conversion over the other dietary treatments. Feeding the S diet to broilers decreased ($P\leq0.05$) carcass yield compared with the other dietary treatment, whereas H fed broilers had lower ($P\leq0.05$) abdominal fat percentage than the M, L, and S fed broilers. Providing the S diet to broilers limited ($P\leq0.05$) total breast weight (Pectoralis major and minor muscles) compared with the H dietary treatment, but broilers fed the M and S diets had lower ($P\leq0.05$) total breast meat yield than broilers given the H diet. The least significance difference

critical value for breast meat yield was 0.48% and the breast meat yield difference between H and L broilers was 0.46% (24.00 vs. 23.54%), thus inferring a breast meat yield difference was approaching significance between the H and L fed broilers. These data indicate that feeding the H diet from 48 to 60 d is advantageous to optimize cumulative feed conversion and maintain optimal total breast meat yield.

Key Words: Amino acid, Broiler, Lysine, Methionine, Threonine

T138 Valine marginality and needs of growing broilers. A. Corzo*[1], M. T. Kidd[1], W. A. Dozier, III[2], and S. L. Vieira[3], [1]*Mississippi State University*, *Mississippi State*, [2]*USDA-ARS*, *MS*, [3]*Universidade Federal do Rio Grande do Sul*, *Porto Alegre, Brazil*.

Valine is likely the fourth limiting amino acid in some diets than contain feedstuffs only from vegetable origin. Three experiments (Exp) from 21 to 42 d of age were conducted to not only corroborate the previous statement, but to validate a Val deficiency and subsequently quantify an adequate ratio to lysine. A high yield broiler male (Ross×Ross 708) was used in all Exp. In Exp 1, L-Thr was included into a corn-soybean meal diet where no other essential amino acid minimums were imposed other than those for Lys, TSAA and Thr. Individually, L-Val, L-Ile, L-Arg and Gly were supplemented by 0.10% to that diet. Based on results obtained for BW gain, feed conversion and abdominal fat weight and percentage, birds were most responsive when L-Val was supplemented to the diet when compared to other supplemented amino acids. Subsequently, Exp 2 compared a corn-peanut meal diet against a corn-soybean meal diet. The corn-peanut meal based diet was formulated to be deficient in Val, which indeed occurred as observed by poor performance BW gain and feed conversion; subsequent supplementation with L-Val validated the Val deficiency. Further, a comparison between the corn-peanut meal L-Val supplemented diet and the corn-soybean meal diet of similar nutritional composition validated the use of the corn-peanut meal based diet in its ability to support adequate growth of broilers. Finally, Exp 3 used the same corn-peanut meal based diet to create a dose-response, where Val would be deficient (0.59% digestible) and gradual increments of dietary Val were accomplished by supplementing L-Val to the diet. Quadratic effects were observed for BW gain, breast meat weight and its yield, where a dietary Val to Lys ratio would be adequate between 74 and 78.

Key Words: Breast meat, Broiler, Lysine, Valine

T139 Selenium sources affect protein concentration, thioredoxin reductase activity and selected production parameters in reovirus infected broilers. S. Burgos*[1], F. W. Edens[1], J. Read-Snyder[1], A. Cantor[2], and S. A. Burgos[3], [1]*North Carolina State University*, *Raleigh*, [2]*University of Kentucky*, *Lexington*, [3]*University of Guelph*, *Guelph, ON, Canada*.

Avian reoviruses (ARV) are members of the *Orthoreovirus* genus within the *Reoviridae* family. Successful ARV infection ultimately result in decreased weight gains coupled with increased mortality. Selenium (Se) is involved with Thioredoxin Reductase (TRX), an enzyme that quenches free radicals that can damage proteins, lipids and nucleic acids. The aim of this study was to determine the effects that Se-containing diets fed to ARV-infected broilers had on protein concentrations, TRX activity, body weights and mortality. Eggs were obtained from Cobb breeders that had been maintained on isocaloric Torula yeast diets containing either no supplemental Se, sodium selenite at 0.3 ppm, or organic Se (SelPlex, Alltech, Inc., Nicholasville, KY) at 0.3 ppm. Chicks hatched from those eggs were placed on Torula yeast broiler diets containing no supplemental Se, 0.3 ppm sodium selenite, or 0.3 ppm organic Se similar to their respective parents' diets. On the day of hatch, 60 chicks per dietary Se treatment were placed into either control or ARV-infected groups in heated-growing batteries in separate isolation rooms. Chicks in the ARV-infected groups were given each an oral gavage of 0.2 mcL of ARV-CU98 ($10^{4.2}$ pfu/chick), and control chicks were given the medium only. At 14 and 21 days of age, the chicks were bled, weighed, killed by CO^2 asphyxiation, and tissues collected for analyses. Data from this 2 X 3 factorially arranged completely randomized experimental design were analyzed using the GLM procedure of SAS. ARV-infected birds had significantly lower average body weights (ABW) at 14 and 21 days ($P<0.0001$), three times higher mortality rates, and decreased tissue protein concentration ($p<0.001$) than controls. Se treatments did not affect ABW and mortality, but did significantly improve plasma protein concentration ($p<0.05$) and TRX activity in both, healthy and virus-challenged bird. Our findings suggest that ARV infection depresses growth, increases mortality and reduces protein concentration on various tissues, whereas Se is beneficial against ARV infection in broilers through an improved antioxidant status.

Key Words: Reovirus, Selenium, Broiler

T140 Effects of reducing dietary protein on performance of White Leghorn layers during late egg production (55 to 67 wks of age). H. M. Yakout*[1], D. Hoehler[2], M. Elliot[3], and C. Novak[1], [1]*Virginia Tech*, *Blacksburg*, [2]*Degussa*, *Kennesaw, GA*, [3]*Wenger's Feed Mill*, *Rheems, PA*.

The use of low protein diets can have potential benefits on reducing N emissions and cost savings by reducing high cost protein sources. An experiment was conducted utilizing 384 Hy-Line W-36 hens which were randomly assigned to one of 4 dietary treatment groups (Trt). Corn-soybean based diets supplemented with commercially available amino acids were used as follows: [1] 17.5% CP + Met ($131.25/ton), [2] 16.5% CP + Met, Lys and Thr ($128.67/ton), [3] 15.5% CP + Met, Lys and Thr ($127.56/ ton), and [4] 14.5% CP + Met, Lys, Thr and Trp ($129.14/ton) were fed from 55 to 67 wks of age. Cage was the experimental unit (4 h/cage; 0.54 in^2/h), and each Trt had 24 reps. Overall, hens had similar feed consumption (FI) in diet 1, 2, 3, & 4 of 99.0, 99.5, 99.1 and 97.9 g/h/d, respectively. Egg production (EP) ranged from 71.4 to 67.1% across all Trt with the highest producers fed diet 2 and the lowest for diet 4. Egg weights (EW) followed a similar performance, as they non significantly decreased from 63.7 g to 63.0 g with protein reduction from 17.5 to 14.5%, respectively. Egg mass (EM) was also not affected by Trt and varied from 44.08 to 44.80 g. Reducing dietary protein reduced ($P \leq 0.003$) dry albumen percent, while numerically increased dry shell percent. Albumen solids were reduced ($P \leq 0.005$) with decreasing dietary protein. Wet albumen ranged from 57.0 to 55.5% ($P \leq 0.03$) for all Trt with the highest at diet 3 and the lowest at diet 4. FI, specific gravity, dry yolk and shell and yolk solids were not significantly affected by Trt. Treatments 1, 2 and 3 were statistically similar when evaluating production performance

and egg components as compared to diet 4. Based on the information gathered from this trial, feeding the 15.5% CP diet with supplemental Met, Lys and Thr matched EP and FE of the high protein diet (17.5% CP + Met). Utilizing such a diet in the field has the potential to save the poultry industry as much as $3.68/ton based on the current study. Additional in house or field studies are needed to validate these findings on increased profitability.

Key Words: Dietary protein, Egg production, Egg mass, Late production, Economics

T141 Effects of dietary amino acid level on egg performance of heavy versus light laying hens. R. L. Payne*[1], P. R. T. Bonekamp[2], J. K. W. M. Sparla[2], A. Lemme[1], and P. J. A. Witten[2], [1]*Degussa Corporation*, *Kennesaw, GA*, [2]*Provimi B.V.*, *Rotterdam, The Netherlands*.

According to the literature, the amino acid (AA) needs of light layer breeds are about 10% less than those of heavy breeds. Thus, the objective of this experiment was to determine the level of AAs needed for heavy and light breeds for optimal performance. Lohmann Brown Classic (heavy) and LSL Classic (light) hens (n = 564) were equally allotted to 12 treatments based on body weight and daily egg mass. Each treatment was replicated 4 times with 11 or 12 individually-housed hens, and the trial was conducted from 24 to 35 weeks of age. The treatments were arranged in a 2 x 6 factorial with 2 breeds (light vs. heavy) and 6 AA levels (550, 600, 650, 700, 750, and 800 mg of true fecal digestible Lys per hen per day (TFD Lys/h/d)). The diets were formulated based on body weight and energy requirements for the heavy or light hens with 10 g of growth per month with a calculated feed intake of 110 or 100 g/h/d, respectively. Minimum ratios of AAs relative to TFD Lys were maintained, and they were Met, 49; Met+Cys, 95; Thr, 68; Trp, 19; Ile, 79; and Val, 87. All diets were isocaloric within breed and adequate in all nutrients with the exception of AA. Laying percentage of the heavy and light breed hens increased ($P < 0.05$) up to 650 and 600 mg TFD Lys/h/d, respectively, but laying percentage was not different ($P > 0.05$) overall. Egg weight, egg mass, and feed per egg mass increased ($P < 0.05$) in both breeds as AA increased through 800 mg TFD Lys/h/d. Overall, the heavy breed hens produced heavier eggs with more mass ($P < 0.05$), while the light breed hens had improved feed per egg mass ($P < 0.05$). These data suggest that both breeds respond to at least 800 mg TFD Lys/h/d for daily egg mass production, which is higher than current recommendations. Furthermore, it seems that heavy breeds need about 10% more AAs than the light breeds to maximize laying percentage, while the light breeds need about 10% more AAs to produce similar egg mass as the heavy breeds.

Key Words: Amino acid, Egg mass, Laying hen, Lysine

T142 Mintrex® organic trace minerals and 25-hydroxycholcalciferol HyD® improve biomechanical properties of turkey bones. E. O. Oviedo-Rondón*[1], P. L. Mente[2], P. R. Ferket[1], J. D. Richards[3], J. Small[1], and J. L. Grimes[1], [1]*North Carolina State University*, *Raleigh*, [2]*North Carolina State University*, *Raleigh*, [3]*Novus International, Inc.*, *St. Charles, MO*.

Spiral femoral fractures and tibia fractures can cause up to 5% of the total mortality in turkey toms. Biomechanical properties of bones can be improved by nutrition. The dietary supplementation of organic trace minerals, MINTREX Pse (MIN) and 25-hydroxycholcalciferol (HyD) was evaluated as an alternative to reduce the incidence of bone abnormalities. Day-old Nicholas 85X700 toms were randomly distributed among 48 pens (4 dietary treatments (trt) x 12 replicates) of 15 poults each. A 2x2 factorial (0 and.1% MIN; 0 and 92 mcg/kg HyD) was evaluated. MIN provided 40 ppm Zn, 40 ppm Mn, and 20 ppm Cu as methionine hydroxy analogue complex and .3 ppm Se as Se yeast. Diets were formulated to be equal in nutrient content and fed ad lib as 8 feed phases until 20 wk. Femur and tibia bones were collected at 18 wks of age from 13 toms per treatment. Compression and tension failure stresses were evaluated in tibiotarsus subjected to three-point and four-point bending. Torsional shear stresses were evaluated in femur bones subjected to external rotation in a single cycle to failure, at an angular displacement rate of 10°/s. Torque and angle data were collected during the test at 100 Hz. Data indicated that MIN increased ($P<0.001$) cortical thickness in the tibiotarsus. No significant ($P>0.05$) effect of trt was observed in the cortical thickness of femur. The maximum force, the moment and the stress required for tibia bones to break, increases ($P<0.001$) with MIN supplementation, but especially ($P<0.05$) when both MIN and HyD were added to the diet. The maximum shear stress at failure of femora bones was improved ($P<0.05$) by MIN and HyD supplementation, a similar effect ($P=0.08$) was observed for failure torque. These results indicate that the supplementation of both MIN and HyD improve the biomechanical properties of tibias and femurs in 18 wk-old turkey toms.

T143 A real time polymerase chain reaction assay for metallothionein to measure bioavailability of zinc sources for chickens. J. D. Richards*, C. A. Atwell, C. W. Wuelling, and M. E. Wehmeyer, *Novus International, Inc.*, *St. Charles, MO*.

It is common to measure bone or tissue zinc to compare the bioavailability of different zinc sources, or to determine the zinc status of an animal. However, zinc deposition into tissues occurs substantially downstream of intestinal zinc absorption, and only a fraction of the absorbed zinc will be deposited in the assayed tissue. Therefore, tissue or bone zinc may not be the most appropriate assay to measure bioavailability. As an alternative, the availability of zinc can be compared by detecting the expression of certain zinc-responsive genes. The metallothionein (MT) protein binds up to 7 zinc atoms, and its mRNA or protein expression has been reported to reflect zinc status in many species, including chickens. A real time polymerase chain reaction (RT-PCR) assay was developed to measure MT mRNA expression in chickens fed different levels or sources of zinc. Initial experiments demonstrated that MT was inducible by zinc in multiple tissues including small intestine, liver and kidney. In contrast, 18S rRNA was not zinc-inducible. MT mRNA levels therefore are normalized in each sample by 18S rRNA levels, as a loading control. In addition, MT levels can be compared across experiments by comparing to a known reference standard. To test whether the MT assay could distinguish between different zinc sources, broilers were placed on a moderately zinc-deficient milo-soy diet for 20 days, then placed on corn-soy treatment diets consisting of an unsupplemented basal diet, or

the basal supplemented with 70ppm zinc from zinc oxide, a zinc amino acid complex, or MINTREX® Zn. Jejunum scrapings were collected two days later and assayed for MT expression. Zinc oxide and the zinc amino acid complex failed to induce MT expression significantly above the basal. In contrast, MT expression in the birds fed MINTREX Zn was significantly greater than in all other treatments. These data suggest that MINTREX Zn is more bioavailable than zinc oxide or the zinc amino acid complex.

T144 The making of heat resistant β-Mannanase (Hemicell®-HR) and its positive impact on broiler growth performance. H. Y. Hsiao*, D. M. Anderson, and L. Liu, *ChemGen Corp.*, *Gaithersburg, MD*.

Feed enzymes, in general, are sensitive to heat and, therefore, their application onto feeds is mostly carried out by spraying in the liquid form post-pelleting. However, the direct application of thermal stable dry enzyme into the mixer still has its attraction. Strains of *Bacillus lentus*, which all produce thermal stable β-Mannanase (Hemicell®-HR) have been obtained by modifying a few selected sites on DNA sequence of the native enzyme and, then, replacing the native gene on the same host cell. Two such mutants were selected. The native and two mutant enzymes have been purified and they were incubated in a water bath at various temperatures for 15 minutes. The native and stable β-mannanase (Hemicell® HR-1 and HR-2) retained its 50% activity at 65°C, 72°C and 82°C, respectively. Two mutants, in their unprotected form, showed a 7°C and 17°C improvement in thermal stability over the native enzyme. All three enzymes were granulated and their thermal stability was tested under various conditioning temperatures (65°C - 90°C) by feed mills at Kansas State University and the University of Georgia. Through the extrapolation, the pelleting temperature causing a loss of 50% activity to the granulated native and two thermal stable β-Mannanase was calculated to be 80°C, 87°C and 107°C, respectively. A 42-day broiler trial was conducted to test Hemicell®-HR1 and the native enzyme for grwoth. The native Hemicell® was sprayed post-pelleting and the granulated Hemicell®-HR-1 was applied into mixer. Both were at about 100MU/ton. All feeds were pelleted between 80-85°C. There was no significant difference in FCR as well as weight gain between these two enzymes. Both enzymes had significant better FCR than the Control ($P<0.05$). The thermal stable β-mannanase added into the mixer showed its full efficacy in promoting broiler growth.

Key Words: β-mannanase, Thermal stable, Mmutant, Broiler, FCR

T145 The effect of B-Mannanase (Hemicell) on the performance of 3 commercial strains of broiler chickens provided with corn-soybean meal diets. M. E. Jackson*[1] and R. W. Gordon[2], [1]*ChemGen Corp*, *Fayetteville, AR*, [2]*Gold Kist Inc*, *Atlanta, GA*.

The enzyme B-mannanase has been shown to improve growth, feed conversion and body weight uniformity in broilers. The mechanism results in an improvement in energy utilization through degradation of highly anti-nutritive B-mannans present in all soybean meals. A 38-day trial was conducted in floor pens with straight run Ross X Cobb, Cobb X Cobb, and Ross X Ross broilers provided with corn-soybean meal based diets with commercial nutrient levels with and without B-mannanase addition at the manufacturers recommended inclusion level (100 MU/ton) for a total of 6 treatments. The study involved 50 birds/pen and 8 replicate pens per treatment. At the conclusion of the study, males and females were weighed separately. The enzyme improved weight gain and feed conversion in all strain and sex combinations at 38 days. Across all strains and sexes, the addition of B-mannanase resulted in a 2.5% improvement in weight gain ($P<.05$) and a 2.6 point improvement in feed conversion ($P<.05$). There were significant strain effects on feed conversion only and there were no significant strain x enzyme interactions. Results of this study suggest that B-mannanase improves live performance in broilers irrespective of sex or strain.

Key Words: B-Mannanase, Broilers, Strain, Sex

T146 Effect of Allzyme® SSF on growth performance of broilers receiving diets containing high amounts of distillers dried grains with solubles. J. L. Pierce*, T. Ao, B. L. Shafer, A. J. Pescatore, A. H. Cantor, and M. J. Ford, *Alltech-University of Kentucky Nutrition Research Alliance*, *Lexington, KY*.

Allzyme® SSF is an enzyme complex produced by solid state fermentation. An experiment was conducted to evaluate the effects of Allzyme® SSF on the growth performance of male broiler chicks when fed diets containing 26% dried distillers grains with solubles (DDGS). A 21-day growth assay was conducted with 144 Cobb broilers allotted to four dietary treatments in a randomized complete block design. The treatments were 1) corn-soy reference diet with 1.24% Lys, 22%CP and 3150 kcal/kg ME; 2) positive control diet containing 25% DDGS with 1.24% Lys, 22%CP and 3150 kcal/kg ME; 3) and 4) containing 26% DDGS with 1.11 % Lys, 21%CP and 2835 kcal/kg ME without and with 200 g/tonne Allzyme® SSF, respectively. Feeding 25% DDGS significantly decreased weight gain (737 vs. 691g, $P<.01$) and gain:feed (0.766 vs. 0.676, $P<0.01$) comparing with corn-soy reference diet. Reducing the dietary energy and crude protein concentration also reduced gain (691 vs. 626 g, $P<0.01$) and gain: feed (0.676 vs. 0.579, $P<0.01$). The addition of Allzyme® SSF tended to increase gain (626 vs. 648 g) and significantly increased gain:feed (0.579 vs. 0.610, $P<0.01$). These results indicate that Allzyme® SSF improves growth and efficiency when high levels of DDGS are used in broiler diets.

Key Words: Broiler chicks, Enzyme, Allzyme®SSF, DDGS, Performance

P147 Four years of molecular analysis of international samples collected on FTA® paper. H. Moscoso*, G. Brown, and C. L. Hofacre, *University of Georgia*, *Athens*.

The Molecular Diagnostic Laboratory at PDRC performs more than 13 different tests for the detection and characterization of avian pathogens for national and international clients. We have shown that avian viruses and bacteria are rendered non-infectious upon contact with the FTA® cards thus allowing collection and transport of samples from overseas to the U.S. in compliance with federal regulations. PCR and RT-PCR have demonstrated that nucleic acids are preserved in specimens stored on FTA® and that its quality is sufficient to yield amplicons suitable for post-PCR analysis. The number of tests for molecular analysis of poultry samples requested by clients from foreign countries has increased almost 100 fold in the past 4 years; from 8 tests in 2002 to more than 800 tests in 2005. This increase is mainly due to the switch in the procedure of inactivation and transport of potential pathogens from phenol-treated to FTA® -collected specimens. The majority of the international molecular tests requested are from Latin America (88%) which is the consequence of a great deal of training and education of laboratory personnel and clinicians from governments, academia and private industries from that area of the world. Mycoplasma PCR is by far the most requested test from overseas representing 68% followed by RT-PCR of IBDV, IBV, and NDV with an average of 11%, 7%, and 5% respectively in the past 4 years. Post-PCR tests such as RFLP and nucleotide sequencing have allowed studying more closely the epidemiology of these diseases in foreign countries resulting in the differentiation of vaccines from pathogens. Cumulative positive cases was 37% for NDV (vaccine and velogenic strains), 36% for adenovirus (serotype 4, 5 and 10), 29% for IBDV (Lukert and variants A and E), 27% for MS (H vaccine and wild types), 23% for MG (ts 11, F strain and wild types), and 8% for IBV (Massachusetts). Tests request from other areas of the world might increase in the near future as sampling is facilitated and transportation cost is reduced using the FTA® cards.

Key Words: Avian pathogens, FTA®, PCR, RT-PCR, Sequencing

P148 Immunopotentiation of avian heterophils with microbial agonists. M. Farnell*[1], A. Donoghue[2], F. Solis de los Santos[3], P. Blore[3], B. Hargis[3], G. Tellez[3], and D. Donoghue[3], [1]*Texas A & M University*, *College Station*, [2]*USDA*, *Fayetteville, AR*, [3]*University of Arkansas*, *Fayetteville*.

The immune system of neonatal chicks is functionally immature during the first week of life. Researchers have previously demonstrated that the avian humoral response can be increased through the use of probiotics. Although the humoral response provides the chick with an effective mechanism to combat pathogens, sufficient antibody titers are not attained until 7 to 10 d post infection. However, the innate immune system (i.e. heterophils) can respond much more quickly to pathogens. The objective of this study was to determine whether probiotic bacteria can also up regulate heterophil function. Heterophils were isolated from the peripheral blood of neonatal chickens by using a discontinuous density gradient. Oxidative burst and degranulation are bactericidal mechanisms used by heterophils to kill pathogens and were used in this study as indicators of heterophil function. We found that each of the 10 ″generally recognized as safe ″ (GRAS) probiotic isolates (designated G1-11) tested, in vitro, were capable of increasing ($P < 0.05$) heterophil oxidative burst and degranulation when compared to unstimulated controls. *Bacillus subtilis* (G3), *Lactococcus lactis lactis* (G6) and *Lactobacillus acidophilus* (G8) isolates were determined to elicit the greatest heterophil response in vitro and were subsequently fed to chicks. Phosphate buffered saline (PBS) or one of these three probiotic isolates (~ 2.5×10^8 cfu/chick; 50 chicks/treatment) resuspended in PBS was administered by oral gavage on the day of hatch. Heterophils were isolated from chicks from each of these four treatment groups 24 h post treatment. Significant increases in heterophil degranulation and oxidative burst were observed with the G3, G6 and G8 treated chicks when compared to heterophils isolated from birds with no probiotic treatment. These data suggest that probiotic bacteria can significantly improve heterophil oxidative burst and degranulation in broilers. To our knowledge this is the first study demonstrating a relationship between probiotics and avian heterophil function.

P149 Real-time RT-PCR for the rapid detection of avian reoviruses. K. Guo*, T. Dormitorio, and J. Giambrone, *Auburn University*, *Auburn, AL*.

Avian reoviruses (ARV) infect a variety of organs and may cause tenosynovitis, malabsorption syndrome, chronic respiratory disease, and immunosuppression in commercial poultry. Vaccination is the main method for preventing ARV infections. However, vaccine effectiveness in the field is variable due to the presence of different antigenic strains. Our objective is to develop a rapid and highly specific method for the detection of ARV strains utilizing Real-time RT-PCR technology. Using specific primer and probes sets, we want this test to detect all ARV infections in the poultry as well as identify specific serologic and pathologic types. The protocol consists of two phases of real-time RT-PCRs, which were conducted in a Roche LightCycler. In the first phase, primer-probe sets were compared and selected to detect all ARVs from North America. Here we report a best primer-probe set, which was designed from a highly conserved region of S4 gene, and its rapid, highly sensitive detection of 8 ARV strains. ARVs were also detected with this test from clinical samples, which were previously found to contain ARVs by other tests. The second phase of the project, the development of primer-probes sets for the detection of serologic or pathologic strains, is in progress.

Key Words: Avian Reovirus, Real-time RT-PCR, Detection

P150 Comparison of mean death time in eggs from several velogenic Newcastle disease virus strains, isolated in Mexico from 1997 to 2006. R. Merino* and N. Calderon, *Universidad Nacional Autonoma de Mexico*, *Mexico City, Mexico*.

Newcastle disease (ND) has major importance in poultry around the world. Exotic ND is responsible for high mortality rate and international commerce restrictions. The objective of this study was to use the mean death time in eggs (MDTE) to compare the virulence of 16 ND virus strains isolated at the UNAM between 1997 and 2006 and the Mexican reference strains Chimalhuacan and Queretaro. All strains were grown in commercial chicken embryo (CCE) and the minimum lethal dose (MLD) was calculated. All strains were standardized to 10^2 MLD/0.1 ml, inoculated into ten 11-day-old embryonating eggs, incubated a 37°C and candled at 2-4 hours intervals. The time at which each embryo was first observed as dead was recorded. The MDTE was compared by ANOVA, $P<0.05$. All 16 strains were identified as velogenic, since the MDTE was lower than 60 hours, except for one isolate from 1998 (MDTE = 61.5 hours). The Mexican reference velogenic strain Chimalhuacan showed a very high virulence (MDTE=39.7 hours, ab), only one isolate from 2005 was similar to it (MDTE= 37.4 hours, a); 11 isolates had MDTE between 41.7 and 48.8 hours (abcdef), including the Queretaro strain (MDTE= 43.2 hours, bc); 4 isolates had MDTE between 50.3 and 59.7 hours (efgh) and only one isolate from 1998 had MDTE= 61.5 hours (h). The Chimalhuacan strain has been previously reported as highly virulent when inoculated in susceptible chickens; according to our results, the Mexican strains of NDV show difference in their virulence, at least one of them (isolated in 2005) could be related to the Chimalhuacan strain, isolated for first time several decades ago. These results show that velogenic strains of Newcastle disease virus can be differentiated by using a standardized dose even when using commercial embryonating eggs to inoculate.

Key Words: Newcastle disease, Velogenic, Mean death time, Commercial embryonating egg, Titration

P151 *In vitro* and *in vivo* transgenic expression of Newcastle disease virus HN protein using an avian adeno-associated virus vector. F. Perozo*[1], P. Villegas[1], C. Estevez[2], I. Alvarado[1], and L. Purvis[1], [1]*Poultry Diagnostic and Research Center*, *Athens, GA*, [2]*USDA*, *Athens, GA*.

The avian adeno-associated virus (AAAV) is a replication defective non-pathogenic virus member of the family *Parvoviridae* that has been successfully used for gene delivery. The generation of recombinant AAAV virions expressing the immunogenic hemagglutinin-neuraminidase (HN) of Newcastle disease virus (NDV) and the immune response induced in chickens was assessed. The feasibility of the *in vitro* generation of the recombinant AAAV virions expressing the HN protein was demonstrated by immunohistochemistry (IHC) and electron microscopy (EM). After *in ovo* or intramuscular inoculation of the recombinant AAAV in specific pathogen free chickens, a systemic immune response measured as NDV specific antibodies detection using enzyme-linked immunosorbent assay and the hemagglutinin inhibition test was observed. Neutralizing antibodies induced by the recombinant AAAV were demonstrated by the virus neutralization test (VN) performed in embryonating eggs.

Key Words: Avian adeno-associated virus, Newcastle disease virus, Hemagglutinin-neuraminidase, Immune response

P152 Innate immune functions and intracellular signaling in wild-type and commercial turkeys. K. Genovese, H. He, C. Swaggerty, and M. Kogut*, *USDA-ARS, FFSRU SPARC*, *College Station, TX*.

The purpose of these studies was to compare heterophil innate immune functions and related intracellular signaling in a commercial line of turkeys to those in a wild-type line. Heterophil phagocytosis of *Salmonella* (SE) and two mechanisms of microbial killing, oxidative burst and cellular degranulation, were assayed. Heterophils from commercial Line A turkeys and from wild-type turkeys were exposed to SE, opsonized SE (OPSE), and PMA for 1 hour. Degranulation was detected by quantifying β–glucuronidase activity in the culture medium following stimulation of heterophils; heterophil oxidative burst was measured by oxidation of DCFH-DA to fluorescent DCF. Heterophils from wild-type turkeys had a significantly greater production of an oxidative burst and degranulation on days 4 and 7 post-hatch than did heterophils from Line A. No differences in the phagocytosis of SE were observed between lines. In signaling studies, heterophils were stimulated for 1 hr with SE or OPSE. After stimulation, cell lysates were tested for mitogen-activated protein kinase (MAPK) activity. Specifically, phosphorylation of extracellular signal-regulated protein kinase (ERK1/2) and p38 MAPK were assayed using commercially available ELISA kits. Total protein tyrosine kinase (PTK) activity was assayed. On both day 4 and day 7 post-hatch, heterophils from Rio Grande turkeys had significantly higher levels of ERK 1/2 and p38 MAPK kinase activity upon stimulation with either SE or OPSE($p< 0.001$). PTK values on day 4 and 7 in Rio Grande turkey heterophils was significantly higher upon stimulation with SE than with OPSE and was significantly ($p<0.001$) higher than the PTK levels in Line A upon SE and OPSE stimulation. In combination, these results show that heterophils from wild-type turkeys function more efficiently than do heterophils from commercial Line A turkeys and that the inefficiency of cellular function observed in heterophils from Line A turkeys may be associated with defects or insufficiencies in the intracellular signaling mechanisms related to the innate immune response.

Key Words: Turkey, Heterophil, MAP kinase, Protein tyrosine kinase, Innate immunity

P153 T-RFLP analysis of the gastrointestinal of broilers affected and unaffected with gangrenous dermatitis. K. Bos*[1], T. Neumann[1], D. Ritter[2], and T. Rehberger[1], [1]*Agtech Products, Inc.*, *Waukesha, WI*, [2]*Mountaire Farms of Delaware, Inc.*, *Millsboro, DE*.

The gastrointestinal (GI) tract of a commercial broilers harbors a dense and metabolically active microbial community. This GI community has been shown to play a large role in animal performance and health status. Recently, gangrenous dermatitis (GD) has reemerged as a significant concern for poultry producers in the United States. One theory states that GD comes from pathogenic bacteria present in the GI community. GD can be treated with antibiotics, but the effects of these antibiotics on the GI microbial community are poorly understood. Classically, traditional plating methods are used to characterize microbial populations. Unfortunately, these techniques are limited in their ability to detect only cultivable microorganisms. The objective of this study was to use terminal restriction length polymorphism (T-RFLP) to: assess the GI microbial community in GD affected and unaffected birds both with and without antibiotic treatment, and

determine bacteria that are unique to each health status. GI tracts from broilers with and without GD symptoms in the same house were collected from farms in Delaware. Genomic DNA was isolated from the mucosal bacteria of the duodenum, jejunum, and ileum of each bird, and analyzed by T-RFLP to characterize the GI communities. Comparisons of terminal restriction fragment (TRF) patterns from the affected and unaffected birds indicated which TRFs appeared to be associated with diseased or healthy status. GD treatment with antibiotics altered the microflora within the GI community in a similar manner in both affected and unaffected birds. These bacterial changes are different than the changes seen in the affected and unaffected birds that had not received an antibiotic treatment. The preliminary identification of the bacteria associated with GD indicated by the TRFs are Clostridial spp., *Mycoplasma* spp. or phytoplasmas, and *Pasteurella* or *Actinobacillus* spp. While the bacteria associated with a nondiseased health status are *Lactobacillus* spp. Overall, T-RFLP has been an effective tool to monitor changes within the GI community of broilers both affected and unaffected by GD, with and without antibiotic treatment.

Key Words: T-RFLP

P154 RAPD comparison of *Clostridium perfringens* isolated from cases of necrotic enteritis and gangrenous dermatitis. T. Neumann*, S. Dunham, J. Skalecki, and T. Rehberger, *Agtech Products, Inc.*, *Waukesha, WI*.

Clostridial diseases have become a major concern in today′s poultry industry. Accompanied by high mortality and reduced efficiency they often inflict a heavy economic burden on producers. Necrotic enteritis and gangrenous dermatitis are among the most common clostridial diseases observed in broiler chickens. The anaerobic, spore-forming bacterium *Clostridium perfringens* is recognized as the causative agent of necrotic enteritis and has also been implicated in gangrenous dermatitis. This opportunistic pathogen is capable of producing a myriad of extracellular toxins and enzymes that degrade host tissues and are responsible for the necrotic lesions observed. RAPD PCR is a technique that can be used to generate a molecular fingerprint of a bacterial species or strain. These fingerprints can then be compared to determine the relationship among the organisms. The purpose of this study was to use RAPD PCR to determine if strains of *C. perfringens* isolated from cases of necrotic enteritis and gangrenous dermatitis are similar. Fourteen broilers showing signs of gangrenous dermatitis were collected for microbiological analysis from an East coast production system. Twenty-two broilers with necrotic enteritis from both East coast and West coast farms were also examined. A total of 153 *C. perfringens* isolates were recovered for the study. All of the isolates were confirmed as type A by a multiplex PCR that amplifies the four major toxins (α, β, ε and iota). Fingerprints generated by RAPD PCR were used to construct a dendrogram in order to study the relationship among the strains. Necrotic enteritis isolates from East and West coast sites clustered separately from gangrenous dermatitis isolates. However, East coast necrotic enteritis isolates were more related to East coast gangrenous dermatitis isolates than West coast necrotic enteritis isolates. These results show that geographic location is an important source of genomic variability in strains of *C. perfringens* type A.

Key Words: Necrotic, Enteritis, Gangrenous, Dermatitis, *Clostridium*

P155 Evaluation of combined sulfonamide activity toward *pasteurella multocida* and *Escherichia coli* using *In Vitro* disk assays. J. Mathers* and S. Clark, *Alpharma Animal Health*, *Fort Lee, NJ*.

The soluble product PoultrySulfa™ is comprised of sulfamethazine, sulfamerazine, and sulfaquinoxaline at a 2:2:1 ratio, and is approved for use as an aid in controlling acute fowl cholera caused by susceptible *Pasteurella multocida* in chickens and turkeys, as well as an aid in controlling coccidiosis in chickens. An evaluation of the constituents of PoultrySulfa™ versus commercial and lab-prepared disks was made, to demonstrate activity versus poultry-derived *P. multocida* and *E. coli* and to compare with a commercial triple sulfa disk. Disks were prepared in the lab for sulfamethazine, sulfamerazine, sulfaquinoxaline, sulfadimethoxine, and PoultrySulfa™ at 0.25 mg per disk. A commercial SSS-25 disk (BD Diagnostics™, #231349) was run for comparison. Fourteen *P. multocida* strains and four *E. coli* were grown overnight and evaluated for disk susceptibility using standardized 6.5 mm diameter disks on Mueller-Hinton agar and incubation at 35ºC. The inhibition zone diameters for *E. coli* were within expected QC ranges. For *P. multocida*, the SSS disk had the best zone diameter correlation with the lab PoultrySulfa™ disk (r=0.831) in comparison to the individual sulfonamides (r=0.329-0.809).

Key Words: Sulfonamide, Fowl cholera, Coccidiosis, PoultrySulfa™, Disk assay

P156 Serotyping of *Escherichia coli* isolates from an integrated poultry company in Mexico. G. A. Ramírez Barrera[1], A. Navarro Ocaña[2], C. Eslava Campos[2], and C. Rosario Cortés*[1], [1]*Aves, FMVZ, UNAM.*, *México, D.F, Mexico*, [2]*FM; UNAM*, *México D.F, Mexico*.

Escherichia coli is a common and important bacterial pathogen that causes at least 5% of the mortality in poultry flocks. Consequently, these bacteria are responsible for significant economic losses to the poultry industry. Pathogenic serogroups of *E. coli* are ubiquitous in environments in which poultry are raised and can cause air sacculitis, pericarditis, peritonitis, salpingitis, synovitis, osteomyelitis, cellulitis or yolk sac infections (YSI). Despite the enormous knowledge about Avian Pathogenic *E. coli* strains exists around the world, in Mexico few information is available. Recently, some articles have reported the characteristics about Mexican strains of *E. coli*. The objective of the present work was to analyze Mexican strains of *E. coli* isolated from a different company from the previously reported in order to determine the serotypes implicated in collibacilosis in Mexico. Ninety seven strains were isolated from samples obtained from Breeder Flock, Hatchery and Broiler Farm. All samples were seed onto MacConkey-Lactose agar, and Blood agar and incubated at 18 hours at 37 ° C. Lactose positive strains were selected. Biochemical testing, and serotyping of *E. coli* were performed. The main serogroups identified were O? (19.58%), O20 (10.30%) O8 (7.21%), O131 (7.21%) and O25 (6.18%). These results did not correspond with those previously reported where the most important serogroups were O19 (12%), O84 (9%), O8 (6%) and O78 (5%). This data suggest that *E. coli* strains associated with collibacilosis in Mexico are diverse and it is necessary to perform further studies to determine the pathogenic properties of each group.

Key Words: *Escherichia coli*, Serotyping, Mexico, APEC

P157 Colicin production in *E. coli* strains isolated from a integrated poultry company in Mexico. S. I. Valencia García and C. Rosario Cortés*, *UNAM*, *México, D.F. Mexico*.

Recently, *E. coli* strains pathogenic to avian species have begun to be grouped as Avian Pathogenic *Escherichia coli* (APEC). Aside from causing embryo mortality, some common features of APEC strains including the production of colicin V, have also been described. Col V, an 88 amino acid polypeptide, is one of the most common among 20 known colicins. At present, Col V is not considered to be a pathogenic feature by itself. In a recent definition of pathogenicity; however, it was proposed that any trait that increases the proliferation or survival of a bacterium during the infection process could be classified as a virulence factor. Thus, Col V production could possibly be considered as a virulence trait since it contributes to the elimination of competing microorganisms. Moreover, it is known that plasmids that encode for colicins also contain genetic information for other virulence factors. The objective for this paper was analyzed the colicin production in *E. coli* strains isolated from a case of collibacilosis in a integrate company located in the Mexican State of Querétaro. Ninety seven strains were isolated from samples obtained from breeder flock, hatchery and broiler farm. All samples were seed onto MacConkey agar, and Blood agar and incubated at 18 hours at 37 ºC. Biochemical tests to detect E. coli were performed. A technique for colicin detection were also performed. Forth phenotypes can be distinguished with the technique: 1) No production of colicins, 2) Production of Col V, 3) Production of Col V and other colicins and 4) Production of colicins different from Col V. The largest group was composed by those strains that produced colicins different from Col V (38.14%), followed by strains that produced Col V and other colicins (28.86%), No colicin producers (25.77%) and strains that only produced Col V (7.21 %). These results suggest that the strains associated to collibacilosis in Mexico are diverse since these results are different from those previously obtained. To better understand the importance of this feature in collibacilosis it is necessary to look for other virulence markers encoded in colicin plasmids.

Key Words: Colicin, *Escherichia coli*, Poultry

P158 Environmental management issues of arsenic in poultry litter. S. Burgos Cáceres*[1] and S. A. Burgos Cáceres[2], [1]*North Carolina State University*, *Raleigh*, [2]*University of Guelph*, *Guelph, ON, Canada*.

Arsenic is a notoriously potent poisonous metalloid used as a component of pesticides, herbicides, insecticides and various alloys. Ingestion of arsenic, both from water supplies and animal tissues, has been scientifically linked as a potential cause of skin, liver, lung, kidney and bladder cancer. It can kill by allosteric inhibition of an important metabolic enzyme (lipothiamide pyrophosphatase) leading to multi-system organ failure, revealed post mortem by red colored mucosa due to severe hemorrhage. Poultry feedstuffs, mainly broilers, can contain trace amounts of arsenic in the form of organoarsenical feed additives such as Roxarsone for its growth-promoting and disease-controlling properties, especially to combat coccidiosis. Disposal of the resulting arsenic-bearing poultry litter is currently unregulated, and it is frequently used to fertilize croplands. Excessive manure applications as an alternative organic fertilizer coupled with abundant irrigation or torrential rains can lead to arsenic leaching and contamination of waterways. On January 22, 2001 the U. S. Environmental Protection Agency adopted a new standard for arsenic in drinking water at 10 ppb, replacing the old standard of 50 ppb, through which all production systems must comply with the new standard by January 23, 2006. Faced with stricter federal regulations and an increasingly demanding customer base, the poultry industry must reassess the implications of managing arsenic levels in poultry wastes. Europe's ban on antibiotics -fully enforced by the beginning of 2006- and current discussions of adding more feed additives that would be faced out by 2016 places increasing pressures on poultry operators desiring to further penetrate foreign markets. In the case for organoarsenical feed additives, it has been suggested that poultry farms can adopt any combination of these three alternatives: 1) completely eliminate its inclusion and replace it with a natural non-toxic alternative, 2) drastically reduce its inclusion rate in diets, and 3) creatively devise another use for poultry wastes instead of land mass applications. Goals for the future include the replacement of coccidiostats with a vaccine.

Key Words: Arsenic, Poultry, Waste, Environment, Roxarsone

P159 Bacterial levels associated with poultry litter treatment (PLT) and aluminum sulfate (Alum). K. S. Mackln*, J. P. Blake, J. B. Hess, and R. A. Norton, *Auburn University*, *Auburn, AL*.

Litter treatments are commonly used to reduce ammonia and bacterial levels. In order to determine the effects of PLT and Alum on reducing bacterial levels two experiments were conducted. Both experiments were performed using clean pine shaving litter that was placed into 16 environmental chambers (2.44 x 2.44 x 2.44 m). Chicks were placed at a density of 70 chicks/pen. In both experiments there were four treatments, with each treatment getting four pens. The treatments comprised of a control (CON) and either PLT or Alum being applied at the following rates: 50, 100 and 150 lbs/1000ft^2. Both experiments had litter collected weekly from three areas within each pen for 7-weeks. Each sample had their pH and percent moisture determined. Bacteriologically total aerobic, anaerobic, Staphylococcus, and C. perfringens levels (cfu/g) were determined and the presence or absence of Campylobacter and *Salmonella* was determined. Bacterial counts and percent moisture data were transformed using log10 and arcsine transformations, respectively. The data was analyzed using GLM with $P<0.05$ and significant means were separated using Tukey's.

The results for PLT show that with an application rate of 50 lb the pH was the same as the CON after 14 days ($P<0.05$). Both the 100 and 150 lb application rates kept the pH lower then the CON and 50 lb rate until day 49. The only difference detected bacteriologically was that the 150 lb rate had lower anaerobic bacterial numbers (11.8) then the CON (12.4) after 49 days ($P<0.05$). Alum treated litter produced a variable pH among the treatments; however the treatments that contained the highest levels maintained a lower pH ($P<0.05$) through day 49. Bacteriologically the only difference was observed at day 49 with the 150 lb Alum rate having lower anaerobic bacterial numbers (9.7) then CON (11.1) and the 100 lb treatment (11.4) at a $P<0.05$. From these results it was concluded that neither PLT nor Alum effect bacterial numbers significantly in fresh litter. The observation in reduced anaerobic numbers on day 49 at the highest application rate may imply that long term usage of these products may reduce some bacterial populations.

Key Words: PLT, Alum, Litter, Poultry, Bacteria

P160 Bactericidal effect of several chemicals on hatching eggs inoculated with *Salmonella* serovar typhimurium. N. A. Cox*[1], L. J. Richardson[1], R. J. Buhr[1], M. T. Musgrove[2], M. E. Berrang[3], and W. Bright[4], [1]*USDA, ARS*, *Athens, GA*, [2]*USDA, ARS*, *Athens, GA*, [3]*USDA, ARS*, *Athens, GA*, [4]*South Carolina State University*, *Orangeburg*.

Breeder flocks and commercial hatcheries represent an early contamination point for *Salmonella* entry into commercial integrated poultry operations. Utilizing effective antimicrobial treatments for hatching eggs is a critical part of reducing the incidence of *Salmonella* colonized chicks on the farm. The objective of this study was to evaluate the bactericidal effect of several chemicals on *Salmonella* contaminated hatching eggs. Four replications (n=10/treatment) were conducted to determine the efficacy of seven commercially available compounds. The compounds tested were A) hydrogen peroxide B) water/oil emulsion droplets stabilized by detergent C) peroxyacetic acid D) four quaternary ammonium compounds attached to a polymer E) two quaternary ammonium compounds, one biquanide compound and bronopol attached to a polymer F) N-alkyl dimethyl benzyl ammonium chloride and stabilized urea and G) polyhexamethylenebiquanide hydrochloride (PHMB). A naladixic acid resistant *Salmonella* serovar Typhimurium was inoculated (10^4 cfu/ml) onto fertile hatching eggs by drip inoculation. Controls included 1) a positive control (no spray application) and 2) water control (spray containing water to take into account rinsing effects). The E and G compounds had a 100% reduction and both of these chemicals included a biquanide. The D and C compounds were also effective with a 95% and 93.5% reduction, respectively. The B and F compounds were the least effective of all chemicals with a reduction of 40% and 47.5% respectively. Hydrogen peroxide, which has been used by the poultry industry, had a 70% reduction and the water control produced a 10% reduction. Several antimicrobials tested were more effective than hydrogen peroxide. More detailed studies will be required to adequately evaluate these antimicrobials.

Key Words: *Salmonella*, Eggs, Bactericide

P161 Efficiency of probiotics, prebiotics and synbiotics on weight increase of chickens. G. Zhang*, L. Ma, and M. P. Doyle, *University of Georgia*, *Griffin*.

With the ban of antibiotics use in animals in Europe, interests in using probiotics, prebiotics and synbiotics for controlling foodborne pathogens such as *Campylobacter* and *Salmonella* in poultry are increasing. There are numerous reports indicating that probiotics, prebiotics and synbiotics were effective in reducing *Campylobacter* and *Salmonella* colonization in poultry. Do they affect chicken growth? The objective of this study was to determine the effect of feeding probiotic bacteria, prebiotics, and synbiotics on weight gain of chickens. Probiotic bacteria (mixture CE 1 included 3 *Lactobacillus salivarius* strains, and mixture CE 2 consisted of CE1 and a *Streptococcus cristatus* strain) were isolated from healthy adult chickens. Prebiotics used were fructooligosaccharide (FOS) and lactose (2.5% in feed). Each treatment had 20 chickens. Day-of-hatch chickens of Ross x Ross were fed with probiotic bacteria at 10^8CFU/chick once by gavage (Trials 1 and 2), or at 10^6CFU/ml in drinking water for the first week except day 3 (Trial 3). On day 3, all treatment chickens were challenged with *Salmonella* Typhymurium at 10^6CFU/chick by gavage (Trials 1 and 2) or through drinking water (Trial 3). Individual chickens were weighed on day 9, 12, 15, 19, and 26. In Trial 1, treatments CE 1 only, CE2 plus FOS, CE2 only, and lactose only significantly (α = 0.05) increased body weight by 83.0 to 100.5 g/chick at day 26 in comparison with control. In Trial 2, treatments CE2 plus lactose and CE2 only significantly increased body weight by 25.6 to 27.7 g/chick at day 12; treatment CE1 plus lactose significantly increased body weight by 42.3 g/chick at day 19. In Trial 3, at day 9 all treatments except for lactose only increased body weight significantly; there was no significant difference between treatments and control in body weight at day 15. It was observed that probiotics and synbiotics were effective in increasing body weight of chickens; prebiotics alone (FOS or lactose) did not have consistent effect on body weight gain of chickens. In conclusion, the probiotics and synbiotics studied could be used to increase weight gain of chickens.

Key Words: Probiotics, Prebiotics, Synbiotics, Poultry, Weight gain

P162 Determination of ileum microbial diversity by denaturing gradient gel electrophoresis analysis of 16S ribosomal DNA amplicons of broilers fed triticale- or corn-based diets and colonized by *Salmonella*. F. B. O. Santos*[1], B.W. Sheldon[1], A. A. Santos, Jr.[1], P. R. Ferket[1], M. D. Lee[2], A. Petroso[2], and D. Smith[2], [1]*North Carolina State University*, *Raleigh*, [2]*University of Georgia*, *Athens*.

Diversity of the bacterial communities in the ileum of broilers was characterized using denaturing gradient gel electrophoresis (DGGE). DGGE separation of polymerase chain reaction (PCR) amplicons of the V2-V3 variable regions of the 16S rDNA is a common method to profile community diversity and has been used to assess the effects of diet and antibiotics on the ileal bacterial community of chickens. Broilers raised either in a litter house or in a non-litter cage system were fed either a finely ground corn- (control), a finely ground triticale- or a whole triticale-based diet from 0-42 d. Microbial DNA was extracted from the ileum content of 42 d broilers and the 16S rDNA gene was amplified by PCR and the amplicons separated by DGGE. Diversity indexes including richness, evenness, diversity, and pairwise similarities coefficient were calculated. Diversity indexes were related to the dietary treatments, housing designs and with changes in *Salmonella* populations of broiler ceca as characterized by the most probable number method (MPN). Higher microbial diversity indexes were observed among birds fed whole triticale-based diets and reared in the litter house. In contrast, finely ground grain treatments had lower microbial diversity and were more heavily colonized by *Salmonella* than the whole triticale treatment. The combination of higher dietary fiber content and increased coarseness of the diet by feeding whole triticale presumably stimulated microbial community diversity and discouraged *Salmonella* colonization through a competitive exclusion type mechanism.

Key Words: *Salmonella*, Broilers, Microbial diversity, Triticale, Whole grain

P163 Genotype analysis of *Campylobacter* spp. isolated from various internal organs of commercial broiler breeder hens. K. L. Hiett*[1], N. A. Cox[1], L. J. Richardson[1], R. J. Buhr[1], P. J. Fedorka-Cray[2], J. S. Bailey[2], and J. L. Wilson[3], [1]*USDA, ARS, PMS*, *Athens, GA*, [2]*USDA, ARS*, *Athens, GA*, [3]*University of Georgia*, *Athens*.

Campylobacter spp. are presently believed to be the leading bacterial etiological agent of acute gastroenteritis in the human population. Evidence implicates poultry as a significant source of the organism for human illness; however, the pathways involved in *Campylobacter* spp. contamination of poultry flocks remain unclear. In an effort to further understand the dissemination of naturally occurring *Campylobacter* spp. through commercial broiler breeder hens, *Campylobacter* spp. isolates previously recovered from the primary and secondary lymphoid organs, liver/gallbladder, and ceca of broiler breeder hens were genotyped using flagellinA Short Variable Region (*flaA*-SVR) DNA sequence analysis. In general, two predominant subtypes were recovered from each flock (representing four different age groups) tested. Interestingly, the flocks tested at 22 and 66 weeks of age revealed two distinct subtypes, that upon further analyses, were determined to delineate into species specific (*C. jejuni* or *C. coli*) subtypes. Isolates that grouped in the *C. jejuni* specific subtype (all isolates recovered from week 66) were recovered from the liver/gall bladder, spleen, and thymus. However, this group did not contain any isolates recovered from the ceca. Isolates that comprised the *C. coli* specific subtype (recovered during weeks 22 and 66) were originally recovered from all locations tested. This investigation demonstrates that similar subtypes of *Campylobacter* spp. are naturally present within the internal organs of the bird′s body. Further delineation of the initially observed difference in recovery locations between *Campylobacter* species is needed.

Key Words: Broiler Breeder, *Campylobacter*, Genotype, Internal organ

P164 Internal and external carriage of inoculated *Salmonella* in broilers during growout. J. A. Cason*, R. J. Buhr, L. J. Richardson, and N. A. Cox, *Russell Research Center*, *Athens, GA*.

Internal and external persistence of inoculated *Salmonella* and spread to uninoculated chicks in the same pens were studied by sampling ceca and rinses of feathered carcasses in two experiments. Half of the day-old chicks in pens were orally inoculated with a nalidixic-acid-resistant strain of *Salmonella Typhimurium* at three levels of inoculum (0.1 mL delivering approximately 4.0 × 102, 104, or 106 cfu). At 3, 6, and 8 weeks of age, equal numbers of inoculated and non-inoculated birds were electrocuted and rinsed in 400 mL of diluent, after which ceca were removed aseptically, with a total of 652 chickens sampled in the two experiments. There were no differences in *Salmonella* incidence between inoculated and non-inoculated birds at any age, so the marker *Salmonella* was well distributed within pens. Total incidence was 70%, 86%, and 83% at the 102, 104, and 106 inoculum levels, respectively. Considering both cecal and rinse samples, incidence was 81%, 84%, and 72% at 3, 6, and 8 weeks of age respectively. There were 95 positives in the cecal samples only, 149 positives in the rinses only, and 275 positives in both ceca and rinse samples, so sampling ceca alone underestimated the total incidence of the marker *Salmonella*.

Key Words: *Salmonella*, Growout, Sampling, Whole carcass rinse, Ceca

P165 Cumulative ammonia quantification from litter with instantaneous flux estimates. D. M. Miles*[1], D. E. Rowe[1], P. R. Owens[2], P. A. Moore, Jr.[3], and D. R. Smith[4], [1]*USDA-ARS Waste Management & Forage Research Unit*, *Mississippi State, MS*, [2]*Purdue University*, *West Lafayette, IN*, [3]*USDA-ARS Poultry Production and Product Safety Research Unit*, *Fayetteville, AR*, [4]*USDA-ARS National Soil Erosion Laboratory*, *West Lafayette, IN*.

Challenges, such as method viability and litter heterogeneity, persist in measuring NH_3 emitted from broiler housing. A chamber acid trap (CAT) system was designed to investigate NH_3 generation. The objectives of this work were to assess the variability of litter generated NH_3 using the CAT system and compare the CAT quantification of NH_3 to instantaneous (i-) flux estimates. Commercial litter, reusing pine shavings bedding, was collected prior to flock 19. The bulk sample was homogenized and randomly assigned in 50 g increments to each of 48 chambers. The CAT system provided approximately 100 ml/min of air to each 1000 ml chamber which exhausted into a series of two flasks containing boric acid. On selected days, the boric acid was titrated with HCl to assess NH_3 volatilization. The i-flux method inverted a 1.98 L container over a 93.8 cm^2 tray (chamber footprint) containing a litter sample. At roughly 2 min intervals, a photoacoustic gas analyzer drew in (and returned) the gas sample from the head space of the inverted container to determine NH_3 concentration. The CAT cumulative NH_3/chamber collected after 1 d averaged 9.05 ± 0.58 mg N and 52.40 ± 1.36 mg N on d 16. The cumulative NH_3 release was predicted as (mg N) = 15.7 ln(day) + 7.16, with R^2=0.99. Converting the cumulative NH_3 from the CAT experiment to flux units (mass/area/time) gave estimates of 40 mg m^{-2} h^{-1} on d 1 and 15 mg m^{-2} h^{-1} on d 16. The i-flux procedure indicated 54 mg m^{-2} h^{-1} at 2 min and 29 mg m^{-2} h^{-1} after 8.5 min. An NH_3 reduction over time is expected; the results indicate that the time selected for flux greatly impacts the magnitude of an estimate. Therefore, extreme care would be required to apply flux calculations in regulatory circumstances. The CAT system offers a viable method for lab-scale NH_3 volatilization mechanistic studies (effects of various physical/chemical/biological or systematic modifications). The relationship of cumulative NH_3 and i-flux requires further characterization, but promise exists for developing predictive models and correlation between the two methods to provide rapid assessment protocols for litter management as regulations for air quality emerge.

Key Words: Ammonia, Broiler, Flux, Litter

P166 Dietary lactose and its effect on the disease condition of necrotic enteritis. J. L. McReynolds*[1], J. A. Byrd[1], K. J. Genovese[1], T. L. Poole[1], S. E. Duke[1], M. B. Farnell[2], and D. J. Nisbet[1], [1]*USDA-ARS-Food And Feed Safety Research Unit*, *College Station, TX*, [2]*Texas A&M University*, *College Station*.

Clostridium perfringens (CP) is the etiologic agent of Necrotic enteritis (NE) and is ubiquitous in nature. The incidence of NE has increased in poultry flocks that have stopped using antibiotic growth promoters. The mechanisms of colonization of CP and the factors involved in onset of NE are not fully understood. Previously, our laboratory has demonstrated that lactose could potentially reduce *Salmonella* and CP in ceca of poultry. In the present investigation, we hypothesized that dietary lactose would reduce the clinical signs of NE and could be used as an alternative to antibiotics. In Exp. 1, day-of-hatch broilers were fed either a non-lactose control diet, a diet with 2.5% lactose, or a diet with 4.5% lactose throughout the experiment. Birds were administered CP (10^7 cfu/mL) daily via oral gavage for three consecutive days starting on d 17. When evaluating the intestinal lesions associated with

NE, birds fed 2.5% lactose had significantly lower ($P \leq 0.05$) lesion scores (0.70 ± .52) compared to the control (1.55 ± .52) or the 4.5% lactose (1.60 ± .52). Microbial analysis suggest that lactose did not affect bacterial populations during the 21d evaluation. In a replicate experiment the overall lesion scores in, were significantly ($P > 0.05$) reduced in birds fed 2.5% lactose compared to the birds fed the control diet with mean lesion scores of 1.10 ± .73 and 1.80 ± .73 respectively. These experiments suggest that lactose could be used as a potential alternative to growth promoting antibiotics to help control this costly disease.

Key Words: *Clostridium perfringens*, Chickens, Lactose, Necrotic enteritis

P167 Use of stochastic modeling to predict prevalence of *Salmonella* postitive broilers entering the processing plant. D. E. Cosby*[1], J. S. Bailey[1], C. L. Hofacre[2], D. Cole[3], M. Finklin[2], and B. J. Turner[2], [1]*USDA*, *Athens, GA*, [2]*University of Georgia*, *Athens*, [3]*Georgia Dept. of Human Resources, Division of Public Health*, *Atlanta, GA*.

In the U.S. salmonellae are responsible for approximately 15% (approximately 40,000 cases per year) of all food borne illnesses and improperly handled or undercooked poultry and eggs are often identified as a source of salmonellosis in humans. Since chickens are a major carrier for salmonellae, determining the prevalence of contaminated chickens entering a plant has become a priority in order to decrease the cross contamination of poultry products exiting the plant. Samples were collected from six individual houses on individual farms and the associated flocks at the processing plant from a single local integrator. On farm (boot socks, drag swabs, litter composites, cloacal swabs, ceca and carcass rinses) and in-plant (ceca and carcass rinses) samples were evaluated to determine the relationships between *Salmonella* prevalence on the farm to that found in the processing plant. Prevalence data was analyzed using Spearman correlation coefficients and regression to determine relationship between on farm data and plant data. Using the data collected, a stochastic model (Crystal Ball 7Â®) was developed to predict the prevalence distribution of *Salmonella* spp., contaminated birds entering the plant. Boot socks showed the strongest correlation with plant carcass rinses (r=0.7882), and cloacal swabs were most predictive of plant ceca (r=0.8111), although neither was significant at α=0.05.

Key Words: *Salmonella*, Prevalence, Stochastic Modeling, Broilers, Processing

P168 Collagen type X and transforming growth factor β-1 in tibia bones are affected by incubation conditions in broilers and turkeys. J. Small*, E. O. Oviedo-Rondón, M. J. Wineland, V. L. Christensen, D. T. Ort, K. M. Mann, M. D. Koci, and S .L. Funderburk, *North Carolina State University*, *Raleigh*.

Previous research in our lab has suggested that temperature (T) and oxygen (O_2) concentrations during the plateau stage of incubation affect several aspects of bone development. Collagen type X (colX) and Transforming Growth Factor β-1 (TGFβ-1) are key indicators of the hypertrophic chondrocyte development and may have implications in tibial dyschondroplasia and other bone disorders. This experiment aimed to evaluate the effects of T and O_2 concentrations during the plateau stage on the activity of colX and TGFβ-1 in tibia bones of broilers and turkeys at day of hatch. Two experiments were conducted with broilers and two with turkeys, under similar conditions, to evaluate either 4 T (36, 37, 38 or 39 °C) or 4 O_2 concentrations (17, 19, 21 or 23% O_2). Two strains of chickens with low (LG) and high (HG) eggshell conductance, and one turkey strain of LG were evaluated in all experiments. In each experiment, standard incubation conditions were used for broiler eggs up to 17 days and turkey eggs up to 24 days. At day of hatch 10 chicks or poults per strain were randomly selected. Legs were dissected and tibias fixed for histological analyses by immunofluorescense. Cell density (cellD) in each zone of the growth plate was calculated in slides stained with H&E. Results indicated that high T depressed the fluorescence of colX and TGFβ-1 in turkeys and chickens. This effect was more pronounced in the LG chicken strain. O_2 concentrations do not affect consistently the fluorescence of these proteins. CellD in the resting zone was increased ($P<0.05$) by the high T in the incubator independently of genetic strain. Temperature also increased cellD in the P zone, but this effect varied according to the genetic line. CellD was not affected ($P>0.05$) by T in the H zone, but both chicken strains had significantly different number of chondrocytes in this area. We concluded that high incubation T may reduce the presence of colX and TGFβ-1 in chicken and turkey tibiotarsus with deleterious effects for bone development.

Key Words: Bone, Broilers, Turkeys, Collagen type X, TGF β-1

P169 Influence of lighting program, temperature, and strain on physiological stress and fear responses of broilers. L. B. Hooie*, R. J. Lien, and J. B. Hess, *Auburn University*, *Auburn, AL*.

Broilers of two strains were exposed to light and temperature treatments to evaluate effects on heterophil to lymphocyte ratio (H:L), plasma corticosterone, and tonic immobility duration (TI). Fifty males of moderate (MY) and high yield (HY) strains were placed by strain in 2 pens in each of 12 rooms. Six rooms were provided bright-long (2 FC; 23L:1D) and six rooms dim increasing (0.1 FC; 20L:4D, 1-10 d; 12L12D, 10-21 d; 15L:9D, 21-28 d; 18L:6D, 28-35 d; 20L:4D, 35-55 d) light treatments. Beginning at 35 d, six rooms were exposed to typical temperatures (avg. daily high of 27C and low of 21C) and six rooms were subjected to cool temperatures (avg. daily high of 24C and low of 17C). Treatments and strains made up a 2 by 2 by 2 factorial arrangement.

At 53 d, H:L was unaffected by temperature but affected by a light treatment by strain interaction (P=0.08) in which the MY strain had increased H:L in the bright-long treatment and decreased H:L in the dim-increasing treatment; whereas, HY strain H:L were intermediate and unaffected by light treatment. Differences in plasma corticosterone at 33 d and 53 d were not significant but followed the same pattern as H:L. At 32 d, TI was significantly greater in the bright-long treatment and HY strain. At 49 d, TI was affected by a 3 way interaction in which the bright-long treatment decreased TI, except in the MY strain at typical temperatures. However, the dim-increasing treatment increased TI, except in the MY strain at typical temperatures. These results indicate that common lighting program and temperature differences may influence stress and fear responses of broiler strains differently.

Key Words: Broiler, Lighting program, Stress, Welfare, Tonic immobility

P170 Evaluation of one hydrogen peroxide disinfectant in floor eggs. V. D. Gonzalez-Reyes, G. Gómez-Verduzco, J. A. Quintana-Lopez, and O. Urquiza-Bravo*, *National University of Mexico*, *Mexico City, Mexico*.

All egg qualities are recognized as its structure and as a production unit, reason why today there are more exigencies in production.

Within the productive system there are many handling practices to obtain a free microorganisms product who could cause alteration like manual egg collection and the geographic location. On the other hand, the disinfection has had success in the destruction of present germs in shell surface without damage in the cuticle, and also no damage in the personnel who is applying it. Of products used in the disinfection of the fertile egg it appears the hydrogen peroxide (H_2 O_2), which has demonstrated to be effective in the destruction of the microorganisms. It offers the advantage as fast evaporation or destruction (it is become in H_2 O and O_2), does not leave scents disagreeable and it is not harmful to the people who apply it. That is why the objective of this work was to evaluate an hydrogen peroxide disinfectant in floor eggs, by external and internal bacteriological sampling, before and after the use of a disinfectant with hydrogen peroxide. 42 eggs from breeder Hy Line W 36 hens were collected from the Medicine Veterinary Faculty experimental farm of the National University of Mexico (UNAM). Each egg was washed with a phosphate buffered solution for an external bacteriological sampling before and after the application of the disinfectant and decimal serial dilutions were made to be plating in solid cultures. Later yolk was collected and it was plated in the same cultures. The application of hydrogen peroxide had a significant reduction ($P<0.01$) compared to eggs with no disinfectant.

Key Words: Disinfectants, Hydrogen Peroxide, Floor Eggs

P171 The effect of egg shape and weight variation on hatchability and hatch of fertile in commercial broiler breeder flocks. J. R. Moyle*, D. E. Yoho, R. S. Harper, A. D. Swaffar, and R. K. Bramwell, *University of Arkansas*, *Fayetteville*.

Commercial breeder and hatchery managers have become increasingly concerned with the perceived variability of hatching eggs produced by modern broiler breeder hens. However, there is little published data in reference to the size and shape variation of broiler breeder eggs and the effect on hatchability. This study evaluated the variability in the weight and shape of eggs produced by hens of different flocks, ages and strains. Broiler breeder hatching eggs utilized were from commercial hatcheries representing different flocks, ages and strains. Individual egg weights were obtained to determine the variation within each flock. After obtaining egg weights, hatching eggs were separated by weight for that flock and returned to the commercial hatchery trays for incubation. To evaluate egg shape variation, dividing the width of each egg by its length created an egg shape index. Each egg was assigned a shape score value between 0-13 based upon this index. All eggs were incubated in commercial hatcheries by weight or shape group and a complete embryo diagnosis of the hatch residue performed. All data were analyzed using JMP statistic software comparing egg weight groups and egg shape index for differences in hatch traits. While there was no significant difference in hatchability between the heavy and average weight eggs for each flock, the light weight eggs from each group had as much as 9% lower hatchability. Additionally, eggs assigned a shape index score that fell outside the normal curve for that flock had significantly reduced hatch of fertile (as much as 22.3% lower hatch for the more oblong eggs as compared to the normal shaped eggs). In summary, hatchability of fertile eggs within a flock is affected by the weight and shape variation within that flock with the lighter and more oblong eggs suffering higher embryo mortality as compared to the average size and shape eggs for that flock.

Key Words: Hatching egg weight, Hatching egg shape, Egg uniformity

P172 Effects of temperature variation in on-farm hatching egg holding units in commercial broiler breeder flocks. D. E. Yoho*[1], S. Henderson[1], A. D. Swaffar[1], S. Martin[2], and R. K. Bramwell[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Cobb-Vantress, Inc.*, *Siloam Springs, AR*.

Hatching egg storage conditions have been evaluated in the past and recommendations presented to receive optimum hatchability. However, most commercial broiler breeder farms on-farm egg storage facilities are not capable of consistently maintaining the optimum storage conditions needed to maintain embryo viability. Therefore, this study was designed to study the effects of fluctuations in on-farm egg storage temperatures on hatchability and embryo livability in commercial broiler breeder flocks. Hatching eggs were obtained from commercial breeder farms the day of lay and prior to their placement in the existing on farm egg storage facilities. Hatching eggs were transported to egg storage facilities and were randomly divided into five groups of 288 eggs per group. Egg storage chambers were maintained at 66, 68, 70, 72 or 74^0 F. All eggs were initially stored for 24 hours at 70 F (21.1 C) with the control eggs remaining at 70 F for three days. After 24 hours storage, equally sized groups of eggs were moved to either two or four degrees below or above the control group. Following this 24-hour period the eggs in the high and low temperature chambers were switched to the alternate high or low temperature group. These temperatures were selected to maintain an average of 70 degrees for all eggs for the three-day storage period. Eggs were then returned to a commercial hatchery for incubation. Following the incubation process, eggs from each treatment were subjected to a complete hatch residue breakout to determine percent hatch and hatch of fertile and embryo mortality. All data were analyzed using JMP statistical analysis program. Fluctuation of on farm egg storage temperatures reduced hatch and hatch of fertile by 3.6% and 2.9%, respectively. In summary, oscillating on-farm egg storage temperatures can cause a significant loss in hatchability.

Key Words: Hatching egg storage, On-farm egg storage, Hatchability

P173 Efficacy of the clay adsorbent, SOLIS™-BASE, in ameliorating the toxic effects of aflatoxin in broiler chicks. H. Choudhury[1], L. B. Linares*[1], R. E. Kutz[1], D. R. Ledoux[1], G. E. Rottinghaus[1], A. J. Bermudez[1], R. B. Shirley[2], and F. A. Uraizee[2], [1]*University of Missouri*, *Columbia*, [2]*Novus International, Inc.*, *St. Louis, MO*.

An experiment was conducted to determine the efficacy of the adsorbent SOLIS™-BASE, in ameliorating the toxic effects of aflatoxin (AF) in broiler chicks. A second objective was to determine the minimum

level of AF that would depress chick performance. Two hundred and fifty day-old male broiler chicks were assigned to a 2 x 5 factorial arrangement of dietary treatments (5 pens of 5 chicks/treatment) from hatch to day 21. Factors were level of adsorbent (0 or 0.2% SOLIS™-BASE) and concentration of AF (0, 0.75, 1.5, 2.25 or 3 mg AF/kg of diet). The addition of SOLIS™-BASE to chick diets at a level of 0.2% did not negatively affect ($P > 0.05$) chick performance, organ weight, or toe ash weight. Feed intake (FI) and body weight gain (BWG) was depressed ($P < 0.0001$) in chicks fed dietary AF concentrations of 1.5 mg AF/kg diet and higher. Feed intake depression ranged from 13 to 33%, whereas BWG gain depression ranged from 9 to 37%. The addition of SOLIS™-BASE to the AF contaminated diets ameliorated the effects of AF on FI (range 5 to 21%) and BWG (range 2 to 20%). Relative liver and kidney weights were higher in chicks fed AF ($P < 0.0001$), and the addition of SOLIS™-BASE to the AF-contaminated diets reduced ($P < 0.05$) the increase in the weight of both organs. Toe ash weights were lower ($P < 0.0001$) in chicks fed AF, and the addition of SOLIS™-BASE to the AF-contaminated diets increased ($P < 0.008$) toe ash weights. Results indicate that SOLIS™-BASE at 0.2% of the diet did not negatively affect chick performance, and was effective in reducing the toxic effects of AF. Data also indicate that a dietary concentration of 1.5 mg AF/kg diet was enough to depress chick performance.

Key Words: Aflatoxin, Adsorbent, Broiler chick, SOLIS™-BASE

P174 Effect of dietary energy and dietary protein in corn-soy diets on post-molt performance,egg components,egg solids and egg quality in phase 1 molted Hyline W-36 hens. P. Gunawardana*, G. Wu, M. M. Bryant, and D. A. Roland, *Auburn University*, *Auburn, AL*.

A 4 × 3 factorial experiment using four added dietary energy (fat) levels [0 (0.00), 79(1.67), 158(3.35) and 238(5.04) kcal ME/kg(%fat) and three protein levels (14.89,16.06 and17.38%) was conducted to determine the influence of dietary energy on performance, egg composition, egg solids and egg quality of Hy-line W-36 hens fed different protein levels. The basal diets of the 17.38, 16.06 and 14.89% protein contained 2751, 2784 and 2815 kcal ME/kg, respectively. This study lasted 12 weeks. Molted Hy-line W-36 hens (n=1440) phase 1 (70weeks of age) were randomly divided into 12 treatments (8 replicates of 15 hens per treatment).Protein had a significant effect on feed intake, Increasing dietary protein linearly increased feed intake from 93.15 to 98.75g/hen/day,resulting in a 6.01% increase of feed intake. Protein also had a significant effect on egg production, egg specific gravity, egg mass, feed conversion, egg weight, percentage of egg shell components, egg yolk color and yolk and albumen weight. Increasing dietary energy by addition of poultry oil also had a linear effect on feed intake at all three protein levels. As added dietary energy increased from 0 to 158 kcal ME/kg, feed intake linearly decreased. However a further increase of added dietary energy from 158 to 238 kcal ME/kg, had no additional effect on feed intake. Increasing dietary energy had a significant effect on egg specific gravity, body weight of hens, feed conversion and egg yolk color. There was a significant interaction between protein and dietary energy on egg specific gravity, percentage of egg yolk solids and egg yolk color. Increasing dietary energy and protein significantly improved feed conversion. Increasing protein intake significantly increased albumen and yolk weight but had no influence on yolk albumen or whole egg solids.

Key Words: Protein, Dietary energy, Hens

P175 Effect of dietary energy, protein and a versatile enzyme in corn-soy diets on hen performance, egg solids, egg composition and egg Quality of Hy-Line W- 36 hens during phase two second-cycle. P. Gunawardana*, G. Wu, M. M. Bryant, and D. A. Roland, *Auburn University*, *Auburn, AL*.

A 4 x 2 x 2 factorial experiment of four energy levels and two protein levels with and without Rovabio was conducted to evaluate the effect of Rovabio Excel, dietary energy and protein on performance, egg composition, egg solids, and egg quality of commercial Leghorns. Hy-line W-36 hens (n=1920, 87wk old) were randomly divided into 16 dietary treatments (8 replicates of 15 hens per treatment). The trial lasted 12 weeks. Protein had a significant effect on feed intake, body weight, yolk solids, and yolk color. As dietary energy increased from 2,792 to 2,990 ME/kg, feed intake linearly decreased from 97.96 to 94.90 g per hen daily, resulting in a 3.1% decrease of feed intake.Added dietary energy had a significant linear effect on daily TSAA and lysine intake, with increase of added dietary energy from 0 to 198 kcal/kg, TSAA and lysine intake decreased by 3.09%. There was a linear response of body weight of hens to increased dietary energy. Dietary energy had a significant effect on yolk solids and yolk color. Egg weight of hens fed the diets supplemented with Rovabio was significantly higher than that of hens fed the diets without Rovabio during wk 3 and 4, and was numerically higher than that of hens fed the diets without Rovabio during other weeks. Rovabio supplementation significantly increased body weight of hens. These results suggest Rovabio had a significant influence on energy utilization of commercial Leghorns during phase 2 of second cycle. More research is needed with Rovabio in young hens to evaluate performance and profits of commercial layers at different egg and ingredient prices.

Key Words: Rovabio, Energy utilization, Hen

P176 The effect of exogenous xylanase on dietary energy, N and amino acid metabolism when included in wheat-based diets and fed to layers. V. Pirgozliev*[1], T. Acamovic[1], O. Oduguwa[1,2], and M. R. Bedford[3], [1]*Scottish Agricultural College, ASRC*, *Edinburgh, United Kingdom*, [2]*University of Agriculture*, *Abeokuta, Nigeria*, [3]*Syngenta Animal Nutrition Inc.*, *Marlborough , United Kingdom*.

Wheat is an important source of energy and amino acids in poultry feed throughout the World. However, the cell walls in wheat are mainly composed of non-starch polysaccharides (NSPs) that may posess antinutritive activity increasing digesta viscosity and reducing bird performance. Exogenous xylanases are enzymes that cleave the NSPs in wheat and reduce their negative effect on the performance. Most published data relates to broiler production and there is a lack of information on the effect of xylanases in layer diets and especially on the effects on dietary energy, nitrogen (N) and amino acid (AA) metabolism. Although energy relates mainly to growth performance, the metabolism of N and AA has also a significant environmental impact. To examine the effect of a novel xylanase (Quantum, Syngenta Animal Nutrition) on performance, dietary energy, N and AA metabolism, five wheat-based diets (control (C), C + 400, + 800, + 1200, + 1600 XU (xylanase units/kg feed)) were fed to eight hundred and ten Lohmann Brown laying hens (28-32w age) in 270 cages (3 birds in a cage). Xylanase supplementation improved N metabolisability and the intake of metabolisable N by 6.3% ($P=0.015$) and 4.2% ($P<0.001$) respectively. The metabolisability coefficients for total and dispensable amino acids also improved ($P<0.05$) by 7.2% and 6.5% respectively.

Dietary xylanase increased (P=0.019) sulphur metabolisability by approximately 2% suggesting an improvement in the utilisation of S-containing amino acids. Dietary AME tended (P=0.152) to increase with enzyme supplementation. Feeding xylanase also improved (P<0.05) the market quality of the eggs increasing the yolk colour and decreasing the number of blood spots. The results of this study showed that dietary xylanase improved the egg quality as well as the metabolisability of N and AA in diets of laying hens thereby reducing adverse environmental impacts.

Key Words: Xylanase, Layers, Amino acids, Egg quality

P177 Requirements for true digestible isoleucine, threonine, and tryptophan for 28 to 36-week-old laying hens. S. Roberts[1], B. Kerr[2], D. Hoehler[3], and K. Bregendahl*[1], [1]*Iowa State University*, *Ames*, [2]*NSRIC, USDA/ARS*, *Ames, IA*, [3]*Degussa*, *Kennesaw, GA*.

Three separate experiments were conducted with Hy-Line W-36 hens to evaluate the true digestible (TD) Ile, Thr, and Trp requirements for egg production (EP), egg weight (EW), egg mass (EM), and feed efficiency (FE). The experiments were conducted simultaneously and were each designed as a randomized complete block design with 60 experimental units (each consisting of 1 cage with 2 hens) and 5 dietary treatments. The treatment diets consisted of a common basal diet (2987 kcal/kg ME; 12.3% CP), formulated using corn, soybean meal, and meat and bone meal. The TD amino acid contents in the basal diet were determined using the total fecal collection precision-fed assay with adult cecectomized roosters. Crystalline L-Ile, L-Thr, and L-Trp (considered 100% TD) replaced cornstarch in the basal diet to yield TD contents of 0.37, 0.50, 0.64, 0.78, and 0.92% Ile; 0.38, 0.45, 0.53, 0.60, and 0.67% Thr; and 0.09, 0.13, 0.17, 0.21, and 0.25% Trp. Crystalline amino acids were added to the test diets at the expense of cornstarch to make the respective test amino acid first limiting. The hens were fed the treatment diets from 26 to 34 wk of age, with the first 2 wk considered a depletion period. EP was recorded daily; EW was determined weekly on 48-h eggs; whereas EM (= EP × EW), feed intake (FI), and FE (= gram EM per gram feed consumed) were recorded weekly. The requirements were determined using the broken-line regression method. The daily FI of hens fed amino acid–adequate diets was 83 g/hen. The maximum responses for EP (%), EW (g), EM (g/hen), and FE (g/g) were 90.5, 53.2, 48.1, and 0.586 for Ile; 93.3, 53.4, 49.8, and 0.588 for Thr; and 91.7, 53.1, 48.7, and 0.573 for Trp; respectively. The daily requirements for maximum EP, EW, EM, and FE were 427, 394, 426, and 415 mg/hen for TD Ile and 400, 418, 414, and 461 mg/hen for TD Thr, respectively. The daily TD Trp requirements for maximum EP, EM, and FE were 119, 120, and 95 mg/hen, respectively. EW was not affected (P > 0.05) by Trp consumption.

Key Words: Amino acid requirements, Laying hens

P178 An adjustable nutrient margin of safety comparison using linear and stochastic programming in an Excel spreadsheet. W. B. Roush*, J. L. Purswell, and S. L. Branton, *USDA-ARS Poultry Research Unit*, *Mississippi State, MS*.

With the diversion of corn to the biofuel industry, it will be necessary to use feed ingredients that have highly variable nutrients. Stochastic Programming is a nonlinear programming approach to constrain risk when dealing with nutrient variability. The use of a margin of safety was suggested by Nott and Combs (1967) as a method to adjust the nutrient matrix to compensate for nutrient variability. To make the adjustment, they suggested subtracting one half of a standard deviation from the mean value of nutrients. This would increase the probability of meeting an animal's requirement from 50% for a LP to 69% for a LP. Pesti and Seila (1999) illustrated how linear programming (LP) and stochastic programming (SP) could be formulated in an Excel spreadsheet program. They used two different scenarios, one showing LP and the other showing SP. The intent of this research is to build upon the work of Pesti and Seila by demonstrating a comparison of LP and SP based on the linear problem proposed in their paper. An Excel workbook was developed consisting of two spreadsheets for LP and SP, respectively. Both approaches use the Solver function for optimization. Ingredients and nutrients were based on the formulation problem for the LP in Pesti and Seila and served as a benchmark for development of the two programs. Standard deviations for energy and the nutrients calculated from CVs, (Zhang,1999) and from the commercial publication of sources for amino acids (Degussa, 2001). The conclusion was that the Excel spreadsheet effectively demonstrated the difference in accuracy and precision of SP versus LP in least cost formulations at a requested risk constraint. At the 50% level of risk, both programs produced the same ration formulations as was expected. At the requested 69% level of risk, the linear program formulated a ration with a 77.26% level of risk while the stochastic program formulated the requested level of 69%. The 77.26% produced a higher cost ration than the 69% stochastic ration.

Key Words: Feed formulation, Linear programming, Stochastic programming

P179 Influence of microbial phytase on true phosphorus digestibility in canola meal fed to broiler chicks. A. Akinmusire* and O. Adeola, *Purdue University*, *West Lafayette, IN*.

Using canola meal (CM) as a model ingredient, our objectives in the study were the application of the regression analysis technique to estimate true P digestibility (TPD) in broiler chicks and the quantification of microbial phytase influence on TPD. Two hundred and eighty eight male broiler chicks were assigned to 6 dietary treatments from day 15 to 21. Experimental diets fed consisted of three graded levels of CM with or without phytase supplementation (a total of six semi-purified and isocaloric diets) in a 3×2 factorial arrangement. Sequential diets formulated with CM (diets 1 through 3) were calculated to contain 1.06, 2.11, and 3.17 g of phytate P/kg of diet respectively. Diets 4 through 6 were identical to diets 1 through 3; except for the addition of Phyzyme XP phytase at 1,000 units (FTU)/kg. Chromic oxide was added to the diets, and P digestibility was calculated using the index method. As dietary P increased from 1.74 to 4.94 g/kg DM and from 1.65 to 4.84 g/kg DM for the phytase unsupplemented and supplemented diets, respectively, total P output in prececal digesta and total P output in excreta expressed on a dry matter intake basis linearly increased (P < 0.01). In addition a clear positive effect (P < 0.01) of phytase was observed in the total P output in prececal digesta and total P output in excreta. Estimated true prececal P digestibility was observed to differ (P < 0.01) between CM without phytase and with phytase (68 vs. 78% respectively). Phytase supplementation equally resulted in a difference (P < 0.01) between true total tract P retention (36 vs. 44%). It may be concluded from this study that approximately

68 and 36% of total P in CM could be digested and absorbed by growing chicks as measured from the prececal digesta and total tract excreta respectively; and that the addition of microbial phytase at 1000 U/kg significantly increases this true prececal P digestibility and true total tract P retention value to approximately 78 and 44% respectively.

Key Words: Canola meal, Chicks, Phosphorus, Phytase, True digestibility

P180 Implications of dietary threonine on crude mucin excretion in broiler chicks and ducklings. N. Horn* and O. Adeola, *Purdue University*, *West Lafayette, IN*.

The effect of dietary threonine on crude mucin excretion was investigated in male broiler chicks and White Pekin ducklings. Seventy-two birds of each species were fed a standard poultry starter diet from day 0 to day 14, then assigned to 3 dietary treatments in a randomized complete block design for a 7-day feeding trial. The dietary treatments consisted of a semipurified isonitrogenous corn-soy bean meal based diet with the addition of crystalline amino acids and graded levels of threonine. Dietary treatments contained approximately low (0.33g/kg), medium (0.58 g/kg), and adequate (0.82 g/kg) levels of threonine based on NRC recommendations. Chromic Oxide was added to the dietary treatments as an indigestible marker. Excreta was collected from day 5 to day 7 of the feeding trial, immediately frozen, and later freeze dried and analyzed for crude mucin. For broiler chicks there was a tendency for linear increase in growth performance ($P < 0.10$) for the 7 day feeding trial, and there were linear increases in dry matter retention ($P < 0.001$) and crude mucin excretion ($P < 0.05$) in response to dietary threonine. For ducklings there were linear increases in growth performance ($P < 0.01$), dry matter retention ($P < .001$), and a tendency for a linear increase in crude mucin excretion ($P < 0.10$) in response to graded levels of dietary threonine. In conclusion, dietary threonine affected dry matter retention, and crude mucin excretion in broilers, whereas in ducklings, growth performance, dry matter retention, and crude mucin excretion were affected. Dietary threonine clearly has implications in regards to dry matter retention, and may be a significant factor in mucin production, with consequences on nutrient absorption in chicks and ducklings.

Key Words: Chick, Duck, Growth, Mucin, Threonine

P181 Enzymatic process of feather meal for improved digestibility. B. E. Spencer*[1], W. C. Huang[1], J. J. Wang[2], and J. C. H. Shih[1], [1]*North Carolina State University*, *Raleigh*, [2]*BioResource International, Inc.*, *Morrisville, NC*.

Feather meal is typically produced by processing feathers by batched or continuous cooking under 130-140°C steam pressure for 30-40 min followed by drying and grinding. As a feed ingredient, feather meal, with a protein content of 85-90%, is underutilized due to its poor digestibility. A preparation of keratinase (KE, 300,000 U/gm), a feather-degrading enzyme, was tested to process feather meal with improved digestibility and nutritional value. An ANCO-Eaglin 133L pilot-scale batch cooker with internal agitator (25 rpm) was used for the study. Feather meal was produced in the lab by mixing 5 kg raw feathers with 6 L of water or buffered solution and cooking at 141°C for 30 minutes, followed by a 5 min vent drying. The final products were dried overnight at 70°C and ground. To test the KE effect, four kinds of feather meal were produced: FMc (control), produced by the standard procedure using water, FMb, produced by using buffer solution (pH 8.0), FMKE5, and FMKE50, cooked with buffered solution and cooled to 60°C, followed by adding KE at 0.1% and 1.0% (w/w = KE: feathers) respectively. The cooked feathers were incubated for 30 minutes at 50-60°C with agitation, dried for an additional 48 hrs at 60°C and ground. Different preparations of feather meal were analyzed using 0.02% pepsin digestion, OPA soluble protein assay and HPLC amino acid analysis. With enzyme treatments, the protein digestibility determined by pepsin and OPA assays showed significant improvement from an average of 52% to 72% for FMKE5 and to 69% for FMKE50. Crude protein levels, as determined by Kjedahl nitrogen, were highest for FMc at 90.0% and lowest for FMKE50 at 87.8%. Lysine levels were lowest in the FMc at 1.77% and highest in FMKE50 at 1.94%. Methionine levels were equal within 0.03% for all treatments. Cysteine levels were lowest in FMc at 4.89% and highest for FMKE5 at 5.72%. KE treated feather meals demonstrated better in vitro digestibility when compared to both the water and the buffer controls. Further analysis will include animal studies for the correlation of amino acid digestibility and nutritional value of the enzymatically processed feather meal.

Key Words: Feather meal, Hydrolysis, Enzyme, Keratinase, Amino acid digestibility

P182 Impact of Availa® /M on growth, feed conversion, femur spiral fracture related mortality, bone morphometrics and carcass yield in tom turkeys. T . Cheng* and T. Ward, *Zinpro Corporation*, *Eden Prairie, MN*.

A total of 900 Nicholas Strain 88 commercial toms were randomly placed into 36 pens. The treatments consisted of (1) Sulfates [100 ppm Zn from $ZnSO_4$ and 110 ppm Mn from $MnSO_4$]; (2) Availa-Z/M ON TOP [Availa-Z/M supplied 40 ppm of Zn and 40 ppm of Mn in additional to their respective $ZnSO_4$ sources]; (3) Availa-Z/M ISO [Availa-Z/M replaced 40 ppm Zn and 40 ppm of Mn from their respective $ZnSO_4$ sources]. No significant difference among the treatments were observed for the final body weight at 140 days of age (20.08, 19.95 and 19.81 kg, respectively). The cumulative feed conversion from the Availa-Z/M ON TOP and Availa-Z/M ISO groups were significantly better than that of the Sulfate group (2.639, 2.575 and 2.568; $P = 0.15$). Overall mortality was not statistically affected by treatments but the Availa-Z/M groups showed numerically lower 106-140 day mortality (7.1, 3.7 and 4.4%) and significantly lower percentage of mortality due to spiral fracture of femur bone (43, 10 and 3%; $P = 0.05$) when compared to the Sulfate group. The Availa-Z/M groups had numerically better breast meat yield (30.83, 31.03 and 30.94%). The long-axis diameter of femur at one third of femur length from the top was significantly longer in the Availa-Z/M groups (19.58, 20.23 and 19.89 mm; $P < 0.01$). The Availa-Z/M groups produced numerically larger cross sectional average of cortical bone wall area when compared to the sulfate group (101.55, 104.07 and 103.60 mm^2). Feeding Availa-Z/M to turkeys improved bone morphometrics, reduced femur spiral fracture related mortality as well as late mortality, improved feed conversion and increased carcass weight and breast meat yield.

P183 A workbook to estimate parameters for nutritional response models. G. Pesti* and D. Vedenov, *University of Georgia*, *Athens*.

Experiments to determine nutritional requirements result in a set of ordered pairs of data consisting of the inputs and outputs. The inputs are various levels of the nutrient in question, and the outputs are response criteria like growth, feed utilization efficiency, carcass yield, measures of bone strength, etc. A Microsoft Excel (One Microsoft Way Redmond, WA 98052 USA) workbook has been prepared to fit several nutritional response models to experimental input/output data. The workbook, called "NRM.xls" and a tutorial on its use are available free of charge at (http://pubs.caes.uga.edu/caespubs/ES-pubs/RB440.htm). NRM.xls attempts to find the best parameter estimates for seven common nutritional models: the Broken Line (ascending linear or quadratic segments), Saturation Kinetics, three and four-parameter Logistics, Compartmental, Sigmoidal Exponential, and Exponential Models. Excel has a built-in module called "Solver" that in used in NRM.xls to minimize the sum of squared errors by changing the values of the parameter cells. In addition to parameter estimates, spreadsheets for each model also calculate the standard errors and 95% confidence intervals for the estimated parameters, as well as goodness of fit (R^2) values of the fitted models.

Each spreadsheet allows for up to 100 pairs of observations to be either entered manually or copied and pasted. Users can modify initial parameter estimates manually to achieve a "visual" fit of each regression model to the data. The "visual" fits result in good starting values for the numerical optimization algorithm and make it easier for the program to find the global minimum SSE and best parameter estimates. Knowing the confidence interval in the requirement estimate or response line enables researchers to determine the value of the experiment. Small confidence intervals suggest adequate replication and reproducible results.

Key Words: Requirement, Modeling

P184 Undergraduate teaching laboratory: Hens age, induced molting and storage effects on egg size and quality. G. M. Pesti*, R. I. Bakalli, and M. Y. Shim, *University of Georgia*, *Athens*.

The objectives of this laboratory exercise are 1) to demonstrate the changes in egg quality that occur during the life cycle of hens laying commercial eggs; and 2) to demonstrate the influence of egg storage time and conditions on changes in egg quality. We have been able to consistently demonstrate significant differences with HyLine W-36 leghorn : 64 young pullets (average age at start = 18.25 weeks) and 126 hens, half of which were molted (average age at start = 73.5 weeks). Birds were housed one per cage with 8 cages per replicate and 8 replicates per treatment. Two weeks before the end of experiment 12 eggs were randomly collected from each replication and half each were kept refrigerated (5 ºC), and at room temperature (20-24 ºC). Parameters measured/calculated include: egg weight, egg specific gravity, Haugh units (HU), relative weight of yolk and albumen, relative egg shell weight, egg shell surface, egg shell index, egg shell thickness, and egg weight decrease. Molted hens produced fewer, but 1.56 g heavier, eggs than un-molted hens (67.14 vs. 65.58, P>0.05). Positive significant effects were observed in specific gravity for molted hens, un-molted hens, and pullets (P=0.0007; 1.084^{a}, 1.079^{b}, and 1.088^{a} g/cm ^{3}, respectively) and HU (P<0.001; 79^{b}, 67^{c}, and 95^{a}, respectively, P<0.05). Significantly different egg shell surface was observed only between old and young hens. There were no significant differences between treatments in yolk or albumen relative weights, relative egg shell weights, or in shell index or egg shell thickness. Egg weight loss for molted hens, un-molted hens, and pullets was significantly different only in eggs kept refrigerated (P=0.0335; 0.78 ^{a}, 0.97 ^{ab}, and 1.21 ^{b}%, respectively). Haugh units remained better for eggs from young hens kept refrigerated (P<0.0001) as well as for eggs kept in room temperature (P<0.0001). The laboratory exercise described allows students to learn how molting, hens age and storage conditions significantly influence on egg size and quality.

Key Words: Laboratory exercise, Leghorn, Molting, Storage, Egg quality

P185 Nutrient digestibility in broilers with inclusion of inulin in the diet. J. A. Hernández Lara*[1], M. E. Juárez Silva[1], F. Pérez-Gil Romo[1], and D. Ortega Alvarez[2], [1]*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán*, *México, D.F, México*, [2]*Megafarma S.A. de C.V*, *México, D.F, México*.

The use of inulin in the diet of chickens as an alternative of using antiobiotics has improved performance and enzymatic activity in the intestinal lumen. Results about the effect of inulin on starch and protein digestibility make available information to design strategies to follow on broilers feeding. The objective of this study was to determine the effect of inulin on apparent digestibility of starch and protein during the first 3 weeks of life. 10 experimental units were used for every treatment, formed by 2 Ross chickens, being the treatments: 0.0%, 0.1%, 0.2% and 0.4% of inulin in the diets with a base of maize-soya. Samples were taken on day 7, 14 and 21 of age, Cr2O3 was included in food as a marker to determine digestibility. Results of starch and protein digestibility showed improvement on day 7 with inulin concentration of 0.4%, while for day 14 and 21 the highest values were obtained with 0.2%. A positive lineal relationship between inulin concentration and digestibility for both nutrients on day 7; for day 14 the relationship stayed only for protein; and for the last period this relationship was negative for both nutrients. These results indicate that inulin concentrations to improve starch and protein digestibility during the first 21 days of chicken's life are 0.4% for the first week and 0.2% for the second to third week.

Key Words: Iinulin, Digestibility, Prebiotic, Starch, Protein

P186 Supplementation with MINTREX® organic trace minerals enhances intestinal health and feed efficiency of turkey poults. D. Bohórquez*[1], A. Santos[1], P. Ferket[1], and J. Richards[2], [1]*North Carolina State University*, *Raleigh*, [2]*Novus International, Inc.*, *St. Charles, MO*.

Dietary MINTREX Pse (MIN, Novus) and 25-hydroxycholcalciferol (HYD) supplementation may improve feed efficiency by enhancing intestinal health through mucosal characteristics. Day-old Nicholas toms were randomly distributed within 12 replicate pens (15 poults/pen) per treatment (TRT) and fed diets that met or exceeded NRC recommendation until 21d. TRT were a 2x2 factorial (0 and .1% MIN; 0 and

92 mcg/kg HYD). The .1% MIN provided 40 ppm Zn, 40 ppm Mn, and 20 ppm Cu as methionine hydroxy analogue complex and .3 ppm Se as Se yeast. All the diets contained similar trace minerals levels (150 ppm Zn, 150 ppm Mn, and 145 ppm Cu). Body weight (BW) and cumulative feed:gain (cFCR) were determined at 21d of age. At 7d, ileum histomorphometry (10 villi/bird) were measured (10 poults/TRT). Villus height (VH), apical width (VAW), basal width (VBW), crypt depth (CD), muscularis depth (MD) and mucosal height (MH) were determined. Villus height-crypt depth ratio (V/C) and apparent villus surface area (VS) were calculated. At 21d, there were no TRT effects on BW, yet a significant MINxHYD effect on cFCR revealed that MIN significantly reduced cFCR only in combination with HYD (1.321 vs 1.301, p<.05). At 7d, significant MINxHYD effects were observed on CD, MD, and V/C. MIN increased CD (42.9 vs 62.2 mcm, p<.01), increased MD (63.4 vs 97.8 mcm, p<.01) and decreased V/C (10.2 vs 7.0, p<.01) with 92 mcg/kg HYD, but not without HYD. However, HYD reduced CD (62.2 vs 42.9 mcm, p<.05), reduced MD (97.8 vs 63.4 mcm, p<.01) and increased V/C (7.0 vs 10.2, p<.05) at 0% MIN but not with .1% MIN. VBW was significantly increased with MIN supplementation (101.7 vs 116.3 mcm, p<.01), whereas VAW was decreased by HYD (70.1 vs 60.7 mcm, p<.01). MINTREX Pse supplementation for turkeys may be an effective way to improve feed conversion, likely by enhancing lateral development of the villus, especially when supplemented in combination with HYD.

Key Words: Turkeys, MINTREX, Organic trace minerals, Feed efficiency, Gut health

P187 Reduction of *Salmonella* shedding of commercial broilers flocks of North Carolina farms by dietary wheat and enzyme supplementation. A. A. Santos Jr*, P. R. Ferket, F. B. O. Santos, and B. W. Sheldon, *North Carolina State University*, *Raleigh*.

Salmonella (SA) colonization in poultry may be influenced by the degree of competitive exclusion from enteric microflora affected by diet formulation. A study was conducted to determine the effect of inclusion of wheat to the diet and dietary enzyme supplementation on SA shedding of commercial broiler chickens (Cobb). As preliminary data (0d), fresh fecal samples were taken from 4 farms (4 houses/farm), such that each farm had broilers of different ages (7, 14, 21, 35d) and fed corn/soy-based diets. Subsequently, 1d old chicks were placed at 4 farms, fed corn/soy/wheat-based diets (whole wheat with 625EXU/kg of xylanase-blend mixed in before pelleting: 25% 1-14d; 5% 14-18d; 0% 18-35d) and fresh fecal samples were collected from these birds on 7, 14, 28 and 35d. Fecal SA prevalence and populations (Log MPN/g) were enumerated using the most probable number (MPN) procedure. Before inclusion of wheat to the diet (0d), SA was recovered from all farms and from 70% of the houses with an average of 2.18 Log MPN/g. After 7d, SA prevalence (75% house, 100% farm) and population (2.66 Log MPN/g) were not statistically different from the preliminary data (P>.05). However, SA prevalence (31% house, 50% farm) and population (1.03 Log MPN/g) were significantly (P<.05) lower at 14d than at 0 and 7d. After 10 d of dietary wheat withdrawal (28d), farm SA prevalence (75%) increased and was not statistically different (P>.05) from the levels of 0 and 7d. However, SA prevalence among the houses (38%) and population (1.29 Log MPN/g) were low and similar to the levels observed at 14d, yet different (P<.05) from the other days (0, 7, 35 d). At 35d (17d after wheat withdrawal), SA shedding increased and levels were similar (P>.05) to 0 and 7d. Additionally, 70% of the houses and 75% of farms, were SA positive with a mean fecal population of 2.25 Log MPN/g. Intestinal colonization and fecal shedding of *Salmonella* was discouraged by dietary inclusion of whole wheat and an enzyme blend containing xylanase.

Key Words: Broilers, Whole Wheat, Xylanase, *Salmonella*, Diet Formulation

P188 Effect of a new coating on the thermotolerance of a phytase product. T. Gravesen*[1], S. Dalsgaard[1], and B. Fryksdale[2], [1]*Danisco Innovations*, *Brabrand, Denmark*, [2]*Genencor International Inc.*, *Palo Alto, CA*.

Phytase is used as an animal feed ingredient globally to improve phytate phosphorus digestibility. Phytases are used in the feedmill in liquid form, applied post-pelleting or in dry form added into the feed mixer. A large proportion of the feed used in the poultry industry is manufactured via steam conditioning and pelleting processes and is therefore subjected to high process temperatures, frequently in the range 85-90°C (185-194°F). Most commercially available phytases lack intrinisic thermostability and require protection in a dry form to survive the subsequent conditioning and pelleting process. A study was carried out at the Technological Institute, Kolding, Denmark to investigate the effect of a new coating on the thermotolerance of a phytase product (Phyzyme XP; 6-phytase, EC 3.1.3.26). The study compared the uncoated phytase product (phytase P), a test coated phytase product (coated phytase P) and another commercially available coated phytase product (phytase R). The phytase products were included in feed at a dose rate of 5000 FTU/kg feed. The feed was subjected to conditioning temperatures of 90°C (194°F) or 95°C (203°F), under standardised processing conditions, representative of the feed industry: corn diet, steam conditioning time 30 seconds; inlet steam pressure 2 bar; pellet diameter 3mm. Phytase activity in the final pelleted feed was expressed as a percentage recovery of the activity in the corresponding mash feed, before processing. Recovery values at 90°C (194°F) for phytase P, coated phytase P and phytase R were 30.3%, 98.6% (SED 6.08%) and 75.1% respectively. Recovery values at 95°C (203°F) for phytase P, coated phytase P and phytase R were 22.5%, 96.3% (SED 7.32%) and 66.4% respectively. In conclusion, applying a new coating to phytase P gave acceptable thermostability up to 95°C (203°F) and resulted in 74% and 30% more phytase activity being recovered following pelleting at this temperature, compared to the uncoated phytase P and phytase R respectively.

Key Words: Enzyme, Phytase, Pelleting, Thermostability, Recovery

P189 Effects of synbiotic and phytogenic feed additives on performance and immune status in broilers. T. Steiner[1], A. Kroismayr[1], M. Mohnl*[1], R. Nichol[2], and S. Attamankune[3], [1]*BIOMIN GmbH*, *Herzogenburg, Austria*, [2]*BIOMIN Laboratory Singapore*, *Lumlukka, Thailand*, [3]*Kasetsart University*, *Kamphaengsaen Nakhon Pathom, Thailand*.

The aim of the trial was to investigate the efficacy of a synbiotic and phytogenic product in comparison to an AGP in broilers. The synbiotic preparation was based on different probiotic strains and fructooligosaccharides (FOS), whereas the phytogenic formula

contained a blend of essential oils and FOS. 2400 one-day-old Ross broiler chicks were assigned to four dietary treatments, comprising 10 replicates per treatment (5 replicates for male and 5 replicates for female) with 60 birds per replicate. The treatments were (1) negative control (NC), (2) NC + synbiotic, (3) NC + phytogenic, (4) NC + AGP (Flavomycin). The synbiotic (Biomin® PoultryStar) was applied via the drinking water on the first three days and at each vaccination, whereas the phytogenic (Biomin® P.E.P.) and AGP were added to the feed throughout the whole period. Monensin (100 g/t) was included in the starter and grower diets as anti-coccidial agent. Mash feed and water were provided ad libitum. Body weight and feed consumption were recorded on day 1, 17, 38 and 45. All birds were subjected to a vaccination program, including Newcastle Disease (ND), Infectious Bursal Disease (IBD) and Infectious Bronchitis (IB). 3 birds out of each replicate were randomly collected for taking blood samples. In these samples ND, IB, and IBD immune status on d 35 were determined by hemagglutination inhibition and ELISA test. After 45 d, performance parameters were numerically improved by supplementation of the diets with Natural Growth Promoters and AGP. Compared to the NC, synbiotic, phytogenic and AGP increased weight gain by 2.8, 4.2 and 4.5%, respectively (1894 vs. 1947 vs. 1973 vs. 1979 g, P>0.05). Gain:feed ratio amounted to 0.56, 0.58, 0.58 and 0.57, respectively (P>0.05), and mortality was 1.12, 0.53, 0.36 and 0.59%, respectively, in treatments 1, 2, 3 and 4. Compared to the NC, immune parameters indicated numerically better values in treatments 2, 3 and 4 for IBD and IB. Based on the performance parameters of the present trial, the synbiotic and phytogenic product represented equivalent alternatives to AGP in broiler production.

Key Words: Synbiotic, Phytogenic, Antibiotic growth promoter, Natural growth promoter, Immune status

P190 Evaluation of broiler performance as affected by acidifier and zinc bacitracin under field conditions. C. Lueckstaedt, T. Steiner, and M. Mohnl*, *BIOMIN GmBH*, *Herzogenburg, Austria*.

Due to recent concerns about residues in animal products and bacterial resistance to antibiotics, alternatives to in-feed antibiotics (AGP) are required. Various feed additives such as organic acids have been studied already. Many scientists reported that the inclusion of organic acids in the diet can enhance growth performance and modulate intestinal microbiota. Ban on antibiotic growth promoters creates significant opportunity for feed acidification was stated recently in a report from Frost & Sullivan. An objective of the study was therefore to test a well balanced acidifier on a sequential release medium against a commercially available AGP (Zinc Bacitracin).

The trial was conducted under field conditions in Argentina. The aim of the trial was to test a well balanced acidifier (2 kg per t of feed) against a commercial piglet diet containing Zinc Bacitracin in a dose of 0.35 kg / t. Feed and water were available ad libitum. The performance of two groups of chicken (30,000 birds in total) was evaluated. Each pen consisted of 15,000 randomly selected male and female birds (Ross line 308). They were kept in pens of 150 m length x 10 m width. The trial period lasted for 42 days, during that period pre-starter feed was given from day 1 to day 14, feed was fed from day 15 till 28 days, while the finisher feed was provided until day 42.

After 42 days broilers in the acidifier treated group were numerically heavier (2236 g vs. 2223 g for the positive control), even though this difference was not statistically significant (P>0.05). The G:F was also not statistically different (P>0.05) between the two treatments (0.51 and 0.53 for acidifier and Zinc Bacitracin, respectively). Mortality in the Zinc Bacitracin treated group was slightly reduced (2.8% vs. 3.1% for the acidifier group) but again without any statistical significance.

It can be therefore concluded, that a well defined acidifier can successfully replace an AGP, such as Zinc Bacitracin, in broiler production under Argentinian conditions.

Key Words: Acidifier, Zinc Bacitracin, Broiler, Antibiotic replacement

P191 Modeling egg weight and shell quality as functions of bodyweight, protein level, and calcium particle size. K. Choate*, R. I. Bakalli, and G. M. Pesti, *University of Georgia*, *Athens*.

One hundred forty-four Hy-Line W-36 hens, 38 weeks of age, were used over a period of five weeks to model the effects of various protein levels and limestone particle size on production parameters and egg shell quality. Six feeding treatments, each in three replicates, where applied from 38 to 43 weeks of age. The treatments included four protein levels (PL: 12.8, 14.4, 16 & 17.6%) with 3.5 % calcium and limestone with two particle size (pulverized and coarse) in three combinations: 100% pulverized, 50% pulverized (PU) and 50% coarse (CR), and 100% coarse limestone, respectively. During the last eleven days (DOT) egg production (EP), feed consumption (FC) egg weight (EWT), egg specific gravity (SG), egg shell weight (SHWT), shell surface (SHS), shell index (SHI), and egg shell thickness (SHTH) where measured daily. Hen's body weights (BWT) were measured in start and end of the experiment, difference=BWG. Dietary protein level had no had no consistent effect on EP (83±2, 86±2, 85±1, and 81±4 percent, respectively) but did significantly effect EWT (P=0.0013; 60.3^{b}, 61.1^{a}, 60.1^{b}, 61.5^{a} g, respectively), feed intake (P=0.0035; 101.7^{a}, 100.0^{ab}, 97.3^{bc}, and 94.9^{c} g/day, respectively). Body gain was significantly decreased with increased protein level (P<0.001; 0.023^{a}, 0.023^{a}, -0.040^{d}, and -0.010^{c} g, respectively). Geometric mean diameter (GMD) for pulverized limestone was 240 microns with 4.4 geometric standard diameter (GSD). Coarse limestone's GMD was 2396 microns with 1.1 GSD. Different limestone particle size did not significantly effect EWT and SHS, but significantly effected egg SG (P<0.0001, 1.081^{c}, 1.083^{a}, and 1.082^{b} g/cm^3), egg SHWT (P<0.001; 5.35^{b}, 5.54^{a}, and 5.46^{a} g, respectively), SHI (P<0.0001; 7.44^{c}, 7.68^{a}, and 7.56^{b} g/cm^2, respectively), and SHTH (P<0.0001; 0.317^{c}, 0.327^{a}, and 0.322^{b} mm, respectively). Best fit prediction equations: EWT= 73.81 - 4.37793 x PL + 0.15562 x PL^2 + 0.01885 x FC + 8.72755 x BWT + 5.00611 x BWG + .08324 x DOT; SG= 84.35 - 0.02767 x FC + 0.05286 x PU - 0.00063 x PU^2 + 0.09868 x DOT; SHWT= 4.21 + 0.006130 x PU -0.000072 x PU^2 + 0.734434 x BWT + 0.470304 x BWG.

Key Words: Calcium sources, Limestone, Particle size, Protein level, Egg quality

P192 Performance of broilers fed with and without prebiotic, probiotic and anticoccidian drugs and challenged with *Eimeria acervulina*. M. B. Cafe*, C. P. Cruz, J. H. Stringhini, L. F. Reis,

L. S. Chaves, and M. A. Andrade, *University Federal of Goias*, *Goiania, Goias, Brazil*.

A 4 X 2 factorial experiment was conducted to determine the effects of prebiotic, probiotic and anticoccidian drugs on performance of broilers challenged or not with *Eimeria acervulina* at 14 days of age with 2.4 x 10^5 oocysts per bird in oral inoculation A total of 80 Cobb male chicks were randomly allocated into a metallic battery divided in eight treatments with five replicates of ten birds each, as follows: T1) diet without anticoccidian and challenged birds, T2) diet with anticoccidian (monensin) and challenged birds, T3) diet with prebiotic (mannanoligosaccharide, MOS) and challenged birds, T4) diet with probiotic and challenged birds, T5, T6, T7 and T8 were the same treatments with unchallenged birds. The performance of the birds was evaluated once a week. The results at 21 days of age showed that weight gain, feed conversion and feed consumption of the inoculated group was worse than not inoculated birds. No statistic differences were observed among unchallenged treatments. For the challenged birds, the monensin treatment showed the best weight gain but not feed conversion and feed consumption. In conclusion, birds challenged with *Eimeria acervulina* showed worse performance, whilst birds supplemented with monensin showed better weight gain. The use of probiotic and prebiotic was not efficient to enhance the performance in birds challenged with *Eimeria acervulina*.

Key Words: *Eimeria acervulina*, Performance, Anticoccidian, Probiotic, Prebiotic

P193 Digestibility of nutrients of diet of broilers fed with and without prebiotic, probiotic and anticoccidian drugs and challenged with *Eimeria acervulina*. M. B. Cafe*, C. P. Cruz, L. F. Reis, J. H. Stringhini, L. S. Chaves, and N. S. Mogyca, *University Federal of Goias*, *Goiania, Goias, Brazil*.

A 4 X 2 factorial experiment was conducted to determine the effects of prebiotic, probiotic and anticoccidian drugs on digestibility of fat and dry matter (DM) of broilers challenged or not with *Eimeria acervulina* at 14 days of age with 2.4 x 10^5 oocysts per bird in oral inoculation. A total of 80 Cobb, male chicks were randomly allocated into a metallic battery divided in eight treatments with five replicates of ten birds each. The treatments were divided in: T1) diet without anticoccidian and challenged birds, T2) diet with anticoccidian (monensin) and challenged birds, T3) diet with prebiotic (mannanoligosaccharide, MOS) and challenged birds, T4) diet with probiotic and challenged birds, T5, T6, T7 and T8 were the same treatments with unchallenged birds. The digestibility trial was performed from 18 to 21 days and was conducted by the traditional method of total excreta collection. Fat and dry matter digestibilities were calculated. The results showed that the digestibility of DM of the inoculated group was 68.1% and for intact birds (not inoculated) 77.2%. For fat digestibility the results showed 32.9% for inoculated birds and 84.1% for not inoculated birds. Among treatments without *Eimeria acervulina* challenged the DM digestibility was not statistic ($P>0.001$) different. For fat digestibility in challenged birds the monensin treatment showed the better digestibility, 64.1%, that was statistic ($P<0.001$) better than Prebiotic, 55.2%, Probiotic, 55.2% and Without Anticoccidian, 59.4%. For not inoculated birds were observed no difference in fat digestibility among treatments. In conclusion, birds challenged with *Eimeria acervulina* decrease dry matter and fat digestibility. Birds supplemented with monensin showed better digestibility. The use of probiotic and prebiotic was not efficient to enhance the digestibility in birds challenged with *Eimeria acervulina*.

Key Words: Digestibility, Anticoccidian, Probiotic, Prebiotic, *Eimeria acervulina*

P194 Nutritional performance of broiler chickens fed diets containing GAT4601 (DP-356Ø43-5)soybean fractions. J. McNaughton*[1], B. Delaney[2], and B. Smith[2], [1]*Solution BioSciences, Inc.*, *Salisbury, MD*, [2]*Pioneer Hi-Bred International, Inc.*, *Johnston, IA*.

Soybeans plants containing event DP-356Ø43-5 (356043) were produced by insertion of the gat gene from *Bacillus licheniformis* and the *gm-hra* gene modified from the herbicide-sensitive soybean gm-als gene. The gene expression products are the glyphosate acetyltransferase (GAT4601) and GM-HRA proteins that confer tolerance to the herbicidal active ingredient glyphosate and acetolactate synthase inhibiting herbicides, respectively. Diets were produced with soybean fractions (meal, hulls, and oil) from a non-transgenic near-isoline (Control), 356043, 356043 treated with herbicides (356043+Gly/SU), and three non-transgenic commercial varieties and were fed to Ross x Cobb broilers (n = 120/treatment group, 50% M and 50% F). Starter (0-21d), Grower (22-35d), and Finisher (36-42d) commercial-type diets contained 30%, 26%, & 21.5% soy meal, respectively. Hulls and oil were added at 1.0 and 0.5%, respectively, across all diets. Pen data was collected weekly. Performance and carcass traits from broilers fed 356043, 356043+Gly/SU, and Control diets were compared to 95% tolerance intervals constructed on 99% of the population using data from broilers fed diets produced with commercial soy varieties. Differences between Control and 356043 or 356043+Gly/SU groups were evaluated at $p < 0.05$. No statistically significant differences were observed in mortality, weight gain, feed efficiency (corrected for mortalities), and carcass yields between broilers consuming diets produced with 356043 or 356043+Gly/SU soybean fractions and those consuming diets produced with Control soybean fractions. Additionally, all response variables in Control, 356043, and 356043+Gly/SU groups fell within the tolerance intervals calculated from broilers fed diets produced with the commercial soybean fractions. Based on the results from this study, it was concluded that 356043 soybean was nutritionally equivalent to Control soybean with a comparable genetic background.

Key Words: Soybeans, *Bacillus licheniformis*, GAT4601, GM-HRA, Chicken

P195 A 49 day evaluation of Bio-Mos® replacement of roxarsone in a commercially based feeding program for broilers. T. Herfel*[1], A. McElroy[1], A. Sefton[2], and C. Novak[1], [1]*Virginia Tech*, *Blacksburg*, [2]*Alltech Inc.*, *Guelph, ON, Canada*.

The inclusion of Bio-Mos as a roxarsone replacement in broilers was evaluated in a 49-day trial. Three thousand and ten broilers were randomly assigned to 1 of 5 dietary corn-soybean meal based trts (14 reps/trt). Dietary trts included a negative (NEG) and positive control (POS; NEG + 27 ppm Bacitracin MD), roxarsone trt (ROX; POS + 50 ppm of roxarsone), Bio-Mos trt (BIO; POS + 0.15 and 0.5%

Bio-Mos added during the starter and grower periods, respectively), and Bio-Mos + All-Lac XCL trt (BIO+LAC; POS + 0.2, 0.1, and 0.05% Bio-Mos during the starter, grower and finishing periods respectively and 0.25g All-Lac XCL/bird sprayed at hatchery). On day 14, 7 pens/trt were infected with Emeria maxima (3 x 104 oocysts/bird) via feed (CH). Production parameters were evaluated at feed change. Right tibias were collected (one bird/pen) on day 28 and 49 to determine bone-breaking strength. Non-challenged (NCH) birds had higher body weight gains (BWG) and lower feed conversion (F:G) from day 0 to 49 than CH birds ($P < 0.05$). Dietary trts were similar from day 0 to 49. On day 28, CH birds had shorter tibias and lower BWG than NCH birds ($P < 0.5$). Bone-breaking strength was similar for all trts. From day 0 to 35, ROX (2.07 kg; 3.23 kg) birds had lower BWG and FI than BIO (2.17 kg; 3.41 kg) and BIO+LAC (2.16 kg; 3.33 kg) birds ($P < 0.05$), while F:G was similar. Additionally, F:G improved by 4 points in BIO+LAC birds compared to BIO birds ($P < 0.05$), while BWG was similar. A trt/challenge interaction occurred from 0 to 35 days ($P < 0.05$) affecting F:G for BIO birds. BIO and BIO+LAC birds performed as well as the NEG and POS birds from 0 to 35 days. FI was depressed by supplementing roxarsone causing lower BWG, but no significant differences were noted in F:G compared to feeding Bio-Mos. Bio-Mos improved BWG compared to roxarsone by increasing FI. Bio-Mos-nor roxarsone improved production parameters compared to control fed birds in the present trial.

Key Words: Bio-Mos®, Roxarsone, Coccidia, Broiler, Performance

P196 Yucca schidigera and quillaja saponaria supplementation in broiler diets. A. Corzo*[1], M. T. Kidd[1], D. Miles[2], W. A. Dozier, III[2], and P. R. Cheeke[3], [1]*Mississippi State University*, *Misssissippi State*, [2]*USDA-ARS*, *Mississippi State, MS*, [3]*Oregon State University*, *Corvallis, OR*.

Yucca schidigera and quillaja saponaria are both rich in saponins and polyphenolic compounds, and have been associated with supplementary effects that improve livestock production with some ammonia emission reduction characteristics. Thus, a broiler study evaluated live performance, carcass characteristics, lymphoid organs, immune responses, and intestinal histology of broilers, and litter pH, N %, moisture %, and ammonia flux. Ross×Ross 708 male broilers were fed either a corn-soybean meal-poultry meal control (C) diet, the C diet plus a commonly used antibiotic (bacitracin methylene disalicylate), C diet plus supplementation with 100 ppm of yucca schidigera and quillaja saponaria (YQ), or the C diet supplemented with 150 ppm of YQ. Feeds were provided in a 3 phase program either as crumbles (0-7d/prestarter; 7-21d/starter) or pellets (21-42d/grower). Body weight at 7, 21, and 42 d was unaffected by the dietary treatments. Cumulative feed conversion was also unaffected at 7 and 21 d, but a trend ($P=0.08$) was observed at 42 d, where both YQ supplemented diets were superior along with the BMD diet when compared to the C treatment. Furthermore, the experimental treatments had superior ($P<0.01$) livability at 21 and 42 d when compared to the birds fed the C diet. Bursa and spleen relative weights were unaffected by dietary treatments. Immune responses, expressed as a primary antibody response to SRBC inoculation and % inflammation to PHAP, were not affected by the dietary treatments fed. Carcass traits were similar among treatments. Jejunal-villi length and width did not differ between the treatments fed. Litter characteristics and ammonia emission were similar across all treatments. Trends were observed in live production and livability that indicate beneficial effects of YQ supplementation in commercial broiler diets. However, further research is warranted to corroborate such results and further evaluate potential ammonia emission reductions.

Key Words: Breast meat, Broiler, Quillaja saponaria, Yucca schidigera

P197 Marine phytoplankton supplementation in broiler diets. A. Corzo*[1], M. T. Kidd[1], and W. A. Dozier, III[2], [1]*Mississippi State University*, *Mississippi State*, [2]*USDA-ARS*, *Mississippi State, MS*.

Many therapeutic attributes have been elucidated over the years to marine products and by-products. For that purpose, a study was conducted to evaluate the response of broilers to dietary supplementation with marine phytoplankton. This product, in dry form, was supplemented at 0 (control), 5,000 and 10,000 ppm to a corn-soybean meal based diet, and fed to Ross×Ross male broilers. Diets were formulated to meet or exceed NRC (1994) recommendations, and were fed in mash form as a starter (0-21 d) and a grower (21-42 d) feeding phase.

On Day 21, live performance was unaffected by marine phytoplankton supplementation with the exception of feed conversion ($P<0.05$), which was increased at 10,000 ppm when compared to the 5,000 ppm and the control group. Body weight was unaffected by dietary treatments, but the treatment with 10,000 ppm supplementation of marine phytoplankton had an increase in feed consumption ($P<0.05$) which translated into an increase in feed conversion ($P<0.01$), when compared to the control and 5,000 ppm-supplemented treatment. At Day 42, birds were processed and no differences were observed for absolute and relative weights of carcass, breast meat and abdominal fat of broilers fed the different dietary treatments. Thymus, spleen and bursa were weighed from a bird corresponding to each experimental unit, and no differences in their relative weights were observed between dietary treatments. There was a numerical increase in early livability with marine phytoplankton supplementation at Day 21 (5,000 and 10,000 ppm = 99%, control = 95.8; $P<0.16$). Further studies are warranted to explore possible benefits of marine phytoplankton supplementation in broiler diets.

Key Words: Breast meat, Broiler, Marine phytoplankton

P198 Effect of the supplementation of the yeast wall cell on the humoral and cellular immune response on commercial broilers diets. G. Gomez Verduzco*[1], M. A. Baladez Lopez[2], A. Cortes Cuevas[2], C. Lopez Coello[1], and E. Avila Gonzalez[2], [1]*National University of Mexico*, *Distrito Federal, D.F, Mexico*, [2]*National University of Mexico*, *Distrito Federal, D.F, Mexico*.

The world-wide tendency is the cattle production using only the genetics, nutrition, handling and health of the animals; reason why the manipulation of the immunological system through the inclusion on the diet of some prebiotics that function immuno-modulating effects, could be considered as an alternative for the control of diseases and the improvement in the poultry production. The yeast walls cells (YWC) have been demonstrated great amount of kindness; the control of viral infections, the resistance in the presentation of diseases, as well as to

increase the efficiency in vaccination. El objective of this study is the use of a YWC in diets for commercial broilers to evaluate the humoral and cellular immune response. A study was conducted on commercial broilers Ross x Ross, they were placed on a open floor housing and they were used with 4 treatments (diets), 1 commercial diet (CD), 2 CD + YWC, 3 CD + antibiotic and 4 CD + PCL + antibiotic. The broilers were vaccinated at 10 days age. 7 and 14 days post vaccination the serum were evaluated with the hemagglutination inhibition test and ELISA against Newcastle virus disease. The cellular immune response was evaluated with mediated cutaneous basophilic hypersensitivity by an interdigital skin test. The groups that were supplemented with YWC demonstrated an improvement in the humoral and cellular immune response. In this work the YWC have a positive immunomodulating effect.

Key Words: Yeast, Immune, Humoral, Cellular, Supementation

P199 The performance of layers fed plant-protein based diets supplemented with fish meal analogue. O. A. Alalade*[1] and A. A. Fatufe[2], [1]*University of Ibadan*, *Ibadan, Oyo state, Nigeria*, [2]*Obafemi Awolowo University*, *Ile-Ife, Osun State, Nigeria*.

The move towards the use of diets devoid of ingredients of animal origin will exacerbate the effect of anti-nutrients on bird's performance and nutrient excretion in the environment. An experiment was carried out to evaluate the effect of fish analogue supplementation on the performance of layers fed plant-protein based diets. Sixty 35-weeks old black Nera layers (1.67Â±0.02 BW) were randomly assigned to 4 treatments with 5 replicates containing 3 birds each in a cage system. Four isonitrogenous diets containing 0, 0.5, 1.0 and 1.5% fish analogue (Biogro Super 70% 5030P, Daweâ€™s Inc. USA) were formulated from a corn-soybean meal basal diet of 17.25% crude protein and 2534kcal/kg ME. Adjusting the levels of soybean meal and wheat bran equalized crude protein. From the results obtained, birds fed fish analogue supplemented diets had a slight decrease ($p<0.05$) in egg weight and egg mass compared with the control. However, differences observed in feed intake, feed efficiency, egg production and body weight gain were negligible. Egg weights were 49.5, 46.6, 45.6 and 47.4g while hen-day productions were 86.5, 82.4, 84.1 and 81.2% on 0, 0.5, 1.0 and 1.5% fish analogue respectively. Overall, the result of this experiment showed that fish meal analogue supplementation did not improve the performance of layers fed plant-protein based diets

Key Words: Layers, Fish meal analogue, Plant-protein based diet, Performance, Feed intake

P200 The use of low protein diets combined with varying levels of metabolizable energy in commercial White Leghorn hens. A. S. Parsons*, D. M. Denbow, and C. Novak, *Virginia Tech*, *Blacksburg*.

Feeding layers a low protein diet typically reduces feed intake (FI), which consequently reduces the intake of other nutrients. The objective of this study was to evaluate the effects of feeding low protein diets with different levels of energy on production parameters, egg yield, physiological status as determined by plasma amino acid levels, and FI regulation as determined by brain catecholamine levels to better understand the mechanism by which low protein diets decrease FI in laying hens. Corn, SBM and wheat midd-based diets consisted of two protein levels (high HP; 18% or low LP; 13%) and two energy levels (high HE; 2850 kcal/kg or low LE; 2780 kcal/kg). All nutrients, less protein and energy, were formulated to meet peak egg production with amino acids (Lys, Met,Thr and Trp) being similar across diets. Diets were randomly assigned to six replicate raised wire cages containing three, 24 week-old commercial White Leghorn Hens (72 in^2/hen). Diet and water were provided for ad libitum consumption from 24 to 36 wks of age. Feed intake ($P = 0.0001$) was decreased in layers fed LP independent of energy level. There was a significant interaction between dietary energy and protein and their affect on brain norepinephrine, epinephrine, dopamine, S-HIAA, HVA and serotonin levels. Brain norepinephrine was lowest in birds fed the low protein diet whereas DOPAC, S-HIAA and serotonin were lowest in birds fed the high protein diet. Brain serotonin and S-HIAA was higher in those birds fed the low protein diet, which appears to correlate with decreased FI. Furthermore, egg production ($P = 0.008$) and egg weight ($P = 0.0003$) were decreased in layers fed LP diets compared to those fed HP diets suggesting that dietary energy and nutrients were shunted from egg production for use in meeting maintenance energy requirements.

Key Words: Low protein, Low energy, Feed intake, Neurotransmitters, Laying hens

P201 Impact of ochratoxin A on broiler kidneys, associated increased levels of uric acid in blood serum and possible counteraction. V. Starkl*[1] and H. Sarandan[2], [1]*Biomin GmbH*, *Herzogenburg, Austria*, [2]*University of Veterinarian Medicine*, *Timisoara, Romania*.

This trial was performed to evaluate the impact of a combination of 500ppb ochratoxin A and 1000ppb deoxynivalenol on histopathology of kidneys and the level of uric acid in the blood serum. Additionally Mycofix® Plus was evaluated on its ability to prevent renal impact of ochratoxin A.

216 day old chickens (males and females) were randomly chosen and divided into 4 treatments. Birds in treatment 1 (T1) were fed a mycotoxin free diet. Treatment 2 (T2) consisted of a diet contaminated with 500ppb ochratoxin A and 1000ppb deoxynivalenol. Diet of treatment 3 (T3) was equally contaminated as T2 but additionally treated with 1 kg of Mycofix® Plus. Treatment 4 (T4) contained 1 kg of Mycofix® Plus and no mycotoxins.

At slaughter, on day 42, organs were examined macroscopically, yet there were no visible changes in color or signs of renal or visceral uric gout. Weights of kidneys were reported in corresponding percentages to the respective bodyweight. No significant differences were found between treatments and sexes. Kidney samples were fixed in alcohol, included in paraffin, sliced and stained using hematoxyline-eosine. No necrotic lesions were found in T1 and T4. T2 was generally more severely affected than T3. Necrotic lesions were present in T2 predominantly in the proximal tubules, showing disappearance of the tubular lumen and hypertrophy of renal glomerules with disseminated focal necrosis and vascular lesions. In T3 less affected epithelium of the proximal tubules was found and additionally it was less necrotic compared to T2 found. Determination of the level of uric acid in blood serum confirmed the damage of the kidneys. The level of uric acid in

T2 was significantly higher compared to T1, T3 and T4. This correlates very well with the severity of renal lesions in T2. Males were more affected than females.

The obtained data confirmed the negative impact of ochratoxin A on kidneys and level of uric acid and suggest that Mycofix® Plus can alleviate nephrotoxicity.

Key Words: Ochratoxin A, Nephrotoxicity, Uric acid, Deactivation

P202 Comparison of organic and inorganic trace mineral sources for growth and production of brown shell laying hens. A. H. Cantor*, J. L. Pierce, A. J. Pescatore, M. J. Ford, T. Ao, and H. D. Gillespie, *Alltech-University of Kentucky Nutritition Alliance*, *Lexington, KY*.

The effect of varying levels and sources (organic *vs.* inorganic) of trace mineral supplements on growth and egg production performance was studied using a commercial strain of brown shell laying hen (Hy-Line Brown). Eight replicate groups of 16 replacement pullets, 2 wk of age, were assigned to each of six dietary treatments, using a randomized block experimental design. Pullets were housed in cages and given *ad libitum* access to feed and tap water. Trace mineral mixes that contained Cu, Mn, Fe and Zn at 25, 50 or 100 per cent of the NRC requirements in the form of inorganic salts or proteinates (Bioplex®, Alltech, Inc.) were added to corn-soybean meal-based grower and layer diets in a 3 X 2 factorial arrangement of treatments . At 16 wk of age, the number of pullets was reduced to 12 per replicate, the pullets were transferred to layer cages (2 per cage) and switched to layer diets, and the photostimulation program was initiated. During the growing period and the first 24 wk of production, body weight was unaffected by treatments. There were no effects of mineral source and level or their interaction on overall hen-day egg production (mean = 81.5%) and shell breaking strength. Mineral level significantly ($P < 0.05$) affected per cent hen-day production during Weeks 1-4 and Weeks 21-24. However, these effects were not persistent. Significant interactive effects of mineral level X source upon egg weight were noted after 12 and 24 wk of production, but not after 8, 16, and 20 wk. Compared with the organic mineral source, per cent shell was significantly higher for the inorganic mineral treatment after 8 wk of production (9.7 *vs.* 9.5), but not thereafter. The results of this study indicated that the lowest levels of Cu, Mn, Fe and Zn supplied as inorganic salts or proteinates added to corn-soybean meals were adequate for supporting growth and production of brown shell hens.

Key Words: Laying hens, Trace minerals, Proteinates, Organic minerals, Egg production

P203 Egg production performance of pearl grey guinea fowl pullets fed diets varying in metabolizable energy and crude protein concentrations from hatch to sixteen weeks of age. S. N. Nahashon*, N. Adefope, A. Amenyenu, and D. Wright, *Tennessee State University*, *Nashville*.

This study was undertaken to assess dietary metabolizable energy (ME) and crude protein (CP) concentrations for optimum performance of pearl gray guinea fowl replacement pullets. In a 3 x 3 factorial arrangement, 540 1-day-old pearl gray guinea keets were randomly assigned to experimental diets with 2,900, 3,000 and 3,100 kcal of ME /kg of diet; each contained 20, 22 and 24% CP, respectively, from 0-8 week of age (WOA). From 9-16 WOA, experimental diets had 3,000, 3,100 and 3,200 kcal of ME/kg of diet, and each contained 17, 19 and 21% CP, respectively. At 17-22, 23-27and 28-56 WOA all experimental birds were fed the same diet at each age period which containing 3,000, 2,900 and 2,800 kcal of ME/kg of diet, respectively. The diets had 18, 17 and 16% CP, respectively. Each dietary treatment was replicated 4 times, and feed and water were provided ad libitum. Body weight were measured weekly from hatch to 16 WOA and at 28-56 WOA the experimental birds were observed for feed consumption (FC), hen-day egg production (HDEP), egg weight (EW), egg mass (EM), feed conversion ratio (FCR), internal egg quality (IEQ), shell thickness (ST) and body weight (BW) at the end of each 28-day lay period for 7 consecutive periods. Mortality was recorded as it occurred. Overall, BW gains were significantly higher ($P<0.05$) in birds fed 3,000 and 3,100 Kcal of ME/kg of diet and 24% CP from hatch to 8 WOA than other dietary treatments. Percent HDEP, EM and IEQ were higher ($P<0.05$) and FCR was lower ($P<0.05$) in pullets fed diets containing 3,000 and 3,100 kcal of ME/kg of diet than those on 2,900 kcal of ME/kg of diet at 0-8 WOA. Birds on 22 and 24% CP diets also exhibited higher HDEP, EM and lower FCR than those on 20% CP diets. However, differences in mean EW, BW and ST were not significant ($P>0.05$) among dietary ME and CP treatments. Thus, feeding 3,000-3,100 Kcal of ME/kg of diet and 22-24% at 0-8 WOA and 3,100-3,200 Kcal of ME/kg of diet and 19-21% CP at 9-16 WOA improved HDEP, EM, IEQ and FCR of Pearl Grey guinea fowl laying pullets at 28-56 WOA.

Key Words: Pearl gray guinea fowl pullets, Metabolizable energy, Crude protein

P204 Effects of paractin (14-Neo-Andro) on vaccine performance, mortality and coccidiosis in chicken. J. Hancke[1] and A. Eng*[2], [1]*Universidad Astral de Chile*, *Valdivia, Chile*, [2]*HP Ingredients*, *Bradenton, FL*.

PURPOSE OF EXPERIMENTS: In the first experiment, we are exploring the effects of using nanomolar concentration of the 14-Neo-Andro compound as feed additives to potentiate vaccine and increase cellular immune response. In the second experiment, we evaluate the effect of PARACTIN as feed additive to reduce the symptoms and mortality of coccidiosis.

MATERIAL & METHODS: New Castle: 960 chickens were divided into two groups. Group 1 (n: 480) were fed with a standard diet (Control). Group 2 (n: 480) received the same diet, but added with 28g of 14-Neo-Andro compound per ton of feed. At day 7, all chickens were vaccinated with Newcastle and at day 10 with infectious bronchitis. At day 10, 21 and 28, samples of blood serum were taken for analysis. Average Daily Gain, Feed Conversion, and Mortality rate were calculated every week. Coccidiosis: 75 chickens randomly divided into 5 groups after the first week. Group 1, control group (n:15) were fed with a standard diet as above. Group 2 to 5 (n: 15) received the same diet, but added with 14-Neo-Andro compound at different levels: 50g/ton, 100g/ton, 150g/ton, and 200g/ton after the first week. At week 3, coccidia were spread into the bedding of all coops. Blood was collected when the chickens were 2, 4 and 6 weeks of age for analysis. Chicken were sacrificed at 6 weeks for lesion scoring.

Average Daily Gain, Feed Conversion, and Mortality Rate were calculated every week.

RESULTS & CONCLUSION: Lose Dose of the 14-Neo-Andro compound was capable to significantly increase the hemoaglutination titers against New Castle vaccine by 60% to 70%, increasing cellular immunity., and lower the mortality rate (8.45% vs 11%). 14-Neo-Andro compound increase average daily gain in chickens infected with Coccidiosis, and significantly reduce mortality rate (46.66%, 33.33%, 20%, 20%, and 0%) and lesion scoring. We conclude that PARACTIN (14-Neo-Andro) is a new immuno-modulating feed addition exhibiting strong potential immuno-stimulating and anti-inflammatory properties.

Key Words: New Castle, Cellular immunity, Coccidiosis, T cell

P205 The dominance of the *Salmonella* serovar Kentucky in chickens is due to its persistence in the gastrointestinal tract of mature birds. A. A. Pedroso*, M. D. Lee, and J. J. Maurer, *University of Georgia*, *Athens*.

Recently, *Salmonella enterica* serovar Kentucky has supplanted *S.* Enteritidis and Typhimurium as the most prevalent serotype in poultry. However, *Salmonella* Kentucky is not commonly associated with human illnesses in the United States. We believe that *S.* Kentucky represents a serovar that is best adapted to colonizing and persisting in poultry, which may explain its dominance on broiler chicken farms. To test this hypothesis, an in vivo competition experiment was performed between *Salmonella* serovars Kentucky and Typhimurium. One day-old chicks were raised until 42 days of age in four separate isolator units. Animals were orally inoculated with either *S.* Typhimurium RifR (n=30), *S.* Kentucky NalR (n=30), or both serovars combined (n=30); as well as negative control birds administered saline (n=30). Small intestine, cecum, liver, spleen and feces were collected at 18, 25, 32, and 39 days after inoculation, homogenized and colony counts were recorded after grown on XLT4 containing the appropriate antibiotic. Twenty-five days after inoculation, *S.* Typhimurium numbers decreased significantly in cecum and feces (4 log10 CFU/g decline), while *S.* Kentucky numbers in the cecum remained relatively high ($1x10^4$ CFU/g). This phenomenon was observed in whether the birds were administered pure cultures or a mix of the two organisms. This suggests that *S.* Kentucky did not inhibit *S.* Typhimurium growth in vivo. In addition, *S.* Kentucky persisted in the chicken's cecum longer and at levels significantly higher than *S.* Typhimurium. These colonization dynamics could explain the spread and eventual dominance of *S.* Kentucky within poultry integrators.

Key Words: Competition, *S.* Typhimurium, Microflora

P206 Effect of probiotic treatment of chicks on phagocytosis of *Salmonella* by isolated macrophages. S. E. Higgins*, J. P. Higgins, G. F. Erf, S. N. Henderson, A. D. Wolfenden, G. Gaona-Ramirez, and B. M. Hargis, *University of Arkansas*, *Fayetteville*.

Previous data have indicated that a *Lactobacillus*-based probiotic culture (FM-B11™) is efficacious for reducing *Salmonella enteritidis* (SE) colonization within 24 h when administered within 1 h of challenge. We hypothesized that the innate immune system, specifically macrophages, may play a role in the observed reduction of colonization. In two experiments, we evaluated the ability of macrophages isolated from chicks to phagocytose SE in situ. Chicks were obtained on day-of-hatch, and two groups were challenged with SE by oral gavage (Exp 1: 2.5×10^3 cfu/chick, Exp 2: 1.4×10^3 cfu/chick) while two groups received vehicle. One h later one challenged and one unchallenged group were treated with probiotic by oral gavage, and the alternate groups received vehicle. At this time, all chicks were also injected IP with 0.5 mL of a 3% sephadex solution. Macrophages were isolated from the peritoneal cavity of chicks 24 h following injection, and cecal tonsils were collected for enrichment and determination of SE colonization. In both experiments, probiotic treatment significantly reduced cecal SE recovery incidence as compared to controls (exp.1: 12% vs 76%, exp. 2: 41% vs 100%, respectively). Macrophages were maintained in tissue culture plates overnight and then assayed for phagocytic activity. Cells were incubated with SE for 30 min, then in medium with gentamicin for 45 min to kill any extracellular SE. The cells were lysed with 10% triton in PBS, and then SE recovered (cfu) per macrophage was determined. In experiment 1, significantly ($p<.05$) more SE were recovered from macrophages derived from probiotic-treated chicks (4.28 cfu/cell) than any other treatment (control 2.10 cfu/cell, SE challenged 1.94 cfu/cell, SE challenged and probiotic treated 2.28 cfu/cell). However, in experiment 2, no significant differences between groups were observed (phagocytosis of SE was less than 1 cfu/ cell in all groups). Although not conclusive, the relatively small phagocytosis enhancement in exp. 1, and lack of observed probiotic effect in exp. 2, may suggest the macrophages are not involved in the SE prophylaxis due to probiotic treatment.

Key Words: *Salmonella*, Probiotic, Macrophage, Chick, Phagocytosis

P207 Evaluation of *in vitro* and *in vivo Salmonella* reduction potential of bacteriophages isolated from different sources. R. L. Andreatti Filho*[1], J. P. Higgins[2], S. E. Higgins[2], G. Gaona-Ramirez[2], A. D. Wolfenden[2], G. I. Tellez[2], and B. M. Hargis[2], [1]*Sao Paulo State University*, *Botucatu, SP, Brazil*, [2]*University of Arkansas*, *Fayetteville*.

Salmonella enteritidis (SE)-lysing bacteriophages (Ø) isolated from poultry or human sewage sources were used to reduce SE in vitro and in experimentally infected chicks. Cocktails of 4 different Ø obtained from commercial broiler houses (CB4) and 45 Ø from a municipal wastewater treatment plant (WT45) were evaluated. In experiment 1, an in vitro crop assay was conducted with selected Ø concentrations (10^5, 10^6, 10^7, 10^8, or 10^9 pfu/mL) to determine ability to reduce SE in the simulated crop environment (16x100mm glass tube, 2 g sterile feed, 6.5 mL saline containing Ø and SE). Following 2 h at 37 C, CB4 or WT45 reduced SE recovery by up to 1.5 or 5 log, respectively, as compared to control. However, CB4 did not affect total SE recovery after 6 h due to Ø-resistant SE growth, whereas WT45 resulted in up to 6 log reduction of SE. In experiment 2, day-of-hatch chicks were challenged orally with $3x10^3$ cfu/chick SE and treated cloacally with $1x10^9$ WT45 pfu/chick one h post-challenge, and then one h later, treated or not with a commercially available probiotic (FM-B11™). Both treatments significantly reduced SE recovery from cecal tonsils at 24 h following treatment as compared to controls, but no additive effect was observed with the combination of Ø and probiotic. In experiment 3, day-of-hatch chicks were challenged orally with $9x10^3$ cfu/chick

SE and treated via oral gavage with $1x10^8$ CB4 pfu/chick, $1.2x10^8$ WT45 pfu/chick, or a combination of both, one h post-challenge. All treatments significantly reduced SE recovered from cecal tonsils at 24 h as compared to untreated controls, but no significant differences were observed at 48 h following treatment. These data suggest that some Ø can be efficacious in reducing SE colonization in poultry during a short period of 24 h or less, but under these conditions, persistent reductions were not observed.

Key Words: *Salmonella enteritidis*, Bacteriophage, Crop assay, Probiotic, Chicken

P208 Nested PCR to detect infectious laryngotracheitis virus (ILTV). O. A. Fagbohun*, J. J. Giambrone, T. V. Dormitorio, and K. Macklin, *Auburn University*, *Auburn, AL*.

A highly sensitive nested PCR was developed to detect ILTV in the litter or from tracheas of chickens, which were vaccinated, exposed to vaccinated birds, or placed on contaminated litter. Tracheal swabs and fecal samples were taken from experimental birds or litter, and examined for ILTV DNA by conventional and nested PCR. Total DNA was extracted from the samples using Qiagen kits. Amplification of the 440bp fragment from the ILTV infected cell protein 4 (ICP4) gene was by the conventional PCR and an internal 190bp fragment was produced by the nested-PCR. Samples from unvaccinated chickens or chickens reared on non-contaminated litter were negative by both tests. ILTV gene fragments amplified by the conventional PCR were faint and sometimes absent, whereas fragments from nested-PCR were clear and always present from ILTV infected birds or contaminated litter. This new test is an improvement over the conventional PCR.

Key Words: Chickens, ILTV, Nested-PCR, Conventional PCR, Gene

P209 Interrelations of ACTH infusion and dietary electrolyte balance on physiological parameters of broiler chickens. H. Olanrewaju*[1], J. Thaxton[2], W. Dozier[1], and S. Branton[1], [1]*USDA/ARS, Poultry Research Unit*, *Mississippi State, Mississippi*, [2]*Mississippi State University*, *Mississippi State*.

The aim of this study was to compare acid-base balance in broiler chickens provided diets containing two diverse dietary electrolyte balances (DEB) administered either ACTH or saline. Diets were moderate (M; 174 mEq/kg) or high (H; 241 mEq/kg) DEB by altering Na-K-Cl based upon actual analysis. These diets were fed ad libitum from d 0 to 49 d of age. Osmotic pumps delivered 8 IU ACTH in saline/kg BW/d for 7 d or the same saline volume as used in ACTH at µL/h for 7 d. Pumps were implanted on d 35 following sample collection. Post-implantation blood samples were taken on d 42 and 49. The experiment was designed as a split plot with main unit consisting of 4 treatments with factorial treatments structure (2 ACTH treatments × 2 diets) arranged in a completely randomized design. Significant DEB × ACTH interactions ($P \leq 0.04$) were determined for pCO_2 and pO_2 at 49 d. These differences infer when the H DEB diet was fed to the control and ACTH groups that pCO_2 and pO_2 were altered, whereas when the M DEB diet was fed to the control and ACTH groups, pCO_2 and pO_2 were without change. Infusion of ACTH increased ($P \leq 0.05$) hematocrit, hemoglobin, pCO_2, corticosterone, osmolality, mean corpuscular hemoglobin concentration (McHc), and HCO_3^- and reduced ($P \leq 0.05$) pO_2, Na^+, K^+, anion gap, pH, Ca_2^+, BW, and Cl^- compared to the control group on d 42 and 49. Birds fed the H DEB diet exhibited higher ($P \leq 0.05$) pO_2 than birds provided the M DEB diet. The diet formulated to H DEB partially blocked the effect of ACTH on pO_2 and pCO_2. However, due to the increased need for O_2 to support gluconeogenic energy production, the bird responded by increased erythropoiesis. This adaptive response provided greater numbers of erythrocytes and thus a higher amount of circulating hemoglobin to deliver O_2 for metabolism. Diet formulated to the H DEB partially attenuated adaptive stress condition.

Key Words: Dietary electrolyte balance, Acid-base balance, Stress, ACTH, Broiler

P210 Effect of dietary copper source and level on in vitro nitric oxide production. E. A. Koutsos[1], V. J. Arias[1], and J. I. Cohen*[2], [1]*California Polytechnic State University*, *San Luis Obispo*, [2]*Micronutrients*, *Indianapolis, IN*.

Research has shown that dietary copper, when fed at levels above the minimum requirement can modulate intestinal physiology and immune responses in growing chickens. This research examined the response of an avian macrophage-like cell line (HD11 cells) to plasma from broiler chicks fed no supplemental copper (8 mg/kg diet; control), Copper Sulfate (188 mg/kg diet; CS) or Tri-basic copper chloride (188 mg/kg diet; TBCC). HD11 cells were cultured with 10% heterologous serum, and the nitric oxide (NO) response was measured in response to lipopolysaccharide (LPS). The initial level of NO in media was greater for TBCC vs. control or CS treatment ($p<0.01$; 0.4% difference); however, the level of NO (24h and 48h post-LPS) was greater for the control and CS vs. TB treatment ($p<0.01$; 50% difference). Subsequent in vitro trials (same in vivo trial serum) examined 4 combinations of TBCC and control serum. NO responses after LPS were reduced as the proportion of TBCC plasma increased ($P<0.01$; $R2=.93$). Serum was then obtained from another in vivo broiler trial and experiments were run again. HD11 cells incubated with 100% TBCC plasma had a higher NO response at 48 h post-LPS as compared to those incubated with control plasma ($p<0.05$). Additionally, plasma was collected from birds treated with LPS in vivo, and with no in vitro stimulation, NO levels were significantly greater from control plasma than from TBCC plasma (34.2 umol/106 cells vs 18.8 umol/106 cells; $p<0.05$). These data demonstrate that copper source affects in vivo plasma parameters such that the NO response to LPS stimulation is altered. Additionally, macrophages cultured with TBCC had a dampened NO response (duration and/or magnitude) compared to macrophages cultured with control or CS plasma.

Key Words: Copper, TBCC, Nitric oxide

P211 PCR-based assay for the differentiation of *Pseudomonas* spp. isolated from poultry. I. Hanning*, A. O'Leary, and M. Slavik, *University of Arkansas*, *Fayetteville*.

The Pseudomonads are the predominate bacteria on spoiled poultry products, can be present in poultry chill waters and processing

equipment, and can be readily isolated from hatcheries, broiler farms, and fresh eggs. The bacteria have several roles within the poultry processing environment, including food spoilage, primary biofilm formers and, in the case of *P. aeruginosa*, as a pathogen. Currently, only traditional agar methods and biochemical based assays are available for detection and differentiation. Biochemical assays take 5 days for results, are expensive, and often produce erroneous results. The objective of this study was to design a rapid PCR based method that could not only distinguish *P. aeruginosa* from other poultry significant Pseudomonads, but also differentiate *Pseudomonas* spp. from non-*Pseudomonas* bacteria in a single PCR reaction. 16s rRNA sequences from 9 poultry significant Pseudomonads were aligned to determine conserved regions from which genus specific primers could be designed. The Gyrase B sub-unit genes from the 9 species of Pseudomonads were used to design species specific primers for the detection of *P. aeruginosa*. The PCR reaction was optimized using the Qiagen Multiplex Kit according to the manufacturer's instructions. The reaction was tested against 16 *P. aeruginosa* strains, 18 *Pseudomonas* non-*aeruginosa* strains, and 17 non-*Pseudomonas* bacterial strains composed of 7 genera and 11 species. The reaction was 100% specific. Furthermore, the assay could be started in as quickly as 20 hours or as soon as bacterial colonies appeared on the agar plate to which the sample had been applied. When compared to methods of traditional plating on differential or selective agar, biochemical assays, and gene sequencing, the PCR based assay was able to eliminate 4 to 6 days from total detection time. In addition, the PCR assay was the least expensive, costing around $0.15 per reaction. Because this PCR based assay reduced detection time to 24 hours and simplified the identification process, it may be used to reduce food spoilage and foodborne illness by identifying sources of contamination and speed the diagnosis of ill birds.

Key Words: Pseudomonas, Detection, PCR, Poultry, Spoilage

P212 Bacteria recovery from genetically featherless broiler carcasses after forced clocal evacuation. J. K. Northcutt*[1], W. D. McNeal[2], K. D. Ingram[1], D. L. Fletcher[3], and R. J. Buhr[1], [1]*USDA-ARS*, *Athens, GA*, [2]*Meyn America. LLC*, *Ball Ground, GA*, [3]*University of Connecticut*, *Storrs*.

A study was conducted to determine external microbiology of genetically featherless broiler carcasses after forced evacuation of clocal material. Full-fed featherless broilers were shackled, stunned, suffocated, weighed and divided into treatments groups (S, W and SW). Carcasses from all treatments were transferred to a separate shackle line and passed through a machine designed to express (squeeze) and remove feces (wash). Treatments were obtained by turning on or off the squeezing and washing components. After treatment, carcasses were subjected to a whole carcass rinse for microbiological analyses. Treatments were as follows: S carcasses were squeezed but not washed; W carcasses were not squeezed but were washed; and SW carcasses were squeezed and washed. When carcasses were washed, they gained weight (8.6 and 2.1 g for W and SW, respectively), while unwashed carcasses (treatment S) lost approximately 6 g of feces. Recovery of *Escherichia coli* (EC), coliforms (CF), and *Campylobacter* (CP) from carcasses did not vary with treatment and levels were approximately 3.4, 3.7 and 2.7 $\log_{10}$ cfu/mL of rinse, respectively. A slightly lower (0.3 log), but significant difference in total aerobic bacteria (APC) was observed for SW carcasses compared to W carcasses. *Salmonella* (SAL) prevalence was similar for all treated carcasses (83 to 90% positive). When the water from the machine's washing component was analyzed, counts for APC, EC, and CF were 3.6, 0.8, and 1.0 $\log_{10}$ cfu/mL lower for W carcasses than for SW carcasses ($P < 0.05$). CP and SAL prevalence in the water collected from the machine after W carcasses were washed was 1/4 and 0/4, respectively. CP and SAL prevalence in the water collected from the machine after SW carcasses were washed was 3/4 and 2/4, respectively. Data from the present study show that fecal material may be expressed and washed off of carcasses immediately after slaughter. This equipment could be used to minimize deposition of organic material onto the carcass and into the scalder and improve bird uniformity at evisceration.

Key Words: Poultry, Carcass bacteria recovery, Broiler carcass evacuation, Carcass washing

P213 Characterization and antimicrobial resistance of *Salmonella* isolated from internal tissues, ceca and rinse samples from commercial broiler chickens. J. S. Bailey*[1], N. A. Cox[2], P. Fedorka-Cray[1], L. J. Richardson[2], and J. Buhr[2], [1]*USDA, ARS, BEAR*, *Athens, GA*, [2]*USDA, ARS, PMS*, *Athens, GA*.

The presence, species, and antimicrobial resistance profile of Salmonella from internal tissues (spleen, liver/gall bladder, thymus, MeckelÃ¢â‚¬â„¢s diverticulum, and free floating yolk), ceca and carcass rinse samples were determined from six-week-old (n=30) and eight-week-old (n=40) commercial broilers from the rehang line before evisceration. *Salmonella Typhimurium* was the predominate (153/175, 87%) serotype of the seven serotypes identified. S. Typhimurium isolates were more frequently associated with internal tissues (102/153, 67%) than with ceca and rinse samples (3/22, 14%). The seven isolates that were pan susceptible were from ceca and rinse samples while 156 of 158 (99%) of isolates resistant to two or more antimicrobials were from internal tissue samples. These data indicate that chickens can harbor the same serotypes with different antimicrobial patterns in tissue samples compared to ceca and rinse samples. Further studies are warranted to determine the relatedness of isolates.

P214 A survey of the quality of six retail brands of boneless skinless chicken breast fillets obtained from retail supermarkets in Athens, Georgia area. H. Zhuang*, E. Savage, S. Kays, and D. Himmelsbach, *USDA-ARS*, *Athens, GA*.

To assess the variation in quality of chicken breast fillets available from retail supermarkets, six brands of boneless skinless fillets without additives were obtained from the fresh counter at grocery stores Athens, GA and the surrounding area during fall of 2005. The samples were stored at -20oC before being cooked using a Henny Penny MCS-6 combi oven. Quality parameters of the fillets were measured on the cooked chicken breast fillets including cook yield, descriptive sensory flavor and texture profiling, and Warner-Bratzler (WB) shear force. Our results show that the average cook yield ranged from 78.1% to 80.9%, the average intensity of descriptive sensory characteristics was less than 5.4 in a 0-15 universal scale, and WB shear force values were less than 5.2 kg. There were no significant differences in the intensity among brands of all flavor attributes and the texture characteristics

associated with moisture. However, significant differences were found among the brands for cook yield, mechanical properties of texture (including springiness, cohesiveness, hardness and chewiness) and WB shear force values. The variation of WB shear force measurements (coefficient of variation) depended on brand. These results indicate that differences exist in the quality and texture consistency among brands of boneless skinless chicken breast fillets available in Athens, Georgia and the surrounding area.

P215 The effect of the addition of a novel source of docosahexaenoic acid (DHA) to layer diets on the DHA content of eggs. A. J. Pescatore*, J. L. Pierce, A. H. Cantor, T. Ao, M. J. Ford, and B. L. Shafer, *Alltech-University of Kentucky Nutrition Research Alliance*, *Lexington, KY*.

A novel source of docosahexaenoic acid (DHA) that is a by product of food grade DHA production was used to enhance the DHA content of eggs. The DHA containing additive was added to corn-soy based layer diets (16% cp, 2815 kcal/kg) at a rate of 1% or 2% of the diet. Dietary treatments were randomly assigned to 27 hens per treatment. The treatment diets were fed for 27 days. Egg samples were collected at day 0 and day 27. The DHA content of the eggs from all hens at the start of the experiment was 1.06 % total fat (w/w). The eggs from hens fed the zero additional DHA diet showed no increase in DHA (1.05%) at 27days. Eggs from hens fed the DHA source for 27 days had a DHA content of 2.85 and 3.40 % (w/w) for the 1 and 2 % inclusion rates, respectively. The levels compare favorably to commercial omega 3 enhanced eggs. The results of this experiment indicate that the inclusion of this DHA source at the rate of 1% will increase DHA level in eggs. Only a slight increase was seen with the 2% inclusion rate compared with 1% inclusion rate and may not warrant the added cost of the higher rate.

Key Words: Layer hen, DHA, Egg

P216 Dietary flaxseed supplementation affects processing yields and meat technological properties. M. Betti*[1], M. J. Zuidhof[2], B. L. Schneider[2], R. A. Renema[1], V. L. Carney[2], F. E. Robinson[1], and D. R. Korver[1], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Alberta Agriculture Food and Rural Development*, *Edmonton, AB, Canada*.

Consumers are becoming more aware of the impact of the food they eat on their health. One of the ways they hope to reduce their risk of cardiovascular disease is by consuming more foods enriched with polyunsaturated fatty acids (PUFA), particularly omega-3 (n-3) fatty acids. Due to the high content of alpha-linolenic, flaxseed is a good source for increasing the omega-3 fatty acid in poultry meat. However, flaxseed has anti-nutritional properties that negatively impact broiler performance. For this reason, a study was conduted to identify an optimum level of enrichment of broiler diets with flaxseed and the optimal length of time they must be provided to ensure a) good processing yield and b) acceptability of broiler meat functional properties such that processing and further processing efficiencies are not compromised. This experiment was conducted as a 2 x 8 factorial, with two dietary levels of ground flaxseed (10 and 17%), and eight durations of inclusion in the diet prior to processing (0 [Control], 4, 8, 12, 16, 20, 24, and 35 d). Six hundred and fifty-six Ross x Ross 308 mixed-sex broilers were evaluated in this study. One hundred twenty-eight carcasses were used for evaluating processing yields and breast and thigh meat quality. No statistical interactions were found between treatments for meat quality traits. With more than 20 d of feeding duration, the diet containing 17% flaxseed decreased BW, and carcass and breast yield compared to the diet containing 10% flaxseed ($p<0.0001$). Carcass temperature was higher ($p<0.001$) in birds fed 10% flaxseed. Feeding 17% flaxseed also decreased cooking yield ($p<0.001$). The duration of feeding flaxseed strongly affected processing yields and technological meat properties. Ultimate pH and cooking yield were strictly related to each of the periods tested ($p<0.0001$; $p<0.001$). In particular, feeding flaxseed for 35 d resulted in a final pH of 5.79, compared to 6.20 in the control. In conclusion, different levels and durations of flaxseed feeding significantly affected yields and technological characteristics of broiler meat.

Key Words: Flaxseed, Polyunsaturated fatty acids, Alpha-linolenic acid, Processing yield, Technological properties

Some companies talk about commitment,

Novus is delivering.

Whether it's liquid methionine analogue in the form of ALIMET® feed suplement; ACTIVATE® organic acid blends; the MINTREX® family of organic trace minerals; or AGRADO® PLUS antioxidants, Novus is delivering products that help drive performance in todays modern agriculture industry.
