Digestibility of DM differed (P < 0.05), whereas digestible DMI and energy expenditure (EE) were similar among treatments (DM digestibility: 49.5, 52.1, 60.9, and 66.5% (SE = 2.22); digestible DMI: 415, 448, 442, and 475 g/d (SE = 26.3); EE: 462, 456, 509, and 476 kJ/kg $BW^{0.75}$ (SE = 17.0) for S, P, A, and G, respectively). Methane emission was 15.8, 20.9, 21.3, and 21.6 l/d for S, P, A, and G, respectively (SE =1.25), and was lower for S compared with other treatments (P < 0.05). There was also a difference (P < 0.05) among treatments in in vitro methane release by ruminal fluid incubated for 3 wk with conditions promoting activity by methanogens (12.9, 21.8, 25.3, and 28.5 ml for S, P, A, and G, respectively; SE = 2.73). In summary, CT-containing forage S decreased methane emission by goats, possibly by altering activity of ruminal methanogenic bacteria, and it did not appear that dietary differences of forages other than CT level might play a significant role in reducing ruminal methane emission.

Key Words: Goats, Methane, Condensed Tannins

T156 Evaluation of level of crude protein and undegradable intake protein level in diets of growing Boer goats fed a complete pelleted ration. G. V. Pollard*[1], K. F. Wilson[2], and M. L. Bolfing[1], [1]*Texas State University*, *San Marcos*, [2]*Animal Feed Technologies*, *Greeley, CO*.

The objectives of this research were to determine the effects of dietary crude protein and undegradable intake protein (UIP) levels on growth and carcass characteristics of crossbred Boer meat goats. Forty-eight crossbred wether goats (23.1 kg) were assigned to 16 pens in a completely randomized design. Crude protein level and UIP level were randomly assigned to goats in a 2 × 2 factorial arrangement. Factors were: A) 15 or 18% CP, and B) 40% or 60% UIP level. All goats received a complete, pelleted diet fed at approximately 3.5% of BW consisting of corn, oats, alfalfa, cottonseed hulls, soybean meal, blood meal, fish meal, dried distillers grains, urea, and monensin with appropriate levels of minerals and vitamins, and free access to water for 84 d prior to slaughter. Levels of cottonseed hulls, blood meal, and soybean meal were altered to produce the diets listed previously. Performance variables measured were ADG, FC (gain/feed), and FI. Carcass variables measured were hot carcass weight (HCW), dressing percentage (DP), body thickness (BT), back fat (BF), leg score, and muscle conformation (MC). Data were analyzed as a factorial with resulting means separated by main effects since no interactions were observed using SAS. As expected, no differences (P = 0.830) were detected for FC and FI due to all goats fed at 3.5% of BW. Average daily gains were lower (P = 0.03) during the initial 28 d period for all treatments than during the final 56 d of the study. Diets containing 60% UIP tended (P = 0.17) to have greater ADG over the entire 84 d, while the diet containing 18% CP and 40% UIP had lower (P = 0.07) ADG. However, no differences (P = 0.38) for growth were detected when comparing 15 and 18% CP diets. Goats receiving diets containing 15% CP tended (P = 0.13) to have heavier HCW. The results of this study suggest that meat goats with Boer influence may not require diets with increased levels of crude protein or undegradable intake protein when fed at 3.5% of BW.

Key Words: Boer, Goat, Protein

T157 Effects of dietary methionine and lysine sources on particular blood parameters in growing goats. Z. H. Sun[1], Z. L. Tan*[1], G. O. Tayo[1,2], B. Lin[1], and S. X. Tang[1], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, P.R. China*, [2]*Babcock University*, *Ikeja Lagos, Nigeria*.

The objective of this study was to study the effects of supplementing various sources of methionine (Met) and lysine (Lys) on certain plasma variables. Four wether goats (20.0±0.5 kg) were used in a 4×4 Latin square experiment and assigned to four dietary treatments: (1) control; (2) control+lipid-coated Met-Zn chelate and Lys-Mn chelate (PML); (3) control+Met-Zn chelate and Lys-Mn chelate (CML); (4) control+DL-Met, L-Lys-HCl (FML). The amounts of Met and Lys supplemented in the four treatments were 0.77 g and 0.91 g per 100 g concentrate (DM basis). Control and FML groups were supplemented with 0.09 g/100 g (DM basis) ZnSO4.7H2O and 0.05 g/100 g MnSO4.H2O in the concentrate to keep the same content of Mn and Zn among the four diets. The basal diet consisted of 50% maize stover and 50% concentrate. Ten ml blood sample was collected from the jugular vein of each goat for analyses of plasma biochemical indices at the end of each period. Goats offered PML had higher plasma growth hormone concentrations than control (P<0.05), and higher plasma insulin concentration than in the FML group (P<0.05) and control (P<0.01). Plasma insulin concentration in CML group was higher than in control (P<0.05). T3 serum concentrations of PML and CML groups were higher than in the FML group and control (P<0.05). The activity of alkaline phosphatase in plasma of PML and CML groups was higher than those of FML group and control (P<0.05), and there was no difference in alkaline phosphatase between PML and CML groups (P>0.05). Plasma levels of triglycerides and total protein and lipase activity did not differ among treatments (P>0.05). The results indicate that chelated Met and Lys supplementation can affect some plasma parameters in growing goats, and the lipid-coated technology could be of potential benefit for AA utilization.

T158 Effects of dietary NDF level on the duodenal and ileal flows of endogenous nitrogen and amino acids in growing goats. C. S. Zhou, Z. L. Tan*, H. L. Jiang, Z. H. Sun, and S. X. Tang, *Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, P.R. China*.

The objective of this study was to investigate effect of dietary NDF levels on the duodenal and ileal flows of endogenous nitrogen (EN) and endogenous amino acids (EAAs) in growing goats. The duodenal EN and EAAs flows were determined by the difference method and the amino acid profile (AAP) as described by Larsen (2000) and Jensen (2006) respectively. The ileal EN and EAAs were measured by the water soluble N (WSN) and linear regression method described by Larsen (2000) and Van Soest (1982) respectively. A trial with four ruminally, duodenally and ileally cannulated goats (BW=25.0±2.5 kg) were allocated to four treatments in a 4×4 Latin square design. Goats were fed diets containing four levels of NDF (39.69%, 36.95%, 34.22% and 31.49%), respectively. The duodenal flow of EN and EAAs was 1.05, 1.12, 1.01, 1.06 g/d (P>0.05) and 12.62, 11.37, 12.19,

11.18 g/d (P>0.05) as determined by the difference method; and 1.31, 1.37, 1.30, 1.36 g/d (P>0.05) and 7.73, 6.79, 6.29, 6.14 g/d (P>0.05) as determined by AAP method respectively for the four dietary treatments. The duodenal EN determined by AAP was 22-29% higher than that determined by the difference method, while the duodenal EAAs determined by the difference method was two times that by AAP. The ileal flow of EN and EAAs was 0.59, 0.58, 0.55, 0.54 g/d (P>0.05) and 5.28, 5.22, 5.16, 5.28 g/d (P>0.05) determined by WSN. The regression equations of the duodenal and ileal flow of EN (Y, g/d) and the flow of N (X, g/d) were Y=0.12X (R^2=0.94, P<0.01) and Y=0.23X (R^2=0.94, P<0.05), respectively. Results indicated that dietary NDF level within the range of 39% to 31% did not affect the duodenal and ileal flows of EN and EAAs and that the determination technique had significant effect on the duodenal and ileal flows of EN and EAAs.

Key Words: Endogenous Nitrogen, Endogenous Amino Acids, Determining Technique

T159 Effects of dietary NDF levels on digestion, serum biochemical parameters and hormonal concentrations in growing goats. X. G. Zhao[1], H. L. Jiang[1], Z. H. Cong[1], S. X. Tang[1], Z. H. Sun[1], Z. L. Tan*[1], and G. O. Tayo[1,2], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, China*, [2]*Babcock University*, *Ikeja Lagos, Nigeria*.

The effects of dietary NDF levels on digestion and serum biochemical parameters were examined in this study. Four growing wether goats (19.6 ± 1.2 kg) were used in a 4×4 Latin square experiment, assigned to one of four dietary treatments. The four diets contained 16.4, 19.9, 23.2 and 26.6% forage with 31.5 (LF), 34.2 (MF1), 37.0 (MF2) and 39.7% (HF) NDF on dry matter basis, respectively. Other chemical components were the same for the four diets. Each experimental period lasted 19 d, which included 14 d of adaptation followed by 7 d sampling period. The amount of feed offered to each goat was restricted to 85% of its ad libitum intake to maintain no orts during the whole experimental period. Blood samples (15 ml) was collected from the jugular vein of each animal at day 19 of each experimental period. The total tract digestibility of DM (P = 0.05), OM (P = 0.01), N (P = 0.01) and NDF (P = 0.05) decreased linearly with increase in dietary NDF level. Goats offered the LF diet had higher levels of serum total protein (P < 0.05) and higher urea nitrogen (P < 0.05) than goats offered MF2 and HF diets. LF diet also resulted in higher amylase activity and serum glucagon concentration than MF1 and MF2 diets, respectively (P < 0.05). Serum trijodthyronin concentration decreased with the increase of dietary NDF level (P < 0.05). Serum lactic acid, glucose, lipase, growth hormone, insulin, leptin, motilin and thyroxin concentrations, and activity of lactate dehydrogenase did not differ between treatments (P > 0.05). The results indicated that increasing dietary NDF content decreased the total tract digestibility of DM, OM, CP and NDF within the current range of 31~40% NDF in dietary DM and partly affected biochemical parameters in growing goats.

T160 Selenium concentrations in forages and in blood of meat goats. T. K. Hutchens*[1], A. H. Cantor[1], H. D. Gillespie[1], P. B. Scharko[1], M. Neary[2], and J. E. Tower[2], [1]*University of Kentucky*, *Lexington*, [2]*Purdue University*, *West Lafayette, IN*.

Forages grown in many areas of the USA are considered to be selenium-deficient. These regions include Indiana and Kentucky. The present study was conducted to determine Se concentrations in pasture and hay samples and in blood and plasma samples of goats consuming these forages. A composite sample of Kentucky 31 tall fescue was obtained in August 2006 from 10 locations within a 10-acre grazing paddock in Dubois, IN. In addition, four grab samples of alfalfa-orchardgrass hay from an early summer cutting were taken. Blood samples were obtained from percentage Boer-crossed meat does, approximately 3 yr of age, in August and December of 2006 and in January 2007. Selenium was determined using a fluorometric procedure following wet digestion. The pasture and hay samples contained 0.055 ± 0.009 µg Se/kg DM and 0.044 ± 0.010 µg Se/kg DM (mean ± SD), respectively. Goats sampled shortly after weaning in August 2006 (n = 10) were on pasture with access to a mineral supplement containing Se. Their respective values (µg/mL) for whole blood and plasma Se were 0.132 ± 0.022 and 0.066 ± 0.011. Does sampled in December 2006 (n = 8) had been bred, were still on pasture and were given hay with access to the mineral supplement. Their whole blood and plasma Se concentrations were 0.191 ± 0.028 and 0.071 ± 0.007 µg Se/mL, respectively. The same does sampled in January 2007 (n = 8) had continued to receive the same feeding regimen. Whole blood and plasma Se concentrations from these goats were 0.198 ± 0.031 and 0.078 ± 0.006 µg Se/mL, respectively. Average Se concentrations for whole blood, but not for plasma, of samples taken in December and January were significantly (P < 0.001) higher than for samples taken in August. These data show that the forages sampled were very low in Se content. In addition, a substantial change in the Se concentration in whole blood, but not in plasma, of breeding does was observed during the course of sampling.

Key Words: Forages, Goats, Selenium

T161 Supplementation with selenium boluses and its effect on milk and blood serum concentration of dairy goats. J. G. Librado Cruz*[1], M. Huerta Bravo[1], M. González Alcorta[1], J. G. García Muñíz[1], P. A. Martínez Hernández[1], and R. López Arellano[2], [1]*Universidad Autónoma Chapingo*, *Chapingo, México*, [2]*Facultad de Estudios Superiores Cuautitlán, UNAM*, *Cuautitlán Izcalli, México*.

The objective of this trial was to determine the effect of supplementing oral selenium (Se) boluses on blood serum and milk selenium concentrations of lactating dairy goats. Forty lactating dairy goats grazing natural rangelands from two flocks (twenty animals for each one) were assigned randomly to two treatments: 0 and 500 mg of Se per bolus. Blood and milk samples were collected at 0, 8, 15, 22, 36, and 50 d post treatment to determine Se concentrations. Data were analyzed using a mixed model with repeated measures. Goat was the random effect while flock and treatment were the fixed effects. Initial live weight, milk yield, and number of kidding were included as covariates, when appropriate. Selenium concentrations were determined by acid decomposition-fluorometric detection. Milk Se concentrations were affected (P = 0.0012) by flock × treatment interaction. In one flock, the supplemented goats had 15.3% more milk Se in comparison with non-supplemented animals. However, there was no response in

milk Se concentration in the other flock. Concentrations of Se in blood serum were influenced (P = 0.0002) by treatment × flock × sampling day interaction. In both flocks, supplemented goats maintained higher Se levels (P < 0.0001) during the experiment than non-supplemented goats (156 ng/mL vs 93.6 ng/mL and 158 ng/mL vs 43.5 ng/mL). Concentrations of Se in blood serum for supplemented goats in both flocks showed a peak at day 8 post dosing that differed (P < 0.0001) from other sampling days. However, this peak was higher (P < 0.0001) in one flock (349 ng/mL vs 201.5 ng/mL). The administration of selenium boluses in dairy goats increases the content of Se in milk, and maintains appropriate levels of this mineral in blood serum during 50 days.

Key Words: Dairy Goats, Milk, Selenium

T162 Effects of fibrolytic enzymes and seaweed extract on performance and carcass characteristics of meat goats fed a non-pelleted diet. G. V. Pollard*[1], K. F. Wilson[2], H. Anderson[3], and R. V. Machen[4], [1]*Texas State University*, *San Marcos*, [2]*Animal Feed Technologies*, *Greeley, CO*, [3]*Anderson Consulting and Training*, *Garden City, KS*, [4]*Texas Agricultural Experiment Station*, *Uvalde*.

Meat goats (n=32), averaging 43.8 kg with a minimum of 75% Boer influence, were utilized to determine the effects of supplemental fibrolytic enzymes and (or) seaweed extract on performance and carcass characteristics when fed a non-pelleted diet. Treatments evaluated were: control, filbrolytic enzymes, seaweed extract, and fibrolytic enzymes plus seaweed extract. The diet utilized in this study was 50% concentrate and 50% roughage with fibrolytic enzymes and seaweed extract added at 200 g and 4.54 kg, respectively, per 907 kg of diet. All diets were fed at 3.5% of body weight along with unlimited access to water for 87 d. Sixteen pens with 2 goats per pen were utilized for this study. All goats were placed on the control diet for 14 d prior to initiation of the study to allow for dietary acclimation. Goats were weighed on 14 d intervals for 84 d, on d 87 all goats were shipped to a commercial slaughter plant where kosher slaughter was performed and carcass data was collected. Carcass variables measured were hot carcass weight (HCW), dressing percentage, body thickness between the eleventh and twelfth rib (BT), back fat, leg score, and muscle conformation. All data were analyzed as a randomized design using the GLM procedure of SAS. Seaweed extract did not improve ADG (P = 0.660) compared to the control (112 g/d versus 98 g/d), while the combination treatment improved (P = 0.048) ADG (162 g/d) and the fibrolytic enzyme treatment tended (P = 0.106) to improve ADG (122 g/d) compared to the control. Carcass characteristics were unaffected by treatment with the exception of BT (P = 0.130) and HCW (P = 0.212) which both tended to be improved by use of the combination treatment compared to the control. The results of this study indicate that fibrolytic enzymes and seaweed extract used in combination can improve performance of meat goats fed high roughage diets.

Key Words: Enzyme, Goat, Seaweed

T163 Effect of fibrolytic enzyme supplementation on fermentation characteristics of ensiled maize stover morphological fractions. Z. H. Sun, Z. L. Tan, and S. X. Tang*, *Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, P.R. China*.

Effect of supplemented fibrolytic enzymes from Trichoderma longibrachiatum on in vitro fermentation characteristic of ensiled morphological fractions of maize stover was determined using gas production technique. Enzymes (Cellulase activity: 2500 IU/ml) mixed with about 1000 g leaf blade (LB), leaf sheath (LS), stem (S) and whole plant (WP) of maize stover at 0, 10, and 20 ml/kg of fresh sample before ensiling, respectively. After 60 d of ensiling, the silage was sampled for determining the gas production. Three goats (18±1 kg), fed a diet consisting of 500 g kg^{-1} concentrate and 500 g kg^{-1} forage containing DE (3.15 Mcal/kg DM) and CP (140 g/kg DM), were used as ruminal fluid donors for the preparation of inoculums. The gas production was measured in each vial after 2, 4, 8, 12, 15, 24, 48, 56 and 72 h of incubation. Gas production data were in triplicate fitted to an equation of GP=P×exp{-exp[1+r×e×(LAG-t)÷P]}; where GP is the gas production at time (t), P is the potential gas production, r is the constant rate of gas production, LAG is the lag time of fermentation. The values of P and r of ensiled S and WP were higher than those of ensiled LB and LS (P<0.05), LAG values of ensiled LB and LS were higher than those of ensiled S and WP (P<0.05). There were differences in P, r and LAG (P<0.05) for S and WP, and in P (P<0.05) for LS and LB among three enzymes treatments. These data suggest that addition of fibrolitic enzymes affected fermentation characteristic for ensiling morphological fractions of maize stover.

T164 Kidding performance of Myotonic and Spanish goats mated to Boer and Kiko sires in an accelerated mating system. S. Wildeus* and J. R. Collins, *Virginia State University*, *Petersburg*.

This experiment evaluated the performance of Myotonic and Spanish does mated to Boer and Kiko sires in an 8-mo breeding scheme. A herd of 50 Spanish and 40 Myotonic does were mated in single sire groups to 4 Boer and 4 Kiko bucks during 30-d breeding periods in November, July and March. Each breeding period was replicated. Does were managed as one group in a pasture-based system, except during mating, and supplemented with concentrate (1.5% BW) during late gestation and lactation. Kids were weaned at 9 wk. Pregnancy was determined on d 1 and 21 after the end of breeding. Data were analyzed in a model that included dam breed, sire breed, and breeding season. Pregnancy rates were 88.3, 13.0, and 64.4% for November, July and March breeding ($P<0.01$), respectively, and were not affected by dam breed. Kidding rates were lower ($P<0.05$) in Myotonic (42.7%) than Spanish dams (63.6%) for March breeding, but similar between dam breeds for November and July breeding. Litter size at birth was greater ($P<0.01$) for November (1.96) than July (1.78) and March (1.70) breeding, and Myotonic dams had smaller litters for March breeding than Spanish dams (1.56 vs. 1.84; $P<0.05$). Litter birth weight was lower ($P<0.05$) for March (4.87 kg) than November (5.51 kg) and July (5.41 kg) breeding. Litter birth weight was heavier in Spanish dams when sired by Boer bucks, while they were heavier in Myotonic dams when sired by Kiko bucks (dam by sire breed: $P<0.05$). Litter ADG and 60-d adjusted weaning weight were greater ($P<0.05$) in Spanish (205 g/d and 18.1 kg) than Myotonic dams (165 g/d and 14.1 kg), and when sired by Kiko (205 g/d and 17.4 kg) than by Boer bucks (164 g/d and 15.2 kg). Spanish does (44.3 kg) were heavier ($P<0.001$) than Myotonic does (34.7 kg), however, litter weight weaned as % doe weight was similar between dam breeds, but higher for November (46.7%) than July (39.6%) breeding, with March intermediate (42.0%). Data indicate that Spanish and Myotonic dams were not well suited for a pasture-based accelerated mating system due to low conception rates following July, and increased pre-natal losses following March breeding.

Key Words: Goats, Kidding Performance, Accelerated Breeding

T165 Effects of alfalfa hay and/or concentrate diets on growth, organ mass, blood and muscle metabolites, and volatile fatty acids in Boer × Spanish male kids. B. Kouakou*, G. Kannan, J. H. Lee, and T. H. Terrill, *Agricultural Research Station, Fort Valley State University*, *Fort Valley, GA*.

Weaned kids (BW = 18 ± .8 kg; n = 36) were used to determine the effect of alfalfa hay, concentrate, or concentrate following hay feeding on performance, organ mass, metabolites and ruminal volatile fatty acids. Kids were stratified by BW, housed in 9 pens (4 kids/pen), with free access to water. Ground alfalfa (Medicago sativa) cube hay or an 18 % CP concentrate diet were fed during two periods of 45 d each. During the first period, two groups of kids (6 pens) were fed hay alone, and one group (3 pens), the concentrate diet. During the second period, one of the hay-fed groups (3 pens) was switched to the concentrate, while the other groups remained on the previous diets. Dietary treatments were HH (Hay, Hay), HC (Hay, Concentrate) and CC (Concentrate, Concentrate) for first and second period diets, respectively. Weights and blood samples were taken every 45 d. At the end of the second period (d 90), all animals were moved to the meat processing facility for overnight holding (water available but without feed). At slaughter, reticulo-rumen and intestines (with and without digesta), and liver weights were recorded. Rumen fluid was collected. Blood samples were analyzed for glucose. Liver and muscle samples were analyzed for glycogen. Proportions of propionate, butyrate, and isovalerate and blood glucose increased with concentrate finishing while proportion of acetate, and acetate:propionate ratio increased with hay finishing. Liver and muscle glycogen concentrations were not influenced by diet. Final weights were lower ($p < 0.001$) for kids fed hay (21.5 and 22.7 kg for HH and HC) compared to those fed concentrate (30.3 kg). Ruminal ammonia was lower ($p < 0.001$), but intestinal and ruminal pH was higher ($p < 0.001$) in goats finished on hay. Liver, rumen (g and % BW), and small intestine (g not % BW) increased ($p < 0.001$) with concentrate feeding. Concentrate finishing increased weight (% BW) of liver and rumen but not the small intestine. Starting weaned kids on alfalfa cube hay and finishing on concentrate for only 45 d may not add benefit in terms of weight gain.

T166 The effect of mixed species grazing management on forage yield and quality. Y. Ghebreiyessus*, V. Bachireddy, S. Gebrelul, R. Payne, and M. Berhane, *Southern University*.

Cow calf production is one of the major sources of income for small farmers in Louisiana. Goat production has great potential to be an alternative source of income. A study to evaluate the effect of mixed species grazing systems on the forage yield and quality was conducted. Animals were grazed on Bermuda grass pastures during the summer and ryegrass during the winter. In a 3×2 factorial, 80 Spanish goats and 28 Brangus cows were randomly assigned to continuous or rotational grazing systems, and three grazing schemes (goat-alone, cattle-alone or mixed). A land area of 28 ha on Bermuda grass was divided into six pastures, 8 ha each for mixed-species grazing, 2 ha each for goats-alone grazing and 5.5 ha each for cattle-alone grazing. The rotational pastures were further divided, using electric fences, into four paddocks. Each paddock was grazed for seven days and allowed to rest for approximately 21 days. Soil samples were collected and based on soil test results, lime and fertilizers 8-24-24 in fall and ammonium nitrated in spring were applied. Forage samples were collected weekly to determine plant height, forage yield and forage quality. Animals were weighed every 28 days. Based on two years data significant difference in forage yield was found among species and species by grazing interaction ($P<0.05$). Yield ranged from 972 to 1,030 kg/ha. Grazing systems did not show significant differences but yield from rotational grazing was higher than continuous. Yield difference between years and among months was highly significant, ranging from 410 to 1,895 kg/ha. Plant height was significant for grazing and species interaction. Lowest plant height of 18 cm was obtained from cattle alone under rotational grazing and highest of 22 cm was from mixed species under rotational grazing. Crude protein varied significantly between years, among months and species and grazing interaction (8.4 to 11.7%, $P<0.05$). ADF values ranged from 37.6 to 38.3% and were significant with all treatments. NDF values ranged from 41.2 to 60.2% and were significant with species and months interaction.

Key Words: Cattle, Forages, Goats

T167 Abundance of mRNA expression and nutritional regulation of somatotropic axis genes in the small intestine of prepubertal dairy heifers fed high-protein high-fat milk replacers. B. T. Velayudhan*, K. M. Daniels, M. L. McGilliard, B. A. Corl, K. F. Knowlton, and R. M. Akers, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Components of the somatotropic axis and nutrition are important in regulating intestinal development as well as maturation of enterocytes. We measured the abundance of mRNA by real-time polymerase chain reaction to test the hypothesis that increased amounts of protein and fat in the diet alters the expression of somatotropic axis genes in the mucosal layer of small intestine. We measured the expression of growth hormone receptor (GHR), insulin-like growth factor-I (IGF-I), IGF-I receptor (R) and IGF binding proteins (BP) -1 to -6 in duodenum, jejunum and ileum. Twenty-four newborn Holstein heifers were randomly assigned to one of 4 milk replacers (MR; n=6/diet): MR 1 was 24 % protein and 17 % fat, MR 2 was 32:17, MR 3 was 31:24 at low level of feeding or MR 4 was 31:24 at high level of feeding. Animals were sacrificed and intestinal tissues were harvested for RNA isolation at 59±2 d. Abundance of mRNA for GHR, IGFBP-3, -4, and -5 was greater (1.8, 2.6, 3.0, 1.7 fold, respectively; P≤0.05) in high protein groups compared to the low protein group (MR 2 +MR 3 + MR 4 VS. MR 1) while GHR, IGFBP-2, -3 and -5 mRNA was greater (0.8, 1.7, 1.6, 1.6 fold, respectively; P≤0.05) with high fat feeding (MR 1 + MR 2 VS. MR 3 + MR 4). Abundance of mRNA expression for IGF-I, IGF-IR, IGFBP-3, -4 and -6 was greater (P≤0.05) in duodenum than jejunum or ileum but IGFBP-2 mRNA expression was greater (P≤0.05) in jejunum than duodenum or ileum. However, mRNA expression for GHR, IGFBP-1 and -5 was not different (P≥0.50) between different intestinal locations. In conclusion, components of the somatotropic axis in prepubertal dairy heifers are differentially expressed in regions of the small intestine and the gene expression is impacted by dietary protein and fat.

Key Words: Prepubertal Heifer, Intestinal Mucosa, GH-IGF Axis Gene Expression

T168 Effect of zilpaterol on cultured bovine satellite cells. E. K. Sissom*[1], D. A. Yates[2], J. L. Montgomery[2], W. T. Nichols[2], M. N. Streeter[2], J. P. Hutcheson[2], and B. J. Johnson[1], [1]*Kansas State University*, *Manhattan*, [2]*Intervet Inc.*, *Millsboro, DE*.

Zilpaterol is a β-adrenergic receptor (β-AR) agonist recently approved to improve production efficiencies and dressing percentage in feedlot cattle. The purpose of these experiments was to determine the effect of various levels of zilpaterol (0, 100 pM, 1 nM, 10 nM, 100 nM, 1 μM, and 10 μM) in culture media on bovine satellite cell proliferation and gene expression. Total RNA was isolated from cells following 48 h zilpaterol exposure in both proliferating myoblast cultures at 96 h, and fused myotube cultures established after 192 h in culture. Real-time quantitative-PCR was performed to estimate mRNA abundance. There was no effect (P > 0.10) of zilpaterol dose on [^{3}H]-thymidine incorporation in proliferating myoblasts. Zilpaterol (1 μM) addition to myoblasts resulted in a decrease (P < 0.05) in β1-AR mRNA. Similarly, zilpaterol (10 nM and 1μM) decreased (P < 0.05) β2-AR and β3-AR mRNA. The expression of IGF-I mRNA was increased (P < 0.05) with zilpaterol (1 μM) addition, and there was a tendency (P = 0.07) for zilpaterol (1 nM) to increase myosin heavy chain mRNA, while 10 nM and 1μM zilpaterol reduced (P < 0.05) myosin heavy chain mRNA levels. There was no effect (P > 0.05) of zilpaterol dose on the expression of genes analyzed in fused myotube cultures at 192 h. Similar to changes in mRNA, western blot analysis revealed the protein content of β2-AR in zilpaterol-treated myoblast cultures decreased (P = 0.05) relative to control. Similar to previous work with other β-adrenergic agonists, zilpaterol did not alter satellite cell proliferation but reduced both mRNA and protein levels of the various subtypes of β-AR in these cultures. The response of zilpaterol on IGF-I mRNA could be mediating changes in protein synthesis and degradation. These data indicate that zilpaterol addition can alter mRNA and protein concentrations of β-AR of muscle cell cultures which in turn could impact responsiveness of cells to prolonged zilpaterol exposure.

Key Words: β-Adrenergic Receptor, Skeletal Muscle, Zilpaterol

T169 Cloning and expression pattern of bovine adipogenin isoform. S. G. Roh*, T. Satoh, and S. Shinichi, *Shinshu University*, *Minamiminowamura, Nagano-ken, Japan*.

The generation of new adipocytes results from differentiation mediated by several transcription factors identified as master regulators for adipogenesis. Recently, we reported that adipogenin, a new adipose-specific gene, was highly expressed in adipose tissues and up-regulated during adipocyte differentiation in bovine and mice. In the process of analyzing the expression of adipogenin in adipose tissues from cattle, we found an isoform of adipogenin cDNA, generated by alternative splicing. Therefore, the objective of this study was to isolate of bovine adipogenin isoform and analyze its expression on adipose tissue and differentiated adipocytes. The putative complete coding sequence of the bovine adipogenin isoform gene is 384 bp in length. The splicing event results a new ORF that could generate an isoform of 127 amino acids. Alignment analysis using BLAST program (NCBI) with bovine genomic (chromosome 13 contig NW_001493160) and cDNA adipogenin isoform sequences indicates that flanking nucleotides of divergence point among sequences of this 133 bp fragment and adipogenin cDNA perfectly match with exonic sequences from exon 1/intron 1 and intron 2/exon 3 junctions, confirming that entire exon 2 is spliced in the another fragment. To amplify specifically the adipogenin isoform, we performed RT-PCR analysis using adipogenin isoform-specific forward primer derived from exon 1/exon 3 junction. Total RNA was extracted from bovine tissues and cultured preadipocytes and differentiated adipocytes in 6-well culture dishes, and cDNA synthesis and PCR reactions were performed. The expression of bovine adipogenin isoform mRNA in adipose tissues was significantly higher (P < 0.05) than that in non-adipose tissues examined. The expression of adipogenin isoform was signficantly highly expressed in adipocytes (P < 0.05) compared to stromal-vascular cells. The levels of bovine adipogenin isoform mRNA significantly increased (P < 0.05) throughout the 10-day of adipocyte differentiation. In conclusion, this spliced form of adipogenin may be another factor in the regulation of adipocyte gene expression and in the adipogenic process.

Key Words: Cattle, Adipogenin, Adipogenesis

T170 Δ^9 Desaturase gene expression in adipose tissues of calf-fed and yearling-fed Steers. M. A. Brooks*[1], C. W. Choi[2], D. K. Lunt[1], H. Kawachi[3], and S. B. Smith[1], [1]*Texas A&M University*, *College Station*, [2]*National Livestock Research Institute*, *Suwon, South Korea*, [3]*Kyoto University*, *Kyoto, Japan*.

There is a growing interest in documenting the effect diet on the ability to convert saturated fatty acids (SFA) to monounsaturated fatty acids (MUFA) by modulating expression of the Δ^9 desaturase gene. We propose that if cattle were raised to a constant body weight, their MUFA:SFA ratio will be the same regardless of being calf-fed (CF) or yearling-fed (YF). Twenty-four Angus cattle were acquired for this study. Baseline cattle were slaughtered at weaning at 8 mo of age (n=4), and the remaining cattle were assigned to CF and YF groups. Eight steers were assigned to the CF group and were slaughtered at 12 mo of age (n=4) and 16 mo of age (n=4). Twelve cattle were assigned to the YF group and slaughtered at 12 mo of age (n=4) 16 mo of age (n=4) and market weight of 525 kg (n=4). Intramusclar lipid (IML) of the LM, fatty acids of s.c. and i.m. adipose tissues, slip points of the s.c. lipids, and mRNA concentrations were measured in adipose and muscle samples of each of the cattle in the study. As the animals aged, a significant rise was seen in IML of both CF ($P<0.01$) and YF ($P<0.01$). Slip points (estimators of melting points) in both CF animals and YF animals significantly decreased with age; however, there was no significant difference in slip points between the 16 mo CF cattle and market weight YF cattle (difference of 1.95°C, $P=0.25$). The s.c. adipose tissue Δ^9 desaturase gene expression was virtually undetectable in both the baseline and 12 mo old YF animals, whereas there was marked expression in all the CF and the other YF cattle. This observation was confirmed by the s.c. adipose tissue MUFA:SFA ratios. The baseline and 12 mo old YF animals showed similar ratios (0.770, 0.707, respectively), whereas there was a significant increase from baseline in the animals that were being fed grain diets (CF 1.01 and 1.02, YF 0.98 and 0.96). The results indicate a repression of Δ^9 desaturase gene expression in YF cattle during the first 4 months after weaning, but a pronounced increase in desaturase gene expression by 16 mo of age, which resulted in similar MUFA:SFA ratios by the time the cattle reached market weight.

Key Words: Adipose Tissue, Beef, Fatty Acids

T171 Impact of irradiation and IgG concentration on absorption of protein and IgG in calves fed colostrum replacer. J. M. Campbell*[1], L. E. Russell[1], J. D. Crenshaw[1], E. M. Weaver[1], S. Godden[2], J. D. Quigley[3], J. Coverdale[4], and H. Tyler[5], [1]*APC, Inc.*, *Ankeny, IA*, [2]*University of Minnesota*, *St. Paul*, [3]*Diamond V Mills*, *Cedar Rapids, IA*, [4]*Texas A&M University*, *College Station*, [5]*Iowa State University*, *Ames*.

The objectives of this study were to evaluate the effect of total IgG mass derived from bovine serum fractions (colostrum replacer; CR) and level of irradiation on 24 h serum IgG levels, protein levels, apparent efficiency of absorption (AEA) of IgG, and the ability to prevent failure of passive transfer (FPT) in day old dairy calves. When irradiated, single dose packs of CR were sent to a commercial irradiation facility for electron beam (e-beam) irradiation at 3-7 kGy (low irradiation; L) or 15-20 kGy (high irradiation; H). Sixty-five Holstein, Jersey, or cross-bred calves were randomly assigned to one of six treatments: 1) 2.0 L pooled pasteurized maternal colostrum (MC); 2) 130 g IgG (460 g of CR) no irradiation (130 NR); 3) 130 g IgG (460 g of CR) low irradiation (130 L); 4) 160 g IgG (518 g of CR) low irradiation (160 L); 5) 190 g IgG (575.4 g of CR) low irradiation (190 L); and 6) 130 g IgG (460 g of CR) high irradiation (130 H). All CR were reconstituted in water and mixed in a household blender to a constant solids concentration of 23%. Maternal colostrum was poor quality providing 33.8 g of IgG/2 L dose resulting in 24 h serum IgG of 3.59 g/L which was lower ($P < 0.0001$) than CR treatments. Increasing IgG mass in the CR (130L, 160L, and 190L) resulted in a linear increase in 24 h serum IgG ($P < 0.02$), total protein levels ($P < 0.07$), and a linear decrease in AEA of IgG ($P < 0.05$). There was no effect ($P > 0.10$) of increasing the mass of IgG fed on the percentage of calves with FPT. Increasing irradiation dose to a high of 15-20 kGy (130H) resulted in a linear decrease ($P < 0.05$) in 24 h serum IgG, AEA of IgG, and increased ($P < 0.07$) the percentage of calves with FPT. Correlation between serum IgG and total protein at 24 h was positive; however, irradiation reduced ($P < 0.01$) at 24 h the serum IgG to total protein ratio. Further studies are needed to determine the effects of irradiation on IgG absorption in the neonatal calf. Colostrum replacers providing 130 g of IgG in the first feeding isolated from bovine serum and receiving either no irradiation or a low level of irradiation are sufficient to prevent FPT in calves.

Key Words: Calf, IgG

T172 Relationship between blood serum IGF-1 and GH concentrations and growth of Holstein steers. N. Torrentera*[1], R. Cerda[1], M. Cervantes[1], P. Garcez[2], and W. Sauer[1], [1]*Universidad Autonoma de Baja Cali*, *Mexicali, Baja, California, Mexico*, [2]*Universidad Autonoma de Mexico*, *Mexico*.

Insulin-like growth factor-1 (IGF-1) and GH have been studied as indicators of growth potential in beef cattle, but the relationship between these and the growth and development of Holstein steers has not been reported. The objective of this study was to relate the concentrations of GH and IGF-1 in blood serum and growth of Holstein calves. Twelve calves weaned at 4±2 d, average age and BW of 45 d and 54,6 kg, respectively, were selected to obtain their BW and blood samples every 28 d during 336 d. Ten blood samples were collected at 30 min intervals, from 0800 to 1300 h, every sampling date. Samples from the same animal and sampling day were mixed, and a serum subsample was used to analyze. The concentrations of IGF-1 and GH were analyzed using RIA test. Linear regression and correlation analyses were performed to determine the relationship between ADG and BW, and serum concentrations of IGF-1 and GH. The correlation values between serum IGF-1 and ADG or BW were consistently positive (0.47 and 0.48, respectively), but the correlation values between GH and ADG and BW were negative (-0.31 and -0.37, respectively). Serum concentration of IGF-1 explained 24% of the variation in ADG, but GH only explained nearly 10% of this variation. There was a significant relationship ($P < 0.01$) between serum IGF-1 and age of the calves. Serum concentration of IGF-1 showed a strong relationship with BW ($R^2 = 0.41$) throughout a 336 d postweaning growth performance. These data indicate that serum IGF-1 may be useful for predicting average daily gain in Holstein steers.

Key Words: Holstein Steers, IGF-1, GH

T173 Serial slaughter evaluation of growth-promoting implants on growth and carcass characteristics in calf-fed Holstein steers. J. L. Beckett*[1], L. D. Luqué[1], P. D. Bass[3], W. T. Nichols[2], and R. J. Delmore[1], [1]*California Polytechnic State University*, *San Luis Obispo*, [2]*Intervet Inc.*, *Millsboro, DE*, [3]*Colorado State University*, *Fort Collins*.

Growth and carcass characteristics of calf-fed Holstein steers implanted with and without growth-promoting implants were evaluated during a serial harvest study. A total of 120 steers (average initial weight = 127 kg) were randomly assigned to either receive implants (I; Syn C at d 0, Rev IS at d 120, and Rev S at d 240) or nonimplanted control (C). Steers were fed a finishing ration continuously from day 0 through 420. Steers were weighed every 30 days from day 0 through 420 days on feed. A total of 8-12 head per treatment group were harvested on days 0, 60, 120, 180, 240, 270, 300, 330, and 420. Data collected included HCW, REA, skeletal maturity, marbling score and fat thickness. Yield grade was calculated and quality grade was determined. By 90 d, I cattle were significantly heavier than C cattle. Average shrunk weights for I cattle were 137, 172, 214, 261, 314, 354, 410, 458, 489, 534, 580, 627, 660, and 695 kg compared with 137, 168, 208, 249, 295, 330, 372, 417, 445 481, 509, 547, 567, 570, and 597 kg for C cattle on days 0, 60, 120, 180, 240, 270, 300, and 420, respectively. Average HCW of I cattle was 19, 32, 39, 47, 59, and 56 kg heavier on day 120, 240, 300, 330, 360, and 420, respectively ($P<0.05$). Dressing percent increased linearly ($P<0.05$) from 53% on day 0 to 62% by d 420, but did not differ by treatment. Fat thickness was not significantly different between the treatments throughout the feeding period ($P>0.05$). I cattle tended to have larger REA than C cattle on days 120, 300, 360 and 420, but the effect was not significant ($P>0.05$). Average REA increased from 26 cm^2 on day 0 to 87 cm^2 on day 420. Marbling score tended to be greater for C cattle on days 120, 180, 270, 300 and 360 ($P>0.05$). Results of this study confirm that growth-promoting implants are effective throughout the growing period in calf-fed Holstein steers. Further, each successive implant is additive to prior growth enhancement.

Key Words: Holstein, Growth Promoters, Serial Harvest

T174 The effect of milk replacer composition on growth and body composition of Holstein heifer calves. S. R. Hill, K. M. Daniels*, K. F. Knowlton, R. E. James, R. E. Pearson, M. L. McGilliard, and R. M. Akers, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Twenty-four newborn Holstein heifer calves (n=6) were fed one of 4 milk replacers: 20/20 (fed at 450 g/d, 20% CP/ 20% Fat, 0.53% P); 28/20 (fed at 970 g/d, 28% CP/ 20% Fat, 0.55% P); 28/28 (fed at 970 g/d, 28% CP/ 28% Fat, 0.46% P); or 28/28+ (fed at 1460 g/d, 28% CP/ 28% Fat, 0.46% P). Calves were purchased from a commercial farm at 3±2 d and arrived in one of three groups. Treatments were assigned randomly within group. Calves were fed 3.4 L of colostrum twice within 16 h of birth. Upon arrival at the research farm, calves were fed a 20/20 milk replacer for the first two feedings. On d 3, treatments were imposed and calf starter (20% CP, 0.48%P) comprised of corn (44.4%), soybean meal (44.4%), cottonseed hulls (11.1%), and molasses (1.0%) was offered free choice. Calves were on study for ~63 d. Total collection of feed refusals, feces and urine was initiated on d 59±2d. Body weight and body size were measured weekly. Calves were harvested at 63 d to evaluate body composition and mammary development (reported elsewhere). Preplanned contrasts were used to compare 20/20 to all, 28/20 to 28/28, and 28/28 to 28/28+. Empty body weight (EBW) gain was greater in calves fed 28/28+ compared to 28/28, however those same calves also had a higher percent of EBW as fat. Calves fed 28/20 had the most protein gain compared to those fed extra energy (28/28) and also had a higher protein as a percent of EBW. The addition of fat to the milk replacer reduced protein gain (kg and % of EBW), increased fat gain (kg and % of EBW), and decreased ash gain (kg and % of EBW). Increasing the volume fed did increase protein gain, fat gain (kg and % of EBW) and ash gain. These results indicate that 20% fat may not be enough energy to support protein gain when CP is greater than 28% of the diet DM. However, frame growth appeared to increase when calves were fed the 28/20 compared to 28/28, indicated by increased ash gain and increased body measurements.

Key Words: Milk Replacer, Calf, Body Composition

Immunology - Livestock and Poultry II

T175 Long-term consumption of resistant starch reduces T cell population and apoptosis in pig colon. M. Nofrarías*[1,2], D. Martínez–Puig[2], J.F. Pérez[2], and N. Majó[1,2], [1]*Centre de Recerca en Sanitat Animal (CReSA)*, *Bellaterra, Spain*, [2]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

The aim of the present study was to assess the effects of a long-term intake of resistant starch on the colonic fermentation and intestinal morphology, including lymphocytic infiltration, apoptosis and proliferation activities. Sixteen growing pigs were fed for 14 weeks on a diet containing a high amount (350 g/kg) of either raw potato starch (RPS; resistant starch type II) or corn starch (digestible starch). On day 97, pigs were euthanised and the gut weighed and sampled. Colonic digesta were analysed for short chain fatty acids concentration. Histological study was performed in tissue samples from proximal colon. The presence of T cells, cells undergoing apoptosis, and proliferative activity were also immunohistochemically determined. After 97 days, the colonic content from RPS pigs was heavier than for CS pigs (1.52 vs. 3.04 kg; $P<0.01$), producing a hypertrophy of tunica muscularis (428 vs. 529 µm; $P<0.01$). The concentration of butyrate was 3-fold higher in proximal colon digesta in RPS pigs (5.86 vs. 16.30 µmol/g; $P=0.02$). RPS fed pigs had reduced crypt depth (429 vs. 416 µm; $P=0.045$) and tended to diminish crypt cell proliferation (35.7 vs. 32.5 cells; $P=0.09$). Fermentation of RPS reduced ($P<0.05$) apoptosis, as number of immunopositive cells for cleaved caspase-3, in the crypts (0.62 vs. 0.32/crypt), lamina propria (1.41 vs. 1.16/1000 μm^2) and lymphoid nodules (5.9 vs. 3.9/1000 μm^2) in the colon. The numbers of intraepithelial T CD3+ cells (6.1 vs. 5.6/crypt; $P=0.027$) and the presence of mucosal lymphoid nodules (0.094 vs. 0.037/mm; $P=0.09$) were also reduced in the colon of RPS pigs. Results in colonic lymphocytic infiltration and apoptosis suggest that long term ingestion of RPS could induce lower immune reactivity in the hindgut.

Key Words: Resistant Starch, Intestinal Apoptosis, Pigs

T176 Utilization of alfalfa and its effects on the immune system during molt. J. L. McReynolds*, K. J. Genovese, H. He, C. L. Swaggerty, J. A. Byrd, D. J. Nisbet, and M. H. Kogut, *USDA-ARS-SPACR-FFSRU*, *College Sation, TX.*

Force molting of laying hens increases enteric foodborne pathogens in the reproductive tract, leading to contaminated eggs and progeny of infected hens. Currently, we lack a complete understanding of how conditions such as molting affect the immune system. Our laboratory is interested in continuing research on feeding alfalfa during a molt to evaluate its effects on heterophils function. Previous reports show that alfalfa is effective in inducing a molt as well as producing protection against *Salmonella enteritidis* (SE) organ invasion. Our laboratory has also shown that immune function is significantly reduced during molting. The present investigation was performed to evaluate heterophil function during an induced molt in hens fed alfalfa. Two replicate experiments utilized hens over 65 wk of age that were divided into 6 groups of 12 hens each and placed in individual laying cages. Two wk prior to dietary changes, hens were placed on an 8-h light and 16 h-dark photoperiod that continued for the 12-day experiment. Blood samples were taken from the hens during three sampling periods, 1-2d, 5-6d, and 11-12d. Treatments groups consisted of non-fed hens (NF), full-fed hens (FF) and alfalfa-fed hens (AF). Heterophil function was measured using several in vitro assays. We evaluated oxidative burst, degranulation, and phagocytosis. The results from the oxidative burst and degranulation assays showed significant ($P \leq 0.05$) increases when the AF birds were compared to the NF controls. Phagocytosis assays showed AF birds had similar net increases to FF birds when compared to the negative control. These results confirm that heterophil function is significantly reduced in NF birds during an induced molt. More importantly AF birds showed an increased immune response during a 12d molting period. Commercial integrators should consider using alfalfa when developing new molting programs.

Key Words: Chickens, Molting, Heterophils

T177 Effect of a direct fed microbial (PrimaLac®) on systemic immunity in developing broilers. C. C. Chiang[1], R. Qiu[2], J. Croom[2], L. Daniel[2], R. Ali[2], and M. Koci*[2], [1]*National Chung Hsing University*, *Taiwan*, [2]*North Carolina State University*, *Raleigh*.

Consumer and political concerns over the sub-therapeutic use of antibiotics in has led an interest in identifying alternative growth promoting dietary supplements such as direct fed microbials (DFM). DFM supplements have been used for decades to promote animal and human health however their mechanism of action is still unclear. The current study investigated the effects of DFM treatment on systemic immune responses in broiler chicks. Day-old broiler chicks were fed a control starter diet (CSD), or CSD plus PrimaLac® (PRM; 0.3% w/w). Each diet group was randomly divided into two treatment groups, one vaccinated i.v. with sheep red blood cells (SRBCs); the other mock vaccinated with normal saline (SAL). Chicks were vaccinated at 7 and 14 days of age, and monitored for the production of antibodies (Abs) against SRBCs by hemagglutination assay. Chicks fed the PRM diet produced higher titers of both total and β-mercaptoethanal resistant anti-SRBCs Abs as compared to the CSD group. Additionally, ex vivo stimulation of macrophages (Mϕ) isolated from PRM and CSD chicks demonstrated an increase in nitric oxide production by Mϕ from PRM treated chicks. Ex vivo analysis of circulating peripheral blood leukocytes (PBLs) suggested ATP utilization of PBLs from PRM-SAL chicks was lower than that of CSD-SAL chicks. However, the ATP utilization of PRM-SRBC chicks was greater than that of CSD-SRBC chicks. This suggests that while DFM may promote a more robust immune response, it may also be able to lower the maintenance cost of leukocytes in resting animals. Further investigation is needed to better understand this association.

Key Words: Probiotic, Direct fed Microbial, Immunity

T178 Effects of yeast culture in broiler diets on performance and immunomodulatory functions. J. Gao[1], H.-J. Zhang[1], S.-H. Yu[1], S.-G. Wu[1], I. Yoon[2], J. Quigley[2], and G.-H. Qi*[1], [1]*Feed Research Institute, Chinese Academy of Agricultural Sciences*, *Beijing, China*, [2]*Diamond V Mills, Inc.*, *Cedar Rapids, IA*.

Abor Acres chicks (n = 960, 1 d old) were randomly assigned to 4 dietary treatments with different levels (0, 2500, 5000 and 7500 mg/kg of the diet) of a commercial yeast culture product (Diamond V XP™ Yeast Culture; YC) to investigate the effects of YC on performance and immunomodulatory function in broilers. Broilers were housed in a three-layer batteries and fed corn-soybean meal based diets for 42 d. Each treatment consisted of 12 replicate pens with 20 broilers per pen. Feed intake and body weight were measured on d 1, 21 and 42. Nutrient digestibility was determined at 2 and 5 wk by total fecal collection. On d 21 and 42, twelve broilers per treatment were sacrificed for gut morphology and immune function measurements. Broilers were vaccinated with Newcastle Disease Virus (NDV) by eye drop on d 7 and 21 and antibody titer was determined on d 14, 21, 28, and 35. Compared with the control group, including YC at 2500 mg/kg improved ($P < 0.05$) ADG and feed efficiency on d 22-42 and 1-42. Yeast culture supplementation did not affect ($P > 0.05$) ADFI. Supplemental YC tended to increase ($P < 0.1$) digestibility of Ca on d 14 and 35 and P on d 14, but did not affect ($P > 0.05$) digestibility of energy, protein, and DM at 14 and 35 d. Added YC increased ($P < 0.05$) antibody titers to NDV on d 14, 21, 35 and 42. Dietary YC increased ($P < 0.05$) serum lysozyme activity and IgM content on d 21 and 42 but did not affect ($P > 0.05$) serum IgA or IgG on d 21 and 42. Added YC increased ($P < 0.01$) secretary IgA content in duodenum on d 21 and 42. Villus height of duodenum, jejunum, and cecum on d 21 and duodenum on d 42 were increased ($P < 0.05$) for broilers fed diets containing 2500 mg/kg of YC. Results suggest that supplementation of YC in broiler diets can improve growth performance, increase the calcium and phosphorous digestibility, and intestinal villus height. Immune functions could be modified with the inclusion of YC in the broiler diet.

Key Words: Immune Function, Yeast Culture, Broiler

T179 Dietary polyunsaturated fatty acids modulate immune responses in dairy cows characterized by an elevated plasma trans-10, cis-12 CLA and n-3 fatty acids but not cis-9, trans-11 CLA. M. Bharathan*, D. J. Schingoethe, R. S. Kaushik, K. F. Kalscheur, G. Moorkanat, and A. Hippen, *South Dakota State University*, *Brookings*.

Fatty acid composition of the diet can affect the membrane fatty acid composition of immune cells resulting in altered membrane-mediated

functions like eicosanoid production and signal transduction. To study the effect of dietary fatty acids on immune response, 12 lactating Holstein dairy cows were randomly assigned to one of four dietary treatments which included control (CTRL), control with 0.5% fish oil (FO), 10% condensed corn distillers solubles (CCDS), and 10% CCDS with 0.5% fish oil (CSFO). Cows were fed individually as total mixed ration once daily for ad libitum consumption for 28 d. Blood samples were collected on d 0, 7, 14, 21 and 28 to isolate peripheral blood mononuclear cells (PBMC) for proliferation assays and phenotypic characterization of bovine leukocyte markers, and whole plasma for analysis of fatty acid composition. Results indicated that feeding of these diets did not affect proliferation of lymphocytes but percentages of CD4+ and CD8+ T-cells decreased, CD14+ cells increased and MHC class II+ cells tended to increase in cows fed CSFO compared to CTRL. In this experiment, total fatty acids in the plasma did not differ due to diet, while total n-3 fatty acids in the plasma (102.9, 135.9 117.9 and 162.2μg/mL of plasma for CTRL, FO, CDS and CSFO, respectively) increased ($P < 0.01$) in CSFO and tended ($P < 0.09$) to increase with FO compared to CTRL. Cis-9, trans-11 C18:2 (conjugated linoleic acid; CLA) in plasma did not differ among diets; however, trans-10, cis-12 C18:2 CLA increased ($P < 0.02$) in CSFO compared to CTRL. Trans-11 C18:1 concentration (8.6, 15.6, 15.0 and 27.8 μg/mL of plasma) increased ($P < 0.01$) in cows fed CSFO while trans-10 C18:1 remained unaffected. Thus a diet rich in polyunsaturated fatty acids appears to decrease cell mediated immunity, but it may increase the innate immune responses and antigen presentation.

Key Words: Polyunsaturated Fatty Acids, Dairy Cows, Immune Response

T180 Plasma prostaglandin and cytokine concentrations in periparturient Holstein cows fed diets enriched in saturated or trans fatty acids. C. Rodriguez-Sallaberry*, C. Caldari-Torres, W. R. Collante, C. R. Staples, and L. Badinga, *University of Florida*, *Gainesville*.

Multiparous (n = 18) and primiparous (n = 12) Holstein cows were utilized to examine the effect of feeding a calcium salt of trans octadecenoic acids (tFA) on plasma prostaglandin (PG) and cytokine concentrations. The control diet was made isocaloric by addition of a highly saturated fat supplement (RBF). Dietary treatments were initiated approximately 28 d prior to expected calving date and continued through d 21 postpartum. Prepartum and postpartum diets were formulated to be isolipidic, containing 1.5% RBF and 1.8% tFA (DM basis). Multiparous cows were heavier (+ 32%) and tended to produce more milk (+ 15%) than primiparous cows. Average plasma NEFA concentration was higher in multiparous cows (+ 70%) than first lactation heifers at 3 wk of lactation. Periparturient tFA supplementation increased plasma $PGF_{2\alpha}$ metabolite (PGFM) concentration in multiparous cows, but not in primiparous cows. Concentrations of PGE_2, tumor necrosis factor-alpha (TNF-α) and interleukin-4 (IL-4) in plasma did not differ between diets and parities. Peripartum tFA supplementation tended to decrease the incidence of postpartum metritis in lactating Holstein cows. Results further confirm that multiparous cows are heavier and produce more milk than first-lactation heifers and raise the possibility that peripartum tFA supplementation may improve the immune competence of the early lactation dairy cow through alteration of peripheral $PGF_{2\alpha}$ concentration.

Key Words: Fat, Cytokine, Dairy Cow

T181 Natural antibody (anti-gal) is a sensitive means for evaluating the effects of diets on turkey humoral immunity. P. Cotter*[1], M. Hulet[2], and A. E. Sefton[3], [1]*Cotter Laboratory*, *Arlington, MA*, [2]*The Pennsylvania State University University*, *University Park*, [3]*Alltech Inc.*, *Guelph, ON, Canada*.

The influence of dietary supplements and growth promoters on immunity in turkeys was studied in serum from four groups of hens. Samples were obtained on d 84 from 10 hens each on two diets and hatched from two breeder flock sources. Diets contained 4% NuPro® in pre-starter and 2% in starter, or penicillin in starter. Natural antibodies reactive with the α-gal epitope (Galα1-3Galβ1-4GlcNAc-R) were detected by rabbit cell agglutination. A strongly agglutinating (HA1) pattern may be differentiated from a minority of weakly agglutinating (HA2) antibody by distinctive clumping. HA1 are presumably predominated by IgM whereas HA2 are IgG. Collectively anti-gal is the most abundant antibody in avian serum and is formed as a response to gut microflora. Microtiter results indicated a significant diet x origin interaction ($P > 0.01$) for HA1 the IgM antibody, but not for HA2. HA1 titers were higher in penicillin fed hens than in NuPro® fed hens from one origin but lower in penicillin fed hens from the second origin. Total IgM, measured by immunodiffusion, indicated a significant effect of breeder flock origin ($P > 0.03$) but there was no diet effect. Complement lysis and IgG agglutination were not affected by diet or breeder flock origin. The immunity parameters of HA1 and total IgM mirrored performance measurements of BW, BWG, feed intake, and feed conversion ($P < 0.0001$) as being affected by origin but not by diet. Poults sourced in VA had lower BWG and lower feed intake which paralleled their lower IgM agglutination titers and lower total IgM. MN sourced poults fed Penicillin had higher IgM agglutination compared with NuPro® fed poults but the reverse was true for poults sourced in VA. The mechanism exerting the source effect is unknown but may lie in yolk composition, perhaps acting via maternal antibody. These might determine gut flora establishment and so account for antibody variation. Thus anti-gal sensitivity indicates its utility as an immunity adjunct in nutritional studies in the turkey.

Key Words: Anti-Gal, Turkey Immunity, Growth Promoters

T182 Effects of feeding blends of grains naturally contaminated with Fusarium mycotoxins on immunocompetence of turkeys. C. K. Girish*, T. K. Smith, H. J. Boermans, and N. A. Karrow, *University of Guelph*, *Guelph, Ontario, Canada*.

An experiment was conducted to examine the effects of feeding blends of grains naturally contaminated with Fusarium mycotoxins on immunological indices (including functions) of turkeys. The efficacy of polymeric glucomannan mycotoxin adsorbent (GMA, Mycosorb®, Alltech, Inc., Nicholasville, KY) in preventing the adverse effects of Fusarium mycotoxins was also evaluated. Three hundred 1-d-old male turkey poults were fed wheat, corn and soybean meal-based starter (0-3 wk), grower (4-6 wk), developer (7-9 wk), and finisher (10-12 wk) diets formulated with uncontaminated grains, contaminated grains and contaminated grains + 0.2 % GMA. Feeding contaminated grains to turkeys significantly increased percent CD4+ lymphocyte populations during wk 6, however there was no change in the percent CD8+ and B-lymphocyte populations. Contact hypersensitivity to dinitrochlorobenzene, which is a CD8+ T-cell-mediated delayed type hypersensitivity response, was significantly decreased after 24 hr and 72 hr by feed-borne mycotoxins compared to controls. Supplementation of the contaminated diet with GMA prevented the decrease in response

after 24 hr. Mitogenic responsiveness of peripheral lymphocytes to concanavalin A and pokeweed was not affected by the feeding of contaminated diet. The feeding of contaminated grains did not significantly alter the serum (IgA, IgM and IgG) or bile (IgA) immunoglobulin levels. In contrast, the secondary antibody (IgG titer) response against sheep red blood cell antigens (CD4+ T cell dependent) was significantly decreased after feeding contaminated grains to turkeys compared to controls and GMA prevented this. It was concluded that the feeding of grains naturally contaminated with Fusarium mycotoxins exerts adverse effects on some of the immunological indices of turkeys and that GMA prevented many of these effects.

Key Words: Fusarium Mycotoxin, Antibody-mediated Immune Trespons, Turkeys

T183 Phage display selection and characterization of single-chain recombinant antibodies against *Eimeria tenella* sporozoites. D. Abi-Ghanem*[1], S. D. Waghela[1], D. J. Caldwell[1], H. D. Danforth[2], and L. R. Berghman[1], [1]*Texas A&M University*, *College Station*, [2]*USDA/ARS*, *Beltsville, MD*.

An antibody library against *Eimeria tenella* sporozoites was constructed by phage display. Total RNA was isolated from the spleen, bone marrow, and ceca of immunized chickens, and was used to reverse-transcribe cDNA. Heavy and light antibody variable genes were amplified from cDNA by PCR. The single-chain antibody fragment (scFv) was obtained by a secondary overlap PCR with primers that incorporate SfiI restriction sites, thus allowing for subsequent cloning into the phagemid vector pComb3X. Vector and scFv were digested with SfiI, ligated, and transformed into competent XL1-Blue *Escherichia coli* cells by electroporation, yielding a library of 7.4 x 10^7 total transformants. The culture was grown under carbenicillin selective pressure, rescued with helper phage, and the antibody-displaying phage was precipitated by PEG/NaCl, and subsequently used in five panning rounds against cryopreserved *E. tenella* sporozoites. Panning on whole cells offered the advantage of isolating antibodies against native epitopes, but required readily available sporozoites for every round of selection. A 1000-fold increase in phage output and a 3,000-fold enrichment were obtained after three rounds of panning, as the binding clones became the dominant population in the library. Ten clones were randomly selected from the last round of panning, and their nucleotide sequences were aligned and compared to chicken germ-line sequences. Analysis of the light chain variable regions revealed possible donor pseudogenes involved in gene conversion events. Possible somatic hypermutation events, a consequence of affinity maturation, were also identified. Soluble antibody was produced in a non-suppressor *E. coli* strain, purified by nickel affinity chromatography, and characterized by immunoblotting. In an immunofluorescence assay, this recombinant antibody showed specific binding to *E. tenella* sporozoites.

Key Words: Phage Display, *Eimeria Tenella*, Single-Chain Antibody

T184 Immune stimulatory CpG oligodeoxynucleotides reduces *Salmonella enterica* subsp. Arizonae organ colonization and mortality in young turkeys. H. He*, K. J. Genovese, C. L. Swaggerty, and M. H. Kogut, *Food and Feed Safety Research Unit, Southern Plain Agricultural Research Center, USDA-ARS*, *College Station, TX*.

Synthetic oligodeoxynucleotides (ODN) containing CpG dinucleotides (CpG ODN) mimics bacterial DNA and are stimulatory to innate immune system in most vertebrate species. The immunostimulatory activities of CpG ODN have been studied extensively and well characterized in human and murine immune cells. However, information on immune responses of avian species to CpG ODN is limited. We have previously investigated immune stimulatory activities of CpG ODN in turkey immune cells. Here, we have further demonstrated that immune stimulatory CpG ODN increases resistance of young turkeys to *Salmonella* infection. In this study, the newly hatched turkeys, obtained from a commercial source, were given CpG-ODNs or a control ODN that does not contain CpG motif at 50 µg/bird via intra-peritoneal (i.p.) injection. Twenty-four hours after the CpG-ODN treatments, turkeys were challenged with live *Salmonella enterica* subsp. Arizonae (SEA) (suspended in PBS). For the organ colonization experiment, 0.5-1x10^7 cfu/bird was given orally to the turkeys. For the mortality experiment, 0.5-1x10^7 cfu/bird was given to the turkey via i.p. injection. Twenty-four hours after the oral SEA challenge, birds were euthanized with CO2 and liver and spleen were aseptically removed from each bird and cultured for the organ colonization of SEA. The mortality was monitored for a period of 7 days after i.p. SEA challenge. A significant reduction ($p<0.05$) of organ invasion by SEA was observed in turkeys pretreated with CpG-ODNs containing the immunostimulatory GTCGTT motif. These CpG-ODNs also significantly reduced mortality of turkeys with acute peritoneal infection of SEA. Our study provides evidence that immunostimulatory CpG-ODN stimulated innate immune activities and enhanced the resistance to infectious pathogens in neonatal turkeys.

Key Words: CpG ODN, Infection, Turkey

T185 Responese of bovine lymphocytes to different CpG motifs. J.-W. Lee*[1] and X. Zhao[2], [1]*National Pingtung University of Science and Technology*, *Neipu, Pingtung, Taiwan*, [2]*McGill University*, *Ste-Anne-de-Bellevue, Quebec, Canada*.

The immunostimulatory effects of bacterial DNA or synthetic CpG oligodeoxynucleotides (ODNs) on mammal cells have been demonstrated, which makes CpG a potential adjuvant for vaccines. However, the immunostimulatory effect of CpG is species-specific and depends on the sequence of CpG mofits. A CpG fragment (2135), containing 3 identical copies of 5′-GTCGTT-3′ motif, was previously reported to have the strongest effects on bovine cells. Based on the sequence of 2135, we replaced the 5′-GTCGTT-3′ motif with 11 other sequences containing CG and investigated their effects on proliferation of bovine peripheral blood mononuclear cells (PBMC). Results showed that the CpG fragment containing 3 copies of 5′-GACGTT-3′ motif had the highest stimulation index (SI) (7.91 ± 1.19). We therefore further examined the effect of this CpG fragment on cytokine expression in bovine PBMC at the transcriptional level by using real-time PCR. Among the 6 cytokines analyzed, the mRNA expression of IL-6, IL-12, IL-21, and IFN-α was increased > 2 fold in response to this CpG fragment. However, the increase was not statistically significant due to large variations among animals. A vaccine trial is currently being carried out to evaluate the antibody response induced by this CpG fragment as the adjuvant.

Key Words: Bovine, Adjuvant, CpG

T186 Effect of dietary P level and pectin infusion on bacterial P incorporation, activity and composition in pigs. B. U. Metzler*[1], W. Vahjen[2], T. Baumgärtel[3], M. Rodehutscord[3], and R. Mosenthin[1], [1]*Institute of Animal Nutrition, University of Hohenheim*, *Stuttgart, Germany*, [2]*Institute of Animal Nutrition, Free University of Berlin*, *Berlin, Germany*, [3]*Institute of Agricultural and Nutritional Sciences Halle-Wittenberg*, *Halle (Saale), Germany*.

Two experiments were conducted to determine the effects of different P levels, phytase supplementation and the intracecal application of pectin on the chemical composition of fecal mixed bacterial mass (MBM), ileal and fecal levels of VFA as well as bacterial species composition. A total of 16 barrows, initial BW of about 30 kg, fitted with a simple T-cannula at the distal ileum, were assigned to 2 experiments in incomplete 4x2 Latin square design. In Exp. 1, the diets were a low-P corn-soybean meal based control diet (Con; 3g P/kg) or the Con supplemented with MCP (monocalcium phosphate; 7g P/kg). In Exp. 2, the pigs received Con or the Con supplemented with 1000 FTU phytase/kg. Additionally, in both experiments, two pigs of each diet and period received an intracecal infusion of pectin (60g/d) via the ileal cannula. After a 15d adaptation, feces were collected for 5d followed by collection of ileal digesta during 2x12h. Counts for total bacteria in ileal digesta and feces and specific bacterial groups in ileal digesta were determined by quantitative realtime PCR. MCP increased the P content in MBM and the proportion of bacterial P in feces (P<0.05), while phytase reduced the P content in MBM (P<0.05). MCP tended (P=0.12) to stimulate the production of total ileal VFA, while pectin tended (P=0.07) to increase fecal VFA. Phytase tended to reduce (P=0.1) total fecal VFA. The interaction pectin x phytase increased (P=0.07) fecal total bacterial counts. MCP tended to reduce (P=0.12) the growth of lactobacilli, while pectin enhanced (P=0.08) the growth of bifidobacteria in ileal digesta. In conclusion, the bacterial P incorporation, fermentative activity and species composition is influenced by both dietary P level and pectin as fermentable substrate.

Key Words: Phosphorus, Pectin, Bacteria

T187 Effects of adding water into the mixer on pellet quality of expander processed barley–oats–soy–based diets for finishing pigs. K. K. Lundblad*[1,2], J. D. Hancock[2], M. Sørensen[3,4], K. C. Behnke[2], E. Prestløkken[1], and L. J. McKinney[2], [1]*Felleskjøpet Fôrutvikling*, *Trondheim, Norway*, [2]*Kansas State University*, *Manhattan*, [3]*University of Life Sciences*, *Aas, Norway*, [4]*AKVAFORSK*, *Aas, Norway*.

A barley-oats-soy-based formula was used to determine the effects of adding water into the mixer on pellet quality of expander-processed diets for finishing pigs. The barley (67% of the diet) and oats (15% of the diet) were ground to a mean particle size of 600 um and blended with soybean meal (9% of the diet), choice white grease (5% of the diet), crystalline amino acids, vitamins, and minerals creating a diet with 0.8% total lysine and 10% total moisture. Treatments were none, 1.5, 3, 6, and 12% water added into the mixer after a 'dry-mix' time of 60 sec. Total mix time was 240 sec. The mixed mash was steam conditioned at 82°C for approximately 20 sec prior to passing through a 100 hp Amandus-Kahl expander. Cone pressure (14 kg/cm2) and production rate (1.1 t/h) were held constant to eliminate the effects of varied cone pressure and throughput on pelleting characteristics of the diet. The conditioned mash was passed through a pellet press (CPM Master Model HD) equipped with a 32-mm thick die having 4 mm openings. Cone temperature (cubic effect, P<0.02) and kWh/t (quadratic effect, P<0.03) increased as water addition into the mixer was increased from none to 12%. Pellet durability index (tumbling box technique) and modified pellet durability index (five hexagonal nuts added into the tumbling box) increased (linear effects, P<0.003) as water addition into the mixer was increased from none to 12%. Means for the none, 1.5, 3, 6, and 12 % additions of water into the mixer were 93, 93, 94, 94 and 95% for pellet durability index and 91, 92, 93, 93 and 94% for modified pellet durability index. In conclusion, expanding barley-oats-soy-based diets resulted in greater pellet durability index although the high durability index for the control diet (93%) left little room for improvement in pellet quality when water was added into the mixer.

Key Words: Pellet, Expander-Conditioning, Pig

T188 Optimal true digestible Ca:P ratio in corn-rough rice-soybean meal-based diets for growing pigs. S. X. Wang*[1], Y. L. Yin[1], R. L. Huang[1], T. J. Li[1], X. F. Kong[1], M. Z. Fan[2], and G. Y. Wu[1,3], [1]*Institute of Subtropical Agriculture, the Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*University of Guelph*, *Guelph, Ontario, Canada*, [3]*Texas A&M University*, *College Station*.

Three experiments were conducted to determine an optimal ratio of true digestible Ca:P in diets for barrows. In Experiment 1, 12 barrows (BW 30.6±1.2 kg) were assigned randomly to be fed two corn-rough rice-soybean meal-based diets containing either 0.32% true digestible P and 0.60% total Ca or 70% of their values for 8 d (6 pigs/diet). Endogenous outputs of Ca and P in feces were 0.85 and 0.57 g/kg DM intake, and the true digestibilities of dietary Ca and P were 78 and 66%, respectively. In Experiment 2, 25 barrows with BW of 32.2±1.8 kg were used to determine Ca and P balances. The diets were formulated to contain 0.32% true digestible P as in Experiment 1, except that the amounts of limestone were adjusted to obtain 5 levels of total Ca: 0.29, 0.45, 0.60, 0.75 and 0.90% (n = 5 pigs/diet). Pigs were fed their diets for 8 d. Based on the true digestibilities of dietary Ca and P in Experiment 1, the ratio of true digestible Ca and P in the five diets were 0.89, 1.37, 1.82, 2.29, and 2.75, respectively. The apparent digestibilities of Ca and P were reduced (P<0.05) with increasing dietary Ca:P ratios. Pigs fed a diet with a Ca:P ratio of 1.82 retained more Ca and P than pigs fed diets with higher Ca:P ratios (P<0.05). In Experiment 3 (a 35-d feeding trial) involving 25 barrows with initial BW of 20.9±0.95 kg, pigs were fed the diets as described in Experiment 2. Barrows fed diets with a true digestible Ca:P ratio of 1.82 exhibited higher (P<0.05) values for feed intake, ADG, and the gain:feed ratio, compared with pigs fed diets with true digestible Ca:P ratios of 2.29 and 2.75. These results suggest that a true digestible Ca:P ratio of 1.82 is optimal for P utilization and growth performance of barrows fed corn-rough rice-soybean meal-based diets.

Key Words: Calcium, Phosphorus, Piglets

T189 Effects of adding water into the mixer on pellet quality of expander-processed corn-soy-based diets for finishing pigs. K. K. Lundblad*[1,2], J. D. Hancock[2], M. Sørensen[3,4], K. C. Behnke[2], E. Prestløkken[1], and L. J. McKinney[2], [1]*Felleskjøpet Fôrutvikling*, *Trondheim, Norway*, [2]*Kansas State University*, *Manhattan*, [3]*University of Life Sciences*, *Aas, Norway*, [4]*AKVAFORSK*, *Aas, Norway*.

A corn-soy-based formula was used to determine the effects of adding water into the mixer on pellet quality of expander-processed diets for finishing pigs. The corn (76% of the diet) was ground to a mean particle size of 600 um and blended with soybean meal (17% of the diet), choice white grease (5% of the diet), crystalline amino acids, vitamins, and minerals creating a diet with 0.8% total lysine and 11% total moisture. Treatments were none, 1.5, and 3% water added into the mixer after a 'dry-mix' time of 60 sec. Total mix time was 240 sec. The mixed mash was steam conditioned at 82°C for approximately 20 sec prior to passing through a 100 hp Amandus-Kahl expander. Cone pressure (14 kg/cm2) and production rate (1.1 t/h) were held constant to eliminate the effects of varied cone pressure and throughput on pelleting characteristics of the diet. The conditioned mash was passed through a pellet press (CPM Master Model HD) equipped with a 32-mm thick die having 4 mm openings. Cone temperature was increased by 17% (linear effect, P<0.03) and kWh/t was increased by 36% (quadratic effect, P<0.03) as water addition into the mixer was increased from none to 3%. There was a trend for fines generated during pelleting to be reduced (P<0.07) but pellet durability index (tumbling box technique, P>0.4) and modified pellet durability index (five hexagonal nuts added into the tumbling box, P>0.2) were not affected by water addition into the mixer. Means for the none, 1.5%, and 3.0% additions of water into the mixer were 4.5, 4.0, and 3.7% for fines, 92, 93, and 94% for pellet durability index, and 90, 91, and 92% for modified pellet durability index. In conclusion, expanding corn-soy-based diets resulted in a pellet durability index of 92% for our control diet leaving little room for improvement in pellet quality when water was added into the mixer.

Key Words: Pellet, Expander-Conditioning, Pig

T190 Effects of fermented wild-ginseng culture by-products on growth performance, blood characteristics, meat quality and ginsenoside concentration of meat in finishing pigs. H. D. Jang*[1], J. H. Cho[1], Y. J. Chen[1], J. S. Yoo[1], J. J. Lee[2], M. H. Han[2], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Choognam, Korea*, [2]*Chungnam Regional Innovation Agency*, *Cheonan, Korea*.

This study was conducted to evaluate effects of fermented wild-ginseng culture by-product on growth performance, blood characteristics, meat quality and ginsenoside concentration of meat in finishing pigs. Forty-eight pigs (Landrace × Yorkshire × Duroc, 76.26±1.06kg average initial body weight) were used in 49d growth assay. Dietary treatments were included 1)CON(basal diet), 2)FWG1(basal diet + 2.5% fermented wild-ginseng cultures by-product replaced lupin in basal diet) and 3)FWG2(basal diet + 5.0% fermented wild-ginseng cultures by-product replaced lupin in basal diet). The pigs were allotted into three treatments with four replicate pens per treatment by completely randomized design. No differences were found among treatments for ADG, ADFI and gain/feed from 0day to 49day of the experiment(P >0.05). Dry matter digestibility was greater in FWG1 treatment than CON treatment (P<0.05). In cholesterol concentration of blood, HDL cholesterol was significantly higher in CON treatment than FWG1 treatment (P<0.05). In meat quality, TBARS was significantly lower in FWG1 and FWG2 treatments than CON treatment (P<0.05). In sensory evaluation, marbling was significantly higher in CON treatment than FWG1 treatment (P<0.05). Firmness in FWG2 and CON treatments were higher than FWG1 treatment (P<0.05). In meat color, L*-value of m. longissmus dorsi muscle was increased in FWG1 treatment compared to CON and FWG2 treatments (P<0.05). a* and b*-value of m. longissmus dorsi muscle were increased in CON and FWG1 treatments compared to FWG2 treatment(P<0.05). Ginsenoside concentration of meat was significantly higher in FWG2 treatment than CON treatment (P<0.05). In conclusion, fermented wild-ginseng culture by-product was effective for improving dry matter, TBARS, firmness, meat color and ginsenoside concentration of meat in finishing pigs.

Key Words: Fermented Wild-Ginseng Cultures By-product, Meat Quality, Pigs

T191 Effect of dietary *Bacillus subtilis* on growth performance, immunological cells change, fecal NH3-N concentration and carcass meat quality characteristics in finishing pigs. J. H. Cho*[1], Y. J. Chen[1], B. J. Min[1], H. J. Kim[1], K. S. Shon[1], O. S. Kwon[1], J. D. Kim[2], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Chungnam, Korea*, [2]*CJ Feed Co. Ltd.*, *Incheon, Korea*.

This experiment was conducted to investigate the effects of dietary Bacillus subtilis on growth performance, nutrient digestibility, immunological cells change, fecal noxious gas and carcass meat quality characteristics in finishing pigs. The dietary treatments were: 1) CON (basal diet), 2) BS0.1(basal diet + 0.1% Bacillus subtilis) and 3) BS0.2(basal diet + 0.2% Bacillus subtilis). Sixty crossbred (Landrace × Yorkshire × Duroc) pigs (89.5±0.11kg average initial body weight) were used in a 42 days growth trial. The pigs were assigned to the treatments according to body weight and each treatment had 5 replicates of 4 pigs per pen in a randomized complete block design. Through the entire experimental period, ADG and ADFI were not significantly different among the treatments. Pigs fed BS0.1 diet significantly increased their gain/feed compared to pigs fed CON and BS0.2 diets($P<0.05$). Also, dry matter(DM) and nitrogen(N) digestibilities were greater in the pigs fed BS0.1 diet than those fed CON diet($P<0.05$). There were no significant differences in fecal NH3-N concentration among the treatments. In blood assay for immunological cells change investigations, red blood cells (RBC) counts increased in the pigs fed BS0.2 diet compared to pigs fed CON and BS0.1 diets. There were no significant differences in carcass pH, drip loss, marbling and firmness. However, sensual color and a*(redness) value of meat in the pigs fed BS0.2 diet were higher than in pigs fed CON diet($P<0.05$). Therefore, this experiment suggested that Bacillus subtilis supplementation could improve nutrient digestibility, RBC counts and carcass meat color of pigs.

Key Words: Bacillus Subtilis, Carcass Meat Quality Characteristics, Pigs

T192 Evaluation of dietary L-carnitine or garlic powder on growth performance, dry matter and nitrogen digestibilities, blood profiles and meat quality in finishing pigs. Y. J. Chen*[1], J. H. Cho[1], I. H. Hwang[2], Y. Hyun[2], T. G. Go[2], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Choognam, Korea*, [2]*Easy Bio System Inc*, *Cheonan, Choognam, Korea*.

The effects of dietary L-carnitine or garlic powder supplementation on growth performance, dry matter (DM) and nitrogen (N) digestibilities, blood profiles and meat quality were investigated in this study. A total of 80 [(Landrace×Yorkshire)×Duroc] pigs with an initial BW of 59.14 kg were randomly assigned to four dietary treatments with five replications per treatment and four pigs per pen. Corn-soybean meal based diets were formulated as control diet and other treatment diets were supplemented with 250 mg/kg L-carnitine, and 1 g/kg or 2 g/kg garlic powder, respectively. After the feeding period, pigs which reached marketing body weight were collected meat samples from slaughter house. During the feeding period, growth performance was not affected by dietary treatments. Both the DM and N digestibilities were improved in 1 g/kg garlic powder supplemented treatment compared to control treatment (P<0.05). White blood cell (WBC) and lymphocyte concentrations were positive influenced by L-carnitine addition whereas garlic powder supplementation did not affect any tested parameter of blood profiles. Backfat thickness was decreased and muscle percentage was increased by the L-carnitine supplementation (P<0.05). Pigs administrated with 1 g/kg garlic powder also tended to decrease backfat thickness and had better meat color, pH value and water holding capacity. In conclusion, dietary supplementation of L-carnitine can increase WBC and lymphocyte concentrations and decrease backfat thickness while garlic powder supplementation can improve the nutrients digestibility and meat quality in finishing pigs.

Key Words: L-carnitine, Garlic Powder, Finishing Pigs

T193 Effects of dietary *Lactobacillus brevis* supplementation on growth performance, dry matter and nitrogen digestibilities, blood cell counts and fecal odor emission compounds in growing pigs. Y. J. Chen*[1], B. J. Min[1], J. H. Cho[1], Q. Wang[1], J. S. Yoo[1], J. D. Kim[2], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Choognam, Korea*, [2]*CJ Feed Inc*, *Incheon, Gyeonggi, Korea*.

This study was conducted to investigate the effects of dietary *Lactobacillus brevis* (3.4×10^8 CFU/g) supplementation on growth performance, DM and N digestibilities, blood cell counts and fecal odor emission compounds in growing pigs. Ninety six crossbred [(Landrace×Yorkshire)×Duroc] pigs with an initial BW of 24.60 ± 1.28 kg were used for 42-d feeding trial according to a randomized complete block design. Three corn-soybean meal based dietary treatments included: 1) CON (basal diet); 2) LB1 (basal diet + *Lactobacillus brevis* 0.2%) and 3) LB2 (basal diet+ *Lactobacillus brevis* 0.4%). There were three dietary treatments with eight replicate pens per treatment and four pigs per pen. Through the entire experimental period, ADG, ADFI and gain/feed were not significantly different among the treatments (P>0.05). Nitrogen digestibility was increased in LB1 and LB2 treatments compared to CON treatment (linear effect, P<0.05), however, DM digestibility was not significantly different among all the treatments (P>0.05). The WBC, RBC and lymphocyte concentrations in whole blood were not affected by treatments (P>0.05). Fecal NH_3-N and H_2S concentrations were significant decreased in LB2 treatment compared with CON treatment (linear effect, P<0.05). Fecal VFA (acetic acid and propionic acid) concentration was also reduced in LB2 treatment compared to CON treatment (linear effect, P<0.05). In conclusion, *Lactobacillus brevis* (3.4×10^8 CFU/g) supplementation at the level of 0.4% can improve nitrogen digestibility and decrease the concentrations of fecal odor emission compounds in growing pigs.

Key Words: *Lactobacillus Brevis*, Odor Emission Compounds, Growing Pigs

T194 Effects of feeding rye silage with different periods on growth performance, blood characteristics and carcass quality in finishing pigs. S. O. Shin*[1], J. H. Cho[1], Y. J. Chen[1], J. S. Yoo[1], J. W. Kim[1], Y. G. Han[2], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Choongnam, Korea*, [2]*Sungkyunkwan University*, *Suwon, Gyeonggi, Korea*.

This experiment was conducted to evaluate effects of feeding rye silage with different periods on growth performance, blood characteristics and carcass quality in finishing pigs. A total of sixteen [(Duroc×Yorkshire×Landrace)] pigs (90.26kg in average initial body weight) were used in individual cage for 30 days assay. Dietary treatments included 1) CON (basal diet), 2) S10 (basal diet for 20 days and 3% rye silage for 10 days) 3) S20 (basal diet for 10 days and 3% rye silage for 20 days) 4) S30 (3% rye silage for 30 days). During the overall periods, there were no significant differences in ADG and gain/feed ratio among treatments (P>0.05). However, ADFI was higher in CON treatment than others treatments (P<0.05). DM digestibility was higher in S20 treatment than S30 treatment (P<0.05). In blood characteristics, pigs fed rye silage were significantly decreased cortisol concentration compared with pigs fed CON diet (P<0.05). Backfat thickness was higher in CON treatment than S20 and S30 treatments (P<0.05). In fatty acid contents of leans, C18:0 and total SFA were significantly higher in CON treatment than others treatments (P<0.05). However, C18:1n9, total MUFA and U:S ratio were significantly lower in CON treatment than other treatments (P<0.05). In fatty acid contents of fats, C18:1n9 and MUFA were similar in S20 and S30 treatments. However, these were higher than CON or S10 treatments (P<0.05). In conclusion, feed intake, DM digestibility, cortisol concentration, backfat thickness and fatty acid composition of pork were affected by 20 d of rye silage feeding.

Key Words: Rye Silage, Carcass Characteristics, Finishing Pigs

T195 Effects of phytogenic substances on growth performance, nutrients digestibility, fecal noxious gas content, blood characteristics, milk characteristics and reproduction in sows and litters performance. Q. Wang*, H. J. Kim, J. H. Cho, Y. J. Chen, J. S. Yoo, and I. H. Kim, *Dankook University*, *Cheonan, Choognam, Korea*.

A total of forty sows (Landrace×Yorkshire) were used to determine the effects of phytogenic feed additive (PFA) on growth performance, nutrients digestibility, fecal noxious gas content, blood characteristics, milk characteristics and litters performance. Dietary treatments included: 1) Control (CON; basal diet), 2) PFA (basal diet + 0.04% phytogenic feed additive). Through the entire experimental period,

ADFI, backfat loss and return-to-estrus intervals were not affected by the treatments ($P>0.05$). Digestibility of DM was increased ($P<0.05$) in sows fed PFA diet compared with sows fed the CON diet. Fecal ammonia nitrogen (NH_3-N) measured at the end of experiment was reduced ($P<0.05$) in sows fed PFA diet. No statistical differences ($P>0.05$) were found in total protein, albumin, immunoglobulin G (IgG), red blood cells (RBC) counts, white blood cells (WBC) counts and lymphocyte on the day of farrowing. On d 1 of lactation, albumin and lymphocyte were decreased ($P<0.05$) whereas WBC was increased significantly ($P<0.05$) for sows fed the PFA diet. On d 21 of lactation, blood characteristics (RBC and WBC) of sows were increased ($P>0.05$) in PFA treatment. IgG content in milk was increased by PFA on day of farrowing ($P<0.05$). Milk protein and solid concentrations were lower in colostrum ($P<0.05$) for sows fed the CON diet. Furthermore, lactose, IgG and IgA in colostrum increased considerably for sows fed PFA diet. There was no difference in piglet performance between treatments ($P>0.05$). In conclusion, feeding 0.04% of PFA improved DM digestibility, RBC and WBC concentrations in blood, and lactose, IgG and IgA production in colostrums and decreased noxious gas concentration.

Key Words: Phytogenic Additives, Sows, Litters

T196 Effects of supplemental humic substances on quality and fatty acid profile of meat in finishing pigs. Q. Wang*, J. H. Cho, Y. J. Chen, J. S. Yoo, and I. H. Kim, *Dankook University*, *Cheonan, Choognam, Korea*.

A total of forty-eight finishing pigs were used to determine the effects of humic substances (HS) on growth performance, blood characteristics and meat quality. Finishing pigs were randomly assigned by weight to three treatments. Dietary treatments included: 1) Control (CON; basal diet), 2) HS1 (basal diet +5% humic substances) and 3) HS2 (basal diet + 10% humic substances). During the entire experimental period, results showed that addition of 100 g kg^{-1} HS to diet significantly increased ADG and G:F ($P<0.05$). At the end of experiment, lymphocyte of pigs fed HS1 or HS2 diet was higher ($P<0.05$) than that for pigs fed CON diet. The Minolta color parameter a* for pigs fed HS2 was similar to that for pigs fed HS1, however, it was higher ($P<0.05$) than that for pigs fed CON diet. Inclusion of either 5 or 10% HS decreased backfat thickness ($P<0.05$). Marbling score was increased ($P<0.05$) in diets supplemented with HS at level of 10%. In the lean samples, HS1 increased ($P<0.05$) the concentrations of C16:0, C18:0, saturated fatty acid (SFA) and unsaturated fatty acid (USFA) and decreased ($P<0.05$) the concentration of C20:0. HS2 diet increased ($P<0.05$) the U:S ratio. In contrast to fat samples, HS2 diet increased ($P<0.05$) the concentrations of C14:0, C18:2. HS1 diet increased ($P<0.05$) the concentrations of C18:0 and SFA and decreased ($P<0.05$) UFA and U:S ratio. The results suggest that HS could be used as feed additive in diet. It could improve growth performance, immunity system and meat quality.

Key Words: Humic Substance, Meat Quality, Finishing Pigs

T197 Effects of dietary herbs and coral mineral complex on growth performance, nutrients digestibility, blood characteristics and meat quality in finishing pigs. Y. Wang*, J. H. Cho, Y. J. Chen, J. S. Yoo, Q. Wang, and I. H. Kim, *Dankook University*, *Cheonan, Choognam, Korea*.

Eighty crossbred ([Landrace×Yorkshire]×Duroc) pigs (initial BW of 58.06 ± 1.47 kg) were used to evaluate the potential effect of supplemental herbs and coral mineral complex (HC), which including 40% herbs: *Semen Ziziphi Spinosae* (Spina Date Seed) 10%, *Pollen Pini* (Pine Pollen) 5%, *Cortex Mori* (White Mulberry Root-bark) 5%, *Semen Plantaginis* (Plantago asiatica) 5%, *Radix Achyranthis Bidentatae* (Achyranthes root) 5%, *Rhizoma Acori Tatarinowii* (Grassleaf Sweelflag Rhizome) 5% and *Herba Capsellae* (Shepherdspurse Herb) 5%, 50% coral mineral (Ca 22%, P 2%, Mg 3%, Mn 0.5%, Na 2%, Cl 1%, Zn 0.5%, Fe 1.5%, Se 1% and other 16.5%) and 10% cromophore, on growth performance, nutrients digestibility, blood characteristics and meat quality in a 8 wk growth trial in finishing pigs. There are 4 pigs per pen and 5 replicates per treatment. Dietary treatments included: 1) CON (control; basal diet), 2) HC0.05 (basal diet + 0.05% HC), 3) HC0.1 (basal diet + 0.1% HC) and 4) HC0.2 (basal diet + 0.2% HC). Average daily feed intake decreased linearly with increasing HC level during wk 4-8 ($P<0.01$) and overall period ($P<0.05$). However, this decrease did not affect ADG and linearly increased G:F during wk 4-8 ($P<0.05$) and overall period ($P<0.10$). Digestibility of DM and N were not affected by dietary treatments ($P>0.05$). Also, IgG concentration was linearly increased with an increasing HC level ($P<0.01$). Cortisol concentration tended ($P<0.10$) to be influenced linearly by level of HC. Supplementation of HC did not improve any measured meat quality ($P>0.05$). Our data indicate that HC inclusion can increase the G:F, as well as IgG and cortisol concentration, however, it had no effects on nutrients digestibility and meat quality.

Key Words: Herb, Coral Mineral, Finishing Pigs

T198 Effects of dietary supplemental Megazone® on growth performance, nutrients digestibility, blood characteristics, meat quality and carcass traits in weaning-to-finishing pigs. Y. H. Kim[1], Y. Wang*[2], J. C. Park[1], H. J. Jung[1], J. H. Cho[2], Y. J. Chen[2], J. S Yoo[2], I. C. Kim[1], S. J. Kim[1], and I. H. Kim[2], [1]*National Livestock Research Institute, RDA*, *Cheonan, Choognam, Korea*, [2]*Dankook University*, *Cheonan, Choognam, Korea*.

This study was conducted to investigate the effects of Megazone® (an alumninosilicate mineral mix, which include 30% quartz, 30% feldspar, 30% ceramic and 10% biotite) supplementation on growth performance, nutrients digestibility, blood characteristics, meat quality and carcass traits in weaning-to-finishing pigs. A total of 48 crossbred ([Landrace×Yorkshire]×Duroc) pigs with initial BW of 4.46 ± 0.18 kg were used in a 21 wks trial. Pigs were randomized allocated to two dietary treatments. There were 6 pens per treatment and 4 pigs per pen. Dietary treatments included: 1) CON (basal diet) and 2) MT (basal diet + 0.8% Megazone®). Through the entire experimental period, there were no effects of dietary Megazone® supplementation on growth performance, nutrients digestibility, blood characteristics and meat quality ($P>0.05$). Also, market weight and backfat thickness were

not different between the two treatments (P>0.05). However, carcass weight and carcass ratio in MT treatment were improved compared with CON treatment (P<0.05). In conclusion, supplementation of Megazone® can increase carcass weight and carcass ratio in weaning-to-finishing pigs, however, it had no effects on growth performance, nutrients digestibility, blood characteristics and meat quality traits.

Key Words: Megazone®, Alumninosilicate, Carcass

T199 Interaction of dietary nutrient density and crowd density on growth performance, nutrients digestibility, blood characteristics and hormone concentration in growing pigs. Y. Wang*, J. H. Cho, Y. J. Chen, H. J. Kim, J. S. Yoo, Q. Wang, Y. Huang, and I.H. Kim, *Dankook University*, *Cheonan, Choognam, Korea*.

A study was conducted to determine the interaction of feeding a high nutrient diet (3,350Mcal/kg, Crude protein 19%, Lysine 1%, Ca 0.8%, P 0.7%) vs. a low nutrient diet (3,350Mcal/kg, Crude protein 18%, Lysine 0.9%, Ca 0.7%, P 0.6%), as well as the crowd density (3, 4 or 5 pigs per pen), on growth performance, nutrients digestibility and blood characteristics. Ninety six crossbred ([Landrace×Yorkshire]×Duroc) pigs (initial BW of 23.47±1.35 kg) were assigned to a 2×3 factorial arrangement of treatments. Growth data were collected at d 0, d 18 and d 36. Overall the experiment, nutrient density main effect were observed on ADG, ADFI and G/F (P<0.05). Also crowd density main effect and nutrient density×crowd density interaction were observed on G/F. Both the DM and N digestibility were higher in the high nutrient diet treatment compared with low nutrient diet treatment (P<0.05). Neither the dietary nutrient density nor crowd density main effects were found on blood characteristics (P>0.10) in this experiment. Epinephrine and norepinephrine concentrations were higher (P<0.05) in high nutrient diet treatment compared with low nutrient diet treatment. Neither the dietary nutrient density nor crowd density main effects were found on cortisol concentration (P>0.05). Our data indicate that significant interaction between nutrient density and crowd density treatments for G/F. ADG and ADFI, as well as epinephrine and norepinephrine concentration have significant nutrient density main effect. Neither the dietary nutrient density nor crowd density effects were found on blood characteristics as well as cortisol concentration in this experiment.

Key Words: Crowd Density, Nutrients Density, Growing Pigs

T200 The effects of environment-friendly diets on the growth performance, nutrient digestibility, fecal excretion, nitrogen excretion and emission gas in swine manure of growing pigs. J. S. Yoo*[1], J. H. Cho[1], Y. G. Chen[1], H. J. Kim[1], Q. Wang[1], Y. Hyun[2], T. G. Ko[2], C. S. Park[3], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Choognam, Korea*, [2]*Dodram B&F Inc.*, *Eumseong, Gyeonggi, Korea*, [3]*EASY BIO System, Inc*, *Seoul, Korea*.

Two experiments were conducted to determine the effects of environment-friendly diets on growth performance, fecal excretion, N excretion and emission of gas in manure for pigs. In Exp. 1, 96 cross-bred pigs were allocated into four treatments. Treatments were 1)AME(adequate ME diet, 3,265 kcal/kg), 2)LME (lower ME diet, 3,100 Kcal/kg), 3)LME 0.05(lower ME diet+α-galactosidase & β-mannanase0.05 %) and 4)LME 0.1(lower ME diet+α-galactosidase & β-mannanase0.10 %). ANE had lower ADFI than others(P<0.05). DM digestibility in AME and LME 0.1 had greater than LME(P<0.05). Energy digestibility is higher in pigs fed AME and LME 0.1 than others(P<0.05). In Exp. 2, 24 crossbred pigs(Avg. 33.71 kg) were used for a 14d trial. Treatments were 1)CP 18% without *Bacillus* sp., 2)CP 18%diet+*Bacillus* sp.0.05%, 3)CP 14% without *Bacillus* sp. and 4)CP 14% diet+ *Bacillus* sp.0.05%. N intake was higher for CP 18% diets than CP 14% diets (P<0.05). DM, N, and energy digestibility were affected by probiotics (P<0.05). With the high CP in diets, energy and N digestibility, urinary N %, urinary N excretion and total N excretion were increased compared with low CP in diets (P<0.05). Among the treatments, DM and N digestibilities, fecal N excretion and N absorption were decreased (P< 0.05), however, fecal excretion, fecal N, urinary N percent, urinary N excretion and total N excretion were increased (P<0.05) when pigs fed without probiotics diets compare with pigs fed with probiotics diets. DM and N digestibility, fecal excretion, fecal N excretion, urinary N percent, urinary N excretion, total N excretion, N absorption and N adsorption ratio were CP × probiotic interactions in (P<0.05). Ammonia(P<0.01) and H2S(P<0.05) in manure were lower in CP 14% diets than CP 18% diets. Also, ammonia and H_2S in manure were CP × probiotic interactions in (P<0.05). In conclusion, low energy and reduction of CP dietary added enzyme and probiotics improved nutrient digestibility and reduced odors emission in manure for growing pigs.

Key Words: Environment-Friendly Diets, Carbohydrase, Probiotics

T201 Growth performance in boars fed diets supplemented with organic selenium. S. M. Speight*, M. J. Estienne, and A. F. Harper, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

The objective was to compare growth performance in boars fed diets supplemented with selenium from either organic or inorganic sources. Crossbred boars (n = 117; 8.3 kg BW) weaned at approximately 28 d of age, were blocked by BW, placed in nursery pens (three boars/pen) and assigned from within block to three treatments: I. a basal diet with no supplemental selenium (controls), II. basal diet supplemented with 0.3 ppm organic selenium (Sel-Plex; Alltech, Inc., Nicholasville, KY) and, III. basal diet supplemented with 0.3 ppm sodium selenite (Premium Selenium 270; North American Nutrition Co., Inc., Lewisburg, OH) (n = 13 pens/treatment). Boars had ad libitum access to feed and water during the 5-wk trial. Among groups, ADG (471 g), ADFI (895 g) and feed/gain (1.9) were similar (P > 0.1). Blood selenium concentrations (ppb) were higher (P < 0.01) for boars consuming Sel-Plex (107.5 ± 4.8) or sodium selenite (114.7 ± 4.8) compared to controls (28.4 ± 4.8). Boars were moved to a grower-finisher barn and continued to receive, on an ad libitum basis, either a basal diet or a basal diet supplemented with either 0.3 ppm Sel-Plex or sodium selenite (n = 11 pens/treatment). The trial ended when boars averaged 136.7 kg. Among groups, ADG (1045 g) and ADFI (2716 g) were similar (P > 0.1). Feed/gain was affected by treatment (P = 0.02) and was lower (P < 0.06) for boars fed Sel-Plex (2.65 ± 0.03) compared with boars fed sodium selenite (2.72 ± 0.03) or controls (2.76 ± 0.03). Backfat thickness (tenth-rib; 12.6 mm) and loin depth (67.0 mm), determined by ultrasound (Sonograder; Renco Corp., Minneapolis, MN), was not affected by treatment (P > 0.1). Blood selenium concentrations (ppb) were higher (P < 0.01) in boars consuming Sel-Plex (198.9 ± 5.5) than in boars consuming sodium selenite (171.4 ± 5.4) or controls (26.7 ± 5.4). In summary, an organic

source of selenium failed to alter ADG or feed consumption in growing boars, but enhanced feed conversion efficiency during the grower-finisher phase of production. (Funded by Alltech, Inc.)

Key Words: Boars, Selenium, Growth

T202 A polymorphism in the calcitonin receptor alters metabolic response to dietary phosphorus deficiency. L. S. Alexander*, S. A. Cutler, M. F. Rothschild, and C. H. Stahl, *Iowa State University*, *Ames*.

While much research has examined methods for reducing the need for dietary phosphate (P) supplementation, little has examined how genetics may affect this need. We have identified a polymorphism in the calcitonin receptor gene, which based on previous work in our laboratory, influences the response to dietary P deficiency. Gilts (42, 8.1+ 2 kg BW) were selected based on this genotype and fed either a P adequate diet or a 20% P deficient diet over a 15 wk period. Each of the genotypes (11, 12, and 22) was evenly distributed across diets. At the end of the trial, radial and metacarpal bones from one leg per pig were collected for bone strength analysis and determination of ash %. Data was analyzed using the GLM procedure of SAS with diet, genotype and genotype*diet treated as fixed effects. Initial BW and final BW were used as covariates for growth performance and bone strength, respectively. Our diets caused a minor P deficiency detectable by reduced (P<0.05) plasma P by 8wk, which remained throughout the study. At 8wk, a significant (P <0.01) genotype*diet effect was seen in plasma levels of 1,25 $(OH)_2D_3$; however, by 14wk only a diet effect remained with the P deficient animals having higher (P<0.05) levels in plasma. Dietary P deficiency lowered bone strength (load at yield and Young's modulus) and ash % (P<0.05), and there tended (P<0.1) to be genotype*diet interactions in these measures in the metacarpals. It appears that during P adequacy, the 11 and 12 genotypes tended to have stronger bones with higher ash % than their 22 counterparts. However under dietary P deficiency, the 11 and 12 genotypes had much greater losses (P<0.05) in all of these bone measures than the 22 pigs. There were no differences in growth performance based on diet, genotype, or the interaction of the two, suggesting that minor P deficiency still has a significant impact on bone integrity, and that this genotype is associated with pigs' response to P deficiency.

Key Words: Phosphorus, Polymorphism, Pig

T203 Evaluation of different additives in weaned pigs. K. J. Touchette*, M. D. Newcomb, and D. W. Giesting, *Cargill Animal Nutrition*, *Elk River, MN*.

A trial was conducted with 48 weaned pigs (17 d, 5.41 ± .11 kg) to evaluate the effect of non-antibiotic additives alone or in combination with antibiotics on nursery performance. Pigs were weaned and individually housed and assigned to one of 4 treatments in a 2x2 factorial arrangement in a RCBD with 2 levels of antibiotics (AB, none or added) and 2 levels of additives (ADD, none or added). The antibiotic used in this study was carbadox fed at 55 mg/kg. A nonspecific stressor was used in this trial. Twelve late nursery pigs that had been reared in an on-site, continuous pig flow environment were housed with nose-to-nose access with test pigs used in this project. Previous work has shown that this stressor application dramatically increases the responsiveness to antibiotic inclusion. The additives used in this study were a combination of enzymes, sweetener, and a *Bacillus* DFM. Pigs were fed a 3-phase 40 d nursery program with diet changes on days 11 and 20. In the first 11 d, both AB (p< .06) and ADD (p< .12) improved ADG. There was an interaction (p< .07) for ADFI, with ADD improving ADFI when AB were in the diet, but no improvement was seen without AB. Feeding AB improved (p < .13) G/F. For phase 2, ADD (p < .11) improved ADG, AB (P < .16) improved ADFI, while there was an interaction (p < .05) for G/F, with ADD improving G/F without AB in the diet, and having no effect on G/F with AB in the diet. For phase 3, there was no effect of trt on feed intake, while there were interactions for both ADG (p < .12) and G/F (p < .01). ADD improved both ADG and G/F in diets without AB, while having no effect in diets with AB. For the entire 40 d nursery trial, both ADD (p < .05) and AB (p < .03) improved ADG, and AB (p < .11) improved ADFI, while there was an interaction (p < .01) for G/F. ADD improved G/F without AB in the diet, while ADD did not affect G/F with AB in the diet. This study demonstrates that this additive mixture and carbadox improve nursery performance, with the best response to ADD coming in diets without AB.

Key Words: Swine, Antibiotics, Additives

T204 Effect of an *Escherichia coli*-derived phytase on bone mineralization, and total and soluble phosphorus in growing pigs fed corn-soybean meal based diets. C. T. Kadzere*[1,4], E. van Heugten[1], J. S. Sands[2], R. Maguire[1,3], and M. Morrow[1], [1]*North Carolina State University*, *Raleigh*, [2]*Danisco Animal Nutrition*, *Marlborough, UK*, [3]*Virginia Polytechnic and State University*, *Blacksburg*, [4]*PDT Global Institute, Inc.*, *Greensboro, NC*.

The effect of an *Escherichia coli*-derived phytase (Phyzyme XP™ 5000L) on bone mineralization, soluble phosphorus P (SP), and total phosphorus P (TP) in feces was evaluated in a 43-d, RCBD study using 30 male, castrated growing pigs (starting BW = 25 kg) fed corn-soybean meal based diets. Pigs were placed in individual pens and assigned to 5 groups of 6 animals each and fed one of 5 diets. A positive control diet (PC) contained NRC (1998) recommended levels of 0.49% TP and 0.52% Ca. TP and Ca in the negative control (NC) diet were reduced to 0.36% and 0.43%, respectively. Diets 250, 500, and 1000 were the same as NC with phytase included at 250, 500, and 1000 U/kg phytase, respectively. Pigs were weighed weekly and had free access to feed and clean water. On d-21 and d-43 fecal grab samples were collected and analyzed for SP, and TP was analyzed in pooled samples collected on d 36, 37, and 38. Pigs were slaughtered on d 43, the right foot removed, and the metacarpal bone taken and analyzed for bone ash. In addition, bone mineral content (BMC), and bone mineral density (BMD) were determined using dual X-ray absorptiometry. Fecal TP (P < 0.0001) and SP (P < 0.0001) decreased linearly with increasing phytase dose. Bone ash increased linearly with increase in phytase dose to 1000 FTU/kg, while only 500 FTU/kg phytase was required to restore bone ash to that of the PC diet. In contrast, the response in BMC and BMD was quadratic in nature with no further improvement above additions of 250 FTU/kg. The results suggest phytase allows dietary Ca and TP in swine diets to be reduced without compromising bone mineralization while decreasing SP and TP excretion.

Key Words: Phosphorus, Phytase, Bone Mineralization

T205 Synthetic lysine inclusion rates in pigs from 1.5 to 5.5 kg fed liquid diets. A. E. Ikard*[1], R. J. Harrell[2], J. Odle[1], L. R. Gast[1], and J. H. Eisemann[1], [1]*North Carolina State University*, *Raleigh*, [2]*Novus International Inc.*, *St. Louis, MO*.

This experiment was designed to determine the amount of synthetic lysine (SL) that could replace protein and maintain performance similar to animals on a control diet containing no SL. Pigs (1.62 ± 0.20 kg BW; age 1d) were randomly allotted to treatments which replaced 0 to 40% of lysine from protein with SL, while maintaining similar amounts of GE and total lysine. The diets were fed on a restricted (RT) basis (n=4/treatment) in order to reduce intake differences among treatments. An additional group was fed the 0% SL diet ad libitum (AL; n=5) to determine feed intake level. Intake for RT pigs was restricted to 80% of AL and adjusted on a daily basis. Pigs fed the AL diet had greater (P<0.01) ADG, G:F, water, CP, fat, and ash accretion than pigs fed RT diets. ADG, G:F, water, CP, and ash accretion decreased (P<0.05) linearly as SL increased in RT diets. CP accretion also showed a quadratic effect (P<0.05) as the accretion decreased more rapidly at greater SL inclusion. Fat accretion increased (P<0.05) linearly as SL increased in RT diets. BUN concentration did not differ (P>0.05) among pigs fed RT diets, but was greater (P<0.01) for pigs fed the AL than RT diets. ADG and CP accretion data were fit to a quadratic equation to estimate the level of SL inclusion that would produce ADG or CP accretion at 95% of the 0% SL diet. These values were 14.8% and 19.0% SL, for ADG and CP accretion, respectively.

Table 1: Effect of SL inclusion (%) on ADG (g/day), G:F, and accretion (g/day)[1,2]

	0%	10%	20%	30%	40%	0% AL
ADG[3]	286	283	268	252	229	363
G:F[3]	1.12	1.14	1.07	0.97	0.86	1.15
Water[3]	180.6	172.8	171.3	155.9	134.2	220.2
CP[3,4]	38.6	38.1	35.4	32.7	26.3	48.7
Fat[3]	16.4	19.6	22.5	25.6	28.4	27.7
Ash[3]	5.4	4.6	4.9	4.5	3.6	6.2

[1]Least square means. [2]RT and AL diets differ for all variables (P<0.01). [3]Linear response to SL level within RT (P<0.01). [4]Quadratic response to SL level within RT (P<0.05).

Key Words: Liquid Diet, Lysine, Pigs

T206 Effect of an *Escherichia coli*-derived phytase on nutrient digestibility in corn-soybean meal based diets for growing pigs. C. T. Kadzere*[1,4], E. van Heugten[1], J. S. Sands[2], R. Maguire[1,3], and M. Morrow[1], [1]*North Carolina State University*, *Raleigh*, [2]*Danisco Animal Nutrition*, *Marlborough, UK*, [3]*Virginia Polytechnic and State University*, *Blacksburg*, [4]*PDT Global Institute, Inc.*, *Greensboro, NC*.

The effect of an *Escherichia coli*-derived phytase (Phyzyme XP™ 5000L) on nutrient digestibility was evaluated in a 43-d, RCBD study using 30 male castrated pigs fed corn-soybean meal based diets. Pigs were placed in individual pens and six animals assigned to each of 5 diets: A positive control diet (PC) with NRC (1998) recommended levels of 0.49% total P (TP) and 0.52% Ca, respectively. Ca and TP in a negative control (NC) diet were reduced to 0.36% and 0.43%, respectively. Diets 250, 500, and 1000 were created by adding phytase to the NC diet to achieve 250, 500, and 1000 U/kg of phytase in feed, respectively. Pigs were weighed weekly and had free access to feed and clean water. Fecal grab samples were collected on 3 consecutive days (d-36, 37, and 38) and pooled. Ileal samples were collected from euthanized pigs on d-43. Feed, fecal, and ileal samples were analyzed for DM, GE, N, Ca, P, Na, K, Cl, amino acids (AA), phytase activity, and acid insoluble ash (indigestible marker). Growth performance was not affected by treatment (P > 0.10). Increasing phytase dose increased the apparent fecal digestibility of P (P < 0.001), fat (P < 0.03) and Cl (P < 0.03). Increasing phytase dose increased the apparent ileal digestibility of P, fat, ash, and Cl in a linear manner to the highest phytase dose of 1000 FTU/kg (P < 0.05). Improvements in ileal DM and CP digestibility with added phytase approached significance (P < 0.07). The apparent ileal digestibility of AA was not different between the NC and PC diets (P > 0.10). However, increasing phytase dose increased digestibility of all AA in a linear manner, being greatest for diets with 1000 FTU/kg phytase and exceeding that of both NC and PC diets. These findings suggest that phytase increases phytate P and trace mineral availability, and has additional benefits, including improved digestibility of DM, CP, fat, and AA.

Key Words: Pigs, Phytase, Nutrient Digestibility

T207 Improving fat utilization by the weanling pig: effects of emulsification, diet physical form and fatty-acid-chain-length on growth performance. K. Price*[1], L. Xi[1], E. van Heugten[1], G. Willis[2], and J. Odle[1], [1]*North Carolina State University*, *Raleigh*, [2]*Milk Specialties Co.*, *Dundee, IL*.

Previous research indicates that dietary fat utilization by the newly-weaned pig is low, while fat digestive capabilities prior to weaning are very high. Sow milk contains approximately 40% fat whereas nursery diets are rarely formulated to contain more than 5%. The aim of this experiment was to determine if emulsification (plus or minus Tween-80), physical form of the diet (liquid vs dry) or fatty acid chain length (medium vs long chain triglyceride) effect fat utilization by the newly weaned pig. Pigs (N= 96) were weaned at 20 ± 0.30 d of age (6.8 ± 0.03 kg) and fed one of eight treatments for 14 d according to a 2x2x2 factorial design. The MCT fat contained primarily C8 and C10 fatty acids while the LCT fat was supplied by choice white grease. Each fat was spray dried with or without the inclusion of Tween-80 emulsifier (at 2% w/w) and comprised 12% of the final diets. Diets were otherwise formulated to exceed NRC nutrient requirements. Liquid diets were reconstituted with water to 13% dry matter and were offered ad libitum via milk-replacer feeders (Kane Manufacturing). Diet physical form greatly accelerated piglet growth (P<0.05), with liquid-fed pigs (488 g/d) out gaining dry-fed pigs (333 g/d) by 47%. Triglyceride chain length also impacted growth (P<0.05), with pigs fed LCT outperforming MCT-fed pigs by 23%. Effects of emulsifier were not detected (P>0.1). Accelerated growth was accompanied by elevated feed intake which was 15 % greater for liquid-fed than for dry-fed pigs and was 22% greater for pigs fed LCT vs MCT. Accordingly, gain:feed was improved by 28% in liquid-fed pigs (P<0.05). Collectively, we infer that feeding liquid diets containing long chain triglycerides will enhance weanling pig growth performance.

Key Words: Weanling Pigs, Milk or Dry Diet, FA Chain Length

T208 Reproductive response of replacement gilts to dietary beta-carotene supplementation. C. A. Mejia-Guadarrama*[1,2], I. Ordoñez-Reyes[2], E. Villagómez-Amezcua[3,2], J. A. Rentería-Flores[1,2], and J. A. Cuarón-Ibargüengoytia[1,2], [1]*CENID-Fisiologíia Animal INIFAP*, *Queretaro, Mexico*, [2]*FESC-Universidad Nacional Autónoma de México*, *Queretaro, Mexico*, [3]*CENID-Microbiología INIFAP*, *D.F., México*.

To determinate the effect of beta-carotene (BC) on the ovulation rate and embryo survival in gilts, a total of 30 LND x DRC gilts were used with an initial weight and age of 130±3.5 kg and 270±0.5 days, respectively. Estrous were synchronized using Regumate in feed for 18 days. Gilts were allotted to two treatments: 1) SBC (BC free) or 2) WBC (BC 255mg/day in feed). Diets were fed starting on day 22 before AI and until day 31 pos-breeding. During the phase previous to AI, gilts received 3 kg/day of a single growing feed (3.2 Mcal ME/kg and 17.5% de CP), containing or not BC (85 mg/kg). Once gilts were inseminated, they were fed 2.2 kg/day of a single gestation feed (3 Mcal ME/kg and 15% CP), containing or not BC (115 mg/kg), until sacrifice. Estrous detection was made twice a day. Gilts were artificially inseminated, and weighed at the beginning of the experiment, after AI, and a day before sacrifice. All gilts were slaughtered at day 31±2, after inseminated, to collect the reproductive tract (ovaries and uterus). Data were analyzed by ANOVA for a completely randomized design. The live body and ovaries weights of gilts were similar (P>0.45) between treatments. Addition of BC to the diet did not modify (P>0.80) the ovulation rate or the ovulation quality (presence of cysts) of the gilts. The potential loss of embryos was lower (P=0.06) in WBC gilts than in SBC gilts (2.2 vs. 3.3 embryos, respectively). When the relative risk of potential loss of embryos was calculated, we found that using BC reduced the loss of embryos 56% compared to SBC. We conclude that BC intake does not alter ovulation rate, but may decrease the risk of embryo losses by 44% compared to gilts not fed BC in diet.

Key Words: Beta-carotene, Embryo Survival, Gilt

T209 The effects of Quantum™ phytase on pig bone ash percentage and performance. A. L. Wagner*[1], A. F. Harper[1], M. J. Estienne[1], M. E. Persia[2], M. R. Bedford[2], and J. Escobar[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*Syngenta Animal Nutrition*, *Research Triangle Park, NC*.

Fat-free metacarpal bone ash percentage (FFBAP) is a sensitive measure of the phosphorus (P) adequacy of swine diets. Two experiments were conducted to determine the effects of two doses of Quantum™ phytase (QP) on FFBAP and performance of pigs fed reduced available P (AP) diets. The positive control diet (PC) met or exceeded NRC (1998) recommendations for all nutrients. The negative control diet (NC), which was similar to PC but deficient in AP, was supplemented with 0, 250 or 500 FTU of QP/kg diet. Pigs were fed a common diet until they reached 10 kg BW, after which experimental diets were fed until the unsupplemented NC group reached 20 kg BW. All pigs (Exp. 1) or four pigs per pen (Exp. 2) were killed and the front right foot was collected for FFBAP analysis. Data were analyzed using ANOVA and means separated using specific pre-planned contrasts. In Exp.1, 24 pigs per treatment (3 pigs per pen of mixed sex) were used. A reduction ($P < 0.01$) in FFBAP (5.5% units), ADFI (119 g), and ADG (155 g) was measured in pigs fed unsupplemented NC compared to PC. Addition of QP to NC increased FFBAP (2.2 and 2.6% units, $P < 0.003$), ADFI (76 and 81 g, $P < 0.06$) and ADG (63 and 49 g, $P < 0.04$) for the 250 and 500 FTU/kg diets, respectively. In Exp. 2, 120 pigs per treatment (12 pigs per pen, split sex with 5 pens of barrows and 5 of gilts per treatment) were used. A reduction ($P < 0.0001$) in FFBAP (5.6% units), ADFI (159 g), and ADG (141 g) was measured in pigs fed unsupplemented NC compared to PC. Addition of QP to NC increased FFBAP (1.8 and 2.8% units, $P < 0.003$), ADFI (18 g, $P = 0.19$ and 23 g, $P = 0.07$) and ADG (18 g, $P = 0.17$ and 50 g $P = 0.004$) for the 250 and 500 FTU/kg diets, respectively. These data demonstrate the ability of QP to increase bioavailability of phytate P and consistently increase pig FFBAP, as well as to increase ADFI and ADG in pigs fed AP deficient diets.

Key Words: Pig, Phytase, Bone Ash

T210 Effect of substitution of sorghum by corn on performance of growing/finishing barrows and gilts. H. Bernal-Barragán*[1], E. Castellanos-Martínez[2], E. M. Romero-Treviño[2], E. Gutiérrez-Ornelas[1], M. A. Cerrillo-Soto[3], A. S. Juárez-Reyes[3], H. Morales-Treviño[1], and J. Colín-Negrete[1], [1]*Fac. de Agronomía UANL*, *Marín N.L., México*, [2]*Instituto Tecnológico de Altamira*, *Altamira, Tamaulipas*, [3]*Fac. de Medicina Veterinaria y Zootecnia UJED*, *Durango, Dgo, México*.

One 35-d trial was conducted to determine the effects of four type of grain mixtures (sorghum or corn) on productive performance of growing pigs. A total of twenty-four crossbred (Landrace × Yorkshire × Duroc) pigs, 12 barrows and 12 gilts (initial body weights of 47.2 ± 4.2, and 43.6 ± 3.8 kg, respectively) were randomly allocated into a 4 × 2 factorial treatment experiment. Pigs were individually fed in 1.5 × 2.2 m pens, daily feed intake and pig's weight were recorded every 7 days. Treatments were related to the grain mixture of diet: 1) 100% sorghum, 0% corn (C0), 2) 65% sorghum, 35% corn (C35), 3) 35% sorghum, 65% corn (C65), and 4) 0% sorghum, 100% corn (C100). Diets were formulated with 16.2% CP, 0.80% Lysine, 0.62% Ca, and 0.50% P. Metabolizable energy content for treatments 1 to 4 were 3.22, 3.26, 3.31 and 3.37 Mcal/kg, respectively. Results were analyzed with the General Linear Model of SPSS, and means were compared using the Duncan test. Barrows had higher (P<0.1) ADG than gilts when they received C65 (1.085 *vs* 0.818 kg/d) and C35 diets (0.995 *vs* 0.839), but ADG was similar (P>0.1) between gender when diets contained either only sorghum (0.912 *vs* 0.919 kg) or corn (0.914 *vs* 0.974 kg/d for barrows and gilts, respectively). No treatment effects (P>0.05) were found for ADFI (3.602 kg/d) and F:G (3.95:1). The highest economic return by animal (P<0.1) was obtained for barrows fed the C35 diet, the lowest for gilts receiving C35 and C65 diets. In conclusion, feeding barrows with diets including a mixture of sorghum and corn, and gilts with either only sorghum or corn may improve the performance and economic return of swine production units.

Key Words: Pigs, Sorghum, Corn

T211 The effects of feeding diets naturally-contaminated with *Fusarium* mycotoxins on protein metabolism in late gestation and lactation of sows and the efficacy of a polymeric glucomannan adsorbent in preventing these effects. G. Diaz-Llano*, C. Caballero-Cortes, R. M. Friendship, and T. K. Smith, *University of Guelph*, *Guelph, ON, Canada*.

The feeding to swine of grains naturally contaminated with *Fusarium* mycotoxins reduces feed intake and increases body weight loss in

lactation. An experiment was conducted to investigate the effects of feeding grains naturally contaminated with *Fusarium* mycotoxins on the metabolic state of skeletal muscle of sows during late gestation and lactation, and to test the efficacy of a polymeric glucomannan mycotoxin adsorbent (GMA, Mycosorb, Alltech, Inc., Nicholasville, KY) in preventing these effects. A completely randomised block design, 32 sows, 8 sows per treatment was employed. Diets were corn, wheat and soybean meal based and were fed from 91 days of gestation until weaning on d 21 post farrowing. The treatments were: (1) control (C), (2) contaminated grains (CG) (3.6 ppm DON + 0.3 ppm 15-acetyl DON + 0.2 ppm zearalenone), (3) contaminated grains + GMA and (4) restricted to 80% of feeding control (RF). The studied variables were feed intake, body weight gain, gain: feed, total serum protein, urea and ammonia, and the ratios of RNA: DNA and protein: DNA in the triceps *bracii muscle*. Means were compared by contrasts and significance was declared at $P \leq 0.05$. Serum protein, urea, ADFI and ADG were not affected by diets, but ammonia was increased with CG and RF treatment and it was reduced with GMA in gestation. In lactation, ADFI was reduced with the feeding of CG and GMA. There were no effects of diet on RNA: DNA ratios in lactation. Protein: DNA was reduced in RF compared to C ($P = 0.04$). In conclusion the feeding of diets contaminated with Fusarium mycotoxins increased serum ammonia, and dietary supplementation with GMA prevented this effect. The reductions in muscle protein: DNA, an index of protein synthesis, were caused mainly by reductions in feed intake and were not directly caused by feed borne Fusarium mycotoxins.

Key Words: Gestating Sows, *Fusarium* Mycotoxins, Lactating Sows

T212 Effects of heat processing of corn and rice on serum ghrelin concentrations in young pigs. D. Menoyo[1], D. G. Valencia[1], V. Barrios[2], M. P. Serrano[1], B. Vicente[1], R. Lázaro[1], J. Argente[2], and G. G. Mateos*[1], [1]*Universidad Politécnica de Madrid*, *Spain*, [2]*Servicio de Endocrinología, Hospital Infantil Universitario Niño Jesús*, *Spain*.

Human and animal studies suggest a role for high glycemic index (GI) diet on feed intake mediated by endocrine signals. Ghrelin is a peptide with potent appetite-stimulating activity that might affect voluntary feed intake. In addition, ghrelin has the specific characteristic of having an acylated group on one of its serine residues (Ser 3), which affects its activity. We have previously reported that type (rice vs. corn) and processing (raw vs. cooked) of the cereal of the diet increases GI in young pigs. This effect might partially explain the increases in feed intake observed when rice replaces corn in pig diets. The present study was designed to elucidate the effects of cereal type and heat processing of the cereal on dynamics of serum ghrelin after a short-term fasting and re-feeding trial. Weanling pigs (BW = 8.10 ± 1.2 kg, n=9 per treatment) were individually penned and fed their respective experimental diets based on milk products, fish meal, and 52% of corn or rice either raw or cooked. Pigs received their experimental diets for two weeks and then they were deprived of food for 12h (start of the experiment, 0h). Afterwards they were re-fed *ad libitum* for 3h and deprived again of food for 6 extra-hours. Blood was collected at 0h, 3h, 6h, and 9h of the experiment. Ghrelin levels were quantified by RIA (Linco Research, St-Charles, MO). Ghrelin levels were not affected by dietary treatment ($P>0.10$), but were modified ($P<0.01$) by time, with a maximum (532 pg/ml) at 6h of the experiment. Analysis of the acylated ghrelin levels will provide further insights on the implication of this hormone in the appetite stimulating effects of rice.

Key Words: Weanling Pigs, Ghrelin, Heat processing

T213 Citric acid and thymol influence gastrointestinal microflora in pigs at weaning. A. Piva[1], E. Grilli*[1], M. R. Messina[1], S. Albonetti[2], V. Pizzamiglio[1], I. Cipollini[1], P. P. Gatta[1], and G. Zaghini[1], [1]*DIMORFIPA*, *Ozzano Emilia, Bologna, Italy*, [2]*DSPVPA*, *Ozzano Emilia, Bologna, Italy*.

Aim of this study was to investigate the role of citric acid (CA) and thymol on growth performance and gastrointestinal microflora in weaning pigs. Ninety-six Landrace × Duroc piglets weaned at 22 days of age (6.7 ± 0.8 kg BW) were divided into four groups of 4 replicates of 6 animals each and assigned to experimental dietary treatments: control diet (T1) or the control diet added with microencapsulated CA (T2), microencapsulated thymol (T3), and a microencapsulated blend providing the same amounts of CA and thymol of the other groups (T4) (EP 1391155B1; US 20040009206A1; Vetagro srl, Italy). Piglets were fed a two-phase diet (0-21 d, 22-42 d) and at 42 days 6 animals per treatment were sacrificed, the GI tract was removed and the contents of stomach, proximal jejunum, distal jejunum, caecum and colon were collected to be analysed for pH, NH_3, VFA, and lactobacilli, coliforms, and *C. perfringens* counts. Live weight at 0, 21 and 42 days was recorded; average daily gain, feed intake and feed conversion rate between 0-21, 22-42 and 0-42 days were calculated. All data were analyzed by ANOVA and differences were considered statistically significant at $P<0.05$. Thymol increased feed intake throughout the study (0-42d, +12.6% T3 vs T1, $P<0.05$); final weights were not different. Microencapsulated CA (T2) or thymol (T3) failed to change bacterial counts along the GI tract, whereas only the microencapsulated blend (T4) significantly reduced by 4 Logs coliforms in caecum compared to control fed piglets (T1= 6.73 ± 0.61, T4= 2.81 ± 3.12, Log CFU/g, $P=0.04$). These data suggests that microencapsulated thymol improved feed intake throughout the crucial 42 days of the post weaning period and that the individual microencapsulated compounds at the supplemented dose were not inhibitory, whereas properly coupled substances may exert a synergistic activity in modulating cecal microflora.

Key Words: Citric Acid, Thymol, Weaning

T214 Use of different soybean and fish meal protein sources in diets for young pigs. M. T. Sánchez[1], D. G. Valencia[1], M. P. Serrano[1], J. Sánchez[2], R. Lázaro[1], and G. G. Mateos*[1], [1]*Universidad Politécnica de Madrid*, *Spain*, [2]*Imasde Agropecuaria*, *Spain*.

A trial was conducted to compare three soybean protein (SOY) sources (SPC, a soy protein concentrate with 54.3% CP; SoyMAX, a high quality soybean meal from Owensboro crushing plant with 48.5% CP, and RSBM, a regular soybean meal with 46.8% CP), and three fish meal (FM) sources (LTFM, a FM spray dried at 70 °C with 71.2% CP; HQFM, a FM steam dried at 80 °C for 50 min with 64.9% CP, and SFM, a FM steam dried at 110 °C for 120 min with 60.7% CP) in piglet feeds on productivity from 23 to 43 d of age and apparent total tract digestibility (ATTD) of nutrients at 34 and 43 d of age. The

protein source tested replaced 5% of the protein provided by RSBM in all the diets. Each treatment was replicated six times (six piglets per replicate). Comparisons were performed to study the effect of protein source (SOY vs. FM), SOY source (SPC vs. SoyMAX vs. RSBM), and FM source (LTFM vs. HQFM vs. SFM). From 23 to 34 d of age pigs fed SOY were more efficient than pigs fed FM (0.91 vs. 0.96 g/g; P<0.05) but no effects were observed thereafter. For the entire experiment source of SOY did not affect performance, but the incidence of diarrhea tended to be lower in pigs fed SPC (P<0.10). Pigs fed LTFM were more efficient than pigs fed SFM, with pigs fed HQFM intermediate (1.04 vs. 1.16 vs. 1.10 g/g; P<0.05). The ATTD of dietary components increased with age. Pigs fed FM had better ATTD of ether extract than pigs fed SOY (P<0.001), but no effect was observed for the other nutrients. The ATTD was better for pigs fed SoyMAX than for pigs fed SPC (P<0.01), with RSBM intermediate. Also, ATTD of FM was the best for pigs fed LTFM (P<0.01). In summary, soy protein concentrate does not improve growth or nutrient digestibility as compared with soybean meal. Pigs fed spray dried fish meal are more efficient and have better digestibility of nutrients than pigs fed fish meal steam dried at 110°C for 120 min.

Key Words: Fish Meal Processing, Soy Protein Concentrate, Piglet Feeding

T215 Segregated early-weaning down regulates the expression of the small intestinal alkaline phosphatase. D. Lackeyram*, C. Yang, T. Archbold, and M. Z. Fan, *University of Guelph*, *Guelph, Ontario, Canada*.

The digestion of non-phytate organic sources of phosphates is effected by the small intestinal alkaline phosphatase (IAP). This enzyme also participates in the absorption of triglycerides as such it is also regarded as a marker enzyme for the functional development of the small intestine. The objectives of this study were to: (i) partition the tissue IAP activity into the brush border membrane (BBM) and intracellular fractions; (ii) examine IAP enzyme abundance in these cellular fractions and (iii) investigate changes in IAP mRNA expression. Ten suckling (SUC) and 10 weaning SEW) piglets, balanced for gender with an average BW of 3kg were used. The SUC group was marked at d 10 and allowed to suckle for 12 d and the SEW group was fed a corn and soybean meal starter-I diet for 12 d. In vitro enzymatic kinetic experiments of jejunal tissue using P-Nitrophenyl phosphate (0-10 mM) was used for enzymatic kinetic expeirment incubations. Quantitative real time RT-PCR was performed on intestinal tissues using the Quantitect SYBR Green RT-PCR kit with a Smart Cycler (Cepheid,CA). Weaning decreased (P<0.05) the maximal specific activity (Vmax, µmol/mg protein.min, n = 60) of IAP (SEW, 0.35±0.02 vs. SUC, 0.44±0.04; SEW, 0.66±0.01 vs. SUCK, 0.73±0.01) in both the tissue homogenate and the BBM, respectively. Similar decreases (P<0.05) were observed in the IAP protein abundance (arbitrary units) in the tissue homogenate (SEW, 1.75±0.27 vs. SUC, 3.33±0.70), intracellular (SEW, 0.79±0.06 vs. SUCK, 1.69±0.17) and BBM fractions (SEW, 0.69±0.12 vs. SUC, 1.89±0.48). Furthermore, SEW reduced (P<0.05) the IAP mRNA abundance (arbitrary units relative to ß-actin) by 2.4 fold (SEW, 0.06±0.01 vs. SUC, 0.14± 0.01). Pearson correlation analyses demonstrated correlations (P<0.05) between Vmax and IAP protein in both tissue homogenate and BBM fractions and between IAP protein and mRNA levels. In conclusion, early weaning down regulates gut IAP expression at the transcriptional and protein processing levels in the pig.

Key Words: Early Weaning, Intestinal Alkaline Phosphatase, Gene Expression

T216 The phosphorus-releasing efficacy of an *E. coli*-derived phytase in young pigs is dose-dependent and is not affected by the addition of a lipid-based coating added for pelleting stability. N. R. Augspurger*[1], A. M. Gaines[1], J. R. Danielson[2], and L. L. Southern[3], [1]*JBS United, Inc.*, *Sheridan, IN*, [2]*University of Wisconsin*, *Madison*, [3]*LSU Agricultural Center*, *Baton Rouge, LA*.

Two trials were done to determine the effect of increasing phytase activity on quantitative P-releasing efficacy of a bacterial-derived phytase (OptiPhos, JBS United, Inc.) in nursery pigs. Individually-fed pigs (n = 8 per treatment, initial BW = 10.2 [Trial 1] and 9.8 kg [Trial 2]) were fed P-deficient corn-soybean meal diets (0.075% available P, 0.60% Ca) supplemented with inorganic P (iP, monosodium phosphate) or phytase. At the end of each trial, a fibula was collected from each pig for determination of bone ash (% [BAP] and milligrams [BAC]). Standard-curved methodology was used to calculate P-release values for phytase. Trial 1 had 4 iP concentrations (0, 0.066, 0.133, or 0.20%) and 250, 500, or 1,000 FTU/kg phytase. In this trial, iP and phytase supplementation increased ($P < 0.01$) ADG, BAC, and BAP over the basal diet. Phytase at 250, 500, and 1,000 FTU/kg released 0.124, 0.140, and 0.179% P, respectively. Trial 2 had 3 iP concentrations (0, 0.075, or 0.15%) and 250, 500, or 1,000 FTU/kg of the phytase with a lipid-based coating that enhances thermo-tolerance at 85 °C, compared to 250 FTU/kg of the uncoated phytase. Supplementation of iP resulted in linear increases in ADG ($P = 0.051$) and BAC and BAP ($P < 0.01$). There was no difference ($P > 0.10$) between the uncoated or coated phytase at 250 FTU/kg for any response. For the coated phytase, BAC was increased ($P < 0.05$) with each increase in activity concentration, but BAP was greater ($P < 0.05$) for pigs fed diets containing 500 and 1,000 FTU/kg coated phytase compared to 250 FTU/kg. Quantitative P-release values for 250, 500, and 1,000 FTU/kg of an *E. coli*-derived phytase with a lipid-based coating were 0.132, 0.169, and 0.223%, respectively; 250 FTU/kg of the uncoated phytase released 0.130% P. These data demonstrate dose-dependent increases in quantitative P-releasing efficacy for an *E. coli*-derived phytase in pigs. The addition of a lipid-based coating to the phytase for pellet stability did not affect its efficacy in pigs.

Key Words: Phytase, Phosphorus, Pigs

T217 Evidence of a preference in piglets for an animal protein hydrolysate. D. Martínez-Puig*[1], M. Anguita[2], F. Baucells[2], E. Borda[1], J. F. Pérez[2], and C. Chetrit[1], [1]*Bioiberica S.A.*, *Barcelona, Spain*, [2]*Dpt. Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona*, *Bellaterra, Barcelona, Spain*.

The transition in piglets from suckling to eating solid feed is associated with a critical period of underfeeding, suboptimal growth rate and increased risk of diarrhea. The objective of the current study was to investigate if the piglets may show a preference for the intake of

diets containing a specific protein concentrate ingredient. To test this hypothesis, we compared a hydrolysate of animal protein (Palbio Inicium™), and a hydrolysate of soy protein, or spray dried porcine plasma (SDPP). 96 piglets were weaned at 21 days of age and randomly subdivided into 3 groups of 32 pigs each. Piglets were distributed into 24 pens (8 replicates of pigs per group). Every group of piglets had the choice between two diets, resulting in three comparisons. In comparison 1, a diet containing SDPP (4%) was tested against a diet containing a soy protein hydrolysate (4%); in comparison 2, a diet containing the animal protein hydrolysate (Palbio Inicium™; 1%) and 3% of a soy protein hydrolysate was compared against the soy diet (4%); and in comparison 3 the diet containing Palbio Inicium™ (1%) was compared against the SDPP diet (4%). Feed intake was registered daily during 7 days after weaning. The percentage of preference (%) was calculated as the accumulated intake of the tested diet divided by the total intake. During the whole period no preference for SDPP diet (46.3%) compared to the soy diet was observed. Contrarily, the animal protein hydrolysate diet was significantly preferred to the soy diet from day 4 (59%; $P<0.05$) until day 7 (65.4%; $P<0.05$). Choice for the animal protein hydrolysate diet was numerically higher compared to the SDPP diet (58%) but differences failed to reach statistical significance. These results suggest that the palatability of a postweaning diet can be improved by incorporating a 1% of an animal protein hydrolysate.

Key Words: Piglet, Preference, Animal Protein Hydrolysate

T218 Effect of coarse ground corn, sugar beet pulp and wheat bran on the colonic morphology in growing pigs. M. Nofrarías*[1,2], M. Anguita[2], M. Roca[1,2], J. F. Pérez[2], and N. Majó[1,2], [1]*Centre de Recerca en Sanitat Animal (CReSA)*, *Bellaterra, Spain*, [2]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

The aim of this work was to evaluate the influence of different types of dietary fiber on the colonic digesta characteristics and intestinal morphology in growing pig. A total of 96 pigs (15±0.2 kg) were fed four experimental diets including a control group (CT) or the same diet including coarse milled corn (CC), 8% sugar-beet pulp (SBP) or 10% wheat bran (WB). Three experimental periods were considered (7, 21 and 42 days) and 8 animals per treatment killed at the end of each period. Proximal colonic digesta was analyzed for cytolytic capacity of the water digesta and microbial diversity. Histological study was performed in tissue samples from proximal colon. Cytolytic capacity of the colonic water tended to increase with the inclusion of WB in the diet ($P=0.091$). Moreover, in the third period, WB-fed pigs had a decrease in the colonic microbial diversity ($P<0.05$). In the early stages (day 7), diets with higher amount of fiber (CC, SBP and WB) increased the presence of inflammatory cells between crypts compared to CT fed pigs (2.42 vs. 1.85 cells; $P<0.05$). However, with time (days 21 and 42), inclusion of SBP in the diet lowered numbers of lymphocytes in the epithelium and in the lamina propia, and the presence of lymphoid nodules in the mucosa of the colon compared with other diets ($P<0.05$). The thickness of tunica muscularis was lower for SBP and WB pigs in the proximal colon ($P<0.05$), whereas no changes in crypt depth and numbers of mitoses were observed. The incorporation of fibrous ingredients in growing pig diets may induce changes on the digesta properties and histology of colonic mucosa. While WB reduced microbial diversity, the incorporation of SBP favoured the adaptation of the animals to the growing pig diet, as suggested by the lowering effect on indicators of mucosa inflammation.

Key Words: Dietary Fiber, Intestinal Histology, Pig

T219 Duodenal infusion of pancreatin to growing pigs fed phytase-supplemented, sorghum-soybean meal diets: Apparent ileal amino acid digestibility. S. Fierro, M. Cervantes*, W. Sauer, A. Morales, N. Torrentera, and A.B. Araiza, *ICA - Universidad Autonoma De Baja California*, *Mexicali, BC. Mexico*.

Phytates in feed ingredients appear to inhibit the activity of pancreatic enzymes in pigs. This experiment was conducted to determine if duodenal infusions of pancreatin, a mixture of lyophilized pancreatic enzymes, improves the apparent ileal digestibility (AID) of amino acids in pigs fed sorghum-SBM diets added with phytase. Eight barrows (Yorkshire-Landrace-Hampshire), average body weight of 38.3 ± 2.8 kg, fitted with two T-cannulas (one in duodenum and other in terminal ileum) were used. Treatments (T) were as follows: T1 = basal sorghum-SBM diet, 13.1% CP; T2 = basal diet supplemented with 1,000 phytase units per kg diet; T3 = as T1 plus pancreatin infusion (591 mg kg-1 of diet); T4 = as T2 plus pancreatin infusion (591 mg kg-1 of diet). Pancreatin was infused into duodenum at every feeding time using a 25-cc syringe. The study was conducted as a replicated 4x4 Latin square design. All diets were added with vitamins and minerals to meet the 1998 NRC standards for growing pigs. Chromic oxide was added to all diets as a digestibility indicator. The AID of essential AA for T1, T2, T3, and T4 were: Arg, 77.8, 78.1, 77.3, 79.0; His, 72.1, 71.4, 69.9, 72.2; Ile, 72.7, 72.1, 70.3, 71; Leu, 77.5, 76.8, 75.3, 76.9; Lys, 63.4, 64,0, 61.8, 60.7; Met, 69.6, 68.2, 66.0, 67.6; Phe, 75.7, 75.0, 73.5, 74.7; Thr, 57.0, 55.2, 54.9, 57.7; Val, 68.3, 67.5, 66.3, 67.4, respectively. There was no effect of duodenal infusion of pancreatin or phytase supplementation ($P > 0.10$) on the AID of essential AA. Also, there was no interaction ($P > 0.10$) between phytase supplementation and pancreatin infusion. The AID of essential AA was 3.2 percentage units higher than non-essential AA. These results indicate that the duodenal infusion of pancreatin does not improve the AID of AA of growing pigs fed sorghum-SBM diets supplemented with phytase.

Key Words: Pigs, Amino Acid Digestibility, Pancreatin

T220 Effect of dietary antibiotics and mannan oligosaccharides on growth performance, carcass characteristics and health of growing/finishing pigs. H. Bernal-Barragán*[1], E. A. Ruiz-Chávez[1], E. Gutiérrez-Ornelas[1], R. Ávalos-Ramírez[2], M. Cervantes-Ramírez[3], and F. Sánchez-Dávila[1], [1]*Facultad de Agronomía, Universidad Autónoma de Nuevo León*, *Marín, Nuevo León, México*, [2]*Fac. de Medicina Veterinaria y Zootecnia UANL*, *Unidad Mederos, Monterrey N.L. México*, [3]*Instituto de Ciencias Agrícolas UABC*, *Ejido Nuevo León, Valle de Mexicali, B.C. México*.

This study was conducted to evaluate the effects of a mannan oligosaccharide product (MOS) and antibiotic (BMD) on growth performance, carcass characteristics and health of growing/finishing pigs. Forty-eight (14 barrows and 32 gilts) crossbred (Landrace ×

Yorkshire × Duroc) pigs (43.5 ± 3.8 kg) allotted by sex and weight, were randomly allocated to one of four dietary treatments in a 2 × 2 factorial, with the factors being MOS (0 or 0.05%) and BMD (0 or 33 ppm). A Basal sorghum-SBM diet was formulated to meet the NRC 1998 standards for swine, and had no addition of pharmacological levels of cooper sulfate. The trial was conducted for 63 days during the summer (av. temperature 29.7°C, and relative humidity 62%). Results were analyzed with the General Linear Model of SPSS, and means were compared using the Duncan test. Average daily gain (0.775 kg/d), ADFI (2.414 kg/d) and F:G (3.12:1) were not affected (P>0.05) by the level of MOS or BMD. Pigs fed the diet added with both MOS and BMD, had higher ADG (P<0.05) than those fed the other three diets (0.855 *vs* 0.749 kg/d). By adding none or both of the additives, pigs had higher (P<0.05) carcass length at slaughter (75.1 *vs* 73.2 cm), than animals fed diets containing either MOS or BMD (Interaction MOS × BMD P<0.05). Pigs receiving BMD had higher (P<0.05) average fat depth than pigs with no BMD in their diet (30.3 *vs* 26.8 mm). Diets containing MOS alone had no effect on growth performance or carcass characteristics of growing/finishing pigs. Health condition of pigs was not affected by treatments. In conclusion, withdrawing BMD from the diet of growing/finishing pigs had no effect on performance or carcass characteristics. Adding MOS had a positive effect on ADG only if BMD was also provided in the diet.

Key Words: Pigs, Antibiotics, Mannan Oligosaccharides

T221 Effect of a dry organic acid blend on lactating sow feed intake and performance. J. Zhao*[1], R. J. Harrell[1], L. L. Greiner[2], X. Wang[3], G. L. Allee[3], F. Navarro[1], and C. D. Knight[1], [1]*Novus International Inc*, *St. Louis, MO*, [2]*Innovative Sow Solutions*, *Carthage, IL*, [3]*University of Missouri*, *Columbia*.

A total of 112 mixed parity (1, 2, or 3) lactating sows (PIC C22) were used to investigate the impact of a dry organic acid blend (DOAB) (ACTIVATE® Starter DA, registered trademark of Novus International, Inc., St. Louis, MO), containing 2-hydroxy-4-(methylthio) butanoic acid calcium, benzoic acid, and fumaric acid, on sow feed intake, wean to estrus interval, and litter growth performance. Sows were blocked by parity and randomly assigned to either a non-medicated basal corn-soybean diet, or the basal diet supplemented with 0.2 or 0.4% DOAB upon entry into the farrowing house. Sows were fed via a HOWEMA automatic feeding system 1.8, 2.7, and 3.6 kg for the day of farrowing, d 1 and d 2 post-farrowing, respectively, and ad libitum until weaning at 17±1 days of lactation. Daily feed intake was higher from 3 to 5 d post-farrowing with 0.4% DOAB supplementation (P < 0.05) compared to 0.2% or controls. Sows consumed 6.3, 6.3, and 7.2±0.3 kg/d feed from 3 to 5 d post-farrowing for the control, 0.2, and 0.4% DOAB, respectively. Feed intake was not affected by DOAB supplementation for the remainder of the study (P = 0.83). The wean to estrus interval was linearly reduced with DOAB supplementation (P < 0.05), with 9.2, 7.7, and 5.5±1.2 days for the control, 0.2, and 0.4% DOAB, respectively. Sow fecal E. Coli and C. perfrigens counts (10 sows/treatment) on d 3 and 10 post farrowing was not different among treatments (P > 0.26). No differences were observed between treatments on litter weights, number weaned, or number of fall behinds (P > 0.31). In summary, DOAB supplementation improved feed intake during 3-5 days postfarrowing and shortened the return to estrus interval.

T222 Broiler performance and yield observed with enzyme supplementation and a corn matrix adjustment for energy. X. Sun*[1], C. Troche[1], A. McElroy[1], J. Remus[2], E. Wong[1], and C. Novak[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*Danisco Animal Nutrition*, *Carol Stream, IL*.

Two studies were conducted to investigate the effect of a corn matrix adjustment and enzyme supplementation on broiler growth and performance from 0 to 49 days of age. A 2 × 2 factorial treatment design was used testing two corn matrix (CME) values for energy (actual ME vs. corn A with matrix increase of 138 kcal ME/ kg – trial 1; corn B with matrix increase of 125 kcal ME/ kg – trial 2) with or without enzyme supplementation (0.5 % Avizyme 1502 – AZ). For each trial, 1,440 Ross 708 male chicks were randomly assigned to one of four dietary trts (9 reps/trt and 40 chicks/ rep) on d 1. Body weight (BW) and feed intake (FI) were recorded at feed changes (d 14, 28, 37) and d 7 and 49. At d 28, subsets of birds were transferred to Petersime batteries to determine feed passage rate. At d 50 and 51, 54 birds per trt were processed to evaluate meat yield. Using corn B, an interaction was observed evaluating BWG with improvements noted when supplementing AZ with no matrix adjustment while reduced with a matrix adjustment to 35 d. The opposite was true using corn A. BWG was similar across trts from d 35 to 49 using either corn. FI followed BWG data using corn B. Using corn A, feeding matrix adjusted diets increased FI as compared to non adjusted diets from 37 to 49 days of age. Additionally, FI of broilers fed the AZ supplemented/ non adjusted diet ate less as compared to broilers fed the adjusted/ with AZ or non adjusted diet from 28 to 37 days of age. Overall, FCR in birds consuming non adjusted diets (corn A and B) was better (P ≤ 0.05) as compared to birds fed CME adjusted diets. Feeding corn A, percent tender was increased (P ≤ 0.05) with enzyme supplementation (4.80 vs. 4.62%). Additionally, percent fat pad was reduced (P ≤ 0.05) with a matrix adjustment for energy using corn A. In conclusion, decisions regarding matrix adjustments to utilize additional energy released with enzyme supplementation are dependant on corn source.

Key Words: Broiler, Enzyme, Matrix Energy Corn Source

T223 The effect of chitosan and natural mineral complex supplementation on egg production and egg characteristic in laying hens. J. S. Yoo*[1], Y. J. Chen[1], J. H. Cho[1], J. H. Lee[2], B. C. Park[2], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Choognam, Korea*, [2]*CJ Feed Inc*, *Incheon, Gyeonggi, Korea*.

This study was conducted to investigate the effects of dietary natural mineral liquid complex(NMLC) on egg production and egg characteristic in laying hens. NMLC is made of *Aretmisia princesm*

pinus, densiflora sieb and Biotite. In Exp 1, a total of two hundred fifty two laying hens were randomly allocated into seven treatments with six replications for six weeks. Dietary treatments included 1) CON(control), 2) M1 0.25(CON+1% chitosan+0.25% NMLC), 3) M2 0.25(CON+2% chitosan+0.25% NMLC), 4) M2 0.50(CON+2% chitosan+0.50% NMLC), 5) M3 0.25 (CON+3% chitosan+0.25% NMLC) and 6) M3 0.50(CON+3% chitosan+0.50% NMLC). During the experiment period, dietary NMLC treatments could improved in egg production, egg shell strength, egg shell thickness, yolk color, haugh unit and mineral ingredients of blood and yolk compared to CON(P<0.05). In conclusion, chitosan 3% showed higher egg production, egg shell strength and yolk color compared others(P<0.05). Also, NMLC 0.5% was more improvement than NMLC 0.25%. In Exp. 2, a total of two hundred forty birds were randomly allocated into four treatments with eleven replications for six wk. Dietary treatments included 1) CON(control) 2) M0.5(CON+3% chitosan+0.5% NMLC), 3) M1.0(CON+3% chitosan +1.0% NMLC) and 4) M1.5(CON+3% chitosan+1.5% NMLC). For overall period, M1.5 had improved egg production compared to others (P<0.05). However, M0.5 showed higher egg weight compared to other treatments(P<0.05). M1.5 showed a statistically improved egg shell strength and thickness compared to CON(P<0.05). Haugh unit was increased in CON and M1.0 compared to M1.5(P<0.05). Ca and Fe concentrations of blood was increased in M1.5 compared to CON(P<0.05). M1.5 improved K concentration of yolk compared to CON(P<0.05). In conclusion, 3% chitosan + NMLC supplementation in layer hen diet improved egg production, egg shell strength, egg shell thickness, Ca and Fe concentrations in blood and K concentration in yolk.

Key Words: Natural Mineral Liquid Complex, Egg Characteristics, Layer

T224 Effects of dietary delta-aminolevulinic acid supplementation on egg production, egg quality and blood parameters in laying hens. Y. J. Chen*[1], J. H. Cho[1], H. J. Kim[1], J. S. Yoo[1], Q. Wang[1], Y. Hyun[2], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Choognam, Korea*, [2]*Easy Bio System, Inc*, *Cheonan, Choognam, Korea*.

Effects of dietary delta-aminolevulinic supplementation on egg production, egg quality and blood parameters were examined in a laying hens feeding trail. Two hundred forty (Hy-line brown, 21 wk old) layers were randomly assigned to four dietary treatments with 10 replications (six layers in adjacent three cages). Dietary treatments were: 1) CON (basal diet), 2) ALA1 (CON + ALA 5 ppm), 3) ALA2 (CON + ALA 10 ppm), 4) ALA3 (CON + ALA 15 ppm). All diets were formulated to meet or exceed NRC (1994) recommendation for laying hens. Egg production and egg weight were not influenced by the ALA supplementation (P>0.05). Egg shell thickness and breaking strength were also not affected by the treatments (P>0.05). Egg yolk index was higher in ALA3 treatment than that of the CON treatment (P<0.05) at the end of 4 and 8 wk. Haugh unit was increased in ALA3 treatment compared with CON and ALA1 treatments at the end of 8 wk (P<0.05). However, yolk color unit was not affected by the ALA supplementation (P>0.05). Serum iron concentration was increased in the ALA2 added treatment compared with CON treatment (P<0.05). Similarly, total iron binding capacity was also higher in the ALA2 treatment than that of the other dietary treatments (P>0.05). The difference of total protein between 8 and 0 wk was higher in ALA2 treatment than CON treatment (P<0.05). No significant effects were observed on Hb, albumin, WBC, RBC and lymphocyte concentrations (P>0.05). In conclusion, dietary ALA supplementation can positively affect egg yolk index, haugh unit and serum iron concentration.

Key Words: Delta-Aminolevulinic Acid, Egg Quality, Laying Hens

T225 Effect of dietary lipids and time of feeding on immune tissue n-6 and n-3 fatty acid distribution during lipopolysaccharide challenge in broiler chickens. D. Gonzalez*, A. S. Abd El-Hakim, M. P. Goeger, and G. Cherian, *Oregon State University*, *Corvallis*.

Due to the distance of shipment or delays in shipment, newly hatched chicks are often subjected to a 48 to 54 hr delayed access to feed and water. Delayed access to feed has been reported to reduce growth and development of the small intestine, reduce organ weights and a lower final body weight. The current study investigated the effect of early vs. late access to feed and dietary lipids on lipopolysaccharide (LPS)-induced alterations in fatty acid metabolism in broiler birds. A total of sixty chicks were used for the study. The chicks were fed a high or low n-3 diet within 5 hrs of hatching (early) or after 24 hrs of hatching (late). LPS injection led to a decrease in total n-6 fatty acids in the liver and spleen when compared with non-injected birds (P<0.05) in all treatments. Feeding high n-3 diets resulted in an increase in n-3 fatty acids in the spleen and liver tissue when compared to low n-3 when exposed to LPS challenge (P<0.05). Time of feeding significantly influenced different parameters in chicks exposed to challenge. When fed late, lower n-6 fatty acid was observed in liver tissue of both high and low n-3 diets than early-fed birds (P<0.05). Plasma non-esterified fatty acids were lowest in high n-3 diet birds fed early (P<0.05). The spleen tissue total fat content was highest in low n-3 birds fed late (P<0.05). There was no difference in the final body weight or organ weights of birds (P>0.05). During inflammation, lipid substrates for the activated immune system are provided by fatty acids. Therefore, dietary and management strategies directed at attenuating immune tissue lipid content may prove beneficial in reducing inflammatory responses and in increasing production performances in broiler chickens.

Key Words: n-3 Fatty Acid, Inflammation

T226 Fiber component type and level affect DDGS nutrient digestibility. M. K. Manangi*[1], C. N. Coon[1], E. E. M. Pierson[2], and M. Hruby[2], [1]*University of Arkansas*, *Fayetteville*, [2]*Danisco*, *St. Louis, MO*.

Due to the increase in production of ethanol from corn, there has been an increase in the availability of distillers dried grains with solubles (DDGS) in US poultry feeds. Globally, the usage of DDGS in poultry feeds is also increasing. In many cases, the practical inclusion of DDGS has been less than science-based recommendations because of the possible impact of its batch-to-batch nutrient variability on poultry performance. A study was conducted to quantify the in vitro characteristics of various samples of DDGS with NIR measurements and correlate these with determined in vivo assays. Each of the seven DDGS samples originated from the same lot of corn. Samples were subjected to proximate, fiber and mineral analyses. Additionally, all DDGS samples were precision-fed to 7 market-age broilers per treatment and total excreta collected during a 48 hours post-feeding

period. There was a strong positive correlation (r = 0.86; P < 0.05) between DDGS dry matter (DM) digestibility and TME. Of the fiber components analyzed, the order of strength for correlations of their in vitro determination with dry matter digestibility (from highest to lowest) was for NDF (r = -0.86; P < 0.05), crude fiber (r = -0.81; P < 0.05), hemicellulose (r = -0.79; P < 0.05) and ADF (r = -0.02; P > 0.05). This information could allow for a more reliable DDGS screening when evaluating nutrient digestibility and ME of this ingredient.

Key Words: DDGS Digestibility, Fiber, TME

T227 Extraction of saponins from guar meal. R. Kakani*, O. Gutierrez, A. Haq, and C. A. Bailey, *Texas A&M University*, *College Station*.

Two different methods were evaluated for extracting saponins from guar meal. In one method 25 grams of guar meal were placed in cellulose extraction thimbles and refluxed with 250 ml methanol for 24 hrs using Soxhlet extraction apparatus. In the second method, 25 grams of guar meal was refluxed directly for 3.5 to 4 hrs in equal volumes of water and absolute ethanol (125 ml of each). A roto-evaporator was used to evaporate the methanol extract to dryness and then approximately 100 ml of distilled water was added back. After filtering the solids from the ethanol-water extract, the ethanol was evaporated with the roto-evaporator leaving a volume of approximately 100 ml. The extracts were transferred to separatory funnels, equal volumes of n-butanol added and after vigorous shaking the solutions were left to partition overnight. The upper, saponin-rich n-butanol fractions were collected separately and the remaining aqueous fractions were partitioned two more times with n-butanol. The pooled n-butanol fractions were next evaporated to dryness, a little water added and then either freeze dried or immediately subjected to preparative reverse phase C-18 (octadecylsilyl coated silica) flash chromatography. The average yield of the freeze dried n-butanol partitions (4 replicates) was 7.34% and 4.91% for the methanol and ethanol methods respectively. These extracts were next evaluated for hemolytic activity using serial dilutions of 3 mg freeze dried extract per ml isotonic saline. Chicken RBCs (100 µl whole blood) were added to 2 ml of the serial diluted isotonic saline and allowed to sit at room temperature for 2 hrs. Both the extracts were hemolytic at concentrations greater than 750 µg/ml.

Key Words: Guar Meal, Saponins Extraction and Yield, Hemolysis

T228 Effects of corn-, wheat-, and flax-based broiler diets with or without enzyme supplementation on proliferation of *Clostridium perfringens*: *In vitro* study. X. Wang*, G. Blank, and B. A. Slominski, *University of Manitoba*, *Winnipeg, Canada*.

Clostridium perfringens is the major predisposing factor for necrotic enteritis in broiler chickens. In this investigation the individual growth of five *C. perfringens* strains was examined using supernatants prepared from either digested or non-digested corn or wheat-based diets mixed with thioglycollate broth and supplemented with or without exogenous carbohydrase enzymes. Following incubation at 40°C for 6 h increases in growth were determined. Overall, compared to the control which consisted of thiogycollate broth plus inocula, the level of vegetative growth was higher with the supernatants. However, among the five strains evaluated no clear pattern emerged with regards to vegetative growth in any of the supernatants regardless of enzyme supplementation. Spore germination of a cocktail consisting of three *C. perfringens* strains was similarly investigated. In all supernatants near complete germination of spores was evident within three hours. Germination was followed by vegetative growth which appeared lowest in the corn-based diet supernatant. Growth following 6 h at 40°C of a five strain cocktail of *C. perfringens* in digesta obtained from broilers fed corn-soya, wheat-barley or flax diets was also investigated. In all cases vegetative growth was not observed. Instead, populations were observed to decrease gradually; the highest and lowest survival occurred with the flax and corn-soya based digesta, respectively.

Key Words: *Clostridium perfringens*, Broiler Diets, Enzyme

T229 Influence of processing conditions of fish meal on digestibility of dietary components in broilers at 21 days of age. A. de Coca-Sinova, A. P. Bonilla, E. Jiménez-Moreno, R. Lázaro, and G. G. Mateos*, *Universidad Politécnica de Madrid*, *Spain*.

Bacterial contamination, in particular Salmonella spp. contamination, limits the use of fish meal (FM) in prestarter diets for broilers. In consequence, FM by–products are generally processed under severe heat conditions (100° C for 120 min) to reduce bacteria load. We studied the effect of processing FM under different time and temperature conditions on total tract apparent retention of nutrients (TTAR) and AME_n of diets in broilers at 21 d of age. There were six dietary treatments that differed in the type of FM used to replace 5% of the crude protein of the diet. There were a control diet (SFM) that included 8.0% of standard FM (100° C for 120 min) and a positive control diet (FMLT) that included 7.1% of a spray dried FM (70° C). In addition, there were four extra diets in which the rendered FM was steam–processed according to a factorial combination of temperature (80° C vs. 90° C) and time (50 vs. 90 min). Each treatment was replicated eight times (10 chicks caged together). The experimental design was completely at random and data were analysed by using a protected t–test and two non–orthogonal contrasts; 1) FMLT vs. SFM and 2) influence of temperature (80 vs. 90° C) and time (50 vs. 90 min) and their interaction. The TTAR of DM, organic matter, nitrogen (N), and AME_n of the diets were determined at 21 d of age. Digestibility was best in broilers fed FM LT or FM processed at 80° C for 50 min. Time but not temperature reduced TTAR ($P \leq 0.01$). The TTAR of all dietary components and AME_n of the diets were higher for FM heated for 50 min than for FM heated for 90 min (69.2% vs. 65.4% for N and 3,041 vs. 2,976 kcal/kg for AME_n, respectively; $P \leq 0.01$). We conclude that digestibility of dietary components is best for spray dried fish meal and that increasing processing time from 50 to 90 min to reduce microorganism load and Salmonella spp. counts might reduce the quality of fish meal in prestarter broiler diets.

Key Words: Fish Meal Digestibility, Processing Conditions, Broiler Chick

T230 Use of activity staining for monitoring site of β-glucanase activity in the gastrointestinal tract of broiler chickens. A. A. Sadeghi*[1] and P. Shawrang[2], [1]*Islamic Azad University*, *Tehran, Iran*,

[2]*Research Center for Agriculture and Medicine, Atomic Energy Organization of Iran*, *Karaj, Iran*.

Ninety day-old broilers were selected and randomly allocated to diet based soybean meal-corn without or with β-glucanase supplementation. At 3 and 6 wk of age, fifteen chickens from each treatment were slaughtered and the crop, gizzard, duodenum, jejunum and ileum contents were emptied and collected for electrophoresis and activity staining. The normal spectrophotometer method for β-glucanase was conducted on collected samples of all treatments. Proteins extracted from the various digesta samples were resolved using SDS-PAGE using 12.5% and native-PAGE using 7% polyacrylamide in the running gel. After SDS-PAGE, the gel was stained with Coomassie blue R-250 and destained. After native-PAGE, the gel related to β-glucanase activity stain was dipped into Lichenan (1.0 g/L solubilized with heat in 100 mM sodium acetate buffer, pH 5.0) and incubated at 50°C for 10 h. β-glucanase activity in native-PAGE gel was detected by overlaying the gel with 2% agar dissolved in above buffer, containing 0.3% congo red for 30 min. Fixation was completed with dilute acetic acid (1:9 v/v with water) for 15 min. Data were analyzed as a completely randomized design using the GLM procedure of SAS (1996). The normal spectrophotometer method failed to detect exogenous β-glucanase activity in the diet as well as in the digesta of crop, proventriculus, gizzard, duodenum and jejunum of broiler chickens fed the β-glucanase diet. Exogenous β-glucanase protein was detected by SDS-PAGE in the enzyme diet as well as in the digesta. Enzyme activity was detected by the activity stain native-PAGE assay in the enzyme diet and the digesta collected from the crop, gizzard and duodenum with the exception of jejunum and ileum. β-glucanase activity in digesta from the crop and proventriculus was higher than that from gizzard and small intestine ($P<0.05$). No activity detected in the small intestine. The result of the study suggests that the activity stain assays allow the detection of low levels of exogenous β-glucanase activity in the diet as well as in the digesta collected from the gastrointestinal tract of the broiler chicken.

Key Words: Native-PAGE, β-glucanase Activity, Broiler Chickens

T231 Differential developmental gene expression of nutrient transporters in the small intestine of male and female chickens from lines selected for high or low juvenile bodyweight. C. R. Miller*, P. B. Siegel, K. E. Webb, Jr., and E. A. Wong, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

The objective of this study was to evaluate the developmental gene expression of nutrient transporters in the small intestine of male and female chickens from lines that had undergone long term selection for high (HWS) or low (LWS) 8-wk body weight. Nutrient transporters investigated were the peptide transporter PepT1, amino acid transporter EAAT3, and monosaccharide transporters GLUT5 and SGLT1. Chicks were reared in batteries with ad libitum access to feed and water. Chicks were weighed and killed on embryonic d 20 (e20), d of hatch (DOH with no access to feed), and d 3 (D3), d 7 (D7), and d 14 (D14) post hatch. RNA was extracted from duodenum, jejunum, and ileum from four males and four females from each line and time point except female D7 (n=2). Expression of nutrient transporters was assayed by real time PCR using the relative quantification method. There was a sex x age interaction in PepT1 gene expression with peak PepT1 expression at a younger age in females than males ($P = 0.0002$). Expression of SGLT1 was higher in females than males ($P < 0.0001$) with a sex x age interaction ($P < 0.0001$). Females induced SGLT1 gene expression on DOH which was maintained through D14. In contrast, SGLT1 gene expression in males gradually increased through D7 and then decreased to DOH levels by D14. Gene expression of EAAT3 and GLUT5 was not different in males and females. These results indicate that expression of PepT1 and SGLT1 are differentially expressed in male and female chickens regardless of selection for high or low juvenile body weight. These results also show a sexual dimorphism in the capacity to absorb peptides and glucose from the intestine, which has implications for the poultry industry with regard to diet formulations for straight-run and sex-separate grow-out operations.

Key Words: Chicken, Nutrient Transporters, Small Intestine

T232 Effect of main cereal of the diet and particle size of the cereal on productive performance and egg quality of brown laying hens in early phase of production. H. M. Safaa[1,2], E. Jiménez-Moreno[1], B. Vicente[1], R. Lázaro[1], X. Arbe[3], and G. G. Mateos*[1], [1]*Universidad Politécnica de Madrid*, *Spain*, [2]*Animal Production Department, Faculty of Agriculture*, *Cairo University, Egypt*, [3]*Cantos Blancos, S.L*, *Guadalajara, Spain*.

A total of 960 Lohmann Brown laying hens was used to study the effect of the main cereal (corn vs. wheat) of the diet and mean particle size (MPS; hammer milled to pass through a 6–, 8– or 10–mm screen) of the cereal on productive performance and egg quality from 20 to 48 wk of age. The six diets were isonutritive and were based on soybean meal, sunflower meal, soy oil, and either corn or wheat. They contained 2,750 kcal AME_n /kg, 16.5% CP, 0.80% total lysine, and 0.40% total methionine. The experimental design was completely at random with six treatments arranged factorially (two cereals and three MPS). Each treatment was replicated eight times (20 hens per replicate). Productive traits were recorded every four weeks and egg quality was measured at 48 weeks of age. Mean particle size of the experimental diets were 935, 1,126 and 1,411 μm for the corn diets and 1,078, 1,262 and 1,335 μm for the wheat diets, ground at 6, 8, and 10–mm, respectively. For the entire experiment the only significant effect on productive traits observed was for feed intake ($P \leq 0.001$) that was greater for hens fed coarse ground cereals (10–mm) than for hens fed fine ground cereals (8– or 6–mm). Also, from 45 to 48 weeks of age hens fed corn had higher proportion of large eggs (≥ 63 g) than hens fed wheat (84.5 vs. 79.4%; $P \leq 0.05$) but no differences were detected in any other period. Dietary treatment did not affect percentage of broken, shell–less, and dirty eggs ($P \geq 0.10$). Percentages of shell, yolk, and albumen, and albumen and shell quality were similar for all treatments ($P \geq 0.10$). We conclude that neither type of cereal nor particle size affect productive performance or egg quality of young hens, except for feed intake that was increased with the coarser particle size.

Key Words: Cereal, Particle Size, Laying Hen Performance

T233 Evaluation of additives in chicks challenged with necrotic enteritis. J. L. Shelton*, A. R. Garcia, and D. W. Giesting, *Cargill Animal Nutrition*, *Elk River, MN*.

Two experiments (EXP) were conducted at the Cargill Animal Nutrition Innovation Center to determine the effect of additives on growth

performance in chicks challenged with Necrotic Enteritis (NE). Both EXP were conducted using battery cages and chicks (6 per pen) were housed from hatching to 21 d (EXP 1) or 28 d (EXP 2). Initial and final body weights (BW) were 40 g and 774 g for EXP 1 and 39 g and 1,248 g for EXP 2. Feed intake and BW were measured weekly for determination of gain and feed efficiency. Chicks had ad libitum access to feed and water. Chicks were inoculated through the feed with coccidia (*E. acervulina*, *E. maxima*, and *E. tenella*) on d 9 and then with*Clostridium perfringens* on d 14, 15, 16, and 17. In both EXP, the treatments included an unchallenged negative control (NC, no additives), a challenged NC, and a challenged positive control (with added virginiamycin, Vm). The additives that were tested in these EXP were *Bacillus* (B), a plant extract (PE), mannan oligosaccharide (M), a prebiotic added at a high (PREH) and a low (PREL) level. In both EXP, adding Vm to the diet of challenged birds improved growth performance relative to those fed the NC. In EXP 1, during the challenge period chicks fed B, B+PE, M, or B+PE+M had increased gain:feed ($p < 0.05$) relative to those fed the NC. The 3-way combination of B+PE+M produced numerical increases in ADG and gain:feed relative to B or M fed alone or the 2-way combinations of B+PE or B+M. In EXP 2, during the challenge period chicks fed B, PREL, PREH, B+PREL had increased ($p < 0.05$) ADG relative to those fed the NC. Also, chicks fed the PREL and B+PREL had increased ($p < 0.05$) gain:feed relative to those fed the NC. For the overall growth period, chicks fed the combination of B+PREH+PE had increased ($p < 0.05$) gain:feed relative to those fed the NC diet. Results from these studies indicate that combining additives of different types could improve performance in chicks challenged with NE, but it is important to choose additives with complementary modes of action.

Key Words: Necrotic Enteritis, Probiotic, Plant Extract

T234 Effects of dietary genistin on performances, organ weight and bone development in young male chicks. G. D. Kim*, J. H. Han, and K. M. Chee, *Korea University*, *Seoul, Korea*.

Genistin together with genistein, daidzin and daidzein is one of the isoflavones (ISF) in soybean meal, a major dietary protein source for poultry. ISF are diphenolic compounds and naturally occurring phytoestrogens. Some of the phytoestrogenic effects of the ISF include anabolic influence on bone metabolism in ovariectomized rats, and growth promoting in pigs. Present study was conducted to investigate effects of dietary genistin, a glucosidic form, on growth performances, bone development, organ weight and secondary sexual development in male chicks. One hundred and twenty eight, d-old male chicks (Hy-Line) were distributed at random in 4 replicates of 8 birds per treatment. A purified-type basal diet consisting of soy protein concentrate (low in ISF) as the only protein source, was supplemented with 4 levels (0, 250, 450, and 650 ppm) of genistin (purity 85%). Dietary Ca level was limited to 50% of the NRC to find out any effects of the genistin on bone development. Feed intake, body weight gain, and feed/gain ratio of the birds during the 3 wk feeding period were not affected by the genistin intake. Average weights of comb, liver, thymus, and F-sac expressed as % body weight at 7th day of the feeding were not different among the dietary grops. However, testicle weights of the birds fed the diets containing the genistin 450 and 650 ppm were significantly lighter (22 & 26 mg) compared to that (32 mg) of the control birds, although the difference disappeared later. Thymus weight of the birds fed the 450 ppm genistin diet for 3 wks was significantly lighter ($P<0.05$) than that of the control (387 vs. 529 mg). Serum alkaline phosphatase activity tended to increase as more genistin intake was consumed. In conclusion, the genistin in purified form seems to have some biological effects in male chicks without changing the overall growth performances.

Key Words: Genistin, Performance, Testicle Weight

T235 Dietary persimmon peel powder and its tannin extract reduce the content of hepatic lipids in laying hens. C. W. Kang*[1], Y. K. Shin[2], S. J. You[1], and B. K. An[1], [1]*KonKuk University*, *Seoul, Korea*, [2]*MK Bioscience Co. Inc.*, *Suwon, Korea*.

The persimmon peel, which is a by-product of dried fruit and juice, has been known as a good source of nutritional antioxidant vitamins, polyphenols and dietary fibers. This experiment was undertaken to evaluate the dietary effects of persimmon peel powder (PP) and its soluble tannin extract (ST) on laying performance, egg quality and physiological characteristics in laying hens. A total of two hundred, 60-wks-old, Hy-Line Brown layers were divided into 5 groups and fed the each experimental diet containing PP 0.15%, PP 0.50%, ST 0.075%, or ST 0.25%, respectively, for 6 wks. There were no significantly differences in the egg production, daily egg mass and feed intake among the groups. The yolk color and eggshell color were significantly improved by the addition of PP and ST into layer diet. Haugh units in PP and ST groups were significantly ($P<0.05$) higher during a week of storage. The concentrations of hepatic total cholesterol, triacylglycerol and phospholipid in hens fed the diet containing PP or ST tended to be reduce as compared to those of the control. The profiles of serum lipid fractions and intestinal microflora were not affected by dietary either PP or ST. In conclusion, the feeding of PP and ST improved the yolk and eggshell colors and Haugh unit during storage. The results also suggested that PP and ST can be used as valuable feed additives for reducing hepatic lipid contents without harmful effects on overall productive performance and physiological responses in laying hens.

Key Words: Persimmon Peel Powder, Soluble Tannin Extract, Hepatic Lipid Contents

T236 Efficacy of a bacillary probiotic in broilers. M. I. Gracia[1], E. Esteve-García[2], P. Cachaldora[3], T. Marubashi[4], E. McCartney[5], and P. Medel*[1], [1]*Imasde Agropecuaria, S.L.*, *Pozuelo de Alarcón, Spain*, [2]*IRTA*, *Constantí, Spain*, [3]*COREN*, *Ourense, Spain*, [4]*Calpis Co Ltd.*, *Tokyo, Japan*, [5]*Pen&Tec Consulting*, *Sant Cugat del Vallès, Spain*.

Four experiments involving 5,524 male broilers in 126 replicates evaluated the efficacy of a bacillary probiotic (Calsporin®, Calpis Co Ltd.) containing 1×10^{10} viable spores of *Bacillus subtilis* C-3102 per g. A completely randomized design was applied in each study using two experimental treatments: 1) basal diet (control), and 2) basal diet with 50 mg/kg of probiotic (supplying 5×10^5 CFU per gram feed) in both starter and grower phases. Two studies used mash feeds and two studies used pelleted feeds. The experimental data were tested for homogeneity, pooled and combined in a meta-analysis. Parameters selected were body weight (g) at 21 and 42 d of age, mortality (%), weight gain (g/d), feed intake (g/d) and feed efficiency (feed/gain) at 1-21, 22-42 and 1-42 d of age, and European Production Efficiency Factor (EPEF) at 1-42 d of age. Probiotic supplementation and

experiment were considered as main effects. At 21 d of age, the broilers fed probiotic weighed 3.2% more than controls (806 *vs* 832 g; P<0.01), and 1.6% more at 42 days of age (P=0.056). Mortality was considered normal (mean 6.4%) in the experimental models used (feeds without coccidiostats and antibiotics, broilers in two studies bedded on once-used litter) and was unaffected by treatment. From 1 to 21 d, the probiotic increased growth (36.4 *vs* 37.6 g/d; P<0.01) and feed intake (59.2 *vs* 60.4 g/d; P<0.05). From 22 to 42 d probiotic supplementation decreased feed to gain ratio (2.02 *vs* 1.96 feed/gain; P<0.05). Over the global period, broilers fed the probiotic grew faster (61.2 *vs* 62.2 g/d; P=0.055), converted better (1.90 *vs* 1.85 feed/gain; P<0.05), and showed better EPEF values (303 *vs* 317; P<0.01) than controls. No interaction between probiotic supplementation and experiment was found, indicating that the effect of the probiotic was homogeneous across trials. In conclusion, these data provide evidence that this probiotic improves broiler performance at a dose of 50 mg/kg.

Key Words: *Bacillus subtilis*, Probiotic, Broilers

T237 Expression profiling of the solute carrier gene family in chicken intestine. H. Li*[1], E. R. Gilbert[1], Y. Zhang[2], O. Crasta[2], D. Emmerson[3], K. E. Webb Jr[1], and E. A. Wong[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*Virginia Bioinformatics Institute*, *Blacksburg, VA*, [3]*Aviagen*, *Huntsville, AL*.

The members of the solute carrier (SLC) family are membrane-associated transporters that facilitate the passage of solutes across cell membranes and play an important role in absorption and distribution of nutrients across the small intestine. Compared to humans, little information is available on the developmental expression of SLC gene family members in chickens. The objective of our research was to determine the mRNA expression profile of the entire SLC gene family in the chick small intestine from late embryogenesis until 2 wk posthatch using Affymetrix chicken genome microarrays. Small intestines from 84 male chicks were collected on embryonic d 18 (e18) and 20 (e20), d of hatch, and d 1, 3, 7, and 14 posthatch. There were 162 SLC genes belonging to 41 SLC families expressed in the chicken small intestine. Fifty-nine SLC transporter genes showed at least a two-fold change (P < 0.01) in expression between e18 and d14, of these 26 showed at least a five-fold change (P < 0.01). The majority of transporters (103/162) showed less than a two-fold change in expression from e18 to d14 posthatch. Forty eight SLC genes showed upregulation (> two-fold) and 11 SLC genes showed downregulation (> two-fold) between e18 and d14. The glucose transporter SLC2A2 showed the greatest upregulation (104-fold) and the organic cation transporter SLC22A13 showed the greatest downregulation (16.5-fold) from e18 to d14. These results enhance our understanding of the relationship between SLC gene expression and the changes in chicken intestinal absorptive function at hatch as the chick shifts from nutrition based on a lipid-rich yolk to exogenous carbohydrate-rich feeds.

Key Words: Solute Carriers, Chicken Intestine, Microarrays

T238 Effects of Versazyme™ on ileal micro-architecture in young broilers as measured by histomorphometrics and scanning electron microscopy. C. C. Chiang[1], M. Chichlowski[2], R. Qiu*[2], J. Croom[2], L. Daniel[2], and J. Shih[2], [1]*National Chung Hsing University*, *Taiwan*, [2]*North Carolina State University*, *Raleigh*.

Versazyme™, a microbial keratinase preparation (400,000 U/g) that enhances protein digestion in poultry, has been previously found to alter intestinal muscle thickness when fed as a supplement to young broilers. To further investigate the effects of Versazyme™ on intestinal structure, 30 male broiler chicks were fed a standard starter diet (22% CP;CON) and 30 fed the starter diet plus 0.1% Versazyme™ (VZ) for 20 d. At hatch (day 0) and at days 3, 6, 14 and 20 post-hatch, six birds from each treatment group were euthanized and sections of the ileum were fixed and embedded in paraffin, sectioned and stained with hematoxylin and eosin in preparation for histomorphometric analysis using a computerized microscopic image analyzer. Histological parameters measured included villus height, villus perimeter, mid-villus width, crypt depth, external muscle layer thickness and height of enterocytes at mid villus. Adjacent pieces of tissue were fixed in glutaraldehyde and osmium tetroxide and examined for surface changes on villi, enterocytes and goblet cells using scanning electron microscopy (SEM). Although changes in histological parameters varied with age ($p \leq .05$), no VZ or age x treatment changes were noted ($p \geq .05$). SEM observations demonstrated several differences in the villi surface between CON and VZ. The surface of villi from VZ birds exhibited highly undulating surfaces with large and deep clefts as compared to CON villi. Furthermore, the surface of VZ villi contained large numbers of crater-like spots or pits, found on the surface of enterocytes or cells adjacent to enteroctyes. It is unclear whether these craters are the site of mucus secretion by goblet cells or represent structural erosion of the epithelial surface. Other changes noted were VZ villi microvilli numbers appeared greater than those of CON. Additionally, VZ villi appeared to have less mucus and mucus-associated bacteria than CON. Although Versazyme™ did not alter the dimensions of major histological features in the ileum of growing broilers in the present study, it did alter the surface characteristics of the villi.

Key Words: Keratinase, Versazyme, Intestinal

T239 Effect of a direct fed microbial on oxidative stress in the ileal and cecal epithelia of broilers. R. Qiu*[1], C. Ojano-Dirain[2], W. G. Bottje[2], C. Chiang[3], M. Chichlowski[1], J. Croom[1], L. Daniel[1], and M. Koci[1], [1]*North Carolina State University*, *Raleigh*, [2]*University of Arkansas*, *Fayetteville*, [3]*National Chung Hsing University*, *Taiwan*.

Two trials were conducted to elucidate the effects of broiler supplementation with Primalac®, a direct-fed microbial supplement (DFM), on cellular oxidative stress in the ileum and cecum. In Trial 1, eighteen broiler chicks (6 chicks per treatment) were fed either a starter pullet diet (17.4% CP; CON), CON + salinomycin (50 ppm; SAL) or CON + Primalac® (0.3%; DFM) for 21 days. At d21, broilers were euthanized and ileal mucosa was sampled. No treatment effects on mitochondrial oxidative stress as measured by increased carbonyl (CARB) concentrations (an index of protein oxidation) were found in ileal mucosa. Trial 2 was conducted as Trial 1 with the following changes. Chicks were fed a broiler starter diet (22% CP). Treatments were CON and DFM (6 chicks per treatment) and at d21, whole ileal tissue, ileal mucosal and cecal epithelial membrane lipid oxidative stress were estimated by malondialdehyde (MDA) concentrations. No differences in MDA were noted in mucosal preparations. DFM decreased whole ileal MDA concentrations by 69% (p= 0.02; .06 and .22 ηmol /μg protein, respectively) as compared to CON. Cecal MDA concentrations increased 124% with DFM as compared to CON (p=.02; 0.068 vs. 0.152 ηmol /μg protein, respectively). These

data suggest that the DFM, Primalac®, has selective antioxidant and pro-oxidative effects on the membranes of ileal enterocytes and cecal epithelial cells. The DFM effects on ileal enterocytes and cecal epithelia may be due to the extent of fermentation activity occurring in digesta at these sites within the digestive tract.

Key Words: Oxidative Stress, Direct Fed Microbial, Gastrointestinal

T240 Influence of *in ovo* feeding on turkey poult quality. J. E. de Oliveira*, P. R. Ferket, M. J. Wineland, and E. O. Oviedo-Rondon, *North Carolina State University*, *Raleigh*.

The quality of day old turkey poults is critical to their survival during the first few days after hatch. Tona et al. (2003) proposed a quality scoring method based on external characteristics like activity, appearance, retracted yolk, eyes, legs, navel, remaining membrane and remaining yolk, believed to describe poult quality. Leg shank relative asymmetry, a measure of early bone development that could influence the incidence of subsequent leg problems, is another indicatory of poult quality. *In ovo* feeding (IOF), shown to promote hatchling development, may improve poult quality and thus reduce the number of culls and early mortality. Two hundred and fifty Nicholas turkey eggs of similar egg weight (82.5±10g) were incubated in a single-stage incubator set at 38C. At 24 days of incubation, half of the eggs were injected into the amnion with 0.4 ml of a nutritive solution, while the other half served as untreated controls. At day of hatch, percent hatchability was recorded, and then poult quality score, body weight (BW), remaining yolk sac (RY), yolk free body weight (YFBW), poult length (PL) and shanks relative asymmetry (RA) were determined on all hatched poults. There were no significant treatment effects on % hatchability, BW, RY, YFBW and PL. The IOF-treated poults had leg shanks significantly more symmetric than the controls (RA of 0.90 vs. 2.13, $p<0.01$), indicating better skeletal development. The IOF-treated hatchlings also had a significantly higher average poult quality score than the control poults (63.0 vs. 77.88, $p<0.05$). Even though the IOF poults may not always positively affect body weight at hatch, improved poult quality score and relative asymmetry indicate that IOF will likely improve the chances of post-hatch survival.

Key Words: In ovo Feeding, Poult Quality, Relative Asymmetry

T241 Bioavailability of zinc-amino acid chelates to zinc nitrate in broiler chickens. S. O. Rao*[1], S. J. Park[1], R. A. Samford[2], and S. W. Kim[1], [1]*Texas Tech University*, *Lubbock*, [2]*Albion Advanced Nutrition*, *Clearfield, TX*.

Relative bioavailability of zinc-glycine chelate I (26.2% Zn, Albion Advanced Nutrition), zinc-glycine chelate II (22.3% Zn, Albion Advanced Nutrition), and zinc-arginine chelate (12.8% Zn, Albion Advanced Nutrition) to zinc nitrate (24.3% Zn) was determined using 447, 1 d old, broiler chickens. Fifteen birds were killed at d 0 and ground for carcass sampling. Remaining 432 birds were allotted to four dietary treatments: CON (with 40 ppm Zn from Zn nitrate), TA (with 40 ppm Zn from Zn-glycine I), TB (with 40 ppm Zn from Zn-glycine II), and TC (with 40 ppm Zn from Zn-arginine). There were six replicates per treatment with initially 18 birds per stainless steel brooder cage with the heater. Birds had feed and water ad libitum during 21 d feeding period. Body weight and feed intake were measured on d 1, 3, 5, 7, 14, and 21. Groups of three birds were randomly selected and killed at d 1, 3, 5, 7, 14, and 21, ground together for each day, sampled, and analyzed for Zn. The ADG of birds were 32.0, 35.6, 35.6, and 35.9 g for CON, TA, TB, and TC respectively during the entire 3 wk period. The ADFI of birds were 42.6, 46.2, 45.7, and 46.1 g for CON, TA, TB, and TC respectively during the entire 3 wk period. However, ADG and ADFI were not different among the treatments. Content of Zn (mg/bird) in bird carcass was the same among the treatments until d 5. However, Zn content was greater ($P < 0.05$) in TA (3.08 mg) than CON (1.89 mg) at d 7 but Zn content was greater ($P < 0.05$) in TC (19.12 mg) than other treatments (13.24, 13.42, and 14.28 for CON, TA, and TB, respectively) by the end of 21 d feeding period. This study indicates that Zn from Zn-arginine is more bioavailable than Zn from inorganic source by broiler chickens during the first 3 wk of their age.

Key Words: Zinc Amino Acid Chelate, Broilers, Bioavailability

T242 The interactive effects of wheat middlings, citric acid, and phytase in a corn soybean meal diet on broiler growth performance. T. O'Connor-Dennie* and J. L. Emmert, *University of Arkansas*, *Fayetteville*.

Previous research conducted during the broiler starter, grower and finisher phases suggested that there was an interaction among wheat middlings (WM), citric acid (CA) and phytase when supplemented to corn soybean diets; combining all three supplements released more P than any supplement alone. In the present experiment the interactive effects among WM, CA, and phytase on daily gain (g/c), daily feed intake (g/c), feed efficiency, adjusted bone strength (kg/mm2), and bone ash percentage was investigated in the grower phase. Broilers were placed on a P-adequate diet from d 0 to 20; on d 20 birds were weighed and allotted to 15 treatments with 5 replicate pens each containing 20 male chicks. The dietary treatments were 1) a corn soybean diet with calculated levels of 0.8% Ca and 0.13 % available P with no supplemental inorganic P (iP), 2) as diet 1 with 0.04% iP, 3) as diet 1 with 0.08% iP, 4) as diet 1 with 0.12% iP, diets 5 to 15) as diet 1 with phytase (300 or 600 FTU/kg), CA (3%), or WM (10%), alone or in combination. At the end of the grower phase 5 birds per pen were killed by carbon dioxide inhalation and right tibias collected for subsequent determination of bone strength and ash analysis. The inclusion of supplemental iP increased gain ($P < 0.05$) and had a tendency to increase feed efficiency. Overall, inclusion of phytase and WM increased gain and feed efficiency, whereas the inclusion of CA only increased feed efficiency ($P < 0.05$). Combining phytase with WM or WM and CA increased gain and feed efficiency compared to diets 1 and 4, or to any supplement alone ($P < 0.05$), and combining all three supplements resulted in the best feed efficiency ($P < 0.05$). Combining WM and CA resulted in gain values greater ($P < 0.05$) than the negative control and equal to diets containing phytase. Results from this experiment confirm the additive effects of phytase with WM and CA, and the combination of all supplements appears to increase P utilization beyond the amount released by the supplements alone.

Key Words: Phytase, Citric Acid, Wheat Middlings

T243 Performance of modern vs 1970's heritage broilers fed drug free recommended and low protein diets. T. A. Woyengo*[1], A. Golian[2], W. Guenter[1], C. Bennett[3], and H. Muc[1], [1]*University of Manitoba*, *Winnipeg, Manitoba, Canada*, [2]*University of Ferdowsi*, *Mashhad, Iran*, [3]*Manitoba Agriculture, Food and Rural Initiative*, *Winnipeg, Manitoba, Canada*.

A study was conducted to compare the performance of a modern broiler breed (Ross; RS) with those of two 1970's heritage broiler breeds (HB1 and HB2) fed drug free recommended protein (RP; 22% CP) and low protein (LP; 19% CP) diets from 1 to 63 d of age. Six hundred mixed sex d old chicks from each of the three breeds were divided into ten groups of equal weight and randomly placed in 30 floor pens. Five replicates pens of each breed were randomly assigned to the RP and LP starter (1-16 d of age) and grower (16-30 d of age) diets, respectively. The LP grower diet was used to feed all birds from 31-63 d of age. The BW gain (BWG) and feed intake (FI) of the RS birds were higher ($P < 0.05$) than those of the two heritage breeds at 16, 30, 35, 49 and 63 d of age. Among the heritage breeds, the BWG and FI of HB1 birds were higher ($P < 0.05$) than those of HB2 birds at all the measured periods. For the entire experimental period, the BWG and FI of RS birds were higher than those of HB1 and HB2 birds by 35.6 and 53.4%, and 21.7 and 37.5%, respectively. The feed conversion ratio (FCR) was also better ($P < 0.05$) for RS birds than for HB1 and HB2 birds. The HB1 and HB2 birds were, however, similar ($P > 0.05$) in FCR. The BWG and FCR of all the three breeds were depressed ($P < 0.05$) when they were fed LP starter and grower diets up to 30 d of age, but not ($P > 0.05$) when they were fed a common finisher diet from 30 to 63 d of age. Regarding FI, a significant depression ($P < 0.05$) of a LP diet on the same was only observed for RS birds from 1 to 35 d of age. For the entire experimental period, the LP starter and grower diets only negatively affected BWG of the RS birds (3992 vs 3771 g/bird). The results show that the modern RS broilers compared with the 1970's heritage breeds have superior performance, but are more sensitive to dietary protein level.

Key Words: Broiler, Breed, Performance

Physiology & Endocrinology - Livestock and Poultry: Estrus Synchronization

T244 Evaluation of 5-day versus 7- day CIDR treatment on reproductive performance of beef cows using a timed AI protocol. D. Gunn*[1], J. B. Glaze, Jr.[2], R. Findlay[3], D. Falk[4], and A. Ahmadzadeh[4], [1]*University of Idaho Extension*, *Fort Hall*, [2]*University of Idaho*, *Twin Falls*, [3]*University of Idaho Extension*, *Pocatello*, [4]*University of Idaho*, *Moscow*.

The objective of this experiment was to determine the effect of reducing the length of CIDR exposure in a CIDR-based timed AI synchronization protocol (CIDR-$PGF_{2\alpha}$-GnRH and AI) on conception and pregnancy rates in multiparous, suckled beef cows. British cross-bred cows (n = 138) were stratified by days postpartum (**dpp**), age and body weight (**BW**) and were randomly assigned to one of the following two treatments: 1) cows (n = 68) received CIDR (d -7) for 7 days, $PGF_{2\alpha}$ (25 mg) at CIDR removal (d 0), GnRH (75 µ) 56 h after CIDR removal and immediate AI (d 3; **7-d CPG**); or 2) cows (n = 70) received CIDR (d -5) for 5 days, $PGF_{2\alpha}$ (25 mg) at CIDR removal (d 0), GnRH (75 µ) 56 h after CIDR removal and immediate AI (d 3; **5-d CPG**). Cows were exposed to bulls 19 days after timed-AI. Pregnancy status was determined by ultrasonography 35 and 68 days after AI. Treatment had no effect on conception to AI (54.41% and 55.71% for 7-d CPG and 5-d CPG, respectively). Pregnancy rate was also unaffected by the treatment protocols (79.41% and 77.14%) for 7-d CPG and 5-d CPG, respectively). Age, BW, and BCS did not have an effect on conception percentage and pregnancy rate. However, dpp had a significant effect ($P < 0.01$) on conception to AI (30% for < 60 dpp vs 80% for >60 dpp) and overall pregnancy rate (50% for < 60 dpp vs. 82% for >60 dpp). Results from this study indicate that reducing the length of CIDR treatment (5 days vs. 7 days) in a CIDR-based timed AI synchronization protocol did not influence conception to AI and pregnancy rate in suckled beef cows.

Key Words: Cattle, CIDR, Timed AI

T245 Effect of reusing CIDRs on the pregnancy rate of beef cattle. M. L. Borger* and W. A. Greene, *The Ohio State University*, *Wooster*.

The main objective of this study was to determine the effect of reusing CIDRs, as a part of a synchronization program, on pregnancy rates (PR) in beef cattle. One hundred-fourteen animals were allotted to two similar groups, new CIDR (N) and used CIDR (U), based upon breed, age, postpartum interval, and postpartum cyclicity (as determined by ultrasonography). All cattle received 100 µg GnRH i.m. on d 0. Also on d 0, cattle in the N group received a new intravaginal releasing device (CIDR), containing 1.38 g progesterone, while U group cattle received a CIDR previously used for 7 d. On d 7, jugular blood samples were collected for plasma progesterone (P4) analyses, CIDRs were removed, and all animals received 25 mg $PGF_{2\alpha}$ i.m. Each removed CIDR was evaluated for signs of vaginal infection and scored from 1 to 5 (1= clear, 5=heavy pus). Animals were observed for estrus 0700 and 1900 and were artificially inseminated (AI) 11-13 h after estrus was observed. If estrus was not observed, animals were timed AI (TAI) and received 100 µg GnRH i.m. 70-72 h after $PGF_{2\alpha}$. Following the synchronization period, repeat breedings were done until d 61. Cows were pregnancy diagnosed by ultrasonography on d 88. N and U groups had similar (P>.05) estrus detection rates [EDR] (47.4 and 59.7%), PR to synchronization (52.6 and 57.9%) and overall PR (86.0 and 93.0%). Cycling (n=91) and anestrous animals had similar (P> .05) EDR (55.0 and 47.8%), PR to synchronization (58.2 and 43.5%), and overall PR (89.0 and 91.3%). Cattle with high vaginal scores (4 & 5, n= 76) and low vaginal scores (1, 2, and 3) had similar (P> .05) PR to synchronization (55.3 and 55.3%) and overall PR (85.5 and 97.4%). The N group had more (P< .05) high vaginal scores than the U group (77.2 and 56.1%). Mean P4 levels (ng/ml) were similar (P> .05) for N (1.9 ± 1.2) and U (1.9 ± 1.4) cattle. P4 levels were higher (P< .05) at CIDR removal for cycling (2.0 ± 1.3) than anestrous (1.4 ± 1.0) cattle. There were no noticeable differences between synchronizing beef cattle with previously used CIDRs and new CIDRs.

Key Words: Synchronization, CIDR Reuse, Progesterone

T246 Evaluation of human chorionic gonadotropin (hCG) as a replacement for GnRH in an ovulation-synchronization protocol before fixed timed AI. M. G. Burns*[1], B. S. Buttrey[1], D. R. Eborn[1], J. E. Larson[2], B. J. Lovaas[2], G. C. Lamb[2], K. C. Olson[1], and J. S. Stevenson[1], [1]*Kansas State University*, *Manhattan*, [2]*University of Minnesota*, *Grand Rapids*.

Two experiments evaluated differences between GnRH and hCG given at the onset of a timed AI protocol and their effects on fertility. In Exp. 1, beef cows (n = 676) at 6 locations were assigned randomly to treatments based on parity, BCS, and days postpartum. On d –20 and –10, blood was collected to determine progesterone (P4) concentrations and assess cyclicity. Blood was collected for P4 analysis at each subsequent handling of 113 cows at 1 location. Cattle were treated with a CIDR insert on d –10 and with 100 μg of GnRH (OvaCyst) or 1,000 IU of hCG (Chorulon; CO-Synch + CIDR). An injection of PGF2α (Prostamate) was given and CIDR inserts were removed on d –3. Cows were inseminated at 62 h (d 0) after CIDR insert removal. Pregnancy was diagnosed at 33 d (range: 32 to 35 d) after AI to determine pregnancy rate (PR). For cows that were pregnant after the first AI, a second pregnancy diagnosis was conducted 35 d (range: 33 to 37 d) after the first diagnosis to determine pregnancy survival. Injection of hCG reduced ($P < 0.001$) PR compared with GnRH, with a greater reduction in noncycling cows. Serum P4 was greater ($P = 0.06$) 7 d after hCG than after GnRH (4.4 ± 0.5 vs 3.2 ± 0.5 ng/mL). In Exp. 2, cattle were assigned randomly to 3 treatments, balanced across the 2 treatments applied in Exp. 1. Cows were injected (same doses as in Exp. 1) with GnRH, hCG, or saline 7 d before first pregnancy diagnosis in Exp. 1. At the time of pregnancy diagnosis, cattle diagnosed not pregnant (n = 328) were given PGF2α and inseminated 56 h later, concurrent with a GnRH injection. Compared with saline (n = 107), injections of GnRH (n = 107) and hCG (n = 114) tended ($P = 0.07$) to reduce PR at second AI (40, 33, and 31%), respectively. Concentrations of P4 did not differ among GnRH, hCG, or saline cows (6.0 ± 0.6, 6.6 ± 0.6, 6.4 ± 0.5 ng/mL, respectively) 7 d after treatment at pregnancy diagnosis. We concluded that hCG compared with GnRH given before first timed AI reduced PR (Exp. 1). Neither GnRH nor hCG may be necessary to initiate a CO-Synch protocol for cows identified not pregnant at 33 d after AI (Exp. 2).

Table 1. Pregnancy rates (PR) and pregnancy survival (PS) after first timed AI

Exp. 1	Exp. 2	PR at first AI, % (no.)	PS 33 to 68 d, % (no.)	PR After 2 AI, % (no.)
	Sal	54.5 (112)	90.2 (61)	67.9 (112)
GnRH	GnRH	55.2 (116)	92.2 (64)	64.3 (115)
	hCG	50.5 (111)	96.4 (56)	65.1 (109)
GnRH Σ		53.4[a] (339)	92.8 (181)	65.8 (336)
	Sal	38.4 (112)	93.0 (43)	62.7 (110)
hCG	GnRH	38.3 (107)	97.6 (41)	61.7 (107)
	hCG	39.8 (118)	95.7 (46)	56.8 (118)
hCG Σ		38.9 (337)	95.4 (130)	60.3 (335)

Key Words: Ovulation Synchronization, hCG, GnRH

T247 Synchronization of estrous with melengestrol acetate and estradiol cypionate in Nellore heifers and Angus dry cows. R. F. G. Peres*[1], O. G. Sa Filho[1], R. L. Valarelli[2], and J. L. M. Vasconcelos[1], [1]*FMVZ - UNESP*, *Botucatu, Brazil*, [2]*Pfizer Animal Health*, *Brazil*.

Two experiments evaluated reproductive performance of Angus dry cows and Nellore heifers treated with melengestrol acetate (MGA; MGA Premix®, Pfizer Animal Health, Brazil) associated to estradiol cypionate (ECP®, Pfizer Animal Health, Brazil). Exp.1 evaluated estrus detection (EDR), conception (CR) and pregnancy rates (PR) in a 10 days breeding season (BS) in Angus dry cows treated with melengestrol acetate. Exp.2 evaluated EDR, CR and PR in the first 10 days of BS and PR in 30 days of BS in Nelore heifers. In both experiments, animals were randomly assigned to receive one of two treatments: Control (no treatments; Exp.1: n=60; Exp.2: n=180) or MGA+ECP (addition of MGA on mineral between days -14 and -1, and 2.0mg i.m. injection of ECP on day -9; Exp.1: n=67; Exp.2: n=321). Estrus behavior observation started on day 0 and cows detected in heat were inseminated after 12h. Data were analyzed by Chi-square. In Exp.1, treatment with MGA+ECP increased EDR (62.7% vs. 36.7%; P<0.01) and tended to increase PR (37.3% vs. 21.7%; P<0.1). The effect of MGA+ECP treatment on PR was mainly due to increase on EDR since no effect on CR was found (59.1% vs. 59.5% for Control and MGA+ECP treatments, respectively). In Exp.2, treatment with MGA+ECP increased EDR (64.2% vs. 30.6%; P<0.0001) and PR in the first 10 days of BS (29.3% vs. 15.0%; P<0.001). The effect of MGA+ECP treatment on PR was mainly due to increase on EDR since no effect on CR was found (49.1% vs. 45.6% for Control and MGA+ECP treatments, respectively). PR in 30 days of BS was higher in heifers treated with MGA+ECP than in Control (55.4% vs. 35.6%; P<0.0001). In conclusion, treatment with MGA+ECP did not alter CR, but increased EDR and PR, allowing higher amount of cattle pregnant in shorter time.

Key Words: MGA, Dry Cows, Heifers

T248 Effect of treatment with melengestrol acetate combined with estradiol cypionate on pregnancy rates along a 70 days breeding season in postpartum Nellore cows. R. F. G. Peres*[1], O. G. Sa Filho[1], R. L. Valarelli[2], and J. L. M. Vasconcelos[1], [1]*FMVZ - UNESP*, *Botucatu, Brazil*, [2]*Pfizer Animal Health*, *Brazil*.

The aim of this trial was to evaluate the effect of treatment with melengestrol acetate (MGA; MGA Premix®, Pfizer Animal Health, Brazil) associated with estradiol cypionate (ECP®, Pfizer Animal Health, Brazil) on pregnancy rates (PR) to natural service of postpartum Nellore cows at 10, 40 and 70 days of breeding season (BS). Postpartum Nellore cows (n=204) were randomly assigned to receive one of two treatments: Control (no treatment; n=102) or MGA+ECP (addition of MGA on mineral between days -14 and -1, and 2.0mg i.m. injection of ECP on day -9; n=102). On day 0, cows from MGA+ECP treatment received calf removal and cows from both two treatment groups were allocated with sires (1/15 proportion) for natural service during 70 days. Pregnancy diagnosis were performed by ultrasound on days 40, 70 and 100 of BS to determine PR at 10, 40 and 70 days of BS. Data were analyzed by Chi-square. Treatment with MGA+ECP increased PR at 10 days (12.7% vs. 4.9%; P<0.05) and at 70 days (55.45% vs.

35.6%; P<0.01), and tended to increase PR at 40 days of BS. (47.1% vs. 35.3%; P<0.1). In summary, treatment with MGA+ECP resulted in a higher proportion of cows pregnant during the BS.

Key Words: MGA, ECP, Natural Service

T249 Effect of estradiol cypionate dosage (1 vs. 2 mg) on estrus detection and pregnancy rates of postpartum Nellore cows synchronized with melengestrol acetate. R. L. Valarelli*[1], O. G. Sa Filho[2], and J. L. M. Vasconcelos[2], [1]*Pfizer Animal Health*, *Brazil*, [2]*FMVZ - UNESP*, *Botucatu, Brazil*.

The aim of this trial was to evaluate the effect of two dosages of estradiol cypionate (ECP®, Pfizer Animal Health, Brazil) on estrus detection (EDR) and pregnancy rates (PR) of postpartum Nellore cows synchronized with melengestrol acetate(MGA; MGA Premix®, Pfizer Animal Health, Brazil). Postpartum multiparous Nellore cows (n=399), evaluated on day -14 by ultrasound to determine presence of corpus luteum (CL), were randomly assigned to receive one of three treatments: Control (no treatment; n=127), ECP1 (addition of MGA on mineral between days -14 and -1, and 1.0 mg of ECP on day -9; n=137) or ECP2 (addition of MGA on mineral between days -14 and -1, and 2.0 mg of ECP on day -9; n=135). On day 0, cows from ECP1 and ECP2 treatments received calf removal and cows from the three treatment groups were observed for estrus behavior during 30 days. Cows were inseminated 12h after heat detection. Data were analyzed by logistic regression, and when effect of treatment was detected, means were compared by orthogonal contrasts (C1: "MGA1" vs. "MGA2"; C2: "Control" vs. "MGA1" + "MGA2"). There was effect of treatment on EDR (Control: 14.9%; ECP1: 48.2%; ECP2: 47.4%; C1: P>0.1; C2: P<0.001) and PR (Control: 7.9%; ECP1: 21.2%; ECP2: 21.5%; C1: P>0.1; C2: P<0.01) in the first 10 days of breeding season (BS). Effect of treatments on PR in the first 10 days of BS was mainly due to increase on EDR, since no effect of treatments on conception was detected. Treatments tended to affect PR in 30 days of BS (Control: 30.7%; ECP1: 31.4%; ECP2: 42.2%; C1: P<0.1; C2: P>0.1). Considering only cows treated with MGA, presence of CL did not affect EDR (47.8%), conception (44.6%) and PR (25.0%) in the first 10 days of BS, and on PR in 30 days of BS (36.8%). In conclusion, regardless of ECP dosage, treatment with MGA+ECP brought heat behavior together in the first 10 days of BS, anticipating conception, and allowed cows without presence of CL to have similar PR than cows with CL.

Key Words: MGA, ECP, Pregnancy Rate

T250 Pregnancy rates in a 10 days breeding season in postpartum Nellore cows treated with melengestrol acetate associated or not with estradiol cypionate. R. L. Valarelli*[1], O. G. Sa Filho[2], M. Meneghetti[2], and J. L. M. Vasconcelos[2], [1]*Pfizer Animal Health*, *Brazil*, [2]*FMVZ - UNESP*, *Botucatu, Brazil*.

The aim of this trial was to evaluate the effect treatment with melengestrol acetate (MGA; .5mg/head/day; MGA Premix®, Pfizer Animal Health, Brazil) associated or not with estradiol cypionate (ECP®, Pfizer Animal Health, Brazil) on pregnancy rate (PR) to natural service of postpartum Nellore cows during a 10 days breeding season (BS). Postpartum Nellore cows (n=1033) were blocked according to presence of corpus luteum (CL; evaluated on day -14 by ultrasound). Within each block, cows were randomly assigned to receive one of three treatments: Control (no addition of MGA; n=67 with CL; n=245 without CL), MGA (addition of MGA between days -14 and -1; n=93 with CL; n=278 without CL) or MGA+ECP (addition of MGA between days -14 and -1, and 2.0mg i.m. injection of ECP on day -9; n=86 with CL; n=265 without CL). On day 0, cows from MGA and MGA+ECP treatments received calf removal and cows from the three treatment groups were allocated with sires (1/15 proportion) for natural service during 10 days. Data were analyzed by logistic regression, and when effect of treatment was detected, means were compared by orthogonal contrasts (C1: "MGA" vs. "MGA+ECP"; C2: "Control" vs. "MGA" + "MGA+ECP"). Treatments affected PR in cows without CL (Control: 12.6%; MGA: 36.3%; MGA+ECP: 38.5%; C1: P>0.1; C2: P<0.001). In cows with CL, treatments affected PR (Control: 40.3%; MGA: 36.6%; MGA+ECP: 54.6%; C1: P<0.05; C2: P>0.1). Beneficial effect of ECP in cows with CL could be due to prevention of development of persistent dominant follicle. Regardless of treatment, body condition score (BCS) affected PR in cows without CL (P<0.0001) but not in cows with CL, indicating that the effect of BCS is mainly in resuming of cyclicity than in conception. In conclusion, in cows without CL, treatment with MGA (associated or not with ECP) increased amount of cows pregnant in a 10 days BS; in cows with CL, treatment with MGA should be associated with ECP for better PR.

Key Words: MGA, ECP, Natural Service

T251 Fixed-time artificial insemination in replacement beef heifers after treatment with human chorionic gonadotropin (hCG), progesterone, and prostaglandin $F_{2\alpha}$. G. C. Lamb[1], J. E. Larson*[1], C. R. Dahlen[2], and G. Marquezini[1], [1]*North Central Research and Outreach Center, University of Minnesota*, *Grand Rapids*, [2]*Northwest Research and Outreach Center*, *Crookston, MN*.

We determined whether pre-treatment with human chorionic gonadotropin (hCG) 14 d prior to estrous synchronization or replacing GnRH with hCG at the time of CIDR insertion would alter pregnancy rates in replacement beef heifers estrous synchronized with the CO-Synch + CIDR protocol. Five hundred forty seven replacement beef heifers were assigned randomly to one of four treatments in a 2 × 2 factorial design: 1) heifers received a 100 µg injection of GnRH at CIDR insertion (d -7) and a 25 mg injection of $PGF_{2\alpha}$ at CIDR removal (d 0), followed in 54 h by fixed-time AI (TAI) with a second injection of GnRH (CG; n=160); 2) CG but the first injection of GnRH was replaced with a 1,000 IU injection of hCG (CH; n=158); 3) CG, plus heifers received a 1,000 IU injection of hCG 14 d prior to CIDR insertion (HG; n=116); and 4) CH, plus heifers received a 1,000 IU injection of hCG 14 d prior to CIDR insertion (HH; n=113). Blood samples were collected on d -24, -14, -7, 0, and 2 to determine concentrations of progesterone. Transrectal ultrasonography was used to monitor ovarian structures on d -7 and 0, plus pregnancy status on d 35. Between pre-treatment factors of control or hCG pregnancy rates were similar, whereas for the factor of GnRH or hCG at CIDR insertion pregnancy rates for the GnRH treated heifers (41%) was greater (P < 0.05) than hCG treated heifers (29%). Heifers treated with hCG at CIDR insertion had an increased (P < 0.05) occurrence of multiple corpora lutea compared to those receiving GnRH at the time of CIDR removal (38.3% vs. 24.0%, respectively) and had increased concentrations of progesterone at the time of CIDR removal (2.68 ng/ml vs 2.10 ng/ml; P < 0.05) and at TAI (0.56 ng/ml vs. 0.39 ng/ml; P < 0.05). We concluded that presynchronization with hCG 14 d prior

to CIDR insertion failed to enhance pregnancy rates and replacing GnRH at CIDR insertion with hCG resulted in decreased pregnancy rates. However, hCG enhanced the incidence of multiple ovulations and concentrations of progesterone at CIDR removal and at TAI.

Key Words: Human Chorionic Gonadotropin, Estrous Synchronization, Beef Heifers

T252 Artificial insemination of superovulated Angus cows using sexed or conventionally frozen semen. G. C. Lamb*[1], B. J. Lovaas[1], S. L. Bird[1], A. Martins[1], J. E. Larson[1], J. C. Rodgers[1], D. J. Frank[2], and D. M. Williams[2], [1]*North Central Research and Outreach Center, University of Minnesota*, *Grand Rapids*, [2]*ABS Global, Inc.*, *DeForest, WI*.

We determined whether embryo production characteristics would be compromised in a superstimulation protocol when sexed semen was utilized for insemination of donors. Thirty two, Angus cows from a single herd were stratified by age and body condition score before random assignment to a switch-back experimental design: 1) cows received four inseminations of conventionally frozen semen at a minimum concentration of 15×10^6 sperm/straw (Conventional; n = 32); and 2) cows received four inseminations of sexed semen at a minimum concentration of 2.1×10^6 sperm/straw (Sexed; n = 32). Cows were blocked by two separate AI sires. During period 1, 10 d after estrus, eight 2× daily injections of FSH were administered to the cows, with cows receiving PGF at the time of the seventh injection of FSH. Cows were inseminated 1× at the time of first detected estrus, 2× 12 h after onset of estrus, and 1× 24 h after onset of estrus. Embryos were collected 7 d after first detected estrus and all embryos were assigned a developmental stage and quality grade. After a 30 d adaptation interval, period 2 was initiated and cows were resynchronized and superovulated using the same protocol as for period 1. The total ova per flush was similar between Conventional (11.7 ± 1.8) and Sexed treatments (12.0 ± 1.6), but the number of transferable embryos was greater ($P < 0.01$) for Conventional (6.5 ± 1.0) than Sexed (4.5 ± 0.9) treatments. In contrast, the mean number of unfertilized ova were greater ($P < 0.05$) for Sexed (6.3 ± 1.0) than Conventional (3.1 ± 1.2) treated cows. The number of degenerate, Grade 2, and Grade 3 embryos were similar among treatments. There were no differences between Bull 1 (44.4%) and Bull 2 (46.7%) in the percentage of transferable embryos recovered. However, fertilization rates and the percentage of transferable embryos where affected ($P < 0.05$) by period and donor. We concluded that insemination of superstimulated donor cows with sexed semen will result in lower transferable embryos and an increase in unfertilized ova than those cows inseminated with conventionally frozen semen.

Key Words: Superovulation, Sexed Semen, Artificial Insemination

T253 Effect of length of treatment with melengestrol acetate (7 vs. 13 days) prior to induction of ovulation on occurrence of short cycle in anestrous Nellore cows. O. G. Sa Filho*[1], R. L. Valarelli[2], and J. L. M. Vasconcelos[1], [1]*FMVZ - UNESP*, *Botucatu, Brazil*, [2]*Pfizer Animal Health*, *Brazil*.

The aim of this trial was to evaluate if treatments with 1.5 mg/day of melengestrol acetate (MGA; MGA Premix®, Pfizer Animal Health, Brazil) during 7 or 13 days prior to induction of ovulation are effective to prevent premature luteolysis in anestrous Nellore cows. Fifty three post-partum anestrous multiparous Nellore cows (evaluated by two ultrasound exams 9 days apart) were randomly assigned to receive one of three treatments: Control (no addition of MGA on mineral; n = 15), MGA-7 (addition of MGA on mineral between days -10 and -3; n=18) or MGA-13 (addition of MGA on mineral between days -16 and -3; n = 20). Ovulation was induced with 48 h calf removal (between days -2 and 0) followed by 100 mcg i.m. GnRH (Fertagyl®, Intervet, Brazil) injection on day 0. Ovarian ultrasound exams were performed to measure size of ovulatory follicle (day 0) and to evaluate ovulation (days 0 and 2). Cows that did not ovulate were excluded from the trial (n = 13). On day 9, ultrasound exam was conducted aiming to determine presence and size of CL, and blood samples were collected for serum progesterone analysis by RIA. Cows were considered having short cycle when luteal tissue was absent and/or serum progesterone was <0.5 ng/mL. Binomially distributed data and continuous data were analyzed by PROC LOGISTIC and PROC GLM of SAS, respectively. Treatments did not affect ovulation rate (Control: 86.7%; MGA-7: 72.2%; MGA-13: 75.0%; P>0.1), but affected size of ovulatory follicle (Control: 9.8±0.4 mm; MGA-7: 10.6±0.4 mm; MGA-13: 11.9±0.4 mm; P<0.01) and percentage of short cycle (Control: 76.9%; MGA-7: 38.5%; MGA-13: 0.0%; P<0.001). In conclusion, feeding anestrous cows with 1.5mg/day of MGA during 13 days decreased percentage of cows with premature luteolysis following the first postpartum ovulation.

Key Words: Melengestrol Acetate, Anestrous Cows, Short Cycle

T254 Effect of length of exposure to exogenous progesterone (3 vs. 6 days) prior to induction of ovulation on premature luteolysis in anestrous Nellore cows. O. G. Sá Filho*, C. R. Zilioti, and J. L. M. Vasconcelos, *FMVZ - UNESP*, *Botucatu, Brazil*.

The objective of this trial was to evaluate if 3 days pre-treatment with exogenous P_4 has the same efficiency than 6 days pre-treatment on prevention of short cycles. Anestrous Nellore cows (evaluated by 2 ultrasound exams 8 days apart; n=109) were randomly divided in two experimental groups: 3d Group - Intravaginal P_4 device (CIDR®, Pfizer Animal Health, Brazil) by 3 days followed by calf removal (CR; 48 hours); Control Group: Intravaginal P_4 device by 6 days followed by CR. At end of CR (day 0), all cows received 100mcg GnRH i.m. injection GnRH (Fertagyl®, Intervet, Brazil). Ovulation was evaluated by two ultrasound exams on days 0 and 2 and only cows which ovulate were used for the study (Control: n=36; Group 3d: n=18). Blood samples were collected on days 0, 5, 7 and 9 for corpus luteum lifespan evaluation by serum P_4 dosage (RIA). Ovulation rate and percentage of short cycles were analyzed by logistic regression and serum P_4 concentrations were analyzed by PROC MIXED of SAS. Ovulation rate was lower (P<0.001) on 3d Group (33.3%, 18/54) than Control (65.4%, 36/55). The frequency of short cycles did not differ among both groups (5.5% vs. 5.5%, P>0.10), as well as serum P_4 concentrations on days 0, 5, 7 and 9 (0.3±0.5 vs. 0.3±0.4; 1.8±0.5 vs. 2.1±0.4; 2.8±0.5 vs. 2.9±0.4; 3.4±0.5 vs. 3.6±0.4 ng/mL respectively; P>0.10). For both treatments, serum P_4 increased between days 0, 5, 7 and 9 (P<0.001), indicating normal development of CL during this period. We concluded that 3 days treatment with P_4 prior to induction of ovulation in anestrous cows warranted normal luteal lifespan.

Key Words: Progesterone, Anestrous Cows, Short Cycle

T255 Ovarian and hormonal responses to a progesterone releasing intravaginal device (PRID) treatment in the presence or absence of estradiol from the early luteal phase in heifers. T. Kuroiwa*, T. Tanaka, and H. Kamomae, *Tokyo University of Agriculture and Technology*, *Fuchu, Tokyo, Japan*.

Some studies have reported that the timing of a progesterone device treatment in the estrous cycle influences the efficacy of estrus synchronization. The aim of this study was to investigate ovarian and hormonal profiles in heifers treated with a PRID with or without 10mg of estradiol benzoate (E) from the early luteal phase. Cycling Holstein heifers were assigned randomly to five groups and received PRID with E (PE0; n=6) or without E (P0; n=5) on Day 0 (= ovulation), or PRID with E (PE2; n=6) or without E (P2; n=6) on Day 2, for 12 days. The control group received a placebo device from Day 0 to Day 14 (Cont; n=5). Ultrasonographic images of the ovary and blood samples were collected throughout the experiment. The proportions of heifers with detected estrus within three days after PRID removal in the PE0, P0, PE2, P2, and Cont groups were 3/6, 2/5, 3/6, 2/6, and 0/5, respectively. There was no significant difference in the mean plasma concentrations of progesterone among the five groups during the period of PRID treatment except for a few days after PRID insertion. The mean area of corpus luteum (CL) in four PRID treated groups was significantly smaller than that in the Cont group ($p<0.05$). CL regression started on Days 10.6±4.4, 10.8±5.4, 14.3±0.5, 13.8±5.6 and 16.8±0.8 in the PE0, P0, PE2, P2 and Cont groups, respectively, and there was a significant difference between PE0 and PE2 ($p<0.05$). In the most heifers that did not exhibit the estrus within three days, no developing dominant follicle was observed at PRID removal. These data suggest that earlier treatment of PRID with E after ovulation advances the regression of CL during the early luteal phase; however, the effective rate for estrus synchronization was around 50 % in all groups. The mechanism for the failure of estrus synchronization seems to be correlated to the absence of growing follicle at the time of PRID removal rather than the regression of CL in the case of PRID treatment from the early luteal phase.

Key Words: Estrus Synchronization, Early Luteal Phase, PRID

T256 A stochastic model to compare breeding system costs for synchronization of estrus and AI to natural service. S.K. Johnson* and R.D. Jones, *Kansas State University*, *Manhattan*.

A partial budget approach was used to stochastically model costs of several systems for synchronization of estrus and AI plus clean-up natural service compared to natural service only breeding systems and to identify the most important factors in determining the differences in the expected economic returns between breeding systems. Three herd sizes, 3 cow to bull ratios and 7 systems for synchronization of estrus were examined, for a total of 63 simulation models. Each model estimated the expected distribution of costs associated with one synchronization system and compared it to the natural service option. Stochastic variables in the model included bull purchase price, percent calf crop, calf price, AI conception rate, cull bull value, cull bull weight, genetic value premium of AI-sired calf, heat detection rate, season pregnancy rate, semen cost, and synchronized calf weight advantage. Cost per pregnancy for breeding systems that included both AI and natural service ranged from $46 to $95. Natural service tended to be a lower cost breeding system at higher cow to bull ratios whereas AI systems were more cost effective at lower cow to bull ratios. Overall, the combination heat detection and clean-up fixed-time AI synchronization systems were economically preferred to natural service 33% of the time, with this value increasing to 41% for synchronization systems using strict fixed-time AI, and 49% for heat detection only systems. Heat detection only systems in large herds using low cow to bull ratios demonstrated a net economic advantage relative to natural service 85% of the time. Genetic value premiums and semen cost were consistently included in the top 3 factors that determined expected economic differences between natural service and AI systems across herd sizes and cow to bull ratios. Variability in bull purchase price was the most important factor when the cow to bull ratio was low. Estrus synchronization and AI were economically advantageous when a sufficient genetic value premium could be obtained from AI-sired calves.

Key Words: Estrus Synchronization, AI, Breeding Costs

T257 Different estrus syncryonization protocols in sheep. B. R. Avila[1], M. T. Sánchez[1], E. O. García*[2], O. D. Montañez-Valdez[3], P. M Molina[1], J. G. Peralta[1], M. E. Ortega[1], and J. L. Cordero[1], [1]*Colegio de Postgraduados*, *Montecillo, Estado de México, México*, [2]*Centro Universitario de la Costa Sur de la Universidad de Guadalajara*, *Aútlan, Jalisco, México*, [3]*Centro Universitario del Sur de la Universidad de Guadalajara*, *Ciudad Guzmán, Jalisco, México*.

The objective of the present experiment was to evaluate different protocols for estrus synchronization in ewes. It was performed in a sheep farm located in the property ″El Tilzapote″, which is located north of the city of Autlán de Navarro, Jalisco, México. Forty adult female crossbreed Katahdin and Pelibuey with over 2 deliveries were used, which were randomly assigned to four treatments of ten ewes each. In treatment A, two dosages of 1 ml de synthetic $PGF_{2\alpha}$ (d-cloprostenol 0.075 mg/ml) were administered on days -22 and -13, and on day -11 a Chronogest intravaginal sponge containing 40 mg fluorgestone acetate (FGA) was inserted, on day 0 sponges were removed and 1 ml intramuscular $PGF_{2\alpha}$ was administered. Treatment B was similar to treatment A but sponges remained for 5 days. In treatment C, two dosages 1 ml $PGF_{2\alpha}$ were administered on day PGFs -24 and -15, on day -7, 50 µg (0.5 ml) of a synthetic GnRH was administered, and on day 0, 1 ml $PGF_{2\alpha}$ In treatment D, three applications of 1 ml $PGF_{2\alpha}$ were given, with 9 day intervals on days -18, -9 and 0. Estrus detection was performed 24 hours after the removal of the intravaginal sponge and the last dosage of $PGF_{2\alpha}$, ewes were observed during 1 h every 4 h, for a period of 4 days. Percentages of onset of estrus and gestation were analyzed with Xi^2 , and onset and duration of estrus with GLM procedure of SAS. The percentage of females detected in estrus were 100, 100, 90 and 80 % for treatments A, B, C, and D, respectively ($P>0.05$); the time to onset of estrus was at 42.8 ± 6.81, 55.20 ± 15.17, 43.55 ± 3.71 and 40 ± 8.28 h for treatments A, B, C, and D, respectively ($P<0.05$); the duration of estrus was 36 7.54, 28.4 ± 3.97, 35.1 ± 5.20 and 42.5 ± 13.68 h for treatments A, B, C, and D respectively ($P<0.05$); the percentage of gestation was of 60 % for treatment A, and 90 % for treatments B, C, and D ($P<0.05$). The estrus cycle of ewes can be synchronized with intravaginal sponges of FGA for 5 days, as well as with GnRH and prostaglandin with similar results of the traditional use of the sponge for 11 days.

Key Words: Estrus, Synchronization, Sheep

T258 Treatment with bST during progestin synchronization increases the blastocyst rate in ewes. A. Montero, J. Hernández, J. Valencia, C. G. Gutiérrez, S. Rojas, and J. Hernández-Cerón*, *Facultad de Medicina Veterinaria y Zootecnia. Universidad Nacional Autónoma de México.*, *Mexico*.

Treatment with bST during synchronization increased prolificacy in sheep. Here, we tested whether a single dose of bST 5 days before the end of progestin treatment improves fertilization and embryo development. Thirty-two ewes were synchronized with progestin and superovulated with FSH. Five days before the end of progestin treatment half of the ewes were injected with 125mg bST (n=16; Lactotropina®, Elanco) or saline solution (control; n=16). Estrus was detected every 2h and estrous sheep were served every 8 h whilst in estrus. Embryos were recovered on day 7 of the cycle. Embryos were assessed microscopically and fixed in 4% paraformaldehyde. Cell numbers in blastocysts were counted after Hoechst staining. In addition, blood samples were collected from 8 sheep per group, starting the day of bST treatment and ending on the day of embryo recovery to determine plasma concentration of IGF-I, insulin and progesterone. The proportions of cleaved and transferable embryos in the morula and blastocyst stage were compared between groups by logistic regression. Cell number, IGF-I, insulin and progesterone plasma concentrations was analyzed by ANOVA. Cleavage rate was greater (P<0.01) in the bST (86) than in the control group (62) whilst transferable embryos did not change (P>0.83; bST=88.5 vs control=87.5). However, the proportion of embryo reaching the blastocyst stage (bST =77.6 vs. control =48.5) and the number of cells in the blastocyst (bST =88.9±3.7 vs. control =76.1\plusmn;3.7) were greater (P<0.01) in bST treated sheep. Plasma concentrations of IGF-I and insulin were higher (P<0.01) in bST treated sheep. No changes were observed in progesterone concentrations (P>0.49). It is concluded that bST treatment is associated with increased IGF-I and insulin concentrations and that treatment during the period of follicular development, fertilization and early embryo development increases cleavage rate and blastocyst development in sheep.

T259 Effect of estradiol–17β supplementation at the last GnRH of the Ovsynch protocol in lactating dairy cows. A. P. Cunha*, J. N. Guenther, E. P. B. Silva, J. B. C. Heijink, and M. C. Wiltbank, *University of Wisconsin*, *Madison*.

The aim of this study was to evaluate whether estradiol supplementation at the last GnRH of the Ovsynch protocol would affect ovulation rate, uterine tone score, and pregnancies/AI (P/AI) in a TAI protocol for lactating dairy cows. Holstein cows (n=391) were assigned to two groups in a CRD design. Control cows were presynchronized (GnRH–7d–PGF2α–3d–GnRH) and 7d later began Ovsynch (GnRH–7d–PGF2α–52h–GnRH–18h–TAI). Treated cows received the same TAI protocol plus 0.5 mg of estradiol–17β (E2) at the second GnRH of Ovsynch. Ovarian ultrasound and uterine palpation were performed in order to assess ovulation, ovulatory follicle size, pregnancy diagnosis and uterine tone score. Ovulation rate differed between 1st and later services (P<0.05) but did not differ between E2–treated vs control cows at 1st service (91.4%, n=81 vs. 90.7%, n=75) and second or later services (76.6%, n=77 vs. 75.3%, n=81). Average ovulatory follicle size was not different between E2–treated and control (14.9 mm vs. 15.1 mm; P>0.10). There was an interaction between season and ovulatory follicle size. Cows ovulated smaller follicles during Aug–Sep when compared with Oct–Jan (average amb. temp.: Aug–Sep=61F; Oct–Jan=36F). E2–treated cows had higher uterine tone scores at TAI than control cows (2.53, n=113 vs. 2.35, n=119; P<0.05). Overall P/AI and pregnancy loss did not differ (P>0.10) between E2 and control; however, parity (P=0.04) and number of service (P=0.03) did have an effect on P/AI. Primiparous E2–treated cows had higher P/AI than multiparous E2–treated cows (53.1% vs 35.5%; P=0.03), and also tended to have better P/AI than primiparous (40.0%, P=0.07) and multiparous control (42.7%, P=0.10) cows. 1st service E2 cows had higher P/AI than later services, but there was no difference between 1st service E2 and 1st service control cows. In conclusion, E2 increased uterine tone, but did not have an overall effect on P/AI. Nevertheless, E2 supplementation at the last GnRH of Ovsynch may increase P/AI in primiparous cows at the first service postpartum.

Key Words: Estradiol, Uterine Tone, Dairy Cow

T260 Effect of GnRH after TAI on subsequent Resynch fertility. A. P. Cunha*, J. A. Powell, J. N. Guenther, E. P. B. Silva, and M. C. Wiltbank, *University of Wisconsin*, *Madison*.

Two experiments were performed to evaluate if GnRH treatment 15–16d after TAI increased pregnancies/AI (P/AI) during the subsequent Ovsynch–TAI in high producing dairy cows. In experiment 1, cows (n=368) were presynchronized (GnRH–7d–PGF–3d–GnRH) and 7d later began Ovsynch (GnRH–7d–PGF–52h–GnRH–18h–TAI).Cows were then assigned randomly but at a 2:1 distribution to one of two groups: 1) G–16 – received GnRH (100µg) 16d after last GnRH of Ovsynch; 2) control – no treatment. Ovarian ultrasound was used to assess ovulation and for pregnancy diagnosis. Macro GLIMMIX of SAS was used for statistical analyses. Ovulation to G–16 differed between open and pregnant cows (43.5% vs 22.4%; P<0.01; n=209). Ovulation to GnRH on day 26 (1st GnRH of Resynch) was higher for G–16 cows that ovulated to G–16 than those that did not (52.4% vs 34.7%; P=0.02; n=161), but there was no difference between G–16 and controls (44.1%, n=93). There was no effect of G–16 on P/AI to previous TAI (40.0% vs. 40.7%; n=368). However, cows that received G–16 had numerically higher P/AI at the subsequent TAI (33.0% vs 26.4%; P>0.10; n=144). In experiment 2, 781 lactating Holstein cows underwent Presynch (PGF–14d–PGF) and 14 days later began Ovsynch (GnRH–7d–PGF–48h–GnRH–16h–TAI). At 15d after last GnRH of Ovsynch cows were assigned to one of two groups: 1) G–15 – received GnRH 15d after last GnRH of Ovsynch; 2) control – no treatment. Cows in G–15 had similar P/AI as Control cows at previous AI (36.3% vs. 33.9%; n=781) but higher P/AI at subsequent AI (38.8% vs 23.7%; P=0.01; n=278). Parity (P<0.05) had an effect on P/AI at subsequent AI with G–15 higher than control in primiparous cows (47.9%, n=48 vs 27.8%, n=36; P=0.05) or multiparous cows in G–15 (31%, n=87; P=0.05) or control (22.2%, n=90; P<0.01). In conclusion, GnRH treatment at 15–16d after TAI increased P/AI at subsequent TAI in lactating dairy cows. The positive effect of post–breeding GnRH on subsequent TAI may depend on ovulation to the GnRH and may possibly improve synchrony for the subsequent Resynch protocol.

Key Words: GnRH, Pregnancy, Dairy Cows

T261 Human chorionic gonadotropin (hCG) and GnRH influences pregnancy survival and resynchronized ovulation before timed AI in Holstein cattle. B. S. Buttrey*, M. G. Burns, and J. S. Stevenson, *Kansas State University*, *Manhattan*.

Treatment with hCG at 4 to 9 d after AI induced ovulation, increased number of corpus luteum (CL), size of the original CL, and increased serum P4 concentrations in lactating dairy cows (JDS 90:331-340; 2007). We hypothesized that replacing the first injection of GnRH (d –7) with hCG or saline in a Resynch-Ovynch protocol would alter pregnancy rates in cows subsequently diagnosed not pregnant (d 0; Exp. 1) and pregnancy survival in cows subsequently diagnosed pregnant (d 0; Exp. 2). Cows in 4 herds were assigned randomly based on lactation number, number of previous AI, and last test-day milk yield to treatments of 1,000 IU of hCG (Chorulon), 100 µg of GnRH (Fertagyl), or saline 7 d before pregnancy diagnosis. In Exp. 1, cows found not pregnant were given PGF2α (Prostamate; d 0), then inseminated 72 h later, concurrent with a GnRH injection (3 herds) or given GnRH 16 to 24 h before AI at 72 h (1 herd). Pregnancy rates were or tended to be reduced by saline (13.1%; n = 510) compared with GnRH (18%; n = 694; $P < 0.02$) or hCG (16.9%; n = 544; $P = 0.08$). In Exp. 2, among pregnant cows treated, pregnancy survival 4 to 9 wk after initial pregnancy diagnosis differed among herds ($P < 0.001$), but a treatment x herd interaction ($P < 0.01$) also was detected (see table). Ovarian structures were monitored in herd 1 by using transrectal ultrasonography 0 and 7 d after treatment with hCG, GnRH, or saline (Exp. 3). Incidence of a new CL was reduced ($P < 0.05$) in pregnant cows 7 d after treatment. A treatment x pregnancy status interaction ($P < 0.05$) was detected. Incidences of ovulation in open cows were: hCG (52.6%; n = 97), GnRH (47.8%; n = 92), and saline (27%; n = 89), whereas those in pregnant cows were: hCG (56.3%; n = 48), GnRH (25%; n = 48) and saline (7.1%; n = 56). Initiating a Resynch-Ovsynch protocol 7 d before pregnancy diagnosis with saline reduced timed AI pregnancy rates (Exp. 1). In pregnant cows treated with GnRH, pregnancy survival was slightly reduced in 2 of 4 herds (Exp. 2). Incidence of new CL was greater after hCG than GnRH in pregnant cows, but not in nonpregnant cows (Exp. 3).

Table 1. Pregnancy survival in dairy cows (Exp. 2)

	Herd 1	Herd 2	Herd 3	Herd 4	Treatment Σ
Days since AI[1]	23-36	31-37	30-36	32-38	
Treatment*	% (no.)	% (no.)	% (no.)	% (no.)	% (no.)
hCG	95.6 (37)	99.1 (106)	86.4 (103)	94.2 (173)	93.6 (419)
GnRH	76.3 (38)	100 (95)	93.3 (105)	92.6 (175)	93.0 (413)
Saline	84.4 (45)	100 (106)	93.9 (99)	96.1 (153)	95.3 (403)

T262 Logistic regression analysis for relationship between the timing of the resumption of normal ovarian cycles and metabolic status in postpartum dairy cows. C. Kawashima*, M. Matsui, E. Kaneko, C. Amaya Montoya, T. Shimizu, N. Matsunaga, K. Kida, Y-I. Miyake, and A. Miyamoto, *Obihiro University of Agriculture and Veterinary Medicine*, *Obihiro, Hokkaido, Japan*.

The duration and severity of negative energy status after parturition are correlated with the interval to resumption of ovarian activity in dairy cows. The aim of our study was to examine the weekly relationship between the timing of the resumption of normal ovarian cycles (NOV) and the metabolic status in postpartum (pp) dairy cows. Blood samples were obtained from 26 multiparous Holstein cows from wk 1 (0 to 6 d after parturition) to wk 10 pp, and measured metabolites (glucose; non-esterified fatty acid, NEFA; total cholesterol; aspartate aminotransferase, AST; γ-glutamyl transpeptidase, γ-GTP), metabolic hormones (growth hormone; insulin-like growth factor-I; insulin) and progesterone concentrations. When the progesterone concentrations in plasma increased to more than 1 ng/ml for 7 to 21 d, the cows was confirmed as having NOV. Cows having the resumption of NOV by wk 3, wk 4 and so on were compared with the remaining cows using logistic regression analysis to identify the independent variables that were effective for predicting the resumption of NOV. The number of cows showing the resumption of NOV by each wk pp was 5 by wk 3, 9 by wk 4, 12 by wk 5, 15 by wk 6, 17 by wk 7, 19 by wk 8 and 22 by wk 9 pp. The analysis showed that the higher probability of the resumption of NOV by wk 3 pp was associated with higher plasma insulin concentrations from wk 1 to wk 3 pp ($P<0.05$). On the other hand, the higher probability of a later (after wk 9 pp) resumption of NOV was associated with higher concentrations of NEFA, AST and γ-GTP ($P<0.05$) in the early pp period. In conclusion, our data suggest that metabolic status in the early pp period influences the timing of the resumption of NOV, in which higher energy status by wk 3 pp has a real-time beneficial effect on early NOV and greater mobilization of body fat stores plus declining of hepatic function in the early pp period has a longer-time inhibitory effect and leads to delayed NOV.

Key Words: Dairy Cow, Metabolic Status, Resumption of Normal Ovarian Cycle

T263 Does synchronization protocol affect conception in lactating dairy cows? J. L. M. Vasconcelos*[1], R. M. Santos[2], B. L. Cardoso[1], F. M. Abreu[1], L. H. Cruppe[1], and S. Soriano[3], [1]*FMVZ-UNESP*, *Botucatu, SP, Brazil*, [2]*UFU*, *Uberlandia, MG, Brazil*, [3]*Faz Colorado*, *Araras, SP, Brazil*.

The objective of this study was to evaluate ovulation, conception and conception of ovulated cows to AI or TAI (Heatsynch+CIDR) protocol, in primiparous and multiparous lactating dairy cows. Lactating Holstein cows, 239 primiparous (36.1±7.2 kg milk/d and 183±139 DIM) and 278 multiparous (39.8±10.7 kg milk/d and 177±139 DIM), from June to August 2006, were randomly assigned to receive one of 2 treatment; AI: cows artificial inseminated 12 h after estrous detection or TAI: cows received HEATSYNCH+CIDR protocol [CIDR insertion (CIDR®1.9mg Pfizer Animal Health) + GnRH (1mL Fertagyl®Intervet) - 7 days - CIDR removed + PGF2α (5mL Lutalyse®Pfizer Animal Health) - 24h - Estradiol Cypionate (0.5mL ECP®Pfizer Animal Health]. Cows detected in estrus were inseminated 12 h later and the remaining were TAI 48 h after the ECP injection. Presence of CL at day seven (ovulation rate) and pregnancy 28 days after AI were evaluated by ultrasonography (Aloka 500; 7.5 MHz linear transrectal probe). The variables: ovulation, conception and conception of ovulated cows were analyzed by the logistic model to evaluate the influence of the covariates (DIM, milk yield, and treatment) on the probability of success for primiparous and multiparous cows. In the primiparous cows, the ovulation, conception and conception of ovulated cows were 92.2; 30.4 and 33.0% for AI group (n=115) and 93.6; 35.5 and 37.9%

for TAI group (n=124). DIM did not affect the ovulation rate but increasing DIM decreased (P=0.028) the conception and conception of ovulated cows. In the multiparous cows, the ovulation, conception and conception of ovulated cows were 85.8; 16.9 and 19.7% for AI group (n=155) and 86.2; 25.2 and 29.3% for TAI group (n=123). Increasing DIM have tendency (P=0.1) to decrease the ovulation rate. TAI cows had tendency (P<0.1) to have higher conception and conception of ovulated cows than cows that were bred after heat detection. Theses results shows that TAI (Heatsynch+CIDR) protocol could increase conception in multiparous lactating dairy cows.

Key Words: Synchronization, Conception, Dairy Cows

T264 Effect of physiological status on the concentrations of progesterone maintained by CIDRs in Holstein cattle. K. T. Wolf*, A. K. Sanders, D. L. Ray, and W. J. Silvia, *University of Kentucky, Lexington*.

The concentrations of progesterone (P) maintained by EAZI-BREED CIDR® Cattle Inserts (Pfizer, New York, NY) were examined in nonpregnant Holstein cattle of three different physiological states: lactating cows (LACT, AVE DIM 112, AVE milk production 42 kg/day), nonlactating cows (DRY) and breeding age heifers (HEIF). Ovaries were scanned ultrasonographically to confirm the presence of a mature corpus luteum. CIDRs were inserted into each animal on the day of CL detection (expt day 0) and removed after 7 days. Each animal received two injections of prostaglandin F2α (Lutalyse® Sterile Solution, Pfizer, 25 mg each, i.m.), the first on the morning of day 1, the second 12 h later, to induce luteolysis. In replicate 1 (LACT n = 6; DRY n = 4; HEIF n = 5), coccygeal blood samples were collected twice daily from day 0 to 9 to quantify P. The concentration of P maintained by the CIDR (CIDR-P) was defined as the mean concentration in samples collected from the AM of day 3 (after luteolysis was complete) through the AM of day 7 (when CIDRs were removed). Milk production was recorded at each milking on days 0 to 9. Body weights were recorded on days 0 and 9. Replicate 2 (LACT n = 9; DRY n = 6; HEIF n = 4) was conducted as Replicate 1 except that blood samples were collected daily from the jugular vein and daily feed intakes were recorded. The effect of physiological state on CIDR-P was determined by ANOVA with replicate and body weight included as covariates. There was an effect of body weight ($p < 0.01$) and physiological state ($p < 0.01$) on CIDR-P. CIDR-Ps were 2.6±0.3 (mean±sem), 2.0±0.2 and 1.5±0.1 ng/ml in HEIF, DRY and LACT groups respectively (groups different; $p< 0.05$). Within the LACT group, the relationships between CIDR-P and milk production or CIDR-P and daily feed intake were small (R-square = 0.09 and 0.14, respectively). Differences in CIDR-P are most likely due to differences in clearance rates. Over the ranges examined in this study, differences in CIDR-P among LACT cows could not be explained by differences in the level of milk production or feed intake.

Supported by the KY Agr. Expt. Stn. and Pfizer.

Key Words: Dairy Cattle, Progesterone, Lactation

T265 Effect of flunixin meglumine at days 15 and 16 after TAI on pregnancy rates in lactating Holstein cows. L. F. M. Pfeifer[1], J. L. M. Vasconcelos*[2], A. Schneider[1], J. Wilson Neto[1], N. J. L. Dionello[1], P. Duarte[1], L. Meneghelo[1], M. N. Correa[1], A. Guzeloglu[3], and W. W. Thatcher[4], [1]*UF Pelotas*, *Pelotas, Brazil*, [2]*FMVZ*, *Botucatu, Brazil*, [3]*Selcuk University*, *Konya, Turkey*, [4]*University of Florida*, *Gainesville*.

Administration of flunixin meglumine to heifers following insemination increased pregnancy rate (PR; Guzeloglu et al., 2006). The objective was to determine if two injections of flunixin meglumine (FM) at days 15.5 and 16.0 to lactating Holstein cows following timed AI would increase PR. The hypothesis is that administration of FM at a critical anti-luteolytic stage of conceptus development will increase PR. The trial was conducted in Brazil from June to September 2006. Lactating Holstein dairy cows (n=87; 30.3±10.2 kg milk/d and 181±152 DIM) were synchronized with one 3 mg norgestomet ear-implant (Crestar®, Intervet) and a 2 mg injection of estradiol benzoate i.m. (EB, Index) given on random days of the estrous cycle. Seven days later 0.53 mg i.m. of sodium cloprostenol, (PGF2α ; Ciosin®, Schering-Plough) was injected, and the implant removed on day 9. Two days later, a 100 µg i.m. of gonadorelin (Fertagyl®, Intervet) was given followed by TAI 12 h later. Cows randomly assigned to the treatment group (n=46) were injected twice with FM (1.1 mg/kg BW; i.m., Banamine®, Schering-Plough) given 12 h apart on the evening of Day 15 and the morning of Day 16. The control group (n = 41) was not treated. PR were the percentage of cows diagnosed pregnant by ultrasonography (Aloka 500, probe 7.5 MHz) at Days 30 and 60 after TAI. Effects of treatment on PR were analyzed by chi-square test. PR in the cows treated with FM were higher at Days 30 and 60 (37 and 37% vs. 17 and 15 %; P<0.05). In lactating dairy cows the beneficial effect of administering two injections of FM at days 15.5 and 16.0 after a timed AI on PR is due likely to its antiluteolytic effect that attenuates the secretion of PGF2α in a manner that is additive to the antiluteolytic effect of the conceptus. Strategies to optimize the dialogue between conceptus and maternal unit leading to maintenance of the CL warrant further investigation.

Key Words: Pregnancy, Flunixin Meglumine, Lactating Cows

T266 Effect of GnRH administered four days after synchronization of ovulation and timed AI on fertility of anovular lactating dairy cows. R. A. Sterry*[1], E. Silva[1], D. Kolb[2], and P. M. Fricke[1], [1]*University of Wiscosin-Madison*, [2]*Lodi Veterinary Clinic*, *Lodi, WI.*

In a previous study (Sterry et al., 2006; JDS 89:4237), treatment with GnRH 5 d after first postpartum TAI increased fertility for anovular but not cycling cows. To further assess this effect, lactating Holstein cows (n=1047) were submitted for first postpartum timed AI (TAI) using a Presynch + Ovsynch protocol, and cows were classified as anovular (n=156) vs. cycling (n=891) using transrectal ultrasonography based on the presence or absence of a corpus luteum (CL) at the first GnRH injection of Presynch + Ovsynch. Anovular cows were randomly assigned to receive either no further treatment (Control, n = 85), or 100µg GnRH 4 d after TAI (G4; n = 71). Ovarian structures were examined using transrectal ultrasonography and blood samples were collected to assess serum progesterone (P_4) at the first GnRH and $PGF_{2\alpha}$ injections of Ovsynch and 4 and 11 d after TAI. For G4 cows, 51% responded by ovulating a follicle in response to GnRH treatment 4 d after TAI; however, pregnancies per AI (P/AI) did not differ (P = 0.24) between G4 cows that ovulated (36%) compared to G4 cows that did not (21%). In addition, control and G4 cows in which an ovulation

was synchronized after Presynch + Ovsynch had similar (P = 0.39) serum P_4 concentrations 11 d after TAI (4.9 vs. 5.3 ng/mL), whereas G4 cows failing to ovulate to GnRH treatment 4 d after TAI had lower (P = 0.06) P_4 (3.9 ng/mL) than control cows and G4 cows that ovulated. Overall, P/AI did not differ (P = 0.89) between control (30%) and G4 (30%) cows. There was a quadratic effect of P_4 at the $PGF_{2\alpha}$ injection of Ovsynch on P/AI, and cows with $P_4 \geq 1.0$ ng/mL at the $PGF_{2\alpha}$ injection of Ovsynch had greater (P < 0.01) P/AI (41%) than cows with $P_4 < 1.0$ ng/mL (12%); however, no treatment difference (P = 0.76) was detected. Although treatment of anovular cows with GnRH 4 d after TAI failed to affect fertility, variation among cows in serum P_4 at the $PGF_{2\alpha}$ injection of Ovsynch dramatically affected fertility of anovular cows.

Key Words: Anovular, Dairy Cow, Ovsynch

T267 Effect of human chorionic gonadotropin or gonadotropin releasing hormone injected 5 or 7 days after 72 h Co-Synch on first service pregnancy rates in lactating dairy cows. R. L. Nebel*[1], J. M. DeJarnette[1], D. A. Whitlock[1], C. E. Marshall[1], M. R. Mink[2], and R. Kasimanickam[2], [1]*Select Sires Inc.*, *Plain City, OH*, [2]*Virginia-Maryland Regional College of Veterinary Medicine*, *Blacksburg*.

Pregnancy failure has been associated with low concentrations of progesterone (P4) as early as d 6 after AI. Normally, blood P4 (timing and magnitude) achieves greater concentrations earlier in pregnant cows. Both human chorionic gonadotropin (hCG) and gonadotropin releasing hormone (GnRH) may increase peripheral concentrations of P4 when given early after AI, either by enhanced endogenous function of the existing CL or by inducing an accessory CL. Two trials were conducted to evaluate the effects of a 5 or 7 d post-AI injection of 100 µg of GnRH or 5 d post-AI injection of 3,300 i.u. of hCG. Cows received Presynch + 72 h Co-Synch with timed AI between 72 and 78 DIM. In trial 1, cows (n = 922) were assigned to receive no post-AI injection or GnRH either 5 or 7 d after AI. In trial 2, cows (n = 513) were assigned to receive hCG 5 d post-AI or serve as non-treated controls. Pregnancy was diagnosed by using transrectal ultrasongraphy and reconfirmed in pregnant cows 21 to 27 d later by transrectal palpation. In trial 1, post-AI GnRH treatment did not affect pregnancy rates (PR). Primiparous cows tended (P = 0.06) to have higher PR (32.8%) than multiparous cows (27.6%), but no interaction with GnRH treatment was detected. In trial 2, post-AI hCG treatment did not affect PR (38.4% vs. 42.3% for control vs. hCG, respectively). Primiparous cows had a higher (P < 0.05) PR (40.4%) than multiparous cows (30.8%), but hCG had no influence on this relationship. A trend (P = 0.09) was detected for higher PR in the Autumn/Winter (46.3%) vs. Summer (35.7%). Though a numeric advantage favoring hCG treatment was observed in Spring (33.2 vs. 45%) and Summer (33.9 vs. 37.5%), the treatment by season interaction was not significant. We concluded that GnRH given either 5 or 7 d post-AI or hCG given 5 d after AI did not increase PR for cows that received timed AI following a 72 h Co-Synch protocol for first service.

Key Words: GnRH, hCG, AI

T268 Effect of time of AI and supplemental estradiol on reproductive performance of dairy cows. J. Hillegass*, F. S. Lima, M. F. Sa Filho, and J. E. P. Santos, *Veterinary Medicine Teaching and Research Center, Univesity of California Davis*, *Tulare*.

Objective was to compare pregnancy rate of dairy cows time-inseminated either at 48 or 72 h after PGF2a and receiving or not estradiol cypionate (ECP) prior to AI. Holstein cows, 971, were randomly assigned to one of four treatments as a 2×2 factorial. All cows received injections of PGF2a at 37 and 51 d in milk (DIM). At 64 DIM, they received GnRH, followed 7 d later by PGF2a. Cows in the CoSynch 48 h (CoS48) received a final injection of GnRH at the moment of timed AI 48 h after PGF2a, whereas cows in the CoSynch 72 h (CoS72) received GnRH and were timed AI 72 h after PGF2a. Half of the cows in each CoSynch received an injection of 1 mg of ECP 24 h after PGF2a (CoS48-NECP, n = 240; CoS72-NECP, n = 246; CoS48-ECP, n = 245; and CoS72-ECP, n = 240). Concentration of progesterone was measured at 57 and 64 DIM to determine cyclic status. A subset of 123 cows had their ovaries examined by ultrasonography to determine diameter of ovulatory follicle and ovulation rate, and blood was sampled 7 d after AI to measure progesterone. Pregnancy was diagnosed at 40 and 68 d after AI. Prevalence of anovular cows at 64 DIM was 27.6%, but it was similar for CoSynch (P=0.67) and ECP (P=0.45). Estrous detection increased (P<0.001) with CoS72 compared with CoS48 (64.5 vs 46.5%) and with supplemental ECP (69.8 vs 41.4%), and cows in estrus had greater (P<0.001) pregnancy rates than those not in estrus (54.7 vs 31.5%). Ovulatory follicle diameter was smaller (P=0.05) in ECP-treated cows, but ovulation rate, double ovulation rate and progesterone concentrations on d 7 after AI did not differ (P>0.10) among treatments. Pregnancy rates at d 40 and 68 after AI were not influenced (P>0.10) by either time of AI or ECP, and at 40 d they were 41.3, 46.7, 45.5 and 43.9 for CoS48-NECP, CoS48-ECP, CoS72-NECP, and CoS72-ECP, respectively. Results indicate that delaying the day of AI from 48 to 72 h and supplemental ECP, in spite of increasing display of estrus at timed AI, did not improve reproductive performance of lactating dairy cows at first AI.

Key Words: Dairy Cow, Estradiol Cypionate, Timed AI

T269 Strategies to maximize ovulation to first GnRH of Ovsynch in lactating dairy cows. N. M. Bello* and J. R. Pursley, *Michigan State University*, *East Lansing*.

Ovulatory response to first GnRH of Ovsynch is a critical determinant for successful synchronization of ovulation in dairy cows. Previous work from our laboratory indicated that 1) a 6-d interval between a $PGF_{2\alpha}$-and-GnRH-based pre-Ovsynch treatment (G6G) and first GnRH of Ovsynch increased the percentage of cows that ovulated in response to first GnRH of Ovsynch; and that 2) size of the follicle that ovulated to 1st GnRH of Ovsynch was positively associated with length of the pre-Ovsynch treatment. Our objective in this study was to evaluate further $PGF_{2\alpha}$-and-GnRH-based pre-Ovsynch strategies of longer intervals between pre-Ovsynch GnRH and first GnRH of Ovsynch. We hypothesized that a longer interval of follicular growth would maximize ovulation at initiation of Ovsynch. Lactating dairy cows (n=165) were assigned to receive either no treatment prior to Ovsynch (Control) or 25 mg of $PGF_{2\alpha}$ (Pre-P) followed 2 d later by 100 µ of GnRH (Pre-G), administered 6 (G6G), 7 (G7G) or 8 (G8G) d prior to first GnRH of Ovsynch. Transrectal ultrasonography was performed to assess follicular size and ovulation throughout Ovsynch. Proportion of cows that ovulated to first GnRH of Ovsynch was 67.5, 94.4, 82.0 and 72.7 % for controls, G6G, G7G and G8G, respectively,

and was greater for G6G versus controls (P<0.02). However, ovulatory response to first GnRH of Ovsynch depended on response to the pre-Ovsynch treatment (P<0.05). In cows that responded to pre-Ovsynch by initiating a new estrous cycle, percentage ovulatory response to first GnRH of Ovsynch was less for G8G (74.0 %; P<0.05) compared to G6G or G7G (96.6 and 92.6 %, respectively). Concentrations of progesterone at $PGF_{2\alpha}$ of Ovsynch were greater for cows that received pre-Ovsynch treatments (5.3±0.4, 4.5±0.5 and 4.4±0.5 ng/ml for G6G, G7G and G8G, respectively) compared to controls (2.4±0.4 ng/ml; P<0.04). In summary, maximal ovulatory response to first GnRH was obtained with a $PGF_{2\alpha}$-and-GnRH based Pre-Ovsynch strategy with either a 6- or 7-d interval between Pre-G and first GnRH of Ovsynch.

Key Words: Dairy Cow, Ovsynch, Ovulation

T270 Pregnancy rates to timed-AI of dairy cows treated with pLH or GnRH. M. G. Colazo*[1], D. J. Ambrose[1], and R. J. Mapletoft[2], [1]*Alberta Agriculture and Food*, *Edmonton, AB, Canada*, [2]*WCVM, University of Saskatchewan*, *Saskatoon, SK, Canada*.

We investigated the use of 25 mg porcine LH (pLH; Lutropin-V, Bioniche Animal Health) or 100 µg GnRH (Fertiline; Vetoquinol NA Inc.) and 500 µg cloprostenol (PG; Estrumate, Schering Plough Animal Health) on ovulatory response and pregnancy rate following timed-AI (TAI) in lactating dairy cows (n = 292). Cows (mean ± SE; 2.4 ± 0.08 lactations, 112.5 ± 3.7 DIM) at two locations were assigned to receive 1 of 4 treatments: GnRH/PG/GnRH, pLH/PG/GnRH, GnRH/PG/pLH or pLH/PG/pLH. Cows were treated at random stages of the estrous cycle with pLH or GnRH im on Day 0, PG im on Day 7, and pLH or GnRH on Day 9 with timed-AI (TAI) 12-16 h later (Day 10). Ultrasonographic examinations were performed in a subset of 216 cows on Days 0, 7, 10, 11, and 14 for ovulation, CL and follicle development, and in all cows on Day 32 for confirmation of pregnancy. Data were compared using GLM and CATMOD procedures in SAS. Proportion of non-cycling cows and cows with ovarian cysts on Day 0 were 14 and 6%, respectively. Ovulatory response to first treatment was 63 vs. 43% for pLH and GnRH groups and 84 vs. 49% for non-cycling and cycling cows (P<0.01). Pregnancy rate to TAI did not differ among treatment groups (P>0.05; 31, 24, 36, and 29% for GnRH/GnRH, pLH/GnRH, GnRH/pLH and pLH/pLH, respectively) but tended to be higher in cows given GnRH on Day 0 (P=0.07; 34 vs 26%). Location, ovulatory response to first pLH or GnRH, cyclicity status, presence of an ovarian cyst, and preovulatory follicle size did not affect pregnancy rate (P>0.05). However, cows that ovulated before TAI (11%) tended to have lower pregnancy rate (P=0.1; 17 vs. 31%). In addition, none of the cows that failed to respond to PG (12%) or ovulate following the second pLH or GnRH treatment (15%) conceived (P<0.01). In summary, cows treated with GnRH on Day 0 had lower ovulation rate but tended to have higher pregnancy rate to TAI. However, pregnancy rate to TAI did not differ among treatment groups.

Key Words: Porcine LH, GnRH, Pregnancy Rate

T271 Prepartum feed restriction and fatty acid supplementation influence reproductive performance of dairy cows. M. G. Colazo*[1], D. J. Ambrose[1,2], A. Hayirli[2], and L. Doepel[2], [1]*Alberta Agriculture and Food*, *Edmonton, AB, Canada*, [2]*University of Alberta*, *Edmonton, AB, Canada*.

We determined the effects of feed restriction and fatty acid supplementation during the dry period on post-calving reproductive performance of dairy cows. Thirty-four d before expected calving, pregnant dairy heifers (n=25) and cows (n=47; 1 to 4 lactations) were randomly assigned to 1 of 6 treatments. Treatments were ad libitum (AL) or 30% restricted (FR) feed intake in combination with 1 of 3 oilseed supplements at 8% of diet DM: canola(C), linola (L) or flax (F) to supply oleic, linoleic or linolenic fatty acids, respectively. After calving, cows were fed a common lactation diet. Measurements of uterus, corpus luteum and follicles were determined by ultrasonography (US) twice weekly from 7 ± 1 d after calving until first ovulation and thereafter every other day until second ovulation. Cows (n=63) were timed-AI (TAI) and 32 d later, pregnancy was diagnosed by US. Data were analyzed using proc GLM and CATMOD. Although none of the animals in FR-L group had retained placenta and/or endometritis (RPE), diets did not affect the incidence of RPE (18%), mastitis (10%) or metabolic diseases (7%). Mean (± SE) interval from calving to uterine involution did not differ among diet groups, but it was longer in cows that had RPE (P<0.02; 32.1 ± 2.7 vs. 24.8 ± 1.3 d). Interval from calving to first ovulation was longer (P<0.05) in cows fed C than those fed either L or F (34.7 ± 3.1, 23.7 ± 3.2 and 21.0 ± 3.1 d, respectively) and in cows with follicles <10 mm at first US (35.1 ± 2.4 vs. 23.8 ± 2.8 d). Conception rate was higher in cows fed AL than in those fed FR (P<0.05; 50 vs. 19%), and in cows with 1 than either 2 or >2 lactations (P<0.02; 56, 18 and 29%, respectively). Conception rates tended (P<0.1) to be lower in cows that had RPE (22 vs. 46%) or that had not ovulated within 4 wk after calving (21 vs. 46%). In summary, cows fed diets supplemented with linola or flaxseed ovulated sooner, and cows with ad libitum feed intake had higher conception rate. Conception rate tended to be higher in cows without RPE, in cows ovulating within 4 wk postpartum, and in first lactation cows.

Key Words: Feed Restriction, Fatty Acid Supplementation, Reproductive Performance

T272 Evaluation of feed restriction and pre-synchronization in a program for estrous synchronization. P. Molina[1], T. Sánchez[1], O. Mejía[2], J. Nuñez[2], E. García*[3], O. D. Montañez-Valdez[4], J. Cordero[1], J. Peralta[1], M. E. Ortega[1], R. Nieto[5], E. Mendoza[1], and R. Avila[1], [1]*Colegio de Postgraduados*, *Montecillo, Estado de México, México*, [2]*Facultad de Medicina Veterinaria y Zootecnia, UNAM*, *Tres Marías, Municipio de Huitzilac, México*, [3]*Centro Universitario de la Costa Sur de la Universidad de Guadalajara*, *Autlán, Jalisco, México*, [4]*Centro Universitario del Sur de la Universidaad de Guadalajara*, *Ciudad Guzmán, Jalisco, México*, [5]*Instituto Tecnológico Agropecuario No.6*, *Huejutla, Hidalgo, México*.

The objective of the experiment was to evaluate the effect of pre-synchronization and feed restriction in the onset, beginning and duration of estrus. Sixty nine Dorset ewes were randomly assigned to four treatments: Treatment 1 (T1): Ewes received one kg of commercial supplement (16% protein) plus one kg of oats straw for 30 days and were synchronized with fluorogestone acetate sponges (FGA, 40 mg) for 12 days; Treatment 2 (T2) ewes received the same diet as T1, but they were synchronized with two doses of $PGF_{2\alpha}$ 16 and 8 days before the FGA sponges; Treatment 3 (T3) ewes were feed restricted and only received 1 kg of oats straw during 30 days, with the same

synchronization regime as T1; and Treatment 4 (T4) received the same diet as T3 and the synchronization regime as T2. A hundred percent of estrus onset for all treatments, but there were differences in beginning of estrus between T4 and T2 with an average time of 50.4 ± 1.83 and 40 ± 2 h, respectively, while for T1 and T3 the average time was 46 ± 2.10 and 49.8 ± 2.88 h (P>0.05). Beginning of estrus was affected for feed restriction, and restricted ewes (T3 and T4) showed estrus later (50.06 ± 1.68 h) compared to not restricted (T1 and T2) ewes (43.09 ± 1.52 h, P<0.05). Duration of estrus was longer in T2 (45.8 ± 2.80 h) compared to T3 (34 ± 1.86), and for T1 and T4 there were 38.7 ±1.37 and 41.3 ± 2.15 h, respectively (P>0.05). In treatments pre-synchronized with $PGF_{2\alpha}$ (T2 and T4) duration of estrus was longer compared with not pre-synchronized, with 43.6 ± 1.80 h and 36.6 ± 1.17 h respectively (P<0.05), while feed restriction did not affect duration of estrus (P>0.05). We conclude that feed restriction affects beginning of estrus, while pre-synchronization prolongs duration of estrus.

Key Words: $PGF_{2\alpha}$, Ewes, FGA

Production, Management & the Environment - Livestock and Poultry II

T275 Human resource management and dairy employee organizational commitment. R. E. Stup*, *The Pennsylvania State University*, *University Park*.

The purpose of this research was to gather information about human resource management (HRM) practices used on dairy farms and effects these practices had on employees' feelings of commitment toward the farm. HRM practices included in the study were selection, benefits, training, performance feedback, communication systems, standard operating procedures, and employee participation. Organizational commitment is the strength of an employee's attachment to the organization where he is employed. Employees committed to the organization are less likely to leave for another job and are more likely to perform at high levels. There are three dimensions of organizational commitment: affective commitment is a feeling of emotional attachment, normative commitment is a feeling of obligation, and continuance commitment is a feeling that the costs of leaving are too high or it is too much trouble to go somewhere else. In February 2005 a survey was sent to owners and employees of dairies with herd sizes of 250 or larger in the Northeast. A total of 131 owners and 201 employees responded. Farm-level response rate was 14.8%. The following HRM practices were significantly ($p < .05$) correlated with affective commitment: level of off-farm training, adequacy of initial training, adequacy of continuing training, satisfaction with training, informal feedback was provided, satisfaction with feedback, satisfaction with performance reviews, and employee participation. Normative commitment was significantly ($p < .05$) correlated with: adequacy of initial training, adequacy of continuing training, satisfaction with training, informal feedback was provided, satisfaction with feedback, satisfaction with performance reviews, employee participation. Further analysis with stepwise multiple regression found satisfaction with feedback, employee participation, and satisfaction with performance reviews were predictive of affective commitment. The same three HRM variables predicted normative commitment as well. The results suggest that managers should focus on feedback and employee participation to build employee commitment.

Key Words: Human Resources, Employee Commitment, Labor

T276 The amount of concentrate offered in automated milking systems does not influence the frequency of visits of dairy cattle consuming high levels of corn silage. A. Bach*[1,2], C. Iglesias[3], M. Devant[2], and A. Ferrer[2], [1]*ICREA*, *Barcelona, Spain*, [2]*IRTA-Unitat de Remugants*, *Barcelona, Spain*, [3]*SEMEGA*, *Girona, Spain*.

The objective of this study was to evaluate whether the amount of concentrate offered in an automatic milking systems (AMS) would modify milking frequency, feeding behavior, and milk production. One hundred and fifteen lactating cows were used in a cross-over design with 2 periods of 90 d each and two treatments: LC (up to 3 kg/d of concentrate at the AMS) or HC (up to 8 kg/d of concentrate at the AMS). Cows were evenly distributed in 2 symmetrical pens, each containing 1 AMS and about 50 cows at any given time. All cows received the same total ration (28% corn silage; 1.67 Mcal of NEl/kg; 16.5% CP, DM basis) but a different proportion of concentrate from this ration was offered at the AMS depending on treatment. The concentrate at the AMS had the same composition in both treatments. Cows were fetched when time elapsed since last milking was greater than 12 h. The amount of concentrate offered at the AMS was proportional to the time elapsed since last visit (125 g/h and 333 g/h for LC and HC, respectively). Milk production (32.5±0.89 kg/d), total number of daily milkings (2.7±0.07/d), number of cows fetched (1.2±0.02/d), or number of voluntary milkings (1.5±0.09/d) were not affected by treatments. The consumption of basal ration was greater ($P < 0.05$) in LC (19.0±0.26 of DM/d) than in HC (14.2±0.27 kg of DM /d), but this difference was compensated by a greater ($P < 0.05$) consumption of concentrate at the AMS in HC (6.8±0.02 kg of DM/d) than LC (2.6±0.02 kg of DM/d) cows. Therefore, total DMI was unaffected. The eating rate of the basal ration was greater ($P < 0.05$) in LC (113.2±0.23 g of DM/min) than in HC (80.7± 0.21 g of DM/min), but the total amount of time that cows devoted to eat was similar between treatments (171.7±5.11 min/d). Offering high amounts of concentrate to the AMS feeding a basal ration rich in corn silage is not an effective method to diminishing cow fetching and increasing number of daily milkings and milk production.

Key Words: Automatic Milking, Concentrate

T277 Effects of dam's dry period length on calf. M. T. Kuhn*, J. L. Hutchison, and H. D. Norman, *Animal Improvement Programs Laboratory*, *Beltsville, MD*.

Recommendations for shortened dry periods have become increasingly common in recent years. While considerable research has been done to determine effects on cow performance, research to determine what,

if any, effect shortened dry periods have on the calf being carried is quite limited, in spite of the fact that in utero weight gain of the calf increases at an increasing rate during gestation, with more than half of fetal weight gain occurring during the last 2 months of gestation. Field data were utilized in this research to compare calving ease (CE) scores and stillbirth (SB) rates across 16 days dry (DD) categories. Heifer ages at first breeding (AFB) were also compared across dam DD categories and the raw percentage of heifers with a first calving was also calculated for each category. The linear, fixed effects model for analysis of CE and SB included herd-year of calving, year-state-month of calving, parity, sex of calf, and DD category. Parity and sex of calf were dropped from this model for analysis of calves' AFB. A total of 454,091 CE, 163,175 SB, and 24,125 AFB records were included for analysis. The number of records for AFB was much smaller because only about 29% of US herds have heifer breedings recorded in the national database and storage of heifer breedings only began in 2003. Although differences were small, CE scores did tend to be lower for dry periods of 0 to 45 d than for 46 to 65 DD, suggesting that calves may be smaller with shorter dry periods. Stillbirths were 1.3% higher for dry periods of 30 d or less, compared to DD between 61 and 65 d. There was no evidence to support an effect on AFB for heifers surviving to breeding age; subclass sample sizes, however, were small and further investigation of this trait may be warranted when more data is available. Simple averages indicated that heifers born after dry periods of 45 d or less survived to first calving 12% less often than heifers born after dry periods of 56 to 70 d. Further research on survival to first calving, adjusting for extraneous effects, is warranted. Results to date indicate a small, but real, negative impact on the calf for dry periods less than 45 d.

Key Words: Days Dry, Survival

T278 An analysis of the relationship between wash water quality and bulk tank milk quality on Ontario dairy farms. N. R. Perkins*[1], D. F. Kelton[1], K. E. Leslie[1], K. J. Hand[2], G. MacNaughton[3], and O. Berke[1], [1]*University of Guelph*, *Ontario, Canada*, [2]*CanWest DHI*, *Guelph, Ontario, Canada*, [3]*Dairy Farmers of Ontario*, *Mississauga, Ontario, Canada*.

The objective of the study was to identify areas of high risk of wash water contamination and to investigate the relationship between bacteria contaminated wash water and elevated Bactoscan bacteria counts in raw milk. Water quality analysis was conducted by the Dairy Farmers of Ontario on all of the 5000 farms in the province on an annual basis, during 2003 and 2004. These water quality data, matched with bacteria counts (Bactoscan determinations) in raw milk during the same time period, were evaluated using linear regression to evaluate the relationship between water contamination and bacteria counts in raw milk. After controlling for potential confounders, the data was used to determine whether the presence of coliform and/or *E.coli* bacteria in the water was associated with an elevated Bactoscan level in raw milk. In addition to regression analysis, the first water quality sample was utilized in a spatial analysis to quantify the prevalence of water contamination and to identify any geographic case cluster formations within the data. An *E.coli* case farm and similarly, a coliform case was any farm that had >0 of the respective bacteria within the water sample. The significant ($p<0.05$) factors associated with Bactoscan levels in raw bulk tank milk in the linear regression analysis included: the presence of *E.coli* bacteria in wash water, an interaction between average herd monthly somatic cell count (SCC) and season, and an interaction between total monthly milk production and average herd monthly SCC. The spatial analysis performed separately for coliforms and *E.coli* identified one cluster of coliform cases and three clusters of *E.coli* cases in southern Ontario. The prevalence of bacteria in wash water is a concern within Ontario, since pasteurization does not kill all bacteria within raw milk. Therefore, milking equipment should be properly cleaned and sanitized in order to ensure the production of a high quality, safe milk product.

Key Words: Raw Milk, Wash Water, Bacteria

T279 Body weight of Holstein heifers as measured by heart girth tape and electronic scale: A comparison. J. E. Wohlt*[1], C. E. Reich[1], and J. Ferguson[2], [1]*Rutgers University*, *New Brunswick, NJ*, [2]*University of Pennsylvania*, *Kennett Square*.

Holstein heifers, 3 to 18 mo, were weighed once monthly (June, July, August, September 2006; n = 128/mo, total n = 514) first by tape (Weight-By-Breed, NASCO) and then on an electronic scale (Allflex Technologies). This comparison was necessary as a 2 y growth database on heifer body weight had been generated using a tape. Data were analyzed by ANOVA using GLM procedures with method and month main effects in the model and pen as a covariant. Body weight was 11 kg greater ($P<0.01$) by scale than tape: 279 vs. 270, 260 vs. 251, 275 vs. 258, 285 vs. 276; respectively by month. The frequency that scale weights were greater than tape weights was constant by month: 74, 70, 76, and 69%; respectively. Method was also evaluated for different levels of body weight: 45.4 kg increments for heifers weighing 91 to 499 kg. Scale weights differed from tape weights only when heifers exceeded 227 kg. Tape and scale weights were significantly ($P<0.01$) correlated: $y = 1.0689x - 7.8$, $R^2 = 0.98$. Growth rate, determined by regression analysis, did not differ when heifer body weight was measured by tape or scale (0.81 vs. 0.82 kg/d). All producers should be monitoring heifer growth. Many methods are available and selection of a method should be appropriate for available facilities, labor and time constraints. If method of weighing changes, then comparisons should be done and correction factors applied to assess body weight data.

Key Words: Dairy Heifer, Tape Weight, Scale Weight

T280 Dairy farm sustainability: The economic component indicators. D. L. Larochelle*, D. P. Parent, G. A. Allard, and D. P. Pellerin, *Laval University*, *Quebec, Quebec, Canada*.

Over the last two decades, the number of dairy farms has declined dramatically and the viability of the family farm has been questioned. A comprehensive research project has been set to evaluate the sustainability of Quebec dairy farms based on their economic, environmental and social components. The objective of the present study was to develop indicators to evaluate the economic sustainability. To identify these indicators, experts working in various areas such as animal production, farm management and financial institutions have been consulted using the Delphi method. This method uses a qualitative sequential approach: each expert submits his own indicators which are later debated in a focus group; the chosen indicators are then classified and ranked and for each indicator, different threshold levels are established by the group to determine the score values.

Indicators are selected based on their sensitivity to predict the economic component of dairy farm sustainability considering the availability and easiness with which the data can be collected and analyzed. From the 139 indicators initially submitted, eight were selected and grouped in five categories. For a total score of 100 points, their weights are:
A- Technical management (/20): 1- Milk yield (L/cow/year). (/8) and, 2- Milk from forage (L/cow/year), (/12)
B- Economic viability (/25): 3- Security margin (Net return surplus on gross income, %), (/15) and, 4- Total farm debt per hectolitre ($/hL), (/10)
C- Expense control (/30): 5- Operational expenses on gross income (%), (/20) and, 6- Machinery expenses per hectolitre ($/hL), (/10)
D- Labor efficiency (/15): 7- Milk per full time worker (FTW), (L/FTW), (/15)
E- Self-sufficiency (/10): 8- Self-sufficiency of forage usage on farm (%), (/10)

The overall score for a given farm is obtained by adding the individual score for each indicator and farms can be compared for their economic sustainability. This new tool will help to evaluate the sustainability of dairy farms at a given point in time and it becomes possible to follow their evolution over the years.

Key Words: Sustainability, Indicators, Farms

T281 A comparison of body temperature measures between Holstein and Gir × Holstein cows in relation to environment and stage of the estrous cycle. S. Dray*, A. Harris, R. Farrar, G. Grissett, S. Laird, and S. Willard, *Mississippi State University*, *Mississippi State*.

Gir × Holstein (G×H) cows have higher body surface and lower rectal temperatures (RT) than Holstein (HOL) cows under heat-stressed conditions. However the influence of coat color and stage of the estrous cycle on body temperatures (BT) have not been evaluated, therefore our objective was to compare BT responses of HOL vs. GxH cows in relation to these parameters (coat color and estrous cycle) during summer heat stress. Non-lactating HOL [n=5 white (WH); n=6 black (BH)] and GxH [n=7 dark (DK); n=4 light (LT)] cows were fitted with the HeatWatch estrus detection system, and an intravaginal temperature (VT; °C) probe inserted to acquire VT (5 min intervals; July-Sept). Cows received two injections of $PGF_2\alpha$ 11 d apart to synchronize estrus (d -10 and 0). From d -10 to d 46 (56 d), measurement periods were conducted weekly (three times AM and five times PM weekly) and included: ambient temperature (AMBT; °C), temperature-humidity index (THI), rectal temperature (RT; °C), respiration rate (RR; breaths per min), digital infrared thermography of the eye (maximum eye temperature; MAX-EYE, °C), and a blood sample (serum) for progesterone (P4) by RIA. Cow BT was analyzed in relation to environmental measures and stage of the estrous cycle [luteal (LUT) vs. follicular (FOL) phases]. Environmental AMBT differed ($P<0.01$) AM vs. PM, with THI ranging from 69.8 to 90.6. Dark (DK) and LT G×H cows did not differ ($P>0.10$) in BT AM or PM. During AM, BH were similar ($P>0.10$) to WH, but differed ($P<0.05$) in PM. Body temperature of HOL cows increased (VT and MAX-EYE; $P<0.05$) from AM to PM, while G×H cows decreased (VT; $P<0.05$) or increased only slightly (MAX-EYE; $P<0.10$) depending on the BT measure. Holstein cows had a greater ($P<0.05$) increase in RR from AM to PM than GxH cows. Body temperature did not differ ($P>0.10$) between breeds within LUT and FOL. Rectal temperature and MAX-EYE did not differ ($P>0.10$) between LUT and FOL, while VT was greater ($P<0.05$) during LUT than FOL. In summary, non-lactating HOL and G×H cows were similar in BT measures during the estrous cycle and in the AM. In the PM, HOL cows exhibited higher BT and RR (affected by coat color) than G×H cows.

Key Words: Gir × Holstein, Body Temperature, Environment

T282 Evaluation of the pedometer system efficiency. R. M. Santos*[1], J. L. M. Vasconcelos[2], and S. Soriano[3], [1]*UFU*, *Uberlândia, MG*, [2]*FMVZ-UNESP*, *Botucatu, SP*, [3]*Fazenda Colorado*, *Araras, SP, Brazil*.

Detection aids which measure changes in activity, mucus conductivity, number of mounts or temperature can be used to improve estrous detection. The pedometer systems register the number of steps an animal takes. As cows in estrus are restless and move around more, an increased pedometer reading may indicate estrus, but high percentage of false positive reactions have been reported. The objective of this study was to evaluate the pedometer system efficiency by using ultrasound examinations weekly. Cycling and not pregnant lactating Holstein cows (n = 89) producing 40.3 ± 8.84 kg milk/d and with more than 40 DPP, housed in a free-stall barn with concrete flooring received a pedometer (pedometers were strapped on the left front leg of each cow and pedometer measurements were recorded three times a day) on day of parturition. The cyclicity was determined by the presence of a corpus luteum (CL) on day 0 of the experiment. During the study (28 days) ovaries were scanned by ultrasound (Aloka-500; 7.5 MHz) once a week, to detect CL regression, ovulation and CL development. Correct pedometer detection was considered when the pedometer system detects the cow in estrous and the original CL regress and a new CL was formed. The false negative was considered when the CL regress but the cow was not detected in estrous by the pedometer system. The false positive was considered when cow was detected in estrous by the pedometer system but the CL did not regress. During the 28 days of experiment the pedometer system appointed 95 heats, 81 (85.3%) were correctly detected and 14 (14.7%) were false positive. Eight heats were not appointed (false negative) by the pedometer system (8.9%; 8/89) during the experimental period. The overall efficiency was 78.6% (81/103). In conclusion, the pedometer system can detect estrus with high efficiency and could be used as a tool for improving service rates.

Key Words: Estrous Detection, Pedometer, Dairy Cow

T283 Effect of nitrogen intake, straw and days of storage on pH, temperature and ammonia emission from dairy cow manure. M. J. Aguerre*[1], M. A. Wattiaux[1], and T. Hunt[2], [1]*University of Wisconsin*, *Madison*, [2]*University of Wisconsin*, *Platteville*.

An experiment was conducted to determine the effects of nitrogen intake and wheat straw addition on NH_3-N emission during manure storage. Two groups of cows (160 vs. 260 DIM) producing 36 and 27 kg/c/d of milk were assigned diets with 17 and 15% CP (DM basis), leading to high nitrogen (**HN**) and low nitrogen (**LN**) intakes, respectively. Manure collected from the barn floor was thoroughly mixed, diluted with water to 10% DM, loaded in 200 L barrels (186

kg) with or without addition of chopped straw (22 g/kg of undiluted manure) and stored in a partially temperature-controlled environment. Manure temperature and pH were recorded and NH_3-N emitted for a 2-hr period was captured in an acid trap on days 0, 3, 6, 12, 28, and 56. Data were analyzed as a randomized complete block with a 2×2 factorial arrangement of treatments and three replications (one in May and two in October). Concentration of NH_3-N in manure at day 0 was 80.0 and 53.8 mg/dl for **HN** and **LN** treatment, respectively; but was not influenced by straw addition. There was no significant effect of straw and no interactions for the reported measurements. Mean manure pH was significantly higher for **HN** than **LN** treatment (see Table). Temperature increased but pH decreased with days of storage. On average NH3-N emission was reduced by 46% on **LN** relative to **HN** treatment. Emission of NH_3-N was highest at day 0, declined to reach a nadir at day 6, and increased numerically thereafter. At day 56 NH_3-N emission was still 44% of day 0 emission. In this trial, NH_3-N emission was correlated with manure pH (r=+0.57, n=72), but not with temperature.

Table 1.

	Treatment		Day[1]						P-value[2]
Item	LN	HN	0	3	6	12	28	56	N Intake
pH	6.42	6.80	8.15^{a}	6.83^{b}	6.61^{c}	6.20^{d}	5.96^{e}	5.94^{e}	<0.01
Temp, °C	17.0	17.0	15.7^{b}	16.2^{b}	15.4^{b}	17.9^{ab}	17.6^{ab}	19.6^{a}	0.97
NH_3 –N, g/m^2 /h	1.13	1.99	2.61^{a}	1.49^{b}	1.12^{c}	1.51^{bc}	1.46^{bc}	1.16^{bc}	0.05

[1, 2] Means within a row with different superscript differ (P<0.05). Days of storage P value was <0.01, 0.03 and <0.01 for pH, temperature and NH_3-N emission, respectively.

T284 Dairy manure estrogens with advanced treatments. Z. Zhao*, K. F. Knowlton, N. G. Love, and Y. Fang, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

In the last few decades, environmental estrogens have raised great concern and interest for their potent endocrine disrupting effects. The objective of this study was to quantify dairy manure estrogens with intensive treatments. In experiment one, 17beta-estradiol (E2) and estriol (E3) were measured in a full-scale manure handling system at Virginia Tech dairy center. This system employs a mechanical separator to separate manure liquids from solids, a short retention time anaerobic settling basin to remove further solids, and three aerated tanks in sequence. The third tank effluent is reused to flush the barn, or applied to crop lands via irrigation. The main slurry from the barn, separator effluent, settling basin effluent, effluent of the first two tanks, and flush water (the third tank effluent) were collected monthly from July 2005 to June 2006. In experiment two, E2 and E3 were determined in the influent and effluent (monthly from August 2005 to April 2006) of an anaerobic digester on a commercial dairy farm. All samples were extracted first with chloroform and NaOH and then with toluene to the base phase after neutralization with acetic acid. E2 and E3 concentrations were assayed via ELISA (Assay Designs, MI). In experiment one, there was a significant difference for both E2 and E3 among sampling locations (P<0.01). Mechanical separation did not affect E2 or E3 content (763.0 and 470.1 pg/ml, respectively), but flush water had a significantly lower E2 (361.0 vs. 880.9 pg/ml, P<0.01) and E3 (167.4 vs. 636.8 pg/ml, P<0.01) compared to the main slurry. In experiment two, E2 (15.9 vs. 9.86 ng/ml, P<0.05) and E3 (7.88 vs. 5.79 ng/ml, P<0.10) were decreased after anaerobic digestion compared to the influent. In conclusion, both manure treatments reduced potential E2 and E3 loading to the environment. A mass-balance analysis of estrogen flow will help understand better what happened to estrogens within the treatment system.

Key Words: Dairy Manure, Estrogens, ELISA

T285 The impact of intake water temperatures on reticular temperatures of lactating dairy cows. J. M. Bewley*[1], D. C. Batson[2], M. W. Grott[1], and M. M. Schutz[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*MaGiiX Inc.*, *Post Falls, ID*.

Automatic temperature recording may allow early detection of disease, estrus, heat stress, and the onset of calving. The MaGiiX™ Cattle Temperature Monitoring System (CTMS, MaGiiX Inc., Post Falls, ID) utilizes a passive bolus equipped with a temperature sensor, a stationary panel reader to query the bolus, and software to collect, analyze, and view data. The biologically inert bolus resides in the cow's reticulum and is queried each time the cow passes the reader. A potential limitation to collection of reticular temperatures is the impact of water temperature and consumption on observed temperatures. A replicated 3×3 Latin Square study was conducted at the Purdue Dairy Research and Education Center to assess the impact of water intake on reticular temperatures using the CTMS. Nine high-producing, mid-lactation 2nd parity cows with low SCC, were selected for this trial conducted on January 16, 17 and 19, 2007. Prior to administering a water treatment, access to feed and water was restricted for at least 2 hours. Baseline reticular (RT) temperatures were established from 3 measurements prior to water intake. Each cow received 25.2 kg of water at one of 3 different temperatures on each day. Water temperatures were Hot (34.3°C (±1.0)), Warm (18.2°C (±0.4)), or Cold (7.6°C (±0.4)) and all 3 temperatures were given to 3 cows on each day. Following water intake, RT and RC were collected every 10-15 minutes for 3 hours. The RT for each treatment followed a consistent pattern: an initial dramatic drop in RT followed by a gradual rise toward baseline. However, at the end of the 3 hour collection period RT had not returned to the baseline (-0.34°C ±0.19). Regression was performed with PROC GLM to assess the impact of water treatment on maximum drop (D) in RT (R^2=0.91). Treatment (P<0.001) and day (P=0.037) affected D, while a cow effect (P=0.163) did not. LSMeans for D were 8.4°C (±0.4), 6.9°C (±0.4), 2.2°C (±0.4), for cold, warm, and hot, respectively.

Key Words: Temperature Monitoring, Reticular Temperature, Water Intake

T286 Predicting cow health and estrus status by measuring change in water intake in dairy cows. J. M. Lukas* and J. K. Reneau, *University of Minnesota*, *St Paul*.

Recent studies in swine have investigated the potential of early disease diagnosis by measuring water intake in growing pigs. Little research has been done on measuring water intake in dairy cows or the change in water intake due to disease. The following study attempts to explore the possibility of early disease and estrus detection by monitoring water intake in dairy cows. Daily readings from 41 water meters placed

in the tie stall St Paul Dairy Barn at the University of Minnesota were collected from September 2005 until July 2006. Each water meter measured the water intake from one water cup. Two cows were assigned to each water cup. All treatments administered to the cows along with breeding and calving dates were also recorded and used to create an event list with event class and corresponding event date for each of the 41 groups of two cows assigned to an individual water cup. Events were grouped into the following classes: bred, calved, mastitis, fever, hypocalcaemia, ketosis, feet and other. Average days in milk for each water cup group were calculated for each day of the study period. The average difference in days in milk within the water cup group was 10.5 days (s.e. 1.54). The water intake data was matched with the mean days in milk and merged with the event list dataset. Each event was also assigned to seven days preceding and seven days following the actual occurrence of an event. Proc mixed procedure of SAS was used to identify events significantly changing water intake with event classes entered as fixed and mean days in milk entered as a random effect. Only average days in milk 0 through 150 were considered in the analysis. Hypocalcaemia was associated with significantly increased water intake while occurrence of fever was associated with a tendency (p-value 0.09). Event classes bred, fresh and other were associated with a significant decrease in water intake (p-values <0.05). Monitoring water intake can help in earlier disease diagnosis and has the potential of predicting change in cow health and estrus status.

Key Words: Water Intake, Estrus Detection, Disease Detection

T287 Factors affecting group sizes within herd and group milk volume compared to total herd volume of milk. R. C. Goodling*, K. E. Griswold, and T. J. Beck, *The Pennsylvania State University Cooperative Extension*, *University Park*.

The percent of cows within herd for days in milk (DIM) cow groups or lactation cow groups and the groups contribution to the total herd milk volume was investigated with 2005 DHIA data from 3953 Pennsylvania dairy herds comprised of 2,800,559 Holstein cow test day records. Data were analyzed using the UNIVARIATE and MIXED procedures of SAS version 9.1. The contribution potential of a cow group to the total herd milk volume was estimated as the difference between the percent of the total herd milk volume produced by a defined group of cows and the percent of the total number of lactating cows represented by that group of cows. For example, if cows from 41 to 100 DIM represented 25% of the lactating cows and produced 30% of the total herd milk volume, then their contribution potential would be + 5%. The statistical model included the fixed effects of DIM group, herd size group, and average daily milk yield group. Milking frequency and bST use were excluded from the analysis. DIM groupings were 1 to 40, 41 to 100, 101 to 200, 201 to 300, and 300+. Herd size groupings were < 50 cows, 51 to 99 cows, 100 to 199 cows, and >= 200 cows. Average daily milk yield groupings were < 27.2, 27.2 to 31.8, 31.8 to 36.3, and >36.3 kg per cow per day. Contribution potential was affected (P<0.0001) by DIM group with 1.0, 3.6, 2.5, –2.4, and –4.9% for 1 to 40, 41 to 100, 101 to 200, 201 to 300, and 300+ DIM, respectively. Interactions of DIM group and herd size groups or average daily milk yield groups were also significant (P<0.0001). These significant interactions were seen for both percent of herd group and percent milk contribution.

Key Words: Daily Milk Production, Herd Size, Days in Milk

T288 Milking parlor employee management on Wisconsin dairy farms. K. J. Hohmann and P. L. Ruegg*, *University of Wisconsin*, *Madison*.

The objective of this study was to evaluate milking parlor employee management practices on dairy farms that had previously participated in a team based milk quality improvement program. A mail survey was sent to farms that had registered for the Milk Money program before June 1, 2005 (n = 326) and a 44% response rate (n = 142) was achieved. Responder herds contained 226 cows (20 to 1200), produced 33 kg/cow/day (18 to 45) and had bulk tank SCC of 245,000 cells/ml (17,000 to 900,000). Most farms milked twice (58%) or three times (40%) a day in parlors (55%) or stall barns (36%). Of responder farms, 72% indicated that they trained milking technicians but most trained only when hired (42%) as compared to monthly training (16%), other (14%) or never (28%). Job descriptions were provided for employees on 31% of farms. Spanish was the first language for employees on 52% of farms. Most responders with Spanish-speaking employees spoke no Spanish (24%) or knew only a few words of Spanish (61%) but a few responders indicated that they could speak some Spanish (14%). Communication problems were apparent on farms with Spanish-speaking employees as 39% never used interpreters, while 6%, 14% and 41% used interpreters yearly, monthly or several times per year, respectively. Twenty-nine percent (n = 32) of 111 producers indicated that employee management was their greatest milk quality challenge. Farms that listed employee management as their greatest milk quality challenge were 5.8 times more likely to employ Spanish-speaking persons (P<0.001), 3.3 times more likely to provide job descriptions (P<0.01) and 15.5 times more likely to train milking technicians (P<0.01) as compared to farms that did not list this concern. This data suggests that employee management remains a challenge for farms that desire to produce high quality milk because of communication issues but that these farms are more active in employee management by training and providing job descriptions.

Key Words: Employee-Management, Dairy, Milking

T289 Bluegrass straw as a partial replacement for alfalfa hay in dairy rations. E. M. O'Rourke*, J. J. Michal, and R. L. Kincaid, *Washington State University*, *Pullman*.

The objectives were to determine the potential of bluegrass straw (BGS) as a partial replacement of alfalfa hay in dairy rations, and if the BGS affected P absorption. Thirty multiparous Holstein cows were assigned to a randomized complete design and fed one of three levels of bluegrass straw (0, 10 and 15% of TMR, DMB). NDF concentrations were 35, 39 and 39% DM for the 0, 10 and 15% BGS diets respectively. Cows were fed their respective treatment diet for 62 d with the first 12 d serving as an adaptation period. Individual feed intakes and milk yields were recorded daily. Samples of blood, milk, and feces were collected on d 1, 37, and 62. At the start of the study, cows averaged 219 ± 15.6 DIM, 661 ± 13 kg BW, and 41.1 ± 1.5 kg daily milk yield. Average DMI (25.4 ± 0.2 kg/d) and milk yield (35.2± 0.4 kg/d) were not affected by treatment but declined with time (P ≤ 0.01). Similarly, milk composition was not affected by dietary treatment but also was affected by time. The concentrations of P in the diets were 0.40, 0.40, and 0.39% DM and P intakes were 142.5, 140.5, and 136.2 g/d, respectively, similar (P ≤ 0.1) among treatments. Inclusion of BGS into the TMR did not affect the concentrations of P in feces (0.63, 0.61 and 0.66% P, DM), P digestibility, estimated using ADL as an internal

marker, nor was plasma inorganic P affected. In conclusion, up to 15% BGS was included in a TMR fed to late lactation cows without affecting performance. However, the inclusion of BGS into the TMR had no affect on P absorption as indicated by fecal P and plasma inorganic P.

Key Words: Bluegrass Straw, Phosphorus, Feces

T290 Scrotal circumference in performance tested bulls: Prediction of measures at 365 days of age from measures at 240 days of age. J. E. Decker*, P. Luna, A. M. Encinias, and M. G. Thomas, *New Mexico State University*, *Las Cruces*.

Bulls must achieve scrotal circumference (SC) of 30 cm by 365 days of age to pass a breeding soundness exam (BSE). At the Tucumcari Bull Test Station in New Mexico, from 1983 to 2006, SC was measured at the delivery of bulls and at the end of a 112-d test on 2514 bulls of 22 breeds. Bulls that had a final SC greater than 30 cm (n=2418) by 365 days of age had an initial SC of 25.3 ± 0.06 cm, and 96 bulls that had a final SC less than 30 cm had an initial SC of 21.8 ± 0.28 cm. Initial SC was measured at approximately 240 days of age and daily gain of SC was 0.08 ± 0.0005 cm. Objective of this research was to estimate a 240-d SC culling level (i.e., initial SC) for bulls to achieve 365-d SC of 30 cm. Associations between 240-d and 365-d SC were evaluated with correlation and multi-variance regression. The lower 95% confidence limit was plotted and probabilities of reaching 30 cm by 365 days of age were estimated for a minimum SC value (i.e., initial SC of a bull test). These probabilities were standardized and calculated using normal distribution. A correlation of 0.52 ($P < 0.01$) was detected between 240 and 365-d SC. Initial SC, year, sire and breed were significant ($P < 0.01$) sources of variation in a mixed prediction model of 365-d SC. Plotting of the lower 95% confidence limit of the predicted 365-d SC regression line suggested a 240-d SC of 22.5 cm as a culling level to achieve 365-d SC of 30 cm; whereas the probability estimated ($P < 0.01$) by standard-normal distribution revealed that 21 cm was needed to achieve 365-d SC of 30 cm. In these data, if a culling level of 21 cm was imposed for 240-d SC, 138 or 5.7% of the 2418 bulls achieving 30 cm by 365 days of age would have been unnecessarily culled, and 63 or 65.6% of the 96 bulls with SC less than 30 cm at 365 days of age would not have been culled. Herein, a limited number of bulls failed a BSE due to SC (n = 96; 3.8%). Because of moderate associations and the large percentage of bulls that would have been culled or selected incorrectly, results suggest that SC at 240 days of age is a weak predictor of SC at 365 days of age.

Key Words: Bulls, Scrotal Circumference, Prediction

T291 Estimation of no-return costs for different cattle identification systems in California. G. Caja*[1,2], F. Haque[2], J. W. Oltjen[2], L. J. Butler[2], J. L. Evans[3], and V. J. Velez[3], [1]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*, [2]*University of California*, *Davis, CA*, [3]*California Department of Food and Agriculture*, *Sacramento, CA*.

Cost of National Animal Identification System (NAIS) compliance at the producer level is a concern among livestock stakeholders in the US. The uncertain feelings expressed by stakeholders serve to frustrate and deter them from NAIS. Little information on cost values of different identification (ID) systems is currently available in the US and abroad, and complete and reliable estimations are required to evaluate their impact to the livestock industry across different segments. Changes in the price of devices and labor alter dramatically the estimated cost values for each ID system. A simulation model, based on a spreadsheet analysis of no-return costs for a Californian environment (UCD-CDFA Direct cost calculator, v. 2.2) was built up for different cattle scenarios (beef cow herd, 10 to 10,000 cows; feedlot, 10 to 100,000 steers; dairy cow herd, 100 to 10,000 cows). Conventional (plastic ear tag, hot and freeze branding, tattooing), electronic (ear tag, bolus, collar) and fingerprinting (retinal scan, DNA biopsying) ID systems were compared. Market prices of ID devices ($0 to $65) and reading equipment ($0 to $2,500); expected losses or unreadable rates for each ID device (0.5 to 15%); labor costs according to static or dynamic reading systems for $15/h salary; and, equipment amortization of 3 yr, were used. Total cost ($/animal and yr) of different ID systems varied markedly according to number of animals, number of readings per year and animal life span. Flat changes in total cost were calculated by sensitivity analysis for most ID systems when animals were >50. Case-study results for a herd of 500 beef cows, 7 yr life span, read 5 times/yr under static conditions, showed wide annual cost ranges according to ID system: conventional ($2.4 to $10.8/animal), electronic ($2.9 to $30.2/animal) and fingerprinting ($5.6 to $63.9/animal). Case-study values for a 500 steer growing-finishing operation, 2 yr life span, read 1 time/yr, were: conventional ($1.3 to $3.2/animal), electronic ($2.6 to $36.7/animal) and fingerprinting ($2.7 to $21.6/animal). Electronic ID systems were in many cases a cost competitive option.

Key Words: Animal Identification, Identification Cost, Cattle

T292 Analysis of birth weight, weaning weight, and pre-weaning gain in Simmental, Zebu and Simmental × Zebu calves on tropical pastures. J. C. Martinez-Gonzalez*[1], A. Azuara-Martinez[2], F. A. Lucero-Magana[1], E. G. Cienfuegos-Rivas[1], and S. P. Castillo-Rodriguez[1], [1]*Agronomia y Ciencias, Universidad Autonoma de Tamaulipas*, *Ciudad Victoria, Tamaulipas, Mexico*, [2]*Direccion General de Educacion Tecnologica Agropecuaria*, *Ciudad Victoria, Tamaulipas, Mexico*.

The productive performance of pure bred Simmental, Zebu and Simmental × Zebu calves were evaluated by analyzing 947 beef cattle records with birth weight (BW), weaning weight adjusted to 205d (WW) and pre-weaning gain (PWG) data. The climate of the region is tropical sub-humid with an average annual temperature and precipitation of 23.6°C and 935.1 mm respectively. Cows were fed mainly on pasture with occasional supplementation in the critical months of the year. Calves were weighed at birth and at weaning (average weaning age 205 days). The data were analyzed by general linear models procedures, using a fixed effect model which included the effects of genotype, year and birth season, sex of the calf and parity number of cow on BW, WW and PWG. The general means ± standard error for BW, WW and PWG were 35.18 ± 6.63, 193.91 ± 38.13 and 0.772 ± 0.179 kg, respectively. The year of birth and parity number affected (P<0.01) BW, WW and PWG. Birth season was an important source of variation (P<0.05) on WW and PWG. Genotype was affected (P<0.01) WW and PWG. The pure bred Simmental calves showed the lighter weights. It was concluded that, Simmental × Zebu calves can be an alternative for beef cattle production in tropical areas.

Key Words: Beff Cattle, Simmental, Weight

T293 Economic strategies for stocking rate and supplementation of stockers grazing rye-ryegrass pastures. F. M. Rouquette, Jr.*[1] and L. Ortega[2], [1]*Texas A&M University System Agricultural Research & Extension Center*, *Overton*, [2]*Agronomy Department, University of Zulia, Venezuela*, *Zulia, Venezuela*.

Increasing stocking rates to maximize gain per unit land area, and use of supplements to substitute for forage availability and increase ADG are management strategies used by stocker operators to increase economic return. The objective of this stocking rate (SR) x supplement (SUP) study was to quantify ADG and gain per ha as a database for assessing economic returns with variable input costs of fertilizer, supplement, and purchase-selling price of stocker cattle grazing ′Maton′ rye and ′TAM-90′ annual ryegrass. Two pasture replicates of 3.7 (LO), 5.2 (ME), and 7.2 (HI) hd/ha (270 kg initial BW/hd) received a daily, hand-fed ration of 98% cracked corn plus Rumensin 80 at 0 (PAS), 0.4% BW (.4 SUP), and 0.8% BW (.8 SUP). The 150-day ADG ranged from 1.5 kg/d for stockers at LO SR plus .8 SUP to .5 kg/d for stockers at HI SR and PAS (P<.01), with respective gain/ha at 1130 kg/ha and 560 kg/ha. Based on actual input costs and animal prices at time of the winter pasture grazing in 2004-2005, respective animal plus pasture costs/kg gain for LO, ME, and HI SR were $.68, $.79, and $1.39/kg for PAS; $.73, $.73, and $.99/kg for .4 SUP; and $.84, $.77, and $1.06/kg for .8 SUP. With initial purchase price of $2.77/kg for steers and $2.53/kg for heifers, the break-even selling price ranged from about $1.83/kg on all LO SR regardless of SUP to $2.10/kg on all HI SR plus SUP and $2.38/kg on HI SR without SUP. The net returns ranged from $622/ha for ME SR and .8 SUP to $-131/ha for HI SR and PAS. The differential returns/ha among SR and SUP strategies showed that an additional $753/ha was obtained by decreasing SR from HI to ME plus SUP at .8% BW. Using .8 SUP at HI SR increased ADG by .45 kg/hd, over PAS, and showed an additional $385/ha advantage due to SUP. Increasing costs of nitrogen fertilizer and corn reduced net returns/ha but had less effect than reduced animal prices and reduced purchase-sell margin.

Key Words: Ryegrass, Stocking Rate, Supplementation

T294 Development of a model for noninvasive evaluation of energy profiles in beef cows. J. F. Odhiambo*, E. E. Felton, R. Helmondollar, J. Y. Pritchard, P. I. Osborne, and R. A. Dailey, *West Virginia University*, *Morgantown*.

Body condition scores (BCS) indicate body energy reserves. However, variations among scorers and regional scoring systems prompted examination of utility of other non-invasive techniques. Spring-calving cross-bred Angus and Hereford cows (n = 150) were evaluated using body weight measurements, BCS, and ribfat and rumpfat ultrasonic scans. Cows were assigned randomly within age to two treatments, early or normal weaning 45 days apart to provide a range of energy states. Data were collected at early weaning, normal weaning, precalving, postcalving and breeding using an electronic weighing system and BCS evaluation by a single observer. Images were collected by positioning the 5.0 MHz transducer directly above the interface of the Biceps femoris and Gluteus medius (rumpfat) and at 75% of the distance from the medial to lateral end of the 12th to 13th intercostal space (ribfat). Data were examined by repeated measures for a split plot design using PROC MIXED procedures of SAS with treatment, age, and treatment x age in the main plot and period and its interactions in the subplot. Although ribfat (P = 0.001) and rumpfat (P = 0.01) differed between treatments, cow weight and BCS did not. Age was linearly related to weight (P = 0.0001), BCS (P = 0.001), ribfat (P = 0.002), and rumpfat (P = 0.001). Age x treatment effects were significant (P = 0.04, 0.001, 0.005 and 0.02 for weight, BCS, ribfat and rumpfat, respectively). Age x treatment x period effect was highly significant for rumpfat (P = 0.0001) followed by ribfat (P = 0.01) and weight (P = 0.05) but not BCS (P = 0.5). Rumpfat was highly correlated to ribfat (r = 0.83), to BCS (r = 0.65), to weight (r = 0.60) and fairly correlated to age, r = 0.27 (P = 0.0001). In conclusion, rumpfat provided a more sensitive measure for energy profiles than cow weight, while BCS was least effective. Because rumpfat and ribfat were highly correlated, assessing effects of both variables was counterproductive in evaluating energy status.

Key Words: BCS, Weight, Rumpfat

Ruminant Nutrition II

T295 Effects of waste products from plant materials on *in vitro* rumen fermentation. D. Tedesco*, S. Stella, L. Garavaglia, C. Barbieri, and S. Galletti, *University of Milan*, *Italy*.

The industrial processing of fruits, vegetables and the extraction of phyto-therapeutic compounds from plants produce many tons of organic wastes that could include valuable compounds (e.g. pectin, poly-phenoles, flavonoids). The objectives of the present study were to evaluate specific post-processing derivative waste products from plant residues (SAFEWASTES, EU project n. 513949) on rumen microbial fermentation by batch incubator system. The in vitro batch culture was carried out with rumen fluid withdrawn from three rumen-fistulated non-lactating dairy cows. The rumen fluid was added to a mineral salt buffer, mixed in a bottle warmed at 39°C, purged with anaerobic grade N2/CO2 (80/20, v/v) and standardized at pH 6.8 ± 0.1. 100 mL of solution were placed in glass bottles supplied with a substrate for microbial growth (0.8 g/100mL alfalfa hay and 0.2 g/100mL corn meal). In this study, a total of 52 SAFEWASTES by-products were tested at three different concentrations. Each test was evaluated in duplicate. The bottles were incubated in a water shaking bath at 39°C for 24 h. The pH was determined at 0, 4, 9, 24h of incubation. At 0 and 9h of incubation the production of VFA and of ammonia N were determined. Total Bacterial Count (TBC) was evaluated at 0h and after 24h of incubation. Statistical analysis was performed using PROC MIXED of SAS. None of the tested substances negatively affected rumen microbial fermentation. TBC value remained stable after 24h of incubation. Among the 52 tested substances, one caused a significative decrease (P<0.05) in ammonia N production in all the concentrations tested. Considering VFA production, an increase in acetic acid yield (P<0.05) was observed following incubation with two SAFEWASTES by-products. These *in vitro* results permitted to identify the substances that will be further evaluated in the *in vivo* trials. Furthermore, if positive physiological functions will be evidenced in other studies (e.g. as antinflammatory, immunostimulant), these substances could potentially have a use as feed additives.

Key Words: Waste Products From Plant Materials, VFA, Rumen Fermentation

T296 Rumen degradation ratios: comparison of frost-damaged wheat with normal wheat. P. Yu* and V. Racz, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

In this study, rumen degradation ratios of structural carbohydrates (SC), non-structural carbohydrate (starch: ST) and crude protein (CP) in the frost-damaged wheat were determined in dairy cows, using Tamminga Rumen Degradation Ratio System. The rumen degradation ratios were compared with the optimum ratio range. The overall test weight losses of the frost-damaged wheat were around 24%. The results showed that: 1) Rumen available insoluble N (EN), SC (ESC) and ST (EST) were 14 vs. 11 (P<0.05), 133 vs. 254 (P<0.05), and 441 vs. 326 g kg-1 DM (P<0.05), respectively, between the normal and frost-damaged wheat; 2) Rumen available soluble N (SN), SC (SSC) and ST (SST) were 3 vs. 6 (P<0.05), 0 vs. 0, and 86 vs. 84 g kg-1 DM (P>0.05), respectively; 3) Total rumen available N (FN), SC (FSC) and ST (FST) were 17 vs. 17 (P>0.05), 139 vs. 254 (P<0.05), and 527 vs. 410 g kg-1 DM (P<0.05), respectively. The degradation ratios were calculated between the total rumen available N and carbohydrates (FN/FCHO), rumen available soluble N and carbohydrates (SN/SCHO), and rumen available insoluble N and carbohydrates (EN/ECHO). The ratios showed a significant difference between the normal and frost-damaged wheat in EN/ECHO ratio (24 vs. 18 g kg -1, P<0.05). The frost-damaged wheat had numerically higher ratio of SN/SCHO (89 vs. 35 g kg-1, P>0.05) and similar FN/FCHO (25 vs. 25 g kg-1) than the normal wheat. These results indicated that the normal and frost-damaged wheat differed in degradation utilization, however, both exhibited an optimal rumen fermentation ratio (optimum: FN/FCHO = 25 to 33 g N kg -1 CHO).

Key Words: Optimal Rumen Fermentation, Degradation Ratio, Frost-Damaged Wheat

T297 Available protein, structural and non-structural carbohydrates: comparison of frost-damaged wheat with normal wheat. P. Yu* and V. Racz, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

In 2004, more than 50% of wheat was frost-damaged, rendering millions of tons of wheat unsuitable for human consumption. So far, little systematic research has been conducted to determine the magnitude of the differences in nutritive value between frost-damaged and normal wheat. In this study, rumen degradation characteristics of structural carbohydrates (SC), non-structural carbohydrate (starch: ST) and crude protein (CP) in the frost-damaged wheat were determined in dairy cows. Measured ruminal degradation characteristics were soluble fraction (S: ST and CP), undegradable fraction (U: SC and CP), lag time (T0: SC and CP) and rate of degradation (Kd: SC, ST and CP) of the insoluble but degradable fraction (D: SC, ST and CP). The overall test weight losses of the frost-damaged wheat were around 24%. The measured characteristics showed significant differences between the normal and frost-damaged wheat. For protein, the frost-damaged wheat was lower (P<0.05) in D (612 vs. 878 g kg-1 CP) and higher (P<0.05) in S (263 vs. 122 g kg-1 CP) and U (125 vs. 0 g kg-1 CP). It was also higher in total available soluble N (6 vs. 3 g kg-1 DM), lower in total available insoluble N (11 vs. 14 g kg-1 DM) than the normal wheat samples. No significant differences were found on T0, Kd, and total available N between the normal and frost-damaged wheat. For non-structural carbohydrate, the frost-damaged wheat tended to be higher (P<0.10) in Kd of ST (45.11 vs. 32.39 % h-1), lower (P<0.05) in rumen available insoluble ST (326 vs. 441 g kg-1 DM), and total rumen available ST (410 vs. 527 g kg-1 DM). There is no difference in rumen available soluble ST (average 85 g kg-1 DM). For structural carbohydrate, the frost-damaged wheat contained higher potentially degradable SC (297 vs. 180 g kg-1 DM, P<0.10), rumen available insoluble SC (254 vs. 133 g kg-1 DM, P<0.05) and total rumen available SC (254 vs. 139 g kg-1 DM). The D, U, Kd and T0 were similar (P>0.05). The results showed that the normal and frost-damaged wheat showed different degradation kinetics, which indicates different nutrient availability.

Key Words: Degradation Kinetic, Frost-damaged Wheat, Protein/ Carbohydrate

T298 Modelling nutrient supply to dairy cattle from normal and frozen sheat: Comparison of the National Research Council-2001 model with the DVE/OEB system. P. Yu*, R. Racz, and J. McKinnon, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

The objective of this study was to 1) predict nutrient supply of frozen wheat to dairy cattle in comparison with normal wheat, and 2) compare the DVE/OEB system (DVE = truly absorbed protein in the small intestine; OEB = degraded protein balance) and the NRC-2001 model in the prediction of nutrient supply to dairy cows from different types of frozen wheat and normal wheat. Comparisons were made in terms of (1) ruminally synthesized microbial CP, (2) endogenous protein, (3) rumen undegraded feed protein, (4) truly absorbed protein in the small intestine, and (5) degraded protein balance. The results showed that the predicted values from the DVE/OEB system and the NRC-2001 model had significant correlations with high R (> 0.90) values. However, using the DVE/OEB system, the overall average microbial protein supply was 13.7% higher (65.2 vs. 56.3 g/kg DM), the digestible rumen undegraded feed protein was 10.0% higher (43.4 vs. 39.0 g/kg DM), endogenous protein was 65% higher (12.3 vs. 4.3 g/kgDM) than that predicted by the NRC-2001 model. However, the truly absorbed protein in the small intestine was similar (96.2 vs. 99.6 g/kg). The difference was also found in the prediction of the degraded protein balances, which was 78% higher based on data from the NRC-2001 model (-16.7 vs. -3.7 g/kg DM). These differences are due to considerably different factors used in calculations in the two models, although both are based on similar principles. This indicates that a further refinement is needed for a modern protein evaluation and prediction system. In addition, this study showed that the normal wheat had no difference in DVE and OEB values, but significant difference in metabolizable protein value (108.1 vs. 95 g/kg DM, P<0.05)

Key Words: Modelling Nutrient supply, Dairy Cows, Frozen Wheat

T299 Feed values of barley varieties could be determined using in vitro gas production technique. M. Rinne[1], S. Ahvenjärvi[1], M. Holma[2], and P. Huhtanen*[1,3], [1]*MTT Agrifood Reserach Finland*, *Jokioinen, Finland*, [2]*RehuRaisio Ltd.*, *Raisio, Finland*, [3]*Cornell University*, *Cornell, NY*.

Fiber (NDF) from cereal grains can in some feeding situations form a considerable proportion of ruminant diets. The in vitro gas production technique provides a method to study separately digestion kinetics of concentrate NDF and cell solubles, which is not achievable in vivo.

Information of NDF digestion is important as it is more variable than digestion of cell solubles. Fourteen barley grain samples representing different varieties grown in the Nordic countries were ground and ND solution was used to extract cell solubles. Indigestible NDF was estimated by a 12 d ruminal in situ incubation (nylon bag pore size 17 μm). In vitro gas production of the intact samples and the NDF residues were determined for 72 h with a 15 min. measurement interval in triplicate runs. The gas curve for cell solubles was calculated by subtraction. The two-pool Gompertz function was fitted to the gas curves, and digestibility of the potentially digestible NDF (pdNDF) was estimated using a dynamic rumen simulation model. The first-order rate of digestion was calculated from the pdNDF digestibility. Concentrations of NDF and iNDF of the samples were 198 (s.d. 22.6) and 34 (s.d. 8.1) g/kg DM, respectively. The rate of digestion of cell solubles was faster than that of digestible fiber [0.143 (s.d. 0.0090) vs. 0.075 (s.d. 0.0097) per h]. The digestibility of pdNDF was on average 0.761 (s.d. 0.0291) and that of cell solubles 0.884 (s.d. 0.0090). There were significant differences between the varieties and especially a hulless variety had a fast rate of pdNDF digestion. The concentration of NDF was negatively correlated to the rate of pdNDF (r = -0.562) and calculated ME concentration (r = -0.867) of the samples. In vitro gas production technique shows potential for studying the differences in digestion properties and feeding value of grain samples.

Key Words: Rate of Digestion, Indigestible Fiber, Cell Solubles

T300 Effect of an exogenous fibrolytic enzyme on in vivo digestibility of King grass hay. J. H. Avellaneda-Cevallos*[1], G. Quintana-Zamora[1], F. Espinoza-Torrico[1], O. Montañez-Valdez[2], I. Espinoza-Guerra[1], R. Luna-Murillo[1], S. González-Muñoz[3], and J. Tuárez-Cobeña[1], [1]*Facultad de Ciencias Pecuarias, Unidad de Investigación Cientifica y Tecnológica, Universidad Técnica Estatal de Quevedo*, *Quevedo, Los Rios, Ecuador*, [2]*Divisíon de Bienestar y Desarrollo Regional, Departamento de Desarrollo Regional, Universidad de Guadalajara*, *Ciudad Guzmán, Municipio de Zapotlán, Jalisco, México*, [3]*Colegio de Postgraduados*, *Texcoco, Estado de México, México*.

The effect of a enzymatic fibrolytic exogenous compound in the digestibility in vivo (DIV), and nitrogen balance in sheep fed with hay of King grass (Pennisetum hydridum) cut at 35 and 70 days was evaluated. Four Pelibuey × Chatadin sheep were used (35±4 Kg BW) in a 4× 4 Latin square design with a 2×2 factorial treatment arrangement (two cutting dates and two levels of enzymes; 0 and 1 g of Fibrozyme/Kg of DM). Four treatments were established: T1: King grass cut at 35 d with enzyme; T2: King grass cut at 35 d without enzyme; T3: King grass cut at 70 d with enzyme; T4: King grass cut at 70 d without enzyme. The DIV of DM (T1: 67.04a, T2:68.25a, T3: 65.08a, T4: 64.33; P>0.05; SEM=2.59), OM (T1: 72.13a, T2: 75.01a, T3: 69.04b, T4: 68.38b; P <0.05; SEM= 1.31) and protein (T1: 68.06a, T2: 69.59a, T3: 58.66b, T4: 58.84b; P<0.05; SEM= 2.22) was substantial on the hay cut at 35 d compared to the hay cut at 70 d, which was not influenced by the enzyme fibrolytic exogenous compound. The retention of nitrogen was superior (P>0.05) for the 35 vs 70 d hay without being influenced by the enzyme compound. In conclusion the enzyme fibrous exogenous do not affect the digestion of the nutrients in the King grass hay.

Key Words: King Grass Hay, Fibrolytic Enzymes, Digestibility

T301 Effects of Bovazyme WP™ on microbial efficiency and metabolism in continuous culture of rumen contents. B. P. House*, L. Holden, and G. A. Varga, *The Pennsylvania State University*, *University Park*.

A continuous culture study was conducted to evaluate the effect of BovaZyme™ (BVZ, York Ag Products, Inc.), a concentrated source of enzymes and other fermentation enhancers, on ruminal microbial metabolism. Diets were formulated to be similar in nutrient composition and consisted of a basal diet without BVZ (control) and a diet with BVZ, equivalent to 2.5g/head/day. Continuous culture fermenters were fed 100g DM/d and conditions included a liquid dilution rate of 13%/hr, solids dilution rate of 4.55%/hr, and a solids retention time of 22 hr. The BVZ significantly increased ruminal digestibility of acid detergent fiber by 16.2% (P=0.05). Though not significant, neutral detergent fiber digestibility numerically increased by 14.6% for BVZ compared to the control. Rumen by-pass nitrogen was decreased 12% (P=0.05), while crude protein digestibility was increased by 9% (P=0.04) for fermenters provided BVZ. Microbial nitrogen (N) production/d of the BVZ diet was 12% higher (P=.04) than the control. There was no change in conversion of feed N to microbial N, however, volatile fatty acids (VFA) produced/unit of microbial N was lower (P=.04) in the BVZ diet, indicating a tendency to partition more feed organic matter to microbes rather than VFA. Total VFA production was not changed due to BVZ, but increases were observed in acetate and butyrate production along with a decrease in propionate production for fermenters provided BVZ compared to the control. As a result, the acetate-propionate ratio increased from 1.60 to 2.14 (P=.09). Comparing changes in pH over time between treatments illustrated that BVZ attenuated a rapid rise in pH 2-3 hours post feeding compared to the control resulting in a more continuous supply of nutrients. Addition of BVZ to the diet resulted in improved rate and extent of fiber digestibility, greater microbial growth and an improved VFA profile compared to the control.

Key Words: Continuous Culture, Feed Enzyme Additive

T302 Effects of yeast and type of starch on pH fluctuation, nutrient digestion and microbial fermentation in a dual flow continuous culture system. D. Moya*, S. Calsamiglia, A. Ferret, and M. C. Fuentes, *Universitat Autonoma de Barcelona*, *Barcelona, Spain*.

Eight 1320-mL dual flow continuous culture fermenters were used in a 2 × 2 factorial design in two replicated periods of 9 d (6 for adaptation and 3 for sampling) to determine the effect of live yeast and type of starch on rumen microbial fermentation and nutrient digestibility. Main factors were live yeast (Saccharomyces cerevisiae CNCM I-1077,Levucell®SC): no yeast (NY) vs 1.3 × 106 CFU of yeast/g of diet (Y); and type of starch: slow degradable (S, a 55% ground corn diet, 17.2% CP, 27.8% NDF) vs rapidly degradable (R, a 89.2% barley diet, 16.1% CP, 16.1% NDF). All fermenters were fed 80 g DM/day of a 10 to 90 forage to concentrate diet in three equal amounts along the day. Fermentation temperature (38.5°C) and liquid (12%/h) and solid (5%/h) dilution rates were maintained constant. The pH was allowed to fluctuate with an upper (6.6) and lower (5.5) limit controlled by infusion of 3 N HCl or 5 N NaOH. Effluent samples were taken from a composite of the three sampling days, and bacteria were isolated from fermenter flasks on the last day of each period for chemical analysis. Treatment R increased (P < 0.01) the true digestion of DM and OM,

and decreased (P < 0.01) the NDF and ADF digestion. Ammonia N flow and CP degradation was higher (P < 0.05) and dietary N flow was lower (P < 0.01) in R compared with S. Treatment Y decreased ammonia (P < 0.05) and dietary (P < 0.10) N flow, and increased (P < 0.05) bacterial N flow, CP degradation (P < 0.10) and the efficiency of microbial protein synthesis (P < 0.10). Treatment R reduced the min to minimum pH (P < 0.05) and increased the area under pH 6.0 (P < 0.01). Treatment Y increased the min until minimum pH in the two types of starch and reduced the area under pH 6.0 in R treatment (P < 0.05). Results from the comparison between R and S were expected. Treatment Y improved N metabolism and reduced the drop of pH after feeding a rapidly degradable starch diet.

Key Words: Yeast, Starch, Microbial Fermentation

T303 Screening for the effects of commercial additives at two pH levels on in vitro rumen microbial fermentation of a high-concentrate beef cattle diet. D. Moya*, S. Calsamiglia, A. Ferret, and J. I. Fandiño, *Universitat Autonoma de Barcelona*, *Barcelona, Spain*.

Ten commercial additives were screened at 3 doses (low, medium and high) and 2 levels of pH (7.0 and 6.0) in a duplicate 10 × 3 × 2 factorial arrangement of treatments to determine their effects on rumen microbial fermentation profile. Treatments were: two sources of tannins (TAN1 and TAN2), three sources of saponins (SAP1, SAP2 and SAP3), two sources of yeast (YEA1 and YEA2), rice fatty acids (RFA), garlic powder (GAR) and one source of natural plant alcaloids (sanguinarine and chelerytrine, NPA). Treatments were tested in triplicate in two consecutive periods in batch cultures. Ruminal fluid was taken from two feedlot steers, mixed with an equal volume of artificial saliva and adjusted to pH 7.0 or 6.0 with 3 N HCl and 5 N NaOH. All tubes were supplied with 0.5 g of DM of a 10 to 90 forage to concentrate diet (16.6% CP, 22.0% NDF, 12.4% ADF). Tubes were filled with 50 ml of fluid, infused with CO2 to remove O2, stamped with gas-release rubber stoppers, and incubated for 24 h at 39°C. Samples were collected for ammonia N and volatile fatty acid (VFA) determinations. Differences were declared at P < 0.05. When pH was 7.0, TAN1, TAN2, SAP2, SAP3 and NPA increased total VFA concentration; TAN1, TAN2, SAP2, YEA1, YEA2, GAR and NPA increased the acetate to propionate ratio; and TAN1 and TAN2 reduced ammonia N concentration, whereas SAP2 and NPA increased it. In contrast, when pH was 6.0, TAN1 reduced total VFA; TAN2, SAP1 and SAP3 increased the acetate to propionate ratio; and TAN1, TAN2 and YEA1 reduced ammonia N concentration, whereas NPA increased it. Results indicate that the effects of commercial additives on rumen fermentation in beef cattle diets may differ depending on rumen pH. When pH was 7.0 most of commercial additives tested had more activity. The increase in total VFA concentration and the reduction in ammonia N concentration observed with tannins suggest that they may be useful in modifying rumen microbial fermentation.

Key Words: Rumen pH, Fermentation, Commercial Additives

T304 Effect of fibrolytic enzyme application to diets differing in concentrate proportion on the performance of lactating dairy cattle. K. G. Arriola*, A. T. Adesogan, S. C. Kim, T. W. Kang, C. M. Huisden, and C. R. Staples, *University of Florida*, *Gainesville*.

This study examined the effect of dietary application of a fibrolytic enzyme preparation containing xylanase, cellulase and esterase activities (Dyadic International Inc., Jupiter, FL) in lactating dairy cows consuming diets with high (48% of dietary DM) or low (33% of dietary DM) proportions of concentrate. Sixty lactating Holstein cows were classified according to milk production and randomly assigned at 22 DIM to four treatment groups arranged in a 2 x 2 factorial design. The trial lasted for 77 d, the first 14 d were used for adaptation to diets and the last 63 d for measurements. Dietary treatments included the following: 1) Low concentrate diet (LC); 2) LC plus enzyme (LCE); 3) High concentrate diet (HC); 4) HC plus enzyme (HCE). The enzyme was sprayed at a rate of 3.4 mg/g of DM on the TMR daily. Four ruminally-fistulated cows were used to measure dietary effects on the ruminal environment. Enzyme application did not affect DM intake (DMI) (P > 0.05) but tended to increase milk yield (P = 0.06; 32.8 vs. 34.7 kg/d) and therefore increased the efficiency of milk production (1.36 vs. 1.55 kg milk/kg DMI; P = 0.008). Increasing the concentrate level increased (P < 0.05) DMI (22.0 vs. 25.5 kg/d), milk yield (32.5 vs. 35.0 kg/d), and milk protein yield (0.92 vs. 1.01 kg/d), but reduced ruminal pH (P < 0.01; 6.31 vs. 6.06) and tended to reduce the efficiency of milk production (P = 0.108; 1.51 vs. 1.40 kg milk/kg DMI). Compared to cows fed HC, those fed LCE had lower DMI (P = 0.009; 21.2 vs. 25.6 kg/d), greater ruminal pH (P = 0.01; 6.36 vs. 6.10) and similar milk yield (P = 0.693; 33.2+1.0 kg/d). Consequently the efficiency of milk production was greater in cows fed the LCE diet than those fed the HC diet (P = 0.003; 1.62 vs. 1.32 kg milk/kg DMI). Therefore this mixture of fibrolytic enzymes increased the amount and efficiency of milk production by dairy cows.

Key Words: Fibrolytic Enzyme, Milk Production, Esterase

T305 Effect of a ruminal buffer and an amilolytic enzymes mixture added to a sorghum grain diet on finishing Criollo lambs. H. A. Lee–Rangel[1], G. D. Mendoza–Martínez[2], S. S. González*[1], G. Ramírez–Valverde[1], and J. H. Avellaneda–Cevallos[3], [1]*Colegio de Postgraduados*, *Montecillo, Edo. México, México*, [2]*UAM Xochimilco*, *México D.F.*, [3]*Universidad Técnica Estatal de Quevedo*, *Quevedo, Ecuador*.

The objective of this trial was to determine the effect of an amilolytic enzymes mixture (enzyme) from *Aspergillus niger* (Glucozime® L-400, Takaterm) and *Bacillus lincheniformis* (α–1, 4 D-glucan hydrolase) (ENMEX, México) plus a buffer (Acid buf®) on finishing lambs performance. The enzyme was sprinkled on ground sorghum (2.6 g/kg DM) and the buffer was added (0.85% DM) to the diet which contained 72% sorghum, 10% corn stover, 9% cane molasses and 7% SBM. The experiment lasted 50 days and treatments (T) were: T1, control (no enzyme or buffer); T2, enzyme; T3, buffer; T4, enzyme + buffer. The experimental design was completely randomized and data were analyzed using PROC MIXED (SAS) with initial BW as a covariable. The experimental units were 32 Criollo lambs (25 ± 2.5 kg initial BW) housed in individual metabolic cages. There were no significant differences (Tukey; P≥0.01) for ADG (264.7, 262.7, 282.5, 284.5 ± 0.02 g/d), DMI (1124.7, 1127.5, 1200.1, 1216.9 ± 65.8 g/d), and feed conversion (4.75, 4.39, 5.3, 4.65 ± 0.47). Therefore, addition of an amilolytic enzymes mixtures plus a buffer did not change performance of finishing Criollo lambs fed a sorghum grain diet.

Key Words: Amilolytic Enzymes, Buffer, Criollo Lambs

T306 Effects of exogenous amylase from Bacillus licheniformis on sheep performance and starch digestion. M. M. Crosby[1], G. D. Mendoza*[2], L. M. Melgoza[2], J. R. Barcena[1], and F. X. Plata[2], [1]*Colegio de Postgraduados*, *Montecillo, Mexico, Mexico*, [2]*Universidad Autonoma Metropolitana Xochimilco*, *Mexico, D.F., Mexico*.

An experiment was conducted to determine the effects of exogenous amylase dose in sheep performance and starch digestion and with a sorghum based diet (68% of the diet). Thirty-six sheep (Creole × Suffolk, 21.66 ± 6.5 kg BW) were assigned the following doses of amylase from B. Licheniformis (g enzyme /kg dry matter of grain): 0.0, 0.6, 1.2, 1.8, 2.4 and 3.0. In vivo starch digestion was not different when dose was increased (94.8, 97.4, 96.0, 95.4, 96.0, 96.8%). No differences were detected ($P \geq 0.05$) in daily gain (215, 206, 223, 220, 222, 209 g/d) among treatments for the increasing doses (0 to 3.0 g respectively). Feed conversion was not affected by enzyme dose (4.54, 4.34, 4.47, 4.43,, 4.38 and 4.47 for the same doses respectively). Sheep performance and starch digestion were not improved with the exogenous amylolytic enzyme.

Key Words: Starch, Digestion, Enzyme

T307 Effect of feeding Fermenten® on rumen fermentation in cows fed different concentrations of sucrose. G. B. Penner*[1], L. L. Guan[1], K. A. Beauchemin[2], and M. Oba[1], [1]*University of Alberta*, *Edmonton, Alberta, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, Alberta, Canada*.

A study was conducted to determine the effect of feeding Fermenten® on rumen fermentation and microbial populations in lactating Holstein cows fed diets differing in sucrose concentration. We hypothesized that Fermenten® would decrease propionate concentration in ruminal fluid, and increase rumen ammonia production; however, these effects would be altered by dietary sucrose concentration. Eight multiparous ruminally cannulated cows (163 ± 55 DIM) were used in a replicated 4 × 4 Latin square design with 21-d periods. Treatments were arranged as a 2 × 2 factorial: Fermenten® inclusion (FERM vs. control) and dietary sucrose concentration (6.5 vs. 2.0% DM). Diets were formulated to contain 18.7% CP, 23.2 % forage NDF and were offered ad libitum. Cracked corn replaced sucrose for the low sugar diets, and urea and soybean meal replaced Fermenten® in the control diets. Ruminal pH was measured for 72 h continuously using the Lethbridge Research Centre Ruminal pH System. No detectable differences were observed for microbial diversity using PCR-DGGE analysis. Ruminal pH parameters were not affected by treatment with mean pH averaging 6.23. Although, FERM did not alter individual VFA concentrations, there tended ($P < 0.10$) to be interactions between FERM and sucrose for propionate and acetate:propionate ratio. For high sucrose diets, FERM tended to increase propionate concentration (21.5 vs. 20.4 % of total VFA) and decrease the acetate:propionate ratio (2.82 vs. 3.01), whereas for low sucrose diets, FERM tended to decrease propionate concentration (20.9 vs. 21.8 % of total VFA) and increase the acetate:propionate ratio (2.80 vs. 2.95). FERM inclusion increased ($P < 0.01$) ruminal ammonia concentration (18.4 vs. 15.7 mg/dl) over the control. These data indicate that Fermenten® affects N metabolism in the rumen regardless of dietary sucrose concentration. However, the effect of Fermenten® on the ruminal VFA profile is dependent on the concentration of sucrose in the diet.

Key Words: Fermentent, Sucrose, Rumen Fermentation

T308 Influence of encapsulation of ascorbic acid to fermentation by rumen bacteria, in vitro. J. E. Garrett*[1], G. Oenga[1], A. Tayal[1], and T. M. Webster[2], [1]*Balchem Corporation*, *New Hampton, NY*, [2]*West Virginia University*, *Morgantown*.

The feeding of ascorbic acid to ruminants has been difficult due to the destructive nature of the rumen bacteria to this easily oxidized compound. The objective of this study was to evaluate the stability of ascorbic acid (AA) to rumen bacterial fermentation in vitro when protected by a lipid encapsulation. Raw ascorbic acid (RAA) was compared with two different encapsulation methods, rumen protected ascorbic acid (RPAA, Vitashure C, Balchem Corporation), and rumen protected ascorbic acid with a high melting point (RPAA-HM, Vitashure 140, Balchem Corporation). Individual samples of each ascorbic acid type were incubated in 50 ml test tubes in triplicate following a modified method of Tilley and Terry (1963) for 30 min, 6 h, 12 h and 24 h. Each tube contained .3 g of equal parts corn and SBM with .01 g of equivalent AA. Blanks were run for naturally occurring AA in the feeds. Each sample was freeze dried after incubation and held for analysis. Blanks and RAA were water extracted to obtain any residual AA. Chloroform was used to dissolve the lipid coating. Distilled water, centrifugation and filtration were used to obtain residual AA from the encapsulated samples. All samples were then immediately analyzed by HPLC for AA. RAA had significantly less ($P<.05$) recovery after 30 min than either RPAA or RPAA-HM (37.3 vs 65.3 and 79.0%, respectively). After 30 min, RAA had 3.05% or less of the initial AA at the other incubation times which was significantly less ($P<.05$) than either encapsulated product. Recovery of AA from RPAA and RPAA-HM was not significantly different ($P>.05$) from each other at the 6, 12 and 24 h incubations, averaging from 43 to 65% recovery. RPAA-HM did have numerically higher recoveries of AA for all time points measured. RAA is extensively degraded by rumen bacteria in less than 6 h. Both encapsulation methods proved to be an effective means of protecting 50% or more of the AA exposed to rumen bacterial fermentation through 24 h.

Key Words: Ascorbic Acid, Encapsulation, Rumen Bacteria

T309 Quantification of Streptococcus bovis and Megasphaera elsdenii in ruminal fluid of dairy cows and beef heifers by real time PCR technique. M. Blanch*, S. Calsamiglia, and A. Castello, *Universitat Autonoma de Barcelona*, *Spain*.

The objective of this study was to develop quantitative real time PCR (qRT-PCR) assays to: a) detect and quantify two rumen bacteria involved in ruminal acidosis: Streptococcus bovis and Megasphaera elsdenii (Exp. 1); and b) determine the variability due to animal, day and hour of sampling (Exp. 2). In Exp. 1, the assays were evaluated using DNA from pure cultures and rumen fluid samples from Exp. 2. The efficiency of the real time PCR assay was 88% and 99% for S. bovis and M. elsdenii, respectively. The specificity of the two primer-probe combinations was confirmed using different bacterial pure cultures as negative controls. In Exp. 2, a comparative study of S. bovis and M. elsdenii rumen populations was conducted using 4 cows and 4 beef heifers (696 ± 94 and 221 ± 17 kg BW, respectively). Cows were fed a 69:31 forage to concentrate total mixed ration ad libitum (15.6% CP, 35.4% NDF) and 3 kg of concentrate (25.8% CP, 21.7% NDF), and beef heifers were fed a 10:90 forage to concentrate ratio diet (15.7% CP, 22.3% NDF). During 5 consecutive days, samples of ruminal fluid were collected at 0, 4, 8 and 12 h after the morning

feeding. S. bovis was 145-fold higher in cows than in heifers. M. elsdenii was 13-fold lower in cows than in heifers. The S. bovis:M. elsdenii ratio was not associated with changes in ruminal pH, because in spite of observing different ratios between heifers and cows (0.83 and 12.3, respectively), their pH was similar (averaged 6.26 ± 0.305). The coefficients of variation were large and always higher in heifers than in cows (from 45.2% to 156.7% in heifers, and from 25.0% to 94.8% in cows), and differed depending on the factor. In heifers, the most variable factor was animal, followed by day and hour. In cows, the factor with the highest variation was day, followed by hour and animal. The qRT-PCR may become a powerful tool to study changes in rumen microbial populations associated to dietary treatments.

Key Words: Rumen Acidosis, Streptococcus Bovis, Megasphaera Elsdenii

T310 The effect of heat stress on rumen microbial composition analyzed by sequence-specific rRNA cleavage method. Y. Uyeno*[1,3], Y. Sekiguchi[1], K. Tajima[2], A. Takenaka[2], M. Kurihara[2], and Y. Kamagata[1], [1]*National Institute of Advanced Industrial Science and Technology*, *Tsukuba, Japan*, [2]*National Institute of Livestock and Grassland Science*, *Tsukuba, Japan*, [3]*National Federation of Dairy Co-operative Associations*, *Tokyo, Japan*.

It is recognized that ruminal microbial fermentation characteristics alter in response to the nutritional shift of the animal under heat-stress conditions. We evaluated the changes of the ruminal bacterial community composition in cows under heat-stress conditions by applying an RNA-based method (sequence-specific small-subunit rRNA cleavage method), which was optimized for the comprehensive description of predominant bacterial groups inhabiting the rumen. The same four Holstein cows were subjected to two separate experiments with the different age and relative humidity (RH) (Experiment 1, nine months, 80% RH; Experiment 2, 15 months, 60% RH). In each experiment, the cows were kept under three temperatures (20°C, 28°C, 33°C) in a climatic chamber for two weeks each. The cattle were offered a mixed ration (45% Italian ryegrass hay silage, 5% alfalfa hay cube, and 50% concentrate) twice a day. Rumen fluid samples were used for total RNA extraction. For quantitative detection, we applied a set of 15 oligonucleotide probes including those which targeted clusters comprised of uncultured rumen bacteria (URB) belonging to the low-GC Gram-positive bacteria phylum. The total amount of 16S rRNAs of those targeted groups accounted for 93% max of the total bacterial 16S rRNAs. The *E. rectale - C. coccoides* group and the genus *Streptococcus* increased, and the genus *Fibrobacter* decreased in response to increasing temperature. In addition, the population of one defined URB cluster was higher at 33°C compared to 20°C, whereas one of the other URB clusters decreased with the temperature rise. These results indicate that exposure to a hot temperature can affect the composition of the ruminal microbial community and that uncultured rumen bacteria play a critical role in ruminal fermentation which can respond to temperature change.

Key Words: Rumen Microbial Community, Heat-Stress, 16S rRNA

T311 Application of carbohydrase inhibitors to moderate rumen fermentation: Continuous culture evaluation. S. M. Speight*[1], D. L. Harmon[1], and J. M. Tricarico[2], [1]*University of Kentucky*, *Lexington*, [2]*Alltech Biotechnology*, *Nicholasville, KY*.

While carbohydrase inhibitors have been widely investigated for regulating human carbohydrate assimilation, their application to animal nutrition has been ignored. Two continuous culture experiments were conducted to determine how microbial-derived α-amylase and α-glucosidase inhibitors affect rumen fermentation. rumen fluid from two mature holstein steers (1045 ± 8.0 kg bw) fed a 50% concentrate, 50% forage diet was strained, mixed, and loaded into 1-l single-flow continuous culture fermenters. McDougall's buffer was continuously infused via a peristaltic pump (60 mL/h). Treatments in Exp. 1 consisted of: no additive, 88 mg and 166 mg acarbose/d. Treatments in Exp. 2 consisted of: no additive, 4 mg, 8 mg, and 12 mg trestatin/d. Treatments were added to a purified diet (90% corn starch, 10% casein salt) that was fed to each vessel twice daily. Each experiment consisted of a 3-d adaptation period followed by a 3-d sampling period. Ammonia, VFA, and pH were measured twice daily. Effluent outflow was collected daily and frozen for subsequent lab analyses. Acarbose and trestatin linearly increased ($P \leq 0.02$) pH and ammonia concentrations. Lactate decreased linearly ($P = 0.02$) with acarbose but was unaffected by trestatin. Acarbose did not affect acetate or propionate but did quadratically decrease ($P < 0.05$) butyrate, valerate and tended ($P = 0.09$) to linearly decrease total VFA concentrations. Acarbose quadratically increased ($P = 0.03$) the molar proportions of acetate and tended to decrease ($P = 0.06$) the molar proportions of propionate. Trestatin linearly decreased ($P = 0.03$) valerate concentrations and increased the molar proportion of acetate (linear; $P = 0.02$). Starch disappearance and effluent N decreased linearly ($P \leq 0.05$) with both treatments. Acarbose increased (linear; $P = 0.03$) effluent energy (kcal/d) whereas trestatin decreased effluent energy (linear; $P = 0.05$). Carbohydrase inhibitors can modify fermentation in a dose dependent manner. They may offer the potential to either moderate the rate of fermentation and/or shift digestion to the small intestine.

Key Words: Carbohydrase Inhibitors, Rumen Fermentation Modulators, Continuous Culture

T312 Efficacy of *Prevotella bryantii* 25A and a mixture of *Enterococcus faecium* and *Saccharomyces cerevisiae* to control sub-clinical acidosis in dairy cows. J. Chiquette*[1], M. J. Allison[2], and M. A. Rasmussen[3], [1]*Dairy and Swine Research and Development Centre*, *Lennoxville, Quebec, Canada*, [2]*Iowa State University*, *Ames*, [3]*SarTec Corporation*, *Anoka, MN*.

The objectives of this study were 1) to evaluate *Prevotella bryantii* strain 25A (P) and a mixture of *Enterococcus faecium* and *Saccharomyces cerevisiae* (ES) as probiotics to sustain higher ruminal pH; 2) to study their effect on animal feed intake, milk production and composition, in dairy cows submitted to a sub-acute rumen acidosis (SARA) challenge. Six ruminally-fistulated Holstein dairy cows in mid-lactation were equally distributed between the following treatments, in a replicated 3 × 3 Latin square design: 1) Control (C), animals were fed a total mixed ration (TMR); 2) TMR + 2g/head/day of ES (5×10^9 CFU); 3) TMR + 25 ml/head/day of P (2×10^{11} cells/dose). The Latin square consisted of 3 weeks (wks) of adaptation, 4 days during which a specific feeding procedure was used to induce SARA and 10 resting days during which the animals were back to the control TMR with no probiotic supplementation. Rumen pH was recorded every 10 min over a

24h-period during each of the three wks of adaptation and during the wk of resting and continuously during the 4 days of SARA. All pH parameters averaged over treatments were different when comparing adaptation wks and challenge wks ($P < 0.001$). ES tended ($P < 0.10$) to increase median pH values obtained during 24h periods (5.6 vs 5.4, for ES and control, respectively). Maximum pH recorded during 24-h periods tended ($P < 0.06$) to be higher when animals received ES than when they were controls (6.6 vs 6.3). Percentage of time during which rumen pH was below the threshold of 5.2 and 5.6 was numerically less with ES than with C (22 vs 35% of time below 5.2 and 46 vs 62% of time below 5.6, with ES and C, respectively). There was no effect of probiotics on dry matter intake. Milk production and composition were not affected by treatments. Treatment P increased ($P < 0.05$) ammonia concentration compared to C during the first day of challenge. Results from this study indicate that ES tended to sustain higher ruminal conditions when animals were induced with SARA, further research is needed to confirm its efficacy in the prevention of SARA.

Key Words: Sub-Acute Ruminal Acidosis, Probiotics, Dairy Cows

T313 Differential effects of supplying reductant as hydrogen, formate or a combination of these on the methane-inhibiting activity of select nitrocompounds in vitro. N. A. Kruegar*, R. C. Anderson, T. R. Callaway, T. S. Edrington, R. B. Harvey, and D. J. Nisbet, *USDA/ARS, Food & Feed Safety Research Unit*, *College Station, TX*.

Short chain nitrocompounds markedly inhibit ruminal methane (CH_4) production, a digestive inefficiency resulting in losses of up to 12% of gross energy intake, but little is known regarding their mechanism of activity. Here, we report the effects of supplying reductant as H_2, formate or both (60 µmol/ml ruminal fluid each) on H_2 and CH_4 accumulation during 24 h incubation (39ºC) of ruminal fluid with or without 12 mM 2-nitro-1-propanol, 3-nitro-1-propionic acid, nitroethanol or nitroethane in vitro (n=3). Reductants were supplied as sodium formate or H_2:CO_2 (80:20); cultures without added H_2 were incubated with 100% CO_2. Analysis of variance revealed main effects (P<0.0001) of nitrocompound, reductant and their interaction on both H_2 and CH_4 accumulation. When reductant was supplied as formate, all nitrocompounds reduced (P<0.05) CH_4 production >99% from that produced by controls incubated with formate alone (13.55±0.9 µmol/ml). Accumulation of H_2 did not differ between any of the incubations containing reductant as added formate alone and averaged 1.07±0.6 µmol/ml. This suggests that the nitrocompounds markedly inhibited methanogenic oxidation of formate and likely inhibited its catabolism to H_2 by other bacteria as well. Conversely, nitro-supplementation decreased (P<0.05) CH_4 production 58 to 97% from that of controls containing no added nitrocompound (11.62±0.9 and 8.43±1.3 µmol/ml, respectively) when reductant was supplied as H_2 or H_2 plus added formate. In this case, however, nitro-supplementation increased (P<0.05) H_2 accumulations >77 to 98% higher than that in non-nitrocompound containing controls (1.66±1.6 and 0.23±0.1 µmol/ml, respectively). These results show that nitro-supplementation more effectively reduced CH_4 production in non-adapted ruminal populations when reductant was supplied as formate rather than H_2 and in both cases inhibited the ability of methanogens to oxidize these reductants.

Key Words: Methane, Nitrocompound, Rumen

T314 Effect of level of dietary malic acid supplementation on rumen methanogenesis and fermentation in beef cattle. P. Foley, J. Callan, D. Kenny*, T. Boland, and F. O'Mara, *University College Dublin*, *Dublin, Ireland*.

The objective of this study was to determine the effect of level of dietary malic acid (MA) on rumen methanogenesis and fermentation in beef cattle. Two Latin square designed experiments took place. In experiment 1 (Exp1) 6 heifers were assigned to one of 3 levels (0%, 3.75%, and 7.5% DMI) of MA inclusion over 3 periods. In experiment 2 (Exp2) 4 fistulated steers were assigned to 1 of 4 levels of MA (0%, 2.5%, 5.0% and 7.5% DMI) over 4 periods, diets consisted of 40:60 Forage:Concentrate ratio with grass silage as the forage. Experimental periods consisted of 28 d, incorporating a 13 d acclimatization period, followed by a 5 d period for Exp1 during which methane (CH4) output was measured using the SF6 tracer gas technique and digestibility was measured by use of the chromic oxide tracer technique dosing twice daily before each feed with 1g Cr2O3, followed by a 10 d rest period. Faeces sub samples were collected from d 16 to 18, dried and analysed for chromium. In Exp2 rumen fluid (RF) was collected from the reticulum area, on d 16 to 18, immediately prior to feeding then 2, 4, 6 & 8 hours post feeding. pH was immediately determined and samples taken for protozoa count, VFA and NH3 analysis. DMI was recorded daily for both experiments. The dietary inclusion of MA led to a linear reduction ($P < 0.05$) in DMI and in total daily CH4 emissions. The highest level of MA led to a 9% reduction ($P < 0.05$) in CH4 emissions per kg DMI when compared to the control diet. There was no effect on ruminal concentrations of VFA with the exception of a tendency towards an decrease in acetate and butyrate with increasing dietary MA. There was a tendency towards lower NH3 with decreasing dietary MA (P=0.05). Ruminal pH was lower ($P < 0.05$) on 5 and 7.5% MA compared with either 0 or 2.5%. However there was no difference between any other treatment comparisons in pH ($P > 0.05$). Protozoal numbers were higher ($P < 0.05$) on 0% MA compared with either 5 or 7.5% MA. Results suggest scope for MA to reduce CH4 emissions however advantages may be negated by depressed DMI.

T315 Usefulness of infrared imaging as a predictor of heat loss and methane production in dairy cows. Y. R. Montanholi*, N. E. Odongo, K. C. Swanson, F. S. Schenkel, B. W. McBride, and S. P. Miller, *University of Guelph*, *Guelph, Ontario, Canada*.

Infrared images (IRI) have proved useful for the assessment of certain phenomena such as the detection of inflammatory illnesses and prediction of meat quality. Conversely, it is less clear if IRI could be used to predict feed efficiency or to assess dietary effects. Herein, relationships among IRI, heat loss (HE) and methane production (CH) were investigated. Four lactating Holstein dairy cows (live weight: 609 + 60.0 kg; milk yield: 27 + 5.1 kg/d; days in milk: 92.5 + 2.6) housed in a tie-stall facility were fed a total mixed ration (TMR) with a forage:concentrate of 60:40 and NE_L of 1.55 Mcal/kg. Cows were allocated to 1 of 2 treatments: TMR plus a control placebo premix (CO) or TMR plus monensin premix (24 mg/kg DM) (MO) offered for ad libitum intake. Each pair of cows (one from each treatment) was monitored 1 day/month (from 09:00 a.m. to 3:30 p.m.) for 6 months. On the sampling days, IRI from the left and right flank (LFK and RFK) and from the rear area (RAR) of the cows were taken every 20 minutes. As well, CH and oxygen consumption were simultaneously monitored around the timing of each set of IRI using an indirect calorimetry unit with two ventilated head-hoods. The oxygen consumption was later

used to calculate heat loss (HE). Heat loss was correlated with LFK and RFK temperatures (r = 0.25 and 0.16; P<0.01) but not with RAR temperature (r = 0.09; P<0.10) across treatments. Within treatment the correlation between HE and CH was higher in the CO vs. MO (r = 0.50 vs. 0.17; P<0.01). HE and CH were more closely associated with RFK and LFK temperatures in CO than in MO-treated cows (HE: r = 0.43 and 0.30 vs. 0.13 and 0.12; CH: r = 0.45 and 0.42 vs. 0.29 and 0.28; P<0.01). Correlations among IRI and HE and CH observed within days and treatments were not uniform. Infrared images may be useful in the assessment of heat losses, methane production and dietary treatment effects but further investigations are warranted.

Key Words: Feed Efficiency, Greenhouse Gas Emissions, Monensin

T316 Profiling energy substrate metabolism in isolated rumen epithelial and duodenal mucosal cells from beef cattle. S. W. El-Kadi*[1], R. L. Baldwin[2], K. R. McLeod[3], N. E. Sunny[1], S. L. Owens[1], and B. J. Bequette[1], [1]*University of Maryland*, *College Park*, [2]*USDA-ARS*, *Beltsville, MD*, [3]*University of Kentucky*, *Lexington*.

The aim of this study was to determine the relative contribution of substrates to Krebs cycle metabolism by rumen epithelial (REC) and duodenal mucosal (DMC) cells. Another aim was to determine the influence of diet type on the selection and metabolism of substrates. Two groups of Angus bulls (n = 6/group) were fed either a 75% Orchardgrass silage (HF) or a 75% concentrate mix (HC) diet for 4 w prior to slaughter. Isolated REC and DMC were incubated in media containing all amino acids, and [U-^{13}C] labeled forms of either glucose, glutamate (GLU), glutamine (GLN), leucine (LEU) or valine (VAL) at four levels. There was a diet × tissue effect on glucose metabolism ($P < 0.001$). For REC, glucose contributed 12% of lactate synthesis in cattle fed the HF diet, compared to 25% in cattle fed the HC diet. Although 25% of lactate synthesis by DMC derived from glucose, diet had no effect and no glucose carbon contributed to Krebs metabolism. There was a diet × tissue effect ($P < 0.01$) on LEU metabolism. LEU contributed 45% to ketoisocaproate synthesis in REC from cattle fed the HC diet but only 35% in REC from the HF group and 35% in DMC from the HC and HF groups. VAL contribution to ketoisovalerate synthesis was greater ($P < 0.001$) in REC (58%) compared to DMC (40%), irrespective of diet ($P = 0.13$). For both LEU and VAL, there was no contribution to Krebs metabolism. There was a diet × tissue × level effect on GLU metabolism ($P < 0.01$); its metabolism to α-ketoglutarate was greater in REC from the HC compared to the HF group, whereas GLU metabolism to α-ketoglutarate was lower for DMC from the HC compared to the HF group. The contribution of GLU to α-ketoglutarate flux ranged from 3% to 63% whereas that of GLN did not exceed 3%. The results indicate that glucose is partially metabolized by isolated REC and DMC, but only to lactate. And, although GLU is a significant contributor to REC and DMC Krebs cycle flux, there is limited catabolism of GLN by these isolated cells for entry into the Krebs cycle.

Key Words: Gastrointestinal, Amino Acids, Glucose

T317 Rumen wall morphology and the change in bovine rumen absorptive capacity induced by varying digesta volume and pH. L. Q. Melo, F. Lopes, M. N. Pereira*, M. C. Guerreiro, S. F. Costa, and J. C. Resende Júnior, *Universidade Federal de Lavras*.

Effects of digesta volume and pH on VFA absorption, and its correlation with rumen wall morphology, were evaluated. Nine fistulated cows formed three conditions. C1 had Holsteins, yielding 25.9 kg/d, and fed on a high grain TMR. C2 had Holstein-Zebu crossbreds, yielding 12.3 kg/d, and fed on corn silage, tropical pasture and concentrate. C3 had non-lactating, grazing Jerseys. The aim was to obtain disparity in rumen morphology. Within each condition, a sequence of three treatments was applied in 3x3 Latin Squares, with seven-day periods: High Volume, High pH (HVHP); Low Volume, High pH (LVHP); and Low Volume, Low pH (LVLP). High Volume was obtained by putting back the whole evacuated rumen digesta (59.5 kg), and Low Volume by returning only 25 kg. Low pH was obtained with a 50% H_2SO_4 solution, capable of decreasing rumen pH to 5 (170 ml, on average). Rumen wall was biopsied on day 1 of period 1. Morphometrics involved four macroscopic and four microscopic variables. Rumen VFA absorption was estimated by the Valerate-CrEDTA technique. Digesta with markers was returned after closing the reticulum-omasum orifice with a sponge. The exponential decay rate in rumen valerate to Cr ratio (k Val/Cr) was estimated with digesta samples obtained every 20-minute for 4 hours. There was strong rumen morphology variability among the groups of cows. Well fed Holsteins had increased rumen wall absorptive surface area and basal cells mitotic index, and decreased thickness of the epithelium and of the keratin layer. Mean rumen pH throughout the four hour sampling period were: 6.78 for HVHP, 7.08 for LVHP and 5.90 for LVLP (P<0.01). The k Val/Cr values for treatments HVHP, LVHP and LVLP were, respectively (%h^{-1}): -19.6, -23.9 and -35.0 (SEM=2.01; P=0.21 for contrast HVHP *vs.* LVHP and <0.01 for contrast LVHP *vs.* LVLP). Rumen valerate clearance by absorption was faster in low pH, while decreasing digesta volume did not elicit such a response. The correlation between the absorptive surface area per cm^2 of rumen wall, and the mean of the three k Val/Cr values of each cow, was -0.90 (P<0.01).

Key Words: Rumen Epithelium, Volatile Fatty Acids, Dairy Cows

T318 Morphophysiologic evaluation of absorption and metabolism of volatile fatty acids by bovine forestomach. J. L. P. Daniel and J. C. Resende Júnior*, *Universidade Federal de Lavras*, *Lavras, MG, Brazil.*

The absorptive surface of the reticulum-rumen (7.7m^2) is higher than that of the omasum (2.1m^2), however, the absorption potential of each compartment is not known. The purpose of this study was to compare, *in vitro*, the VFA absorption and metabolism capacity of the rumen and omasum. After the slaughter, fragments of the rumen wall and omasum laminae were taken from eight adult cross-bread bovines. The fragments were dissected and an isolated fragment of the mucosa was fit in a tissue diffusion chamber. 25mM of valeric acid and 1mM of Cr-EDTA was added to the ruminal fluid and placed on the mucosal side (pH=6.8) and Krebs-Ringer bicarbonate buffer on the serosal side (pH=7.4). The fractional absorption rates were measured by the exponential decay rate of the VFA:Cr. The percentage of metabolized acid was determined by the difference between VFA concentration on mucosal and serosal sides. The absorption surface of the rumen fragment (57.6cm^2) was higher (P<0.001) than that of the omasum (2.5cm^2), because of the ruminal papillae. The fractional absorption rate was higher (P<0.001) in the omasum (9.1%.h^{-1}.cm^{-2}) than in the rumen (0.4%.h^{-1}.cm^{-2}). When the total area was considered the

absorption potential of the omasum was higher (P<0.001) than the rumen. The percentage of metabolized acetate (10.9%) was lower than propionate (31.1%) which was lower than butyrate (39.8%) and valerate (42.6%). When the mucosae areas were considered, there was an interaction (P<0.001) between the percentage of metabolized VFA and the forestomach compartments. In the rumen, the percentage of metabolized VFA was similar (0.68%.cm^{-2}), but in the omasum, the valerate (15.5%.cm^{-2}) was more metabolized than butyrate (14.6%.cm^{-2}) which was higher than propionate (11.58%.cm^{-2}) and acetate (4.33%.cm^{-2}). The estimated metabolism considering the total area was higher (P<0.001) in the omasum than in the rumen. The VFA absorption potential of the omasum is higher than that of the rumen and this could explain, at least partially, the higher VFA metabolization rate found in the omasum wall.

Key Words: Rumen, Omasum

T319 Evaluation of procedures for isolation of ruminant enterocytes. P. R. Regmi*, W. T. Dixon, and M. Oba, *University of Alberta*, *Edmonton, AB, Canada*.

The objective of this study was to evaluate the procedures for isolation of ruminant duodenal mucosal cells (DMC) to be used for *in vitro* studies. Duodenal segments were obtained from a local abattoir immediately after slaughter. The DMC were isolated using three different procedures previously used for sheep (procedure A), pig (procedure B) and cow (procedure C). In the procedure A, the mucosal scrapings collected from the duodenal segment were incubated at 37°C for 20 minutes in a solution containing collagenase, dispase, and $CaCl_2$. In the procedure B, the duodenal segment was filled with Krebs Henseleit buffer containing EDTA without enzymes, and incubated at 37°C for 50 minutes. In the procedure C, the duodenal segment filled with Krebs-Ringer HEPES buffer (KRB-HEPES) containing bovine serum albumin (BSA) was incubated at 37°C for 15 minutes and after discarding the buffer, it was again filled with KRB-HEPES containing hyaluronidase and BSA for 2 minutes to isolate the DMC. The total viable cells per isolation from 50 cm long duodenal segment were significantly higher ($P < 0.05$) for the procedure C ($1.85 \times 10^9 \pm 0.04 \times 10^9$) compared to the procedures A ($1.66 \times 10^9 \pm 0.04 \times 10^9$) and B ($1.58 \times 10^9 \pm 0.07 \times 10^9$). The cell viability immediately after isolation were significantly lower ($P < 0.05$) for the procedure B (78.7 ± 1.8%) compared to the procedures A (85.5 ± 0.8%) and C (88.5 ± 1.7%) and the cell viability after 6 hours was 84.0 ± 0.7, 75.0 ± 1.7 and 86.0 ± 1.7%, respectively for procedures A, B and C. These observations indicate that all the procedures can isolate sufficient viable ruminant DMC for *in vitro* studies, however the number of viable DMC 6 hours after isolation was highest for the procedure using KRB-HEPES containing hyaluronidase.

Key Words: Ruminants, Duodenal Mucosal Cells, Cell isolation

T320 Ruminal, but not abomasal, infusion of starch differentially increases expression of concentrative nucleoside transporter (CNT) mRNA by small intestinal (SI) epithelia of forage-fed beef steers. S. F. Liao*, M. J. Alman, E. S. Vanzant, E. D. Miles, D. L. Harmon, K. R. McLeod, J. A. Boling, and J. C. Matthews, *University of Kentucky*, *Lexington, KY, USA*.

This experiment was conducted to determine if expression of SI concentrative nucleoside transport proteins (**CNT1, 2, 3**) are responsive to luminal supply of rumen-derived bacteria (hence, nucleic acid substrate), energy, or both. Eighteen ruminally and abomasally catheterized Angus steers (BW˜250 kg) were assigned (n=6) to either water (control) or ruminal or abomasal corn starch (α-amylase hydrolysate, at 20% of ME intake) infusion treatments and fed an alfalfa-cube diet at 1.5× NE_m requirement. After a 14 to 17-d infusion period, steers were killed and duodenal (**D**), jejunal (**J**), and ileal (**I**) epithelia were harvested for total RNA extraction. Real-time PCR analyses were conducted to quantify the relative RNA (CNT:18S) expression of CNT1, CNT2, and CNT3 mRNA. Within control steers (n=6), 1.2- and 2.5-fold more (P<0.02) CNT1 was expressed by J than by D or I, respectively. For both CNT2 and CNT3, more (P<0.01) mRNA was expressed by D (9.8- and 1.9-fold) and J (11.4- and 3.1-fold) than by I, respectively. Within a tissue site, the expression of CNT1 or CNT2 mRNA was not affected by infusion treatments, but CNT3 mRNA expression by D (0.65- and 0.69-fold) and I (2.3- and 1.1-fold) of the ruminally starch-infused steers was greater (P<0.04) than by the water- or abomasally starch-infused steers, respectively. These results indicate that these known CNT mRNA are expressed throughout SI epithelia and that CNT3 mRNA expression by D and I epithelia likely is upregulated in the presence of increased nucleoside supply, but not of increased luminal energy (starch) supply.

Key Words: Bovine, Regulated gene expression, SLC28

T321 Effect of hybrid (high starch content vs. high NDF digestibility) and maturity of corn silage on dairy cow performance. R.L.G. Zom*[1], H.A. van Schooten[1], and H. van Laar[2], [1]*ASG Wageningen University & Research Centre*, *Lelystad, Netherlands*, [2]*Nutreco Ruminant Research Centre*, *Boxmeer, Netherlands*.

A 2×2 factorial designed experiment was conducted to evaluate the effects of hybrid (S: high starch content vs. F: high NDF digestibility) and maturity (30 vs. 36% DM) of corn silage on *in situ* degradation and dairy cow performance. Seventy-two HF cows were assigned to four silage treatments and individually fed. Mixtures containing one of the corn silages, haylage and soy bean meal (70:18:12 DM basis) were offered *ad libitum*. Additionally, each cow received 7 kg/d of concentrate. Intake, milk yield and milk composition were analyzed for wk 1 until wk 15 of lactation. The treatment period was from wk 5 to wk 15 of lactation. Pre-treatment data (wk 1 to 4) were used as covariates. In addition, fresh silage samples were ruminally incubated to determine the rate and extent of starch and NDF degradation. Maturity increased starch content and proportion of rumen by-pass starch. Proportion of rumen by-pass starch in hybrid S was 33% and 54% for 30 and 36% DM, respectively, and in hybrid F 23% and 33%. NDF content was higher for hybrid F than for S. All silages had similar NDF degradation characteristics. Despite corn hybrids were from different selection traits, within maturity, starch content was similar. Maturity decreased NDF intake (8.5 vs. 8.2 kg/d; p<0.05) and increased starch intake (4.4 vs. 5.0 kg/d; p<0.001). Maturity had no effect on yields of milk and milk components. Hybrid S increased the intakes of NEL (158 vs. 164 MJ/d; p<0.05), starch (4.6 vs. 4.9 kg/d; p<0.05) and DM (23.1 vs. 23.9 kg/d; p<0.1). Hybrid S improved the yields of milk (39.6 vs. 37.9 kg/d; p<0.05), protein (1.28 vs. 1.21 kg/d; p<0.01) and lactose (1.86 vs. 1.78 kg/d; p<0.01) compared to hybrid F. Observed differences may be associated with a more efficient energy utilization due to a shift in starch digestion from the rumen

to the intestine for hybrid S as indicated by the higher proportion of by-pass starch.

Key Words: Corn Silage, Starch, NDF

T322 Effects of a bacterial inoculant on fermentation, nutritive quality and degradability of corn, soybean and combined corn-soybean silages. L. O. Abdelhadi*[1] and J. M. Tricarico[2], [1]*Est. El Encuentro, Research & Extension in Ruminant Nutrition*, *Cnel. Brandsen, Argentina*, [2]*Alltech Inc.*, *Nicholasville, KY.*

A randomized complete block design with a 2x3 factorial treatment arrangement was used to evaluate the effects of a bacterial inoculant (Sil-All®, Alltech Inc., Nicholasville, KY) on fermentation, nutrient composition and OM degradability (**OMD**) of ensiled corn (DK682RR, Dekalb, Colon, Argentina), soybean (DM4800, Don Mario, Chacabuco, Argentina) and the corn-soybean combination (56% corn and 44% soybean, DM basis). Inoculation (0 or 5 g/ton fresh matter) and ensiled crop (corn, soybean or combination) were the factors examined. All crops were fine chopped (9 mm) and ensiled in polyethylene bags (70m long x 2.75m diameter) using a forage inlay machine. Bacterial inoculation was randomly assigned to each crop or crop combination within a bag and applied directly with the chop harvester applicator. Composite samples (9 sub-samples) were collected for each treatment combination in each block before and after ensiling for 60 d. Samples were analyzed for DM, OM, CP, NDF, WSC, starch, EE and OMD after incubation with ruminal fluid for 3, 6, 12, 24, 48 and 72h. True protein, pH and NH_3-N were also determined on silage samples. Digestible DM yield (tons/ha) before ensiling was similar for corn (13.7) and the combination (12.3) and lower ($P<.05$) for soybean (5.7). As expected, nutrient composition for the crop combination was intermediate between corn and soybean both before and after ensiling. No interactions (inoculation x crop) for nutrient composition, fermentation or OMD were detected. Silage pH was lower ($P<.05$) for corn (3.90), intermediate for the combination (4.17) and greater for soybean (4.84). Inoculation increased ($P<.05$) true protein (60.5 vs. 54.4 %CP) and WSC (8.47 vs. 6.08 %DM) concentrations and the total amount of digestible OM (66.7 vs. 61.2 %OM) across all silages without changing the rate of OMD. We conclude that ensiling corn and soybean in combination provides a single feedstuff with intermediate nutrient composition without negatively affecting yield or total nutrient supply to the ruminant. In addition, bacterial inoculation improved silage nutritive quality across all crops.

Key Words: Corn Silage, Soybean Silage, Inoculant

T323 Effects of a bacterial inoculant on fermentation, nutritive quality and degradability of combined corn-soybean silages in different geographical regions across Argentina. L. O. Abdelhadi*[1] and J. M. Tricarico[2], [1]*Est. El Encuentro, Research and Extension in Ruminant Nutrition*, *Cnel. Brandsen, Argentina*, [2]*Alltech Inc.*, *Nicholasville, KY.*

A randomized complete block design with a 2x5 factorial treatment arrangement was used to evaluate the effects of a bacterial inoculant (Sil-All®, Alltech Inc., Nicholasville, KY) on fermentation, nutrient composition and OM degradability (**OMD**) of corn (DK684RR2, Dekalb, Colon, Argentina) and soybeans (Groups 5.5 grain varieties) ensiled in combination. Bacterial inoculation (0 or 7.5 g/ton fresh material) and geographical-climatological location (Castelli, Jesús María, Pehuajó, Río Cuarto, Tucumán) were the two factors examined. The corn-soybean combination was harvested at each location when corn was at half milk line of grain maturity and soybean was at R6 stage of growth (full seed). Crops were chopped together at harvest (30±1.5% soybean inclusion on a DM basis in all silages) and ensiled in polyethylene bags (70 m long x 2.75 m diameter) using a forage inlay machine. Bacterial inoculation was randomly assigned within each block and applied directly with the chop harvester applicator. Composite samples (9 sub-samples) were collected for each treatment in each block before and after ensiling for 60 d. Samples were analyzed for DM, OM, CP, NDF, WSC, starch, true protein and OMD after incubation with ruminal fluid for 3, 6, 12, 24, 48 and 72h, and pH was also determined on silage samples. As expected, geographical location had a dramatic influence on digestible DM yield, nutrient composition and OMD of the combined crop before ensiling. No interactions (location x inoculation) were detected for fermentation, nutrient composition or OMD. Inoculation had no effects on pH, DM, OM, NDF, or ADF concentrations, but increased ($P<.05$) CP (9.8 vs. 9.1 %DM), true protein (49.7 vs. 47 %CP) and starch (17.2 vs. 15.1 %DM) concentrations and the total amount of digestible OM (71.4 vs. 66.7 %OM) across all locations without changing the rate of OM digestion. We conclude that bacterial inoculation improved silage nutritive quality and OM digestibility of the corn-soybean combination across all geographical locations.

Key Words: Corn Silage, Soybean Silage, Inoculant

T324 Effects of a bacterial inoculant on fermentation, nutritive quality and degradability of different sorghum silage hybrids. L. O. Abdelhadi*[1] and J. M. Tricarico[2], [1]*Est. El Encuentro, Research and Extension in Ruminant Nutrition*, *Cnel. Brandsen, Argentina*, [2]*Alltech Inc.*, *Nicholasville, KY.*

Two studies were conducted on consecutive years (2005 and 2006) to evaluate the effects of a bacterial inoculant (Sil-All®, Alltech Inc., Nicholasville, KY) on silage fermentation, nutrient composition and OM degradability (**OMD**) of different sorghum hybrids. Four hybrids (**ABMR** = sweet brown mid rib sorghum, **FBMR** = forage brown mid rib sorghum, **GRAN** = grain sorghum, **SUDG** = sudangrass sorghum) were ensiled in 2005 and five hybrids (idem 2005 plus **SGRA** = high grain sudangrass sorghum) in 2006. A randomized complete block design with a factorial treatment arrangement was used in each study. Bacterial inoculation (0 or 5 g/ton fresh material) and sorghum hybrid were the two factors examined. Data were analyzed separately for each year. Sorghum was harvested at early dought stage of grain maturity, fine chopped (9 mm) and ensiled in polyethylene bags (70 m long x 2.75 m diameter). Bacterial inoculation was randomly assigned within each block and applied directly with the chop harvester applicator. Composite samples (9 sub-samples) were collected for each inoculation x hybrid combination in each block before and after ensiling for 60 d. Samples were analyzed for DM, OM, CP, NDF, WSC, starch, true protein and OMD after incubation with ruminal fluid for 3, 6, 12, 24, 48 and 72h, pH and NH_3-N were also determined on silage samples. As expected, hybrid had a dramatic influence on nutrient composition and OMD in both studies. Inoculation had no effects on nutrient composition or OMD in 2005. Inoculation increased ($P<.05$) the concentrations of DM, NDF and the rate of OMD in 2006. The hybrid

x inoculation interaction was significant for starch and pH. Inoculation reduced ($P<.05$) starch concentration on high grain hybrids but not on low grain hybrids. Inoculation decreased ($P<.05$) pH in all hybrids except ABMR and SGRA. We conclude that bacterial inoculation effects were inconsistent across studies but improved silage fermentation and the rate of OM digestibility in 2006.

Key Words: Sorghum Silage, Sorghum Hybrids, Inoculant

T325 Effect of alfalfa silage storage structure and roasting corn on production and ruminal metabolism of lactating dairy cows. S. J. Krizsan*[1], G. A. Broderick[2], R. E. Muck[2], C. Promkot[3], S. Colombini[4], and Å. T. Randby[1], [1]*Norwegian University of Life Sciences*, *Ås, Norway*, [2]*US Dairy Forage Research Center*, *Madison, WI*, [3]*Khon Kaen University*, *Khon Kaen, Thailand*, [4]*University of Milano*, *Milano, Italy*.

The objective of this study was to determine if feeding roasted corn as the principal concentrate source would improve production and nutrient utilization when supplemented to lactating cows fed one of 3 different alfalfa silages (AS). Forty-two lactating Holstein cows (6 fitted with ruminal cannulas) averaging 77 DIM and producing 43 kg milk/d pretrial were assigned to 2 cyclic change-over designs. Treatments were AS, ensiled in bag, bunker, or O_2-limiting tower silo supplemented with ground shelled corn (GSC) or roasted GSC (RGSC). Experimental diets contained 40% AS, 15% corn silage and 35% of either GSC or RGSC on DM basis. No significant interactions between AS and corn sources were detected for any production trait. Although chemical composition of the 3 AS was similar, feeding AS from the O_2-limiting tower silo elicited positive production responses ($P<0.01$). Yields of 3.5% FCM and fat were increased 1.7 kg/d and 150 g/d, and milk fat content was increased 0.3%, when cows were fed diets based on AS from the O_2-limiting silo compared with the other 2 AS. The responses in milk fat were paralleled by an average increase in ADF digestibility of 270 g/d for cows fed AS from the O_2-limiting silo. However, ruminal concentrations of lipogenic VFA were unchanged with AS source. Cows fed RGSC consumed 0.6 kg/d more DM and yielded 30 g/d more protein and 50 g/d more lactose than cows fed GSC diets ($P=0.02$). There was no evidence of increased total tract digestibility of OM or starch, or reduced ruminal NH_3 concentration, when feeding RGSC. Free AA increased, and isovalerate decreased in rumen fluid from cows fed RGSC diets ($P<0.01$). However, responses in production with roasted corn were mainly due to increased DMI, which increased the supply of energy and nutrients available for synthesis of milk and milk components.

Key Words: Alfalfa Silage Storage Structure, Milk Production, Roasted Corn

T326 Changes in fermentation end products and the use of real-time quantitative PCR to monitor the dynamics of *Lactobacillus buchneri* in alfalfa silage. R. J. Schmidt*, J. A. Mills, W. Hu, C. M. Klingerman, E. E. McDonell, and L. Kung Jr., *University of Delaware*, *Newark*.

This study was conducted to determine the fermentation profile and the growth of lactic acid bacteria (LAB) and *L. buchneri* in alfalfa silage treated with 1) nothing (C), 2) *Lactobacillus buchneri* 40788 (400,000 cfu/g) (Lallemand Animal Nutrition, Milwaukee, WI) (LB), or 3) *L. buchneri* 40788 (400,000 cfu/g) and *Pediococcus pentosaceus* (100,000 cfu/g) (Lallemand Animal Nutrition) (LBC). Wilted (45% DM), chopped and treated forage was packed and vacuum-sealed in polystyrene bags and ensiled for 2, 5, 45, 90 and 180 d. The experiment was a completely randomized design and data were analyzed using the GLM procedure of the SAS. Lactic acid bacteria (LAB) in forage and silage were quantified on MRS media, and *L. buchneri* was quantified by qPCR using a unique set of oligonucleotide primers. Fresh forage had 5.52 log cfu/ g of LAB and 3.79 log cfu/g of *L. buchneri*. After 2 d of ensiling, numbers of LAB increased to more than 8 log cfu/g for all treatments. In contrast, the numbers of *L. buchneri* in C remained below 4 log cfu/g but was about 7 log cfu/g in LB and LBC. As ensiling progressed, numbers of *L. buchneri* in C remained lower than 6 log cfu/g but approached 9 log cfu/g in LB and LBC ($P < 0.05$). The pH was lowest ($P < 0.05$) in LBC when compared to C and LB after 2 and 5 d of ensiling but pH was lowest ($P < 0.05$) for C compared to LB and LBC thereafter. Treatments LB and LBC had more acetic acid than C at 45 d of ensiling ($P < 0.05$), which coincided with detectable amounts of 1,2 propanediol. From day 5 onward, LB and LBC had less residual water soluble carbohydrates but more NH_3-N than C ($P < 0.05$). Although naturally occurring amounts of *L. buchneri* can be detected in alfalfa, this population is unable to dominate silage fermentation. Inoculation with *P. pentosaceus* provided a faster rate of fermentation in the early stages of ensiling and did not impair the later effects of *L. buchneri* on the silage fermentation.

Key Words: Alfalfa Silage, *L. buchneri*, Real-Time qPCR

T327 Effect of feeding corn silage based diets deficient in either predicted ruminal nitrogen or metabolizable protein on nitrogen utilization and efficiency. E. B. Recktenwald*, D. A. Ross, and M. E. Van Amburgh, *Cornell University*, *Ithaca, NY*.

The objective of this experiment was to evaluate nitrogen (N) utilization in high producing lactating dairy cattle under conditions of a predicted (1) negative rumen N balance (Diet T), (2) negative metabolizable protein (MP) balance (Diet N), or (3) positive rumen N and MP balances (Diet P). Eighty-eight multiparous lactating Holstein cows (83 ± 20 DIM), were blocked by milk yield and parity and assigned to three diets differing in N content. The diets were formulated with CPM Dairy V3 using library values for all feeds except corn silage. The diets consisted of approximately 50% corn silage, 2% wheat straw and 48% of a diet specific mix. Monensin was included in the diets at 300 mg/cow/d. A transition period of 7 d preceded the treatment period of 100 d. The study was analyzed as a mixed model with repeated measures by week using Proc Mixed (SAS, 2004) and orthogonal contrasts were used to assess differences. Body weight and body condition score did not differ. Dry matter intake and 3.5% FCM were lower for cows fed Diet T however feed efficiency was higher. Plasma urea N values were different among treatments and reflected the amount of N intake. Milk fat depression (MFD) was observed in all cows. To assess the impact of monensin on MFD, 11, 15, and 16 cows from the N, P, and T diets, respectively, were maintained on the diet after the treatment period with no monensin and milk fat percent increased by 30%. Nitrogen efficiency was improved through diet manipulation; however the data suggest greater improvements are possible.

Table 1.

	Diet T	Diet N	Diet P	Contrast P values T vs N	T vs P	N vs P
Diet CP, % DM	14.1	14.0	16.3			
Predicted MP balance, g/d	91	-145	264			
Predicted rumen N balance, g/d	-39	27	29			
DMI, kg/d	24.2	25.5	25.7	0.08	0.03	0.93
Milk, kg/d	43.3	42.6	45.0	0.80	0.23	0.06
3.5% FCM, kg/d	36.4	36.5	39.1	0.99	0.05	0.07
Fat, %	2.54	2.67	2.68	0.45	0.44	1.00
Protein, %	2.90	2.92	2.93	0.93	0.84	0.98
PUN, mg/dL	7.13	8.40	11.31	<0.01	<0.01	<0.01
Milk N:Intake N	0.36	0.33	0.31	<0.01	<0.01	<0.01

Key Words: Nitrogen, Efficiency, Metabolizable Protein

T328 Effects of cutting height and bacterial inoculation on fermentation, nutritive quality and degradability of two corn hybrids. L. O. Abdelhadi*[1] and J. M. Tricarico[2], [1]*Est. El Encuentro, Research & Extension in Ruminant Nutrition, Cnel. Brandsen, Argentina*, [2]*Alltech Inc., Nicholasville, KY.*

A randomized complete block design with a factorial arrangement of treatments was used to evaluate the effects of a bacterial inoculant (Sil-All®, Alltech Inc., Nicholasville, KY) on fermentation, nutrient composition and OM degradability (**OMD**) of two corn hybrids harvested at 20 or 40 cm from the ground. The study included one high grain yield (DK682RR, Dekalb, Colon, Argentina) and one high forage yield (DK790S, Dekalb) hybrid. Hybrids were grown in three 2-hectare plots (block) and harvested at half milk-line stage of grain maturity. Fine chopped (9 mm) corn plant was stored in polyethylene bags (70m long x 2.75m diameter) using a forage inlay machine. Inoculation (0 or 5 g/ton fresh matter) was randomly assigned to each hybrid x cutting height combination within a bag. A composite sample (9 sub-samples) was collected for each treatment combination in each block before and after ensiling for 60 d. All samples were analyzed for DM, OM, CP, NDF, WSC, starch, and OMD after incubation with ruminal fluid for 3, 6, 12, 24, 48 and 72h. True protein, EE, pH and NH_3-N were also determined on silage samples. No interactions were observed before ensiling. Digestible DM (tons/ha) only tended (P<.14) to increase in high grain over high forage yield corn (13.1 vs. 13.0) or 20 over 40 cm cutting height (13.8 vs. 12.3), suggesting the importance of grain concentration on total nutrient supply. High grain yield corn had greater (P<.05) pH, and concentrations of true protein, WSC, and starch but lower NH_3-N and NDF than the high forage yield corn. The rate of OMD was also greater (P<.05) in high grain than in high forage yield corn. Cutting height had no effects on silage fermentation, nutritive value or OMD. Inoculation increased (P<.05) silage CP and true protein concentrations and the total amount of digestible OM in both corn hybrids without changing digestion rate. We conclude that cutting height did not affect silage quality, while bacterial inoculation improved it regardless of hybrid or cutting height. In addition, high grain yield corn provided more nutrients than high forage yield corn after ensiling.

Key Words: Corn Silage, Cutting Height, Inoculant

T329 Continuous culture fermentation of a corn silage-based total mixed ration with additional forage from pasture. R. E. Vibart*, V. Fellner, and S. J. McLeod, *North Carolina State University*, *Raleigh*.

Cultures of mixed ruminal microorganisms were used to examine fermentation profile of diets consisting of either a nutritionally-balanced TMR (**100T**) or one of the following three TMR-pasture combinations: 1) 85% TMR plus 15% pasture (**85T**), 2) 70% TMR plus 30% pasture (**70T**), and 3) 55% TMR plus 45% pasture (**55T**). The pasture portion of the three TMR-restricted diets was annual ryegrass harvested at a height that simulated animal grazing. The forage:concentrate ratio ranged from 40:60 (100T) to 67:33 (55T). Increasing the amount of forage offered to the fermentors altered the molar proportions and daily production of volatile fatty acids (VFA). Total VFA tended (P = 0.08) to be greatest (108.0 mmol/d) for 55T compared to all other treatments (92.5 mmol/d). Reduced (P < 0.05) apparent and true OM degradability was reported for the diets that exhibited the lowest pH values (5.65 and 5.68 for treatments 70T and 100T, respectively). Increasing the amount of forage offered to continuous cultures resulted in increased (P < 0.05) ratios of acetate to propionate and decreased methane production. There was a linear increase (P < 0.05) in the flow of microbial biomass with increasing proportion of forage from pasture. Our data suggest that increased forage from pasture improved ruminal fermentation by supporting greater fermentation and ruminal pH. Despite similar ammonia-N concentrations, increasing the proportion of forage from pasture enhanced nitrogen capture and increased microbial protein flow.

Key Words: Pasture, Total Mixed Ration, Mixed Ruminal Cultures

T330 Partial mixed rations (PMR) as alternative feeding systems for lactating dairy cows in southeastern U.S. R. E. Vibart*, V. Fellner, J. C. Burns, G. B. Huntington, and J. T. Green, *North Carolina State University*, *Raleigh*.

Beginning March 2005, thirty lactating Holstein cows were used in a randomized complete block design to evaluate the partial replacement of a total mixed ration (TMR) by ryegrass pasture on animal responses over an eight week period. Cows averaged 36.6 ± 1.5 kg milk, 125.7 ± 6.7 days in milk, 1.9 ± 0.2 lactations, 607.3 ± 11.9 kg bodyweight, and 2.88 ± 0.06 body condition score at the initiation of the trial. Cows were assigned to an all-TMR diet (**100T**, no access to ryegrass pasture) or one of the following three formulated (actual) PMR: 1) 85% (89%) TMR + 15% (11%) pasture, **85T**; 2) 70% (79%) TMR + 30% (21%) pasture, **70T**; and 3) 55% (65%) TMR + 45% (35%) pasture, **55T**. Cows on pasture grazed as a single group for 7 h/d between the a.m. and p.m. milking. Pasture intakes were measured weekly on one cow selected randomly from each grazing treatment. Pasture dry matter intake was different (P < 0.05) among grazing treatments and averaged 6.9, 4.2, and 2.2 kg/d for 55T, 70T, and 85T, respectively. Fat corrected milk yield was greatest (P < 0.05) for 85T (34.0 kg/d) and lowest for 70T (29.8 kg/d). Milk fat from cows with the greatest pasture intake had greater concentrations of conjugated linoleic acids and decreased concentrations of saturated fatty acids. By week eight, concentrations of plasma nonesterified fatty acids (185.3 vs. 92.5 μeq/L) and plasma urea nitrogen (12.4 vs. 6.7 mg/dl) were greater for 100T compared to the three grazing treatments, respectively, but plasma glucose concentrations did not differ among treatments. Offering pasture did not replace TMR, but lowering TMR intakes lowered total dry matter

intake. Feed efficiencies (kg feed/kg milk) were 0.60, 0.61, 0.56, and 0.68 for treatments 55T, 70T, 85T, and 100T, respectively. Our data shows that cows on a PMR with 11% pasture resulted in the best lactation performance. Although the two treatments offered the greatest amounts of TMR resulted in greater milk yields, all three grazing treatments exhibited enhanced feed efficiencies compared to an all-confinement diet.

Key Words: Total Mixed Ration, Pasture, Lactation Performance

T331 Variability in total mixed ration neutral-detergent fiber analysis among commercial laboratories. A. N. Hristov*[1], S. Zaman[1], M. Vander Pol[1], W. J. Price[1], and D. Mertens[2], [1]*University of Idaho*, *Moscow*, [2]*U.S. Dairy Forage Research Center*, *Madison, WI*.

The objective of this study was to test the variability in amylase-treated NDF (aNDF) of TMR samples among commercial feed analysis laboratories. Two TMR were prepared that varied in the DM proportion of concentrates (corn and barley grains) replacing forage (alfalfa hay and corn silage): 55% (HCD diet) vs. 40% (LCD diet). Replicated TMR and individual feed samples were dried at 65°C to constant weight and ground through a 4-mm screen. Aliquots were sent to 12 commercial and 2 research laboratories for aNDF analysis; all laboratories, except one, re-ground the samples and used amylase and sodium sulfite. The aNDF contents of TMR were estimated based on aNDF content of the individual feeds reported by each laboratory. Results were analyzed statistically using the UNIVARIATE and MIXED procedures of SAS. Method of analysis (crucible vs. filter bag) was used as a classification variable in the statistical analysis. Concentration of aNDF in HCD and LCD by laboratories using the crucible method was 29.2±0.28 and 33.7±0.20%, respectively (n=48). Laboratories using filter bags reported 29.9±0.37 and 33.9±0.39% aNDF, respectively (n=36). Method of analysis had no effect (P = 0.520) on the aNDF values, but variability among laboratories was significant (P = 0.032 and 0.038, HCD and LCD, respectively). The variance estimates for the two methods of aNDF analysis were not statistically significant (P = 0.229 and 0.208, crucibles and filter bags, respectively). There was a significant variability in the analysis of some feeds: barley grain averaged 20.3±1.15% (min=14.0, max=31.0%) and whole cottonseed averaged 45.6±1.51% aNDF (min=35.5, max=56.2%). Estimated aNDF of TMR, based on analysis of individual feeds, were slightly greater than analyzed aNDF values (by 0.32±0.170, P = 0.067 and 0.42±0.135%, P = 0.003 for HCD and LCD, respectively).

Key Words: Neutral-Detergent Fiber, Total Mixed Ration, Analysis

T332 Nutritional quality of sugar cane treated with calcium oxide. A. W. P. Freitas*[1], F. C. Rocha[2], J. L. Fagundes[1], and R. Fonseca[2], [1]*APTA Regional*, *Adamantina, São Paulo, Brazil*, [2]*Unesp - Dracena*, *Dracena, São Paulo, Brazil*.

The aim of this research was to determine the effect of application of different levels of CaO (0.25; 0.5; 1.0; 2.0 and 4.0%) on the nutritional quality of sugar cane. The sugar cane, variety IAC 86-2480, was harvested manually, and chopped in 2 cm lengths with a stationary chopping machine. Each parcel consisted of 50 kg of chopped sugar cane. Individual samples were collected before treatment application (time 0), and after 9 hours. Samples were dried at 70 °C for 48 h in an oven and ground to pass a 1 mm screen. Dry matter content, ash, crude protein, NDF, ADF, water soluble carbohydrate (WSC), lignin and hemicelluloses concentration and in vitro dry matter digestibility (IVDMD) were determined as described by Silva and Queiroz (2002) and pH as described by Bolsen et al. (1992). The results were analyzed by one-way analysis of variance and regression analysis using SAEG 9.1. The forage dry matter decreased linearly ($P<0.01$) with the increase of calcium hydroxide levels, while NDF, Hemicelluloses and DMIVD adjusted to a quadratic ($P<0.01$) model. The data show that application of increasing levels of calcium oxide affects the forage in two steps. First, there was a solubilization of the WSC, resulting in the observed increase in cell wall components concentration. Secondly, the higher levels of the alkali start to affect the cell wall components, which can be observed by the decreasing concentrations of hemicelluloses and NDF. A rather unexpected finding from the experiment was the quadratic behavior of the IVDMD, with a maximum estimated value of 68.5% of IVDMD for the calcium oxide level of 1.75%. This observation can be explained by the degradation of the WSC, with the increasing levels of calcium oxide, which is the most digestible part of the sugar cane. It is concluded that 1.75% is the optimal level of calcium oxide to enhance the nutritional quality of sugar cane for ruminants.

Key Words: Alkali, Hydrolyses, Ruminant

T333 Effects of increasing level of corn distiller's dried grains plus solubles on in situ disappearance in steers offered medium-quality grass hay. J. L. Leupp*, G. P. Lardy, and J. S. Caton, *North Dakota State University*, *Fargo*.

Five ruminally and duodenally cannulated beef steers (446 ± 42 kg of initial BW) were used in a 5 × 5 Latin square to evaluate effects of increasing level of supplemental corn distiller's dried grains with solubles (DDGS; 25.4% CP, 9.8% fat, DM basis) on in situ rate of DM, NDF, and ADF disappearance and CP kinetic parameters of hay and DDGS. Dietary treatments consisted of grass hay (10.2% CP; DM basis) offered ad libitum, free access to water and trace mineral salt block, and one of five levels of DDGS (0, 0.3, 0.6, 0.9, and 1.2% BW DDGS; DM basis). Diets met or exceeded DIP requirements (microbial yield = 10.5%). All supplements were fed at 0600 before hay. Steers were adapted to diets for 14 d followed by a 7-d collection period. Hay DM disappearance responded cubically ($P = 0.02$) with the greatest rate of disappearance at 0.9% DDGS and least at 1.2% DDGS. Hay NDF and ADF disappearance were not affected ($P \geq 0.23$; 3.74 ± 0.45%/h and 3.72 ± 0.46%/h, respectively) by treatment. Hay CP degradation rate increased (linear; $P = 0.0025$) with increasing DDGS while extent of CP degradation decreased quadratically ($P = 0.02$) with the lowest extent at 0.9% DDGS. Hay soluble and slowly degradable CP fractions were similar ($P \geq 0.93$; 25.5 ± 1.7% and 63.0 ± 1.7%, respectively) across treatments. A cubic effect ($P = 0.03$) was noted for DDGS DM disappearance with the greatest disappearance at 0.9% and the least at 0.6% DDGS. No differences ($P \geq 0.45$) among treatments were observed for DDGS NDF or ADF disappearance (3.04 ± 0.71%/h and 3.19 ± 0.94%/h, respectively). Soluble CP degradation fraction decreased (linear; $P = 0.01$) and slowly degradable CP fraction increased (linear; $P = 0.002$) with increasing DDGS. A linear increase ($P < 0.0001$) was observed for CP degradation rate with increasing DDGS. Treatment did not affect ($P = 0.23$) extent of DDGS CP

degradability (99.8% ± 0.2). Using moderate to high levels of DDGS in forage diets resulted in increased degradation rates of CP. Results indicate up to 1.2% BW DDGS can be fed in forage-based diets without adverse effects.

Key Words: Distiller's Dried Grains with Solubles, Medium-Quality Forage, Steers

T334 Evaluation of corn and soybean co-products in beef cattle finishing diets. P. M. Walker*[1], D. Adams[1], and L. A. Forster[2], [1]*Illinois State University*, *Normal*, [2]*Archer Daniels Midland, Co.*, *Decatur, IL*.

Dried distillers grains with solubles (DDGS) and soy hull (SH) supplies have increased due to renewable fuels legislation. This trial evaluated the effects of diets containing 0, 25, or 40% DDGS and 44% SH, and length of time on feed (156, 187, or 263d) on the feedlot performance of 192 Angus crossbred steers (initial wt = 348±1.9 kg). Following an 84d receiving period (P1) in which steers were fed diets containing either shelled corn (SC), SH, or DDGS at 1 or 2% BW, steers were blocked by intake level and assigned within blocks to six dietary treatments (P2) with 4 replicates (24 pens, 6 or 10 steers/pen). Treatments were: 70.5% SC, 13.5% grass hay (GH), 13.5% soybean meal (T1); 59.0% SC, 13.5%GH, 25% DDGS (T2); 40.0% DDGS, 44.0% SH, 13.5%GH (T3); T3 fed for 28d (T4), 56d (T5), or 84d (T6) followed by T2 fed to harvest. Steers were harvested after 156, 187, or 232d on the P2 diets. Data were analyzed using previous dietary treatment (P1) and harvest date as covariates; no interactions were observed between covariates and P2 treatments. Carcass measurements were similar between P2 treatments except for liver abscess scores [T1 higher ($P< 0.05$) than T2-T6]. Length of time on feed increased carcass wt, rib fat, KHP, marbling score and yield grade. Total DMI was similar between T1 and T2 but was higher ($P< 0.05$) for T3-T6. ADG (μ=1.51±0.02kg) and feed efficiency (G:F) (μ=0.12±0.005) were similar between T1 and T2 but lower ($P< 0.05$) for T3-T6 (ADG μ=1.45±0.02kg, G:F μ=0.11±0.005). No significant differences in cost of gain were observed between treatments. Mean carcass measurements were: carcass wt=403±0.8kg, rib fat=20.57±0.01mm, ribeye area=84.3±0.9 sq cm, KHP=2.8±0.1%, marbling score=7.64±0.1 (7=avg choice), yield grade=4.24±0.1, liver score=1.5±0.2 (range=1-5) and dressing percent=62.5±0.2. These data suggest that feeding cattle higher rates of DDGS and SH will result in similar quality and yield grades but will require higher total feed intake with lower ADG than diets containing whole shelled corn or limited to 25% DDGS.

Key Words: DDGS, SH, Finishing Steers

T335 Effects of dietary fat concentration and wet sorghum distiller's grains plus solubles on feedlot performance and carcass characteristics of finishing heifers. J. C. Silva*[1], N. A. Cole[2], M. S. Brown[1], D. L. Mitchell[1], C. H. Ponce[1], and D. R. Smith[1], [1]*West Texas A&M*, *Canyon*, [2]*USDA ARS CPRL*, *Bushland, TX*.

Three hundred ninety-eight crossbred yearling heifers (initial BW = 373.5 kg) were used in two experiments to examine the effect of dietary fat concentration on the feeding value of wet sorghum distiller's grains plus solubles (WSDGS). Treatments included two 92% concentrate diets based on steam-flaked corn (SFC) with 0% or 3% added fat from yellow grease and three diets with 15% WSDGS and either 0, 1.5, or 3% added fat from yellow grease (4 pens/treatment within study). Heifers were fed an average of 106 d before slaughter. Overall DMI was 6.1% greater ($P < 0.01$) for heifers fed WSDGS than for those fed SFC. Among heifers fed WSDGS, DMI was greatest for heifers fed 1.5% fat ($P = 0.04$; quadratic). Overall ADG was 5% greater ($P = 0.04$) for WSDGS compared to SFC. Among WSDGS, ADG tended to be greater for 1.5% fat ($P = 0.12$; quadratic). The ADG:DMI did not differ between SFC with 0 or 3% fat, nor was ADG:DMI altered by replacing a portion of SFC with WSDGS ($P > 0.36$). However, ADG:DMI increased linearly as more fat was added to WSDGS diets ($P = 0.06$). Hot carcass weight was increased an average of 5 kg ($P = 0.05$) when WSDGS replaced a portion of SFC, but carcass weight was greatest for heifers fed WSDGS with 1.5% fat ($P = 0.09$, quadratic). Heifers fed SFC without fat had a larger LM area, lower marbling score, less rib fat, and a lower yield grade ($P < 0.08$) than heifers fed SFC with 3% fat. Heifers fed WSDGS had more rib fat and a higher yield grade ($P < 0.03$) than heifers fed SFC. Inclusion of fat in SFC diets did not alter the distribution of carcass quality grades, but SFC with 3% fat produced fewer ($P = 0.01$) yield grade 1 carcasses than when fat was not fed. Feeding WSDGS did not alter carcass quality grade distribution compared to feeding SFC, but WSDGS produced fewer yield grade 3 carcasses ($P = 0.03$) than SFC. Heifers fed WSDGS had a higher DMI and greater ADG than heifers fed SFC, but gain efficiency did not differ. Adding more than 1.5% fat to diets containing WSDGS tended to reduce growth performance.

Key Words: Fat, Growth Performance, Sorghum Distiller's Grains

T336 Using high-lysine proteins to supplement diets based on dried distillers grains with solubles did not improve lactation performance. E. A. French*, M. He, and L. E. Armentano, *University of Wisconsin*, *Madison*.

The objectives of this study were to compare production responses of lactating dairy cows fed dried distillers grains with solubles (DDGS) combined with other protein sources varying in lysine content. Twenty four lactating Holstein cows (six primiparous and eighteen multiparous) were used in four, replicated 6 × 6 Latin Squares, with 21-d periods. All diets contained 37% corn silage, 18% alfalfa silage, 5% cottonseed and 40% concentrate (DM basis). DDGS at 13% and 18% of diet DM was supplemented with Aminoplus®, a soy-based bypass protein source (13AP and 18AP). DDGS (18% of diet DM) was also supplemented with commodity soybean meal (18SBM), blood meal (18Bl), blood and fish meal (18BlF) and Aminoplus® and blood meal (18APBl). Diets were formulated to have similar NDF and fat concentration. The 18APBl positive control diet was 18.5% CP but the other five diets were isonitrogenous (17.0% to 17.4% CP), No significant differences were found across treatments for DMI (25.3 kg/d), yield of milk (44.5 kg/d), milk protein (1346 g/d), fat (1458 g/d) and lactose (2170 g/d) or milk fat concentration (3.28%). Milk protein percent was higher for the 18APBl diet vs 18AP (3.05% vs. 3.00%; $P<0.05$, one-tailed). This last result implies the cows in this study could respond to added protein, albeit slightly. Therefore, either our hypothesis that diets containing more available lysine would cause increased production responses was incorrect, or the diets did not improve the lysine status of the cows. In either case the quality of the protein in all these 18% DDGS diets appears similar.

Key Words: Dried Distillers Grains with Solubles, Dairy Cows

T337 Effect of feeding dry glycerin to early postpartum Holstein dairy cows on milk production and metabolic profiles. Y.-H. Chung*[1], D. E. Rico[1], A. Martinez[1], K. S. Heyler[1], C. M. Martinez[1], T. W. Cassidy[1], V. Noirot[2], A. Ames[3], and G. A. Varga[1], [1]*Dairy and Animal Science, The Pennsylvania State University*, *University Park*, [2]*Phodé*, *Albi, France*, [3]*NutriLinx, LLC*, *Montpelier, VT*.

Effect of feeding dry glycerin to 39 multiparous Holstein dairy cows (control: n = 19 and glycerin: n = 20; lactation number = 2.2 ± 1.3 SD) on lactational performance and metabolic profiles was investigated. Dry glycerin (minimal 63% of glycerol) was fed at the level of 250 g/cow/d as a topdress to the common lactating TMR from parturition to 21 days postpartum. Individual milk was sampled from 2 consecutive milkings weekly and analyzed for components. Blood was sampled from the coccygeal vein at 4, 7, 14 and 21 days in milk and analyzed for glucose and blood urea nitrogen (BUN). Urine was tested for acetoacetate level weekly using ketostix. Feed intake, milk production and BUN were not affected by glycerin. Percentage of milk protein tended to be lower numerically (P = 0.17) and % of milk fat tended (P = 0.07) to decrease at a faster rate for glycerin supplemented cows than control cows, however yield of milk protein or fat was not different indicating a dilution effect. Cows receiving glycerin tended to have numerically lower urine ketones compared to control cows (6.8 vs. 17.9 mg/dL; P = 0.18). A tendency for treatment by time interaction (P = 0.14) was observed on urine ketones showing that cows receiving glycerin tended to have lower urine ketones on wk 1 and 2 of lactation compared to cows receiving no glycerin. Plasma glucose on wk 2 of lactation corresponded to urine ketones results showing that cows receiving glycerin tended to have higher plasma glucose than cows receiving no glycerin. Results from urine ketones and plasma glucose indicated that at the same level of production, cows receiving glycerin were in a better metabolic status than cows receiving no glycerin. Urine ketones for all cows at any sampling time were below the moderate level (40 mg/dL) for urine ketones during the experimental period.

Key Words: Dry Glycerin, Early Postpartum

T338 Variation over one year of nutrient content of wet brewers grains from a commercial brewery. J. E. Wohlt* and M. L. Westendorf, *Rutgers University*, *New Brunswick, NJ*.

Trailer shipments of wet brewers grains from Anheuser-Busch, Inc., Newark, NJ were sampled daily and composited weekly for 12 months. Both wet and pressed grains were produced at this site. The 48 samples were analyzed at Cumberland Valley Analytical Services, Morgansville, MD. Results for all nutrients are reported as mean (%), SD, and range, respectively. Four of 48 samples contained greater than 40% DM. DM averages of the 48 samples were 34.5%, 4.9 and 27.7 to 51.0 for mean, standard deviation, and range, respectively. Protein fractions were: CP %/DM 33.6, 1.9, and 29.6 to 37.4; soluble protein %/CP 8.3, 1.9, and 4.4 to 12.2; TA-NPN%/CP 9.6 3.7, and 2.9 to 26.6; degradable protein %/CP 28.8, 2.5, and 24.4 to 35.3. The COV for soluble protein and TA-NPN exceeded 20%. Carbohydrate fractions were: starch %/DM 4.3, 1.1, and 2.9 to 7.5; sugar %/DM 4.8, 1.5, and 2.4 to 8.2 with COV exceeding 25%. Fiber fractions were: ADF %/DM 29.9, 1.9, and 18.1 to 25.5; NDF %/DM 48.5, 1.7, and 44.3 to 52.1; lignin %/DM 5.5, 0.3, and 4.9 to 6.2. Fat was: 9.0%, 0.5, and 8.0 to 9.8. Ash was: 7.2%, 2.4, and 3.9 to 9.8 with a COV of 33.0%. Small amounts of macrominerals were present (% of DM): Ca 0.21, 0.02, and 0.17 to 0.26; P 0.55, 0.02, and 0.50 to 0.62; Mg 0.20, 0.02, and 0.16 to 0.24; K 0.09, 0.01, and 0.07 to 0.13; Na 0.010, 0.002, and 0.007 to 0.015. Data illustrate that the nutrient content of wet grains from a single supplier can vary. Simply analyzing or monitoring DM content will not be sufficient when formulating diets.

Key Words: Brewers Grains, Nutrient Content, Variability

T339 The effect of feeding dried distillers grains plus solubles to lactating dairy cows on milk production and excretion of urinary purine derivatives. B. N. Janicek*[1], P. J. Kononoff[1], A. M. Gehman[1], and P. H. Doane[2], [1]*University of Nebraska*, *Lincoln*, [2]*ADM Animal Nutrition Research*, *Decatur, IN*.

The objective of this experiment was to evaluate the effects of feeding dried distillers grains plus solubles (DDGS) on lactational performance of Holstein dairy cows. In addition, we evaluated urinary excretion of purine derivatives (PD) as an indirect estimator of ruminal microbial crude protein production (MCP). Twenty one multiparous and thirteen primiparous mid–to–late lactation cows averaging 178 ± 36 DIM and 651 ± 65 kg BW were randomly assigned to one of two diets in a three period cross–over design. During each of the 21–d periods, cows were offered one of two diets which were chemically similar but differed by the rate of inclusion of DDGS. Dietary treatments were either control (no DDGS) or 30% of diet DM as DDGS. Dried distillers grains plus solubles replaced a portion of dietary forages and concentrates. Diets were formulated to contain similar amounts of CP, NDF, and energy. Dry matter intake was not different (P = 0.19) between treatments (22.8 and 24.0 ± 0.65 kg/d) nor was 3.5% FCM (34.4 and 34.9 ± 1.24 kg/d; P = 0.69). Percentages of milk fat and true protein did not differ between treatments averaging 3.67 ± 0.07% and 2.99 ± 0.03%. The ratio of PD to creatinine was not affected (P = 0.83) by DDGS feeding (2.43 and 2.45 ± 0.07). Similarly, allantoin to creatinine ratios were not different (P = 0.57) between diets (2.23 and 2.28 ± 0.07 respectively). Estimated MCP was not affected (P = 0.80) by DDGS addition (1636 and 1656 ± 58 g/d). In conclusion, purine excretion and estimates of rumen microbial crude protein production were not affected by feeding higher amounts of DDGS. Production results suggest that dairy diets may be formulated to contain DDGS at 30% of the diet DM and maintain acceptable DMI, milk production and milk composition.

Key Words: Dairy Cow, Distillers Grains Plus Solubles, Urinary Purine Derivatives

T340 Effects of Optigen® on fermentation, digestion, and N partitioning in rumen-simulating fermenters fed diets with distillers dried grains. G. A. Harrison*, J. M. Tricarico, M. D. Meyer, and K. A. Dawson, *Alltech Biotechnology*, *Nicholasville, KY*.

The effects of Optigen® (blended, controlled-release urea) on ruminal fermentation, digestion, and N flow in diets with and without distillers dried grains (DDG) were investigated in single-flow rumen-simulating fermenter cultures. Data from 5 experiments (44 cultures) were included in this meta-analysis. Cultures were fed 50% forage diets (corn silage and alfalfa hay), DDG at 0 (DDG0) or 20% (DDG20), and 2 levels of Optigen (0 and 0.55% DM). NPN from Optigen replaced 7.6% of dietary N. Cultures were fed 12.5 g as fed of experimental

diets twice daily for 6 days. Target dilution rate was 0.045 h^{-1}. Samples were collected from cultures prior to morning feeding during the last 3 d of experiments for fermentation analysis. Effluent weights were recorded each day and a composite sample for each fermenter used for DM, OM, and NDF disappearance determination. Nitrogen flow measures were estimated by using purine to N ratios for effluent DM and bacteria. Data were analyzed using the PROC MIXED Model of SAS. Least-square means were compared using Scheffe's test for simultaneous inference. Culture fluid pH, ammonia, and digestion were similar between all-natural protein and Optigen cultures (P>0.10). Cultures receiving Optigen had greater protein degradability (64.0 vs. 67.6, P<0.01) than all-natural protein cultures. Bacterial N yields (0.352 vs. 0.359 g, P>0.10) were not affected by protein source. Cultures fed DDG20 diets had lower ammonia concentrations (5.25 vs. 3.29 mg/dl, P<0.01) and lower true DM digestibility (63.4 vs. 61.1%, P<0.01). DDG20 cultures degraded less protein (68.8 vs. 62.8% of CP, P<0.01) and produced less bacterial N (0.362 vs. 0.349 g/d, P<0.05), but were more efficient (35.1 vs. 36.9 g bacterial N/kg fermentable carbohydrate, P<0.01) than DDG0 cultures. Negative effects of 20% DDG dietary inclusion on N flow in rumen-simulating fermenters were partially negated by addition of Optigen.

Key Words: Non-Protein Nitrogen, Optigen, Distillers Dried Grains

T341 Performance of dairy cows fed glycerol as a primary feed ingredient. S. S. Donkin*[1], M. R. Pallatin[1], P. H. Doane[2], M. J. Cecava[2], H. M. White[1], E. Barnes[1], and S. L. Koser[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*ADM Animal Nutrition Research*, *Decatur, IN*.

Growth of the corn ethanol industry is creating a need for inexpensive feed energy alternatives for lactating dairy cows while concurrent expansion in soydiesel production is expected to promote favorable pricing for glycerol, a primary coproduct material. The objective of this study was to determine the feeding value of glycerol for lactating dairy cattle as a replacement for corn. Sixty lactating Holstein cows, housed in individual tie stalls, were fed a base diet consisting of corn silage, legume forages, corn grain, soyhulls, roasted soybean and protein supplements. After a 2-week acclimation period, cows were fed diets containing 0, 5, 10 or 15% glycerol on a DMB. Glycerol and corn gluten feed in a ratio of 6.25:1 replaced an equivalent amount of corn grain to achieve desired percentages of glycerol in the diet. Cows were milked twice daily and weekly milk samples were analyzed for fat, protein, lactose, total solids, milk urea N, and somatic cells. Body weights and body condition scores were obtained at the beginning and the end of the study. Milk production was 37.0, 36.9, 37.3, 36.4 ± 0.6 kg/d and feed intake was 24.0, 24.5, 24.6, 24.1 ± 0.5 kg/d for 0, 5, 10 and 15% glycerol treatments respectively and did not differ (P > 0.05) except for a modest reduction in feed intake during the first 7 days of the trial for 15% glycerol (treatment x time effect; P < 0.05). Milk composition was not altered in response to glycerol with the exception of decreased (P < 0.05) milk urea nitrogen from 12.5 ± 0.4 mg/dl to an average of 10.6 ± 0.4 mg/dl with glycerol addition. Cows fed 10 and 15% glycerol gained more weight (P < 0.05) than those fed 0 or 5% glycerol; however, body condition scores did not differ among treatments. The data indicate that glycerol is a suitable replacement for corn grain in diets for lactating dairy cattle. Glycerol can be included at rates up to 15% of diet DM without adverse effects on milk production or milk composition.

Key Words: Glycerol, Milk, Biofuels

T342 Evaluation of protein fractionation and ruminal and intestinal digestibility of corn milling co-products. J. M. Kelzer*[1], P. J. Kononoff[1], K. Karges[2], and M. L. Gibson[2], [1]*University of Nebraska*, *Lincoln*, [2]*Dakota Gold Research Association*, *Sioux Falls, SD*.

Inputs for the Cornell-Penn-Miner Dairy model require feed protein to be divided into five fractions: A = non-protein nitrogen; B1 = rapidly degraded true protein; B2 = moderately degraded true protein; B3 = slowly degraded true protein; and C = undegraded true protein. The objectives of this study were to characterize feed protein fractions and evaluate differences in rumen undegradable protein (RUP), RUP digestibility (dRUP), and amino acid concentration in the RUP of seven corn milling co-products. The corn co-products and their respective CP (% DM) included Germ (16.3), Bran (13.5), High Protein Dried Distillers Grains (HPDDGS; 47.2), Dried Distillers Grains (DDGS1; 30.1), Dried Distillers Grains (DDGS2; 28.9), Wet Corn Gluten Feed (WCGF; 26.7), and Wet Distillers Grains (WDGS; 29.9). Two ruminally and duodenally fistulated Holstein steers averaging 665 kg were used to determine RUP and dRUP. Samples of each feed were ruminally incubated for 16 hours. After simulated abomasal digestion, designated samples were inserted into the duodenum and collected in the feces. Protein fractions A, B1, B2, B3, and C are characterized as follows (% CP): Germ = 30.0, 15.0, 38.1, 13.5, 3.4; Bran = 33.5, 4.0, 54.3, 6.0, 2.2; HPDDGS = 7.4, 0.6, 82.4, 8.8, 0.8; DDGS1 = 17.0, 7.0, 67.0, 4.8, 4.2; DDGS2 = 17.9, 2.1, 41.0, 11.1, 27.9; WCGF = 36.6, 15.9, 33.2, 10.1, 4.1; and WDGS = 18.6, 2.4, 53.1, 11.0, 14.9. The proportions of RUP ($P < 0.01$) and dRUP ($P < 0.01$) were different and are reported as follows (% CP): Germ = 16.5, 66.8; Bran = 20.7, 65.8; HPDDGS = 55.2, 97.7; DDGS1 = 33.2, 92.0; DDGS2 = 56.3, 91.9; WCGF = 11.5, 51.0; and WDGS = 44.7, 93.1. The concentrations of Lys ($P < 0.01$) and Met ($P < 0.10$) in the RUP were different and are listed as follows (%CP): Germ = 2.9, 1.9; Bran = 3.2, 1.4; HPDDGS = 2.0, 3.2; DDGS1 = 1.9, 2.0; DDGS2 = 1.9, 2.4; WCGF = 3.5, 1.6; and WDGS = 1.9, 2.3. Comparison of the co-products defined differences in protein fractions, RUP, dRUP, and post-ruminal Lys supply.

Key Words: Protein, Dairy, Co-Products

T343 Evaluation of ruminal fermentability of corn milling co-products using in vitro gas production. P. J. Kononoff*[1], L. O. Tedeschi[2], M. L. Chizzotti[2], J. M. Kelzer[1], K. Karges[3], and M. L. Gibson[3], [1]*University of Nebraska*, *Lincoln*, [2]*Texas A & M University*, *College Station*, [3]*Dakota Gold Research Association*, *Sioux Falls, SD*.

The kinetics of ruminal fermentation influences the feeding value of corn milling co-products. The objective of this study was to evaluate kinetics of gas production in vitro and fermentability of 7 corn milling co-products. For each feed, the concentration of NDF with sodium sulfite, lignin, starch, and sugar (%DM) were: Germ = 30.1, 4.4, 28.8, 9.2 %, Bran = 21.2, 2.85, 32.0, 5.0 %, High Protein Corn Distillers Grains (HPDDGS) = 22.5, 4.55, 9.50, 0.85 %, Dried Distillers Grains (DDGS1) = 30.2, 4.4, 7.4, 3.5 %, Dried Distillers Grains (DDGS2) = 33.9, 10.1, 6.9, 4.8 %, Wet Corn Gluten Feed (WCGF) = 36.9, 3.2, 9.8, 4.5 %, and Wet Distillers Grains (WDGS) = 30.8, 5.9, 3.7, 3.0 %. Feed samples (200 mg each) were inoculated with rumen fluid and media in an anaerobic condition and fermented in vitro for 48 h. Gas production was continuously measured using a computerized system and data was fitted to an exponential model: $y = a \times (1 - \text{Exp}(-b \times (\text{time} - c)))$, where y = gas production (ml), a is the asymptote of gas

production (ml), b is the rate of degradation (1/h), and c is the lag time. The asymptote (a) of gas production was different among feeds (P = 0.04), with a mean and SEM of 52.1 ± 3.9 ml for Germ, 50.1 ± 3.4 ml for Bran, 37.5 ± 3.4 ml for HPDDGS, 38.6 ± 3.4 ml for DDGS1, 40.1 ± 3.0 ml for DDGS2, 39.0 ± 3.4 ml for WCGF, and 40.7 ± 3.4 ml for WDGS. The lag (c) of gas production was not different among feeds (P = 0.15), with a mean and SEM of 1.42 ± 0.34 h for Germ, 1.25 ± 0.29 h for Bran, 0.65 ± 0.30 h for HPDDGS, 0.38 ± 0.30 h for DDGS1, 0.60 ± 0.27 h for DDGS2, 0.89 ± 0.30 h for WCGF, and 0.35 ± 0.30 h for WDGS. Fractional gas production rates (b) were significantly different among feeds (P < 0.01), with a mean and SEM of 19.3 ± 1.8 for Germ, 16.2 ± 1.5 for Bran, 16.1 ± 1.5 for HPDDGS, 14.6 ± 1.5 for DDGS1, 10.3 ± 1.4 for DDGS2, 11.9 ± 1.5 for WCGF, and 9.1 ± 1.5 for WDGS. Results of this study demonstrate that corn milling co-products differ in chemical composition and that differences also exist in the pattern of ruminal fermentation and nutrient availability.

Key Words: Gas Production, Rumen Fermentation, Corn Milling Co-products

T344 Blood metabolites profiles of dairy cows fed wet corn distillers grains during early lactation. G. S. Mpapho*, A. R. Hippen, K. F. Kalscheur, and D. J. Schingoethe, *South Dakota State University*, *Brookings*.

Multiparous Brown Swiss (n=16), and Holstein (n=18) cows were used in a randomized complete block design to evaluate glucose, cholesterol, and blood urea nitrogen (BUN) concentrations for cows fed wet distillers grains (WDG) at 15% of diet dry matter during early lactation. Cows were paired during the close up period by breed and anticipated calving date and randomly assigned to 1) Control (CON): containing 0% WDG and 2) WDG included at 15% of diet dry matter. Energy density and crude protein content of diets were 1.44 and 1.58 Mcal NEl/kg and 14.5 and 17.2 % for pre- and postpartum diets, respectively, and were similar for CON and WDG. Prepartum diets were fed from 28 d until calving whereas postpartum diets were fed from calving to 70 days in milk (DIM). Diets were offered for ad–libitum intake. Blood was sampled approximately 4 h after feeding at 4, 7, 14, 21, 28, 35, 42, 49 and 56 DIM. Blood samples were analyzed for glucose, cholesterol, and BUN. Dry matter intake (DMI) and energy corrected milk (ECM) for cows fed WDG and CON were unaffected by dietary treatments during the first 70 DIM (23.2 vs 22.5 kg/d; P = 0.46 and 40.1 vs 41.6 kg/d; P = 0.41), respectively. Cows fed WDG had greater glucose concentration (P < 0.05) than those fed CON (64.4 and 60.0 mg/dL). Glucose concentrations in the blood were greater in Holstein than Brown Swiss cows (64.7 and 59.7 mg/dL; P = 0.04). Glucose also varied by DIM with lowest concentrations at 21 DIM (57.6 mg/dL) and greatest at 49 DIM (71.2 mg/dL). Plasma cholesterol was not affected by treatment (114.9 and 118.7 mg/dL; P = 0.74) for both the WDG and CON, respectively. Cholesterol varied by DIM with lowest concentrations at 4 DIM (104.2 mg/dL) and greatest at 56 DIM (137.9 mg/dL). BUN was affected by diet (13.8 and 12.1 mg/dL; P = 0.04), for WDG and CON. No interactions of diet and other main effects were observed for glucose, cholesterol and BUN. Relative to CON, feeding WDG at 15% of ration DM led to a more favorable metabolic profile postpartum as evidenced by increased concentrations of plasma glucose in early lactation.

Key Words: Distillers Grains, Glucose, Cholesterol

T345 Rumen fermentation with dried distillers grains versus soybean protein as a source of rumen undegraded protein for lactating dairy cows. B. W. Pamp*, K. K. Kalscheur, A. R. Hippen, and D. J. Schingoethe, *South Dakota State University*, *Brookings*.

The objective of this research was to evaluate the effect of level and source of rumen-undegraded protein (RUP) on lactation performance and rumen fermentation. Evaluation of source of RUP was accomplished by comparing dried corn distillers grains with solubles (DDGS) to soybean protein. Five ruminally cannulated Holstein cows (122 ± 45 DIM) were used in a 5 × 5 Latin square with 28 d periods. Diets were formulated to provide 3 concentrations of dietary RUP (% of DM) from 2 different sources: 1) 5.3% RUP (control), 2) 6.8% RUP from soybean protein, 3) 6.8% RUP from DDGS, 4) 8.3% RUP from soybean protein, and 5) 8.3% RUP from DDGS. All diets were formulated to contain 10% RDP. Diets consisted of 38.5% corn silage, 16.5% alfalfa hay, and 45% concentrate (DM basis). DMI increased (P < 0.05) with the addition of supplemental RUP (21.0, 21.7, 22.6, 22.7, and 23.1 kg/d). Milk production was greater (P < 0.01) for cows fed diets containing DDGS vs. soybean protein (31.8, 32.3, 34.8, 32.6, and 36.7 kg/d). Protein yield increased (P < 0.01) when soy protein was replaced with DDGS (0.86, 0.86, 0.94, 0.87, and 0.99 kg/d). MUN increased (P < 0.01) as dietary RUP increased (13.6, 15.1, 14.9, 19.0, and 18.7 mg/dl). Increasing dietary RUP increased (P < 0.01) ruminal NH_3 concentrations (4.76, 5.19, 5.39, 6.75, and 5.66 mg/dl). Ruminal concentrations of propionate decreased (P < 0.01) when soy protein was replaced with DDGS and increased (P < 0.01) when the dietary RUP concentration was increased (22.1, 26.0, 23.1, 23.9, and 23.2 mg/dl). Concentrations of butyrate in the rumen increased (P < 0.01) when DDGS replaced soy protein (11.2, 10.9, 12.1, 11.3, and 13.0 mg/dl). The ratio of acetate to propionate increased (P < 0.01) when DDGS replaced soy protein. Increasing RUP in the form of DDGS increased milk production and NH_3 concentrations but decreased propionate concentrations to a greater extent than RUP supplied by soybean protein.

Key Words: Dried Distillers Grains, Soybean Protein, Rumen Fermentation

T346 Effects of alcohol-fermented feedstuff supplemented with chitooligosaccharide on growth performance, blood metabolites and meat composition of Korean steers. B. K. Park[1], I. S. Yuh*[2], S. K. Hwang[2], B. J. Hong[2], and J. S. Shin[2], [1]*National Livestock Research Institute, Rural Development Administration*, *Pyeongchang, Korea*, [2]*College of Animal Life Sciences, Kangwon National University*, *Chuncheon, Korea*.

Fifty Korean steers (average body weight=592.0±45.8kg) were used in the experiment to determine the effects of supplementing chitooligosaccharide (COS) on growth performance, blood metabolites and meat composition in Korean steers fed alcohol-fermented feedstuff (AFF). Steers were randomly assigned to feeding groups of AFF without COS (T1), AFF supplemented with 0.01% of COS (T2), AFF supplemented with 0.02 % of COS (T3), AFF supplemented with 0.05 % of COS (T4), and AFF supplemented with 0.1 % of COS (T5). Average daily gain (ADG) was lower in T5 than in T1 (p<0.05). Concentration of blood albumin was lower in T2 than in the other treatments (p<0.05). Concentration of blood glucose was lower in T1 than in the other treatments (p<0.05). Concentrations of blood low density lipoprotein (LDL)-cholesterol and triglyceride were lower in

T4 than in T1 ($p<0.05$). Back fat thickness was higher in T2 than in T1 or T5 ($p<0.05$). Longissmus muscle area was higher in T5 than in T1 ($p<0.05$). Marbling score, meat color, fat color, maturity, and texture were similar between treatments ($p>0.05$). Protein content of longissmus muscle was higher in T4 than in T3 or T5 ($p<0.05$). Cholesterol and linolenic acid contents of longissmus muscle were higher in T1 than in the other treatments ($p<0.05$). Arachidonic and docosahexanoic acid contents of longissmus muscle were higher in T5 than in T1 ($p<0.05$). Lightness among surface colors of longissimus muscle was lower in T1 than in T5 ($p<0.05$), and hue angle was lower in T1 than in the other treatments ($p<0.05$). Present results indicate that 0.05 or 0.1% supplementation of COS to AFF is more favorable in terms of blood metabolite, carcass characteristics and composition, and surface color of longissimus muscle.

Key Words: Alcohol-fermented Feedstuff, Chitooligosaccharide, Korean Steers

T347 Effects of added yeast culture on lactating dairy cows with subacute ruminal acidosis. M. S. Douglas*, O. AlZalhal, S. L. Greenwood, M. Or-Rashid, and B. W. McBride, *University of Guelph*, *Guelph, Ontario, Canada*.

Of the many challenges today's dairy producers face, subacute ruminal acidosis (SARA) is of increasing concern as producers try to maximize production with higher grain diets. It was hypothesized that inclusion of a yeast culture (Diamond V XP, Yeast Culture, Diamond V, Cedar Rapids, Iowa) *Saccharomyces cerevisiae (S. cerevisae)* in the diet would have a stabilizing affect on the animals' rumen pH and DMI (dry matter intake). The objective of the study was to examine the effect of SARA and added yeast culture interaction on rumen pH, DMI and milk yield. Six multiparous, ruminally fistulated Holstein cows (639 + 51 kg BW) were blocked by DIM (early, moderate and late) and then randomly assigned to a SARA diet (n=3) or control diet (n=3). The trial consisted of 2 weeks pre-yeast followed by 2 weeks of 112g yeast addition into the rumen through the fistula. Ruminal pH was continuously recorded, milk samples were taken 3 d/wk and milk yield and DMI were recorded daily. Data were averaged by week and analyzed by yeast addition using PROC MIXED of SAS with repeated measures where the effect of yeast addition was tested by the contrast describing the time (wk) and time by diet interaction. The results show no effect of week or week by diet interaction on mean rumen pH, time spent below pH 6.0, 5.8 and 5.6, DMI or milk yield.

Table 1. The effect of yeast culture on ruminal pH, dry matter intake, and milk yield in Holstein dairy cows.

	Control		SARA			P Value		
Item/wk	1	2	1	2	SEM	Diet	wk	wk x Diet
Mean pH	6.11	6.06	5.77	5.85	0.05	0.03	0.78	0.32

T348 Effect of feeding system on lactation characteristics and milk components in dairy cattle. M.-C. Ferland*[1], D. Lefebvre[2], and K. M. Wade[1], [1]*McGill University*, *Montreal, QC, Canada*, [2]*Valacta*, *Ste. Anne de Bellevue, QC, Canada*.

The objective of this study was to evaluate the effect of two different feeding systems on the milk composition of dairy cattle. A total 9,163,240 test-day records from 570,083 Holstein cows from 5191 different herds, and 434,018 test-day records from 27,110 Ayrshire cows from 652 different herds covering a period of five years were obtained from the Québec dairy herd improvement agency (Valacta). In addition to test-day records, information on lactation, feed composition and feeding systems was also available. For both Ayrshire and Holstein cows the feeding system had an effect on milk yield and milk urea nitrogen (MUN) concentration on a test-day basis. Cows served a diet prepared with a Total mixed ration (TMR) compared to cows served a diet in a Traditional way (TRAD) tended to produce more milk. Average milk yields for Holsteins in the respective feeding systems were 26.29 kg/day and 29.28 kg/day; the equivalent values for Ayrshire were 21.44 kg/day and 23.23 kg/day. Peak milk yield for cows fed TRAD was generally lower and achieved earlier in lactation (45 - 60 DIM) compared to cows fed TMR (60 - 75 DIM). Lower MUN concentrations were observed when cows were fed TMR compared to TRAD. Holstein averages were 11.45 mg/dL and 10.61 mg/dL while Ayrshire averages were 12.40 mg/dL and 11.04 mg/dL for TRAD and TMR respectively. Over the lactation period the differences in MUN concentration between TMR fed and TRAD fed cows are even more pronounced beyond 30 DIM. Ayrshire cows also displayed a small difference in milk protein content between the two types of feeding system. TRAD fed cows had lower milk protein content (3.40%) compared to TMR fed cows (3.45%) but when milk protein content was observed over the lactation period, greater differences were observed beyond 90 DIM. When the lactose content of Holstein test-day records was studied over the lactation period, TMR fed cows had a better persistency of lactose content than TRAD fed cows after 90 DIM although the average lactose content only showed small numerical differences (4.52% and 4.57% for TRAD and TMR respectively).

Key Words: Dairy Feeding System, Milk Urea Nitrogen, Milk Components

T349 Effect of rumen protected choline (Reashure®) and rumen protected methionine on milk yield, and composition in lactating dairy cows. S. Emanuele*[1], T. Hickley[1], and R. Carvalho Bicalho[2], [1]*Balchem*, *New Hampton, NY*, [2]*Cornell University*, *Ithaca, NY*.

Holstein cows were used to evaluate the impact of rumen protected choline (Reashure®), (18 g/cow/day) and rumen protected methionine (Smartamine®), (18 g/cow/day) on milk yield and composition in a well-managed commercial herd. Experimental treatments were 1) control, no rumen protected choline or methionine, 2) rumen protected methionine (RPMET) and 3) rumen protected choline (RPC). Cows were assigned to treatment groups based on DIM and parity. The experimental period was 10 weeks which included a 2 week pretrial covariate period. DIM at the start of the trial were 224, 212 and 217 for control, RPMET and RPC treatments. Diets were formulated using CNCPS model software. Lysine and methionine as a percent of metabolizable protein (MP) was estimated using CNCPS software and was 7.17 and 2.03% in control and RPC diets. Lysine and methionine as a percent of MP in the RPMET diet was 7.12 and 2.41%. Weekly

averages for milk yield data were analyzed using the mixed model procedure of SAS (SAS Institute, Inc., Cary, NC). Covariates used in the analysis were pretrial milk yield, parity and DIM. Supplementing rumen protected choline (RPC) to late lactation cows increased milk yield compared to RPMET (P<0.05). There was a trend for increased milk fat % on the RPC treatment (P<0.09). Supplementing RPMET increased milk protein % compared to RPC (P< 0.05). There was no difference among treatments for milk protein yield. Actual milk fat yield was increased 4.9% on RPC treatment compared to control. Milk income per cow was increased by 2.5% when RPC was fed to late lactation cows.

Table 1. Effect of treatments on animal performance

Item	Control, n= 254	RPMET, n=263	RPC, n=253	SE

T350 Effects of choline and rumen protected choline (Reashure®) on milk production, milk composition and blood metabolites of lactating dairy cows. A. Toghdory[1], S. Emanuele*[2], T. Ghoorchi[3], and A. Naserian[4], [1]*Islamic Azad University*, *Gorgan, Iran*, [2]*Balchem Corporation*, *New Hampton, NY*, [3]*Gorgan University of Agricultural Sciences*, *Gorgan, Iran*, [4]*Ferdowsy University*, *Mashhad, Iran*.

Eight multiparous Holstein cows with an average milk production of 34.6 kg/d and body weight of 662.5 kg were used to evaluate the effect of choline chloride or rumen protected choline (Reashure®) on animal performance. The experimental design was a 4X4 Latin Square with 21 day periods. Experimental treatments were: 1) no choline (NC), 2) choline chloride (CC) fed at 50 g/d, 3) rumen protected choline (RPC 25) fed at 25 g/d and 4) rumen protected choline (RPC 50) fed at 50 g/d. Rumen protected choline was blended with 0.25kg of ground corn and fed once per day. Diets contained 17.4% crude protein, 21% ADF, 34% NDF and 41% NFC. Diet content of lysine and methionine as a percent of metabolizable protein was 6.48 and 1.9%, estimated using CPM ration software. Animals were milked three times per day. Milk yield was measured at each milking during the last 7 days of each period. Individual milk samples for component analysis were collected on the last 2 days of each period and pooled from 3 consecutive samples. Dry matter intake as a percentage of body weight was 3.52% and not different among treatments. Supplementing cows with choline chloride did not affect animal performance compared to control. Supplementing cows with rumen protected choline (RPC 50) increased milk yield, 4% FCM, milk fat % and milk fat yield compared to cows not receiving choline.

Table 1. Effect of treatments on animal performance

Item	NC	CC	RPC 25	RPC 50	SE
Milk Yield, kg/d	34.3[b]	34.9[ab]	34.4[ab]	36.0[a]	0.53
4% FCM, kg/d	31.7[b]	31.6[b]	32.7[ab]	34.4[a]	0.74
Milk fat yield, kg/d	1.20[b]	1.17[b]	1.26[ab]	1.33[a]	0.038
Milk protein yield, kg/d	1.03	1.06	1.04	1.09	0.019

Key Words: Choline, Dairy Cow, Reashure

T351 Effect of rumen protected choline (Reashure®) supplemented to high-producing cows on milk production, milk components, and intake. M. B. de Ondarza*[1], S. Emanuele[2], and D. Putnam[2], [1]*Paradox Nutrition*, *West Chazy, NY*, [2]*Balchem Corporation*, *New Hampton, NY*.

The objective of the trial was to determine if feeding a small amount of rumen protected choline to lactating multiparous Holstein cows would affect milk components and milk yield. Half of the cows (n=153) received Reashure® (12.3 g/cow/day) and half did not (n=158) for the four week study. The study was conducted in a well managed commercial herd. Daily pen dry matter intakes were monitored. Daily milk production of individual cows was recorded. Milk was sampled on weeks 3 and 4 of the study and analyzed for milkfat, true protein, SCC, and MUN content. All diets contained Alimet® and monensin. The control diet contained 7.06% lysine and 2.01% methionine as a percent of MP estimated by CPM ration software. Cows fed rumen protected choline consumed significantly less dry matter than control cows (23.00 vs. 23.82 kg/cow/day for Reashure® vs. control cows (P<0.001). Overall milk production was not affected by treatment (P>0.20), 43.92 kg/day and 43.85 kg/day for the Reashure® and control diets. There was no difference due to treatment in 3.5% FCM (P>0.20). However, cows between 101 and 200 DIM produced significantly more 3.5% FCM (P<0.01). Milkfat (%) was affected positively by Reashure® (P=0.011) with 3.63% milkfat for cows fed Reashure® and 3.44% for cows on the control diet. Production of milkfat was increased by treatment with 1.57 kg/day for cows fed Reashure® and 1.49 kg/day for cows fed the control diet (P=0.067). Cows between 101 and 200 DIM produced significantly more milkfat when fed Reashure® (P<0.01). Cows on the Reashure® and control diets produced milk with a similar percentage of true milk protein (2.87% vs. 2.86%, (P>0.20). However there was a trend for greater milk protein % in cows between 0 and 100 DIM, (P<0.09) for cows fed Reashure®. There was no difference among treatments in true milk protein yield, MUN (mg/dl), or SCC (P>0.20). These data suggest that supplementation of rumen protected choline to high-producing cows may improve efficiency of milk production and milkfat synthesis.

Key Words: Rumen-Protected Choline, Milk Production, Reashure

T352 Effects of rumen protected choline during transition phase on metabolic profile and ovarian activity in Italian Friesian dairy cows. F. Abeni[1], M. G. Terzano[2], M. Speroni[1], L. Migliorati[1], P. Cavassini[3], and G. Pirlo*[1], [1]*CRA Istituto Sperimentale per la Zootecnia*, *Cremona, Italy*, [2]*CRA Istituto Sperimentale per la Zootecnia*, *Roma Monterotondo , Italy*, [3]*Ascor Chimici s.r.l*, *Bertinoro, Italy*.

The objective of this paper was to report the effects of supplementation of rumen protected choline (RPC) to transition cows on plasma metabolites and ovarian activity resumption (OAR). Twenty-two Italian Friesian cows were randomly assigned by expected calving date, parity, and previous milk yield to either be supplemented with RPC from d -21 relative to expected parturition until 35 DIM, or to consume basal diet only (CON). Treatment with RPC was obtained adding 50 g of RPC top dressed product (Sta-Chol®, Ascor Chimici, Italy, with 50% choline as choline chloride) per cow, just after TMR distribution. Jugular blood samples were collected before feeding, once just before the trial start, and then weekly until the 10th wk of lactation. Pre and postpartum data were analyzed separately. Effects of treatment were measured on plasma glucose, NEFA, cholesterol, BHBA, triglycerides, and OAR (monitored by plasma progesterone). Statistical analysis was performed by a randomized block design, with supplementation (RPC vs. CON), and week of trial as main factor, with cow repeated in time, while OAR data were analyzed by one-way ANOVA. Cows fed RPC had higher plasma urea (4.06 vs. 3.54 mmol/L; $P<0.05$) during prepartum. Plasma glucose was lower (3.26 vs. 3.52 mmol/L; $P<0.05$) and BHBA was higher (0.496 vs. 0.390 mmol/L; $P<0.05$) in RPC cows at the beginning of lactation, but without differences in clinical signs of ketosis (absent in both groups). Postpartum plasma triglycerides level was higher (0.104 vs. 0.084 mmol/L; $P<0.05$), and there was a trend ($P<0.10$) showing lower plasma values of NEFA and NEFA/cholesterol ratio in RPC cows, reaching significant difference at 4 wk ($P<0.05$) for both items. No significant difference was observed in DIM at OAR. Supplementation with RPC improved metabolic profile of peripartum dairy cows in order to prevent the risk to develop fatty liver syndrome.

Key Words: Choline, Dairy Cow, Metabolic Profile

T353 Effects of rumen protected choline during transition phase on production responses in Italian Friesian dairy cows. F. Abeni[1], M. Speroni[1], M. G. Terzano[2], L. Migliorati[1], P. Cavassini[3], and G. Pirlo*[1], [1]*CRA Istituto Sperimentale per la Zootecnia*, *Cremona, Italy*, [2]*CRA Istituto Sperimentale per la Zootecnia*, *Roma Monterotondo , Italy*, [3]*Ascor Chimici s.r.l*, *Bertinoro, Italy*.

The objective of this paper was to report the effects of supplementation of rumen protected choline (RPC) to transition cows on production responses. Twenty-two Italian Friesian cows were randomly assigned by expected calving date, parity, and previous milk yield to either be supplemented with RPC from d -21 relative to expected parturition until 35 DIM, or to consume basal diet only (CON). Treatment with RPC was obtained by the addition of 50 g RPC top dressed product (Sta-Chol®, Ascor Chimici, Italy, with 50% choline as choline chloride) per cow, just after once daily TMR distribution. Body condition score (BCS) was measured weekly from -21 to +70 DIM. Milk production was automatically recorded at each milking, within an automatic milking system, whereas milk composition was determined every 2 weeks. Statistical analysis was performed by a randomized block design, with supplementation (RPC vs. CON), and time as main factors, with cow repeated in time; BCS variation was analyzed as a simple one-way ANOVA. Milk production (34.8 vs. 29.9 kg/d; $P<0.001$), ECM (34.9 vs. 31.1 kg/d; $P<0.01$), fat yield (1.26 vs. 1.11 kg/d; $P<0.05$), and protein yield (1.10 vs. 1.00 kg/d; $P<0.05$) were higher for the RPC group, whereas no significant differences between treatments were evidenced in fat and protein content. Prepartum BCS was lower in the RPC group (3.27 vs. 3.49; $P<0.01$); however, BCS variation throughout the treatment period (-21 to 35 d relative to calving date) had a trend to be higher in the RPC group (0.83 vs. 0.61; $P=0.14$). The differences in BCS variation suggest a better management of body fat reserves in the transition phase of RPC cows. From the results obtained in the present trial, on a small number of cows, peripartal supplementation of RPC at the considered level seems to improve productive performance in an extent which encourages further studies on a larger number of cows.

Key Words: Choline, Dairy Cow, Milk Yield

T354 Effects of feeding rumen-protected choline (RPC) on health and reproduction of dairy cows. F. S. Lima*[1], M. F. Sa Filho[1], J. E. Garrett[2], and J. E. P. Santos[1], [1]*Veterinary Medicine Teaching and Research Center, University of California Davis*, *Tulare*, [2]*Balchem Corporation, Animal Health & Nutrition*, *New Hampton, NY*.

Objectives were to determine the effects of feeding RPC on health and reproduction in dairy cows. In Experiment 1 (E1), 369 cows were fed 15 g/d of RPC (Reashure, Balchem Encapsulates) from 25 d before calving to 80 d in milk (DIM). In E2, 578 primigravid cows were fed 15 g/d of RPC in the 21 d before calving. Health of cows was monitored daily in the first 80 DIM by the research team in E1 and by farm personnel in E2, both following the same disease case definitions. Cows were presynchronized with 2 injections of PGF2a given 14 d apart and then subjected to a timed AI using the CoSynch protocol (d 0, GnRH, d 7, PGF2a, d 10 GnRH and timed AI) initiated either 10 or 14 d after the second PGF2a for E1 and E2, respectively. Data were analyzed using the Logistic procedure of SAS (2001). In E1, feeding RPC reduced ($P<0.05$) the incidence of ketonuria (10.7 vs 28.8%), clinical ketosis (4.0 vs 11.3%), and relapse of clinical ketosis (2.3 vs 6.8%). Incidence of retained placenta, postpartum fever, puerperal metritis, metritis and displacement of abomasum did not differ ($P>0.10$) between treatments, but mastitis was reduced ($P=0.06$) in cows fed RPC compared with controls (14.8 vs 22.5%), and cows fed RPC experienced fewer ($P=0.04$) cases of mastitis (0.19 vs 0.33/cow). Cyclicity prior to the CoSynch protocol was similar ($P=0.67$) between treatments and averaged 81.7%. Conception rates at first (48.2 vs 41.2%; $P=0.20$) and second postpartum AI (23.7 vs 19.8%; $P=0.47$) did not differ between RPC and control. In E2, RPC did not affect ($P=0.41$) incidence of clinical ketosis (7.0 vs 3.7%), reduced ($P=0.02$) the incidence of retained placenta (2.1 vs 6.7%), but more ($P<0.02$) RPC cows experienced postpartum fever (17.2 vs 11.4%) and metritis (35.4 vs 21.8%) than controls. Conception rates at first (50.6 vs 50.8%; $P=0.83$) and second AI (38.8 vs 46.4%; $P=0.49$) were similar between RPC and control. Feeding RPC prior to and after calving improved postpartum health, but did not significantly influence uterine health or reproductive performance of dairy cows. When fed only prepartum to primigravid cows, RPC had mixed effects on health, but did not influence reproduction.

Key Words: Choline, Dairy Cow, Reproduction

T355 Interrelationships of dietary supplies of choline and methionine on productive performance of Holstein dairy cows. B. J. Thering*[1], J. M. Ramos-Nieves[1], J. L. Lukas[1], D. E. Putnam[2], and T. R. Overton[1], [1]*Cornell University*, *Ithaca, NY*, [2]*Balchem Encapsulates*, *New Hampton, NY*.

Holstein dairy cows (n=60) in early lactation were used to investigate the interrelationships between dietary supplies of choline and methionine (Met) on productive performance. During wk 11 of lactation, cows (n=10 multiparous and n=5 primiparous) were assigned to one of four dietary treatments in a completely randomized design with a 2 x 2 factorial arrangement of treatments. Main effects were supplementation with 0 or 15 g/d of rumen-protected choline (Reashure™, Balchem Encapsulates, New Hampton, NY) and 0 or 14 g/d of rumen-protected Met (Mepron M85, Degussa Corporation, Kennesaw, GA). Treatments were administered by daily topdress from wk 11 through 18 of lactation. Cows were fed a diet formulated to supply Met and Lys at 1.94 and 6.79% of metabolizable protein, respectively. Covariate data collected during wk 10 of lactation was used during statistical analysis of all variables. Dry matter intake (25.4, 25.0, 25.4, and 25.4 kg/d for control, choline, Met, and choline+Met, respectively) and milk yield (43.7, 44.1, 44.5, 44.1 kg/d) were not affected ($P > 0.60$) by treatment. Supplementation with Met tended ($P < 0.09$) to decrease milk fat percentage (3.68 vs. 3.55%) and supplementation with choline tended ($P < 0.06$) to decrease milk true protein percentage (2.86 vs. 2.82%). Percentages of lactose and total solids in milk were not affected ($P > 0.13$) by treatment. Yields of milk components were not affected ($P > 0.24$) by treatment. Supplementation with choline tended ($P < 0.10$) to increase concentrations of milk urea N (13.1 vs. 13.6 mg/dL). Body weight and body condition score were not affected ($P > 0.19$) by treatment. Interactions of parity with either the main effects or the interaction of the main effects were not significant ($P > 0.10$) for any variable. Overall, supplementation with either choline or methionine resulted in only minor effects on productive performance; interactions of choline and methionine were not evident for any of the variables studied in this experiment.

Key Words: Dairy Cow, Choline, Methionine

T356 Effects of feeding protected choline on arrival or during Optaflexx feeding on performance or carcass characteristics of feedlot cattle. R. K. Gill*[1], C. R. Dahlen[2], N. DiLorenzo[1], and A. DiCostanzo[1], [1]*University of Minnesota*, *St. Paul*, [2]*University of Minnesota Northwest Research & Outreach Center*, *Crookston*.

One hundred eighty seven crossbred yearling steers (average initial BW = 306 kg) were allocated to 16 pens (9 to 14 steers/pen) to evaluate the effects of feeding ruminally protected choline (**RPC**) on arrival or during Optaflexx feeding on performance and carcass characteristics. Steers were fed a finishing diet based on corn silage (13.0 %), high moisture corn (63.5 %), dry rolled corn (18.0 %), and mineral supplement (5.5 %) on a DM basis. Pens were randomly assigned to one of four dietary treatments: 1) no RPC added in the protein supplement (**Control**), 2) feeding 20 g RPC/hd/d in the protein supplement from d 1 to d 42 (**Initial 42**), 3) feeding 20 g RPC/hd/d during the last 28 to 42 d on feed (**Final 42**), or 4) or feeding 20 g RPC during both the initial 42 d and final 28 to 42 d on feed (**Both**). All dietary treatments received the ß-agonist Optaflexx during the final 28 to 42 d on feed. Dry matter intake (9.81 ± 0.26 kg/d), ADG (1.87 ± 0.03 kg/d), and G:F (0.19 ± 0.07 kg) were unaffected by dietary treatment ($P > 0.05$). Hot carcass weight, dressing percentage, KPH, fat thickness, and rib eye area were also unaffected by dietary treatment ($P > 0.05$). Carcasses from steers of all treatments were, on average, low choice quality grade with average yield grade 2.0. Previous research has demonstrated that optimum performance with RPC occurs with 20 g of RPC supplementation daily. Further research is warranted to test duration of RPC supplementation during the finishing period alone or in combination with β-agonists.

Key Words: Choline, Feedlot Cattle, Performance

T357 Field studies adding dl-methionine hydroxy analogue calcium to lactation cow rations. D. Nuzback*[1], G. Bowen[1], R. Anderson[1], M. Vazquez-Anon[1], and M. Hutjens[2], [1]*Novus International*, *St.Louis, MO*, [2]*University of Illinois*, *Urbana*.

Four commercial high producing herds (Dairy A, a MN herd; Dairy B, a WI herd; Dairies C and D, IL herds) were supplemented with 25 grams per cow per day of the calcium salt of 2-hydroxy-4- methylthio butanoic acid (84 % HMTBa; MFP ^TM^, Novus International, Inc.), a source of methionine. The experimental design included a pre-treatment period, a treatment period (treat) of 90 days, and a post-treatment period. Milk production data were collected using PC DART or Dairy Comp 305 record systems with the pre- and post-treatment data averaged for the control period. A total of 1,938 cows met the experimental criteria (milk production data from Oct., 2005 to June, 2006). SAS statistical software was used to evaluate the treatment differences. Cows in the four herds receiving HMTBa produced 1.96 kg more milk per cow ($P = 0.01$), averaging 41.8 kg (treat) while control cows averaged 39.9 kg. Milk protein yield was increased by 52 grams per day in the supplemented cows compared to the controls ($P < 0.01$). Control cows averaged 1,185 grams of protein compared to supplemented cows yielding 1,237 grams of milk protein. Milk fat yield increased, but was not significantly different. Table 1 summarizes individual farm milk production responses. The economic benefit was a 5:1 benefit to cost ratio based on $12 per 45 kg of milk and a 10 cent investment for HMTBa.

Table 1. Milk production yield response by herd

Dairy	Herd Size (total)	Cows (included)	Control (kg/cow)	Treat (kg/cow)	SE (+/-)
A	1400	1005	41.9	43.9	0.19
B	1250	782	39.9	41.0	0.18
C	150	119	39.1	41.1	0.48
D	70	32	38.4	41.1	1.03

Key Words: Amino Acid, Milk Yield, Milk Protein

T358 Influence of dietary protein on growth, fluoride kinetics and radiology of long bones of crossbred calves exposed to high fluoride diets. J. D. Lohakare*[2,1], A. K. Pattanaik[2], and S. A. Khan[2], [1]*University of Bonn*, *Bonn, Germany*, [2]*Indian Veterinary Research Institute*, *Izatnagar, India*.

Effects of dietary protein levels on the performance of crossbred calves exposed to high fluoride diets were investigated. Accordingly, 30

crossbred calves (6-8 months) were distributed randomly into a 2×3 factorial arrangement involving two levels of dietary fluorine (F; 0 and 200 mg/kg), and three levels of dietary protein (CP; 100, 75 and 125 % of Kearl recommendation). All the calves were fed on a standard diet consisting of concentrate mixture and ad libitum wheat straw. There was daily recording of dry matter intake as well as fortnightly monitoring of live weight changes. A metabolism trial was conducted towards the end of the 210 days of experimental feeding to assess the fluoride kinetics. The results revealed that average daily gain of the calves was significantly (P<0.05) influenced by both dietary CP as well as F levels, being lower on low protein (319±50.4 vs. 400±27.0 and 407±34.5g) and high F (289±27.9 vs. 462±17.1g), respectively. Similar was the case in terms of feed conversion efficiency; it was lower (P<0.05) upon low CP and high F feeding. Moreover, a significant interaction between F and CP indicated a lower (P<0.05) feed efficiency when F was added to low CP diet. The mean daily intake, excretion and retention of F were higher (P<0.01) in the F supplemented calves. No effect of dietary protein levels was apparent on fecal fluoride excretion. A significant (P<0.01) interaction between protein and F levels was evident in the urinary excretion of F; calves on low protein diet exhibiting lower urinary excretion. Consequently, the bioavailability of F tended to be higher on low than normal or high protein diets. Lateral radiographs of metacarpal and metatarsal bones taken at 90 and 210 days of the study revealed significant effects of high fluoride diet on bone width, cortical thickness and medullary cavity but without any influence of dietary protein levels. Overall, it is concluded that while feeding of high CP did not exert appreciable protective effects, provision of low CP diet aggravated the performance-reducing effects of high fluoride diet.

Key Words: Fluorine, Protein, Calves

T359 Organic selenium (Sel-Plex®) improves selenium content in milk and cheese of dairy goats. G. Caja*[1], C. Flores[1], A. A. K. Salama[1], J. Saldo[1], and G. Bertin[2], [1]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*, [2]*Alltech France*, *Levallois-Perret, France*.

Thirty Murciano-Granadina dairy goats were used to study the lactational effects of inorganic Se (SS, selenium selenite, Na2SeO3) and organic Se from selenized Saccharomyces cerevisiae CNCM I-3060 (SP, Sel-Plex®, Alltech) in a source and dose response experiment. Goats were allocated to 4 balanced groups to which dietary treatments were randomly assigned: control (without Se supplement, C), inorganic (0.3 mg Se as Na2SeO3, SS-0.3), and 2 doses of organic selenium (0.3 mg and 0.45 mg Se as Sel-Plex®; SP-0.3 and SP-0.45, respectively). Concentrate mixture (0.8 kg/d), in which Se source was included, was fed individually. Forage diet (65% chopped tall fescue hay and 35% alfalfa hay pellets) was offered ad libitum for each group. The experiment lasted for 30 wk (wk 6 to 35 of lactation) and included a covariate period (P1, wk 1 to 2) on C diet, supplementation period (P2, wk 3 to 18), and washing out period (P3, wk 19 to 30) again on C diet. Milk yield was recorded weekly, and samples for milk composition analysis and technological dairy traits evaluation were taken biweekly. Milk was bulked for each group at wk 18 for cheese making. Milk (Se content) and blood (haematological and biochemical analysis) sampling was done at wk 2, 3, 4, 8, 12, 16, 18, 24, and 30. No differences in DM intake, milk yield or milk quality traits were detected between treatments. Concentrations of Se in milk varied (P < 0.001) between treatments during p2 and were 8.8, 13.8, 19.5, and 39.7 µg/l for c, ss-0.3, sp-0.3, and sp-0.45, respectively. during p1 and p3, there were no differences between treatments in milk se (4.9 and 7.8 µg/L, respectively). During P2, Se and glutathione peroxidase (GPX) concentrations in blood increased (P < 0.01) by Se supplementation with no difference between SS-0.3 and SP-0.3 and SP-0.45 values being the highest (P < 0.01). Concentrations of Se in fresh cheese were 61, 99, 160, and 368 µg/kg in C, SS-0.3, SP-0.3, and SP-0.45, respectively. In conclusion, organic Se was more effective than inorganic Se in increasing the concentration of Se in milk and cheese in dairy goats, indicating an improved bioavailability of Se from selenized Saccharomyces cerevisiae CNCM I-3060.

Key Words: Organic Selenium, Dairy Goats, Mineral Nutrition

T360 Utilization of TRC Nutritional Laboratories trace mineral compost for growing and finishing beef cattle. D. R. ZoBell*, J. O. Hall, R. D. Wiedmeier, and C. K. Chapman, *Utah State University*, *Logan*.

The objectives of this study were to determine the effect of TRC Trace Mineral Compost Material (TMCM) on production characteristics and whole body mineral status of growing and finishing beef cattle. A total of 45 British-based crossbred steer calves (initial wt. 293 kg) were used during the growing and finishing phases of this study. There were 9 pens with 3 pens per treatment and 5 steers per pen. All calves in the growing (84d) and finishing (140d) studies received a standard barley-based growing (34% barley DMB) or finishing diet (77.3% barley DMB). Treatment consisted of a Control (C), Treatment 1 (T1) and Treatment 2 (T2). All calves received .045 kg of limestone per day during the finishing phase and 50,000 IU Vit A for the growing and finishing periods. The C calves received .045 kg d-1 of a standard TM salt; T1 calves .022 kg d-1 of salt (99%) and .07 kg d-1 of TMCM; T2 calves received .022 kg d-1 of salt and .14 kg d-1 of TMCM. True cut liver biopsy samples were collected from all calves at the beginning of the growing and finishing studies and at trial termination to monitor levels of Ca, Co, Cu, Fe, Mg, Mn, P, K, Se, Na and Zn. There were no differences between treatments for DMI, ADG, FE or carcass characteristics during growing or finishing (P>0.05). Generally, the treatments resulted in an increase in liver mineral levels as the study progressed through growing and finishing (P<0.05). However, Se and Co were low initially and remained so through finishing for T1 and T2 calves (P<0.05). The results indicated that feeding TMCM did not adversely affect production through all phases of production.

Key Words: Minerals, Beef Cattle, Liver

T361 Influence of chromium supplementation during growing period on performance of Brahman cross bull calves. R. Barajas*[1], E. A. Velazquez[1], B. J. Cervantes[2,1], F. Juarez[1], and J. A. Romo[1], [1]*FMVZ-Universidad Autonoma de Sinaloa*, *Culiacan, Sinaloa, Mexico*, [2]*Ganadera Los Migueles SA de CV*, *Culiacan, Sinaloa, Mexico*.

Sixty Brahman cross bull calves (BW = 244 ± 2.2kg) were used in a 91 d feedlot experiment to determine the influence of chromium supplementation during the growing period on performance of Brahman cross bull calves. Bull calves were received in a big pen (35 × 45 m) and fed a corn silage-based diet and rested 10 d, after that the animals

receive an implant containing estradiol and trenbolone (Component TES with Tylan; Elanco Animal Healt de Mexico). Bull calves were sorted by weight into groups of five, allotted to pens (6 x 12 m) in a randomized block design. Treatments consisted of: 1) corn silage-based starting-diet during the first 28 d and the next 63 d fed a ground corn soybean meal-based growing-diet without supplementary chromium (Control); 2) control diet and 2.2 mg of supplementary Cr/head daily during the first 28 d in the feedlot; or 3) control diet and 2.2 mg of supplementary Cr/head during 91 d of entire experiment. Chromium was supplied as chromium methionine (MiCrOPLEX; Zinpro Co) mixed in 1 kg of ground corn and top dressed in the feed bunk. During the 28 d of receiving period Cr supplementation had no effect (P > 0.25) on average daily gain (1.39 ± .08 kg/d), DMI (6.53 ± .22 kg/d) and feed/gain ratio (4.77 ± .26 kg kg/kg). From d 29 to d 91, cattle performance was not affected (P > 0.6) by treatments. Over the complete 91 d experiment, bull ending weight (384.7 ± 6.66 kg) was similar (P = 0.72) for all treatments. Average daily gain (1.542 ± .07 kg/d) was not affected (P = 0.85) by Cr supplementation. The addition of chromium in the diet did not modify (P > 0.50) DMI (7.197 ± .27 kg/d) or feed/gain ratio (4.68 ± .18 kg/kg). Observed/expected net energy of maintenance was 26% higher than expected from dietary composition and was not altered (P = 0.8) by chromium supplementation. These results suggest that organic chromium supplementation may not be necessary for rested bull calves fed corn silage based-diets.

Key Words: Bull-Calves, Chromium, Growth-Performance

T362 Effects of potassium, alcoholic diet and vitamin E to minimize transport stress in Korean steers. J. S. Shin*[1], B. Y. Choi[1], H. Kim[1], C. S. Ra[1], B. J. Hong[1], J. S. Oh[1], and B. K. Park[2], [1]*College of Animal Life Sciences, Kangwon National University*, *Chuncheon, Korea*, [2]*National Livestock Research Institute, Rural Development Administration*, *Pyeongchang, Korea*.

This study was conducted to compare and evaluate effects of potassium, alcoholic diet, and vitamin E on transport shrinkage, blood metabolites, and meat color from transport stress in Hanwoo steers. Experiments were divided into four treatment groups; control (general feeding system), alcoholic diet (1.58kg/animal/day), potassium (1.45% of total dry matter intake), and vitamin E (500IU/animal/day). And each treatment had ten steers. Transport shrinkage was higher in control than in alcoholic diet, potassium or vitamin E ($p<0.05$). Concentrations of serum creatinine, glucose, total protein, and insulin of control were increased after transport compared with before transport ($p<0.05$). But those of alcoholic diet, potassium, and vitamin E were decreased after transport compared with before transport ($p<0.05$). Concentrations of serum calcium and cortisol were increased after transport compared with before transport regardless of treatments ($p<0.05$). But concentrations of serum inorganic phosphorus and triglyceride were decreased after transport compared with before transport regardless of treatments ($p<0.05$). Meat color were lower in alcoholic diet and vitamin E than in control ($p<0.05$). Fat color, marbling score, back fat thickness, and meat production index were similar between treatments ($p<0.05$). Lightness among surface colors of longissimus muscle was higher in vitamin E than in control ($p<0.05$), and chroma value was lower in control than in alcoholic diet, potassium or vitamin E ($p<0.05$). Therefore, results suggest that transport stress was decreased by alcoholic diet, potassium, or vitamin E. Also, potassium and alcoholic diet are more favorable in terms of transport shrinkage and blood metabolite. And vitamin E has positive effects on meat color and surface colors of longissimus muscle in Korean steers.

Key Words: Transport Shrinkage, Meat Color, Korean Steers

T363 The effects of maternal natural source vitamin E supplementation on suckling calf immune function. M. Richardson*[1], S. Lake[1], P. Gunn[1], S. Eicher[2], R. Lemenager[1], and N. Pyatt[3], [1]*Purdue University*, *West Lafayette, IN*, [2]*USDA-ARS*, *West Lafayette, IN*, [3]*ADM-Animal Nutrition Research*, *Decatur, IN*.

The objective of this study was to determine the effects of maternal supplementation of natural-source vitamin E (NSVE) and a commercially available mixture containing NSVE on suckling calf immune response. Eighty Angus beef cows (initial BW = 608 kg; initial BCS = 5.9) were randomly assigned to one of three isocaloric dietary treatments: 1) corn-based supplement with no added vitamins or minerals (CON), 2) corn-based supplement containing 1000 IU NSVE/d (VITE), and 3) corn-based supplement containing a commercially available mixture formulated to contain 1000 IU of NSVE/d (VITE+). Supplementation began 3 wks prepartum and continued through wk 8 of lactation. Blood was collected from calves at 24 h for analysis of IgG concentration as an indicator of passive transfer. At 19 d of age, blood was collected from calves to determine the presence of CD14 and CD18 receptors on leukocytes. At 25 and 40 d of age, calves were injected with hen egg albumin (OVA) and bled weekly until d 60 of age to determine total antibodies produced to OVA. Maternal NSVE supplementation did not influence (P > 0.05) calf ADG or 24 h IgG concentrations. Calves suckling VITE and VITE+ dams tended to have greater (P = 0.19) CD14 levels than CON calves while CD18 tended to be greater (P = 0.18) in VITE+ than VITE and CON calves. A treatment × day interaction (P < 0.001) was detected for total antibodies produced to OVA. Total antibodies produced at d 14 tended to be greater (P = 0.06) in VITE+ than CON calves, indicating an accelerated response time to the OVA challenge; however, VITE calves had greater (P = 0.05) antibody production to OVA at d 28 than CON calves. In conclusion, maternal NSVE supplementation appeared to improve immune function in suckling calves with an increase in antibodies produced at d 14 and 28 and tended to increase CD14 and 18 receptors; however, calf performance was not affected.

Key Words: Beef Calves, Immune Response, Vitamin E

T364 Effects of a humate product on growth performance, carcass merit, and tissue and serum mineral composition of individually-fed steers. M. S. Brown[1], T. E. Lawrence[1], C. H. Ponce*[1], R. Pulikanti[1], C. S. Smith, Sr.[1], D. L. Mitchell[1], B. Sumerford[2], and J. D. Davenport[2], [1]*West Texas A&M University*, *Canyon*, [2]*Entex Energy*, *Amarillo, TX*.

Humate is composed of salts of humic and fulvic acids, Fe, and Al, and has reduced in vitro ammonia emissions from cattle waste at high rates of application. The objective of the present study was to evaluate the influence of a humate product (HA4, Entex Energy, Amarillo, TX) on performance, carcass merit, and tissue and serum mineral composition of beef steers. Twenty-seven crossbred steers (479 kg initial shrunk weight) were fed a 90% concentrate diet based on

steam-flaked corn containing 0, 0.5, or 1.0% of diet DM as HA4. Steers were housed in individual pens and fed treatments for 94 days before slaughter. Dietary HA4 did not affect (P > 0.10) overall DMI (8.41, 8.51, and 8.65 ± 0.3 kg/d), ADG (1.31, 1.37, and 1.36 ± 0.06 kg/d), or feed efficiency (6.45, 6.33, and 6.41 ± 0.28) for steers receiving 0, 0.5, and 1.0% HA4, respectively. Carcass marbling score, external fat thickness, LM area, and yield grade were not influenced by treatment (P > 0.10). After slaughter, bone and soft tissue samples were collected from the wholesale foreshank (IMPS 117) for mineral analysis. Sodium concentration in soft tissue was 8% greater when 1.0% HA4 was fed (P < 0.05, quadratic), whereas sulfur and zinc concentrations were increased by feeding 0.5% HA4 and returned to control values when 1.0% HA4 was fed (P < 0.05, quadratic). Bone Ca, Mg, and Na concentrations were reduced (P < 0.05, quadratic) by 0.5% HA4, but concentrations of these minerals were similar between 0 and 1.0% HA4. Aluminum was not detected in soft tissue samples, and bone Al was above the assay limit of detection (5 ppm) in only 1 or 2 animals/treatment. Serum Fe concentration on d 94 was increased by feeding 0.5% HA4 (P = 0.08; quadratic), and serum iron binding capacity on d 94 was increased by feeding either 0.5 or 1.0% HA4 (P = 0.03, quadratic; 408, 515, and 483 ± 24 ug/dL). Data suggest that HA4 may be fed up to 1% of diet dry matter for less than 100 days without an adverse impact on animal performance, carcass merit, or tissue composition.

Key Words: Humic Acid, Iron, Mineral Composition

T365 Impact of dietary K:Na:Mg ratios on the mineral utilization and rumen activity in fistulated non-lactating cows fed diets containing untreated corn silage and Silo-King®treated alfalfa haylage. G. A. Ayangbile*, D. Jones, and J. Horst, *Agri-King, Inc.*, *Fulton, IL.*

The dietary K:Na:Mg ratios influence the systemic acid base balance in dairy cows. The impact of this ratio on the rumen activity and nutrient utilization were evaluated. In a 4 × 4 latin square experimental design, non-lactating cows were fed a TMR containing a) 80% untreated corn silage:20% Silo-King® treated alfalfa haylage (80:20, CS/Hlg), b) 60:40, CS/Hlg, c) 40:60, CS/Hlg, and d) 20:80, CS/Hlg. The K concentration decreased with increased haylage, Na concentration was constant, and Cl and Mg increased as haylage increased. Cows were adapted to the diets for 16 d, followed by 5 d collection. Total DM fecal output was collected, and spot urine samples were collected at random before feeding (0 h) and after feeding (4 h). Blood and rumen fluid were obtained at 0 h and 4 h after feeding. These samples were processed, stored and later analyzed for minerals and VFA. Eletrolytes and Mg digestibilities were higher (P<.05) for the diet with the lowest K. Similar significant increases were observed for other minerals except copper. Absorption and retention of Ca, P and Mg were higher (P<.05) in diets with less K. The rumen ultracentrifuged soluble Na and P were higher for all cows at 0 h (net secretion), but lower after feeding. There was a linear decrease (P<.05) in soluble K, P, Mg, Mn, and Fe at 4 h after feeding. The total daily urine output was lower (P<.05) for cows with less dietary K. Results indicate a lower K:Na ratio and Mg adjustment in a high soluble protein type diet may help improve the mineral utilization and stabilize the mineral balance in the rumen.

Key Words: K:Na:Mg Ratios, Rumen Minerals, Treated Forage

T366 Effect of growth-rate on fat-soluble vitamin, copper and zinc concentrations in the circulation of neonatal calves. B. J. Nonnecke*[1], M. R. Foote[2], R. L. Horst[1], W. R. Waters[1], B. L. Miller[3], T. E. Johnson[3], and M. Fowler[3], [1]*National Animal Disease Center*, *Ames, IA*, [2]*Iowa State University*, *Ames*, [3]*Land O'Lakes Research Farm*, *Webster City, IA*.

Effects of three, targeted growth-rates on plasma concentrations of fat-soluble vitamins and mineral in preruminant calves were evaluated. Calves (9±2 d of age) were assigned randomly to treatments designed to achieve three targeted rates of gain [No-Growth (NG) = 0.0 kg/d, Low-Growth (LG) = 0.55 kg/d, or High-Growth (HG) = 1.2 kg/d] over an 8 wk period. Milk replacer intakes needed to achieve specified growth-rates were estimated using the NRC Nutrient Requirements of Dairy Cattle calf model computer program. All calves were fed a 30% CP, 20% fat, MR reconstituted to 14% DM. Diets were formulated to ensure that protein was not limiting. Because vitamin concentrations in the MR were based on DM intake of HG calves, NG and LG calves were supplemented with additional vitamins once weekly to compensate for reduced MR consumption. Growth rates for NG (0.11 kg/d), LG (0.58 kg/d), and HG (1.16 kg/d) calves differed throughout the study. Although vitamin A and D, and zinc concentrations were unaffected (P>.05) by growth rate, vitamin D concentrations increased (P≤0.05) and zinc concentrations decreased (P≤0.05) with time. Throughout the study these concentrations remained within normal ranges for the preruminant calf. Vitamin E and copper were affected by growth rate. At wk8, HG calves had lower (P≤0.05) vitamin E concentrations than LG and NG calves. Copper concentrations were greater (P≤0.05) for HG calves than LG and NG calves from wk4 to wk7. Vitamin E was unaffected by age (P=0.12); whereas, copper decreased (P≤0.05) with age. Concentration ranges for both variables were within ranges considered normal for neonatal calves. Results suggest that growth rate during the neonatal period may influence vitamin E and Cu availability, with vitamin E playing a pivotal role as lipid-phase antioxidant and the latter as a trace element intimately associated with a number proteins, including essential enzymes.

T368 Short term response of lactating cows to the supplementation of high citrus pulp content diets with corn and organic trace minerals. S. C. Salvador, M. N. Pereira*, J. F. Santos, L. Q. Melo, and M. L. Chaves, *Universidade Federal de Lavras*, *Brazil*.

Substitution of corn by citrus pulp may reduce the cost of dairy diets. However, differences in ruminal fermentation of these substrates may affect animal performance and the economic efficiency of dairy production. This experiment evaluated the response of lactating cows to the inclusion of finely ground mature flint corn to pelleted citrus pulp diets. Treatments with corn contained 10% corn and 24% citrus pulp while citrus diets contained only 33% citrus pulp as the energy concentrate. The complete substitution of inorganic sources of Cu, Mn, Se, Zn and Cr by organic sources was simultaneously evaluated. Four corn silage based diets were generated by a factorial arrangement of the two factors. Sixteen cows received the treatments in 4 4x4 Latin

squares with 21 d periods. The effect of substituting inorganic by organic mineral sources was not conclusive. Daily dry matter intake was 19.4 kg for citrus diets and 20.5 kg with corn (P=0.03). Intake of digestible organic matter was increased by corn supplementation (P<0.01). There was a trend for a decreased fractional rate of *in situ* ruminal degradation of corn silage dry matter (P=0.11) and for increased size of the indigestible fraction (P=0.15) for diets with corn, suggesting that forages degradation did not determine intake. Milk production was 27.5 kg for citrus and 28.4 kg with corn (P=0.04). Corn supplementation increased milk protein production and content (P=0.03) and had no effect on fat secretion (P>0.24). The concentration of purine derivatives in urine was numerically greater for the diets in which corn partially substituted citrus pulp. Diets formulated exclusively with citrus pulp may function when milk payment is based on volume, but some corn starch inclusion seems to be desirable when milk solids is valued.

T369 Effects of trace mineral sources on bioavailability and function in dairy cattle. B. J. Thering*[1], R. M. Ehrhardt[1], M. Vazquez-Anon[2], J. D. Richards[2], and T. R. Overton[1], [1]*Cornell University*, *Ithaca, NY*, [2]*Novus International*, *St. Louis, MO*.

Multiparous Holstein cows (n=30) were used to determine effects of trace mineral source on bioavailability, functional proteins, and performance. All cows were fed a basal diet formulated to meet NRC (2001) requirements for Zn (47 ppm), Cu (11 ppm), Mn (43 ppm; excess) and Se (0.27 ppm) from feedstuffs and inorganic sources beginning 3 wk prior to the experiment. Following covariate data collection, cows were assigned to one of three treatments and diets were top-dressed with either a rice hull carrier (NRC) or one of two organic trace mineral plus biotin mixtures providing 322 mg Zn, 150 mg Cu, 130 mg Mn, 3.78 mg Se, and 20 mg of biotin per day for 4 wk. One mixture was MINTREX® organic trace minerals (Mintrex) and the other (AA-complex) was Met and Lys complexes of trace minerals, Se-yeast, and biotin. Liver Cu concentrations tended to be increased for cows fed Mintrex and AA-complex compared to NRC following 4 wk (481, 539, 562 ppm; P<0.10) and overall liver Se concentrations tended to be increased by Mintrex and AA-complex compared to NRC (1.49, 1.89, 2.09 ppm; P<0.10), but overall liver Mn and Zn were not affected by treatment. Metallothionein mRNA in liver was increased at wk 1 for cows fed Mintrex (P<0.05) and unchanged in cows fed AA-complex or NRC. Cows fed Mintrex had higher milk Mn during wk 4 compared to NRC (17.6, 24.0, 20.1 ug/kg; P<0.04). Whole-blood Se was increased in cows fed Mintrex compared to NRC (19.9, 21.4, 21.1 µg/dL P<0.05). Treatment did not affect plasma and liver superoxide dismutase and glutathione peroxidase. Milk yield and DMI were not affected by treatment, but cows fed Mintrex had increased (P<0.05) milk fat (3.48, 3.81, 3.51%), true protein (3.12, 3.20, 3.14%), and total solids (12.1, 12.5, 12.2%). Overall, supplementation with both forms of organic trace minerals resulted in increased bioavailability, but Mintrex supplementation further increased liver MT expression and milk component content compared to either the control or AA-complex treatments.

Key Words: Trace Mineral, Bioavailability, Dairy Cow

T370 Milk yield and reproductive performance in Holstein cows supplemented with Chromium in early lactation. B. Lavín-Garza[1], A. Garza[2], M. Daccarett[3], F. R. Valdez[4], C. A. Meza-Herrera[5], and R. Rodríguez-Martínez*[6], [1]*Beta Santa Mónica*, *San Pedro, Coahuila, México*, [2]*Beta San Gabriel*, *Francisco I. Madero, Coahuila, México*, [3]*Private Consultor*, *Madera, CA*, [4]*Kemin Agri. Food Norteamerica Inc.*, *Des Moins, IA*, [5]*Unidad Regional Universitaria de Zonas Áridas-Universidad Autónoma Chapingo*, *Bermejillo, Dgo., México*, [6]*Universidad Autónoma Agraria Antonio Narro Unidad Laguna*, *Torreón, Coah., México*.

Chromium is an essential mineral in diets for humans and laboratory animals because it is an active component of the Glucose Tolerance Factor and its effect on milk yield and reproductive performance in cows has been reported, both in multiparous as well as on primiparous cows. However, reports regarding its function are contradictories denoting a better milk yield and reproductive performance in primiparous than multiparous cows. The aim of this study was to evaluate Cr supplementation upon milk yield and reproductive performance during early lactation in dairy cows. The study was carried out in Northern Mexico (25° NL, 102° WL, 1,100 m). A total of 147 cows were assigned to four groups: 1) PCr, (n=36, primiparous cows) and 2) MCr (n=39, multiparous cows), both supplemented with 10 mg Chromium essential base (KemTRACE Cr 0.04% Kemin Industries, Des Moines, Iowa, USA) mixed in the total mixed ration, and 3) PnCr, (n=38) and 4) MnCr, (n=34), primiparous and multiparous cows, respectively, both without Cr supplementation. Response variables considered total milk yield per cow per day (TMY), peak milk yield (PMY), days to peak milk yield (DPMY), days at first IA (DIA), and number of services per conception (SPC). Variables were recorded and analyzed by the Proc GLM of SAS. No Differences (P>0.05) in PMY between PCr AND PnCr occurred (41.0 vs 40.3 l), but MCr-cows had higher (P<0.01) PMY than MnCr (62.9 d vs 57.6 d). A decreased (P<0.01) DPMY was observed in PCr-cows with respect to PnCr-cows (70.6 d vs 100.7 d), but were similar (P>0.05) in both primiparous groups. TMY and DIA were similar (P>0.05) in both supplemented and non-supplemented primiparous and multiparous cows. SPC was lower (P<0.01) in PCr with respect to PnCr (1.6 vs 2.4), while differences between MCr and MnCr groups did not occurred. These results support the importance of Cr supplementation in dairy cows, upon milk yield and reproductive performance, especially in primiparous cows managed under intensive conditions.

Key Words: Chromium, Milk Yield, Reproductive Performance

T371 Blood mineral, hormone, and osteocalcin responses of multiparous Jersey cows to an oral dose of 25-hydroxyvitamin D_3 prior to parturition. M. S. Taylor*, K. F. Knowlton, M. L. McGilliard, and J. H. Herbein, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Increasing blood calcium (Ca) prior to parturition could attenuate the severity of periparturient hypocalcemia. Jersey cows tend to be susceptible to peripartutient hypocalcemia, therefore our objective was to evaluate the effects of a prepartum oral dose of vitamin D_3 (D_3) or 25-hydroxyvitamin D_3 (25-OH) on factors associated with peripartum blood Ca regulation in Jersey cows. Twenty-seven multiparous Jersey cows were randomly assigned to receive an oral bolus containing corn starch (control) or corn starch plus 15 mg of 25-OH or 15 mg of D_3 at 6 d prior to expected parturition. Cows were maintained in individual

box stalls from 20 d prior to parturition and fed a common diet. Jugular blood samples were collected at -14, -13, -5, -4, -3, -2, -1, calving, 1, 3, 5, 7, 9, 11, 13, 28, 56, and 84 d. After calving cows were housed in a free-stall barn and consumed a common diet. Colorimetric assays were used to analyze Ca, P, and Mg concentrations in serum. Osteocalcin (OC), an indicator of bone formation, was determined using a competitive immunoassay. Serum 25-hydroxyvitamin D_3 and parathyroid hormone (PTH) were determined only in samples obtained from -5 through 13 d. Blood Ca, P, and Mg decreased around the time of calving and then increased over time. Serum OC was higher in second lactation cows compared with cows entering their third or fourth lactation. Serum 25-hydroxyvitamin D_3 was higher for cows dosed with 25-OH (119.0 pg/ml) compared with those dosed with D_3 (77.5 pg/ml) or control (69.3 pg/ml). Cows dosed with 25-OH tended to have lower serum PTH concentration, but treatments did not affect serum Ca, P, or Mg. Although results indicated a 60% increase in serum 25-hydroxyvitamin D_3 due to a single oral dose of 25-OH prior to calving, the amount administered in this study apparently was not sufficient for initiation of any improvement in Ca homeostasis at parturition.

Key Words: Calcium, Osteocalcin, Cow

T372 Changes in phosphorus metabolism of ruminants fed with different cation anion balances and proportions of roughage and concentrate. M. S. V. Salles[1], M. A. Zanetti[2], T. M. Ribeiro[2], and S. F. M. Bonilha*[1], [1]*Agência Paulista de Tecnologia dos Agronegócios*, *Assis, São Paulo, Brazil*, [2]*Faculdade de Zootecnia e Engenharia de Alimentos - USP*, *Pirassununga, São Paulo, Brazil*.

There is an increasing environmental concern about P excretion from feedlot cattle to the environment. As dietary cation anion balance (DCAB) may change mineral retention, research leading to appropriate DCAB can help minimize such impact. Thus, two experiments were carried out in the FZEA/USP (Brazil) aiming to access DCAB effect in diets with different proportions of roughage and concentrate on the phosphorus metabolism of young ruminants. On each experiment, 24 Holstein calves (91.43 ± 12.44 Kg of average BW for the first and 117.62 ± 20.88 for the second experiment) were randomly allotted to individual cages and fed during 35 days the following treatments: DCAB of -123, +218 and +341 mEq/kg of DM, in a diet of 60% of roughage (corn silage) and 40% of concentrate (60R40C) in the first experiment and DCAB of -127, +207 e +397 mEq/kg of DM in a diet of 40% of roughage and 60% of concentrate (40R60C) in the second experiment. Ionic coefficients were achieved through addition of ammonium sulphate or sodium bicarbonate. Balance of P was determined by total feces and urine collection during five days. All P determinations were carried out through a colorimetric method (725 nm reading). Data were analyzed in a completely randomized design using PROC GLM of SAS. Orthogonal polynomial contrasts were used to partition treatment effects, and adopted the significance level of P<0.10. Results are presented on table 1. The higher P retention occurred in DCAB +341 with diet 60R40C and in DCAB +207 in diet with 40R60C; however, the diet that excreted less P was with DCAB +341 with diet 60R40C (5.68 g/day).

T374 Cobalt/vitamin B_{12} status of embryo donor ewes, but not recipients, affects neonatal lamb behavior. C. M. Dwyer*, C. J. Ashworth, J. J. Robinson, J. A. Rooke, T. G. McEvoy, and L. M. Mitchell, *SAC*, *Edinburgh, UK*.

Earlier reports indicate that lambs born to ewes sub-clinically deficient in cobalt/vitamin B_{12} during pregnancy are slow to stand and suck and have increased morbidity and mortality. These problems are not prevented by cobalt supplementation during mid to late pregnancy, suggesting that they originate during early development. The aim of this study was to distinguish between the effects of cobalt/vitamin B_{12} status of ova and of the recipient ewe on lamb behavior using reciprocal embryo transfer. Ewes from cobalt-deficient farms were either untreated (-Co, n=82) or were given an intra-ruminal cobalt-containing bolus 30 days before embryo transfer (+Co, n=82). Day 6 embryos were recovered from 33 superovulated -Co or +Co ewes and transferred singly to -Co or +Co recipient ewes. Lamb behavior (n=48 lambs) was recorded by focal observation at birth and during the first 3 days of life by scan sampling at 2-hourly intervals. Data were analysed by linear mixed models using natural log transformations of behavior data that were not normally distributed. Circulating concentrations of vitamin B_{12} on the day of ovum recovery were higher in +Co than -Co donors (P<0.001). Concentrations of vitamin B_{12} were lower in -Co compared to +Co ewes during pregnancy (P<0.001) and in lambs born to -Co compared to +Co ewes at birth (-Co=543 pmol/l, +Co=1805 pmol/l s.e.d.=92.1, P<0.001). There was no effect of donor or recipient cobalt/vitamin B_{12} status on lamb birth weight, on lamb behavior immediately after birth, on mean ewe-lamb distance during the first 3 days of life, or on any aspect of ewe behavior. However, lambs from +Co donors were more active than lambs from -Co donors; they stood more frequently (% observations active: +Co donor=29.6, -Co donor=22.0, s.e.d.=2.4, P<0.01), were more frequently observed interacting with their mother (% observations: +Co donor=6.3, -Co donor=3.1, s.e.d.=1.2, P<0.01) and spent more time exploring their

environment (% observations: +Co donor=16.6, -Co donor=6.9, s.e.d.=2.3, P<0.001). These data indicate that nutrient status prior to mating and during the early cleavage stages of embryo development affects lamb behavior.

T375 Effects of maternal nutrition and selenium supply on visceral organ mass of pregnant ewe lambs. J. J. Reed*[1], T. L. Neville[1], K. A. Vonnahme[1], P. P. Borowicz[1], J. B. Taylor[2], D. A. Redmer[1], J. S. Luther[1], C. J. Hammer[1], L. P. Reynolds[1], and J. S. Caton[1], [1]*Center for Nutrition and Pregnancy, Animal and Range Science Department, North Dakota State University*, *Fargo*, [2]*USDA-ARS, U. S. Sheep Experiment Station*, *Dubois, ID*.

To examine effects of maternal nutrient restriction or excess and dietary Se on maternal visceral organ mass, 82 pregnant Rambouillet ewe lambs (52.2 ± 0.8 kg) were allotted randomly to one of 6 treatments in a 3 x 2 factorial design. Groups included plane of nutrition (60% [RES], 100% [CON], and 140% [HIGH] of requirements) and dietary levels of Se (adequate Se [7.4 µg/kg BW] vs. high Se [85 µg/kg BW]; from Se enriched yeast). Selenium treatments were initiated at breeding and nutritional treatments on d 40 of gestation. All diets were fed once daily in a complete pelleted form (36.5% beet pulp, 22.3% alfalfa meal, 16.2% corn, 18% soybean hulls, and 7.0% soybean meal; 14.4 % CP, 2.63 Mcal ME/kg; DM basis). Within 24 h after parturition, ewes were necropsied and tissues harvested. Empty maternal BW was least ($P < 0.01$) in RES, intermediate in CON, and greatest in HIGH. Selenium supplementation did not alter empty maternal BW. Mass (g) of the rumen, reticulum, omasum, abomasum, liver, pancreas, spleen, omental fat, kidney, and perirenal fat were least ($P < 0.01$) in RES, intermediate in CON, and greatest in HIGH ewes. When expressed as g/kg of empty BW, the responses to treatment differed; for example, for abomasum, jejunum, and large intestine, RES had greatest ($P < 0.01$), CON intermediate, and HIGH the least. Supplemental Se increased ($P < 0.10$) ruminal, abomasal, and small intestinal mass (g/kg empty BW) compared with adequate Se. No other differences in visceral organ mass were observed in response to Se supplementation. These data indicate that maternal nutrition has large impacts on visceral organ mass and that Se supplementation at supranutritional levels alters the mass of some gastrointestinal organs in pregnant ewe lambs.

Key Words: Maternal Nutrition, Selenium, Visceral Organ Mass

Animal Behavior & Well-Being - Livestock and Poultry II

377 Cross ventilation in commercial livestock trailers shows promise for improving comfort, reducing weight loss and reducing environmental contaminants. T. H. Friend*, N. M. Giguere, and P. D. Krawczel, *Texas A&M University*, *College Station*.

A practical method of creating cross ventilation in commercial livestock trailers is being developed and evaluated. An initial series of trials determined traveling at highway speeds generated winds only ranging from 1 to 5.6 kmph in the commercial livestock trailers. Subsequent trails found that simulated environmental contaminates (smoke) could be cleared six times faster from a 5.2 × 2.4 m compartment of a semi trailer traveling 89 kmph using cross ventilation created by three externally mounted 12.5 × 10 cm (W × D) intake scoops facing forward, and another set of three exhaust scoops mounted on the opposite side of the trailer facing back. The efficacy of creating cross ventilation in the zone between the deck and the bodies of cattle was then investigated in two cool-weather trials, each with a ventilated and a control trailer transporting 80 calves to the same destination. Calves averaged 275 kg, came from the same source, and transport averaged 11.5 h in duration. Fifty-three 14 × 14 × 7 cm (L × W × D) scoops were mounted on the lowest set of two punches (25 cm above deck) on alternate panels (80 cm intervals) of every compartment in the ventilated trailer. The scoops on one side of the trailer were set as intakes while those on the opposite side were oriented to exhaust air. Temperature within the cross-ventilated trailer ranged from 0 to 4°C lower than in the control trailer, with the differential highly dependent on the speed and direction of prevailing winds. Ammonia concentrations averaged 35.5% lower in the ventilated trailer. Calves in the ventilated trailer had an average weight loss of 4.7% while calves in the control trailer lost 5.8%. Sodium concentrations were elevated ($P > 0.05$) in the non-ventilated calves 8.5 h post transport indicating greater dehydration in the non-ventilated calves. Creating cross ventilation through the use of external air scoops has the potential to improve the well-being and health of livestock, and merits further research.

Key Words: Transportation, Ventilation, Cattle

378 Genetic basis of different effects of chronic intermittent social stress on immune function and survivability in laying hens. A. G. Fahey*[1,2], R. M. Marchant-Forde[2], and H. W. Cheng[2], [1]*Purdue University*, *West Lafayette, IN*, [2]*USDA-ARS*, *West Lafayette, IN*.

Chronic social stress has a large impact on animals' susceptibility to disease. This study was designed to examine the effects of genetic selection and genotype-by-environmental interactions on chicken immune parameters and longevity. Chickens from HGPS (selected for high production and survivability, also called KGB, kind gentle birds previously) and DXL (Dekalb XL, a commercial strain) were used in this study. Chickens were housed in 8 bird cages (213 cm^2/bird) from 34 - 45 wks of age. During the test period, two birds were moved between cages within the same genetic line to create a social instability called chronic intermittent social (CIS) stress. At 45 wks of age, blood samples were collected from the bronchial vein within two minutes after removing the chickens from their cages for immunological and corticosterone analysis from ten cages per line. Following euthanasia, body weight and several organ weights were measured. Results showed that DXL hens had a heavier adrenal weight (both absolute and relative weight) ($P<0.05$) than HGPS hens, while there were no differences in the body weight and weights of the spleens and livers between DXL and HGPS hens ($P>0.05$). Compared to the HGPS hens, DXL hens also had a higher portion of $CD8^+$ cells ($P<0.01$), resulting in a lower $CD4^+$:$CD8^+$ ratio ($P<0.05$). There were no significant differences for plasma concentrations of corticosterone between the hens from DXL and HGPS lines ($P>0.05$). Results also showed that DXL hens had a higher mortality than HGPS hens ($P<0.01$). The data suggests that, compared to HGPS hens, chronic intermittent social stress may adversely affect the immune function and survivability of DXL hens. The results indicate that, similar to other animals, there are heritable components in chickens' disease resistance and stress response, which is regulated differently by genotype-by-environment interactions.

Key Words: Stress, Hens, Immune

379 Different effects of individual identification systems on chicken well-being. R. L. Dennis*[1,2], A. G. Fahey[1,2], and H. W. Cheng[1], [1]*Livestock Behavior Research Unit, USDA-ARS*, *West Lafayette, IN*, [2]*Purdue University*, *West Lafayette*.

Individual identification is a common method used in animal research. This study was designed to examine if various common identification systems, i.e., leg bands (LB), wing bands (WB), neck tags (ST), and livestock marker (LM), have different effects on hens' behavioral and physiological homeostasis. At 18 wk of age, hens were paired in all combinations of treatments and control (C, unmarked hens; n=10) in a novel cage for 5 trials of 1 hr each to test the effects of markers on social behaviors. Increased feather pecking (FP) was exhibited in WB hens compared with C hens ($P<0.10$) but not in LB, ST or LM hens ($P>0.10$). Increased FP in hens with WB may suggest an increase

in social stress and may lead to increased feather and body damage. No effect of identification treatment was evident on frequency of aggressive behaviors (P>0.10). At 20 wk of age, absolute fluctuating asymmetry (FA), but not relative FA, of shank length and width was more significant in LB hens (P<0.05), and tended to be significant in WB (P<0.10), but not in ST or LM hens, compared to C hens. Asymmetry of the shank is often a result of high stress levels, including social stress. Body weight (BW) measures at 20 wk showed hens with LB, but not WB, ST or LM, were significantly lighter than C hens (P<0.05), possibly as a result of decreased access to resources, increased metabolism or decreased appetite due to elevated stress. Increased FA and decreased BW are evidence of a disruption of the hens' physiological homeostasis due to increased stress. Leg banded hens also tended to have lower percent heterophil (P<0.10), indicative of increased stress and reduced immunocompetence. Our findings provide clear evidence of the negative effects of WB and LB systems on hens' well-being, altering both physiological and behavioral homeostasis, possibly leading to misinterpretation of experimental results.

Key Words: Identification System, Feather Pecking, Hen

380 The relationship between residual feed intake and feeding behavior in growing heifers. G. M. Bingham*, T. H. Friend, G. E. Carstens, and P. A. Lancaster, *Texas A&M University*, *College Station*.

The objective of this study was to determine if feeding behavior is correlated with feed efficiency traits in growing heifers. Individual dry matter intake (DMI) was measured in Brangus heifers (n = 115) fed a roughage-based diet (ME = 2.1 Mcal/kg) for 70 d using Calan gate feeders (6 heifers/pen). Residual feed intake (RFI) was computed as the residuals from linear regression of DMI on mid-test $BW^{0.75}$ and average daily gain (ADG), and heifers with the highest (n = 18) and lowest (n = 18) RFI were identified for feeding behavior measurements. During wk 5 through 8 of the 70-d feeding trial, continuous video recordings were obtained for all heifers. Video images for 2 sets of 4 24-h periods, 2 wk apart, were analyzed for the selected animals. All occurrences of feeding were timed and counted per day, and the 8 24-h periods averaged to derive mean head-down duration and meal frequency per heifer. Head-down duration (HD) was defined as the total min per day the animal's head was down in the feed bunk. A meal was defined as to include all visits an animal made to the feed bunk that were separated by less than 5 min. The resulting data were compared between the 2 groups analyzed using one-way ANOVA. Average RFI scores for low and high RFI heifers were -1.03 and 1.00 ± 0.33 kg/d. Low RFI heifers consumed 22.5% less (P < 0.001) DMI, but had similar BW and ADG compared to high RFI heifers. Heifers with low RFI spent more time (P < .05) eating (152 vs 124 ± 10 min/d), but had similar meal frequencies (14.78 vs 15.11 ± 0.54 meals/d) compared to high RFI heifers. Pearson correlation coefficients were used to determine the relationship between RFI and HD and meal frequency. There was a negative correlation (r = -0.39, P < 0.05) between RFI and HD, but meal frequency was not correlated with RFI (r = 0.05). These data suggest that RFI is moderately correlated to HD but not meal frequency in growing calves.

Key Words: Residual Feed Intake, Feeding Behavior, Cattle

381 The effect of the autosort system on swine behavior. A. E. DeDecker*, J. M. Suchomel, and J. L. Salak-Johnson, *University of Illinois*, *Urbana*.

Limited data exist on the impact that autosort, a relatively new, behavior-based production system has on pig well-being. The objective of this study was to examine the effect various autosort floor layouts have on the behavior and well-being of wean-to-finish pigs. At weaning, 622 ± 13 pigs were randomly assigned to a water pen (WP; 20% floor space), food court (FC; 40% floor space), or fast lane (FL; 12.5% floor space per zone) autosort layout, or conventional large pen (CV). Behavior data was collected by live observations during a 3-week training period and at loading. Continuous video-records were used for scan sampling to determine the total number of animals performing a specific behavior at a specific time. Specific behaviors for loading and training were observed and recorded. Data were analyzed using Chi-Square and a MIXED procedure of SAS with repeated measures. During training the WC pigs went in and out of the scale at a faster rate than did FC or FL pigs (P≤0.05). The FC pigs spent more time (P=0.02) engaged in aggressive encounters than did pigs in the FL. The FL pigs hesitated more (P=0.03) upon entering the scale than did pigs in the WC, whereas the FC pigs hesitated more (P = 0.03) upon entering the scale compared with the FL pigs. The time spent eating or drinking and the number animals engaged in these behaviors at one time was significantly affected by treatment. For example, time spent eating among 1-5 pigs was greater (P≤0.05) for the CV pigs than for the FC, WC, or FL pigs, whereas time spent eating among >10 pigs was greater (P<0.0001) in FC layout than in the CV pens. Vocalization and prod use was greater (P≤0.01) among CV pigs compared to WC, FC, or FL at loading. FC had a greater number of lame animals when being removed from the pen than did CV (P=0.01). The number of rears at loading were greater (P<0.001) for CV pigs than WC pigs. The CV pigs had greater difficulty loading onto the truck than did pigs from FL (P=.05) and WC (P=0.02). These data indicate that autosort layouts can affect various behaviors, ease of handling, and loading throughout the wean-to-finish phase, thus using behavior to optimize these layouts is important.

Key Words: Autosort, Behavior, Well-being

382 Movements of translocated desert mule deer in Sierra del Carmen, Coahuila, Mexico. J. L. Martinez* and L. A. Harveson, *Sul Ross State University*, *Alpine, TX*.

Population of desert mule deer (Odocoileus hemionus crooki) have shown declines in the past, to an extent where for several decades they were considered to be in danger of extripation. The goal of this research is to restore population density of desert mule deer to the Sierra Maderas del Carmen of Mexico. Near 200 mule deer will be captured using net-guns and helicopter and transported to Sierra del Carmen. 40 to 50 deer will be randomly selected for our study and mortality sensitive radio-transmitters will be affixed to each mule deer, they will be monitored 3 to 5 times a week. Movements will be monitor to survey site fidelity and post release movements. Home range and movement rate comparisons will be made between seasons, sexes, and age classes. We are expecting 75% of the sample size to remain (site fidelity) within 15 kilometers from the release site. Mortality of radio-collared desert mule deer will be determined by mortality-sensitive transmitters, each mortality will be recorded and investigated. Habitat maps will be generated from black and white

and color infrared photographs or from concurrent SRSU research projects. Vegetation composition will be collected from transects. Species composition, canopy coverage, and other physical attributes will be used to describe habitats. Habitat preference will be determined using habitat selection ratios. Results from habitat analysis will identify key habitats relative to forage production, escape cover, and fawning habitat. The results of this study will aid future restoration efforts for desert mule deer. By the end of the study there will be a geographical representation of the habitats for mule deer of the Sierra del Carmen that will allow resource managers and landowners to establish realistic population objectives to minimize predator-specific mortalities, plus knowledge in the identification of crucial habitat for fawning, forage and escape habitat. Finally, this study will generate a management guideline for desert mule deer in Northern Mexico.

Key Words: Mule Deer, Site Fidelity, Maderas del Carmen

383 Exercise increases bone density in the joints and limbs of gestating stall-housed gilts. E. L. Schenck*[1], K. A. McMunn[2], D. Rosenstein[3], B. D. Nielsen[3], B. T. Richert[1], J. N. Marchant Forde[2], and D. C. Lay Jr.[2], [1]*Purdue University*, *West Lafayette, IN*, [2]*USDA-ARS-MWA*, *West Lafayette, IN*, [3]*Michigan State University*, *East Lansing*.

Lameness in breeding age gilts and sows is a major cause of early culling, causing increased economic loses and welfare concerns. Stall-housed sows tend to have more joint, foot and leg problems than group-housed sows. The aim of this study was to determine if exercise would decrease lameness, increase bone density, and increase muscle mass of gilts that were exercised versus not exercised during gestation. The study was composed of three treatment groups; control (C, n=8, no exercise), high exercise (H, n=5, 121.9 m 2 d/wk and 426.7 m for 3 d/wk) and low exercise (L, n=5, 121.9 m 5 d/ wk). All gilts were stall-housed for the duration of gestation and H and L gilts were exercised from d 35 to 110 of gestation. Blood was taken on d -14, 35, 56, and 110 of gestation and at the end of lactation via jugular veni-puncture and collected serum was analyzed for osteocalcin by an enzyme immunoassay (EIA). At the end of lactation, sows were sacrificed and the left fore- and hind limbs were harvested. Specific muscles and bones from the fore and hind limbs were dissected out, weighed, and removed. Hooves were scored based on number and severity of lesions, cracks, and bruises. The patella and calcaneous bone density was determined by dual energy x-ray (DEX) scans. All other bone mineral density was determined by computed tomography (CT). Osteocalcin concentration in the L group was greater ($P<0.05$) than C at d 35 and 56 and tended to be greater ($P<0.1$) at d 110. There was no difference in hoof scores, muscle/body weight ratio, or in bone mineral density of the patella or calcaneous. Bone density (mg/cm3) was greater ($P<0.05$) in the femur and the humerus of the L group compared to that of the C group and tended ($P<0.1$) to be higher in the femur compared to the H group. The bone density of the radius of the H group was greater ($P<0.05$) than both L and C groups. Scapular and proximal humerus articular cartilage scores of the L group were greater ($P<0.05$) than both H and C groups. Exercise appears to increase bone density, however the relationship with exercise amount and intensity is not clear at this point.

Key Words: Swine, Lameness, Bone Strength

384 Effects of pre-weaning strategies on blood metabolites, behavior, and performance of beef calves. H. T. Boland*[1], G. Scaglia[1], W. S. Swecker, Jr.[2], and N. C. Burke[2], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*Virginia-Maryland Regional College of Veterinary Medicine*, *Blacksburg*.

Traditionally, beef calves are abruptly weaned from their dams at 6 to 8 mo of age. Alternate weaning strategies have been suggested to reduce stress and improve performance of post-weaned calves. Two alternate weaning strategies were compared to abrupt weaning over a 2 yr period in spring-born, Angus-cross steers (yr 1, n=48; yr 2, n=54). Steers (IBW: yr 1=241 ± 5 kg, yr 2=242 ± 3 kg) were allotted to three treatments 7 d before weaning: fence-line (FL, separated from dam by a fence), nose clips (NC, placement of anti-suckling device and remained with dam), or control (CTRL, remained with dam and abruptly separated on d 0). On d 0, all steers were transported (170 km) away from their dams, held in a dry-lot with hay and water overnight, and placed in pastures on d 1. Steers were maintained in their pre-weaning treatment groups for a 42 d backgrounding period. Blood was collected by jugular venipuncture on d -7, 0, 1, 7, and 42. Serum was analyzed for NEFA, blood urea nitrogen (BUN), creatine kinase (CK), and glucose. Pedometers recorded steps/d for 7 d pre-weaning and 6 d post-weaning. Average daily gain was calculated from weights on d -7, 0, 1, 14, 28, and 42. Data were analyzed using PROC MIXED with Tukey's adjustment for means separation. Year was the repeated measure and paddock was the experimental unit. Model included year, day, treatment, and treatment x day interaction. There was a year effect for NEFA, BUN, and glucose ($P<0.05$). Within CTRL and NC treatments, CK was highest ($P<0.05$) on d 1, while FL steers had similar levels of CK on d -7 and 1. On d 0, NC steers had higher NEFA concentrations ($P<0.05$) than FL or CTRL steers. Fence-line steers took more ($P<0.05$) steps than NC steers on d -7 and -6. Over the 7 d pre-weaning period, NC calves took the least ($P<0.05$) number of steps. Post-weaning, CTRL steers took more ($P<0.05$) steps overall than FL or NC, due to more steps/d taken on d 1 and 6. Overall, ADG was lowest ($P<0.05$) for NC calves. The use of nose-clips in this study did not seem to benefit calves while FL management may be less stressful than abrupt weaning.

Key Words: Stress, Weaning, Behavior

385 Effect of stocking density on cow comfort indices. P. D. Krawczel*[1,2], H. M. Dann[1], C. S. Ballard[1], and R. J. Grant[1], [1]*W.H. Miner Agricultural Research Institute*, *Chazy, NY*, [2]*The University of Vermont*, *Burlington*.

The objective of this study was to evaluate the effect of stocking density (100, 113, 131, and 142%) on cow comfort index (CCI; # of cows lying in stalls (# of cows lying or standing within a stall)$^{-1}$) × 100), stall standing index (SSI; # of cows standing in stalls (# of cows lying or standing within a stall)$^{-1}$) × 100), and stall use index (SUI; # of cows lying in stalls (total # cows - # of cows eating)$^{-1}$) × 100) during a 24-h period, a 4-h peak lying period (0000 to 0400), and a 1-h period after milking. Holstein cows (n = 136) were assigned to 4 pens within a freestall barn in a 4 × 4 Latin square design. At 100% stocking density, a stall and headlock was provided for each cow and the greater densities were simulated by denying access to stalls and headlocks. Indices were calculated from video data recorded continuously for 2 d after 5 d of acclimation to each stocking density and analyzed with 10-min scan samples for the percentage of cows

lying in stalls, standing in stalls, standing in alleys, and feeding. During the 24-h period, treatment tended ($P = 0.07$) to affect CCI and SSI; however, SUI decreased at higher stocking densities ($P = 0.02$). Treatment effects were observed in CCI, SSI, and SUI between 0000 and 0400 ($P < 0.05$). Treatment did not affect indices during the 1 h after milking ($P > 0.1$). The increased percentage of cows standing in alleys at higher stocking densities ($P < 0.001$) indicated reduced comfort, which was only incorporated into SUI. These results indicated that increased stocking densities affected cow comfort indices; SUI more accurately reflected cow comfort on a pen level at higher stocking densities; and measuring SUI during peak lying was recommended for an accurate assessment of comfort on a pen level.

Table 1. Differences in CCI, SSI, SUI, and standing behavior at each stocking density during a 24-h period and between 0000 and 0400

Time	Variable	100%	113%	131%	142%	SE
24 h	CCI, %	80.7	81.9	82.9	82.6	1.1
	SSI, %	19.3	18.1	17.0	17.3	1.1
	SUI, %	70.1^{a}	70.2^{a}	68.6^{ab}	66.3^{b}	1.2
	Standing, %	10.9^{c}	12.0^{c}	14.4^{b}	16.5^{a}	1.2
0000 to 0400	CCI, %	85.4^{ab}	86.7^{a}	86.3^{ab}	84.5^{b}	1.2
	SSI, %	14.6^{ab}	13.3^{b}	13.7^{ab}	15.6^{a}	1.2
	SUI, %	80.3^{a}	79.5^{a}	74.8^{b}	69.6^{c}	1.4
	Standing, %	5.3^{d}	7.4^{c}	11.6^{b}	15.3^{a}	0.5

386 Space requirements of weaned pigs during transportation. M. A. Sutherland*, N. Krebs, L. E. Hulbert, J. S. Smith, and J. J. McGlone, *Texas Tech University*, *Lubbock*.

The space allowances provided to weaned pigs are based on professional experiences of producers. The objective of this research was to establish a first estimate of the space requirements of weaned pigs based on measures of animal well-being. A commercial semi-trailer was fit with compartments that provided 0.05, 0.06 and 0.07 square meters per pig (5.2 ± 0.10 kg) with a constant 100 pigs per compartment on both the upper and lower decks. The trailer was fit with HOBOs to record temperature, humidity and wind speed. Cameras were placed in each experimental compartment to record behavior of the pigs during transport. Prior to transport, blood samples were taken from 4 pigs per compartment for physiology and immune measures and weights and lesion scores were recorded. Pigs were then transported for 2 h to the wean-to-finishing site using the same route for each replication. At the finishing site, blood samples were taken from experimental pigs for physiological and immunological measures, weights, and lesion scores. This experiment was replicated 4 times during winter. Temperature and humidity within the compartments were effected by an interaction between space allowance and deck ($P < 0.001$). Cortisol, neutrophil to lymphocyte ratio and lesion scores were increased ($P < 0.001$) during transport regardless of space allowance, deck or gender. Different space allowances during transport did not influence any performance or physiological measures measured in this study. Increased cortisol concentrations and neutrophil to lymphocyte ratio in transported weaned pigs suggests that these pigs experienced stress, however space allowances within the range of spaces tested did not appear to influence this response. In winter, space allowances of 0.05, 0.06 and 0.07 square meters per pig do not influence pig well-being as measured by body weight changes and physiological measures.

387 Behavior of beef calves weaned by traditional, fenceline and two-step methods. J. M. Siegford*, D. D. Buskirk, and M. K. Sharra, *Michigan State University*, *East Lansing*.

Traditional abrupt weaning of beef calves causes behavioral, physiological, and immunological stresses in calves which may persist for days to weeks. Non-abrupt weaning methods, such as fenceline and two-step weaning, may reduce weaning stress by simulating the natural weaning process by providing calves with maternal contact while nursing is prevented. The effects of three weaning methods on the behavior of calves were compared using direct observations and pedometers equipped with accelerometers and inclinometers. Over two years, 224 Angus-Simmental calves were evenly allocated by weight and sex into three treatments: 1) abrupt-weaned (AW); 2) fenceline-weaned (FW); and 3) two-step-weaned (TW). On day 0 (d 0) calves were prevented from nursing by removing AW dams to remote pastures, placing FW dams and calves across a fence, and fitting TW calves with a plastic nose flap. On d 5, TW and FW dams were moved to remote pastures. Instantaneous observations of behavior were performed each year on 10 calves per treatment every 20 minutes from 0900-1200 and 1400-1700 on d 1 and 6 after weaning. Pedometers recorded activity, standing, lying and number of steps from d 0-10. On d 1, AW calves stepped more, were observed walking more, and were more active ($P<0.01$) than FW and TW calves. On d 1, FW calves stepped more and were observed walking more ($P<0.01$) and were more active ($P<0.05$) than on subsequent days. On d 1, AW and FW calves grazed less than TW calves ($P<0.01$). AW calves vocalized more than TW ($P<0.01$) but not FW calves on d 1. More standing was observed on d 1 than on d 6 ($P<0.05$) but was not recorded by pedometers. Pedometers recorded less lying by AW on d 1 compared to lying by AW on other days. Data from observation and pedometers yielded similar results for active behaviors. However, results differed for standing and lying, likely because pedometers recorded over 24 h while observations were done during the day. Removal of dams on d 5 did not significantly affect behavior of FW and TW calves. Non-abrupt weaning appears less behaviorally stressful on calves.

Key Words: Calf, Stress, Pedometer

388 Prediction of degree of mastitis from repeated measurements of lactate dehydrogenase (LDH) in milk. N. C. Friggens*[1], M. G. G. Chagunda[1], M. Bjerring[1], C. Ridder[2], S. Højsgaard[1], and T. Larsen[1], [1]*University of Aarhus, Faculty of Agricultural Sciences*, *Denmark*, [2]*Lattec I/S*, *Hillerød, Denmark*.

This study aimed to test a model for mastitis detection using a logic that allows examination of time-related changes and a progressive scale of mastitis state (i.e. not using specificity/sensitivity). The model (Chagunda et al., 2006, J. Dairy Sci. 89:2980) produces a Mastitis Risk for each cow, on a scale 0 (completely healthy) to 1 (full blown mastitis). The main input is LDH (µmol/min/l) x milk yield. A test set containing 602 lactations and 849 mastitis cases was used. Proportional samples were collected from each cow at each milking and analysed for LDH and Somatic Cell Counts (SCC). The basis for the health definitions was vet treatment records. A refinement of the health definitions was made using systematic positive deviations in log(SCC) to indicate untreated infections. 2 subsets of cows were identified: mastitic cows and cows completely free of mastitis (healthy controls). The time-series profiles of these 2 groups in a 60-day window around day of vet treatment were examined. Model reliability throughout all stages of lactation and degrees of infection was examined using SCC as a continuous measure of degree of infection. The time-profile for the health controls was flat with a median Mastitis Risk of 0.02. In contrast, the profile of the mastitic cows increased above the control cows baseline from about -6 days, rising to a Mastitis Risk value of 0.20 at day 0, and declining back to the control cow level after treatment. Differences between mastitic and healthy cows were significant from –4 to +2 days from vet treatment. When cases were time-aligned to peak of infection rather than vet treatment there was a much sharper peak to the time-profile of mastitic cows. The median Mastitis Risk at peak was 0.62, the mean was 0.80, and the value of 0.62 had a less than 1% probability of actually coming from a healthy control. Testing against SCC on the whole dataset showed that only 2.1% of all Mastitis Risk values had an error greater than 0.7. This model is as accurate as the best published detection systems and was able to detect significant differences between mastitic and healthy cows 4 days before treatment.

Key Words: Mastitis Detection, Dairy Cow, Time Series

389 Effects of energy balance and *Streptococcus uberis* intrammamary infection challenge on gene expression profiles in bovine mammary tissue. K. M. Moyes*, J. K. Drackley, D. E. Morin, S. L. Rodriguez-Zas, R. E. Everts, H. A. Lewin, and J. J. Loor, *University of Illinois*, *Urbana*.

Cows experiencing severe postpartal negative energy balance (NEB) are at greater risk of developing mastitis than cows in positive energy balance (PEB). Objectives were to compare mammary tissue gene expression profiles during a *Streptococcus uberis* (*S. uberis*) mastitis challenge between lactating cows subjected to feed restriction to induce NEB (n = 6) and cows fed *ad libitum* to maintain PEB (n = 5). All cows had composite SCC <200,000 cells/mL prior to the study, and milk from all quarters was bacteriologically negative. Cows were paired based on parity, DIM, and milk yield. NEB cows were feed-restricted to 60% of calculated NE_L requirements for 7 d, and cows fed PEB were fed the same diet *ad libitum*. At 5 d after feed restriction, one rear mammary quarter of each cow was inoculated (IN) with 5,000 cfu of *S. uberis* (O140J). At 20 h post-IN, before the expected peak in clinical signs, both rear mammary quarters (IN and control) were biopsied for RNA extraction. A 13,257 oligonucleotide (70-mers) array and qPCR were used for transcript profiling. Annotation was based on similarity searches using BLASTN against human, mouse and bovine RefSeq, human, mouse, and bovine UniGene, and bovine TIGR. Cy3- and Cy5-labeled cDNA from mammary tissue and a reference standard were used for hybridizations. Energy balance (NEB vs. PEB) resulted in 347 differentially expressed genes (ANOVA $P < 0.05$) compared with 113 due to infection status (IN vs. control), and 23 genes for the interaction (energy balance × infection status). Among genes downregulated with NEB, Ingenuity Pathway Analysis identified small molecule biochemistry (20 genes), cancer (19), lipid metabolism (15), molecular transport (11), and cell morphology (10) as some of the most enriched molecular functions. Genes upregulated by NEB were associated with cell growth/proliferation (33), cell death (24), gene expression regulation (21), and cell signaling (19). Results indicate that energy balance and intramammary infection alter mammary gene expression.

Key Words: Genomics, Nutrition, Immune Response

390 The effect of negative energy balance on immune response to *Streptococcus uberis* mastitis challenge in dairy cattle during mid-lactation. K. M. Moyes*, J. L. Salak-Johnson, D. E. Morin, J. K. Drackley, and J. J. Loor, *University of Illinois*, *Urbana*.

Fourteen multiparous Holstein cows were used to determine effects of negative energy balance (NEB) on immune response to *Streptococcus uberis* (*S. uberis*) mastitis challenge during mid-lactation. Before the study, milk from all quarters of each cow were bacteriologically negative, with composite SCC < 200,000 cells/mL. Cows were paired based on parity, DIM and milk yield. At ~90 DIM, half of the cows were feed-restricted to 60% of calculated NE_L requirements based on body weight and milk production to induce NEB. Feed restriction lasted 7 d. Control cows were fed the same diet ad libitum (i.e. positive energy balance; PEB). Five d after feed restriction, one rear quarter in all cows was inoculated with 5,000 cfu of *S. uberis* (O140J). Health exams were performed, and jugular blood and aseptic quarter milk samples collected daily until inoculation and every 6 h post-inoculation for 36 h. Blood was analyzed for NEFA, BHBA, triglyceride (TG), glucose, cholesterol, and albumin. Blood neutrophils were isolated for determination of chemotaxis and phagocytosis capabilities *in vitro*. Quarter milk samples were analyzed for SCC and *S. uberis* concentration. Data were analyzed with the MIXED procedure of SAS with repeated measures. All cows developed local and/or systemic signs of mastitis after *S. uberis* inoculation. The NEB cows had higher ($P < 0.01$) blood concentrations of blood NEFA, BHBA, TG and cholesterol and lower ($P < 0.01$) glucose than PEB cows. Heart rate and rectal temperature were lower ($P < 0.05$) in NEB cows than PEB cows. Neutrophil phagocytic capability was greater ($P < 0.05$) in NEB cows than PEB cows. No differences were observed with regards to neutrophil chemotaxis, SCC, or *S. uberis* concentration in milk between groups. Our results suggest that cows subjected to nutrition-induced NEB had an enhanced immune response during mid-lactation.

Therefore, energy balance status might affect immune response to invading pathogens in periparturient cows.

Key Words: Energy Balance, Mastitis, Dairy Cattle

391 Multiplex PCR system for the detection of mastitis-causing pathogens. J. M. St-Pierre*, C. Thibault, and N. Bissonnette, *Agriculture and Agri-Food Canada*, *Sherbrooke, Quebec, Canada*.

Mastitis causes severe economic losses in the dairy industry each year. The need to understand the genetic factors implicated is therefore critical to help prevent the disease. Our project has many features to help determine which factors participate in the host's response to mastitis. The first phase of this experiment is to identify cows that are susceptible or resistant to the illness. As mastitis can be caused by multiple bacteria, the most prevalent ones are Escherichia coli, Staphylococcus aureus, Streptococcus agalactiae, Streptococcus dysgalactiae, Streptococcus uberis and Klebsiella pneumoniae. It has also been reported that Mycoplasma bovis is an important mastitic pathogen, but it is seldom identified because conventional culture methods can take up to 2 weeks and it is believed that it would most likely be a co-infection agent with Streptococci. We have designed a PCR multiplex system that amplifies specific genes for each of the bacterial species mentioned previously. Capillary electrophoresis is used to detect the PCR fragments as each pair of gene-specific primers is coupled to a fluorochrome that is detected by the laser of a genetic analyser. Because of the capacity of the genetic analyser to perceive many colors concurrently we are able to identify all 7 pathogens simultaneously even if they are not supposed to be present in mastitic milk at once. Therefore insuring that if an infection is caused by many microorganisms they will all be detected. The sensitivity of this method can be compared to that of microbiological methods and is more sensitive than a PCR on agarose gel though our test is more rapid than other PCRs because of the multiplexing component. Our system was tested with purified bacterial DNA. Further optimisation for the extraction of DNA directly from milk is required. As the technique is optimised we will be able to identify which animals come in contact with any of these bacterial species and develop or not the disease. This is a crucial step for our understanding of the genetic contribution to the mammary gland's immune system.

Key Words: Mastitis, Multiplex PCR, Pathogen

392 Efficacy of treatment protocols for Gram negative and no growth clinical mastitis in dairy cattle. J. R. Wenz*, *Washington State University*, *Pullman*.

The purpose of this study was to compare the efficacy of intramammary (IMM) ceftiofur hydrochloride (SP) with a protocol of no IMM antibiotics (NT) for the treatment of clinical mastitis with a Gram negative (GN) or (NG) culture result on a 1500 cow commercial dairy. Milk was aseptically collected from the affected quarter(s) of cows with systemically mild clinical mastitis for bacteriologic culture. Even numbered cows received SP (125 mg once a day for 5d). Odd numbered cows received NT. Outcomes evaluated were average days in sick pen (SPD), clinical recurrence in the same quarter 15-60d later (RECUR), loss of quarter (DRIED) and death/culling within 30d (D/C). SPD of cows with a GN culture result in the NT group were fewer than those in the SP group (P<0.0001). No difference was seen in cows with a NG culture result. The % of GN cows with >8 SPD was higher in the SP group than in the NT group (P=0.03), however, there was no difference for NG cows. There was no difference in RECUR or D&C between treatment groups, regardless of culture result. For cows with an NG culture result there were more cows in the NT group with a DRIED outcome compared with those in the SP group (P=0.02), however, there was no difference in GN cows. Results suggest SP treatment did not improve outcomes of cows with mild GN clinical mastitis compared to those receiving NT but may reduce loss of quarter in cows with mild NG clinical mastitis.

Table 1. Outcomes of mild clinical mastitis episodes by treatment and culture result

	GN		NG	
Outcome	NT	SP	NT	SP
SPD	6.0+/-2.1	8.6+/-3.0	7.4+/-5.1	7.5+/-1.8
%SPD>8d	3/27(11%)	11/29(38%)	20/81(25%)	24/85(28%)
RECUR	3/33(9.1%)	4/42(9.5%)	10/88(11%)	9/93(9.7%)
D/C	3/41(7.3%)	5/52(9.6%)	2/104(1.9%)	2/114(1.8%)
DRIED	1/41(2.4%)	2/52(3.8%)	15/104(14%)	6/114(5.3%)

Key Words: Mastitis, Gram Negative, Ceftiofur

393 The effect of uterine infusion of ceftiofur in the immediate postpartum on uterine health in dairy cows. R. G. Bruno*, M. F. Sa Filho, D. F. Resende, F. S. Lima, and J. E. P. Santos, *Veterinary Medicine Teaching and Research Center, University of California Davis*, *Tulare*.

Objective was to evaluate the effect of intrauterine antibiotic treatment on uterine health in dairy cows. Holstein cows, 379, were randomly assigned to no treatment (Control, n=188), or a single uterine infusion (Infusion, n=191) of 500 mg of ceftiofur hydrochloride (Spectramast DC, Pfizer Animal Health) at 2 d in milk (DIM). Cows were categorized as high risk for uterine disease if they had one or more of the following: major assistance at calving, deliver of twins, retained placenta, or milk fever. Uterine discharge was evaluated using the Metricheck (Simcrotech, Hamilton, New Zealand) at 2, 15 and 29 DIM, and classified based on the aspect, color and odor as normal, clinical endometritis and metritis. An aseptic uterine flush was performed at 36 DIM, and recovered fluid was subjected to microbiologic culture and cytological examination. A threshold of 18% of polymorphonuclear leukocytes as proportion of total cells (leukocytes + endometrial cells) in the cytology categorized cows with subclinical endometritis. Ovaries were examined twice by ultrasonography to determine cyclic status at 42 DIM. Data were analyzed using the LOGISTIC procedure of SAS (2001). Infusion reduced (P=0.06) the proportion of high-risk cows that required further antibiotic treatment (27.4 vs 45.8%), but did not influence (P>0.10) median mucus score at 15 (3 vs 4) and 29 DIM (2 vs 2). Incidence of metritis was similar (P=0.88) between treatments and affected 22.5 and 22.9% of Infusion and Control cows, respectively. Treatment did not affect (P>0.10) prevalence of positive uterine culture, Arcanobacterium pyogenes, or of subclinical endometritis, which affected 37% of the cows. High risk cows had greater (P<0.05) incidence of metritis (31.9 vs 16.2%), and cows with metritis were

more likely (P=0.03) to have positive uterine culture (61.0 vs 46.3%). Treatment did not (P=0.15) affect cyclic status at 42 DIM, but cyclic cows were less (P=0.02) likely to have A. pyogenes (7.8 vs 15.6%) and to be positive for subclinical endometritis (29.8 vs 44.5%). Single infusion with 500 mg of ceftiofur did not improve uterine health of dairy cows.

Key Words: Ceftiofur, Dairy Cow, Uterine Health

394 Metabolic profiles of dairy cows that develop metritis. J. M. Huzzey*[1], T. F. Duffield[2], S. J. LeBlanc[2], D. M. Veira[3], D. M. Weary[1], and M. A. G. von Keyserlingk[1], [1]*University of British Columbia*, *Vancouver, Canada*, [2]*University of Guelph*, *Ontario, Canada*, [3]*Pacific Agri-Food Research Centre*, *Agassiz, BC, Canada*.

The aim of this study was to describe the metabolic profiles of Holstein cows with severe metritis (SM; n=12), mild metritis (MM; n=27), and without metritis (n=23). Holstein dairy cows were monitored from 2 wks before to 3 wks after calving. Individual DMI was monitored continuously and serum NEFA, BHBA, calcium and haptoglobin were measured on d -20±5, -6±2, -2±1 and d 0 relative to calving, and then every 3 d until d+21. Vaginal discharge, rated on a 5-point scale, was assessed every 3 d until d+2; these scores and daily rectal temperatures were used to assess metritis severity. Clinical diagnosis of SM and MM was made on d 5.3±1.9 and d 9.1±3.9 after calving, respectively. NEFA levels were higher in the SM and MM cows relative to healthy cows on d-6 (P=0.02). On this day, cows with a NEFA concentration ≥0.3mmol/L were 4.3 times more likely to be diagnosed with severe or mild metritis (P=0.03). The sensitivity and specificity for this predictive threshold were 40% and 87%, respectively. There were no differences in BHBA among health groups. Calcium levels were lower in the SM cows, particularly between d+3 to d+12 after calving (P≤0.02), likely because DMI was lower in this group compared to healthy cows (P<0.01). Haptoglobin was 0.51g/L higher in the MM and 0.63g/L higher in the SM cows relative to the healthy animals between d0 and d+12 (P<0.05), with peaks on d +3 for the healthy and MM cows and on d+6 for the SM cows. On d+3 cows with a haptoglobin concentration of ≥1g/L were 6.3 times more likely to develop severe or mild metritis (P=0.004). The sensitivity and specificity for this predictive threshold were 49% and 87%, respectively. Because differences in measures of energy metabolism and inflammation occurred before metritis developed, NEFA concentrations at d-6 and haptoglobin concentrations at d+3 relative to calving may be useful for monitoring the risk of metritis in dairy cows.

Key Words: Metabolites, Metritis, Periparturient

395 JDIP – Direction for Johne's research. K. E. Olson*[1], S. J. Wells[2], and V. Kapur[2], [1]*KEO Consulting*, *Schaumburg, IL*, [2]*University of Minnesota*, *St. Paul*.

The Johne's Disease Integrated Program (JDIP) is a consortium whose mission is to promote animal biosecurity through development and support of projects that enhance knowledge, promote education, develop real-world solutions and mitigate losses from Johne's disease (JD). Approximately 140 individuals from 30+ academic, government and industry organizations are part of JDIP. A primary benefit is the networking that facilitates translation of results from cutting edge research programs to practical solutions with field application. Primary funding is from a USDA–CSREES–NRI CAP program competitive grant. Through JDIP, Johne's research and education needs are prioritized, with modest competitive grants awarded to address priorities. The initial round of funding ends in 2007. Five project areas have been identified for future JDIP activity: Project 1 – Epidemiology and Transmission - Determine within farm transmission dynamics of *Mycobacterium avium subsp paratuberculosis (MAP)* along with its molecular epidemiology and evaluate effectiveness of recommended management practices on reducing the incidence of infection; Project 2 – Diagnostics and Strain Differentiation – Use information gained from initial JDIP projects to develop and validate more accurate, rapid diagnostic tests, and tools to better quantify positive samples; Project 3 – Basic Biology and Pathogenesis – Build on prior work to develop a better understanding of mechanisms that impact virulence and survivability of *MAP*, helping to improve diagnostics and identify vaccine candidates; Project 4 – Host Genetics, Immunology, and Vaccine Development – Identify genetic markers for susceptibility to JD in cattle, compare efficacy of mutant vaccines in animal models, test candidate vaccines on the immune response and in vivo survival of *Map*; Project 5 – Education and Extension – Complete national survey of barriers to participation in JD program, identify stakeholder educational needs and design programs to meet them. Increase awareness of JDIP by outreach to producer media and meetings. The JDIP program is developing a strong translational pipeline for development of real world solutions to mitigate losses associated with JD.

Key Words: Johne's Disease, MAP, JDIP

396 Serum non-esterified fatty acid (NEFA) and beta-hydroxybutyrate (BHB) through the transition period of Holstein cows in different regions of North America. M. E. Carson*[1], T. F. Duffield[1], S. J. LeBlanc[1], K. E. Leslie[1], S. M. Godden[2], M. B. Capel[3], M. W. Overton[4], and D. Vallejo[5], [1]*University of Guelph*, *Ontario, Canada*, [2]*University of Minnesota*, *St Paul*, [3]*Perry Veterinary Clinic*, *Perry, NY*, [4]*University of Georgia*, *Athens*, [5]*University of California, Davis*, *Tulare*.

The objective of this field study was to evaluate the concentrations of serum non-esterified fatty acid (NEFA) and beta-hydroxybutyrate (BHB) through the transition period of Holstein cows in four different regions. Data were collected from 1812 cows in 45 herds across Midwest, Northeast (including Ontario, Canada), Southeast and Western United States. Each herd in the Midwest and Northeast regions had approximately 35 cows per herd enrolled in the study, whereas in the Southeast and Western herds included approximately 60 and 80 cows per herd, respectively. Cows were sampled 1 week prior to the expected calving date, and again in weeks 1, 2, and 3 postpartum. All serum collected was shipped to the Animal Health Laboratory at the University of Guelph for NEFA and BHB analysis. Results for NEFA and BHB by region and time relative to calving are shown in Table 1. Cows in the West showed a smaller prevalence of NEFA levels ≥0.4 mmol/L in the week prior to parturition, whereas herds in the Northeast had the greatest prepartum NEFA with 44% of cows ≥0.4mmol/L. Similarly, the Northeast had the greatest mean BHB at week 1 postpartum. The prevalence of subclinical ketosis in week 1 postpartum was greatest in Northeast and Midwest herds and smallest in West and Southeast herds. It appears that regional differences may exist for

serum NEFA and BHB levels and prevalence of subclinical ketosis during the transition period. The reasons for these apparent differences merit further investigation.

Table 1. Distribution of prepartum non-esterified fatty acid (NEFA) and postpartum beta-hydroxybutyrate (BHB) concentrations in dairy cows in North America.

Region	No. of Cows	No. of Herds	Mean (±SD) NEFA	Proportion of cows with high NEFA (≥0.4 mmol/L)	Mean (± SD) BHB	Proportion of cows with subclinical ketosis (BHB ≥1400 µmol/L)
Midwest	570	17	0.38 (±0.3)	39%	940 (±715)	15%
Northeast	652	20	0.41 (±0.3)	44%	1044 (±772)	20%
Southeast	177	3	0.37 (±0.3)	40%	867 (±1015)	8%
West	413	5	0.26 (±0.2)	20%	798 (±569)	9%

Key Words: Dairy Cows, Transition, Metabolic Parameters

397 An evaluation of meloxicam (Metacam®) as an adjunctive therapy for calves with neonatal calf diarrhea complex. C. G. Todd*[1], D. R. McKnight[2], S. T. Millman[1], T. F. Duffield[1], and K. E. Leslie[1], [1]*University of Guelph*, *Guelph, ON, Canada*, [2]*University of Guelph*, *Kemptville, ON, Canada*.

Diarrhea is a significant health problem among neonatal dairy calves. In some countries, calves with diarrhea may be treated with supportive therapies, such as non-steroidal anti-inflammatory drugs. The aim of this research was to examine the efficacy of meloxicam as an adjunctive therapy for calves with diarrhea, as determined by measures of calf performance, behavior and health. For this double-blind controlled trial, 62 Holstein bull calves were purchased at birth and transported to a calf research facility. At the naturally occurring onset of diarrhea, the calves were enrolled in the study, and randomly assigned to receive a single subcutaneous injection of meloxicam (0.5 mg/kg BW) or an equal volume of placebo solution. Individual milk, water and calf starter ration intakes were determined daily for all calves until 56 days of age. Daily fecal consistency scores and weekly body weight measurements were also collected for each study calf. Following the onset of diarrhea, calf feeding behavior and general activity, as well as lying and standing postures were observed for five consecutive days. During this trial, 56 calves developed diarrhea and were treated with meloxicam (n=28) or placebo (n=28). Meloxicam-treated calves began consuming starter ration significantly earlier than placebo calves ($p<0.05$), had improved starter intakes ($p<0.05$) and experienced greater body weight gain over the study period ($p<0.05$). There was no difference in weaning weight among the study calves ($p>0.05$); however, meloxicam-treated calves tended to wean at an earlier age (47 days versus 41 days, respectively, $p=0.16$). Compared to calves receiving placebo, meloxicam-treated calves were more sedentary for the first two days after developing diarrhea, and then became considerably more active during the remainder of the observation period ($p<0.05$). The occurrence of abnormal lying postures did not differ among the study calves ($p>0.05$). These results provide evidence of improved calf well-being and indicate that meloxicam may be an appropriate supportive therapy for calves with diarrhea.

Key Words: Calf, Diarrhea, Non-steroidal Anti-inflammatory Drug Therapy

398 A diagnostic algorithm, in a dashboard environment for common dairy cow health concerns. D. T. Galligan*[1], D. Remsburg[1], J. Ferguson[1], R. Munson[1], and G. Licitra[2,3], [1]*University of Pennsylvania*, *Kennett Square*, [2]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [3]*DACP University of Catania*, *Catania, Italy*.

Dairy producers are often confronted with cows displaying various clinical signs indicative of various **health conditions** (ketosis, DA (+/- torsion), mastitis, RP, metritis, pneumonia, hardware, lameness, milk fever etc). The interpretation of these clinical signs (heart rate, temperature, respiration, rumen sounds, posture, neurological signs, ketosis test results, serum protein level) as well as historical information (lactation number, production profile etc) will often determine a **presumptive diagnosis** as well as a standard treatment response. The presumptive diagnosis in this program is based on an algorithm that looks at the hierarchy of clinical signs associated with a disease condition. A graph of the relative % matching signs for each of the disease condition is presented to the user as well as a treatment window for the conditions diagnosed. Often the decision to treat a cow is based on her expected value relative to a replacement (or alternative opportunity) as well as the immediate therapeutic cost and expected prognosis to the current condition. The expected prognosis is based on the increased risk of culling associated with the difference diagnosed conditions. A dashboard (Flash) file was developed with the algorithm based on interviewing several veterinarians with considerable practice experience and reports in the literature estimating the increased odds of culling due to a given condition. The dashboard environment allows the use of sliders for data entry and a response gauge estimating survival to the next lactation. The program can be run on a stand alone computer or off the web.

Key Words: Health, Algorithm

399 Effects of reduced freestall access during the dry period upon cellular immune function and transition health of dairy cows. T. F. Gressley*, K. K. Fried, J. M. Velasco, E. D. Reid, T. C. Hausman, K. M. Moyes, J. L. Salak-Johnson, and G. E. Dahl, *University of Illinois*, *Urbana*.

The objectives of this study were to determine if limiting freestall access of dry cows impacted immune function or transition health. Our model examined one aspect of overcrowding, reduced freestall availability, without changing feed access, water availability, or area per cow. Twenty Holstein cows were randomly assigned to either a 70% stall availability treatment (70SA; n=10) or a 100% stall availability treatment (100SA; n=10) 1 wk following dry off on d 51 ± 6 prior to expected calving. Cows on the 70SA treatment only had access to 7 freestalls in a 10-freestall bay, whereas cows on the 100SA treatment had access to all 10 freestalls. Short-term treatment effects on neutrophil phagocytosis and chemotaxis and lymphocyte proliferation were measured 4 and 24 h after treatment assignment. Lymphocyte proliferation was measured again at 2 and 5 wk post-treatment. Locomotor scores and postpartum disease prevalence were also recorded for these 20 cows and a second cohort of 20 cows subjected to the same treatments. In the short-term, immune cell activity was enhanced among cows on the 70SA treatment compared to cows on 100SA. Lymphocyte proliferation was increased in response to ConA ($P = 0.02$) and tended to increase in response to PHA ($P = 0.14$), suggesting an increased responsiveness of T-cells. The percentage of neutrophils engulfing 1 or more fluorescent beads was greater

among 70SA cows than the 100SA cows (P < 0.05). Long-term there was a tendency for cows in the 70SA treatment to have increased LPS-induced B-cell proliferation compared to 100SA cows (P = 0.09). Postpartum disease prevalence was similar for cows on both treatments. There were interactions between treatment and cohort and week and cohort on locomotor score (P < 0.05). Locomotor score did not change over time for cohort 1 cows or for the 100SA cows in cohort 2, but it worsened over time for the 70SA cows in cohort 2. A moderate reduction in freestall access in dry cow facilities should not adversely affect immune function, but it may negatively impact hoof health.

Key Words: Transition Cows, Freestall Availability, Immune Function

Beef Species I

400 Post-weaning growth performance of heifers grazing Tasmanian native pastures and the estimation of inbreeding levels using random amplified polymorphic DNA markers. A. E. O. Malau-Aduli*[1] and M. Dunbabin[2], [1]*University of Tasmania*, *Hobart, Tasmania, Australia*, [2]*'Bangor', Dunalley*, *Tasmania, Australia*.

The aims of this study were to evaluate the growth performance of Hereford, Angus, Hereford × Angus and Hereford × Saler heifers within the same herd grazing native pastures and to estimate homozygosity and inbreeding coefficients using random amplified polymorphic DNA (RAPD) markers. Post-weaning liveweight (BW), average daily gain (ADG) and body condition score (BCS) on a scale from 0 to 5 were monitored monthly from 2005 to 2006. Genomic DNA was extracted from blood samples, amplified using RAPD primers, fragments resolved by gel electrophoresis and banding patterns elucidated under UV light. Estimation of homozygosity through band sharing patterns was utilised in determining within-breed inbreeding levels. Regardless of breed, LWT, BCS and ADG of heifers followed a typical sigmoid curve pattern characterised by a decline in average BW from 200 kg in May to 188 kg in June, a continuous monthly increase through to March 2006 when it reached a peak (380 kg) before a final decline to 375 kg in May. The BCS ranged from 1.6 to 3.6 while ADG ranged from -0.4 to 1.5 kg/d. Significant genetic variation was observed between the different breeds in that BCS and BW of purebred Angus heifers were lower than those of purebred Hereford and their crosses with Angus and Saler. Average BW of the Angus breed ranged from 164-349 kg, with BCS ranging from 1.4 to 3.3 compared to the Hereford (186-383 kg, 1.6-3.6), Hereford × Angus (192-383 kg, 1.7-3.6) and Hereford × Saler (192-385 kg, 1.6-3.7), respectively. The ADG of the Angus was not different from those of Hereford and their crosses indicating that the Angus was perhaps better in terms of feed efficiency since they probably ate less and gained the same weight as the heavier breeds that must have eaten more commensurate with their maintenance requirements. The strongest residual correlation (r=0.98) was between BW and BCS. Average band sharing frequencies ranged from 0.60 in the crossbreds to 0.96 in the purebreds with estimated inbreeding coefficients ranging from 0.5% to 3%, respectively, which is very low.

Key Words: RAPD Markers, Post-weaning Growth, Beef Cattle

401 Influence of breed on postpartum interval and estrous cycle length in beef cattle. R. A. Cushman*, M. F. Allan, R. M. Thallman, and L. V. Cundiff, *USDA, ARS, Roman L. Hruska U.S. Meat Animal Research Center*, *Clay Center, NE*.

Before genetic markers can be generated for fertility in beef cows, greater characterization of reproductive phenotypes is needed. The present study tested the hypotheses that 1) breeds vary in postpartum interval (PPI) and estrous cycle length, 2) a longer estrous cycle immediately prior to breeding increased pregnancy rates, and 3) a greater number of cycles prior to breeding increased pregnancy rates. Postpartum interval, estrous cycle length, and number of cycles prior to breeding were examined in F1 cows (n = 519) obtained from mating Hereford, Angus and USMARC III cows to Hereford, Angus, Simmental, Limousin, Charolais, Gelbvieh, and Red Angus sires. Cows were classified as having 0, 1, 2, or 3 observed estrous cycles prior to breeding, and breed effects on PPI, number of cycles, and estrous cycle length were examined using the MIXED procedure of SAS. Sire breed of the cow influenced the length of the PPI and number of cycles prior to the start of breeding (P < 0.001). Simmental-sired cows had the shortest PPI and greatest number of cycles prior to breeding; Limousin-sired cows had the longest PPI and least number of cycles prior to breeding. Cows with a greater number of cycles prior to breeding did not have greater pregnancy rates than cows that had not exhibited estrus prior to breeding (P = 0.87). In cows that cycled prior to breeding, the length of the estrous cycle immediately prior to breeding was influenced by dam breed and body condition score (BCS, P < 0.01). Cows out of Hereford dams had shorter estrous cycles than cows out of USMARC III or Angus dams, and estrous cycle length increased as body condition score increased. Pregnancy rate decreased as length of the estrous cycle prior to breeding increased (P = 0.05, -2.2% per day of cycle length), suggesting that there may be an influence of length of the estrous cycle immediately prior to breeding on conception rates due to prolonged follicles with lower quality oocytes. Breed differences in PPI and estrous cycle length suggest that there are genetic components to these traits.

Key Words: Beef Breeds, Pospartum Interval, Reproductive Efficiency

402 Effect of an artificial sweetener and yeast product combination on immune function measurements, growth performance, and carcass characteristics of beef heifers. R. R. Reuter*[1,2], J. A. Carroll[2], M. S. Brown[3], N. E. Forsberg[4], Y.-Q. Wang[4], R. Mock[5], J. D. Chapman[6], and M. L. Galyean[1], [1]*Texas Tech University*, *Lubbock*, [2]*USDA-ARS Livestock Issues Research Unit*, *Lubbock, TX*, [3]*West Texas A&M University*, *Canyon*, [4]*Oregon State University*, *Corvallis*, [5]*Texas Veterinary Medical Diagnostic Laboratories*, *Amarillo, TX*, [6]*Prince Agri-Products*, *Quincy, IL*.

One hundred ninety-nine crossbred beef heifer calves (205 ± 7.9 kg initial BW) were used in a 44-d receiving trial with 2 dietary

treatments (9 pens/treatment) in a completely random design. Diets were a steam-flaked corn- and alfalfa hay-based control (CON) diet or the same diet (ADD) with added artificial sweetener (Sucram; Prince Agri-Products; 198 mg/kg of diet DM) and a source of yeast and B-complex vitamins (OmniGen-AF; Prince Agri-Products; 0.8% of diet DM). Heifers were weighed and bled on d 0, 16, 30, and 44 after arrival at the feedlot. Serum was collected from jugular venipuncture blood samples and analyzed for cortisol, cytokine, and acute-phase protein concentrations, L-selectin expression, and respiratory virus titer. At d 44, the heifers were transported to a commercial feedlot, fed for 200 d, and individual carcass data were collected at slaughter. Morbidity (9.5%) and mortality (0.5%) were less than expected and not affected by treatment ($P > 0.63$). On d 16, ADD decreased ($P < 0.001$) haptoglobin concentration, but diet did not affect ($P > 0.43$) other measures of immune function. Diet had no effect on ADG, DMI or G:F ($P > 0.32$) in either the initial 16-d after arrival or the overall 44-d receiving period. Receiving period diet had no effect on carcass characteristics, except that ADD decreased marbling score ($P = 0.045$), marbling score adjusted to a constant fat thickness ($P = 0.08$), and tended ($P = 0.11$) to decrease percentage of heifers that graded USDA Choice. Results were inconsistent with previous research, possibly because animals were not exposed to the treatments prior to the stress period and did not experience a substantial pathogen challenge.

Key Words: Beef Cattle, Immune Function, Sweetener

403 Evaluation of the effects of two commercially available modified live vaccines for bovine respiratory disease complex on naïve beef steers. W. J. Horne*[1], K. S. Barling[2], A. D. Herring[1], D. K. Lunt[1,3], A. Thomas[2], and J. E. Sawyer[1], [1]*Texas A&M University Department of Animal Science*, *College Station, TX*, [2]*Novartis Animal Health US, Inc*, *Larchwood, IA*, [3]*McGregor Agricultural Research Center*, *McGregor, TX*.

A study was conducted to evaluate effects of two commercially available modified live respiratory vaccines (MLV) on performance and antibody formation in beef steers. Naïve (confirmed seronegative to IBR and BVDV Types 1 & 2) beef steers (n = 107) were stratified by BW and randomly assigned to treatment within strata. Treatments consisted of either vaccine A (Type 1 BVD, IBR, PI3, BRSV), vaccine B (Types 1 & 2 BVD, IBR, PI3, BRSV), or control (physiological saline) administered SQ. Animals were fed individually in Calan™ gates with rectal temperature (RT) (d 0, 1 3, 7, 14, 28), body weight, BVDV Type 1, BVDV Type 2, and IBR titer responses collected serially (d 0, 14, 28, 42) post-vaccination. Data were analyzed as repeated measures in time using mixed models procedures. At d 14, no differences existed for BVDV Type 1 or Type 2 antibody titers. At d 28 and 42, steers receiving B had the highest (P<0.01) BVDV Type 1 titer response: A produced higher titers (P<0.01) than control. At d 28, steers receiving B had a greater (P<0.01) BVDV Type 2 titer response than A- and control-treated steers. On d 42, B generated the highest (P<0.01) titer response: A was greater (P<0.01) than controls. Titers for IBR on d 14, 28, and 42 were greatest in steers receiving A (P<0.01): B produced higher IBR titers than control (P < 0.01). Treatment had minimal effect on RT. Time affected RT (P < 0.01), which declined through d 3, increased through d 14, and then stabilized. A treatment by day interaction occurred for ADG (P<0.01). Gain declined throughout the study for steers receiving control or B. For steers receiving A, ADG was higher (P<0.01) for the middle third of the feeding period, such that overall ADG was similar for all treatments (P = 0.10). Inoculation with vaccine B resulted in the highest increase in BVDV Type 1 and 2 titers, without decreasing overall ADG relative to other treatments. Vaccine A produced the highest IBR titers. Vaccination with a MLV can create adequate immune responses without negatively altering feeding performance of beef steers.

Key Words: Modified Live, Vaccine, Bovine

404 Management factors affecting selling prices of Arkansas beef calves: 2000 vs. 2005. B. L. Barham and T. R. Troxel*, *University of Arkansas Cooperative Extension Service*, *Little Rock, AR*.

Five USDA certified livestock market reporters collected data from weekly livestock auctions in Arkansas from January 1 to December 31 in both 2000 and 2005. The market reporters collected information from 17 markets in 2000 and 15 markets in 2005. The data collected included calf gender, horn status, fill, condition, health, weight and price. A total of 533,283 feeder cattle were sold through these livestock auctions in 2000, and data was randomly collected on 81,703 (15.3%) head. A total of 581,413 feeder cattle were sold through these livestock auctions in 2005, and data was randomly collected on 52,401 lots consisting of 105,542 (18.2%) head. The average selling prices for 2000 and 2005 were $92.91 and $118.32/45.45 kg, respectively. Data were analyzed by subtracting the actual selling price from the average selling price for the given year. All dollar value results are reported as a deviation from the respective year mean and expressed as dollars/45.45 kg. Arkansas cow-calf producers castrated more (8.9%) bull calves before selling in 2005 than in 2000 (P < 0.01). Buyers paid a higher premium for steers ($6.48 vs. $6.02; P < 0.0001) and paid less for bull calves ($0.30 vs. $1.68; P < 0.001) in 2005 than in 2000. Additionally, cattle buyers discounted horned cattle greater in 2005 than 2000 (-$2.86 vs. -$0.51; P < 0.0001). Thin cattle in 2000 received a discount (-$1.91) but in 2005 received a premium ($1.67). The percentage of calves with dead hair, stale, sick, bad eye(s) and lame was low in 2000 and even lower in 2005 (P < 0.01). Arkansas cow-calf producers sold more calves in groups (26% vs. 19%; P < 0.01) and fewer calves individually in 2005 than they did in 2000 (75% vs. 81%; P < 0.01). Buyers paid a higher premium for cattle sold in groups in 2005 than in 2000 ($4.05 vs. $3.09; P < 0.001). Cow-calf producers can do more to improve the quality and selling price of feeder cattle by making genetic selection and management changes.

Key Words: Beef Cattle, Selling Price, Price Comparisons

405 Impact of the phenotypic expression of calf genetics on the selling price of calves sold in Arkansas livestock markets: 2000 vs. 2005. B. L. Barham* and T. R. Troxel, *University of Arkansas Cooperative Extension Service*, *Little Rock, AR*.

Five USDA certified livestock market reporters collected data from weekly livestock auctions in Arkansas from January 1 to December 31 in both 2000 and 2005. The market reporters collected information from 17 markets in 2000 and 15 markets in 2005. The data collected included breed or breed type, color, muscle thickness, frame score, weight and price. A total of 533,283 feeder cattle were sold through these livestock auctions in 2000, and data was randomly collected on 81,703 (15.3%) head. A total of 581,413 feeder cattle were sold through

these livestock auctions in 2005, and data was randomly collected on 52,401 lots consisting of 105,542 (18.2%) head. The average selling prices for 2000 and 2005 were $92.91 and $118.32/45.45 kg., respectively. Data were analyzed by subtracting the actual selling price from the average selling price for the given year. All dollar value results are reported as a deviation from the respective year mean and expressed as dollars/45.45 kg.. More number 2 muscle score cattle and fewer number 1, 3 and 4 muscle score cattle were sold in 2005 than 2000 ($P < 0.01$). In 2005, buyers paid a higher premium for muscle score 1s than in 2000 ($2.58 vs. $0.02; $P < 0.0001$). The Arkansas cow-calf producer marketed more large-framed and fewer medium- and small-framed calves in 2005 than in 2000 ($P < 0.01$). The cattle breeds or breed types that increased in value from 2000 to 2005 were Angus x Hereford, Angus, Angus x Charolais and Brahman ($P < 0.0002$). Buyers discounted Charolais x Limousin, Charolais, Charolais x ¼ Brahman, Hereford x Limousin, Hereford x Charolias, Limousin, Limousin x ¼ Brahman, Simmental, Saler, Longhorn and ¼ Brahman Cross more in 2005 than in 2000 ($P < 0.01$). The calf colors that received an increase in selling price were yellow-white face, black-white face, grey-white faced, black and gray. White, red-white face and red calves were discounted in 2005 compared to 2000. Cow-calf producers can do more to improve the quality and selling price for the feeder cattle by making genetic selection and management changes.

Key Words: Feeder Cattle, Selling Price, Beef Calves

406 Carcass trait characterization of retained and purchased Alabama feeder calves. S. V. Free*, W. C. Rutherford, J. B. Elmore, G. S. Hecht, and L. A. Kriese-Anderson, *Auburn University*, *Auburn, AL*.

Alabama Beef Connection (ABC) (n=6,222) and Alabama Pasture to Rail (P2R) (n=901) cattle carcass traits were analyzed to compare Alabama feeder cattle finished in the High Plains region of the United States. Cattle consigned to P2R were retained, co-mingled loads of cattle having known birth dates and parentage. ABC-enrolled cattle were usually load lots of feeder cattle sold as calves by cow/calf producers desiring carcass data. Some ABC-enrolled cattle were load lots of retained or co-mingled feeder calves. Traits of hot carcass weight (HCW), 12th rib fat (BF), longissimus dorsi area (REA), USDA yield grade (YG) and marbling score (MS) were analyzed in SAS using a general linear model. Fixed effects included cattle year of enrollment (2003-2006), market method (tele-auction (TA), private treaty (PT), retained (RT) or co-mingled retained (CT)), and data source (P2R or ABC). The traits BF, MS, REA, and YG were analyzed with a covariate of harvest date or HCW. Harvest date served as a covariate for HCW. With either covariate of harvest date or HCW, market method and year were significant sources of variation ($P<0.05$). The TA carcasses were the lightest. With either covariate RT and CT carcasses had significantly more BF than TA or PT cattle. These results were similar for YG. Using HCW as a covariate for YG, ABC calves had significantly higher YG than P2R calves ($P<0.05$). For REA, only HCW was a significant covariate. The TA and PT carcasses had the largest REA followed by CT and RT ($P<0.05$). P2R carcasses had larger MS than ABC carcasses ($P<0.05$). For both covariates, TA and RT carcasses had higher ($P<0.05$) MS than CT. No differences were detected between PT and RT carcasses for MS. Despite these differences of carcass traits among various marketing methods of Alabama cattle, all values fell within the accepted industry carcass standards.

Key Words: Beef Cattle, Carcass Traits, Marketing

407 Carcass trait characterization of Alabama feeder calves fed in two regions of the United States. W. C. Rutherford*, S. V. Free, J. B. Elmore, G. S. Hecht, and L. A. Kriese-Anderson, *Auburn University*, *Auburn, AL*.

To assess the carcass quality of Alabama born cattle, carcass data from cattle (n=7,144) fed in two regions (Midwest (MW) and High Plains (HP)) were analyzed. All cattle were sold as feeder calves through a tele-auction (TA) or private treaty (PT). Market option (MO), region (R) and their interaction was used in a general linear model in SAS to analyze data. Model A used harvest date (KD) as a covariate and Model B used hot carcass weight (HCW). Traits analyzed were hot carcass weight (HCW), 12th rib fat thickness (BF), marbling score (MB), USDA yield grade (YG) and longissimus dorsi area (REA). Region, R × MO and KD were significant for HCW ($P < 0.05$). The MW × TA cattle had heavier HCW than HP × PT ($P < 0.05$). Both had heavier HCW than MW × PT and HP ×TA which were similar. Region, MO, R × MO and KD were significant for BF ($P< 0.05$). The HP × TA cattle had significantly less BF than the other three interaction classes ($P < 0.05$). The R × MO interaction was significant for MB. The HP × TA cattle had significantly more MB compared to the other three interaction classes ($P< 0.05$), which were similar. Region and the R × MO interaction were significant for YG ($P < 0.05$). The R × MO effect was significant for YG. The MW × PT cattle had significantly better YG than the other three interaction classes ($P < 0.05$). Region, MO and KD were all significant for REA ($P < 0.05$). The HP-fed cattle had significantly larger REA than cattle fed in the MW ($P < 0.05$) and TA cattle had significantly larger REA than PT cattle ($P < 0.05$). Model B showed covariate HCW was significant for BF ($P <.05$). R, MO and HCW were all significant for MB ($P <.05$). HP fed cattle had more MB than the MW fed cattle ($P <.05$) and TA cattle had more MB than PT cattle ($P <.05$). The HP-fed cattle had significantly more MB than the other three interaction classes ($P < 0.05$). The MO, R × MO and HCW were significant for YG ($P < 0.05$). The MW × PT cattle had a significantly better YG than the other three interaction classes. Region and R × MO significantly affected HCW ($P < 0.05$). The HP-fed cattle had larger REA than the MW-fed cattle. Carcass data from these Alabama feeder calves is comparable to data of the 2000 National Beef Quality Audit.

Key Words: Beef Cattle, Carcass, Quality

408 Comparison of carcass trends of Alabama cattle with national quality audit reports. J. B. Elmore*, L. A. Kriese-Anderson, W. C. Rutherford, S. V. Free, G. S. Hecht, and W. F. Owsley, *Auburn University*, *Auburn, AL*.

Since 1991, national beef quality audits have been concerned with increasing hot carcass weight and stagnant USDA quality grades. Data from two sources containing carcass data from Alabama feeder calves were analyzed to determine if Alabama carcass trends were similar to

national trends. Hot carcass weight (HCW), 12th rib fat thickness (BF), longissimus dorsi area (REA), USDA yield grade (YG) and USDA marbling score (MS) were analyzed using records from the Alabama Beef Connection (ABC) and Alabama Pasture to Rail Program (P2R). The ABC database contained 5,160 records from 2003 to 2006 on cattle sold as feeder calves and fed primarily in the Midwest and High Plains regions of the United States. The P2R database contained 4,997 records from 1994 to 2005 of co-mingled retained ownership cattle fed in the High Plains region of the United States. Data were analyzed using a general linear model in SAS. Fixed effects included year, breed of sire and region fed. A covariate of harvest date was included for all traits. The HCW of Alabama feeder cattle have not followed audit trends. Hot carcass weights have tended to increase nationally (344 to 361 kg). In P2R cattle, HCW has significantly decreased from 352 kg in 1994 to 335 kg in 2005. The ABC cattke show a similar trend (392 kg in 2003 to 351 kg in 2006, $P<0.05$). In both data sets, REA remained stable across all years (P2R 87.04 cm^2; ABC 88.11 cm^2, audit 84.5 cm^2). The MS trend was significantly positive across years in both datasets. The P2R data from 1994 moved from a MS of 411 to 484 in 2006 ($P<0.05$). The ABC data from 2003 to 2006 moved from a MS of 484 to 490 ($P<0.05$). Back fat and YG were the most variable carcass traits for Alabama across years with positive and negative trends ($P<0.05$). Feedlot, market conditions and weather probably affected these traits as much as genetic predisposition. Alabama cattle are generally YG 2 cattle (P2R 2.54 vs. ABC 2.56; audit 3.0). This is primarily due to 3.23 cm^2 more REA than required for the associated HCW. Alabama results do not agree with audit findings of increased HCW and REA over time.

Breeding and Genetics - Livestock and Poultry: Analyses and Methods I

409 Using epidemiological models and genetic selection to identify theoretical opportunities to reduce disease impact. G. D. Snowder*, *USDA, ARS, U.S. Meat Animal Research Center*, *Clay Center, NE*.

Selection for disease resistance is a contemporary topic with developing approaches for genetic improvement. Merging the sciences of genetic selection and epidemiology is essential to identify selection schemes to enhance disease resistance. Epidemiological models can identify theoretical opportunities for genetic selection to reduce the impact of a disease. Potential selection venues may be more appropriately comprehended by compartmentalization of disease components using epidemiological models. This study considers the standard Susceptible, Infected, Recovered (SIR) epidemiological model and five other common epidemiological models (MSIR, SEIR, SIS, Carrier State, and SIR Vector) with genetic selection alternatives. Theoretical modeling of genetic selection effects on epidemiological models were used to: predict the economic effect of selection, estimate the optimal number of resistant animals to prevent an epidemic, and determine genetic selection alternatives. Selection alternatives to genetic disease resistance include lowering the probability of being infected, tolerance for the pathogen, longer latency period, less severe clinical expression, faster recovery rate, and compensatory rebound. These selection alternatives can result in favorable changes to the differential equations for susceptibility, infected, and recovery rates. Potentially undesirable consequences due to selection can be predicted, such as an increase in the size of sub clinical populations harboring and shedding pathogens. When applied to actual data for bovine respiratory disease, this approach identifies the complexity of genetic resistance to this disease while detecting potential opportunities for genetic selection. When a disease such as bovine respiratory disease is caused by different pathogens (bacterial, viral, mycoplasmal, etc.) with different pathways of infection, the probability of reducing the disease prevalence with genetic selection is diminished.

410 Assessment of different selective phenotyping design strategies for genetical genomics studies with outbred F2 populations. F. F. Cardoso*[1,2], J. P. Steibel[1], G. J. M. Rosa[3], C. W. Ernst[1], R. O. Bates[1], and R. J. Tempelman[1], [1]*Michigan State University*, *East Lansing*, [2]*Embrapa Pecuária Sul*, *Bagé, RS, Brazil*, [3]*University of Wisconsin*, *Madison*.

Quantitative genetic analysis of transcriptional profiling experiments is emerging as a promising approach to discover candidate genes underlying variation of complex biological traits. However, adoption of these genetical genomics approaches is currently limited by the high cost of microarrays. We studied variants of three recently proposed design strategies to optimally select subsets of individuals for transcriptional profiling including maximizing genetic dissimilarity between selected individuals, maximizing the number of recombination events in selected individuals, and selecting phenotypic extremes within genotypes of a previously identified quantitative trait locus (QTL). We also investigated two other options, namely purely random selection and profiling animals with the highest and lowest phenotypic values within each family-gender subclass. A simulation study was conducted based on linkage map and marker genotypes provided from a dataset on Chromosome 6 for 510 F2 animals from an actual pig resource population. Comparisons between methods were based on a biallelic QTL with pleiotropic effects on a phenotypic trait and a particular expression profile. The model included an overall mean, fixed additive QTL and sex effects and random polygenic and family effects. Bivariate (gene expression with phenotypic data) mixed model analyses were conducted for subset selection intensities of 80/510, 160/510 and 240/510. All methods were deemed to be similar for the mean absolute distance of the estimated QTL to the true QTL location. Precision and bias of estimates of QTL effects was further assessed by their Mean Square Error (MSE). The genetic dissimilarity and extremes within genotype methods had the smallest MSE and maximum sensitivity, outperforming all other selection strategies, particularly at the smallest proportion of selected samples (80/510).

Key Words: Genetical Genomics, Selective Phenotyping, QTL

411 Different methods of selecting animals for genotyping to maximize the amount of genetic information known in the population. M. L. Spangler*[1], R. L. Sapp[2], J. K. Bertrand[1], M. D. MacNeil[2], and R. Rekaya[1], [1]*University of Georgia*, *Athens*, [2]*USDA-ARS Fort Keogh Livestock and Range Research Laboratory*, *Miles City, MT*.

It is possible to predict genotypes of some individuals based on genotypes of relatives. Different methods of sampling individuals to be genotyped from populations were evaluated using simulation. Simulated pedigrees included 5,000 animals and were assigned genotypes based on assumed allelic frequencies (favorable/unfavorable) of 0.3/0.7, 0.5/0.5, and 0.8/0.2. A real beef cattle pedigree which included 29,101 animals was used to test selected methods using simulated genotypes with allelic frequencies of 0.3/0.7 and 0.5/0.5. For the simulated pedigrees, known and unknown allelic frequencies were assumed. The methods used included random sampling, selection of males, and selection of both sexes based on the diagonal element of the inverse of the relationship matrix (A-1) and absorption of either the A or A-1 matrix. For random sampling, scenarios included selection of 5 and 15% of the animals while all other methods presented concentrated on the selection of 5% of the animals for genotyping. The methods were evaluated based on the percentage of alleles correctly assigned after peeling (AKP), the probability of assigning true alleles (AKG) and the average probability of correctly assigning the true genotype (APTG). As expected random sampling was the least desirable method. The most desirable method in the simulated pedigrees was selecting both males and females based on their diagonal element of A-1. Increases in AKP and AKG ranged from 26.58 to 29.11% and 2.76 to 6.08%, respectively, when males and females (equal to 5% of all animals) were selected based on their diagonal element of A-1 compared with selecting 15% of the animals at random. In the case of a real beef cattle pedigree, selection of males only or males and females yielded similar results and both selection methods were superior to random selection.

412 Effect of raw data normalisation on detection of differentially expressed genes in cDNA microarray experiments. C. Dimauro, N. P. P. Macciotta*, and A. Cappio-Borlino, *Dipartimento di Scienze Zootecniche, Università di Sassari*, *Sassari, Italia*.

cDNA microarrays allow for the monitoring of the expression of thousands genes in parallel in different tissues or conditions. However, the interpretation of microarray experiments requires large manipulation of raw fluorescence data that may seriously affect the reliability and repeatability of final results. Two data processing main steps can be identified: normalization, i.e. the pre-scaling of data to correct for technical biases; choice of a suitable statistical model to detect differentially expressed genes, controlling for false discovery rate. Whereas the impact of the latter has been widely investigated, the influence of normalization techniques has not been fulfilled to date. In this work, four different combinations of normalization techniques have been carried out on published fluorescence data generated in an experiment aimed at defining the temporal gene profiling of liver from periparturient dairy cows (GEO accession n.GSE2692). The normalizations were aimed at removing bad spots, correcting for background intensity (2 corrections), bias and dye effect. Differentially expressed genes were detected, for all combinations, with a gene-specific linear mixed model that included the fixed effect of treatment, and random effects of array and cow, plus the random residual. The range of differentially expressed genes ranged from about 2500 to 4000 among the different combinations, with a statistical significance threshold of 0.05, increasing dramatically to a range of about 300 to 500 when a Bonferroni corrected statistical test was applied. The percentage of genes commonly detected in the different combinations is between 20-50% and 2-8% for unadjusted and adjusted tests respectively. Moreover a great variation in the results can be still observed whether mean or median fluorescence intensity data was used. All these results highlight a relevant impact of normalization techniques on detection of differentially expressed genes in cDNA microarrays experiments and strongly suggest that consistent comparisons should be made by using the same normalization procedures.

Key Words: cDNA Microarrays, Normalisation, Differentially Expressed Genes

413 Methods to explain genomic estimates of breeding value. P. M. VanRaden and M. E. Tooker*, *Animal Improvement Programs Laboratory, USDA*, *Beltsville, MD*.

Genetic markers allow animal breeders to locate, estimate, and trace inheritance of many unknown genes that affect quantitative traits. Traditional models use pedigree data to compute expected proportions of genes identical by descent (assumed the same for all traits). Newer genomic models use thousands of marker genotypes to obtain actual fractions of DNA shared by any two individuals. Full sibs, for example, may actually share 45% or 55% of their DNA rather than the 50% expected in the traditional relationship matrix. The actual percentage of shared genes has a standard deviation (SD) equal to 50% divided by the square root of twice the number of independent loci affecting the trait. This SD does not decrease below 3.5% even with very large numbers of loci on 30 chromosome pairs because loci on the same chromosome are linked rather than independent. Accounting for these small differences in the relationship matrix and tracing individual genes can increase reliability, especially if the number of genotyped individuals is large. Reliability from parent average is <50% and is the upper limit for individuals without phenotypic data or progeny in traditional models. With genotypes and phenotypes for full sibs, genomic models can increase the reliability to 62% with 100 full sibs or 95% with 1000 full sibs. If no sibs have both genotypes and phenotypes but 100 full sibs of each parent do, reliability can increase to 57%. Less gain is provided from each distant relative, but the number of distant relatives may be very large. “Unrelated” individuals actually share many unknown common ancestors born prior to the known pedigree file and thus can provide additional information. More markers are required to estimate and trace genetic effects for distant rather than close relatives because the shared DNA segments are shorter. More markers are also required when more loci affect a trait. Another useful concept is the proportion of genes in common that affect a particular trait, called a quantitative trait loci (QTL) relationship matrix. Genetic evaluations should be more accurate if genomic relationships replace the traditional relationships computed from pedigrees.

Key Words: Relationship Matrix, QTL, Genomics

414 Efficient estimation of breeding values from dense genomic data. P. M. VanRaden*, *Animal Improvement Programs Laboratory, USDA*, *Beltsville, MD*.

Genomic, phenotypic, and pedigree data can be combined to produce estimated breeding values (EBV) with higher reliability. If coefficient

matrix Z includes genotypes for many loci and marker effects (u) are normally distributed with equal variance at each, estimation of u by mixed model equations or EBV by selection index equations that include a genomic relationship matrix (G) are equivalent models. Matrix G is analogous to traditional relationship matrix A and is obtained by subtracting allele frequencies from coefficients of Z and then dividing the revised Z Z' by the number of marker effects (m). Equations that include either Z'Z or Z Z' are dense and can be solved by several methods tested on simulated data. Off-diagonals count individuals that inherited two different alleles (in Z'Z) or alleles shared by two individuals (in Z Z'). Algorithms that estimate marker effects using Z'Z and then sum to obtain EBV are more efficient than those that use Z Z' unless m greatly exceeds the number of genotyped individuals (n). With direct inversion to obtain reliabilities, computing times increase by n^3 for EBV or m^3 for marker effects. With iteration to estimate u, computing times increase with the number of iterations (i) times m^2. The algorithm known as iteration on data reduces memory, and a simple trick can increase speed. For each individual, its genotypes (left-hand sides) are multiplied by previous round estimates and this sum minus the diagonal coefficient is used to adjust right-hand sides instead of summing off-diagonals times previous solutions again for each effect. Computing time is linear with number of effects in the model (not quadratic as in many previous algorithms) and linear with total number of genotypes, increasing with i times n times m. More iterations and under-relaxation were required for convergence as m increased. The methods include only phenotypes (or daughter deviations) for genotyped individuals, but future algorithms ideally should also include phenotypes of un-genotyped individuals, perhaps by absorbing equations for marker effects into equations for EBV.

415 Recursive algorithm to compute inbreeding coefficients assuming non-zero inbreeding of unknown parents. I. Aguilar* and I. Misztal, *University of Georgia*, *Athens*.

The objectives of this study were to investigate a recursive algorithm to calculate inbreeding coefficients using rules from the tabular method and to expand it to consider animals with missing parent information using VanRaden's method. For each animal x present in the pedigree, the inbreeding coefficient F_x is calculated as $0.5R_{sd}$, where R_{sd} is the numerator relationship between sire and dam of the animal x. Computation of R_{sd} is recursive and involves tracing the ancestors. Three cases are considered. In the first case, if $x=0$ or $y=0$, $R_{xy}=0$. In the second case, if $x=y$, $R_{xy}=1+F_x$. Finally, $R_{xy}=0.5(R_{sy}+R_{dy})$, being x younger than y; and s,d sire and dam of x. The modification was done in the first case, where $x=0$ or $y=0$ denote unknown parents. Let a negative code denote the year of birth of their progeny, and b_i be an average inbreeding of all animals born in year i. Then $R_{xy}=2b_i$, where b_i is based on x and y code: if $x<0$ and $y>0$, $b_i=b_{-x}$; if $x>0$ and $y<0$, $b_i=b_{-y}$; and if $x<0$ and $y<0$, $b_i=max(b_{-x},b_{-y})$. The algorithm is iterative, in the first round b_i is zero, and in the others b_i is the average of inbreeding of animals with year of birth i, considering only the inbreeding coefficient of animals with known parents. Testing involved 17 million US Holsteins. Solutions were compared with two algorithms. Convergence was reached in 6 rounds. The computing time per round was 4 minutes, 2 times lower than the implementation of VanRaden algorithm based on tabular method, and two times higher than the algorithm by Meuwissen and Luo, which assumes zero inbreeding of unknown parents. The presented algorithm can also be used for other purposes, including computing of relationship of groups of animals (e.g., sires) using the full pedigree, or creation of nonadditive relationships.

Key Words: Inbreeding Coefficient, Unknown Parent, Recursive Algorithm

416 A social competitive model with the categorical expression. I. Misztal and R. Rekaya*, *University of Georgia*, *Athens*.

A model by Muir and Schinckel used to model social competition among animals assumes that the animal competitive effects are expressed on a continuous scale. This may not be realistic and could lead to theoretical problems such as variance inflation. A model is proposed where these effects could be expressed in a few discrete categories (strongly dominant, .., independent,.., passive) or as binary (dominant, passive). Let y_{ij} be a record generated under a set of environmental effects i, and let d_j and c_j be the direct and competitive effects of animal j, respectively. Further, let $\alpha(k,x_i)$ be the effect of animal with dominance status k on its mates in the same pen in a set of environmental effects represented by x_i. Let p_j be a social dominance category of animal j. The model could be represented as:

$$y_{ij}= other + d_j+ \Sigma\, \alpha(p_k,x_i) +e_{ijk}$$

where *other* are effects other than animals, and the summation are over all the remaining animals in the pen. If only two categories are considered, the model simplifies to:

$$y_{ijk}= other +d_j-\alpha(1,x_i)q_j +e_{ijk}$$

where q_j is 1 if animal j is dominant, and 0 otherwise. Additionally, the dominance category of an animal can be described through a liability model:

$$l_{ij}= other +c_j+e_{ij}$$

where l_{ijk}, is an unobserved liability. Assignment of liabilities to categories can involve either fixed or variable thresholds. Thresholds that are independent of pen effect can result in multiple occurrences of "dominant" animals per pen. If there is only one dominant animal per pen, thresholds need to be adjusted for every pen to result in the desired decomposition of categories. If the dominance status of all animals is known, implementation of the proposed models can be achieved through a modified linear-threshold model. If the dominance status is not known, an additional step is needed where the dominance status is inferred using the observed data via a Bayesian MCMC approach. The social dominance model that assumes a categorical expression can allow for a more realistic expression of social dominance for animals housed in pens.

Key Words: Social Dominance, Competition

417 Comparison of two methods for computing approximated accuracies for growth traits in random regression models. J. P. Sanchez*[1,2], I. Misztal[1], and J. K. Bertrand[1], [1]*University of Georgia*, *Athens*, [2]*University of Leon*, *Leon, Spain*.

The random regression model (RR) fitted direct genetic and permanent environmental effects, maternal genetic and maternal environmental effects, and the residual variance, all using linear splines. Knots were set at 1, 205 and 365 d. Approximate accuracies were obtained by a method specifically designed for RR by Tier and Meyer (2004) (M1),

and by a method developed for multiple-trait models by Strabel and Misztal (2001) (accf90 program; M2). In both methods the only fixed effect considered was the contemporary group (CG). D1 was a simulated data set containing 30,250 animals, 5,000(250) base dams(sires) and 5 generations (G) of 5,000 animals, 3 measurements (M) per animal, distributed in 15 CG (GxM combination). The sex rate in non base animals was 1 M:4 F. D2 was a data set of 1,812,871 records of Gelbvieh animals in 199,168 CG. Initial analyses involved D1, where the exact accuracies were also computed by inversion (M3). Regression coefficient, intercept and R2 of direct accuracies when M1 was regressed on M3 at 205 days (Weaning Weight) for males were 0.95, 0.03 and 0.99. The same quantities of M2 on M3 were 0.96, 0.04 and 0.99, and of M1 on M2 were 0.98, 0.00 and 0.98. The corresponding numbers for females were 1.06, -0.01, 0.99 (M1 on M3), 1.09, 0.00, 0.99 (M2 on M3), and 0.98, 0.00, 1.00 (M1 on M2). For maternal effects both methods showed similar performance and errors. Both M1 and M2 overestimated accuracies for base dams with many offspring. Using data set D2 without distinction of sex and retaining only animals with computed accuracy >= .6 for M1, similar statistics for M1 on M2 were 1.05, -0.06, 0.97 (1.13, -0.14, .96) for direct (maternal) effects. Computing requirements for D2 were 8 CPU min. and 878 Mb. of RAM with M1 and 7 min. and 326 Mb. with M2. A multiple trait accuracy algorithm is useful for computing accuracy of a RR linear spline model when there is at most one observation per trait and no interest on other ages than those defining traits.

Key Words: Accuracy, Beef Cattle, Linear Splines

418 Equivalent mixed model equations for genomic selection. D. J. Garrick*, *Colorado State University*, *Fort Collins*.

Henderson's mixed model equations are used for genetic evaluation from pedigree and performance information. Equations are solved for factors influencing a trait (eg direct genetic, maternal genetic, maternal permanent environment). Assumptions to obtain BLUP include the var-cov matrix between effects on one animal (eg G0) and the var-cov matrix of additive effects between animals (numerator relationship or A matrix). These var-cov matrices are commonly full rank, and their inverses are used in computations. Widespread implementation has occurred because A-1 is sparse and can be easily made directly from pedigrees. Genetic merit is assumed to result from an infinitesimal number of genes of small effects. An incidence matrix is used to relate genetic merit to phenotypes. This indicator matrix contains one or more unit elements that identify the animals own additive and any other effects. The number of equations increases each evaluation, in proportion to the number of new animals. Genomics has delivered an apparently very different approach to selection. Genetic merit can be considered the finite sum of perhaps tens of thousands of effects, physically located at some place on the genome whose transmission can be traced through genetic markers or haplotypes. Genomic selection might involve mixed model equations that ignore animal effects but include haplotype effects. Pedigree relationships are not necessarily required, the dense markers being used to trace identity by descent (IBD) at each locus and these IBD probabilities being used to construct incidence matrices. Such equations would not increase according to the number of new animals added over time, only the number of new markers or haplotypes. Total genomic merit of candidates would be obtained by summing up many relevant haplotype effects.

An equivalent model can be written that does not explicitly fit haplotype effects but total genomic effects for each animal. This demonstrates the similarity between total genomic selection and conventional A matrix evaluation. The animal-based formulation may be computationally attractive in the short-term when there are more haplotype effects than animals with markers.

Key Words: Genetic Evaluation, Equivalent Models

419 Detection and use of single gene effects in large animal populations. N. Gengler*[1,2], S. Abras[1], M. Szydlowski[1], and R. Renaville[1], [1]*Gembloux Agricultural University*, *Gembloux, Belgium*, [2]*National Fund for Scientific Research*, *Brussels, Belgium*.

Unbiased estimation of single gene effects can only be achieved by estimating them simultaneously with other environmental and polygenic effects in mixed inheritance models. As in large animal populations the vast majority of animals are however not genotyped, missing genotypes have to be estimated. Currently used methods as iterative peeling or MCMC are unpractical for large datasets. Recently an alternative method to estimate missing gene content, defined as the number of copies of a particular allele was developed. Unknown gene content is approximated from known genotypes based on the additive relationships between animals. In this study the proposed method was tested for the detection of candidate gene effects for bovine transmembrane GHR on first lactation milk, fat and protein test-day yields in Holsteins. The GHR gene was estimated to show moderate to small gene substitution effects of 295 g/day for milk, -8.14 g/day for fat yield and -1.83 g/day for protein yield for a phenylalanine replacement by a tyrosine (frequency 23.3%). Only 961 mostly recent sires out of 2,755,041 animals were genotyped. The accuracy of the procedure was then estimated by doing 15 simulations using gene dropping and adjustment of the observed 12,858,741 records using the estimated parameters. The new method to estimate missing gene content resulted to be functional and accurate as relative bias in the estimation of allele frequency was very low (0.2%) as were the biases for moderate allele substitution effects (milk: 3.7%; fat yield: 3.3%). Biases were larger for traits with smaller substitution effects (protein yield: 55.3%). The new method has the potential to allow even in very large animal population with few genotyped animals reliable estimation and use of moderate to large single gene effects.

Key Words: Single Gene Effects, Large Population, Estimation of Gene Content

Breeding and Genetics - Livestock and Poultry: New Challenges and Opportunities From Automation of Animal Data Recording

420 Current and near term technologies for automated recording of animal data for precision dairy farming. G. Katz*[1], A. Arazi[1], N. Pinsky[1], I. Halachmi[2], Z. Schmilovitz[2], E. Aizinbud[1,2], and E. Maltz[2], [1]*SAE Afimilk*, *Kibbutz Afikim, Israel*, [2]*Institute of Agricultural Engineering, Agricultural Research Organization - The Volcani Center*, *Bet Dagan, Israel*.

Data monitoring in the modern dairy farm enables the ongoing control of production, animal health and welfare. It is used for management planning, early disease diagnosis control and retrospective analysis of performance from single cow to herd. Currently most data is extracted manually, yet manual observation is gradually being replaced in many milking systems by automated recording(milk yield, milk conductivity, activity recording and body weight measurements) leading to better data, both in quantity and quality. Two new additional sensors are introduced: a milk analyzer and a behavior meter both are already installed and used in several commercial and research farms. The first gives real time measurements of milk solid concentrations and indicates the presence of blood and the level of somatic cells in the milk. The behavior meter continuously records the laying time, laying bouts and the activity of the individual cows. These additional sensors open new horizons. Herd genetics may be improved by selection based on frequent milk solids determination in individual cows in herds where milk is not tested regularly. Automated daily determination of fat corrected milk and body weight enables the prediction of dry matter intake for better use of computer controlled self feeders and asses the required rest periods for individual lactating cows. Daily solids determination alerts to any sudden changes in fat and protein content of the milk, of individual cows, groups or the whole, ensuring its economic value. Early diagnosis of sub acute ruminal acidosis and ketosis by using milk fat concentration, fat to protein ratio and weight changes in both individual and groups of cows, allows for better prevention policy and prompt treatment. The cow-behavior enables animal welfare assessment in different environmental conditions and stress situations, as well as reproductive and health status. These new sensors, in addition to the present ones (which record milk yield, milk flow rate, milk electric conductivity and daily body weight) will therefore improve individual cow health, overall herd performance and management decision making.

421 Thriving in a declining market – the new service paradigm for DHI's. N. Petreny*, *CanWest Dairy Herd Improvement*, *Guelph, Ontario, Canada*.

Exponential growth of computing capabilities and the development of advanced analytical instrumentation now offer ability to transfer traditionally centralized functions to the individual farm level – including record processing and milk analysis. The resulting challenge for the broader industry is the loss of data that supports traditional herd improvement and genetic evaluation activities as isolated data islands are created within the industry. Handling of independent data streams will become more complex and the underlying elements of data collection will become increasingly variable. Without evolution, the slow death of traditional dairy herd improvement (DHI) activities shall occur as organizations operate using historic service guidelines designed for the wrong customer, fail to innovate and adopt technology applications at a rate significantly slower than the dairy farm customers they service (in-voluntary obsolescence). Herd improvement organizations must shift their primary focus to supporting dairy herd profitability and not act as data collectors for genetic evaluation and breed improvement activities – both of which should be a by-product of the core DHI services. Technologies must be harnessed to enhance the profitability of customers by personalizing services and extracting more information from data and milk samples. Current Information technologies will now accommodate active benchmarking and individual farm adjustment factors. New analytical technologies allow for cost effective health and disease diagnostics from the millions of milk samples currently collected. Innovation requires continuous planning, research and investment. Businesses not reinvesting in infrastructure have a limited future as assets near the end of their life without a replacement plan. Dairy is no exception. Efforts to retain traditional agencies with a withering client base by operating a skeleton service will not last. The DHI sector needs to ensure that partnerships, economies of scale and innovation are implemented at the organizations level at a speed at least equal to the farm adoption rate.

Key Words: DHI, Technology, Innovation

422 Harnessing automatic data collection to enhance genetic improvement programs. G. R. Wiggans*[1], M. A. Faust[2], and F. Miglior[3,4], [1]*Agricultural Research Service, USDA*, *Beltsville, MD*, [2]*ABS Global, Inc.*, *Deforest, WI*, [3]*Agriculture and Agri-Food Canada*, *Sherbrooke, QC, Canada*, [4]*Canadian Dairy Network*, *Guelph, ON, Canada*.

Automatic data collection can improve data accuracy, reduce cost of obtaining data, and enable addition of other traits. In the United States, genetic improvement programs for dairy cattle have benefited from a long history of innovation related to data collection and processing: computerization in the 1950s, establishment of laboratories for component testing in the 1960s, electronic transfer of data from farms and laboratories in the 1980s, on-farm data entry in the 1990s, and the recent use of hand-held devices. The recent evolution of increasing emphasis on fitness relative to yield is likely to be hastened because of automated data collection. Electronic milk meters currently are used for 7% of DHI cows and can provide data on total yield, milking speed, and milk conductivity. Other sensors may be added to detect progesterone levels, milk temperature, and information on component concentration. The expected widespread adoption of radio-frequency identification will facilitate electronic collection of data by improving the reliability of identification determination. Electronic scales may be justified as a way to determine body condition score automatically. Hand-held computers may facilitate collection of health data and increase uniformity across herds. Weather data may be used to account for environmental effects better. As the number of traits increases, herds that can supply more data will become increasingly important. A separate progeny-test category may be developed for farms that collect all data electronically and have those data monitored closely. Owners could be paid for their data on a quality basis, thus adding a source of revenue. Such herds could also have parentage verification to improve accuracy further. Automated data collection along with parentage verification offers substantial opportunities for genetic improvement of overall economic merit.

Key Words: Automatic Data Collection, Genetic Improvement, Fitness Traits

423 Optimal number of replications for the Meullenet-Owens-Razor-Shear (MORS) and tenderness variations between right and left broiler breast fillets. Y. S. Lee*, A Saha, C. M. Owens, and J. F. Meullenet, *University of Arkansas*.

MORS is a relatively new method for measuring poultry meat tenderness which is less time-consuming than the Warner-Bratzler and Allo-Kramer shear and shown to be equivalent in performance. However, the number of measurements for MORS to provide a reliable estimate of the tenderness of an experimental unit has not been investigated. There is also limited information available on the variation in tenderness between right and left fillets from a single carcass. The objectives were (1) to determine the number of recommended measurements to be taken on a fillet using MORS and (2) to examine differences in tenderness between the two halves of a fillet. Sixty birds were deboned at either 1.75 or 6 h postmortem (PM). Eight shears were taken on each cooked fillet at predetermined locations and the shear energy (MORSE) calculated in N.mm. The average from 8 measurements per fillet was considered to yield a representative estimated tenderness for the experimental unit (fillet half) and averages of 2 to 8 measurements were considered as potentials for a recommended number of shears. The appropriate number of replications was determined by simple regression using the average of 8 measurements as Y and the average of 2, 3, 4, 5, 6 or 7 as X. A composite hypothesis testing a slope of 1 and an intercept of 0 was then tested. The hypothesis (H0: intercept=0 and slope=1) for number of shears of 2, 3 and 4 was rejected implying that mean MORSE were in these cases not equivalent to mean MORSE for 8 shears. Averages of 5, 6 or 7 measurements did not significantly differ from 8 measurements. For 5 shears, the average error rate was found to be 0.78%. The overall correlation between left and right MORSE was found to only be 0.70. Overall correlations were better for fillets deboned after 6 hrs of aging. The recommended number of shears to be performed on pectoralis major muscles is 5 but error rates could be further reduced with 6 shears. This study also does not seem to indicate that left and right fillets are completely identical in tenderness especially for short aging durations.

Key Words: MORS, Tenderness, Broiler Breast Fillet

424 Carbon monoxide in MAP chicken breast fillets and drums as a food safety intervention to reduce pathogen loads and extend shelf-life. A. M. Lopez*[1], G. Poullier[2], A. M. Luna[1], C. Z. Alvarado[1], L. D. Thompson[1], M. M. Brashears[1], and J. C. Brooks[1], [1]*Texas Tech University*, *Lubbock*, [2]*Toulouse University*, *Toulouse, France*.

The Food and Drug Administration (2002) approved carbon monoxide (CO at 0.4%) as a component of a gas mixture in a modified atmosphere packaging (MAP) systems to maintain wholesomeness, provide flexibility in distribution and reduce shrinkage in meat; however little research has been done in poultry. This project evaluated the effect of MAP with CO on the growth of pathogens and quality parameters in poultry products, and its effectiveness as a possible food-safety intervention. Three replications of 144 samples each were conducted with skin-on drums and skin-off breasts fillets. The samples were either used as controls or inoculated with 1 × 104 cfu/g of a 3-strain Salmonella cocktail. Samples were stored at (4°C) in one of four packaging types: control (PVC overwrap); 0.4% carbon monoxide / 30.0% carbon dioxide / 69.6% nitrogen,;30% CO2 / 70% N2; or vacuum for 0, 3, 7, 14, 18, 21 days. Analyses included Salmonella enumeration, color (L*,a*,b*),TBARS, odor, Psychrotroph counts, aerobic plate counts (APC), coliforms, and generic E. coli. There were no differences in Salmonella growth or TBARS over time within treatments. However, psychrotrophs, coliforms, APC, and generic E. coli, were significantly lower in the MAP packages compared to control packages. Fresh color and odor were retained in the CO-packaged breasts and drums when compared to the other treatments. Therefore, some components of shelf-life of breast fillets and drums can be extended with MAP and CO MAP.

Key Words: Carbon Monoxide, Chicken Breasts, Salmonella

425 Quality of shell eggs stored under modified atmosphere packaging using gas mixtures containing CO and CO_2. D. Aggarwal*, C. Alvarado, C. Brooks, D. Wester, A. Tittor, A. M. Luna, and L. Thompson, *Texas Tech University*, *Lubbock*.

The effect of three types of modified atmosphere packaging (MAP) on the quality attributes of oiled fresh USDA Grade AA shell eggs during of storage was investigated. Shell eggs were subjected to one of four packaging treatments: (1) control - air; (2) 20% CO_2/0.4% CO/79.6% N_2; (3) 20% CO_2/80% O_2; and (4) 20% CO_2/80% N_2. Eggs were stored for up to 30 days in a retail case at a temperature of 6 ± 10°C (refrigerated) or on shelves at 21 ± 10°C (abusive). Eggs were packaged 8 to a tray with a tray considered as the experimental unit. Two trays per treatment per temperature per day were prepared in each trial with a total of three trials being conducted. Packages were opened and sampled on days (D) 1, 7, 14, 21, and 30 for determination of pH (yolk, albumen, whole egg), color (L^*, a^*, b^*), TBARS, foam capacity and stability, Haugh units, and yolk index (YI). Data were analyzed by ANOVA in a 2 (temperature) × 4 (packaging treatment) × 5 (time-points) factorial design using programs in SAS. Where appropriate, means were separated by LSMeans. Whole egg pH was lower throughout storage at both temperatures for the three MAP treatments ($P < 0.0001$). Albumen pH for MAP treatments was significantly lower regardless of temperature as compared to the controls ($P < 0.0001$). At 21°C, there was a significant decline in yolk index of the control eggs during storage compared to the eggs from the three MAP treatments (D1: control YI = 0.36 vs MAP average YI = 0.39, $P > 0.05$; D30: control YI = 0.25 vs D30 MAP average YI = 0.40, $P < 0.0001$). MAP treatment was effective at 21°C in maintaining Haugh units during storage compared to the control packaging. MAP was effective in reducing egg deterioration and loss of functional quality during storage at refrigerated and abusive storage temperatures.

Key Words: Shell Eggs, MAP Packaging, Yolk Index

426 Optimizing NaCl marinade concentrations to improve meat tenderness, flavor, and juiciness of early deboned broiler breast fillets. C. M. Owens, S. C. Purcell*, A. Saha, and J. F. Meullenet, *University of Arkansas*, *Fayetteville*.

Previous studies show that marination of broiler breast meat improves meat quality attributes and yield. Marinades typically contain salt and phosphates; however, due to increased health awareness, trends for lower salt content have increased. The purpose of this study was to evaluate the effect of various salt concentrations on early-deboned boneless breast fillet tenderness and juiciness. One hundred fifty broilers, six-weeks of age, were processed via automated line, chilled in a two-stage process, and deboned at 2 h postmortem. Test fillets were vacuum tumbled for 30 min with a 15% marinade containing phosphate (0.45%) and salt (NaCl) concentrations of 0.33, 0.50, 0.75, or 1.0 %. Control samples were neither tumbled, nor marinated. Cooked fillets were subjected to instrumental analysis using the MORS method (total energy; TE) and consumer sensory analysis using hedonic and Just About Right scales to assess texture, intensity of tenderness, saltiness and juiciness. Tenderness of breast fillets was highly correlated to salt concentration; TE decreased with increasing salt concentration indicating improved tenderness due to marination. Salt concentrations of 0.5% or more resulted in a significant decrease in TE compared to control. According to the consumer panel, a minimum of 0.33% salt was needed to improve texture/tenderness; values further improved as salt concentration increased. Less than 16% of consumers considered marinated fillets as ″too tough″ compared to 49% who considered the control fillets ″too tough″. The attribute, ″saltiness,″ increased as the levels of salt concentration increased, but even at the highest level (1%), only 14% of consumers considered fillets ″too salty″. When compared to the control, marinating with any level of salt improved juiciness. However, marinating with less than 1%, many consumers (31-41%) considered the cooked products ″too dry″. These results suggest that marination of early deboned breast fillets, even with low salt concentrations, can improve tenderness; however, marinating with lower levels of salt may lead to a less juicy product.

Key Words: Marination, Salt, Tenderness

427 Alpha, gamma, and acetate tocopherol determination in chicken muscle by HPLC. C. Narciso-Gaytán*, D. K. Shin, C. A Bailey, A. V. Haq, A. R. Sams, and M. X. Sánchez-Plata, *Texas A&M University*, *College Station*.

The amount, type and activity of vitamin E isomers in chicken muscle influence the lipid and nutritional stability of the meat. The objective of the present study was to estimate the presence and quantify the deposition of alpha and gamma tocopherol, and tocopherol acetate in breast and thigh muscles, affected by dietary fat/oil source and supplemented level of vitamin E. Six hundred Cobb × Ross broilers were fed for 6 weeks with a basal corn-soybean meal diet including soybean, palm kernel or animal/vegetable oil, each supplemented with 33 or 200 mg/Kg of dl-α-tocopheryl acetate. Broilers were randomly assigned into 6 treatments and 4 repetitions, with 25 birds each. After slaughtering of broilers, breast and thigh muscle samples were collected, vacuum-packed and kept frozen at -20°C for further analysis. A 1.0 g muscle sample was mixed with 250 mg ascorbic acid and 7.3 ml of KOH solution (11% in ethanol:water: 55:45) with subsequent incubation for 20 min in a 70°C water bath, hexane was used to separate the tocopherol isomers from the mixture. Tocopherols were extracted by reverse phase (mobile phase: methanol:n-propanol:water 78:17:5) and quantified by photo diode detection (210 and 295 nm wavelength). Efficiency recovery was determined by adding 8 µg of gamma tocopherol. Tocopherol acetate was detected only at 210 nm, while alpha and gamma tocopherols were observed in both 210 and 295 nm. The results showed no interactions in either tocopherol isoform with respect to dietary fat, vitamin E or muscle type. Dietary supplementation of vitamin E increased the deposition of alpha, and acetate, but gamma tocopherol. All tocopherol isoforms were significantly higher in thigh, than breast muscle ($P<0.05$). In conclusion, dietary supplementation of vitamin E increases alpha tocopherol and tocopherol acetate in breast and thigh chicken muscles.

Key Words: Vitamin E, Chicken Muscle, HPLC

428 Fatty acid composition of the gestation and lactation diet affects the fatty acid composition of the backfat of the progeny. G. Bee*, *Agroscope Liebefeld-Posieux, Research Station (ALP)*, *Posieux, Switzerland*.

The aim of the study was to determine the effect of 2 dietary fats (coconut fat [**CF**] and soy oil [**SO**]), which differs in their SFA, MUFA, and PUFA content, supplemented to the gestation and lactation diet of 16 multiparous Swiss Large White sows on the fatty acid (**FA**) composition of the backfat of their progeny at 105 kg BW. At weaning 4 gilts from each CF and SO sow were selected and fed a standard starter and grower diet from 9 to 63 kg BW. In the finishing period (66 to 105 kg BW) 2 gilts were fed a finisher diet (**A**) with the same FA composition (expressed as % total FA; SFA: 25.8; MUFA: 26.6; PUFA: 47.6) as the growing diet, whereas 2 littermates were fed a more saturated finishing diet (**B**; SFA: 28.8%; MUFA: 25.1%; PUFA: 46.1%). Growth performance, carcass characteristics, and the FA composition of the backfat was assessed. Regardless of the diet fed in the finishing period, progeny from CF sows grew slower (0.65 vs. 0.68 g/d; $P = 0.08$) and were less efficient (0.38 vs. 0.39 kg/kg; $P = 0.06$) than gilts from SO sows. Gilts in treatment B had lower carcass yield (82.0 vs. 81.4%; $P = 0.02$), higher percentage lean meat (59.3 vs. 58.5%; $P = 0.09$), lower percentage backfat (11.2 vs. 11.7%; $P = 0.08$), lighter hearts (408 vs. 428 g; $P = 0.05$) and kidneys (285 vs. 300 g; $P = 0.05$) and heavier livers (1551 vs. 1483 g; $P = 0.02$) compared to A gilts. The backfat of gilts in treatment B had higher ($P < 0.01$) SFA (40.2 vs. 39.3%) and MUFA (42.6 vs. 41.1%) and lower PUFA (17.2 vs. 19.7%) concentrations than the backfat of A gilts. These differences were primarily due to higher levels of stearic (23.5 vs. 22.9%), palmitoleic (2.0 vs. 1.8%), oleic (39.3 vs. 38.1%), and lower linoleic acid (14.6 vs. 17.1%) levels ($P < 0.01$ for each). Feeding the more saturated finisher diet decreased the PUFA content to a greater extent in the backfat of gilts born from CF (16.6%) than SO (17.7%) sows (maternal feeding × finisher diet interaction; $P = 0.04$). These findings revealed that not only the FA composition of the growing finisher diet but also the FA of the maternal diet affects the FA composition of the backfat of slaughter pigs.

429 Comparison of vitelline membrane strength amongst breeds of commercial layers. D. R. Jones[1] and K. E. Anderson*[2], [1]*USDA, Agricultural Research Service, Egg Safety and Quality Research Unit*, *Athens, GA*, [2]*Department of Poultry Science, North Carolina State University*, *Raleigh*.

The strength and elasticity of the vitelline membrane is important for both food safety and product quality concerns. The strength of the

membrane has been associated with the ability of microorganisms to enter the nutrient rich yolk. Also, contamination of commercially prepared albumen with yolk during separation can lead to greatly diminished albumen functionality. A study was conducted to determine the strength and elasticity of the vitelline membrane of eggs from six strains of commercial laying hens (3 white, 3 brown). Two different probes were utilized to assess the membrane: 75 mm disc (2.0 g trigger force) and 1 mm, rounded end probe (0.2 g trigger force). Eggs were collected on three consecutive days from layers which were part of the North Carolina Layer Management and Performance Test. All eggs were stored at 4C until tested 5 d after lay. A TA.XTplus Texture Analyzer with a 750g load cell and test speed of 1mm/s was utilized for all measurements. Twelve eggs from each strain were tested daily for each probe. Force measurements for the disc ranged from 132.43 – 173.08 g ($P < 0.05$) with elasticities of 8.25 – 9.49 mm ($P < 0.01$). The 1 mm probe recorded average force measurements of 2.26 – 2.60 g ($P < 0.01$) and elasticities of 2.87 – 6.78 mm. Both probes identified the same strain of layers as producing eggs with the lowest vitelline membrane strength and the least elastic membrane. Force measurements recorded by the disc were much greater and were more closely associated with the linear detection region of the load cell. The disc probe allowed for a more complete assessment of membrane strength than the 1 mm probe due to the high percentage of the membrane having the force exerted upon it. The 1 mm probe could provide insight into the strength at a single point on the membrane where bacteria could attack. The choice of testing probe can have a direct effect on the outcome of the results and should be based on the precise quality concern being targeted.

Key Words: Shell Egg, Vitelline Membrane Strength, Yolk Quality

430 Postmortem sarcomere length characterization between *Psoas major* and *Longissimus dorsi* muscles in cattle. I. Zapata*[1], M. Yamaguchi[1], J. Wakamatsu[2], A. Hattori[2], and M. Wick[1], [1]*The Ohio State University*, *Columbus*, [2]*Hokkaido University*, *Sapporo, Japan*.

Understanding the biological mechanisms of postmortem events in muscle is of enormous importance for the meat industry due to its relation with quality. Although studies have attempted to relate sarcomere length to tenderness, there is a paucity of research on their postmortem characterization between the *Psoas major* (PM) and *Longissimus dorsi* (LD). The aim of this study was to characterize the postmortem sarcomere length of PM and LD muscles in cattle. Samples from the PM and LD muscles were removed from 32 animals at 45 min postmortem at the abattoir in the Ohio State University meat science laboratory. Muscle tissue free of evident fat or connective tissue was dissected from each sample and fixed in a glutaraldehyde/cacodylic acid buffer pH 7.1. Samples were homogenized in cacodylic acid buffer pH 7.1, mounted on glass slides and sealed. Slides were observed by phase contrast microscopy and images were captured with a CCD camera. Sarcomere lengths were measured using image analysis software. Statistical analysis of the sarcomere length was performed using the MIXED procedure from SAS. Representative samples from both muscles were postfixed with osmium tetraoxide and embedded in Eponate resin. Thin sections were obtained and mounted on copper grids, stained with uranyl acetate and lead citrate. Grids were observed using transmission electron microscopy (TEM) and images were taken. Phase contrast based sarcomere lengths of the PM and LD were significantly different ($P < 0.001$). Least square mean estimated lengths were 1.897 ± 0.067 µm for LD and 2.461 ± 0.067 µm for PM. Measured lengths of TEM images were consistent with the measured lengths from phase contrast microscopy. These data demonstrate clear differences in the postmortem architecture between the two muscles. Although tenderness values were not measured in this study, these results indicate that the difference in tenderness generally accepted to exist between the filet mignon (PM) and the ribeye (LD) may be related to the differences in initial sarcomere lengths.

Key Words: Microscopy, Postmortem, Sarcomere Length

431 Cholesterol quantification in meat and meat products. T. T. N. Dinh*[1], L. D. Thompson[1], J. C. Brooks[1], M. F. Miller[1], and J. R. Blanton, Jr.[2], [1]*Texas Tech University*, *Lubbock*, [2]*Intervet Inc.*, *Millsboro, DE*.

The objectives of this study were to develop an accurate and precise method for cholesterol quantification in meat samples based on modifications to an existing procedure (AOAC Official Method 994.10), and to apply this method to evaluate the differences in cholesterol content of longissimus muscles (LM) from Angus (AN, n = 5), Brahman (BR, n = 4), and Romosinuano (RM, n = 9) breeds. Validation of this method was performed using a meat homogenate (Standard Reference Material 1546) from National Institute of Standards and Technology (NIST), and LM samples from the three breeds with fat contents ranging from 2.4% to 9.3%. The results indicated that the modified method was efficient and accurate with cholesterol recovery exceeding 95%. The method was also found to be repeatable with an average coefficient of variation of 3.12%. The modification reduced 90% of chemicals used and eliminated time-consuming steps that hindered high throughput application of the traditional method. Application of this method for cholesterol quantification of LM samples revealed differences among the three breeds evaluated. The Angus LM with a higher fat content (50% higher than BR and RM) was associated with significantly higher cholesterol concentrations (70.25 mg/100 g) compared to Brahman and Romosinuano purebreds (64.77 mg/100g and 65.76 mg/100g; $P = 0.005$ and $P = 0.006$; respectively). Cholesterol concentration was found to be related to fatness of LM muscle from the three breeds ($r = 0.90$, $P < 0.001$). Cholesterol concentrations found in LM were slightly higher than those reported in the USDA National Nutrient Database for Standard Reference for separated lean of Choice rib-eye. This modified method was reliable and should be evaluated for adoption as an appropriate method for cholesterol quantification in meat samples.

Key Words: Cholesterol Quantification, Gas Chromatography, Beef Longissimus Muscle

432 Round muscle profiling of tenderness and postmortem proteolysis. M. J. Anderson*, S. M. Lonergan, and E. Huff-Lonergan, *Iowa State University*, *Ames*.

Definition of characteristics of individual muscles from the round will make it possible to consistently add value to individual cuts.

Therefore, the objective of this study was to determine the biochemistry underlying the differences in tenderness of specific muscles of the round. Ten beef cattle were slaughtered and the longissimus dorsi (LD) and the round muscles gracillus (GR), adductor (AD), sartorius (SAR), vastus lateralis (VL), and vastus intermedius (VI) were removed. Samples were aged 1, 3, 7, or 14 d. Objective tenderness measurements (star probe) and western blots for troponin-T to determine protein degradation were preformed. For troponin-T degradation, two bands (Upper intact band, UI; 30kDa degradation product band, 30kDa) were measured and compared to a reference. On d 1 star probe analysis found that VL required more force to penetrate ($P=0.04$) than VI, SAR, and GR. VI had a lower force ($P=0.04$) than LD. UI band of VI was less intense ($P<0.01$) than AD, GR, and LD. LD had a more intense ($P<0.01$) UI band than all other muscles except the AD. 30kDa was less intense ($P=0.016$) than GR, LD, and VI. On d 3 VL required more force ($P<0.01$) than all other muscles except the AD. AD required more force than GR, SAR, and VI and LD required more force than GR. UI band was less intense ($P<0.01$) for VI than LD, AD, and GR. The UI band from LD was more intense ($P<0.01$) than all other muscles except AD. 30kDa band of AD and LD were more intense ($P<0.01$) than all other muscles with the exception that LD tended to be more intense ($P=0.069$) than VL. On d 7 LD, AD, and VL all required more force ($P<0.01$) than GR, SAR, and VI. 30kDa band of LD was more intense ($P<0.01$) than all other muscles. On d 14 VL required more force ($P<0.01$) than all other muscles except AD, and AD required more force ($P<0.01$) than GR, SAR, and VI. 30kDa band of LD was more intense ($P<0.01$) than all other muscles. 30Kda band of AD was more intense ($P<0.01$) than SAR and VI, and VI was less intense ($P<0.01$) than VL. These data show that physical and biochemical differences exist between individual muscles of the round and may provide insight on ways to add value to individual cuts.

Key Words: Troponin-T, Tenderness, Beef

433 MSTN regulates IGF-2 but not IGF-1 expression during myogenesis of cattle. M. Miyake*, S. Hayashi, Y. Imai, K. Watanabe, S. Ohwada, H. Aso, and T. Yamaguchi, *Tohoku University*, *Sendai, Japan*.

Myostatin (MSTN) is a member of TGF-β superfamily that negatively regulates skeletal muscle mass. Conversely, insulin-like growth factor (IGF)-1 and IGF-2 are essential for the development, regeneration and hypertrophy of skeletal muscle. Although it seems that MSTN and IGF cooperate on skeletal muscle development, their mutual relationship still remains unclear. The present study was carried out to investigate the effects of MSTN on the IGF-1 and IGF-2 expression in Japanese shorthorn cattle. We first examined the IGF-1 and IGF-2 expression in the normal and regenerating the *M. longissimus thoracis* of normal-muscled (NM) and double-muscled (DM) cattle and next the effects of MSTN on the IGF-1 and IGF-2 expression in primary myoblast cultures derived from the *M. longissimus thoracis* of NM and DM cattle. The mRNA expression of IGF-2 was higher in the *M. longissimus thoracis* of DM than NM cattle although IGF-1 mRNA was similarly expressed in the normal and regenerating muscle of both cattle. In the differentiation medium cultures (DF cultures) but not the growth medium cultures (GR cultures), the mRNA expression of IGF-2 was significantly higher in DM than NM myoblasts. However, there were no changes of IGF-1 mRNA expression in the GR and DF cultures. In the both of NM and DM myoblast cultures, MSTN inhibited the fusion of myoblasts and the mRNA expression of MyoD and myogenin. Moreover, MSTN suppressed the mRNA expression of IGF-2 but not the mRNA expression of IGF-1 in DF cultures of NM and DM myoblasts. An inhibitor, SB431542, to activin receptor-like kinases (MSTN signaling molecules) abolished MSTN inhibitions on the fusion and MyoD mRNA expression of myoblasts. The mRNA expression of IGF-2 was augmented by an addition of SB431542 or both of MSTN and SB431542 in DF cultures. These results strongly indicate that IGF-2 expression is regulated by MSTN via activin receptor type IIB-Smad signaling pathway but IGF-1 expression is independent of MSTN during myogenesis of cattle.

Key Words: Myostatin, IGF-2, Bovine Myogenesis

434 Predicting lamb tenderness using proteomic analysis of 36 hour postmortem muscle. M. S. Updike*, A. Nichols, J. M. Reddish, H. Zerby, and M. Wick, *The Ohio State University*, *Columbus*.

Tenderness is one of three main components affecting palatability in lamb along with flavor and juiciness. Currently, carcasses are sorted into palatability classes using quality grade, a score based on physiological age and the amount of intramuscular adipose, which is only moderately correlated to tenderness. A method that would rapidly and accurately predict tenderness would be an advantage to the lamb industry. The long term goal of our laboratory is to create an immunochemical test strip which can accurately predict tenderness for consumers (7-14 d postmortem) at the time the carcasses move from the cooler for fabrication (24-48 h postmortem). Previous research from our lab used bovine myofibrils from 36 h to predict 7 d tenderness as proof of principle. To expand upon that research, 40 cross-bred lambs were harvested at The Ohio State University meat lab. Samples of Longissimus dorsi were taken at 36 h postmortem for proteomic analysis. Chops were assayed for tenderness using Warner Bratzler sheer (WBS) force at 7 d postmortem. Proteomic analysis samples were solublized in urea/thiourea buffer and run on SDS-PAGE using 5-20% gradient polyacrylamide gels. The gels were stained with Sypro Ruby® and the images were digitized. The resulting images were analyzed and the percent contribution of each band to the total was used in a reverse step wise regression on the WBS force value for that sample. Fourteen bands from the 36 h proteomic samples were identified that are associated with and predictive of 7 d tenderness ($r^2 = 0.88$, $p \leq 0.01$). These results suggest that an immunochemical test strip used at 36 h postmortem, based on these proteins, could accurately predict tenderness of lamb when it is consumed at 7 to 14 d postmortem.

Key Words: Lamb, Proteomics, Tenderness

435 Efficacy of the adsorbent AflaDetox in reducing the toxicity of dietary aflatoxin B1 in broilers. M. Denli*[1], J. C. Blandon[1], M. E. Guynot[2], S. Salado[2], and J. F. Perez[1], [1]*Animal Nutrition, Management and Welfare Research Group, Universitat Autònoma de Barcelona.*, *Barcelona, Spain*, [2]*Adiveter S.L. Agro-Reus*, *Tarragona, Spain*.

An experiment was conducted to evaluate the ability of AflaDetox as aflatoxin binding agent to reduce the deleterious effects of aflatoxin B1 (AFB1) in broiler diets. One hundred and twenty Ross 308 d-old male broiler chicks were individually weighed and assigned to eight treatments for 42 d. A 2 x 4 factorial arrangement of treatments was used. This involved the use of AFB1 at 0 or 1 mg /kg feed and AflaDetox at 0, 1, 2, and 5 g/kg feed. Animals were fed on the ground during the first 7 d, and in cages (3 chicks/cage; 5 cages/treatment) from 7 to 42 d. The BW, feed intake (FI), and feed conversion rate (FCR) were measured weekly. At the end of the experiment, blood samples were taken for serum analysis, the birds were sacrificed and the weights of liver and spleen were recorded. Dietary inclusion of AFB1 decreased ($P < 0.05$) BW (2,355 vs 2,049 g) and FCR (1.62 vs 1.78). It also resulted in a higher ($P < 0.05$) relative liver weight (2.09 vs 2.70%) and also higher ($P < 0.05$) serum activities of alkaline phosphatase (ALP; 2302 vs 3456 U/L) and aspartate aminotransferase (AST; 235.9 vs 314.5 U/L). A positive interaction ($P < 0.05$) was observed between AflaDetox and AFB1 contamination for most of the parameters studied. The addition of 1 g AflaDetox in the AFB1 contaminated diet increased ($P < 0.05$) BW and reduced ($P < 0.05$) the relative weight of liver (2.31%) and the serum activities of ALP (2103 U/L) and AST (257 U/L). Inclusion of AflaDetox at 2 or 5 g/kg feed in the AFB1-contaminated diets also improved ($P < 0.05$) FCR. The results indicated that inclusion of AflaDetox in contaminated diets may reduce the adverse effects of AFB1.

Key Words: Aflatoxin B1, Adsorbent, Poultry

436 Effect of OcraTox on the performance and egg quality of laying hens exposed to Ochratoxin A. M. Denli*[1], J. C. Blandon[1], M. E. Guynot[2], S. Salado[2], and J. F. Perez[1], [1]*Universitat Autonoma de Barcelona*, *Barcelona, Spain*, [2]*Adiveter, Agro-Reus, Tarragona*, *Spain*.

The efficacy of OcraTox (ADIVETER, S. L.) as an inhibitor of the deleterious effects of ochratoxin A (OTA) in laying hens was evaluated. A total of twenty-eight, 47-wk-old, Hisex-Brown laying hens, were divided into 4 groups (7 hens per group) with similar initial BW (1,793 ± 18 g) and egg production (99.8 ± 0.4%). Animals were distributed individually in cages and fed the following diets for 3 wk: 1) Control, 2) 5 g OcraTox/kg feed, 3) 2 mg OTA/kg feed and 4) 2 mg OTA/kg feed + 5 g OcraTox/kg feed. Daily feed consumption and egg weight were registered daily and feed efficiency was calculated as feed consumed per kg of egg. Percentage of egg production and egg mass (g/hen/d) were registered daily and calculated at the end of the study. Egg quality was studied by collecting the last 3 eggs produced by hen at the end of the trial. On day 21, blood samples were taken from all birds for analysis of serum biochemistry, the birds were sacrificed, and the weight of liver and spleen were recorded. Compared with the control, OTA decreased ($P<0.05$) feed consumption (127 vs 147 g/d), the egg mass (55.4 and 62.0 g) and albumen height (4.9 and 5.6 mm), yolk redness (18.8 and 20.1) and yellowness (44.4 and 46.3). Inclusion of OcraTox in the OTA diet increased ($P< 0.05$) feed consumption (136.7 g/d) and egg mass (59.4 g). It also alleviated ($P<0.05$) the negative effects of OTA on egg quality by improving albumen height (5.7 mm), yolk redness (20.7) and yellowness (46.0) to values no different ($P>0.05$) from control. Dietary inclusion of OTA decreased ($P<0.05$) serum concentrations of triglyceride, (785.2 and 1071.0 mg/dL), Ca (22.9 and 24.6 mg/dL), and P (4.1 and 5.7 mg/dL). It also increased ($P<0.05$)activity of alkaline phosphatase (1940.5 and 474.0 U/L). Inclusion of OcraTox in the diet ameliorated the negative effects of OTA on serum components that are usually altered by OTA. It is concluded that the use of OcraTox may diminish the deleterious effects promoted by OTA in laying hens.

Key Words: Ochratoxin A, Adsorbent, Laying Hens

437 Partitioning of external and internal bacteria carried by broiler chickens before processing. J. A. Cason*, A. Hinton, Jr., J. K. Northcutt, R. J. Buhr, K. D. Ingram, D. P. Smith, and N. A. Cox, *Russell Research Center*, *Athens, GA*.

Broiler chickens from the loading dock of a commercial processing plant were sampled to determine incidence and counts of index/indicator and pathogenic bacteria. Feathers were removed by hand from ten 6-wk-old chickens from each of seven different flocks and were rinsed in 400 mL of 0.1% peptone water. The heads and feet were removed and rinsed and the picked carcass was also rinsed (each in 200 mL of 0.1% peptone water). The ceca, colon, and crop were aseptically removed and stomached separately in 100 mL of peptone water. *Campylobacter* was present in six of the seven flocks. *Salmonella* was isolated from 50 of the 70 carcasses with at least two positive carcasses in each flock. More ($P < 0.05$) coliforms and *Escherichia coli* were found in the ceca than in the feather. Total external and internal counts were quite similar. Counts of *Campylobacter* were higher ($P < 0.05$) in the ceca and colon than in other samples. *Salmonella* was isolated in external samples from 46 of the 50 positive carcasses. *Salmonella* presence was approximately equivalent in all samples, indicating that contamination was distributed through all external and internal sampling sites. *Salmonella*-positive samples did not have higher counts of coliforms or *E. coli*. There were low correlations ($P < 0.05$) for counts of coliforms, *E. coli*, and *Campylobacter* in the ceca/feathers and ceca/colon comparisons, but not for *Salmonella*. The results emphasized that the pattern of bacterial contamination before processing is complex and highly variable.

Key Words: *Salmonella*, *Campylobacter*, Processing

438 *Campylobacter* colonization is reduced and gastrointestinal architecture is altered in turkey poults fed bacteriocins. I. Reyes-Herrera*[1], K. Cole[1], F. Solis de los Santos[1], A. M. Donoghue[2], N. J. Stern[3], E. A. Svetoch[4], B. N. Eruslanov[4], V. V. Perelygin[4], E. V. Mitsevich[4], I. P. Mitsevich[4], V. P. Levchuk[4], M. B. Farnell[2], P. J. Blore[1], and D. J. Donoghue[1], [1]*University of Arkansas*, *Fayetteville*, [2]*PPPSRU, ARS, USDA*, *Fayetteville, AR*, [3]*PMSRU, ARS, USDA, Russell Research Center*, *Athens, GA*, [4]*State Research Center for Applied Microbiology*, *Obolensk, Russian Federation*.

Campylobacter is a leading cause of foodborne illness in the U.S. Recent studies showed the reduction of *Campylobacter jejuni* in broiler chickens treated with bacteriocins produced by *Bacillus circulans* and *Paenibacillus polymyxa*. As *Campylobacter coli* is the most prevalent *Campylobacter* isolate recovered in turkeys, the objectives of this study were to evaluate the efficacy of these bacteriocins against *C. coli* colonization and the effect on the gastrointestinal architecture of young turkeys. In three separate trials, a total of 15-d-of hatch poults (n = 45/trial) were orally challenged on d 3 with approximately 10^6 cfu of a mixture of three *C. coli* isolates. Immediately before the bacteriocin treatment (d 10), cecal *Campylobacter* concentrations averaged 1.1 x 10^7 cfu/g of cecal contents (n = 15/trial). On d 10 to 12 posthatch, two treatment groups were given free access to feed supplemented with either one of two purified and microencapsulated bacteriocins, whereas the control group received untreated feed (n = 10/treatment group in each trial). After the 3-d dosing period, ceca and duodenal loops were collected. In each trial, we observed the elimination of detectable concentrations of cecal *Campylobacter* (detection limit, 1 x 10^2 cfu/g of cecal contents) vs the controls (1 x 10^6 cfu of *Campylobacter*/g of cecal contents). The evaluation of gastrointestinal samples showed a reduction ($P < 0.05$) in duodenal crypt depth and goblet cell numbers in the turkeys treated with either bacteriocin vs the controls. These modifications in gastrointestinal architecture may provide understanding of how bacteriocins inhibit *Campylobacter*.

Key Words: *Campylobacter*, Bacteriocin, Gastrointestinal Architecture

439 Litter treatment with aluminum sulfate produced a modest reduction in cecal *Campylobacter* colonization in chickens. M. L. Dirain, F. Solis de los Santos, I. Reyes-Herrera, P. J. Blore, and D. J. Donoghue*, *University of Arkansas*, *Fayetteville*.

Campylobacteriosis is a significant health problem worldwide and poultry products are a significant source of transmission. Treatment of poultry litter with aluminum sulfate (Alum) has been reported to reduce enteric *Campylobacter* concentrations in broilers. Little is known about how Alum reduces enteric *Campylobacter* concentrations. Therefore, this study was conducted to determine whether Alum reduces *Campylobacter* colonization in the ceca of broilers by reducing horizontal transmission between birds or by reducing *Campylobacter* concentrations in birds already colonized (therapeutic efficacy). Newly hatched broilers were reared in either no (controls), low (2.4 kg/3.0 m^2), or high (4.8 kg/3.0 m^2) levels of Alum (AlClear+). For the horizontal transmission group, *Campylobacter*-negative birds were reared with *Campylobacter*-positive ones that served as carriers. The carrier birds were fitted with leg bands to distinguish them from the rest of the birds in the pen. For the therapeutic efficacy group, all birds were inoculated with *Campylobacter* prior to placement in pens. During wk 1, 2, 4, and 6, cecal *Campylobacter* concentrations were determined in 10 birds from each treatment group. Furthermore, 20 g of litter were also collected once per week from each pen to monitor litter pH. For both the horizontal and vertical treatment groups, birds reared on high or low Alum also had lower ($P < 0.05$) cecal *Campylobacter* concentrations (approximately 2 logs) when compared with positive controls in pens not treated with Alum. The decline was similar for both groups. These changes were associated with a weekly reduction in litter pH in Alum treated pens when compared with the controls ($P \leq 0.05$). It is possible that the acidic environment of the litter reduces environmental *Campylobacter* levels and enteric recolonization via litter consumption (pecking). This may be the mechanism by which Alum reduces *Campylobacter* concentrations in poultry.

Key Words: *Campylobacter*, Colonization, Aluminum Sulfate

440 Effect of various concentrations of potassium hydroxide and lauric acid on native bacterial flora of broiler carcasses. A. Hinton Jr*, J. K. Northcutt, J. Cason, D. P. Smith, and K. D. Ingram, *Russell Research Center*, *Athens, GA*.

Experiments were conducted to determine the bactericidal effect of various concentrations of potassium hydroxide (KOH)-lauric acid (LA) solutions on native bacterial flora of broiler carcasses. A mixture of 1.0% KOH and 2.0% LA was prepared and filter sterilized. The 1.0% KOH-2.0% LA solution was diluted with sterile distilled water to prepare solutions of 0.25% KOH-0.5% LA and 0.5% KOH-1.0% LA. Eviscerated carcasses were washed twice in solutions of different concentrations of KOH-LA or in distilled water by shaking carcasses in 400 mL of the liquids for 1 min. Following each wash, a whole-carcass-rinse (WCR) was performed by using 400 mL phosphate buffer. Total plate count (TPC) of bacteria was performed. *Campylobacter* and *Escherichia coli* in the native bacterial flora were also enumerated by culturing the rinsates on plate count agar, *Campylobacter* agar, and 3M petrifilm *E. coli*/coliform count plates, respectively. Results indicated that fewer TPC bacteria were recovered from carcasses washed in either concentration of KOH-LA than from carcasses washed in distilled water. However, there was no difference ($P > 0.05$) in the number of bacteria recovered from carcasses washed in different concentrations of KOH-LA. While log 3.45 cfu/mL were recovered from carcasses washed in water, only log 1.43 cfu/mL were recovered from carcasses washed in 1.0% KOH-2.0 %. Additionally, there was no difference ($P > 0.05$) in the number of *Campylobacter* recovered from carcasses washed in water or in 0.25% KOH-0.50% LA. No *Campylobacter* were recovered from carcasses washed in 0.50% KOH-1.00% LA or 1.00% KOH-2.00% LA. There was no difference ($P > 0.05$) in the number of *E. coli* recovered from carcasses washed in water, 0.25% KOH-0.50% LA, or 0.50% KOH-1.00% LA. No *E. coli* were recovered from carcasses washed in 1.0% KOH-2.0 % LA. The results showed washing broiler carcasses in solutions of KOH-LA to have the potential to reduce bacterial contamination. The efficacy of these acids to induce a bactericidal effect, however, appears to depend on the concentration used.

Key Words: Poultry Processing, Lauric Acid, Potassium Hydroxide

441 Numbers of bacteria recovered from broiler carcasses and chiller water treated with hypochlorous and carbonic acids. J. K. Northcutt*[1], R. I. Huezo[2], K. D. Ingram[1], D. P. Smith[1], A. Hinton, Jr.[1], and J. A. Cason[1], [1]*USDA-Agriculture Research Service*, *Athens, GA*, [2]*The University of Georgia*, *Athens*.

A study was conducted to determine effects of treating poultry chiller water with a mixture of hypochlorous and carbonic acids. Broiler carcasses and chiller water were obtained from a commercial processing facility which had recently installed a TOMCO Pathogen Management System™ to recycle water in the middle compartment of a three-section chiller. Carcasses were sampled prechill and post-chill

during first and second shifts, while chiller water was sampled from the beginning and end of each of the three chiller compartments. Carcasses were subjected to a whole carcass rinse (WCR) in 0.1% peptone. Numbers of *Escherichia coli* (EC), coliforms (CF), and *Campylobacter* (CP) were determined from the WCR and chiller water samples. Prevalence of *Salmonella* (SAL) was also determined on the WCR and chiller water samples. Shift had no effect on numbers (EC, CF and CP) or prevalence (SAL) of bacteria recovered from carcasses or chiller water samples. On average, prechill levels of bacteria recovered from rinses were 2.6, 2.9 and 2.6 $\log_{10}$ cfu/mL for EC, CF and CP, respectively. Ten out of 40 (25%) prechill carcasses were positive for SAL. After chilling, numbers of EC, CF, and CP recovered from carcass rinses decreased by 1.5, 1.5, and 2.0 $\log_{10}$ cfu/mL, respectively. However, prevalence of SAL on post-chill carcasses (22% positive) was similar to prechill SAL prevalence. When chiller water samples were tested, EC, CF, and CP were recovered only in water collected from the first compartment of the chiller. Two out of four (50%) water samples collected from the entrance of the first compartment of the chiller tested positive for SAL. The results showed that a mixture of hypochlorous and carbonic acid can be used to recycle poultry chiller water and still achieve reductions in numbers of EC, CF, and CP and no increase in prevalence of SAL recovered from broiler carcasses.

Key Words: Poultry, Immersion Chilling, Carcass Bacteria

442 Effect of time and sand abrasion on recovery of aerobic bacteria, *Escherichia coli*, and coliforms from broiler carcasses. J. F. Hannah*[1], N. A. Cox[2], D. P. Smith[2], J. A. Cason[2], D. L. Fletcher[3], J. K. Northcutt[2], R. J. Buhr[2], and L. J. Richardson[2], [1]*University of Georgia*, *Athens*, [2]*USDA-ARS, Russell Research Center*, *Athens, GA*, [3]*University of Connecticut*, *Storrs*.

An experiment was conducted to determine effects of rinse time and sand abrasion on bacteria from whole broiler carcass rinses (WCR). Twelve eviscerated broiler carcasses were obtained from a commercial processing plant prior to chilling. Six carcasses were rinsed in 400 mL of 2.0% buffered peptone for 1 and 4 min in a mechanical shaker. The remaining carcasses were rinsed in the same manner, but with 100 g of sterile sand added to the rinse solution. Rinses were analyzed for aerobic bacteria (APC), *Escherichia coli*, and coliforms. For APC, *E. coli*, and coliforms, the levesl recovered from the sand rinses were higher ($P < 0.05$) than the levels recovered from the peptone rinses. The APC, *E. coli*, and coliforms collected from the peptone rinses were 4.0, 3.1, and 3.4 $\log_{10}$ cfu/mL of rinse, respectively. The APC, *E. coli*, and coliforms collected from the sand rinses were 4.6, 3.7, and 4.1 $\log_{10}$ cfu/mL of rinse, respectively. There were no differences ($P > 0.05$) in bacterial recovery between the two rinse times for either treatment. A secondary determination of treatment efficacy was conducted by swabbing a 25 cm^2 area of breast skin before and after rinsing. Using sand abrasion during WCR increased ($P < 0.05$) bacterial recovery and rinsing time was found to have no effect ($P > 0.05$)on such recovery. Additionally, WCR was a more sensitive method for recovery of bacteria than swabbing.

Key Words: Whole Carcass Rinse, Sand Abrasion, Bacteria

443 Bactericide and bacteriostatic activity of Chrysactinia Mexicana Gray in hens challenged with *E. coli* and *S. thypi*. J. C. Garcia-Lopez*, L. O. Hernandez-Artega, J. M. Pinos-Rodriguez, and B. I. Juárez-Flores, *Universidad Autónoma de San Luis Potosi*, *San Luis Potosi, S.L.P. México*.

Bactericide and bacteriostatic activity of Chrysactinia Mexicana Gray extract was evaluated in hens challenged with *S. thypi*, and *E. coli*. In the first part an in vitro trial five plant extracts were evaluated; aqueous, methylene chloride, ethanol and hexane. Zones of growth inhibition were measured for the bactericide trial and minimum inhibitory concentration (MIC) was determined. For the *in vivo* phase 30 Plymouth Rock Barred hens 21 weeks old (10 hens/treatment) were used with the following treatments: T1 control with no pathogen challenge and no plant extract; T2 pathogen challenged and ethanol extract of *C. mexicana* and; T3 pathogen challenged and bacitracin zinc. Colony-forming units (CFU) were counted in gizzard, crop, duodenum and cecum contents. There were differences ($P<0.05$) in the zones of growth inhibition of aqueous extract for *S. thypi* with the highest inhibition growth at a concentration of 20 mg/ml. In *E. coli* no differences were observed ($P>0.05$). For the chloride methylene extract, no differences ($P>0.05$) were found between the concentrations used in both pathogens. In the ethanolic extract there were differences ($P<0.05$) in the two bacteria with different concentrations being 20 mg/ml where the highest zones of growth inhibition hales were found. For the hexane extract there were differences ($P<0.05$) only for *S. thypi* with 20 mg/ml. The results for the minimum inhibitory concentration obtained for the ethanolic extract of *C. mexicana* showed a MIC for S. typhi of 0.025 mg/ml and *E. coli* 0.020 mg/ml. In the second phase the in vivo trial showed differences ($P<0.05$) for gizzard, crop and duodenum contents with a decreased number of CFU with the C. mexicana extract than those found with the use of bacitracin zinc. The number of CFU cecum content were similar ($P>0.05$) for the plant extract and the antibiotic. Results show that plant extract may be used to help to increase health status in hens in the backyard production systems in rural areas.

Key Words: Chrysactinia Mexicana, *E. coli*, Hens

444 Reduction of *Salmonella* in whole and ground turkey meat at refrigerated and elevated temperatures using lactic acid bacteria. J. Johnson*, C. Z. Alvarado, and M. M. Brashears, *Texas Tech University*, *Lubbock, TX*.

Lactic acid bacteria (LAB) are inhibitory against various pathogenic bacteria during growth and storage of ground meat. Thus, addition of LAB to turkey meat could provide an inhibitory effect on pathogens such as *Salmonella* due to production of inhibitory compounds. Three experiments were conducted with ground turkey (stored at 5°C) and portioned whole turkey meat (stored at either 5 or 37°C). Ground turkey was inoculated with 1 x 10^4 cfu/g of a 4-strain *Salmonella* cocktail. The two treatments included control (no LAB) and 1 x 10^6 cfu/g cocktail mixture of the 4 strains of LAB. The samples were stored in tray packs for 5 d at 5°C and were tested on d 0, 1, 2, and 3. Initial *Salmonella* counts on d 0 were similar but on d 3 the LAB-treated samples had a 2 log reduction in total *Salmonella*. In experiments 2 and 3, whole turkey breast lobes were inoculated with 1 x 10^4 cfu/g of the *Salmonella* cocktail. The two treatments included control (no LAB) and 1 x 10^6 cfu/g cocktail mixture of the 4 strains of LAB. The samples were stored in tray packs at either 5°C for 0, 1, 2, and 3 d or at 37°C for 0, 1, 2, and 4 h. In the 5°C study, there was a 2 log reduction by d 3 in the LAB-treated samples. In the elevated temperature study

(37°C), there were no differences in *Salmonella* at 0 or 1 h. However, by 2 h post-inoculation there was a 1.5 log decrease in the LAB-treated samples. By 4 h post-inoculation, there was a 2 log decrease in *Salmonella* recovery in the LAB-treated samples. Thus, our LAB cocktail appears to reduce growth of *Salmonella* in ground and whole turkey meat at refrigerated and elevated temperatures.

Key Words: *Salmonella*, Lactic Aid, Turkey Meat

445 Evaluation of serum as an indicator of antibiotic residues in edible poultry tissues. I. Reyes-Herrera*, V. Aguiar, M. L. Dirain, F. Solis de los Santos, J. H. Metcalf, P. J. Blore, and D. J. Donoghue, *University of Arkansas*, *Fayetteville*.

The FDA and USDA monitor food products, including poultry, to detect and prevent unsafe residues (e.g., drugs or pesticides) in the food supply. Monitoring procedures often require analysis of specific edible tissues (e.g., muscle). A potentially better option would be to evaluate blood samples collected directly from the processing line. Blood samples are usually easier to obtain and less expensive to analyze, do not require destruction of the carcass, and would represent any residue in the entire flock as opposed to an individual sample. However, it is unknown if residues in blood are correlated with residues in edible tissues. The objective of this study was to determine if antibiotic residue concentrations in blood are predictive of their concentrations in muscle tissues. The model antibiotic tested in this study was enrofloxacin. In this study, 5-wk-old broiler chickens (n = 156) were divided into two treatment groups and were dosed with either 25 ppm/3 d or 50 ppm/7 d of enrofloxacin (Baytril) in the drinking water. Blood and breast muscle samples were collected from six birds/group at 0, 1, 3, 6, 12, or 24 h during the first day of dosing and then every 48 h during the dosing period and every 12 h during the withdrawal period for up to 60 h post-withdrawal. Enrofloxacin was detectable within 1 h of dosing, reaching its plateau phase at 12 h (234 and 122 ppb for muscle and serum, respectively, for the 12-h sample from the 25 ppm/3 d dosing group), and was detectable for 36 h after drug withdrawal in both serum and muscle tissues. For all collection periods, enrofloxacin concentrations in blood (serum) were approximately half of those in muscle tissues. Because of this consistent relationship, monitoring blood samples may be an effective method to estimate antibiotic concentrations in edible tissues.

Key Words: Enrofloxacin, Edible Tissues, Poultry

446 Effects of blood in egg albumen on *Salmonella* survival and growth. D. P. Smith* and M. T. Musgrove, *USDA, Agricultural Research Service*, *Athens, GA*.

Two trials were conducted to determine effects of blood in table egg albumen on survival and growth of *Salmonella*. White-shell table eggs with blood spots were collected from a commercial egg processing plant after candling. In each trial eggs were broken out and approximately 4 mL of clear albumen (CLEAR) and 4 mL of bloody albumen (BLOOD) from each of 10 eggs were placed in sterile test tubes and inoculated with a nalidixic acid-resistant *Salmonella* Typhimurium. For inoculation, 0.1 mL of a *Salmonella* suspension (containing 2.9 log cfu/mL in Trial 1 and 7.1 log cfu/mL in Trial 2) was added to each tube. Tube contents were mixed and incubated at 22°C for 24 h. Immediately after inoculation and again after 24 h, 0.1 mL from each tube was plated onto brilliant green sulfa agar with nalidixic acid and incubated at 37°C for 24 h. Results were reported as log cfu/mL albumen. No differences ($P > 0.05$) in mean *Salmonella* counts were found for CLEAR or BLOOD samples in Trial 1 (averaging 1.6) or in Trial 2 (averaging 4.6) immediately after inoculation. In Trial 2, CLEAR samples had lower ($P < 0.05$) counts of *Salmonella* than BLOOD samples (4.8 vs 5.2) after 24 h. A vaild test was not appropriate for Trial 1 (24 h samples) because of reporting negative results due to the low inoculation level. Incidence of positive *Salmonella* samples in Trial 1 after 24 h was 3/10 for CLEAR samples and 8/10 for BLOOD samples. Results indicated that *Salmonella*, at the low inoculation level, appeared to survive somewhat better in bloody albumen than in clear albumen. At the high inoculation level, *Salmonella* numbers increased slightly in albumen without blood, but higher numbers were detected in bloody albumen. Thus, blood in the albumen of table eggs appears to support survival and growth of *Salmonella*.

Key Words: Table Eggs, Blood Spots, *Salmonella*

Forages and Pastures - Livestock and Poultry: Understanding Diet Selection in Temperate Biodiverse Pasture Systems

447 Dietary selection: The current state of knowledge. A. J. Rook*, *Private Consultant*, *Okehampton, UK*.

The current state of knowledge regarding dietary selection will be reviewed with particular emphasis on implications for temperate biodiverse pasture systems. It will be contended that dietary selection is not only key to optimising animal performance in these systems but also to minimising environmental impacts, whether through enhancing biodiversity and thus ecosystem functionality, minimising the impacts of animal excreta or reducing the carbon footprint of these production systems. Consideration will be given to progress made and key gaps in knowledge with respect to 5 questions. What do animals choose to eat? Where do they choose to eat? When do they choose eat? What mechanisms do they use to achieve these choices? Finally and most crucially, why do they make these choices? Methodological barriers to progress and the potential of new technologies to overcome them will be considered. Emphasis will be given to the importance of interdisciplinary collaboration and research at disciplinary interfaces. Key advances in recent years include the recognition of the importance of partial preferences, the complexity of spatial and temporal patterns in dietary choices, the role of social behaviour in modifying foraging decisions and the phenotypic plasticity in responses consequent upon learned behaviours from the dam or other conspecifics. However, most of this progress has been made using simple model and often artificial systems. In many cases we know the limits of the animals abilities in key traits but not how they interact in real world situations. Other key issues identified for further research include: 1) a better identification of the currencies that animals use to make their foraging decisions and the trade off between these currencies and with other behavioural needs; 2) a better understanding of the interplay between genetic,

ontological and environmental factors influencing foraging behaviour; 3) the need to better understand and integrate spatial and temporal variation into practical systems. A key component in delivery of this knowledge will be further improvement in our capacity to model these complex systems based on multi-species swards.

Key Words: Dietary Selection, Biodiversity, Pasture Systems

448 Genetic control of dietary choice in farm animals: A combination of nature and nurture. R. M. Lewis*[1] and G. C. Emmans[2], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*Scottish Agricultural College*, *Edinburgh, Scotland, UK*.

Dietary choices reflect an animal's physiological state, such as its degree of maturity or pregnancy. As genotype affects growth and body composition it is expected to affect dietary intake and choice. Experience also affects dietary choice. Genetic variation in state variables such as growth rate and fatness of gain, which is substantial, conditions dietary choice. Evolutionary theory predicts that animals that forage more effectively will also survive and reproduce more effectively. Thus, natural selection will favor those adaptations, that may be morphological, physiological or behavioral, that enhance an animal's fitness within the constraints of its feeding environment. In wild animals in natural environments, body homeostasis appears to be genetically controlled, in part mediated through the animal's feed choice and intake. Obesity and anorexia, extremes on the continuum of body composition, seldom if ever occur because of reductions in fitness. Farm animals no longer subsist within the conditions in which they originally evolved. In controlled environments, feed energy may be in abundance and diet choice limited or non-existent. Artificial selection for increased growth rate and, more recently, against fatness, may interact with the rules that govern diet selection. Poultry provide a striking example. Selection for rapid growth over the past 50 years has increased food intake relative to body mass, with broilers growing four times more quickly and reaching market weight (2.2 kg) at about 6 weeks. In broiler breeders, feed intake is routinely controlled to avoid reproductive difficulties and to enhance livability. Lines selected for human purposes still appear to use the pre-existing rules controlling feed intake. The evidence on the selection of diet composition, either in controlled circumstances or in grazing mixed swards, is far less clear. In ruminants, there are no satisfactory models for predicting diet composition for existing genotypes. The effects, if any, of genetic selection is also unclear.

Key Words: Dietary Choice, Genetic Delection, Intake Models

449 Learning and dietary choice. J. J. Villalba*, *Utah State University*, *Logan*.

Early studies of foraging assumed diet selection was genetically programmed, and livestock production systems have traditionally viewed grazing animals as ″machines″ whose nutritional needs had to be provided in a prescribed manner. However, physiological needs and behavioral responses are not fixed. Rather, they have a significant learned component that enables animals to balance their diets when allowed to select among alternatives. Genes affect morphology and physiology, creating the bounds within which animals can use nutrients and cope with toxins, but genes do not operate in isolation. They are expressed, beginning at conception, through the interplay with the social and biophysical environments where an individual is reared. These interactions allow individuals to learn through trial and error (individual learning) and from the experience of others (social learning). Individual learning is illustrated by food preferences, which emerge from the animal′s experience with the interrelationship between a food′s flavor and its postingestive consequences. The senses of smell and taste enable animals to discriminate among foods. Postingestive feedback calibrates preference for food with its homeostatic utility. This mechanism allows animals to avoid poorly nutritious foods and foods high in toxins and to prefer nutritious foods, substances with health benefits, or arrays of foods that complement one another biochemically. Social learning is manifest through mother and peers. Lessons learned early in life from mother create a dichotomy between the familiar and the unfamiliar (novel), which is essential for survival. Animals prefer the familiar to the novel, and they regard anything novel with caution. Understanding how learning affects animal behavior and performance can facilitate the design of sustainable grazing systems to improve the quality of land as well as the nutrition, health and welfare of animals. Incorporation of learning into grazing systems involves offering livestock diverse and biochemically complementary plant species, such that through individual and social experiences animals balance their consumption of nutritional and medicinal compounds.

Key Words: Diet Selection, Learning, Experience

450 Forage factors and dietary choice. D. F. Chapman*[1], A. J. Parsons[2], J. Hill[1], and K. Venning[1], [1]*University of Melbourne*, *Melbourne, Victoria, Australia*, [2]*AgResearch*, *Palmerston North, New Zealand*.

When offered a free choice between different forage species presented in a pasture association, ruminants will choose a mixed diet, even when one dietary component could meet all of their nutritional needs. Thus, preference and selection cannot be explained simply by the common measures of species nutritive or feeding value. The question then arises, what is the nutritional basis of the dietary choices that animals make? This review focuses on the forage composition factors that might be implicated in dietary choices made by grazing ruminants. The satiety theory is used to develop propositions about the physico-chemical attributes of forages that influence grazing behaviour. We present evidence that animals eating only clover (with relatively high rumen degradable protein content) take shorter meals than animals eating only grass (with relatively low rumen degradable protein content), or a mixture of grass and clover. Thus, total daily intake is reached by different combinations of meal length, meal number and intake rate on pure clover, pure grass, and mixed diets. We extend these observations by proposing that satiety in the case of the clover-only diet is related to the rate of release of ammonia from the soluble protein fraction of the forage, and subsequent uptake in the blood to levels that can approach toxicity if the ammonia is not removed by excretion as urea. Mixing grass with the clover allows animals to eat longer meals, perhaps because the better dietary balance of energy to soluble protein helps control ammonia accumulation rates. Rumen ammonia and gas profiles from in vitro studies suggest that digestive efficiency is optimal at a dietary clover: grass ratio of approximately 0.7:0.3, which corresponds closely to the partial preferences observed in free choice field experiments. Direct, real-time information on the relationships

between forage physico-chemical factors and meal initiation, cessation, and dietary switching is needed to further develop propositions about the control of dietary choices.

Key Words: Grazing, Intake, Dietary Choice

451 New approaches to grazing effects on pasture composition and productivity. E. A. Laca*, *Plant Sciences, University of California*, *Davis*.

Herbivory can have dramatic impacts on productivity, composition and functioning of grassland and pasture ecosystems. Yet, our ability to manage these effects has been limited, both by the traditional paradigms and by factors selected to manage grazing systems. These paradigms assume that grazing, plant growth, and ecological interactions are uniform and vary continuously over space and time. Management factors considered are total and seasonal forage demand, animal density, and duration of grazing. A typical analysis of grazing systems under this paradigm is a plot of herbage mass vs. time with various levels of stocking rate. Diet selection is represented as the proportion of each species grazed, which potentially affects the competitive interactions among pasture species across the pasture. These interactions are assumed to be constant over space and time. Further progress in grazing science and management requires implementation of a new and more complex paradigm that incorporates spatially and temporally distributed ecological interactions such as herbivory, growth, competition, and abiotic conditions. Although it is well established that grazing impact on a plant depends on its individual state, this has rarely been fully incorporated in the study and planning of grazing. The temporal and spatial dynamics of productivity and composition of pastures is sensitive to the initial state of the sward and to the spatiotemporal distribution of defoliation at scales much smaller than the typical paddock. Competitive dominance among plant species varies with ecological conditions. Thus, impact of defoliation on competition varies over space and time. I outline a model that shows the convergence of new ecological understanding of herbivory and pasture dynamics towards a new paradigm for researching grazing management tools. Technologies to monitor and control animal distribution are evolving rapidly and create management and research opportunities to experimentally address a new paradigm where there is a tighter link between manipulation of grazing and practical results.

Goat Species: Nutrient Requirements of Goats

452 Goat species: Nutrient requirements of goats - Introduction. J. E. Huston*, *Texas A&M University*, *San Angelo*.

The National Research Council recently released the first issue of *Nutrient Requirements of Small Ruminants* addressing the nutrient requirements for goats along with those for sheep and various cervid and camelid species. Specialists from various regions within the U.S., Australia, and Mexico were appointed in April 2004, and charged with gathering existing information and writing the report. The report was prepared to accommodate a broad readership that varied in both informational interest (species, physiological bases for nutrient requirements, tabular data, practical application, etc) and depth of training. Fourteen chapters summarize published information on comparative anatomy and gastrointestinal function, functions and requirements of nutrients, nutrient sources and intake, common deficiencies and deficiency symptoms, and other considerations as they pertain to the species considered. Usually, general discussion of the chapter topic is followed by discussions targeting the individual species. An extensive list of references is provided at the conclusion of each chapter. Individual tables list the nutrient requirements for the different species, and feed composition tables describe common feedstuffs, novel feedstuffs, and mineral supplements. The tables listing the nutrient requirements of goats provide separate entries for dairy, meat, and Angora goats as influenced by age, sex, body size, physiological stage (e.g., maintenance, growth, breeding, gestation, and lactation), and level of production (e.g., growth rates, litter sizes, and levels of milk production). Tables listing contents of common feedstuffs and mineral supplements are extensive and similar to those contained in other National Research Council reports. The table describing novel feedstuffs is unique to this publication and compiles information on feeds particularly important to small ruminants in their natural settings and managed by individuals of diverse cultures. The authors of this report are excited about its use in providing information to its readership and its role in stimulating discovery of new research information for subsequent improved issues.

Key Words: Nutrient Requirements, Small Ruminants, Goats

453 Energy and protein requirements of goats. M. Huerta Bravo*, *Universidad Autónoma Chapingo*, *Chapingo, México*.

The objective is to disseminate the new NRC recommendations about energy and protein for goats. Previous energy maintenance requirements were estimated as metabolizable energy (MEm) with a single equation for all goat types and conditions, with an adjustment for activity. Now, maintenance requirements (ME_m) are given for suckling or preweaning, growing, and mature goats. Also, goat breeds are grouped as meat, dairy, indigenous, and Angora. A 15 percent difference in ME_m among intact males vs females and wethers is assumed. An adjustment factor for body condition score and weeks after low nutritional plane stops and adequate nutritional plane starts may be included to estimate ME_m. Grazing activity considers grazing plus walking time, organic matter digestibility, and terrain score to calculate an adjustment for ME_m. Additionally, ME_m may be adjusted by environmental temperature. Metabolizable energy for gain considers suckling or preweaning, growing, and mature goats. For angora goats, requirements for gain are separated for nonfiber tissue gain (ME_{tg}) and clean mohair fiber gain (ME_f). Metabolizable energy requirements for

lactation (ME_l) are estimated as 1.25 Mcal for I kg of 4 percent fat corrected milk, and a value was given for mobilized tissue. Pregnancy requirements consider average birth weight per kid, day of gestation, and litter size. Previous protein requirements were given as crude (CP) or digestible crude protein. The new recommendation considers metabolizable protein (MP) for all functions. A conversion of MP to CP is given to facilitate its use. An estimate of rumen degraded intake protein is also given as a general guideline.

Key Words: Energy, Protein, Goats

454 Vitamin requirements of goats. B. W. Hess*, *University of Wyoming*, *Laramie*.

Vitamins are a group of complex organic nutrients that are essential for multiple metabolic processes but, unlike other organic nutrients, vitamins are required in minute amounts (µg to mg/d). Because estimates of endogenous vitamin losses are non-existent, vitamin requirements are based on animal responses during feeding trials. Recommendations for vitamin requirements are complicated by selection of the criteria by which the vitamins are judged adequate or inadequate. As in past NRC publications, vitamin requirements of goats are often derived from values for sheep. Unlike previous requirements for vitamin A, newly established requirements are based on the animal′s ability to maintain 20 µg of retinol/g of liver and are expressed as retinol equivalents (RE). Daily intake of 31.4 RE/kg of live BW is deemed necessary for animals at maintenance. Vitamin A requirements increase to 45.5 RE/kg of live BW for nannies during late gestation, 53.5 RE/kg of live BW for lactating nannies, and 100 RE/kg of live BW for growing kids. Due to insufficient data published to the contrary, the vitamin D requirements for all classifications of goats are comparable to previous recommendations. Daily vitamin E intake of 5.3 IU/kg of live BW is required to maintain blood α–tocopherol concentrations ≥ 2 µg/mL. Provision of 5.6 IU/kg of live BW during late gestation is recommended to increase serum α–tocopherol concentrations of the neonate. Vitamin E requirements increase to 10 IU of vitamin E/kg of live BW when the goal is to enhance immune response or extend the storage case life of meat. In general, vitamin K and water–soluble vitamin requirements of goats can be met by escape of dietary sources from ruminal metabolism and through endogenous synthesis (microbial or bodily). Although several studies have demonstrated production or health benefits when diets have been supplemented with water–soluble vitamins, the amounts of vitamins given to induce such responses are usually for specialized situations and may not necessarily reflect requirements for various production functions. Additional research is needed to establish recommendations for requirements of water-soluble vitamins for goats.

Key Words: Goats, Vitamins, Requirements

455 Revised guidelines for mineral requirements of goats. S. G. Solaiman*, *Tuskegee University*, *Tuskegee, AL*.

Mineral requirements of an animal largely reflect the nutritional demands during different physiological phases. Minerals are required for maintenance, growth, conceptus product formation, and milk production. Borderline mineral intake may compromise animal performance and longevity. Specific mineral deficiencies vary and animal may deplete the pool of tissue minerals before deficiency symptoms are exhibited. Inadequate mineral supplies may reduce production, prolong the duration of parturition, increase the number of stillbirths and result in a higher occurrence of skeletal problems. Many advances in mineral nutrition and metabolism have resulted in establishing guidelines for requirements of different species. However, there are relatively few original scientific research reported on mineral nutrition and metabolism of goats that can be used in establishing the guidelines for this species. Also most of the reported literature is largely speculation based on analogy with cattle and sheep, thus, made our task more challenging. However, few advances in recent years have allowed more specific recommendations for some macro and trace minerals based on goat data. The present report is an assessment of original research conducted on goats and where possible, mineral requirements are calculated by factorial methods using goats, cattle and sheep data. Therefore, the proposed requirements are generalizations and their application to specific breeds and conditions may vary.

Key Words: Goat, Minerals, Requirements

Growth and Development - Livestock and Poultry I

456 Specie and age effects on IGF mRNA expression in the amniotic and allantoic membranes and jejunum of developing avian species. D. M. Karcher* and T. J. Applegate, *Purdue University*, *West Lafayette, IN*.

Insulin-like growth factor (IGF) concentrations change in amniotic and allantoic fluids during development in the chicken, duck, and turkey. However, IGF contribution by the embryo has not been evaluated. This study investigated mRNA transcript abundance in the amniotic and allantoic membranes and jejunum throughout development and among three avian species. Eggs were set (540/specie) and 5 embryos were sampled every other day during incubation through 7 days post-hatch. RNA was extracted and mRNA transcripts for IGF-I, IGF-II, and IGF-R were evaluated by quantitative PCR at d -7, -4, 0 (hatch), 1, 3. Statistical differences were detected using proc mixed in SAS. The starting abundance of chicken IGF-I mRNA in the allantois increased 25-fold from d -7 of incubation to d -4. Within d -4, chicken IGF-I transcript abundance was 8.6 times greater than turkey ($P<0.05$) in the allantoic membrane. However, no differences were detected in membranes for IGF-II or IGF-R among species. The jejunum was evaluated prior to hatch and both jejunum and jejunum mucosa post-hatch. IGF-I transcript abundance was 3.4 fold higher ($P<0.05$) in the chicken compared to turkey at d -7. Turkey and duck were significantly lower ($P<0.05$) than chicken at d -4 in the jejunum. The chicken jejunum IGF-I transcript peaked at 1 d post-hatch versus ($P<0.05$) hatch and 3 d post-hatch. Chicken IGF-I mRNA in the jejunum was significantly higher ($P<0.05$) than both duck and turkey at 1 d post-hatch. The IGF-I mRNA in the duck's jejunal mucosa peaked at 3 d post-hatch and was significantly greater ($P<0.05$) than turkey and chicken at 3 d post-hatch. Chicken jejunum contained significantly ($P<0.05$) more IGF-I transcript when compared to the jejunum mucosa at 1 d post-hatch, while duck jejunum mucosa was statistically ($P<0.05$)

greater than the jejunum at 3 d post-hatch. Greater transcript abundance in the mucosa at 3 d post-hatch may lead to higher IGF-I protein expression enhancing IGF-I effects on jejunum mucosa. No differences were observed in jejunum or jejunum mucosa for IGF-II or IGF-R during the incubation or post-hatch periods for all three species suggesting the majority of transcript is produced within the mucosa.

457 The role of glypican-1 glycosaminoglycan chains in myogenic satellite cell proliferation, differentiation, and fibroblast growth factor 2 responsiveness. X. Zhang*[1], C. Liu[1], K. E. Nestor[1], D. C. McFarland[2], and S. G. Velleman[1], [1]*Ohio Agricultural Research and Development Center, The Ohio State University*, *Wooster*, [2]*South Dakota State University*, *Brookings*.

The glypicans are a family of cell-surface heparan sulfate proteoglycans consisting of a core protein covalently attached with glycosaminoglycans (GAG). Only glypican-1 is expressed in skeletal muscle and increases in expression during myoblast differentiation. Previous studies have suggested that glypican-1 influences fibroblast growth factor 2 (FGF2) signaling pathway by its heparan sulfate chains. A turkey glypican-1 full length cDNA (1,650 bp, GenBank acc. no. AY551002) with three potential GAG attachment sites at Ser483, Ser485, and Ser487 was cloned into the pCMS-EGFP vector. To investigate the functional contribution of each GAG chain, the wild type glypican-1, one-chain and no-chain mutants, and the pCMS-EGFP vector without an insert were transfected into turkey myogenic satellite cells. The transfected cell cultures were assayed for cell proliferation, differentiation, and FGF2 responsiveness. All the data were summarized as mean ± SEM analyzing by an ANOVA and two-sided P values of $P < 0.05$ were considered statistically significant. The overexpression of wild type glypican-1 increased FGF2 responsiveness during proliferation and increased the process of differentiation but did not affect proliferation when compared to the one-chain, no-chain mutants, and the pCMS-EGFP vector without an insert. To support the overexpression data, glypican-1 expression was reduced using a small interfering RNA against turkey glypican-1. Inhibition of glypican-1 expression decreased myogenic satellite cell proliferation, differentiation and FGF2 responsiveness during proliferation. We conclude that glypican-1 function requires all the GAG chains for myogenic satellite cells to increase FGF2 responsiveness during proliferation and to affect the process of differentiation.

458 Reduction in cell responsiveness to transforming growth factor-beta by decorin overexpression increases satellite cell proliferation and differentiation. X. Li*[1], D. C. McFarland[2], and S. G. Velleman[1], [1]*Ohio Agricultural Research and Development Center, The Ohio State University*, *Wooster*, [2]*South Dakota State University*, *Brookings*.

Muscle development is a highly organized process regulated by interactions between muscle cells and their extracellular matrix (ECM) environment. The ECM, through its regulation of growth factors, plays a pivotal role in muscle growth and repair. Transforming growth factor-beta (TGF-β) is a potent inhibitor of muscle cell proliferation and differentiation. Decorin, a small ECM proteoglycan, binds to TGF-β and modulates TGF-β activity during muscle cell growth and development. However, its interaction with TGF-β is not well characterized. The objective of this study was to examine the interaction of TGF-β and decorin during myogenesis. Chicken myogenic satellite cells isolated from the pectoralis major muscle were used to investigate the biological functions of TGF-β and decorin during myogenesis. Satellite cells are considered to be myogenic precursors for muscle growth and repair. In the present study, the satellite cells were transfected in vitro with a full-length chicken decorin cDNA. The effect of decorin on cell proliferation was monitored by measuring the DNA content of sample wells. The effect of decorin on cell differentiation was assessed by measuring changes in muscle-specific creatine kinase levels. Decorin overexpression increased both satellite cell proliferation and differentiation rates compared to the control cells. Furthermore, decorin overexpressing satellite cells were less sensitive to TGF-β during both proliferation and differentation. These results suggest that decorin reduces satellite cell responsiveness to TGF-β signaling, leading to an increase in satellite cell proliferation and differentiation.

Key Words: Decorin, Transforming Growth Factor-Beta, Satellite Cell

459 Bone mineralization in four Cobb pedigree lines of meat-type chickens. P. Talaty*[1], M. N. Katanbaf[2], and P. Y. Hester[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*Cobb-Vantress, Inc.*, *Monticello, KY*.

Previous work in our laboratory showed that 4 strains of commercial broilers (Cobb 500, Cobb 500T, Ross 308, and Cobb 700) did not differ in bone mineralization (Talaty et al., 2006, Poultry Sci. 85: (suppl. 1): 16). The purpose of the current study was to determine the variability of bone mineral density (BMD) and bone mineral content (BMC) of the tibia and humerus of four pedigree lines of Cobb breeders from 6 to 24 wk of age. Four purebred lines (A, B,C, and D) of male and female Cobb breeders were each placed in littered floor pens of 3 replicates each from hatch to 24 wk of age at stocking densities similar to industry standards. Feed restriction was initiated at 6 wk of age. Healthy birds without lameness and broken bones were selected for scans at 6, 15, and 24 wk of age. Different birds were scanned at each age. Bone mineralization of 9 birds/line/sex/age was determined using dual energy X-ray absorptiometry (DEXA).Using the mixed model procedure of SAS, mineralization data were analyzed using an analysis of covariance with BW as a covariant. Results indicated that the CV for BMD and BMC ranged from 11 to 19%. The BMD was similar among pedigree lines. An age related increase ($P < 0.001$) in BMD occurred between 6 wk (mean = 0.224^{b} g/ sq cm, CV = 14%) and 15 wk (mean = 0.244^{a} g/sq cm, CV = 13%) with no further increase noted at 24 wk of age (mean = 0.244^{a} g/sq cm, CV = 17%). The BMC was similar among pure-bred lines of Cobb chickens at 6 and 15 wk of age; however, at 24 wk of age, Line C had higher BMC than Lines A and D, but did not differ from Line B resulting in a line × age interaction ($P < 0.01$).The higher BMC of Line C was mainly due to increase bone length and bone area. Since differences in BMC among lines did not occur until 24 wk of age and there were little to no differences in BMD among pedigree lines of chickens suggest that 6 to 8 wk old progeny derived from these lines may not differ in bone mineralization.

Key Words: Bone Mineralization, Bone Mineral Density, Pedigree Chickens

460 Identification of two novel chicken growth hormone-releasing hormone receptor (GHRHR) splice variants: Implications for the role of Asparagine residue (Asp^{56}) in receptor activation and direct ligand-receptor interaction. C. Y. Wang*, Y. Wang, A. H. Y. Kwok, and F. C. Leung, *The University of Hong Kong*, *Hong Kong, HK-SAR, China*.

In this study, two novel Growth Hormone-releasing Hormone Receptor (GHRHR) splice variants, named cGHRHR-v1 and cGHRHR-v2 respectively, were identified from chicken pituitary using RT-PCR assay. cGHRHR-v1 is a variant of 383 amino acids and characterized by an N-terminal deletion of 36 amino acid residues (encoded by exon 3) including an asparagine at position 56 (Asp^{56}) conserved in all members of subfamily B-III G protein-coupled receptor. cGHRHR-v2 is a C-terminally truncated receptor variant of 284 amino acids with 4 putative transmembrane domains, which arises from alternative usage of a splicing acceptor site located at the 3′ end of intron 8. Using pGL3-CRE-luciferase reporter system, the functionalities of the two variants were examined in CHO cells. cGHRHR-v2 could not transmit signal after agonist treatment. In contrast, cGHRHR-v1 is still likely a functional receptor. Both GHRH and pituitary adenylate cyclase-activating polypeptide (PACAP) could activate cGHRHR-v1 at high dosages (GHRH $\geq 10^{-8}$M; PACAP, $\geq 10^{-6}$M) and GHRH appeared to be much more potent than PACAP, suggesting that cGHRHR-v1 is a membrane-spanning receptor with an impairment in high affinity ligand binding, rather than in receptor activation or ligand-binding specificity. Meanwhile, this finding points out the possibility that Asp^{56} is not critical for receptor activation and direct ligand-receptor interaction. To substantiate this hypothesis, using site-directed mutagenesis, two receptor mutants with replacement of Asp^{56} by Ala or Gly were generated. Expectedly, GHRH and PACAP could activate both receptor mutants with slightly, but significant, reduced potencies. Taken together, our findings not only suggest that cGHRHR variants may play a role in controlling normal pituitary functions, but also support the notion that Asp^{56} is nonessential for receptor activation and direct ligand-receptor interaction.

Key Words: GHRH, GHRHR, Pituitary

461 Feed restriction alters the temporal expression of skeletal fast myosin isoforms in the breast muscle of diverse lines of turkeys. K. M. Huffman*, J. M. Reddish, M. S. Lilburn, and M. Wick, *The Ohio State University*, *Columbus*.

Significant increases for body weight and breast muscle proportion in commercial broiler and turkey strains have been made by genetic selection; however, the mechanisms of breast muscle growth and effects of such selection have not been fully explained. Our hypothesis is that feed restriction alters the temporal expression pattern of neonatal fast skeletal and adult fast skeletal myosin isoforms in the Pectoralis major (PM) of developing poults. We evaluated this hypothesis with a poultry growth model consisting of a random bred control line (RBC2) and a line selected for body weight at 16 weeks of age (F-line). The F-line has significantly heavier breast muscle weight than the RBC2 but the RBC2 breast muscle in proportion to body weight is similar to the F-line. Physiological differences between the lines have been normalized in previous research by restricted intake. We duplicated this approach to compare the temporal expression of neonatal and adult myosin isoforms in both restrict fed and ad libitum fed F and RBC2 poults. Our objective, using a quantitative indirect enzyme linked immunosorbent assay (ELISA) with fast skeletal myosin isoform specific monoclonal antibodies, was to investigate the affect of feed restriction on the temporal expression of neonatal and adult myosin isoforms in developing poults. Conclusions were made by comparing the ratios of the neonatal and adult myosin isoforms in the PM from the control line of poults (RBC2) and the F-line poults under ad libitum and restrict fed nutritional environments. Our results demonstrate that adult myosin isoform expression is delayed in both the F- and RBC2-lines undergoing feed restriction ($p<0.05$). Similarly, feed restriction resulted in a delay in the down-regulation of the neonatal myosin isoform at 14 and 21 d of age in both lines ($p<0.05$). These results confirm our hypothesis, that feed restriction alters the age related expression pattern of both the neonatal and adult myosin isoforms in the pectoralis major of both turkey lines.

Key Words: Muscle, Turkey, Myosin

462 Expression of the carbohydrate response element binding protein gene and related genes involved in hepatic lipogenesis during post-hatch development of broiler chickens. M. Proszkowiec-Weglarz*[1], B. D. Humphrey[2], M. P. Richards[1], R. W. Rosebrough[1], J. P. McMurtry[1], and R. Angel[3], [1]*USDA-ARS*, *Beltsville, MD*, [2]*California Polytechnic State University*, *San Luis Obispo*, [3]*University of Maryland*, *College Park*.

Carbohydrate response element binding protein (ChREBP) and sterol regulatory element binding protein-1c (SREBP-1c) are key regulators of glucose metabolism and lipid synthesis in mammals. In response to glucose (ChREBP) and insulin (SREBP-1c), these two transcription factors regulate expression of lipogenic genes such as acetyl-CoA carboxylase (ACC), fatty acid synthase (FAS), stearoyl-CoA desaturase 1 (SCD1), ATP citrate lyase (ACL), and malic enzyme (ME). ChREBP dimerizes with Max-like protein X (Mlx) and binds to carbohydrate response element sites in target gene promoter regions. Expression of ChREBP and SREBP-1c is regulated, in part, by the nuclear liver × receptor (LXR). Since the ChREBP gene has not been identified in birds, the aim of this work was to clone and determine the expression of ChREBP and related genes in broilers during post-hatch (PH) development. To determine mRNA expression by RT-PCR and capillary electrophoresis, total RNA was isolated from 10 different tissues from 3-wk-old birds and from the livers of birds at 0, 1, 2, 3, 4, 6, and 8 d PH that were fed or fasted for 48 h PH. ChREBP, SREBP-1c, Mlx, and LXR gene homologues were expressed in all tissues examined at 3 wk. ChREBP demonstrated significant tissue-specific expression with the highest mRNA levels in liver and duodenum. Fasting for 48h PH did not change the level of ChREBP or Mlx mRNAs in liver, whereas SREBP-1c mRNA was lower at 2 d in fasted compared to fed chicks. Hepatic ACC, FAS, SCD1, and ME mRNAs increased in response to feeding. Fasting for 48 h PH delayed the rise in lipogenic gene mRNAs but had no effect on plasma insulin or glucagon. We conclude that ChREBP and Mlx genes are expressed in chickens. However, the role of these transcription factors in the glucose-dependent regulation of lipogenesis remains to be shown in birds.

Key Words: ChREBP, Lipogenesis, Chicken

463 The activation of insulin and nutrient signaling components leading to translation initiation in skeletal muscle of neonatal pigs is developmentally regulated. A. Suryawan*, R. A. Orellana, A. S. Jeyapalan, H. V. Nguyen, J. R. Fleming, and T. A. Davis, *USDA/ARS Children's Nutr. Res. Ctr., Department Pediatrics, Baylor Coll. of Med.*, *Houston, TX*.

Insulin (INS) and amino acids (AA) act independently to stimulate protein synthesis in skeletal muscle of neonatal pigs and the responses decrease with development. The purpose of this study was to compare the effect of INS and AA on the activation of signaling components leading to translation initiation and how these responses change with development. To examine the independent role of INS, hyperinsulinemic-euglycemic-euaminoacidemic clamps were performed in fasted 6-d-old (n=4) and 26-d-old (n=6) pigs to raise plasma insulin from 5 (fasting level) to 30 (fed level) μU/ml while AA and glucose were maintained at fasting levels. To elucidate the independent role of AA, a balanced AA mixture was infused into fasted 6-d-old (n=4) and 26-d-old (n=6) pigs to raise branched-chain amino acids from 500 (fasting level) to 1000 μmol/L (fed level) while INS and glucose were maintained at fasting levels. INS, but not AA, increased the phosphorylation of protein kinase B. Both INS and AA increased the phosphorylation of mammalian target of rapamycin (mTOR), ribosomal protein S6 kinase-1, and eukaryotic initiation factor (eIF) 4E-binding protein 1 (4E-BP1) and these responses were higher in 6-d-old compared to 26-d-old pigs ($P<0.05$). In 6-d-old pigs, both INS and AA reduced the binding of raptor to mTOR ($P<0.05$). Both INS and AA decreased the binding of 4E-BP1 to eIF4E ($P<0.05$) and increased eIF4E binding to eIF4G ($P<0.05$); these effects were greater in 6-d-old than in 26-d-old pigs ($P < 0.05$). Furthermore, neither INS, AA, nor age had any effect on the phosphorylation of eukaryotic elongation factor 2. Our results suggest that the activation of many of the insulin and nutrient signaling components leading to translation initiation is developmentally regulated and parallels the developmental decline in protein synthesis in skeletal muscle of neonatal pigs.

Immunology - Livestock and Poultry II

464 Effects of maternal nutrition and selenium supplementation on absorption of IgG and survival of lambs. C. J. Hammer*[1], K. A. Vonnahme[1], J. B. Taylor[2], D. A. Redmer[1], J. S. Luther[1], T. L. Neville[1], J. J. Reed[1], J. S. Caton[1], and L. P. Reynolds[1], [1]*North Dakota State University*, *Fargo*, [2]*USDA-ARS, U.S. Sheep Experiement Station*, *Dubois, ID*.

To examine the effects of maternal nutrition with or without additional selenium (Se) on absorption of IgG and survival of lambs, 82 Rambouillet ewe lambs were allotted randomly to one of six treatments in a 3 x 2 factorial design. Groups included dietary levels of Se [Adequate Se (ASe, 7.4 μg/kg BW) vs. High Se (HSe, 85 μg/kg BW)], and plane of nutrition [60% (RES), 100% (CON), and 140% (HIGH) of NRC requirements for gestating lambs]. Basal diets were fed once daily in a complete pelleted form and HSe ewes received a Se pellet to meet the required Se level. Upon parturition, lambs were immediately separated from their dams, weighed, and serum samples obtained. Lambs were fed artificial colostrum for the first 20 h after which lambs were fed milk replacer. The artificial colostrum contained 64.3 g IgG/L and lambs received 10.6 g IgG/kg BW divided into seven feedings. At 24 h post-parturition serum samples were obtained to assess IgG status. Lambs were reared similarly in a temperature controlled (12°C), and ventilated facility for the duration of the study. Signs of illness prompted treatment following protocol. Morbidity was assessed as number of days treated for respiratory or gastrointestinal symptoms. Mortality was calculated as days in flock. Plane of maternal nutrition affected ($P < 0.05$) ability of lambs to absorb IgG after birth, with 24 h IgG concentrations of 2276, 1586, and 1214 mg/dl for lambs from RES, CON, and HIGH respectively. Selenium supplementation of ewes decreased ($P < 0.01$) 24 h IgG concentrations in lambs from 1912 mg/dl for ASe to 1472 mg/dl for HSe. Morbidity was not different for lambs from ewes in any of the treatment groups. Mortality was greater ($P < 0.01$) for offspring of ewes in the HIGH group; this group also had the lowest 24 h IgG concentration. Lambs born from ewes on a high or low plane of nutrition or with high dietary Se appear to have an altered ability to absorb IgG after birth. Further research is needed to determine the mechanisms by which this occurs.

Key Words: IgG, Mortality, Lamb

465 Effect of supplementation with a *Bacillus*-based direct-fed microbial on immune development of dairy calves. K. Novak*[1], E. Davis[1], C. Wehnes[1], T. Rehberger[1], D. Shields[2], and J. Coalson[2], [1]*Agtech Products, Inc.*, *Waukesha, WI*, [2]*Merrick's, Inc.*, *Union Center, WI*.

Immune development was evaluated in 65 Holstein bull calves in response to the addition of a *Bacillus*-based direct-fed microbial (DFM) to electrolyte scour treatment. Calves were assigned to three treatments based on the presence of scours: non-scouring, electrolyte, and electrolyte+DFM. Scouring calves received electrolyte for a mandatory two days. Blood was sampled from eight calves from each treatment on d 3, 7, 14, 21, 28, and 42 post-placement for an analysis of leukocyte populations by flow cytometry. Immune cell populations were determined using a panel of monoclonal antibodies specific for various cell surface markers, including, CD4 (T helper cells), CD8 (cytotoxic T and natural killer cells), CD25 (IL-2 receptor), CD62L (L-selectin), TCR1 (γδ T cell receptor), AM-2 (activated γδ T cells), CD45RO (memory T cells), CD172a (monocytes), and CD14 (LPS receptor). Activated immune cells ($CD8^-CD25^+$) were greater ($P = 0.05$) in electrolyte+DFM calves compared to electrolyte and negative control calves. L-selectin expression on leukocytes ($CD8^-CD62L^+$) was greater ($P = 0.05$) in calves on either electrolyte treatment compared to negative control calves. Electrolyte+DFM calves had a greater ($P = 0.05$) γδ T cell population ($CD8^-TCR^+$) compared to electrolyte and negative control calves. Calves provided the electrolyte treatment had a greater ($P = 0.05$) cytotoxic memory T cell ($CD8^+CD45RO^+$) population than the negative control calves; whereas, the electrolyte+DFM calves

showed an intermediate response between the two. The proportion of activated γδ T cells ($TCR1^+AM\text{-}2^+$) was greater ($P = 0.05$) in electrolyte+DFM calves compared to electrolyte and negative control calves. Monocytes expressing LPS ($CD172a^+CD14^+$) did not differ on d 3, 7, 21, and 42 post-placement, but on d 28 this population was lower ($P = 0.07$) in electrolyte+DFM calves compared to negative control calves (treatment x day interaction, $P = 0.10$). The results of this study indicate that supplementation with a *Bacillus*-based DFM at the incidence of scours has the potential to enhance innate and adaptive immune development in calves.

Key Words: Probiotic, Immunity, Bovine

466 Effects of an immunostimulatory feed additive on neutrophil function and development of titer in ruminant livestock. N. E. Forsberg*[1,3], Y. Wang[3], S. Puntenney[3], and J. Burton[2], [1]*Oregon State University*, *Corvallis*, [2]*Michigan State University*, *East Lansing*, [3]*OmniGen Research*, *Corvallis, OR*.

OmniGen-AF increases expression of molecular markers of innate immunity. These markers include neutrophil L-selectin, interleukin-1B and interleukin-8R. Ability of this product to augment expression of markers has been noted particularly in animals which have been immunosuppressed. Goals were to determine whether changes induced by the product at the molecular level translated into changes in neutrophil function and in development of titer against a vaccination program. In the first study, immunosuppressed sheep (0.1 mg Azium/hd/d) were fed either a control ration or a ration containing OmniGen-AF (5 g/d) for 31 d. At the end of the study, blood samples were recovered and neutrophils were purified using a Percoll gradient. Phagocytosis and respiratory burst assays were completed using commercial ELISA kits. In the second study, Angus cattle (275 kg) were assigned to one of three diets (0, 15 and 30 g/hd/d of OmniGen-AF). Calves were vaccinated with the Pfizer J5 E. coli vaccine on d 7, 21 and 35 and J5 titer was assessed within IgM, IgG1 and IgG2 fractions at d 56. Beginning on d 56 all animals were placed on the control diet and titer was again assessed on d 82. Neutrophils recovered from immunosuppressed sheep displayed enhanced function. Phagocytosis was increased ($P<0.01$) by 40% and respiratory burst activity was increased 2-fold ($P<0.01$). In growing cattle no differences in J5 titer were detected within the IgM fraction. At d 56, the additive did not affect ($P>0.05$) J5 titer in the IgG1 fraction; however, J5 titer in the IgG2 fraction was elevated 2-fold ($P<0.05$) in the animals fed 30 g/head OmniGen/d. At d 82, J5 titer in control-fed animals had declined to levels which were similar to those on d 0; however, animals which had been fed OmniGen-AF at the 15g or 30g levels had elevated J5 titer ($P<0.05$) in the IgG1 fraction. No differences ($P>0.05$) in J5 titer within the three experimental groups were noted in the IgG2 fraction on d 82. Anecdotal reports indicate benefit of the OmniGen-AF product for herd health. Enhanced neutrophil function and enhanced responses to vaccination programs may underlie these reports.

Key Words: Immunity, OmniGen-AF, Titer

467 Induction Of proinflammatory cytokines and constitutive expression Of Nramp1 in bovine blood neutrophils after exposure to *E. coli* endotoxin (LPS). A. Morris*, Z. Liu, and M. Worku, *North Carolina Agricultural and Technical State University*, *Greensboro*.

The pattern of constitutive and inducible expression of genes associated with the inflammatory response is important in defining innate (natural) resistance/susceptibility to diseases. Natural Resistance Associated Macrophage Protein1 (Nramp1) is expressed in macrophages and polymorphonuclear leukocytes. Studies have shown that Nramp1 is critical for resistance to several diseases. Mutations in Nramp1 are associated with increased disease susceptibility. Human polymorphonuclear leukocytes (PMN) are the major site of Nramp1 expression, followed to a lesser degree by monocytes (MN). Expression of Nramp1 by bovine PMN and the effect of mediators of inflammation such as *E. coli* endotoxin (LPS) have not been defined. The objectives of this study were to evaluate the expression of Nramp1 mRNA and determine how Nramp1 expression is regulated in bovine blood PMN upon LPS stimulation. Bovine blood PMN were isolated from three clinically healthy Holstein Friesian cows. The PMN were then incubated (37°C, 5% CO2, 15 min) in the presence or absence of LPS (100ng). Control cells were maintained in phosphate buffered saline (PBS). RNA was then isolated using Tri reagent (SIGMA) and the quality and quantity of RNA was determined using a Bioanalyzer (Agilent). Isolated RNA (600ng) was used to prepare cDNA (Ambion-Retroscript). Specific primers for Nramp1, IL-1β, IL-8 and GAPDH as loading control were used for RT-PCR. Nramp1 was constitutively expressed in both LPS and PBS treated bovine PMN. There was an induction of IL-1β and IL-8 genes upon LPS stimulation. These results indicate that Nramp1 is constitutively expressed in bovine blood PMN. No further up regulation was observed by exposure to LPS (100 ng) for 15 min. However this dose and time of exposure was sufficient to induce the transcription of the proinflammatory cytokines like IL-1β and IL-8. Variation was observed in the levels of gene expression between cows. Further studies will fine tune the response to activation by LPS.

Key Words: Polymorphonuclear Neutrophils, Nramp1, LPS

468 Growth performance and immunocompetence of heat stressed broilers fed different sources of dietary fatty acids. M. O. Smith*[1] and J. R. Bartlett[2], [1]*University of Tennessee*, *Knoxville*, [2]*Tuskegee University*, *Tuskegee, AL*.

One hundred and forty four male broilers were used to evaluate the effects of two sources of fatty acids on growth and immune competence of heat stressed broilers. Four replicate groups of twelve chicks each were assigned to three dietary treatments consisting of a basal diet supplemented with corn oil, fish oil (menhaden), or fish oil plus zinc and raised in battery brooders. On day 22, chicks were transferred to either a thermoneutral, TN (23.9 C) or a heat stress, HS (23.9 - 35 C, diurnal cycling) environmental chamber. Humoral immunity was assessed by injecting birds intravenously with 1 mL of 7% sheep red blood cell suspension followed by evaluation of sera for total, mercaptoethanol-resistant (ME-R), and mercaptoethanol-sensitive (ME-S) antibody titers. Cell-mediated immunity was assessed by using a sephadex stimulation method to recruit and harvest abdominal exudate cells (AEC), and phagocytic ability of macrophages determined. On day 50, birds were weighed, slaughtered, and thymus, spleen, liver, and bursa of Fabricius collected and weighed. Sources of dietary fatty acids did not impact growth, however, HS birds consumed 11% less feed and gained 8% less weight than TN birds. Bursa and thymus weights were reduced by 23% and 24% respectively in HS birds but diets had no effect. Number of AEC and incidence of macrophages were not affected by fatty acid source but the percent phagocytic

macrophages decreased under HS. Total ME-S (IgM) and ME-R (IgG) antibody titers were highest (P< 0.03) for fish oil + Zn while total and IgM titers were reduced (P<0.01) by HS. Results indicate that feeding fish oil can assist birds to mount an effective immune response during HS.

Key Words: Heat stress, Broiler, Immunocompetence

469 Immunopathology and cytokine responses in broiler chickens coinfected with eimeria maxima and clostridium perfringens using an animal model of necrotic enteritis. H. S. Lillehoj*[1], S. S. Park[1], P. C. Allen[1], S. FitzCoy[2], and D. A. Bautista[3], [1]*U.S. Department of Agriculture-ARS*, *Beltsville, MD*, [2]*Schering-Plough Animal Health*, *Millsboro, DE*, [3]*University of Delaware*, *Georgetown*.

The incidence of necrotic enteritis (NE) due to Clostridium perfringens (CP) infection in commercial poultry has been increasing at an alarming rate. While pre-exposure of chickens to coccidia infections is believed to be one of the major risk factors leading to NE, the underlying mechanisms of CP virulence remain undefined. The objectives of this study were to utilize an experimental model of NE produced by Eimeria maxima (EM) and CP coinfection to investigate the pathological and immunological parameters of the disease. Broilers coinfected with EM plus CP exhibited more severe gut pathology compared with animals given EM or CP alone. Additionally, EM/CP coinfection increased the numbers of intestinal CP bacteria compared with chickens exposed to an identical challenge of CP alone. Coinfection with EM and CP repressed nitric oxide synthase gene expression that was induced by EM alone, leading to lower plasma NO levels. Intestinal expression of a panel of cytokine and chemokine genes following EM/CP coinfection showed a mixed response depending on the transcript analyzed and the time following infection. In general, IFN-α, IFN-γ, IL-1β, IL-2, IL-12, IL-13, IL-17, and TGF-β4 were repressed, while IL-8, IL-10, IL-15, and LITAF were increased during coinfection compared with challenge by EM or CP alone. These results are discussed in the context of EM and CP to act synergistically to create a more severe disease phenotype leading to an altered cytokine/chemokine response than that produced by infection with the individual pathogens.

Key Words: Necrotic Enteritis, Clostridium Perfringens, Eimeria Maxima

470 Intestinal cytokine responses to Salmonella enterica serovar typhimurium infection in young chicks. Y. O. Fasina*[1], P. S. Holt[2], E. T. Moran[1], R. W. Moore[2], D. E. Conner[1], and S. R. Mckee[1], [1]*Auburn University*, *Auburn, AL*, [2]*USDA-ARS Egg Safety & Quality Research Unit*, *Athens, GA*.

Vaccination has been proposed as one of the best ways to control Salmonella infection in poultry. Cytokines are essential effector molecules for innate immunity and have been proposed as adjuvants that can improve efficacy of vaccines. Thus, we designed an experiment to determine the effect of Salmonella typhimurium (ST) infection on the expression of selected pro-inflammatory cytokines (IL-1, IL-6, IFNy) and IL-10 (an anti-inflammatory cytokine) in the intestine of chicks. A 14-day experiment was conducted using 112 day-old chicks. Chicks were randomly allocated to 2 treatments; treatment 1 (CN) consisting of chicks that were not challenged with ST, and treatment 2 (STC) consisting of chicks that were challenged with ST at 4 days of age. Chicks were fed a corn-soybean meal diet. On days 4 and 9 post-challenge (PC), intestinal ST levels were enumerated on XLT4 agar. On days 5 and 10 post-challenge, intestinal tissue samples were collected (from jejunum, ileum and cecum) and analyzed by quantitative Reverse Transcriptase-Polymerase Chain Reaction (RT-PCR) procedure to determine the level of expression of cytokine genes. CN chicks remained ST-free throughout the experiment. Intestinal level of ST in STC chicks was 4.05 ± 3.30 log10 CFU at 4 days PC, indicating that ST challenge was successful. Expression levels (mRNA levels) of the pro-inflammatory cytokines were higher in STC chicks compared to CN chicks in all tissues. Specifically, at 10 days PC, jejunal fold change in mRNA was highest ($p < 0.05$) for IL-6 (2.62). Also, cecal fold change in mRNA was highest ($p < 0.05$) for IL-1 (1.71). In all tissues, IL-10 had the lowest mRNA levels. It was concluded that ST infection induced an inflammatory immune response characterized by increased expression of proinflammatory cytokines (IL-1, IL-6, and IFNy).

Key Words: Salmonella Typhimurium, Pro-inflammatory Cytokines, Broiler Chicks

471 Comparative expression of activin receptor type IIB in bovine peripheral blood mononuclear cells. S. Tanaka*, S. Hayashi, Y. Taketa, M. Miyake, K. Watanabe, S. Ohwada, H. Aso, and T. Yamaguchi, *Laboratory of Functional Morphology, Graduate School of Agricultural Science, Tohoku University*, *Sendai, Japan*.

Myostatin, a member of the transforming growth factor-β (TGF-β) superfamily, acts mainly as a negative regulator of skeletal muscle mass through the signal transduction of activin receptor type IIB (ActRIIB). Double-muscled (DM) cattle with mutations of myostatin gene result in a marked muscle hypertrophy. TGF-β1 is a critical factor in regulation of T cell-mediated immune responses and in the induction of immune tolerance. In addition, Activin A, which belongs to the same TGF-β superfamily member as myostatin, is involved in inflammatory responses. These findings indicate that myostatin may be related to immune responses. The present study was conducted to investigate the comparative expression of ActRIIB in bovine peripheral blood mononuclear cells (PBMC). The peripheral blood was collected from Holstein cattle (n=3). PBMC were prepared by density gradient centrifugation using Lympholite-H, and T cells, B cells and monocytes were isolated by magnetic cell sorting (MACS) method. Total RNA was extracted from MACS-isolated T cells, B cells and monocytes and the mRNA expression of ActRIIB was analyzed by PCR method with bovine specific primers. Furthermore, ActRIIB positive cells in PBMC, T cells, B cells and monocytes were analyzed by flow cytometry using anti-bovine CD3, anti-bovine BB2, anti-bovine CD14 and anti-human ActRIIB antibodies. The ActRIIB mRNA was expressed in T cells, B cells and monocytes but less in B cells. The ActRIIB positive cells in PBMC were 31.0±3.9%. The percentages of ActRIIB positive cells were 48.0±3.4%, 24.1±2.0% and 53.47±4.7% in T cells, B cells and monocytes, respectively. Thus, ActRIIB was preferentially expressed in T cells and monocytes. These results strongly suggest that myostatin primarily acts on T cells and monocytes, and regulates the function of their cell types to mediate immune responses in cattle.

Key Words: Activin receptor type IIB, Lymphocytes, Bovine

Joint National Extension Workshop: Accountability Issues in Extension: Identifying, Measuring and Reporting Impacts

472 Introduction and Washington update. R. D. Reynnells*, *USDA/CSREES/PAS*, *Washington, DC*.

Presentations in this first of two Joint National Extension Workshops (Dairy, Poultry and Animal Science) address accountability issues (identify, measure, and report). Administrators and those who market Extension to decision makers will detail our responsibilities to create and maximize benefit from reports of accomplishment, and how this information is used to promote Extension programs at the state and Federal levels. The value of Extension is understood by many stakeholders. Extension personnel may feel their value is intuitively obvious and that decision makers do not appreciate their value and dedication to our food production systems and society. To be recognizable and have the potential for being appreciated, Extension's impact must be transmitted to administrators, legislators, and other decision makers and society. Discussions will include how impact reporting is used at the college level and how Federal reports are generated, tips on effectively communicating achievements through multiple uses of information, along with how funding support may be enhanced by impact statements. Promotion of Extension requires evaluation based information generated by county and state level personnel. The desire of faculty to create reports is enhanced by their recognition that the information is used by Federal and other officials in decision making and the marketing of extension. A successful documentation and reporting model for Extension will be presented. The Special Recognition Award for Poultry Extension faculty is presented to Casey Ritz, University of Georgia. The 2007 Farm Bill, and how we address animal welfare issues (e.g., Animal Welfare Assessment Contest; Future Trends in Animal Agriculture) will be discussed. Budgetary constraints have reduced direct involvement in multi-state research committees and participation in other important meetings. The 2008 National Poultry Waste Management Symposium Coordinator is Casey Ritz, University of Georgia. The PSA Support Personnel Award leadership has been transferred to the committee chair, which now will change each year as is done for other awards committees.

Key Words: Accountability, Extension, Impact Reporting

473 Accountability for administrators—impacts with impact. B. D. Moser*, *The Ohio State University*, *Columbus, OH*.

While Extension has been improving lives for 90 years, there is a necessity for greater accountability of efforts more than at any other time in our history. It is only through a focused, concerted effort to better identify and leverage these defined impacts that Extension will continue to thrive through the 21st century. At the college/university level, these impact data have far-reaching influences on: internal annual specialist evaluations by administrators; inclusion in the Promotion & Tenure process; more successful grant proposal applications and funding; measuring trends; identifying future programming needs and opportunities; media releases; and effectively communicating with our community leaders, stakeholders, state legislators, congressional leaders and county commissioners. Just as important, this information provides the important documentation and programmatic justification needed to provide comprehensive data in compliance with annual federal reporting requirements. At OSU, we utilize a Logic Model in a web-based Extension and Research planning and reporting system, which combines defined program development and evaluation to identify impacts. Through program development, the change (outcome/impact) needed is identified (knowledge, skills, attitudes, behavior, economic impact). Programs and participation are then needed to manifest this change (activities/outputs). Finally, resources (inputs) to create and conduct the programs result in impacts (outcomes). To ensure the success of this Logic Model, it is important that all Extension specialists and programming leaders recognize and embrace the long-term benefits of adequately describing, documenting and reporting outcomes/impacts. Most specifically, the result of well-written impact statements often lead to increased support and funding opportunities.

Key Words: Accountability, Extension, Impacts

474 What information do I need to keep Extension funded? J. C. Wade*, *National Association of State Colleges and Land Grant Universities*, *Washington, DC*.

Cooperative Extension is a partnership among federal, state and local agencies that works to provide research-based information to agricultural and other producers and to consumers and ordinary citizens. Funding such a complex organization requires national and local strategies that combine the substantial human resources from across the nation into a coherent strategy with a limited number of goals, but high expectations. NASULGC helps to coordinate a multifaceted strategy. Mostly volunteer supporters of the Land-Grant Universities are teamed to garner the best for support of the System among public policy makers and stakeholders from across the country. Linking to this well informed support group is paramount to continued funding. NASULGC-based committees and task forces work to find these successes. Success requires strategies directed at both legislators and agency personnel. This presentation will review the status of FY2007 and FY2008 Federal appropriations and the 2007 Farm Bill.

Key Words: Cooperative Extension, Funding, Policy

475 How plans of work and annual reports are used at the federal level. B. Hewitt*, *Cooperative State Research Education Extension Service*.

This session presents a quick overview of the ways in which data from the State Plans of Work (POWs) and annual reports have and will be used to meet Federal planning and accountability requirements. In addition to serving as reports to National Program Leaders (NPLs) within CSREES to help them in planning future work, CSREES uses data from the POWs and annual reports to address Federal requirements. These requirements include the President's Management Agenda (PMA), Budget-Performance Integration (BPI), and the

requirements for the Office of Management and Budget (OMB) for the Program Assessment Rating Tool (PART) and Research and Development Investment Criteria. To meet these internal and external needs, CSREES developed a self-assessment and peer review process known as the Portfolio Review Expert Process (PREP). This session will review the relationships among the PREP, PART, and BPI. It will also describe the ways that government performance information is presented by OMB to the public.

Key Words: Budget, Plans of work, Performance

Nonruminant Nutrition: Lessons and Logistics of Application of Digestible Amino Acids in Diet Formulation

476 Amino acid digestibility measurements of feedstuffs – Lessons from poultry studies. V. Ravindran*[1] and W. L. Bryden[2], [1]*Massey University*, *Palmerston North, New Zealand*, [2]*University of Queensland*, *Gatton, Australia*.

It is now accepted that the analysis of ileal contents rather than of excreta is a more reliable method for assessing amino acid (AA) digestibility of feedstuffs for poultry. However, a major problem faced by the users of currently available digestibility databases is the confusion that exists about various terminologies used to describe AA digestibility, highlighting the need in the industry to agree on a standard methodology to measure and describe AA digestibility estimates. Lessons learnt from ileal digestibility assays, which were developed in our Laboratory for a large-scale survey of poultry feedstuffs, will be discussed and a standard mehodology for poultry digestibility assays will be presented. The relative merits of apparent and true digestible AA systems, however, will continue to be a subject of debate among nutritionists. The measurement of true digestibility includes a correction for endogenous AA secretions determined in the same digestibility assay. The concept of standardized digestibility system that overcomes the limitations of apparent and true digestible AA systems will be discussed. This system is comparable to true digestibility system, with the only difference being that it involves a correction for basal endogenous losses that need not be determined in the same digestibility assay. The basal endogenous AA loss is defined as the minimal loss of endogenous AA which occurs irrespective of feed ingredient or dietary composition and could be measured by feeding of low levels of highly digestible proteins (e.g. casein, wheat gluten) or the regression method. However, only limited published data is available on the endogenous amino acid losses at the distal ileum of poultry. Since the transformation to standardized digestibility values will require reliable estimates of basal endogenous amino acid losses at the ileal level, further research on this subject is warranted. Some key areas for future research will be highlighted.

Key Words: Amino Acid Digestibility, Endogenous Losses, Poultry

477 Methodology for endogenous flow estimates for standardization of digestible amino acids. S. A. Adedokun*[1], O. Adeola[1], C. M. Parsons[2], M. S. Lilburn[3], and T. J. Applegate[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*University of Illinois*, *Urbana/Champaign*, [3]*The Ohio State University*, *OARDC Wooster*.

The importance of formulating poultry diets on a digestible amino acid basis cannot be over emphasized based on the need to reduce safety margins associated with diet formulation, especially when diets are formulated on a total amino acid basis. In addition to the undigested and unabsorbed amino acids of dietary origin, amino acids of endogenous origin which can either be basal or diet specific are also found in ileal digesta. Hence there is the need to standardize apparent digestibility coefficients. The improvement in techniques used in amino acid analysis as well as a shift from excreta sampling to ileal digesta has resulted in more accurate amino acid digestibility coefficients. Despite this, however, it is important to determine the relative amino acids in the digesta that are of endogenous origin. Although the need for standardization and the associated advantages of standardized values is still subject to debate it is however, important to evaluate how values from various methodologies compare. Several methods have been used for standardizing digestibility coefficients. A number of methods have been used to estimate ileal endogenous amino acid (IEAA) flow. These include the classical methods comprising of the regression method, the use of nitrogen-free diet (NFD), and fasted roosters. The criticisms with the last two methods are that the animal is not in a physiological state and the IEAA flow is underestimated. Other methods include feeding of completely digestible protein (CDP), peptide alimentation ultrafiltration techniques (enzymically hydrolyzed casein), the use of isotope markers, and the homoarginine technique. Different methods have resulted in different endogenous flow estimates with NFD method having the lowest values when compared with flows from the regression and CDP methods. In addition to the influence of methods on IEAA flows, the influence of age on flow is also important. For example, IEAA flow has been shown to decrease by about 50% between d 5 and d 15 in broiler chicks.

Key Words: Amino Acid, Endogenous Flow, Poultry

478 Ileal digestibility of amino acids: Lessons from pig studies. O. Adeola*, *Purdue University*, *West Lafayette, IN*.

It is recognized that only a part of the dietary amino acid supply is digested, absorbed, and utilized by animals. Ileal amino acid digestibility is considered the best measure of the amino acid value of feed ingredients. Formulation of broiler chicken diets on a digestible amino acid basis should greatly reduce feed cost and nitrogen emissions from broiler operations, decrease safety margins, and increase the accuracy of predicting performance and the uniformity of product after processing. An important component is accurate datasets on ileal digestibility of amino acids in feed ingredients. Generating the datasets on ileal amino acid digestibility values require quantifying the disappearance of ingested amino acids from the gastrointestinal tract immediately anterior to the ileocecal junction. Ileal amino acid digestibility values may be expressed as apparent ileal digestibility, which is the proportion of amino acid ingested that is not accounted

for in the total ileal outflow of amino acids and emphasizes that the outflow contains amino acids of both dietary and endogenous origins. Total ileal outflow of amino acids therefore consists of unabsorbed dietary amino acids and those of endogenous origin secreted into the gastrointestinal tract that were not absorbed prior to exit from the ileum into the ceca. Ileal outflow of amino acids of endogenous origin consists of basal outflow that is not dependent on feed ingredient composition and specific outflow, which is ingredient composition dependent. Thus, ileal digestibility values may be also expressed as standardized ileal digestibility or true ileal digestibility, which reflect the correction of the apparent ileal digestibility for basal or specific ileal outflow of amino acids, respectively. There is evidence from swine literature that standardized ileal amino acid digestibility values are more likely to be additive in mixtures of feed ingredients and research is needed for a variety of feed ingredients to confirm that this also holds in broiler chickens.

Key Words: Amino Acids, Digestibility, Ileal Flow

479 Digestible amino acid formulation of poultry feeds; practical considerations. D. J. Burnham*, *Aviagen, Inc*, *Huntsville, AL*.

Poultry Feed Formulation has evolved from an Art more toward a Science over the past forty years. Sound nutrition research and computing technology has developed alongside analytical techniques to allow us to refine our formulation techniques. Digestible amino acid formulation is part of the science. Unfortunately, there is still a lot of Art since as an industry we are not yet fully utilizing the all of the Science that is available to us today. The United States Poultry Industry has up until recently been extremely fortunate with an abundant supply of high quality inexpensive ingredients. So, the pressure to make full use of the science has not been there. This does not however mean that this is the best or most profitable approach. There are a number of feed ingredients that have very variable digestibilities; these include, meat and bone meal, poultry by product meal, feather meal, distillers grains and solubles and others. Any ingredient that undergoes processing, primarily heat treatment, stands the risk of being damaged. Formulating on a total basis ignores these effects, and will vastly over value a poor ingredient or undervalue a well processed ingredient. Ingredient buyers are charged with buying ingredients at the lowest price, not the best value. In addition, the most limiting amino acids are now commercially available in synthetic form, these are 100% digestible. Evaluating their value when formulating on a total basis undervalues thevalue by at least 10%, as the assumption is that all other ingredients are 100% digestible. The most common reason given for not formulating on a digestible basis is that we do not have accurate digestibility values. The truth is that the values may be a few points out, but using an 85% digestibility coefficient when it is actually 87%, is a lot more accurate than assuming it is 100%. Indications are that the status quo is changing as bio-fuels compete for the same resources. The products we may have to use vary in digestibility more than current ingredients and we need to make sure we understand how to use them to optimize performance and maximize profitability of our operations.

Key Words: Digestible, Amino Acids, Poultry

Nonruminant Nutrition: Poultry Nutrition - Enzymes, Feeds, Feed Ingredients, and Manufacturing

480 Influence of prepress solvent extracted cottonseed meal supplemented with exogenous enzyme and digestible lysine on performance, digestibility, carcass and immunity responses of broilers chickens. T. Mushtaq*[1], M. Sarwar[1], G. Ahmad[1,2], M. A. Mirza[1], and U. Noreen[1], [1]*University of Agriculture*, *Faisalabad, Pakistan*, [2]*Shamim Feed Industries*, *Bahawalpur, Pakistan*.

The response of broiler chickens to 2 levels of endo-1,4-β xylanase (EC 3.2.1.8) and endo-1,3-β glucanase (EC 3.2.1.6) combination (with and without), 3 levels of digestible lysine (0.8, 0.9 and 1.0% with the applicability of ideal protein concept) and 2 levels of cottonseed meal (CSM; 20 and 30%) were evaluated in $2 \times 3 \times 2$ factorial arrangement. A total of 2448 male Hubbard broiler chicks were fed on the practical vegetable based mash diets having 2750 kcal ME/kg and 18.50% CP from 1 to 42 d of age. The supplemental enzyme had minimum 1,100 units of endo-1,4-β xylanase and 100 units of endo-1,3-β glucanase kg-1 of finished diet. The addition of CSM at 30% resulted in increased arginine to lysine ratio. The CSM at 30% depressed BW gain and mortality during 1 to 21 d and BW gain and feed:gain during 1 to 42 d. A depression in dressing and breast percentages were also observed by the addition of 30% CSM. The digestible lysine at 1.0% depressed the BW gain and lowered the mortality during 1 to 21 d whereas the BW gain and feed:gain were unaffected among the three digestible lysine levels. The antibody titers against Newcastle and infectious bursal disease viruses were improved with the increasing levels of digestible lysine. The enzyme supplementation improved the AME and digestibility coefficient of nitrogen when it was used with 30% CSM. No effect of enzyme, lysine, CSM or their interactions was observed on serum iron, gizzard and liver weights or abdominal fat percent. In conclusion, the enzyme supplementation failed to show any improvement in performance in CSM based diets and increasing digestible lysine in such diets did not improve the growth performance and carcass characteristics probable due to high arginine contents.

Key Words: Cottonseed Meal, Enzyme, Digestible Lysine

481 Growth, carcass nutrients accretion and nutrient retention of broiler chicks receiving phytate- or polysaccharides-degrading enzymes. O. A. Olukosi*[1], A. Cowieson[2], and O. Adeola[1], [1]*Purdue University*, *West Lafayette*, [2]*Danisco Animal Nutrition*, *Marlborough, Wiltshire, UK*.

Broiler chicks were used to determine efficacy of a cocktail of xylanase, amylase and protease (XAP) or phytase for enhancing growth, carcass nutrient accretion and total tract nutrient retention. Carcass nutrient accretion from 0 to 21 d post hatch was determined using comparative slaughter technique. Thirty chickens were used as initial slaughter group. Four hundred and fifty chickens were allocated to 5 treatments in a randomized complete block design; each treatment had 6 replicate cages with 5 birds per replicate cage. The treatments were: (1) positive

control (PC) with adequate P and ME; (2) negative control (NC) marginal in P and ME; (3) NC plus phytase at 1,000 FTU/kg; (4) NC plus XAP added at 650, 1,650 and 4,000 U/kg of xylanase, amylase and protease, respectively; and (5) NC plus phytase and XAP at levels in 3 and 4, respectively. The diets were corn-soybean meal based with wheat as a source of non-starch polysaccharides. Phytase alone or combined with XAP improved ($P < 0.05$) all of the growth response criteria; XAP alone did not improve any of these response criteria; there were no phytase×XAP interaction. Phytase alone or combined with XAP improved ($P < 0.01$) carcass ash accretion. Phytase alone or combined with XAP improved ($P < 0.05$) carcass DM, fat and protein accretion, there was no phytase×XAP interaction for the nutrients accretion. Phytase improved ($P < 0.05$) ME, DM and P total tract retention; XAP improved ($P < 0.05$) Ca and tended to improve ME and total tract DM retention. There was phytase×XAP interaction ($P < 0.05$) only for P retention. Phytase combined with XAP improved ($P < 0.05$) retention of DM, P and Ca and ME above NC treatment. In conclusion, combination of phytase and XAP improved growth performance, carcass nutrients and ash accretion and total tract nutrients retention in broilers receiving corn-soybean meal diet marginally deficient in P and ME containing added wheat.

482 Nutritional evaluation of new corn distillers dried grains with solubles (DDGS) produced by the enzymatic milling (E-Mill) and elusieve processes. E. Kim*, C. Parsons, V. Singh, and R. Srinivasan, *University of Illinois*, *Urbana*.

Ethanol production is expected to greatly increase in the next five years and in response to this increase, new processes are being developed to maximize ethanol production from corn and to create new, more highly marketable corn distillers dried grains with or without solubles (DDGS or DDG, respectively). This current study evaluated coproducts produced from two different modified processes, the enzymatic milling (E-mill) and the Elusieve process. The E-mill process subjects the corn kernel to enzymes that hydrolyze starch and aids in removing the germ, pericarp, and endosperm prior to fermentation. The Elusieve process utilizes sieving the finished coproduct, DDGS, and then elutriating with air to remove fiber from the DDGS samples. To nutritionally evaluate the products produced from these new processes, a precision-fed rooster assay using cecectomized roosters was conducted to determine TME_n and amino acid digestibilities. When the E-mill DDG was compared to a conventionally processed DDGS, there was a large increase in protein content from 29.9 to 56.4%. The TME_n of the E-mill DDG was significantly increased by more than 10% compared to the conventional DDGS and amino acid digestibility coefficients for the E-mill DDG were significantly increased by 7 to 10 percentage units for most of the amino acids. When DDGS was subjected to the Elusieve process, the resulting DDGS had increased protein content and TME_n, particularly when high air velocities were used. The most effective Elusieve treatment increased the protein content from 29.9 to 37.2% and increased the TME_n by approximately 7%. The results of this study indicate that the Elusieve and E-Mill processes can be used to enhance the nutritional value of DDGS for poultry.

Key Words: Modified Distillers Dried Grains With Solubles, Processing Technologies, Precision-Fed Rooster Assay

483 Phytase in ethanol production process improves nutritive value of DDGS. M. Hruby*[1], J. K. Shetty[2], G. Chotani[2], T. Dodge[2], and C. N. Coon[3], [1]*Danisco*, *St. Louis, MO*, [2]*Genencor*, *Palo Alto, CA*, [3]*University of Arkansas*, *Fayetteville*.

A study was conducted to evaluate the effect of phytase treatment in different ethanol production processes, i.e conventional hot cook and Granular Starch Hydrolyzing Enzymes (GSHE) process on the nutritive value of distillers dried grains with solubles (DDGS). The samples were analyzed for dry matter, oil, starch, rate of starch digestion (RSD), crude protein, NDF, ADF, crude fiber, ash, sugar, total phosphorus and phytate phosphorus. Each DDGS sample was precision-fed to market-age broilers and total excreta collection was conducted during 48 hours after DDGS feeding. Almost no phytate P was detected in DDGS samples from the phytase-containing ethanol processes. DDGS derived from the phytase treatment had significantly higher true metabolizable energy (TME) and digestibility of some amino acids.

Key Words: Phytase, Ethanol Process, DDGS Digestibility

484 Effects of mega doses of phytase on broiler chick body composition. J. Puttress*[1], W. W. Saylor[1], R. Angel[2], A. D. Mitchell[3], and M. E. Persia[1], [1]*University of Delaware*, *Newark*, [2]*Unviersity of Maryland*, *College Park*, [3]*USDA*, *Beltsville, MD*.

Phytate is found in seed-based feedstuffs and can bind, among others, Ca, trace minerals and possibly starch and protein reducing bioavailability of these nutrients. New evidence suggests that phytate has additional antinutrient properties. Phytase hydrolyzes P bound to phytate increasing phytate P utilization and reducing the antinutritional effects of phytate. An experiment was conducted to determine the effects of mega doses of phytase on body composition of chicks fed adequate nonphytate P (nPP). There were five experimental treatments including a control diet (0.45% nPP) and the same diet supplemented with 500, 7500 and 15000 FTU of OptiPhos™ (an E. coli phytase; EP), and 15000 FTU of Ronozyme™ (a fungal phytase; FP). Each treatment was fed to eight replicate groups of eight male Ross 308 chicks from 8 d to 22 d. On d 22, the chicks were euthanized and frozen for dual energy X-ray absorptiometry (DXA) scanning before being ground for wet chemistry body composition analysis. Ground carcass samples were lyophilized and freeze ground for crude protein, crude fat, and ash determination. Phytase supplementation did not affect DXA lean or fat tissue accumulation, but all levels of phytase increased body mineral content over the control diet (10.11 to 10.60 g/chick v. 8.74 g/chick; $P = 0.0007$). Wet chemistry analysis showed increased crude protein of carcasses from chicks supplemented with 15000 FTU of FP compared to 15000 FTU of EP (338 v. 285 g protein/chick; $P = 0.0097$). Total carcass crude fat was increased in birds fed 15000 FTU of phytase compared to all other treatments (167 and 168 v. 151 to 155 g fat/chick; $P=0.0024$). Supplementation of birds with 7500 FTU of EP resulted in increased total carcass ash compared to birds supplemented with either 500 FTU of EP or 15000 FTU of PF (53.5 g ash/chick v. 46.1 and 44.0 g ash/chick; $P = 0.0459$). Supplementation of broiler diets with mega doses of phytase can alter chick body composition of birds fed adequate dietary nPP.

Key Words: Phytase, Body Composition, DXA

485 The effect of genotype and choice-feeding on organically-reared broilers fed diets devoid of synthetic methionine. A. L. Rack*, N. P. Buchanan, J. M. Hott, S. E. Cutlip, and J. S. Moritz, *West Virginia University*, *Morgantown*.

In light of the impending ban on synthetic methionine in organic poultry diets, researchers have focused on finding alternative strategies to supply this amino acid. The objectives of this study were two-fold: 1) to assess performance and carcass characteristics of a slow-growing and fast-growing broiler genotype fed diets devoid of synthetic methionine and 2) to determine performance and carcass quality effect, of choice-feeding. Inclusion of fish meal and high percentages of soybean meal enabled the specific genotype methionine requirement to be met. All diets were certified organic. Slow-growing broilers (Gourmet Black) were raised from 1-83 days, and fast-growing broilers (Cobb 500) were raised from 1-54 days. One hundred fifty birds from each genotype were reared indoors during the starter period. The broilers were transferred at the end of the starter period to houses located on the West Virginia University certified organic farm. Broilers had access to pasture for at least eight hours daily, and were exposed to natural fluctuations of environmental conditions. Choice or no choice feeding management was implemented in the grower and finisher periods. Choice-feeding management was defined as providing one feeder of ground corn and one feeder of the remaining complete diet ingredients in each pen. No choice-feeding management was defined as providing two feeders of complete diet in each pen. Birds on no choice management showed higher LWG ($p \leq 0.05$) compared to choice managed birds. Slow-growing broilers had higher FCR ($p \leq 0.05$) than the fast-growing genotype. Slow-growing birds also had lower breast yield ($p \leq 0.05$), than the fast-growing genotype. The fast-growing no choice birds had higher breast yield than the choice birds of the same genotype ($p \leq 0.05$). Fast-growing genotypes were superior in performance and carcass characteristics. Choice-feeding management did not improve performance and carcass characteristics.

Key Words: Synthetic Methionine, Organic, Broilers

486 Meat meal extract as a risk factor for the development of heart failure in fast growing commercial broilers. S. Nain*, B. Laarveld, and A. A. Olkowski, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

The etiologies of heart failure in laboratory animals and humans have been found to be associated with thermal food processing. Cooked meat contains a number of mutagenic heterocyclic amines and other compounds which have been shown to produce cardiomyocyte necrosis and myofibrillar degeneration. It is likely that heterocyclic amines also are present in broiler diets because meat meal (MM) and fish meal are commonly included after rendering at high temperature. Our objectives were to evaluate whether compounds present in MM are associated with risk of heart failure in broilers. Extract from MM was obtained by extracting commercial product with acidified methanol at a ratio 1:4 (wt/vol). The treatment and control diets were prepared by mixing the condensed MM extract or placebo (condensed extraction medium) with commercial broiler feed. A total of 238 birds were randomly allocated to two groups (control and treatment) with 3 replications per group. The birds were housed in raised perforated floor pens in an environmentally controlled room. Feed and water were provided ad libitum. The temperature during the first 7 days was maintained at 34°C followed by a gradual decrease to a level approximately 30% lower than that set for normo-thermal brooding. Broilers fed diet spiked with MM extract showed a higher incidence ($P \leq 0.05$) of ascites (73.9%) vs the control group (62.2%). Also the incidence of sudden death syndrome tended to be numerically higher in the MM treatment group (6.7%) vs the control group (5.9%). Post mortem examination revealed that broilers fed diet containing MM extract showed a higher frequency of cardiac lesions such as ventricular dilation, valve degeneration, and pericardial effusions. The severity of the lesions was more pronounced ($P \leq 0.05$) in the group fed the diet with MM extract. We conclude that methanol soluble factors present in MM precipitate patho-physiological changes in cardiac function and cause a higher incidence of heart failure in susceptible broilers.

Key Words: Broilers, Meat Meal, Heart Failure

487 Muscle proteins recovered from trout frames: Potential pellet binding agent and source of essential amino acids. C. K. Gehring*, J. Jaczynski, and J. S. Moritz, *West Virginia University*, *Morgantown*.

Pelleted diets improve live weight gain and feed efficiency over mash diets when fed throughout the grower period. Optimal broiler performance is contingent upon high pellet quality; however, due to manufacturing volume, transportation and handling, pellet quality in the broiler industry is often poor. While various pellet binding agents are available, one that is also a highly available source of essential amino acids has not been identified. The objective of this study was to recover muscle proteins from trout frames and investigate their use as a protein source and potential pellet binding agent. Proteins were recovered from trout frames via the isoelectric solubilization/precipitation method and the amino acid profile of the isolated protein slurry was analyzed. Concentrations of essential amino acids following solubilization at pH 12.0 were found to be (mg/g): isoleucine (42.11), leucine (69.5), lysine (76.34), methionine (26.21), phenylalinine (35.48), threonine (38.38), tryptophan (11.00), valine (49.93), and histidine (22.61). The essential amino acids were found to be at a high concentration (45%) of total amino acids. Solubilization at acidic pH resulted in greater percent yield on a dry matter basis: percent yield was 70.92 at pH 2.5 versus 55.83 at pH 12.0. Essential amino acid content was reduced by solubilization at pH 2.5 compared to pH 12.0 by 14.54%, 12.29% and 10.76% for methionine, lysine and threonine, respectively. Thus, solubilization at pH 12.0 was determined to be optimal. Alluding to its possibility as a pellet binding agent, trout muscle protein was found to form a stable thermally-induced gel. These results indicate that recovered muscle protein from trout frames may have potential as a high quality protein source and pellet binding agent. Future research will examine the effects of trout protein slurry on pellet quality and manufacturing variables using our pilot feed mill and true amino acid digestibility will be established by precision feeding cecectomized roosters.

Key Words: Pellet Quality, Pellet Binding Agent, Essential Amino Acids

488 Effects of diet preconditioning on the true metabolizable energy of guar meal. O. Gutierrez*, A. L. Cartwright, and C. A. Bailey, *Texas A&M University*, *College Station*.

Several studies report adaptive physiological responses in animals fed high-fiber diets resulting in increased capacity for nutrient utilization. This study was conducted to determine whether similar adaptation occurs with respect to true metabolizable energy (TME) of guar meal (GM) in adult Leghorn roosters. Guar meal contains approximately 11% crude fiber and 18% residual gum, which is comprised of a β-1→ 4-linked D-mannopyranose chain with α-1→6-linked D-galactopyranose branches. A total of 28 roosters were subjected to an initial assay in order to establish a baseline TME for GM. A cross-over designed feeding experiment followed, in which basal diets and high-fiber diets (25% GM) were administered for a period of three weeks before subsequent bioassays were conducted. Results of this experiment indicate that birds which consumed the high-fiber diet prior to assay had a ~9 % reduction in their ability to utilize energy from GM than birds fed the basal diet. Physiological responses were reversible, in that birds consuming the high-fiber diet initially reverted to increased levels of energy utilization when administered the basal diet. However, this increase in energy utilization was intermediate to baseline observations and most likely indicates that additional time is required for the complete recovery of the digestive ability of birds fed high-fiber diets.

Key Words: Diet Preconditioning, True Metabolizable Energy, Guar Meal

489 Energy, protein, and starch digestibility of pea as affected by grind size and cold pelleting in broiler chickens. S. M. Ebsim*, T. D. Warkentin, and H. L. Classen, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

Pea is an accepted ingredient in poultry feeding but information on the impact of feed processing on its nutritional value is minimal. Therefore, a 2 x 2 factorial arrangement was used to study the impact of hammer mill screen size (3.125 mm – S; 6.25 mm – L) and feed form (mash – M; cold pelleting – P) on the rate and degree of pea nutrient utilization in broiler chickens. Pea-based (89.7% pea) were fed from 0 to 21 d of age and included acid insoluble ash as a digestibility marker. Feces were collected from d 19 to 21 for determination of apparent metabolizable energy (AME). Digesta samples were collected from the anterior and posterior of both the jejunum and ileum at 21 d of age to determine the rate of starch and protein digestibility. There were no significant interactions between treatments and therefore the results are presented as main effects. Finer grinding resulted in a higher diet AME ($P<0.01$) than course grinding (S – 2748 kcal/kg vs L – 2537 kcal/kg) but cold pelleting had no effect on this trait. Protein and starch digestion were not affected by grind size except in the posterior ileum where the starch (70.1 vs 59.7%) and apparent protein digestibility (82.4 vs 77.1%) were increased ($P<0.01$) by the S treatment. In contrast, cold pelleting increased the digestibility of protein in the posterior jejunum and anterior ileum ($P<0.01$) but not in the posterior ileum. Starch digestibility was increased by cold pelleting in all portions of the intestine ($P<0.05$) with digestibility values of 59.6% and 70.21% in the posterior ileum for mash and cold pelleting treatments, respectively. The data demonstrate that 15-22% of pea starch and 11-16% of pea protein was digested in the ileum. In conclusion, fine grinding and cold pelleting independently affected the AME, protein, and starch digestibility of pea for broiler chickens.

Key Words: Broiler, Starch, Protein

490 Nutritional value of corn versus sorghum when ground through different screen sizes and used in diets for broiler chicks. C. Feoli*[1], J. D. Hancock[1], M. C. Herrera[2], G. M. Herrera[2], M. J. Rios[2], F. Vargas[3], and S. C. Mason[4], [1]*Kansas State University*, *Manhattan*, [2]*Universidad Nacional Agraria*, *Managua, Nicaragua*, [3]*Asociacion Nacional de Productores de Sorgo*, *Managua, Nicaragua*, [4]*University of Nebraska*, *Lincoln*.

Seven hundred twenty 1-d-old broiler chicks (Cobb x Cobb with an average initial body weight of 43 g) were used in a 14-d growth assay to determine the nutritional value of corn (No. 2 yellow corn imported from the United States) vs sorghum grain (Pinolero-1, a locally adapted variety with white seeds). The corn and sorghum were ground through a hammermill with screens having 6.4 vs 4 mm diameter openings to yield a 2 x 2 factorial arrangement of treatments. The birds were allotted into 1.8-m x 3.4-m pens with 30 birds/pen and six pens/treatment. Feed (meal form) and water were consumed on an ad libitum basis with the diets formulated to 1.29% Lys, 0.99% Met+Cys, 1.1% Ca, and 0.49% available P. Chicks had greater ($P < 0.008$) average daily gain (ADG) when the cereal grains were ground through the smaller screen size and this effect was most pronounced for chicks fed diets with sorghum (cereal grain x screen size interaction, $P < 0.04$). There were no effects ($P > 0.20$) of grain source or screen size on average daily feed intake (ADFI) but gain to feed ratio (G:F) was markedly improved when sorghum grain was ground through the screen with smaller openings (grain source x screen size interaction, $P < 0.006$). For the diets with corn ground through 6.4 and 4 mm screens and the diets with sorghum ground through 6.4 and 4 mm screens, ADG was 31.1, 31.4, 29.2, and 31.6 g/d, ADFI was 47.4, 50.9, 49.1, and 47.7 g/d, and G:F was 0.66, 0.62, 0.59, and 0.66 g/g, respectively. In conclusion, when ground to an appropriately fine particle size, Nicaraguan sorghum grain was equal to imported corn in nutritional value for broiler chicks.

Key Words: Sorghum, Particle Size, Broilers

491 Live performance evaluation of broilers fed all vegetable corn-soy diets supplemented with an Alpha Amylase - Beta Glucanase blend. S. L. Vieira*, D. M. Freitas, J. L. Coneglian, J. E. M. Peña, and J. Berres, *Universidade Federal do Rio Grande do Sul*, *Porto Alegre, RS, Brazil*.

The use of enzyme blends directed to improve nutrient and energy utilization in broiler feeds is increasing. Generally, non starch polysaccharides are preferred target substrates for exogenous enzymes. Starch, however, is not completely digested by chickens. In this study, 1,750 Cobb X Cobb 500 broiler chicks were placed in 70 floor pens, 25 per pen. All birds were fed corn-soybean meal all vegetable diets in feeding programs composed by 7 treatments and 10 replications in a Randomized Block Design. Feeds were provided from 1 to 7, 8 to 21,

22 to 35 and 35 to 40 days. A Positive Control feeding program was formulated with ME levels as follow: 2,950; 3,050; 3,100 and 3,150 kcal ME/kg. Three Negative Controls had 60, 90, and 120 kcal ME/kg graded reductions related to the Positive Control. Supplementation of the lowest energy Negative Control with 200, 300 and 400 g/Ton of an alpha amylase â€“ beta glucanase blend (Ronozyme A - 200 kilo-Novo alpha-amylase units and 350 fungal beta-glucanase units per g) was used in the other three feeding programs. All diets had nutrients to meet or exceed NRC (1994). Body weight, feed intake and feed conversion were weekly evaluated. At the end of the study, broilers demonstrated gradual losses in their performance in parallel with the graded reductions in feed energy. However, including the enzyme at 300 and 400 g/Ton of feed partially alleviated these negative effects. Taking the overall feed conversion in consideration, benefits of enzyme inclusion were similar to those obtained with feeding programs having 30 and 60 kcal ME/kg higher than the Negative Control, respectively for 300 and 400 g/Ton. The observation of the weekly results indicated that enzyme efficacy was mainly demonstrated after 21 days of age. Mortality was not affected by the treatments.

Key Words: Broiler, Enzyme, All Vegetable Feed

Physiology & Endocrinology - Livestock and Poultry: Role of Lipids and Fatty Acids in Regulation of Reproductive Function

492 The role of omega-3 and -6 fatty acids in regulation of reproductive function in horses. E. L. Squires*, *Colorado State University*, *Fort Collins*.

Semen contains high levels of polyunsaturated fatty acids (PUFA), in particular the long-chain fatty acids docosapentaenoic acid (DPA) and docohexaenoic acid (DHA). Ability of sperm to resist cold shock is related to lipid composition of the sperm membrane. Approximately 30% of stallions have sperm that do not withstand the rigors of cooling and/or freezing. Three studies have focused on the effect of DHA supplementation to stallions. Brinsko et al. (2005) used 8 stallions in a 2×2 cross-over design. Stallions served either as control or were fed a DHA-enriched product for 14 weeks. They reported a 3-fold increase in the semen levels of DHA. Although DHA supplementation had no effect on fresh semen, it did increase total, progressive and rapid motility after 48 hr of cooling and after freezing and thawing. The most dramatic response to DHA was seen in those stallions that prior to treatment had <40% motility after 24 hr of cooling. Harris et al. (2006) conducted a similar study in which 6 stallions were fed either a basal diet with no supplementation or a basal diet supplemented with 29 g of PUFA. Supplementation resulted in a 46% increase in daily sperm output at the end of the 90-day trial. Supplemented stallions also had a higher percentage of morphologically normal spermatozoa. In the third trial, conducted at Colorado State University, 10 stallions were collected daily for 8 days and the data used to establish baseline values for seminal characteristics. Stallions were assigned to either a control diet or control diet containing 270 g DHA product. There was a significant increase in the daily number of motile sperm in the ejaculate of fresh semen, as well as semen stored for 24 hr at 5°C. These combined studies demonstrated that supplementation of stallions with PUFA containing DHA resulted in improvement in sperm numbers and semen quality.

Key Words: Stallion, Omega-3 Fatty Acid, Semen

493 Addition of protected fat in ewes with different corporal condition on superovulation and conception rate. P. Molina[1], T. Sánchez[1], O. Mejía[2], J. Nuñez[2], E. García*[3], O. D. Montañez-Valdez[4], J. Cordero[1], J. Peralta[1], M. E. Ortega[1], R. Nieto[5], E. Mendoza[1], and R. Avila[1], [1]*Colegio de Postgraduados*, *Montecillo, Estado de México, México*, [2]*Facultad de Medicina Veterinaria y Zootecnia, UNAM*, *Tres Marías, Municipio de Huitzilac, México*, [3]*Centro Universitario de la Costa Sur de la Universidad de Guadalajara*, *Autlán, Jalisco, México*, [4]*Centro Universitario del Sur de la Universidad de Guadalajara*, *Ciudad Guzmán, Jalisco, México*, [5]*Instituto Tecnológico Agropecuario No.6*, *Huejutla, Hidalgo, México*.

Thirty days before synchronization there were two groups of Dorset ewes in very good body condition: In T1 ewes were fed with commercial supplement and oat straw, and in T2 ewes were fed with oats straw to lower the body condition of this group and both groups received this diet for a month. Then six ewes of each group were superovulated (donors) and the rest remained as receptor ewes (T1 n=20; T2 n=16). At the beginning of the superovulation treatment dorsal fat of the ewes was measured with ultrasound and body weight was recorded. During the first 8 days of synchronization and superovulation treatment both groups received 100 g of protected fat and same diet as T1, synchronization for donors and receptors was performed by sponges of fluorogestone acetate (FGA, 40 mg) during 12 days. Receptor ewes received 200 U.I of eCG 12 h before sponges removal. Donor ewes were superovulated with decreasing doses of FSHp two days before and after sponges removal and embryos were obtained and transferred seven days later. Average weight of ewes at the beginning of estrus synchronization was 68.9 and 64.6 kg, for T1 and T2, respectively (P=0.07), while average dorsal fat was 2.5 and 1.97 mm for T1 y T2, respectively (P<0.05). At synchronized estrus ewes of T1 and T2 weighted 71.69 and 69.03 kg (P>0.05) and dorsal fat measures were 3.5 and 3.29 mm (P>0.05). All ewes from T1 (100%) showed response to superovulation, while in T2 only 66.7%. Ewes from T1 showed an average of 9.5 ± 0.85 corpus luteum, compared to T2 with 14.75 ± 2.36 (P<0.05). Number of embryos recovered for T1 was 7.17 ± 1.10 and 11.5 ± 2.36 for T2 (P=0.09). Average number of good quality embryos was 6.7 ± 0.84 for T1 and 8 ± 2.86 for T2 (P>0.05). Percentages of conception rate were 35% and 31.5%, for T1 and T2, respectively (P>0.05). Under the conditions of the present experiment was observed that ewes with lower dorsal fat, with the addition of protected fat for a short period increased ovulation rate but not gestation rate.

Key Words: FSH, Embryos, Dorset

494 Dietary omega-3 and omega-6 fatty acids and reproduction in dairy cattle. L. Badinga* and C. Caldari-Torres, *University of Florida*, *Gainesville*.

Fat supplementation has become a common practice in the dairy industry due to the inability of high-producing dairy cows to maintain a positive energy balance during the transition to lactation. Available

evidence indicates that dietary supplementation of long-chain fatty acids stimulates ovarian follicular development, increases serum progesterone concentration, attenuates eicosanoid synthesis, and improves fertility rates in cattle. In several animal models, supplemental n-3 polyunsaturates inhibit prostanoid synthesis, whereas n-6 polyunsaturated fatty acids tend to increase peripheral prostaglandin $F_{2\alpha}$ concentration. A recent study indicated that the net inhibitory effect of n-3 fatty acids on eicosanoid synthesis may vary, depending on the ratio of n-6 and n-3 fatty acids in the uterus. Evidence also is rapidly accumulating that supplemental polyunsaturated fatty acids not only regulate prostaglandin biosynthesis, but may also affect the production of inflammatory biomarkers in livestock. This may lead to earlier recovery of immune functions in lactating dairy cows fed a fat-supplemented diet. The objective of this review is to summarize the effects of dietary n-3 and n-6 polyunsaturates on reproductive efficiency and to discuss the putative mechanisms by which these fatty acids may affect reproductive responses in dairy cattle.

Key Words: Omega Fatty Acid, Reproduction, Dairy Cow

495 Reproductive function in dairy cows fed a lipid encapsulated conjugated linoleic acid supplement. G. E. Mann*[1], A. L. Lock[2], D. E. Bauman[3], and N. R. Kendall[1], [1]*University of Nottingham*, *Sutton Bonington, Loughborough, UK*, [2]*University of Vermont*, *Burlington*, [3]*Cornell University*, *Ithaca, NY*.

In attempting to address the problem of poor energy status during the early post partum period the intrinsic drive of the modern Holstein to partition energy intake toward increased milk output has exasperated attempts to reduce negative energy balance through improvements in diet. However, recent studies have shown that feeding of lipid encapsulated conjugated linoleic acid (LE-CLA) during the early post partum period can reduce milk fat and thus milk energy. In this study we have investigated reproductive function in multi parous Holstein-Friesian dairy cows fed LE-CLA. The study was carried out between September and March in cows individually fed a typical TMR ration based on maize and grass silage including rolled wheat, sugar beet pulp nuts, molasses and minerals. From day 21 following calving until day 100, cows received 84g of either LE-CLA containing a 50:50 mixture of cis-9, trans-11 and trans-10, cis-12 CLA supplying 7.5g of each isomer (n=13) or an equivalent amount of rumen-inert fat (Megalac; n=13) top dressed onto the standard ad lib TMR. Throughout the study daily milk samples were collected for progesterone analysis in order to accurately monitor reproductive function. During the study cows were inseminated at natural oestrus, observed by skilled stockmen according to the normal herd management routine. The proportion of LE-CLA cows showing normal cycles (12/13) was greater ($P<0.05$) than that seen in the control cows (6/13). During the trial period a greater ($P<0.05$) proportion of LE-CLA cows were inseminated (11/13) than control cows (5/13) and by the end of the trial period 7/13 LE-CLA cows had conceived compared with 4/13 control cows. The mean day of first insemination was 66±4 for the CLA treated cows and 75±9 for the control cows. These results show improved reproductive function in post partum dairy cows during the feeding of LE-CLA. The LE-CLA used in this trial was supplied by BASF.

Key Words: Cow, CLA, Reproduction

496 Dietary lipids and reproduction in beef cattle. R. N. Funston*, *University of Nebraska*, *West Central Research and Extension Center, North Platte*.

Inadequate dietary energy intake and poor body condition can negatively affect reproductive function. Supplemental lipids have been used to increase energy density of the diet and may also have direct positive effects on reproduction in beef females. Several fatty acid sources have been studied as they relate to reproductive function. Plant derived oils appear to have the greatest impact on reproduction, common sources include: sunflower, safflower, cottonseed, rice hulls, and soybeans. Animal tallow and calcium salts of fatty acids escape rumen biohydrogenation to a greater extent and are incorporated into adipose tissue and milk. Effects on reproductive function appear to be more variable. Polyunsaturated fatty acids such as those in fishmeal also bypass the rumen but have been documented to affect reproductive processes. Lipids have been fed before and after calving, during the breeding season, and during heifer development. Response to lipid has been investigated through measuring: body weight and body condition score, age at puberty, postpartum interval, first service conception rates, pregnancy rates, calving interval, mammary gland development, milk yield, milk composition, calving difficulty, and calf birth and weaning weight. Animal response appears to be dependent on body condition score, age (parity), nutrients available in the diet (pasture or range conditions), and type of lipid supplemented. To elucidate potential mechanisms of action scientists have investigated: changes in follicular and uterine development, hormonal profiles, brain function, and embryonic development. Feeding supplemental lipid has resulted in varied and inconsistent results on reproductive function. Elucidating mechanisms of action on how supplemental lipid can influence reproductive function has been a difficult process. The complexity of the reproductive system and makeup of lipid supplements are often confounded by management conditions and forage quality both in research and commercial feeding situations. This has contributed to inconsistencies in research findings.

497 The role of dietary omega-3 and omega-6 fatty acids in swine reproduction. S. K. Webel*, J. D. Spencer, and A. M. Gaines, *JBS United, Inc.*, *Sheridan, IN*.

The positive impact on reproduction of altering the omega-3:6 ratio by including supplemental omega-3 fatty acids (FA's) from marine sources has been reported for both the boar and sow. The lipid components of the spermatozoa plasma membrane contains a high level of polyunsaturated FA's. Inclusion of dietary omega-3 FA's to increase the ratio of decohexaenoic acid (DHA) in the plasma membrane has been associated with improved sperm cell viability as measured by motility, cytology, storability and increased number of AI doses obtained per ejaculate collection (Maldjian et.al. 2003, AOCS Press). Increasing the ratio of marine source omega-3 FA's in sow diets from day 60 of gestation to farrowing improved piglet prenatal survival (Rooke, 2003 Minn. Nut. Conf). Further positive effects of altering the omega-3:6 ratio were discussed and reviewed by Levis and Reese (AASV, 2003). Research in our laboratory has demonstrated the benefits of increasing dietary levels of marine sourced omega-3 FA's

on litter size in gilts (Spencer, et.al. JAS 82, Suppl. 2, p81) and sows (Webel, et.al. 2003, JAS 81, Suppl 1, p18). Improved embryo and fetal survival is the hypothesis for the observed increase in litter size. Additional recent research has demonstrated alteration in tissue concentrations and ratios of specific omega3 FA's in the fetus and newborn piglets, when gestation diets of dams were supplemented with dietary sources of marine omega-3 FA's. This enrichment of tissue omega-3 has been associated with increased preweaning survival, weaning weight, immune function and grow-finish performance. The authors will review and discuss relevant literature as well as additional unpublished research.

498 Influence of hatching egg weight and Japanese quail breeder flock age on embryonic mortality stages, hatchability and chick quality measurments. T. M. El-Sheikh*, *Sohag University*, *Sohag, Egypt*.

This study was carried out to determine the effects of the breeder age and the egg weight of the Japanese quail on the hatchability, the embryonic mortality, and one-day old chick quality. twenty-four hundred eggs were obtained from the hens at the age of 8 weeks, at the age of 16 weeks and at the age of 24 weeks. The eggs were grouped according to their weight as follows; 8.5-10.5, 10.51-11.5 and 11.51-13.5 g. The traits measured were embryonic mortality, fertility, hatchability and hatching chick quality. Pre-incubation, early, mid and late embryonic mortality were 3.18, 5.81, 7.35 and 9.76%; 3.35, 5.56, 7.62 and 10.41 and 1.85,3.02, 3.99 and 5.21% respectively, for 8, 16 and 24 weeks parents age.The percent of pre-incubation, early, mid and late embryonic mortality were 1.96, 4.55, 5.85 and 7.61%, respectively for the smaller eggs, 3.12, 4.79, 6.86 and 8.98 for mid egg weight and 3.31,5.04, 6.25 and 8.79% for the largest egg weight. Malformation and malposition of the embryonic dead and piped eggs were affected by breeder age and egg weight. Fertility was decreased as the parents age increase while the opposite trend was found with hatchability. Fertility, hatchability of set eggs and hatchability of fertile eggs were 81.44, 58.81 and 73.43%, respectively, for the youngest flock, 78.51, 61.48, 78.31% for mid flock age and were 73.73,62.68, and 85.12% for the oldest flock age. The breeder age and egg weight had significant effect on fertility, hatchability hatched and chick quality ($P<0.05$). Abnormal chicks, dead in shell and naval wet were increased with older parents and small egg weights. It was observed that the chick weight increased in parallel with increasing egg weight. The average chick weight was 10.94, 11.06, and 12.32 for parent flock of 8, 16, and 24 weeks of age , respectively. The average chick weight was 9.88, 11.01, and 12.23 grams for smaller, mid and bigger egg weight, respectively. The incubation period was shorter with increasing egg weight and breeder age.

Key Words: Quail Breeder Age, Chick Quality, Hatchability

499 WITHDRAWN BY AUTHOR.

500 Effects of supplemental dietary phytase and 25-hydroxycholecalciferol on the digestive and reproductive organ characteristics of commercial layers inoculated Before or at the Onset of Lay with the F-Strain of *Mycoplasma gallisepticum*. E. D. Peebles*[1], S. L. Branton[2], M. R. Burnham[1], S. K. Whitmarsh[1], and P. D. Gerard[1], [1]*Mississippi State University*, *Mississippi State*, [2]*Poultry Research Unit, Agricultural Research Service, United States Department of Agriculture*, *Mississippi State, MS*.

In 3 trials, the effects of dietary supplementation with phytase (PHY) and 25-hydroxycholecalciferol (25-D3) on the digestive and reproductive organ characteristics of commercial layers that were inoculated pre-lay (12 wk of age) or at the onset of lay (22 wk of age) with the F-Strain of *Mycoplasma gallisepticum* (FMG), were assessed at 58 wk of age. Experimental layer diets which included either a basal control diet or a control diet supplemented with 0.025 % PHY (600 FTU / kg of diet) and 25-D3 (34.5 µg pure crystalline / kg of diet) were fed from 20 through 58 wk of age. As a percentage of total oviduct weight, magnum weight was lower in birds that were inoculated (sham or FMG) at lay onset compared to those that were inoculated pre-lay, and in FMG-inoculated birds, relative duodenum length was greater in those inoculated at 12 compared to 22 wk. Also, as percentages of organ weight or length, infundibulum length and isthmus weight were increased, whereas duodenum length was decreased by dietary supplementation with PHY and 25-D3. The overall timing (12 versus 22 wk) of inoculation can affect the reproductive organ characteristics of layers; whereas, more specifically, the timing of an FMG inoculation may affect their digestive organ structure. Furthermore, independent of inoculation timing and type, both the reproductive organ and digestive systems of laying hens may be influenced by dietary supplementation with PHY and 25-D3.

Key Words: *Mycoplasma Gallisepticum*, Phytase, 25-Hydroxycholecalciferol

501 Validity of fertilization assessment of broiler hatching eggs. R. W. Keirs*, P. D. Gerard, and E. D. Peebles, *Mississippi State University*, *Mississippi State*.

Validation of broiler breeder flock hatching egg fertilization is important for monitoring the efficacy of breeder programs, a hatchery's efficiency including each incubational unit, the variability of a flock's hatch in different machines, inventory accountability, and in developing pragmatic hatching parameter baselines. This study included eggs from 6 flocks set in multi-stage incubators, and filling all 90 trays (15,120 eggs) of a single hatcher. Total egg residue (non-fertilized and all embryos) left on trays after hatch pull were accounted for by the Hatching Efficiency Analysis System (HEAS). Validation of fertilization levels were obtained utilizing only 4 trays of hatch residue which were pre-selected under the HEAS program. These residue

results, each which were from 1 breeder flock, were compared to the same results from the entire 90 hatcher trays (15,120 eggs) for the same flock and hatcher. The locations of all 4 of the pre-selected trays of hatch residue were within the first vertical row as one faces the hatcher. Starting at the top of the row and progressing downwards, tray levels 1, 5, 10, and 15 were selected. Also, through similar comparisons, the validity of using 2 or 8 trays rather than 4 was considered. A computer statistical model was generated in which the SD of non-fertilized eggs remaining on 2, 4, or 8 trays, which represented sub-samples of all 90 trays of a given flock, were used. The validity of fertilization level was found to be proportional to the computed SD, and increased as SD decreased with increasing fertilization and number of trays sampled. To test the validity of fertilization determination using only 4 trays, the 6 breeder flocks (28-59 wk of age) were arranged by increasing fertilization using the 90 tray results (85.7, 93.2, 95.2, 95.5, 96.6, and 97.5%). The validity of fertilization determination using 4 trays, when expressed as a percentage of their respective 90 tray results, were 99.8, 98.8, 98.0, 99.0, 98.9, and 99.4%. The collective validity of the 6 flocks and all 4 tray groups was 99.7%.

Key Words: Broiler Hatching Eggs, Fertilization, Incubation

502 Effectiveness of immersion of hatching eggs into disinfectant solutions in a commercial hatchery. J. M. Mauldin*[1], A. L. O'Shaughnessy[2], and M. T. Musgrove[3], [1]*The University of Georgia*, *Athens*, [2]*United Promotions, Inc*, *Atlanta, GA*, [3]*ARS-USDA*, *Athens, GA*.

This study was conducted at a broiler hatchery and compared effects of immersing hatching eggs into disinfectant solutions. Treatments consisted of untreated control, Virkon (1000 ppm), and Timsen (400 and 800 ppm). Treatments were evaluated by comparing microbial recovery, incubation moisture loss, chick wt, and breakout analysis. Each of 30 egg trays within a farm buggy was randomly assigned to a treatment group. Eggs from treatment groups were immersed into a 114 L vat of 37°C disinfectant solution for 150 s. The untreated control group was not dipped. Each tray was weighed and marked by group and placed into setter buggy. Ten eggs from each group were sealed in bags and transported to the lab. Ten egg shells per treatment were crushed in diluent and individually analyzed for presence and level of aerobic microorganisms, Enterobacteriaceae, and fungi using standard cultural methods. The test egg buggy was then incubated. On d 17 eggs were transferred to hatcher, each tray was reweighed to determine % moisture weight loss. On d 21 the hatch was pulled and 100 chicks per tray were weighed. All unhatched eggs were subjected to breakout analysis. Results are listed for the four treatments: untreated controls, Virkon 1000 ppm, Timsen 400 ppm, and Timsen 800 ppm. Prevalence of aerobic microorganisms in treated eggs was 100%, 90%, 50%, and 40%, respectively. Enterobacteriaceae prevalence results were 30%, 10%, 10%, and 0% while fungi prevalence results were 70%, 40%, 30%, and 40%. Aerobic bacteria levels were 4.3, 2.9, 0.7, and 0.4 log cfu/mL egg sample. Enterobacteriaceae levels were 0.4, 0.4, 0.3, and 0 log cfu/mL egg sample. Fungi levels were 0.7, 0.3, 0.2, and 0.3 log cfu/ml. These results demonstrate that immersion of eggs into Timsen solutions at 400 and 800 ppm was superior for egg sanitation. No significant differences among treatments were noted for daily % moisture loss or in chick wt as % of initial egg wt. Small differences were noted in some hatchability and breakout analysis measurements.

Key Words: Hatching Eggs, Sanitation, Hatchability

503 Effects of multistage or single-stage incubation on broiler chick quality and performance. B. D. Fairchild*[1], J. M. Mauldin[1], and R. J. Buhr[2], [1]*University of Georgia Poultry Science Department*, *Athens*, [2]*USDA, ARS*, *Athens, GA*.

Single-stage (SS) incubation has benefit over multistage (MS) incubation by matching incubator environment to embryo needs. Eggs from a young breeder flock may be incubated differently than eggs from old flocks. Information on chick quality and performance are scarce. The objective of this study was to compare quality and performance of chicks of three breeder flock ages when incubated in MS or SS. Heritage chicks from young, prime and old flocks were incubated at a broiler hatchery in either Jamesway MS or SS incubators. Chicks (450) from each treatment were placed in floor pens and provided standard diets and water ad libitum. Each pen contained 55 chicks with 0.7 ft2 per bird. Feed and BW were obtained at 0, 7, and 21 d and mortality monitored daily. On hatch day, BW with and without yolk, liver, heart and intestine wt and length were obtained from 10 chicks from each treatment. Data were arranged in a 2x3 factorial and analyzed by the GLM procedure of SAS. Chicks from SS were larger than MS chicks. Relative organ wt was not different. Residual yolk and intestinal wt per mm of intestine were greater in SS than MS. Chick BW from old breeders were larger than chicks from prime breeders which were larger than those from young breeders. An age difference in residual yolk was noted and followed the same trend as chick BW. There was an interaction between breeder age and incubation treatment for intestinal length and relative liver wt. MS incubation did not influence breeder age effects on either variable. However, SS incubation increased intestinal length in chicks from prime flocks compared to other ages. Relative liver wt were greater in SS chicks from young breeder flocks than the other ages. No differences in SS and MS treatments were noted after hatch. By 7 d, significant effects were due to breeder age in feed consumed, BW and feed conversion. At 21 d, no differences in BW were noted, but chicks from young breeder flocks had better feed conversion. SS incubation appears to improve some characteristics associated with chick quality and may improve 7 d performance. However, these differences were not observed at 21 d.

Key Words: Broiler Performance, Incubation, Breeder Age

504 Comparisons of hatchability measures in Jamesway Platinum single stage incubators with Jamesway Multistage incubators in broiler hatchery in Georgia. J. M. Mauldin*, S. A. Kuzniak, and T. L. Gardino, *The University of Georgia*, *Athens*.

A research project was conducted at a broiler hatchery to compare 3 120,000 egg capacity Jamesway Platinum single stage (SS) incubators with multistage (MS) Jamesway incubators. Comparisons included hatchability, hatchability of fertile eggs, embryo mortality, contamination and other hatchability parameters. The study was divided into 3 periods because of an airflow problem during the first 7 mo of the study (May, 2005- Dec., 2005 -- period 1). During period 2 (Jan., 2005 – Dec., 2005) data were collected in SS incubators only while engineers corrected the airflow problem. These results are not given since there were no comparisons of incubator types. In Periods 1 and 3 (May, 2006 – Jan., 2007), eggs from the same flocks were divided into SS and MS. For all 3 periods, a breakout analysis was conducted on each Monday hatch day by selecting 2 trays per incubator buggy, SS and MS and examining all unhatched eggs. For period 1,

percentages for fertility, hatchability, hatch of fertiles (HOF) were 94.09, 82.26, and 87.43, respectively in MS. SS percentages for the same parameters were 93.54, 80.36, and 89.51. The differences between hatchability and HOF were significant (p<.05). Early and late embryo mortality percentages for MS were 4.52 and 2.31; SS, 4.05 and 2.97. Differences were significant (p<.05). SS had significantly higher percentages (p<.05) for pips and cull chicks than MS (1.15 vs. 0.57 and 0.84 vs. 0.43). SS had significantly fewer (p<.05) contaminated eggs than MS (0.17% vs. 0.25%). Changes in the airflow during period 2 resulted in a dramatic improvement in many hatchability percentages in period 3 for SS. For example, hatchability and HOF were significantly higher (p<.05) at 84.08% and 89.74% in SS than MS 83.05% and 89.12%. Also, significant improvements (p<.05) were noted in comparisons of embryo mortality in SS (early dead=3.59% and late dead=2.21%) vs. MS (4.34% and 2.86%). As in the first period, the period 3 incidence of contaminated eggs was significantly lower in SS incubated eggs than in MS (0.22%, SS; 0.28%, MS).

Key Words: Single Stage, Hatchability, Embryo Mortality

505 A comparison of effects of single stage vs. multistage incubation on hatching egg moisture weight loss and chick weights in a broiler hatchery in Georgia. J. M. Mauldin*, S. A. Kuzniak, and T. L. Gardino, *The University of Georgia*, *Athens*.

A Research project was conducted at a broiler hatchery in Georgia comparing 3 120,000 egg capacity Jamesway Platinum single stage (SS) incubators with existing multistage (MS) Jamesway machines. Comparisons were made between the two incubator types for incubation egg moisture wt loss, egg wt at transfer, and chick wt as a percentage of initial egg wt. The study was divided into 3 periods because an airflow problem was recognized during the first 7 mo of the study (May, 2005- Dec., 2005, period 1). During period 2 (Jan., 2005 – Dec., 2005) data were collected in SS incubators only while engineers adjusted airflow distribution. Consequently, there are no comparative data to present in this period. In period 3 (May, 2006 – Jan., 2007) data were collected for both types of incubators. In Periods 1 and 3, eggs from the same flocks were divided into SS and MS incubators. In the hatchery, 1 tray of eggs per setter buggy (168 eggs/tray) was weighed as initial egg wt. At transfer, the same trays were weighed for transfer wt and percent moisture loss. 100 chicks in each of 2 trays/buggy were weighed for chick wt as % of initial egg wt. In Period 1, the initial egg wt averaged 60.03 g in MS and 59.37 g in SS. Transfer wt during period 1 averaged 52.22 g/egg in MS and 53.66 g/egg in SS. Differences were significant (p <.05). Moisture wt loss means at transfer were significantly different (p <.05); 12.83% for MS and 9.60 %, SS. At hatch, MS incubated chicks averaged 66.84 g and SS, 68.27 g. Differences were significant (p <.05). Period 3 resulted in initial average wt/egg of 61.44 g for MS and 60.38 g, SS. Transfer wt means were 53.76 g, MS and 55.00 g, SS. Differences were significant (p <.05). Moisture wt loss was significantly different (p<.05) between MS, 12.51% and SS, 8.91%. Chick wts averaged 40.77 g, MS and 41.49 g, SS. Chick wts as % of initial egg wt were 66.36%, MS and 68.71% for SS. Differences were significant (p <.05).

Key Words: Single Stage, Incubation, Moisture Wt Loss

506 Effect of single-stage incubation temperature profile and delayed placement on broiler performance to 40 days of age. J. T. Brake*, E. O. Oviedo-Rondon, P. W. Plumstead, K. E. Brannan, N. Leksrisompong, and J. H. Small, *North Carolina State University, Department of Poultry Science*, *Raleigh*.

Eggs produced by a 57-wk-old Ross 344 x Ross 708SF broiler breeder flock were subjected to four temperature profiles during incubation. Air temperature was either 36.9°C (Early Cool (EC)) or 38.0°C (Early Hot (EH)) during E 0-E 3 and then 37.5°C to E 17. From E 17 to hatching at E 21 air temperature was either 36.9°C (Late Cool (LC)) or 38.0°C (Late Hot (LH). Thus, four combinations (ECLC, ECLH, EHLC, and EHLH) were created. The chicks were sexed and half were placed within 2 h of removal from the hatcher at 504 h of incubation while half were held in the hatchery at 24-27°C for an additional 24 h before placement in the same facility. The chicks were then grown to 41 d of age to evaluate both live performance and carcass characteristics. The BW at placement followed the order of ECLC>EHLC>ECLH>EHLH for both sexes with an average BW of 45.1 g. The order completely reversed by 7 d in males but was no longer evident at 40 d. However, only the ECLC females were smaller than the other incubation groups at 7 d and there were no differences at 40 d. Delayed placement decreased 7d BW by 25 g in males and 19 g in females but only the males still exhibited a reduced BW at 40 d of age (2777 versus 2844 g) in conjunction with a reduced percentage dressed carcass. Surprisingly, the delayed placement chicks exhibited numerically reduced mortality at both 7 and 40 d of age.

Key Words: Incubation, Broilers, Chick Quality

507 The effect of flock age and egg storage period on organ development and broiler performance. A. Afsar[1], O. Elibol[1], and J. T. Brake*[2], [1]*Faculty of Agriculture, Department of Animal Science,Ankara University*, *Ankara, Turkey*, [2]*North Carolina State University, Department of Poultry Science*, *Raleigh*.

This study investigated the effects of broiler breeder flock age and length of egg storage on d-old broiler chick organ weights and subsequent broiler performance. Hatching eggs were obtained from Ross 344 male × Ross 308 female broiler breeders at 34 and 59 wk of age. Eggs were stored for 1, 5, or 10 d at 18 C and 75% RH prior to setting in Petersime incubators in a commercial hatchery under standard conditions. Chicks were necropsied at hatching at 504 h of incubation to detemine BW and weights of the heart, liver, gizzard, and yolk sac. There were 480 d-old male chicks assigned to 24 pens in a 3 × 2 factorial design with 4 replicates of 20 birds each. All chicks were reared in a floor pen experimental house under the same feeding, management, and immunization program with 20 chicks per square meter. Broiler BW, feed consumption, and livability were subsequently determined at 21 and 42 d of age. The percentage yolk sac was increased but percentage liver and gizzard were decreased by increased length of storage or greater flock age. Broiler BW was decreased at 21 and 42 d of age by increased length of storage (P<0.01) but was negatively affected by greater flock age only at hatching and 21 d. These data demonstrate that extended periods of egg storage change the relative development of broiler chick organs and permanently reduce broiler growth.

Key Words: Broilers, Incubation, Egg Storage

508 Optimizing brooding temperatures for large high yield broilers. E. O. Oviedo-Rondón*, M. J. Wineland, S. Funderburk, H. Cutchin, and J. H. Small, *Department of Poultry Science, North Carolina State University*, *Raleigh*.

Brooding is one of the most critical phases of broiler life due to their inability to thermoregulate. During the first days of life, birds mature from poikilothermic to homeothermic entities, and their body temperature is directly affected by ambient temperature. Two experiments were conducted in a commercial farm to estimate the best brooding temperature profiles for Ross-708 broilers raised to 9 weeks. The company standard house target temperature recommendations (CON) were compared with brooding profiles chosen to optimize the flock average rectal temperature (OB). Two paired houses with a comparable composition of day old broilers were used. In the first experiment, 19,800 chickens were placed in each house and processed at 66 days of age, during Winter/Spring conditions. In the second experiment 21,000 chickens per house were placed and processed at 63 days during Fall/Winter conditions. Rectal temperatures of at least 25 chickens per house were taken daily for the first two weeks and once a week until 35 days of age. House target temperatures were slowly reduced to avoid flock average rectal temperatures increasing above 105°F during the first 5 days. After first week, house target temperatures were adjusted to avoid average rectal temperatures rising above 107.5°F. Total BW, FCR, mortality, propane gas consumption, and flock uniformity were evaluated. Final average flock BWs were 77 and 50 grams better in the OB compared to CON in the first and second experiment, respectively. The OB group had better FCR in the first trial (1.88 vs 1.92) and no difference in the second trial (1.96). Flock uniformities improved with OB and gas consumption was reduced in 39%. The remarkable improvements in live performance and propane gas usage obtained with the OB treatment indicated that brooding temperatures could be optimized to maximize broiler performance and profitability.

Key Words: Broiler, Brooding Temperatures, Thermoregulation

509 Influence of photoperiods and light intensities meeting American and European guidelines on broiler performance. R. J. Lien*, J. B. Hess, and L. M. Stevenson, *Auburn University*, *Auburn, AL*.

Broilers were subjected to photoperiods and intensities which independently meet US National Chicken Council (NCC) or European Union (EU) guidelines to determine effects on performance. Seventy broilers were placed in each of 12 light controlled rooms. Six rooms were subjected to NCC photoperiods (long) (wk 1, 23L:1D: wk 2-6 20L:4D; wk 7, 23L:1D) and six to EU photoperiods (short) (d 1-3, 23L:1D; d 4-46, 14L:4D:2L:4D; d 47-49, 23L:1D). Six rooms were subjected to a common US intensities (dim) (wk 1, 0.25 FC; wk 2-6, 0.025 FC; wk 7, 0.25 FC) and six to EU intensity (bright) (wk 1-7, 2 FC). BW and feed consumption were determined at 9, 23, 37 and 49 d. Ten birds/sex/room were processed at 49 d to determine parts weights and yields. Data were analyzed as a 2X2 factorial arrangement. Short-dim decreased 9 d BW; otherwise, BW were unaffected by treatment. Feed consumption was reduced by dim intensity at 9 and 23 d, and short photoperiod at 23 d. Feed conversion was reduced by dim intensity at 9 and 23 d, and in the long-dim treatment at 49 d. Uniformity was increased by short photoperiod at 23 d, and in long-dim and short-bright treatments at 49 d. Nine d mortality was increased by short-dim treatment. At 49 d, mortality was increased by short-dim, reduced by long-dim and short-bright, and intermediate in the long-bright treatment. Carcass yield was increased by bright intensity and long photoperiod. Wing weight was increased by dim intensity. Total breast and fillet weights were increased by long-bright, decreased by long-dim and short-dim, and intermediate in short-bright treatments. Front half and total breast yield were increased by long-bright treatment. Wing yield was increased by long-dim, reduced by long-bright and short-bright, and intermediate in the short-dim treatment. Fillet yields were increased by long-bright, slightly reduced by short-bright, and markedly reduced by long-dim and short-dim treatments. Results indicate differences in photoperiod and intensity specified by EU and NCC guidelines will influence both broiler live and processing performance.

Key Words: Broiler Chicken, Photoperiod, Light Intensity

Ruminant Nutrition: Acid:Base Balance/Metabolism - Dairy

510 Calcium homeostasis, acid-base balance, and health status in periparturient Holstein cows fed diets with low cation-anion difference. W. X. Wu[1,2], J. X. Liu*[1], G. Z. Xu[1], and J. A. Ye[1], [1]*Institute of Dairy Sciences, Ministry of Education Key Laboratory of Molecular Animal Nutrition, Zhejiang University*, *Hangzhou, China*, [2]*College of Animal Science, Guizhou University*, *Guiyang, China*.

Forty multiparous Holstein dry cows on d 21 prepartum were randomly allocated to four blocks of 10 cows to examine the effects of reducing the dietary cation-anion difference (DCAD) on calcium homeostasis, acid-base balance, health status, and subsequent lactation performance. The reduced DCADs (Na + K - Cl - S, mEq/kg DM) of +150, +50, -50, and -150 were obtained by addition of anionic salts. Reducing DCAD resulted in mild metabolic acidosis indicated by the sharp decline of urinary pH, and minor reductions of blood pH and HCO_3^- concentration. Greater plasma calcium availability was sustained at the highest level in cows fed -150 DCAD diet close to the time of calving, and the reduced DCAD had a close association with the means of plasma calcium from d 3 prepartum to d 3 postpartum. On d 1 and 2 postpartum, the highest colostrum composite calcium concentration was observed in cows receiving -150 DCAD diet. No case of milk fever occurred within any diets, but feeding negative DCAD diets improved cow health status over the two positive DCAD diets. The milk yield and fat, protein, and lactose compositions; and 4% fat-corrected milk production were not significantly affected by DCAD treatments. It is suggested that urinary pH is an effective indicator of extracellular fluid acid-base balance, and that feeding negative DCAD in late gestation period is beneficial for dairy cows in blood calcium homeostasis and improvement of health status.

Key Words: Dietary Cation-Anion Difference, Calcium Homeostasis, Periparturient Holstein Cows

511 Dietary Na:K ratio effect on milk performance and mineral metabolisms in mid-lactation cows during summer. W. Hu* and L. Kung, Jr., *University of Delaware*, *Newark*.

The objective was to determine the effect of dietary Na:K ratio on milk performance and mineral metabolisms in lactating cows during summer. Fifteen mid-lactation Holstein cows averaging 160 days in milk were used in a replicated 3 × 3 Latin square design with treatments of dietary Na:K molar ratios (0.21, 0.53, and 1.06). The diets contained 0.25% Na and 2.00% K, 0.50% Na and 1.60% K, and 0.75% Na and 1.20% K [on a dry matter (DM) basis] respectively, with same dietary cation-anion difference (DCAD) of 33 meq (Na + K - Cl - S)/100 g of DM. Quadratic effect of the Na:K ratio occurred ($P = 0.03$) on DM intake (28.4, 27.5, and 28.3 kg/d). The Na:K ratio did not affect ($P > 0.10$) milk yield (39.2, 39.0, and 39.4 kg/d), milk composition (3.68, 3.53, and 3.59% fat; 3.00, 3.00, and 3.02% protein; and 8.60, 8.62, and 8.63% SNF), coccygeal venous plasma concentrations of HCO_3^- (30.0, 28.2, and 29.6 meq/l), Na^+ (137.2, 136.1, and 136.7 meq/l), K^+ (4.61, 4.52, 4.46 meq/l), Cl^- (98.2, 97.2, and 97.1 meq/l), Ca (9.99, 10.11, and 10.08 mg/dl), and Mg (2.55, 2.42, and 2.50 mg/dl), and urinary pH (8.35, 8.40, and 8.40) and Cl^-:creatinine (4.97, 4.20, and 3.88). Urinary Na^+:creatinine (1.80, 4.21, and 7.42; $P < 0.01$), Ca:creatinine (0.035, 0.041, and 0.064; $P < 0.01$), and Mg:creatinine (0.53, 0.60, and 0.77; $P < 0.01$) increased linearly with increasing the Na:K ratio; whereas, urinary K^+:creatinine decreased linearly as the Na:K ratio increased (22.4, 15.9, and 10.3; $P < 0.01$). Milk performance of mid-lactation cows was similar across dietary Na:K ratios with the same DCAD of 33 meq/100 g of DM.

Key Words: Sodium, Potassium, Performance

512 Fertilization using potassium chloride decreased the DCAD of timothy hay. M. Oba*[1], R. Hohm[2], R. McKenzie[2], and T. Dow[2], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Alberta Agriculture and Food*, *Lethbridge, AB, Canada*.

The objective was to evaluate effects of KCl fertilization on dietary cation-anion difference (DCAD) of timothy (*Phleum pratense* L.) hay. We hypothesized that KCl fertilization would be effective at reducing DCAD of timothy hay. Treatments were fertilization protocols with a 2 × 5 factorial arrangement using two sources of potassium fertilizer (KCl vs. KNO_3) and five rates of application (0, 50, 100, 200, and 400 kg of K/ha), and replicated in two locations: Bow Island and Lethbridge. Soil K concentration (0-15 cm) was greater at Bow Island compared to Lethbridge (293.3 vs. 187.7 ppm). For timothy grown in Bow Island, the K concentration was 1.64, 1.71, 1.69, 1.73 and 1.73 %DM for the K fertilization of 0, 50, 100, 200 and 400 kg/ha, respectively (linear effect: $P < 0.05$). The Cl concentration was increased from 0.20 to 0.93 % (quadratic effect: $P < 0.01$) and DCAD value decreased from 289 to 122 meq/kg DM (linear effect: $P < 0.01$) by KCl fertilization while they were not affected by KNO_3 fertilization. Similarly, in Lethbridge, K concentration of timothy hay was 1.52, 1.61, 1.67, 1.65 and 1.64 %DM for the K fertilization of 0, 50, 100, 200 and 400 kg/ha, respectively (quadratic effect: $P < 0.01$). The Cl concentration was increased from 0.12 to 0.78 % (quadratic effect: $P < 0.01$) and DCAD value was decreased from 237 to 91 meq/kg DM (linear effect: $P < 0.01$) by KCl fertilization. The KCl fertilization increased the K concentration of timothy hay by 5% and 10%, but increased the Cl concentration by 365 and 550 % in Bow Island and Lethbridge, respectively. Consequently, KCl fertilization decreased DCAD of timothy by more than 50% in both locations. Depending on the soil type, KCl may be an alternative and inexpensive source of Cl to produce low-DCAD timothy hay.

Key Words: KCl Fertilization, Timothy Hay, dietary Cation-Anion Difference

513 Timothy hay differing in DCAD value affected Ca homeostasis in periparturient dairy cows. M. Oba*[1], G. B. Penner[1], G. F. Tremblay[2], and T. Dow[3], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Agriculture and Agri-Food Canada*, *Québec, QC, Canada*, [3]*Alberta Agriculture and Food*, *Lethbridge, AB, Canada*.

The objective was to evaluate effects of timothy (*Phleum pratense* L.) hay differing in dietary cation-anion difference (DCAD) on the capability to maintain Ca homeostasis in periparturient dairy cows. We hypothesized that feeding low-DCAD timothy hay to prepartum cows would improve their Ca homeostasis right after calving. Thirty-five dry pregnant cows entering the second lactation or greater were used in a randomized block design. The timothy hay was obtained from an established timothy stand under a pivot irrigation system; $CaCl_2$ was applied to the area between the second and third pivot towers at 224 kg/ha to produce the low-DCAD timothy hay, and control timothy hay was grown on the area between the forth and fifth pivot towers of the same field. The Cl concentration was 1.05 and 0.07% DM, and DCAD value was 45 and 227 meq/kg DM, for low-DCAD and control timothy hay, respectively. Experimental diets, containing timothy hay at 65% of dietary DM (low DCAD vs. control), were fed ad libitum starting 30 d prior to the expected calving date. At the beginning of the study, urine pH and blood bicarbonate concentration averaged 8.24 ± 0.11 and 28.4 ± 0.8 m*M*, respectively. The low-DCAD treatment decreased ($P < 0.05$) urine pH compared to control at 21 d (7.72 vs. 8.34), 14 d (7.70 vs. 8.23), and 7 d (7.68 vs. 8.23) before calving, and decreased ($P < 0.05$) blood bicarbonate concentration 14 d (26.2 vs. 30.3 m*M*) and 7 d (26.9 vs. 30.8 m*M*) before calving. In addition, cows fed the low-DCAD treatment had greater ($P < 0.05$) ionized Ca concentration compared to control at 0 h (1.07 vs. 0.97 m*M*) and 8 h (1.07 vs. 0.99 m*M*) post-calving; the treatment effect disappeared beyond 16 h post-calving. These data indicate that timothy hay differing in DCAD value affects the acid-base balance of periparturient dairy cows, and that low-DCAD timothy hay may prevent postpartum hypocalcemia.

Key Words: Chloride Fertilization, Timothy Hay, Hypocalcemia

514 Effects of hypocalcemia at calving on intake, behavior and 305 milk production. J. M. Huzzey[1], T. F. Duffield[2], S. J. LeBlanc[2], D. M. Veira[3], D. M. Weary[1], and M. A. G. von Keyserlingk*[1], [1]*University of British Columbia*, *Vancouver, Canada*, [2]*University of Guelph*, *Ontario, Canada*, [3]*Pacific Agri-Food Research Centre*, *Agassiz, BC, Canada*.

Sub-clinical disease is often overlooked and rarely treated. The objective of this study was to describe the effects of sub-clinical hypocalcemia occurring shortly after calving on feed/water intake, feeding/drinking behavior and the longer-term effects on milk production. Intake and behavior of 93 Holstein dairy cows were

monitored from 3 wks before until 3 wks after calving. Within 24 h after calving a blood sample was taken from each cow and analyzed for serum total calcium (Ca) concentration. Daily milk yields were collected on each cow until 305 DIM. 28 cows were identified as hypocalcemic on the day of calving (Ca concentration was ≤ 1.8 mmol/L). Hypocalcemic cows had similar intakes to cows without hypocalcemia during the 3 wks before and 2 wks after calving, however DMI was on average 2 kg/d less in the hypocalcemic group during wk 3 (P=0.02). There were no differences in feeding time between the two groups of cows over the course of the study (P=0.2). Cows with hypocalcemia on the day of calving consumed on average 12 kg/d more water during wk 2 and wk 3 after calving relative to cows with normal calcium levels (P≤0.05), but there were no difference between these groups in drinking behavior before or after calving. Hypocalcemic multiparous cows produced more milk during early and mid-lactation (P<0.01). Over the course of their 305 lactation hypocalcemic multiparous cows produced on average 1190 kg more milk then multiparous cows with calcium concentrations >1.8mmol/L on the day of calving (P<0.01). The greater requirements for calcium by cows with higher milk production may explain their increased risk of hypocalcemia and suggests that cows with higher potential may require special treatment.

Key Words: Hypocalcemia, Transition Cows, Feeding Behavior

515 Strong ion concentrations in ruminal fluid of lactating dairy cows fed diets varying in fermentibility. C. S. Mooney* and M. S. Allen, *Michigan State University*, *East Lansing*.

The objective of this experiment was to determine relationships among concentrations of strong ions and hydrogen ions in ruminal fluid of cows fed diets varying in fermentibility. Eight ruminally cannulated Holstein cows in early lactation were used in an experiment with a duplicated 4 × 4 Latin square design. A 2 × 2 factorial arrangement of treatments was used with main effects of dietary starch concentration (32% vs. 21%) and conservation method of corn grain (dry, 90% DM or high-moisture, 63% DM). Ruminal fluid samples (n = 2,304) were collected through a ruminal cannula every twenty minutes for 24 h per period during which feeding behavior and ruminal pH were monitored continuously. Hydrogen ion concentration of ruminal fluid was related negatively to sodium concentration (r = -0.50, P < 0.0001), positively to potassium (r = 0.28, P < 0.0001) and ammonium (r = 0.38, P < 0.0001) concentrations, and not highly related to chloride concentration (r = 0.04, P = 0.09). Change in ruminal potassium concentration was related to meal size (r = 0.83, P < 0.0001) which was expected because of influx of potassium from the diet. However, meal size and ruminal sodium concentration were negatively related (r = -0.64, P < 0.0001) despite influx from saliva and the diet. Sodium concentration of ruminal fluid was negatively related (r = -0.75, P < 0.0001) to the sum of potassium and ammonium concentrations causing the sum of sodium, potassium, and ammonium concentrations to be relatively constant (140.0 ± 9.8 mEq/L, mean ± SD, n = 2246). Hydrogen ion concentration of ruminal fluid was related negatively to strong ion difference measured as ruminal concentrations of sodium plus potassium minus chloride (r = -0.43, P < 0.0001). An alkalizing strong ion difference was measured in all ruminal fluid samples (n=2245). Maintenance of total cation concentration of ruminal fluid balances the charge of dissociated fermentation acids, maintains the bicarbonate pool, and controls ruminal osmolality.

Key Words: Rumen pH, Sodium, Potassium

516 Feed efficiency of lactating dairy cows is related to dietary energy density. D. P. Casper*[1] and D. R. Mertens[2], [1]*Agri-King, Inc.*, *Fulton, IL*, [2]*USDA-ARS Dairy Forage Research Center*, *Madison, WI*.

Monitoring of the Feed Efficiency **(FE)** of lactating dairy cows has become more important in recent years due its direct effect on the profitability of the dairy operation. Our objective was to identify those variables associated with energy metabolism that influence the FE of lactating dairy cows. The Energy Metabolism Database is a compiled dataset of all energy and N balance trials that were conducted at the Energy Metabolism Unit of the USDA-ARS, which contains approximately 2,940 individual energy and N balance digestion trials with measurements of respiratory exchange using open circuit respiration chambers. Only 1,289 of these individual metabolism trials used lactating dairy cows of different breeds and stages of lactation that were fed diets that varied in forage types, grain sources, protein sources, and fat supplements. All data were analyzed using linear regression procedures of SAS. The initial data analysis indicated that ruminal acidosis may have occurred and affected FE results. Thus, metabolism trials of lactating dairy cows having inverted fat and protein ratios (acidosis criteria) where removed, which resulted in 460 observations for evaluating variables related to FE. The amount of dry matter absorbed by lactating dairy cows had a significant effect on FE (FE = 0.46+.067*DM Absorbed, g/d; R^2=.36, *P*<.01). In addition, the greater the energy density of the diet (NE_L, Mcal/kg), the greater the FE of lactating dairy cows (FE = 0.004 + 1.156*NE_L, Mcal/kg DM; R^2=.55, *P*<.01). As expected, FE was positively related to milk production (FE = 0.60 + 0.03*Milk, kg/d; R^2=.77, *P*<.01). It appears that ruminal acidosis negatively effects digestibility thereby affecting the energy metabolism of the lactating dairy cow. Without acidosis, the FE of lactating dairy cows was determined by the energy density of the diet. Improving the energy density of the diet through enhanced dry matter digestibility will improve FE and thereby increase profitability of the dairy operation.

Key Words: Feed Efficiency, Energy Density, Acidosis

517 Factors affecting milk urea nitrogen in dairy cattle. J. Ramírez*[1], D. Lefebvre[2], and K. M. Wade[1], [1]*McGill University*, *Montreal, QC, Canada*, [2]*Valacta*, *Ste. Anne de Bellevue, QC, Canada*.

The aim of this study was to estimate non-nutritional and nutritional factors that influence milk urea nitrogen (MUN) using machine-learning techniques. 2,253,667 milk test-day records were collected by the Quebec dairy herd improvement agency (VALACTA). The files contained test-day, body-weight and diet-composition records of 611,358 cows from 5,886 farms over a period of 5 years. A database was constructed from the animal identification file, test-day file, body-weight, and feed file. Descriptive statistical analysis was performed including breed (Ayrshire, Brown Swiss, Holstein and Jersey), parity, stage of lactation, season, year, and sampling time. Mean MUN values were 12.11, 13.44, 11.06, and 13.8 mg/dL in Ayrshire, Brown Swiss, Holstein and Jersey, respectively. These values decreased with increasing body weight. In Holsteins, MUN levels increased with parity number but parity variations were numerically small. The MUN concentration was lower during the first 30 DIM, but increased in subsequent months. There was a strong negative relationship between MUN and milk yield. Temporal variations suggested a drop in the levels of MUN during the summer followed by a peak during the fall

months. For an analysis using machine-learning techniques, MUN values were grouped into three classes (low, medium, and high). For each of the four breeds, a decision tree was induced to identify potential interactions among the variables in the dataset. Results for the Ayrshire breed indicated that MUN variations were principally due to SCC and time of milk sampling. Body-weight, DMI, and time of milk sampling had a strong influential effect on medium levels of MUN in Jerseys, while MUN levels in Holsteins seemed to be strongly influenced by the interaction of milk fat with SCC and stage of lactation.

Key Words: Milk Urea Nitrogen, Machine Learning, Ddecision Trees

518 The relevance of milk components for the assessment of the energy, protein and structure balance of Holstein Friesian cows. M. Kaske*[1,2], S. Seggewiss[2], K. Horstmann[2], M. Spolders[3], and U. Meyer[3], [1]*Physiology Weihenstephan*, *Technical University Munich*, [2]*Clinic for Cattle*, *University of Veterinary Medicine Hannover*, [3]*Institute of Animal Nutrition*, *Federal Agricultural Research Centre Braunschweig*.

The objective was to characterize the usability of milk component data for the assessment of the alimentary supply of dairy cows. Therefore, the correlations between energy, protein and structure balance and milk constituents (analysed twice per week) were estimated in 50 Holstein Friesian cows (8709 +/- 1472 kg FCM). Cows were fed maize and alfalfa silage (65:35 w/w; 5.9 MJ NEL/kg DM) ad libitum via computerized feeder stations and concentrates (8.3 MJ NEL/kg DM) according to milk yield by automatic feeders. For each cow, daily energy balance [EB], protein balance [PB] (on the basis of nXP) and structure balance [SB] (Hoffmann, 1990) were calculated. The value of the "9-field-table" (used to assess the energy supply based on milk protein and the protein supply based on milk urea) was tested for each month of lactation; a balanced supply was defined as ± 15 MJ NEL/d and +/- 300 g nXP/d. - The EB of the cows was assessed correctly for 30.8–42.7% and the protein balance for 38.5–72.9 % of the samples. Only 13.8–32.2% of the samples were catagorized correctly for both parameters. A significant negative correlation between EB and milk yield was found during the first four months of lactation (r = -0.15 to -0.30); thereafter, EB and milk yield were positively correlated (r = 0.15). EB was negatively correlated to milk fat content (r = -0.16 to -0.54), fat-protein-ratio (r = -0.33 to -0.44) and fat-lactose-ratio (r = -0.28 to -0.59). SB and milk fat were positively correlated (r = 0.24 to 0.28). - The effects of an energy restriction were examined on days 15, 29, 43 and 78 post partum by withdrawal of 8-10 kg concentrates for 24 hours. Milk yield and milk components did not change significantly compared to the days before restriction, but on the following day milk yield and milk protein decreased and milk fat content, fat-protein-ratio and fat-lactose-ratio increased significantly. - Conclusions: Milk fat content and fat-protein-ratio reveal severe energetic and structural deficits only on a herd basis. EB and PB of individual cows can not be assessed reliably by evaluation of milk components.

Key Words: Energy Balance, Milk Components, Milk Protein

519 Evaluation of acute phase reactants and indices of liver function in serum from dairy cows fed different levels of energy prepartum. N. A. Janovick Guretzky*[1], H. M. Dann[1], M. Bionaz[1], E. Trevisi[2], G. Bertoni[2], and J. K. Drackley[1], [1]*University of Illinois*, *Urbana*, [2]*Universita Cattolicà del Sacro Cuore, Zootecnica*, *Piacenza, Italy*.

Markers of inflammation have been associated with fatty liver in dairy cows. To investigate effects of prepartum plane of nutrition on inflammation and liver function, serum from 73 multiparous Holstein cows was used to profile acute phase response reactants and enzymes associated with liver function. Dietary treatments were assigned by expected date of parturition in a 3 x 2 factorial design. During the far-off (FO) period, cows were assigned to 1 of 3 dietary treatments: 1) fed ad libitum to supply ≥150% of NE_L requirements (HI) for dry cows in late gestation (NRC, 2001); 2) fed a diet containing chopped wheat straw to limit intake to approximately 100% of NE_L requirements (LIM); and 3) limit-fed to 80% of NE_L requirements (LO). During the close-up (CU) period, cows were fed ad libitum to supply ≥150% of their requirement for NE_L (ADLIB) or restricted to 80% of their requirement for NE_L (REST). At parturition, all cows were fed a common lactation diet. Data for variables analyzed in serum obtained pre- and postpartum were analyzed using repeated measures. Cows fed HI had lower (FO, $P<0.02$) paraoxanase prepartum compared with LIM or LO. Cows fed HI-REST tended to have higher haptoglobin prepartum than cows fed HI-ADLIB or LO-REST (FOxCU, $P=0.07$). Cows fed HI tended to have lower (FO, $P=0.06$) albumin compared with LIM and higher (FO, $P=0.04$) bilirubin postpartum compared with REST. Cows fed ADLIB had higher (CU, $P=0.04$) aspartate transaminase than REST cows regardless of FO treatment. Concentrations of total lipid and triglyceride in liver postpartum were positively correlated ($P<0.04$) with bilirubin and ceruloplasmin and negatively correlated ($P<0.01$) with paraoxanase measured postpartum. Overfeeding during the dry period may have compromised liver function postpartum and contributed to inflammation and development of fatty liver.

Key Words: Inflammation, Fatty Liver, Periparturient Period

520 Gene expression in adipose tissue of the dairy cow during late pregnancy and lactation fed control diets or diets with supplemental chromium: Integration of gene expression into metabolic models. J. P. McNamara*[1], J. M. Sumner[1], J. L. Vierck[1], and A. Jourdan[2], [1]*Washington State University*, *Pullman*, [2]*Kemin Industries, Inc.*, *Des Moines, IA*.

We conducted an analysis of gene expression in adipose tissue of dairy cattle in late pregnancy and early lactation. One objective was to determine gene expression between 30 days prepartum and 30 DIM; another was to determine if dairy animals fed supplemental Chromium Propionate had responses gene expression. Adipose tissue was biopsied from Holstein dairy cattle at 30 days pre and post partum. We extracted complete mRNA from samples from 3 cows at each time point (same cows, repeated measures) for gene array analysis. Among those genes increasing ($P < 0.10$) to 30 DIM were those signaling for myosin heavy chain, several immunoglobulins and receptors, and neutrophil beta-defensin 5. Among those decreasing ($P < 0.10$) from 50 to over

75 % included acetyl CoA Carboxylase (-79 %), ATP citrate lyase (-75 %), insulin receptor induced protein (-77 %), IGFI (-30 to 50%), and IGFBP3 (-55 %). Leptin expression (Genbank: NM_173928.1) was reduced 57 %. In a separate study, we fed 10 mg/d of chromium from 21 d prepartum through 35 DIM. There were 223 genes that were increased 2-fold or more at d -7 versus controls, and 1150 were decreased 50% or more compared to control. There were 3517 genes lower in supplemented cows in which at least one of the signals had an expression of 50 or more on the Affymetrix chip. There were 24 genes that increased and 347 that decreased in CrP supplemented animals at both days. The primary functional cluster of genes that were up regulated in supplemented animals included those functioning in cell synthesis and in the immune system, such as myosin heavy chain and immunoglobulin A receptor. Genes decreased at both times to chromium were NADH dehydrogenase, t-cell receptor, and prostaglandin PGH2. Leptin expression was decreased by KT at d 28, as was growth hormone receptor mRNA. We have integrated a preliminary gene expression map with a mechanistic model of metabolism in dairy cattle.

Key Words: Adipose, Gene Array, Lactation Model

Ruminant Nutrition: Corn Milling Co-Products - Beef

521 Environmental concerns with feeding corn milling co-products in feedlot diets. T. J. Klopfenstein* and G. E. Erickson, *University of Nebraska*, *Lincoln*.

The grain to ethanol industry is rapidly expanding which creates challenges and opportunities for the cattle feedlot industry. This expansion creates competition for grain; however, byproducts may offer opportunities to reduce costs of production. Meta analysis indicates that wet distillers grains have 25 to 45% more feed value than corn and wet corn gluten feed has equal to or 9.4% more energy than corn depending on the plant processes. Priced at or below the price of grain, byproducts are economically advantageous to the feedlot industry. Ethanol is produced from the starch in grain so by removing the starch, nutrients are concentrated in the byproducts (three times in distillers grains). The two nutrients of concern, from an environmental standpoint, are N & P. Nitrogen is a concern primarily because it is volatilized from the surface of open feedlot pens. Alternatively, P is not volatilized...what the cattle excrete is what must be managed in the manure. A diet containing 40% distillers grains on a dry basis has about 18% CP which is about 50% above the animal's requirement. All of the excess N is excreted. A diet with 40% gluten feed is near the animal's requirement for CP. Byproduct diets are less digestible than corn based diets and the additional OM in the manure helps retain some of the excess N. Frequent cleaning is also beneficial. There is still a net loss of N as ammonia. A diet with 40% byproduct has about 0.5% P which is about three times the requirement. This essentially doubles the land necessary to utilize the manure compared to a corn-based diet. For a 25,000 hd feedlot that may add $2 to $3 per animal to distribute the manure. However, because of the value of the P as fertilizer there is actually a net benefit of $3 to $5 per animal fed. Phosphorus is a distribution issue with byproduct feeding, not a negative economic issue. While ammonia loss from open feedlots is not currently regulated, it may be in the future. Methods of maintaining the N in the manure to capture its value as fertilizer need to be researched for both diets with and without byproducts.

Key Words: Cattle Feeding, Nitrogen, Phosphorus

522 Effect of modified wet distillers grains level on feedlot cattle performance and nitrogen mass balance. M. K. Luebbe*, G. E. Erickson, T. J. Klopfenstein, and M. A. Greenquist, *University of Nebraksa*, *Lincoln*.

A summer feedlot trial was conducted to evaluate the impact of modified wet distillers grains plus solubles (52% DM, WDGS) level on steer performance, manure N removed, and N lost via volatilization. Ninety-six yearlings (373 ± 24 kg) were stratified by BW and assigned randomly to 12 pens. Steers were fed for 133 d from June to October. Treatments consisted of 0, 15, and 30% dietary inclusion of WDGS (DM basis) replacing corn (CON, 15WDGS, 30WDGS, respectively). Basal diets consisted of high-moisture and dry-rolled corn fed at a 1:1 ratio, 7.5% alfalfa hay, 5% molasses, and 5% supplement (DM basis). The CON and 15WDGS diets were balanced for MP using the 1996 NRC, and 30WDGS was in excess of requirements. Nitrogen excretion was determined by the difference between N intake and individual steer N retention. Total N lost was calculated by subtracting manure and runoff N from excreted N. Dry matter intake tended ($P=0.09$) to increase linearly with WDGS level. Average daily gain was lower ($P=0.05$) for CON compared with 15 and 30 WDGS (1.80, 1.94, and 1.91 kg, respectively). Carcass measurements, G:F, and final BW were not influenced ($P>0.10$) by WDGS level. Manure OM linearly increased ($P=0.02$) with WDGS level. Nitrogen intake was greatest ($P<0.01$) for 30WDGS, intermediate for 15WDGS, and least for CON (42.9, 35.5, and 28.9 kg•steer^{-1}over 133 d, respectively). Nitrogen retention did not differ ($P=0.16$) among WDGS level. Excretion of N was greatest ($P<0.01$) for 30WDGS, intermediate for 15WDGS, and least for CON (38.0, 30.5, and 24.3 kg, respectively). Manure N was greater ($P<0.01$) for 30WDGS (10.2 kg) compared with 15WDGS (6.5 kg) and CON (5.8 kg). Runoff N was not different ($P=0.54$) among WDGS level. Amount of N lost was greatest ($P<0.01$) for 30WDGS, intermediate for 15WDGS, and least for CON (26.5, 20.0, and 14.1 kg, respectively) but percent loss (percent of excreted N) was not different ($P=0.32$) among treatments. In this study feeding WDGS balanced for MP or in excess of requirements resulted in improved ADG and more N in the manure for 30WDGS. However, the amount of N lost was increased when WDGS was fed.

Key Words: Cattle, Nitrogen, Waste Management

523 Effect of wet distillers grains level on phosphorus balance in beef feedlots. M. K. Luebbe*, G. E. Erickson, T. J. Klopfenstein, and M. A. Greenquist, *University of Nebraska*, *Lincoln*.

The effect of wet distillers grains plus solubles (WDGS) level on P mass balance was evaluated in two experiments. Calves were fed 167 d from November to May (WINTER) and yearlings were fed 133 d

from June to October (SUMMER). Treatments consisted of 0, 15, and 30% dietary inclusion of WDGS (DM basis) replacing corn (CON, 15WDGS, 30WDGS, respectively). Modified WDGS was fed in the SUMMER experiment. Basal diets for both experiments consisted of high-moisture and dry-rolled corn fed at a 1:1 ratio, 7.5% alfalfa hay, 5% molasses, and 5% supplement (DM basis). Mass balance of P was evaluated by measuring P in diets, manure, soil on the pen surface, and runoff. Dietary treatments were fed in the same pens for both experiments. Diet P composition (DM basis) averaged 0.34, 0.39, and 0.47% in both experiments for CON, 15WDGS, and 30WDGS, respectively. When WDGS was fed, P intake linearly increased (P<0.05) for both experiments. Retention of P linearly increased (P<0.05) with WDGS level in the WINTER trial due to ADG response but was not different (P=0.16) among WDGS levels for the SUMMER trial. Excretion of P linearly increased (P<0.01) in both experiments with 3.88, 5.13, and 6.37 kg •steer^{-1} in the WINTER and 3.77, 4.62, and 5.76 kg •steer^{-1} excreted in the SUMMER for CON, 15WDGS and 30WDGS, respectively. Similarly, manure P linearly increased (P<0.01) with 2.77, 3.82, and 4.49 kg •steer^{-1} in the WINTER and 2.05, 2.57, 4.32 kg •steer^{-1} in the SUMMER for CON, 15WDGS and 30WDGS, respectively. Correcting manure for soil P accounts for 98, 79, and 102% of excreted P in the WINTER and 87, 62, and 57% of excreted P in the SUMMER for CON, 15WDGS, and 30WDGS, respectively. Runoff P was not different (P>0.10) among WDGS level and averaged 3.8, and 9.5% of excreted P for WINTER and SUMMER, respectively. These results suggest that increasing dietary P will increase manure P and the amount of land needed for manure application when WDGS are used by feedlot cattle.

Key Words: Cattle, Phosphorus, Nutrient Management

524 Evaluation of dried distillers grains or soybean hulls with and without Optigen II® to background beef calves. J. L. Wahrmund* and M. J. Hersom, *University of Florida*, *Gainesville*.

The objective of this study was to determine the effects of supplementing a controlled-release source of DIP (Optigen) when feeding dried distillers grains (DDG) or soybean hulls (SBH) to weaned beef calves. Fifty-six Angus steers (initial BW=236 ± 25 kg) were blocked by BW and randomly allotted to one of four supplement treatments. Treatments included: 1) 1.19 kg DDG (0.82 kg CP, 2.4 kg TDN); 2) 1.19 kg DDG, 45.5 g Optigen (1.11 kg CP, 2.4 kg TDN); 3) 2.63 kg SBH (0.83 kg CP, 4.7 kg TDN); 4) 2.63 kg SBH, 45.5 g Optigen (1.11 kg CP, 4.7 kg TDN). Amounts of DDG and SBH were formulated to supply equal CP. Optigen was included to determine the effect of a slow-release DIP source in these diets. All steers were allowed ad libitum access to bahiagrass hay and individually supplemented via a Calan Gate system for 42 d. On d 0, 14, 28, and 42 BW was recorded and a blood sample was collected for analysis of plasma urea nitrogen (PUN) and glucose concentration from all steers. Supplement treatment had no effect on final BW (P=0.97, mean=273 kg). 42 d ADG did not differ (P=0.17, mean=0.88 kg/d) among treatments. No differences in plasma glucose concentrations were observed (P=0.54, mean=69.2 mg/dL) between supplement treatments. PUN concentrations exhibited a treatment x day interaction (P=0.001). On d 14, 28, and 42 steers consuming only DDG had greater (P<0.05) PUN concentrations than steers consuming only SBH (10.3 vs. 8.6 mg/dL). Additionally, on d 14, 28 and 42 steers consuming Optigen had increased (P<0.05) PUN concentrations compared to steers not offered Optigen (11.6 vs. 8.5 mg/dL). On d 14 and 42, PUN concentration did not differ (P=0.45, 0.77) between DDG and SBH+Optigen steers. The inclusion of a controlled-release DIP source did not affect steer performance. However, Optigen was effective at increasing PUN concentrations above 10 mg/dL, indicating adequate DIP for forage fermentation within the rumen.

Key Words: Steers, Supplementation, Protein

525 Carcass and meat quality characteristics of distiller's co-product-supplemented pasture- and feedlot-finished beef steers. R. C. Knock*[1], A. H. Trenkle[1], E. J. Huff-Lonergan[1], S. M. Lonergan[1], J. R. Russell[1], P. M. Dixon[1], K. M. Carnagey[2], and D. C. Beitz[1], [1]*Iowa State University*, *Ames*, [2]*Wake Forest University School of Medicine*, *Winston-Salem, NC*.

British breed beef steers (n = 48; 370 kg) were assigned to pasture or feedlot diets and one of two concentrations of 25-hydroxyvitamin D_3 (VITD; 0 or 500 mg) to evaluate VITD and distiller's co-product supplementation effects on performance, carcass traits, and fatty acid composition. Pasture-finished cattle received 6.8 kg/hd per day of pelleted distiller's grains, wheat midds, and soy hulls. The feedlot diet contained 10% wet distiller's grains. Steers were harvested after 112, 133, or 154 d on feed (DOF) to minimize 12th rib fat differences. Steers (n = 24) received 25-hydroxyvitamin D_3 boluses orally 7 d prior to assigned harvest date. At harvest, carcass data and longissimus (LM), semimembranosus (SM), and gracilis (GR) muscles were collected for analysis. At harvest, feedlot steers were heavier (P = 0.0370; 584 kg; 132 DOF) than pasture-fed steers (563 kg; 130 DOF) and had greater ADG (P < 0.0001; 1.74 vs. 1.51 kg/d). Pasture-fed steers had less (P < 0.0001) 12th rib fat and (P = 0.0108) kidney, pelvic, and heart fat as well as lower (P = 0.0141) marbling scores than did feedlot steers (Slight^{45} vs. Slight^{90}). Lipid percentage differed by muscle (P < 0.0001) as GR had the least lipid followed by SM and LM (1.54, 1.94, and 2.54% of tissue, respectively). Pasture-fed steers had greater LM C18:2 cis-9, trans-11 (CLA) and C18:3n3 concentrations (P < 0.0001) than did feedlot steers (0.95 and 0.63 vs. 0.19 and 0.26 mg/100 mg lipid, respectively). Feedlot steers generally had greater monounsaturated fatty acid percentages, except for C18:1 trans-9 and trans-11 isomers. VITD did not affect performance or carcass traits. Data indicate it is possible to finish steers on pasture by supplementing with distiller's co-products without substantially increasing time needed to reach market weight and still maintain increased CLA compared with feedlot-finished steers.

Key Words: Beef, Distiller's Grains, Pasture-Finished

526 Evaluation of dried distillers grains or soybean hulls to background beef calves. J. L. Wahrmund* and M. J. Hersom, *University of Florida*, *Gainesville*.

The objective of this study was to determine the effects of supplementing dried distillers grains (DDG), soybean hulls (SBH), or combinations of the two to beef steers consuming low quality hay. Fifty-six Angus steers (initial BW=275 ± 27 kg) were blocked by BW and randomly allotted to one of four supplement treatments. Treatments included: 1) DDG (2.8 kg); 2) DDG/SBH (1.93 kg DDG, 0.98 kg SBH); 3) SBH/DDG (0.96 kg DDG, 2.05 kg SBH); 4) SBH (3.12 kg).

Supplements were formulated to be isoenergetic, and steers were individually supplemented via a Calan Gate system for 42 d. All steers were allowed ad libitum access to bahiagrass hay. On d 0, 14, 28, and 42 BW was recorded and a blood sample was collected for analysis of plasma urea nitrogen (PUN) and glucose concentration from all steers. Supplement treatment had no effect (P=0.79) on final BW (mean=306 kg). From d 0 to 14, ADG of DDG steers was 0.27 kg/d less (P<0.05) compared to treatments containing SBH (mean=0.60 kg/d). Across all 42 d, ADG of SBH steers was less than DDG/SBH (P=0.06, 0.80 kg/d) or SBH/DDG (P=0.03, 0.83 kg/d), but was not different (P=0.45) than DDG steers (0.72 kg/d). Plasma glucose concentrations were not different (P=0.85, mean=77.98 mg/dL) between supplement treatments. PUN concentrations exhibited a treatment × day interaction (P=0.01). On d 0, PUN concentration did not differ (P=0.65, mean=6.4 mg/dL) between treatments. However, on d 14, 28, and 42 PUN concentrations of DDG and DDG/SBH steers (15.87, 13.98, 12.51 and 11.47, 11.67, 12.79) were greater (P<0.05) compared to SBH/DDG or SBH steers (9.49, 8.45, 9.57 and 5.25, 5.46, 5.91). Supplementing steers consuming low-quality forage with a combination of co-products resulted in improved BW gain and nitrogen metabolism. The combination of 0.9 kg DDG and 2.05 kg SBH optimized calf performance.

Key Words: Steers, Supplementation, Co-Products

527 Effect of wheat base distillers grains in a barley ration on the performance and carcass quality characteristics of feedlot steers. R. M. Beliveau*, J. J. McKinnon, and V. J. Racz, *University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*.

The objective of this experiment was to evaluate the effects of titrated levels of wheat-based dried distiller's grains with solubles (DDGS) on feedlot performance and carcass characteristics of growing cattle. Two hundred weaned calves (290±5kg) were randomly assigned to one of 20 pens and fed one of 5 DDGS treatments. During backgrounding, the barley grain-based control diet was formulated to 12% CP, 28% RUCP, 1.52 and 0.93 Mcal / kg NE_m and NE_g, respectively. In treatments 2 through 5, DDGS replaced barley grain at levels of 8.1, 16.2, 24.2 and 32.1% of the ration dry matter. The finishing barley grain-based control diet was formulated to 12% CP, 27% RUCP, 1.90 and 1.26 Mcal / kg NE_m and NE_g, respectively. DDGS replaced barley grain in treatments 2 through 5 at levels of 5.9, 11.7, 17.5 and 23.3% of the ration dry matter. Crude protein and RUCP levels increased in a linear fashion as DDGS inclusion level increased. The backgrounding period lasted 85 d. The targeted end-point for finishing was a shrunk body weight of 600 kg. During the 85 d backgrounding period, ADG and DMI increased (P≤0.01) quadratically as DDGS inclusion level increased. Feed efficiency was significantly improved (P≤0.05) at the 2 highest levels of DDGS inclusion. During the first 56 d of finishing there was a linear increase (P≤0.05) in ADG and a cubic increase in DMI as DDGS inclusion level increased, however over the entire trial there was no (P≥0.05) ADG response to DDGS inclusion. Ultrasound backfat and ribeye area measurements were not (P≥0.05) affected by treatment. Similarly, carcass weights and quality traits including dressing percentage, marbling, fat thickness and yield grade were not influenced (P≥0.05) by treatment. The results of this trial indicate that for feedlot cattle, the energy value of wheat-based DDGS is at least equal to that of barley grain with no adverse effects observed on cattle performance or carcass quality.

Key Words: Wheat-Based Dried Distiller's Grains, Cattle, Barley

528 Dry distiller's grains with solubles in steam-flaked or dry-rolled corn diets with reduced roughage levels. M. L. May*, M. L. Hands, M. J. Quinn, B. E. Depenbusch, J. O. Wallace, C. D. Reinhardt, and J. S. Drouillard, *Kansas State University*, *Manhattan*.

A study was conducted to evaluate the use of 25% dry corn distiller's grains with solubles (DG) as a partial replacement for dry-rolled corn or steam-flaked corn in finishing diets containing either high (15%) or low (5%) levels of corn silage (CS). Crossbred heifers (n=582; BW 377 ± 0.4 kg) were housed in 24 dirt surfaced pens with 21-25 heifers per pen and fed finishing diets once daily for 110 d. Experimental diets were: steam-flaked corn without DG and 15% CS (SFC), SFC with 25% DG and 15% CS (SFCHigh), SFC with 25% DG and 5% CS (SFCLow), dry-rolled corn with no DG and 15% CS (DRC), DRC with 25% DG and 15% CS (DRCHigh), and DRC with 25% DG and 5% CS (DRCLow). Within grain source, DMI were similar for cattle fed 0 and 25% DG. The 5% CS groups consumed less feed daily and also were more efficient. Yield grade and carcass quality were not affected by inclusion of DG. Results indicate that roughage levels can be reduced in feedlot diets containing DG with no adverse effects on efficiency, health, or carcass quality.

Table 1. Performance of cattle fed steam-flaked or dry-rolled, reducing roughage levels, and with or without disitller's grains

Item	DRC	DRC High	DRC Low	SFC	SFC High	SFC Low	Contrasts 1	2	3

529 Use of distiller's dry grains in steam-flaked corn finishing diets with reduced roughage levels. M. L. May*, M. J. Quinn, B. E. Depenbush, and J. S. Drouillard, *Kansas State University*, *Manhattan*.

A finishing study was conducted to evaluate the use of dry corn distiller's grains (DDG) in steam-flaked corn (SFC) diets, and to examine the potential for reducing the level of Corn Silage (CS) when DDG is substituted for a portion of SFC. Crossbred heifers (n=377; BW 378±1.4 kg) were fed diets consisting of 0% DDG with 15% CS (CON), 25% DDG with 15% CS (HIGH), or 25% DDG with 5% CS (LOW). Heifers were individually weighed and assigned randomly to feedlot pens containing 15 to 16 animals each, with eight pens per treatment. Heifers were fed twice daily ad libitum for 85 d. There were no differences among treatments with respect to ADG, G:F, final weight, carcass weight, subcutaneous fat thickness, carcass quality grade, or yield grade (P > 0.10). Compared to cattle fed the CON diet, heifers fed LOW had decreased DMI (9.01 vs. 8.52 kg/d) and higher dressing percentage (63.23 vs 63.73%). Inclusion of DDG with 15%

CS reduced LMA when compared to CON (86.1 vs 82.5 cm^2; P < 0.04). Partial replacement of SFC with DDG yields satisfactory performance and carcass characteristics in cattle fed diets with CS as the roughage source. Additionally, it is possible to remove a significant portion of dietary roughage in diets containing DDG without compromising performance.

530 Effect of crude glycerin in finishing cattle diets. N. A. Pyatt, P. H. Doane, and M. J. Cecava*, *ADM Animal Nutrition Research*, *Decatur, IN*.

One hundred fifty-eight Angus-cross steers (387.4 ± 1.6 kg) were used in a 2 × 2 factorial to assess the effects of diet type (grain or co-product) and crude glycerin on feedlot performance. The grain diet consisted of (DM basis) 70% cracked corn, 15% corn silage, 10% DDGS, and 5% supplement; the co-product diet consisted of 35% cracked corn, 30% DDGS, 15% soyhulls, 15% corn silage, and 5% supplement. Glycerin replaced 0 or 10% corn in both diet types. Cattle were blocked by weight (4 pens per treatment), weighed at 28-d intervals, and processed at a constant backfat endpoint (116 to 153 d on feed). Period and cumulative (d 1-116 and 1-153) data were analyzed. No significant (P>0.10) interactions were observed. Cumulative ADG was 11.4% greater in cattle fed grain diets with glycerin and 2.5% better for steers fed co-product diets with glycerin. Cattle fed co-product diets had 9.7% greater (P<0.05) DMI relative to cattle fed grain diets (8.74 vs. 9.59 kg/d, respectively). Feeding glycerin resulted in 10.1% lesser (P<0.05) DMI (9.65 vs. 8.68 kg/d, respectively). Glycerin decreased DMI by 8.1% for the grain diet and 11.8% for the co-product diet. Feed efficiency was 11.0% greater (P<0.05) for cattle fed grain diets versus co-product diets. Glycerin improved feed efficiency by 19.2% (P<0.05). Feed efficiency improved by 21.9% and 16.4% when glycerin was fed in the grain and co-product diets, respectively. These data suggest that feeding crude glycerin can improve efficiency of cattle fed high-grain diets. Furthermore feeding crude glycerin in combination with co-products like DDGS and soyhulls may diminish feed intake but improve feed efficiency.

Key Words: Feedlot Cattle, Crude Glycerin, Co-Products

531 The effect of forage allowance and stage of growth on average daily gain, frothy bloat, and rate of ruminal in vitro gas production in steers grazing wheat pasture. W. E. Pinchak*[1], B. R. Min[1], D. P. Malinowski[1], J. W. Sij[1], J. D. Fulford[1], and R. Puchala[2], [1]*Texas Agricultural Research Center*, *Vernon, TX85*, [2]*E (Kika) dela garza American Institute for Goat Research Center*, *Langston, OK*.

A combination of grazing and in vitro experiments were conducted over 3 yrs. to determine the effect of plant chemical composition, forage allowance and two stages of growth on the severity of bloat and ADG in steers grazing wheat forage. Concurrently, in vitro ruminal gas production was quantified at the same time of bloat measurement. Wheat forage protein dynamics, related with forage allowance and plant stage of growth, are presented. ADG was greater for high forage allowance than for low forage allowance during yr 2004 ($P < 0.01$) and 2005 ($P < 0.001$). Mean bloat score tended to differ with forage allowance during vegetative ($P = 0.07$) and reproductive ($P = 0.16$) stages of growth. Across the yrs, average percentage of bloated steers in the low forage allowance treatment was consistently less (21 vs. 45%; $P < 0.001$) than in animals grazing the high forage allowance treatment. Bloat frequency on wheat forage is temporally variable with most frothy bloat occurring during the vegetative stage of growth (32%) compared to the reproductive stage of growth (13%). Frothy bloat negatively effected (r = -0.37 to -0.54; $P < 0.001$) and linearly decreased ($P < 0.001$) ADG in steers grazing wheat forage. Average in vitro potential gas and methane production were greater ($P < 0.001$) for the reproductive stage of growth than for vegetative stage of growth. Wheat forage bloat is a complex disorder that varies across stage of plant growth, forage allowance and experimental yrs. Frothy bloat negatively impacts ADG and animal performance.

Key Words: Average Daily Gain, Frothy Bloat, Gas Production

Teaching/Undergraduate & Graduate Education: Shaping Animal Sciences Curricula for 2020

532 Animal sciences curricula: A historical perspective. J. A. Sterle*, *Texas A&M University*, *College Station*.

When the Land Grant University system was officially started at the time President Lincoln signed the Morrill Act in 1862, animal husbandry courses were already being taught at various colleges and universities across the country. Soon, individual courses began to develop into series, and series into an overall curriculum. Originally set up to teach farmers' and ranchers' sons new technological advancements so they could return to the ranch, courses included nutrition, animal breeding and reproductive physiology. Curricula in animal science departments across the nation has developed, ebbed and flowed over time in response to a variety of factors. "Husbandry" became "science", and not in name only. New disciplines, from ethology to genomics, and new technology, from molecular biology techniques to artificial insemination brought about new courses and new requirements in

degree plans. Departments of Animal Science, Dairy Science, and Poultry Science faced the decision of whether to remain separate entities or join together. Capstone courses became popular in the 1990s, bringing together concepts and information from multiple courses, bridging gaps between them. Changing demographics influenced courses as well. These changes not only included the addition and eventually acceptance of women in the animal science field, but also the more recent influx of students with little to no animal agriculture background. This latest change is currently forcing many departments to go "back to the basics", and teach students things that were previously assumed known, such as how to handle livestock, or explaining more of the "whys" of production practices, instead of only the "hows". Career opportunities have also influenced curricula. Instead of graduating and moving back home to take over the family operation of producing food and fiber, today's graduates choose from a huge variety of professions previously unheard of, including the feeding or pharmaceutical industries, meat science and food safety, and public policy. Professional school opportunities are also accepting more animal science graduates than previously, including veterinary, medical, dental and law school.

Key Words: Teaching, Curricula

533 Changing demographics and enrollment trends. K. L. Esbenshade*, *North Carolina State University*, *Raleigh*.

The demographics of the population in the US are shifting resulting in changes in the composition of students attending higher education (HE) and studying agriculture and related subjects. Between 1900 and 2000, the US population living in metropolitan areas increased from 28% to 80%, the average age increased from 22.9 to 35.3 years, and the percent non-white increased from 12 to 25. The US foreign-born population was 13.6% in 1900, 4.7% in 1970 and 7.9% in 1990. Before 1960, more than 80% of the immigrants were European, after which the majority of immigrants were from Latin America and Asia. The current distribution of non-whites is not equal among the states, with southern and western states being more diverse. The number of high school graduates peaked in 1978 and has remained steady during the past decade averaging 2.7 million students annually. Between 1970 and 2000, enrollment and degrees awarded in HE increased 78% and 72%, respectively, with associate, bachelor (B), master (M) and doctoral (D) degrees increasing, respectively, 129%, 48%, 103% and 40%. In 2004, 14.8 million undergraduate students were enrolled and 1.4 million B degrees awarded. Between 1976 and 2004, B degrees awarded to females increased from 46% to 59%, to minority students from 17% to 34%, and to nonresident aliens from 2% to 3%. Between 1970 and 2000, the number of B, M and D degrees awarded in agriculture and natural resources (ANR) increased 84%, 74% and 4%, respectively, representing 1.9% of the total B degrees awarded in 2000. ANR B degrees awarded to females were 4% in 1970 and 45% in 2000, and to minority students were 9% in 1991 and 11% in 2003. The number of B degrees in animal science (ANS) increased 27% between 1987 and 2003 representing 17% of ANR degrees in 2003. B, M and D degrees awarded to females in ANS were, respectively, 70%, 53%, and 34% in 2002. The demographic trends in the US are projected to continue with the population becoming older, more diverse and living in major metropolitan areas. HE, ANR and ANS must adapt their academic programs to be relevant and to serve these populations in the future.

Key Words: US Demographics, Enrollment, Students

534 Curricular trends: Shifts in traditional animal sciences courses and degree programs. J. C. Swanson* and D. A. Nichols, *Kansas State University*, *Manhattan*.

During the past 20 years dramatic changes have taken place in animal agriculture. Concurrent with this change has been shifts in the demographic of students entering into the animal sciences. Scientific discoveries and development of technologies in the animal sciences have widened the scope of opportunity beyond the traditional staples offered in animal science teaching programs. For example, some departments have introduced a biotechnology option for students desiring a career path that could lead to employment in different scientific communities. Companion animal science, equine science, zoo or exotic animal biology and management, and food safety and biosecurity are examples of emerging areas where students desire to apply their animal science training. The current focus on animal care, welfare assessment, and auditing may offer placement opportunities for students in food animal production programs, government animal care assurance, or in biomedical research facilities. Animal science departments should consider the unique niche it occupies in the understanding of the biology, care, production, and management of animals under domestic or captive conditions. Also, regional differences in student demographics and stakeholder needs play a role in curricular development or revision. We are not proposing an abandonment of current livestock and poultry curricula. We propose to extend our expertise in the understanding and management of animals, and the related development and application of science and technologies, for students interested in alternative career paths.

Key Words: Animal Science, Curriculum, Trends

535 Thinking outside of the box: Incorporating innovative experiential & inquiry-based learning opportunities. J. N. Spain*, *University of Missouri*, *Columbia*.

Student learning is accomplished through a wide array of teaching methods. Lectures and note-taking is a staple approach applied in large and small courses. In animal agriculture, we have an opportunity to incorporate active engagement of students through experiential and inquiry-based learning. The use of teaching farms allows instructors to take advantage of place based learning that allows students to connect new knowledge to several senses. The ability of instructors to challenge students to apply knowledge and facts to problems that are real life scenarios gives students a learning advantage. Indeed, experiential learning can be incorporated into the curriculum from first semester introductory courses through capstone courses that utilize student managed teaching herds and flocks. Challenging students through learner driven inquiry-based learning is also effectively incorporates into animal/dairy/poultry science curriculum. One prime example is undergraduate discovery research which allows the student to experience the research process. Another example of inquiry based learning involves the use of bioethics based courses. Experiential and inquiry based learning is effectively used to enhance student learning and understanding.

Key Words: Experiential Learning, Inquiry Based Learning, Animal Science

536 Thinking outside the box: Linkages with agencies and educational opportunities for undergraduates and graduate students. M. A. Ottinger*, *University of Maryland*, *College Park*.

The range of career paths and training requirements has become increasingly complex in the animal sciences. As a result, our students often spend most of their time in the classroom and some highly motivated students seek experience at veterinary clinics to meet the criteria for acceptance to professional school. Experiential learning and internships provide opportunities for broadening the experiences of our students outside the classroom. Internships in agriculture related organizations, which may be involved in research, policy, or many other potential activities provide wonderful opportunities for our students to deepen their understanding of the demands of various careers. At the University of Maryland, our students can work with numerous federal and state agencies, other universities, and private corporations. Working relationships with these entities may be on many levels, including MOUs, centers, adjunct faculty, or informal collaborations. Student internships may be for academic credit, as volunteer or paid positions. It is critical that these experiences have some type of structure to ensure high quality and commitment by student and the agency mentor. The types of positions and several methods for structuring this program will be discussed, including establishing MOUs and consideration of appropriate work demands and deliverables from the student. These partnerships with scientists and professionals in regional federal and state agencies can provide benefits for our students, including extending their technical capabilities and providing experience in a range of potential career choices. These experiences will encourage our young scientists to become enthusiastic contributors to agricultural sciences and energize them in interesting career paths in global agricultural programs. Furthermore, networking with our international collaborators will keep us on the cutting edge of international advances in agriculture and in affiliated disciplines.

Key Words: Experiential Learning Opportunities, MOUs with Agencies, Internships and Academic Credit for Student Interns

537 Animal sciences curricula: Future directions. T. Field*, *Colorado State University*, *Fort Collins*.

The fortunate reality of offering a futuristic perspective is that we are rarely held to account for our predictions. Nonetheless, our profession and our students will be faced with one certainty - change. Demand for food, fiber, and other products originating from livestock and poultry will increase on a global scale. Concurrently, consumers will demand higher value, more convenience, better food safety, environmental compatability, and evidence of excellent animal husbandry in our production practices. The opportunities for graduates of animal, dairy, and poultry science programs will continue to diversify as will the availability of enhanced tools and technologies that can be applied in the industry. Practioners of our craft in the future will have to successfully merge biological, financial, public policy, marketing, and human resources skills to be successful in the future. While technical training will continue to be an important focus of our teaching efforts, our students will not be well prepared for the challenges that will confront them unless they receive an education that is also broad in scope - particularly at the bachelors and masters levels. Curriculum design must also accomodate training that moves students beyond disciplines and into the realm of systems thinking and multi-disciplinary problem solving. Effective curricula will contain significant experiential learning opportunities, case-based course design, and international study. The challenge of the future will be to find the optimal balance of rigor, depth, breadth, and customization in the development of a course of study.

Growth and Development - Livestock and Poultry II

538 Ontogenic expression of microRNA in bovine mammary gland. A. V. Capuco*[1], L. L. Coutinho[2], C. M. Evock-Clover[1], A. Minuti[3], T. S. Sonstegard[1], Y. R. Boisclair[4], M. E. Van Amburgh[4], G. Bertoni[3], and L. K. L.K. Matukumalli[1], [1]*Bovine Functional Genomics Laboratory, USDA-ARS*, *Beltsville, MD*, [2]*University of Sao Paulo-ESALQ*, *Piracicaba, SP, Brazil*, [3]*Institute of Zootechnics, Catholic University*, *Piacenza, Italy*, [4]*Cornell University*, *Ithaca, NY*.

MicroRNAs (miR) are small RNA molecules (~22 nucleotides) that are important regulators of numerous biological processes, including organ and tissue morphogenesis and function. In this capacity, most miR inhibit protein synthesis by binding to the 3′-untranslated region of targeted mRNA species. Hundreds of genes can be regulated in this fashion. The objective of this experiment was to evaluate expression of miR in mammary tissue from Holstein cows at different developmental and functional stages. Tissues were obtained from: prepubertal heifers (6 mo) that were (1) intact, (2) ovariectomized, (3) intact + estrogen, (4) ovariectomized + estrogen; (5) from primiparous cows, 100-250 d of gestation; (6) from lactating cows, 14 d lactation; (7) from cows during the dry period, 40 d dry and 20 d prepartum. Total RNA was extracted from three or four animals at each stage and pooled to determine patterns of miR expression by hybridization to a microarray containing modified RNA targets complementary to all known mirR. Expression of miR such as miR-221 and miR-127 appeared to be differentially expressed prepubertally. Expression of miR-615 was enhanced by estrogen treatment and miR-29a by ovariectomy. During first gestation, expression of miR-20a was increased. During lactation, miR were typically expressed at low levels, but there was increased expression of a limited number of miR, including miR-326 and miR-350. During the dry period, there was increased expression of miR-542-5p and miR-690. We subjected individual RNA samples to quantitative RT-PCR and confirmed patterns of expression revealed by microarray in 4 of 5 genes tested. Our quantitative RT-PCR results confirmed the utility of evaluating miR expression by microarray and suggested that miR function as regulators of mammary gland development and function.

539 Growth hormone stimulates growth hormone receptor expression through STAT5-activation of growth hormone receptor 1A promoter in the bovine liver. H. Jiang*, Y. Wang, M. Wu, and R. Torres-Diaz, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

The objective of this study was to determine whether and how growth hormone (GH) regulates hepatic expression of GH receptor (GHR) mRNA and protein in cattle. Ribonuclease protection assays revealed that injection of recombinant bovine GH in a slow-release formula increased both hepatic GHR and insulin-like growth factor I (IGF-I) mRNAs one week after initiation of treatment. The increases in GHR and IGF-I mRNAs were highly correlated. Western blot analysis showed that the injection also increased GHR protein level in the liver. In cattle and several other mammals, hepatic GHR mRNA is expressed as variants that differ in the 5′-untranslated region, due to use of different promoters in transcription and/or alternative splicing. We found that GH injection increased the expression of the liver-specific GHR mRNA variant 1A (GHR1A), without affecting GHR1B and GHR1C mRNAs, the other two major GHR mRNA variants in the bovine liver. Transient transfection analyses of a 2.7 kb GHR1A promoter in reconstituted GH-responsive cells showed that GH could robustly activate reporter gene expression from this promoter, suggesting that GH augmentation of GHR1A mRNA expression in the liver is at least partially mediated at the transcriptional level. Further transfection analyses of serially 5′-truncated fragments of this GHR1A promoter narrowed the GH-responsive sequence element down to a 210 bp region that contained a putative signal transducer and activator of transcription 5 (STAT5) binding site. Electrophoretic mobility shift assays demonstrated that this putative STAT5 binding site was able to bind to STAT5b protein. In transfection assays, deletion of this putative STAT5 binding site abolished most of the GH response of the GHR1A promoter. These observations together suggest that GH stimulates the expression of one GHR mRNA variant, GHR1A, through binding STAT5 to its promoter, thereby increasing GHR protein expression in the bovine liver.

Key Words: Cattle, Growth Hormone Receptor, Liver

540 Temporal longissimus muscle gene expression profiles due to plane of dietary energy in early-weaned Angus steers. D. E. Graugnard*, S. L. Rodriguez-Zas, D. B. Faulkner, L. L. Berger, R. E. Everts, H. A. Lewin, and J. J. Loor, *University of Illinois*, *Urbana*.

Energy-dense nutrients might trigger long-term genomic adaptations of economic importance in skeletal muscle of young steer calves. Objectives were to evaluate temporal gene expression profiles in longissimus muscle (LM) of early-weaned (~140 d age) Angus steers (n = 6/diet) fed a high-grain (HiE, NE = 1.43 Mcal/kg) or high-byproduct (HiF, NE = 1.19 Mcal/kg) diet for 120 d, at which point all steers were switched to a common feedlot diet until slaughter. LM biopsies for transcript profiling and blood for metabolite analyses were collected at 0, 60, and 120 d of feeding. BW, ADG, back fat (d 60 and 120), and marbling scores (d 60 and 120) also were measured. A 13,257 bovine oligonucleotide (70-mers) array was used for transcript profiling. Annotation was based on similarity searches using BLASTN and TBLASTX against human, mouse, and bovine UniGene databases, the human genome, and the cattle TIGR database. Cy3- and Cy5-labelled cDNA from LM and a reference standard were used for hybridizations. Feeding HiE vs. HiF resulted in greater (time × diet $P < 0.05$) temporal blood glucose concentrations (88 vs. 80 mg/dL on d 120), whereas HiF increased (time × treatment $P = 0.06$) blood β-hydroxybutyrate (BHBA) concentration (0.48 vs. 0.36 mmol/L on d 120) to a greater extent than HiE. ADG over the 120 d tended ($P = 0.08$) to be greater with HiE (3.6 vs. 3.4 kg/d). ANOVA (FDR $P = 0.10$) identified 504, 67, and 141 differentially expressed genes due to time, diet, and diet × time, respectively. Genes associated with aspects of metabolism (e.g. protein or fatty acid synthesis), development, and signal transduction activity predominated among those affected by time × treatment. Results suggest that high plane of dietary energy during the early growth phase might improve efficiency of gain at least in part through the provision of a specific pattern of nutrients (e.g. glucose vs. BHBA) to skeletal muscle, which can in turn directly or indirectly promote genome-wide alterations in gene expression affecting tissue growth and development.

Key Words: Genomics, Growth, Energy

541 Creation of a gene atlas in cattle using sequence-based transcriptional profiling. T. S. Sonstegard*[1], J. W. Keele[2], G. P. Harhay[2], T. P. L. Smith[2], L. K. Matukumalli[1,3], G. Liu[1], C. P. Van Tassell[1], and L. J. Alexander[4], [1]*USDA, ARS, Beltsville Agricultural Research Center*, *Beltsville, MD*, [2]*USDA, ARS, U.S. Meat Animal Research Center*, *Clay Center, NE*, [3]*George Mason University*, *Fairfax, VA*, [4]*USDA, ARS, Livestock and Range Research Laboratory*, *Miles City, MT*.

Numerous opportunities to advance the understanding of how heritable variation affects economically important traits are being provided through resources generated from the Bovine Genome Sequencing project. Success in these investigations relies upon the depth in which the sequence assembly is annotated. In humans and biomedical model species, extensive annotation to identify genes and report relative levels of expression in various tissues has been accomplished by creation of Gene Atlas databases that provide researchers instant access to the expression profile of a gene under study. Similarly, we are constructing a Bovine Gene Atlas database that will house transcript profiles from 100 different bovine tissues collected from major organ systems. RNA was extracted using tissues derived from the genome sequencing cow and her offspring. Transcript profiles were captured using a digital, sequence-based approach known as Sequence-By-Synthesis from a Clonal Single Molecule Array. Yield of 20 bp cDNA sequence tags exceeded more than 5 million counts per sample. The more than 500 million tags were grouped according to tissue of origin, sequence similarity and genome map position in order to assign gene identities and account for potential sequencing errors. To test the correlation between the sequence tag data and a known pathway for synthesis of 3, 16 or 17-Glucuronide, tag counts for gene members of this pathway were compared between adult testes, two stages of uterus development, muscle, and placentome. Tag count analysis revealed this metabolic pathway is greater than 50 fold more active in ovary and uterus versus testes, placentome, and muscle. We conclude relative levels of expression for nearly all genes, even those for rare and species-specific transcripts, can be accurately determined. Such a framework of expression data will allow determination of regional transcriptional control, tissue phylogeny and interconnected gene networks. This Gene Atlas will be provided as a query-based resource to other researchers through a Web accessible database.

Key Words: Cattle, Gene Expression, Transcription

542 Effect of an enhanced-growth feeding program on gastrointestinal tract and spleen development. M. Terré*[1], M. Devant[1], A. Aris[1], and A. Bach[1,2], [1]*IRTA-Unitat de Remugants*, *Barcelona, Spain*, [2]*ICREA*, *Barcelona, Spain*.

Eighteen Holstein male calves (4.4 ± 1.85 d old) were arranged in 2 groups to study the effect of an enhanced-growth (EF) and conventional feeding program (CF) on gastrointestinal tract (GIT) and spleen development. Calves were fed a milk replacer (21% CP, 19.2% fat) at increasing rates during 4 d until reaching 4 l/d at 12.5% DM. Calves on CF received 4 l/d at 12.5% DM until weaning, and EF calves were fed 4 l/d at 15% DM from 5-11 d, 4 l/d at 18% DM from 12-18, 6 l/d at 18% DM from 19-38 d, and 3 l/d at 18% from 39-45 d. Calf starter was offered ad libitum until the end of the study (54 d). Individual calf starter consumption and BW were recorded. Half of the calves of each treatment were euthanized at 4 wk of study, and the rest at 54 d. Then, the spleen was dissected and weighed. Each anatomical part of the GIT was separated, weighed, emptied, weighed again, and pH of the contents of each GIT segment measured. Calves on EF grew faster ($P < 0.05$) than CF calves (0.82 vs 0.50 ± 0.089 kg/d, respectively). Starter intake was greater ($P < 0.05$) in CF than EF calves from 30 to 33 d, but lower ($P < 0.05$) from 48 to 54 d. Calves on CF had a greater ($P < 0.05$) rumen pH at 4-wk and 7-wk sacrifices (5.47 ± 0.056) and a lower abomasum pH ($P < 0.05$) at 4-wk sacrifice (3.01 ± 0.362) than EF calves (5.26 ± 0.056 and 5.04 ± 0.362, respectively). The spleen weight of EF calves was greater ($P < 0.05$) than that of CF calves (0.32 vs 0.24 ± 0.022 kg, respectively), but when expressed as a percentage of BW there were no differences between treatments. Abomasum weight expressed as a percentage of total GIT weight was greater ($P < 0.05$) in CF than in EF calves (11.0 vs 8.8 ± 0.54, respectively), but jejunum-ileum weight expressed as a percentage of GIT was greater ($P < 0.01$) in EF than in CF calves (50.4 vs 46.7 ± 0.98, respectively). Although EF calves grew faster, abomasum weight decreased and jejunum-ileum weight increased as a percentage of GIT when raising calves on an enhanced-growth feeding program.

Animal Behavior & Well-Being - Livestock and Poultry: New Methodologies Symposium

543 Utilizing neural network analysis in animal behavior studies. W. B. Roush*, *USDA-ARS Poultry Research Unit*, *Mississippi State, MS*.

The objective of this presentation is to introduce the concept of artificial neural networks (ANN) and the related technologies of fuzzy logic (FL) and genetic algorithms (GA) to the analysis of animal behavioral responses. These technologies have been developed in the areas of Artificial Intelligence and Artificial Life for the study of Complex Systems. ANN were inspired by the biological neuron with inputs, a processing unit, and output(s). The concept for ANN is very similar to the concept of regression analysis. A fundamental difference is that regression analysis is philosophically linear; whereas, ANN are nonlinear. Most biological responses are nonlinear in nature and therefore a nonlinear analytical technique like ANN can more accurately and precisely be used to analyze the data. An example is the analysis of the effect of stressors (e.g., debeaking, coccidiosis, electrical shock, ammonia, heat stress, and noise) on the live gain response of birds. FL and GA are related computer techniques that can be used for analysis and optimization. FL can represent imprecise concepts such as hot, cold, heavy, light, comfort, and stress. The technique has been applied to the problem of defining stress of caged laying hens based on a FL representation of mortality, corticosterone level and egg production. Fuzzy Cognitive Maps (FCM), based on the principles of FL, can be used to define social conditions as defined by interactive matrices. An example is the structuring of a virtual world involving the interaction between sharks, fish and dolphins. GA optimize by evolving the inputs of a formula (e.g. ANN) into an optimal solution. Artificial intelligence and Artificial Life techniques such as ANN, FL and GA promise to provide powerful tools for the analysis of animal behavior studies.

544 Identification of QTL affecting disposition in *Bos indicus* influenced cattle. C. A. Gill*, C. R. Boldt, C. A. Abbey, M. A. Wegenhoft, D. K. Lunt, J. E. Sawyer, A. D. Herring, and J. O. Sanders, *Texas A&M University*, *College Station*.

Disposition was measured in 2 resource populations: 614 progeny from 40 *Bos indicus* (Brahman or Nellore) x Angus reciprocal backcross families and 3 F_2 families (Angleton herd); and, 465 progeny from 17 Nellore x Angus F_2 families and paternal half-sib families produced by natural service (McGregor herd). In the Angleton study, disposition scores were taken twice (weaning and slaughter) using a 1 to 5 scale. In the McGregor study, overall disposition and 4 component traits of behavior (aggressiveness, nervousness, flightiness, and gregarious) were measured 1 mo after weaning by a panel of 4 evaluators using a 1 to 9 scale. Steer progeny were scored again about 1 wk prior to slaughter by a single evaluator and overall disposition was scored prior to slaughter. The MIXED procedure of SAS was used to analyze disposition with fixed factors of sire, family nested within sire, birth year-season combination and sex x family within sire interaction, plus sequence within pen within birth year-season combination for the McGregor study. Mendelian and partially imprinted QTL for overall disposition were detected following interval mapping by linear regression under a line-cross model using residuals from the Angleton study. Three QTL on BTA 5, 17 and 25 affecting disposition at weaning and 2 QTL on BTA 1 and 18 affecting disposition prior to slaughter were estimated to have additive effects. Three QTL on BTA 4, 9 and 25 affecting disposition prior to slaughter were estimated to have dominance effects. A QTL affecting disposition at weaning on BTA13 was estimated to be partially maternally imprinted, while a QTL on BTA8 affecting disposition prior to slaughter was estimated to be partially paternally imprinted, and a QTL on BTA16 was estimated to be partially maternally imprinted. Only the QTL on BTA25 appeared to affect both weaning and final disposition. We have begun to characterize candidate genes for these QTL. We expect to validate these QTL in the McGregor study and to identify QTL for the 4 component traits of behavior.

545 Mathematical modeling and analysis of use of space. M. C. Christman*[1], C. P. Miller[1], and I. Estevez[2], [1]*University of Florida*, *Gainesville*, [2]*University of Maryland*, *College Park*.

Spatial confinement imposes behavioral restrictions on animals because of limitations in movement and use of space. Such limitations are particularly exacerbated in farm animals that are maintained in intensive commercial production systems. Despite the important consequences of space availability/quality on the health and welfare of farm animals, many existing studies do not include study of patterns of movements because of the lack of adequate statistical methods for descriptors for movement and behavior in confined space. We describe a complex computer simulation of individual-based movement in confined space and its application. Our objective is to obtain a process model simulating animal movement and behavior that can be used to study statistical methodology as it relates to testing hypotheses about the effects of varying density and available area for confined animals. Our animal model is the domestic fowl Gallus gallus domesticus although the model can be used with other species that are found in limited or confined habitat. We simulate movement as a correlated random walk with additional controls to allow for the ability to manipulate the reaction of the animal to boundaries, the tortuosity of its steps, and the degree to which it avoids areas already visited. In addition, the model can be modified to allow for behavior that changes through time such as might occur with age and to incorporate behavior in response to new resources or to other animals within its space. Using this model, we have developed new descriptors of movement and use of space in confined regions. For example, we have developed new measures of tortuosity and core areas that are useful for distinguishing among the effects of varying environments. The model can also be used to do power analyses in order to determine adequate sample sizes and sampling regimes such as the interval between observations of a focal animal. We demonstrate use of these new methods using data from an experiment on domesticated fowl in which density and pen size was varied and show that our new methods are better than those originally developed for animal studies in unconfined space.

Key Words: Correlated Random Walk, Behavior, Domestic Fowl

546 Major pitfalls in animal welfare research. J. J. McGlone*[1], L. E. Hulbert[1], N. Krebs[1], M. A. Sutherland[1], and J. W. Dailey[2], [1]*Texas Tech University*, *Lubbock*, [2]*USDA Livestock Issues Research Unit*, *Lubbock, TX*.

Animal welfare researchers are obligated to provide the best quality of research possible to meet scientific standards and society concerns. The conclusions derived from studies can have major consequences on animals and the animal industries. However, major pitfalls are far too common in animal welfare research. The following potential problems (not in priority order) associated with these specialized types of investigations include: 1) Lack of statistical replication/duplication within studies, lack of simultaneous inter-institution replication and related ethical considerations of inappropriate sample sizes, 2) Lack of a defined biological or applicable control, 3) Lack of including both physiology and behavior data collected in a study, which then requires an entire new study to gather the missing information, 4) Lack of collaboration between research competitors, some of which have special skills, 5) Ambiguity, inaccuracy, lack of precisions and insufficient depth of behavioral and physiological measures, 6) A reliance solely on incomplete electronic data bases and inattention to early, valuable work that is relevant or directly answers the question at hand, 7) Inconsistent behavioral definitions, setting up a difficulty in comparing and interpreting research. 8) An inability to understand the meaning of changes in behavior or physiology (sometimes simply due to this neonatal science), 9) Lack of agreement on appropriate measures/standards of animal welfare, 10) Inappropriate anthropomorphism. While it is important that scientists have empathy and show compassion for animals, the necessary leap from human perception to animal perception should be executed with caution and discretion. All of these tribulations could result in flawed conclusions, which could have detrimental effects on regulations and actual animal welfare.

Key Words: Animal Welfare, Methods, Behavior

Animal Health - Livestock and Poultry: Bovine II

547 New frontier in monitoring, early diagnostics and prevention of ketosis in dairy cows. K. L. Ingvartsen*, N. C. Friggens, and T. Larsen, *University of Aarhus, Faculty of Agricultural Sciences*, *Tjele, Denmark*.

The objective of this presentation is to give a status on the opportunities for prevention of e.g. ketosis in dairy cows using future monitoring systems. Although the incidence of clinical ketosis is generally low, sub-clinical ketosis is important as it occurs more frequently. It may increase the risk of other diseases, involuntary culling and impair production and reproduction. The large between-cow variation in e.g. β-hydroxybutyrate (BHBA), calls for proactive prevention of ketosis by identifying and changing e.g. nutrients to 'high risk cows'. Such cows may be in imbalance - situations where the regulatory mechanisms are insufficient for the animals to function optimally leading to a high risk of disease. We have developed a model for the prediction of the risk of ketosis in dairy cows using in-line measurements of BHBA in milk (Nielsen et al., JDS 88, 2441-2453). The model is designed to function solely on the basis of milk BHBA but other data can be included as additional risk factors for ketosis. Outputs of the model are the risk of ketosis (value between 0 and 1, where 0 = no risk and 1 = full blown ketosis) and how many days until the next milk sample should be taken and analyzed for BHBA. Prototype sampling systems for in-line measurement of e.g. BHBA in milk that utilize the above model have been developed. Such systems open up for 'Status oriented strategies based on risk management' that allow, on farm and at individual cow level, adjustment of feeding and management based on automatically registered indicators to reduce the risk of diseases but at the same time improve production and reproduction (Ingvartsen 2006, Anim. Feed Sci. Tech. 126: 175-213). A challenge in building such strategies is to better understand the biological basis of the imbalance measured and thus to be able to predict individual animal responses to changes in e.g. nutrient supply or management to overcome the imbalance. Progress towards a better understanding will come through a combination of classical physiology, metabolic network mapping (e.g. proteomics) and quantitative modeling.

Key Words: In-line Monitoring, Ketosis, Disease Prevention

548 *Neotyphodium coenophialum* alters blood metabolites involved in nitrogen, energy, and mineral metabolism in growing steers. K. R. Brown*[1], L. R. Harrison[2], J. L. Klotz[3], J. R. Strickland[3], J. A. Boling[1], and J. C. Matthews[1], [1]*Department of Animal and Food Sciences*, *Lexington, KY*, [2]*Livestock Disease Diagnostic Center*, *Lexington, KY*, [3]*Forage-Animal Production Research Unit, USDA-ARS, University of Kentucky*, *Lexington, KY*.

Blood metabolite changes in steers during summer-long grazing of toxic endophyte-infected pastures were investigated as a part of a larger study for determination of physiological genomic and metabolic pathways for alkaloid metabolism. Blood cell counts, differentials, and serum metabolites of growing steers grazing fescue infected either with high (HE) or low (LE) amounts of toxic endophyte for 85 d were determined. Experimental treatments consisted of steers grazing either a LE (6.8% infection) mixed grass-tall fescue pasture (n = 9; BW = 266 ± 10.9 kg; 5.7 ha) or a HE (62.8% infection) tall fescue pasture (n = 10; BW = 267 ± 14.5 kg; 5.7 ha). Blood samples were collected by jugular venipuncture on d 0, 36, 57, and 85 of the study. Values presented are those for which no treatment × day of trial interaction was observed. Steers grazing HE pastures had decreased serum alanine transferase ($P < 0.02$, 10.2%), aspartate aminotransferase ($P < 0.04$, 9.9%), albumin ($P < 0.01$, 4.3%), and albumin:globulin ($P < 0.05$, 6.4%). No changes were observed for γ-glutamyl transferase, blood urea nitrogen, creatitine, total protein, globulin, or total bilirubin compared to the LE steers. Lactate dehydrogenase ($P < 0.01$, 13.4%) and glucose ($P < 0.05$, 6.3%) were lower in the HE steers. Serum concentrations of magnesium, sodium, and chloride did not differ, but phosphorus was lower ($P < 0.02$, 5.9%) in steers grazing the HE pasture compared to LE. No differences were observed in packed cell volume, red blood cells, hemoglobin, white blood cells, segments, lymphocytes, monocytes, and eosinophils between the two treatments. This study suggests chronic exposure to toxic endophyte-infected tall fescue selectively decreased blood components that are important indices for growth and metabolic function.

Key Words: Endophyte, Fescue, Metabolite

549 Changes in lying behavior of lactating dairy cows associated with body condition score and milk yield. J. M. Bewley*[1], R. E. Boyce[2], L. Munksgaard[3], C. Drummond[4], J. Hockin[4], B. Scott[4], and M. M. Schutz[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*IceRobotics, Ltd.*, *Roslin, Scotland, UK*, [3]*Danish Institute of Agricultural Sciences*, *Research Centre Foulum, Denmark*, [4]*Barony College*, *Dumfries, Scotland, UK*.

The lying time (LT) of lactating Holstein-Friesian cows of varying body condition scores (BCS) and milk yield were measured using IceTag™ animal activity monitors in the Barony College dairy herd. A three-week average BCS was calculated for each cow and in total 84 cows were divided equally between 3 BCS categories (BCAT) [Thin(T): BCS <2.75; Moderate(M): 2.75≥BCS<3.25; Heavy(H): BCS≥3.25] and 2 stage of lactation categories (LCAT, < or > 150 days in milk). The cows were kept in two management systems (MS, parlor (n=24) or AMS, (n=60)). Behavior was recorded for 5-7 days for each cow. An average of October and November test day fat and protein corrected milk was calculated for each cow (FPCM). Cows that exhibited clinical lameness before or during the observation period were excluded. For cows exhibiting estrus, the day of and the day prior to breeding were removed. When LT, hours standing, or number of steps taken within an individual day differed from an individual cow's weekly average by 2 or more standard deviations, these observations were removed. The final analysis included 79 cows (433 observations). The effects of FPCM , BCAT, week, and day within week were included in a mixed model (p=0.0074, 0.1223, 0.0007, and 0.0070, respectively). Effects LCAT, MS, FPCM/BCAT interaction, and pregnancy status were not significant and not included in the model. Lying time decreased with increasing milk yield. The LSMeans for LT within BCS category were 10.96(±0.293), 10.43(±0.286), 10.10 (±0.288) for H, M, and T, respectively, with H and T significantly different (P=0.0412). Both BCS and milk yield affected the lying behavior of the cows. Thin cows may be challenged to meet generally recommended lying times of 10 hours per day, though specific lying times for different body conditions remain to be determined.

Key Words: Lying Behavior, Activity Monitor, Automatic Monitoring

550 Rectal versus peripheral temperature measurement using radio-frequency implants in steers challenged with lipopolysaccharide during periods of heat stress. E. D. Reid*[1], J. M. Velasco[1], and G. E. Dahl[2], [1]*University of Illinois*, *Urbana*, [2]*University of Florida*, *Gainesville*.

Heat stress in cattle reduces production and profit for livestock owners. Heat stress causes an increase in body temperature, which makes it difficult to identify sick animals in systems using rectal temperature as a tool to assess animal health. Injectable radio frequency implants (RFI) that can monitor temperature at the site of implantation are available and readings are positively correlated with rectal temperature (RT) during periods of heat stress. These RFI also exhibit a negative correlation with RT when cattle are challenged with lipopolysaccharide (LPS). We hypothesized that the RFIs, implanted under the scutiform cartilage of the ear of steers would be positively correlated to RT during controlled heat stress, and would exhibit a negative correlation to RT during a challenge with LPS during heat stress. To test this hypothesis, four steers (127 ± 7 kg) were moved into controlled environment chambers with individual stalls (2 steers per chamber), implanted with RFI, and allowed 2 wk to acclimate. One chamber remained at 20 C, the other was increased to 35 C starting at 0800 for a period of 48 hours. LPS was administered to all steers at 1000 on day 2. The steers were then given a 2 wk adjustment period at 20 C, and the temperature was increased in the opposite chamber, resulting in a crossover statistical design with each steer as its own ambient control. Rectal and RFI temperatures were logged at 5 min intervals. Ambient temperature was also recorded every 5 min and was included as a covariate in the statistical model. Pearson correlation coefficients for RFI and RT were 0.08 (P=0.44) during heat stress, 0.20 (P=0.05) during heat stress with LPS challenge, 0.41 (P<0.01) during the ambient period, and -0.42 (P<0.01) during the ambient period with LPS challenge. Individual response varied; some exhibited negative correlation while others exhibited positive correlation. These data do not support the hypothesis and suggest that individual response be considered when identifying models for use of RFI in temperature monitoring.

Key Words: RFID, Temperature, LPS

551 Hemodynamics in the caudal artery of yearling steers following removal from toxic tall fescue and placement on non-toxic diets. G. E. Aiken*[1] and L. K. McClanahan[2], [1]*USDA-ARS-FAPRU*, *Lexington, KY*, [2]*University of Kentucky*, *Lexington*.

Doppler ultrasonography was used to monitor changes in blood flow characteristics of the caudal artery in yearling steers after being removed from toxic 'Kentucky 31' fescue pastures and placed on non-toxic diets. Ergot alkaloids, produced by the *Neotyphodium* endophyte that infects tall fescue, bind α-adrenergic receptor sites that constrict peripheral vascular tissues and reduce the animal's ability to dissipate body heat. Forty steers were stratified by BW for assignment to five, 3.0-ha pastures. The steers were grazed for 112 d starting on 2 June, 2005. Upon termination of grazing on 12 September, thirty-six of the steers were randomized into groups of three for placed into small pens and fed a wet corn silage-concentrate mixture ad libitum. Ultrasound scans of the caudal artery at the 4th coccygeal vertebrae were taken using an Aloka 3500 Ultrasound Unit (Aloka, Inc., Wallingford, CT). Three cross-sectional scans were taken to determine mean artery lumen area, and three Doppler spectra with a longitudinal transducer orientation were collected to estimate mean velocity, heart rate, stroke volume, and flow rate. Ultrasound measures were collected at 0 (initial measures), 1, 7, and 71 days on non-toxic diets (DNTD). Temporal changes in ultrasound measures were analyzed with mixed models. Initial caudal artery area (5.4 mm^2) had increased ($P < 0.001$) by 7 DNTD (6.6 mm^2) and further increased ($P < 0.001$) by 71 DNTD (7.2 mm^2). Heart rate was initially low (111 beats/min), but increased ($P < 0.01$) to 124 beats/min by 7 DNTD. Heart rates were similar ($P > 0.10$) between 7 and 71 DNTD. Stroke volume tended ($P < 0.10$) to increase between 0 (0.40 mL) and 7 (0.5 mL) DNTD, but had substantially increased ($P < 0.001$) from the initial volume by 71 DNTD (0.58 mL). Initial flow rate (38.3 mL/min) increased ($P < 0.05$) by 7 DNTD (47.5 mL/min) and further increased ($P < 0.001$) by 71 DNTD (61.8 mL/min). Results indicated that vasoconstriction can be reduced, but not eliminated, in 7 d after cattle are removed from toxic fescue and placed on non-toxic diets.

Key Words: Tall Fescue, Ergot Alkaloids, Vasoconstriction

552 Response of digital dermatitis to treatment with topical lincomycin or oxytetracycline: comparison of gross visual and histopathological observations one month after treatment. B. Nuccitelli[1], S. L. Berry*[1], D. H. Read[2], R. L. Walker[2], and T. R. Famula[1], [1]*University of California*, *Davis*, [2]*California Animal Health and Food Safety Laboratory*, *Davis, CA*.

Cows were enrolled in the study if they had active digital dermatitis (DD) on one or both rear feet. Twenty-five cows were allotted to 3 groups: 1) treated with 10 g lincomycin HCl (n=11), 2) treated with oxytetracycline HCl (n=11), or 3) no treatment (n=3). Cows were restrained on a tilt-table; lesions were photographed and 6 mm punch biopsies were taken and placed in formalin to be examined for histopathology. For treated cows, lincomycin HCl or oxytetracycline HCl was mixed with sufficient deionized water to make a paste, applied to a 4X4 gauze, placed on the lesion, and held in place with a light bandage. Control cows were bandaged after biopsy but received no topical antimicrobial. Lesions were re-photographed at approximately days 14 and 30. At the d 30 examination, biopsies were taken adjacent to the site of the first biopsy and submitted for histopathology. The pathologist (DHR) had no knowledge of treatment groups when he examined the samples submitted. Based on gross examination at d 14, 20/22 of the treated lesions appeared to be healed (improved lesion score, no pain, and no visible activity). Based on gross examination at d 30, 18/22 treated lesions appeared to be healed and 4/22 lesions appeared to be active. Two of the 3 lesions on control cows appeared active and were painful; the 3rd lesion appeared to be healing. Of the 18 lesions that appeared to be healed, 10/18 (55%) were classified histologically as active or incipient. Histologic evaluation of activity of DD lesions was based on the degree to which there was: 1) loss of the epidermal barrier, 2) invasion of the stratum spinosum and 3) invasion of the papillary dermis by profuse numbers of slender, spiral organisms. Histological examination agreed with gross visual examination prior to treatment with antimicrobials but did not agree 1 month after the lesions were treated. We could not distinguish between recurrent lesions or new infections.

Key Words: Digital Dermatitis, Footwarts, Lameness

553 Mechanical properties of the solear hoof horn of heifers before and during the first lactation as a prediction of lameness susceptibility. B. Winkler[1], J. K. Margerison*[2], and C. S. Brennan[2], [1]*University of Plymouth*, *Plymouth, UK*, [2]*Massey University*, *Palmerston North, New Zealand*.

Mechanical tests were completed on samples of sole hoof horn taken from 20 heifers at 2 months before parturition (p1) and 100 days postpartum (p2). Simultaneously, all claws were assessed for the lesions score (LS) in the sole horn. Heifers were kept at pasture prepartum and housed loose in a straw bedded yard postpartum. Hoof samples were collected from all claws and analysed for elastic modulus (ELM) and puncture resistance (PR), each measurement was replicated five times on the same area of each claw. Data was analysed by ANOVA GLM using period and claw as fixed effects. PR force of the sole horn was significantly greater in front claws (FC) when compared to hind claws (HC) ($P<0.05$) (p1- FC 8.2, HC 7.4N, p2- FC 11.1, HC 10.3N). The PR force and ELM significantly increased postpartum compared with prepartum ($P<0.01$) (p1- 7.8, p2- 10.7N and p1- 86.9, p2- 118.0N/mm2), while the LS of the claw horn increased between periods ($P<0.001$) (p1- 73.1, p2- 186.5). No significant difference in LS was found between FC and HC in the prepartum period, however LS was significantly greater in the HC compared with the FC in the postpartum period ($P<0.001$) (HC 223.7, FC149.3). Prepartum ELM and PR force were not correlated with lesion score either pre or postpartum. However, postpartum ELM and PR force were significantly negatively correlated ($P<0.01$) to the increase in lesion score between periods ($R=0.65$). Mechanical tests reflected the changes in housing and in haemorrhage levels that occurred between p1 and p2.

Key Words: Lameness, Dairy, Hoof Tissue

554 Effect of sample thickness, tissue moisture content and storage methods on the punch resistance and elastic modulus of the bovine hoof horn. B. Winkler[1] and J. K. Margerison*[2], [1]*University of Plymouth*, *Plymouth, UK*, [2]*Massey University*, *Palmerston North, New Zealand*.

Tissue sample treatment and storage was assessed using hooves of six beef cattle (24 and 28 months) from an abattoir. Tissue samples from the sole and white line of each claw (5 and 2 of International Foot Map) and kept in sealed plastic bags at room temperature until conditioning from physiological moisture content (0) and relative humidity (RH) 11, 33, 58, 75 and 97%; sample thickness (0.05 and 0.3 mm); storage duration in plastic bags 2°C for 0, 48, 96, 144 and 192 hours and freezing (-20°C) for 7, 14 and 28 days. After treatment tissue samples were tested 12 times for punch resistance (PR) and elastic modulus (EM) using a Texture Analyser. Samples were tested for DM content. Increase in DM resulted in a significant ($P<0.01$) linear increase in the PR (N) of the sole (PR= 0.490; DM: 24.39, Rsq.= 0.54) and the white line horn (PR= 0.430; DM: 24.87, Rsq.= 0.64). The EM (N/mm2) of the sole horn was significantly ($P<0.01$) positively exponentially related to the DM (EM= 0.0602e0.1012x, Rsq.= 0.81). DM varied from 63.7 to 89.1%, PR of the sole horn from 6.24 to 24.66N, PR of the white line horn from 2.17 to 18.60N and EM from 85.5 to 751.9N/mm2. The days (1 to 8) taken to analyse the samples and freezing for up to 28 days had no significant effect on the DM and PR of the sole and white line horn. There was a significant ($P<0.01$) increase in the EM of the sole horn when samples were frozen for 28 days. PR increased in a positive significant ($P<0.001$) linear in relation to the thickness (mm) of the area tested (PR= 6.679 + 34.531 thickness, Rsq.= 0.66).

Breeding and Genetics - Livestock and Poultry: Dairy Cattle II

555 Performance and physical conformation of first parity backcross Holstein x Jersey cattle and their Holstein contemporaries. K. A. Weigel*, T. J. Halbach, C. Maltecca, and P. C. Hoffman, *University of Wisconsin*, *Madison*.

The experimental population for the present study consisted of 194 backcross females, which were the offspring of 7 young Jersey x Holstein sires and 167 lactating Holstein dams, as well as 90 pure Holstein females, which were the offspring of 57 young Holstein sires and 83 lactating Holstein dams. These animals were born from November 2003 to January 2007 at the University of Wisconsin - Madison Integrated Dairy Facility. All first parity crossbred cows (N=40) and Holstein cows (N=23) were classified for linear type traits by a trained evaluator between 50 and 200 d postpartum. A linear model, which included fixed effects of classifier, days in milk, and pen, indicated that crossbred cows had shorter stature ($P<0.0001$), more strength ($P<0.05$), lower dairy form score ($P<0.10$), more slope from hooks to pins ($P<0.01$), narrower rump ($P<0.0001$), steeper foot angle ($P<0.01$), closer front teat placement ($P<0.10$), and straighter rear legs when viewed from the rear ($P<0.05$). Mean differences in body depth, rear legs when viewed from the side, fore udder, rear udder height, rear udder width, udder cleft, udder depth, teat length, and udder tilt were not significant. Crossbred cows were 35 kg lighter ($P<0.10$) at first calving, however, mean birth weight of their calves did not differ. Likewise, mean body condition score at first calving did not differ, nor did mean body condition score at breeding. Peak milk yield of crossbred cows was 4 kg lower ($P<0.05$), although fat and protein percentage did not differ. Based on these data, it appears that crossbreeding may improve mobility traits and reduce maintenance feed costs (through decreased body size), albeit at the expense of milk production.

Key Words: Dairy, Crossbreeding, Type

556 Crossbreds of Jersey/Holstein compared to pure Holsteins for production, fertility, and udder traits during first lactation. B. J. Heins, L. B. Hansen, A. J. Seykora, A. R. Hazel*, J. G. Linn, and D. G. Johnson, *University of Minnesota*, *St. Paul*.

Jersey/Holstein crossbreds (n = 76) were compared to pure Holsteins (n = 73) for 305-d milk, fat, and protein production, days open, number calving a second time, and udder traits during first lactation. Cows were housed at two University of Minnesota research facilities and calved from September 2003 to May 2005. Jersey/Holstein crossbreds were bred to Montbeliarde sires, and Holstein cows were bred to Holstein sires. Best Prediction was used to calculate actual production (milk, fat, and protein) for 305-d lactations. Adjustment was made for age at calving and herd-year and records less than 305 d were projected to 305 d. Jersey/Holstein crossbreds (249 kg) and pure Holsteins (251 kg) were not significantly different for fat production, but pure Holsteins had significantly higher milk (7179 kg vs. 6600 kg) and protein (224 kg vs. 209 kg) production than Jersey/Holstein crossbreds. Least squares means for days open were 136 for Jersey/Holstein crossbreds and 159 for pure Holsteins. Jersey/Holstein crossbreds had a higher percentage of cows that calved a second time than pure Holsteins, (87% vs. 77%) respectively. Udder clearance, front teat placement, and teat length were measured during first lactation. Udder clearance was measured from the ground to the bottom of the udder and front teat placement was the distance between the front teats. Age at calving, herd-year, stage of lactation, breed, and random effect of sire within breed were included in the statistical model. Jersey/Holstein crossbreds had significantly less udder clearance than pure Holsteins, (47.2 cm vs. 54.6 cm) respectively. Jersey/Holstein crossbreds and pure Holsteins were not significantly different for front teat placement (15.3 cm vs. 13.7 cm) and teat length (4.5 cm vs. 4.4 cm), respectively.

Key Words: Crossbreeding, Heterosis, Production

557 SNPs in the 3'UTR of Stearoyl-CoA desaturase gene in Canadian Holsteins and Jerseys. P. M. Kgwatalala, E. M. Ibeagha-Awemu*, J. F. Hayes, and X. Xhao, *McGill University*, *Ste Anne De Bellevue, Quebec, Canada*.

Stearoyl-CoA desaturase (SCD) catalyzes the synthesis of conjugated linoleic acid (CLA) and monounsaturated fatty acids (MUFA) in the mammary gland. A two to three-fold variation in CLA and desaturase index have been reported among animals on the same diet. We hypothesized that SNPs in the 3´UTR of the SCD gene result in different 3'UTR regulatory variants which influence the production of SCD enzyme and consequently its activity in the mammary gland, which may explain some observed variations in CLA and MUFA

content of milk fat between Holsteins and Jerseys and within these breeds. The main objective of our study was therefore to determine the existence of SNPs in the 3'UTR of the SCD gene in Canadian Holsteins and Jerseys. Genomic DNA from 46 randomly selected Holsteins and 35 randomly selected Jerseys was used for selective amplification and direct sequencing of the 3'UTR of the SCD gene. A total of fifteen SNPs (G1571T, G1644C, C1763A, T2053C, A2584G, T2668C, A3007G, C3107T, G3208A, T3290C, G3497A, G3682A, A4399T, C4533T and G4881A) were uncovered in the 3'UTR of the SCD gene. The SNPs linked together resulting in 3 regulatory variants in Holsteins: H1 (G1571G1644C1763C2053 A2584 C2668 A3007 C3107 G3208T3290 G3497 G3682A4399C4533G4881), H2 (G1571G1644A1763 C2053 A2584 C2668 G3007 C3107 G3208T3290 G3497 G3682 A4399 C4533G4881) and H3 (T1571C1644A1763T2053 G2584 C2668 G3007 T3107 A3208 C3290 A3497A3682 T4399T4533A4881) and only H1 and H3 variants in Jerseys. The H1 regulatory variant was the most prevalent in both breeds suggesting it may be the wild regulatory variant at the SCD locus, followed by the H3 variant. The search for functional motifs in the 3´UTR region of the SCD gene revealed the presence of internal ribosome entry site (IRES) motif in the H1 regulatory variant and its total absence in the other two regulatory variants. SNPs in the 3'UTR of the SCD gene may thus contribute to existing variations in CLA and MUFA content of milk fat between and within Holsteins and Jerseys.

Key Words: Singl Nucleotide Polymorphisms, SCD Gene, Regulatory Variants

558 Estimation of yields for long lactations using best prediction. J. B. Cole*[1], P. M. VanRaden[1], and C. M. B. Dematawewa[2], [1]*Animal Improvement Programs Laboratory, USDA*, *Beltsville, MD*, [2]*Virginia Polytechnic Institution and State University*, *Blacksburg*.

Lactation records of any length now can be processed with the selection index methods known as best prediction. Previous programs were limited to the 305-day standard used since 1935. Best prediction (BP) was implemented in 1998 to calculate lactation records in USDA genetic evaluations, replacing the test interval method used since 1969 to calculate lactation records of any length at dairy record processing centers. Best prediction is more complex but also more accurate, particularly when testing is less frequent. Programs were reorganized to output better graphics, give users simpler access to options, and provide additional output, such as BP of daily yields. Simple diagnostic plots are now available for milk, fat and protein yields and somatic cell score, and BP of individual daily yields, test day yields, and herd lactation curves can be obtained by the user for production of publication-quality figures. Test-day data for Holstein cows were extracted from the national dairy database, including lactations longer than 305 d. Records from first through fifth parities were included if lactation lengths were at least 250 d, records were made in a single herd, at least five tests were reported, and only twice-daily milking was reported. After edits, 171,970 first- and 176,153 later-parity records were available. Lactation lengths averaged 362 d in first and 369 d in later parities. 23.9% of first and 27.5% of later parities were longer than 305 d, and 3.3% and 3.4%, respectively, were longer than 500 d. Average yields at any day in milk were estimated using a 4-parameter exponential function. Correlations among test day yields were estimated using an autoregressive matrix to account for biological changes and an identity matrix to model daily measurement error. Autoregressive parameters (r) were estimated separately for first- (r=0.998) and later-parity (r=0.995) cows. These r were slightly larger than previous estimates due to the inclusion of the identity matrix, which accounts for test day variation. Many cows can produce profitably for >305 days in milk, and the revised program provides a flexible tool to model these records.

Key Words: Best Prediction, Milk Yield, Long Lactations

559 Genetic parameter estimates for days open by using a random regression model to analyze data from a long-term designed selection experiment. G. A. Gutierrez*, M. H. Healey, and P. J. Berger, *Iowa State University*, *Ames*.

The objective of this study was to estimate genetic parameters for days open (DO) by using a covariance function(CF)-random regression model. Data were collected at the Ankeny dairy research farm at Iowa State University from 1986 to 2004. A total of 3830 records from Holstein cows (n=766) were used in the analysis. Data were restricted to less than 6 parities. All cows were required to have a first parity record, but all cows did not have an opportunity to have completed all parities. Data were analyzed using two models: 1) a repeatability animal model, fixed effects for line of sire selection (high or average PTA fat plus protein), year-season, parity, and linear-Legendre polynomial (LLP) for age at calving(Average=39, min=20, max=90, and SD=16 mo), random effects for animal and permanent environment; and 2) random regression model, fixed effects as defined above for model 1, random LLP coefficients for additive genetic and permanent environment effects. Analyses were implemented by using ASREML v1.1. The covariance matrix of random regression coefficients was used to define the CF for the additive genetic and permanent environmental (co)variances across the trajectory of age at calving from 20 to 90 mo. In model 1, estimated values of heritability and repeatability for DO were 0.08 and 0.09, respectively. In model 2, the additive genetic variance tended to increase with age at calving. Heritability estimates were 0.07,0.08,0.09,0.10,and 0.10, respectively, at 24, 36, 48, 60 and 72 mo. The genetic correlation between records at different ages was fixed at 0.99. The percentage of phenotypic variance explained by permanent environmental variance varied from 3 to 19% across the 5 fixed ages. Repeatability ranged from 0.17 to 0.29. Permanent environmental correlations were highly variable; $r_{(24,36)}$=0.88, $r_{(24,48)}$=0.06, $r_{(24,60)}$= -0.48, and $r_{(24,72)}$= -0.65. Implication of this research is that CF-random regression approach gives a better description of the full (co)variance structure for repeated measurements of DO across a trajectory of age at calving than the repeatability model.

Key Words: Days Open, Random Regression, Holstein

560 Construction and application of a bovine high-density SNP assay. C. P. Van Tassell*[1], L. K. Matukumalli[1,4], C. Taylor[5], T. P. L. Smith[3], T. S. Sonstegard[1], R. D. Schnabel[2], M. V. B. De Silva[1], G. R. Wiggans[1], G. Liu[1], S. Moore[6], and J. F. Taylor[2], [1]*USDA, ARS Beltsville Agricultural Research Center*, *Beltsville, MD*, [2]*University of Missouri*, *Columbia*, [3]*USDA, ARS, US Meat Animal Research Center*, *Clay Center, NE*, [4]*George Mason University*, *Fairfax, VA*, [5]*Illumina, Inc.*, *San Diego, CA*, [6]*University of Alberta*, *Edmonton, AB, Canada*.

Bovine genomics has entered a new era and has been transformed by the availability of the whole genome sequence data. An additional resource currently under development is a 60,000 single nucleotide polymorphism (SNP) array that will soon be made commercially available. Targeted content for this SNP array includes all chromosomes with even-coverage throughout the bovine genome. The SNP array will be used in several large-scale genotyping projects, with over 10,000 animals genotyped. Resulting genotypes for Angus, Brown Swiss, Holstein, and Jersey animals will be used to construct breed specific haplotype maps and develop genomic selection procedures to enhance the prediction of genetic merit via integration with predictions from the national cattle evaluation. To date, nearly 2.5 million putative SNP have been predicted and/or obtained from publicly available databases. Validation of these SNP by resequencing has resulted in a wide range of success rates (from <40% to ~90%) correlating to the source of the in silico derived SNP. To supplement coverage for the design of the proposed SNP assay, we have generated over 24 million short DNA sequence reads and have identified approximately 50,000 new putative SNP among these sequences. Validation of these SNPs is currently in progress. The final assay is expected to be available by mid-summer, 2007.

Key Words: Genome Selection, Single Nucleotide Polymorphism, Marker Assisted Selection

561 Estimation of genetic parameters with random regression models using test-day records beyond 305 days in milk. J. Bohmanova[1], F. Miglior*[2,3], and J. Jamrozik[1], [1]*University of Guelph*, *Guelph, ON, Canada*, [2]*Agriculture and Agri-Food Canada*, *Sherbrooke, QC, Canada*, [3]*Canadian Dairy Network*, *Guelph, ON, Canada*.

Effect of inclusion of test-day records recorded after 305 days in milk on variance components estimates was investigated. Currently, only test-day records measured ≤305d are utilized in the Canadian genetic evaluation. Since increasing number of cows has longer lactation than 305d, it is of interest to also include test-day records measured after this cut-off point. However, such a change requires re-estimation of variance components. Two data sets were sampled from the Canadian national database. Data were test-day yields of milk, fat and protein and somatic cell score from the first three lactations of Canadian Holsteins recorded from 1988 to 2006. The first data set consisted of 96,756 test-day records of 6235 cows, with days in milk from 5 to 365d. The second data set was a subset of the first one and comprised 89,429 records with days in milk ≤305d. The pedigree file contained 18,178 animals. A multi-trait multi-lactation random regression model (RRM) with fixed effects of herd x test-date and fixed regression on days in milk nested within age x season class was implemented. Legendre polynomials were used to model fixed and random regression for additive genetic and permanent environmental effect. Heterogeneous residual variance was modeled with a step function with four intervals. Variance components were estimated using Bayesian procedures via Gibbs sampling. Posterior means of the parameters were estimated using 90,000 samples after 10,000 burn-in iterations. The problem of overestimation of variances at the edges of lactation connected to use of RRM with Legendre polynomial was observed with both datasets. However, with the first dataset (containing later test-day records) the increase in estimates occurred at larger days in milk and estimates of additive genetic variance of milk yield at 305d were by 1, 4 and 7 kg^2 lower. Adoption of RRM with later test-days can provide better prediction of 305d breeding values due to utilization of more data and better genetic parameters. Confirmation of predictive ability of RRM with the new parameters is in progress.

Key Words: Random Regression, Test Day Model, Variance Component

562 Selection of dairy cow families for superior pregnancy rate. C. N. Vierhout*, S. P. Washburn, R. L. McCraw, E. J. Eisen, and J. P. Cassady, *North Carolina State University*, *Raleigh*.

The objective of this study was to determine if dairy cow families could be used to select for superior pregnancy rate. Holstein cow records in 13 southern states were obtained from Dairy Records Management Systems. Cows were included from historical records dating back to birth year of 1981 or 1982 as the foundation cows. Historical records included cows calving and completing lactations through August, 2005. Cows from various generations were then put in maternal family groups using dam identification within herd. Milk production and calculated pregnancy rate (based on days open) deviations were obtained within herd-year-season. A family value was calculated by averaging the first and second lactations across parity by degree of relationship to the individual (free of progeny information) for generation one though four. Each family entered into one of four quartiles based on average deviations milk production and one of four quartiles for average deviations in pregnancy rate. Analysis was performed on fifth generation members to determine if milk production and pregnancy rates in the fifth generation were significantly associated with historical performance of the respective cow families. Average of the standardized values for milk production has improved (-0.09 to -0.01) from generation one to five while pregnancy rate decreased from (0.17 to 0.05) in the same period for cow families having daughters represented in the fifth generation. After adjustments for sire predicted transmitting ability (PTA), maternal-grandsire PTA, and family quartile for milk or pregnancy rate in the model the effect of maternal cow family remained highly significant for pregnancy rate ($P<0.0001$, $R^2=0.0147$) and milk production ($P<0.0001$, $R^2=0.010$). Thus, there may be potential economic value in considering maternal family history for pregnancy rate when selecting future bull dams.

Key Words: Pregnancy Rate, Days Open, Female Fertility

563 Mapping of quantitative trait loci economic important traits in Canadian holstein bulls. D. Kolbehdari*, S. Moore, and Z. Wang, *University of Alberta*, *Edmonton, Alberta, Canada*.

A whole genome scan for mapping quantitative trait loci (QTL) for economic important traits was performed in this study. Fifteen hundred and thirty-six bovine single nucleotide polymorphisms (SNPs) were selected to design the genotyping assay. The SNPs were distributed throughout the genome based on bovine genome assembly (Btau_2.1) and design at the Bovine Genomic lab of the University of Alberta. A total of 462 Canadian Holstein bulls with general pedigree, 319 originating from 10 core sire families, were genotyped using the designed assay. Among these SNPs, 139 were not amplified well during the genotyping, and therefore were removed from the linkage analysis. The SNPs physical position and the orders were recomputed based on the updated 7.1 X Bovine Genome Assembly (Btau_3.1). The

average polymorphism information content of the SNPs was 0.287 (0 to 0.375). The average SNP heterozygosity was 0.329 (0 to 0.50). Initial linkage analysis using variance component approach for milk, fat and protein yield has detected QTL at regions of the chromosomes known to harbor QTL based on previous studies. It is anticipated that this study will validate some of the QTL already mapped and new QTL will be discovered.

Key Words: Mapping QTL, Linkage Analysis, Dairy Cattle

564 Economic value of a marginal increase in pregnancy rate in dairy cattle. A. De Vries*, *University of Florida*, *Gainesville*.

Objective of this study was to estimate the economic value of a marginal (1-percentage point) increase in 21-d pregnancy rate in dairy cattle. The computer simulation program DairyVIP (http://dairy.ifas.ufl.edu/tools) was used. Based on user-defined inputs such as lactation curves, 21-d service rates, probabilities of conception, feed intake, involuntary culling, body weights, and costs and prices, DairyVIP first optimizes breeding and replacement decisions for individual dairy cows and then calculates many herd statistics such as pregnancy rate and profit per slot per year. An average herd in the US was modeled. Key default values were: service rate 43%, probability of conception 40% and slightly decreasing by DIM, heifer price $1600, and milk price $31/cwt. Default pregnancy rate was 16% and profit per slot per year was $389. Service rates and probabilities of conception were changed simultaneously and similarly. The economic values of a 1-percentage point increase in pregnancy rate around 7%, 14%, 18%, 23% and 34% were $32.04, $14.49, $9.92, $6.76, and $3.31 per slot per year, respectively. The greatest contributing factors were reductions in herd turnover costs resulting from lower cull rates. Sensitivity analysis by changing the default heifer price, milk price, milk yield, and risk of involuntary culling independently by 20% revealed that heifer price had the most effect on the economic value of a marginal increase in pregnancy rates. When heifer price was $1920, economic values were respectively $41.93, $17.89, $11.84, $7.98, and $3.73. When heifer price was $1280, economic values were respectively $21.71, $10.59, $7.44, $5.27, and $2.72. Twenty percent lower risk of involuntary culling and less time to become pregnant before culling also increased the economic value of marginal increases in pregnancy rates, but typically not more than $2. Greater milk price and greater milk yield increased the marginal value only when pregnancy rate was greater than 14%. In conclusion, the economic value of a marginal increase in 21-d pregnancy rate is considerably greater at lower levels of pregnancy rates.

Key Words: Pregnancy Rate, Economics, Value

565 Relationships between locomotion and lesion score, punch resistance and Holstein (HUKI) conformation scores. B. Winkler[1] and J. K. Margerison*[2], [1]*University of Plymouth*, *Plymouth, UK*, [2]*Massey University*, *Palmerston North, New Zealand*.

Dairy heifers (n 20) were used to assess locomotion, lesions score (LS) in the sole horn and hoof samples were collected from all claws and analyzed for elastic modulus (ELM) and puncture resistance (PR), each measurement was replicated five times on the same area of each claw. All heifers were assessed (HUKI) for conformation. Elastic modulus of the tension test of the sole at day 100 postpartum was significantly ($P<0.01$) negatively correlated to locomotion score at 154 dpp ($R2 = - 0.61$). HUKI score for rear legs was significantly ($P<0.05$) and positively correlated to punch resistance of sole and white line horn at 40 days prepartum ($R2 = 0.55$ and 0.50) and elastic modulus of sole at 50 dpp ($R2 = 0..53$). HUKI score for feet was significantly ($P<0.01$) and positively correlated to punch resistance and negatively correlated to lesion score of white line area at 40 days prepartum ($R2 = - 0.50$) and to the number of days the animals were severely lame throughout the lactation ($LS > 4$ ($R2 = - 0.50$)). HUKI locomotion score was significantly ($P<0.05$) and positively correlated to punch resistance of the white line horn at 100 dpp ($R2 = 0.50$). HUKI total score for legs and feet was significantly ($P<0.05$ to 0.01) negatively correlated to punch resistance of white line horn at 150 dpp ($R2 = - 0.50$) and the number of days the animals were severely lame throughout the lactation ($LS > 4$ ($R2 = - 0.48$)). HUKI total final score was significantly ($P<0.05$ to 0.01) negatively correlated to punch resistance of white line horn at 50 and 150 dpp ($r = - 0.50$) and to the punch resistance of the sole horn at 150 dpp ($R2 = - 0.60$).

Companion Animals: Pet Food Ingredients - Mining, Dredging, and Extrapolating Effective Nutrient Delivery

566 Advances in evaluating pet food ingredients: Methodologies. G. C. Fahey, Jr.*, *University of Illinois*, *Urbana*.

Many ingredients exist that may be included in complete and balanced diets for pets. Dogs and cats are unique in that they can spend considerable numbers of years in the senior and (or) geriatric states, making the list of potential dietary ingredients even longer than would be the case for other species. It is important that ingredients be described in detail in order to allow for maximal utilization of their nutrients. Several levels of evaluation exist, beginning with a thorough analytical description of the ingredient. Modern analytical methods allow for near complete descriptions of macronutrients and micronutrients. In vitro testing constitutes the next level of evaluation and is very useful in predicting digestive physiological behaviors. The third level of evaluation is conducted in vivo with an animal model (e.g., use of the cecectomized rooster to determine true metabolizable energy and true amino acid digestibility values). The fourth and final level of evaluation is conducted with the target species and can take a number of forms: palatability, growth performance, and tolerance assays; digestibility evaluations, both ileal and total tract; balance studies; and gestation/lactation performance tests.

Key Words: Pet, Nutrient Bioavailability, Ingredients

567 AntiNutrients: Factors limiting utilization of nutrients in pet food ingredients. C. M. Grieshop* and G. Kuhlman, *The Iams Company*, *Lewisburg, OH*.

Companion animal nutritionists face many of the same challenges as other species animal nutritionists regarding the need to understand and correctly process ingredients used in their diet formulations. As with many farm animal diets, certain ingredients contribute antinutritional factors that require unique handling practices or formulation strategies to allow their optimal use. Many of the vegetable protein sources commonly used in farm animal diets (ie.soybean meal and corn gluten meal) are also used in companion animal diets and as with all species, unique amino acid composition or particular nutrient inhibitors, (ie.trypsin inhibitor in soybean meal) must be accounted for and properly handled before these ingredients can be used in companion animal diets. When ingredients such as these are incorporated into pet food diets the same precautions must be taken to deal with antinutritional factors as with diets of most species. In addition, some of the more unique ingredients that are used in companion animal diets also offer challenges in obtaining maximal nutritional value. Chicken by-product meal; a major protein source found in many companion animal diets, can be extremely variable in digestibility due to: different processing conditions, time of year the birds are harvested, type of bird used, and content. Another commonly used protein source, fishmeal, can be highly variable in salt and fatty acid content. In addition, companion animals have unique vitamin and mineral requirements as it has recently been realized that due to very poor bioavilability, copper sources obtained form copper oxide should not be considered when meeting the copper needs of the cat. Further confounding these issues, is the fact the pet food diets are most often produced under high temperature high moisture conditions and these processing variables can alter starch cook, nutrient availability and overall product digestibility. Raw material quality, processing conditions, and final diet content can all play a significant role in the ability of the animal to optimally utilize all available nutrients.

568 Proteins: Advances in rendering animal and marine products. C. R. Hamilton* and D. Kirstein, *Darling International Inc.*, *Irving, TX*.

The United States rendering industry (RI) annually processes over 23.6 million t of animal byproducts and mortalities to make 45,000 t of red meat and 4 million t each of animal proteins (AP) and animal fats. Research to improve the nutritional value of AP and develop novel proteins is sponsored by both industry and individual companies. Industry research is managed by the Fats and Proteins Research Foundation (FPRF) and the Animal Co-Products Research and Education Center at Clemson University (ACREC). Research from FPRF studied factors affecting AA digestibility of conventional AP. For meat and bone meal (MBM), AA digestibility is affected by processing temperature, but not by specie the raw material was derived from or ash content. Reducing processing temperature improved total essential AA digestibility 9.1%. Other processes to improve the value of AP in pet food include air classification to make low-ash AP and blending AP to improve nutrient consistency. Enzymes may improve digestibility and antigenicity by hydrolyzing fish, poultry or mammalian proteins. Enzymatic hydrolysis of beef protein resulted in low molecular wt peptides (31.7% < 2,000 Da; 88.9% < 10,000 Da). A primary focus of ACREC is improving the microbial safety of rendered products to support a Code of Practice (COP) adopted by the RI. Facilities certified under this COP must comply with government regulations and demonstrate use of certain good manufacturing practices (GMP) and HACCP-like programs. Issues which restrict use of traditional AP in pet food include consumer acceptance of AP in pet foods, bovine spongiform encephalopathy (BSE), trends to use only products derived from animals inspected and passed for human consumption and pending regulations. Regulatory issues, consumer pressures and lost markets have caused the RI to preferentially fund ACREC research that focuses on development of new, non-nutritional uses for animal proteins. For the RI to also develop new and novel products for pet food, the pet food industry must commit to pay for their value and utilize sufficient volumes of such new products.

Key Words: Rendering, Animal Proteins, Pet Food

569 Fatty acids: Approaches to prevent or modify nutrient damage from oxidation. R. G. Brannan*, *Ohio University*, *Athens*.

Petfood fatty acids provide energy and essential dietary fatty acids which, however, are prone to lipid oxidation. Lipid oxidation is a chemical process catalyzed by free radicals formed from reactive oxygen and nitrogen or other pro-oxidants such as enzymes or transition metals. Primary products of lipid oxidation are lipid hydroperoxides, which decompose into many secondary products that research has shown may be efficiently absorbed in the intestine. Consumption of oxidized fatty acids may promote an increase in cellular oxidative stress which could lead to the promotion of oxidation-related disease syndromes. Fatty acids in petfoods can be from meat or added in bulk or emulsified form. Meat, especially precooked and restructured meat products, have low oxidative stability. The type of fatty acids from bulk oils or emulsified systems is often determined by nutritional targets that focus on n-3 and n-6 fatty acids ratios and the presence of essential fatty acids such as eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Thus, vegetable and marine oils are often chosen due to their high unsaturated and n-3 levels. However, vegetable and marine oils suffer from high susceptibility to oxidation, a condition that is exacerbated during storage at ambient temperature. There are many antioxidant choices that can be utilized in fatty acid-containing petfoods. Free radical scavengers detoxify free radicals produced during lipid oxidation. Metal chelators, singlet oxygen quenchers, and enzyme inhibitors all work to inhibit lipid oxidation catalysts. Certain other molecules work synergistically with antioxidants to enhance or prolong antioxidative activity. Regardless of the type, these antioxidants can be naturally derived or synthetic. However, the efficacy of any antioxidant system will necessarily depend on other physical and chemical factors such as location, interactions with other ingredients, and environmental conditions. Approaches to prevent or modify oxidative damage to fatty acids must take into account both the chemical reactivity of the antioxidant and the physical environment of the system.

Key Words: Fatty Acid, Lipid Oxidation, Antioxidants

570 Minerals: Effect of form on requirements and bioavailability. L. L. Southern*, *LSU Agricultural Center*, *Baton Rouge, LA*.

Organic (non-salt) trace minerals have been reported to have positive effects on reproduction, immunity, overall productivity, and integrity of hair, skin and hooves. Organic trace minerals are widely used in the dairy, swine, and poultry industries by feeding consultants, and by large animal enterprises. Seemingly, these entities would only use these minerals if economic value was obtained. Unfortunately, there is not a lot of comparative scientific data to support these suggestions. In general, organic trace minerals (depending on source) are more bioavailable than inorganic minerals. This response is based primarily (but not always) on tissue mineral concentrations. However, the higher bioavailability of organic trace minerals would not seem to account for some of their proposed benefits. Examples of results among different species for the trace minerals Zn, Mn, Cu, Se, Cr, and I will be discussed. For example, organic Zn fed during lactation increased number of pigs born alive and improved immune status of the pigs, but data are limited. Organic Mn and Cu are usually more bioavailable, based on slope ratio technique for tissue concentrations, than inorganic Mn and Cu (usually the sulfate form), but there is very little comparative scientific data to assess the proposed benefits of organic Mn and Cu supplemented as the only organic mineral in the diet. Organic Se supplementation results in greater tissue concentrations of Se, but inorganic forms have equal or greater efficacy in affecting GPX activity. In broilers previously fed organic Se compared with those fed inorganic Se, tissue Se concentrations and GPX activity were greater when the broilers were subsequently fed a Se deficient diet. Organic Cr supplementation decreases plasma glucose levels, increases glucose clearance rate, and improves numbers of pigs born - these responses are relatively consistent. Excess iodine intake of dams at levels well below those considered toxic may have negative effects on the offspring. Where applicable, how these results may apply to companion animals and the selection of trace mineral form will be highlighted.

571 Protein interactions in heat-treated milk and effect on rennet coagulation. P. Kethireddipalli* and D. G. Dalgleish, *University of Guelph*, *Guelph, ON, Canada*.

The underlying molecular processes that cause impaired rennet clotting of heat-treated bovine milk were investigated. Firstly, the effect of whey protein(WP)/ κ-casein complexes bound to the casein micelle, on the elastic modulus (G') and gelation times (T) of renneted heat-treated milk was examined. Milks with different levels of micelle-bound WP (<5% to ~80%) were produced by heating skim milk at 90°C for 10 min at pH values ranging from 6.3 to 7.1. WP was quantified using SDS-PAGE. Lower pH produced higher micellar WP association and vice versa. Using oscillatory rheometry, we found that compared to unheated milk (G', 83.5 Pa; T, 10 min) all heat-treated milks, after renneting, showed a remarkable reduction in G' (0.1 to 2.1 Pa) and a large increase in T (55 to 130 min). It did not seem to matter if the WP/ κ-casein complexes were predominantly bound to the casein micelle (pH 6.3) or were largely present as soluble protein complexes in the lactoserum (pH 7.1). In the second part, the individual effects of casein micelles and lactoserum on the rennet gelation properties of heated milk were investigated. Two different milk systems were examined; one was prepared by re-suspending casein micelles from milk heated at pH values 6.3, 6.7, or 7.1 in native serum from unheated milk, and the other contained native micelles from unheated milk in the serum from the various pH- and heat-treated milks. Heat- and pH-modified casein micelles suspended in normal serum significantly lowered the G' values of the resulting rennet gels. With the exception of pH 6.3, the heated lactoserum also interfered with gelation of heat-treated milks. In the final part of the study, the serum from heat-treated milks was further examined after its ultrafiltration (removes WP/ κ-casein complexes) or its dialysis against unheated milk (restores ionic composition). Both these processes significantly improved serum performance. This clearly demonstrated that not only serum ionic factors, but also serum WP/ κ-casein complexes, and heat-modified casein micelles (with or without associated WP) significantly interfere with the rennet gelation of heat-treated milks.

Key Words: Heat-treated Milk, Rennet, WP/κ-casein Complexes

572 Flavor variability and stability of US-produced whole milk powder. M. A. Lloyd* and M. A. Drake, *North Carolina State University*, *Raleigh*.

Whole milk powder (WMP) produced in the United States (U.S.) is used both domestically and internationally. Much of the available literature on WMP was generated using internationally produced WMP. Flavor variability and stability of US-produced WMP has not been characterized. The objectives of this study were to characterize flavor and flavor variability of domestic WMP. Freshly produced WMP was collected from 4 production facilities at 5 timepoints over a year period. At each timepoint, two 23-kg bags from different production runs were collected. Each sample was analyzed initially and every 2 months for flavor profile, volatiles, color, water activity, and moisture over a year of storage. Samples were reconstituted to 10% solids using deodorized water for descriptive and volatile analysis. Volatile analysis was performed using solid phase microextraction (SPME) followed by gas chromatography/mass-spectrometry. Relative abundance was calculated for the following compounds, based on the internal standard recovery (2-methyl-3-heptanone): toluene, hexanal, 2-heptanone, heptanal, octanal, 2-nonanone, nonanal, 2-undecanone, delta-decalactone, and delta-dodecalactone. Descriptive analysis was conducted using a 10-member trained panel. All WMP were between 2-3% moisture and 0.11-0.25 water activity initially. WMP varied in flavor and volatile composition within and between production facilities ($p<0.05$). WMP had distinct flavor profiles initially, with varying levels of cooked, milkfat, and sweet aromatic notes ($p<0.05$). Several samples also had feed flavors. During storage, grassy and painty flavors developed while sweet aromatic flavor intensities decreased ($p<0.05$). Some WMP developed grassy or painty flavors as early as 4 months, and all samples developed painty flavor by 12 months. Painty and grassy flavors were confirmed by increased levels of lipid oxidation products such as hexanal, heptanal, and octanal ($p<0.05$). There is wide variation in flavor and flavor stability of U.S. WMP. Further research should be done to determine specific factors that can be controlled to optimize flavor and flavor stability.

Key Words: Whole Milk Powder, Flavor, Stability

573 The effect of pH and ionic calcium on the heat stability of sterilized and UHT milk. M. J. Lewis* and A. S. Grandison, *School of Chemistry, Food and Pharmacy, The University of Reading*, *Reading, Berkshire, UK*.

It has long been recognized that milk salts, in particular divalent cations and pH, are important factors in determining milk processing behavior, particularly in influencing the stability of the protein in aggregation, gelation and precipitation reactions, and in the fouling of heat exchanger surfaces with mineralized deposits. However, practical information supporting this is not so readily available and the much reported heat coagulation time is not easy to perform nor widely used in the dairy industry as a quality assurance indicator of heat stability. This paper investigates the role of pH and ionic calcium on heat stability issues during UHT processing and in-container sterilization of milk. It has been found that problems encountered at UHT conditions relate primarily to sediment formation and fouling, whereas those encountered during in-container sterilization relate to gelation and thickening, although a lesser amount of sediment is also formed. Thus it is hypothesized that different mechanisms are involved in the two processes. This is being further investigated by manipulating pH and ionic calcium in milk by methods such as calcium-removal, calcium fortification and addition of phosphate and citrate stabilizers. The changes in pH and ionic calcium brought about by these processes not only affect heat stability, but also influence Maillard reactions, especially during in-container sterilization, which might be detrimental to product quality. The aim is to provide some practical guidelines that can be used to predict the intrinsic stability of casein micelles to high temperature sterilization.

Key Words: Ionic Calcium, pH, Heat Stability

574 Isolation, composition and rennet-gelling functionality of milk fat globule membrane fractions from regular buttermilk, whey buttermilk, and washed cream buttermilk. B. Manion* and M. Corredig, *University of Guelph*, *Guelph, Ontario, Canada*.

There has been increasing evidence of the health benefits associated with the consumption of some components of the milk fat globule membrane (MFGM) (i.e. phospholipids and immunoproteins). The objective of this work was to characterize the composition and processing functionality of MFGM-rich fractions. Three different fractions were prepared from industrially-upscalable processes, namely, microfiltration of buttermilk (MFGM), concentration of whey buttermilk (WR) and buttermilk derived from washed cream (WBM). MFGM was prepared by concentration and diafiltration through 1.4 µm ceramic membrane of fresh buttermilk with 2% sodium citrate. WR was obtained by concentration of fresh buttermilk from whey cream through 0.1 µm PVDF membranes. WBM was prepared from cream reconstituted back to the original volume with water and recentrifuged, and then churned to obtain the serum fraction. Proximate analysis, electrophoresis, and phospholipids analysis by HPLC were used to characterize the composition of each fraction. The amount of MFGM-derived material was MFGM>WR>WBM (from high to low), in both proteins and phospholipids, and the MFGM fraction contained the lowest level of caseins. Soy oil (10%) emulsions were prepared with 3% WR and WBM, 0.5% Tween 20 and 3% MFGM with various levels of Tween added. The renneting behavior of recombined milk (to 3.3% protein from skim milk powder) with 4% oil was tested. Milk containing MFGM-emulsions created the stiffest gels and showed the earliest onset of gelation compared to the other recombined milks. On the other hand, milk with oil droplets covered with WR-stabilized emulsions formed gels with low elastic modulus and showed longer gelation times than the other treatments. These results demonstrated that differences in the composition of the MFGM material at the interface affect the renneting behavior of recombined milk.

Key Words: Milk Fat Globule Membane MFGM, Buttermilk, Rennet Gelation

575 Fat globule interfacial composition affects the texture and microstructure of rennet-induced casein gels. Z. Gaygadzhiev*, M. Alexander, A. Hill, and M. Corredig, *University of Guelph*, *Guelph, ON, Canada*.

Model systems, containing both fat globules and casein micelles, were prepared to study the interactions occurring between filler particles and protein networks in rennet-induced casein gels. Anhydrous milk fat was emulsified in solutions of sodium caseinate (NaCas) or whey protein isolate (WPI). Pre-gelation stages of rennet coagulation were observed using Transmission Diffusing Wave Spectroscopy (DWS). Gelation was studied using small deformation rheological measurements and gel microstructure was characterized with laser confocal microscopy. Systems containing WPI-stabilized fat globules reached the gelling point, as determined by the cross-over of G'/G'', earlier than those containing no fat globules (control), although the values of final storage moduli were of a similar magnitude for both systems. The light scattering experiments also revealed that the changes in the DWS parameters (1/l*, apparent hydrodynamic radius, mean square displacement slope) occurred earlier for systems containing WPI emulsified fat globules In contrast, emulsification of fat globules with NaCas greatly retarded the gelation process and inhibited aggregation of casein micelles.

576 Acoustical emissions generated by *E. coli* bacteria. C. L. Hicks*[1], J. M. Stencel[2], H. Song[2], and F. A. Payne[1], [1]*University of Kentucky*, *Lexington*, [2]*Tribo Flow Separations*, *Lexington, KY*.

Escherichia coli 15q and 15cc bacteria in TSB medium, at 32°C for greater than 5 h was monitored using contact acoustic sensors (20 to 50 kHz and 50 to 200 kHz) attached to the sides of the growth vessel. Acoustical emissions generated by the bacteria was picked up as a waveform and each waveform was referred to as a 'Hit'. Hits were analyzed for rate of accumulation and periodic cycles. Fast Fourier transform analysis was used to calculate average peak frequency emissions. Initial analysis showed that Hit detection from the 20 to 50kHz sensor began within 5 min after the medium was inoculated with *E. coli* 15cc. Hit detection from the 50 to 200 kHz sensor became more apparent as the organism entered the log phase and displayed a linear natural log increase in Hits during the log growth phase. Periodic cycles of 1.66 sec and 33.6 sec were observed during the early stages of growth suggesting that *E. coli* 15cc was involved in uniform sequenced activities, possibly quorum sensing. The average peak frequencies data showed shifting in frequencies as the bacteria

moved from the lag, log, and stationary phases. Differences between *E. coli* 15q and 15cc could be observed within the first 60 min of incubation (20 to 50 kHz sensor) with 15q producing 7average peak domains (frequencies) and 15cc producing only 5. After 5 h of incubation 15q produced only one broad peak domain while 15cc generated one defined domain and two smaller domains. Average peak frequencies for *E. coli* 15cc and 15q were sufficiently different in frequency and intensity during the lag, log and stationary phases that specific strain identification might be possible. Thus, acoustic emissions from bacteria may be unique enough to acoustically fingerprint bacteria and result in a rapid assay method.

577 An assay system for probiotic lactic acid bacteria recognizing human blood type A-antigen that competitively excludes harmful intestinal bacteria. T. Saito*[1], N. Wakahara[1], H. Uchida[1], H. Kinoshita[1], Y. Kawai[1], H. Kitazawa[1], K. Miura[2], A. Horii[2], K. Kimura[3], and N. Taketomo[3], [1]*Graduate School of Agricultural Science, Tohoku University*, *Sendai, Miyagi, Japan*, [2]*Graduate School of Medicine, Tohoku University*, *Sendai, Miyagi, Japan*, [3]*Meiji Dairies Corporation*, *Odawara, Kanagawa, Japan*.

A new evaluation system for selecting probiotic lactic acid bacteria (LAB) with specific adhesion to human colonic mucin that recognizes different ABO-blood types was developed in our laboratory [1,2]. Sixteen strains including *L. gasseri* OLL2804 showed strong adhesion to human blood type-A antigen [GalNAc-α-1-3 (Fuc-α-1-2) Gal-] from the intestinal mucosa were selected from 283 probiotic strains using the biosensor, BIACORE, that employs surface plasmon resonance (SPR)[3]. Similarly, 16 and 11 strains of LAB were selected with strong affinity to human B-antigen [Gal-α-1-3 (Fuc-α-1-2) Gal-] and H-antigen [Fuc-α-1-2 Gal-], respectively [4]. At the same time, we surveyed for colonic harmful bacteria that recognize the blood type antigens (sugar moities on intestinal mucin) using the same BIOCORE recognition system as for OLL2804. Forty strains were isolated from the surface of human colon using TS, MRS, BL and XM-G agar medias incubating at 37°C for 24 hrs. Cells from isolated strains were analyzed using BIACORE against BSA-A (neoglycoprotein, BSA introduced A-antigen trisaccharide). After 16s RNA fragment sequencing, two strains of *Staphylococcus* sp. and one strain of *Escherichia coli* were identified as harmful bacteria recognizing the human blood type-A antigen. We are now determining competitive exclusion of them using OLL2804 in the human intestine. This new assay system will be useful in the selection of probiotic candidates for functional foods including yogurt.

Key Words: Probiotic Lactic Acid Bacteria, BIACORE, Human Blood Type

578 Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) expressed on the cell surface of *Lactobacillus plantarum* LA 318 mediates adhesion to human colonic mucin. H. Kinoshita*[1], H. Uchida[1], T. Kawasaki[1], N. Wakahara[1], H. Matuo[1], Y. Kawai[1], H. Kitazawa[1], S. Ohmura[2], K. Miura[2], K. Shiiba[2], A. Horii[3], and T. Saito[1], [1]*Graduate School of Agricultural Science, Tohoku University*, *Sendai, Miyagi, Japan*, [2]*Department of Surgery, Tohoku University Graduate School of Medicine*, *Sendai, Miyagi, Japan*, [3]*Department of Molecular Pathology, Tohoku University School of Medicine*, *Sendai, Miyagi, Japan*.

Members of the genus *Lactobacillus* are often isolated from the alimentary canals and feces of man and animals and are used in fermented food as probiotics. We showed *L. plantarum* LA 318 isolated from human transverse colon is a potential probiotic bacterium that shows high adhesion to human colonic mucin (HCM) mediated by a surface cell wall protein (1). The adhesion test used the BIACORE assay. PBS-washed bacterial cells showed a significant decrease in adherence to HCM as did GHCl treated cells. The component in the PBS supernatant fraction adhered to the HCM and was shown to be a 40 kDa protein using SDS-PAGE. Using homology comparisons of N-terminal to sequence databases, this protein was identified as glyceraldehyde 3-phosphate dehydrogenase (GAPDH). The purified GAPDH adhered to the HCM. The data strongly suggests the GAPDH of the LA318 strain is the adhesin. It has been reported that pathogens, such as *Candida albicans*, possess GAPDH on their cell surface that show binding activity to fibronectin etc. There is no report showing GAPDH exist on the cell surface of *Lactobacillus* probiotics that recognize HCM. This is the first report of GAPDH expressed on the cell surface of lactobacilli that also adhere to mucin; suggesting *L. plantarum* LA 318 adheres to HCM using GAPDH binding activity to colonize the intestine. Because LA 318 strain possesses the same adhesin as pathogens, this may prevent these pathogens from infecting the intestine. This suggests this probiotic can be ingested by mouth to work effectively by replacing pathogens in the intestine; and may be used in probiotic food products including functional yogurt.

579 Development and optimization of food-grade antimicrobial lactic acid bacteria isolated from raw milk. A. Ichinomiya*, K. R. Nauth, and V. V. Mistry, *South Dakota State University*, *Brookings*.

Producing safe products and extending the shelf life by reducing or eliminating foodborne pathogens are a challenge for the food industry. To meet the growing consumer demand for safe and natural foods, natural protection based on antimicrobial agents has been added to the product. Nisin is the one such natural food preservative. Nisin is a peptide produced by certain strains of *Lactcoccus lactis* subsp. *lactis* during fermentation. It has antimicrobial activity against broad range of Gram positive bacteria such as Clostridia and Listeria. Today nisin is permitted by law to be added to foods in more than 50 countries. The present study was performed to isolate nisin–producing *Lactcoccus lactis* subsp. *lactis* from raw milk, to evaluate the isolates for antimicrobial activity against food spoilage organisms and selected food pathogens, and to develop optimum conditions for maximal antimicrobial production. Milk samples from the raw milk tank or cows on the university dairy farm were collected and screened by the agar overlay method. Identification of the isolates was observed by Gram staining, 4% sodium chloride MRS media incubation, arginine catabolism and catalase test. The activity of nisin was calculated by agar diffusion method that nisin–producing lactic acid bacteria inhibit *Lactococcus lactis* subsp. *cremoris* ATCC 19257 as a nisin sensitive indicator strain. Several nisinproducing lactic acid bacteria strains were found in the raw milk. For optimal production of nisin, *Lactococcus lactis* needs complex nutrition such as nitrogen and phosphate in the medium. They affected the nisin production and biosynthesis. Their

addition to media increased the antimicrobial activity. The component of the antimicrobial activity will be characterized and optimized in substrate containing milk, whey, or, permeate.

Key Words: Antimicrobial Agents, Nisin, Natural Preservative

580 Challenge testing the lactoperoxidase system against against a range of bacteria using different activation agents. L. W. T. Fweja, A. S. Grandison*, and M. J. Lewis, *The University of Reading*, *Reading, Berkshire, UK*.

Lactoperoxidase (LP) exerts antimicrobial effects in combination with H_2O_2 and either SCN^- or a halide. Garlic extract (GE), in the presence of ethanol (E), has also been used to activate the LP system. This study aimed to determine the effects of three different LP activation systems (LP/SCN^-/H_2O_2; LP/I^-/H_2O_2; LP/GE/E) on the growth and activity of three test organisms (*Staphylococcus aureus; Pseudomonas aeruginosa; Bacillus cereus*). UHT milk was used as reaction medium and the growth pattern of the organisms and a range of keeping quality (KQ) indicators (pH, titratable acidity, ethanol stability, clot on boiling) were monitored during storage at the respective optimum growth temperature for each organism. LP/I^-/H_2O_2 reduced bacterial counts below the detection limit shortly after treatment for all three organisms, and no bacteria could be detected for the duration of the experiment (35-55 hours). The KQ data confirmed that the milk remained unspoilt at the end of the experiments. LP/GE/E, on the other hand, had no effect on the growth or KQ with *P. aeruginosa*, but gave a small retardation of growth of the other two organisms, accompanied by small increases (5-10 h) in KQ. The effects of the LP/SCN^-/H_2O_2 system were intermediate between the other two systems and differed between organisms. With *P. aeruginosa* the system exerted total inhibition within 10 h of incubation, but the bacteria regained viability after a further 5 h, following a logarithmic growth curve. This was reflected in the KQ indicators which implied an extension of 15 h. With the other two bacteria, LP/SCN^-/H_2O_2 exerted an obvious inhibitory effect giving a lag phase in the growth curve of 5-10 h and KQ extension of 10-15 h. When used in combination, I^- and SCN^- clearly competed for LP system intermediates and displayed negative synergy with respect to both bacterial growth and KQ.

Key Words: Lactoperoxidase, Keeping Quality, Antibacterial

581 Characterization of immuno active peptides present in cell free preparations obtained from milk fermented by L. Helveticus. A. M. Tellez*[2,1], M. Corredig[3,1], L. Brovko[2,1], and M. Griffiths[2,1], [1]*University of Guelph*, *Guelph, Ontario, Canada*, [2]*Canadian Research Institue for Food Safety*, *Guelph, Ontario, Canada*, [3]*Food Science Department*, *Guelph, Ontario, Canada*.

Interest in the ability of bioactive peptides to impact on immune system has grown considerably in the past decade. Fermented milk has been proposed as a source of those bioactive compounds. The objectives of this research were to confirm the effect of bioactive compounds from milk fermented by Lactobacillus helveticus (LH-2) on the nonspecific host defense system, and purify and characterize the active peptides. For this reason, the cell free supernatant obtained from centrifugation of the fermented milk was tested and an in vitro study using macrophages (RAW 264.7 cell line) was performed. Cytokines production (IL-6, TNF-α±, and IL -1β), Nitric Oxide (NO) production and Phagocytosis effect were used as biomarkers. Cytokine production in culture supernatants was assessed by ELISA. Trypsin-hydrolyzed fermented milk was used as negative control, and bacterial lipopolysaccharide (LPS) was the positive control. Macrophages stimulated with supernatant showed higher production of cytokines and NO compare with LPS. Phagocytosis effect was positive for macrophages stimulated with supernatant (50.75 % ±1.2). The supernatant from fermented milk was analyzed using size exclusion chromatography (SEC) and nine fractions were collected. All fractions were tested for activity. Two fractions (excluded volume and a fraction eluting at 15 minutes) produced higher response when used to stimulate macrophages compared with the other fractions (0.37 and o.25 ng/µg of protein). These results confirmed fermenting milk with Lactobacillus helveticus (LH-2) improves bioactivity, and suggested that specific peptides released during fermentation enhance immune response by modulating macrophage activity.

Dairy Foods: On the Road from Analysis and Discovery of Functional Milk Bioactives to New Products and Health Outcomes

582 An approach to capturing and translating the biological activities and health outcomes of milk components. S. L. Freeman*, *University of California*, *Davis*.

Chronic disease, complex metabolic disorders and obesity dominate the current health landscape. Food has contributed to the problem and therefore food-based interventions offer great potential for not only preventing disease, but also promoting health. To translate the knowledge from analysis and discovery of functional milk bioactives to new products & health outcomes requires different methods, approaches and techniques for studying and validating benefits of these different milk components in a scientifically substantiated manner. Successfully modulating metabolism and immune protection through rational food ingredients and products offers novel solutions to lifestyle and food choices. Milk is an appropriate model for delivering health benefits because it has evolved to nourish, protect and promote infants to not only survive but also thrive. Fundamentally, the components of milk guide health at a time of extreme vulnerability following birth. Understanding milk from this perspective of how it interacts with different biological processes will enable the development of new food products to guide health in different target population. Integrating food science, molecular biology, physiology, nutritional and clinical aspects to capture and apply the knowledge generated is a key to the development and documentation of effective dairy products. The emphasis has to be on documenting the biological activity of different milk components and how they can be applied to measurable health benefits.

583 The glycome and the glycoproteome of milk. C. Lebrilla*, B. German, D. Mills, and S. Freeman, *University of California*, *Davis*.

Oligosaccharides and proteins are the third and fourth most abundant components in human milk. Surprisingly, oligosaccharides and glycoproteins have not been tradditionally well studied despite their importance as potential bioactive components in milk. The glycomic and glycoproteomic analyses of milk provide opportunities for understanding the role of milk in nutrition and as a potential source of bioactive compounds. New analytical tools are being developed that make the analysis of oligosaccharides and glycoproteins possible. Many of these tools are based on mass spectrometry and liquid chromatography separation. In this presentation, our approach to the analysis of glycans (oligosaccharide) and glycoprotein components of various types of milk from primates to humans will be discussed. Separation methods including nanoflow liquid chromatography and high performance mass spectrometry are employed to characterize the constintuents of milk. The milk of five mothers are examined for a period of several months. The oligosaccharide components, the proteins, and the glycoproteins are examined during the period. Changes in the protein expression of specific proteins are observed. The oligosaccharide constituents are relatively constant but very individually while the glycosylation on proteins change dramatically. The implications of these variations are discussed.

Key Words: Mass Spectrometry, Glycome, Glycoproteome

584 Production and use of high CLA foods in human health. D. E. Bauman*[1], C. Tyburczy[1], A. M. O'Donnell[1], and A. L. Lock[2], [1]*Cornell University*, *Ithaca, NY*, [2]*University of Vermont*, *Burlington*.

Consumers are increasingly aware of the link between diet and health, and the potential role for functional food components in disease prevention. Conjugated linoleic acid (CLA) has been identified as a bioactive component of dairy products that may benefit the maintenance of human health. The major CLA isomer in dairy products is cis-9, trans-11 (rumenic acid; RA), and it originates predominantly in the mammary gland by endogenous synthesis from rumen-derived vaccenic acid (trans-11 18:1; VA) via the enzyme D9-desaturase. Milk fat concentrations of RA can be markedly increased by manipulation of the cow's diet (e.g. polyunsaturated fatty acid-rich oils, lush pasture) and by selection of individuals naturally producing elevated levels. The content of RA varies with the total fat content of the dairy product; therefore, whole fat products such as cheese, ice cream and butter provide the most CLA to the dietary intake. Furthermore, the ratio of VA to RA is ~ 3:1 in milk fat, and VA can also be used for endogenous synthesis of RA in human tissues. When consumed as a natural component of the diet, the RA in milk fat has been consistently shown to have anti-carcinogenic and anti-atherogenic effects in biomedical studies using animal models of human disease. VA is the predominant trans fatty acid in milk fat and the fact that humans can convert it to RA provides a compelling explanation for the observed differences in epidemiological studies investigating the effects of natural and industrial derived trans fatty acids on coronary heart disease. Biomedical studies with animal models have also demonstrated that milk fat-derived VA is anti-carcinogenic through its conversion to RA. Nevertheless, extrapolating these results to humans has been limited and problematic because chronic diseases have long latency periods and often have no consensus biomarkers. Overall, dairy products enriched in CLA represent functional foods that offer potential benefits for human health and the prevention of chronic diseases.

Key Words: CLA, Milk Fat, Human Health

585 Sources and characteristics of milk fat globule membranes. R. E. Ward*, *Utah State University*, *Logan*.

In raw milk, the fat is dispersed as colloidal particles ranging in diameter from 0.1 μm to over 15 μm, each coated in a bilayer of plasma membrane which originates from the secretory cell. The estimated surface of milk fat globular membrane (MFGM) in one milliliter of whole milk is estimated to be 500 cm2. MFGM is found in significant quantities in dairy products such as cream, cheese, cheese whey, butter serum and buttermilk. In recent years, technologies have been developed to isolate fractions from these materials rich in MFGM, and the composition and ingredient functionality of the resulting material depends on the physical treatments applied. Utilization of MFGM as an ingredient is limited by its batch-to-batch variability and susceptibility to oxidation. The MFGM is composed of proteins and lipids in approximately a 1:1 ratio with a small contribution of non lactose carbohydrate. Recent proteomic analyses of the MFGM from human, bovine and murine milks have identified over one hundred unique peptides sequences associated with this material. According to gene ontology classifiers, proteins of the MFGM are involved in membrane trafficking, cell signaling, lipid metabolism, and defense against pathogens, as well as other processes. The lipid fraction of the MFGM is primarily composed of triglycerols, and polar lipids such as sphingomyelin, phosphatidylcholine, phosphatidylethanolamine, and phosphatidylinosotol with smaller amounts of phosphatidylserine, gangliosides and ether-linked lipids. The unique nature of the lipid secretion process, the vast surface area of MFGM in milk, and the growing list of bioactive constituents suggests potential nutritional functionality. MFGM is unique compared to other bioactive ingredients because of the compositional diversity and density of molecules associated with the surface. It is not unreasonable to expect synergisms in bioactivity among components, which would provide an interesting model for product development. Incorporation of MFGM and fractions thereof into foods will be expedited by scientific demonstration of beneficial bioactivity.

Key Words: MFGM, Bioactive

586 Fall growth potential of cereal-grain forages. J. L. Gunsaulis[1], W. K. Coblentz*[2], R. K. Bacon[3], R. K. Ogden[3], K. P. Coffey[3], D. S. Hubbell, III[4], J. V. Skinner, Jr.[3], and J. D. Caldwell[3], [1]*Arkansas Cooperative Extension Service*, *Fayetteville*, [2]*US Dairy Forage Research Center*, *Marshfield, WI*, [3]*University of Arkansas*, *Fayetteville*, [4]*Livestock and Forestry Branch Station*, *Batesville, AR*.

In Arkansas, producers utilizing cereal grains as fall forage for weaned calves usually do not produce a grain crop the following summer. Our objectives were to evaluate eight diverse varieties of wheat (*Triticum aestivum* L.), oat (*Avena sativa* L.), rye (*Secale cereale* L.), and triticale (X *Triticosecale* Wittmack) specifically for their potential to accumulate forage DM during the fall. All varieties were drilled into prepared seedbeds at Fayetteville and Batesville during early September of 2004 and 2005. Beginning in mid-October, plots were harvested for DM yield at 2-wk intervals that continued through December. Variety × harvest date interactions or tendencies for interaction ($P \leq 0.069$) were observed for all combinations of site and year. For Fayetteville 2004, triticale and oat varieties accumulated DM in a cubic ($P \leq 0.040$) pattern, most likely because growing tillers exhibited stem elongation, and then were susceptible to freeze damage in late December. Generally, wheat and rye varieties accumulated DM in less complex patterns over harvest dates, but the maximum numerical yield for any wheat variety was 2,554 kg/ha compared to 4,661 kg/ha for oat. For Batesville 2004 and Fayetteville 2005, DM yields for varieties ranked similarly, but respective overall mean yields (490 and 988 kg/ha) were only 25 and 50% of those for Fayetteville 2004 (1,960 kg/ha) due to drought. For Batesville 2005, favorable growing conditions coupled with a sharp mid-November freeze (-7°C), created yield responses that were unique relative to other site-years. Yield of DM increased quadratically ($P \leq 0.002$) for wheat, rye, and triticale varieties throughout the sampling period, accumulating a mean maximum yield of 4,148 kg/ha on the final harvest date. In contrast, oat varieties were especially sensitive to freezing temperatures in November, and averaged only 2,484 kg/ha on the same date. Producers requiring high-quality forage in the fall and winter can usually improve fall production by using oat or other species that exhibit stem elongation; however, this trait will likely increase susceptibility to freezing temperatures, thereby making continued growth into the winter or winter survival problematic.

Key Words: Cereal Grains, Yield

587 Increasing non structural carbohydrates in alfalfa improves in vitro microbial N synthesis. R. Berthiaume*[1], C. Benchaar[1], A. V. Chaves[3], G. F. Tremblay[2], Y. Castonguay[2], A. Bertrand[2], G. Bélanger[2], R. Michaud[2], C. Lafreniére[1], and A.F. Brito[1], [1]*Agriculture & Agri-Food Canada*, *Sherbrooke, QC*, [2]*Agriculture & Agri-Food Canada*, *Quebec, QC*, [3]*Agriculture & Agri-Food Canada*, *Lethbridge, AB*.

Insufficient readily fermentable energy in alfalfa reduces forage N use efficiency by ruminants. Our objective was to compare the effect of contrasting levels of non structural carbohydrates (NSC; sugars + starch) in alfalfa on rumen microbial fermentation. More than 500 genotypes from the alfalfa cultivar AC Caribou grown near Québec City were individually harvested at the late flowering stage. Harvested genotypes were transferred to a draft oven, dried at 55°C, and ground (1-mm). Samples were analyzed for soluble carbohydrates by HPLC and for starch using a colorimetric method. Genotypes having respectively the highest and lowest NSC concentrations (around 20 genotypes in each group) were pooled to constitute two contrasted 1-kg forage samples. Samples of high (170 mg/g DM) or low (66 mg/g DM) NSC were respectively allocated to separate dual flow fermenters (1300 mL) in a completely randomized design with 3 replications. Rumen inoculum was obtained from 4 ruminally fistulated cows fed a 50:50 forage to concentrate early lactation TMR (16.7% CP, 34.4% NDF). A 10-d incubation period was used with the first 6 d for adaptation followed by 4 d of sampling. Alfalfa digestibility (DM, OM, NDF, ADF and N), fermentation end-products (VFA, NH_3-N), pH and microbial protein synthesis (using ^{15}N as a microbial marker) were determined and results were analysed as repeated measures using the MIXED procedure of SAS. Increasing NSC concentration in alfalfa had no effect on digestibility but decreased ruminal pH (6.85 vs. 7.08; $P = 0.02$) and NH_3-N concentration (316 vs. 409 mg/L; $P = 0.04$), and increased the molar proportion of butyrate (11.6 vs. 9.0%; $P = 0.04$). More importantly, microbial N flow was higher with high than with low NSC alfalfa (0.306 vs. 0.270 g/d; $P = 0.03$). These results suggest that increasing the concentration of NSC in alfalfa enhances microbial N synthesis in the rumen.

588 Effect of a biological silage inoculant on the quality parameters under laboratory and field conditions. Y. Acosta Aragón*, G. Boeck, A. Klimitsch, and G. Schatzmayr, *Biomin GmbH, Austria*, *Herzogenburg, Lower Austria, Austria*.

The silage quality (laboratory and field trials) and the silage quality and cost effectiveness (field trials) using a biological silage inoculant (BSI) were determinated. Three silage laboratory trials with three different raw materials were performed using a BSI (blend of hetero- and homofermentative bacteria). Grass, luzerne and whole plant corn (WPC) were ensiled in buckets (dry matter DM of 33-36, 52-56 and 29-33 %, respectively).The BSI was applied at a rate of 2×105 CFU/g of raw material and compared with other biological and chemical inoculants. The silos were opened after 2 or 3, 7, 14 and 50 days of ensiling. pH value, sugar and organic acids were analysed, as well as the aerobic stability. The control group produced less lactic and acetic acid (in all tested substrates) and more butyric acid (grass silage) than the group with the inoculant. BSI silages showed a better aerobic stability (7 days), low DM losses and no negative points compared to the control group. For the WPC silages, pH values in all treatments were low but the silage with BSI showed highest amount of acetic acid (31.4 g/kg DM) which results in good aerobic stability (7 days) without dry matter losses and no negative points. For field trials, the silages (grass, alfalfa and WPC) with very variable DM contents (from about 20 to more than 45 %) shown to have good parameters as low pH value (3.8-4.5), high lactic and acetic acid (about 60-70 and 10-30 g/ kg DM respectively) and lower butyric acid content (< 3 g/ kg DM), increasing the Net Energy for Lactation (NEL) content in about 0.05-0.18 MJ/ kg DM. To estimate the profit in use of the silage inoculants, the parameter NEL with or without the use of BSI was selected over the other silage quality parameters. The calculation of the profit estimation included the price of the used product (1.8 euros/

treated ton), the net energy and corresponding milk production plus. The profit per ton can reach up to 5.21 euros/ treated ton.

Key Words: Silage, Inoculant, Aerobic Stability

589 Molasses effects on Kochia scoparia characteristics as an Iranian native forage in the form of silage. B. Saremi*, A. R. Shahdadi, and H. Zaher Farimani, *Education center of Jihad-e Agriculture, Khorasan razavi,, Mashhad, Iran*.

The objective of this study was to introduce Kochia scoparia as native forage in Iran and to investigate characteristics of its ensiling with different amounts of molasses (0, 5 and 10 percent) via a factorial experiment based on a completely randomized design. Kochia scoparia was harvested from desserts around Sabzevar city in northeast of Iran (Khorasan-razavi) using Sabzaver Jihad-e agriculture branch facilities. This study was done at the education center of Jihad-e agriculture in Mashad city. Kochia was chopped at 8±1.25 cm and completely mixed with different amounts of molasses (According to as fed weight), then ensiled in experimental silos (polymer buckets, 40 cm height and 30 cm diameter). 24 experimental silos were divided between treatments (0, 5 and 10 percent molasses) and opened 1, 2, 3 and 21 days after ensiling. Samples were taken and pH was determined immediately using on farm pH meter (Greisinger electronics, GPHR 1400 A). Fresh samples were mixed with distilled water (1:1), and then pH was determined. Another sample was frozen for future chemical analysis. DM, OM, ADF, Ca and P were determined using standard methods. Data was analyzed using SAS 9.1 and means were compared using Duncan test ($P<0.05$). Results showed that silage pH decreased with increasing molasses levels ($P<0.0001$). Also pH was decreased with a low rate up to 21 days after ensiling in comparison with corn silage that received 4.5% molasses after 2 days. DM content increased with molasses addition but reduced with days after ensiling ($P<0.0001$). OM increased with addition of molasses ($P<0.0061$) but reduced with days after ensiling ($P<0.0015$). This was because molasses has a higher DM content with respect to Kochia and nutrients usage by silage micro flora increased with molasses addition. Ca content of silage was not affected by day or treatments.

Table 1. Chemical composition of ensiled Kochia scoparia with different amounts of molasses in various days

Items	% Molasses				SEM

590 Feeding value of silage made from Panicum maximum with or without Leuceana leucocephala or Gliricidia sepium as supplementary feeds for weaned rabbits. A. M. Raji*[1,2], A. T. Adesogan[1], J. A. A. Sansi[2], and R. A. Salako[2], [1]*Department Animal Sciences, University of Florida*, *Gainesville*, [2]*Federal College of Animal Health and Production Technology, IART*, *Ibadan, Oyo, Nigeria*.

Ensilage is one of the methods that have been employed to conserve or preserve excess forages for use during the period of scarcity in term of quality and quantity in most tropical countries. Three different silage products were prepared using the mixture of Panicum maximum and Gliricidia sepium (A), Panicum maximum and Leucaena leucocephala (B); and panicum maximum alone (C), which served as the control experiment. The silages were opened after 4 months of ensilage and fed to weaned rabbits as supplements. The treatment diets were grouped in A, B and C. The feeding trial lasted for 12 weeks. The daily feed intake, refusal, and weekly weight gain of the experimental animals was measured. Significant ($P<0.05$) variations were noted among the treatment diets for nutrient composition, silage properties, feed intake and weight gained by the rabbits. The ADF of the silage produced ranged from 16.7% for treatment diet C to 35.6% for B, while the NDF ranged from 21.3% for treatment A to 40.5% for treatment C. The CP content of the silage prepared ranged from 6.5% for treatment C to 14.4% for treatment B. pH was raised with the inclusion of the browse plants . It ranged from 4.09 for C to 4.20 for A. Feed intake (g/DM) varied widely, it ranged from 62.6 for A to 99.4 for B while the weight gained/day/animal was highest for rabbits on treatment diet B (7.8g), while rabbits on A (2.4g) gained least. The raised pH value from grass alone versus grass/legume mixture is an indication of the influence of lactic acid production during fermentation of the product. This is an added advantage for effective preservation. The reduced feed intake of diet A is, however, unexpected and could be a result of mimosine breakdown during fermentation that resulted in unpalatable end product. These subsequently reduce the acceptability of the silage by the animals thus leading to reduced feed intake, eventually resulting in weight loss. The study revealed an improved performance of rabbits in terms of weight gain and quality of silage produced when G. sepium and P. maximum were combined.

Key Words: Silage, Panicum Maximum, Rabbit

591 Water soluble carbohydrates relative to protein in fresh forages: Impact on efficiency of nitrogen utilization in lactating dairy cows. D. Pacheco*[1], G. A. Lane[1], J. L. Burke[2], and G. P. Cosgrove[1], [1]*AgResearch Grasslands*, *Palmerston North, New Zealand*, [2]*Massey University*, *Palmerston North, New Zealand*.

Nitrogen utilization efficiency for milk production (NUEm: g milk N per g of N intake) in systems based on grazing of temperate forages is lower than in systems based on concentrates and conserved forages. Forages with higher content of water soluble carbohydrates (WSC) have been proposed as a solution to increase the efficiency of conversion of dietary nitrogen into milk with concomitant reduction on the environmental impact of excreta nitrogen. We have conducted a series of experiments over 2 years to study the role of WSC for pasture-fed cows in New Zealand. In our experiments, NUEm estimated at different times of the year has failed to show consistent, significant differences among grasses with differing concentrations of WSC (diploid perennial [*L. perenne*] and tetraploid annual ryegrasses [*L. multiflorum*] with

″high″ WSC, compared with a diploid perennial ryegrass control). Meta-data (n=129, each one the mean of an experimental group of animals) from our experiments to-date has been examined to find possible explanations for the lack of consistent responses to the WSC. A regression tree analysis was performed (partition 70:30 in the data for training and validation), to predict NUEm from the values of chemical composition of the forage on offer at times of milk sampling (CP, fat, ADF, NDF, WSC, and ash % of DM; from NIRS). Splitting of nodes was constrained to $P<0.10$, resulting in 2 rules for classification ($r^2= 0.56$, validation data set). CP values higher than 23.2 % DM resulted in mean NUE of 0.20, while CP values below 23.2 % DM resulted in mean NUEm of 0.25. In the latter group, a mean NUEm of 0.23 was obtained from the subset with WSC lower than 21% DM; while WSC content higher than 21% resulted in a mean NUEm of 0.27. The analysis suggests that benefits of high WSC concentrations on NUEm are more likely to occur below a CP content threshold in fresh forages, regardless of the cultivar.

Key Words: Nitrogen Utilization, Fresh Forages, Water Soluble Carbohydrates

592 Contribution of plant mediated proteolysis to total protein degradation of fresh forages in the rumen of dairy cows. D. Pacheco*, W. C. McNabb, H. S. Easton, and B. Barrett, *AgResearch Grasslands*, *Palmerston North, New Zealand*.

Ruminal degradation of proteins in grazed forage is caused by intrinsic and extrinsic proteolytic processes mediated by plant and ruminal microorganism enzymes, respectively. The objective of this experiment was to measure the contribution of intrinsic proteolysis to the total crude protein (Nx6.25) degradation in tall fescue (FS: *F. arundinacea*), red clover (RC: *T. pratense*), perennial ryegrass (RG: *L. perenne*), and white clover (WC: *T. repens*) leaves. Representative leaf samples were harvested from field grown plots over four consecutive summer days, for use in *in sacco* incubations in a balanced design with 2 cows. Grass leaves were chopped into 1 cm segments, legume leaves were picked and left undamaged. Samples were sealed in permeable (Dacron 50 micron pore size) and impermeable (polyethylene) bags and incubated for 0, 1, 2, 3, 4, 6, 8, 12, 18 and 24 h. Protein degradation was measured by analysis of the residues in retrieved bags. For each forage, samples exhibited higher protein degradation levels ($P < 0.01$) in the permeable treatment than in the impermeable one. Plant-mediated protein degradation in the impermeable treatment was confirmed by the recovery of amino acids (170 (SE 15.7); 110 (SE 18.3); 177 (SE 9.2) and 251 (SE 66.6) mg total amino acids/g CP) at 24 h for FS, RC, RG and WC, respectively. Protein degradation measured in the permeable treatment bags was higher ($P < 0.05$) than the impermeable one after 6, 12, 8 and 6 h for FS, RC, RG and WC, respectively. Plant-mediated proteolysis estimated from asymptotic values of the degradation curves reached 0.26 (FS: SE 0.028); 0.14 (RC: SE 0.075); 0.33 (RG: SE 0.07) and 0.35 (WC: SE 0.029) of the initial amount of protein incubated. These values accounted for 0.34, 0.16, 0.41 and 0.42 of the asymptotic value for protein degradation measured from the permeable treatment, respectively. Variation in plant-mediated proteolysis deserves further exploration as a tool for improving nitrogen usage in the fresh-forage fed ruminants.

Key Words: Protein Degradation, Forages, Dairy Cows

593 Relationships between silage fermentation characteristics and feed intake by dairy cows. I. Eisner[1], K.-H. Suedekum*[2], and S. Kirchhof[1], [1]*University of Kiel*, *Kiel, Germany*, [2]*University of Bonn*, *Bonn, Germany*.

The feeding value of silage is defined mainly by the contents of net energy for lactation, crude protein and cell wall components. In addition, the quality of silage is determined by fermentation products. A number of experiments have shown that the varying concentrations of these attributes affect feed intake. Unfortunately, the results are controversial. Therefore, this study had the objective to quantify the effects of fermentation end products on intake of grass, corn, and legume silages based on a meta-analysis of literature data. In addition, the accuracy of multiple regression models was tested by including silage fermentation characteristics into equations for feed intake prediction. The meta-analysis revealed that the concentration of acetic acid was closely and negatively correlated with silage intake when concentrate and forage were offered separately. These results supported previous studies in which acetic acid was supplemented directly into the silage before feeding. The effects of other short-chain fatty acids and of lactic acid and ammonia were unclear. Literature data were either controversial or effects were affected by collinearity between fermentation products. Protein quality appears to be an important factor for feed intake. Proteolysis during ensiling has increased the concentration of soluble nitrogen in silage and has consistently reduced silage intake. Amines have been suggested as being responsible for reduced silage intake but experimental evidence so far did not support this hypothesis. Total acid concentration was closely and negatively related to total feed intake in diets fed as total mixed rations (TMR). In the data set used for the meta-analysis of diets with forage and concentrate offered separately, inclusion of the acetic acid concentration in a model with animal-associated factors such as milk yield and body weight resulted in an improved accuracy of the prediction of total feed intake. The total acid concentration was the best factor that increased the fit of a model for feed intake prediction when diets were fed as TMR. In conclusion, current equations for feed intake prediction need and warrant further development.

Key Words: Silage, Intake, Fermentation

594 Alfalfa harvested in the afternoon increases performance of lactating dairy cows. A. F. Brito*[1], G. Tremblay[2], D. R. Ouellet[1], A. Bertrand[2], Y. Cantonguay[2], G. Belanger[2], R. Michaud[2], H. Lapierre[1], and R. Berthiaume[1], [1]*Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada*, *Sherbrooke, QC, Canada*, [2]*Soils and Crops R&D Centre, Agriculture and Agri-Food Canada*, *Ste-Foy-Normandin, QC, Canada*.

Alfalfa (*Medicago sativa*) harvested in the afternoon has been shown to have greater concentration of total nonstructural carbohydrates (TNC) than that harvested in the morning. Our objective was to determine the effects of alfalfa cut either in the afternoon (PM, 1800) or in the morning (AM, 0600) on performance and ruminal metabolism of lactating dairy cows. Alfalfa was conserved as silage (50% DM) into individually wrapped large rectangular bales. Sixteen multiparous Holstein cows (8 ruminally cannulated), in mid to late lactation, were assigned in a crossover design (24-d periods) to one of two treatments: PM vs. AM silage. Cows were fed only silage that contained on average (g/kg DM) 211 vs. 214 CP and 126 vs. 99.3 TNC for PM vs. AM, respectively. Dry matter intake (DMI), and yields of milk, milk protein

and milk fat were greater with PM than with AM silage. Reduced milk urea nitrogen (MUN) with feeding PM compared to AM silage indicates improved N utilization. Ruminal pH tended to be lower on AM than on PM silage; this was probably associated to the increased ruminal acetate and total volatile fatty acids (VFA) on alfalfa cut in the morning. The greater ruminal acetate:propionate ratio observed with AM silage suggests that ruminal metabolism was shifted towards lipogenesis. Overall, increased alfalfa silage TNC content with afternoon harvest resulted in improved performance of dairy cows.

Table 1.

Item	AM silage	PM silage	SED	*P*
DMI, kg/d	18.8	20.0	0.22	<0.01

Goat Species

595 *In vitro* larval activity and *in vivo* gastro-intestinal parasites infestation in goats grazing tropical legumes. K. A. H. Valentin*[1], B. R. Min[2], E. Valencia[1], A. Rodriguez[1], W. E. Pinchak[2], J. E. Miller[3], and J. P. Muir[4], [1]*University of Puerto Rico*, *Mayaguez, Puerto Rico*, [2]*Texas Agricultural Research Center*, *Vernon*, [3]*Louisiana State University*, *Baton Rouge*, [4]*Texas Agricultural Research Center*, *Stephenville*.

In Exp. 1, eight naturally parasite-infected growing Boer goats were randomly allocated to two treatments. One treatment (n = 4; initial LW = 18.8 ± 0.5 kg) entailed grazing of Arachis (*Arachis pintoi*) from September to December 2006 with a second treatment of Calliandra (*Calliandra calothyrsus*) (n = 4; initial LW = 14.4 ± 0.5 kg) grazing up to 84 days. In Exp. 2, three purified tannins (Calliandra, lespedeza (*Lespedeza cuneata*), and Acacia (*Acacia angustissima* var. hirta) and commercially available tannin monomers (ellagetannin, gallotannin, and catechin) were used *in vitro* to determine the effect of legume forage tannins and monomers on the larval migration inhibition (LMI %) rates of infective third-stage larvae of *Haemonchus contortus* (*H. contortus*). For the *in vitro* study, Calliandra was chosen because of anthelmentic activity measured in Exp. 1, while, Lespedeza and Acacia tannins were included because of known anthelmentic activity. Exp. 1 mean fecal egg counts (5262 vs. 7644 eggs/g; $P < 0.001$) and FAMACHA score (2.5 vs. 2.9; $P < 0.02$) were lower for Calliandra than for Arachis. ADG (11.1 vs. -34.7; $P < 0.02$) and packed cell volume (22.3 vs. 20.5; $P = 0.13$) were greater for Calliandra than for Arachis, respectively. *In vitro* DM digestibility was lower ($P < 0.001$) for Calliandra but crude protein and condensed tannins were greater ($P < 0.01$) than for Arachis. In the presence of 2 and 4 mg purified tannin/ml (using a Sephadex LH-20), LMI rates of *H. contortus* increased with Lespedeza and Calliandra extracts. There was no dose response of Acacia extract on LMI. *H. contortus* exhibited dose dependent ($P < 0.01$) response to 1, 2, and 4 mg/ml of ellagetannin, gallotannin, catechin tannin monomers though differential inhibitory activity was observed: ellagetannin > gallotannin > catechin.

Key Words: Gastrointestinal Nematodes, Tannins, Tropical Legumes

596 Effects of hay inclusion on intake, total tract nutrient utilization and ruminal fermentation of goats fed spineless cactus (Opuntia fícus-indica Mill) based diets. E. L. Vieira[1], A. M. Batista[1], A. Guim[1], F. F. Carvalho[1], A. C. Nascimento[1], R. F. Araújo[1], and A. F. Mustafa*[2], [1]*Universidade Federal Rural de Pernambuco*, *Pernambuco, Brazil*, [2]*McGill University*, *QC, Canada*.

A study was conducted to determine the effects of increasing levels of tifton bermudagrass hay in cactus-based diets on total tract nutrient utilization and ruminal fermentation parameters of goats. Five ruminally fistulated goats were used in a 5 × 5 Latin square experiment with 17-d periods. Experimental diets contained (g/kg) 765, 670, 572, 473 and 373 spineless cactus and 50, 150 250, 350, and 450 tifton bermudagrass hay, respectively. Results showed that that DMI increased qudratically (P<0.05) while intake of OM, CP and NDF increased linearly (P<0.05) as the level of hay in the diet increased. However, intake of non-fiber carbohydrates (NFC) decreased quadratically (P<0.05) as a result of hay inclusion. Total tract digestibility of DM (average 70.6%), OM (average 73.7%), CP (average 80.4%), NDF (average 55.3%), and NFC (average 90.4%) were not influenced by hay level in the diet. Nitrogen retention was similar for all dietary treatments, however, N supply to the small intestine increased quadratically (P<0.05) as the level of hay in the diet increased. Hay inclusion linrealy increased (P<0.05) ruminal pH and NH3-N concentration, and rumen content of DM and NDF. Rumen turnover of DM and NDF quadratically decreased (P<0.05) while rumen disappearance of DM and NDF increased quadratically (P<0.05) as the level of hay in the diet increased. It was concluded that inclusion of tifton bermudagrass hay in high cactus diets improved feed inake without adversely affecting total tract nutrient urilization or ruminal fermentation. A minimum of 150 g/kg of hay should be included in high cactus diets to avoid digestive disturbances and maximize feed intake.

Key Words: Goats, Nutrient Utilization, Spineless Cactus

597 Evaluation of Chevon on risk factors for coronary heart disease. D. D. Burnett*, S. B. White, M. M. Corley, and R. N. Corley, III, *Tuskegee University*, *Tuskegee, AL*.

Chevon (goat meat) is consumed world-wide and consumption in the United States has increased recently due to many factors including its potential as a healthy alternative to traditional meats. Goats deposit most of their fat internally versus intramuscularly in other livestock species thus chevon contains relatively less fat than other meat products and appeals to health conscious consumers. The serum lipid profile represents the types and amounts of circulating lipids, and in general meat fats have been implicated in the elevation of circulating lipids particularly LDL and total cholesterol (TC) fractions. This is associated with an increased risk for Cardiovascular (CVD), which is the leading cause of death in the United States. Over 50% of deaths from CVD result from Coronary Heart Disease (CHD), a major form of CVD in which diet plays a pivotal role. The objective of this study was to evaluate chevon as a primary protein source on risk factors for CHD. Fifty male Golden Syrian hamsters 4-weeks in age were randomly assigned to one of 5 dietary treatments. Retail meat cuts were used in diet formulation with lean beef, pork, chicken, chevon or casein serving as the sole protein source. Diets were fed ad libitum for twenty-eight days and voluntary feed intake (VFI) and average daily gain (ADG) was recorded. On day 28, the hamsters were fasted for 24 hours, euthanized and blood was collected for plasma lipid analysis. VFI for chevon was lower ($P<0.05$) than for all other diets. VFI for casein was 4.7% lower than beef and pork and was similar to chicken. ADG was 12.9% higher ($P<0.05$) for the animals consuming the beef and pork diets compared to chevon, chicken and casein, which supported similar gains ($P>0.05$). Plasma levels of LDL, HDL, and TC were not influenced by diet ($P>0.05$). Chevon did not affect the serum lipid profile, although it is important to note that the lean meat cuts in this study appeared to be heart healthy relative to casein. Future research will include the use of more economical cuts of meat in diet formulation and to determine the contribution of endogenous lipids to the serum lipid profile as affected by diet.

Key Words: Chevon, Cardiovascular Disease, Serum Lipid Profile

598 Effects of stabilized rice bran on growth, feed efficiency, carcass characteristics, and occurrence of urinary calculi in wether Boer goats fed a complete pelleted diet. G. V. Pollard*[1] and R. V. Machen[2], [1]*Texas State University*, *San Marcos*, [2]*Texas Agricultural Experiment Station*, *Uvalde*.

Sixteen wether Boer goats individually penned were utilized in a 102 d study to determine the effects of stabilized rice bran (RB) on ADG, feed efficiency, carcass characteristics, and occurrence of urinary calculi. Treatments evaluated were: control (no added RB), 45 g/d RB, 90 g/d RB, and 135 g/d RB, these diets accounted for 0, 0.8, 1.6, and 2.4 g supplemental P/d, respectfully. Goats were fed at 3.25% BW for 102 d once daily with free choice access to water and weighed every 14 d. Any goat that developed symptoms of urinary calculi was treated for the blockage and to alleviate symptoms. Goats that died were necropsied and stones were collected and bladders examined for evidence of rupture. On d 102 all goats were shipped to a commercial slaughter plant where carcass data were collected. Data were analyzed as a randomized design using the GLM procedure of SAS. Goats fed the control diet and 45 g/d RB had greater ($P =0.041$) overall ADG, FG, and 102 d live weights than those fed 90 g/d RB or 135 g/d RB. A primary area of interest in this study was the relationship between RB and occurrence of urinary calculi. In total five goats developed calculi on this study, three (two deaths) on the 135 g/d RB treatment and two (one death) on the 90 g/d RB treatment. Goats receiving the control and 45 g/d RB had greater ($P = 0.035$) hot carcass weight than goats fed the 90 g/d and 135 g/d RB diets. Fat thickness (FT) and leg circumference (LC) did not differ ($P = 0.247$) among goats fed the control, 45 g/d RB, or 90 g/d RB, while the 135 g/d RB treatment had lower ($P =0.088$) FT and LC. Muscle confirmation was greatest ($P = 0.051$) for goats fed the control and 45 g/d RB diets, with the 90 g/d RB diet being intermediate, while the 135 g/d RB diet was lowest. Animal performance varied greatly across treatments, but was consistently lower for goats receiving 90 g/d RB and 135 g/d RB, and the only occurrences of urinary calculi developed on these treatments.

Key Words: Goat, Growth, Urinary Calculi

599 The performance of Spanish kids born under mixed-species grazing system. S. Gebrelul, T. Walsh*, Y. Ghebreiyessus, V. Bachireddy, and R. Payne, *Southern University*, *Baton Rouge, LA*.

Records of 542 body weights, body condition (BCS) and FAMACHA (FS) scores were analyzed to evaluate the performances of Spanish kids born under mixed species grazing system. In a 2×#42 factorial, 40 Spanish does and 14 Brangus cows were randomly assigned to continuous (CONT) or rotational grazing (ROT) systems, and two grazing schemes, goats alone (GTA) or grazed mixed with cattle (MXD). A land area of approximately 20 ha on Bermuda grass was divided into four pastures, two 8 ha each for mixed-species grazing and two 2 ha each for goats-alone grazing. The rotational pastures were further divided, using electric fences, into four paddocks each to facilitate rotational grazing. Each paddock was grazed for 7 days and allowed to rest for approximately 21 days. Measurements on kids born during 2005 and 2006 were taken every 28 days. Body weights were analyzed using SAS's Proc MIXED procedure where grazing schemes, grazing system, months of grazing, year of birth and interactions were included as fixed and animals as random effects in the model. Chi-square analysis was used for BCS and FS. All fixed effects were significant ($P<0.05$) sources of variation. MXD kids weighed more (19.2±0.4 vs. 15.2±0.4 kg, $P<0.01$) than GTA kids. CONT kids were heavier (18.0±0.4 vs. 16.50.04 kg, $P<0.05$) than ROT kids. Body weights ranged from 7.9±0.2 in April to 21.8±0.5 kg in October. Within each month, MXD kids were heavier ($P<0.05$) than GTA kids. Significantly more GTA kids (31.5% vs. 18.5%) scored BCS of 2 or lower, while significantly more MXD kids scored (25.5% vs. 17.7%) BCS 3 or higher. Differences ($P<0.05$) in FAMACHA score of 2 were observed in GTA and MXD kids (22.2 vs. 14.4%) as well as in kids in CONT or ROT (19.6 vs. 15.7%) grazing system. Results suggested that goats could graze with cattle to efficiently utilize available forage resources under limited resources farming systems.

Key Words: FAMACHA, Goat, Mixed Grazing

600 The performance of Spanish does under mixed-species grazing system. S. Gebrelul, T. Walsh*, Y. Ghebreiyessus, V. Bachireddy, and M. Berhane, *Southern University*, *Baton Rouge, LA*.

A long-term, mixed grazing project was designed to determine the performance of goats grazing with cattle. In a 2×2 factorial, 40 Spanish goats and 14 Brangus cows were randomly assigned to continuous or rotational grazing systems, and two grazing schemes. Approximately 20 ha of Bermuda grass were divided into four pastures, two 8 ha for mixed species grazing and two 2 ha for grazing goats alone. The rotational pastures were subdivided into 4 equal sized paddocks, in which each paddock was grazed for 7 d and rested for 21 d. Goat weights, body condition scores and FAMACHA scores were collected every 28 d. Records of 1437 weights were analyzed using SAS MIXED procedure where grazing schemes, grazing systems, months of grazing and interactions were included as fixed and animals as random effects in the model. Body condition and FAMACHA scores were analyzed using Chi-square. Weights of goats grazing with cattle (36.9 ± 0.6 kg) were heavier ($P<0.01$) than goats grazed alone (34.6 ± 0.6 kg). A similar effect was noted using grazing system ($P<0.001$), where goats continuously grazing averaged 37.7 ± 0.6 kg, as compared to 33.8 ± 0.6 kg for those rotationally grazed. Significant weight differences ($P<0.01$) where observed in the interaction of grazing scheme and system with goats grazed with cattle continuously weighing more (39.9 ± 0.8 kg) as compared to the other three interactions. The majority of goats, regardless of grazing scheme or system, tended to have a body condition score between 2 and 3 on a 5 point scale. A shift in the scores was observed starting in the spring and moving toward fall, where there was an increase in those scoring 3 or better. Similar trends were observed with FAMACHA scores, with the majority of goats scoring a 2 or 3. A shift in FAMACHA scores was observed starting in the spring through the fall, with a decrease in those scoring 4 and an increase in those scoring 3. Preliminary results suggest that goats could graze together with cattle to efficiently utilize available forage resources.

Key Words: FAMACHA, Goats, Mixed Grazing

601 The effect of mixed species grazing systems on soil compaction and permeability. Y. Ghebreiyessus*, V. Bachireddy, S. Gebrelul, R. Payne, M. Berhane, and Z. Augustine, *Southern University*, *Baton Rouge, LA*.

A study to evaluate the effect of mixed species grazing systems on soil physical properties particularly soil compaction and permeability was conducted. Animals were grazed on Bermuda grass pastures during the summer and ryegrass during the winter. In a 2×2 factorial, 40 Spanish goats and 14 Brangus cows were randomly assigned to continuous or rotational grazing systems, and two grazing schemes (goats alone and goats mixed with cattle). A land area of approximately 20 ha on Bermuda grass was divided into four pastures, two-8 ha each for mixed-species grazing and two-2 ha each for goats-alone grazing. The rotational pastures were further divided, using electric fences, into four paddocks each to facilitate controlled grazing. Each paddock was grazed for 7 days and allowed to rest for approximately 21 days. Soil physical properties that determine soil compaction and permeability were collected in Fall and Spring seasons. The parameters were penetrometer reading, bulk density, soil water content and soil infiltration rate. Based on one year data significant difference in penetrometer readings was found between seasons, grazing systems, among species and grazing by specie interactions. Soils with rotational cattle grazing were more compact compared with the other treatments. Mean penetrometer readings were 4.4 ± 0.1 and 4.19 ± 0.2 revolutions for the rotational and continuous grazing, respectively. Soil compaction by goats was the lowest (3.4 ± .2 revolutions). Bulk density, which is a measure for soil compaction, was significant among species with cattle grazing 1.48 and goats 1.34 Mg/m3. Soil water content was higher (25.6 vs. 19.7, $P < 0.05$) in spring than fall, indicating more compaction in spring months. Soil permeability was significantly higher (0.45 vs. 0.13 cm/hr, $P < 0.05$) with goat grazing as compared with cattle grazing.

Key Words: Goats, Mixed Grazing, Soil Compaction

Joint National Extension Workshop: Changing the Future of Food Animal Production

602 Introduction to the symposium: The lengthening chain of change. R. E. Stup*, *The Pennsylvania State University*, *University Park*.

Extension has a rich history of helping farmers to adopt new technology and improved management practices. Throughout most of Extension's history change could be initiated by exposing farmers to information that demonstrated the benefits of the new technology or practice. Extension educators used on-farm demonstration, farmer meetings, newsletters, factsheets and many other methods to present research-based information to farmers. The farmer evaluated the concept he was presented with and made a decision about whether, when, and how to apply the change in his own farm. This method of change could be viewed as a short chain of change extending from education to implementation (i.e. extension educator presents concept to farmer who decides and implements the change). This chain of change was successful throughout much of the twentieth century and in many cases it is still successful today. In recent decades, however, farmers have expanded operations and thus increased the number of people employed. As farms grew larger, the farm owner was less likely to personally perform production operations, because other employees did that. The chain of change from education to implementation grew longer as employees were added to farms (i.e. extension educator presents concept to farmer, farmer decides whether and when to implement change, farmer trains and directs employees, employees implement change). In addition, the implementation end of the chain sometimes looks more like a web because multiple employees are involved in implementation. Obviously, this chain is much longer and more prone to breaks. The longer and more complex chain of change that we deal with today requires Extension to understand organizational change processes, not just individual education processes. This is a significant challenge and opportunity for Extension. It is a challenge because change management involves learning a new set of skills. It is an opportunity because there are few other entities in the agricultural sector that focus on organizational change. This session will introduce you to change processes and share how some Extension educators have dealt with rapidly changing industries.

Key Words: Change Management, Extension, Industry Changes

603 Adapting extension to rapidly changing industries: A pork industry experience. M. T. See*, *North Carolina State University*, *Raleigh*.

Extension programs have been delivered to the pork industry by NC State University since 1918. Over much of this period the NC pork industry experienced steady growth. However, since 1990 the NC pig crop increased four-fold from 5.1 million head to 20.1 million pigs in 2006. Today NC is recognized internationally for its large, modern and vertically integrated industry. Rapid growth was accompanied by increases in vertical integration, changing regulation, expanding workforces, and rapid technology adoption. These trends continue along with industry consolidation, internationalization, and changes in language and culture of workers. With changes of this magnitude occurring among our clientele, changes in programming offered and delivery methods were required. Local delivery of extension programs to the pork producers centers on manure management allowing county agents to specialize in an area where every producer and contract grower needs assistance. In addition, NC has state legislation requiring manure management plans and continuing education of producers. Traditional programs in nutrition, health, reproduction, genetics and management occur predominantly among peer groups including extension specialists, industry scientists and managers. Understanding the management and decision making structure of producers is required to design appropriate technology transfer methods. Our swine extension programs have a large component of production research, addressing industry needs and technology adoption. As financial resources for extension have declined our programs have grown through increased partnership with producer associations, production companies, and allied industry. We jointly offer educational programs with NC Pork Council, National Pork Board, and specific production companies on a cost-recovery basis. Electronic information transfer has become common place and allows us to reach a broad audience. Changing our extension programs as the NC pork industry has changed has allowed us to continue to provide relevant, research based information to pork producers helping them to efficiently and responsibly produce a quality product for consumers.

Key Words: Extension, Pigs, Pork

604 Adapting extension to the rapidly changing dairy industry. E. R. Jordan*, *The Texas A&M University System*, *Dallas*.

Over the last 50 years, the dairy industry has undergone dramatic changes. The number of milking cows has been cut from 21 million head on 2.9 million farms in 1955 to just over 9 million on less than 80,000 farms in 2005; thus herd size has grown from 7 cows per herd to over 110 cows. At the same time production has tripled, from less than 2700 kg of milk per cow to 8900 kg per cow. Numerous technological advances from artificial insemination to total mixed rations have been adopted by the industry to enhance productivity of the modern dairy cow. Extension educators have facilitated the transfer of these technological advances by using on-farm demonstrations, conducting producer educational meetings, and generating fact sheets and newsletters to disseminate information. Through these techniques producers progressed through the five stages of adoption for new technologies—awareness, interest, evaluation, trial and adoption. With the advent of computer technology and internet distribution of information, innovative producers are accessing information through alternative sources and implementing practices without waiting for unbiased scientific results on the benefits of a product. Extension will continue to have a role in differentiating beneficial products or practices for innovators and early adopters; however the timeline for evaluation will be accelerated. This accelerated pace of evaluation will result in the Extension professional functioning as a researcher and educator simultaneously. An increasing workforce at the non-managerial level provides another audience for Extension educators. The focus of these educational programs will be on proper techniques and explaining the importance of given procedures. To effectively reach this audience, educational programs will frequently be in a second language and written materials will be translated or an alternative medium (video or podcast) may be required for those with limited formal education. Although many techniques traditionally used to promote change can be adapted to today's clientele, it is imperative for Extension to remain relevant and that modern delivery methods be adopted.

Key Words: Extension, Delivery Methods, Technology Transfer

605 Extension's responsibility in responding to emergency and controversial issues. J. F. Ort*, *North Carolina State University*, *Raleigh*.

Extension's programs vary from state to state, but the system is united by a shared mission of helping people put research-based knowledge to work. Amid debate surrounding contentious issues such as land and water use, animal rights, and genetically modified organisms, Extension best fulfills this mission by serving as the go-to source for unbiased expertise, and by convening and facilitating informed communication among various stakeholders. Likewise, Extension has an important role to play in delivering information that helps industry and society prepare for, respond to and recover from emergencies, such as those brought about by natural disasters and disease outbreaks. Three regional conferences to be held in 2007 are designed to help government, industry and other stakeholders fully understand the capacity to which Extension can serve in animal agrosecurity, and the reasons why serving in regulatory and advocacy roles can undermine Extension's ability to achieve its important educational mission.

Key Words: Extension, Emergency Issues, Controversial Issues

606 The effect of dietary omega-3 fatty acids on adipose tissue cellularity in grower/finisher pigs. S. A. Meers*, C. R. Dove, and M. J. Azain, *University of Georgia*, *Athens*.

The objective of this study was to determine the effects of feeding a diet containing omega-3 fatty acids during grower and/or finisher phases on adipose tissue composition and cellularity. The study was designed as a 2 x 2 factorial arrangement, with main effects of feeding omega-3 fatty acids in the grower diet and/or finisher diet. Diets were corn-SBM based diets such that the grower diet (G) was calculated to contain approximately 3327 kcal/kg ME, 17.9% CP and, 1.0% lysine, while the finisher diet (F) was calculated to contain 3340 kcal/kg ME, 17.0% CP and, 0.9% lysine. Omega-3 fatty acids were supplemented in the form of 2% fish oil (Virginia Prime Gold, Omega Protein, Houston, TX) in the n-3 diets, while the Control diets had 2% soybean oil added to them. Pigs (n=92, initial bw 29.26±0.19 kg) were allocated by gender and weight to pens where Control or Omega-3 diet treatments were assigned at random. Pigs were fed the G diets for 35 d and switched to the F diets, with half of the pigs in each dietary treatment maintained on the same diet and half switched to the other diet (Control or Omega-3). Pigs were maintained on their respective diets for an additional 35 d. Pigs were weighed and feed intake recorded approximately every 2 weeks. There were no differences in ADG, ADFI, or G:F across diet treatments. A subset of pigs from the larger study were selected from each diet treatment and slaughtered at d 35 (n=4) and d 70 (n=8) to obtain ISQ, OSQ, and leaf fat, and loin muscle samples. Across treatments cell diameter and volume were 61.79±0.98 µm and 1.2 *10^5 µm/cell, respectively at d 35, as compared to 67.81±2.4 µm and 1.6 *10^5 µm /cell at d 70 ($P< 0.02$ and $P<0.02$, respectively). There was a trend ($P < 0.07$) for a decrease in average cell size in omega-3 fatty acid fed pigs. These results suggest that diets can be supplemented with omega-3 fatty acids without affecting growth performance and that omega-3 fatty acids may attenuate adipocyte filling.

Key Words: Omega-3 Fatty Acid, Cellularity, Pig

607 Effect of amino acid program (Low vs. High) and dried distiller's grains with solubles (DDGS) on finishing pig performance and carcass characteristics. R. Hinson*[1], G. Allee[1], G. Grinstead[2], B. Corrigan[2], and J Less[3], [1]*University of Missouri*, *Columbia*, [2]*Vita Plus Corp.*, *Madison, WI*, [3]*ADM Specialty Feed Ingredients*, *Decatur, IL*.

A total of 882 TR-4 x C22 barrows (initial BW = 31.9 kg) reared in a commercial research facility were allotted to one of six dietary treatments in a completely randomized block design with 7 replicate pens per treatment (21 pigs/pen). Treatments were arranged as a 2×3 factorial with the main effects of synthetic AA program (Low vs. High) and DDGS addition (0, 10, and 20%). Pigs were fed the experimental diets in a 5-phase finisher-feeding program, with Ractopamine at 5 ppm during the final 21 d phase. At market weight (127 kg BW), pigs were marketed by intact pen to Cargill Meat Solutions (Beardstown, IL) for carcass data collection. No AA×DDGS interactions were observed for growth performance or carcass traits. High levels of synthetic AA inclusion resulted in increased ($P < 0.05$) overall ADG (1.06 vs. 1.03 kg/d) and ADFI (2.93 vs. 2.85 kg/d) and heavier ($P < 0.01$) final BW (129.6 vs. 126.7 kg) and carcass weight (95.8 vs. 93.5 kg). Overall ADG (1.03 vs. 1.06 kg), ADFI (2.86 vs. 2.93 kg), final BW (127.1 vs. 130.4 kg), and carcass weight (93.9 vs. 96.3 kg) were reduced ($P < 0.01$) when DDGS was included in the diet, with no differences ($P > 0.05$) between DDGS levels. Backfat depth (20.8 vs. 19.6 mm) and $/pig received (114.27 vs. 112.21) was increased ($P < 0.01$) in the high AA pigs. The feeding of DDGS reduced the $/pig received when compared to the control diet (112.35 vs. 115.03, $P < 0.01$). The feeding of high AA levels resulted in increased performance throughout the study and increased return/pig. The feeding of DDGS reduced overall growth performance, with minimal effects on carcass traits. The decision on the use of DDGS in G-F diets is an economic decision based on the relative cost of feed ingredients, and the economic value of the reduced growth performance. Diets with aggressive use of synthetic AA and DDGS resulted in similar benefits as observed in traditional corn-SBM diets.

Key Words: Pigs, Amino Acids, Dried Distiller's Grain with Solubles

608 Effects of co-products from the ethanol industry on pig performance and carcass composition. M. R. Widmer*[1], L. M. McGinnis[1], D. M. Wulf[1], and H. H. Stein[2], [1]*South Dakota State University*, *Brookings*, [2]*University of Illinois*, *Urbana*.

An experiment was conducted to investigate pig performance and carcass composition of pigs fed diets based on distillers dried grains with solubles (DDGS), high-protein distillers dried grains (HP DDG), and corn germ. Eighty-four pigs (initial BW: 22 kg) were allotted to 7 treatments with 6 replicates per treatment and 2 pigs per pen. Diets were fed for 114 d in a 3-phase sequence. The control diet sequence was based on corn and soybean meal. Two diet sequences were formulated using 10 or 20% DDGS in each phase. Two additional diet sequences contained HP DDG in amounts sufficient to substitute 50 or 100% of the soybean meal used in the control sequence (20 and 40%, 15 and 30%, and 10 and 20% HP DDG in phase 1, 2, and 3, respectively). The last 2 diet sequences contained 5 or 10% corn germ in the diets fed in each phase. Results of the experiment showed that for the entire experiment, ADG, ADFI, G:F, and final BW were not affected by the inclusion of DDGS or HP DDG in the diet. However, final BW increased (linear, $P \leq 0.05$) and ADG tended to increase (linear, $P = 0.06$) as corn germ was included in the diet. Hot carcass weight (HCW), dressing percentage, and carcass composition were not influenced by the addition of DDGS to the diets. There was no effect of HP DDG on HCW, dressing percentage, lean meat percent, and 10^{th} rib backfat, but LM area and LM depth were reduced (linear, $P \leq 0.05$) as HP DDG was added to the diet. Hot carcass weight, dressing percent, LM area, and LM depth was not influenced by the inclusion of corn germ in the diets, but there was an increase in lean meat percent and a decrease in 10^{th} rib backfat as corn germ was included in the diets (quadratic, $P \leq 0.05$). In conclusion, DDGS and corn germ do not negatively affect pig performance or carcass composition if included in diets fed to growing-finishing pigs in amounts of up to 20 and 10%, respectively. Also, HP DDG does not affect pig performance, but may reduce LM area and LM depth if substituting all the soybean meal in the diets.

Key Words: Corn germ, DDGS, HP DDG

609 Effect of corn distiller's dried grains with solubles (DDGS) withdrawal program on growth performance and carcass yield in grow-finish pigs. A. M. Gaines, J. D. Spencer, G. I. Petersen*, N. R. Augspurger, and S. J. Kitt, *JBS United, Inc.*, *Sheridan, IN*.

The purpose of this research was to evaluate the effect of DDGS (11.8% crude fat, 27.7% CP; and 0.81% Lys, as-fed basis) withdrawal prior to marketing on growth and carcass yield in grow-finish pigs. A total of 1,117 PIC pigs (66.1 ± 1.0 kg) were allotted to one of four treatments in a randomized complete block design with 12 replicate pens/treatment. Treatments included: a corn-soybean meal diet with 0% DDGS (Trt 1) or 30% DDGS (Trt 2), or the DDGS withdrawn from the diet three (Trt 3) or six weeks (Trt 4) prior to marketing of pigs. Diets were formulated to the same standardized ileal digestible lysine and energy level (ME basis). Pigs were fed from 66 to 128 kg BW in a 3 phase program (Phase 1, 29 d; Phase 2, 21 d; and Phase 3, 20 d). At trial termination, pigs were marketed by intact pen for carcass data collection. For the overall period, there were no differences ($P > 0.30$) in ADG or ADFI among treatments. However, G/F was lower ($P < 0.02$) for pigs fed 30% DDGS compared to pigs fed 0% DDGS or the 6-week withdrawal program (0.312, 0.305, 0.307, and 0.309 kg/kg, respectively). For pigs on the 3- and 6-week DDGS withdrawal programs, G/F was similar ($P > 0.10$). Carcass weight was reduced ($P < 0.01$) for pigs fed 30% DDGS continuously; however, the withdrawal of DDGS (3 or 6 weeks) improved ($P < 0.05$) carcass weight and was similar ($P > 0.05$) to pigs fed 0% DDGS (97.8, 94.8, 96.7, and 97.5 kg, respectively). The reduction in carcass weight of pigs fed 30% DDGS was due to a reduction ($P < 0.01$) in carcass yield (77.1, 75.9, 76.5, and 77.1%, respectively). Removal of DDGS from the diet 3- or 6-weeks prior to marketing improved ($P < 0.05$) carcass yield, but only the 6-week removal fully restored yield. There were no differences in loin depth ($P < 0.46$) or percent lean ($P < 0.56$) among treatments. This research demonstrates that continuous feeding of 30% DDGS up to market weight may result in similar growth performance, but carcass yield is negatively impacted. It does appear that the withdrawal of DDGS prior to marketing may help negate this effect.

Key Words: Dried Distiller's Grains with Solubles, Swine, Growth and Carcass

610 Effects of a Pichia-expressed phytase on performance and P excretion of growing pigs. L. M. McGinnis*[1], M. R. Widmer[1], C. L. Wright[1], T. M. Parr[2], and H. H. Stein[3], [1]*South Dakota State University*, *Brookings*, [2]*Syngenta Animal Nutrition*, *Research Triangle Park, NC*, [3]*University of Illinois*, *Urbana*.

Two experiments were conducted to evaluate the effects of feeding a Pichia-expressed phytase, Quantum™ phytase (QP), to growing pigs. In Exp. 1, 60 growing pigs (initial BW: 23 kg) were allotted to 3 treatments with 2 pigs per pen and 10 pen replicates per treatment. The positive control diet (PC) was a corn-soybean meal diet containing 1.0% dicalcium phosphate and 0.20% digestible P. The negative control diet (NC) and the QP diet were similar to the PC diet with the exception that only 0.32% dicalcium phosphate was used. The QP diet contained 500 FTU/kg of phytase equivalency and the concentration of digestible P was calculated at 0.10 and 0.20% in the NC and the QP diets, respectively. The experiment lasted 42 d. Pigs fed the PC and QP diets had greater ($P \leq 0.05$) ADG (0.92 and 0.91 vs. 0.82 kg/d), G:F ratio (0.41 and 0.43 vs. 0.37 kg/kg), and final BW (62.52 and 61.15 vs. 57.67 kg) than pigs fed the NC diet. There were, however, no differences between pigs fed the PC and QP diets. In Exp. 2, nine barrows (initial BW: 22 kg) were placed in metabolism cages and allotted to three 3 x 3 Latin squares with 3 diets and 3 periods. The 3 diets were similar to the diets used in Exp. 1. Urine and feces were collected for 5 d of each period. Pigs fed the QP diet had a lower ($P \leq 0.001$) fecal P excretion (7.63 g/5d) and a greater ($P \leq 0.01$) apparent total tract digestibility (ATTD) of P (62.46%) than pigs fed the PC diet (11.57 g/5 d and 56.35%) or the NC diet (11.73 g/5d and 41.85%). Fecal Ca output was lower ($P \leq 0.001$) for pigs fed the QP diet than for pigs fed the PC or NC diets (6.48 vs. 7.62 and 9.96 g/5d). The ATTD for Ca in pigs fed the QP (76.4%) or PC (75.5%) diets were not different, but they were greater ($P \leq 0.001$) than the ATTD for NC fed pigs (66.0%). The results confirm that low-P, QP-containing diets support pig performance to the same degree as a high-P diet, but pigs fed the QP diet have a lower fecal excretion of P and Ca than pigs fed a high P diet.

Key Words: Phosphorus, Pigs, Quantum phytase

611 Effect of form of fat and NDF addition on apparent ileal and apparent total tract digestibility of fat in diets fed to growing pigs. D. Y. Kil*[1], T. E. Sauber[2], and H. H. Stein[1], [1]*University of Illinois*, *Urbana*, [2]*Pioneer Hi-Bred Intl. Inc.*, *Johnston, IA*.

An experiment was conducted to measure the effect of the concentration and form (liquid or intact) of dietary fat and the concentration of dietary NDF on the apparent ileal (AID) and apparent total tract (ATTD) digestibility of dietary fat by growing pigs. Eleven barrows (initial BW: 38.1 ± 1.2 kg) were fitted with a T-cannula in the distal ileum and allotted to an 11 × 11 Latin square design. Four diets containing 0.92% NDF and 1.3, 3.2, 5.1, or 6.9% liquid fat (LF) from corn oil were prepared. Three additional diets were formulated by adding 3.0, 6.0, and 9.0% NDF from solka floc to the diet containing 5.1% LF. The remaining 4 diets were prepared by mixing varying amounts of whole corn germ meal and defatted corn germ meal to produce diets containing 3.0, 5.3, 7.7, or 9.7% of intact fat (IF). Ileal digesta and fecal samples were collected from pigs and AID and ATTD of fat were calculated for each diet and linear and quadratic effects of the inclusion of LF, IF, and NDF were calculated. Preplanned contrasts were used to compare AID and ATTD of the 2 forms of fat and to compare AID and ATTD. The AID of fat increased (linear and quadratic, $P \leq 0.05$) as the inclusion of fat increased regardless of the form of fat (67, 82, 88, and 83% for LF and 53, 65, 71, and 70% for IF). The ATTD of fat also increased (linear and quadratic, $P \leq 0.05$) as the inclusion of fat increased regardless of the form of fat (65, 76, 88, and 86% for LF and 48, 57, 69, and 72% for IF). On average, the values for AID (80 vs. 65%) and ATTD (79 vs. 61%) were greater ($P \leq 0.01$) for LF than for IF. There was no effect of the dietary inclusion of NDF on the AID of fat, but the ATTD exhibited a quadratic relationship ($P \leq 0.05$) with increasing level of dietary NDF (88, 85, 85, and 87% for 0, 3, 6, and 9% NDF in the diet). There were no differences between AID and ATTD of fat regardless of the diets being fed. These results suggest that LF is better digested by growing pigs than IF, but the dietary concentration of NDF does not influence the AID of fat.

Key Words: Dietary Fat, Digestibility, Pigs

612 Performance and phosphorus status of growing pigs are improved by a multi-enzyme complex containing NSP-enzymes and phytase. A. V. Mori, J. Kluess*, R. Maillard, and P. A. Geraert, *Adisseo France SAS*, *Commentry, France*.

The effect of a multi-enzyme complex containing carbohydrolase and phytase activities on performance, bone mineralization and phosphorus status of growing pigs fed a corn-barley based diet was investigated. Twenty-four (initial body weight BW: 25 kg) individually penned pigs were allotted to one of three diets in a complete randomized block design during a 6-wk study: positive control PC meeting requirements (3230 kcal/kg metabolizable energy ME, 17.9 % crude protein CP, 0.22 % available phosphorus avP, 0.67 % calcium Ca); negative control NC reformulated below requirements (-80 kcal/kg ME, -0.3 units CP, -0.13 units avP, -0.08 units Ca) and NC supplemented with the enzyme complex Rovabio™ Max (NCE). Rovabio™ Max provided 1,100 visco units (equivalent to 70 AXC) of endo-β-1,4-xylanase, 100 AGL units of endo-1,3(4)- β-glucanase, and 350 RPU of 3-phytase per kg of diet. Enzyme-supplementation significantly increased BW gain in the negative control (36.1 vs 40.1 kg, P<0.05) reaching the same performance as the positive control. Feed conversion ratio tended to be improved (P=0.07). Furthermore, enzyme addition tended to improve bone ash (%) content (17.4 vs 18.7 %; P=0.06) and P content (2.9 vs 3.2 %; P=0.07) in comparison to the negative control. Weight of the metacarpus was significantly higher (19.2 vs 21.7 g; P<0.01). Plasma P concentration showed a significant improvement of 18.5 % (P<0.05) and faecal P excretion was significantly reduced by 16.9 % (1.36 vs 1.13 %; P<0.05) due to the enzyme supplementation. In conclusion, supplementation with the multi-enzyme complex Rovabio™ Max of a corn-based diet reformulated below requirements for ME, CP, P and Ca improved growth performance, P status and excretion in the growing pig. This combination of NSP-enzymes and phytase is an efficient strategy to enhance the nutritional value of swine diets.

613 Comparison of particle size analysis of ground grain with or without the use of a flow agent. R. D. Goodband*[1], W. Diederich[2], S. S. Dritz[1], M. D. Tokach[1], J. M. DeRouchey[1], and J. L. Nelssen[1], [1]*Kansas State University*, *Manhattan*, [2]*Mid-West Laboratories*, *Omaha, NE*.

According to the American Society of Biological and Agricultural Engineers' standard, particle size analysis of grain can be conducted with or without the use of a flow agent. Because two procedures can be used, particle size results can be variable, depending on whether the laboratory uses a flow agent or not. Therefore, the objective of this study was to determine if the two procedures (with or without flow agent) were similar as measured by a Method of Agreement analysis. A total of 603 ground corn samples were analyzed for particle size with or without 0.5 g of synthetic amorphous precipitated silica (Sipernat® 22-S) per 100 g of sample. Results indicated a bias between the two procedures. Particle size analysis conducted with a flow agent will result in a mean particle size that is approximately 80 µ smaller than the result from analysis without a flow agent. There was no evidence the slope (0.027) of the comparison was different than zero (P = 0.13), indicating a similar bias across the range of particle sizes tested (400 to 1000 µ), but the intercept (-80.2 µ) was highly significant (P < 0.01). The same procedures were used in comparing particle size standard deviation. Using a flow agent produced a greater particle size standard deviation value than without a flow agent. Unlike the bias for the particle size analysis, the standard deviation values showed a significant bias that changed with increasing particle size. There was strong evidence that the slope of this line (0.460) was different than zero (P<0.05), indicating that the magnitude of difference between the two procedures increased as the standard deviation of the sample increased. Results of this study indicate that there are differences in results between the two procedures. Therefore, selection of one of the two procedures as the official standard is necessary. Also, it is important to know if a flow agent was, or was not, used in the analysis when interpreting results.

Key Words: Flow Agent, Particle Size, Quality Control

614 Effects of a dry organic acid blend on growth performance and carcass parameters in growing-finishing pigs. J Zhao*[1], R. J. Harrell[1], B. R. Hinson[2], G. L. Allee[2], F. Navarro[1], and C. D. Knight[1], [1]*Novus International Inc*, *St. Louis, MO*, [2]*University of Missouri*, *Columbia*.

A total of 720 growing pigs (40.2 ± 1.1 kg BW) were used to investigate the effect of a dry organic acid blend (DOAB) (ACTIVATE® Starter DA, registered trademark of Novus International, Inc., St. Louis, MO), containing 2-hydroxy-4-(methylthio) butanoic acid calcium, benzoic acid, and fumaric acid, on growth performance and carcass parameters. Nutrient adequate non-medicated corn soybean meal diets were supplemented with DOAB at 0 (control), 0.1%, and 0.2% for 12 weeks. Pigs were blocked by sex (20-22 pigs/pen) with 10 replicate pens per treatment and 16 replicate pens for controls. All pigs received ractopamine during the last 3 weeks (5.0 ppm and 7.5 ppm for week 1, week 2 and 3, respectively), and were harvested at Tyson's Columbus Junction plant in Iowa. Average daily gain and ADFI were linearly increased with DOAB supplementation from d 0-21 (P< 0.05) and tended to be increased for the overall period (d 0-84, P < 0.09) with no differences in feed efficiency (P > 0.38). The ADG was 1.04, 1.07, and 1.07±0.01 kg/d, and ADFI was 2.61, 2.66, and 2.70±0.03 kg/d for the 0, 0.1, and 0.2% DOAB, respectively, from d 0-84. Pigs fed DOAB had heavier body weights compared to controls (linear, P < 0.05) at d 21. Pigs fed DOAB had heavier final bodyweights than controls (P < 0.05), 127.0, 130.0, and 130.2±0.9 kg for the 0, 0.1, and 0.2% DOAB, respectively. Mortality and morbidity were not different among treatments (P = 0.69). Pigs fed DOAB had 2.5 kg heavier carcass weights (linear, P < 0.05), increased grade premium by 5% (linear P < 0.05), and higher pig value by 2.8% (linear P < 0.05). No differences were observed in back fat depth, loin depth, lean percentage, or sort loss (P > 0.30). In summary, dietary DOAB increased growth performance, final BW, carcass weights, and increased grade premium and individual pig value.

615 Dietary arginine supplementation enhances the growth performance of milk-fed piglets. Y. Kang*[1], Y. L. Yin[1], R. L. Huang[1], X. F. Kong[1], T. J. Li[1], I. Shinzato[2], S. W. Kim[3,4], and G. Y. Wu[1,4], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Ajinomoto*, *Tokyo, Japan*, [3]*Texas Tech University*, *Lubbock*, [4]*Texas A&M University*, *College Station*.

This study was designed to determine the effect of dietary L-arginine (Arg) supplementation on the growth performance of milk-fed piglets. The milk replacer powder consisted of 60% dried whey, 26% dried skim milk, 6.2% a-casein, 3.6% lactose, 1.65% glucose, 1% calcium lactate, 1% dihydrocalcium phosphate, 0.1% vitamin premix, 0.2% mineral premix, 0.1% lysine, 0.1% methionine, and 0.05% antibiotic. Seventy piglets (Landrace–Yorkshire) with similar BW (2.75 ± 0.05 kg) from 14 sows (5 piglets/sow) were weaned at 7 d of age and housed individually. Piglets were assigned randomly on the basis of BW and litter origin to one of the five treatments (14 piglets/treatment; 7 males and 7 females), representing dietary supplementation with 0.0% (control), 0.2%, 0.4%, 0.6% and 0.8% Arg (on the basis of milk powder). Milk powder was dissolved in water to obtain 18% DM, and the resultant liquid milk was fed to piglets every 4 h for 14 d. On d 0, 7, and 14, the BW of piglets was measured and jugular venous blood samples were obtained for analysis of insulin and growth hormone. There were no differences in any measured parameter between male and female piglets. Feed intakes did not differ among all the groups of piglets. ADG was similar among piglets supplemented with 0.0%, 0.2% and 0.4% dietary Arg. However, dietary supplementation with 0.6% and 0.8% Arg for 14 d increased (P<0.05) the BW of piglets by 18% and 23%, respectively, as well as ADG by 41% and 53%, respectively, compared with control piglets. Additionally, dietary supplementation with 0.6% and 0.8% Arg increased (P<0.05) plasma concentrations of insulin and growth hormone by 24â€“27% in piglets on d 14. Collectively, these results indicate that Arg availability is a major factor that limits the maximum growth of milk-fed piglets.

Key Words: Arginine, Piglets, Growth Performance

616 Production of the recombinant bovine lactoferricin and its beneficial supplementation to the diet for weaned pigs. Z. R. Tang*[1], Y. M. Zhang[1,2], Y. L. Yin[1], A. F. Stewart[3], and G. Y. Wu[1,4], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Gene Bridges GmbH, BioInnovation Zentrum*, *Am Tatzberg, Dresden, Germany*, [3]*BioInnovation Zentrum, Technical University of Dresden*, *Am Tatzberg, Dresden, Germany*, [4]*Texas A&M University*, *College Station*.

This study was conducted to produce a new antimicrobial polypeptide, bovine lactoferricin (44 amino acids), using the gene engineering technology and to determine its nutritional efficacy as an additive to the diet for weanling pigs. After both *cipA* and *cipB* genes in *photorhabdus luminescens* subsp. *Akhurstii* were knocked-out using the Red/ET homologue recombination technology, a mutant (the *photorhabdus luminescens* TZR) was obtained as the host bacterial strain for protein expression. The expression plasmid pBAD-CipB-BLfcin-Ampin was constructed and transformed to the host bacterial strain, which produced high levels of the recombinant bovine lactoferricin (rBLfcin) under the induction of L-arabinose. The resultant rBLfcin reached 10% of the total bacterial protein. Experiments in vitro showed that rBLfcin had a similar antimicrobial activity to bovine lactoferricin isolated from the bovine milk. A feeding trial was conducted with 60 piglets which were weaned at 21 d of age (5.42±0.59 kg), fed a corn- and soybean meal-based diet supplemented with 0 or 0.01% rBLfcin or 0.01% polymyxin sulfate (an antibiotic), and challenged with pathogenic E. coli (k88, k99, and k149); there were 20 pigs per dietary treatment. Compared with control pigs, dietary supplementation with 0.01% rBLfcin for 3 wk increased ADG by 21%, improved the gain:feed ratio by 16%, and reduced diarrhea incidence (P<0.01). Growth performance was similar between rBLfcin- and polymyxin sulfate-supplemented pigs. Our results indicate that rBLfcin is an effective alternative to a feed antibiotic for enhancing growth performance in weaned pigs.

Key Words: Bovine Lactoferricin, Recombination Technology, Weaned Piglets

617 InraPorc: A model and decision support tool for the nutrition of growing pigs and sows. J. van Milgen*, J. Noblet, M. Étienne, A. Valancogne, S. Dubois, and J. Y. Dourmad, *INRA*, *Saint Gilles, France*.

InraPorc is a model allowing the evaluation of different nutritional strategies for growing pigs and sows. The core of the model is the definition of the animal's phenotypic potential in which both the feed intake capacity and production potential are described. The latter includes body weight gain and the shape of the growth curve for growing pigs. For sows, the production potential is determined by the changes in body weight and backfat thickness (during gestation and lactation and up to the eighth litter), litter size and litter growth. Both the sow and the growing pig models are based on the premise that nutrients are transformed into body protein and body lipid that cumulate progressively into two body pools. Lactating sows may also mobilize nutrients from these body pools to support milk production. Both models operate internally using established concepts of nutrient utilization (e.g., standardized ileal digestible amino acids, ideal protein, metabolizable or net energy). The decision support tool was designed around a common feed modules and specific modules for growing pigs and sows. The feed module allows characterizing the nutritional values of feeds and includes the complete INRA-AFZ tables of feed ingredients. Using a feeding strategy (type and quantities of feed), the user can graphically evaluate the use of nutrients by the pig. This includes the utilization of energy and amino acids for the main physiological functions, identification of (potentially) limiting nutrients, and input-output balances for N, P, Ca, Cu and Zn. In addition, the user can compare different nutritional strategies (different types or quantities of feed) and evaluate the effects on animal performance. The target audience for the model and tool include professional nutritionists and educational institutions. All underlying hypotheses and model equations are freely available and the software is from Inra at a modest cost. A slightly limited version of the software is available free of charge for academic institutions.

Key Words: Nutrition, Model, Pigs

618 Differential effects of leucine on translation initiation factor activation and protein synthesis in skeletal muscle, renal and adipose tissues of neonatal pigs. J. Escobar*, H. V. Nguyen, and T. A. Davis, *USDA/ARS, Children's Nutrition Research Center, Baylor College of Medicine*, *Houston, TX*.

In adult rats, protein synthesis in skeletal muscle and adipose tissue increases in response to pharmacological doses of leucine (Leu) administered orally. In neonatal pigs, a physiological increase in plasma leucine stimulates protein synthesis in skeletal muscle without increasing hepatic protein synthesis. However, the effect of a physiological increase in plasma leucine on renal and adipose tissue on protein synthesis has not been investigated in neonates, an anabolic population highly sensitive to amino acids and insulin. Thus, 11 crossbred pigs were food-deprived for 14 h and intra-arterially infused with Leu (0 or 400 $\mu mol \bullet kg^{-1} \bullet h^{-1}$). Protein synthesis and the activation of translation initiation factors were measured after 60 min in gastrocnemius muscle, kidney, and adipose. We have previously shown that this Leu infusion protocol increases plasma Leu to levels that mimic the physiological postprandial level. The elevation in plasma Leu increased the phosphorylation of eukaryotic initiation factor (eIF) 4E binding protein-1 (4E-BP1) in gastrocnemius muscle and kidney ($P < 0.0001$) and adipose tissue ($P = 0.06$). Infusion of Leu increased ($P < 0.04$) the phosphorylation of ribosomal protein (rp) S6 kinase (S6K1) in gastrocnemius muscle and adipose tissue but not in kidney ($P = 0.21$). A concomitant increase ($P < 0.03$) in the phosphorylation of rpS6 was measured in gastrocnemius muscle and adipose tissue but not in kidney ($P = 0.12$). Fractional rates of protein synthesis were increased in gastrocnemius muscle ($P = 0.003$) but not in adipose ($P = 0.29$) or renal ($P = 0.64$) tissues. The results show that a physiological increase in plasma leucine in neonatal pigs stimulates protein synthesis in skeletal muscle in association with the activation of translation initiation factors. However, leucine does not increase protein synthesis in adipose or renal tissues despite increased activation of translation initiation factors. (NIH AR 44474 and USDA 58-6250-6-001)

619 Developmental expression and resveratrol regulation of the porcine lipoprotein lipase (LPL) gene. T. Z. Shan*, Y. Z. Wang, J. X. Liu, and Z. R. Xu, *Institute of Feed Science*, *Hangzhou, Zhejiang,China*.

Two experiments were conducted to evaluate the developmental expression of the porcine LPL in porcine adipose tissues and resveratrol (RES) regulation of LPL in stromal-vascular (SV) cell cultures. In experiment 1, thirty female (Duroc – Landrace – Yorkshire) pigs in five groups of six pigs each, aged at 1 d, 7, 14, 21 and 28 wk were used to study the gene expression of LPL in subcutaneous adipose tissue (SAT), peritoneal adipose tissue (PAT) and omental adipose tissue (OAT) by means of semi-quantitative RT-PCR. In experimental 2, adipose tissue from 7 d-old female (Duroc – Landrace – Yorkshire) pigs was digested and SV cells were obtained and seeded at a density of 3 – 104 cells/cm2 on six-well (35-mm) tissue culture plates in DMEM/F12 medium containing 10% fetal bovine serum (FBS). After 10 d of growing, cultures were washed free and used for three treatments (6 replicates per treatment) for 24 h. The treatments were: control group, DMEM/F12 medium +10% FBS; RES group, DMEM/F12 medium + 10% FBS + 80 Î¼M RES; insulin group, DMEM/F12 medium +10% FBS + 100nM insulin. The results showed that there were two distinct phases of changes in adipose tissue LPL mRNA level. In the first phase (from 1 d to 7 wk), LPL mRNA level significantly increased ($P < 0.01$), and this phase was characterized by a strong positive correlation between LPL mRNA level and adipose index as well as body weight. In the second phase (from 7 to 28 wk), LPL mRNA level gradually decreased, and the LPL mRNA levels were inverse correlated significantly with both the body weight and the adipose index. Body weight and adipose index increased significantly with age ($P<0.01$). The SV cell cultures results showed that supplemental RES significantly increased the LPL gene expression by 33.0% ($P<0.05$) as compared with the control and increased by 39.7% ($P<0.05$) as compared with the insulin group. There were no difference between insulin treatment and the control. These results could provide some information for practical methods of regulating and improving efficiency of lean meat production and meat production quality.

Key Words: Lipoprotein Lipase, Resveratrol, Pig

620 Effects of dried distillers grains and conjugated linoleic acid on gene expression for key enzymes in fatty acid synthesis. H. M. White*, S. S. Donkin, M. A. Latour, and S. L. Koser, *Purdue University*, *West Lafayette, IN*.

Feeding distillers dried grains with solubles (DDGS) to swine may adversely affect carcass fat quality. Commercial gilts were fed DDGS at 0, 20, or 40 percent of total ration during the last 30 days of the finisher phase. Beginning ten days prior to slaughter, one-half of each DDGS group received either 1% conjugated linoleic acid (CLA) or 1% choice white grease. At slaughter, liver was collected for RNA isolation and backfat was collected for fatty acid and mRNA analysis. Abundance of fatty acid synthase (FAS), carnitine palmitoyl transferase I (CPT-I), acetyl-CoA-carboxylase (ACC), stearoyl-CoA desaturase (SCD1), and glycerol-3-phosphate dehydrogenase (GAPDH) mRNAs were determined using Quantitative Real-Time PCR. Abundances of mRNA for lipogenic genes were normalized to GAPDH expression within each sample. Abundance of FAS, CPT-I, ACC and SCD1 mRNAs in adipose and liver samples were not different ($P > 0.05$) for DDGS and control pigs. The addition of CLA to the diets did not alter ($P > 0.05$) FAS or CPT-I but tended to decrease abundance of ACC ($P = 0.10$) and SCD1 ($P < 0.15$) mRNA levels in adipose tissue. The ratio of saturated to unsaturated fatty acids was decreased ($P < 0.05$) with DDGS (0.64, 0.57, and 0.54 ± 0.01 for 0, 20, and 40% DDGS respectively) and was increased from 0.56 to 0.61 ± 0.01 with CLA. Feeding DDGS decreased pork quality as determined by decreased ratios of saturated:unsaturated fatty acids. There was no interaction effect ($P > 0.05$) for DDGS and CLA on any of the transcripts measured or measures of pork quality. These data indicate that the effects of DDGS to reduce pork quality are not linked to changes in lipogenic gene expression. Feeding CLA leads to increased pork quality through alterations in SCD1 to increase the ratio of saturated to unsaturated

fatty acids. Furthermore, DDGS and CLA appear to act in opposing directions on pork quality yet only CLA impacts lipogenic gene expression in adipose tissue.

Key Words: Distillers Grains, Conjugated Linoleic Acid, Gene Expression

621 Effect of dietary protein fluctuations and Paylean® on performance and carcass traits of finishing pigs. M. S. Edmonds*[1] and D. H. Baker[2], [1]*Kent Feeds, Inc.*, *Muscatine, IA*, [2]*University of Illinois*, *Urbana*.

Two trials with finishing pigs were conducted to evaluate the effects of fluctuating dietary CP levels and ractopamine (Paylean®, Elanco Animal Health) on performance and carcass traits. In Trial 1, 408 finishing pigs (mixed sex) were assigned to one of four treatments. Average initial and final weights were 89 and 123 kg, respectively. Pigs on treatments 1-4 were fed 16, 11, 16 or 13% CP from wk 0 to 2, respectively. During wk 2-5, the pigs were then fed 15, 18.33, 18 or 20% CP for treatments 1-4, respectively, with treatments 3 and 4 also containing supplemental Paylean (10 mg/kg) during wk 2-5. Overall (wk 0-5), gain, gain:feed, loin depth, percentage of lean and dressing percent were improved (P≤.05) from supplemental Paylean. No significant overall (wk 0-5) treatment differences due to protein regimen occurred between treatments 1 and 3 compared with treatments 2 and 4. Trial 2 involved 172 finishing pigs (mixed sex) in two treatments. Average initial and final weights were 91 and 136 kg, respectively. The diets consisted of: 1) control (16% CP from d 0-14, 18% CP + Paylean (5 mg/kg) from d 14-24, and 18% CP + Paylean (10 mg/kg) from d 24-35); 2) extreme CP variations (ECPV = 12.5% CP from d 0-14, 20.33% CP + Paylean (5 mg/kg) from d 14-24, and 20.33% CP + Paylean (10 mg/kg) from d 24-35. During d 0-14, pigs on the ECPV treatment (12.5% CP) had reduced (P≤.05) gains (-12.8%) and poorer gain:feed ratios (-11.7%) compared with those on the control diet (16% CP). During d 14-35, however, pigs on the ECPV treatment (20.33% CP) had improved (P≤.08) gains (+5.8%) along with a 5.1% improvement in gain:feed compared with those on the control diet (18% CP). Despite the wide dietary CP fluctuations for pigs in Trial 2, performance, gain:CP intake, and carcass traits were similar for both treatments over the 35-d test period. These data suggest that pigs can exhibit compensatory responses to varying CP levels and can perform as well as pigs fed diets with more constant levels of CP.

Key Words: Protein Level, Pigs, Compensatory Growth

622 Determining the optimum dietary tryptophan to lysine ratio in 25 to 40 kg growing pigs. A. D. Quant*[1], M. D. Lindemann[1], G. L. Cromwell[1], B. J. Kerr[2], and R. L. Payne[3], [1]*University of Kentucky*, *Lexington*, [2]*USDA*, *Ames, IA*, [3]*Degussa Corporation*, *Kennesaw, GA*.

There continues to be discussion regarding the optimum dietary Trp:Lys ratio in pigs. Some of the variation in results reported in the literature may be due to whether the ratios are stated on a total or digestible amino acid basis, and whether Lys was truly below a known requirement. After determination of a SID Lys requirement for similar size pigs, a 21-d study was conducted to determine the optimum standard ileal digestible (SID) Trp:Lys ratio in growing pigs fed a corn-soybean meal diet based on growth performance and plasma urea N (PUN) concentrations. Crossbred pigs (n=120; initial BW: 25.78 ± 2.47 kg) were blocked by gender and BW and allotted to 5 treatments with 5 pigs/pen. Graded levels of crystalline Trp were added to the basal diet, which contained 0.66% SID (0.75% total) Lys, to create various Trp:Lys ratios (SID/total basis; 12.43/14.22%, 13.92/15.54%, 15.42/16.86%, 16.92/18.18%, and 18.42/19.50%). Pigs were allowed ad-libitum access to feed and water throughout the entire experimental period. Following evaluation of the linear and quadratic nature of the responses by ANOVA, broken-line regression analysis was used to determine the optimum Trp:Lys ratio. As the SID Trp:Lys increased from 12.43% to 18.42%, ADG increased (0.56, 0.65, 0.79, 0.79, and 0.81 kg/d) linearly ($P < 0.001$) and quadratically ($P = 0.009$) with an optimum SID Trp:Lys ratio estimate for ADG of 15.70% ($P < 0.001$). ADFI increased (1.31, 1.46, 1.73, 1.67, and 1.73 kg/d) linearly ($P < 0.001$) and quadratically ($P = 0.007$) with an optimum SID Trp:Lys ratio of 15.50% ($P < 0.001$). Feed:gain decreased (2.34, 2.27, 2.19, 2.16, and 2.13 kg/d) linearly ($P < 0.001$) but not quadratically ($P = 0.36$). PUN decreased (10.43, 9.30, 8.21, 8.55, and 9.25 mg/dL) linearly ($P = 0.069$) and quadratically ($P = 0.015$) and the optimum SID Trp:Lys ratio was 15.64% ($P = 0.007$). The overall optimum SID Trp:Lys ratio was determined as 15.61% based on the mean of the estimates for growth performance and PUN concentrations which equates to 17.02% on a total amino acid basis.

Key Words: Lysine, Tryptophan, Pigs

623 Tryptophan improves weight gain associated with increased plasma ghrelin level induced by oral ingestion of tryptophan in weaned pigs. J. Yin*, H. Zhang, and D. Li, *China Agricultural University*, *Beijing, China*.

Two experiments were conducted to determine whether ghrelin, a 28-amino acid peptide produced mainly by the stomach, was involved in tryptophan-mediated growth stimulation in swine. In experiment one, 48 crossbred barrows (8.23±0.13 kg) were housed individually and randomly allotted to 6 treatments with a 2×3 factorial design to test the effects of food intake (ad lib vs. limit fed) and tryptophan level (0.12, 0.19 and 0.26%) on growth performance. At the end of the 21-day experiment, plasma was sampled and insulin and acylated ghrelin were assayed using commercial available kits. Ad lib fed pigs gained more weight, but had poorer feed conversion than limit fed pigs. Weight gain, food intake and feed conversion all improved with increased dietary tryptophan. In limited fed groups, pigs pair-fed the same amount of feed whose weight gain was improved by 0.19 and 0.26% tryptophan diet relative to 0.12% tryptophan diet. Ad lib feeding increased plasma insulin. However, plasma insulin was unaffected by the level of dietary tryptophan. Plasma ghrelin levels and ghrelin mRNA level in gastric fundus and duodenum were significantly higher in pigs fed 0.19 and 0.26% tryptophan diet compared with pigs fed 0.12%. In the second experiment, 18 weaned crossbred barrows were divided into three treatments involving oral infusion of saline, tryptophan (40 mg/kg BW) or 5-Hydroxytryptophan (40 mg/kg BW). After 7-day interval, pigs were subjected to jugular vein infusion of the same amount of saline, tryptophan or 5-hydroxytryptophan. Plasma ghrelin levels at 20, 40 and 60 min after treatment were increased by oral ingestion rather than vein infusion of tryptophan. Oral ingestion of tryptophan increased food intake 2, 8, and 24 hrs after ingestion.

Both oral ingestion and jugular vein infusion of 5-hydroxytryptophan induced lower food intake than the saline control. In conclusion, tryptophan increased weight gain and food intake may be induced by raised plasma ghrelin which triggered by oral ingestion rather than jugular vein infusion of tryptophan.

Key Words: Tryptophan, Ghrelin, Growth

624 Nitrogen balance, ammonia and odor emissions in growing pigs fed reduced crude protein diets. D. V. Braña*[1,2], H. A. Rachuonyo[1], and M. Ellis[1], [1]*University of Illinois*, *Urbana*, [2]*INIFAP*, *Queretaro, Mexico*.

The effect of reducing dietary CP level in the diet of growing pigs (20.5 ±1.8 kg) was evaluated in two experiments. The treatments consisted of 2 diets formulated to contain either a normal or a reduced CP level (19 or 14%), where the true ileal digestible lysine (0.85%), energy level (3.33 Mcal ME/kg), and ideal AA patterns (Lys, Thr, Met, and Trp) were kept constant. Study 1 was conducted to measure the amount of nitrogen loss as aerial ammonia and odor offensiveness in the air from pigs (n=24; from 17.9 ±0.76 to 30.5 ±1.02 kg of BW) confined in dynamic airflow chambers for 21 days. Study 2 was carried out using the same diets, to evaluate the impact on N balance from pigs (n=24; from 17.7 ±1.29 to 21.4 ±1.72) confined individually in metabolic crates. In Study 1, reducing dietary CP did not affect ($P > 0.05$) growth performance, but tended to decrease the slurry pH ($P = 0.09$) from 6.7 to 6.2 ±0.18. There was an interaction ($P < 0.001$) between diet and sampling day; initial ammonia levels were similar ($P > 0.1$) for the two dietary treatments, however, after 10 d on the study ammonia levels were lower ($P < 0.001$) for the reduced crude protein diet. Odor analyses from samples taken on d 14 and 21, assessed by olfactometry with an 8-member panel, did not differ by treatment (511.7 and 540.0 ±115.58 odor threshold, respectively, for the reduced and normal CP diets; $P > 0.2$), but did differ ($P < 0.01$) by sampling day, as the odor intensity in both diets increased with time (440.1 and 611.6 ±111.29 threshold values at day 14 and 21, respectively). For Study 2, N intake was reduced 26.6% ($P < 0.001$) by the reduced CP diet. Fecal N excretion was similar ($P > 0.2$) for both diets, however, urinary N excretion differed ($P < 0.001$). Reducing CP decreased ($P<0.001$) urinary N excretion by 56% and total N excretion by 41%. Overall, every one percentage unit reduction in CP (combined with AA supplementation) lowered total N losses (fecal + urinary) by 8% and ammonia production by 15%, but did not change odor intensity.

Key Words: Ammonia, Odor, Nitrogen Balance

625 Performance of pigs fed diets supplemented with DL-Methionine or liquid MHA-FA from 6 - 25 kg. O. S. Santos*[1], A. B. Borbolla[1], A. P. Pineda[1], R. F. Flores[1], A. P.-S. Pineli-Savedra[2], and D. H. Hoehler[3], [1]*Universidad Nacional Autónoma de México*, *Mexico City, Mexico*, [2]*CIAD*, *Hermosillo, Sonora, Mexico*, [3]*Degussa Corporation*, *Kennesaw, GA*.

One hundred and fifty weaned pigs (6.3 ± 1.3 Kg) were randomly allocated into five different treatments consisting of a control diet, and two sources (DL–Met or liquid methionine hydroxy analog MHA-FA), with two levels each of methionine. Pigs were fed a phase 1 (6–8 Kg), phase 2 (8–12 kg) and a phase 3 diet (12 – 25 kg). Lysine (%) and ME (Mcal/kg) of phase 1, 2 and 3 diets were 1.64/3.4; 1.42/3.4 and 1.28/3.3, respectively. Graded levels of DL–Met (treatments 2 and 3) and liquid MHA–FA (treatments 4 and 5) were supplemented at 65/100% corresponding weight/weight ratios. Feeding period was 8 days each for phases 1 and 2, and 20 days for phase 3. Data were subjected to GLM and LSM procedures of SAS. In phase 1, ADG was lowest ($P \leq 0.05$) for control pigs with no significant differences among the other treatment groups (212, 303, 285, 297 and 254 g/d for Trt 1, 2, 3, 4 and 5). ADFI was not different in any treatment evaluated (367, 392, 372, 383 and 367 g/d, for Trt 1, 2, 3, 4 and 5). FC was higher ($P \leq 0.05$) for control, with no difference in the other treatments (1.7, 1.3, 1.3, 1.3, 1.5 for Trt 1, 2, 3, 4, and 5). In phase 2, ADG was not different among Met-included groups, however, control pigs showed a reduced ($P = 0.08$) gain (430, 507, 508, 493 and 512 g/d for Trt 1, 2, 3, 4 and 5). ADFI was not affected by either source or level of Met (695, 728, 740, 732, and 747 g/d for Trt 1, 2, 3, 4 and 5). No differences were detected among the sources or levels of Met (1.6, 1.5, 1.5, 1.5 and 1.5 for Trt 1, 2, 3 , 4 and 5). In phase 3 –in contrast to previous phases– ADG was not different between control and treatment groups (562, 585, 577, 578 and 560 g/d for Trt 1, 2, 3, 4 and 5). ADFI increased ($P \leq 0.05$) when Met was included in treatment 2 and 4, as compared to control pigs (1038 and 1030 vs. 955 g/d, respectively). Trt 3 and 5 was not different to control. FC was not significantly influenced by either treatment (1.7, 1.8, 1.7, 1.8, 1.8 for Trt 1, 2, 3, 4 and 5).

Key Words: DL-Methionine, Pigs, MHA-FA

626 Low protein diets for pigs treated with ractopamine. G. E. Lanz A*[3,1] and J. A. Cuaron I[2], [1]*Paiepeme A.C.*, *Queretaro, Mexico*, [2]*CNI-Fisiologia Animal, INIFAP*, *Queretaro, Mexico*, [3]*FESC UNAM*, *Ajuchitlan, Queretaro, Mexico*.

The aim of this experiment was to demonstrate that RAC may be used with diets containing less than 16% crude protein (CP), as long as a 0.82% level of true ileal digestible lysine (LysD) is kept and the relation with the other limiting amino acids is maintained, obtaining favorable results for lean tissue gain. A total of 40 barrows were used with an initial weight of 80 ± 8.95 kg. Animals were allotted to 4 treatments 1) Positive Control: 16% CP + 0.60% LysD; 2) Negative Control: 14% CP + 0.60% LysD; 3) RAC normal protein: 16% CP + 0.82% LysD + RAC; 4) RAC lower protein: 14% CP + 0.82% LysD + RAC, each with 10 replicates per treatment. The RAC dosage was 5 ppm for the first 14 days and 10 ppm for the last 7 days. Levels of LysD were established as the population's requirement and according to the expected response of lean growth by RAC. According to LysD, limiting amino acids were included in concentrations sufficient to meet an Ideal Protein pattern, for control pigs, and adjusting the Threonine:Lysine ratio to 64% for pigs treated with RAC. Pigs were weighed every 7 days until the end of the experiment. Daily feed intake (DFI), daily bodyweight gain (DBG), feed efficiency (GxF), and daily lean tissue gain (DLTG), were estimated. Animals were humanly sacrificed to estimate carcass and industrial lean cuts yield. There were no differences by protein level and there were no interactions between RAC and protein level ($P \geq 0.05$). The RAC effects were clear, despite the protein level in diet. In both treatments with RAC, body weight gain (ADG), was improved by 11%; feed efficiency was improved by 15%, and FFLG was improved by 39%, compared to pigs not fed RAC. Also RAC improved carcass yield (head and feet on) by more than 1 percent unit; RAC augmented carcass lean cuts by more than

4 kg. Since there were no differences between treatments with RAC, but there were differences with those that did not contain RAC, we conclude that it is possible to use RAC with diets containing less than 16% CP.

627 Effects of ractopamine level and feeding duration on the performance and carcass characteristics of late finishing market pigs. C. W. Parks*[1], G. L. Allee[2], R. B. Hinson[2], and S. N. Carr[1], [1]*Elanco Animal Health*, *Greenfield, IN*, [2]*University of Missouri*, *Columbia*.

A study was conducted to evaluate the effects of Ractopamine HCl (RAC; Elanco Animal Health, Greenfield, IN) on the performance and carcass characteristics of late-finishing pigs. A total of 1,680 pigs w/ an average BW of 101 kg were used in a 3x2x2 factorial design consisting of 3 RAC levels (0, 5, and 7.4 ppm RAC), 2 RAC feeding durations (21 or 28 d prior to slaughter), and 2 genders (barrows and gilts). Diets were corn-soybean meal based and were formulated to contain 0.94% TID lysine. There were no dose x duration, nor gender x dose interactions; therefore, main effects of dose are presented. Pigs fed 5 and 7.4 ppm RAC had greater ADG (P<0.0001) and G:F compared to controls (P<0.0001). In addition, pigs fed 7.4 ppm had improved ADG (P<0.0001) and G:F (P<0.0001) as compared to pigs fed 5 ppm RAC. Feed intake was unaffected by treatment (P<0.14). Carcass data indicated an increase in HCW (P<0.0001) and yield (P<0.03) in RAC-fed pigs compared to control pigs. There were no differences observed in back fat depth due to treatment (P<0.18). However, there was an increase in LM depth due to both RAC treatments compared to controls (P<0.0001), as well as a significant improvement in lean percentage when feeding 5 ppm RAC compared to controls (P<0.05). These results indicate that RAC at 5 and 7.4 ppm improve the growth performance and carcass characteristics of late-finishing pigs.

Effects of ractopamine dose on performance and carcass characteristics

Measurement	0 ppm RAC	5 ppm RAC	7.4 ppm RAC	SEM
ADG, kg	0.76[a]	0.85[b]	0.91[c]	0.010
ADFI, kg	2.57	2.56	2.60	0.017
G:F	0.30[a]	0.33[b]	0.35[c]	0.003
HCW, kg	89.7[a]	92.2[b]	93.6[c]	0.405

628 The effect of dietary lysine or methionine and copper/manganese on osteochondrosis lesions and cartilage properties in pigs. N. F. Frantz*, J. L. Nelssen, G. A. Andrews, M. D. Tokach, S. S. Dritz, R. D. Goodband, and J. M. DeRouchey, *Kansas State University*, *Manhattan*.

An 84-d growth study with 120 gilts (initially 40.5 kg BW, 10 replications with 2 gilts per pen) was conducted to determine the influence of dietary lysine level and added methionine, copper, and manganese on osteochondrosis (OCD) occurrence in swine. Gilts were fed below (0.71% phase I and 0.53% phase II), at (0.89% phase I and 0.71% phase II), or above (1.16% phase I and 0.98% phase II) their requirement for true ileal digestible lysine (Lys) with standard concentrations or high added methionine (1%), Cu (250 ppm) and Mn (220 ppm) in a 3 × 2 factorial. At the end of the experiment, the distal aspect of the left humerus and femur of 60 gilts (one per pen) was evaluated for incidence of OCD and cartilage samples tested for compression and shear properties. Each joint was sliced into 3 mm sections and given a severity score for abnormalities on the external joint, the underlying articular cartilage surfaces, and physeal growth plate. Increasing dietary Lys increased (P < 0.01) ADG, but feeding high Met/Cu/Mn decreased ADG (P < 0.02). In pigs fed standard Met/Cu/Mn, increasing dietary Lys decreased cartilage shear energy (quadratic, P < 0.01); however, no other instron measurements were affected by Lys (P > 0.24). The addition of high Met/Cu/Mn had no effect on any cartilage instron measurements (P > 0.23). All animals had OC lesions at either the humerus or femur. Overall severity score did not correlate with ADG (R2 = 0.03) or weight (R2 = 0.02). Increasing dietary Lys concentration (P > 0.64) did not effect the overall severity score (abnormalities × severity); however, the addition of high Met/Cu/Mn tended (P < 0.09) to reduce the overall severity score of OC compared to pigs fed diets with normal Met/Cu/Mn. Feeding growing gilts to maximize growth performance with high dietary Lys may increase the severity of OC lesions, while a diet with additional Met/Cu/Mn above requirements may aid in the reduction of OC abnormalities and severity.

Key Words: Finishing Pigs, Osteochondrosis, Cartilage

629 Effects of different Ractopamine withdrawal times on growth performance and fat free lean growth rate in finishing pigs. G. E. Lanz A*[3,1], M. Lucero P[3,1], and J. A. Cuaron I[2], [1]*Paiepeme A.C.*, *Queretaro, Mexico*, [2]*CNI-Fisiología Animal, INIFAP*, *Queretaro, Mexico*, [3]*FESC UNAM*, *Ajuchitlan, Queretaro, Mexico*.

Some programs for the use of Ractopamine–HCl (RAC) include resting periods to avoid receptors saturation. To identify the effects of RAC withdrawal on growth performance and fat free lean growth rate in finishing pigs, 159 pigs (BW = 82 kg) half gilts and barrows, were allotted to 3 diets: 1) Control: 3.35 Mcal ME and 17%CP; 2) RACHP: 3.35 Mcal, 19%PC, 10ppm RAC; 3)RACNP: as control plus 10 ppm RAC. After 21d on trial, all the animals changed to a finisher diet (3.35 Mcal ME/kg, 15%CP, 0.67% digestible Lys) consumed by 0, 7, 14, 21 or 28 d. After each withdrawal time animals were removed from the experiment (5 animals per withdrawal time per diet). Growth performance (ADFI, ADG, and Feed:Gain), and real time ultrasound (Aloka 500) measurements (back fat and loin depth) were taken weekly to estimate lean growth rate. After 21d on Study, RAC pigs were heavier (P≤0.001) than CON pigs; animals on RACNP consumed more feed than RACHP (3.23 vs 3.07 kg/day, respectively, P≤0.05). There was no difference in ADG or Feed:Gain by CP level, but between RAC and CON pigs (P≤0.001). The RAC diets improved FFLG (0.352 vs 0.430 kg/day P≤0.001) compared to CON pigs, but no differences

(P≥0.05) by CP level were detected. After 7 d of RAC withdrawal, ADG was depressed (P≤0.01) compared to CON pigs (0.650 vs 0.836 kg/day, respectively). However, no differences (P≥0.05) were detected at any time during RAC withdrawal for ADFI, F:G back fat or loin depth, as RAC pigs equal CON pigs' growth performance after day 7. The drop in ADG (after 7d) that resulted from RAC withdrawal, denied the advantages of RAC use, this should be considered in use–rest–use programs to establish a resting period no longer than 7 days.

Key Words: Ractopamine, Withdrawal, Finishing Pigs

Nonruminant Nutrition: Understanding Protein Synthesis and Degradation and Their Pathway Regulations

630 Postnatal ontogeny of skeletal muscle protein synthesis in pigs. T. A. Davis*, A. Suryawan, R. A. Orellana, and M. L. Fiorotto, *USDA/ARS Children's Nutrition Research Center, Baylor College of Medicine*, *Houston, TX*.

The neonatal period is characterized by rapid growth and elevated rates of synthesis and accretion of skeletal muscle proteins. The fractional rate of muscle protein synthesis is very high at birth and declines rapidly with development. The elevated capacity for muscle protein synthesis in the neonatal pig is driven by the high ribosome content and, together with an increased efficiency of the translation process, promotes accelerated protein synthesis rates. Feeding profoundly stimulates muscle protein synthesis in neonatal pigs and the response decreases with age. The feeding-induced stimulation of muscle protein synthesis is modulated by an enhanced sensitivity to the post-prandial rise in insulin and amino acids. The developmental decline in the response to insulin and amino acids parallels a marked fall in the feeding-induced activation of translation initiation factors that regulate the binding of mRNA to the 40S ribosomal complex. The abundance and activation of many known positive regulators of the nutrient- and insulin-signaling pathways that are involved in translation initiation are high and that for many negative regulators are low in skeletal muscle of younger pigs. Thus, the activation and/or abundance of the positive regulators, insulin receptor, insulin receptor-substrate-1, phosphoinositide-3 kinase, phosphoinositide-dependent kinase-1, protein kinase B, mammalian target of rapamycin, raptor, ribosomal protein S6 kinase-1, eukaryotic initiation factor (eIF) 4E-binding protein 1, and eIF4E associated with eIF4G are greater in 7- than in 26-day-old pigs. The activation of negative regulators, protein tyrosine phosphatase-1B, PTEN, protein phosphatase 2A, and tuberous sclerosis complex 1/2 are lower in 7- than in 26-day-old pigs. The developmental changes in the abundance and activation of these signaling components likely contribute to the high rate of protein synthesis and rapid gain in skeletal muscle mass in neonates. 631 Measuring in vivo intracellular protein degradation rates in animal systems. W. G. Bergen*, *Auburn University*, *Auburn, AL*.

Whole body protein degradation, synthesis and accretion have been determined in animals utilizing isotopic tracers and urinary excretion of irreversible skeletal muscle metabolic end-products combined with various techniques to estimate changes in body protein content. Method refinements have centered on improvements of whole body isotope-kinetic approaches and explorations of tissue specific protein turnover of liver, small intestines and skeletal muscle proteins or specifically myofibrillar, sarcoplasmic, and connective tissue protein fractions of skeletal muscles. Utilizing contemporary GC-MS technology and isotopic infusion strategies, direct measurement of fractional protein synthesis (FSR) with stable isotopes of branched chain amino acids coupled with tissue amino acid specific activity values based on keto leucine or keto valine has emerged as the most robust technique to measure FSR in various tissues in animals and humans. Direct measures of whole body protein degradation or fractional breakdown rate (FBR) based on skeletal muscle irreversible metabolite excretion, such as 3- methyl histidine (3MH), in pigs has severe limitations. Some workers have addressed direct measures of skeletal muscle protein breakdown in pigs utilizing 3MH with compartmental kinetic models, but regrettably such procedures have not widely utilized. Contrariwise, the urinary 3MH excretion method has some merit in ruminants. Our understanding of the mechanisms and regulation of protein synthesis and protein breakdown has advanced to a point where it may be possible to use surrogates/markers to provide directional data, either enhanced or attenuated, for FSR and FBR. Rates of expression or activation status of regulatory transcription factors, initiation factors or signal pathway components, such as mTOR, eIF-4 and PKB, and abundance of mRNA for components of the intracellular proteolytic pathways may be exploited to study relative rates of FSR, FBR, muscle growth and metabolic efficiency in food producing animals.

632 The non-lysosomal Ca^{2+}-dependent protein degradation pathway: The calpains, proteasome, and myofibrillar protein turnover. D. E. Goll*, G. Neti, S. W. Mares, and V. F. Thompson, *University of Arizona*, *Tucson*.

It is now clear that proteins in cells turnover metabolically, that the rate of this turnover can vary widely in response to physiological demand, and that turnover of proteins assembled in intracellular structures requires first disassembly of the proteins from the structure followed by their degradation. The proteasome is the major mediator of intracellular protein degradation, but the proteasome cannot degrade proteins assembled in intracellular structures, and the mechanism by which proteins are disassembled before their degradation remains unknown for most structures. It is also unclear how myofibrillar proteins, which must be assembled in myofibrils to be functionally contractile, are removed from this structure before degradation. It was proposed over 30 years ago that the calpains may initiate myofibrillar protein turnover by removing an outer layer of filaments from myofibrils, and that the calpain-removed proteins are then degraded by intercellular proteases, predominantly the proteasome. Studies have reported that striated muscle contains a group of myofilaments, ~ 10-15% of total myofibrillar protein, that can be released from myofibrils by triturating in the presence of ATP. These easily releasable myofilaments (ERMs)

are postulated to be intermediates in myofibrillar turnover. It is unclear whether ERMs are indeed a subset of myofilaments on the surface of myofibrils or whether they are simply removed by shearing during trituration and more filaments can be removed by repeated trituration. We have found that ERMs can be prepared from either rat or bovine muscle; that the yield is less than previously reported (0.5-0.8 % of myofibrillar protein); that once removed, repeated trituration does not yield more ERMs; and that ERMs can not be obtained from thoroughly washed myofibrils where presumably the ERMs have already been removed. Hence, ERMs seem to be a real subset of filaments. Mild treatment with calpain increases the yield of ERMs by 2 to 2.5-fold, so the calpains can release ERMs as proposed over 30 years ago. Supported by NRI, NIH, MDA.

Key Words: Calpain, Proteasome, Myofibrillar Protein

633 The mTOR-signaling pathway in regulating metabolism and growth. X. Yang*, C. Yang, A. Farberman, C. F. M. de Lange, J. France, and M. Z. Fan, *University of Guelph*, *Guelph, Ontario, Canada*.

The mammalian target of rapamycin (mTOR) plays key roles in cell growth and the cell cycle and acts as a central regulator of protein synthesis and ribosome biogenesis at transcriptional and translational levels. mTOR senses and integrates signals from mitogens and nutrients. Ribosomal protein S6 protein kinase S6K1 and eukaryotic initiation factor 4E binding protein 4E-BP1 are currently the two best-known downstream effectors of mTOR signaling. Interactions of mTOR with raptor or rictor result in two types of mTOR complexes with the former being the primary controller of cell growth and the latter mediating effects that are insensitive to rapamycin such as cytoskeletal organization. Upstream elements of mTOR signaling include Ras-homolog enriched in brain (Rheb), and tuberous sclerosis complex 1 and 2 (TSC1/2) with TSC2 as the linker between PI3K/Akt or Ras/Raf/MEK/ERK pathways and the mTOR pathway. AMP activated kinase (AMPK), an important cellular energy sensor, can work with mTOR signalling to maintain cellular energy homeostasis. Nutrients and hormonal factors can differentially mediate metabolism and cellular growth via the mTOR pathway with effectors specific to organ or tissue types involved.

Key Words: Growth, Metabolism, Mammalian Target of Rapamycin (mTOR)

634 Relationship between leptin and carcass quality and yield grade in a population of Certified Angus Beef–type cattle. D. L. McNamara*[1], T. B. Schmidt[3], E. L. Walker[4], M. M. Rolf[1], A. N. Brauch[1], W. Pittroff[2], and D. H. Keisler[1], [1]*University of Missouri*, *Columbia*, [2]*University of California*, *Davis*, [3]*Mississippi State University*, *Starkville*, [4]*Missouri State University*, *Springfield*.

Leptin is a protein hormone secreted by adipocytes. Serum concentrations of leptin increase with adiposity in various species, including beef cattle. In this investigation, we utilized a relatively uniform population of cattle — i.e. those destined for a Certified Angus Beef–type market, to determine the relationship between serum concentrations of leptin and phenotypic variables associated with carcass quality. This work differs from our prior investigations in which we utilized a non–uniform and random population of cattle from a commercial slaughter facility. Our hypothesis was that serum concentrations of leptin would be higher in heifers than steers and that serum concentrations of leptin would be an accurate, positive indicator of carcass quality and yield grades in a Certified Angus Beef–type population of cattle. In the current investigation blood samples were collected at slaughter and analyzed for serum concentrations of leptin from 2,815 black slaughter steers and heifers. The PROC GLM method of SAS was used with leptin as the dependent variable and all carcass merit variables analyzed as independent variables within the model. Any independent variables that were not significant within the model were removed from the final analysis. We observed that leptin levels were significantly greater in heifers than steers (25.12 vs 20.94 ng/ml, respectively; $P < 0.0001$). Independent of gender however, leptin concentration at the time of slaughter was a significant predicative indicator of the carcass quality grades: select, low choice, upper two-thirds choice, high choice, and prime (20.60, 22.16, 23.38, and 25.99 ng/ml, respectively; $P < 0.006$). Likewise, USDA Yield grades were resolvable by leptin levels at Yield grades 2, 3, and 4 (20.95, 23.32, and 25.74, respectively; $P < 0.001$), but incapable of resolving Yield grade 4 vs. 5 cattle — a threshold point (yield grade >3) at which carcasses typically begin to be discounted for excessive fat. We suggest that these data provide evidence that serum concentrations of leptin are indicative of the greater fat mass across gender and carcass merit.

Key Words: Leptin, Adipose, Carcass

635 Variation in maintenance energy requirements of gestating beef cows and relationships with calf performance and plasma IGF-I. M. J. Prado-Cooper*, N. M. Long, R. P. Wettemann, G. W. Horn, L. J. Spicer, and C. R. Krehbiel, *Oklahoma Agricultural Experiment Station*.

Variation in maintenance energy requirements (MR) was determined in spring-calving Angus × Hereford cows during gestation in each of two years (yr 1, n = 27; yr 2, n = 32). A second objective was to determine if MR were related to plasma concentrations of IGF-I and postnatal calf growth. Nonlactating cows (4 to 7 yr of age) with a BCS of 5.0 ± 0.2, and BW of 582 ± 37 kg, in the second to third trimester of gestation, were individually fed a complete diet in amounts to meet predicted MR (Model 1, NRC 2000). After 2 wk, daily feed intake was adjusted each 7 d until constant BW was achieved. Regression analysis was used to determine constant BW. Final BCS averaged 5.0 ± 0.2 (yr 1) and 4.6 ± 0.4 (yr 2). Daily MR averaged 0.0892 (yr 1) and 0.0930 (yr 2) (Mcal/$BW_{kg}^{.75}$). Cows were classified based on MR as low (> 0.5 SD less than mean, L), moderate (± 0.5 SD of mean, M) or high (> 0.5 SD more than mean, H). The greatest differences in MR for all cows were 29% (yr 1) and 24% (yr 2). ADG and IGF-I were

analyzed using the GLM and MIXED procedures (SAS), respectively. In yr 1, 205 d BW of calves (200 kg) was not influenced by MR. Plasma concentrations of IGF-I (yr 2), after consuming NRC predicted MR, were greater ($P < 0.005$) for M cows (66.5 ± 4.8 ng/mL) compared with L cows (38.9 ± 5.7 ng/mL), and H cows (52.8 ± 4.8 ng/mL) were not different from M or L cows. After 3 wk of constant BW, concentrations of IGF-I were not different ($P = 0.14$) among L, M and H cows (40.2, 52.1 and 51.2 ± 4.4 ng/mL, respectively). Concentrations of IGF-I in plasma were not correlated with dietary intake (Mcal/d) or BW. With ad libitum intake (yr 2), ADG of the cows was influenced by MR; L cows had less ($P < 0.01$) ADG compared with M and H cows (1.0, 1.4, 1.6, ± 0.3 kg/d, respectively). Variation in MR of cows during gestation was not associated with performance of calves. Identification of cows that require less energy to maintain weight may increase efficiency of production.

Key Words: Maintenance, Beef Cattle, Calves

636 Negative energy balance increases prandial ghrelin and growth hormone concentrations in lactating dairy cows. B. J. Bradford* and M. S. Allen, *Michigan State University*, *East Lansing*.

The reported effects of feeding on growth hormone (GH) secretion in ruminants have been inconsistent, and may be influenced by energy status of animals. High-producing dairy cows in early lactation and late lactation were used to assess the effects of energy balance on temporal variation of plasma metabolites and hormones. Cows were fed a TMR once daily, and feed was withdrawn for 90 min prior to feeding. Beginning at the time of feed withdrawal, plasma samples were collected via jugular catheters hourly for 24 h. Concentrations of non-esterified fatty acids and GH were measured for all samples, while insulin, glucose, and acylated (active) ghrelin were quantified for 4 sample times around feeding. Blood plasma data was analyzed using a mixed model with repeated measures over time. As expected, calculated energy balance was significantly lower in early lactation than late lactation cows (-10.4 vs. 1.7 Mcal retained /d, $P < 0.001$). Following the primary meal of the day, a GH surge was observed in early lactation but not in late lactation cows (time × stage of lactation interaction: $P < 0.01$). This difference was not explained by temporal patterns in non-esterified fatty acid, insulin, or glucose concentrations. However, a preprandial ghrelin surge was observed in early lactation only (76.8 vs. 40.1 pg/mL, $P < 0.05$), suggesting that ghrelin was responsible for the prandial GH surge in this group. Results of a stepwise regression statistical analysis showed that both preprandial ghrelin concentration and energy balance were significant predictors of prandial GH increase over baseline. Adaptations to negative energy balance in lactating dairy cattle likely include enhanced ghrelin secretion and greater GH response to ghrelin.

Key Words: Fhrelin, Growth Hormone, Energy Balance

637 Effect of ghrelin and obestatin infusion on milk production, body condition score, and energy balance in dairy cows. J. R. Roche*[1,2], A. J. Sheahan[1], L. M. Chagas[1], D. Blache[3], D. P. Berry[4], and J. K. Kay[1], [1]*Dexcel*, *New Zealand*, [2]*University of Tasmania*, *Australia*, [3]*University of Western Australia*, *Australia*, [4]*Teagasc Moorepark*, *Ireland*.

Ghrelin is an endogenous ligand of the growth hormone secretagogue receptor and a potential orexigenic agent in monogastrics and ruminants. Obestatin has been reported to have the opposite effect, reducing appetite. Fifty one multiparous cows were randomly allocated to one of three groups (n=17 cows/treatment); a control (C) and cows continuously infused with either 0.74 μmol/d of ghrelin (G) or obestatin (O) subcutaneously. Infusions began 20 days in milk and treatments continued for 8 wk. Milk yield was recorded daily and milk composition weekly. Blood was sampled every two wk. Generalized linear models were used to determine the treatment effect on average daily and cumulative milk production and daily composition, plasma ghrelin, growth hormone, IGF-1, leptin, NEFA and glucose. Mixed models, with cow included as a repeated effect, were used to determine treatment effects on weekly milk production, body weight and body condition score (scale 1-10). Parity, breed, wk of the yr at calving, treatment, wk post-calving and the 2 wk pre-experimental average of each measure (covariate) were included as fixed effects. Despite a numerical tendency for G cows to produce more milk (1,779kg) than either C (1,681kg) or O (1,714kg) cows during the eight wk period, differences were not significant ($P=0.39$). Similarly, there was no significant effect of treatment on milk fat, protein or lactose per cent or yield. Similarly, treatment did not affect DMI. Cows infused with G lost significantly ($P<0.05$) more BCS (0.68 BCS units) over the 8 wk study period than the O infused (0.40 BCS units) or C (0.25 BCS units), which did not differ significantly from each other. Treatment had no significant effect on BW change. Although, treatment did not significantly affect plasma ghrelin, IGF-1, or growth hormone concentration, plasma NEFA concentration was elevated ($P<0.05$) and there was a tendency ($P<0.10$) for plasma leptin to be reduced in G cows. Results indicate an effect of ghrelin infusion on lipolysis.

Key Words: Ghrelin, Obestatin, Dairy

638 Expression of ghrelin and the growth hormone secretagogue receptor 1a (GHS-R1a) in the reproductive tissues of Holstein heifers. M. L. Rhoads*, J. B. Wheelock, L. L. Hernandez, R. P. Rhoads, and R. J. Collier, *University of Arizona*, *Tucson*.

The hormone ghrelin and the active form of its receptor (growth hormone secretagogue receptor 1a; GHS-R1a) are expressed in the reproductive tissues of several species and may be involved in the metabolic regulation of reproductive function. However, little is known about the expression of ghrelin and GHS-R1a in the reproductive tissues of dairy cattle. The objective of this study was to characterize the expression of ghrelin and GHS-R1a in the reproductive tissues of dairy cattle. Reproductive tissues (follicle, CL, ampulla, isthmus, uterine horn, endometrium and uterine body) were collected from three Holstein heifers immediately following slaughter. Samples of the GI tract (reticulum, rumen, omasum, abomasum, duodenum, jejunum, ileum and colon) were simultaneously collected for comparative purposes. Ghrelin and GHS-R1a mRNA abundance were evaluated by real-time RT-PCR. Within the reproductive tract, ghrelin and GHS-R1a gene expression was detectable in all tissues with the greatest expression in the ampulla (0.99 ± 0.09 and 1.94 ± 0.14 AU, respectively; $P<0.001$). Ghrelin expression did not differ based on proximity to the corpus luteum. However, GHS-R1a expression was lower in the ipsilateral ampulla than in the contralateral ampulla (1.14 ± 0.20 vs. 2.75 ± 0.20 AU; $P<0.02$). GHS-R1a mRNA was detected in bovine oocytes and IVF-produced d 8 embryos whereas ghrelin expression was detectable, but low. Among the GI tissues, ghrelin

expression was greatest in the duodenum (12.71 ± 0.65 AU; P<0.001) and was also high in the abomasum (3.27 ± 0.65 AU; P<0.13) while, numerically, GHS-R1a mRNA concentrations were greatest in the ileum (4.45 ± 0.37 AU) and jejunum (3.88 ± 0.37 AU). Both ghrelin and GHS-R1a are expressed throughout the reproductive tract, albeit at lower concentrations than in some GI tissues. The observed patterns of expression suggest that the metabolic regulation of reproduction may be mediated through ghrelin signaling during the early stages of embryo development.

Key Words: Ghrelin, GHS-R1a, Dairy Cattle

639 Seasonal effects on twenty-four hour patterns of melatonin in blood and milk of dairy cows. N. Castro*[1,2], M. T. Kollmann[3], V. Lollivier[4], S. Richter[1], A. Baumert[1], O. Wellnitz[1], and R. M. Bruckmaier[3], [1]*University of Bern*, *Bern, Switzerland*, [2]*Las Palmas de Gran canaria University*, *Las Palmas, Spain*, [3]*Technical University Munich*, *Germany*, [4]*INRA*, *France*.

Pineal secretion of melatonin (MEL) is usually low during light exposure and high during the night. In this study MEL concentration in blood and milk was measured every h during 24 h (7.00 AM-6.00 AM) in June and December in 12 high yielding dairy cows which were housed under natural light conditions in Switzerland, i.e.at 16 and 9 h daylight respectively. Blood samples were taken and the whole available milk was collected by machine milking after an i.v. injection of 1 i.u. of oxytocin every h. No artificial light was used throughout the experiment except for small head lamps during sampling in the dark nights. MEL in blood and milk was determinated by ELISA. For all statistical analyses a general linear model procedure with repeated measures and post hoc Tukey analysis was used. Both MEL blood and milk concentration showed a diurnal pattern with high levels during scotoperiod and low levels during photoperiod. In June melatonin blood levels (pg/ml) were 2.3 ± 0.2 during the day (08.00 to 22.00 h), started to increase at 23.00 h (16.0 ± 3.8) and decreased to baseline at 07.00 h (5.3 ± 2.2). Peak MEL was observed at 01.00 h (25.3 ± 6.2). In December MEL blood levels increased already at 17.00 h (16.3 ± 3.3) and the decrease started at 07.00 h (12.2 ± 2.2) Peak MEL was 40.4 ± 5.2 at 22.00 h. Areas under the curve (AUC) were calculated for samples from 23.00 h to 06.00 h. AUC/h in blood and in milk was higher ($p < 0.05$) in winter than in summer (22.4± 2.4 and 16.2 ± 2.3, 7.2 ± 1.0 and 2.2 ± 0.5, resp.). In all individuals MEL was higher in blood than in milk in both seasons. AUC of milk melatonin concentration was 20 ± 7 % in summer and 35 ± 7 % in winter of the MEL in blood. In conclusion, milk MEL is elevated, in parallel with blood MEL, albeit at a lower level, most likely being transferred by the way of diffusion with water.

Key Words: Melatonin, Daylight, Milk

640 Effect of restricted feeding and monopropylene glycol postpartum on metabolic hormones and postpartum anoestrus in grazing dairy heifers. L. M. Chagas*[1], P. J. S. Gore[1], K. A. Macdonald[1], and D. Blache[2], [1]*Dexcel Limited*, *Hamilton, New Zealand*, [2]*The University of Western Australia*, *Crawley, Australia*.

Pastoral dairying in New Zealand requires a 12 months calving interval to balance cow nutrient demands with pasture growth, however, in 30% of cows postpartum anoestrous interval (PPAI) exceeds 80 days resulting in lost productivity. Supplementary feeding can overcome low pasture availability and a previous study showed that 250 ml of monopropylene glycol (MPG) given twice a day to Holstein-Friesian heifers calving in low body condition score (BCS; 2.8) reduced PPAI. In that study 82% of heifers given MPG were cycling by 12 weeks postpartum compared to 28% of controls. A further study was undertaken with MPG supplements and feed restriction using heifers calving in good BCS (3.1). Treatments comprised of *ad libitum* pasture (Adlib; n=18) and two groups given restricted pasture (RES; n=18) and restricted pasture with MPG (250 ml twice daily; RESM; n=13) given from calving for 150 days. *Ad libitum* feeding resulted in greater BW, milk, protein and fat yield than other groups (P<0.05). Plasma concentration of insulin, IGF-I, growth hormone (GH), leptin, glucose and non-esterified fatty acids (NEFA) were measured weekly. Treatment effects on these constituents were minor, with low concentrations of insulin at week 3 (P<0.05) and greater NEFA concentrations in weeks 2-5 than in the RES heifers than other groups (P<0.05). Restricted feeding lowered leptin concentration relative to Adlib group in weeks 3, 5-7 and 12, and at week 6 when compared to the RESM group (P<0.05). During the metabolic challenge with MPG insulin secretion was stimulated. In the present study there was no difference in PPAI among the groups. We concluded that the most important impact on PPAI in heifers is BCS at calving. Restricted feeding and MPG supplementation of heifers calving in good BCS, affects milk production rather than PPAI. Supplementation with MPG can reduce PPAI of heifers with low BCS (2.8), but when BCS is 3.1 supplements are of little benefit to pasture fed heifers.

Key Words: Postpartum Anestrous, Monopropylene Glycol, Dairy Heifer

641 Hypothalamic genes expression in early- and late-maturing *Bos indicus* heifers. A. Vaiciunas*[1], L. L. Coutinho[2], and L. F. P. Silva[1], [1]*University of São Paulo*, *Pirassununga, SP, Brazil*, [2]*University of São Paulo*, *Piracicaba, SP, Brazil*.

The molecular mechanism by which leptin signaling in the hypothalamus might permit the initiation of puberty has not been elucidated. One possible mechanism for leptin molecular action on the reproductive axis is affecting NPY signaling. It was our objective to test whether early-maturing *Bos indicus* heifers have altered expression of hypothalamic genes related to leptin signaling. Among a population of 500 heifers between 20 and 25 months of age, 100 heifers were selected base on breed attributes (Nelore), month of birth, and body weight (280 to 300 kg). These 100 heifers were scored as prepubertal or pubertal according to the presence or not of a palpable corpus luteum (CL). Ten heifers without a CL and ten heifers with a palpable CL received a prostaglandin injection, and according to visual observation of heat and rectal palpation, 6 prepubertal and 6 pubertal heifers were selected for the experiment. These 12 heifers were slaughtered and samples of hypothalamus were collected and frozen in liquid nitrogen. Expression of Ob-Rb, SOCS-3, NPY, NPY-Y1 and NPY-Y4 was quantified by real-time PCR using the ribosomal protein RP-L19 as a reference gene. Hypothalamic expression of Ob-Rb, SOCS-3 and NPY was not different between groups of heifers. It was thought that late-maturing heifers could be resistant to leptin due to an increased expression of SOC-3, or a decreased expression of Ob-Rb at the hypothalamus, but our results did not corroborate with this hypothesis. There was a tendency for NPY-Y1 and NPY-Y4 expression to be reduced in

heifers that reached puberty earlier (P=0,10). Expression of NPY-Y1 was 8.3-folds lower and NPY-Y4 expression was 14.3-folds lower in early-maturing than in late-maturing heifers. When analyzed together, there was an 11-fold reduction in NPY receptors expression in early-maturing heifers, and this effect was statistically significant (P=0.03). These results suggest that, because of the lower expression of NPY receptors, the hypothalamus of early-maturing heifers could be less sensitive to NPY inhibition, and therefore reach puberty with lower levels of circulating leptin.

Key Words: Bovine, Neuropeptide-Y, Puberty

642 Evaluating reproductive and immune consequences of endocrine disrupting chemicals in an avian bioassay. M. A. Ottinger*[1], E. T. Lavoie[1], and M. J. Quinn[2], [1]*University of Maryland, College Park*, [2]*U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen, MD*.

The avian embryo provides a self contained system for studying the consequences of exposure to endocrine disrupting chemicals (EDCs). Therefore, the avian embryo is an appealing ′bioassay′ for detecting EDC effects in birds. Japanese quail were used to evaluate endocrine disruption by several EDCs, including estradiol, trenbolone, vinclozolin, methoxychlor, DDE, atrazine, and PCB 126. A number of endocrine, neuroendocrine and immune endpoints were evaluated for endocrine disruption in the Japanese quail embryo, juvenile/maturing, and adult, including serum or fecal estradiol and androgen concentrations, histology and morphology of the bursa and gonad, and hypothalamic aromatase activity, monoamine content and GnRH-I concentration. Maturation and male mating behavior were evaluated post-hatch to compare discernable EDC effects in hatchlings compared to long-term effects impacting reproductive function in adults. Results showed that all chemicals impaired male sexual behavior, regardless of androgenic or estrogenic mode of action. The GnRH-I system in hatchlings was sensitive to many of the EDCs, with up to a 50% decrease in content at some EDC doses. Similarly, hypothalamic dopamine levels were decreased by some EDCs in hatchlings; fewer effects were observed in adults. Gonadal steroids and thyroid gland hormones were decreased with EDC exposures. Immune response show long-term effects of EDC exposure, relative to bursal morphology and antibody responses. Our data provide supporting evidence that even low level exposure to selected EDCs exerts effects on the development of the reproductive axis, with additional impacts on other physiological systems, including the immune system. The embryo appears to be more vulnerable than the adult to sublethal and low level exposure; possibly due to compensation of physiological systems as the animal matures. Multiple endpoints appear to be necessary for detection of endocrine disruption due to differing modes of action and toxicity of EDCs. Supported by EPA R826134010 (Star Grant), NSF 9817024, and EPA R-2877801(MAO).

643 Differential expression of adiponectin, adiponectin receptor 1 (AdipoR1) and leptin mRNA in different adipose depots in sheep. A. Lemor*[1], M. Mielenz[1], M. Altmann[2], E. von Borell[2], and H. Sauerwein[1], [1]*University of Bonn, Germany*, [2]*Martin-Luther-University, Halle-Wittenberg, Germany*.

The adipokines adiponectin and leptin are important in lipid metabolism and glucose homeostasis. Adiponectin is inversely related to leptin secretion and is associated with insulin resistance. Data on the expression of adiponectin and its receptor AdipoR1 are mainly limited to monogastric species, whereas for ruminants corresponding data are scarce. We aimed to characterize mRNA expression for adiponectin, AdipoR1 and leptin mRNA in different sheep fat depots. Subcutaneous (sc) and visceral (vc) fat was dissected from carcasses of 10 male crossbred sheep (40 kg b.w.). Sc fat was sampled at 3 different sites: close to the sternum (S), withers (W) and the base of the tail (T); vc fat was sampled from perirenal (P) and mesenteric (M) depots. The mRNAs of adiponectin, AdipoR1 and leptin were quantified by real-time RT-PCR. For adiponectin, no differences were found between depots (p=0.36); whereas AdipoR1 mRNA concentrations were higher ($p<0.05$) in P compared in W, T and M. Leptin mRNA concentrations were higher in S than in both vc depots ($p<0.05$). Sc leptin mRNA values were correlated with the total sc fat fraction of the carcass ($p<0.05$, r=0.41) but not with vc fat. In contrast, vc adiponectin tended to be correlated with the vc carcass fat (p=0.1, r=0.40) but not with sc. A trend for a correlation was found between AdipoR1 with adiponectin (p=0.08, r=0.36 (sc), p=0.09; r=0.41 (vc)) in both adipose depots. In conclusion, our findings indicate a constant expression of adiponectin mRNA in different sheep fat depots, which is in contrast to reports from monogastric species. AdipoR1 as well as leptin mRNA seems to be differentially expressed in different adipose depots of sheep.

Key Words: Adiponectin, Adiponectin Receptor 1, Leptin

644 Prolactin levels and ovulation rate in crossbreed ewes with induced oestrus during the anoestrous season and the effect of bromocryptine and naloxone. V. O. Fuentes-Hernandez*[1], R. Orozco[1], J. J. Uribe[1], V. M. Sanches[2], and P. I. Fuentes[3], [1]*Universidad de Guadalajara*, [2]*FMVZ Universidad Michoacana de San Nicolas Hidalgo*, [3]*Hospital Pemex Sur de Alta Especialidad Mexico DF*.

With the objective of studying the effect on naloxone and bromocryptine on the ovulation rate and the plasmatic levels of Prolactin in the crossbreed ewe during the anoestrous season. 40 crossbreed ewes were allocated at random in to four groups of 10. All ewes received an intravaginal sponge with 40 mg Medroxiprogesterone acetate for a period of 14 days and on sponge withdrawal 250 I.U. of Ecg was administered by intramuscular injection. During the period of sponge treatment, ewes were medicated as follows: Group 1 (n = 10) was treated with 0.5 mg bromocryptine im at 12 hour intervals. Group 2 (n = 10) was treated as group 1 and an implant of 15 mg of naloxone was applied subcutaneously. Group 3 received a subcutaneous implant of 15 mg NaloxoneGroup and group 4 (n = 10) was sham treated. In group 1 it was observed that bromocryptine decreased significantly ($p<$ .001 Prolactin plasma levels, In group 2 bromocryptine + Naloxone treated ewes plasma Prolactin levels were decreased significantly ($p<.001$) in a similar pattern as observed in group 1. In group 3 prolactine levels were decreased significantly ($p<.05$). Control group 4 prolactine levels remained unchanged. After sponge withdrawasl and eCG injection oestrus was present in all groups. 6 to 8 days after estrus CL were observed by laparoscopy under ketalar xylazne anaesthesia, ovulation rate in bromocriptine and control groups was not significantly different (2.1 ± .4 and 2.2 ± .5 respectively). In bromocryptine

naloxone and naloxone treated ewes ovulation rate was significantly increased as compared with controls (2.9 ± .5 and 3.1 ± .4 Respectively p< .01). It was concluded that endogenous opioids are important modulators of ovulation.

Key Words: Ewe, Estrus, Naloxone

645 Luteinizing hormone-releasing hormone immunization alters pituitary hormone synthesis and storage in bulls and steers. K. J. Wells*[1], T. W. Geary[2], D. M. de Avila[1], J. de Avila[1], V. A. Conforti[1], H. Ulker[1], D. J. McLean[1], A. J. Roberts[2], and J. J. Reeves[1], [1]*Washington State University*, *Pullman*, [2]*USDA ARS Fort Keogh*, *Miles City, MT*.

Objectives of this study were (1) to determine if trenbolone acetate (TBA) co-administered with LHRH immunization would suppress reproductive function in beef bulls and (2) to examine the effects of LHRH immunization and TBA treatment on pituitary function. To address these objectives 44 Angus x Hereford bull calves (mean BW = 225 ± 2 kg; mean age = 187 ± 6 d) were randomized into eight treatments in a 2 × 2 × 2 factorial experiment, with castration, LHRH immunization, and TBA administration as treatment factors. Calves immunized against LHRH received a primary injection of ovalbumin-LHRH-7 fusion protein on d 0, followed by two booster injections on d 42 and 196. Calves treated with TBA were implanted on d 224. Mean LHRH antibody binding activity in serum increased after each booster for immunized calves, but was negligible in non-immunized animals throughout the experiment. Concentrations of testosterone in serum were lower ($P < 0.0001$) by d 84 and scrotal circumference smaller ($P < 0.05$) by d 168 in LHRH immunized bulls compared to non-immunized bulls. Treatment with TBA tended ($P = 0.07$) to decrease concentrations of testosterone in serum from bulls. Testes + epididymides weights at slaughter (d 272) were lighter ($P < 0.0001$) for immunized compared to non-immunized bulls. Both LHRH immunization and castration resulted in decreased anterior pituitary stores of LH and FSH ($P < 0.001$). Immunization against LHRH suppressed expression of the LH β, and common α-subunit genes ($P < 0.0001$), while castration increased expression of the same two genes ($P = 0.02$). Synthesis and storage of LH and FSH, as measured by pituitary LH and FSH content and expression of the LH β-subunit and common α-subunit genes, was suppressed by LHRH immunization.

Key Words: LHRH Immunization, Trenbolone Acetate, Pituitary

646 Glial cell line-derived neurotrophic factor enhances porcine oocyte developmental competence in vitro. K. Linher*[1], D. Wu[1,2], and J. Li[1], [1]*University of Guelph*, *Guelph, Ontario, Canada*, [2]*Sichuan Agricultural University*, *China*.

The success of early embryonic development depends on oocyte nuclear and cytoplasmic maturation. We have investigated whether glial cell line-derived neurotrophic factor (GDNF) affects the in vitro maturation (IVM) of porcine oocytes and their subsequent ability to sustain preimplantation embryo development. GDNF and both its co-receptors, GDNF family receptor α-1 (GFRα-1) and the rearranged during transformation (RET) receptor were expressed in oocytes and their surrounding cumulus cells derived from small and large follicles. When included in IVM medium, GDNF significantly enhanced cumulus cell expansion of both small ($P<0.05$) and large ($P<0.001$) cumulus-oocyte complexes. It also significantly increased the percentage of small follicle-derived oocytes maturing to the metaphase II (MII) stage ($P<0.01$), although the nuclear maturation of large oocytes was not significantly affected. Examination of cyclin B1 protein expression as a measure of cytoplasmic maturation revealed that in the presence of GDNF, cyclin B1 levels were significantly increased in large follicle-derived oocytes ($P<0.05$). Although not significant, cyclin B1 expression was also elevated in small follicle-derived oocytes to levels comparable to untreated large oocytes. After parthenogenetic activation, a significantly higher percentage of both small and large follicle-derived oocytes that were matured in the presence of GDNF developed to the blastocyst stage compared to untreated controls ($P<0.05$). Indeed, GDNF enhanced the blastocyst rate of small follicle-derived oocytes to levels comparable to those obtained for large oocytes matured without GDNF. Our study provides the first functional evidence that GDNF enhances oocyte maturation and preimplantation embryo developmental competence in a follicular stage-dependent manner. This finding may provide insights for improving the formulation of IVM culture systems, especially for small follicle-derived porcine oocytes.

Key Words: GDNF, Oocyte Maturation, Preimplantation Development

Ruminant Nutrition: Corn Milling Co-Products - Dairy

647 Maintaining milk components when feeding co-products of corn ethanol production. L. Armentano*, *University of Wisconsin*, *Madison*.

Use of DGS at 15 to 20% of ration DM may be economical, but requires caution to ensure optimal production of milk protein and fat. DGS can affect milk protein yield through altered diet carbohydrate and protein profile. Adequate dietary degradable protein should be supplied from other sources, and some attention to the lysine concentration in the remaining undegraded protein sources is warranted. However, recent research with modern DGS suggests that lysine content is less of a concern than previously thought. Starch content of the diet should be monitored for adequacy if DGS replaces grain. Laboratories may analyze DGS NDF with Na sulfite and NDFCP without sulfite. Using these values to calculate NFC as 100- ash - CP - NDF - Ether Extract + NDFCP, will overestimate NFC. Several characteristics of DGS may impact milk fat yield and composition. Excess oil may be present in diets with DGS. Different analytical methods (acid hydrolysis ether extract, ether extract variations) may not accurately measure fatty acids in DGS, and this content will vary. To the extent that DGS carbohydrate displaces starch, this will tend to have a positive effect on milk fat production, but care must be taken if DGS NDF replaces physically effective fiber from forages. Low forage fiber combined with high oil could trigger milk fat depression. If DGS is added to low oil diets, and diet oil is thereby increased, there may be less secretion of fatty acids shorter than 16 carbons, however, this may be compensated

for by an increase in 18 carbon fatty acids arising from the increased dietary supply. Adding fat to diets often increases milk yields more than it does milk fat or protein yields. This is generally an economically positive response for low cost oils, but may be interpreted by casual observers as a decrease in fat or protein due to lowered milk fat concentration. Field reports of milk fat depression probably relate to all of the above considerations. New processes will result in co-products that differ in composition from DGS.

Key Words: Distillers Grains

648 Phosphorus utilization in dairy cows fed increasing amounts of dried distillers grains with solubles. K. Mjoun*, K. F. Kalscheur, B. W. Pamp, D. J. Schingoethe, and A. R. Hippen, *South Dakota State University*, *Brookings*.

When phosphorus (P) is fed in excess of the dairy cow′s requirement, an increase in fecal excretion of P is expected, which can lead to environmental pollution. The objective of this experiment was to investigate the effect of dietary concentration and source of P on P utilization in lactating dairy cows. Five multiparous Holstein cows fitted with rumen cannula were used in a 5 × 5 Latin square design with 28-d periods. A basal diet was formulated to contain 0.28% of P. Two additional dietary concentrations of P (0.34 and 0.40%) were formulated by including soybean products (SB), with increasing amounts of a supplemental source of P (dicalcium phosphate) or increasing amounts of dried distillers grains with solubles (DG), without a supplemental source of P. Experimental diets were formulated to provide: 1) 0.28% P (no supplemental P); 2) 0.34% P from SB and 0.18% supplemental P; 3) 0.40% P from SB and 0.36% supplemental P; 4) 0.34% P from DG (11% DG); and 5) 0.40% P from DG (22% DG). With increasing dietary P concentration (0.28, 0.34, and 0.40%), increases in P intake (68.7, 78.7, and 98.4 g/d, $P < 0.001$), fecal P output (28.2, 33.8, and 42.3 g/d, $P = 0.01$), net absorption (31.2, 39.0, and 47.0 g/d, $P = 0.04$)), and net retention of P (4.6, 12.6, and 19.5g/d, $P = 0.07$)) were observed; however, none of these parameters was affected by altering the source of P. Phosphorus excreted in milk was greater ($P = 0.001$) for DG diets compared with SB diets (28.9 and 25.8 g/d) primarily because of greater ($P = 0.01$) milk production for DG diets compared with SB diets, 35.9 and 34.4 kg/d, respectively. Milk P concentration was constant across all diets (0.083% P) regardless of dietary P concentration. Apparent P digestibility was similar for all diets averaging 52.9%. Total and inorganic water soluble P, indicators of P susceptibility to runoff, were unaffected by diet averaging 2.53 and 1.82 g/kg of feces DM, respectively. Data from this experiment suggest that feeding DG can sufficiently meet P requirements of high producing dairy cows without supplementary mineral source.

Key Words: Phosphorus, Fecal Excretion, Dried Distillers Grains with Solubles

649 The effect of replacing corn dry distillers grains with triticale dry distillers grains on milk yield and composition of lactating dairy cows. A. M. Greter*, E. C. Davis, G. B. Penner, and M. Oba, *University of Alberta*, *Edmonton, Alberta, Canada*.

The objective of this study was to compare milk yield and composition of dairy cows fed corn dry distillers grains with solubles (CDDGS) or triticale dry distillers grains with solubles (TDDGS) as a protein supplement. Thirty lactating Holstein cows (128 ± 57 DIM) were used in a crossover design with 14-d periods. Cows were assigned to one of two diets containing either CDDGS or TDDGS, at 20% of dietary DM, with barley silage, alfalfa silage, dry rolled barley, and the premix of minerals and vitamins. Both experimental diets were formulated to contain 16.7% crude protein and 22.0% forage neutral detergent fiber. Dry matter intake and milk yield were not affected by treatment, and averaged 23.2 and 31.5 kg/d, respectively. However, cows fed TDDGS decreased concentration of milk urea nitrogen compared to those fed CDDGS (15.7 vs. 16.6 mg/dl; $P < 0.01$), indicating that less N might be wasted in cows fed TDGGS. There were interactions between parity and treatment for 4%-FCM yield, milk fat concentration, and milk fat yield ($P < 0.05$). Multiparous cows fed TDDGS had greater 4%-FCM yield (32.8 vs. 26.9 kg/d) and milk fat concentration (3.81 vs. 3.46%) compared with primiparous cows fed TDDGS although there were no differences for cows fed CDDGS. In addition, multiparous cows fed TDDGS had greater milk fat yield compared with primiparous cows fed CDDGS or TDDGS (1.29 vs. 1.08 or 1.01 kg/d). These data indicate that high producing dairy cows may benefit more from TDDGS than lower producing cows. Consistent with this speculation, the response in milk yield to TDDGS relative to CDDGS in individual cows was positively related to their pretrial milk yield ($P = 0.03$). The results of this study demonstrate that TDDGS can replace CDDGS without negative impacts on lactation performance, however, its effects on the efficiency of N utilization is of further research interests.

Key Words: Triticale Distillers Grain, Corn Distillers Grain, Milk Production

650 Response of lactating Holstein cows to increased amounts of wet corn gluten feed. M. J. Brouk*[1], J. F. Smith[1], and K. N. Grigsby[2], [1]*Kansas State University*, *Manhattan*, [2]*Cargill, Inc.*, *Blair, NE*.

Forty, lactating Holstein cows were allotted into groups of five animals and assigned to one of eight pens containing 10 freestalls each. Each group contained 3 primiparious and 2 multiparious animals and groups were balanced by milk production and days in milk. Diets were formulated to contain 0%, 12%, 24% or 36% WCGF (wet corn gluten feed) on a dry matter basis. Increasing levels of WCGF and heat treated expeller soybean meal replaced a portion of the corn silage, alfalfa hay, corn grain, soybean meal and soybean hulls of the 0% diet to maintain similar concentrations of crude protein, ruminally undegraded crude protein and neutral detergent fiber. A 4×4 Latin square design with 4-wk periods allowing for 2 wk of adjustment followed by 2 wk of data collection was utilized. Milk weights were recorded at each milking and weekly milk samples, am and pm, were collected for milk component analysis. Milk and feed data were averaged by pen and week prior to analysis. Addition of WCGF to the diet reduced the dry matter content of the TMR. Dry matter intake was unaffected (P>0.1) by treatment. Cows fed 36% WGCF produced more (P<0.01) milk for diets containing 0%, 12%, 24% and 36% WGGF (36.6, 37.6, 38.8 and 40.5 kg/cow/d, respectively). Percentages of milk fat and lactose were unaffected (P>0.1) by diet. Diets containing either 24 or 36% WCGF resulted in greater (P<0.01) 4% fat and energy corrected milk production as compared to diets with 0 or 12% WCGF. Production of milk fat and protein was greater (P<0.01) when feeding WCGF. Increased milk, protein and fat production with increasing amounts of WCGF without a change in DM intake, suggests that total diet digestibility was increased when WCGF replaced diet ingredients that

were possibly less digestible than WCGF. Diets containing WCGF also resulted in greater (P<0.01) fat intake due to the fat associated with WCGF. These data show that WCGF can be utilized effectively at 36% of the ration dry matter if concentrations of RUP, CP and NDF are maintained in the diet.

651 Increased diet fermentability reduces production response to corn distiller's grains in lactating cows: A statistical analysis. M. Hollmann*, D. K. Beede, and M. S. Allen, *Michigan State University*, *East Lansing*.

Increasing supply of corn distiller's grains (DG) has raised questions regarding the extent to which they can be used in dairy cow diets. A database was created of treatment means (n = 122) reported in 23 peer-reviewed journal articles published between 1982 and 2006. The database included 4% fat-corrected milk yield (FCM) response to DG treatment compared with control (no DG), DG (% of dietary DM), and various indicators of diet fermentability including forage type, concentration of cereal grain in DG diet, and grain fermentability. Forage type was classified as alfalfa (n = 27), corn silage (n = 49), or a mixture of each (n = 46), grain concentration was classified as high (> 20% of dietary DM; n = 34) or low (≤ 20 % of dietary DM; n = 13), and grain fermentability was classified as high moisture corn (HMC; n = 9) or dry corn (DC; n = 38); responses with diets including more than one grain source (n = 8) were eliminated from the analysis. Supplementation of DG ranged from 4.2 to 42% of dietary DM. Response to DG ranged from -5.0 to 5.6 kg/d for FCM (mean = 0.6 kg/d), but response was not related to DG concentration of diets (P > 0.15). Fat-corrected milk yield was affected by forage type (P < 0.001), percent grain (P < 0.01), and grain fermentability (P < 0.03); these three factors explained 56% of the variation in FCM from DG supplementation. Among forage types, FCM response to DG was greatest for alfalfa (2.6 kg/d), lowest for corn silage (-2.1 kg/d), and intermediate for the mixture (1.3 kg/d). Response of FCM to DG was greater when concentration of corn grain in the diet was low (1.5 kg/d) compared with high (-0.2 kg/d) and for DC (1.1 kg/d) compared with HMC (0.1 kg/d). Increasing fermentability of forages (corn silage > alfalfa), corn grain (HMC > DC), and increasing the grain concentration of diet resulted in lower and sometimes negative FCM responses to DG supplementation. Fat-corrected milk yield response to DG supplementation is likely greatest when diet fermentability is limited.

Key Words: Milk Fat Depression, Ethanol Byproduct

652 Dried distillers grains + solubles from wheat fed to dairy cows. T. Andersson*[1], M. Murphy[1], E. Nadeau[2], and M. Carlsson[2], [1]*Lantmännen Feeds*, *Stockholm, Sweden*, [2]*Swedish University of Agricultural Sciences*, *Skara, Sweden*.

The coproduct, dried distillers grains + solubles (DDGS), from ethanol production for biofuels based on wheat, has more RDP and NDF with a lower digestibility compared to DDGS from corn. To compliment wheat DDGS in diets based on grass silage the silage should be low in protein and high in digestible fiber (DNDF). Four groups of dairy cows (10 per group) were used in a 4 by 4 Latin Square experiment with four treatments and four 3-wk periods. The treatments were a normal grass-clover silage (17.8% CP, 46.2% NDF) with 1 kg DDGS (C), an adapted silage (14.6% CP, 52.9% NDF) with 1 kg DDGS (A), 2.5 kg DDGS (A+2.5) or with 4 kg DDGS per cow and day (A+4). The Total Mixed Rations (TMR) had similar contents of CP (17.5%), starch (17.5%), and NDF (37.5%). Diet A+4 had less DNDF and more RDP. TMR were fed ad lib. Intake was recorded on the last 10 days and milk production on the last 4 days of each period. Fecal samples were collected from three cows in each group for analysis. Data were analyzed with PROC GLM in SAS. DMI was greater for A+4 (23.9 kg) than for A and A+2.5 (22.5 kg; SEM=0.40). Diet A tended to give a higher milk yield, 38.3 kg d-1, than C, 37.1 kg d-1 (SEM=0.35), as well as a higher ECM. Diet A produced more ECM per kg of DM intake than A+4 and C, 1.81 vs.1.63 (SEM=0.042). Diets A+2.5 and A+4 gave higher percentages of milk fat than diet A, 4.12 vs. 4.01% (SEM=0.03). Diet A gave the highest percentage and yield of milk protein (3.52 vs. 3.47%, SEM=0.01 and 1.32 vs. 1.27 kg, SEM=0.01). Diet A+4 resulted in a higher body condition score (3.01) than diets C (2.92) and A+2.5 (2.87; SEM=0.03). Fecal pH was lowest for A (6.97 vs. 7.55; SEM=0.11). The declining milk protein contents in A+2.5 and A+4 compared to A might indicate lower protein quality in wheat DDGS. Inclusion of DDGS was positive for milk fat percentage, probably related to the fiber content. Grass-clover silage and 5% of DDGS gave similar performance as adapted grass silage and 20%

653 Interactions of yeast culture and dried distillers grains plus solubles in diets of lactating dairy cows. A. R. Hippen*[1], D. J. Schingoethe[1], K. F. Kalscheur[1], P. Linke[1], K. Gross[1], D. Rennich[1], and I. Yoon[2], [1]*South Dakota State University*, *Brookings*, [2]*Diamond V. Mills, Inc.*, *Cedar Rapids, IA*.

Sixteen multiparous Holstein cows (127 ± 52 DIM) were used in four replicated 4 × 4 Latin squares with 4-wk periods to evaluate interactions of dietary yeast culture (YC, Diamond V XPC™ Yeast Culture, Diamond V Mills, Cedar Rapids, IA) and dried distillers grains plus solubles (DDGS) on production of milk and milk components when fed diets containing low amounts of forage fiber. Treatments were a 2 × 2 factorial arrangement of: 1) no YC with no DDGS (NYND); 2) no YC with DDGS at 20% of diet DM (NYD); 3) 14 g/d YC with no DDGS (YND); and 4) 14 g/d of YC with DDGS (YD) at 20% of diet DM. Diets consisted of corn silage (27%), alfalfa hay (18%), and a concentrate mix (55%) on a DM basis. Diets were isocaloric and isonitrogenous. Forage NDF was calculated to be 19.3% of diet DM. Dry matter intake (26.0 kg/d) was similar for all diets. Milk production (42.5, 41.6, 44.8, and 42.3 kg/d for NYND, NYD, YND, and YD, respectively) increased (P = 0.05) with the addition of YC and decreased (P = 0.04) in diets containing DDGS. Milk fat percentage (3.23, 3.07, 3.21, and 3.00%) and yield (1.38, 1.26, 1.44, and 1.28 kg/d) were decreased (P < 0.05) by the addition of DDGS but were not affected by YC. Milk true protein concentrations (3.05, 3.04, 3.02, and 3.08%) were similar for all diets; however, the addition of YC increased (P = 0.05) yield of true protein (1.29, 1.26, 1.35, and 1.30 kg/d). Concentrations of MUN (11.2, 10.9, 10.7, and 12.4 mg/dl) increased (P < 0.01 for YC × DG) when both YC and DDGS were included in the diet. The DDGS decreased (P = 0.02) yields of energy-corrected milk (ECM; 41.1, 39.1, 43.0, and 39.7 kg/d) and tended to decrease (P = 0.08) feed efficiency (1.56, 1.53, 1.66, and 1.53 kg ECM/kg DMI). Body weights and condition scores were not affected

by treatments. Results suggest that, in diets containing minimal amounts of forage fiber, DDGS at 20% of diet DM will contribute to milk fat depression. The addition of YC did improve milk and milk protein yields but did not prevent milk fat depression caused by DDGS. Production responses to YC were similar when cows were fed DDGS or non-DDGS diets.

Key Words: Yeast Culture, Distillers Grains, Lactating Cows

654 Lactation performance of cows fed diets using soybean or byproduct protein sources. Z. Wu* and J. D. Ferguson, *University of Pennsylvania*, *Kennett Square*.

Milk production and economic returns were determined for dairy cows fed diets utilizing soybean or byproduct protein sources. Thirty-nine Holsteins (averaging 95 DIM, SD = 54) were utilized in an 8-wk trial. The soy diet utilized 16% soybean meal and roasted soybeans as the sole supplemental protein source, whereas the byproduct diet used 6.5% mixed fishmeal, brewer's grain, and corn gluten feed (equal proportions) to replace part of the soy combination while still containing 10% soybean meal and roasted soybeans. The diets contained 50% forage, with 30% contributed from corn silage; the remaining forage was alfalfa silage during the first 4 wk (period 1) or sorghum silage for the second 4 wk (period 2). Average DMI was similar between protein sources in both periods. Milk yield was higher during the first half than the second half of the trial, but similar between protein sources in each period. Milk fat and protein concentrations and FCM increased during the second part of the trial, but did not differ between protein sources. Milk fat and protein yields did not differ during the trial or with protein source. There was no interaction between protein and forage sources in lactation measurements. Economic analysis using averages of the two periods showed $0.21/d less on feed cost and $0.13/d more in income over feed for soy than byproduct protein sources. Soy protein source resulted in better economic returns than mixed fishmeal, brewer's grain and corn gluten feed with similar milk production responses. (Partially supported by Pennsylvania Soybean Promotion Board, Salisbury, MD)

655 Ruminal fermentation and total tract apparent digestibility in dairy cows fed increasing concentrations of corn germ. M. M. Abdelqader*, A. R. Hippen, D. J. Schingoethe, and K. F. Kalscheur, *South Dakota State University*, *Brookings*.

Four multiparous Holstein canulated cows (132 ± 36 days in milk) were used in a multiple 4 × 4 Latin square design with 4-wk periods to determine the effects of feeding corn germ on ruminal fermentation and total tract apparent digestibilities. Diets were formulated with increasing concentrations of corn germ at 0, 7, 14, and 21% of the diet DM. All diets contained 55:45 forage to concentrate ratio, where forage was 60% corn silage and 40% alfalfa hay. Dietary fat increased from 4.6% in the control diet to 8.3% at the highest inclusion rate of corn germ. Feeding increasing concentrations of corn germ resulted in a quadratic response in DMI (24.5, 27.7, 27.0, 24.1 kg/d; $P < 0.05$). Ruminal pH tended to linearly decrease (6.49, 6.51. 6.41, 6.37; $P = 0.08$) as concentrations of corn germ increased in the diet. Dietary treatments had no effect on the total concentrations of VFA; however, increasing the concentrations of corn germ linearly decreased the molar proportion of acetate (62.8, 61.6, 61.9, 59.4; $P < 0.001$) and linearly increased the molar proportion of propionate (20.9, 21.9, 21.5, 23.4; $P < 0.001$). Increasing corn germ in the diet had no effect on the total tract apparent digestibility of DM, CP, ether extract and total fatty acids. The addition of corn germ resulted in an increase in the total tract digestibility of C18:2 (95.8, 97.3, 97.8, 98.4 %; $P < 0.01$) and C18:1 (80.9, 88.4, 92.0, 90.0%; $P < 0.001$). However, total tract apparent digestibility of C18:0 and total C18 fatty acids were not affected by dietary treatments. Inclusion of corn germ in dairy cow diets had no adverse effect on ruminal fermentation and total tract nutrient utilization. Corn germ provides an alternative fat source in dairy cow diets.

Key Words: Corn Germ, Dairy Cows, Fermentation

656 Wheat grain as a prepartum cereal choice to ease periparturient stress in Holstein cows. H. Amanlou[1], D. Zahmatkesh[1], and A. Nikkhah*[1,2], [1]*Department of Animal Science*, *Zanjan, Iran*, [2]*Department of Animal Science*, *Winnipeg, MB, Canada*.

Wheat grain is a unique cereal rich in easily-fermentable starch and low in cation-anion difference. The controlled prepartum dietary inclusion of wheat grain, thus, has the potential to ease adapting the rumen environment to the high-starch lactation diets, stimulate feed intake, reduce hypocalcemia by reducing extracellular alkalinity and a moderate induction of bone resorption, and improve milk yield in periparturient cows. Our principal objective was to underline the importance of wheat grain as a proper cereal choice in the preparturient diet. Twenty-four dry multiparious cows and sixteen pregnant heifers were blocked based on parity and projected calving date and fed a prepartum diet containing either 1) ground wheat grain (WG) or 2) ground barley grain plus wheat bran (BGW i.e., control diet) from 28-d prepartum until parturition. Cows were kept in loose houses, group-fed, and fed the BGW diet during 21-d postpartum. Feeding WG instead of BGW increased blood glucose (58.3 vs. 52.8 mg/dl, P=0.01), attenuated hypocalcemia (9.5 vs. 7.8 mg/dl, P<0.01), and reduced urine pH (6.4 vs. 6.9, P<0.01) at 7-d prepartum. At 1-d postpartum, WG-fed cows had higher blood glucose (63.0 vs. 56.2 mg/dl, P=0.03) and calcium (7.0 vs. 5.5 mg/dl, P<0.01) than BGW-fed cows. Prepartum feeding of WG instead of BGW led to enhanced (P<0.05) milk fat percent (3.7 vs. 3.5%) and 3.2% fat-corrected milk yield (34.8 vs. 31.3 kg/d) during 21-d postpartum. Blood proteins at 7-d prepartum were higher (P<0.05) and placenta was expelled sooner (P=0.08) in

wheat grain-fed cows than in other cows. Treatments did not affect milk protein; changes in body condition score; total time spent eating, ruminating, and chewing; blood levels of urea nitrogen, cholesterol, and phosphorous; fecal pH; and calving difficulty. Therefore, the prepartum provision of WG (18% on a dry matter basis) instead of BGW proved effective in the simultaneous improvement of calcium and energy states, and thereby, in easing the periparturient stress in Holstein cows.

Ruminant Nutrition: Intake and Performance - Beef

657 Factors affecting residual feed intake in feedlot steers. J. W. Homm*, L. L. Berger, and S. L. Rodriguez-Zas, *University of Illinois*, *Urbana*.

Profitability in beef production is a function of both inputs and outputs. The beef industry has focused on outputs such as weight, gain, and carcass merit. Feed costs are estimated to be approximately 60% of the total cost of production, and therefore represent an opportunity to increase profitability through improving feed efficiency. Four hundred six steers (330.1 + 47.07 kg) originating from four different sources and from 29 different Simmental, Angus, and Simmental X Angus sires were used to determine factors affecting feed efficiency in feedlot steers. Seven dietary treatments were used that were composed primarily of corn, corn-based co-products and/or soy hulls. Daily individual animal intakes were recorded by the Growsafe® feed monitoring system. All steers were weighed and ultrasound measurements of marbling score, backfat thickness, and ribeye area were taken approximately every 28 d through 146 d. A total pen collection method established the digestible energy (DE) content of each diet. Residual feed intake (RFI, Mcals of DE/d) was not ($P > 0.05$) correlated to body weight (BW) or average daily gain. However, RFI was highly positively correlated to DE intake (Mcals/d) and average daily dry matter intake (ADDMI). RFI was negatively correlated to gain to feed (G:F) and was lowly, but significantly correlated to empty body fat. G:F was highly correlated to BW, average daily gain (ADG), ADDMI, and DE intake. Dietary treatment accounted for the majority of the variation (43%) in RFI. Dietary treatment and ADG accounted for approximately 51% of the variation in intake over maintenance requirements. Steers that ate more than 15 Mcals of DE per day over their maintenance requirements were less efficient than those eating less than 15 Mcals of DE per day over their maintenance requirements. Sire effects accounted for 9% of the variation in RFI. The range of RFI for progeny of the 29 sires was -2.10 to 2.22 Mcals of DE per day.

Key Words: residual Feed Intake, Steers, Feed Efficiency

658 The effect of residual feed intake rank in beef cows on forage intake and pasture carrying capacity. A. Meyer*, R. Kallenbach, M. Kerley, and K. Ladyman, *University of Missouri*, *Columbia*.

During the summer of 2005, residual feed intake (RFI) was calculated for 42 purebred Hereford heifers using the GrowSafe feed intake system. The heifers were ranked by RFI and split into low RFI (highly efficient), mid RFI, and high RFI (lowly efficient). After their first calving season, the low and high RFI groups were used to determine the difference in their grazed forage intake. Each group was split into two reps and grazed non-endophyte infected tall fescue-based pastures (1.8-2.4 ha/paddock) for 84 d. The cows were weighed on d 0, 21, 42, 63, and 84 and body condition scored (BCS) on d 0, 42 and 84. At the beginning of the experiment and every 21 d thereafter, the grazed pastures were sampled for DM on offer. To measure forage accumulation, each paddock had 10 exclosures that were sampled for forage DM and moved every 21 d. Rising plate meter (RPM) readings were taken weekly, and paddock size was adjusted as needed to keep forage availability similar between groups. RPM readings and date of experiment were used in a stepwise model selection to predict forage DM yield. These yields and exclosure growth data were then used to calculate dry matter intake (DMI). Low and high RFI groups did not differ ($P>.05$) in BW change or BCS change over the trial (19.5 vs. 22.1 kg and 0.11 vs. 0.10 BCS). The average DM yield for all paddocks was 2336 kg DM/ha. The average NDF, ADF, and CP were 72.1, 42.4, and 6.8%, respectively. Low RFI cows had a 21% numerically lower DMI than high RFI cows (12.4 vs. 15.6 kg, $P=0.23$). The average acres needed per paddock over the trial was numerically less for low RFI than high RFI cows (1.71 vs. 1.82 ha, $P=0.35$). The average DM on offer over the trial tended to be lower for low RFI than high RFI cows (4215 vs. 4376 kg, $P=0.06$). Although differences seen between low and high RFI cows were not statistically different, this could be due to the difficulty of measuring forage intake during the growing season and the low number of replications. Additional studies are necessary to confirm these differences.

Key Words: Beef Cows, Feed Efficiency, Forage Intake

659 Evaluation of feed efficiency in Santa Gertrudis steers and relationships with temperament and feeding behavior traits. R. R. Gomez*[1], B. M. Bourg[1], Z. D. Paddock[1], G. E. Carstens[1], P. A. Lancaster[1], R. K. Miller[1], L. O. Tedeschi[1], D. K. Lunt[2], S. A. Moore[3], and D. S. DeLaney[3], [1]*Texas A&M University*, *College Station*, [2]*Texas A&M University*, *McGregor*, [3]*King Ranch*, *Kingsville, TX*.

The objectives of this study were to characterize feed efficiency traits in growing calves, and to examine their relationships with temperament and feeding behavior traits. DMI and feeding behavior traits were measured over a 70-d period using a GrowSafe® feeding system, following a 28-d adaptation period, in Santa Gertrudis steers (n = 118, initial BW = 308.8 ± 27.8 kg). Meal duration (min/d) and meal frequency (meals/d) were averaged over the 70-d period. Body weights were measured at 14-d intervals. Steers were fed a roughage based diet (ME = 2.26 Mcal/kg DM). Chute scores (1 to 5) were recorded and exit velocity (EV) measured as the rate of distance traveled (m/s) while exiting a confined area on days -28, 0, and 70. Residual feed intake (RFI) was calculated as the residual from the linear regression of DMI on mid-test BW^0.75 and ADG. Overall mean (±SD) of ADG, DMI and RFI were 0.84 ± 0.16, 9.44 ± 0.99, and 0.0 ± 0.86 kg/d respectively. RFI was correlated ($P < 0.05$) with DMI (0.86) and feed conversion ratio (FCR; 0.50), but not with ADG or MBW. Steers with low RFI consumed 19.1% less DMI and had 18.7% lower FCR than steers with high RFI. Meal duration was not correlated with ADG or FCR, but was moderately correlated ($P < 0.05$) with DMI (0.35) and RFI (0.34). Meal frequency was not correlated with ADG, FCR, DMI

or RFI. Initial CS and EV were both correlated ($P < 0.05$) with ADG (-0.26, -0.28), but not with DMI. Initial CS tended to be correlated ($P < 0.10$) with FCR (0.17) but not with RFI. Initial EV was not correlated with any other performance, efficiency, or feeding behavior traits. Initial CS was correlated with meal duration but not meal frequency. These results suggest that initial temperament traits may be predictive of subsequent performance of growing calves.

Key Words: Temperment, Feeding Behavior

660 Relationships of feed efficiency with carcass and non–carcass tissue composition in Angus bulls and heifers. F. R. B. Ribeiro*[1], G. E. Carstens[1], P. A. Lancaster[1], L. O. Tedeschi[1], and M. E. Davis[2], [1]*Texas A&M University*, *College Station*, [2]*The Ohio State University*, *Columbus*.

Objectives of this study were to characterize feed efficiency traits and examine their relationship with carcass and non-carcass tissue composition in Angus bulls and heifers. Individual DMI were measured in Angus bulls (n = 16) and heifers (n = 16) fed a corn-based diet (ME = 2.85 Mcal/kg) for 70 d using Calan gates. BW was measured at 14-d intervals. Residual feed intake (**RFI**) was computed as the residual from the linear regression of DMI on mid-test $BW^{0.75}$ and ADG within gender. Low RFI calves consumed 17% less feed than high RFI calves, but had similar ADG and BW. Within bulls and heifers, calves were separated into two groups: high and low RFI (n =8/gender). Upon harvest, gastrointestinal tract (**GIT**) and visceral organs were removed, dissected, and weighed. The 9-11th rib tissue was analyzed for protein and lipid content. There were no significant differences between low and high RFI groups for final BW (360.7 ± 42.4 kg), HCW (259.5 ± 44 kg) and empty BW (**EBW**; 384.3 ± 61.5 kg). There were also no significant difference for total internal fat (82 ± 20.1 g/kg EBW), and carcass lipid (30.3 ± 6.8 %), however low RFI calves had greater ($P < 0.05$) carcass protein content than high RFI calves (15.7 vs. 15.1 %). RFI groups had similar liver (13.5 ± 1.3 g/kg EBW) and heart (3.8 ± 0.3 g/kg EBW), however low RFI calves had smaller empty GIT than high RFI calves (99.3 vs. 103.6 ± 1.52 kg). As expected, heifers had more carcass lipid (35.3 vs. 25.9 ± 1 %) and IF (101.1 vs. 65.98 ± 2.2 g/kg EBW) than bulls. These results showed that RFI had minimal effects on carcass and non-carcass tissue composition.

Key Words: Carcass, Non–Carcass, Residual Feed Intake

661 The effects of sorting steers by weight into calf-fed, summer yearling and fall yearling feeding systems. D. R. Adams*, T. J. Klopfestein, G. E. Erickson, M. K. Luebbe, and M. A. Greenquist, *University of Nebraska*, *Lincoln*.

Cattle are commonly sorted at weaning into different production systems. Our objective was to determine if sorting cattle by BW decreases variation in HCW and decreases overweight carcasses (431 kg). Steers (n=288) were purchased from two ranches in the fall. All the cattle were assigned randomly into sorted or unsorted groups (n=144). The unsorted group was then assigned randomly to one of three feeding times: calf-fed, summer yearling or fall yearling. The calf-feds were fed from November to May. The summer and fall yearlings grazed cornstalks together through the winter until spring and then grazed cool season grass until May. The summer yearlings entered the feedlot in May and were fed until October. The fall yearlings grazed pasture until September when they entered the feedlot and were fed until January. In the sorted group, the heaviest 1/3 were fed as calf-feds. When the cattle were brought off of grass in May, the heaviest 1/2 of the remaining sorted group were fed as summer yearlings, while the lightest 1/2 went to pasture and then were fed until January. Both the sorted and unsorted groups were treated as one group during grazing. When entering the feedlot, the cattle were assigned randomly into six pens per group per feeding time and pen was experimental unit. Sorting cattle did not affect overall performance. There was no affect on HCW, ADG, gain efficiency, yield grade 4 and higher, fat thickness, and marbling ($P > 0.21$). Sorting cattle decreased the variation in HCW and the number of carcasses over 431 kg. Carcass weights were 389 kg, S. D. = 30 kg for sorted cattle compared to 390 kg, S. D. = 48 kg for unsorted cattle. The unsorted group had 20.8% of the carcasses heavier than 431 kg while only 7.04% of the carcasses were over 431 kg in the sorted group. Sorting cattle decreased the variation of HCW and the number of overweight carcasses without affecting fat thickness.

Key Words: Carcass Characteristics, Feedlot Cattle, Sorting

662 The effect of Bos Koolus fed during summer on the feedlot performance and carcass characteristics of steers. I. Loxton[1], T. Grant[2], D. Reid[3], R. Lawrence*[4], and N. Kempe[5], [1]*Beef Support Services*, *Yeppoon, Queensland, Australia*, [2]*Department of Primary Industries and Fisheries*, *Theodore, Queensland, Australia*, [3]*Department of Primary Industries and Fisheries*, *Rockhampton, Queensland, Australia*, [4]*Integrated Animal Production*, *Toowoomba, Queensland, Australia*, [5]*Feedworks*, *Burleigh Heads, Queensland, Australia*.

Feedlot cattle over summer experience high heat load events that increase core body temperature, reduce feed and water intake, depress animal performance and increase morbidity. Mortalities may result. To manage the consequences of high heat load, the dietary inclusion of betaine, an osmolyte was studied. In an unreplicated pilot study, 32 Angus and Angus crossbred steers were fed a diet with or without 20 g/d betaine incorporated as a Bos Koolus (BK) supplement for 100 days over summer from December 2005 to March 2006 in a central Queensland, Australia feedlot research facility. All steers had access to shade. Nineteen of the steers (10 Control and 9 BK) were surgically implanted with Sirtrack digital temperature transmitters adjacent to the peritoneum at a paralumbar site. Animal measurements included growth, core body temperature at 15 minute intervals, and carcase attributes at slaughter. Climatic parameters were measured in an unshaded environment every 30 minutes enabling calculation of Accumulated Heat Load Units (AHLU). Three significant heat load events, with AHLU to 130 were recorded during the study. Bos Koolus inclusion showed some evidence of increased overall steer growth (1.21±0.07 SEM vs. 1.17±0.07 SEM kg/d), increased exit liveweight (598.6±6.7 SEM vs. 594.4±5.2 SEM kg) increased carcase weight (314.0±4.3 SEM vs. 306.1±2.2 SEM kg), increased subcutaneous fat depth (16.6±1.1 SEM vs. 14.4±0.7 SEM mm, P8 site), while overall DMI (9.92 vs. 9.67 kg/d) and water consumption (37.0 vs. 33.3 L/d) increased, compared with Control. The average core body temperatures of both Control and Bos Koolus treated steers were similar. Therefore, Bos Koolus has shown potential to ameliorate the effects of heat stress in feedlot cattle.

663 Effect of Ractopamine HCl on growth and carcass traits of finishing heifers fed to slaughter. S. B. Laudert*, G. J. Vogel, A. L. Schroeder, and W. J. Platter, *Elanco Animal Health*, *Greenfield, IN*.

Two studies were conducted at research facilities in TX and KS to evaluate the effects of ractopamine hydrochloride (RAC) on growth performance and carcass traits of finishing heifers. The studies consisted of 3 treatments (0, 200 mg•hd^{-1}•d^{-1} and 30.3 ppm RAC), 14 replications per treatment and 3405 cattle (492.8 kg). Days on feed averaged 142 and 185, with the RAC diets fed for the last 28 and 32 d prior to slaughter at the TX and KS sites, respectively. Rations were representative of the geographic area of the studies and met or exceeded National Research Council nutrient requirements of finishing heifers. Rumensin®, Tylan® and MGA® were fed at label dosages. TX heifers received an initial Revalor® IH followed by Revalor H re-implant approximately 77 d pre-slaughter. KS heifers received a Revalor 200 at processing and were not re-implanted. Heifers were slaughtered at commercial beef facilities and standard carcass data collected. Data were analyzed using a mixed model procedure of SAS with pen as the experimental unit and initial weight as a covariate. Feeding RAC at 200 mg•hd^{-1}•d^{-1} or 30.3 ppm increased live weight gain, lowered feed intake and improved feed conversion. Heifers fed the RAC diets had heavier carcass weights, and increased dressing percentages and LM areas compared to heifers fed the control diet. Dietary RAC treatment did not impact marbling score, fat thickness, KPH, or yield grade. Feeding RAC to heifers for the final 28 to 32 d of the finishing period increased live weight and carcass gain and improved feed efficiency with no impact to carcass quality.

Table 1. Effect of Ractopamine on finishing heifers

Item / RAC Treatment	0	200 mg	30.3 ppm	SE
RAC intake, mg•hd^{-1}•d–^{1}	0	200	234

664 Plasma urea-N response to dosages and delivery patterns of Estradiol 17-beta and Trenbolone Acetate. S. L. Parr*, R. H. Pritchard, and K. W. Bruns, *South Dakota State University*, *Brookings*.

Two experiments were used to assess the effect of implant dose and delivery pattern on anabolic status via plasma urea-N (PUN) concentrations when steers were fed finishing diets. In Exp.1 crossbred steers (n=64; BW=368 kg) received the following implant dosages (IMP) of estradiol (E) and trenbolone acetate (TBA) in milligrams given on d 0; 1) 0E/0TBA; 2) 8E/40TBA; 3) 16E/80TBA; and 4) 24E/120TBA. Blood was drawn (n=40) on d 0, 2, 7, 14, 21, 28, 42 and 70. Implants increased 136 d ADG (1.2^{c}, 1.4^{b}, 1.4^{b}, and 1.6^{a} kg/d; $P < 0.05$) and HCW (330^{c}, 347^{b}, 345^{b}, and 362^{a} kg; $P < 0.05$). Concentrations of PUN averaged across days 28, 42 and 70 were higher for IMP 1 than IMP 2 or 4 (9.5^{a}, 7.7^{b}, 8.1^{ab} and 7.4^{b}; $P < 0.05$) and tended to be higher than IMP 3 ($P < 0.10$). In Exp.2 steers (n=192; BW=372 kg) received one of 4 IMP treatments, IMP A) 0E/0TBA and 3 implanted strategies which resulted in equal cumulative dosages of E and TBA: IMP B) 8E/40TBA given on d 0, 42, and 84; IMP C) 12E/60TBA on d 0 and 63; and IMP D) 24E/120TBA on d 0. Steers were sorted to IMP within frame size (FSL=large; FSS=small). Blood was drawn (n=72) on d -1, 41, 62, 83 and d 125. Implanted cattle had greater ($P < 0.05$) 133 d ADG and HCW than control. Concentrations of PUN increased from d 0 to 125 (6.4, 7.7, 8.9, 10.2, and 10.5 mg/dl; $P < 0.05$). At d 41, implants lowered PUN concentrations (8.5^{a}, 7.7^{b}, 7.2^{b} and 7.4^{b} mg/dl; $P < 0.05$). At d 62 PUN concentrations were lower for IMP B and C compared to control; IMP D PUN concentration were intermediate (9.8^{a}, 8,3^{b}, 8.4^{b} and 9.0^{ab} mg/dl; $P < 0.05$). A FS x IMP interaction existed at d 83 and d 125. In FSL, IMP did not affect PUN (10.4 mg/dl; $P > 0.10$) at these times. However, in FSS the PUN concentrations were lower for IMP B and C than IMP A or D (11.6^{a}, 9.5^{b}, 9.1^{b}, 11.0^{a} mg/dl; $P < 0.05$). In Exp.2 smaller framed steers did have an increased response to implant delivery patterns that involved repeated lower dosing. The observed changes in PUN concentrations were responsive to time but not to dosage.

665 Using programmed feeding to manage young beef cows. J. D. Shockey*, P. A. Beck, P. Gregorini, C. B. Stewart, and S. A. Gunter, *University of Arkansas Division of Agriculutre, SWREC*, *Hope*.

On 10 November 2005, 52 non-lactating cows (BW = 434 ± 1.3 kg) of mostly Angus breeding were stratified by BCS, parity, BW, and distributed randomly into four 0.81-ha drylots. The cows were bred to calve in February 2006 for the first (n = 37) or second (n = 15) time. Cows in 2 pens were program fed a high-concentrate diet during 2 feeding periods, gestation (84 d) and lactation (56 d). The diet was fed in amounts to meet the cows' NEm requirements at each stage of production as described by the NRC (2000). The diet was formulated to be 12.1% chopped corn stalks, 67.8% hominy feed, 1.5% cottonseed meal, 2.3% minerals, 0.5% urea, and 15.9% water on an as fed basis (79% DM; 12.3% CP, 2.1 Mcal of NEm/kg [DM basis]). Cows in the other 2 drylots were fed long-stem bermudagrass hay (9.4% CP, 1.1 Mcal of NEm/kg [DM basis]) plus a hominy feed based supplement. Cow BW after the first 84 d tended ($P \leq 0.09$) to be improved by programmed feeding (430 kg) compared to hay feeding (474 kg); but no difference was noted ($P = 0.20$) after 56 d of lactation. Body condition score did not differ ($P \geq 0.36$) before calving, but BCS (9 point scale) was higher ($P = 0.05$) during lactation for program-fed cows (6.1) than hay fed (5.3). Total DMI was reduced 27% or more ($P < 0.03$) for cows that were program fed compared to hay fed cows during gestation and lactation. Program-fed cows had a pregnancy rate of 92% compared to 80% for hay-fed cows ($P = 0.37$; SE = 7.8). Milk samples were collected March 30 and May 11; percentage protein and fat did not differ ($P \geq 0.34$) between treatments. Calving date, calf birth weight, agility, vigor, and calving ease did not differ ($P \geq 0.42$) between treatments. On March 30, May 11, and July 6, calves from program-fed cows tended ($P \geq 0.14$) to be heavier than the

calves nursing hay-fed cows. These data suggests that calves nursing program-fed cows probably had a higher plain of nutrition and performed better than calves nursing hay-fed cows.

Key Words: Beef Cows, Programmed Feeding, Hominy

666 Performance of beef cows fed free-choice whole cottonseed and hay during winter. G. M. Hill*[1], M. H. Poore[3], M. E. Pence[2], and B. G. Mullinix, Jr.[1], [1]*University of Georgia*, *Tifton*, [2]*University of Georgia Vet. Diagnostic Ctr.*, *Tifton*, [3]*North Carolina State University*, *Raleigh*.

In a 2-yr experiment, beef cows were fed supplemental whole cottonseed [WCS; DM, CP, crude fat, (% DM), respectively, 92.2, 23.5, 17.8], and free-choice bermudagrass hay [DM, CP, NDF (% DM), respectively, 90.9, 10.2, 77.8] in hay rings on dormant pastures (n=6, 0.89 ha each). Non-pregnant cows (n=84, 42/yr) were of Breed Type 1 (BT1, Angus =32, Polled Hereford =9) or Breed Type 2 (BT2, Brangus=28, Braford=15). Cows were ranked by BW within BT, and randomly assigned to dietary treatments: Low WCS (LCS; 0.25 % initial BW); Medium WCS, (MCS; 0.5 % initial BW), and WCS fed free-choice (FCS) for 63d (2005) and 70d (2006). Initial and final BW were means of consecutive daily unshrunk BW. On d 1 and d 63 (2005), d 70 (2006), 13th rib ultrasound fat (UR, cm) and rump (URP, cm) were determined. Initial BW, cow age (CA), initial UR, and initial URP for 2005 and 2006, respectively, were: 517.4 ± 99.2, 578.9 ± 78.4 kg, $t = 3.15$, $P < 0.05$; 3.67 ± 1.87, 6.33 ± 2.88 yr, $t = 5.02$, $P < 0.01$; 0.60 ± 0.43, 0.78 ± 0.27 cm; 0.55 ± 0.61, 0.51 ± 0.22 cm, and these values were used as covariates. The DMI of WCS, hay and total diet (kg) on LCS, MCS, and FCS, respectively, were: 1.4c, 9.5b, 10.9b; 2.4b, 11.5a, 13.9a and 4.1a, 10.4ab, 14.4a; within WCS, hay or diet, means with uncommon letters differ ($P < 0.01$). The ADG for cows in 2006 was adjusted to 63 d, and the 2-yr 63-d ADG (Table) was higher for FCS. Cow UR and URP changes were greater in 2006 than 2005, and URP had greater positive changes for MCS and FCS than LCS. Positive changes in UR occurred for MCS and FCS, and negative changes for LCS. Cow ADG and UR were affected by BT × CA interactions ($P < 0.10$) with ADG (kg) and UR (cm), respectively, for CA < 3 yr at 0.44, 0.01 vs. 0.63, 0.07 for BT1 vs. BT2; and CA > 4 yr at 0.41, 0.12, vs 0.44, -0.02 for BT1 vs. BT2, SE 0.07, 0.05. Feeding WCS free-choice increased cow ADG, and MCS and FCS resulted in increased cow body condition.

Table 1.

Item	2005	2006	SE	P <	LCS	MCS	FCS	SE	P <

Key Words: Cow, Cottonseed, Ultrasound

667 Evaluation of NRC (1996) model energy requirement and DMI equation accuracy and precision for wintering beef cows in western Canada. J. L. Bourne[1], H. C. Block*[1], H. A. Lardner[2], and J. J. McKinnon[1], [1]*University of Saskatchewan*, *Saskatoon, SK, Canada*, [2]*Western Beef Development Centre*, *Humboldt, SK, Canada*.

Three years of winter feeding trials using 90 Angus cows (15 pens of six) fed typical wintering diets formulated to stage of pregnancy were used to evaluate NRC (1996) energy requirement and DMI equation accuracy and precision. Data collection included pen DMI, individual cow weights, body condition scores, calving dates and weights, and daily temperature and wind speed. Diet energy density was estimated from nutrient analysis of composited weekly feed samples. Equation evaluations compared observed and predicted DMI and conceptus corrected ADG for the second and third trimesters using regression, means comparison, concordance correlation coefficient (CCC), and total deviation index (TDI) methods. Across all three years, second trimester DMI was over predicted ($P<0.01$) with low precision (CCC = 0.24, 90% TDI = n/a) using actual environmental conditions, but not ($P=0.34$) when assuming thermal neutral (TN) conditions, although precision remained low (CCC = 0.25, 90% TDI = 1.91 kg/d). Third trimester DMI was also over predicted ($P<0.01$) with low precision (CCC = 0.12, 90% TDI = 1.57 kg/d) using actual environmental conditions, but was largely under predicted ($P<0.01$) with worse precision (CCC = -0.01, 90% TDI = 2.34 kg/d) when assuming TN conditions. Across all three years, second trimester ADG was largely under predicted ($P<0.01$) with low precision (CCC = 0.50, 90% TDI = 0.58 kg) using actual environmental conditions, but over predicted ($P<0.01$) with similar precision (CCC = 0.51, 90% TDI = 0.50 kg) when assuming TN conditions. Third trimester ADG predictions using actual environmental conditions were inaccurate ($P<0.01$) with low precision (CCC = 0.20, 90% TDI = 0.70 kg) and worsened (CCC = -0.01, 90% TDI = n/a) when assuming TN conditions where ADG was over predicted ($P<0.01$). These results indicate a lack of accuracy and precision with the current NRC (1996) model energy requirement and DMI equations that was not addressable by assuming TN conditions. Future research should be targeted at alternate DMI equations and refinements to maintenance and gain requirements.

668 Improving fecal near-infrared reflectance spectroscopy predictions of botanical composition of ruminant diets. J. W. Walker*, B. S. Engdahl, E. S. Campbell, and C. J. Lupton, *Texas Agricultural Experiment Station*, *San Angelo, TX*.

Near infrared reflectance spectroscopy of fecal samples (FNIRS) can be used to predict the botanical composition of herbivore diets. FNIRS has been used to predict the percentage sagebrush, leafy spurge, and spotted knapweed in sheep diets; and juniper and leafy spurge, in goat diets. Calibrations were developed using fecal diet pairs from feeding trials where the percentage of the species of interest was known. Calibration statistics consistently show that useful calibrations can be developed. However, the results of independent validations show a loss precision and a considerable reduction in accuracy. The objective of this research is to conduct a meta analysis to determine the strengths and limitations of FNIRS for predicting botanical composition of herbivore diets. Independent validation statistics compared to calibration and cross-validation statistics indicate that the coefficient of variation is reduced by 30 – 50 percent and the bias is increased 2 – 4 fold. Predictions of samples that are different from calibration samples should be considered an interval scale of measurement. Microhistological estimates of botanical composition are less precise than independent validations, which limits the use of this technique as a standard analytical procedure. Predictions of botanical composition

are affected by the design of the feeding trial. Trials should include 4 or more different background forages and 4 levels of the target plant, including 0. Dried forages, even those species with high levels of volatile secondary plant compounds, appear to provide calibrations as accurate and precise as calibrations using fresh or frozen plant material. The addition of samples to the calibration equation from animals on the same base forage but with 0 levels of the predicted species as animals being predicted can improve the precision and accuracy of predictions significantly. Animal variables such as breed, sex and age can affect fecal spectra but not necessarily the prediction of the target plant.

Sheep Species: Biology and Management of Low-input Lambing Management in Easy-Care Systems

669 Genetic and physiological effects on maternal behavior and lamb survival. C. M. Dwyer*, *SAC*, *Edinburgh, UK*.

Failure in the development of the ewe-lamb bond has been implicated in 80% of lamb pre-weaning deaths. Increased shepherding inputs have been used to improve lamb survival. However, a better understanding of the ewe-lamb bond and applying management and genetic techniques to improve this relationship provide a sustainable route to reduce lamb mortality. Appropriate expression of maternal behavior by the ewe (licking the lamb, low-pitched bleating, udder acceptance) can be disturbed in primiparous ewes, and in ewes undernourished in pregnancy. In addition, using two breeds of sheep (Scottish Blackface, Suffolk), we have shown that significant variation exists between breeds in both the quality of maternal behavior (e.g. percent time spent licking lamb in 2 hours after lamb birth: Blackface = 60.7%, Suffolk = 43.8%, s.e.d. = 2.6%, $P < 0.001$), and lamb vigor (e.g. time to stand after birth (min, means with 95% confidence intervals): Blackface = 15.3 (12.1 to 19.4), Suffolk = 25.7 (20.3 to 32.6), $P < 0.001$). Embryo transfer between breeds demonstrates that these behavioral differences are intrinsic to the breed and are not influenced by partner behavior. The observed behavioral differences result in higher lamb mortality in the Suffolk breed compared to Blackfaces (14% vs. 3%, $P < 0.001$). Investigation of maternal physiology showed higher circulating concentrations of estradiol, and estradiol:progesterone ratio, in Blackface ewes in late gestation in comparison to Suffolk ewes (estradiol concentration (pg.ml): Blackface = 11.4, Suffolk= 7.9, s.e.d. = 0.9, $P < 0.001$), and estradiol concentration was correlated with maternal licking and low-pitched bleating ($r^2 = 20\%$, $P < 0.005$). These data suggest that genetic differences in maternal behavior in sheep may be mediated by variation in the physiological processes underpinning the onset of maternal care. In addition to breed differences in behavior, significant sire effects within breed exist for lamb vigor, and lamb behaviors are heritable ($h^2 = 0.15$ to 0.35). Taken together these data suggest there is considerable potential to improve lamb survival by selection and management to improve ewe maternal behavior, and by genetic selection for lamb vigor.

Key Words: Maternal Behavior, Neonate Survival, Sheep

670 Management of maternal-offspring behaviour to improve lamb survival in low input systems. J. Everett-Hincks* and K. Dodds, *AgResearch*, *Invermay Agricultural Centre, Mosgiel, Otago, New Zealand*.

This paper provides an investigation into the environmental and management effects on lamb survival on high performing sheep farms in New Zealand. Improved lambing percentage is the biggest contributor to higher profits on New Zealand sheep farms. Many sheep breeders have selected and bred ewes for increased fecundity over the last four decades. Lamb survival is an important issue in highly fecund sheep flocks. The increased proportion of ewes having triplets is of concern to farmers and to industry as lamb mortality in the 24 hours post-partum is highest in triplets. The majority of lamb deaths occur in the first three days after birth and range from 5 to 30% for individual sheep flocks. These losses are unacceptable from animal welfare and production perspectives. The ability of a lamb to survive to weaning is determined by the successful execution of a number of processes. These are driven by genetics, behaviour, physiology and the environment, including on farm management practices. This study investigated the effects of dam body condition in pregnancy, weather over lambing, lamb birth weight and maternal behaviour on single, twin and triplet lamb viability at birth and survival through to weaning for 24 industry flocks (28525 lambs; 3474 singles, 18510 twins, and 6541 triplets) from 2003 to 2005. Ewes with higher body condition scores in mid pregnancy had heavier lambs at birth. Lambs weighing 6 to 8 kg at birth were more likely to be viable at birth and survive to weaning than heavier or lighter lambs. Weather conditions during late pregnancy proved as important as conditions during lambing in determining lamb viability and survival through to weaning. Older ewes and ewes with triplets require considerably more attention for farmers to realise their production potential. This paper explores the effect of environmental and management factors on lamb birth weight and survival and uses this information to formulate appropriate management programmes to improve lamb survival rates under low-input farming systems.

Key Words: Lamb Survival, Management, Sheep

671 Evaluation of Dorper, Dorset, Katahdin, and Rambouillet crossbred ewes in high- and low-input production systems. K. A. Leymaster*, *USDA-ARS, U.S. Meat Animal Research Center*, *Clay Center, NE*.

The primary objective was to evaluate wool (Dorset, Rambouillet) and hair (Dorper, Katahdin) dam breeds for their ability to complement Romanov germplasm as crossbred ewes managed in distinct production systems. Romanov ewes were mated with 18 rams of each dam breed to produce crossbred ewes for evaluation through 3 yr of age in two production systems. In the high-input system, labor and harvested feed were provided for sheep in confinement facilities and ewes were limited to rearing two lambs with additional lambs reared artificially. Ewes in the low-input system lambed on pasture and were responsible for rearing all lambs. No labor or supplemental feed were provided before weaning. A total of 830 crossbred ewes produced 1,962 litters and 4,171 lambs from 2,172 multisire exposures to two terminal sire

breeds (Suffolk, Texel). Fertility rate (FR), number born (NB), lamb losses between birth and 24 wk (LOSS), number at 24 wk (N24), and 24-wk litter weight (LTRWT) were analyzed as a trait of the ewe. Effects of year of birth, dam breed, production system, sire breed, ewe age and their two-way interactions were estimated. Random effects of sires of crossbred ewes and repeated effects of ewes across ages were fitted. Ewe age affected all traits and often interacted with dam breed and production system ($P < 0.05$). The interaction of dam breed x sire breed on FR ($P < 0.05$) was due to change in rank as well as magnitude. Suffolk-sired litters had greater LOSS and lesser N24 than litters by Texel rams ($P < 0.05$). Interactions of dam breed with production system were not detected. The high-input system had greater ($P < 0.05$) values than the low-input system for NB, N24, and LTRWT24 and approached significance for FERT and LOSS. Main effects of dam breed were detected ($P < 0.05$) only for NB and N24, with Katahdin crossbred ewes producing the most lambs, followed by Dorset and Dorper and then Rambouillet. Other key traits need to be considered before use of these dam breeds is recommended.

Key Words: Production Systems, Hair Breeds, Sheep

672 Pasture lambing prolific sheep. J. W. McNally*, *Tamarack Lamb & Wool*, *Hinckley, MN*.

Since the 1960s most Midwestern farm flocks have adopted an intensive sheep management system that entails winter lambing inside a barn. While this system has become very specialized, the high labor requirement of winter lambing, and the high cost of lambing indoors has meant most farm flocks have remained rather small and insignificant in financial contribution. Most flock owners responded by pushing lambing rates higher with a corresponding assumption that prolific sheep require extra care and attention that can only be afforded by lambing indoors. Tamarack Lamb & Wool added the Booroola *Fec*B gene to Dorset ewes in 1987 through selective crossbreeding, resulting in a lambing rate of 240 to 280% in ewes that carry the *Fec*B gene. Previously a fall and winter lambing flock, the flock was moved to late spring pasture lambing to accommodate the growing numbers of sheep. The benefits of lambing on pasture included better milk production and greater newborn survival, lower labor, considerably lower input costs, and the ability to run much larger numbers of sheep limited only by the forage resources that could be fenced. The core management considerations for pasture lambing are: 1) proper timing of lambing to synchronize with lactation quality feed and reasonable weather; 2) proper management of forage resources; 3) suitable animal genetics; and 4) minimal disturbances in the lambing paddock such as dogs, people, predators, first time mothers, or supplementary feeding. Tools used to manage feed and animals include 1) use of drift lambing; 2) set stocking after lambing; 3) rotational grazing; and 4) use of high energy tillable crops for fall finishing. Pasture lambing requires education of both sheep and shepherd. A new set of stock handling skills are required from the shepherd, and sheep can take several years to unlearn their barn lambing habits. Over the past 16 years the system used at Tamarack Lamb & Wool has been so successful that it has remained remarkably the same. The greatest change has been to relax the labor requirement as the sheep have become increasingly proficient at rearing lambs on pasture.

Key Words: Management, Lambing, Sheep

673 What does it mean to be locally adapted and who cares, anyway? F. D. Provenza*, *Utah State University*, *Logan*.

Sustainability is about ongoing adaptation in ever changing environments. What might that mean in the 21st Century? In ″The Long Emergency″ Jim Kunstler argues the availability of fossil fuels will decline severely in the first half of the 21st Century, and the massive deficits won't be countered by alternative sources of energy. This seeming catastrophe will create opportunities as communities come to rely on foods locally produced. Agriculture will be at the heart of communities, but its lifeblood won't be fossils to fuel machinery or fertilizers, herbicides and insecticides to grow and protect plants in monocultures, antibiotics and anthelmintics to maintain the health of herbivores, or nutritional supplements and pharmaceuticals to sustain humans. Rather, from soils and plants to herbivores and people we'll learn what it means to be locally adapted. Plants will be used as nutrition centers and pharmacies, their vast arrays of primary (nutrients) and secondary (pharmaceuticals) compounds useful in nutrition and health. Animals will be locally adapted to landscapes where they'll live from conception to consumption. Livestock will be produced in easy-care systems that match their production needs with locally available forages, and that involve an ongoing dialog among genes, social and biophysical environments, one that causes neurological, morphological and physiological changes in utero and early in life and confers survival advantages as the environment of rearing matches the environment where animals then live. Historically, the likelihood of a match was high as animals were conceived, reared, and reproduced in the same environment, and the strong fidelity animals' show to the sites where they are reared ensures they are locally adapted. Fossil-fuel subsidized management practices have created mismatches by requiring mother and offspring to be separated early in life and offspring to live in environments different from where they were conceived and reared. In this century, we will of necessity create easy-care ecosystems that nurture relationships among soil, water, plants, herbivores and people to sustain their collective wellbeing.

Key Words: Sustainability, Adaptability, Profitability

Teaching/Undergraduate & Graduate Education: Teaching Session I - Assessment & Evaluation

674 Evaluation and accreditation of agricultural research and teaching programs. J. R. Swearengen*, *AAALAC International*, *Frederick, MD*.

Considerable misunderstanding still exists regarding the process which AAALAC International uses for accrediting agricultural research and teaching programs. The objective of this presentation is to clarify the methodology used by AAALAC International to evaluate agricultural programs. It will include a review of the standards used by AAALAC International for evaluating the program of animal care and use specifically for agricultural programs and walk through the process of how a site visit is conducted. Specific examples of what is expected from both facility and programmatic perspectives will also be presented. This review will include a look at common physical plant issues such as barns, fences, pastures and paddocks and programmatic issues such as farrowing crate size, winter calving, and extension sites. With increasing scrutiny from the public sector on issues of animal well-being in production agriculture and agricultural research and teaching, the ability to demonstrate sound animal care will continue to grow in importance. AAALAC International accreditation is a confidential, external peer-review system utilizing experts in the fields of agricultural research and teaching. Accreditation not only provides for public accountability, but also establishes a quality assurance mechanism which emphasizes performance standards and peer review. These benefits, as well as others, will be discussed as they apply to agricultural programs. Having a full understanding of the AAALAC International accreditation process as it pertains to agricultural research and teaching will help attendees make informed decisions about the need and value of accreditation for their programs.

Key Words: Accreditation, Agricultural, Research

675 Development and use of a learning outcomes based assessment tool. J. L. Beckett*, *California Polytechnic State University*, *San Luis Obispo*.

Both universities and accrediting agencies are increasing efforts directed toward assessing the degree to which students are learning and the effectiveness of educational programs. However, assessing learning is a challenging and multi-layered task. Well defined and measurable learning outcomes assessment tools can facilitate the process and make it more useful and meaningful. At Cal Poly, a software program has been developed to create the learning outcomes process, print rubric scoring tables, data collection sheets, track and analyze data and print reports. A 4-point rubric scoring system (outstanding, proficient, approaching proficiency and needs improvement) was developed for assessing student learning along with criteria to categorize student work into those 4 proficiency levels. Questions embedded in final exams of capstone courses have been the primary artifacts used for assessment. Because several (36) learning outcomes have been defined and it is not appropriate, practical, or even desirable to assess all artifacts for all learning outcomes each time assessment is conducted, a flexible rubric scoring system was developed to rapidly create individualized rubric scoring sheets for assessing the specific learning outcomes to be evaluated in each set of artifacts. Additionally, a system for data collection was developed, including standard operating procedures. A data tracking system was created to simplify data entry and promote ease of data analysis and tracking. Because learning outcomes are aligned with programmatic, College and University objectives, data can be mined for trends by learning outcome, or by any combination of learning objectives. With these tools, faculty time is used effectively and the assessment coordinator can quickly and efficiently prepare for each assessment event, summarize the data, and expeditiously provide results to the faculty for rapid feedback and evaluation. By engaging faculty in the assessment process and using tools to simplify the assessment procedures, implementation of meaningful assessment has been put in place to provide guidance in curriculum development and ultimately enhance student learning.

Key Words: Education, Assessment, Learning Objectives

676 Assessment of predictors of critical thinking ability in animal science undergraduates. L. M. Morgan*, *Clemson University*, *Clemson, SC*.

Critical thinking and independent decision–making are essential for graduates seeking employment. Previous research shows that seniors in a college of agriculture scored lowest on a critical thinking ability construct, and higher on basic cognitive ability and applications ability constructs. Multiple predictors have been studied to identify their influence on critical thinking ability. Possible factors studied have included: age, gender, GPA, learning style, and classification. Therefore, the focus of this study was to quantify the critical thinking ability of students in selected classrooms in an animal science department and determine what demographic information served as a reliable predictor of critical thinking ability. The Watson–Glaser Critical Thinking Appraisal (WGCTA) test, form A and B, from Harcourt Assessment provided means to objectively assess a student′s critical thinking ability. The WGCTA seeks to provide an estimate of an individual′s standing on a composite of attitude, knowledge, and skills by means of evaluating the student′s ability to think critically in five categories: 1) Inference; 2) Recognition of Assumptions; 3) Deduction; 4) Interpretation, and 5) Evaluation of Arguments. Categories are weighted equally and final score is on a 0–80 scale. Each student (n=90)completed a questionnaire to determine demographic information with respect to: age; gender; classification; GPA, and previous judging experience. All data were analyzed for mean and standard deviation of final scores. Raw scores were then standardized and compared using a z–score. Mean score was 58.4 and standard deviation was 7.00. Multiple indicators for critical thinking ability were observed; students in the 18–20 age range (n=42), those who reported ≥3.4 GPA (n=26), and those who had experience judging in 4H and on a competitive judging team (n=3) scored higher than 87% of all students tested. Classification does not appear to influence critical thinking ability. Age, GPA, and previous judging experience do appear to predict critical thinking ability.

Key Words: Critical Thinking, Watson-Glaser

677 Critical thinking dispositions of undergraduates in two animal science courses at the University of Georgia. T. D. Pringle*, J. L. Douglas, and J. C. Ricketts, *The University of Georgia*, *Athens*.

Students in two University of Georgia (UGA) Animal Science (AS) courses were utilized to evaluate the critical thinking disposition (CTD) of a sub-population of UGA undergraduates and to compare CTDs across two courses taught using different teaching methods. Fall semester 2006 students enrolled in the Introduction to Animal Science (ADSC 2010; n=71) and Live Animal and Carcass Evaluation (ADSC 3200; n=18) courses were asked to complete a CTD Assessment (UF-EMI) at the beginning of the semester and a modified UF-EMI at the end of the semester, which included a retrospective and a current assessment. Students were asked to respond to 26 prepared statements using a 5-point scale (1=strongly disagree to 5=strongly agree). Responses to the statements were divided into three constructs. Engagement (E) which measures students' predisposition to searching for opportunities to use reasoning, anticipating situations that require reasoning, and confidence in reasoning ability; cognitive maturity (M) which measures predisposition to being aware of the complexity of problems, being open to other view points, and being aware of their and other's biases and predispositions; and innovativeness (I) which measures predisposition to being intellectually curious and having a desire to know the truth. Data were analyzed using SPSS, with $P<0.05$ used for significance. At semester's beginning, standardized and summated mean scores for E, M, I and total disposition were 79.27 (43.60), 77.97 (31.19), 80.15 (28.05), and 79.07 (102.79), respectively. Across all categories, UF-EMI scores were higher at the end of the semester than at the beginning. Change in UF-EMI was higher for students in the upper level ADSC 3200 course than the ADSC 2010 course. While AS majors had lower UF-EMI scores than non-majors, AS majors had greater UF-EMI gains in all constructs. Lastly, year in school did not result in differences in UF-EMI scores, while surveyed females scored somewhat higher than males. These data provide a snapshot of the CTD of UGA AS students and suggest that hands-on, experiential learning courses are important to the CT development of AS students.

Key Words: Critical Thinking, Disposition

Teaching/Undergraduate & Graduate Education: Teaching Session II - Curricular Innovation

678 Food Animal Scholars Program: An early selection program for undergraduates at North Carolina State University interested in pursuing a career in veterinary medicine working with food animals. W. L. Flowers*, C. R. Parkhurst, J. A. Moore, C. S. Whisnant, S. L. Pardue, and C. M. Williams, *North Carolina State University*, *Raleigh*.

The College of Agriculture and Life Sciences (CALS) and the College of Veterinary Medicine (CVM) at North Carolina State University developed a program to identify and prepare students for careers in food animal medicine. The program began in 1992 and was called the Swine and Poultry Scholars program. Initially, one student interested in swine and one in poultry were selected during the first semester of their freshmen year by a committee of CALS and CVM faculty. Students were chosen on the content of an essay and recommendations. Those selected were guaranteed admission to the CVM after completing their undergraduate degree in either Animal or Poultry Science provided they met all the minimum qualifications required including minimum GPA and extracurricular requirements. Each scholar was assigned two mentors – one in CALS and one in the CVM. Responsibilities of the mentors involved meeting with the students to monitor academic progress and provide extracurricular opportunities for them to interact with veterinarians and researchers in the swine and poultry industries. Upon admission into the CVM, there was no binding commitment for students to specialize in food animals. In 2003, the program was expanded to include 6 recipients and 2 alternates with an interest in any of the food animal species and renamed the Food Animal Scholars Program. Selection of students was moved to the second semester of their sophomore year. Participation in extracurricular activities with food animals and GPA were included in the selection criteria. The mentoring program remained basically the same and students were required to enroll in the food animal track upon entry into the CVM. Between 1994 and 2003, only 28% (4/14) of the Swine and Poultry Scholars selected have completed (or are in the process of completing) the program and either are working (or intend to work) with food animals upon receiving their DVM. Since the changes implemented in 2003, 73% (16/22) of the Food Animal Scholars are still in the program.

679 Design and development of a synchronously-delivered graduate course designed for the evaluation and practice of scholarship in animal sciences. L. A. Kriese-Anderson[1] and D. R. Mulvaney*[1,2], [1]*Auburn University*, *Auburn, AL*, [2]*Biggio Center for the Enhancement of Teaching and Learning*, *Auburn, AL*.

The professional life of academics is highly dependent on effective scholarship and the ability to evaluate publications for credibility. Often times, graduate programs rely heavily on transfer of scholarship skills from major professors. Built on a premise that there is a need by graduate students for development of these skills early in their career, our objective was to design and pilot a masters level graduate course targeting learning outcomes of increased awareness, knowledge and skills around scholarship to include proficiency in: conducting literature searches, evaluating research, scientific literature, writing technically for grant proposals as well as writing to transform technical scientific findings into more simplified forms of scholarship appropriate for various and broadened audiences. The course established concepts of working in a learning community (LC) and employed discussion of philosophies of scholarship, methods of research, evaluation of scientific writing, evaluation and practice of written proposals for funding and the process of publishing research findings. The course was delivered synchronously using videoconferencing technologies. Each of the eleven students played a pivotal role in professionally researching facts about writing and evaluating literature and preparing this information for others in the class. Students considered themselves members of a LC thus taking ownership and then chose to energetically and actively, bring learning opportunities to other members of the LC.

Selected formative and summative evaluation rubrics were developed to assess learning outcomes. A five point scale was applied to a 33 question pre- and post-course survey of knowledge or abilities around scholarly practices. Post-course responses increased by 2 points for most survey questions allowing a conclusion that the course was relevant and appropriately designed to meet student needs.

Key Words: Graduate Students, Scholarship, Animal Sciences

680 The value of writing to a real-world audience for animal science students. M. W. Orth*, *Michigan State University*, *East Lansing*.

For most writing assignments, the students' target audience is a professor, an individual who will be highly knowledgeable and trained in the subject matter of the written work. However, upon graduation, students will communicate with people from a diversity of backgrounds. An assignment was designed to have students in Growth and Musculoskeletal Biology (a junior-senior level animal science course) write to a much younger audience relative to a university professor. Students were asked to read 2 papers from *Nature* on bone metabolism and then write a one-page summary describing bone turnover to high school sophomore biology students using an age-appropriate vocabulary. A first draft was submitted, critiqued, and returned for revision. The final draft was collected, copied, and given to students at a local high school to read during their class period. These students critiqued the papers and filled out an evaluation on how well they understood bone turnover after reading the paper. Questions in the evaluation included ″Were there words in the paper that you did not understand? If so, please write them down" and "Based on the paper you just read, write down what you believe are the three most important processes involved in replacing old bone with new bone″. They were also asked to recommend a grade. The writing exercise is good for college students because they must translate technical biological concepts into language that typical teenagers can comprehend. As a side note, the two years the college students have done this assignment, the average grades have been higher on the quiz covering bone metabolism relative to the year before the assignment was initiated (80% and 91% vs. 76%). Thus, this assignment may be helping them better understand bone metabolism. The high school students enjoyed reading and grading the papers and took it quite seriously. Their suggested grades generally reflected the quality of the written work. Writing projects like this can facilitate the students' comprehension of a subject and prepare them for communicating to different audiences.

Key Words: Writing, Communication, Bone

681 Tracking undergraduate student performance while learning molecular genetics concepts. B. S. Walters* and T. J. Buttles, *University of Wisconsin*, *River Falls*.

This Scholarship of Teaching and Learning (SoTL) project documented students' understanding of the molecular genetics concepts that form the heart of modern biotechnology. The project studied animal, plant, and food science majors in three semesters of an agricultural biochemistry course. It is a 200 level class made up of sophomores through seniors with 50-60 students enrolled each semester. The starting point was to determine students' experience in related courses and level of prior understanding. As a pretest, students were asked to complete a short questionnaire containing questions on related courses and defining 5 terms. Two additional data collection points were utilized. A quiz on DNA structure and types of RNA was given during the unit. The second course exam included questions on DNA and protein synthesis. For data analysis students were grouped based on the related courses completed and in-progress. Mean pretest scores, change from quiz to exam, and change from pretest to exam were calculated. Because of the wide variation across semesters each class was treated as an individual case. The largest group of students (44% - 56% each semester) had completed both introductory biology and genetics classes. The second largest group (17% - 21%) had completed both introductory biology and genetics while taking animal or plant breeding concurrently with biochemistry. The third largest group (9.6% - 17%) had completed introductory biology while taking genetics concurrently with biochemistry. Mean pretest scores ranged from 16% - 36% for group 1, 18% - 30% for group 2, and 10% - 27% for group 3. The mean improvement from quiz to exam on the DNA structure questions ranged from 14% - 32% for group 1, 10% - 50% for group 2, and -17% - 49% for group 3. The mean improvement from quiz to exam on the protein synthesis questions ranged from 30%- 32% for group 1, 24% - 49% for group 2, and 9% - 23% for group 3. The mean improvement from pretest to exam on the protein synthesis questions ranged from 45% - 66% for group 1, 49% - 69% for group 2, and 38% - 62% for group 3.

Key Words: Undergraduate Education, Teaching, Biotechnology

682 Bringing the industry into the classroom: Media interview project. J. A. Sterle*, *Texas A&M University*, *College Station*.

Twenty-one undergraduate students (18 freshmen, 2 sophomores, 1 senior; 18 females and 3 males) were enrolled in ANSC 107: General Animal Science – Honors Section. In comparison to previous years, most students were not Animal Science majors nor did they have an agricultural background. Students randomly drew one of 11 topics and were given a specific scenario unique to their topic on a later date. Topics included: Use of hormones as growth promotants, the Horse Slaughter Prevention Act, Arizona Proposition 204: Use of sow gestation stalls, use of antibiotics in livestock, and animal well-being. Students were required to research the topic, including opposing views, and write a six to ten page paper on the issue. Three weeks after receiving the scenarios, students received media training from National Pork Board′s Operation Main Street program. Students prepared message points and were then interviewed by a media professional and videotaped. Students were given a short survey to complete anonymously. Eighteen of 21 students returned the survey (85.7%). The following Likert scale was used: 1 = very uncomfortable; 2 = slightly uncomfortable; 3 = neither comfortable or uncomfortable; 4 = fairly comfortable; 5 = very comfortable. Results are presented in Table 1. Students were also asked about perceived change in level of knowledge about current issues facing animal agriculture. Response average was 4.67 with 1 = none; 2 = a little; 3 = some; 4 = quite a bit; 5 = a tremendous amount. These results indicate that students′ perceived knowledge level of current issues and level of comfort with speaking in various situations increased by completing this project.

Table 1. Response of students when asked about comfort level of speaking in different situations.

How comfortable were you with:	Prior to project	After project
Public speaking overall	2.67	3.72
Speaking in front of peers	3.39	4.33
Speaking with the media	1.83	3.50
Speaking in front of large groups	1.94	2.88
Discussing issues facing animal agriculture	2.17	4.06

Key Words: Teaching, Media, Issues

683 Development of time-enhanced internet-based distance education in feed mill management and feed formulation. P. R Ferket*, *North Carolina State University*, *Raleigh*.

Availability or access to feed science programs at land-grant Universities is limited and does not supply feed industry employment demand. The average number of employees at feed plants decreased by 33% from 2000 to 2005, and few employees can take leave for training in priority matters such as regulatory compliance, feed safety, quality assurance, and worker safety (Gill, 2006). Using WebCTVista™ (http://vista.ncsu.edu), a course entitled ″Feed Mill Management and Feed Formulation (PO425-601)″ was developed and delivered to distance education students during 6 consecutive semesters. This 3-credit hour course included 4 learning modules: 1) feed industry, mill design, and management; 2) manufacturing and process control; 3) regulations and quality control; and 4) formulation and product development. Each module included virtual lectures (image-enhanced text, audio, and video), interactive self evaluation, discussion boards, creative assignments, and exams. Enrollment data and learning performance and evaluations of students enrolled in PO425-601 was compared to the on-campus section of the same course (PO425-001). Average annual enrollment in PO425-001 was 17 students, but the addition of PO425-601 increased enrollment to 41 and 44 students in 2005 and 2006, respectively. The 601 section was preferred by about 80% of the PO425 enrollment, and half were full-time feed industry employees. Average final grade and performance distribution were similar between sections 001 and 601. Overall course evaluation score (out of 5) from students enrolled in sections 001 and 601 were 4.56±0.53 and 4.0±.75, respectively. The use of the internet was found to be an effective and feasible teaching method to deliver highly technical information to students with time and travel limitations, such as those employed by the feed industry. Sequel distance education courses (″Advanced Feed Mill Operations and Management″ and ″Feed Quality Assurance and Formulation″) are being developed based on the model of PO425-601 to complete a certificate or minor degree program.

Key Words: Feed Mill Management, Distance Education, Internet Technology

684 The fundamentals of collegiate poultry judging. J. C. Butler* and P. A. Curtis, *Auburn University*, *Auburn, AL*.

Collegiate poultry judging is a powerful recruiting tool for a department and can also be an excellent way for undergraduates to interact and explore potential options for graduate school. Every year two collegiate contests are held, the National Collegiate Poultry Judging contest at the University of Arkansas and the US Poultry and Egg National Poultry Judging contest at Louisiana State University. In 2006 twelve universities competed for the national title, half of which have a strong poultry program. Several factors that may influence a school's decision to start a judging program include the willingness of a professor to provide leadership, availability of space on the farm for rearing and holding birds, funding and student interest. For those schools willing to make the necessary commitments, the judging team experience can be an excellent recruiting instrument. Our goal at Auburn University is to appeal to high school seniors and incoming freshman who currently utilize technology in their day-to-day social networking. In an effort to adapt to the learning practices of digital natives we have incorporated technology in Auburn University's inaugural poultry judging class. A unique approach to this experience at Auburn University is the use of technology as a teaching enhancement. A DVD was created which allows the students to see inside the hen and see the how the egg is formed This DVD entitled, "The Virtual Chicken: The Female Reproductive Tract," is used as an introduction to the egg quality judging experience. This DVD shows how defects such as blood spots and body checks occur. IPods are made available to students who do not currently own one. In addition, short podcasts have been developed for study tools to use outside the classroom. The podcasts provide the students with the basics they need to know for each judging ring. Technologies being utilized in this class may be of interest to other universities offering this course. Samples of these technology enhancements will be shown during the presentation.

Key Words: Collegiate Poultry Judging, Recruiting, Education

POSTER PRESENTATIONS

Animal Behavior & Well-Being - Livestock and Poultry III

W1 Laying hens in conventional and enriched cages. G. B. Tactacan*, J. D. House, and W. Guenther, *University of Manitoba*, *Winnipeg, MB, Canada*.

Concerns regarding the welfare of laying hens raised in battery cages have led to the development of enriched cages that allow hens to perform natural behaviors including nesting, roosting and scratching. This study was conducted to compare indices of production and welfare in birds housed in two different caging systems. Shaver White hens were housed from 21 to 45 weeks of age in either conventional battery cages (n = 500; 5 hens/cage; floor space = 87.1 in^2/hen) or enriched cages (Hellman; n = 480; 24 hens/cage; floor space = 99.6 in^2/hen). Enriched cages were provided with a nest, scratch pad and perches. Egg production, incidence of cracked, dirty or soft shelled eggs were recorded daily throughout the experiment. Feed consumption, egg weight and specific gravity were monitored at the end of every 28-d period. Plumage condition was evaluated on the neck, breast, back, tail, vent and wing regions at 35 weeks. Data were analyzed using t tests. The type of cage did not affect the hen-day egg production, feed consumption or egg weights. No significant differences were observed in specific gravity, percentage of cracked and soft shelled eggs between conventional and enriched cages, however, the incidence of dirty eggs was significantly higher ($P < 0.05$) in enriched cages (Enriched = 10.59% ± 2.95; Conventional = 3.78% ± 0.84). Plumage condition of the wings and back region of birds reared in the conventional cages were significantly higher ($P < 0.05$) and lower ($P < 0.05$), respectively, compared to birds reared in the enriched cages. All other body regions did not show significant differences. Overall, laying performance, egg quality measures and plumage condition appear to be similar for hens housed in the two cage systems tested.

Key Words: Laying Hen, Conventional, Enriched

W2 Evaluation of weight shifting as a pain indicator in lame pigs. L. Anil*, S. S. Anil, J. Deen, S. V. Westen, and S. K. Baidoo, *University of Minnesota*, *St. Paul*.

Lameness is a putatively painful condition, common in pig farms. Generally, both pain and lameness in animals are assessed subjectively, often anthropomorphically. An objective measure to assess lameness and the level of pain in lame pigs is necessary to evaluate pain alleviating interventions in lame pigs. The objective of the present study was to evaluate weight shifting as an objective indicator of pain in lame pigs. An analgesic was used in this study on the assumption that if analgesia could improve the condition it was pain that the animal was experiencing. This preliminary study involving 15 pigs was conducted at the swine research unit of the University of Minnesota at Waseca, MN. Visibly lame pigs were made to stand on slatted floor (12.7 cm solid portion and 2.54 cm slot) and on rubber mats (1.9 cm thickness) and number of weight shifting per minute was recorded. Subsequently the same pigs were treated with an analgesic (Flunixin meglumine 2.2 mg/kg body weight, intra-muscularly) and the number of weight shiftings per minute was recorded on both floor types 45 min after the injection. The measurements were repeated three times on alternate days with the same pigs during a continuous 5 days period. Within each floor type category the number of weight shifting before and after analgesic treatment were compared (Wilcoxon signed rank test).Similarly, the number of weight shifting before and after analgesic treatment was compared (Wilcoxon signed rank test) between floor types. The results indicated a higher ($P \leq 0.05$) number of weight shifting on slatted floor prior to analgesic treatment compared to post analgesic treatment, whereas the number of weight shifting on rubber mat were similar before and after analgesic treatment. Both before and after analgesic treatment, the number of weight shifting was lower on rubber mat compared to slatted floor ($P \leq 0.05$ for both). The study indicated that weight shifting may be considered as an objective indicator of the level of pain in lame pigs.

Key Words: Lameness, Pig, Pain

W3 Development of a feed-restriction model to identify factors responsible for fescue toxicosis-induced reduction in food intake. S. Raney*, P. A. Eichen, and D. E. Spiers, *University of Missouri*, *Columbia*.

Fescue toxicosis is caused by consumption of ergopeptine alkaloids produced by an endophytic fungus (Neotyphodium coenophialum) in tall fescue, and is characterized by reduced productivity. The primary contributors to the reduced productivity are decreased feed intake and growth. There have been few attempts to characterize these changes in performance. A study was conducted to develop a model

for this component of fescue toxicosis using rats in a feed restriction experiment described previously by others. Each animal was trained over a minimum 11 d period to eat their entire daily ration from 1300 to 1500. The advantage of this approach is that one can effectively evaluate the effect of potential treatments more precisely over a 2-h period than over 24 h. Group I animals were first fed ad libitum an endophyte-free seed (E-) diet, then restricted E- diet, then restricted endophyte-infected seed (E+) diet, and lastly ad libitum E- diet. There was no significant decrease in feed intake ($\alpha = 0.05$) from restricted E- diet to restricted E+ diet, but reduced growth while on E+ diet. Return to E- diet restored growth rate. A different routine was used with Group II. Rats were first fed ad libitum ground commercial diet, followed by restricted ground diet, then restricted E- diet, and lastly restricted E+ diet. Initial exposure to restricted diet decreased feed intake and growth rate ($\alpha = 0.05$), followed by partial recovery or adaptation over the next 4 d. Shift to restricted E- produced no change in feed intake and a greater return of growth rate. Restricted E+ diet intake reduced feed intake and growth rate within 24 h ($\alpha = 0.05$). This reduction was stable over the entire 2 week period. These responses agree with previous studies using long-term ad libitum E+ treatment. This new model can now be used to identify mechanisms for fescue toxicosis-induced reduction in feed intake and growth, and develop potential treatments.

Key Words: Fescue Toxicosis, Feed Intake, Rat

W4 Assessing the performance of Redbro Cou Nu chickens in different environments. W. L. Willis[1], M. Johnson[1], C. Hatcher*[1], and R. Joyce[2], [1]*North Carolina Agricultural and Technical State University*, *Greensboro*, [2]*Joyce Foods, Inc.*, *Winston Salem, NC*.

An experiment was conducted to evaluate feed type, placement time and density on the production performance of the Label Rouge chicken. Five hundred four day of hatch Redbro Cou Nu chickens were weighed, randomly assigned to two placement densities (1.0 sq ft vs 2.0 sq ft), replicated four times with 30 or 60 chicks per floor pen, with two pens for each density fed a convention or organic starter/grower diet for 9 wks, and two groups of 72 chicks housed for 3 or 6 wk for placement on pasture. Chicks were weighed weekly, mortality recorded daily, and feed consumption measured at the end of the trial. Body weights at 9 wks of age for the conventional feed and two placement densities were very similar (2.580 vs 2.540 kg) whereas, the organic chickens with more space had higher weights (2.720 vs 2.540 kg), respectively. Birds given 1 sq ft of space consumed less feed for both conventional and organic treatments. Chickens placed on pasture at 6 wks had higher body weights (2.373 vs 2.274) when compared to the 3 wk placed chickens. Mortality for the indoor chickens was similar and very low for both treatment groups. The chicks placed outside at three weeks suffered greater losses from hawks than the six wk placement group. The orientation of the house to the hawk's perch site is believed to have influenced the early placed chicks' susceptibility. The results from this study showed that not much production advantage is gained by the expensive organic feed and placement density indoors and placement time outdoors influence production parameters.

Key Words: Redbro Cou Nu Chickens, Placement Density, Organic Feed

W5 The effect of mushroom and pokeweed extract on *Salmonella* in molting hens. W. L. Willis*, O. Isikhuemhen, I. Goktepe, M. Reed, and C. Murray, *North Carolina Agricultural and Technical State University*, *Greensboro*.

The present investigation was conducted to evaluate the effects of mushroom and pokeweed extract in the drinking water of leghorn laying hens during a 10 d molting period. The trial consisted of 54 Single Comb White Leghorn hens approximately 77 wks of age. The layers were subjected to one of nine treatment (trt) groups, replicated three times with two hens per replicate cage. The treatments consisted of 1) Full-fed + H20; 2) Full-fed + mushroom; 3) Full-fed + pokeweed; 4) Non-fed molt + H20; 5) Non-feed molt + mushroom; 6) Non-fed molt + pokeweed; 7) Full-fed alfalfa meal + H20; 8) Full-fed alfalfa meal + mushroom and 9) Full-fed alfalfa meal + pokeweed. The pokeweed extract showed antimicrobial activity against Salmonella spp. in the crop ranging from 5-20 % of the initial control. Hens treated with crude pokeweed extract and no feed had the highest reduction in Salmonella spp. count. There was a reduction of Salmonella spp in alfalfa + mushroom (2.6 log 10) when compared to the non-fed + mushroom (2.8 log 10) and the Full-fed + H20 (2.9 log 10). The level of Salmonella spp. in the ceca of hens subjected to fasting exceeded 3.0 log10 in trt 4, whereas the alfalfa mushroom combination showed a lower level of 2.7 log 10. *Salmonella enteritidis* was isolated from the ovary and spleen (66%) in trts 2, 3, and 9, but not in the liver of any trt's. Egg production lagged behind more in trt's 8, 9 and 5, respectively, than any other treatments. No differences were noted in body or organ (liver, spleen, ovary) weight reduction between treatments. These results indicate that pokeweed and mushroom extracts exhibits antimicrobial activity against Salmonella spp. and such activity are expected to increase with higher concentration of extracts.

Key Words: Laying Hens, Molting, *Salmonella*

W6 Control of feral hog populations: a domestic pig model to attract and repel feral hogs using odors. N. Krebs, L. E. Hulbert*, and J. J. McGlone, *Texas Tech University*, *Lubbock*.

Controlling feral hog populations is important to farmers and communities because of economic and health concerns. Traps work better if an attractive substance such as corn is present. The aim of this study was to determine which odors were attractive or repulsive to feral hogs, using a domestic pig model. Weaned pigs (n = 72) were exposed in a Y-maze for 6 consecutive days to 6 randomly assigned odor treatments: control (air, CON), maple syrup (MS), NH_3, CORN, CO_2 and ChileGard™ (CHILE, habanero-based product). Twelve litter-replicates were used in this replicated latin square design (6 piglets/litter×6 treatments). Pigs were placed in a Y-maze (one arm contained nothing, the other the treatment) for one minute while video recorded. The time spent towards the treatment was divided by the total time spent in the right and left arms to express a Preference Index (PI, in %). The test day (TD)×treatment interaction was significant ($P < 0.05$). The data were analyzed per TD and compared to PI=50% (no preference). All means presented below were different ($P < 0.05$) than 50% (< 50% = aversion, > 50% = attraction). On TD 1, PI was more ($P < 0.05$) than 50 % (66.1 % ± 7.95) for CON, indicating a side preference. Pigs also preferred the odor of CORN (73.2 % ± 12.2).

All PIs were therefore compared to each TD's CON PI. On TD 2, pigs preferred NH_3(72.3 % ± 10.7) or CHILE (69.8 % ± 11.0) compared to CON. On TD 3, the PI to NH_3 was 25.8 % ±13.0 and 37.3 % ± 6.38 for CHILE, while on TD 4, the PI to CHILE was 76.3 % ± 14.1. On TD 6, pigs showed an aversion to NH_3(32.6 % ± 14.0) and a preference for MS (75.2 % ± 10.7). These results may indicate that pigs were attracted to familiar odors (CORN and NH_3) when in a novel testing environment. CHILE and NH_3 had variable effects. The PI to MS was superior to 50% only on TD 6; pigs may not have an innate preference to this novel odor. This domestic pig model must be tested in the field, but pigs were clearly attracted to a familiar feed odor (CORN) which may be useful in the field if pigs are first accustomed to the odor of corn. None of the odors tested were clearly aversive.

Key Words: Pigs, Feral Hogs, Odors

W7 Adaptation of Angus steers to long-term heat stress in the field using controlled heat challenge. B. Scharf*, L. E. Wax, D. H. Keisler, and D. E. Spiers, *University of Missouri*, *Columbia*.

Most heat stress studies are conducted using short-term, controlled exposure (i.e., 1-2 weeks) in environmental chambers or long-term summer exposure to variable field environments. This study combines both situations by utilizing the controlled conditions in the Brody Environmental Center (BEC) at the University of Missouri to effectively provide each animal with an initial baseline 'stress test.' This was followed by placement in the summer field environment (South Farm, University of Missouri) for ~3 months, to create the long-term (i.e, real world) scenario, after which animals were given another 'stress test' to determine adaptive change. Six Angus steers (365 ± 10kg BW) were housed in the BEC for 7 days at air temperature (Ta) of 20°C (TN), followed by 7 days of cyclic heat stress (HS; Ta=26°C night; 36°C day). Respiration rate (RR) and rectal temperature (Tre) were measured 6 times daily. Sweat rate was measured at shaved sites (shoulder, rump) on select days. Following the initial test, steers were placed on pasture from May to September, 2006, when Ta and THI ranges were 7.0 - 38.1°C and 49.8 - 86.9, respectively. Pre-summer (**PRE**) Tre and RR were not different from post-summer (**POS**) values at TN ($P > 0.09$). Both groups increased Tre during HS ($P < 0.0001$), with **POS** animals stabilizing faster than **PRE** animals. In comparison with Tre response to HS, RR increased more rapidly, exhibited greater **PRE** to **POS** separation, and stabilized faster to suggest that it is a more sensitive measure of HS adaptation. Sweat rate rapidly increased prior to Tre and RR during HS ($P < 0.0001$), with **PRE** level rising above **POS** ($P < 0.001$) to indicate that sweat rate is a reliable indicator of short-term heat response and adaptation. However, sweat rate decreased in **PRE** steers to **POS** level after a few days, even though Tre and RR were still elevated. This suggests that reduction of sweat rate, and possibly water loss, is more important than reduction of body temperature during heat stress.

Key Words: Cattle, Heat Stress, Adaptation

W8 Dietary supplementation with omega-3 fatty acids affects sexual behavior in boars. M. J. Estienne* and A. F. Harper, *Virginia Polytechnic Institute and State University*, *Suffolk*.

Enhancing semen quality and sexual behavior would increase efficiency in commercial boar studs. We reported (2007; J. Anim. Sci. 85[Suppl. 2]:20) that dietary supplementation with omega-3 fatty acids increased the number of spermatozoa by over 9 billion/ejaculate during a 16-wk trial. Here we report the effects of omega-3 fatty acids on sexual behavior. Yorkshire x Landrace boars, trained to mount an artificial sow, were fed 2.2 kg of a control diet (n = 12) or the control diet top-dressed with 0.3 kg of an omega-3 fatty acid supplement (JBS United, Inc., Sheridan, IN) (n = 12), daily for 16 wk. Semen was collected and libido assessed once weekly. Data were analyzed by ANOVA using a model that included treatment, period (Period 1 = wk 0 to 7 and Period 2 = wk 8 to 15), and treatment x period. The elapsed time from entering the collection pen until first interaction with the artificial sow was affected by period (15.4 sec and 8.6 sec for Periods 1 and 2, respectively; SE = 1.4; $P = 0.04$). There was a tendency ($P = 0.09$) for an effect of treatment x period for the interval between entering the collection pen and the first attempt to mount, and was 99.1 sec and 128.1 sec for controls, and 135.4 sec and 102.9 sec for boars fed omega-3 fatty acids, for Periods 1 and 2, respectively (SE = 17.4). Duration of ejaculation was affected by treatment (343.9 sec for controls and 388.8 sec for boars fed omega-3 fatty acids; SE = 7.2; $P = 0.05$). Elapsed time from entering the collection pen until the start of ejaculation (264.3 sec), and the number of false mounts (mounting the artificial sow but dismounting before a complete ejaculation was collected; 1.8) were not affected by treatment, period, or treatment x period ($P > 0.1$). Dietary supplementation with omega-3 fatty acids affected sexual behavior in boars by decreasing the time between entering the collection pen and first attempting to mount, and increasing the duration of ejaculation. (Funded by Virginia Agricultural Council)

Key Words: Boars, Sexual Behavior, Omega-3 Fatty Acids

W9 Evaluation of physiological differences in heat tolerant (Romosinuano) and heat susceptible (Angus) Bos taurus cattle during controlled heat challenge. B. Scharf*[1], L. E. Wax[1], J. A. Carroll[2], D. G. Riley[3], C. C. Chase Jr.[3], S. W. Coleman[3], D. H. Keisler[1], and D. E. Spiers[1], [1]*University of Missouri*, *Columbia*, [2]*USDA-ARS, Livestock Issues Research Unit*, *Lubbock, TX*, [3]*USDA-ARS, SupTropical Agricultural Research Station*, *Brooksville, FL*.

A study was performed to evaluate differences in thermoregulatory ability of two Bos taurus breeds with known differences in heat tolerance. Nine Angus (304 ± 7 Kg BW; **AG**) and nine Romosinuano steers (285 ± 7.5 Kg BW; **RO**) were housed in the Brody Environmental Center at the University of Missouri. Steers were housed for 14 d at thermoneutrality (21°C; TN) before initiation of heat stress. Heat stress (HS) consisted of daily cyclic air temperature (26°C night; 36°C day) for 14 d. Steers were fed a typical feedlot diet at 1.6% of BW/d. Rectal temperature and respiration rate were measured six times daily. Sweat rates were recorded on specific days throughout the study on shaved shoulder and rump sites. Analysis was repeated measure ANOVA. Respiration rate at TN was higher ($P < 0.001$) in **AG** than **RO**, by ~20 BPM. Angus steers maintained a higher rectal temperature (+0.5°C) than **RO** at TN ($P < 0.0001$). Sweat rates were also higher at TN (+6 $g/m^2/h$; $P < 0.03$). Both breeds initially increased sweat rate 4-fold during HS ($P < 0.0001$), followed by reduction after 3 d ($P < 0.0001$). Sweat rate during HS was higher ($P < 0.0001$) in **AG** compared to **RO** by ~90 $g/m^2/h$. Both breeds increased respiration rate by ~ 30 BPM during HS, with **AG** steers exhibiting the higher rate ($P < 0.0001$). Rectal temperature increased during HS for both breeds ($P < 0.0001$),

but was higher in **AG** breed ($P < 0.001$). Romosinuano steers exhibit a lower sweat and respiratory rates than **AG** during HS, while maintaining the lower rectal temperature. Indices of heat loss used in this study suggest that these avenues are not used to generate a lower rectal temperature seen in Romosinuano cattle during heat stress.

Key Words: Cattle, Heat, Tolerance

Animal Health - Livestock and Poultry: Bovine II

W10 Tumor necrosis factor-α (TNF-α), nitric oxide (NO), and xanthine oxidase (XO) responses to endotoxin (LPS) challenge in steers: Effect of progesterone (P4) and estradiol (E2) treatment. S. Kahl* and T. H. Elsasser, *USDA, Agricultural Research Service*, *Beltsville, MD*.

The severity of host response in some diseases differs between sexes and this dimorphism has been attributed to the immunomodulating effects of steroid hormones. In females, prevailing P4 or E2 concentration during different estrous cycle phases have been suggested to affect the immune responses to a disease stress. Our objective was to determine in steers the effect of P4 or E2 treatment on circulating concentrations of immune response mediators after two consecutive LPS challenges (LPS1 and LPS2, 6 d apart; 2.5 μg/kg BW, i.v., *E. coli* 055:B5). Plasma concentrations of inflammatory initiation cytokine TNF-α, nitrate+nitrite (NOx, estimate of NO production), and XO activity (mediator of superoxide production), were measured. Twenty crossbred steers (392 ± 7 kg) were fed a forage-concentrate diet (15% CP) to appetite and assigned to control (C, n = 7), P4 (n = 8) or E2 (n = 5) treatment. Progesterone (1 mg/kg BW; i.m.) and 17β-estradiol (E2, 2 mg/steer, i.m.) was injected 5, 3, and 1 d before LPS1 and LPS2. For each challenge, jugular blood samples were obtained at 0, 1, 2, 3, 4, 7, and 24 h relative to LPS injection. The primary response to LPS challenge was measured as area under the time × concentration curve (AUC). Compared to C, P4 treatment decreased plasma TNF-α AUC after LPS1 (5.68 vs 8.15 ng/mL × h, $P = 0.08$) and NOx AUC after LPS2 (32.3 vs 131.2 μM × h, $P < 0.05$). In contrast, E2 treatment augmented ($P < 0.01$) plasma TNF-α (14.66 vs 5.96 ng/mL × h) and NOx (299.8 vs 131.2 μM × h) responses to LPS2. Plasma XO AUC was increased ($P < 0.01$) over C by E2 treatment after both LPS1 (406.8 vs 179.4 mU/mL × h) and LPS2 (413.1 vs 156.5 mU/mL × h). Results indicate that in cattle, circulating P4 and E2 may, respectively, attenuate or amplify the TNF-a response to LPS challenge as well as the subsequent responses of immune mediators (NO, XO) involved in oxidative damage to animal tissues.

Key Words: Endotoxin, Estradiol, Progesterone

W11 Prevalence of *Chlamydophila spp.* in randomly selected dairy farms in the western part of Germany. K. Kemmerling*[1], U. Mueller[1], M. Mielenz[1], K. Sachse[2], J. Winkelmann[3], F. Jaeger[4], and H. Sauerwein[1], [1]*Insitute of Animal Science, Physiology & Hygiene Group, University of Bonn*, *Germany*, [2]*Federal Research Institute for Animal Health*, *Jena, Germany*, [3]*North-Rhine-Westphalian Chamber of Agricultural Matters*, *Roleber , Germany*, [4]*North-Rhine-Westphalian Ministry of Enviroment, Conservation, Agriculture and Consumers Protection (MUNLV)*, *Duesseldorf, Germany*.

Infections with intracellular bacteria of the genus *Chlamydophila* are associated with various symptoms such as infertility in cattle. Serological studies suggested a high level of exposure to *Chlamydophila spp.* but systematic epidemiological investigations for the DNA-based detection of *Chlamydophila spp.* are only scarcely available. The objective of our study was to characterize the prevalence of *Chlamydophila spp.* in dairy cows in the western part of Germany (North-Rhine-Westphalia) since the epidemiological status of dairy cattle infection with *Chlamydophila spp.* in North-Rhine-Westphalia (NRW) was unknown. In total 100 dairy farms were randomly selected. For this purpose the dairy cow stocking rate in the different administrative districts of NRW was taken into account. Ten dairy cows per farm or at least 10% of the stand density per farm were sampled. For the detection of *Chlamydophila spp.* vaginal swabs from non-pregnant, early lactating dairy cows were analysed using an established highly sensitive genus specific real-time PCR. At present, samples from 80 dairy farms i.e. from 870 individual dairy cows have been analysed. Positive testings were observed in 61% of the farms and in 15% of the cows. The lower prevalence observed on a per cow basis might be explained by the discontinued shedding of the pathogen. Nevertheless, our results suggest that *Chlamydophila spp.* is widely spread in NRW. To evaluate the impact of *Chlamydophila* infections on heard health and fertility and to developed strategies to counteract *Chlamydophila* associated health disturbances, further investigations are needed.

Key Words: *Chlamydophila*, Dairy Cows, PCR

W12 Growth, health, and select immunologic and metabolic functions of preruminant calves housed in warm and cold environments. B. J. Nonnecke*[1], R. L. Horst[1], M. R. Foote[2], B. L. Miller[3], T. E. Johnson[3], and M. Fowler[3], [1]*National Animal Disease Center*, *Ames, IA*, [2]*Iowa State University*, *Ames*, [3]*Land O'Lakes Research Farm*, *Webster City, IA*.

The physiological response of the preruminant calf to cold-stress has not been studied extensively. This study examined effects of sustained environmental cold on growth performance and health of preruminant calves. Functional measures of energy metabolism, fat-soluble vitamin and mineral status, and immune competency were also evaluated. Holstein calves, 3 to 10d of age, were assigned randomly to warm or cold environments and kept in these environments for 7wk. Cold environment calves (n=15) were exposed to temperatures maintained as close to 2°C as possible. Frequent wetting of the environment and calves was used to augment effects of the cold environment. Warm environment calves (n=14) were maintained as close to 15°C as possible. Warm environment humidity was not manipulated. Preventative medications or vaccinations that might influence disease resistance were not administered. Non-medicated MR (20% CP and 20% fat fed at .45 kg/d) and calf starter (ad libitum) were fed to all calves. During the 7wk period, cold environment temperatures averaged almost 20oC lower ($P \leq .05$) than warm environment temperatures. Relative humidity averaged 10% higher ($P \leq .05$) in cold environment. Warm environment calves were healthier and needed less medical

intervention. Growth rate was unaffected (P>.05) by environmental temperature; however, cold environment calves consumed more (P≤.05) starter at wk5, 6 and 7. Blood glucose concentrations were lower (P≤.05) and NEFA concentrations were higher (P≤.05) in cold environment calves, indicative a state of mild negative energy balance. Serum tumor necrosis factor, interferon and fat-soluble vitamin concentrations as well as antibody responses induced by vaccination were not affected (P>.05) by sustained exposure to cold. These results suggest that environmental cold has minimal effect on growth but does compromise calf health.

Key Words: Preruminant Calf, Cold Stress, Calf Health

W13 Pasteurization of colostrum reduces the incidence of paratuberculosis in neonatal calves. J. R. Stabel*, *USDA-ARS-NADC*, *Ames, IA*.

Feeding colostrum from infected dams to neonatal calves is one mode of transmission of paratuberculosis (Johne's disease). Recent studies have demonstrated improved morbidity and mortality rates in calves fed colostrum replacers or pasteurized colostrum. In the present study, the potential benefits of feeding pasteurized colostrum was demonstrated in calves born to dams naturally infected with *Mycobacterium avium* subsp. *paratuberculosis*. Calves were separated at birth from their dams and randomly allocated into a group fed the dam's colostrum, followed by feeding the dam's milk for 3 weeks (DC; n = 6), or into a group fed pooled pasteurized colostrum and milk replacer (PC; n = 5). After 3 weeks, calves were then weaned onto calf starter and housed and fed in a similar manner throughout the rest of the study. Blood and fecal samples were taken at birth and monthly throughout the 12-month study. Calves were necropsied at the end of the study and tissues were cultured for *M. paratuberculosis*. Twenty-five tissues were taken at necropsy and cultured for *M. paratuberculosis*. Sixteen of the 25 tissues were positive across treatment groups, with 14 of 16 tissues positive for DC calves and 9 of 16 tissues positive for PC calves. The degree of colonization within a tissue was low and varied between calves even within a treatment group. Fecal shedding was minimal during the study with 2 calves from each treatment group shedding negligible amounts of *M. paratuberculosis*. As a measure of early immune response to infection, blood obtained from calves was stimulated in vitro with *M. paratuberculosis* antigen preparations and IFN-gamma secretion was measured. Antigen-specific IFN-gamma was consistently higher throughout the study in calves fed colostrum and milk from their infected dams (0.95 vs 0.43 Abs540nm). These results indicate that feeding a source of clean colostrum to neonatal calves may reduce their exposure to *M. paratuberculosis*.

Key Words: *Mycobacterium avium* subsp. *paratuberculosis*, Calves, Colostrum

W14 Effects of pre- and postpartum feeding fish meal on total leukocyte and differential counts in transition and early lactating cows. A. Heravi Moussavi*[1], M. Danesh Mesgaran[1], T. Vafa[1], and A. Soleimani[2], [1]*Center of Excellence for Animal Science, Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavy, Iran*, [2]*Azad University of Kashmar*, *Kashmar, Khorasan Razavy, Iran*.

The study was designed to test the effects of dietary fish meal supplementation on total leukocyte and differential counts in transition and early lactating cows. From approximately 21 d before anticipated calving until 35 d postpartum, cows (n = 10; 5/treatment) were fed diets that were isoenergetic containing 0 (Control) or 3.5% and 1.95% fish meal during prepartum and postpartum, respectively. Holstein cows were blocked in pairs based on their previous 305 d milk, parity (2nd and 3rd to 5th) and expected calving dates. Cows within each block were randomly assigned to one of the two treatments. Blood samples were obtained by coccygeal venipuncture within one week before calving and weekly after calving using EDTA as the anticoagulant. In the blood samples total leukocyte and differential counts were determined. The data were analyzed using the MIXED model for a completely randomized design with repeated measures. The model included treatment, time and the interaction. Results showed that the total leukocytes were similar among groups (7296 and 8134 ± 599 for control and supplemented groups, respectively). The effect of time was significant (P< 0.05) and the interaction of time and treatment was not significant. Percentage of neutrophils (42.95 and 53.77 ± 4.3, respectively), lymphocytes (53.94 and 42.85 ± 4.4, respectively), and monocytes (2.88 and 2.96 ± 0.3, respectively) were all similar between control and supplemented groups. Except than monocytes percentage which was affected by time (P< 0.001), others were similar during the study. Results from this experiment demonstrate that dietary fish meal supplementation pre- and postpartum had no apparent effect on total leukocyte and differential counts in transition and early lactating dairy cows.

Key Words: Dairy Cows, Fish Meal, Leukocyte

W15 New intramammary infections during the dry period: The effect of short (30 days) vs. long (45 or 60 days) dry periods. A preliminary report. G. T. Church*[1], L. K. Fox[1], J. M. Gay[1], C. T. Gaskins[1], and C. S. Schneider[2], [1]*Washington State University*, *Pullman*, [2]*University of Idaho*, *Moscow*.

Lactating dairy cattle from 3 herds in eastern Washington and 1 herd in Idaho were enrolled in a study to test the hypothesis that cows given a **short** (theoretical 30-d dry) dry period would have no more **new intramammary infections (IMI)** than cows given a **long** (theoretical 45-d or 60-d dry) dry period. Cows were assigned systematically without bias to treatments groups. One tube of either a commercial lactating (short) or dry-cow (long) formulation of cephapirin was administered to each lactating quarter per treatment group. Duplicate quarter foremilk samples were aseptically collected prior to dry-off and single quarter foremilk samples were collected 2, 7, 14, and 21 days post partum. **Pathogens** were classified as major (coagulase positive staphylococci, streptococcal species, and coliform species) minor (coagulase negative staphylococci and corynebacterium species) or other (gram positive bacilli and arcanobacterium pyogenes). **Cured** mammary quarters were free of IMI by the pathogen isolated from milk before dry-off. **Not cured** mammary quarters had the same pathogen in milk before dry-off and after parturition. Mammary quarters with **new IMI** had a new or different pathogen in milk post partum as compared to the dry-off sample. It appears that there is approximately a 40% increase in new IMI's in long (n=23) vs. short (n=14) dry periods.

Table 1. The number of quarters that cured, did not cure, or acquired a new IMI through the dry period

	Short Dry Period			Long Dry Period		
Pathogen	Major	Minor	Other	Major	Minor	Other
Cured	1	42	2	3	31	3
Not Cured	–	15	–	–	16	–
New IMI	5	8	1	2	21	–

Key Words: New Intramammary Infection (IMI), Dry Period

W16 Muscarinic receptors in the bovine gastrointestinal tract: mRNA expression and receptor binding in healthy cows and in cows with cecal dilatation-dislocation. E. C. Ontsouka*, R. M. Bruckmaier, A. Steiner, and J. W. Blum, *University of Berne, Vetsuisse Faculty*, *Berne, Switzerland*.

Acetylcholine interacts with muscarinic receptors (M) to mediate gastrointestinal (GI) smooth muscle contractions. We have compared mRNA levels and binding sites of M1 to M5 in muscle tissues from the fundus abomasi, pylorus, ileum, cecum, proximal loop of the ascending colon (PLAC), and external loop of the spiral colon (ELSC) of healthy slaughter cows (n=7). Furthermore, we have compared mRNA levels of M2 and M3 in full-thickness biopsies from the ileum, cecum, PLAC and ELSC of healthy (n=7) and of cows with cecal dilatation-dislocation (CDD; n=7). The mRNA levels were measured by qRT-PCR. The inhibition of [3H]-QNB binding by M antagonists [atropine (M1-5), pirenzepine (M1), methoctramine (M2), 4-DAMP (M3), and tropicamide (M4)] served to identify receptor subtypes at the protein level. Maximal binding (Bmax) was determined during saturation binding with atropine as a competitor. Location and group differences of Bmax and mRNA levels were tested for significance by ANOVA. The mRNA levels of M1, M2, M3 and M5 represented 0.2, 48, 50, and 1.8%, respectively, of total M, whereas mRNA of M4 was not detected. The mRNA levels of M2 and M3 in the ileum were lower ($P < 0.05$) than in other GI–locations. Atropine and antagonists for M1, M2 and M3 inhibited [3H]-QNB binding according to a one– or a two-site receptor model . The M4 antagonist had no effect on binding. Bmax in the fundus, pylorus, and PLAC was lower ($P < 0.05$) than in the ELSC, and lower ($P < 0.05$) in the pylorus than in the ileum. In cows with CDD, mRNA of M2 (cecum, PLAC and ELSC) and M3 (all locations) were reduced by 47 to 67% and 73 to 85%, respectively, as compared to healthy cows. In conclusion, M2 and M3 appeared to be the most important M for GI motility in cows. The decreased levels observed in cows with CDD may indicate involvement of these two receptor subtypes in the motility disorder leading to CDD.

Key Words: Cattle, Motility Regulation, Receptor Expression

W17 mRNA expression of motility-mediating receptors from the abomasum to the spiral colon of healthy cows and of cows suffering from left-sided abomasal displacement. E. C. Ontsouka*, M. Niederberger, A. Steiner, R. M. Bruckmaier, and M. Meylan, *Vetsuisse Faculty, University of Berne*, *Berne, Switzerland*.

Dairy cows frequently suffer from left-sided displacement of the abomasum (LDA), which causes important economical losses. Although the symptoms of LDA are well known, the pathogenesis of the disease remains unclear. Motor functions of the gastrointestinal (GI) tract are tightly controlled by the enteric nervous system, modulated by the sympathetic and parasympathetic nervous systems, involving α- and β-adrenergic receptors (AR), as well as muscarinic receptors (M) on nerve terminals and smooth muscle cells in the wall of GI organs. In addition, a non-adrenergic and non-cholinergic pathway also influences GI motor functions via motilin receptors (MTL-R). To investigate if the expression of receptors mediating motility vary in the GI tract of dairy cows depending on their health status, we have compared mRNA levels of α2AD-AR, β2-AR, M2, M3, and MTL-R in full-thickness specimens from the abomasum (fundus abomasi, pylorus), duodenum, cecum and external loop of the spiral colon (ELSC) of freshly slaughtered healthy cows (H; n=8) and of cows with LDA (D; n=8). The mRNA levels were measured by qRT-PCR and normalized relative to GAPDH. Receptor mRNA levels were evaluated using the repeated procedure of mixed model (SAS). Differences between H and D within locations were investigated with the t-test. The mRNA levels of α2AD-AR, β2-AR, M2, M3, and MTL-R varied among GI locations ($P < 0.05$). The mRNA levels of all five receptors were lower ($P <0.05$) in the duodenum of D than of H. In addition, the mRNA levels of β2-AR were higher ($P < 0.05$) in the ELSC of D than of H. In conclusion, differences between H and D of mRNA levels for α2AD-AR, β2-AR, M2, M3 and MTL-R in the duodenum, suggests that LDA might be caused by a primary motility disturbances in this GI location rather than in the abomasum itself.

Key Words: Bovine, Gastrointestinal Motility, Receptors

W18 The relationship between postpartum uterine bacterial infection (BI) and subclinical endometritis (SE). R. O. Gilbert*, N. R. Santos, K. N. Galvão, S. B. Brittin, and H. B. Roman, *Cornell University*, *Ithca, NY*.

The reported prevalence of SE exceeds reported prevalence of uterine BI after completion of postpartum involution. The objective was to investigate the relationship between uterine BI and SE. Samples for simultaneous uterine culture and cytology were obtained from 56 Holstein cows in a single herd at 0, 7, 21, 35 and 49 (± 3) DIM. Overall positive culture was 57%, 71%, 55%, 26% and 36%, respectively. On d 0 and 7 the commonest aerobic pathogens cultured were E. coli and Streptococcus spp and from d 21 Arcanobacterium pyogenes (Apyo) predominated. Amongst anaerobes, Clostridium perfringens was cultured frequently on d 0 and 7, but seldom thereafter. Prevotella melaninogenica (Pmel), and Fusobacterium necrophorum were cultured at low rates throughout. The median proportion of neutrophils (PMN) at each time point was 37%, 20%, 41%, 7% and 4% ($P < 0.01$). The proportion of other cell types at each time point did not differ with days postpartum. The median proportion of macrophages (LMN) was zero at each time point (range; 0 to 10%), and the median proportion of lymphocytes (SMN) was 2.0% (range; 0 to 13.5%). Bacterial isolates were not correlated to proportion of LMN or SMN. On d 0 there was a significant negative correlation between PMN proportion and bacterial isolates (aerobic, $r = -0.46$, $P = 0.03$; and anaerobic, $r = -0.47$, $P = 0.07$). PMN proportion at d 0 was also negatively correlated with PMN on d 49 ($r = -0.48$, P 0.01). This suggests that prompt PMN recruitment to the uterus after parturition limits bacterial infection and reduces the risk of later SE. The PMN proportion on d 49 was correlated to

the presence of Apyo ($r = 0.49$, $P < 0.01$) and anaerobes, particularly Pmel ($r = 0.44$, $P < 0.01$). In turn, the presence of these pathogens was affected by the presence of E.coli on d 7 ($r = 0.40$, $P < 0.01$). By multiple linear regression, the presence of Apyo or Pmel explained 48% of the variance in PMN on d 49 ($P < 0.01$). The proportion of PMN on d 49, previously shown to be significantly correlated to subsequent reproductive performance was correlated to uterine BI, which was more prevalent on d 35 and 49 than previously reported.

Key Words: Endometritis, Bacteria, Dairy Cow

W19 The recurrence of mycoplasma mastitis investigated by bulk tank analysis. V. Punyapornwithaya*, L. K. Fox, D. D. Hancock, and J. M. Gay, *Washington State University*, *Pullman*.

The objective of this study was to determine the epidemiology of the recurrence of mycoplasma investigated by culture of bulk milk. Fourty farms that had *Mycoplasma spp.* culture from bulk tank milk were investigated for 1 year by further monitoring bulk tanks to determine the prevalence of recurrence of this agent. Dairies had at least 5 bulk tank milk cultures during the study. Bulk milk samples collected within the same month from 10 farms after the first positive culture were evaluated for *Mycoplasma spp*. Milk samples were plated on mycoplasma agar and incubated at 37°C with 10% CO_2 for 7 days. The percentage of farms with a recurrence of mycoplasma mastitis was 57.5% (n=23/40). The mean number of recurrences within 1 year was 2.45. Bulk milk samples from 4 herds that were examined in the same month of a first positive culture of Mycoplasma spp. were negative at the second test, as opposed to the 6 herds also tested twice in the same month that remained positive. This study suggested that the prevalence of recurrence infection of mycoplasma mastitis was greater than 50%. Cultures of bulk tank milk can be used to monitor mycoplasma mastitis, and help dairy managers use it as a tool to control the disease.

Key Words: *Mycoplasma spp.*, Mastitis, Recurrence

W20 Use of a calcium bolus to improve calcium homeostasis after calving. J. D. Sampson*[1], J. N. Spain[1], L. Carstensen[2], and C. Jones[3], [1]*University of Missouri*, *Columbia*, [2]*Boehringer Ingelheim Denmark A/S*, *Copenhagen O, Denmark*, [3]*Boehringer Ingelheim Vetmedica, Inc.*, *St. Joseph, MO*.

Milk fever occurs in 5-10% of dairy cows, and the incidence of subclinical hypocalcemia is likely several times greater. Milk fever increases the risk of numerous periparturient disorders such as ketosis and dystocia. Providing periparturient cows with supplemental calcium may decrease the risk of hypocalcemia. The objective of this study was to investigate the effects of Bovikalc™, an oral calcium supplement, on calcium homeostasis during the first 24 h after calving. Multiparous Holsteins (n=20) were blocked by parity and day of calving and randomly assigned to one of two treatment groups. Control (C) cows received no calcium supplement. Treatment group (B) received one bolus immediately after calving and a second bolus 12 hours after calving. All cows were housed in a sand bedded free stall barn with free access to clipped pasture and fed a TMR formulated to meet NRC requirements. Prepartum blood samples were taken at approximately 24 and 48 hours prior to calving. Ionized blood calcium (iCa) was measured using an IDEXX Vet Stat Analyzer. Cows with an iCa level of 1.10 mmol/L or less were included in the study. Blood and urine samples were collected at 0, 1, 6, 12, 13, and 24 hours postpartum. Blood was analyzed for iCa and pH. Urinary pH was measured. Rectal temperatures and clinical scores for appetite, ataxia, fecal consistency, and muscle tremors were recorded at 0, 6, 12, and 24 hours postpartum. iCa levels were not different between treatment groups (1.24 vs. 1.22 and 1.19 and 1.18 mmol/L for C and B at -48 and -24 h, respectively. iCa levels were similar at calving (0h, 0.95 vs. 0.94 for C and B, respectively, P=0.84. iCa levels differed due to treatment over time (P=0.02). iCa were significantly higher in cows given the bolus at 1 and 13 hour. Urine pH was different by treatment (P=0.002) and by treatment over time (P=0.003). Urine pH decreased in cows given B from 7.58(0h) to 6.79 (24h) compared to 8.00 (0h) to 8.09 (24h) for control cows. Blood pH was not different (P=0.27). Calcium supplementation with Bovikalc™ after calving decreased urine pH and increased iCa levels compared to control cows.

Key Words: Milk Fever, Calcium, Dairy

W21 Dietary fish oil does not impact the response of early lactating cows to an endotoxic mastitis challenge. M. K. Yelle*, D. W. Kim, E. J. DePeters, and M. A. Ballou, *University of California*, *Davis*.

Cows in early lactation are more susceptible to the deleterious local and systemic effects of the acute phase response. Supplementing fish oil in many animal models attenuated the acute phase response. The objective was to determine the effects of supplementing fish oil during the peripartum period on the pathophysiological response to an intramammary LPS challenge. 42 multiparous, Holstein cows were completely randomized to one of three treatments at 3 weeks prepartum. Treatments were no supplemental lipid or supplemental lipid, 250 g (prepartum) or 1% of the previous day's intake (postpartum), from either Energy Booster® (EB) or fish oil (FO). Supplemental lipid was fed as a bolus prior to the AM feeding. At 7 DIM cows supplemented with lipid were infused with 100 µg of E coli LPS into one rear quarter; cows not supplemented with lipid served as un-infused controls. DMI was measured daily and clinical measures taken at 0, 1, 2, 3, 4, 5, 6, 8, 12, 24, and 72 h. Blood samples were collected at 0, 2, 4, 6, 8, 12, 24, and 72 h for biochemical analyses. Milk samples were collected before and from the 6 milkings following the LPS challenge. All data will be reported as EB versus FO respectively. For EB and FO, LPS caused a significant increase in both rectal temperature and heart rate, which peaked at 6 h. Total white blood cell counts decreased following LPS, reaching nadir after 6 h. Supplemental lipid source had no effect on any clinical response. Feed intake significantly decreased the day LPS was infused (16.6 and 17.0%). LPS increased serum glucose levels and caused a significant biphasic decrease in NEFA, reaching nadir at 4 and 8 h and returning to baseline levels within 24 h. Milk production in the infused quarter decreased dramatically over the first two milkings (33.9 and 41.8%) and returned to baseline by the 5th milking. Control quarters also decreased and reached nadir at the 1st milking (15.4 and 12.9%) but quickly recovered to baseline production by the 2nd milking. Supplementing fish oil had no ameliorative effect on either the local or systemic acute phase response of early lactating, Holstein cows.

Key Words: Endotoxin, Mastitis, Transition

W22 *Escherichia coli* lipopolysaccharide upregulates the expression of both toll like receptor 4 and 2 (TLR4 and TLR2) in cultured bovine mammary epithelial cells. E. M. Ibeagha-Awemu*[1], J.-W. Lee[2], A. E. Ibeagha[1], D. D. Bannerman[3], M. J. Paape[3], and X. Zhao[1], [1]*McGill University*, *Ste Anne De Bellevue, Quebec, Canada*, [2]*National Pingtung University of Science and Technology*, *Neipu, Pingtung, Taiwan*, [3]*United States Department of Agriculture*, *Beltsville, MD*.

Bovine mammary epithelial cells contribute to the innate immune response to intramammary infection. Their ability to mount such a response is dependent upon mammary epithelial recognition of the invading pathogen by specialized receptors. Toll-like receptor 4 (TLR4) is one such receptor that recognizes and is specifically activated by lipopolysaccharide (LPS), a component of the outer envelope of gram-negative bacteria. Recently, it was shown that Staphylococcus aureus, a gram-positive bacteria, initiated the upregulation of both TLR2 and TLR4 in the bovine mammary gland. Because the mammary gland is known to elicit a robust innate immune response to *Escherichia coli*, we hypothesized that LPS could similarly induce upregulation of TLR4. To evaluate this, MAC-T cells (a bovine mammary epithelial cell line) were incubated in the presence or absence of 1 μg/ml LPS for 24 hrs. Expression of TLR2 and TLR4 were analyzed at both the mRNA and protein levels by quantitative real time PCR and flow cytometry, respectively. The mRNA for both receptors in treated cells was upregulated by 2.0 (TLR4) or 2.2 (TLR2) fold ($P<0.01$) in comparison to untreated cells. Similarly, specific antibodies against TLR2 and TLR4 detected the increased surface expression of the toll proteins. The mean channel fluorescence in treated cells as compared to untreated cells was 1224 vs. 554 for TLR4 and 3394 vs. 1671 for TLR2, respectively. These results demonstrate that LPS upregulates both TLR4 and TLR2, similar to that reported with ligands from S. aureus. This suggests that the bovine mammary epithelium possesses the necessary immune repertoires required to mount a robust defense against *E. coli*. This may also indicate a positive adaptation by the mammary epithelial cells to effectively deal with different types of mastitis pathogens.

Key Words: Lipopolysaccharide, TLR4 and TLR2, Mastitis

W23 Effect of supplementation with a *Bacillus*-based direct-fed microbial on calf growth, *Clostridium perfringens* shedding, and incidence of scours. C. Wehnes*[1], E. Davis[1], K. Novak[1], V. Patskevich[1], T. Rehberger[1], D. Shields[2], and J. Coalson[2], [1]*Agtech Products, Inc.*, *Waukesha, WI*, [2]*Merrick's, Inc.*, *Union Center, WI*.

Electrolytes are common and effective treatments for dehydration in calves; however, electrolytes do not treat the primary cause of dehydration, bacterial and viral associated scours. The objective of this study was to evaluate the efficacy of the addition of a *Bacillus* direct-fed microbial (DFM) to an electrolyte as therapy for scours. The DFM was evaluated based on calf performance and fecal *C. perfringens* shedding. In October 2006, 65 Holstein bull calves were placed in outdoor hutches and 21 calves were randomly selected to determine preliminary *C. perfringens* fecal shedding. Calves were assigned to three treatments based on the presence of scours: non-scouring, electrolyte, and electrolyte+DFM. Scouring calves received electrolyte for a mandatory two days. Fecal samples were collected on d 1, 3, 7, 14, 21, 28, and 42 post-placement and enumerated for *C. perfringens*. *C. perfringens* colonies were harvested and DNA was extracted. Putative *C. perfringens* colonies were confirmed as *C. perfringens* via multiplex Polymerase Chain Reaction (mPCR) for the four major *C. perfringens* toxin genes (α, β, ε, and ι). randomly amplified polymorphic dna pcr (rapd pcr) was performed to characterize *C. perfringens* isolates. By d 14, 49 of the 51 scouring calves were treated. Although results indicate that electrolyte+DFM calves began the trial with significantly greater ($P = 0.01$) populations of fecal *C. perfringens*, by d 7 the electrolyte+DFM significantly reduced ($P = 0.002$) populations of fecal *C. perfringens* compared to electrolyte alone. Electrolyte+DFM calves had significantly higher ($P = 0.02$) ADG than both non-scouring and electrolyte treated calves in wk 1. Gain:feed was significantly greater ($P = 0.04$) in electrolyte+DFM calves than calves administered electrolyte and non-scouring treatments during wk 8. Results indicate that supplementation of electrolyte+DFM reduced *C. perfringens* fecal shedding and improved gain during wk 1. The DFM may have other ancillary benefits after feeding has ended, as evidenced by improved gain:feed in wk 8.

Key Words: Probiotic, Bovine, Electrolyte

W24 Prevalence, etiology and antimicrobial sensibility of subclinical mastitis. M. C. Rubio Robles*, M. A. Luque, R. Verdugo, R. Chin, R. Félix, E. Hernández,, T. Leal, and J. Mena, *Universidad Autonoma de Sinaloa*, *Culiacan, Sinaloa, Mexico*.

Mastitis is an inflammation of the mammary gland, the subclinical mastitis is characterized not to cause a visually inflammation of the mammary gland, nor macrocospic changes in milk, being necessary for their diagnosis tests that allow to detect the involved microorganisms. both clinical and subclinical forms of mastitis cause a reduction in milk quality and quantity and is recognized as a cause of major economic loss to the dairy industry. The objective of this study was to determine the prevalence of subclinical mastitis and its causal agents in familiar dairy stables, in San Jose of the Brecha, located in 137 km Culiacán-Guasave highway; municipality of Guasave, Sinaloa, Mèxico. where sampled 24(100%) cows of American Swiss Brown with Brahman, 3 to 8 childbirths and weights of 350 to 400 kg, fed at prairie, including all the cows of milks, except less than 15 days of lactation and more than 7 months of gestation; using the California mastitis test, resulted 100% of the dairy stables presence of subclinical mastitis; 62.5%(15) of the cows was positive, and 37.5%(9) negative. In the positive cows 26(27.08%) of the quarters were infected with some degree of mastitis, 57.69%(15) degree 1, 34.61%(9) degree 2 and 7.69%(2) degree 3. The positive samples were analysed with bacteriological and antibiograms in the Bacteriology laboratory of the FMVZ-UAS. showed 18.18%(2) development of Staphylococus spp, rest 81.1%(9) was negative. In antimicrobial sensitivity Staphylococus spp was resistant to the Enoxacin and the Dicloxacillin, very susceptible and moderately susceptible to penicillin and the anetilmicin. it is concluded that the prevalence of subclinical mastitis in San Jose of the Brecha is present in all the familiar dairy stables and a considerable proportion in cows, which can trigger another type of mastitis (clinical) producing lost economic considerable the producers.

Key Words: Mastitis, Dairy Cattle, Prevalence

W25 A cross-sectional survey of *Salmonella* serotypes from dairies with a history of Salmonellosis in the Great Lakes Region of the United States. C. Wehnes*, V. Patskevich, K. Mertz, and T. Rehberger, *Agtech Products, Inc.*, *Waukesha, WI*.

Characterization of *Salmonella* shedding to identify cattle and herd associated risk factors has been well researched; however, there is a paucity of data characterizing *Salmonella* strains across dairies. For these reasons, a cross-sectional survey of *Salmonella* on dairies with a history of Salmonellosis was performed with the objectives of assessing *Salmonella* prevalence, serotype, and strain diversity. From June to December 2006, fecal samples from cows and calves as well as bedding samples from cow, calf, and sick cow pens were collected from eight independent dairy farms experiencing Salmonellosis. Each sample was cultured for *Salmonella*; putative colonies were confirmed as *Salmonella* via a latex agglutination assay (Remel, Lenexa, KS). DNA was extracted from *Salmonella* positive colonies and Randomly Amplified Polymorphic DNA Polymerase Chain Reaction (RAPD PCR) was performed. RAPD PCR products were analyzed using BioNumerics software (Applied Maths Inc. Austin, TX) to assess *Salmonella* diversity. Of the 196 fecal and 104 bedding samples collected, 42 (21%) and 37 (36%) contained *Salmonella* respectively. Serogroups found included B (13%), C (52%), D (3%), and E/G (32%). A total of 342 isolated *Salmonella* colonies were collected throughout the study. The results of the *Salmonella* genotypic diversity survey indicate that the strain richness (S) and evenness (E_D) for the 342 *Salmonella* isolates was 56 and 0.35 respectively at 80% similarity using the Pearson similarity coefficient with the unweighted pair group method using arithmetic averages (UPGMA). The reciprocal of the Simpson Index (1/D) was 19 and D_{max} was 56. The RAPD PCR results indicate that these farms contained *Salmonella* strains with little genotypic diversity within each farm. Conversely, the genotypic diversity between farms is large with few overlapping strains present. Future research should focus on further characterizing *Salmonella* from dairies as a means to understand the basis of farm specific isolates.

Key Words: Dairy, Diversity, Prevalence

W26 Correlating body weight and temperature changes after antibiotic treatment of morbid stocker calves with health and growth performance throughout the receiving phase. S. Behrends*, E. B. Kegley, and J. A. Hornsby, *University of Arkansas*, *Fayetteville*.

Records from market stressed bull and steer calves (n = 383) initially weighing 237 ± 46 kg were studied to identify an easily obtainable measurement that could be taken after an antibiotic treatment (AT) and used as a prognostic tool for calves affected by bovine respiratory disease (BRD). Calves were evaluated for signs of BRD and assigned a critical illness score of 1 (normal) to 5 (moribund). Based on these evaluations calves ≥ 2 were pulled. Calves that exhibited a rectal temperature of ≥ 40°C were weighed and administered an AT. Rectal temperatures and body weights (BW) were taken 2 to 3 d after each treatment (according to product label). Calves that continued to exhibit a rectal temperature of ≥ 40°C were administered another AT. Calves were treated with up to 3 antibiotics and were considered chronic if they did not respond (temperature < 40°C) to the third treatment. A negative correlation existed between calves administered one AT and BW on d 7 and 42 (r = -0.15; P < 0.01 and r = -0.24; P < 0.0001 respectively). Body weights on d 15 and 42 were negatively correlated with whether calves were administered a second (r = -0.14; P = 0.02 and -0.23; P < 0.0001, respectively) and third (r = -0.13; P = 0.03 and r = -0.23; P = 0.0001, respectively) AT. Body weight change during the AT period (between initial pull and recheck) was negatively correlated with the need for a second and third AT (r = -0.14; P = 0.03 and r = -0.29; P = 0.005, respectively). Rectal temperature change (between initial pull and recheck) during the first AT period was correlated with those calves that were treated a second and third time (r = 0.36; P < 0.0001 and r = -0.33; P < 0.0001). Weight and temperature change during AT appear to both be useful indicators of potential outcomes for calves that are affected by BRD.

Key Words: Stocker Calves, Bovine Respiratory Disease, Antibiotic Treatment

W27 Feeding unprotected fish oil 3 weeks prepartum alters the fatty acid composition of plasma in both the cow and calf at parturition, but had no effect on bactericidal or cytokine function. M. A. Ballou*, R. C. Gomes, and E. J. DePeters, *University of California*, *Davis*.

Previous research from our lab demonstrated that supplementing a milk replacer with fish oil attenuated the acute phase response in calves; however it took weeks to months of fish oil (FO) supplementation before docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) reached a new steady state, respectively. The objectives were to determine whether feeding a rumen unprotected FO would alter the fatty acid (FA) composition of plasma from both the cow and calf at parturition; as well as evaluate bactericidal and cytokine function. 30 Holstein cows were completely randomized to one of two treatments at 3 wk prepartum. Treatments were either 250 g of (1) Energy Booster® (EB) or (2) FO fed as a bolus prior to the AM feeding. Plasma was sampled from each cow at enrollment and from the cow and calf on the day of parturition for FA analyses of plasma phospholipids. At enrollment and parturition peripheral blood mononuclear cells (PBMC) were isolated from the cow and cultured with phytohemagglutin; IFN–γ and TNFα were quantified. Whole blood bactericidal capacity against 3 microorganisms was evaluated at enrollment, parturition, and +21 d. In the calf, the whole blood bactericidal assay was measured 2 h after parturition, +1, and +21 d. In the cow FO increased the concentrations of EPA (3.38 vs. 0.62 g/100g FA), and DHA (2.74 vs. 0.29 g/100gFA) when compared to EB. Furthermore, FO increased EPA (0.81 vs. 0.39 g/100g FA) and DHA (2.09 vs. 1.12 g/100g FA) concentrations in the calf at calving. FO had no effect on the arachidonic acid concentration in the cow and calf. FO had no effect on the production of IFN–γ and TNFα from PBMC cell cultures. Furthermore FO had no effect on the bactericidal capacity of blood from either the cow or calf against any of the microorganisms. Supplementing the close-up diet with FO dramatically altered the FA composition of plasma from the cow and her calf at parturition. However, the plasma concentrations of EPA and DHA in the calf were below what can be acquired by supplementing the calf during the neonatal period.

Key Words: Immune, Fish Oil, Fatty Acid

W28 Relationship of plasma immunoglobin G concentrations to temperament and growth performance. K. R. Parker*[1], S. T. Willard[2], R. D. Randel[3], T. H. Welsh, Jr.[4], and R. C. Vann[1], [1]*MAFES-Brown Loam Experiment Station*, *Raymond, MS*, [2]*Mississippi State University*, *Starkville*, [3]*Texas A&M University Agricultural Research & Extension Center*, *Overton*, [4]*Texas A&M University*, *College Station*.

This study was designed to assess the relationships between immune function, innate temperament and growth performance. Blood samples and BW were taken from spring born calves (n = 196) at 24h, 48h, 14d, and 84d post-calving. At birth calves were assigned a calf vigor score, calving ease score and dams were given a BCS according to Beef Improvement Federation guidelines (2002). Plasma was harvested via centrifugation and concentrations of immunoglobin G (IgG) were determined by ELISA. Temperament data were recorded in the form of pen scores (PS) and exit velocity (EV). These measures were taken along with BW at 28d pre-weaning, weaning, 28d post-weaning, 56d post-weaning and as yearlings. Overall temperament scores (TPS) were assigned to each animal by averaging PS and EV over the four time periods. Statistical analyses were performed using the Proc Mixed procedure of SAS and where appropriate repeated measures analyses were used. Calves were ranked based on their TPS as follows: calves 1 SD above the mean were considered temperamental (T, n=26), calves 1 SD below the mean were considered calm (C, n=36), all other calves were considered intermediate (I, n=127). Calves were classified based on their IgG concentration with calves 1 SD lower than the mean ranked low (L, n=3), calves 1 SD above the mean ranked high (H, n=27), and remaining calves ranked moderate (M, n=159). Heavier calves at birth ($P \leq 0.05$) had lower IgG at 24h and 48h. Calves with higher IgG at 48h exhibit greater ($P = 0.062$) ADG between weaning and 56d. Calves with higher IgG concentrations did not experience calving difficulties ($P \leq 0.001$). Scrotal circumference (SC) at weaning and 56d post-weaning were higher ($P \leq 0.03$) for calves with greater 48h IgG concentrations and were higher in calves classified as calm. Calves with higher immune classification had improved growth performance after weaning. These results suggest that IgG classification could be useful in predicting growth performance after weaning.

Key Words: Immunoglobin, Beef Calves, Temperament

W29 Impact of entomopathogenic fungus *Metarhizium anisopliae* on cattle naturally infested by adult *Haematobia irritans* in temperate Mexico. E. Maldonado-Simán[1], R. D. Améndola-Massiotti*[1], E. Galindo-Velasco[2], C. A. Angel-Sahagún[2], L. Bermúdez-Villanueva,[1], and R. Lezama-Gutiérrez[2], [1]*Universidad Autónoma Chapingo*, *Chapingo, México, México*, [2]*Universidad de Colima*, *Tecomán, Colima, México*.

Farmers tend to control horn fly (*Haematobia irritans* L.) with heavy pesticide applications which increase the risks of insecticide residues in products and the environment; therefore, biological pest control is considered to be ecologically safer. The University of Colima, Mexico recently developed a biopesticide based on the spores of the fungus *Metarhizium anisopliae* Ma34 as a natural pathogen. No studies have tested on the field the action of this entomopathogenic fungi on the control of *H. irritans*; therefore, the aim of this study was to asses the efficacy of *M. anisopliae* on the control of *H. irritans* in naturally infested cattle. The study took place in the Experimental Station of the University of Chapingo (temperate central area of the country). Twenty two grazing Holstein cows were randomly allocated into two groups of the same size, which grazed in different paddocks. Cows in the treated group were sprayed every seven days with a conidial suspension of *M. anisopliae* (strain Ma34) at a concentration of 1×10^8 conidia/ml. Eight applications took place during the experimental period. The other group remained as untreated control. The horn fly burdens were recorded on days 0, 1, 2, 3, 4, 5, 6 and 7 post-treatment. Cows sprayed with *M. anisopliae* showed fly counts 28% lower than the untreated control ($P<0.05$). Since the experiment took place during the second half of the fall, horn fly counts became lower through time (from week one to week eight) in both treatments, being reduced from 156 to 24 flies per cow in the sprayed cows and from 216 to 37 flies per cow in the untreated cows; the reduction due to the application remained fairly constant. This result shows that *M. anisopliae* (strain Ma34) was effective in the control of adult *H. irritans* and might be a promising substitute of chemical pesticides.

Breeding and Genetics - Livestock and Poultry III

W30 The genes commonly expressed at early embryonic stages in mammals. C. Y. Lien*, E.-C. Lin, C. C. Hsu, S. T. Ding, and W. T. K. Cheng, *National Taiwan University*, *Taipei, Taiwan*.

The early stages of embryogenesis are critical for mammalian embryo development. Several key developmental events occurred in these stages, such as cell growth, migration, differentiation, and morphogenesis. In spite of the importance occurring in the early embryogenesis, limited information has been provided by previous studies. The UniGene database in the National Center for Biotechnology Information (NCBI) was designed to collect sequences of expressed sequences tags (ESTs) and mRNA to provide many sets of transcript sequences from the same transcription locus.The purpose of this study is to utilize the UniGene database to screen those commonly expressed genes with related functions at early embryonic stages in mammals. Those unigene entries of embryos before implantation collected from *Bos taurus*(Bt), *Mus musculus* (Mm) and *Sus scrofa* (Ssc) were 1,727, 13,923 and 3,982, respectively. The unigene sequences of Mm (13,923) were used to search against (blastn) the unigene sequence sets of Bt (1,727) and Ssc (3,982) to obtain 972 and 2,039 commonly expressed genes (bit score ≥ 200), respectively. However, there were 417 unigene entries commonly expressed in all these three species. The 417 commonly expressed genes annotated to have certain gene identity in public databases for Bt, Mm and Ssc were 339, 361 and 151, respectively. Furthermore, those commonly expressed unigenes of Mm were annotated their functional classification using Gene Ontology terms into three categories: biological process (P), molecular function (F) and cellular component (C). The results showed the number of commonly expressed genes with functional annotation were 160 (P), 169 (F) and 153 (C), respectively. The commonly expressed genes and their related functions might be annotated using alignment tool among sequence databases of different species. The analytical procedure in this study would assist animal scientists to screen the commonly expressed genes with fundamental roles and functions.

Key Words: Early Embryonic Stages, Commonly Expressed Genes, Mammals

W31 Environmental and genetic effects on growth traits of farmed red deer. R. Ramírez-Valverde*, A. Sánchez-Cervantes, J. G. García-Muñiz, and R. Núñez-Domínguez, *Universidad Autónoma Chapingo*, *Chapingo, México, México*.

Currently, there are in Mexico only a handful of farms with farmed red deer; however, in recent times their number has increased, therefore, it is important to characterize this species under main production systems. The objective of this study was to identify environmental and genetic effects on growth traits, in a herd of farmed red deer in Mexico. The animals were raised on an intensive rotational grazing system of grass-legume mixed temperate pastures. Evaluated traits (n=270 to 428) were weights at birth (BW), weaning adjusted to 100 d (WW) and yearling (YW), for males and females born from 1996 to 2003. Analyses were performed using the MTDFREML program. Final univariate animal models considered the fixed effect of sex-year (contemporary group), age of dam at calving as a covariate for BW and WW, and the direct (BW, WW and YW) and maternal (WW) random genetic effects. Contrasts were performed to determine statistical differences within fixed and covariates effects. Genetic evaluation was carried out in the total of the pedigree (n=528). Means and standard deviations for BW, WW and YW, were 8.7±1.2, 42.4±5.6 and 80.8±13.3 kg, respectively. Means for BW, WW and YW of males were higher (P<0.05) than those of females (4.6, 9.9 and 21.9%, respectively). There were differences between contemporary groups (P<0.05). Linear and quadratic age of the dam affected (P<0.05) both BW and WW. For BW, the heaviest weights were predicted for dams with an age of 36.9 months, while for WW a maximum was achieved at 108.7 months of age. Estimators of direct heritability were 0.00, 0.41 and 0.17, for BW, WW and YW, respectively. Maternal heritability for WW was 0.22. Standard deviations of direct breeding values were 1.4 and 1.3 for WW and YW, and 1.0 for maternal WW. As expected (no selection for growth traits), genetic trends for WW and YW were not different from zero (P>0.05). Based on the genetic variability of WW and YW, the results suggest the possibility of genetic improvement of those traits through selection in this herd.

Key Words: Heritability, Grazing, Animal model

W32 Effects of selected weather factors on feed intake of Angus, Polled Hereford, and Simmental beef bulls during feedlot performance tests. G. T. Tabler, A. H. Brown, Jr.*, E. E. Gbur, I. L. Berry, Z. B. Johnson, D. W. Kellogg, and K. C. Thompson, *University of Arkansas*, *Fayetteville*.

Selected weather data were analyzed to more closely define the relationship between climate and feed intake of three breeds of beef bulls during feedlot performance tests. Intake data originated from Angus (n = 282), Polled Hereford (n = 440) and Simmental (n = 372) bulls in University of Arkansas Cooperative Bull Tests from 1978 to 1990. Bulls were given a 21-d adjustment period, then individually full-fed a total mixed ration twice daily in the same stall for 140 d. Initial age and weight were recorded at start of each test with weights taken at 28-d intervals. Data were pooled, divided into five 28-d periods beginning with start of each test, with data from each period and breed analyzed separately. Initial age and weight were included in principal components regression as independent variables to adjust for initial animal differences. Principal component (PC) analysis was utilized to reduce number of independent variables in the regression and overcome collinearity concerns associated with numerous climatic variables. Initial weight and initial age had positive regression coefficients throughout the trial for each breed. Regression coefficients for effects of weather variables ranged from positive to negative depending on period and breed. No weather variable had a consistent effect throughout all five periods across all three breeds; although, effect of barometric pressure was positive in all periods for Polled Hereford and Simmental bulls. Results indicated rainfall, relative humidity, barometric pressure, day length, and wind speed have individual effects on feed intake. Additional evidence is provided indicating that temperature alone is inadequate to represent effects of weather on feed intake of various beef cattle breeds used in production systems today.

Key Words: Beef Cattle, Breed, Climate

W33 Promoter region of the bovine growth hormone receptor (GHR) gene: Resequencing, SNP detection, and association with performance traits in Brangus bulls. A. J. Garrett*[1], G. Rincon[2], J. F. Medrano[2], G. A. Silver[1], and M. G. Thomas[1], [1]*New Mexico State University*, *Las Cruces, New Mexico, United States*, [2]*University of California*, *Davis*.

Expression of the growth hormone receptor (GHR) gene and its binding with growth hormone is essential for growth. A TG microsatellite exists in the 5′ untranslated region (UTR) of bovine GHR segregating a short (11 bp) and a long (14-16 bp) allele. Favorable associations with carcass characteristics have been found with the longer allele in Angus cattle. Herein, a 1000 bp region flanking the TG microsatellite was resequenced to detect SNPs and completed an association study of genotype/haplotype to phenotype in performance tested Brangus (3/8 Brahman x 5/8 Angus; n = 340 from 80 sires) bulls. Target region was resequenced in twenty four familialy unrelated beef animals including Simmental, Angus, Brahman, and Brangus. Nine sequence variations were identified and 5 were genotyped via Taqman® assays. Haplotype analysis indicated polymorphisms were in phase ($r^2 = 0.84$; $D' = 0.92$) and an A/G tag SNP (125634) was identified. Mendelian segregation was verified using three generation families. The A allele was derived from Brahman and the G allele was derived from Angus. The AA genotype of the SNP was found to be a predictor of yearling weight with AA genotype being heavier ($P < 0.05$) than the AG or GG genotypes. Least squared means for intramuscular fat percentage (IMF) for genotypes of the SNP were 3.55, 3.60, 3.73 ± 0.08 for AA, AG, and GG genotypes respectively, suggesting an inverse relationship between yearling weight and IMF. Regression on the number of favorable alleles summed across markers appeared additive with a slope coefficient of 0.10 ($P < 0.03$). Prediction analysis involving haplotypes suggested animals possessing Angus alleles had greater (0.69 > 0.64 ± 0.03 cm, $P < 0.05$) rib fat than those possessing Brahman alleles. A GHR SNP in the 5′ UTR was associated with growth and carcass traits. The favorable allele segregated from Angus and appears additive for IMF in Brangus bulls. The A/G tag SNP may offer an alternative method of genotyping to the TG microsatellite in association studies involving body fat traits and yearling weight in Brangus cattle.

Key Words: Cattle, SNP, Growth Hormone Receptor

W34 Animal model analyses of additive and non-additive genetic effects for 205-day weight in a Nellore x Hereford multibreed population in Brazil. A. de los Reyes[1], M. A. Elzo*[2], V. M. Roso[3], R. Carvalheiro[3], L. A. Fries[3], and J. L. Ferreira[1], [1]*Federal University of Goias*, *Goiania, GO, Brazil*, [2]*University of Florida*, *Gainesville*, [3]*GenSys Associated Consultants*, *Porto Alegre, RS, Brazil*.

Choosing an appropriate model to obtain reliable estimates of additive and nonadditive genetic effects is essential for the implementation of a sound crossbreeding program. The objective of this study was to assess the importance of direct and maternal breed additive, dominance, and epistatic recombination group effects for 205-d weaning weight (W205) in a large Nellore x Hereford multibreed population using 11 homoscedastic animal models. Four epistatic recombination expressions were evaluated: 1 (Dickerson) = NsHs + NdHd; 2 (Fries) = 0.5(HETs + HETd); 3 (Kinghorn) = 2NaHa; and 4 (Elzo) = 1 - NsNsNdNd - HsHsHdHd; N = Nellore fraction, H = Hereford fraction, HET = heterozygosity, a = animal, s = sire, and d = dam. The data file had 124,638 W205, 3,768 contemporary groups (CG = herd-year-season-management group-sex of calf), 1,078 sires, and 88,750 dams. The pedigree file included 202,475 animals. Fixed effects were CG, cow age at calving (fourth degree polynomial), weaning age as a deviation from 205 d (third degree polynomial), direct and maternal breed additive effects (models 2 to 11), direct and maternal heterosis (models 3 to 11), and direct and maternal epistatic recombination effects (direct: models 4 to 11; maternal: models 5, 7, 9, 11). Random effects were direct and maternal additive genetic effects, maternal permanent environmental effects, and residual effects. Additive relationships were accounted for. The Akaike (AIC) and Bayesian (BIC) information criteria were used to compare models. Inclusion of direct and maternal heterosis, and direct and maternal epistatic recombination (all definitions) showed an improvement in model fitting according to AIC and BIC (except for maternal epistatic recombination in models 9 and 11). Thus, both heterosis and epistasis need to be accounted for in genetic evaluation models for this multibreed population.

Key Words: Cattle, Multibreed, Recombination

W35 Growth and pubertal development of F_1 bulls from Hereford, Angus, Norwegian Red, Swedish Red and White, Friesian, and Wagyu sires. E. Casas*, D. D. Lunstra, L. V. Cundiff, and J. J. Ford, *USDA, ARS, U.S. Meat Animal Research Center*, *Clay Center, NE*.

The objective of the study was to characterize growth, testicular development and puberty between 9 and 14 mo of age in bulls (n = 120) produced by mating sires from Hereford (H), Angus (A), Norwegian Red (N), Swedish Red and White (S), Friesian (F), and Wagyu (W), to MARC III (¼ Hereford, ¼ Angus, ¼ Red Poll, ¼ Pinzgauer) cows. Traits evaluated were birth weight, weight at 200 d, weaning weight (at 215 d), yearling weight, average daily gain from 8 to 14 mo of age, paired testis volume growth from 8 to 14 mo of age, age at puberty (determined by production of 50 x 10^6 sperm with 10% motility), age at freezable semen (determined by production of 500 x 10^6 sperm with 50% motility), paired testis weight, and daily sperm production per testis pair at 15 mo. At birth; animals with H and F inheritance were heavier (43 kg and 41 kg, respectively, $P = 0.04$), when compared to those with N, S, and W inheritance (39 kg, 38 kg, and 38 kg, respectively). Differences in weight were also observed at one year of age ($P = 0.004$), where the heaviest animals were those with A inheritance (450 kg), while the lightest animals were those with W inheritance (403 kg). Bulls with W inheritance had the lowest ($P = 0.0003$) average daily gain (1.13 kg/d) when compared to bulls with inheritance from H (1.23 kg/d), A (1.29 kg/d), N (1.27 kg/d), S (1.24 kg/d), and F (1.27 kg/d). No differences ($P = 0.14$) were observed for paired testis volume growth rate. They ranged from 1.95 in A sired to 1.66 cm^3/d in W sired bulls. There was a tendency ($P = 0.06$) of sire breed for age at puberty. The range was from 268 to 302 d. There were no differences ($P > 0.05$) for paired testis weight and daily sperm production. Growth of animals with W inheritance is slower than animals with N, S, F, H, or A inheritance. At 15 mo of age testicular development was similar for all breeds despite predicted differences in mature body weight.

Key Words: Beef Cattle, Bulls, Puberty

W36 Evaluation of post-weaning phenotypic residual feed intake in an Angus-Brahman multibreed herd of beef cattle. M. A. Elzo*[1], G. R. Hansen[2], J. G. Wasdin[1], J. D. Driver[1], and J. L. Jones[1], [1]*University of Florida*, *Gainesville*, [2]*North Florida Research and Education Center*, *Marianna, FL*.

Residual feed intake (RFI) has become ubiquitous for evaluating feed efficiency in cattle. The objective here was to evaluate phenotypic RFI in a group of 200 bull, heifer, and steer calves of breed compositions ranging from 100% Angus (A) to 100% Brahman (B). Calves were born in Gainesville, Florida, from December 2005 to March 2006, and moved to a GrowSafe automated feeding facility in Marianna, Florida, in September 2006. Calves were randomly allocated to 10 pens of 20 calves each by sire group (1 = A, 2 = ¾ A ¼ B, 3 = Brangus, 4 = ½ A ½ B, 5 = ¼ A ¾ B, and 6 = B) and sex (bull, heifer, and steer). Calves were fed a concentrate diet composed of whole corn, soybean hulls, corn gluten feed, cottonseed hulls, and a protein, vitamin, and mineral supplement (DM = 91.2%, CP = 17.3%, DIP = 11.3%, NEm = 1.7 mcal/kg, and NEg = 1.2 mcal/kg). There was a pre-trial adjustment period of 21 d. Individual daily feed intake and weekly weights were obtained during a 70-d feeding trial. Phenotypic RFI was computed as the difference between the actual feed intake and the expected feed intake (function of average daily gain and metabolic mid-weight). Phenotypic RFI was analyzed using a homoscedastic mixed linear model. Fixed effects were pen, age of dam, sex of calf, initial age, initial weight, Brahman fraction of calf, and probability of A and B alleles at 1 locus in the calf. Random effects were sire and residual. Important effects were sex ($P < 0.002$; Males had lower RFI than females), initial weight ($P < 0.02$), and Brahman fraction ($P < 0.02$; Brahman had lower RFI than Angus). Subsequently, calves were assigned to 3 RFI groups: high (calf RFI > mean + 0.5 SD), low (calf RFI < mean - 0.5 SD), and medium (calf RFI between mean ± 0.5 SD; SD = 2.1 kg). High and medium RFI group estimates were higher ($P < 0.001$) for daily feed intake and feed conversion ratio, and lower ($P < 0.001$) for average daily gain and final weight than those of the low RFI group.

Key Words: Cattle, Feed Intake, Multibreed

W37 Regression of feed intake on selected environmental factors for beef bulls during postweaning feedlot performance tests. G. T. Tabler*, A. H. Brown, Jr., E. E. Gbur, Jr., I. L. Berry, Z. B. Johnson, D. W. Kellogg, and K. C. Thompson, *University of Arkansas*, *Fayetteville*.

Selected weather data were analyzed to identify and quantify effects on feed intake of performance-tested beef bulls. Feed intake data originated from bulls (n = 1,874) in University of Arkansas Cooperative Bull Tests during 52 trials from 1978 to 1990. Bulls were given a 21-d adjustment period then individually full-fed a total mixed ration twice daily in the same stall for 140 d. Initial weight and age were recorded at start of each test with weights taken at 28-d intervals. Selected environmental variables used in the final analysis included maximum temperature, relative humidity, barometric pressure, rainfall, day length and wind speed. Data were pooled, divided into five 28-d periods with each period analyzed separately using all animals over all tests. Principal component analysis was used to reduce number of independent variables in the regression and overcome collinearity associated with numerous weather-related variables. Initial age and weight were included in principal components (PCs) regression as independent variables to adjust for initial animal differences. Feed intake was influenced by five PCs representing initial weight, initial age, maximum temperature, day length, rainfall, relative humidity, barometric pressure and wind speed throughout the study. Regression coefficients for initial weight and initial age were positive for each period on trial. Coefficients for environmental factors on feed intake ranged from positive to negative during various periods throughout the study. No single environmental variable had a consistent effect throughout all five periods. Results indicated numerous environmental factors influence feed intake throughout a feeding period and effects may vary as feeding period progresses, increasing the difficulty of accurate feed intake predictions.

Key Words: Beef Cattle, Day Length, Feed Intake

W38 Genetic parameters for growth traits and their relationships with yearling wool weight in Baluchi sheep breed of Iran. A. Kamali*[1], H. R. Mirzaee[1], H. Naeemipour[2], A. Delghandi[3], and H. Farhangfar[2], [1]*Zabol University*, *Zabol, Iran*, [2]*Birjand University*, *Birjand, Iran*, [3]*Jihade Agriculture*, *Mashhad, Iran*.

In this study heritabilities of and genetic correlations among birth weight (BWT), weaning weight (WWT), pre-weaning average daily gain (ADG0-3) and yearling wool weight in Baluchi sheep breed of Iran were estimated. Data were a total of 4099 records collected from a flock of Baluchi sheep breed in Abbas Abad breeding center located in northeast of Mashhad. Analyses were carried out applying restricted maximum likelihood statistical method using univariate and bivariate animal models. Heritability estimates for BWT, WWT, ADG0-3 and yearling wool weight in the univariate analyses were found to be 0.074, 0.03, 0.172 and 0.075 respectively. In the univariate analyses, direct and maternal additive genetic and environmental random effects as well as fixed effects of year, season of lambing, sex, birth type and age of dam (linear and quadratic covariates) were included. Based on bivariate analyses, genetic correlations among growth traits were 0.069 between BWT and WWT, 0.995 between WWT and ADG 0-3. Wool weight had high positive genetic correlations with BWT (0.899), WWT (0.647) and ADG 0-3 (0.737) suggesting that a correlated response would be expected for yearling wool weight as the direct genetic selection is practiced based upon weight traits.

Key Words: Baluchi Sheep, Growth Traits, Wool

W39 Estimation of genetic parameters for pre and post weaning average daily gains in a flock of Iran-black sheep breed of Iran. H. Farhangfar*[1], M. H. Molaee[2], and H. Naeemipour[1], [1]*Birjand University*, *Birjand, Iran*, [2]*Zabol University*, *Zabol, Iran*.

In this study a total of 1068 growth records obtained from Iran-black sheep breed (a synthetic breed resulted from crossing between Baluchi and Chios breeds) covering the period from 1988 to 2002 was used to estimate direct and maternal heritabilities for pre and post weaning average daily gains as well as genetic and environmental correlations between the traits under consideration. The number of lambs, sires, dams and total animals in the pedigree file were 1068, 56, 526 and 1496 respectively. The average daily gains for pre (0-3 months) and post weaning (3-6 months) ages were 188 g and 87 g respectively. AI-REML algorithm in a bivariate animal model was used to estimate genetic, permanent and temporary environmental variance and covariance components utilizing DMU package. In the model, systematic environmental factors of year and month of birth, sex, birth type, covariate of dam age, covariate of lamb age at weighing, and random effects of direct and maternal additive genetic as well as maternal permanent environment were included. For both traits, the covariance between direct and maternal genetic effects was assumed to be nonzero in the bivariate animal model. Direct and maternal heritability estimates for pre weaning average daily gain were 0.037 and 0.132 respectively and the corresponding figures for post weaning average daily gain were 0.007 and 0.017 respectively. Direct additive genetic correlation between pre and post weaning daily gains was -0.253. The results showed that for pre and post weaning daily gains, direct and maternal genetic effects were positively correlated (0.992 and 0.126 respectively). Permanent and temporary environmental correlations between pre and post weaning daily gains were found to be 0.579 and -0.231 respectively.

Key Words: Iran-Black Breed, Average Daily Gain, Genetic Parameters

W40 Genetic analysis of birth and weaning weights in a flock of Iran-black sheep breed of Iran. H. Farhangfar*[1], M. H. Molaee[2], and H. Naeemipour[1], [1]*Birjand University*, *Birjand, Iran*, [2]*Zabol University*, *Zabol, Iran*.

To estimate genetic parameters and genetic trends for birth and weaning weights in a flock of Iran-black (a synthetic breed resulted from crossing between Baluchi and Chios breeds) sheep breed of Iran, a total of 1362 weight records collected during 1988-2002 was used. The number of lambs, sires, dams and total animals in the pedigree file were 1362, 56, 612 and 1876 respectively. The average birth and weaning weights were 3.63 Kg and 19.91 Kg respectively. Genetic, permanent and temporary environmental variance and covariance components were estimated using AI-REML algorithm in a bivariate animal model consisted of the environmental factors of year and month of birth, sex, birth type, covariates of dam age (for both traits) and

lamb age at weaning (for weaning weight only), and random effects of direct and maternal additive genetic as well as maternal permanent environment. The covariance between direct and maternal genetic effects was assumed to be nonzero in the animal model. The analysis was undertaken by DMU package. Direct and maternal heritability estimates for birth weight were 0.072 and 0.097 respectively and the corresponding figures for weaning weight were 0.067 and 0.094 respectively. The additive genetic correlation between birth and weaning weights was found to be 0.936. The results showed that direct and maternal genetic effects for birth weight were negatively correlated (-0.032) while there were positively correlated (0.908) for weaning weight. Regression analysis of average predicted breeding value of lambs on year of birth indicated that there were no statistically significant annual increases at genetic level for both traits over the period of study.

Key Words: Iran-Black Breed, Heritability, Genetic Trend

W41 Estimation of genetic parameters for early growth traits in the Mehraban sheep using different models. P. Zamani*[1] and H. Mohammadi[2], [1]*Bu-Ali Sina University*, *Hamedan, Iran*, [2]*Agricultural-Jahad Organization*, *Hamedan, Iran*.

Genetic parameters for birth weight (BW), weaning weight (WW) and pre-weaning daily gain (PWDG) in Iranian Mehraban sheep were estimated using Restricted Maximum Likelihood (REML) procedure. Six different animal models were fitted, differentiated by including or excluding maternal effects and with and without covariance between maternal and direct genetic effects. The direct heritability estimates (h^2) ranged from 0.26 to 0.53, 0.18 to 0.32 and 0.15 to 0.33 for BW, WW and PWDG, respectively. The estimates were substantially higher when maternal effects, either genetic or environmental, were ignored from the model. The maternal heritability (h^2m) for BW was 0.25 when only maternal genetic effect was fitted in the model as second random effect. It was decreased to 0.14 when the maternal permanent environmental effect was added to model. More complete models resulted in more accurate estimations.

Key Words: Mehraban Sheep, Early Growth Traits, Genetic Parameters

W42 Application of logistic regression model to estimate phenotypic trend for twining trait of Baluchi sheep in Abbasabad breeding station of Mashhad. H. Farhangfar*[1], M. Molaee[2], and H. Naeemipour[1], [1]*Birjand University*, *Birjand, Iran*, [2]*Zabol University*, *Zabol, Iran*.

Twining, as a trait associated with prolificacy in sheep, has long been recognised of economic importance which is usually expressed in a binary mode and discrete phenotypic distribution. For analysis of twining in a given population, usual statistical methods which are based upon normality distribution of the variable cannot be used but instead generalized linear models should be applied. In the present research, in order to study some environmental factors (year of lambing, dam age and lamb birth weight) affecting on twining and to estimate phenotypic trend a total of 5100 birth records belonging to 1681 ewes lambing from 1984 to 2003 in a large flock of Baluchi sheep breed in Abbasabad breeding station of Mashhad was used. Only the records of singles and twins were used in this study. The average ewe age and birth weight of lambs were 2.79 years and 4.25 Kg respectively. Twining information was analyzed by a logistic regression using GENMOD procedure of SAS programme. The results obtained showed that year of lambing, dam age at lambing and lamb birth weight had statistical significant effect on the probability of twining. The probability of twining had a positive correlation with dam age while it was negatively correlated with lamb birth weight suggesting that birth weight of individual lambs born from twin-lambing ewes is expected to be lower as compared to lambs born from single-lambing ewes. The results also revealed a positive significant phenotypic trend for the probability of twining over the period of 20 years which was estimated to be 0.01 per year of lambing.

Key Words: Baluchi Sheep, Twining, Logistic Regression

W43 Genetic parameters estimation of Cashmere production for an indigenous goat in southern Khorasan province of Iran by using a repeatability model. H. Naeemipour*, H. Farhangfar, M. R. Asghari, and M. Bashtani, *Birjand University*, *Birjand,Iran*.

A total of 1490 Cashmere production records obtained from 567 indigenous goats in southern Khorasan province of Iran was used to estimate genetic parameters. Data were collected between 2000 and 2003. A single trait repeatability animal model in which fixed effects of sex, birth type, year of shearing and lamb age (linear and quadratic covariates) as well as additive genetic and environmental random effects were included. (Co) variance components were estimated by restricted maximum likelihood procedure using Powel algorithm applied in DFREML software. The results revealed that the estimates of heritability and repeatability of Cashmere production were 0.16 and 0.53 respectively indicating that a large proportion of total phenotypic variance is contributed by temporary environmental variation.

Key Words: Goat, Cashmere, Genetic Parameters

W44 Effect of genotype on characteristics of porcine aortic valves and bovine pericard as substitute heart valves. S. De Smet*[1], W. Deklerck[1], E. Claeys[1], G. Van Nooten[2], and K. Narine[2], [1]*Laboratory for Animal Nutrition and Animal Product Quality, Department of Animal Production, Ghent University*, *Melle, Belgium*, [2]*Department of Cardiac Surgery, University Hospital Ghent*, *Ghent, Belgium*.

Porcine aortic valves and bovine pericardium are frequently used as bioprosthetic heart valves. However, the life span of these valves is limited due to calcification and structural failure. Characteristics of the original fresh tissue in relation to the animal genotype may be involved in this life span variability. The aim of this study was therefore to measure some compositional and structural (stress test) characteristics of porcine aortic valves and bovine pericardium in genotypes widely differing in morphology and muscle physiology. Slaughter pigs of different sex, stress genotype and IGF2 genotype were sampled. Pericardium was taken from double-muscled Belgian Blue young bulls and culled cows, and from dairy cows. Bovine pericardium contained more total collagen ($P<0.001$), soluble collagen ($P<0.05$) and less uronic acid ($P<0.001$) compared with porcine valve leaflets.

The maximum load, extension and stiffness of bovine pericardium were more than twice as high (P<0.001). There were few differences between slaughter pig genotypes. Valve leaflets from stress positive pigs had a higher soluble collagen content and a lower uronic acid content compared to those from stress negative pigs (P<0.05). The uronic acid content was slightly higher in barrows compared to gilts (P<0.01). There were no differences in the pericardium characteristics of different cow types. However, soluble collagen content, extension and maximum load were all higher (P<0.001) in young slaughter bulls compared to culled cows. Consideration of the animal genotype might be warranted in studying the relationship between properties of fresh tissue and the durability of a bioprosthesis.

Key Words: Heart Valve, Pig, Cattle

W45 Response to genetic selection for *longissimus*color in Landrace swine: Status following two generations of selection. A. C. Naber*, K. M. Brueggemeier, S. J. Moeller, H. N. Zerby, and K. M. Irvin, *The Ohio State University*, *Columbus*.

The objective of the study was to measure response to selection for decreased longissimus Minolta L* (L) color in a population of Landrace swine. The population was established in 2002 from females obtained from 13 herds and males from 17 different genetic lines. Populations were established in two seasons (January and July farrowing) within a year. Two generations of random mating preceded separation of the populations, within season, in the year 2004 into Select (S; selected for darker loin L) and Control (C, Average EBV for loin L) based on an estimated breeding value (EBV) for L in candidate males. Available female litter mates were split into S and C randomly. After initial designation, the S and C populations were closed within a season and generations did not overlap. Selection in subsequent generations was focused on the male, and based on EBV for L. Matings within S and C were assigned randomly, while attempting to minimize full- and half-sib matings. Animal model EBVs were calculated based on sibling date within a replicate and using MTDFREML for L. Average EBVs of parent males, across seasons, for S and C in 2004 were -1.50 and 0.52 units, and in 2005 were -1.59 and 0.17 units, respectively. Responses, following two generations of selection, were evaluated using a mixed model with a fixed effect of treatment (S or C) and random harvest group within season for quality measures and season for measures of growth and carcass traits. Results indicate that S and C populations were not different for L (P = 0.18), although numerically, L was 1.0 unit less (darker) in the S population. After two generations of selection, S pigs had less (P < 0.01) loin area and greater days to 113 kg, with a trend for fatter 10th rib backfat (P < 0.08) than C pigs. No differences were observed between C and S pigs for visual loin color, marbling or loin shear force following two generations of selection. Heritability of L was estimated to be 0.36, providing a strong genetic basis for differentiation of the S and C lines if selection is effective in forthcoming generations.

Key Words: Swine, Selection, Pork Quality

W46 Genetic parameters for different measures of feed efficiency and their relationships with its component traits in Duroc pigs. M. A. Hoque*[1], K. Suzuki[1], H. Kadowaki[2], and T. Shibata[2], [1]*Tohoku University*, *Miyagi, Japan*, [2]*Miyagi Prefecture Animal Industry Experiment Station*, *Japan*.

Genetic parameters for feed efficiency traits on 380 boars and their component traits on 1642 pigs (380 boar, 868 gilts, and 394 barrows) in 7 generations of Duroc population were estimated with REML. Feed efficiency traits were included feed conversion ratio (FCR) and residual feed intake (RFI), and their component traits were daily gain (DG), metabolic body weight (MWT), and daily feed intake (FI). Three measures of RFI were calculated as the difference between actual and expected feed intake. They were calculated by the residual of phenotypic (RFI_p) and genetic (RFI_g) regressions from the multivariate analysis of FI on MWT and DG, and by the difference between actual feed intake and predicted nutritional requirement (RFI_n). The mean values for RFI_p and RFI_g were close to zero (-0.05 and -0.03 kg/day, respectively), and for RFI_n was negative (-0.11 kg/day). Most of the traits studied were moderately heritable (ranging from 0.34 to 0.53), except for FCR, which was low (0.27). The genetic and phenotypic correlations between DG and FI were high (0.77 and 0.51, respectively), while between MWT and FI were low (0.26 and 0.14, respectively). The corresponding correlations between RFI_p and RFI_g were above 0.95 implying that they might be regarded as the same trait. The genetic and phenotypic correlations of FCR with different measures of RFI were high but lower than unity. RFI_p was phenotypically independent of its component traits, MWT (r_p = 0.01) and DG (r_p = 0.03). RFI_g was genetically independent of MWT (r_g = -0.04), whereas there was a weak genetic relationship (r_g = 0.15) between RFI_g and DG. RFI was more heritable than FCR, and the genetic and phenotypic correlations of RFI_p and RFI_g with FI were positive and stronger than of FCR with FI. These results provide evidence that RFI_p or RFI_g should be included for genetic improvement of feed efficiency in Duroc pigs breeding program.

Key Words: Duroc Pigs, Feed Efficiency, Genetic Parameters

W47 Genetic parameters for carcass traits and their genetic relationships with feed efficiency traits in Duroc pigs. M. A. Hoque*[1], K. Suzuki[1], and T. Oikawa[2], [1]*Tohoku University*, *Miyagi, Japan*, [2]*Okayama University*, *Japan*.

Genetic parameters for carcass traits on 1642 pigs (380 boar, 868 gilts, and 394 barrows) and their genetic relationships with feed efficiency traits on 380 boars in 7 generations of Duroc population were estimated. Carcass traits were backfat thickness (BFT), loin eye muscle area (EMA), intra-muscular fat (IMF), and meat tenderness (MTR). Feed efficiency traits included feed conversion ratio (FCR) and residual feed intake (RFI). Three different measures of RFI, i.e., phenotypic (RFI_p), genetic (RFI_g), and nutritional (RFI_n) RFI were calculated by the difference between actual and predicted feed intake. The RFI_p and RFI_g were estimated, respectively, by the residual of phenotypic and genetic regressions of FI on MWT and daily gain. The RFI_n was estimated by the difference between actual and expected feed intake that predicted by the nutritional requirement. The heritability estimates for all the carcass traits were moderate (ranged from 0.38-0.46), except for BFT, which was high (0.72). Measures of RFI were positively correlated with IMF (r_g=0.14, 0.17, and 0.18 for RFI_n, RFI_p, and RFI_g, respectively), and negatively correlated with EMA (r_g=-0.61, -0.57, and -0.56 for RFI_n, RFI_p, and RFI_g, respectively). The genetic correlations of feed efficiency traits (FCR and all the measures

of RFI) with BFT were favorable (positive). BFT was more strongly correlated with RFI ($r_g \geq 0.76$) than with FCR ($r_g = 0.58$). Selection responses in feed efficiency traits through selection for daily gain, EMA, BFT, and IMF were small but in the desired direction, i.e. breeding values for feed efficiency traits decreased as selection generation progressed. Large responses in IMF and weak responses in EMA, BFT and MTR would be expected. This study provides evidence that selection against either RFI_p or RFI_g would give similar correlated response in carcass traits.

Key Words: Carcass Traits, Feed Efficiency, Genetic Relationships

W48 Prediction of number born alive and weaning weight of litter in first parity using performance test traits in four breeds of swine. Z. B. Johnson*, *University of Arkansas*, *Fayetteville*.

The objective of this study was to examine relationships between performance test traits and subsequent reproductive performance in first parity females in four breeds of swine. Performance test records were collected in a commercial swine operation from 1992 to 1999. All females were grown to 100 d of age. At this time pigs were weighed (WT100) and selected for performance testing based on a combination of maternal and performance indexes which were different for each breed. Pigs were weighed at the end of the 77-d performance test and ADG calculated. Backfat (BF), loin eye area (LEA), and body length (LEN) were measured. Number of live born pigs (NBA) and weight of litter at weaning (WWL) were recorded. Regression analyses were used to determine if NBA and WWL could be predicted using previous performance test records of the dam. Regression models included effects for contemporary group of the dam, maternal grandsire, and sire of the litter, and WT100, ADG, LEA, BF, and LEN as covariates. In Landrace, ADG was a significant covariate ($P = 0.02$) for NBA. For Yorkshire, LEN was a significant ($P < 0.01$) covariate for NBA; ADG ($P = 0.06$) and LEA ($P < 0.01$) were significant covariates for WWL. In Duroc, WT100 ($P < 0.01$) and LEN ($P = 0.02$) were both significant covariates for NBA, while LEN ($P = 0.03$) was a significant covariate for WWL. In Hampshire ADG was a significant ($P = 0.05$) covariate for NBA, and WT100 ($P < 0.01$), ADG ($P = 0.01$) and BF ($P = 0.03$) were significant covariates for WWL. Regression models accounted for 37 to 59 % of the variation in NBA and WWL; however, the majority of this variation was due to contemporary group, maternal grandsire and sire of the litter. No covariate alone contributed more than 1% to the total variation in NBA or WWL, implying that while significant ($P < 0.05$) relationships did exist these covariates would probably not be useful in predicting these litter traits.

Key Words: Litter Size, Weaning Weight, Performance Test Traits

W49 Estimation of the additive and dominance variances in SA Landrace pigs. D. Norris*[1], L. Varona[2], D. P. Visser[3], H. E. Theron[3], and S. F. Voordewind[3], [1]*University of Limpopo*, *Polokwane, South Africa*, [2]*Center UDL-IRTA*, *Lleida, Spain*, [3]*ARC-Animal Improvement Institute*, *Irene, South Africa*.

The objective of this study was to estimate dominance variance for number born alive (NBA), interval between parities (FI) and 21- day litter weight (LWT21) in South African Landrace pigs. A total of 26223 NBA, 16370 FI and 21335 LWT21 records were analysed. Bayesian analysis via Gibbs sampling was used to estimate variance components and genetic parameters were calculated from posterior distributions. Estimates of additive genetic variance were 0.669, 43.46 $d^2$and 9.02 kg^2 for NBA, FI and LWT21, respectively. Corresponding estimates of dominance variance were 0.439, 123.68 d^2 and 2.52 kg^2, respectively. Dominance effects were important for NBA and FI. Permanent environmental effects were significant for FI and LWT21 It may be beneficial to evaluate non-additive genetic merit of individuals and families in addition to their transmitting abilities. A breeding program that capitalizes on non-additive genetic merit may be desirable.

Key Words: Non-Additive Genetic Effects, Bayesian Analysis, Genetic Parameters

W50 EpiSNP: A computer package for genome-wide analysis of SNP epistasis and single-locus effects of quantitative traits. L. Ma*, D. Dvokin, J. R. Garbe, and Y. Da, *University of Minnesota*, *St. Paul*.

The EpiSNP computer package is designed for genome-wide analysis of SNP epistasis and single-locus effects on quantitative traits and is applicable to all bi-allelic candidate genes. The statistical tests were based on an extended Kempthorne model that allows Hardy-Weinberg disequilibrium and linkage disequilibrium for genome-wide single-locus testing and pairwise epistasis testing of potentially large numbers of SNPs. The package currently has four individual programs. The main program, EPISNP, offers tests of three single-locus effects, SNP marker effect, additive and dominance effects, and tests of five pairwise effects, two-locus interaction, additive x additive, additive x dominance, dominance x additive, and dominance x dominance epistasis effects. The CPUHD program estimates the CPU time and disk space required to execute the EPISNP program, the EPISNPPLOT program produces graphical views of single-locus significant results and sample sizes for each chromosome, and the EPINET program draws figures of epistasis networks. The EpiSNP computer package including the user manual is freely available at http://animalgene.umn.edu.

Key Words: SNP, Genome-Wide Association, Epistasis

W51 SPSSQTL: A computer program for calculating statistical power and sample size for QTL and candidate gene detection. J. R. Garbe*, L. Ma, and Y. Da, *University of Minnesota*, *St. Paul*.

The SPSSQTL computer program offers calculations of statistical power and sample size for detecting two single-locus effects (additive and dominance) and four epistasis effects (additive x additive, additive x dominance, dominance x additive, and dominance x dominance) of a QTL or a candidate gene. The program consists of one dialog box with fields for the user to enter parameter values for calculating statistical power or sample size. For detecting additive and dominance QTL effects, the user has a choice of F-2 or reciprocal backcross (RBC) design. For detecting epistasis QTL effects, the F-2 design is assumed. To calculate statistical power, the user needs to enter parameter values of QTL heritabilities (measures of QTL effect size), type-I error, recombination frequency between the marker and QTL, and sample size. To calculate sample size, the user needs to enter

statistical power in addition to all the above parameter values except sample size. Changing any field in the dialog box will cause the calculated power or sample size to be updated. For candidate gene testing, power and sample size are calculated by setting the marker-QTL recombination frequency to zero. The program including the user manual is freely available at http://animalgene.umn.edu.

Key Words: Statistical Power, Sample Size, QTL

W52 The effect of two freezing rates and two equilibration times on semen post-thaw motility of bad freezer bulls. G. Rocha-Chavez[1], J. M. Tapia-Gonzalez[1], J. G Michel-Parra[1], M. A. Pinto-Jacobo[2], and G. Gonzalez-Guerra*[1], [1]*CUSUR Univ de Guadalajara*, *Cd Guzman, Jalisco, Mexico*, [2]*URPJ*, *Guadalajara, Jalisco, Mexico*.

It is a well known fact that beef cattle living in tropical areas tend to have low freezability on their semen intended for artificial insemination. The objective of this study was to determine the effect of two freezing rates and two equilibration times on post thaw motility of low freezability semen. Each ejaculate from six bulls known as bad freezers was diluted 1:1 with Andromed® extender, split in four parts and allocated in a 2x2 factorial arrangement into one of the following experimental groups: (1) semen equilibrated for 4 hr and slow freezing rate (FR); (2) semen equilibrated for 4 hour and fast FR; (3) Semen equilibrated for 24 hr and slow FR; (4) semen equilibrated for 24 hr and fast FR. Each of the six bulls (3 simmental and 3 brahaman) was collected 10 times and semen was frozen on 0.5 cc straws using a standard protocol. Equilibration was made at 4°C and freezing rates were 0.5°C/min and 4°C/min for low and fast respectively. Motility readings were made on thawed semen after being frozen for at least a 24 hr period. All readings were made in duplicate using video recording technology and descriptive statistics was used for initial arrangement of data. The chi squared procedure was used for finding differences between treatments. Readings on post-thaw motility of 47 ± 7.7, 52 ± 5.6, 58 ± 3.2 and 49 ± 6.3 % were found for treatments 1, 2, 3, and 4 respectively with no statistical differences between treatments except for group 3 ($P<0.05$). No interaction between breeds and treatment was found. It was concluded that, under conditions of this study, longer equilibration periods and slower freezing rates are beneficial for semen of low freezability.

Key Words: Semen, Freezability, Bulls

W53 Effect of selection for increased egg production, age, and sex on turkey breast muscle development. C. S. Coy*, K. E. Nestor, and S. G. Velleman, *Ohio Agricultural Research and Development Center, The Ohio State University*, *Wooster*.

Genetic selection plays an important role in breast muscle development in turkeys. Previous studies have shown a correlation between growth selection and altered breast muscle morphology leading to muscle fiber damage. In a recent study, genetic selection for increased egg production showed no significant changes in breast muscle morphology from 8 to 16 wk of age between a line (E) selected for increased egg production and its randombred control line (RBC1). However, there was a significant interaction between line and age suggesting that the E and RBC1 line may develop differently. Morphological structure of the breast muscle was better in males than females. The purpose of this study was to examine breast muscle morphology changes in the E and RBC1 lines during key stages of muscle development. Breast muscle morphology was observed at embryonic d 25, and 1, 4, 8, 16, and 20 wk posthatch in the E and RBC1 lines. Breast muscle samples from 10 birds per age-line-sex subgroup were collected, fixed, processed, embedded in paraffin, sectioned, and stained with hematoxylin and eosin. Representative muscle sections from each bird were scored by 4 individuals based on breast muscle morphology. Scores ranged from 1 (little extracellular space and indistinct muscle fibers) to 5 (large extracellular space and distinct muscle fibers). Posthatch breast muscle morphology scores did not differ between the E and RBC1 lines, but age and sex differences were significant. The morphological scores were best at embryonic d 25 but declined significantly at 1 wk posthatch. Scores improved significantly from 1 to 4 wk posthatch and remained constant through 20 wk posthatch. Males had higher scores than females. The results of this and previous studies suggest that selection for increased egg production may be associated with a slight reduction in breast muscle morphology scores at 16 wk of age.

Key Words: Turkey, Genetic Selection, Muscle

W54 Sequence homology comparison between goose and chicken liver cDNA libraries. Y. H. Wang*[1], E.-C. Lin[1], M. C. Hsu[2], C. Y. Lien[1], B. T. Tsai[1], C. F. Yen[1], H. W. Lin[1], S. T. Ding[1], W. T. K. Cheng[1], K. T. Yang[3], M. C. Huang[3], Y.-H. Fan[3], S.-H. Chiou[3], C. F. Chen[3], Y. P. Lee[3], [1]*National Taiwan University*, *Taipei, Taiwan*, [2]*National Taitung Junior College*, *Taitung, Taiwan*, [3]*National Chung Hsing University*, *Taichung, Taiwan*.

The DNA sequence information of goose is very limited in the public databases. In this study, we utilized expressed sequence tags (ESTs) of goose and chicken liver cDNA libraries for sequence homology comparison. The goose and chicken cDNA libraries were constructed by using livers from 4 Taiwanese native chickens and 6 White Roman geese. There were totally 2,400 and 6,686 clones sequenced in the goose and chicken liver cDNA libraries, respectively. After excluding sequences with low quality, short and low complexity, 8,403 high quality sequences (2,075 of goose; 6,328 of chicken) were clustered and assembled using tgicl package (from TIGR website) with minimum requirements of 65 base pairs overlapping and 95% similarity. Totally 605 clusters (≥2 sequences per cluster reaching the requirements, averaging 9.3 sequences per cluster) were found with 636 contigs assembled in those clusters. The number of clusters with sequences from both of goose and chicken was 29, which are highly similar in the cDNA sequences between the two species. There were 14 clusters which have different contigs per cluster assembled from either goose or chicken sequences only. Such clusters might represent certain differences happened in the same gene between goose and chicken. To assist the comparison of sequence homology, the remaining clusters were searched against NCBI NT database using blastn. There were 76 clusters annotated to be 35 gene identities, which indicated more variation of sequence in such clusters than the previous two categories. However, the other 486 clusters could not be classified that might result from the lack of enough sequence information from goose. This comparison might provide more information for the further genomic studies of goose.

Key Words: Goose, Chicken, Sequence Homology

W55 Combining ability of characteristics of egg quality of quail for analyze system of diallel crossbreds. A. Piccinin, J. N. Gimenez, C. H. M. Malhado, C. Móri, C. Andrighetto, R. M. S. Emediato*, S. A. Maestá, A. A. Ramos, H. C. Gonçalves, and E. N. Martins, *São Paulo State University*, *Botucatu, São Paulo, Brazil*.

The goal of this trial was to indicate crossbreds to improve quality of eggs of quail. It was used a system of diallelic crossbreds between three ancestries. Effect of general capacity of combination, specific capacity of combination and reciprocal effect have been estimated. It was studied characteristics as specific gravity, height of albumen, Haugh unit, egg yolk percentages, shell and albumen. Ancestries 1 and 2 have improved the indices of specific gravity, and ancestry 3 improved the percentage of egg shell and consequently shelf-life, when the general capacity of combination is considered. lineages of crossbred 1x2 was more efficient for Haugh unit and albumen height, indicating bigger shelf-life of these eggs. Lineages of the crossbred 1x3 and 2x3 have shown to be the best option for specific gravity and percentage of egg shell, respectively, which resulted in better egg quality. The reciprocal effect have shown significant in the majority of the characteristics, in the partial periods. Crossbreds between males of ancestry 2 with females of ancestry 1 have provided lineages with bigger height of albumen, Haugh unit and percentage of egg shell, and males of ancestry 3 with females of ancestry 2 have provided lineages with bigger specific gravity, percentage of egg yolk and egg shell. Both crossbreds can be used in programs of genetic improvement aiming get better internal quality of eggs.

Key Words: Diallelic Crossbreds, Egg Quality, Quail

W56 Long-term effects on the expression of the intestinal Na-P type IIb cotransporter in broilers fed phosphorus deficient diets early in life. C. M. Ashwell*[1] and R. Angel[2], [1]*North Carolina State University*, *Raleigh, NC*, [2]*University of Maryland*, *College Park, MD*.

To determine the effects of dietary P on the expression of the chicken intestinal Na/Pi type IIb cotransporter (NaPcoT) experimental diets were formulated to be deficient in P. Male Ross 308 chicks were fed either a control (C) consisting of 1.11% Ca and 0.50% available P or a low (L) diet containing 0.59% Ca and 0.25% available P from hatch to 4 d of age (90hr). All birds were then fed a C diet consisting of NRC recommended levels of Ca and P until d 22. From d 22 to d 38 the birds were either maintained on a C (0.7%Ca and 0.3%P) or an L diet (0.4% Ca and 0.12% P). The three dietary treatments, C-C-C, C-C-L, and L-C-L met all other NRC (1994) nutrient recommendations. Performance data were collected for each dietary phase including weight gain, feed conversion, bone ash, and specific nutrient retention. RNA extracted from each of the regions of the small intestine were reverse transcribed to produce cDNA and analyzed by real-time PCR for the levels of both the NaPcoT mRNA and 18s rRNA. The effect of dietary treatment was determined by analyzing the resulting Ct values for each amplification and determining the $\Delta\Delta$Ct using the level of 18s rRNA as an internal standard for normalizing the amount of RNA in each reaction. The reduction of P in the post hatch diet had a significant effect on the expression of the NaPcoT by stimulating an average 2.8-fold increase in the mRNA levels in the small intestine. The most interesting aspect of this effect of diet on expression of NaPcoT in the intestine is the increase in expression levels later in life (d38) of the birds that experienced the low P diet for the first 90 hr post-hatch in comparison to the controls. This data correlates well with the apparent increase in efficiency of nutrient uptake measured in these birds. This clearly establishes that 'imprinting' or permanent modifications are occurring in the animal post-hatch that are long term and allow for significant increases in NaPcoT expression and improved P utilization when P deficient diets are fed in the grower/finisher phases.

Key Words: Gene Expression, Conditioning, Imprinting

W57 Analysis of expressed sequenced tags from abdominal muscle cDNA library of the pacific white shrimp *Litopenaeus vannamei*. J. Cesar, B. Zhao, and J. Yang*, *University of Hawaii*, *Honolulu*.

As the shrimp industry expand rapidly worldwide, the pacific white shrimp, *Litopenaeus* vannamei, is becoming an economically important species in aquaculture. Along with culture technology and disease resistance, genetic enhancement of growth rate is an important aspect of shrimp aquaculture. Although abdominal muscle accounts for 90% of shrimp meat, little is known about the shrimp muscle genes, particularly the muscle regulatory genes. To identify the critical genes responsible for shrimp muscle growth and metabolism, we established a cDNA library based on juvenile abdominal muscle by a PCR-based SMART^{TM} cDNA technology. Library size was 5.0 x 10^6 pfu independent clones per microgram of starting DNA vector with the percentage of recombinant clones >95%. Single pass sequence analysis of 311 randomly picked positive clones revealed 197 expressed sequence tags with average insert size of 745 nucleotides. BLASTn searches using the sequences identified 161 unique clones, including 45 high (>98%) identity matches to previously identified genes; 36 medium (80% to 98%) identity matches (>100 bits hit score and <2 x 10^{-19} E-value); 76 unknown sequences; 2 sequences matching hypothetical protein sequences, 2 sequences matching DNA microsatellite markers with short TG, GA and CAA repeats in the database. Among the 45 high identity-matched ESTs, 12S ribosomal RNA, actin 1, actin 2 and arginine kinase and beta-actin were most abundant with 5 to 13 clones each. Primary hit sequences originate from shrimp, insects, mammal, lobsters, crabs, crayfish, and barnacle. According to the inferred or known functions of the gene products, genes were categorized as muscle structural proteins (28%), followed by unknowns (24%), protein synthesis (18%), enzymes (14%), carrier protein (6%), ion channel (2%), DNA replication (2%). In summary, more than 25% of the ESTs identified a new gene from the cDNA library supports full-scale EST strategy for discovery of the transcripts or genes that regulate abdominal muscle biology. A further analysis and identifications of the full-length cDNA sequences will significantly facilitate shrimp genomic program.

Key Words: cDNA Library, Expressed Sequence Tag, Shrimp

W58 Higher oxidative product in UHT drinking milk originated from milk powder than that from raw milk. S. Santinate, W. Suriyasathaporn, and P. Vinitchaikul*, *Chiang Mai University*, *Muang, Chiang Mai, Thailand*.

In Thailand, the most popular liquid milk product is UHT milk. In our UHT commercial milk, it is originated from 2 sources of milk including raw milk and milk powder, whereas the latter will be recombined with water. Autoxidation takes place throughout storage of the powder, especially during importing processes time interval. The most important secondary product of autoxidation is the malondialdehyde (MDA) that is usually used as an indicator of the lipid peroxidation process. This product imparts that the milk quality has been decreased including off-flavors and loss of nutrients. Therefore, the objective of this study was to determine whether UHT milk originated from raw milk (RAW) had lower MDA than that from milk powder (POW). In addition, interval to expiration date was controlled from MDA production during storage after UHT milk process. Four commercial UHT liquid milk products known for sources of milk were selected. Approximately 15 packages of each commercial milk product with variation of expiration dates were collected from markets. MDA were measured. Analysis of variance was used to test whether MDA of among UHT milk were different from one another. Pearson correlation coefficient was used to evaluate the relationship between interval to expiration date and MDA. Means and standard error of means from RAW1, RAW2, POW1 and POW2 were 1200 + 92, 1460 + 95, 1945 + 85 and 1848 + 79 ppb, respectively. Statistical analysis showed that RAW1 and RAW2 were different from POW1 and POW2 ($P<0.05$). Higher intervals to expiration date decreased MDA concentrations ($p = -0.23$, $P< 0.05$). This indicates that UHT milk has lower quality from milk powder than raw milk. Increasing storage times after production process is associated with increase of malondialdehyde concentrations.

Key Words: Malondialdehyde, UHT Milk, Raw Milk

W59 Effect of cold storage and packaging material on butter flavor. P. R. Lozano[2], R. E. Miracle*[1], A. J. Krause[1], K. R. Cadwallader[2], and M. A. Drake[1], [1]*North Carolina State University*, *Raleigh*, [2]*University of Illinois*, *Champaign-Urbana*.

Sweet cream butter in the United States is often stored for several months under refrigerated and frozen storage in bulk (25 kg blocks) and quarters (commercially-packaged sticks). Deterioration of flavor may occur during this time. The objective of this study was to evaluate the flavor of bulk and stick butter across frozen and refrigerated storage under different packaging conditions. Butter (bulk and quarters) was collected on two occasions from two West coast facilities. Two packaging materials (wax parchment paper and foil) were represented. Butters were stored at 4°C or -20°C and evaluated after 0, 6, or 12 months storage. Descriptive sensory analysis using a trained panel was used to document flavor changes. Volatile compounds of butter and packaging material were identified using dynamic headspace analysis (DHA), solid phase micro-extraction (SPME), and solvent assisted flavor evaporation (SAFE) followed by gas chromatography mass spectrometry (GC-MS) and gas chromatography olfactometry (GC-O). The most intense aroma-active volatile components of pasteurized AA butter were butanoic acid, d-decalactone, 1-octen-3-one, dimethyl trisulfide and diacetyl. Lipid oxidation products and methyl ketones increased as a function of storage time. Butter stored at refrigeration temperatures (4°C) showed greater flavor deterioration by sensory and instrumental analyses than butter stored at freezing conditions (-20°C). The intensity and relative abundance of styrene increased as a function of storage time at refrigeration temperature. Butter frozen for 12 months exhibited lower levels of styrene and a flavor profile more similar to fresh butter compared to butter refrigerated for 12 mo. Foil wrapping material performed better than wax parchment paper to prevent styrene migration to butter, in minimizing the increase in the intensity of lipid oxidation and hydroxyl acid products, and in the loss of fresh butter flavor.

Key Words: Butter, Storage Stability, Packaging

W60 Persistence of conjugated linoleic acid (CLA) on three dairy products. M. A. Rodriguez[1], P. Pellegrini[1], G. Muset[1], P. Gatti[1], D. A. Garciarena[2], and G. A. Gagliostro*[2], [1]*Instituto Nacional de Tecnología Industrial (INTI). Lácteos*, *Buenos Aires, Argentina*, [2]*Instituto Nacional de Tecnología Agropecuaria (INTA)*, *Balcarce, Argentina*.

The study was designed to test the persistence of 9-cis 11-trans CLA on yogurt, white cheese and pasteurized milk elaborated from raw milk of high CLA content (3.54 g/100g FA). Six Holstein cows (520 ± 60 kg liveweight) producing about 10 kg of milk grazed an oat pasture (2800 kg DM/ha; 11 kg pasture DM/cow) and received also a TMR composed by corn grain (1.3 kg DM/cow/d), corn silage (5.6 kg DM/cow/d), sunflower oil (0.8 kg/cow/d), fish oil (0.24 kg/cow/d) and sunflower meal (0.89 kg DM/cow/d). After 10 days of adaptation individual milk samples were collected and transformed into yogurt, white cheese and pasteurized milk reproducing industrial conditions. Fatty acid composition of milk and dairy products was analyzed by gas chromatography. Differences in CLA concentration between raw milk and products were stated using the T-test for paired observations. In the case of pasteurized milk, two different processes were carried out at 72 °C for 15 seconds (HTST) and at 140 °C for 5 seconds (UHT). Results showed an average increase of CLA of 0.08 g/100g (ranging from 0.02 to 0.11 g/100g) over raw milk ($P<0,11$) for HTST and 0.07 g/100g (-0.03 to 0.19 g/100g) for UHT ($P<0,93$). White spreadable cheese elaborated from HTST pasteurized milk after adding a mesophilic starter and chymosin showed a CLA increase of 0.04 g/100g ranging from -0.04 to +0.09 g/100g ($P<0.97$). The six elaboration trials of yogurt using HTST pasteurized milk and adding sugar, non-fat milk powder and starter showed an average decrease in CLA of 0.19 g/100g ranging from -0.45 to +0.15 g/100g ($P<0.88$). The results showed that variations in CLA content were not significant whatever the dairy product tested. In this study, the CLA present in the raw milk was not lost during the processes of milk transformations. Negative metabolic actions of the starter or heat affects on final CLA content in the products were not detected.

Key Words: Conjugated Linoleic Acid, Dairy Products, Pasteurized Milk

W61 Effects of refrigeration and calcium on whey protein aggregation. M. R. Costa*[1,2], G. Brisson[1], M. L. Gigante[2], P. S. Tong[1], and R. Jiménez-Flores[1], [1]*California Polytechnic State University*, *San Luis Obispo*, [2]*State University of Campinas*, *Campinas, Brazil*.

Aggregation of whey proteins in 5% protein solution was studied using a laser diffraction particle size analyzer. Two whey protein concentrate powders (WPC80) with similar composition were evaluated: WPC1 was produced by traditional commercial procedures, and for WPC2 the liquid whey protein concentrate (LWPC, obtained by ultrafiltration) was refrigerated (4°C, overnight) prior being spray-dried. We studied the effects of refrigeration, adding calcium (50mM $CaCl_2$) to each of the WPC solutions, and heating (50°C/8min). Our results show that WPC1 solutions did not have particles larger than 6µm initially. However, calcium addition produced large aggregates (10-60µm diameter) that became the main volumetric fraction (78.6±0.2%). Aggregation was independent of heating, and the formed aggregates did not change after either heating or overnight refrigeration. In the WPC2 solutions, calcium addition did not have the same pronounced impact on aggregate formation as in the WPC1 solutions. The main volumetric fraction in the calcium-added solutions switched from particles smaller than 2µm to particles between 2 and 10µm diameter (54.5±0.8%) only after heating. However, after overnight refrigeration these largest aggregates were partially disrupted into the smallest particles, which returned as the main volumetric fraction (58.6±0.7%). The addition of β-mercaptoethanol (0.1%) had no particle size distribution effect over the solutions, while the presence of urea (4M) changed the turbid solutions immediately to clearer ones. This suggests the contribution of non-covalent interactions to aggregates formation. In addition to the noticeable large aggregate formation, our results show that refrigerating the LWPC prior spray-drying reduced the proteins susceptibility to $CaCl_2$-induced aggregation in the reconstituted WPC. The aggregates formed in this solution after calcium addition were not too big and reversible by refrigeration, indicating they were held together by hydrophobic interactions. In contrast, the $CaCl_2$-induced aggregates from WPC manufactured without the refrigerating step were much larger and formed irreversible aggregates.

Key Words: Whey Protein Concentrate, Whey Protein Aggregation, Particle Size Distribution

W62 Seasonal variation of conjugated linoleic acid (CLA) and n-3 fatty acids of goat milk fat and its transfer into cheese. A. Nudda[1], G. Battacone[1], S. Testone[2], and G. Pulina*[1], [1]*Dipartimento di Scienze Zootecniche - Università di Sassari*, *Sassari, Italy*, [2]*Associazione Regionale Allevatori della Sardegna*, *Cagliari, Italy*.

The seasonal variation in conjugated linoleic acid (CLA), vaccenic acid (VA) and n-3 fatty acid contents in goat milk and the extent of their transfer from milk into cheese fat were investigated. Samples of milk and of the derived fresh cheese were collected in two milk processing plants located in middle-east Sardinia (Italy) every two weeks from early-spring (March-April) through early-summer (July). The concentrations of individual fatty acid in each sample of milk and cheese were determined by gas chromatography. Data were analyzed with a linear model that included the effect of processing plant, period and source (milk or cheese). Concentrations of CLA, VA and omega-3 fatty acids did not differ between milk and cheese (c9,t11 CLA content 0.62 and 0.67 mg/100 mg FA, VA content 1.09 and 1.06, and omega-3 content 0.88 and 0.79, respectively for milk and cheese). The FA composition of both milk and cheese was significantly affected by period of sampling: the mean of C18:3 n-3 concentration decreased linearly from early spring to early summer (0.91 vs 0.61 mg/100 mg FA). On the other hand, the means of VA and c9,t11 CLA decrease markedly from March (1.93 and 0.98, respectively) to April (1.03 and 0.66, respectively), and remain stable until early summer. A possible explanation for the different pattern of individual fatty acids can be found in the farming system of goat in this geographic area, where natural pasture and Mediterranean maquis scrubs represent the main feeding source. The reduction of C18:3 n3 in milk, for example, may reflect the reduced availability of grass, which is the main source of C18:3 n-3 fatty acid, that occurs in late spring-summer. No differences were observed between the two cheese plants for c9,t11 CLA and VA concentration in milk and cheese. *Acknowledgements: Research supported by the Ministry of University and Research (FISR grant).*

Key Words: Conjugated Linoleic Acid, Goat Milk, Cheese

W63 Survey of fluid milk quality. C. A. Boeneke*, K. J. Aryana, D. W. Olson, and J. L. Vargas, *Losuisiana State University Agricultural Center*, *Baton Rouge*.

Nineteen dairy processing plants located in the west, midwest, and southern regions of the U. S. were surveyed in order to determine milk quality. Whole, two percent, and skim milks were obtained in duplicate from the plants. Milk samples were shipped overnight to the Dairy Science Building at Louisiana State University. A temperature control was included with each set of samples. One set of milk samples were evaluated upon arrival for sediment, freezing point, lab pasteurization counts, coliform counts, standard plate counts, protein, fat, and somatic cells. Milks were evaluated for flavor using the Collegiate Dairy Products Evaluation Score Sheet. Milks were then stored at 7° C for two weeks. At the end of the two week period, milks were evaluated again for flavor by a 5 member trained panel. The entire experiment was repeated once every three months over a nine month period. Coliform counts on fresh samples were all less than ten colony forming units (CFU's) per ml. Standard plate counts ranged from less than 100 to 6300 CFU's per ml. No sediment was found in any of the samples. Samples received scores ranging from 8 to 9 out of 10 possible points for sensory evaluation upon arrival with the most common criticism being cooked. Sensory evaluation scores at the end of the two week period ranged from 1 to 9 out of 10. Common criticisms of samples were cooked, rancid, unclean, and fermented fruity. Region of the U. S. the samples were received from showed no differences in the quality of the samples.

Key Words: Shelf Life, Milk, Quality

W64 Effect of total protein content and whey to casein ratio on the texture of ice cream. J. M. Morton[1], P. Quok*[2], J. Estrade[1], W. Wang-Nolan[1], S. Vink[1], and P. S. Tong[1], [1]*Dairy Products Technology Center*, *San Luis Obispo, CA*, [2]*California Polytechnic State University*, *San Luis Obispo*.

Whey protein concentrate (WPC) is used in ice cream for its nutritional and functional properties. The functional properties of WPC enhance freeze-thaw stability and help minimize ice crystal formation, which

improve texture and mouthfeel. This study examined the effect of total protein content and whey to casein ratio (W/C) on the texture of ice cream. Regular (4.1%) and high (5.7%) protein ice creams were prepared with W/C levels of 1:1, 1:2, 2:1, and 4:1, for a total of 4 matched treatments and 1 matched control (no WPC). Nonfat dry milk and WPC 34 were used to adjust W/C and total protein content. Ice cream samples were tempered at -15°C for 4 to 6 hours before cutting. Twelve, 2.5 cm cubes were cut from the core of each ice cream block, positioned with the same surface facing up in covered serving cups, and stored at -18°C until testing the following day. Nine judges trained in descriptive analysis of ice cream evaluated the texture of the samples from first inspection, visual, to final mastication stage, chew down. Judges rated the intensities of each textural component on 15 cm line scales anchored by reference standards. Judges individually evaluated each sample in triplicate following a balanced block test design with a randomized, sequential monadic serving order. ANOVA of the data showed that when total protein content and W/C were accounted for, significant differences ($p \leq 0.05$) existed for hardness, rate of breakdown, rate of melt, and density. The high protein ice creams were less icy, softer, oilier, less foamy, and had higher mouthcoating than regular protein ice creams. Ice creams with the highest W/C were stickier, softer, foamier, and had higher rates of breakdown and melt. These findings suggest that both total protein content and milk protein composition affect ice cream texture.

Key Words: Ice Cream, Whey Protein, Sensory

W65 Influence of form of vitamins on yogurt characteristics. B. Dufrene*[1] and K. J. Aryana[2], [1]*Louisiana State University*, *Baton Rouge*, [2]*Louisiana State University Agricultural Center*, *Baton Rouge*.

Vitamins A and D are commonly added during the processing of some dairy products. Objective was to study the effect of liquid and powdered forms of vitamins A and D added separately during the manufacturing of yogurt. Vitamin A palmitate and Vitamin D_3 were incorporated at the rate of 1000 IU and 200 IU respectively per 8 oz of yogurt. Syneresis, pH, viscosity, color (L^*, a^* and b^*) sensory, lactic acid bacterial counts were enumerated on the yogurts at 0, 1, 3 and 5 weeks of storage. The treatment x storage time interaction effect was not significant for any of the attributes studied other than lactic acid bacterial counts. For lactic acid bacterial counts significant difference were noticed between vitamin D_3 liquid at weeks 0 and 5, vitamin A liquid at weeks 0 and 5, vitamin A powder at weeks 0 and 5, vitamin D_3 liquid and powder at week 0. There was no treatment effect for any of the characteristics studied. Storage time was significant for flavor appearance, body texture, L^* and a^*. As storage time increased to week 5 there was a significant drop in flavor and body texture compared to week 0. Lightness values significantly increased and a^* values significantly decreased at week 5 compared to week 0. The form of vitamin, liquid or powder, did not have any effect on the characteristics of yogurt.

Key Words: Vitamin, Form, Yogurt

W66 Effects of raw milk storage time and pasteurized milk storage temperature on milk shelf-life. G. B. Sanvido, D. Y. Kabuki, M. R. Costa*, and M. L. Gigante, *State University of Campinas*, *Campinas, SP, Brazil*.

The effects of psychrotrophic microorganisms development on pasteurized milk shelf-life were not a concern in Brazil until recently when raw milk cold storage start to be required by law in this country. This work evaluated the effects of raw milk storage time (0, 4 or 7 days at 5°C) and pasteurized milk storage temperature (5°C or 10°C) on its shelf-life. Milk was submitted to HTST pasteurization process (72°C/15sec), cooled at 5°C and then packaged in low-density polyethylene bags. Raw and pasteurized milk were initially analyzed by physicochemical (acidity, pH, total nitrogen, soluble nitrogen at pH 4.6 and TCA 24%) and microbiological analyses (standard plate, psychrotrophic microorganisms and Pseudomonas spp counts), and these parameter were monitored during storage of both raw and pasteurized milk. Raw milk also was initially analyzed for antibiotic presence and somatic cell count, and pasteurized milk for Coliform and Salmonella spp counts. Pasteurized milk shelf-life was defined as the time necessary to reach 8×10^4 ufc/mL on the standard plate count. A Split-split-plot design was used and the whole experiment was repeated three times. The longer raw milk storage time, the higher were acidity, proteolysis and bacteria counts. The standard plate, psychrotrophic and Pseudomonas spp counts increased from around 10^3, 10^3 and 10^2 ufc/ml (day 0) to 10^8, 10^7 and 10^6 ufc/ml (day 7), respectively. The lag phase was significantly longer for all analyzed microorganisms at shorter raw milk storage time and lower pasteurized milk storage temperature. The longer raw milk storage time and lower pasteurized milk storage temperature, the longer was its shelf life. The milk processed right after milking and stored at 5°C had 10.7 days of shelf-life while the milk processed after 7 days of raw milk storage and stored at 10°C had just 2.3 days of shelf-life. These results confirm the importance of having short raw milk storage time and low pasteurized milk storage temperature, besides good quality raw milk, to extend the pasteurized milk shelf-life and guarantee a safe product during this period.

Key Words: Shelf-Life, Pasteurized Milk, Raw Milk

W67 Colostrum fortified probiotic fat free yogurt. E. Albers[1], O. Cueva[1], and K. J. Aryana*[2], [1]*Louisiana State University*, *Baton Rouge*, [2]*Louisiana State University Agricultural Center*, *Baton Rouge*.

Colostrum is a good source of immune and growth factors. The probiotic bacterium *Lactobacillus acidophilus* offers several health benefits. Objective was to study the effect of colostrum on the physicochemical, microbiological and sensory characteristics of yogurt containing *Lactobacillus acidophilus*. Colostrum powder was added during yogurt mix preparation at 0, 4, 8 and 12 g per 228 g (8 oz) cup of yogurt. Colostrum incorporation in the manufacture of yogurt with *L. acidophilus* increased apparent viscosity, b^* (yellowness) values and decreased pH, syneresis, L^* (lightness) and a^* values. Colostrum incorporated at 4 or 8 g per 228 g yogurt increased lactobacilli counts over storage while use of colostrum at 12 g significantly decreased lactobacilli counts at 35 days of storage. Colostrum incorporated at 4 g per 228 g of yogurt improved the sensory characteristics namely, flavor, appearance and color, and body and texture of the yogurts. Colostrum incorporated at 12 g per 228 g of yogurt adversely affected product flavor and made the yogurts lumpy and too firm. It is perceived that the health benefits of colostrum can be added to probiotic yogurts by incorporation of colostrum at 4 g per 228 g of yogurt without adversely influencing product characteristics.

Key Words: Colostrum, Yogurt, Probiotic

W68 The effect of the ratio of ice cream mix to yogurt on the properties of the resulting yogurt ice creams. D. Olson*, K. J. Aryana, and C. Boeneke, *Louisiana State University Agricultural Center*, *Baton Rouge*.

The effect of varying the ratio of ice cream mix to whole milk yogurt on the characteristics of the resulting yogurt ice creams was investigated. Ratios of ice cream mix to yogurt included 0% ice cream mix and 100% yogurt (I) for the air-whipped and frozen yogurt control, 25% ice cream mix and 75% yogurt (II), 50% ice cream mix and 50% yogurt (III), 75% ice cream mix and 25% yogurt (IV), and 100% ice cream mix and 0% frozen yogurt (V) for the ice cream control. The resulting mixes were analyzed for total solids content, fat content, pH, and viscosity and frozen in a batch freezer. The frozen products were analyzed for sensory properties (flavor and body/texture), rate of meltdown of 100 g of frozen product at 21°C (volume after 1 h and time for 15 mL to melt), and MRS lactobacilli counts. The total solids contents were 11.7, 18.0, 26.4, 33.2, and 40.6%, and the fat contents were 3, 4, 7, 11, and 13% for I, II, III, IV, and V, respectively. The pH ranged from 4.54 for I to 6.73 for V. The I sample had the highest viscosity. The frozen products IV and V received the highest sensory scores, while I and II had the highest MRS lactobacilli counts. The rate of meltdown increased with increasing proportion of ice cream in the yogurt ice creams as no meltdown after 1 h was observed for I. Times needed to collect 15 mL of frozen product ranged from 40 min for V to 115 minutes for I. Yogurt ice cream made from IV had more desirable properties than yogurt ice cream made from II and III.

Key Words: Yogurt, Ice Cream, Yogurt-Ice Cream

W69 Characteristics of ice cream as influenced by a weight loss ingredient. K. J. Aryana*[1], D. Olson[1], and A. Greenbaum[2], [1]*Louisiana State University Agricultural Center*, *Baton Rouge*, [2]*Louisiana State University*, *Baton Rouge*.

Obesity is a health problem in the United States. A novel form of (-) hydroxycitric acid is being marketed as a weight loss ingredient (WLI). The objective was to study the effect of various amounts of the WLI on the physico-chemical, microbiological and sensory characteristics of ice cream. The WLI was incorporated into ice cream mixes at 0 (control), 1.5, 3.0 and 4.5 g per 473 mL of ice cream. Three replications were performed. Viscosity and pH were determined on ice cream mixes after one day of aging. Meltdown time for the first 15 mL, meltdown volume in one hour, bacterial counts, sensory flavor and body texture, heat shocked flavor and body texture were determined at weeks 2, 5, 9, 13 after product manufacture. The WLI decreased pH, increased viscosity of the ice cream mixes and increased meltdown volume of the ice creams. Use of WLI at 3.0 and 4.5 g resulted in faster meltdown and increased aerobic counts of the ice creams. The WLI did not influence flavor, body texture and heat shocked body texture of the ice creams. Use of WLI at 1.5 and 3.0 g resulted in the best heat shocked flavor. The WLI can successfully be used in ice cream manufacture.

Key Words: Obesity, Weight Loss, Ice Cream

W70 Influence of garlic on the characteristics of yogurt. K. Bridges[1] and K. J. Aryana*[2], [1]*Louisiana State University*, *Baton Rouge*, [2]*Louisiana State University Agricultural Center*, *Baton Rouge*.

Garlic has been researched for its ability to reduce cholesterol and triglycerides, prevent cancer, reduce blood pressure and hardening of the arteries and clotting and protect the liver. Garlic may also increase the effects of the immune system and reduce blood sugar levels. Objective was to study the influence of garlic on the microbiological physico-chemical, and sensory characteristics of yogurt. Powdered garlic was incorporated into the plain yogurts at 0, 0.5, 1 and 2 g per 8 oz of yogurt. Product manufacture was replicated three times. Garlic did not influence the lactic acid bacterial counts, the syneresis (released serum) and the pH of the yogurts. Garlic adversely influenced the flavor of the yogurts.

Key Words: Garlic, Spice, Yogurt

W71 Fatty acid composition of dairy foods and their intake in humans. T. R. Dhiman*, A. Hopkins, and N. Garg, *Utah State University*, *Logan*.

The objective of this study was to analyze dairy products and relate to fatty acid (FA) intake in humans. A total of 180 samples of dairy foods were collected from 43 different stores in selected 17 counties of Utah. Within the selected counties, cities, towns and stores were selected using random sampling tables. The samples included: 23 whole milk, 13 cream, 17 butter, 12 yoghurt, 13 sour cream, 12 cottage cheese, 14 cream cheese and 76 cheeses. Food samples were analyzed for FA profile, including conjugated linoleic acid (CLA). FA intake, g per serving was calculated. Fat, grams per 100 g of product and serving size data from USDA approved food labels and the USDA National Nutrient Database was used to calculate the FA intakes. Data was statistically analyzed as a two way factorial design. To simplify the presentation FA were grouped into saturated FA (SFA), *trans* FA, monounsaturated FA (MUFA), CLA, polyunsaturated FA (PUFA), n-6 FA, and n-3 FA. The proportion of SFA, in dairy foods (n=180) ranged from 63.9-66.3% of total FA, with fluid milk being lower than other dairy products. The proportions of total *trans* FA (C16:1 and C18:1) ranged from 4.52-5.31% of total FA. Cheese samples had lower total *trans* FA compared to other foods. The proportions of MUFA ranged from 24.7-26.1% of total FA, with fluid milk being higher than other dairy foods. The mean CLA content was 0.58 ± 0.05 % of total FA and did not differ among tested dairy foods. The proportions of PUFA, n-6 and n-3 FA ranged from 4.45-4.93, 3.19-3.80 and 0.51-0.64% of total FA in foods, respectively. The average intake of *trans* FA and MUFA was 0.4 and 0.5 g, 2.1 and 2.7g, from one serving of milk (240-ml) and cheese (28.35 g), respectively. Consuming one serving of whole milk or cheese provided 0.05 and 0.07 g of CLA, respectively. Assuming 69.25 g/d of fat intake in adult human with 5.2% as *trans* fat, our results suggest that one serving of whole milk contributes about 10% of total trans fat intake. Using the value 0.182 g of CLA intake/d in the United States from National Academy of Science report, consuming one serving of whole milk and cheese together will provide 66% of total daily CLA intake.

Key Words: Milk, Fatty Acid, Dairy

W72 High pressure processing prevents formation of overset eyes in Swiss cheese. N. Koca*[1,2], N. A. Kocaoglu-Vurma[2], V. M. Balasubramaniam[2], and W. J. Harper[2], [1]*Ege University*, *Bornova, Izmir, Turkey*, [2]*The Ohio State University*, *Columbus*.

Formation of overset eyes is a common problem encountered by Swiss cheese manufactures when lower than traditional cook temperatures (< 48°C) are used to produce Kosher whey. High pressure processing (HPP) can reduce the oversetting by eliminating nucleation sites and changing textural properties, provided that the starter cultures necessary for formation of characteristic eyes are not negatively affected by HPP. The objective of this study was to explore the effect of HPP on culture viability, eye formation, and textural characteristics of Swiss cheese. Swiss cheese was produced using 200 L pilot scale vats. The cheese blocks were divided into pieces (6x6x5 cm), brined, and vacuum packaged. Sample temperature was adjusted before pressure treatment to reach to 25±2°C during processing. Cheese samples were pressure treated at 50, 100, 200, 300, 400, 500 and 600 MPa over various pressure holding times (up to 15 min). Two sets of cheese samples held at refrigeration and room temperatures were used as controls. *Lactobacillus* spp., *Streptococcus thermophilus*, and *Propionibacterium* spp. were enumerated immediately after HPP and at the end of warm room ripening. Cheese samples were evaluated for eye formation at the end of warm room ripening. The texture profile and the pH of the samples were also determined. All pressure treatments with holding time of 5 min prevented the formation of overset eyes, 15 min treatments resulted in complete elimination of eye formation. The cheeses pressurized at 400 MPa for 5 min had excellent eye characteristics. Sample cohesiveness values increased until 400 MPa for the 5 min application whereas springiness values decreased until 300 MPa. Pressures above 300 MPa reduced the viable counts of *S. thermophilus* and *Lactobacillus* spp. whereas the propionibacteria counts remained unaffected. High pressure application has the potential to reduce overset eyes, and provides valuable information in understanding the relationship between texture of the cheese and oversetting.

Key Words: High Pressure Processing, Swiss Cheese, Eye Formation

W73 Effect of UHT and HTST processing on sweetness perception in sucrose–sweetened milk. J. M. Morton[1], S. J. Gualco*[2], P. Durongwong[2], J. Estrade[1], S. Vink[1], and P. S. Tong[1], [1]*Dairy Products Technology Center*, *San Luis Obispo, CA*, [2]*California Polytechnic State University*, *San Luis Obispo*.

Sensory analyses of milk have found Ultra High Temperature (UHT) processing to have a significantly different effect on the sensory properties of milk compared to High Temperature Short Time (HTST) processing. UHT processing of milk increases cooked and sulfur aromas and flavors as well as viscosity, which may suppress sweetness perception in UHT milks. We hypothesize that changes in these sensory modalities lead to a decrease in perceived sweetness, which would have significant ramifications for sucrose-sweetened flavored milks. Low fat (1% fat) milk was heat treated via either HTST (72.5°C for 15 seconds) pasteurization or indirect heat UHT (138.9°C for 3 seconds) process. Sucrose was added post-processing at levels of 1, 3, 5, 7, 9, and 11 percent by mass to produce 12 matched treatments plus 2 matched controls. Nine judges trained in descriptive analysis of sweetened milk evaluated the milks for appearance, aroma, taste, flavor, texture, and aftertaste. Judges individually evaluated each sample five times following a balanced block test design with a randomized, sequential monadic serving order. Although UHT and HTST milks differed significantly in aroma, flavor, and aftertaste ($p < 0.05$), ANOVA did not indicate a significant difference in sweetness intensity between matched UHT and HTST milks. However, Principle Components Analysis (PCA) of the milks revealed strong positive relationships between sucrose concentration and overall flavor, overall aftertaste, artificial sweetness, and sweetness intensity, with UHT milks showing a stronger relationship to these attributes than HTST milks. UHT milks were more strongly correlated with overall aroma, cooked aroma, opacity, viscosity, yellow color, and milky aftertaste than their HTST counterparts. These results suggest that sucrose-sweetened milks may be either UHT processed or HTST pasteurized without making adjustments to sucrose levels for equal sweetness intensity. Perceived sweetness appears to be more important for overall flavor and aftertaste in UHT processed milks.

Key Words: Sensory, Milk, Descriptive Analysis

W74 Gelation of β-lactoglobulin at low pH: Concentration effects. P. Mudgal*, C. R. Daubert, and E. A. Foegeding, *North Carolina State University*, *Raleigh*.

A modification procedure for whey proteins was patented by the Food Rheology laboratory at NC State University. This procedure imparts cold thickening functionality to whey proteins. Understanding the effect of protein concentration on thermal gelation and final functionality of the modified whey ingredient at low pH is the objective of the current study. Protein solutions of varying concentrations (c = 2-9 % w/w) were made from BioPure® β-lactoglobulin. Solutions were then pH adjusted to 3.35 with 6N HCl, followed by 3 hours of heating at 85°C. Following overnight incubation, specific viscosities of these solutions were determined at 25°C using a Cannon-Fenske capillary viscometer. From the results, intrinsic viscosity of heated β-lactoglobulin solutions was approximated to be 5 ml/g. The specific viscosity data was used to identify a critical concentration, reflecting a coil overlap concentration for biopolymer solutions. This concentration likely indicates the beginning of secondary interactions arising from the thermal treatment. To investigate the concentration effects on final functionality of a modified β-lactoglobulin ingredient, powders were prepared using two concentrations above (7, 9 % w/w) and two below (3, 5 % w/w) the critical concentration (6.9 % w/w). All powders were reconstituted in water at 10 % wt/wt and hydrated at 5°C for 24 hours. Shear rate sweeps were performed at 25°C to evaluate the thickening functionality. Significant differences were observed in apparent viscosities of solutions above and below critical concentration. Apparent viscosity at shear rate (˜10 s^{-1}) were found to be 3.28, 4.04, 31.9 and 3950 mPa-s for powders made from 3, 5, 7, and 9 % concentrations respectively. These results clearly show that preliminary protein concentration has significant effect on final ingredient functionality. Understanding these effects may be crucial to development of ingredients with improved functionality and provide insight into bio-molecular interactions during the gelation process of whey proteins at pH 3.35.

Key Words: Beta-Lactoglobulin, Gelation, Concentration

W75 Development of the hazard analysis and critical control points (haccp) in a milk pasteurizing plant. J. Aranda*, D. N. Garza, R. González, and L. A. Villarreal, *Universidad Autónoma de Nuevo León*, *San Nicolás de los Garza, México*.

The analysis of hazard and critical control points (HACCP) is a system dedicated to guarantee the harmlessness of the foods. The present work was carried out, in a milk pasteurizing plant with the purpose of evaluating the pre-requirements that should exist for the implementation of the HACCP. This evaluation was divided in three stages, in the first one it was carried out a diagnosis of the plant. This stage was focused on: the knowledge of the policies of the company, the existence of process manuals, the analysis of the production data, and quality of the product (according to NOM-091-SSA1-1994 NOM-184-SSA1-2000). It was registered 1053 data corresponding to the milk delivery for one year by the suppliers of the municipalities of Apodaca, Zuazua, Ramones, Santa Rosa, Dr. González, Salinas, Agualeguas and Marín. N. L., Mexico. In the second stage it was carried out an evaluation of the degree of fulfillment of the good manufacturing practices (GMP) and of standard operating procedures (SOPs). In the third stage it was developed a model of the system of analysis of hazards and critical control points, following the methodology of the HACCP. According to the results it was found that: the density, the percentage of water and the freezing point presented bigger deviation in most of the cases, as much in non-pasteurized milk as in the finished product, according to the NOM's indicated before. Regarding the degree of fulfillment of the GMP, the plant registered a percentage of fulfillment of 65.26%. Using the decision tree to identify the critical control points (CCP), the pasteurization stage was identified as CCP1 (it eliminates the hazard) and the storage and the transport as CCP2 (it controls the hazard).

Key Words: HACCP, Dairy, Quality

W76 Temporal global transcriptome analysis of *Lactobacillus acidophilus* during growth in milk. M. A. Azcarate-Peril* and T. R. Klaenhammer, *North Carolina State University*, *Raleigh*.

Microarray hybridization experiments were employed to monitor gene expression of *Lactobacillus acidophilus* NCFM cells propagated in 11% skim milk (SM) during early, mid and late logarithmic phase, and stationary phase. Approximately 21% of 1,864 ORFs were differentially expressed at least in one time point. Genes differentially expressed in SM included several members of the proteolytic enzyme system. Expression of *prt*P (proteinase precursor) and *prt*M (maturase) increased over time as well as several peptidases and transport systems. Expression of Opp1 (oligopeptide transport system 1) was highest at 4h, while gene expression of Opp2 increased over time reaching its highest at 12h. These results suggest that Opp1 and Opp2 have different specificities. Expression of LBA1525HPK-LBA1525RR, a previously characterized two-component regulatory system involved in acid resistance (Azcarate-Peril *et al.*, AEM, 71:5794), increased during early log and early stationary phase of growth. These results correlated well with survival experiments previously conducted that indicated that a chromosomally interrupted HPK mutant was more sensitive to acid challenge during early logarithmic phase of growth. To investigate the relationship between milk, growth and probiotic properties, *L. acidophilus*, 15 derivative strains, with mutations in genes identified in the microarray analysis as important for growth in milk, were selected for further analysis. Acidification rates were measured and correlated with the initial cell concentration in order to determine if any of the inactivated genes were involved in acidification activity and, hence, growth in milk in *L. acidophilus*. Five mutant strains with mutations in the surface layer protein *cdp*A, mucin-binding protein, putative myosin cross-reactive antigen, and a nicotinic acid mononucleotide adenylyltransferase *nad*D showed significantly ($P < 0.1$) different *tm* values than the parent control.

Key Words: Lactobacillus, Gene Expression

W77 Validation of Petrifilm plates for enumeration of total bacteria, psychotropic bacteria, and coliforms in goat milk. S. S. Chen[1,2], J. S. Van Kessel[3], B. Bah[1], F. Z. Ren[2], and S. S. Zeng*[1], [1]*Langston University*, *Langston, OK*, [2]*China Agricultural University*, *Beijing, China*, [3]*USDA-ARS*, *Beltsville, MD*.

Petrifilm™ Aerobic Count (AC) and Coliform Count (CC) plates were validated against standard methods for enumeration of coliforms, total bacteria, and psychrotrophic bacteria in raw (n = 39) and pasteurized goat milk (n = 17) samples. All microbiological data were transformed into log form and statistically analyzed using paired comparison t-test of SAS. There were no significant differences ($P < 0.01$) between Petrifilm™ CC and the standard Violet Red Bile Agar Petri dish method. Petrifilm™ AC was as accurate ($P > 0.05$) as the standard Petri dish methods for both total bacteria and psychrotrophic bacteria when the total bacteria count was less than $1x10^6$ CFU/ml. Correlations between Petrifilm™ plates and the standard Petri dish agar methods were high (r = 0.992, 0.997, and 0.974 for coliform, total bacteria, and psychrotrophic bacteria, respectively). In conclusion, Petrifilm™ AC and CC plates can be used as alternatives to standard methods for enumeration of total bacteria, psychrotrophic bacteria, and of coliforms, respectively. Advantages of Petrifilm™ plates include rapidity, ease of performance, labor saving, and no need for agar preparation or autoclaving. This validation is of practical importance to goat milk producers and processors because of the limited numbers of goat milk samples available daily and the lack of advanced laboratory facilities on most goat farms and in most goat milk processing plants.

Key Words: Goat Milk, Petrifilm Plates, Bacteria Count

W78 Applying slide-cover-glass method for cultivating anaerobic rumen fungi and employing polymerase chain reaction technique for their molecular identification. M. H. Sekhavati, M. R. Nassiry, M. Danesh Mesgaran*, and H. Tavasoli, *Ferdowsi University of Mashhad*, *Mashhad, Iran*.

The objective of the present study was to introduce a simple method (slide-cover-glass) for cultivating anaerobic rumen fungi and their molecular identification using PCR method. Rumen fluid, from a rumen fistulated sheep (live weight of 45 Kg) fed a 50:50 concentration:hay ration, was clarified by centrifugation at 10000 × g for 30 min and used as a source of inoculum. Then, 10 µ l inoculum was added to 290 µ l rumen fluid-agar medium (RFM) which were obtained in medium 10, containing antibiotic. This mixture was placed on a sterile slide on a warming table, covering it with a sterile cover glass, sealing their edges with paraffin, then incubated at 39°C for 3 days. After observing

the colonies on slides using an inverted microscope, in attempt to isolate specific fungi, colonies were picked and transferred into broth medium. DNA was extracted from pure culture medium by Guanidine Thiocyanate-Silica Gel method. Primers NS1 (5′GTAGTCATAT-GCTTGTCTC-3′) and NS2 (5′GGCTGCTGGCACCAGACTTGC-3′) were used to amplify a fragment from SSU 18S rDNA. In a volume of 20µl PCR reactions contained: 50 ng of template DNA, 2 µl 10-X PCR buffer , 2.5 mM MgCl2, 200 µM each dNTPs, 10 pM of each primer, and 1 U Taq DNA polymerase. Thermal conditions for 35 cycles were 95 °C (40 sec), 45 °C (40 sec), and 72 °C (1 min) . PCR products were visualized by electrophoresis on 1.3% agarose gel stained with etithium bromide. Microscopic studies on slide-cover-glass shows some anaerobes with filamentous colonies like fungi and the 550-bp fragment of nuclear-small-subunit (SSU; 18S rDNA) confirmed it. Since, Hungate roll tube technique for culturing and counting some anaerobes with vegetative growth is problematic, even impossible; therefore, it seems that this culturing method allows the handling of anaerobic rumen fungi in a more convenient approach.

Key Words: Slide-Cover-Glass, Anaerobic Rumen Fungi, PCR

W79 Quantification of *Staphylococcus aureus* which harboring sea in milk by real-time PCR. Y. Li* and Y. Jiang, *Key Lab of Dairy Science, Ministry of Education, Northeast Agricultural University*, *Harbin,China*.

Abstract: The presence of *Staphylococcus aureus* in milk, especially which produce enterotoxin A, is of major concern in the dairy industry. Staphylococcal enterotoxin A (SEA) is among the most potent of the growing list of known enterotoxins produced by *Staphylococcus aureus*, and a doses of less than µg of enterotoxins in contaminated food, which is produced by more than 105 CFU/g, will produce symptoms after 1-6 h in sensitive persons (FDA reported). In this study, we developed two real-time PCR assays, using either fluorophore-labeled DNA probes or DNA-binding dye SYBR Green, to identify the *Staphylococcus aureus* ATCC 13565 which harboring SEA genes. The detection procedure was applied to sterile milk samples artificially contaminated by *Staphylococcus aureus* ATCC 13565. And the assays we developed enable us to detect 83 CFU/ml in sterile milk. Both of the assays can be accomplished within 8 hours. The work really can offer a very quick, reliable alternative to identify the *Staphylococcus aureus*. And it would be offer great help to the further detection of *Staphylococcus aureus* which harboring sea genes in raw milk.

Key Words: Quantification, *Staphylococcus aureus*, Milk

W80 Detection of viable *Listeria monocytogenes* in milk by Real time RT-PCR. B. Yan* and Y. Jiang, *National Research Center of Dairy Engineering and Technology*, *Harbin, Heilongjiang, China*.

Detection of pathogens, such as *Listeria monocytogenes*, in contaminated food by PCR can result in false-positive data due to the amplification of DNA from nonviable cells. In this paper, a new method based on real-time reverse transcription PCR (RT-PCR) amplification of mRNA for the specific detection of viable was developed. Listeriolysin O (hlyA) gene was used as amplification targets. Total RNA from *Listeria monocytogenes* was isolated, and was amplified by real-time RT-PCR with a previously reported Taqman probe and primers specific for hlyA genes. The results show that this assay was positive for the *Listeria monocytogenes* standard strains and negative for all other strains such as *Staphylococcus aureus*, *Salmonella* and *Escherichia coli*. In pure culture, the sensitivity of detection Listeria monocytogenes is ca. 3×102 CFU/ml after enrichment 1-h, ca. 30 CFU/ml after enrichment 3-hrs. The feasibility of real-time RT-PCR amplification for the detection of viable *Listeria monocytogenes* was validated in artificially contaminated milk. Following a 6-hrs enrichment incubation *Listeria monocytogenes* could be detected that was originally inoculated in milk with ca. 17 CFU/ml. These results support the availability of real-time RT-PCR amplification of mRNA as a sensitive method for the specific detection of viable *Listeria monocytogenes* and indicate that this method may prove effective in the detection of this pathogen in milk products and other ready-to-eat.

Key Words: *Listeria monocytogenes*, Viable, Artificially Contaminated Milk

W81 PCR detection by rapid obtaining *Salmonella* in raw milk with filtration method. L. Wei and J. Yu-jun*, *National Research Center of Dairy Engineering and Technology*, *Harbin, Heilongjiang, China*.

A rapid, simple and sensitive PCR assay was developed for the determination of *Salmonella* in raw milk. Although many assays based on PCR for detecting food borne pathogen have been established, most of those techniques require 8~12h preenrichment step and thus are time consuming. This assay used filtration method to direct obtain bacteria in milk. Upon addition of disodium EDTA to skim milk which had been artificially contaminated by *Salmonellae*, casein micelles was dispersed to micromicelles and filtrated through 0.45 µm filter membrane. The Salmonellae in milk could been obtained from the membrane. It was then proceed with PCR to detect the bacteria which has been rapidly obtained by filtration method. The PCR system had been optimised to provide the best resolution of these analytes. The assay can be completed in 6.5h and reach 1~10 cfu/ml detection limit. To compare with other PCR assays, this assay without 8~12h preenrichment step saved a lot of time. The assay could be used for detecting *Salmonella* in raw milk and deserved to be generalize and applied to routine detection for food borne pathogen in raw milk.

Key Words: *Salmonella*, PCR, Filtration

W82 Acoustical emissions generated by *Lactococcus lactis* ssp *lactis* C2. C. L. Hicks*[1], J. M. Stencel[2], and H. Song[2], [1]*University of Kentucky*, *Lexington*, [2]*Tribo Flow Separations*, *Lexington, KY*.

Lactococcus lactis ssp *lactis* C2 bacteria in M17 medium and M17 agar was monitored (at 32°C for11 h) using contact acoustic sensors (20 to 50 kHz and 50 to 200 kHz) attached to the sides of the growth vessels. Acoustical emissions detected as waveforms, where each wave was referred to as a 'Hit' were generated by the bacteria . Hit sensitivity was in the µsec range. Fast Fourier transform analysis was used to calculate average peak frequencies of the emissions. Initial analysis showed that Hit detection began within 5 min after the medium was inoculated with *L. lactis* ssp *lactis* C2. Hits per min in

the agar medium increased from time of inoculation until the 9th h (beginning of the stationary phase) and then decreased until the 11th h. When C2 was grown in M17 broth and infected with c2 phage multiple periodic cycles of 36 min could be observed which appeared to match the phage lysis cycles. The average peak frequencies data showed a shift in frequencies as the bacteria moved from the lag into the log phase (from inoculation to 150 min). Some peak frequencies shifted by as much as 5 kHz during this growth period while most peaks had shifts in their relative intensities that increased or decreased with time. When average peak frequency data from C2 and *E. coli* 15q were compared (from the first 60 min of growth) only three of the peak frequencies were in alignment, while all other peak frequencies appeared to result from different acoustical emitting activities. These data suggest that average peak frequencies for C2 and *E. coli* 15q were sufficiently different in frequency and intensity during the initial lag phase that specific strain identification might be possible. Thus, acoustic emissions from bacteria may be specific enough to acoustically fingerprint bacteria and result in a rapid assay method.

Key Words: Acoustic, Lactococcus, Assays

W83 Survey of lactic acid bacteria in Hispanic-style cheeses for antimicrobial activity. J. A. Renye*, G. A. Somkuti, and D. L. Van Hekken, *Eastern Regional Research Center, USDA-ARS*, *Wyndmoor, PA*.

Lactic acid bacteria isolated from Hispanic-style cheeses were screened for antimicrobial activity against dairy starter bacteria (*Lactococcus lactis* and *Streptococcus thermophilus*) and potential foodborne pathogens or spoilage organisms (*Listeri*a, *Escherichia, Staphylococcus*, *Shigella*, *Salmonella*, *Enterobacter* and *Pseudomonas*). The LAB species screened included *S. thermophilus* (8), *S. macedonicus* (7), *L. lactis* (4), *Leuconostoc mesenteroides* (13), *Lactobacillus plantarum* (8), *Enterococcus faecium* (14), and *Enterococcus faecalis* (11). The LAB isolates were grown overnight in M17 (streptococci) or MRS (lactobacilli and leuconostocs) medium and tested for antimicrobial activity by the agar-well diffusion method. One *S. thermophilus* isolate showed activity against both *S. thermophilus* and *L. lactis* target strains, while another inhibited *L. lactis* only. The *L. lactis* target strain was also inhibited by one *L. lactis* and one *E. faecium* isolate. All 8 *L. plantarum* isolates inhibited the growth of *P. fluorescens*. Four of the isolates were also inhibitory to *E. coli* and *S. epidermidis*, while 2 other isolates inhibited only *E. coli*. All 6 of *L. mesenteroides* strains showed activity against *P. fluorescens*. The 3 *E. faecium* isolates active against *Listeria monocytogenes* were further screened by PCR for genes encoding known bacteriocins. Two of the isolates were shown to have PCR products corresponding to enterocins A, P and L50B. The third *E. faecium* isolate did not test positive for any of the known enterocins (A, B, P, BC25, L50A, L50B and Q), suggesting the possibility of a novel antimicrobial peptide. None of the isolates screened showed activity against *S. sonnei*, *S. infantis* and *E. sakazakii*. Further biochemical characterization of the antimicrobial compounds produced by the LAB is in progress.

Key Words: Antimicrobial, Bacteriocin, Lactic Acid Bacteria

W84 Production of bacteriocins by staphylococcal strains isolated from Brazilian cheese. M. A. V. P. Brito[1] and G. A. Somkuti*[2], [1]*EMBPRAPA Dairy Cattle Research Center*, *Juiz de Fora, Brazil*, [2]*Eastern Regional Research Center, USDA-ARS*, *Wyndmoor, PA*.

A total of 285 staphylococcus isolates were recovered from *Minas frescal* cheese, a traditional Brazilian fresh cheese made with pasteurized milk, and screened for the production of antibacterial substances. The staphylococci were isolated from 50 lots of commercial cheese and cultured on mannitol salt agar. Isolates were evaluated for colony and cell characteristics, catalase production and further classified as coagulase-positive (169) or coagulase-negative (116) by the tube coagulase test. Bacteriocin activity of cell-free supernatants of overnight cultures was tested by the agar-well diffusion method with *Listeria monocytogenes* Scott, *L. ivanovii*, *Staphylococcus aureus* 305 and *Streptococcus agalactiae* 5778 as targets. Bacteriocin production was associated with 30 coagulase-positive staphylococci (10%), including activity against *L. monocytogenes* (24), *S. aureus* 305 (26), *L. ivanovii* (13) and *S. agalactiae* (3). Plasmid samples isolated from bacteriocin-producing isolates were checked with PCR techniques using primers specific to the staphylococcal bacteriocins aureocin A70 and A53, and staphylococcin BacR1. All 24 isolates with antilisterial activity yielded PCR products and positive Southern blots indicating the presence of the aureocin A70 structural gene but only 20 of the 24 isolates carried the 8-kb plasmid that is usually associated with aureocin production. The 5 additional isolates active against *S. aureus* 305 only and tested negative with BacR1 primers may be producers of novel bacteriocins. The results have shown that antilisterial cheese isolates of *S. aureus* produced plasmid borne aureocin A70 similar to strains often recovered from bovine milk. The presence of bacteriocin activity may increase the competitiveness of the producing strain and may also have a role in preventing contamination by *L. monocytogenes*.

Key Words: Bacteriocin, Staphylococcus, Cheese

W85 Inhibitory effect of *Lactobacillus* species on *Streptococcus mutans in vitro*. W. Y. Yang[1], A. R. Hostetler[1], C. S. Huh[2], and H. S. Kim*[1], [1]*Culture Systems, Inc.*, *Mishawaka, IN*, [2]*Korea yakult Co.*, *Yongin Si, Kyunggi Do, Korea*.

S. mutans has been recognized as an important etiological agent in human dental caries. It has been suggested that these cariogenic bacteria could be eliminated from dental plaque by application of *Lactobacillus* or bacteriocin-like inhibitory substances. Recent clinical and experimental observations showed that specific probiotic microorganisms may provide therapeutic benefits in human dental disease. However, few data exist on the ability of *Lactobacilli* to inhibit the growth of *S. mutans*. The purpose of this study was to isolate and characterize *Lactobacilli* that inhibit the growth of *S. mutans* and to test the possibility that probiotic *Lactobacillus* strains are able to reduce dental caries. Four *Lactobacillus* species, *Lactobacillus fermentum* CS6039, *Lactobacillus reuteri* CS6032, *Lactobacillus acidophilus* CS6051, *Lactobacillus fermentum* CS332, were isolated from volunteers classified as having good oral hygiene and breast feeding mothers. The inhibition of *S. mutans* treated with probiotics was monitored by agar plate assay, competition test, and a turbidity and inhibition method. Using the agar plate assay and competition test, the diameters of the clearance zones surrounding the inoculated bacteria (which indicated the presence of bacteriocin produced by probiotic cultures) were measured. All tested-lactic acid bacteria were able to

inhibit the growth of *S. mutans in vitro*, with *L. fermentum* CS6039 exhibiting the highest inhibition. The turbidity and inhibition method was also performed to confirm the results from agar plate assay and competition test. All of the probiotic cultures, except *L. reuteri* CS332, significantly inhibited growth of *S. mutans* ($P<0.05$). Based on these data, we suggest that lactic acid bacteria have a beneficial impact on inhibition of S. mutans and preventing dental caries.

Key Words: *Lactobacillus*, *Streptococcus Mutans*, Inhibition

W86 Lipid binding characterization of lactic acid bacteria in dairy products. D. Bachiero*, S. Uson III, and R. Jimenez-Flores, *California Polytechnic State University*, *San Luis Obispo*.

Probiotic bacteria are defined as a supplement that provides well being to the consumer when they are live and active. These microorganisms have gained more attention because of their known health benefits such as gastrointestinal health, enhancement of the immune system and their ability to inhibit pathogenic bacteria. However, there is still disagreement in defining their mechanisms of activity as well as methods of assessing them. An important limitation is the lack of knowledge regarding the nature in which these bacteria interact and bind in the gut as well as in the dairy system. Many studies have focused on the protein binding properties while the binding to lipids has been poorly studied. We focused on developing an assay that gives a quantitative measurement of lactic acid bacteria's (LAB) affinity to bind to various lipids found in dairy foods. LAB strains used in this study were genetically characterized, isolated and typed using pulse field electrophoresis. Cells were used in their exponential phase of growth for the experiments. An immunobloting technique was used as a quantitative measurement of bacteria's binding to various lipids from milk or buttermilk. Extracted lipids were separated on a TLC silica membrane, blotted on to PDF membranes and then exposed to biotinylated bacteria, to observe binding affinity. The bacteria/lipid interaction was measured using Avidin-HRP and Diaminobenzidine for a visual color reaction. We found two types of lipid binding: non-specific binding to triglycerides (non-polar lipids), in which the lipid concentration was the significant variable, and strain specific binding to phospholipids (polar lipids), where regardless of composition, each strain showed specific binding affinity. More importantly, these results show the specificity of binding as the direct result of the degree of processing of the dairy product. Those powders undergoing supercritical fluid extraction showed an increase in binding to phospholipids. These results will help in the design and formulation of dairy foods containing probiotic strains thus optimizing the bacteria's beneficial effects on health.

Key Words: Lactic Acid Bacteria, Binding, Lipids

Egg and Meat Science and Muscle Biology - Livestock and Poultry III

W87 Growth of muscular and adipose tissues of young heifers from different genetic groups. E. Rodrigues, M. D. B. Arrigoni, A. M. Jorge, P. S. A. Moreira, W. Bianchini, J. C. Hadlich, C. Andrighetto, C. L. Martins, D. D. Millen*, and R. D. L. Pacheco, *FMVZ/UNESP–Botucatu*, *São Paulo, Brazil*.

The objective of this study was to evaluate the growth of young heifers from different genetic groups (GG) in an intensive meat production system. It was used 42 animals of 4 different GG: 12 3/4 Canchim × 1/4 Nellore (3/4 CN), 12 1/2 Canchim × 1/2 Nellore (1/2 CN), 10 Crossbreed where the Simmental had predominance (SI) and 10 Three way cross – 1/4 Simmental × 1/4 Nellore × 1/2 Angus (TC). The Canchim breed is composed by 5/8 Charolais and 3/8 Nellore (Zebu breed). The experiment was conducted at the experimental feedlot of the Veterinary Medicine and Animal Science College, São Paulo State University, Botucatu campus (UNESP), Brazil. The animals received creep feeding supplementation and were weaned at 210 days of age with 247.4 ±16.48kg. It was analyzed the body weight characteristics, average daily gain (ADG), muscular and fat tissues growth. Real time ultrasound evaluation was used to measure rib eye area (REA, Longissimus dorsi muscle), back fat thickness (BFT) and P8 (Top rump, Biceps femoris) fat thickness. The animals were fed for 132 (±14) days in feedlot system with a high concentrate diet. ADG was measured every 28 days. The heifers were slaughtered when the final weight of 350 kg and 5mm of back fat thickness predicts were reached. TC heifers had smaller ($P<0.05$) final (TC=61.6, 3/4 CN=69.4, 1/2 CN=66.2, SI= 65.2) and adjusted at 100 kg/BW (TC=15.2, 3/4 CN=17.8, 1/2 CN=17.7, SI=18.9) rib eye area (cm^2) compared to the others GG. This group also had a greater ($P<0.05$) final body weight in kilos (TC=405, 3/4 CN=390, 1/2 CN=374, SI=350), better ADG ($P<0.01$) in kilos/day (TC=1.07, 3/4 CN=1.04, 1/2 CN=0.95, SI=0.94) and an intermediate days of feeding. There was not significant differences for initial REA, BFT and P8, but when the values were adjusted for fewer days of feeding (114 days), greater values ($P<0.01$) were found for TC and SI for P8 114 (TC=8.8, 3/4 CN=6.5, 1/2 CN=5.7, SI=8.4) and for SI for REA 114 (TC=55.7, 3/4 CN=55.3, 1/2 CN=52.7, SI=65.2). Thus, heifers TC performed better than other GG tested showing a grain adaptation as zebu percentage in GG composition got lower.

Key Words: Rib Eye Area, Back Fat Thickness, Ultrasound

W88 Evaluation of performance, tissue growth and meat tenderness of Nellore, Brangus and Canchim young bulls. R. B. Rodrigues, M. D. B. Arrigoni, E. Rodrigues, D. D. Millen, R. D. L. Pacheco*, H. N. Oliveira, C. C. Laurino, M. V. Fossa, L. M. N. Sarti, M. Parrili, S. A. Matsuhara, C. L. Martins, J. P. S. T. Bastos, and T. M. Mariani, *FMVZ/UNESP–Botucatu*, *São Paulo, Brazil*.

This study had the objective to compare three different genetic groups with different zebu percentage in their compositions: Nellore (N), Brangus – 5/8 Red Angus, 3/8 Nellore (BC) and Canchim – 5/8 Charolais, 3/8 Nellore (CC). It was used 87 animals (27 CC, 30 N and 30 BC) separated by genetic groups and randomly disposed. The weaning weight in kilos was 244.6, 243.6 and 295.0 for N, BC and CC respectively with 8 months old, which were supposed to be slaughtered with 15 months of age around 450 to 500kg in a commercial packing plant. The experiment was conducted at the experimental feedlot of the Veterinary Medicine and Animal Science College, São Paulo State University, Botucatu campus (UNESP), Brazil. The feeding period

was 158 days including 28 days of adaptation using a high concentrate diet. The dry matter intake (DMI) was measured every day, subtracting the waste from the amount fed. Average daily gain (ADG) and feed efficiency (FE) were obtained every 28 days, weighting the animals after 16 hours withheld the feed. Simultaneously, real time carcass ultrasound was used to measure Longissimus dorsi area (LEA) and subcutaneous fat thickness (SFT). For carcass evaluation, samples of LEA between twelfth and thirteenth ribs were collected from the left carcass to evaluate tenderness by shear force method (SF). DMI and FE did not differ (P>0.05) among the genetic groups tested. ADG in kilos/day differed (P<0.05) from CC to the other two groups (CC=1.46, BC=1.22 and N=1.14). LEA differed in cm^2 (P<0.05) for all treatments (CC=86.92, BC= 77.01 and N=71.14). SFT in millimeters showed difference (P<0.05) in all treatments (CC=3.91, BC=6.67 and N=5.15). According to SF in kilograms force the CC group presented significant difference (P<0.05) when compared to the other two groups (CC=3.98, BC=2.75 and N=2.74). The results indicated that CC had a better ADG, a faster and longer muscular growth than BC and N, but had the worst fat deposition and SF in this experiment; what may be explained for the major frame size of the animals used to compose this GG: the Charolais.

Key Words: Performance, Tissue Growth, Shear Force

W89 Efficacy of blood hemoglobin as an indicator of pork quality. A. N. Lepper*, H. N. Zerby, S. J. Moeller, K. M. Brueggemeier, and A. C. Naber, *The Ohio State University*, *Columbus*.

The objective of the study was to assess the efficacy of pre-harvest blood hemoglobin level as a predictor of pork quality in market weight swine. Market weight swine (n = 110) were harvested over three dates, following a 12 h rest in a commercial packing. Each harvest group consisted of proportional numbers of purebred Berkshire, Landrace and the reciprocal crossbred pigs. Blood hemoglobin (HB, Hemocue Hb 201) content was obtained from a sample collected 24 h prior to harvest via the anterior vena cava. Carcass backfat (BF), loin muscle area (LMA) and loin quality traits, including Minolta L* and a*, visual color (C), marbling (MARB), firmness (F), wetness (W), and pH were measured at 24 h post-harvest. Warner-Bratzler Shear (WBS) force assessment of the loin was completed on a chop aged for 7 d post-harvest. Data were analyzed using multi-trait analysis of variance for dependent carcass and pork quality measures. Fixed effects included breed combination and sex with a random harvest date effect. Residual correlations were estimated after accounting for model effects to determine associations among traits and simple correlations were estimated. After adjusting for breed, gender and harvest date effects BH was only associated (P < 0.05) with WBS (r = 0.23). Significant simple correlations were observed between HB and WBS (r = 0.22, P < 0.05) and pH (r = -0.28, P < 0.01) with the simple correlation between Minolta a* (r = 0.17, P < 0.06) approaching significance. The results indicate blood hemoglobin level, collected prior to harvest was not a good indicator of subsequent pork quality and would not be an effective tool for selection of live pigs as breeding animals to improve pork quality.

Key Words: Pork, Quality, Hemoglobin

W90 Evaluation of Haugh Units and yolk index as criteria to establish a low temperature storage limit for refrigerated shell eggs. D. Shin*[1], C. Narciso-Gaytan[1], M. Sartor[1], J. R. Regenstein[2], and M. X. Sánchez-Plata[1], [1]*Texas A&M University*, *College Station*, [2]*Cornell University*, *Ithaca, NY*.

More than 89.9 billion eggs are distributed yearly in the U.S., most of them as table eggs transported and stored under refrigerated conditions. The USDA recommends the storage of shell eggs at temperatures below 7.2°C (45°F) for food safety reasons. However, no lower temperature storage limit has been recommended. Recent industry reports indicate that storage of shell eggs at low temperatures -close to 0°C (32°F) - may be associated with quality deterioration effects such as "running whites" and "flaccid yolks". The goal of this study was to establish a low temperature storage limit for shell eggs based on the effect of low temperatures in conventional egg quality parameters including Haugh units, yolk index, albumen pH, yolk pH, vitelline membrane strength and cake density during prolonged storage. Fresh shell eggs, at least six per measurement for each of three replications, were stored under controlled refrigerated conditions at -1.1, 0.6, 2.2, 3.9, 5.6 and 7.2°C. Samples were taken at days 0, 2, 7, 14, 21 and 28. As expected, Haugh units decreased while albumen pH increased during storage at all temperatures. Significant Haugh unit differences (*P<0.05*) were observed in eggs after 14 days of storage. High storage temperatures caused a faster decline in Haugh units and yolk indexes when compared to the lower temperatures evaluated. However, after 28 days of storage differences were more evident, indicating higher quality preservation at temperatures below 2.2°C. Results indicate that a low temperature storage limit for shell eggs could be established between 0.6 and 2.2°C, especially if eggs were to be stored beyond two weeks under these conditions.

Key Words: Shell Eggs, Storage Temperature, Haugh Units

W91 The acceptance of brown-shelled eggs in a white-shelled egg market. N. P. Johnston*[1], L. K. Jefferies[1], B. Rodriguez[2], and D. E. Johnston[1], [1]*Brigham Young University*, *Provo, UT*, [2]*University of San Andres*, *La Paz, Bolivia*.

In recent years brown-shelled (BS) eggs have gradually entered the traditional white-shelled (WS) egg markets as a distinctive mode for packaging specialty eggs. A test was conducted at the Brigham Young University Sensory Laboratory to gain an understanding of how consumers view various attributes of the BS egg relative to the WS egg. The objectives were two fold, first to see how the consumer viewed properties of eggs by color and secondly the preference for brown color intensity. It was hypothesized that consumers would view BS eggs as more nutritious and more likely laid cage-free. It was further hypothesized that the darker colored BS eggs would be preferred to lighter ones. To test the hypothesis 52 panelists, all women who routinely purchased and consumed eggs, completed the evaluation. Of the panelists 46.2% consumed eggs daily and the remainder (53.8%) at least twice weekly. Frequency of egg purchases were weekly (9.6%), every two weeks (30.8%), and every three to four weeks (48%). 26.9% purchased specialty eggs (omega-3, organic or cage free). The panelists preferred WS eggs (90.4%), but as hypothesized BS eggs were viewed as likely more nutritious, flavorful,

fresher, higher in omega-3, and originating from a "farm flock" fed only organic ingredients. To test the preference for shade of BS eggs, a set six eggs with varying intensities of brown color was evaluated for appearance using a 9 point hedonic scale. The egg color intensities were measured using a Hunter Colorflex Spectrophotometer and the CIEL* system. The L* values ranged from 83.2 for WS eggs to 63.6 to 46.5 for the BS eggs. Contrary to our hypothesis there was a significant (P<0.05) preference for the lighter shades of brown (L* 63.6 and 53.3). Using the same scale panelists then compared BS to WS eggs. Again the two most lightly tinted BS eggs were found most comparable WS eggs in acceptability and better (P0<.05) than the darker colored BS eggs. In conclusion WS eggs were preferred over brown eggs but BS eggs were viewed as likely more nutritious, flavorful and fresher, and laid in a non-caged setting. Panelists preferred the appearance of the lightly tinted to darker BS eggs.

Key Words: Eggs, Color, Preference

W92 Nutritional composition of raw and fried enhanced or non-enhanced boneless chicken breast fillets. J. Kiker*[1], J. Howe[2], J. Holden[2], J. Boyce[1], A. Luna[1], C. Alvarado[1], D. Wester[1], and L. Thompson[1], [1]*Texas Tech University*, *Lubbock*, [2]*Beltsville Human Nutrition Research Center*, *Beltsville, MD*.

Research was conducted to determine the nutritional value of enhanced (E) and non-enhanced (NE), raw or battered and breaded (BB) fried boneless chicken breast fillets. Two trials were conducted in which 65 fillets per trial were E by injection with a 0.6% NaCl/0.4% Na triphosphate solution, and 65 fillets were not E. Injected fillets retained 9.2% solution based on the raw NE weights. After equilibration at 4°C for 48 h, half of the fillets from each treatment were BB using an automatic system, and then fried in a commercial fryer to an endpoint temperature of 74°C. ANOVA and means separation by LSMeans were conducted using GLM procedures in SAS. Percentage moisture was similar in raw fillets (75.8%, P > 0.05), while raw fillets were higher in moisture than cooked (E-fried 55.31% and NE-fried 52.15%, P < 0.0001). Cooking concentrated ash (E-fried 2.33% vs E-raw 1.89%, P < 0.0001; NE-fried 1.36% vs NE-raw 1.03%, P < 0.0001). Means for percentage protein were greater in NE than in E fillets (NE 21.7% vs E 19.0%, P < 0.03). Fat content was higher in E-fried (6.6%) compared to NE-fried fillets (4.7%, P < 0.0001). Phosphorus and sodium contents were significantly higher in E than NE-fillets (252 mg P/100 g, 586 mg Na/100 g vs. 200 mg P/100 g, 296 mg Na/100 g, respectively, P < 0.0001). A 100-g serving of NE-fried breast fillet would provide 43.4% of the daily reference value (DRV) for protein, 7.2% of the DRV for fat, 12.3% of the DRV for Na, and 20.0% of the reference daily intake (RDI) for P. In contrast, a 100-g serving of E-fried fillet would provide 38%, 10.2 % and 24.4% of the RDV for protein, fat and sodium, and 25.2% of the RDI for P. Enhancement increased moisture content in the cooked product by 6.1%, Na by 98.0%, and P by 26.0%.

Key Words: Chicken Breast Fillets, Composition, Enhancement

W93 Physical and chemical meat traits of young heifers from different genetic groups. E. Rodrigues, M. D. B. Arrigoni, A. M. Jorge, P. S. A. Moreira, W. Bianchini, D. D. Millen, R. D. L. Pacheco*, J. C. Hadlich, C. Andrighetto, and C. L. Martins, *FMVZ/UNESP–Botucatu*, *São Paulo, Brazil*.

The objective of this study was evaluate physical (marbling, tenderness, evaporation losses (EL), leak losses (LL) and total losses in the cooking (TLC)) and chemical (Humidity, crude protein and lipids) meat traits from different genetics groups of young heifers finished in feedlot. Marbling was determined by a subjective score (1–5). The animals were divided in four groups: 12 3/4 Canchim × 1/4 Nellore (3/4 CN), 12 1/2 Canchim × 1/2 Nellore (1/2 CN), 10 Crossbreed where the Simmental had predominance (SI) and 10 Three way cross – 1/4 Simmental × 1/4 Nellore × 1/2 Angus (TC). The Canchim breed is composed by 5/8 Charolais and 3/8 Nellore. The experiment was conducted at the experimental feedlot of the Veterinary Medicine and Animal Science College, São Paulo State University, Botucatu campus (UNESP), Brazil. The SI animals had higher (P<0.01) marbling scores (TC=2.3, 3/4 CN=2.0, 1/2 CN=2.0, SI=2.5) when compared to 3/4 CN and 1/2 CN. For tenderness, measured by shear force in kilograms force, there was no significant difference (P>0.05) after seven days of ageing with the meat samples at zero Celsius degree (TC=2.1, 3/4 CN=2.0, 1/2 CN=2.1, SI=1.8). Regarding EL, LL and TLC, in percentage, the 1/2 CN was better (P<0.05) than others groups tested (EL: TC=11.8, 3/4 CN=12.9, 1/2 CN=7.5, SI=12.6; LL: TC=2.7, 3/4 CN=3.2, 1/2 CN=1.5, SI=3.3; TLC: TC=14.6, 3/4 CN=16.1, 1/2 CN=9.0, SI=15.9). There were no significant differences (P>0.05) among the genetic groups evaluated regarding chemical analysis, observing the mean values of 74.86%, 22.15% and 1.39% for humidity, crude protein and lipids, respectively. The 1/2 CN presented less losses when compared to the other groups tested. The meat of young heifers finished in feedlot is ideal for the packing plants and consumers requirements in Brazil.

Key Words: Meat, Heifers, Feedlot

W94 Evaluation of meat tenderness of forage-finished cattle produced in Hawaii and factors affecting the tenderness. Y. S. Kim*, A. Ong, N. Bobbili, M. DuPonte, G. K. Fukumoto, and C. N. Lee, *University of Hawaii, Manoa*, *Honolulu*.

The objective of this study was to evaluate the current status of meat tenderness of forage-finished cattle produced in Hawaii and to determine what production factors affect the meat tenderness of forage-finished cattle. Two ribeye steak samples from the 12th rib were obtained from 191 forage-finished cattle sacrificed at two local slaughter houses on Hawaii Island. The steak samples were vacuum-packaged in Kapak pouches individually and aged for 2 wk at 4°C, then were stored at -20°C for later proximate analysis and measurement of shear force values of cooked steaks. The vacuum-packaged steak samples were thawed and cooked in a water bath at 70°C for 1 h, cooled to room temperature, and shear force values were measured from 1.3 cm core samples (6 per steak). Information on animal age, breed, carcass weight and sex was obtained during sample collection from the slaughter houses. Carcass weight ranged from 353 lb to 939 lb with a mean value of 601.8 lb. Intramuscular fat content ranged from 0.19% to 14.11% with a mean value of 4.49%. Shear force value ranged from 2.41 kg to 9.41 kg with a mean value of 5.21 kg. The shear force value of heifers (5.52±0.133 kg) was higher (p<0.05) than that of steers (4.96±0.148 kg). The shear force value of the age group between 24-36 months (4.97±0.137 kg) was lower (P<0.05) that that of the age group over 36 months (5.51±0.149 kg) or the age group below 24 months (5.23±0.321 kg). The shear force value of Hereford breed (n=19, 6.24±0.288 kg) was higher (P<0.05) than that of Angus (n=53, 5.19±0.172 kg), or Bos taurus crosses (n=76, 5.06±0.144 kg),

or other breeds (n=25, 4.91±0.251 kg). Correlation coefficient of shear force value with intramuscular fat was 0.025, indicating that the intramuscular fat is not a good indicator for meat tenderness of forage-finished beef. In conclusion, the results of this study indicate that meat tenderness of forage-finished cattle can be improved by proper selection of breed types and slaughter age.

Key Words: Forage-Finished Beef, Meat Tenderness

W95 The effect of dietary mushroom supplementation on egg characteristics and production attributes of leghorn hens. W. L. Willis, O. Isikhuemhen, A. Ely, D. Coverington, and C. King*, *North Carolina Agricultural and Technical State University*, *Greensboro*.

An experiment was conducted to assess the effect of Shitake (Lentinus edeods) mushroom powder on laying hens' performance and their egg characteristics. Sixteen 45 wk old Single Comb White Leghorn hens were divided into control and experimental treatment groups, replicated four times with two hens per replicate cage group. The experimental hens were fed a 20% mushroom powder supplemented ration and the control received a standard laying ration for a period of one month. Body weights and egg components were weighed for each treatment group. Total fat (as triglycerides) saturated fat (as fatty acids), transfat (as fatty acid) and the percentage saturated, monounsaturated, polyunsaturated and unknown fat were determined in eggs from treatments. The hens fed the supplemented mushroom powder diet had a higher average body weight loss, whereas, the control fed hen exhibited a higher average weight gain. Egg production was not significantly affected by diet. The feeding of 20% mushroom powder for this short duration, however, resulted in higher numerical values for egg whites and yolks (63.4 vs 62.7 and 36.2 vs 34.9), respectively. There was no significant ($p<0.05$) differences in saturated, monounsaturated, polyunsaturated and unknown fats between the two treatments. There was a trend for higher total fat, saturated (as fatty acids), and transfat in the mushroom supplemented hen eggs. Although the effects of dietary mushroom were not statistically significant with respect to fats and egg components, the results indicate that the use of an appropriate level of powder or extract in laying hen diets will change the parameters studied.

Key Words: Laying Hens, Mushroom, Saturated Fats

W96 On the tenderness of commercial boneless skinless broiler breast meat. Y. S. Lee*, C. M. Owens, and J. F. Meullenet, *University of Arkansas*, *Fayetteville*.

Although broiler processing practices have been fairly uniform across the industry, this is changing with the advent of specialty poultry processors. For example, immersion chilling has been the standard in industry but recent product introductions have included air chilling. Furthermore, although the enhancement of broiler breast meat is still common, non-enhanced and natural products have been introduced to satisfy market demand. The objective was to assess the level of tenderness of commercial products representing various industry practices. Six commercial boneless skinless breast meat products representing 4 brands were purchased at local supermarkets on four occasions over a period of 3 months. Two products followed an air chill process with no enhancement and carcass aging durations of ~ 24 hrs. Two of the water chilled products were enhanced with up to 15% of a solution containing chicken broth while the other two contained up to 3% of water retained. Aging duration for the water chilled products was thought to follow standard practices (4-6 hrs). All products were cooked covered to an internal temperature of 71°C in a convection oven. Tenderness was instrumentally measured by the Meullenet-Owens-Razor-Shear (MORS) using a TA-XT2 plus Texture Analyzer (Texture Technologies Corp., Scarsdale, NY). Cooking loss was also calculated. Both air chilled and one enhanced products were found to be most tender with MORS energy values corresponding to moderately tender meat. The two water-chilled but non-enhanced products corresponded in average to tenderness levels considered by consumers as slightly tough. Cooking loss of the two air chilled products (13.5-15.5%, respectively) were significantly lower than that of water chilled products (18.7-22.6%). Results showed an array of tenderness in commercial products with several products showing unacceptable tenderness. Sensory analysis and consumer acceptance of such products should be further assessed to determine if tenderness is a key driver of acceptance and if other characteristics are also important to liking.

Key Words: Tenderness, Broiler Breast Fillet, Chilling

W97 Feeding wet distillers grains plus solubles reduces shelf life and increases lipid oxidation during retail display of beef steaks. A. S. de Mello Junior*, B. E. Jenschke, C. R. Calkins, L. M. Grimes, J. M. Hodgen, and G. E. Erickson, *University of Nebraska*, *Lincoln*.

Strip loins (*M. Longissimus lumborum*), tenderloins (*M. Psoas major*) and top blades (*M. Infraspinatus*) from 46 carcasses of calf-fed, crossbred steers, were evaluated to test the effect of wet distillers grains plus solubles (**WDGS**) in beef cattle finishing diets on beef shelf-life (color and oxidation). The animals were randomized into three groups (0%, 15% or 30% WDGS – DM basis) and fed for 133 d. After grading, the short loins (IMPS # 174) and shoulder clods (IMPS # 114) were vacuum-packaged and shipped to the University of Nebraska Meat Laboratory. At 7 d postmortem, two steaks were cut from each strip loin, tenderloin and top blade. One steak was vacuum packaged and frozen (-16°C) immediately until a measurement of rancidity could be made (thiobarbituric acid reactive substances - TBA). The other steak was divided in two and the halves were wrapped in oxygen-permeable film and displayed for 3 and 7 days under simulated retail conditions (200-250 ft-candles light, 2°C). For the top blade and strip steaks, inclusion of 30% WDGS in the diet resulted in higher levels of oxidation (higher TBA values) in the lean after 7 d display (Top blade: 3.84^{a}, 5.04^{a}, 8.42^{b} for 0, 15 and 30% WDGS, respectively; $P < 0.001$. Strip steaks: 2.02^{a}, 3.77^{b}, 4.81^{b}, respectively; $P = 0.001$). There were no effects of WDGS on TBA values of tenderloin steaks ($P = 0.191$). After 3 d of retail display, steaks from cattle fed WDGS were numerically higher in TBA values than those from controls ($P = 0.075$ for top blades and 0.285 for strips). Top blade steaks from cattle fed 15 or 30% WDGS were darker (lower L^* values) than controls ($P < 0.028$). Top blade and tenderloin steaks from cattle fed 30% WDGS were significantly less red (lower a^* values) after 3 d of retail display ($P < 0.040$). These data indicate that feeding WDGS can compromise the shelf-life of steaks.

Key Words: Distillers Grains, Oxidation, Shelf-Life

W98 Mapping tenderness of the *M. Serratus ventralis*. L. M. Grimes* and C. R. Calkins, *University of Nebraska*, *Lincoln*.

To map the tenderness of beef *M. Serratus ventralis* (**SV**) muscles and evaluate the effectiveness of an enhancement strategy, beef chucks (n = 32), with the brisket and shoulder clod removed, were obtained from both sides of 8 USDA Choice and 8 USDA Select-grade beef carcasses two days post mortem. At 7 d postmortem, SV from one side were enhanced (**E**) with a 12.5% solution containing beef broth, salt, phosphate, and rosemary extract; and alternate sides were the control (**C**). Both C and E muscles were blade tenderized once as a whole muscle and cut into halves by a medial cut from dorsal to ventral, splitting the muscles into anterior and posterior halves. The halves were cut into steaks beginning at the dorsal edge, creating 4 to 8 steaks per half. All steaks of the E muscles were then blade tenderized again. Steaks were vacuum packaged and frozen. Every other steak from each SV was thawed overnight, cooked to an internal temperature of 70°C, cored, and sheared to obtain Warner-Bratzler shear force values (**WBS**). Cores were taken approximately every 2.54 cm from anterior to posterior throughout the steak. Regardless of grade, E samples produced significantly lower WBS values ($P < .001$) than C samples, decreasing WBS from 3.85 kg to 2.99 kg, a reduction of 22%. For USDA Select muscles, the most ventral steak was least tender ($P < .001$) and the most anterior location within the steak was the toughest. For USDA Choice samples, differences occurred from anterior to posterior, not dorsal to ventral ($P > 0.050$). All WBS means from the posterior side of Choice-grade SV muscles were numerically lower than the anterior side. Tenderness varies throughout the SV, and enhancement techniques can decrease WBS values. Across both grades, the least tender areas were those toward the anterior portion of the carcass. It appears that steaks could be cut from the posterior portion of the SV, as WBS values were in the acceptable range.

Key Words: Enhancement, Serratus Ventralis, Tenderness Mapping

W99 Correlations among carcass, meat and eating quality traits of finishing pigs. C. C. Tsai*[1], L. L. Lo[1], Y. C. Yang[1], R. S. Lin[2], T. H. Huang[3], J. Chen[1], L. C. Lee[1], P. Y. Lo[1], and H. J. Chien[1], [1]*Chinese Culture University*, *Taipei, Taiwan, ROC*, [2]*National ILan University*, *ILan,Taiwan ROC*, [3]*Taiwan Farm Industry Co., Ltd.*, *Pingtung, Taiwan, ROC*.

To establish the relationships among meat and eating quality, carcass and meat quality data were analyzed from 120 Duroc and Landrace (DL) crossbred pigs. Pigs were raised under commercial farm condition, and were transported to a commercial slaughter plant when reached the slaughter weight to collect the carcass performance data. Sections of Longissimus muscle (LM) from 9th to last rib were removed and transported to Chinese Culture University for meat quality evaluations. Carcass traits included the 10th rib backfat thickness, LM area (LMA), and the subjective scores of color, firmness, and marbling and the meat quality traits included were color, pH, shear force value, water holding capacity, chemical analysis and sensory evaluation. Backfat at the 10th rib was significantly correlated with drip loss (-0.37), water holding capacity (0.20), ash (0.21) and intramuscular fat content (0.50). The saleable lean weight was also correlated with water holding capacity (0.38) water (-0.42), and protein (0.364). Higher ultimate LM pH was associated with lower L value (-0.69), lower b value (-0.61), more water, less ash, less protein, and more intramuscular fat content ($P<0.05$). Marbling score was significantly associated with intramuscular fat content (0.53), and Hunter L value was correlated with color score (-0.28). Eating quality of juiciness, tenderness, and flavour scores were significantly correlated with ultimate pH, drip loss and water holding capacity. These results indicate that many factors might influence the eating quality of pork, and the correlation information may provide some knowledge to DL producers to improve their pork′s competitiveness.

Key Words: Carcass Performance, Meat Quality, Pigs

W100 A novel laser air puff and shape profile method for predicting tenderness of broiler breast meat. Y. S. Lee*, A Saha, C. M. Owens, and J. F. Meullenet, *University of Arkansas*, *Fayetteville*.

The laser air puff with shape profiles is a novel non-destructive method for predicting poultry meat tenderness from the raw state. It has the advantages of being non-contact and non-destructive and could be implemented in an on-line setting for classifying tough and tender meat at line speeds. The objective was to examine the potential application of this new system to assess poultry meat tenderness. Ninety broilers were deboned at either 1.75, 4 or 24 h postmortem (PM). The raw breast fillets were first scanned on a conveyor belt longitudinally by a laser distance sensor to obtain overall shape profiles and scanned again with a pressurized source of air (30 psi). The profile created with air was overlapped over the original profile to examine differences between the two profiles. Five parameters including height and length of each fillet were calculated and used to establish a model to predict tenderness. Instrumental and sensory analysis on cooked meats was conducted by the Meullenet-Owens-Razor-Shear (MORS) and seven trained panelists, respectively. Hardness and MORS Energy (MORSE) were modeled with the parameters extracted from the air puff system. Both models were highly significant ($P<0.0001$). Predicted values obtained from the models and observed values of individual fillets were subjected to Logistic regression to classify tender and tough meat. Tender fillets, in the predicted tender group, represented 75% and 81% based on hardness and MORSE, respectively. This represents a 20% improvement in the number of tender fillets after classification. Of the parameters used for the prediction, those measuring the amount of deformation due to the pressurized air were negatively correlated to tenderness, indicating that tender cooked meat sustains more deformation by pressurized air in its raw form. The results suggested that this new system could potentially be implemented as an on-line tool for sorting poultry breast fillets by tenderness levels.

Key Words: Air Puff, Broiler Breast Fillet, Tenderness

W101 Effect of morphological traits on intake characteristics of four grass species found in temperate biodiverse pasture systems. K. J. Soder* and M. A. Sanderson, *USDA-ARS, Pasture Systems & Watershed Mgmt. Research Unit*, *University Park, PA*.

Meadow fescue (MF, *Festuca elatior*), orchard grass (ORG, *Dactylis glomerata*, L.), quack grass (QG, *Elytrigia repens*), and reed canarygrass (RCG, *Phalaris arundinacea*) were sown in micro-sward boxes (79 cm × 47 cm × 11.5 cm) to investigate intake characteristics of four grass species. Once established, micro-swards were defoliated at 21-d intervals before being offered to non-pregnant, non-lactating Holstein cows in short-term tests. Boxes were weighed (± 0.1 g) before and after each test during which cows were allowed to take approximately 50 bites. Bite mass, DM content, sward surface height, tiller length and density, and leaf width, length and area data were collected. Mean DM bite mass was greatest for QG and RCG. Sward surface height was greatest for RCG and lowest for MF. Tiller length was greatest for ORG. Tiller density was greatest for MF and QG. Leaf width was greatest for ORG and RCG. Leaf length was greatest for ORG and lowest for QG and RCG. Leaf area was greatest for ORG and RCG. Sward surface height was the best predictor of DM bite mass, which may lead to greater apparancy of that species, thus the grazing animal may consume more material from that species, potentially subjecting that species to greater grazing selection than others in the same sward. However, implications on long-term survival of that species would be dependent on residual and sward re-growth characteristics after repeated defoliation.

Table 1.

	MF	ORG	QG	RCG	SE
Forage DM, %	21.9	21.4	28.0	26.5	3.05

W102 Estimation of forage intake and the presence of alkaloids in ruminal fluid and forage in steers grazing three different fescue types. R. L. Stewart, Jr*, G. Scaglia, J. P. Fontenot, W. S. Swecker, Jr., A. O. Abaye, J. H. Fike, and M. A. McCann, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

During two consecutive grazing seasons, DMI of steers grazing 'Kentucky-31' endophyte infected (E+), endophyte free (E-), and Q4508-AR542 non-ergot alkaloid-producing endophyte infected (Q) tall fescues (*Festuca arundinacea*) was estimated. Also, ergovaline (EV) and lysergic acid amide (LSA) were quantified in forage and ruminal fluid of steers grazing E+. Estimates of DMI did not differ ($P = 0.88$) when based on samples collected at 0800, 1700, or a composite of the two sampling times. Estimation of DMI using handplucked samples tended to be higher ($P = 0.06$) than from whole plant clipped samples. In 2004, estimated DMI of steers grazing E- was higher ($P < 0.001$) than Q and E+. In 2005, DMI of steers grazing E- was higher than Q and E+ in June ($P < 0.05$), and higher ($P < 0.05$) for steers grazing E- than Q in September. Lysergic acid amide, an analog of lysergic acid, and EV were present in E+ forage throughout the grazing season but were not detectable in E- and Q. Similarly, LSA appeared in ruminal fluid of steers grazing E+, but not in steers grazing E- and Q. Ergovaline was not detectable in ruminal fluid of steers grazing any of the three fescue types. The appearance of LSA in ruminal fluid through the season was similar to patterns of forage alkaloids (LSA and EV). Lower DMI may affect performance of steers grazing of E+. Low DMI of steers grazing Q suggests that the fescue variety Q4508 may not be the optimal variety for the incorporation of non-ergot alkaloid-producing endophyte strains. Additionally, the appearance of LSA in ruminal fluid of steers grazing E+ suggests that this ergot alkaloid may contribute to fescue toxicosis.

Key Words: Dry Matter Intake, Ergot Alkaloids, *Festuca arundinacea*

W103 Efficacy of EndoFighter™ for stocker cattle grazing endophyte-infected tall fescue pastures during late summer and fall. R. Norman[1], C. D. Lane[1], S. S. Block[2], W. W. Gill[1], A. E. Fisher[1], R. L. Mills[1], B. T. Campbell[1], F. N. Schrick[1], and J. C. Waller*[1], [1]*University of Tennessee, Knoxville*, [2]*ADM Animal Nutrition Research*, *Decatur, IL*.

An 84 d grazing trial was conducted (Aug 24–Nov 17) near Spring Hill, TN was to determine the efficacy of EndoFighter™, an ADM Alliance Nutrition, Inc. product designed to be fed to cattle grazing or fed endophyte-infected fescue. Jesup tall fescue pastures grazed in this trial were > 90% infested with *Neotyphodium coenophialum* (E+). Sixty weaned crossbred heifers (325 kg) were used in a randomized block design, blocked by weight, breed and previous treatment and randomly allotted to pastures with four animals per 1.2-ha paddocks and five replications per treatment. Treatments were ADM Alliance Nutrition, Inc mineral products: 1) Mastergain® mineral = Control; 2) EndoFighter™ mineral; 3) Prototype mineral. Heifers had free choice access to E+ grass, water and shade. Heifers were weighed on d 0, 1, 28, 56, 83, and 84. Initial and final weights were an average of the two beginning and ending weights, respectively. Data collected were initial, d 28, d 56, and final weights, and ADG (period 1 = d 1 to 28; period 2 = d 29 to 56; period 3 = d 57 to 84; total = d 1 to 84). Blood serum was collected at d 0, 28, 56, and 84 for prolactin analysis. Mineral consumption and animal grazing behavior were determined at 14-d intervals. Data were analyzed using the MIXED procedure of SAS. For all variables, contrasts were performed to compare Control to mineral supplements containing EndoFighter™ or Prototype. Total ADG (kg) and average daily mineral consumption (g) were: 0.61, 170*; 0.56, 122*; 0.50, 146; for Control, EndoFighter™ and Prototype, respectively (*$P < .09$). Serum prolactin was not different ($P > .05$) among treatments. According to National Weather Service data for

Franklin, TN, the maximum temperature reached at least 32.2° C on four days of the trial. Animal performance and prolactin levels were not significantly affected by the feeding of EndoFighter™ or Prototype in this trial. Mild weather conditions may have contributed to the lack of responses observed because heifers were not stressed by a combination of E+ and elevated ambient temperature.

Key Words: Beef Heifers, Tall Fescue, EndoFighter™

W104 Effect of cultivar and defoliation frequency on forage yield of *Chloris gayana* kunth in a moderate saline soil of the semiarid chaco of Argentina. M. V. Cornacchione*[1], H. E. Pérez[2], and A. E. Fumagalli[1,3], [1]*Instituto Nacional de Tecnología Agropecuaria*, *Santiago del Estero, Argentina*, [2]*Instituto Nacional de Tecnología Agropecuaria*, *Leales, Tucumán, Argentina*, [3]*Universidad Nacional de Santiago del Estero*, *Santiago del Estero, Argentina*.

The aim of the trial was to evaluate the effect of four cultivars and clipping frecuency on forage production, leaf:stem ratio, dead leaf proportion anf leaf protein content of *Chloris gayana* in a moderate saline soil (from 0 to 60 cm depth, the avg. ECe=9.6 dS/m and avg. pH=7.95). The experimental design was a completely randomized block in a split-plot arrangement with four replicates. The main plot had three tetraploid and one diploid cultivar; Callide, Boma, INTA-PEMAN (Experimental line; EL), and Topcut respectively. The grasses were sown in February of 2005. The split-plot consisted of two defoliation treatments (beginning November 2005 to May 2006): every seven weeks clipping (SWD) and the other at the end of the growing season (mature forage defoliation, MFD). Cultivar × defoliation interaction was not statistically significant for all variables, except for the % of dead leaf (P<0.01). Cultivars did not differ in forage yield, but forage production was greater in MFD (9850±1580 kg DM/ha; P<0.01) than SWD (6380±1048 kg DM/ha). Leaf:stem ratio was similar among cultivars, but did differ (P<0.01) in response to defoliation treatment (3.67±0.80 vs. 0.63±0.10 for SWD and MFD respectively). Under SWD Topcut and Callide had less % of dead leaf (P<0.01; 4.29±0.76 and 4.45±0.83 respectively) than Boma and EL (6.95±1.36 and 7.86±1.6), but in MFD % of dead leaf was significantly different among cultivars (P<0.01). Thus Callide, EL, and Boma had approximately 34, 64, and 75% more dead leaf than Topcut (on average 70.19±1.35, 86.05±1.12, 91.72±1.74 and 52.32±9.69). Leaf CP was significantly greater in SWD vs. MFD (P<0.01; 7.51±0.50 vs. 3.74±0.86 for SWD vs. MFD). EL, Boma and Topcut were similar in leaf CP (6.1±1.74, 6.05±2.18 and 5.50±2.64, respectively) and Callide was lower (4.83±2.24; P<0.01). In conclusion the seven weeks defoliation frequency decreased forage yield, however this frecuency consistently improved forage quality and reduced the proportion of dead leaf. Among cultivars Topcut was superior due to less proportion of dead leaf.

Key Words: *Chloris gayana*, Forage Production, Saline Soil

W105 Effect of herbage depletion on cattle grazing dynamics in wheat pastures. P. Gregorini*[1], M. Bowman[3], W. Coblentz[4], P. A. Beck[2], and S. A. Gunter[2], [1]*USDA–ARS*, *University Park, PA*, [2]*University of Arkansas SWREC*, *Hope*, [3]*University of Arkansas*, *Fayetteville*, [4]*USDA–ARS*, *Madison, WI.*

Two complementary experiments were conducted to assess grazing dynamics, intake rate, quality and ruminal degradation kinetics of herbage consumed under three herbage depletion levels. In the first experiment (behavioral), three rumen cannulated steers faced (15 min. grazing session) grazing scenarios simulating the levels of pasture depletion at three sward surface heights (ungrazed, 21 cm, CNTL; medium, 14 cm, MD; and high depletion level, 7 cm, HD). Grazing scenarios were sampled for green leaf and stem mass. Intake rate was determined by rumen evacuations. Grazing dynamic was determined by bite/min, bite depth, eating step/min, eating distance, potential area harvested while grazing, and bites and intake/feeding station. Also, quality of potential herbage eaten was estimated by herbage hand-plucking. In the second experiment (ruminal degradation kinetics) samples of herbage eaten by steers during the grazing sessions of the first experiment were incubated in situ in five rumen fistulated steers. The soluble, degradable and undegradable consumed herbage DM fractions were determined, as well as the DM disappearance rate, lag time and DM effective degradability. Green leaf and stem mass quadratically concave decreased (P = 0.01) from CNTL to HD. Treatment did not affect herbage DMI (675 g, SE = 45; P = 0.14) during the grazing sessions; but tended (P = 0.06) to decrease herbage DMI/ feeding station with increasing depletion level. Depletion led steers to a quadratically convex increase in eating steps/ min, eating distance and potential area harvested while grazing (P < 0.05). Depletion did not affect bite rate (33 bites/min SE = 6; P = 0.10); but led to shallower bites (P < 0.01). None of the herbage potentially consumed and ruminal degradation kinetics parameters were affected by treatment (P > 0.05). Under these experimental conditions, steers adapted grazing dynamics to sustain a constant nutrient intake. Behavioral adaptations would make nutrient intake rate less sensitive to certain herbage depletion levels.

Key Words: Grazing Behavior, Herbage and Nutrient Intake, Ruminal Degradation Kinetics

W106 Evaluation of ryegrass-based pastures grazed under the leaf stage concept in commercial dairy farms in the highlands of Costa Rica. J. M. Sánchez*[1,2], L. Villalobos[1,3], and A. Martínez[1,2], [1]*Universidad de Costa Rica*, *San José*, [2]*Centro de Investigación en Nutrición Animal*, *San José, Costa Rica*, [3]*Escuela de Zootecnia*, *San José, Costa Rica*.

Perennial ryegrass (Lolium perenne) grows year round in the highlands of Costa Rica (2700 to 3200 m in altitude) and does not require annual reseedings as it often does in temperate climates, due to the lack of frost in this tropical region. These characteristics as well as its high DM yield and good nutritional value makes this pasture a good alternative for dairy farmers in the area. Because of the irregular topography and the diversity of microclimates in the highlands of Costa Rica, dairy farmers have had to apply plant phenological concepts such as leaf stage, to determine when to graze this pasture. The aim of this study was to analyze the yield, utilization of the pasture on offer and botanical composition of ryegrass-based pastures, and nutritional value according to NRC (2001) proposed methodologies, in four farms located between 2700 and 3200 m in altitude in the Central Mountains of Costa Rica. Farms were selected at random and pastures were grazed at 32 to 45 d intervals. Measurements and samples were taken every two months during a year period. Results show cows in the four farms grazed ryegrass at a proper vegetative stage, since the average number of leaves found before defoliation was 2.85, and this grass is

considered a 3 leaf plant. Likewise, botanical composition analysis shows that 75.9% of the biomass was ryegrass, 13.9 other grasses, 6.1 clover, 1.3 weeds and 2.8 senescent material. Average DM yield was 18 t/ha/year, which is similar to those obtained in temperate climates under ideal conditions of environment and management. Pastures in the four evaluated farms were established more than 15 years ago. On average, pasture contained 25.2% CP, 49.8% NDF, 25.6% ADF, 15.4% NFC, 3.3% Lignin and 1.53 Mcal/ kg NEL (3X), all on DM basis. Agronomic and nutritional data shows the grazing system based on the leaf stage concept is a good tool for managing ryegrass-based pastures in areas where topographic and climate conditions are diverse.

Table 1.

Farm Nº	Nº of leaves at grazing	Regrowth period, d	DM yield, kg/ha/cut	% of grass on offer utilized	CP DM%	NL_L (3X) Mcal/kg DM

W107 Supplementation of digestible fiber and glucomannan to tall fescue pastures: Dry matter intake and fecal alkaloid concentration. R. L. Mills*[1,2], C. J. Richards[2], and J. C. Waller[1], [1]*The University of Tennessee*, *Knoxville*, [2]*Oklahoma State University*, *Stillwater*.

An 84 d randomized block design utilizing 96 weaned beef calves (238.8 ± 20.1 kg) in each of two consecutive years was used to assess the efficacy of digestible fiber and glucomannan (MTB-100®, Alltech, Nicholasville, KY) supplementation. Groups of four test calves were randomly assigned to 24 endophyte-infected tall fescue (*Lolium arundinaceum* Schreb. S.J. Darbyshire) spring pastures (1.23 ± 0.06 ha) with additional grazer calves used in a put-and-take system. Pastures, blocked by previous productivity, were randomly assigned to one of five treatments: 1) no supplementation (CON); 2) supplemented with soybean hulls (SH) at 0.33% BW (DM basis; LO); 3) supplemented with SH at 0.66% BW (DM basis; HI); 4) LO plus 20 g/d MTB-100®; and 5) HI plus 20 g/d MTB-100®. Calves had free-choice access to water and a loose vitamin/mineral mix. Chromic oxide was dosed and fecal grab samples obtained (d 54 to d 59) to estimate fecal output and fecal alkaloid concentration determination. Total DMI was calculated using IVDMD and fecal output. Data were analyzed using the MIXED procedure in SAS with contrasts of main effects of SH level (LO vs. HI), MTB, SH level x MTB, and CON vs. supplemented (SUPP). No interaction between SH level and MTB was observed ($P > 0.10$). Supplementation increased forage DMI and total DMI ($P < 0.01$) by 3.0 and 4.3 kg/d above the control with HI SH tending to increase total DMI by 8.9% over the LO SH level ($P = 0.06$). Fecal ergot alkaloid concentration decreased ($P < 0.01$) 31.3% with supplementation and was not affected by MTB ($P > 0.05$). Increasing from LO to HI SH tended to decrease fecal alkaloid concentration 11.2% ($P = 0.08$). These results indicate that digestible fiber supplementation can increase total intake and reduce fecal alkaloid concentration of calves grazing endophyte infected tall fescue pastures, but addition of glucomannan had no influence.

Key Words: Tall Fescue, Soybean Hulls, Glucomannan

W108 Evaluation of endomycorrhizal colonization in three species of crassulacean acid metabolism in northern part of Mexico. J. R. Martinez*[1], M. A. Peña[2], R. E. Vazquez[1], E. Gutierrez[1], E. Olivares[1], J. A. Vidales[1], and R. D. Valdez[3], [1]*Facultad de Agronomia, UANL*, *Monterrey, Mexico*, [2]*INIFAP*, *General Teran, Mexico*, [3]*CRUCeN, Universidad de Chapingo*, *Zacatecas, Mexico*.

An experiment was conducted (from April to October of 2006) to evaluate the mycorrhizal colonization in the radical volume of agave (Agave americana), spineless prickly pear (Opuntia sp.), and native prickly pear (Opuntia lindheimeri). This project was carry out because these plants have been less studied than C3 species as enhancers of degraded areas, as well as their forage value in semidesert zones. Mycorrhizal colonization can help to survive this species when they are transplanted into eroded soil by improving water and nutrient transport. This work was analyzed using a 3×2 factorial arrangement of treatments including three species: agave, spineless prickly pear and native prickly pear, inoculated with 100 spores and not inoculated, using three pots by treatment. Fungus used for the inoculation was Glomus intraradices. Mycorrhizal colonization and count of spores were evaluated, and mycorrhizal colonization was transformed to Arcsen. Both variables were greater ($P<0.05$) for native prickly pear and agave than spineless prickly pear. Mycorrhizal colonization was 73.8, 71.9 and 60.6% for agave, native prickly pear and spineless prickly pear, respectively. Spore count was greater ($P<0.05$) for agave and native prickly pear than spineless prickly pear. Spore count were 10,000, 9,150 and 4,400 spores per 100 g of dry ground for agave, native prickly and spineless respectively. It was possible to colonize roots of agave and prickly pear by inoculating with spores of Glomus intraradices.

Key Words: Mycorrhiza, Prickly Pear, Agave

W109 Evaluation of EndoFighter™ in a tall fescue grazing system for beef cattle. A. E. Fisher*[1], S. S. Block[2], K. J. Daniels[2], M. A. Franklin[2], N. A. Pyatt[2], and J. C. Waller[1], [1]*University of Tennessee, Knoxville*, [2]*ADM Animal Nutrition Research*, *Decatur, IL*.

The objective of this project was to evaluate EndoFighter™ mineral fed to stocker cattle grazing endophyte-infected tall fescue (*Festuca arundinacea*) pasture during summer grazing conditions. EndoFighter™ mineral was supplied by ADM Alliance Nutrition, Inc. and is recommended for use when beef cattle are grazing endophyte-infected tall fescue. The study was conducted near Dandridge, TN from April through September 2006, using 125 beef steers (avg initial wt = 274 kg) in a 126-d grazing period. Three groups were placed at Location 1 and two groups at Location 2, which were less than one mile apart. At both locations, steers were allotted to one of two treatments: Control (n=53, ADM Alliance Nutrition, Inc. MasterGain® mineral CTC/IGR) and Treatment (n=67, MasterGain® with EndoFighter™ CTC/IGR).

Mineral mixtures were formulated for consumption of 0.11 kg/h/d. Cattle grazed tall fescue-dominated pasture and were supplemented with corn gluten feed pellets at 1.36 kg/h/d. Forage samples were collected for Ergovaline analysis. Individual animal weights were recorded on d 1, 63 and 126 and behaviors were recorded twice per week at 1300 for the duration of the trial. Recorded behaviors were grazing (shade or no shade), lying (shade or no shade) and at water. The maximum temperature reached at least 29.4° C on 72 days of the trial. Five steers were removed from experiment due to morbidity. All data were analyzed using the MIXED procedure of SAS with individual as the experimental unit for growth, hair coat and body condition. Differences were determined at $P < 0.05$. Treatment cattle had a higher average daily gain than Control cattle (0.80 vs. 0.69 kg/h/d, respectively, $P < 0.01$). Cattle behavior was affected by treatment with more Treatment cattle observed grazing than control (761 vs. 200 occurrences, respectively, $P < 0.01$) and more Control cattle located in shade than Treatment (1394 vs. 1413 occurrences, respectively, $P < 0.01$). Offering a mineral product containing EndoFighter™ resulted in better gains and more grazing behavior by cattle grazing tall fescue pasture during the summer.

Key Words: Beef Cattle, Tall Fescue, EndoFighter™

W110 Changes in chemical composition and vertical distribution of kura clover-reed canarygrass swards relative to days of regrowth. K. L. Kammes*, D. K. Combs, and K. A. Albrecht, *University of Wisconsin*, *Madison*.

Knowledge of the plant-animal interface is essential to better understand intake, ingestive behavior, and diet selection of grazing dairy cows. Four 0.75 ha pastures with a mixture of 45% kura clover (*Trifolium ambiguum* Bieb.) and 55% reed canarygrass (*Phalaris arundinacea* L.) were used in a randomized complete block design to evaluate changes in chemical composition and vertical distribution of swards in relation to days of regrowth across periods, cuts, species, and layers. Samples were taken from four separate plots at nine time points throughout the trial which consisted of three periods (June 5-19, July 5-19, and July 24-August 7) with three regrowth ages in each period. Days of regrowth at the start of each period were 17, 26, and 31, respectively, followed by two subsequent samplings with 7 days between each sampling within a period. Pastures were mechanically harvested once before period 1 and twice before periods 2 and 3. Herbage samples were cut at ground level and bundled together to maintain the vertical structure of the sward. Each sample was divided into either reed canarygrass (RCG) or kura clover (KC) and then cut into 10-cm layers starting from the base of the plant. The layers were analyzed for neutral detergent fiber (NDF) and crude protein (CP). The NDF concentration ranged from 23 to 35% and 56 to 67% of DM for KC and RCG, respectively, with the highest concentration in the lower layers that contain mainly petioles and stems. Concentration of CP ranged from 17 to 31% and 11 to 24% of DM for KC and RCG, respectively, being highest in the upper strata that primarily consist of leaves and leaf blades. When the sward was analyzed as a whole; there was a single linear relationship between NDF (slope = 0.44) and CP (slope = -0.25) and days of regrowth, regardless of period or cut. By knowing the chemical composition of the vertical distribution and the depth of grazing, it is possible to predict the chemical composition of herbage selected by ruminants.

Key Words: Pasture, Intake, Dairy

W111 Growth performance and immune function of fall-born beef calves weaned from endophyte infected tall fescue pastures on different dates in the dpring. J. D. Caldwell*[1], K. P. Coffey[1], W. K. Coblentz[1], R. K. Ogden[1], M. L. Looper[2], D. L. Kreider[1], J. A. Jennings[2], D. S. Hubbell, III[1], T. W. Hess[1], and C. F. Rosenkrans, Jr.[1], [1]*University of Arkansas*, *Fayetteville*, [2]*USDA-ARS*, *Marshfield, WI*.

Fall-born calves grazing *Neotyphodium coenophialum*-infected tall fescue [*Lolium arundinaceum* (Schreb.) Darbysh.] (E+) should benefit from early weaning because of reduced exposure to E+ toxins, but our previous research has not supported this hypothesis. Gelbvieh × Angus calves (n=238) were used in a 3-yr study to determine the optimal time to wean fall-born calves grazing E+ pastures. Cow-calf pairs were allocated randomly by weight and age to one of four weaning dates: 1) March 13 (177 d of age; MrW), 2) April 13 (204 d of age; ApW), 3) May 11 (236 d of age; MyW), and 4) June 8 (264 d of age; JuW). At weaning, calves were weighed, vaccinated, blood collected, and calves were moved to a 3.2-ha pasture adjacent to their dams. After 14 d, blood samples were collected a second time, and calves were weighed and moved directly to wheat (MrW and ApW) or bermudagrass (MyW and JuW) pastures. Calf BW did not differ ($P>0.21$) among treatments on the earlier weaning dates, but BW on the June weaning date, actual and 205-d adjusted weaning BW, ending BW (14 d following the June weaning date), and BW change between the March and June weaning dates increased linearly ($P<0.05$) across treatments. Response to bovine virus diarrhea and infectious bovine rhinotracheitis vaccination measured 14-d post-weaning increased ($P<0.05$) linearly, and that of bovine respiratory syncytial virus increased ($P<0.05$) linearly and quadratically across treatments. Total antioxidant potential at weaning and change during weaning increased ($P<0.05$) linearly across treatments. Predominantly linear trends were observed ($P<0.05$) across treatments for various serum minerals and red and white blood cell counts. Delaying the weaning of fall-born calves grazing E+ pastures until early June may be beneficial for calf growth and immune function.

Key Words: Calves, Fescue, Weaning Date

W112 Intensive short duration grazing of fescue pastures to extend the grazing season of winter wheat. W. A. Phillips*, B. K. Northup, and B. C. Venuto, *USDA-ARS Grazinglands Research Laboratory*, *El Reno, OK*.

Over 10 million ha of winter wheat (*Triticum aestivum* L.) are planted in the southern Great Plains (SGP) each year, and serves as the major forage resource for millions of stocker calves before they enter the feedlot for finishing. If more BW gain is produced during the stocker phase, then the amount of feed grains used during the finishing phase will be less. This experiment examined the feasibility of using a perennial cool-season grass to extend the period of grazing for winter wheat and produce more kg of BW/calf. Three, 1.7-ha 2-yr old tall fescue (*Festuca arundinarea* Var. Jessup ″Max-Q™) pastures were used for short periods of intensive grazing in the spring (S) and fall (F). The pastures were fertilized each year with 56 kg of N/ha (F and S) and 22 kg of P/ha (F only). Calves (n= 215; 280 ±32 kg BW) used were predominately British breeds, less than 12 months of age. A different set of calves were used in each grazing period (3 S and 3 F periods). Standing crop available for grazing at the start of the grazing period was used to determine the stocking rate. Data were analyzed using a mixed model to determine the impact of grazing period on

stocker performance with pasture serving as the experimental unit and year (n=3) was random. Pastures produced more (P < 0.01) forage in the S than in the F (4490 vs. 2230 kg DM/ha) and the stocking rate was greater (P < 0.01) in the S than in the F (2290 vs. 1450 kg BW/ha). Length of the grazing period and the number of grazing d/ha were not different (P > 0.10) between S (35 d and 259 d/ha) and F (39 d and 245 d/ha), but ADG was greater (P < 0.01) during the S as compared to the F (1.02 vs. 0.57 kg). As a result, BW gain/ha were greater (P < 0.01) during the S than in the F (264 vs. 140 kg/ha). Under intensive short-duration grazing management, fescue pastures can be used to extend the traditional SGP winter wheat grazing season and would result in greater BW gain/calf. Shifting land resources from wheat to fescue production did not decrease gross returns to the enterprise but did change the month of the year calves would be purchased and sold.

Key Words: Stocker Cattle, Wheat Pasture, Fescue

W113 Growth and reproductive performance of heifers grazing Jesup tall fescue varying in endophyte status. M. E. Drewnoski*, E. J. Oliphant, J. T. Green, jr, M. E. Hockett, and M. H. Poore, *North Carolina State University*, *Raleigh*.

The objective of this study was to investigate the effects of endophyte free (E-), endophyte-infected (E+) and novel endophyte-infected (EN) Jesup tall fescue on the ADG and reproductive performance of heifers. The trial was conducted over three consecutive years. In early December of each year, 48 Angus cross heifers (initial body wt 266 kg) were randomly assigned to treatment (trt) and strip-grazed on stockpiled E+, E- or EN fescue. In late February, heifers were removed from pastures and fed trt hay. In late March, heifers were synchronized using a controlled intravaginal drug-releasing device, (CIDR®) for 7d followed by injection with PGF2α. Heatmount detectors (Kmar®) and observation for behavioral estrus were used to detect estrus for three estrous cycles. Heifers were artificially inseminated 8 to12 hrs after the onset of standing estrus. In mid-April heifers moved back on to trt pasture and rotationally grazed until late June. At the end of the trial, heifers had been maintained on E+, E- or EN (pasture or hay) for a total of 152, 188 and 191 days in years 1, 2, and 3, respectively. Conception was determined by transrectal ultrasonography at approximately 30, 60 and 90 days after synchronization. When grazing stockpiled fescue, pasture ADG of heifers did not differ among the trt (P = 0.13). Winter gains were 0.50, 0.57 and 0.51 kg/d (SE ± 0.04) for E+, E- and EN, respectively. However, during the late spring, heifers on EN and E- had higher pasture ADG than the heifers on E+ (P < 0.01). Spring gains were 0.24, 0.75, and 0.71 kg/d (SE ± 0.03) for E+, E- and EN, respectively. Response to synchronization and conception to synchronization did not differ among trt (P = 0.21; P = 0.34). The number of services to conception did not differ among trt (P = 0.39) and was 2.24, 2.34 and 1.99 for E+, E- and EN, respectively. Pregnancy rate did not differ among trt (P = 0.63) and was 54, 65, and 65 % for E+, E- and EN, respectively

Key Words: Reproduction, Endophyte, Heifer

W114 Comparison of bloat potential between hard red and soft red winter wheat. M. S. Akins*[1], E. B. Kegley[1], K. P. Coffey[1], K. S. Lusby[1], W. K. Coblentz[2], R. K. Bacon[1], J. C. Moore[1], J. D. Caldwell[1], and J. V. Skinner Jr.[1], [1]*University of Arkansas*, *Fayetteville*, [2]*USDA-ARS*, *Marshfield, WI*.

Some aspects of wheat pasture bloat have been researched extensively, but little research has evaluated the effect of wheat type on bloat. Forty-eight Angus heifers (238 ± 12 kg BW) and 8 Gelbvieh by Angus ruminally cannulated heifers (515 ± 49 kg BW) grazed 1-ha pastures of either hard red (HR) or soft red (SR) winter wheat (*Triticum aestivum* L.) to evaluate the effect of wheat type on bloat potential. Cattle grazed from November 11 to 22 and from November 26 to December 7, 2006 in a crossover design. Bloat was scored at 1000 and 1600 daily. Rumen samples were taken the last 2 d of each period at 0600, 1200, and 1800, and then evaluated for pH, foam production/strength, and consistency. Forage availability was not different ($P > 0.05$) between HR and SR. Respective initial and final forage availabilities were 1385 and 1071 kg/ha for HR, and 1504 and 901 kg/ha for SR. Overall, the stocker calves bloated 2.1% of the observations with no difference between HR and SR ($P = 0.52$). Rumen fluid pH did not differ between HR and SR ($P = 0.89$) at any point in the day (overall mean = 5.95). Consistency of the rumen fluid differed ($P < 0.0001$) across wheat types. Fluid from heifers on SR flowed 7.4 cm and HR flowed 9.5 cm in a consistometer. There was also a type by time interaction ($P = 0.03$) with SR at 1200 and 1800 being more viscous than SR at 0600 and HR at all times. Foam production as determined by bubbling CO_2 gas through rumen fluid was greater ($P = 0.01$) for SR (9.1 cm) compared to HR (5.7 cm). Foam strength measured as a percentage of initial foam height was greater ($P = 0.01$) for SR (45%) than for HR (28.5%). Differences ($P = 0.001$) between sampling times occurred, with foam strength at 0600 (18%) being less than at 1200 (43%) and 1800 (48%). Therefore, SR had a higher bloat potential than HR based on rumen fluid measurements, but no differences were observed in the frequency of bloat in stocker cattle.

Key Words: Wheat Pasture Bloat, Hard Red, Soft Red

W115 The effect of initial spring grazing date and stocking rate on sward profile during the main grazing season. E. Kennedy*[1,2], M. O'Donovan[1], F. O'Mara[2], and L. Delaby[3], [1]*Teagasc*, *Dairy Production Research Centre, Moorepark, Fermoy, Co. Cork, Ireland*, [2]*School of Agriculture, Food Science and Veterinary Medicine*, *UCD, Belfield, Dublin, Ireland*, [3]*INRA*, *UMR Production du Lait St. Gilles, France*.

The objective of this study was to establish the effect of initial spring grazing date and stocking rate on sward profile of *Lolium perenne* during the main grazing season. Sixty-four spring calving dairy cows were randomly assigned to 4 grazing treatments. The treatments were comprised of 2 swards, early (E) and late (L) grazed. Two stocking rates (SR), high (H) and medium (M), were applied across each sward. The early grazed sward was created by grazing half the area once between 16 February and 4 April. The remaining area was ungrazed from the previous October (late grazed sward). The SR imposed were 5.5 cows/ha (EH), 4.5 cows/ha (EM), 6.4 cows/ha (LH) and 5.5 cows/ha (LM). The study was completed over 4×21–day rotations from 16 April to 3 July 2004. Measurements reported were taken during the 2 (R2) and 4 (R4) grazing rotations. Pre–grazing herbage mass > and <4cm was measured. Pre and post–grazing extended tiller heights (ETH) and extended sheath heights (ESH) were measured on 100 tillers in each treatment paddock. The morphological composition of herbage for each treatment was ascertained weekly by cutting a sample from ground level with a scissors. Tiller density was also calculated.

Data were analyzed using analysis of variance. Pre–grazing sward height, ETH, ESH, DM yield > and < 4cm were significantly higher for the LH and LM swards during R2. However, the leaf:stem ratio was higher for the early grazed swards. Post–grazing measurements were higher (P<0.001) for the late grazed sward during R2. The leaf % was higher on the early grazed swards (P<0.05) however leaf yield (P<0.05) was higher on the late grazed swards. Dead % and yield were lower on the early grazed sward during R2. There were no differences in morphological composition or pre and post grazing measurements during R4. These results suggest that swards should be grazed early in spring and stocked at a medium SR from April to July.

Key Words: Grazing Date, Stocking Rate, Sward Profile

W116 Comparing finishing beef cattle performance and forage characteristic of ryegrass (*Lolium perenne*), rye (*Secale cereale*) and oats (*Avena sativa*). A. C. Pereira*, E. J. Bungenstab, J. C. Lin, B. Gamble, S. P. Schmidt, C. Kerth, and R. B. Muntifering, *Auburn University*, *Auburn, AL*.

Ryegrass (*Lolium perenne*), rye (*Secale cereale*) and oats (*Avena sativa*) were compared as pasture sources for forage-finished beef. Replicate 1.42-ha paddocks (2 per forage) were established and stocked with three Angus × Continental crossbred steers (374 kg ± 5.54 initial BW) per paddock for an 84-day finishing phase. All steers had access to salt and minerals free choice. Grazing was initiated on Jan. 19, 2006, when average forage mass reached at least 1000 kg/ha. Forage mass and nutrient composition were determined by clipping 0.25-m^2 quadrats (n=8 per paddock) prior to the beginning of grazing and continued every two weeks during the trial. Stocking rates were adjusted following quadrat clipping by using put-and-take steers to maintain forages in the vegetative stage. Comparisons of animal performance ended when steers reached 530 kg. Statistical analyses were performed using the PROC GLM procedure in SAS. Daily gain per animal (1.81 kg/d) did not differ ($P > 0.10$) among treatments. rye compared with oats and ryegrass had more CP (18.9%, 17.5% and 17.6% respectively; $P < 0.05$), but ryegrass had less ADF (19.3%, 25.4% and 23.3%; $P < 0.05$) and NDF (37.7%, 46.7% and 44.5%; $P < 0.05$) compared with rye and oats. Total gain per ha was less for ryegrass compared with rye and oats (322 kg/ha, 394 kg/ha and 399 kg/ha; $P < 0.05$). Pasture with oats and rye increase beef production per hectare compared to ryegrass by increasing stocking rate without decreasing daily gain or diet quality.

Key Words: Small Grain, Finishing, Pasture

W117 Performance of stocker cattle grazing two sorghum × sudangrass hybrids under various stocking rates. K. C. McCuistion*[1], F. T. McCollum[2], L. W. Greene[3], B. W. Bean[2,3], and R. VanMeter[3], [1]*Texas A&M University*, *Kingsville*, [2]*Texas Cooperative Extension*, *Amarillo*, [3]*Texas Agricultural Experiment Station*, *Amarillo*.

Summer annual forages are a practical roughage source for stocker cattle operations on the Texas High Plains because of their high yielding potential and energy content. The objective of this study was to describe the relationship between weight gain, stocking rate (SR), and forage quantity and quality for two types of sorghum × sudangrass (SS) hybrids (*Sorghum bicolor* (L.) Moench) using regression analysis. Steer calves (231 ± 4 kg) were grazed for 84 d during the summers of 2004 and 2005. Twelve experimental pastures (6 per SS type) were planted to a brown midrib (BMR) or photoperiod sensitive (PS) SS. Each pasture was assigned a different SR ranging from 2.33 to 4.10 AU × ha^{-1} × 84 d^{-1}. Initial, final and 28 d incremental weights were taken and used to calculate ADG and gain/ha. Forage was sampled on weigh days to determine forage availability, in vitro true digestibility (IVTD), and crude protein (CP) levels over the grazing season. Forage availability was reduced as SR increased after 56 and 84 d of grazing ($P < 0.01$). Stocking rate did not affect IVTD ($P = 0.20$) or CP ($P = 0.43$). Average daily gains were not affected by SR during the first 28 and 56 d of grazing ($P > 0.31$); this implies that gains are less sensitive to SR because forage quantity and quality are uniformly higher earlier in the grazing season. Gain/ha increased linearly in response to SR during the first 28 ($R^2 = 0.60$) and 56 d ($R^2 = 0.80$) of grazing. After 84 d of grazing and a more complete utilization of forage resources, the response of ADG and gain/ha was curvilinear in nature. At light to moderate SR, ADG and gain/ha were higher for the BMR; whereas the PS maintained ADG and gain/ha at higher SR. Our results indicate that cattle grazing these forages were capable of gaining over 1 kg × $head^{-1}$ × d^{-1} and up to 420 kg/ha over an 84 d grazing season but response was dependent on SR.

Key Words: Brown Midrib, Sorghum × Sudangrass, Stocking Rate

W118 Nutritive value of marafalfa grass under tropical dry forest conditions. T. Clavero* and R. Razz, *Facultad de Agronomia. Universidad del Zulia*, *Maracaibo, Zulia, Venezuela*.

Marafalfa grass (*Pennisetum purpureum* × *Pennisetum glaucum*) is a high quality tropical grass which has potential as forage for ruminants but questions remain about quality response to defoliation management. A plot study undertaken on the tropical north coast of Venezuela, assessed the effect of defoliation interval on herbage quality of marafalfa grass. The study included three defoliation frequencies (3, 6 and 9 weeks). Treatments were replicated three times in a randomized block design. Measurements included total nitrogen (TN), *in vitro* dry matter digestibility (IVDMD), acid detegent fibre (ADF), neutral detergent fibre (NDF), lignin (L) and total non-structural carbohydrates (TNC). Data were subjected to analysis of variance, using general linear models procedures of SAS statistical package. Treatments means were constrasted using Tukey test. Nutritive quality of marafalfa grass declined from three to nine weeks of growth. At each interval TN content declined significantly ($P \leq 0.05$). ADF and L only increased significantly ($P \leq 0.05$) between six and nine weeks. The highest value of IVDMD (62.45%) was obtained on three weeks of growth and declined on 10.35 digestible units from 3 to 9 weeks. TNC concentrations increased linearly as defoliation interval increased. Values for TNC concentrations ranged from 13.5 to 20.1 %, for 3 and 9 weeks, respectively. This study showed that the quality of marafalfa grass becomes less favorable with advanced maturity, this could be due to the rapidly increase and accumulation of dead leaf tissue and the lignification of the cell walls. It is suggested that marafalfa grass be harvested at about six weeks of growth to optimize nutritive value.

Key Words: Marafalfa Grass, Nutritive Value, Defoliation

W119 Comparing wether kids on summer cultivated pasture and mesquite rangeland with and without maize grain supplement. S. Pagan-Riestra*[1,2], J. P. Muir[1], K. A. Littlefield[1,4], and S. M. Weiss[3], [1]*Texas Agricultural Experiment Station*, *Stephenville*, [2]*Texas A&M University*, *College Station*, [3]*University of the U.S. Virgin Islands Experiment Station*, *Kingshill, St. Croix*, [4]*Tarleton State University*, *Stephenville, TX*.

Cultivated pastures and supplements are needed to complement rangeland-based goat production in warmer regions of North America during the hot and dry months of June through September. To address this need, growing Spanish X Boer wether kids (average 25 kg) grazing cutlivated pasture (primarily annual legumes and *Amaranthus retroflexus*) were compared to kids on honey mesquite native rangeland (NR; *Prosopis glandulosa* var. *glandulosa*) with an understory dominated by little bluestem (*Schizachyrium scoparium*) during the summers of 2002 and 2003 in north-central Texas. Wethers within both pasture and rangeland were supplemented with maize meal at 0, 0.5, or 1.0% BW. Herbage biomass in the cultivated pasture peaked in July whereas biomass in the NR tended to peak in August. Kids supplemented with 0.5% BW maize on the rangeland had 61% greater average daily gains (ADG) than unsupplemented animals whereas those on cultivated pasture had to be supplemented at 1.0% BW maize before showing an increase in ADG (31%) compared to unsupplemented animals. Unsupplemented wether kids on rangeland gained only 30.5% the ADG of kids fed a balanced feedlot diet (159 g ADG) while kids on cultivated pasture gained 53.3% of those fed a balanced feedlot diet, indicating that neither forage-based system was able to provide the nutrition needed to achieve maximum gain potential. Improved pasture and maize meal supplement both have potential for increasing wether kid ADG compared to rangeland during dry hot summer months.

Key Words: Wether Kids, Improved Pastures, Corn Supplement

W120 Cactus pear cladodes as a source of forage for growing-finishing lambs in Central Mexico. G. Aranda-Osorio*, C. A. Flores-Valdez, and M. Cruz-Miranda, *Universidad Autonoma Chapingo*, *Chapingo, Mexico*.

The objective of this study was to evaluate the effect of cactus pear (nopal) cladodes in diets for growing-finishing lambs on dry matter intake (DMI), total and average daily gain (TLWG and ADG), feed conversion (FC) and profitability (P). Fifty four male lambs (Corriedale × Criollo) with an average initial liveweight of 20.2 kg (± 3.2 kg) were used. Triads of lambs were formed with similar liveweight and housed in a pen (experimental unit), which were randomly alloted to the following treatments: 1) T0% inclusion of Nopal (Control); 2) T15% Nopal, cactus pear at 15 % (DM basis) of the ration, and 3) T30% nopal, cactus pear at 30 % (DM basis) of the ration. The diets were formulated in order to fulfill the nutritional requirements for a growing-finishing lambs according to NRC (1985). The experiment was a completely randomized design with three treatments and six replicates. The cladodes were chopped (approximately 2.5 cm2 and mixed by hand with the diet in the feedbunk at each feeding. Lambs were fed twice a day, at 08:00 h and 16:00 h. The experiment lasted 71 days (adaptation: 14 days, experimental period: 56 days). The inclusion of 15 or 30 % cactus pear in dry matter basis represented 55 and 75 % as fed basis for T15% and T30%, respectively. Results showed that initial liveweight was similar (P>0.01) among treatments, as well as the ADG between T0% (34.54 kg) and T15% (33.95 kg), but T30% (30.71 kg) was lower (P<0.01). DMI was consistently similar (P>0.01) between T0% (0.928 kg) and T15% (0.993 kg) and higher (P<0.01) than T30% (0.615 kg). Average feed conversion was similar (P>0.01) between T0% (5.14) and T15% (5.09) but higher (P<0.01) than T30% (3.44). Lambs fed with high ratio of cactus pear (T30%) were more efficient in converting feed to live weight. The inclusion of cactus pear reduced feed cost by approximately 48 and 65 % for T15% and T30%, in relation to T0%. Thus, live weight gain cost was reduced by about 29.1 and 64.3 % in T15% and T30% in relation to T0%. The inclusion of cactus pear between 15 and 30% may represent an important alternative to feed growing-finishing lambs without affecting animal performance and, on the other hand, may reduce production costs.

Key Words: Cactus Pear, Forage, Lamb Perfomance

W121 Supplementation effects of Calliandra (Calliandra calothyrsus) on weight gains and efficacy of control of gastrointestinal nematodes in weanling goats. A. Acero*, E. Valencia, and A. A Rodríguez, *University of Puerto Rico, Mayaguez Campus*, *Mayaguez, Puerto Rico*.

Information on shrub and tree legumes for supplemental feeding and their effects on weanling goat weight gains or efficacy of control of gastrointestinal nematodes (GIN; Haemonchus contortus) are limited. Calliandra (Calliandra calothyrsus) is a tree legume with high protein concentration (CP; 22%) and condensed tannin (CT; 19 to 30%). Its high CP makes it an alternative for supplementing low quality grass diets of small ruminants and its high CT may reduce GIN infestation. An experiment was conducted to determine the effects of Calliandra on average daily gain (ADG) and efficacy against GIN on weanling Boer goats. Eight weanling goats (12.4 kg) were randomly assigned to two treatments; a base diet of guineagrass hay (GH; Panicum maximum Jacq.) and leaves and twigs of freshly cut Calliandra (FC) supplemented at 20% of expected dry matter (DM) intake based on 3% LW. After morning supplementation, goats grazed native pastures ad libitum. Goats were weighed bi-weekly, and throughout the trial, feces and blood (every 21 d) were taken from individual animals to determine fecal egg counts (FEC) and blood pack cell volume (PCV). Crude protein for grazed pastures, GH and FC were 5.4, 5.0, and 14%, respectively. Nuetral detergent fiber averaged 77, 72, and 65% for grazed pastures, GH and FC, respectively. FAMACHA© score were also taken on individual animals every 14 d. Data were analyzed using repeated measures analysis. Supplementation with FC did not have any effect on ADG, FAMACHA scores (3.4) and PCV (26%). Fecal egg counts (FEC), however, were significantly lower (p<0.05) in goats supplemented with FC than for GH. Adjusted means were 638.2 eggs/g and 982.1 eggs/g for FC and GH, respectively. This reduction in FEC with FC can reduce the frequent use of antihelmintic. Further studies will compare antihelmintic treatment with varying inclusion rates of FC on weanling goats.

Key Words: Calliandra, Gastrointestinal Nematodes, Boer Goats

W122 Luster measurement in mohair produced by Angora goats. C. J. Lupton*, B. S. Engdahl, F. A. Pfeiffer, and J. W. Walker, *Texas Agricultural Experiment Station*, *San Angelo*.

Luster in mohair is the shiny appearance of the fibers when they are illuminated. This important trait contributes to the different and unique appearance of mohair compared to other animal fibers of similar physical dimensions. Luster is assessed subjectively by breeders, a practice that has resulted in a high level of luster in most Angora goat fleeces. Goniophotometers (GON) are used to provide standard measurements of luster in fibers. A GON test is expensive ($600 per 25 fibers) and is not used by breeders. The objective of this experiment was to evaluate 3 methods for their ability to produce low-cost, accurate measurements of luster. The methods were subjective scoring using 3 experienced individuals and objective measurement using near-infrared reflectance spectroscopy (NIRS, Model 6500M, Foss North America, Eden Prairie, MN) and automatic image analysis (Optical Fibre Diameter Analyser 100 [OFDA], BSC Electronics, Ardross, W. Australia), Three people scored luster (0 = no luster, 5 = excellent luster) in 89 parted fleeces. The correlation (r) between luster scores of the 3 appraisers ranged from 0.54 to 0.64 indicating the scores were not in close agreement. NIRS spectra were measured on greasy and cleansed samples (630) representing a broad range of Angora goat fleeces. Other properties measured on the samples using the OFDA included mean fiber diameter (SD and CV), medullation and opacity. Spectrally and visually different samples (8) were selected from this population (luster range 9.2 to 13.6%) for GON analysis. Standard GON results were used to develop a NIRS calibration equation (SEC and r^2 were 0.9% and 0.7, respectively) and a multiple regression equation ($P < 0.02$ for entry) incorporating fiber diameter and opacity for which r^2 was 0.9 and the SE of predicted luster was 0.6%. Agreement between the NIRS predictions and estimates from the regression equation was not perfect ($r^2 = 0.6$, slope = 0.7). Based on this small (but highly selected) sample, luster in mohair appears to be estimated more precisely and accurately from fiber diameter and opacity data than from NIRS spectra.

Key Words: Angora Goat, Luster, Mohair

W123 Effects of feed restriction and subsequent realimentation on tissue and mohair fiber by growing Angora goats. R. Puchala*, A. Patra, A. L. Goetsch, G. Animut, and T. Sahlu, *E (Kika) de la Garza American Institute for Goat Research, Langston University*, *Langston, OK*.

Forty-eight Angora goat wethers (16.7 ± 0.43 kg initial BW and 6 mo of age) were used in a 24-wk experiment to evaluate effects of level of feed intake on current and subsequent tissue (non-fiber) and mohair fiber growth. In Phase 1, 12 wk in length, different amounts of dehydrated alfalfa pellets were fed to provide ME according to NRC requirements adequate for tissue and mohair fiber growth (g/d) of 0 and 0 (0L), 15 and 1.5 (15L), 30 and 3.0 (30L), 45 and 4.5 (45L), 60 and 6.0 (60L), and 75 and 7.5 (75L), respectively. Alfalfa pellets were consumed ad libitum in Phase 2. Digestibility of OM was similar among treatments in both phases. In both phases ME intake (MEI) increased linearly ($P < 0.05$) with increasing level of DMI in Phase 1 (Phase 1: 5.40, 5.24, 6.00, 7.15, 7.89, and 8.04 MJ/d; Phase 2: 10.93, 11.00, 12.02, 13.50, 13.59, and 16.32 MJ/d for 0L, 15L, 30L, 45L, 60L, and 75L, respectively). Energy expenditure in Phase 1 increased linearly ($P < 0.05$) with increasing level of DMI (3.67, 3.87, 3.91, 4.18, and 5.20 MJ/d for 0L, 15L, 30L, 45L, 60L, and 75L, respectively) and was similar among treatments in Phase 2 (6.45 ± 0.40 MJ/d). Tissue growth increased linearly ($P < 0.05$) with increasing DMI in Phase 1 (15.3, 30.9, 49.2, 58.9, 62.5, and 72.1 g/d) and was similar among treatments in Phase 2 (105.6, 108.3, 91.9, 81.9, 76.0, and 97.0 g/d for 0L, 15L, 30L, 45L, 60L, and 75L, respectively). Mohair fiber growth was similar among treatments in Phase 1 (6.6, 6.6, 6.0, 6.2, 7.8, and 7.0 g/d) and in Phase 2 (6.6, 6.8, 5.5, 6.1, 9.2, and 7.3 g/d for 0l, 15l, 30l, 45l, 60l, and 75l, respectively). mohair diameter increased linearly ($p < 0.05$) with increasing dmi in phase 1 (21.7, 21.8, 22.1, 23.4, 23.8, and 23.0μm) and in phase 2 (25.4, 25.5, 26.0, 27.1, 27.0, and 27.1μm for 0l, 15l, 30L, 45L, 60L, and 75L, respectively). In conclusion, growing Angora goats partition nutrients to maintain mohair fiber growth with limited MEI and decrease energy expenditure to lessen the ME requirement for maintenance, resulting in compensatory tissue growth upon realimentation.

Key Words: Angora Goats, Feed Restriction, Mohair

W124 Effects of selection for increased juniper consumption on body weight and mohair production of Angora goats. F. A. Pfeiffer*, E. S. Campbell, B. S. Engdahl, T. D. Lovett, C. J. Lupton, C. A. Taylor, D. F. Waldron, and J. W. Walker, *Texas Agricultural Experiment Station*, *San Angelo*.

Juniper infestation is undermining the productivity of rangelands in the Edwards plateau region of western Texas. Angora goats have demonstrated their ability to consume considerable quantities of low quality browse plants including juniper. A selection experiment for above- (high, H) and below-average (low, L) juniper consumption in Angora goats has been in progress for 4 yr. Juniper consumption was measured using fecal near-infrared reflectance spectroscopy. An objective of the experiment was to establish the effects of the selection protocol on BW, mohair production, and fiber characteristics. Mature females (age > 1.5 yr, 767 records) and kids (114 records) were weighed and shorn twice a year (February and August) having been maintained for most of the year in the same range environment. Yearling males (40 records) were removed from the range to participate in a central performance test in which weight gain was also measured. Raw fleeces were weighed and analyzed for clean yield, fiber diameter, staple length, medullation, and curvature (a measure of crimp). Clean mohair production efficiency ranged from 0.027 to 0.052 to 0.073 kg/kg BW for kids, mature females, and pen-fed yearling males, respectively, with no differences ($P > 0.05$) between H and L goats in any group. Mature H females produced slightly finer (1 micron, $P < 0.005$) mohair with correspondingly higher (1 deg/mm, $P < 0.001$) curvature than L goats. The opposite trends were present in the kids, those animals resulting from the most selection, and no difference ($P > 0.55$) was present between the fiber diameters of H and L male goats. There was a tendency ($P = 0.07$) for L male goats to have higher BW than H goats. For all other fiber traits, H did not differ ($P > 0.1$) from L goats. To date, selection for increased and decreased juniper consumption in free-ranging Angora goats has produced either very small or no differences in BW or fiber traits.

Key Words: Angora Goat, Mohair, Juniper

W125 Participant demographics of a web-based certification program for meat goat producers. R. C. Merkel*, T. A. Gipson, S. P. Hart, and T. Sahlu, *E (Kika) de la Garza American Institute for Goat Research, Langston University*, *Langston, OK*.

In 2006, a Langston University-led consortium of 11 universities and 5 meat goat producer groups unveiled an on-line training and certification program (http://www2.luresext.edu/training/qa.html). The program consists of 22 learning modules. Participants take pre- and post-tests to pass the 16 required and a minimum of 3 elective modules for certification. As of February, 2007, 256 participants from 9 countries (US – 245, Canada – 3, India – 2, Australia, Jamaica, Malaysia, Nigeria, Pakistan, Romania – 1 each) have registered for the program. Thirty-nine states are represented with the top 5 states representing 55% of total participants (OK – 59, MO – 24, TX – 20, TN and KS – 16 each). Sixty-five percent of respondents classified themselves as part-time farmers/ranchers, 19% full time, and 16% no response. Fifty-one percent classified farm size as less than 40 acres and only 16% > 160 acres. Average herd size for 54% of respondents was 49 or fewer animals (34% < 25 goats). Only 13% of respondents owned >100 goats. Males comprised 56% of participants and females 37%, with the remainder not responding. Sixty-three percent of respondents reported membership in the American Boer Goat Association; 16% American Meat Goat Association; 13% American Kiko Goat Association; 6% U.S. Boer Goat Association; and 4% International Kiko Goat Association. Demographic data suggest that an on-line certification program is an acceptable method to provide information to small holder meat goat producers.

Key Words: Goats, Certification, Internet

W126 Effectiveness of a web-based certification program for meat goat producers. S. P. Hart*, R. C. Merkel, T. A. Gipson, and T. Sahlu, *E (Kika) de la Garza American Institute for Goat Research, Langston University*, *Langston, OK*.

In 2006, a Langston University-led consortium of 11 universities and 5 meat goat producer groups unveiled an on-line training and certification program (http://www2.luresext.edu/training/qa.html). The program consists of 22 learning modules in which participants take pre- and post-tests (requiring a score of ≥85%) to pass the 16 required and a minimum of 3 elective modules for certification. As of February, 2007, 256 participants have registered for the program. Least square means were lower for pre- vs post-tests (68 vs 90% ± 1.53; $p<0.001$) with an average increase in score of 22 percentage points. Largest increases in pre- vs post-test scores were seen in the Reproduction (48 vs 89% ± 3.7) and Nutrition (54 vs 90% ± 3.0) modules with lowest increases in test scores seen in the Livestock Guardian Dogs (77 vs 91% ± 5.4), Herd Health Procedures and Prevention (73 vs 90% ± 4.6), and Marketing (75 vs 87% ± 2.7) modules. Knowledge transfer was evident through the increases in test scores. These data suggest that an on-line testing and knowledge dissemination program is acceptable for many goat producers as a means to increase knowledge of goat production practices.

Key Words: Goats, Certification, Internet

W127 Goat conferences in Arkansas. J. A. Pennington*, *University of Arkansas Cooperative Extension Service*, *Little Rock*.

Surveys were conducted of goat conferences in Arkansas to determine needs and characteristics of producers as the conferences have evolved from a single youth dairy goat conference, initiated in 1994, to ten goat conferences throughout the state in 2006. Average attendance in 2006 at the conferences was 92; attendance on Saturdays averaged 121 and attendance on weekdays averaged 63. Conference attendees were primarily interested in meat goats (68% meat goats, 14% dairy goats, and 18% combination of meat goats, dairy goats, and/or sheep). Additionally there were several county workshops. Surveys of goat producers at the conferences indicated that the topics most requested were 1) marketing of the goats, 2) controlling internal parasites, and 3) feeding and forages for goats. Other topics requested included diseases and their treatment, kidding management, predator control, breeding and genetics, fencing, and product preparation. Youth activities for fitting and showmanship were included in all Saturday programs which had a registration fee. Speakers at the conferences include state extension agents and specialists, local producers, usually a goat specialist from an adjoining state, and related industry personnel. In 2006, five no-fee conferences with the Natural Resources Conservation Service consisted of lecture topics in the a.m. and a farm visit in the p.m. to demonstrate forages, facilities, and fencing. Evaluations for conferences on Saturdays during the past four years ranged from 4.2 to 4.7 out of 5.

Key Words: Conference, Extension, Goat

W128 Estimation of meat goat carcass composition using regression analysis. K. E. Logan*, H. N. Zerby, S. J. Moeller, T. J. Fraley, and D. A. Mangione, *The Ohio State University*, *Columbus*.

Percentage Boer meat goats (N = 135) ranging in live weight from 15.5 to 45 kg (avg. = 29.5, std. dev. = 6.6 kg) were harvested to assess the impact of live and carcass measurements as predictors of carcass primal (P) and total muscle (TM) weights. Goats were obtained from two sources: auction market (N = 104) and a local exhibition (N = 31). Live weight (LW), carcass weight (CW), backfat thickness (BF), ribeye area (REA), weight of primal cuts (leg, loin, rack, and shoulder), and complete carcass dissection (weight of fat, bone, and muscle) were recorded. Data were analyzed as a complete set and within CW subclasses using stepwise regression ($P < 0.15$). Dependent variables were P and TM weights. Model R^2 for estimation of P from significant independent variables LW, REA and BF was 0.91 with a partial R^2 of 0.86 for LW. The R^2 for estimation of P from CW and BF was 0.97 with a partial R^2 of 0.97 and 0.002, respectively. Estimations of TM from a model including LW (partial $R^2 = 0.81$) and REA (partial $R^2 = 0.07$) or CW (partial $R^2 = 0.94$) and REA (partial $R^2 = 0.005$) were slightly reduced when compared with estimation of P. Subset analyses were conducted within the following CW intervals; < 20 (N = 11), 21 to 25 (N = 19), 26 to 30 (N = 49), 31 to 35 (N = 18), 36 to 40 (N = 11), 41 to 45 (N = 12) and ≥46 (N = 11). Model R^2 within subset for estimation of P from CW, REA and BF ranged from 0.46 to 0.80 and was lowest in the 26 to 30 kg weight range. Partial R^2 for REA were significant in the < 20 ($R^2 = 0.06$) and 26 to 30 ($R^2 = 0.05$) CW ranges only for the estimation of P. Backfat thickness contributed significant partial R^2 of 0.04, 0.25, and 0.06 in CW ranges 26 to 30, 31 to 35, and

36 to 40 kg, respectively for estimation of P. Model R^2 were reduced in all CW subclasses when estimating TM, regardless of significant independent effects in the model. Results indicate that CW and LW account for a large proportion of total variation in P and TM across the data set and within CW subclasses, and the incremental increase in R^2 is small when adding BF and/or REA to the prediction model.

Key Words: Composition, Dissection, Goat

W129 Effect of hydrodynamic pressure processing on chevon quality characteristics. K. R. Eega*[1], J. H. Lee[1], M. B. Solomon[2], T. D. Pringle[3], K. W. McMillin[4], and G. Kannan[1], [1]*Fort Valley State University*, *Fort Valley, GA*, [2]*USDA/ARS Food Technology and Safety*, *Beltsville, MD*, [3]*University of Georgia*, *Athens*, [4]*Louisiana State University*, *Baton Rouge*.

Hydrodynamic pressure processing (HDP) technology, which involves exposure of packaged meat to a supersonic shock wave under water, created by a small amount of explosive, has been shown to improve meat tenderness; however, its effect on chevon tenderness has not been studied. The objective of this experiment was to determine the effects of HDP on the quality characteristics of boneless chevon leg steaks. Eighteen male Spanish goats (8 mo of age) were slaughtered and the carcasses kept at 2°C for 24 h, fabricated, and the leg primal cuts sliced into 2.5 cm-thick steaks. The bone from each slice was removed and the steaks were vacuum packaged and frozen. The steaks were transported frozen to the Food Technology and Safety Lab at Beltsville, MD, where they were thawed overnight (4°C), and then repackaged for HDP processing. Steaks from the left leg of each carcass were subjected to HDP treatment and those from the right were kept as untreated controls (n = 18/treatment). Cooking loss, Warner-Bratzler shear force value, thiobarbituric acid reactive substances (TBARS), and color values were determined on the semimembranosus muscles of both treated and control steaks. Hydrodynamic pressure processed steaks had lower shear force values compared with control steaks ($P < 0.05$). Cooking loss tended to be higher ($P < 0.1$; SEM = 1.11) in treated steaks (31.9%) compared with control steaks (29.6%). The TBARS values were 1.2 and 1.1 mg melonaldehyde/kg sample, respectively, in treated and control steaks. The CIE L*, a*, and b* color values determined after a 40-min bloom period were not different between HDP-treated and control steaks. The results indicate that HDP processing can improve the tenderness of chevon without significantly affecting other meat quality characteristics.

Key Words: HDP Processing, Chevon, Tenderness

W130 Quality characteristics of jerky made from Hydrodynamic Pressure processed (HDP) chevon and beef. K. R. Eega*[1], J. H. Lee[1], M. B. Solomon[2], T. D. Pringle[3], K. W. McMillin[4], and G. Kannan[1], [1]*Fort Valley State University*, *Fort Valley, GA*, [2]*USDA/ARS Food Technology and Safety Laboratory*, *Beltsville, MD*, [3]*The University of Georgia*, *Athens*, [4]*Louisiana State University*, *Baton Rouge*.

Hydrodynamic pressure (HDP) processing has been reported to improve tenderness of beef and pork, but its effect on goat meat (chevon) has not been studied. This experiment was conducted to determine the effects of HDP processing on quality characteristics of chevon and beef jerky. Vacuum packaged frozen boneless chevon leg cuts (n = 32) and cuts from beef top rounds (n = 32) were thawed and either subjected to HDP processing or kept as untreated controls (n = 16/treatment/species). A commercial seasoning was used to produce jerky from Semimembranosus muscle strips ($10 \times 5 \times 0.5$ cm) obtained from each cut. The Commission Internationale de I'Eclairage (CIE) L*, a*, and b* color values of chevon jerky were higher in the HDP-processed group compared with the control group, and the average color values were higher ($P < 0.01$) in chevon compared with beef jerky. Dry matter and ash contents were higher in chevon compared with beef jerky ($P < 0.01$), while the fat content was not influenced by animal species. Tenderness scores from an eight-member trained panel were higher ($P < 0.01$) for beef (4.7 ± 0.11) compared with chevon jerky (3.9 ± 0.11), with jerky samples from HDP-processed beef receiving the highest tenderness ratings. Juiciness and flavor scores were also higher ($P < 0.01$) for beef jerky compared with chevon jerky. The TBARS values of vacuum-packaged chevon jerky increased with storage time (30, 60, or 90 d at 2°C), while the values did not change in beef jerky (species × storage time, $P < 0.05$). Yeasts and molds were not detected and the total plate counts were generally < 1.00 $\log_{10}$ CFU/g in jerky samples during the 90-d storage period. Results showed that HDP processing significantly improved the quality characteristics of jerky. Jerky made from beef had better organoleptic and storage properties than chevon jerky.

Key Words: Chevon, HDP Processing, Jerky

W131 Chemical composition and quality of chevon as influenced by a diet high in condensed tannins. M. Vanguru*, J. H. Lee, D. A. Moore, B. Kouakou, T. H. Terrill, and G. Kannan, *Fort Valley State University*, *Fort Valley, GA*.

Sericea lespedeza, a legume high in condensed tannins (CT), has been reported to decrease nematode infections in meat goats, although its effect on the quality of meat has not been studied. This study was conducted to determine the effects of a high CT-containing diet on goat meat (chevon) quality characteristics. Twenty Boer × Spanish goats (6 mo of age; BW = 19.2 ± 0.74 kg) were assigned to pens (5 goats/pen), and each pen was allotted to one of two dietary treatments of 75% hay and 25% supplement: sericea hay plus a corn-based supplement (18 % CP) consisting predominantly of corn and soybean meal for 14 wk (SER) or Bermuda grass hay plus the corn-based supplement (BER; n = 10 goats/treatment). At the end of the feeding trial, goats were slaughtered using standard procedures. After 24 h of cooler storage (4°C), the carcasses were fabricated to obtain 2.5-cm thick loin chops (Longissimus dorsi, LD) for meat quality analysis. No significant differences were found between SER and BER groups in moisture (73.2 vs 72.8%), protein (24.7 vs 23.8%), fat (3.11 vs 2.71%), and ash (1.83 vs 1.59%) percentages of LD muscles. The L* (lightness), a* (redness), and b* (yellowness) color values were not affected by the dietary treatment, although the L* values tended to be higher ($P < 0.10$) in loin chops from the SER group compared with those from the BER group. No differences ($P > 0.05$) were found in the thiobarbituric acid reactive substances in LD muscles between the two treatment groups. The Warner-Bratzler shear force values (4.76 vs 4.66 ± 0.43 kg) and cooking losses (19.6 vs 19.1 ± 1.13 %) of loin chops were also not influenced by the dietary treatments. The results indicated that a diet containing high levels of CT did not influence the composition and quality of meat in goats, although high CT diets may affect meat color.

Key Words: Chevon Quality, Goats, Sericea Lespedeza

W132 The small ruminant nutrition system: Development of a goat submodel. A. Cannas*[1], L. O. Tedeschi[2], and D. G. Fox[3], [1]*University of Sassari*, *Sassari, Sardinia, Italy*, [2]*Texas A&M University*, *College Station*, [3]*Cornell University*, *Ithaca, NY*.

The Small Ruminant Nutrition System (SRNS) is a computer model based on the structure of the Cornell Net Carbohydrate and Protein System for Sheep. A version of the SRNS for goats is under development. In the SRNS for goats, energy and protein requirements are predicted based on the equations developed for the SRNS for sheep, modified to account for specific requirements of goats. Energy requirements for basal metabolism of dairy goats averaged 125%, 117%, and 105% of those of sheep for dairy goats, Angora goats, and indigenous goats, respectively. Maintenance MP requirements were the same as used for sheep regarding urinary and fecal endogenous nitrogen, but hair and scurf were modified for goats. NE requirements for lactation were specific for goats. The relationships among body condition score (BCS, 0-5 scale), full BW (FBW), body composition and growth requirements developed for sheep was used for goats. The SRNS submodel to predict supply of nutrients was used for goats as well, except for the prediction of DMI, which was based on equations specific for goats. The evaluation of the SRNS for goats based on literature data showed that while in different breeds of goats it predicted very accurately the relationship between BW and BCS at any BCS, but it markedly over-predicted body fat concentration in the empty BW. Based on data gathered from the literature (24 treatment means), the SRNS predicted the growth rate of kids with good accuracy (mean bias was 8 g/d and root of the MSE of the prediction was 26.2 g/d). Further improvements of the goat submodel are planned to account for feed selectivity, body composition of different breeds, physical activity of grazing goats, and environmental effects on requirements and intake.

W133 Short-term trends of Boer and Kiko bucks in a central performance test. T. A. Gipson*[1], L. Dawson[2], and T. Sahlu[1], [1]*E (Kika) de la Garza American Institute for Goat Research, Langston University*, *Langston, OK*, [2]*Oklahoma State University*, *Stillwater*.

Increasingly meat goat producers in the U.S.A. are basing selection decisions upon performance traits and are relying upon central performance tests to objectively select bucks. Since 1999, the Langston University central performance test (LUCPT) has evaluated 398 bucks representing 70 breeders and 8 states. Two breeds have been tested, Boer and Kiko, the former accounting for 95% of the bucks enrolled. Therefore, the objective of this study was to evaluate the trends of the performance traits over the last 8 years (1999 to 2006) of LUCPT bucks. Traits evaluated were ADG, feed:gain ratio (FE), loin-eye area (LEA), and residual feed intake (RFI). An analysis of covariance was conducted with performance traits as the dependent variables, breed as the independent variable, and linear and quadratic effects of year as covariates. Over the 8 years, ADG increased linearly (yearly rate = 7.3 (g/d)/yr±1.25); FE decreased linearly (yearly rate = -0.08/yr±0.029); LEA increased quadratically (linear yearly rate = 1.15 cm^2/yr±0.223; quadratic yearly rate = -0.10 (cm^2)/yr^2±0.024); and RFI increased quadratically (linear yearly rate = 0.039 (g/d)/yr±0.0162; quadratic yearly rate = -0.005 (g/d)/yr^2± 0.0017). The two latter traits increased then decreased over time so that the traits in 2006 were virtually the same as in 1999. Breed influenced ($P < 0.05$) all performance traits: ADG averaged 277±2.9 for Boer and 206±13.8 g/d for Kiko; FE averaged 6.8±0.07 for Boer and 7.6±0.32 for Kiko; LEA averaged 11.4±0.11 for Boer and 9.2±0.53 cm^2 for Kiko; and RFI averaged -0.03±0.008 for Boer and 0.04±0.038 g/d for Kiko. Phenotypically across breeds, FE was positively correlated ($P < 0.05$) with LEA ($r=0.18$) and with RFI ($r=0.41$) but negatively correlated with ADG ($r=-0.49$). ADG was positively correlated ($P<0.05$) with LEA ($r=0.24$). Generally, ADG increased and FE decreased in desirable directions indicating that meat goat producers may be basing selection upon economically important traits, especially ADG which is easily measured on-test and on-farm. LEA and RFI remained unchanged, indicating that meat goat producers may not consider them important or they do not understand them.

Key Words: Central Performance Test, Goat

W134 Influence of dietary condensed tannins on gastrointestinal tract, skin, and carcass bacterial counts in meat goats. J. H. Lee*, D. A. Moore, M. Vanguru, B. Kouakou, T. H. Terrill, and G. Kannan, *Fort Valley State University*, *Fort Valley, GA*.

Diets high in condensed tannins (CT), such as sericea lespedeza hay, have been reported to reduce gut microbial loads in ruminants. This experiment was conducted to determine the effects of feeding higher levels of CT on gut, skin, and carcass microbial counts in goats. In a Completely Randomized Design, twenty Boer × Spanish kids (6 mo of age) were fed ground sericea (2 pens, SER) or Bermuda grass hay (2 pens; BER), 75% of daily intake for 14 wk with a corn-based supplement (25% of intake) (n = 10 goats/treatment). At the end of the feeding trial, the animals were slaughtered using standard procedures. Skin swab samples were made on the hind legs (5 × 5 cm area) prior to slaughter. Immediately after evisceration, rumen and rectal samples, as well as carcass swab samples were collected to assess bacterial loads. Concentrations of rumen volatile fatty acids were significantly different between dietary treatments. Goats fed sericea hay had higher ($P < 0.05$) contents of butyric (8.66 vs 7.16 mM), isobutyric (1.94 vs 1.44 mM), isovaleric (3.03 vs 2.13 mM), and valeric (1.43 vs 1.07 mM) acids than those fed Bermuda hay; however, the content of acetic acid (78.6 vs 64.4 mM) was higher ($P < 0.05$) in the BER group than in SER group. Generic E. coli (2.24 vs 0.93 $\log_{10}$ CFU/g) counts of rumen contents were higher in the SER group compared with BER group. However, microbial counts in feces were not different between dietary treatments. The aerobic plate counts on skin in the SER and BER groups were 4.58 and 4.46 $\log_{10}$ CFU/cm^2, respectively ($P > 0.05$). Carcass aerobic plate counts were 3.12 and 2.65 $\log_{10}$ CFU/cm^2 in SER and BER groups, respectively ($P > 0.05$). Total coliform and E. coli counts on skin and carcass were estimated to be <1.00 $\log_{10}$ CFU/cm^2. The results indicated that CT in the diet may influence rumen volatile fatty acid composition, but may not reduce the gut bacterial loads.

Key Words: *E.coli*, Goat, Sericea lespedeza

W135 Dietary regimen and gastrointestinal tract microbial loads in meat goats. J. H. Lee*, B. Kouakou, and G. Kannan, *Fort Valley State University*, *Fort Valley, GA*.

Microbial load in the gastrointestinal tract (GIT) can be related to contamination of skin/hide and carcass surfaces in ruminants. Thirty-six Boer × Spanish goats (BW = 17.7 kg) were used to determine the effects of dietary treatment on volatile fatty acid concentrations (VFA) in rumen and microbial loads of GIT contents. Animals were randomly allotted to nine pens, and each pen (4 goats/pen) was assigned to one of three dietary treatments for 90 d (3 pens/treatment): (1) a hay diet, consisting of alfalfa (Medicago sativa) hay alone (H); (2) a 18% CP concentrate diet, consisting predominantly alfalfa meal and yellow corn (C); or (3) a combined diet, consisting of the hay diet for the first 45 d, followed by the concentrate diet (HC). At the end of the feeding trial, goats were slaughtered using standard procedures. Immediately after evisceration, rumen fluid and rectal samples were aseptically collected from each animal to determine the microbial loads. Rumen fluid was also collected and prepared for determination of VFA. No significant differences were found in rumen fluid VFA among treatments, although the acetic acid concentration was high in the H group (66.27 mM), low in HC group (34.61 mM), and intermediate in C group (44.18 mM; $P < 0.05$). The total plate counts were not different ($P > 0.05$) among treatments for rumen fluid and fecal (rectal) samples. The E. coli counts in the rectal samples were lower in the H group (6.43 $\log_{10}$ CFU/g), compared with C (8.21 $\log_{10}$ CFU/g) or HC (8.40 $\log_{10}$ CFU/g) groups. However, no significant differences were found in the E. coli counts of rumen fluid samples among the dietary treatments. The mean (± SEM) rumen E. coli counts were 1.38, 1.65, and 2.51 ± 0.560 $\log_{10}$ CFU/g in H, C, and HC groups, respectively. The results indicated that either concentrate diet or a diet change from hay to concentrate may increase fecal shedding of E. coli in meat goats.

Key Words: Diet, *E. coli*, Goats

W136 Impact of types of pelleted feed and two pellet to hay ratios on the development of urolithogenic compounds in meat goats. K. Sullivan[1], S. Freeman*[1], M. Poore[1], E. van Heugten[1], K. Ange-van Heugten[1], and B. Wolfe[2], [1]*North Carolina State University*, *Raleigh*, [2]*The Wilds*, *Cumberland, OH*.

Goats and giraffes both have documented problems with urolith formation. Since research in giraffes poses logistical challenges, 18 buck goats were used as a model. Our objective was to determine the impact of two commercial pellets used as feed for giraffes (ADF-16, A; and Wild Herbivore, W) and two hay to pellet ratios (80:20, 80H; and 20:80, 20H) in a 2 × 2 factorial design. Total feces and urine were collected over 2 5-d periods separated by 9d for N and mineral balance determination. Fresh urine samples were collected twice during each collection period and evaluated microscopically for urolithic crystal content. Ruminal fluid was collected by rumenocentesis 2 hr post-feeding once at the end of the trial. Analysis of feedstuffs showed % CP, % NDF, % Ca, and % P to be 20.2, 43.9, 1.5, and 0.2 for the alfalfa hay; 19.4, 30.0, 0.8, and 0.7 for A; and 14.2, 54.4, 1.0, and 0.4 for W, respectively. DM and water intake were higher for the 20H than 80H bucks ($P \leq 0.05$ and 0.10, respectively); however, there were no treatment differences in DM digestibility. Retention of N was higher in bucks fed 20H diets ($P \leq 0.05$). Crystals observed were predominantly calcium phosphate. Crystal counts were not influenced by diet; however, crystal scores were higher in animals receiving 20H diets ($P \leq 0.10$). Ruminal NH_3 was higher in A bucks than W while urine pH was higher in W bucks than A. Urine pH was also higher for 80H than 20H ($P \leq 0.05$). Our data suggest that the proportion of hay offered to the goats was a greater influence on urinary calcium phosphate crystals than was pellet type.

Table 1. Impact of hay level and pellet type on meat goats

DM Basis	80HA	80HW	20HA	20HW

W137 Comparison and accounting for differences of three phytase activity assay methods. J. D. Weaver* and X. G. Lei, *Cornell University*, *Ithaca, NY*.

Phytases are now widely used throughout the world as feed additives for simple-stomached animals to increase phosphorus bioavailability and reduce phosphorus content in the excreta. Phytase activity is measured colorimetrically by the complexing of molybdenum with liberated phytate-phosphate. There are three different methods of assaying phytase activity: the molybdenum blue method with reduction of the phosphomolybdate complex by ascorbic acid (method 1), the molybdovanadate method (method 2), and the acetone phosphomolybdate method (method 3). Since different conditions may affect enzyme activity, we compared these three methods in order to characterize the relative impact of each assay condition on the activity outcome. Two commercialzed phytase enzymes, *Aspergillus niger* PhyA and *Escherichia coli* AppA2, were used for the assay comparison. When PhyA samples were analyzed, method 2 gave different ($P < 0.05$) activity values from that of method 1 or 3. In the case of AppA2 enzyme, all three methods gave different ($P < 0.05$) activity values. The greatest disparity was between methods 1 and 2 for AppA2 (2.8-fold, $P < 0.05$), and this difference was attributed to buffer, 39%; pH, 30%; and Triton X-100 and bovine serum albumen, 32%. The lower substrate concentration of method 3 versus method 1 reduced the activity of PhyA by 22%, without affecting the activity of AppA2. The presence of Trtion X-100 and bovine serum albumen in the exraction buffer for AppA2 tended to increase the phytase activity value ($P = 0.06$-0.08). These results help clarify discrepancies between various research groups and assist consumers in choosing a phytase additive.

Key Words: Phytase, Assay, Conditions

W138 Effects of dietary supplementation of an enzyme blend on digestibility of nutrients in the hindgut of growing pigs. F. Ji*[1], D. Casper[2], D. Spangler[2], K. Haydon[3], and J. E. Pettigrew[1], [1]*University of Illinois*, *Urbana*, [2]*Agri-King, Inc.*, *Fulton, IL*, [3]*Prince Agri Products*, *Quincy, IL*.

To measure the impact of a beta glucanase/protease enzyme blend product (EBP) on the digestibility of nutrients in the hindgut of pigs, 12 cannulated barrows (38.2 ± 0.5 kg) were blocked on previous feed intake (FI) and randomly assigned to 1 of 4 treatments using a 4 x 4 latin square design replicated 3 times. Treatments were hydrolyzed casein for measurement of endogenous N flow reported elsewhere, Basal diet (B), B + 0.05% EBP (EBP1), B + 0.10% EBP (EBP2). The B consisted of corn and soybean meal (SBM) having 3.36 Mcal ME/kg and 1.2% total lysine. The periods consisted of 4 d of adaptation, 5 d of fecal collection, 3 d of transition, and 2 d of ileal collection. Pigs were fed and feces were collected twice daily at 12-h intervals. Ileal effluent was collected continuously for 12 h each d. The FI of each square during period 1 was 85% of the minimum FI of 4 pigs during the preliminary period, equalized within square, and increased by 100g/d in each subsequent period. The difference between fecal and ileal digestibility (DFID) and digestibility based on the nutrients entering the hindgut (DNH) were calculated. The DFID of hemicellulose was higher ($P < 0.05$) in B than in EBP1 and EBP2 (Table 1). The DNH of EBP1 and EBP2 was higher ($P < 0.05$) in CP and tended to be higher ($P = 0.06$) in DM than that of B. In conclusion, this study showed that EBP increased the hindgut digestibility of CP but reduced that of fiber in growing pigs fed a corn-SBM diet because of greater intestinal NDF digestibility occurring with EBP.

Table 1. Digestibility (%) of nutrients in the hindgut.

Nutrient	B	EBP1	EBP2	SD[1]
n	11[2]	12	12	
DFID				
DM	17.25	19.68	18.32	3.79
Energy	16.00	18.19	16.96	3.86
CP	9.13	12.86	11.15	4.01

W139 Effect of sex and feeding level on meat quality and fatty acid profile of backfat of Iberian pigs reared under intensive production systems. M. P. Serrano[1], D. G. Valencia[1], R. Lázaro[1], A. Fuentetaja[2], and G. G. Mateos*[1], [1]*Universidad Politécnica de Madrid*, *Spain*, [2]*Copese*, *Segovia, Spain*.

Iberian (IB) pigs are the ancestral dark-haired pigs of Spain, originally reared under free range conditions and sacrificed at 160 to 180 kg BW. Usually both sexes were castrated. Currently, many IB pigs are reared indoors and fed on concentrates to meet the increasing demand for IB products. We studied in 160 crossbred (Duroc sire x IB dam) pigs the effects of sex (EF, entire females; CF, castrated females; CM, castrated males) and feeding level (*ad libitum* vs. 23% restriction of *ad libitum* feed intake from 42 to 112 kg BW) on meat quality and fatty acid (FA) profile of backfat (BF). From 112 kg BW to slaughter at 152 kg BW, all pigs were fed *ad libitum*. Each treatment was replicated four times (seven pigs). Samples of *Longissimus muscle* (LM) were taken at the last rib level and of BF at tail insertion. No differences were detected between EF and CF for any trait studied ($P > 0.10$). The LM of CM and CF had more fat (8.3 vs. 5.8%; $P < 0.01$) and less crude protein (21.1 vs. 21.7%; $P < 0.05$) and moisture (70.4 vs. 72.3%; $P < 0.01$) than the LM from EF. In all cases the intramuscular fat content of EF was sufficient to generate cured products of high quality. Meat color was not affected by sex ($P > 0.10$). Feeding level did not affect chemical composition or color of LM ($P > 0.10$). Subcutaneous fat was more unsaturated (60.9 vs. 59.9%; $P < 0.01$) in EF than in CM or CF mostly because of the higher linoleic acid content (9.2 vs. 8.6%; $P < 0.01$). *Ad libitum* fed pigs had higher percentage of oleic acid and monounsaturated FA ($P < 0.001$) and lower of stearic acid and saturated FA ($P < 0.001$) than restricted fed pigs. We conclude that entire females are an alternative to castrated males and castrated females to produce Iberian cured products of high quality. Also, a 23% feed restriction from 42 to 112 kg body weight modified slightly the fatty acid profile of backfat but not meat quality.

Key Words: Iberian Pig, Duroc Pig, Pork Quality

W140 Effects of conjugated linoleic acid (CLA) on sow reproductive performance. R. Patterson*, M. L. Connor, and C. M. Nyachoti, *University of Manitoba*, *Winnipeg, Manitoba, Canada*.

The ability of CLA to improve reproductive performance was evaluated using 14 mixed parity Cotswold sows in a completely randomized repeated measured design. Treatments were arranged as a 2x2 factorial with diet (0% or 2% CLA) and parity (I = Immature or M = Mature) as follows: 1) 0%-I n = 3; 2) 0%-M n = 3; 3) 2%-I n = 4; 4) 2%-M n = 4. Diets were fed as gestation rations from d 85 to 112 of pregnancy and for 4 d post-weaning, and as lactation rations from d 112 of gestation until weaning at 17±1 d of age. Blood was collected from sows on gestation d 85, 105, 112 and lactation d 1, 3, 17 and 4 d post-weaning and from piglets on d 3 and 17. Sow BW, back fat depth and feed intake and piglet BW were determined on the same d as blood sampling. Blood samples were analyzed for PUN, IgA and IgG concentrations. BW and back fat depth were used to estimate whole body nutrient status. Dietary CLA had no effect ($P > 0.10$) on sow ADFI and BW during gestation and lactation periods although sows fed CLA-supplemented diets had less back fat than control sows during gestation ($P = 0.05$) but not lactation ($P = 0.15$). Immature sows fed CLA-supplemented diets tended ($P = 0.09$) to lose less back fat than control sows during lactation. Dietary CLA increased sow whole body protein percentage during gestation but not during lactation ($P = 0.05$) but had no effect on whole body lipid content ($P > 0.10$). Piglets nursing sows consuming CLA-supplemented diets were lighter than piglets nursing control sows ($P = 0.06$). However, dietary CLA did not affect total litter weight ($P > 0.10$). Although dietary CLA had no effect on the concentrations of IgA and IgG of sows and piglets ($P > 0.10$), piglets nursing CLA-supplemented sows had greater PUN concentrations compared to piglets nursing control sows at d 3 and 17 of age ($P < 0.01$). While supplementation of sow diets with CLA did not

improve litter performance or immune status pre-weaning, when provided to immature sows, dietary CLA has the potential to diminish deleterious body condition loses associated with lactation.

Key Words: CLA, Sows, Piglets

W141 Apparent and standardized ileal amino acid digestibilities in pea and pea protein isolate fed to growing pigs. F. O. Opapeju, G. Borgesa*, R. Patterson, and C. M. Nyachoti, *University of Manitoba*, *Winnipeg, Manitoba, Canada*.

Four Cotswold barrows (50.41 ± 5.05 kg BW), each fitted with a T-cannula at the distal ileum, were used to determine apparent (AID) and standardized (SID) ileal digestibility of amino acids (AA) in whole pea and pea protein isolate (PPI) from the same batch of whole pea. Pigs were allotted to diets containing either pea or PPI as the sole source of protein and formulated to contain 15.5% crude protein (CP) in a simple crossover design. Pigs were fed twice daily (0830 and 1530) at 2.6 times maintenance energy requirement. The experiment consisted of two 6-d experimental periods. During each period, pigs were adapted to experimental diets for 4 d followed by 12 h of continuous ileal digesta collection on d 5 and 6 to determine AID. The SID of CP and AA were determined by correcting AID values for basal endogenous AA losses using published values. Chromic oxide (0.3%) was included in the diets as an indigestible marker. The AID (%) of CP (88 vs. 80), Ile (91 vs. 79), Leu (92 vs. 81), Lys (93 vs. 84), Phe (92 vs. 84) and Val (89 vs. 76) for indispensable AA and Asp (91 vs. 81), Glu (94 vs. 87) and Ser (89 vs. 78) for dispensable AA were higher ($P < 0.05$) in PPI than in pea. Similar to AID results, PPI contained higher ($P < 0.05$) SID (%) values than pea for Ile (96 vs. 84), Leu (96 vs. 85), Lys (99 vs. 88) Phe (95 vs. 87), and Val (95 vs. 82) for indispensable AA and Asp (95 vs. 85), Cys (85 vs. 77), Glu (108 vs. 100), and Ser (97 vs. 86) for dispensable AA. The results indicate that PPI has higher AID and SID values for most indispensable AA compared with whole pea.

Key Words: Amino Acid Digestibility, Pea Protein Isolate, Pigs

W142 Growth performance and carcass characteristics of growing pigs fed crude glycerol. P. J. Lammers*[1], M. S. Honeyman[1], B. J. Kerr[2], T. E. Weber[2], and K. Bregendahl[1], [1]*Iowa State University*, *Ames*, [2]*USDA-ARS, Swine Odor and Manure Management Research Unit*, *Ames, IA*.

Growth performance and carcass characteristics of growing pigs fed crude glycerol were determined in a 138-d feeding trial conducted at Iowa State University, Ames, IA. Crude glycerol was obtained from AG Processing Inc., Sergeant Bluff, IA and contained 84.51% glycerol, 12.24% water, 2.93% sodium chloride, and 0.32% methanol. Pigs were weaned at 21d of age and fed a commercial starter-pellet for 1 wk. Eight days post-weaning, 96 pigs (48 gilts, 48 barrows) with an average BW of 8.0 ± 0.2 kg were allotted to 24 pens (4 pigs/pen). Gender distribution and pen weight was balanced at the start of the experiment. Dietary regimes were randomly assigned to each pen, with dietary treatments being 0, 5, and 10% crude glycerol inclusion in corn-soybean meal based diets. Within each phase, diets were offered ad libitum in meal form and formulated to be equal in ME, NaCl, and Lys with other AA balanced on an ideal AA basis. There were 5 dietary phase changes over the 138-d trial. Pigs were weighed once every 2 wk with the change in the dietary phase occurring on a day that all pigs were weighed. Feed disappearance was recorded at the time of pig weighing, and G:F calculated. On d 138, all pigs were weighed (mean BW 133 ± 2.3 kg) and scanned using real-time ultrasound. Least-squares means of growth performance and carcass characteristics were compared using PROC MIXED of SAS. There was no difference in ADG ($P = 0.93$), ADFI ($P = 0.65$), or G:F ($P = 0.13$) among the 3 dietary treatments over the 138 d trial. Dietary treatment did not affect backfat depth ($P = 0.14$), loin muscle area ($P = 0.12$), or percentage fat free lean on a live basis ($P = 0.13$). Pig gender affected backfat depth ($P < 0.001$) and percentage fat free lean on a live basis ($P < 0.001$), but there was no diet by gender interaction for any parameter measured. Growing pigs can be supplemented with up to 10% crude glycerol without affecting growth, efficiency of gain, or carcass composition.

Key Words: Crude Glycerol, Pigs

W143 True phosphorus digestibility of feedstuffs determined with growing and finishing pigs. S. Bunzen, H. S. Rostagno*, L. T. Albino, L. R. Apôlonio, and C. G. Borsatto, *Federal University of Viçosa*, *Viçosa, MG, Brazil*.

The objective of this study was to determine the true phosphorus digestibility coefficients (TPDC) of 18 feedstuffs commonly used in swine diets, including: plant sources, animal by-products and inorganic sources of phosphorus. A complete randomized experimental design was applied in a trial with individual metabolic cages with three replicates per treatment and one pig (barrow) per experimental unit, in a 2 x 2 x 20 factorial arrangement of two methodologies applied simultaneously (Cr2O3 as fecal marker and total fecal collection), two growth phases (Growing with 37.5Kg and finishing with 72.5 Kg) and 18 feedstuffs. Two additional diets were included in the factorial experiment; a reference diet (0.17% P) where the evaluated feed ingredients were included to furnish either 0.15 or 0.20% P, and a low P diet (0,03% P) to estimate fecal P endogenous losses. There was no difference ($P>0.05$) between the two methodologies evaluated (marker 64.5% TPDC vs. total collection 65.8% TPDC). The TPDC of plant feedstuffs was lower ($P<0.05$) when determined with growing pigs as compared to the values obtained with finishing pigs. The TPDC of plant sources for the growing and finishing phases were, respectively: Corn, 54.8 and 81.9%; sorghum, 51.5 and 82.5%; corn gluten feed (22% CP), 33,3 and 49,4%; corn gluten meal (60% CP), 48.6 and 57.8%; cottonseed meal (30% CP), 34.8 and 46.4%; wheat bran & middling, 52.2 and 59.3%; soybean meal, 51,0 and 53,4%; soybean full fat extruded, 44.7 and 66.9% and yeast from alcohol distillery, 62.2 and 70.9%. The TPDC of animal by-products and inorganic sources of phosphorus showed no effect of growing phase ($P>0.05$), with the following average values: meat and bone meal (41% CP), 62.9%; feather and poultry by-products meal, 52.5%; feather meal, 90.8%; fish meal, 88.5%; dried whey, 92.0%; dicalcium phosphate, 66.4%; monocalcium phosphate, 76.1; monodicalcium phosphate, 80.6% and steamed bone meal, 61.8%.

Key Words: Digestible Phosphorus, Feedstuffs, Swine

W144 Effect of phytase on phosphorus and calcium digestibility in lactating sows. J. Tossenberger[1], L. Babinszky*[1], and I. Kühn[2], [1]*University of Kaposvár*, *Kaposvár, Hungary*, [2]*AB Enzymes GmbH*, *Darmstadt, Germany*.

The objective was to determine the effect of dietary phytase supplementation on Ca and P digestibility in lactating sows. The trial used hybrid sows [(Large White x Landrace; average parity: 3.8; 8 sows per treatment (Trt)]. Diets were wheat-barley-soybean meal based and followed NRC energy and amino acid recommendations (1998). Diet in Trt1 had no inorganic P (P_t:3,6 g/kg, Ca:4,3 g/kg) and no phytase supplementation. Dietary P content in Trts2, 3 and 4 was the same as in Trt1, but all were supplemented with phytase (type: 6-phytase produced by *trichoderma reesei*) at a rate of 125 PPU/kg (Trt2), 250 PPU/kg (Trt3) and 500 PPU/kg (Trt4), respectively. Faeces were collected between days 18 and 22 of lactation. Data were analyzed with ANOVA (SAS, 2004). It was concluded based on the results that the feed intake of negative control sows was significantly below ($P \leq 0.05$) the feed intake of animals fed the phytase supplemented diets. Apparent P digestibility was found to be unusually low in contrast to the relatively high values generally described for wheat-barley based diets. This is probably attributable to the low P intake due to low dietary P levels, and to the high endogenous P-portion of the total faecal P excretion. Each of the tested phytase dosages (125 PPU/kg; 250 PPU/kg; 500 PPU/kg) resulted in a further significant ($P \leq 0.05$) increase of P digestibility (Trt1: 22.3%, Trt2: 29.9%, Trt3: 33.5%, Trt4: 36.1%). The expected maximum of P digestibility can not be estimated on the basis of phytase dosages tested. As a result of the lowest phytase dosage (125 PPU/kg) Ca digestibility increased significantly ($P \leq 0.05$). Further increase of the phytase dosages (250 and 500 PPU/kg Phytase) were not accompanied by a further increase of dietary Ca digestibility ($P \geq 0.05$). Supplementation of the wheat-barley-soybean meal based diet of lactating sows (without P_i supplementation) with 100 PPU/kg of this 6-phytase, is expected to increase the P digestibility by 2.6% (R^2: 0.84).

Key Words: Lactating Sow, Phosphorus Digestibility, Phytase

W145 Effect of dietary fat and restriction on productivity and fatty acid composition of Iberian pigs. J. Viguera*[1], M. Señorón[2], M. Cortés[3], J. Peinado[1], J. Ruiz[3], and P. Medel[1], [1]*Imasde Agropecuaria, S.L.*, *Pozuelo de Alarcón, Spain*, [2]*SAT Villa Vieja*, *Olivenza, Spain*, [3]*Universidad de Extremadura*, *Cáceres, Spain*.

A total of 160 Iberian x Duroc pigs (50% male, 50% female, all castrated) of 40.3±2.7kg of initial BW was used to study the influence of dietary fat source and feed restriction on productivity and subcutaneous fatty acid composition. There were 3 experimental periods; i) grower: 40–80kg BW, 98d of trial, common diets *ad lib*; ii) fattening: 80–114kg BW, four treatments arranged as a 2x2 factorial design: *ad lib* (31d) *vs* restricted (51d), diets containing Iberian lard –IL– *vs* oleic acid enriched sunflower oil –OESO– and iii) finisher: 114kg–slaughter, 77d, diets based on IL or OESO *ad lib*. Final BW and experiment duration were 167.4 *vs* 171.5 kg, and 206 *vs* 226 d, for pigs fed *ad lib* and restricted, respectively. The oleic levels were 1.72, 2.65, 2.55 and 3.75% for IL and OESO diets in the fattening and finisher periods, respectively. Each treatment was replicated four times (ten pigs housed together). Productivity was measured per pen every 28d, and biopsies were taken at 98, 129, 149, 207 and 225d for fatty acid analysis. In the grower period, restricted pigs showed lower feed intake, and poorer growth and feed conversion (4,777 *vs* 2,784 g/d, 1,130 *vs* 582 g/d and 4.23 *vs* 4.80 feed/gain, respectively, $P<0.05$). However, in the finisher period, pigs restricted in the grower period had better growth and feed conversion (652 *vs* 778 g/d and 5.94 *vs* 5.23 feed/gain, $P<0.05$) and tended to eat more (3,868 *vs* 4,054 g/d, $P=0.09$) than pigs fed *ad lib*. For the whole period, restricted pigs in the grower period ate and grew less but showed better feed conversion than pigs fed *ad lib* (614 *vs* 581 g/d, 2,994 *vs* 2,759 g/d and 4.88 *vs* 4.75 feed/gain, respectively; $P<0.05$). In addition, feed restriction slightly decreased oleic acid and increased linoleic acid at 129 and 149d. Fat sources did not modify any performance parameter. However, IL consumption slightly increased palmitic acid at 207d, and decreased linoleic acid at 225d and oleic acid at 149, 207 and 225d. It is concluded that the restriction level tested increased the growth period, but improved feed conversion by 2.7%. Fat sources tested caused slight variations in the fatty acid composition.

Key Words: Iberian Pig, Fat Sources, Restriction

W146 Effect of dietary fat on productivity, fatty acid composition and lipid oxidation in Iberian pigs. J. Viguera*[1], M. Señorón[2], M. Cortés[3], J. Peinado[1], and J. Ruiz[3], [1]*Imasde Agropecuaria, S.L.*, *Pozuelo de Alarcón, Spain*, [2]*SAT Villa Vieja*, *Olivenza, Spain*, [3]*Universidad de Extremadura*, *Cáceres, Spain*.

A total of 160 Iberian x Duroc pigs (50% males and 50% females, all castrated) of 35.8±1.3 kg of initial BW was used to study the influence of dietary fat source on productivity, fatty acid composition of intramuscular (IM) fat, and lipid oxidation of pork. A common diet was used from 35 to 110 kg BW. There were four treatments depending on the source of supplemental fat (5 %) from 110 to 170 kg BW: 1) Iberian lard –LARD–, 2) oleic acid enriched sunflower oil –OESO–, 3) olive fatty acid distillers –OFAD– and, 4) olive oleins –OLEI–. The oleic acid levels of the diets were 2.56, 3.77, 3.60, 3.81% for treatments 1 to 4, respectively. Each treatment was replicated four times (ten pigs housed together). After slaughter, samples of the *longissimus* muscle of the last rib of two pigs selected at random per replicate were obtained to quantify the fatty acid composition of the neutral (NL) and polar (PL) lipid fractions of IM fat, and 2–thiobarbituric acid reactive substances (TBARS) at 0, 50, 100 and 200 min of induced lipid oxidation. Pigs fed OFAD showed higher final BW and better feed conversion ratio than pigs fed OESO (172.6 *vs* 163.7 kg and 5.51 *vs* 6.14 g feed/g gain respectively; $P<0.05$). In the PL fraction of IM fat, pigs eating OFAD showed higher linoleic acid values than pigs eating diets with OLEI, LARD and OESO (0.77 *vs* 0.61, 0.56 and 0.48 %; $P<0.01$); pigs fed OESO had more oleic acid than those fed LARD (18.7 *vs* 15.8 %; $P<0.05$); and pigs supplemented with OESO and OLEI showed the highest percentage of polyunsaturated fatty acids ($P<0.05$). At 100 and 200 min, meat from pigs fed LARD showed significantly higher levels of TBARS than those fed the others fat sources. It is concluded that fat sources tested in this study did not modify substantially the fatty acid composition of intramuscular fat. However, diets supplemented with vegetable fats reduced the lipid oxidation of pork loin, probably due to the presence of compounds with antioxidant activity.

Key Words: Intramuscular Fatty Acids, Iberian Pig, Fat Sources

W147 Effect of lignocellulose intake on the ileal endogenous amino acid losses in growing pigs. L. Babinszky*, J. Tossenberger, and J. Tenke, *University of Kaposvár*, *Kaposvár, Hungary*.

Lignocellulose based fiber (LCF) ingredients are increasingly used in pig diets. We studied the changes of ileal endogenous nitrogen (EN) and amino acid (EAA) excretion in response to the LCF supplementation of N-free diets. A total of 12 hybrid barrows were used in the trial (4 treatments, 3 per treatment, 2 replicates, live weight 30±3 kg). Prior to the trials pigs were fitted with a PVTC cannula. The rate of ileal EN and EAA excretion was measured in a total of 4 treatments where N-free diets contained 20-, 36-, 52 and 68 g/kg LCF. Daily rations of the N-free diet contained 2 times the maintenance energy requirement (920 KJ ME/kg$^{0.75}$/d). Diet specification and the DM, CP and AA content of the digesta were determined in accordance with AOAC (1996). Water holding capacity (WHC) of the diets was determined according to Robertson and Eastwood (1981). Trial data were analyzed with ANOVA and regression analysis (SAS, 2004). Our data show a difference of only 18.3 % between the EN excretion of pigs consuming the lowest (20g/kg) and the highest (68g/kg) level of LCF in their diet. The decrease was found to be the largest with MET (21 vs. 11 mg/100 g DMI), THR (81 vs. 52 mg/100 g DMI), TRP (14 vs. 9 mg/100 g DMI). The decrease of LYS excretion was 27.5 % (58 vs. 42 mg/100 g DMI). The probable cause of decrease is the higher WHC due to the increasing dietary LCF level (data not shown). A close linear relationship ($R^2 = 0.99$) was found between the dosages of LCF and the EN excretion of growing pigs. Similarly to the findings for N-excretion a close linear relationship ($R^2 = 0.9 – 0.99$) was found between the dietary LCF content and the rate of ileal EAA excretion. Our data underline that in the calculation of true amino acid digestibility of pig diets no uniform adjustment should be applied to the rate of ileal EN and EAA excretion, and in addition to the crude fiber and NDF content of the diets also the fiber source and its WHC should be taken into account.

Key Words: Lignocellulose, Endogenous Amino Acids, Pigs

W148 The effect of wheat dried distillers grains plus solubles in diets for fattening pigs with or without xylanase. K. Sigfridson and A.-K. Haraldsson*, *Lantmännen*, *Lidköping, Sweden*.

The ethanol production from wheat is growing in Sweden and the volumes of DDGS will increase. Two feeding experiments were performed in order to evaluate wheat DDGS for pigs and the effect of xylanase on a DDGS based diet. Exp 1 comprised of 3 diets, formulated with 0% (control), 10 % and 20% DDGS. Each diet was fed to18 pens (2 pigs/pen). In exp 2 diets with 0% (control), 20% DDGS and 20% DDGS + 200 FXU endo-1,4-beta-xylanase (Ronozyme WX) were fed to 12 pens/treatment (4 pigs/pen). The control diets were based on wheat, barley, RSM, SBM and peas. All diets had a calculated energy value of 12.4 MJ ME/kg and 15% CP. The standardized ileal digestible lysine was 7,7 g (8,5-8,9 g total) and 7,1 g (8,0-8,2 total) per kg for exp 1 and 2, respectively. The pigs were fed each diet from 22 to 110 kg LW, close to ad libitum before 60 kg and restricted after 60 kg LW (34 MJ/d). Data was analysed as least square means (PROC GLM, SAS). At 20% DDGS inclusion level the diets were to 90-95% based on wheat products and barley. To compensate for the decrease in protein quality, the use of pure lysine, threonine and methionine were increased by over 100% in the experimental diets compared to the control. In exp 1, pigs fed the control diet had a DWG of 897g/d, a FCR of 33,6 MJ/kg and 58,2% lean meat content (carcass quality). The DDGS diets did not significantly influence any of these parameters. In exp 2, the performance of the control diet was similar to exp 1, but the DWG and FCR were significantly ($p<0,05$) lower for the diets with 20% DDGS (-4%). Since wheat DDGS is rich in low digestible carbohydrates, the addition of xylanse was thought to improve the DDGS based diet, but no such effect could be proven. It can be concluded that wheat DDGS can be used to fattening pigs, but the inconsistent results from these experiments indicate that variation in the nutritional value of the product can have a significant negative effect on pig performance. Thus, it is of great importance that producers of DDGS provide a consistent product and that the knowledge of energy content and protein digestibility is improved.

Key Words: Wheat DDGS, Fattening Pigs, Xylanase

W149 Isolation and characterization of Bacillus sp. PPS-52 producing thermophilic protease. S. J. Lim and D.-K. Kang*, *Dankook University*, *Cheonan, Choongnam-do, Rep. of Korea*.

Protease enzyme enhances the nutritional value of animal feeds. A thermophilic bacterium PPS-52 showing proteolytic activity against both skim milk powder and defatted soybean was isolated from pig feces. The isolate was found to be the Gram-positive, non-motile, catalase-positive, and spore forming strain. Under an electron microscope, the cells were observed to be rod-shaped. The 16S rDNA sequences of the isolate PPS-52 showed high homology (99%) with that of Bacillus amyloliquefaciens, examined by similarity search using the GenBank database, thus named Bacillus amyloliquefaciens PPS-52. The purification and characterization of the thermophilic protease are under way.

Key Words: Thermophilic Protease, Bacillus

W150 Comparison of the digestible energy content of corn and triticale when fed to finishing pigs. C. Feoli*, J. D. Hancock, C. R. Monge, and T. L. Gugle, *Kansas State University*, *Manhattan*.

A total of 96 finishing pigs (average initial BW of 91 kg) was used in a 5-d experiment to determine the DE content of corn and triticale. The diets were either corn- or triticale-based with added vitamins, minerals, and amino acids. The result was diets with 97.5% corn and 97.8% triticale. Pigs used in the experiment were sorted by sex and ancestry, blocked by BW, and assigned with 12 pigs/pen and four pens/treatment. Feed (meal form) and water were consumed on an ad libitum basis. The pigs were allowed to adjust to the experimental diets for 4 d. Feces were collected from no less than six pigs per pen (via rectal massage) on the afternoon of the fourth day and morning of the fifth day. The fecal samples were dried, ground, and analyzed for concentrations of DM, N, and GE with Cr2O3 used as an indigestible marker. Digestibility of DM was greater ($P < 0.03$) for pigs fed corn vs. triticale (82.8 vs. 81.2%, respectively). However, the opposite was true for digestibility of N ($P < 0.002$) with values of 67.8% for corn and 74.7% for triticale. Digestibility of GE was not different ($P > 0.26$) among the treatments (81.1 and 80.5% for the corn and triticale, respectively). However, because of the greater GE in the triticale, it still had a higher DE content ($P < 0.02$) in triticale with DE value of

3,376 than that of 3,261 kcal/kg in corn. In conclusion, our results indicated that triticale was utilized well by finishing pigs supporting greater digestibility of N and having greater DE than corn.

Key Words: Triticale, DE, Pigs

W151 DXA scans of pig feet accurately predict bone ash content. L. E. Hoffman*, T. Burgers, D. K. Schneider, and T. D. Crenshaw, *University of Wisconsin*, *Madison*.

Dual-energy X-ray absorptiometry (DXA) offers a rapid method to predict bone ash content of humans, animals, and tissues. Earlier work in our laboratory demonstrated that the GE Lunar Prodigy instrument (software version 10.10.038), in selected scan modes, accurately predicted the bone ash content of pigs from 1 to 60 kg. The current experiment was designed to assess the accuracy of DXA scans of pig feet as a rapid screening method to evaluate qualitative responses by pigs to nutrient treatments affecting mineral status. The front foot was selected as an easily accessible sample to collect from carcasses in a slaughter plant. The front foot included all bones distal of the carpal bones. Ten pig feet were aligned parallel to the DXA bed and placed in various orientations to determine which position allowed the most accurate prediction of bone ash content. Orientations included 1) direction of hoof, hoof either scanned first or carpal bones first, 2) dewclaw orientation, dewclaws facing up or down. Another variable included variation in background material, either 2.5 cm or 5 cm thick rice bags, and the position of rice bags, either both beneath the foot or one below and one above the foot. Following scans all bones within each foot were dissected, dried at 100°C for 24 h, and ashed at 750°C for 12 h. Total bone ash content from each foot was compared by regression analysis with bone mineral content (BMC) from DXA scans within each orientation and type of background material. Selection of the regression models to most accurately predict bone ash content from DXA scans were based on the model with a coefficient closest to 1.0. The model selected (ash = -0.403 + 0.988*BMC, R^2=0.979) was based on scans with the hoof scanned first, dewclaws down, and two rice bags beneath the foot. The model with the lowest coefficient (ash = 11.6 +0.717*BMC, R^2=0.836) was based on scans with hoofs scanned last, dewclaws up and one rice bag. In conclusion, DXA scans of pig feet can accurately predict bone ash content of the foot, but foot orientation and background material are important variables.

Key Words: Bone Ash, DXA, Pig Feet

W152 Short-term excesses of potassium bicarbonate for prevention of fatigue in market pigs. J. R. Danielson*, J. L. Reichert, J. A. Kane, and T. D. Crenshaw, *University of Wisconsin*, *Madison*.

The objective of this study was to determine the efficacy of excess cations for prevention of acidosis in market pigs following a brief period of aggressive handling. Thirty two pigs (~115 kg) were used in two replicate trials (16/trial). Pigs were allowed access to either alkaline (ALK, 30.2 g $KHCO_3$/liter) or water (W) treatments via a nipple waterer. Following a 24-h water restriction, pigs were allowed access to ALK or W treatments for 18 h. Pigs were housed 4/pen and allowed ad libitum access to a standard diet. Handling protocols, gentle (GE) or aggressive (AG) were applied to randomly selected pigs within each pen. Total distance for each handling protocol was ~ 960 ft. For AG pigs, handling involved movement through a restricted chute (5 times) with intentional crowding and application of shocks with an electrical prod. The GE pigs were walked the same distance and passed through a restricted chute (5 times) with only a hurdle board used to guide the pigs. In the first trial, 2 pigs from each pen were assigned to GE and AG treatments. In the second trial, 1 pig from each pen was GE and 3 were AG handled (in order to obtain more AG observations). Immediately after completion of handling treatments, venous blood was collected in 10 mL heaprinized vacutainer tubes for blood gas, NH_4 and lactate assays. Blood gas values (SBE, standard base excess, pH, HCO_3) were reduced ($P<0.05$) in AG vs GE pigs, but NH_4 and lactate concentrations were increased ($P<0.05$), consistent with acidosis following AG handling. Differences in blood gas values were not detected ($P>0.10$) between ALK and W treatments within handling protocols. However, in AG pigs given ALK, plasma NH_4 concentrations were greater ($P<0.05$) than pigs given W. Likewise, plasma lactate in ALK pigs tended ($P<0.10$) to be higher than W pigs after AG handling. Conclusions from these data are compromised by measurements obtained from a single time point following AG handling. More frequent sampling intervals are needed to assess the changes in acidosis with ALK treatments after AG handling.

Key Words: Fatigue, Acidosis, Potassium

W153 Effects of dietary supplemental Megazone® on growth performance, nutrients digestibility, blood characteristics, meat quality and carcass traits in weaning-to-finishing pigs. Y. H. Kim*[1], Y. Wang[2], J. C. Park[1], H. J. Jung[1], J. H. Cho[2], Y. J. Chen[2], J. S Yoo[2], I. C. Kim[1], S. J. Lee[1], H. K. Moon[1], and I. H. Kim[2], [1]*National Livestock Research Institute*, *Cheonan, Chungnam, Republic of Korea*, [2]*Dankook University*, *Cheonan, Chungnam, Republic of Korea*.

This study was conducted to investigate the effects of Megazone® (an alumninosilicate mineral mix, which include 30% quartz, 30% feldspar, 30% ceramic and 10% biotite) supplementation on growth performance, nutrients digestibility, blood characteristics, meat quality and carcass traits in weaning-to-finishing pigs. A total of 48 crossbred ([Landrace×Yorkshire]×Duroc) pigs with initial BW of 4.46 ± 0.18 kg were used in a 21 wks trial. Pigs were randomized allocated to two dietary treatments. There were 6 pens per treatment and 4 pigs per pen. Dietary treatments included: 1) CON (basal diet) and 2) MT (basal diet + 0.8% Megazone®). Through the entire experimental period, there were no effects of dietary Megazone® supplementation on growth performance, nutrients digestibility, blood characteristics and meat quality ($P>0.05$). Also, market weight and backfat thickness had no differences between the two treatments ($P>0.05$). However, carcass weight and carcass ratio in MT treatment were improved compared with CON treatment ($P<0.05$). In conclusion, supplmentation of Megazone® can increase carcass weight and carcass ratio in weaning-to-finishing pigs, however, it has no effects on growth performance, nutrients digestibility, blood characteristics and meat quality traits.

Key Words: Megazone®, Alumninosilicate, Digestibility

W154 Pharmacological addition of zinc to diets inhibits phytase activity but does not compromise inorganic phosphorus (iP) retention in young growing pigs. K. M. Retallick*, M. T. Repinski, J. L. Reichert, J. R. Danielson, D. K. Schneider, and T. D. Crenshaw, *University of Wisconsin*, *Madison*.

Pharmacological Zn addition interferes with apparent P retention in pigs fed diets formulated with phytase. Whether Zn directly inhibits phytase or simply inhibits availability of P is not clear. Hypothetically, bone mineral accumulation is compromised in growing pigs by adding Zn to diets with phytase. Forty eight crossbred (PIC Cambrough X Line 19) pigs (initial BW = 9.1+0.10 kg) were randomly allotted within gender and weight blocks to one of eight diets. Pigs were individually fed assigned diets for 56 d. Pig weights and feed consumptions were recorded weekly. Pigs were scanned by dual-energy X-ray absorptiometry (DXA) using a GE Lunar Prodigy (software version 10.10.038). Total bone mineral (BMC, g) and Ca and P retentions were based on differences between individual pig scans at 56 d and predicted BMC on d 0. BMC on d 0 was predicted from earlier trials as BMC = 24.1+14.1*BW, R^2=0.92. Experimental design of dietary treatments involved a slope ratio comparison of iP (0, 0.12 and 0.24% added iP) and phytase (Natuphos to provide 200, 400, and 600 FTU/kg diet) additions to a basal diet. Two diets included ZnO (2000 mg/kg) additions to mid-point levels of each group, 0.12% iP and 400 FTU. Dose response relationships in BMC gain (g/d) were detected (P<0.05) in pigs fed iP or phytase diets. Added Zn reduced (P<0.01) BMC gain in pigs fed diets with phytase, but not iP. Ca and P retention was calculated from BMC gain, assuming a constant Ca (38%) and P (18%) content in bone ash and a constant distribution of total body Ca (96%) and P (80%) within skeletal tissue. Pigs fed diets with iP retained (P<0.05) more P than pigs fed equivalent diets with phytase, even though BW gain was not different (P>0.20). Thus, assumed P equivalency values for phytase did not meet expectations. P retention in pigs fed added Zn was reduced if fed 400 FTU/kg diets, but not if fed diets with 0.12% iP. Added Zn reduced (P<0.05) efficiency of P retention in pigs fed phytase (24% vs 33%), but not iP (34% vs 33%). In summary, Zn interferes with phytase activity, but not iP bioavailability.

Key Words: Efficiency, Mineral Accretion, Phosphate

W155 Effects of dietary supplementation of ginseng by-product on growth performance and pork quality parameters in finishing pigs. J. C. Park*, Y. H. Kim, H. J. Jung, S. D. Lee, H. D. Jang, I. C. Kim, S. J. Lee, and H. K. Moon, *National Livestock Research Institute*, *Cheonan, Chungnam, Republic of Korea*.

The objective of the present study was to investigate the effects of dietary supplementation of ginseng by-product on growth performance and meat quality in finishing pigs. The animals used in the experiment were a total of 24 Landrace × Yorkshire and the average weight was 65.81±2.02 kg. The experimental diets were basal diet (CON) and supplemented diet with 2.5% ginseng by-product (GBP) which replaced lupin in the basal diet. The diets were fed for 60 days. The pigs were divided into three replicates of four pigs in each treatment according to completely randomized design. In growth performance, average daily feed intake was lower (P<0.01) in GBP than in CON. In biochemical composition of plasma, total protein (P<0.05), blood urea nitrogen (P<0.05), glucose (P<0.05), albumin (P<0.05), calcium (P<0.05) and inorganic phosphate (P<0.05) were increased in GBP when compared to CON. Carcass and meat quality were not different between treatments. Total ginsenoside content of meat was higher (P<0.01) in GBP than in CON. TBARs was significantly lower in GBP than in CON for 6 d (P<0.05). The results indicate that dietary supplementation of ginseng by-product affected positively biochemical composition of plasma, total ginsenoside content and TBARs of pork. This study, therefore, suggests that ginseng by-product could be used in the finishing diet of pigs.

Key Words: Ginseng By-Product, Finishing Pigs, Biochemical Composition

W156 Comparative determination of true digestibility and the fecal endogenous calcium losses associated with soybean meal for growing barrows and gilts by the regression analysis technique. Y. Zhang*[1], J. Wang[2], S. Yan[1], Y. L. Yin[3], and M. Z. Fan[4], [1]*Inner Mongolian Agricultural University*, *Huhhot, China*, [2]*The Chinese Academy of Agricultural Sciences*, *Beijing, China*, [3]*Institute of Subtropical Agriculture, the Chinese Academy of Sciences*, *Changsha, China*, [4]*University of Guelph*, *Guelph, Canada*.

Two digestibility experiments were conducted to comparatively determine true digestibility and the fecal gastrointestinal endogenous calcium (Ca) losses associated with conventional solvent-extracted soybean meal (SBM) for growing barrows and gilts. Experiment 1 was conducted with six Yorkshire x Landrace cross-bred barrows with an average initial BW of 28.6±1.8 kg. Experiment 2 was conducted with six Yorkshire x Landrace cross-bred gilts with an average initial BW of 27.6±3.0 kg. Pigs in both experiments were fed six cornstarch-based semi-purified diets containing six levels of total Ca (0.79, 1.19, 1.55, 2.07, 2.38 and 2.81 g/kg DMI) from SBM according to a 6x6 Latin square design for six periods. Chromic oxide (3.5 g/kg diet, on as-fed basis) was included as a digestibility marker. Each experimental period consisted of 8 d with a 6-d adaptation and a 2-d collection of representative fecal samples. There were linear relationships (P<0.05) between the apparent fecal digestible and the total Ca intake in both the barrow and the gilt experiments, indicating true Ca digestibility and the endogenous fecal Ca losses associated with SBM could be measured by the simple linear regression analysis technique. True fecal Ca digestibility (44.3 ± 8.4 vs. 23.4±1.8%, n = 36) and the fecal endogenous Ca loss (1.08 ± 0.01 vs. fecal, 0.43 ± 0.001 g/kg DMI, n = 36) associated with SBM were higher (P<0.01) in the growing barrow than in the gilt. Our results suggest that there are likely differences in true Ca digestibility measured in feed ingredients between barrows and gilts. Barrows may have a high digestive capacity in processing dietary Ca, however, they may have a higher level of Ca requirement for the maintenance due to the larger fecal endogenous Ca loss compared with the gilt.

Key Words: Calcium, Fecal Endogenous Loss, True Digestibility in Pigs

W157 Evaluation of corn grain with the genetically modified event DAS-59122-7 fed to growing-finishing pigs. H. H. Stein*[1], D. W. Rice[2], B. L. Smith[2], M. A. Hinds[2], T. E. Sauber[2], C. Pedersen[3], D. M. Wulf[4], and D. N. Peters[4], [1]*University of Illinois*, *Urbana*, [2]*Pioneer Hi-Bred International Inc.*, *Johnston, IA*, [3]*Danisco Animal Health*, *Marlborough, UK*, [4]*South Dakota State University*, *Brookings*.

An experiment was conducted to assess the nutritional equivalency of corn grain with the genetically modified input trait Cry34/45Ab1 containing the DAS 59122-7 event. This modified transgenic grain is resistant to western corn rootworm and is also tolerant to the herbicide glufosinate-ammonium. The modified grain, a non-transgenic near-isoline control grain, and a commercial hybrid were grown in 2005 in isolated plots (201m apart) at the same location. A total of 108 pigs were allotted to corn-soybean meal diets containing each of the 3 grains as the sole source of corn. Pigs were fed grower diets from 37 to 60 kg, early finisher diets from 60 to 90 kg, and late finisher diets from 90 to 127 kg. Within each phase, data for ADG, ADFI, and G:F were calculated. At the conclusion of the experiment, pigs were harvested at a meat science laboratory and data for carcass quality were collected. Estimate statements were used to compare values from pigs fed diets containing the control corn and pigs fed diets containing the modified corn. Pigs fed diets produced with conventional corn were used as an additional comparator to evaluate the biological significance of any statistical differences. For the entire experimental period, pigs fed the control and the modified corn had similar final BW (128.9 vs. 127.1 kg), ADG (1.02 vs. 1.00 kg per day), ADFI (2.88 vs. 2.80 kg per day), and G:F (0.356 vs. 0.345 kg per kg). Likewise, no differences in dressing percentage (76.48 vs. 76.30%), loin eye area (49.8 vs. 50.4 cm^2), 10^{th} rib back fat (2.20 vs. 2.12 cm) and lean meat (52.9 vs. 53.4%) were observed between pigs fed the control and the modified corn grain. It is concluded that the nutritional value of the modified transgenic corn grain containing event DAS-59122-7 is similar to that of its non-transgenic counterpart.

Key Words: DAS-59122-7, Pigs, Transgenic Corn

W158 Reactive lysine in distillers dried grains and distillers dried grains with solubles measured with the homoarginine or the furosine procedure. A. A. Pahm*[1], C. Pedersen[2], D. Simon[3], and H. H. Stein[1], [1]*University of Illinois*, *Urbana*, [2]*Danisco Animal Nutrition*, *Marlborough, UK*, [3]*South Dakota State University*, *Brookings*.

The objective of this study was to measure the concentration of reactive Lys in 36 samples of distillers dried grains with solubles (DDGS) and in 1 sample of distillers dried grain (DDG) using the homoarginine procedure and the furosine procedure. The standardized ileal digestibility (SID) of Lys in these samples had previously been measured using growing pigs. The homoarginine procedure allows for a direct measurement of reactive Lys by converting all reactive Lys in the sample to homoarginine via guanidination with O-methylisourea. The homoarginine concentration in each sample can then be directly measured. The furosine procedure on the other hand measures the concentration of furosine in each sample, which allows for the calculation of the un-reactive (blocked) Lys in the samples. By subtracting the amount of un-reactive Lys from the total Lys in the sample, the concentration of reactive Lys is calculated. Results of the experiment showed that the concentration of reactive Lys was 74.5% of the total Lys in the samples if the homoarginine procedure was used and 82.5% if the furosine procedure was used. Therefore, the amount of un-reactive Lys in the samples was calculated as 25.5 and 17.5%, respectively, by the homoarginine and the furosine procedures. This indicates that a relatively large proportion of the Lys in DDGS and DDG has been heat-damaged during drying of the samples. The values for reactive Lys were correlated with the concentrations of SID Lys in the samples. The results of these analyses indicated that reactive Lys measured by the homoarginine procedure or the furosine procedure was correlated with SID Lys with reasonable accuracy (r^2 = 0.69 and 0.65, respectively; $P \leq 0.01$). It is concluded that some of the Lys in DDGS and DDG is un-reactive and that the concentrations of un-reactive and reactive Lys in the samples may be measured using either the homoarginine or the furosine procedure.

Key Words: Furosine, Homoarginine, Reactive Lys

W159 Ensilage of the high moisture sorghum related to the endosperm structure and starch granules. A. B. R. C. Lopes*[1], D. A. Berto[1], M. Cereda[2], M. Leonel[2], and C. Costa[1], [1]*FMVZ/UNESP*, *Botucatu, SP, Brazil*, [2]*Cerat/FCA/UNESP*, *Botucatu, SP, Brazil*, [3]*FAPESP*, *São Paulo, SP, Brazil*.

The high moisture sorghum grains, naturally moist or reconstituted grains, offers advantages if compared to dry grains, as it deactivates the tannin and improves the protein digestibility. Thus, positive results were obtained in studies that employed the sorghum silage for poultry and piglets. The storage of grains picked with high moisture under anaerobiosis conditions can be a more practical solution, if compared to the dry grains. The silage offers reduced production costs and presents agronomical advantages, such as early harvest (about three to four weeks in advance), enabling a more effective utilization of the harvesting machines, thus leaving the area free for other cultivations, reduced contamination and losses in the field (stratification, insects and fungi) and in the harvest process, reduced qualitative and quantitative losses of grains attacked by worms and moths in the storage area, better digestibility and animal performance. The purpose of this study was to evaluate the ensilage effects of high moisture sorghum grains on the silo temperature, quality parameters and the changes in the endosperm and starch granules. The treatments were studied: dry grinded sorghum (low tannin); dry grinded sorghum (high tannin); high moisture grinded and ensilaged sorghum (low tannin); high moisture grinded and ensilaged sorghum (high tannin). The values of pH silages varied between 3.80 to 4.0. The high moisture grain ensilage and chemical preservation determined a reduction of the starch contents, if compared to the dry sorghum. During the ensilage process, there was a rupture of the proteic matrix (that involves the starch granules), and structural alterations, such as the increase of the pore diameters, similar to that occurring in the enzymatic digestion.

Key Words: Starch, Temperature Monitoring, Silage of High Moisture Grains

W160 Effect of weaning age on nursery pig growth performance. B. E. Bass*, C. L. Bradley, Z. B. Johnson, J. W. Frank, and C. V. Maxwell, *University of Arkansas*, *Fayetteville*.

Two studies were performed to determine the effect of weaning age on pig performance in the nursery. Feed intake and BW were recorded at the end of each phase. Initial BW was used as a covariate in the data analysis. In experiment 1, 270 pigs [GPK348 × EB and (GPK348 × GPK4) × EB] were weaned at an average of 18.2 d of age (BW = 6.42 kg) or 20.8 d of age (BW = 6.48 kg) and housed 9 pigs/pen in a wean-to-finish facility. Pigs were fed common Phase 1 (d 0 to 13) and Phase 2 (d 13 to 34) diets. There were no differences in BW, ADG, ADFI, or G:F with weaning age in the wean-to-finish facility.

In experiment 2, 252 pigs (GPK35 × EBX) were weaned at an average of 19.0 d of age (BW = 5.91 kg) or 21.8 d of age (BW = 6.55 kg) and housed 6 pigs/pen in an offsite nursery. Pigs were fed common Phase 1 (d 0 to 13), Phase 2 (d 13 to 28), and Phase 3 (d 28 to 41) diets. Pigs weaned at 21.8 d of age were heavier than pigs weaned at 19.0 d of age at the end of Phase 1 (10.15 vs. 9.83 kg), Phase 2 (19.23 vs. 18.52 kg), and Phase 3 (28.95 vs. 27.77 kg) ($P < 0.05$). Additionally, ADG was greater for pigs weaned at 21.8 d during Phase 1 (302 vs. 277 g/d), Phase 2 (606 vs. 578 g/d), Phase 3 (748 vs. 710 g/d), and over the entire nursery period (554 vs. 525 g/d) ($P < 0.05$). Pigs weaned at 21.8 d of age also had greater ADFI than those weaned at 19.0 d of age during Phase 1 (379 vs. 351 g/d), Phase 2 (996 vs. 927 g/d), Phase 3 (1422 vs. 1315 g/d), and over the entire nursery period (936 vs. 867 g/d) ($P < 0.05$). There were no differences in G:F between the two weaning groups. Results of this study indicate that differences exist in performance due to weaning age when pigs are weaned into an offsite nursery, with pigs weaned at 21.8 d of age having improved overall growth performance compared to 19.0 d of age. It appears that the increased performance throughout the nursery period in the group weaned at 21.8 d of age can be attributed to increased feed intake, and not improved feed efficiency.

Key Words: Pigs, Weaning Age, Growth

W161 The endosperm structure and starch granules to ensilage of high moisture corn grains. A. B. R.C. Lopes*[1], D. A. Berto[1], M. Cereda[2], M. Leonel[1], and C. Costa[1], [1]*Faculdade de Medicina Veterinária e Zootecnia/UNESP*, *Botucatu, SP, Brazil*, [2]*Cerat/FCA/UNESP*, *Botucatu, SP, Brazil*.

In order to evaluate the effects of high moisture corn grains silage related to the product's final quality and the modifications in the endosperm and starch grains, the following treatments were studied: The following types of treatment were studied (T): T1- Dry whole corn; T2- Dry grinded corn; T3- High moisture grinded and ensiled corn. The high moisture corn grains were grinded at a mill using a 6-mm sieve, while the dry corn was triturated using a 2mm sieve. The silages were stored in 100-liter plastic silos. The temperature monitoring inside four silos of each type of treatment was performed using copper-constantan thermocouples (T type) of PVC insulation and 2X24 AWG, coupled to a data acquisition system equipped with own software, programmed to perform readings at regular intervals of 10 seconds. The temperatures were stored, and the system produced an average value each two hours, also recording the ambient temperature of the places where the silos where located. The samples of dry grains and high moisture ensiled grains were collected and immediately submitted to the pH, granulometry and moisture analyses. The determination of the total starch content followed the methodology of the International Norm ISO 6647. Analyses in scanning microscope were conducted to evaluate the endosperm and the starch granule structures, at the laboratory of the Electronic Microscopy Center of UNESP Biosciences Institute, in Botucatu. The high moisture grain ensilage determines a reduction of the starch contents, if compared to the dry corn. There were some changes during the ensilage process: the rupture of the proteoleic matrix (that involves the starch granules), and structural alterations, such as the increase of the pore diameters and the central concavity, similar to that occurring in the enzymatic digestion.

Key Words: Starch, Temperature Monitoring, High Moisture Grains

W162 Effects of feeding alfalfa on nursery pig growth performance. C. L. Martin*[1], J. W. Frank[1], Z. B. Johnson[1], G. M. Weiss[2], and C. V. Maxwell[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Progress Plus LCC*, *Lancaster, WI*.

Two experiments were conducted to determine the effects of feeding high quality, low fiber alfalfa on growth performance during the nursery period. Typical nursery diets were fed in three phases. Diets in each phase consisted of 0, 5, or 10% alfalfa. A late fall cutting of alfalfa leaves and stems were used in experiment 1 and alfalfa leaves were used in experiment 2. Diets were fed from d 0 to 42 after weaning [Phase 1 (d 0-14), Phase 2 (d 15-28), and Phase 3 (d 29-42)]. In experiment 1, 270 pigs (initial BW = 6.65 ± 0.01 kg) were blocked by BW and randomly allotted to one of the three treatments and reared in a wean-to-finish facility (9 pigs/pen). In Phase 1 and 2, ADG decreased quadratically with increasing alfalfa level ($P = 0.03$). There were no significant differences in growth performance during Phase 3. Overall, ADG (0.493, 0.506, 0.474 kg/d; respectively, $P = 0.02$) and final BW (26.92, 27.38, 26.09 kg/d; respectively, $P < 0.02$) increased quadratically with increasing level of alfalfa. In experiment 2, 234 pigs (initial BW = 6.23 ± 0.01 kg) were blocked by BW and randomly allotted to one of three treatments and reared in a conventional nursery (6 pigs/pen). In Phase 1, ADG, ADFI, G:F and BW decreased linearly with increasing level of alfalfa ($P < 0.03$). During Phase 2, ADG, ADFI, and BW decreased quadratically with increasing level of alfalfa ($P < 0.03$). There were no significant differences in growth performance during Phase 3. Overall, ADG (0.437, 0.425, 0.391 kg/d; respectively) ADFI (0.647, 0.642, 0.601 kg/d; respectively) and BW (24.29, 23.96, 22.59 kg; respectively) decreased linearly with increasing level of alfalfa ($P < 0.01$). In summary, feeding greater than 5% alfalfa during Phase 1 and 2 to pigs during the nursery period may decrease average daily gain and body weight. However, Phase 3 nursery diets containing 10% alfalfa had no effect on growth performance.

Key Words: Pigs, Alfalfa, Growth

W163 Effect of *Ascophyllum nodosum* extract on growth performance, nutrient digestibility, carcass characteristics and selected intestinal microflora populations of grower-finisher pigs. G. E. Gardiner[1,2], A. J. Campbell[1,3], J. V. O'Doherty[3], E. Pierce[3], P. B. Lynch[1], F. C. Leonard[3], C. Stanton[1,2], R. P. Ross[1,2], and P. G. Lawlor*[1], [1]*Teagasc, Moorepark Research Centre*, *Fermoy, Co. Cork, Ireland*, [2]*Alimentary Pharmabiotic Centre*, *Cork, Ireland*, [3]*University College Dublin*, *Belfield, Dublin, Ireland*.

Two experiments were conducted to assess the effect of dietary supplementation with increasing levels of *Ascophyllum nodosum* extract (ANE) on growth performance, carcass characteristics, diet digestibility and gastrointestinal microflora of grow-finisher pigs. In experiment 1, 360 pigs were allocated, based on live-weight and sex, to one of four treatments as follows; control diet (no ANE), control diet plus 3 g/kg ANE, control diet plus 6 g/kg ANE and control diet plus 9 g/kg ANE. These diets were fed *ad-libitum* up to slaughter. At slaughter, ileal, caecal, colonic and rectal digesta as well as ileum and colon tissue were sampled from eight animals per group for microbiological analysis. In experiment 2, eight male pigs were allocated to a control diet (no ANE) or the control diet plus 2.5 g/kg ANE to determine effects of ANE on coefficient of total tract apparent digestibility (CTTAD) of nutrients and nitrogen (N) balance. Supplementation with increasing levels of ANE resulted in reduced

daily gain, carcass weight and kill-out yield during the combined grower-finisher period (P<0.05); however, there were no effects of treatment on feed intake, feed conversion ratio or carcass characteristics. Increasing levels of dietary ANE resulted in decreased ileal coliform counts (P<0.05). Increasing dietary ANE levels tended to increase adherent lactobacilli in the colon (P=0.08) but caecal bifidobacteria declined (P<0.05) and there were trends towards a linear reduction in colonic bifidobacteria (P=0.08) and towards a quadratic effect on rectal lactobacilli (P=0.08). Intestinal pH was unaffected by ANE supplementation (P>0.05). In experiment 2, the CTTAD of nutrients was unaffected by the inclusion of ANE (P>0.05). Overall, the intestinal coliform reductions obtained suggest that ANE may provide a dietary means to improve gut health in finishing pigs. However, the negative effects on growth performance observed in healthy animals will most likely limit the commercial use of dietary ANE as a feed additive.

Key Words: *Ascophyllum nodosum*, Intestinal Microflora, Pig

W164 Effects of energy and lysine intake during late gestation and lactation on the lactational performance in multiparous sows. S. Heo, Y. X. Yang, Z. Jin, J. H. Yun, J. Y. Choi, B. K. Yang, and B. J. Chae*, *Kangwon National University*, *Chuncheon, Kangwon-Do, Republic of Korea*.

A 3 × 2 factorial experiment was conducted to evaluate different dietary levels of energy and lysine during late gestation and lactaion period on reproductive performance in multiparous sows. A total of 36 sows (Yorkshire × Landrace, 3-4 parity) were divided into 6 treatments and each treatment had 6 replicates comprising 1 sow/pen. Treatments consisted of three energy levels (3,265, 3,330, 3,400 ME/kg) and two lysine levels (0.6, 0.8%) during late gestation (from 80th day) and three energy levels (3,265, 3,330, 3,400 ME/kg) and two lysine levels (1.0, 1.3%) during lactation, respectively. The experiment started at 80th day of gestation and the lactational period lasted for 25 days. The higher lysine group significantly affected body weight change (p<0.05) and backfat thickness change (p<0.001) of multiparous sows during both late gestation and lactation. Average daily feed intake was not affected (p>0.05) by either energy or lysine in the diets. During lactation, live birth weight/litter (p<0.01), weanling weight/litter (p<0.01) and growth rate of piglets (p<0.05) were increased as lysine intake was increased. No difference was found piglet's growth performance by dietary energy levels. Wean-to-estrus interval was reduced (p<0.001) in the high lysine group. In conclusion, higher lysine levels than those suggested by NRC (1998) improved body condition and reproductive performance during late gestation and lactation in multiparous sows.

Key Words: Multiparous Sows, Energy, Lysine

W165 Effects of dietary energy and lysine levels during late gestation and lactation on the lactational performance in primiparous sows. S. Heo, Y. X. Yang, Z. Jin, J. H. Yun, J. Y. Choi, B. K. Yang, and B. J. Chae*, *Kangwon National University*, *Chuncheon, Kangwon-Do, Republic of Korea*.

The effects of energy and lysine intake during late gestation and lactation on reproductive performance of primiparous sows were evaluated using 36 gilts (Yorkshire × Landrace). The sows were allocated to six dietary treatments according to a 3 × 2 factorial arrangement and each treatment had 6 replicates comprising 1 sow/pen. Treatments consisted of three energy levels (3,265, 3,330, 3,400 ME/kg) and two lysine levels (0.6, 0.8%) during late gestation (from 80th day) and three energy levels (3,265, 3,330, 3,400 ME/kg) and two lysine levels (1.0, 1.3%) during lactation (25 days), respectively. Gilts fed the high lysine diet gained more weight (p<0.01) and higher backfat thickness (p<0.05) than those fed the low lysine diets. A same trend was shown during lactation. Average daily feed intake was not affected (p>0.05) by either energy or lysine. Birth weight (p<0.001), weanling weight (p<0.001) and growth rate of piglets (p<0.001) were increased as lysine intake increased during lactation. High dietary lysine levels during lactation decreased wean-to-estrus interval (p<0.01). From the present study, it can be concluded that higher lysine levels than those recommended by NRC (1998) could improve the reproductive performance during late gestation and lactation in primiparous sows.

Key Words: Primiparous Sows, Energy, Lysine

W166 Effect of GnRH-analogue and chromium methionine supplementation on reproductive performance of the female pig. J. A. Romo*[1], R. Barajas[1], J. J. Valencia[2], E. Silva[3], and F. Juarez[1], [1]*FMVZ-Universidad Autonoma de Sinaloa*, *Culiacan, Sinaloa, Mexico*, [2]*FMVZ-Universidad Nacional Autonoma de Mexico*, *Mexico, D.F., Mexico*, [3]*FMVZ-Universidad de Colima*, *Colima, Colima, Mexico*.

To determine the effect of GnRH-analogue injection (GnRH-A) and chromium methionine (CrMet) supplementation on reproductive performance of young and multiparous sows, two experiments were performed. Experiment 1: One hundred twenty eight hybrid young sows were used, in a randomized experimental design with a factorial arrangement 2 x 2. Young sows were designed for receive: Diets supplemented or not with 0.4 ppm of Cr (Microplex®, Zinpro Co.) during tree subsequent reproductive cycles, and the application or not of 50 µg de GnRH-A (Fertagyl®, Intervet Lab) four days before of the weaned. Chromium addition and GnRH-A application had not effect (P > 0.16) on the litter size and litter weight at time born; however, the farrowing rate at first service after weaning was improvement (P < 0.02) both for Cr or GnRH-A used alone or together (76% vs. 89%). Cr supplementation diminished (P < 0.001) 35% the interval weaning-first oestrus (7.89 vs. 5.11 d), and GnRH-A application diminished (P = 0.02) 25% this variable (7.41 vs. 5.59 d). An interaction (P < 0.05) Cr x GnRH-A was found, where young sows receiving joint Cr and GnRH-A treatments shown the lowers values. Experiment 2: Two hundred thirty nine multiparous hybrid sows were used, to probe the same treatments that experiment 1. Cr addition and GnRH-A application had not effect (P > 0.23) on the litter size, litter weight at time born, and the farrowing rate at first oestrus after weaning of the multiparous sows. Cr supplementation diminished (P < 0.01) the interval weaning-first oestrus (5.36 vs. 4.53 d). An interaction (P = 0.04) Cr x GnRH was observed where sows receiving joint Cr and GnRH-A treatments had higher values than sows that received Cr only. These results suggest that both chromium supplementation and GnRH-A injection are able to improve reproductive performance in both young and mature sows.

Key Words: Chromium, GnRH-A, Sows

W167 Effects of yeast culture supplementation to lactation diet on lactation performance of sows. C. Vasquez*[1], A. T. Moore[1], C. R. Richardson[2], and S. W. Kim[1], [1]*Texas Tech University*, *Lubbock, TX, USA*, [2]*Texas State University*, *San Marcos, TX, USA*.

This study was conducted to determine the effect of yeast culture (Gro-Tec) supplementation to lactation diet on lactation performance of sows. Twenty-four pregnant sows were selected for this study. All pregnant sows were fed the same 2 kg gestation diet (12.2% CP, 3.1 Mcal ME/kg) per day until farrowing. Two sows did not farrow and thus eliminated from the study. Immediately after farrowing, sows were allotted to two dietary treatments (11 sows each). Treatments were: (1) CON (sows fed a corn-soybean meal basal diet during lactation); and (2) GT (sows fed a basal diet with 60 g yeast culture/day, top-dressed). The basal diet contained 19.2% CP and 2.37 Mcal ME/kg. Sows received yeast culture (top-dressed) from d 0 to d 17 of lactation (at weaning) according to their assignment. Within a treatment, litter size was set to 9 pigs by cross-fostering and this was done by 36 h post-farrowing. Sow had access to feed and water ad libitum during 17-d lactation. Voluntary feed intake was measured daily. Sow body weight was measured at d 0 (within 12 h farrowing), 7, 14, and 17 of lactation. Body weight of nursing piglets was also measured at d 0, 7, 14, and 17 of age. Sows weaned the litter at d 17 of lactation and moved back to gestation crates. Number of days-return-to-estrus was measured for each sow. Litter size and litter weight at birth did not differ between the treatment groups. Litter size at weaning did not differ between the treatment groups. However, litter weight gain of GT (18.1 kg) tended to be greater (P=0.052) than that of CON (16.6 kg). Body weight of sows after farrowing did not differ between the treatment groups. Body weight loss during the 17 d lactation period was 11.7 kg for CON and 17.3 kg for YC but there was no statistical difference. Voluntary feed intake of sows and days return-to-estrus did not differ between the treatment groups. This study indicates a possible benefit of yeast culture supplementation on litter weight gain.

Key Words: Yeast Culture, Sow, Litter Weight Gain

W168 Antibiotics, acidifiers or yeast on the productive performance of growing pigs challenged with *Salmonella cholerasuis*. A. A. Martinez*[1], J. Lopez[1], J. N. Vazquez[1], B. Merino[2], G. E. Lanz[2], and J. A. Cuaron[3], [1]*CENID-Microbiologia,INIFAP*, *Mexico*, [2]*PIEPEME, A.C.*, *Mexico*, [3]*CENID-Fisiologia Animal, INIFAP*, *Mexico*.

The effect of different feed additives used as non-antibiotic growth enhancers, under an induced salmonella infection, was studied using 96 pigs with an average BW of 42.18+ 7.02 kg. The animals were randomly assigned to six dietary treatments (given in four 21 days feeding phases): CON: Control (without additives); ATB: Antibiotic, Chlortetracycline (200 ppm) and furazolidone 220 ppm during feeding phase one and Tylosine (110 ppm) during feeding phase three; SC: Live yeast, *Saccharomyces cereviseae*, strain Sc47 at 3 kg/MT; BAC: Benzoic acid 5 kg/ton; COA: a commercial mix of organic acids that included Phosphoric cid, formic acid and lactic acid (2kg/ton); ORE: oregano extract 500 g /ton. During phase 4 no additives were used. Each treatment had 4 replicates with 4 pigs each. Performance was measured during 90d. On days 12 and 16, pigs were challenged orally with $1x10^9$ cfu of *Salmonella cholerasuis*, isolated from a clinical case. ADG decreased from day 12 to 34 post inoculation in all treatment groups, this growth depression was less severe (P<0.01) on pigs receiving BAC. Daily feed intake was similar (P>0.05) among treatments during all the study period. Accumulated ADG was greater (P<0.01) for ATB, SC and BAC (848, 804 and 830g respectively) vs. CON, COA and ORE (760, 760 and 769g respectively). The antibiotics used during phase 1 were specific for the control of Salmonella; in preious studies, SC has shown a great capacity to precipitate pathogenic salmonellae and BAC greatly reduces microbiological counts in feces; acidifying agents or herbal extracts have unspecific effects, thus these results are not surprising and give light to alternative preventive treatments for oral infections.

Key Words: Organic Acids, Yeast, Salmonella

W169 Benzoic acid as feed additive for growing pigs naturally infected with *Salmonella cholerasuis*. A. A. Martinez*[1], J. Lopez[1], B. Merino[2], J. Cervantes[3], and J. A. Cuaron[4], [1]*CENID-Microbiologia, INIFAP*, *Mexico*, [2]*PAIEPEME, A. C.*, *Mexico*, [3]*DSM Nutritional Products*, *Mexico*, [4]*CENID-Fisiologia Animal, INIFAP*, *Mexico*.

A total of 120 pigs were used to evaluate the effects of adding benzoic acid (BZA), alone or in combination with antibiotics, to enhance productive performance of growing-finishing pigs recovering from a natural salmonella infection (*Salmonella cholerasuis*) adquired at site 2 facility. With the appropriate use of antibiotics, the infection was apparently controlled and, twelve days after, pigs were moved (BW=18.9+1.2 kg) to a site 3 facility (day 0), where they were allotted to 6 treatments, from a 2x3 factorial arrangement: BZA (0 or 5 kg/ton); and the use of antibiotics: Control (none added), growth enhancement antibiotic (Virginiamicine, 10ppm) or therapeutic antibiotic for unspecific respiratory diseases (Tylosine, 110 ppm). Each treatment had 4 replicates with 5 pigs per replicate. On d-42 of the experiment, clinical signs of salmonellosis were observed and the presence of *Salmonella spp*., probably carried out from the site 2 facility, was confirmed by bacteriological studies. BZA and the use of antibiotics did not result (P>0.05) in an interaction for any of the response criteria. There were no differences among treatments (P>0.05) on morbidity, but mortality was reduced (P<0.08) after BZA and the therapeutic antibiotic compared with the control (1.2 and 2.4 vs. 6%). Daily feed intake was not affected by Treatments (P>0.05), but BZA and the therapeutic antibiotic improved daily weight gain (P<0.01) during the first 28 days; this response was sustained until day 49 (P<0.06), but later period responses were similar (P>0.24). After 105 days, use of the therapeutic antibiotic during recovery resulted in pigs 7kg heavier (P<0.01) and BZA gave an advantage of 4kg (P<0.06) in the same period, over Control and the antibiotic as a growth enhancer. Tylosine actes to prevent possible respiratory consequences; BZA could be of help in the control of intestinal problems, but apparently it is not a substitute for the therapeutical use of antibiotics.

Key Words: Benzoic Acid, Salmonella, Pigs

W170 Response of grower pigs to dietary inclusion of naked oats (Avena nuda). P. B. Lynch*[1], P. G. Lawlor[1], and J. Burke[2], [1]*Teagasc, Moorepark Research Centre*, *Fermoy, Co. Cork, Ireland*, [2]*Teagasc, Oakpark Research Centre*, *Carlow, Ireland*.

Naked oats (Avena nuda) is a crop with potential agronomic advantages when used in a cereal rotation in Ireland. In contrast to hulled oats

(Avena sativa) naked oats is low in fibre and high in oil and protein. The oats have been fed to pigs with varying degrees of success. The object of this trial was to evaluate naked oats as a direct replacement for wheat in diets for grower pigs in the weight range 14 to 34kg. Single-sex pairs of pigs (n=48) were used in a randomised complete block design with four treatments. The control diet contained (g/kg) barley - 225, wheat - 455, soya bean meal - 180, heat treated soya beans - 100, lysine HCl - 4, DL-methionine - 2, L-threonine - 1.5, minerals and vitamins. The diet contained (calculated values) 14.1 MJ digestible energy, 196g crude protein and 13g total lysine, 5.0g methionine, 3.5g cystine, 8.6 threonine and 2.5g tryptophan. Naked oats replaced wheat at 100, 200 and 300g/kg. The diets were fed ad libitum as 5mm pellets. Daily weight gain was 719, 695, 673 and 694 (NS, s.e. 23.7 g/day), feed conversion ratio (FCR) was 1.52, 1.59, 1.61 and 1.56 (s.e. 0.026) for control, 100, 200 and 300 inclusion levels. The quadratic effect for treatment differences in FCR was significant (P<0.05). It is concluded that naked oats can replace wheat in the diet of young growing pigs at up to 300g/kg.

Key Words: Naked Oats, Grower Pigs

W171 Comparison of growing swine performance when diets containing DL- methionine and cull chickpeas in substitution of soybean meal and corn. J. M. Uriarte*, J. F. Obregón, H. R. Guemez, O. S. Acuña, and F. G. Ríos, *Universidad Autónoma de Sinaloa*, *Culiacán, Sinaloa, México*.

To determinate the effect of substitution of soybean meal and corn for cull chickpeas on growth performance, 48 pigs (BW = 27.475 ± 0.896 kg; Large white x Landrace x Large white x Pietrain) in groups of four were placed in 12 concrete floor pens (2.5 x 2.5 m). Pens were fed one fo three diets: 1) Diet with 17.21 % CP and 3.35 Mcal ME/kg, containing corn 71.0 %, soy bean meal 25 %, and premix 4 % (CONT); 2) Diet with 17.1 % CP and 3.35 Mcal ME/kg with corn 37 %, cull chickpeas 50 %, soybean meal 9 %, and premix 4 % (CHP50) and 3) Diet similar to CHP50 with 0.2 % of DL-methionine additioanated (CHP50M). Pigs were weighed at days 0 and 49 of experiments and feed intake was recorded daily. ADG and feed intake/gain ratio were calculated from these data. Body weigth at day 49 (56.063, 51.688 and 53.125 kg) were not affected (P=0.09) by CONT, CHP50 and CHP50M, respectively. ADG (0.584, 0.429 and 0.525 kg) was not similar (P=0.05) between CONT and CHP50. Feed intake (1.459, 1.441 and 1.472) was not modified (P=0.85) by treatments. Feed/gain ratio (2.506, 2.936, and 2.9811) was different (P=0.01) between CONT with CHP50 and CHP50M treatments. It is concluded, that cull chickpeas additionated with 0.2 % of DL-methionine can be used up 50 % in diets for growing pigs without affecting body weight, average diary gain and feed intake, but increased feed intake/gain ratio.

Key Words: Chickpeas, Growth Performance, Methionine

W172 Use of a selected clay in growing pigs fed zearalenone contaminated sorghum grain. J. Lopez[1], A. A. Martinez*[1], D. V. Gonzalez[1], and J. A. Cuaron[2], [1]*CENID-Microbiologia, INIFAP*, *Mexico*, [2]*CENID Fisiologia Animal, INIFAP*, *Mexico*.

Certain clays are used as feed additives to decrease the effects of mycotoxins. An experiment was conducted to evaluate the use of a selected clay (Mexsil)® on the prevention of growth depression of growing pigs consuming a grain naturally contaminated and with marginal toxic levels of mycotoxins. One hundred an twenty pigs (30.03 kg avg. initial BW), were allotted to 4 dietary treatments, from outcome groups formed by litter of origin, sex and weight, in a Randomized Complete Block design. Treatments were a 2x2 factorial arrangement: level of zearalenone (ZEA) in sorghum (LOW, 21.6 to 41.6 and HIGH, 111.2 to 146.6 mg/ton) and the addition or not of Mexsil®(Control and 5 kg/ton). Performance was measured during 98 days. As the inclusion of sorghum grain in three feeding phases, as well as the daily feed intake increased, the dose (µg/ kg BW) of ZEA received went from 1.66 to 0.91 for the LOW and from 5.87 to 2.98 for HIGH, for the feeding phases 1 to 3. For these reasons, differences in response to the addition of Mexsil®and the level on ZEA were greater during days 0 to 70 of the experiment. No clinical signs of mycotoxicosis were observed. Daily feed intake and feed efficiency were not affected by the level of ZEA (P>0.05), but ADG was lower (P<0.01) for pigs consuming the HIGH level of mycotoxins (755 vs. 837 g). Mexsil® addition improved (P<0.05) ADG (814 vs. 778 g) as was able to maintain gains of pigs consuming ZEA at higher levels. Mexsil® and ZEA did not result in an interaction for any of the response criteria. Use of this clay was effective to improve productive performance of pigs in presence of a subclinical levels of ZEA.

Key Words: Zearalenone, Clay, Pigs

W173 Effects of flaxseed and carbohydrase enzyme on portal blood short chain fatty acids, caecal digesta amine content and tissue fatty acid profiles in piglets. E. Kiarie*, B. A. Slominski, and C. M. Nyachoti, *University of Manitoba*, *Winnipeg, MB, Canada*.

We previously demonstrated that piglets fed flaxseed (FS)-containing diets with or without a multi-carbohydrase enzyme (CE) blend had reduced ileal microbial activity. Further studies were conducted to determine portal venous plasma short chain fatty acids, cecal spermidine, loin and liver fatty acid profiles and fecal fat digestibility. Ninety-six weaned pigs (6.1 kg initial BW) were assigned to 4 diets in a completely randomized design (6 replicate pens of 4 pigs each). Diets consisted of a basal diet containing 0% or 12% FS and were fed with or without CE containing pectinase, cellulase, mannanase, xylanase, glucanase and galactanase activities. Diets were fed for 28 d after which time fresh fecal samples were collected and 1 pig per pen was held under a surgical plane of anesthesia to sample portal blood. Pigs were then killed by an intracardiac injection of sodium pentobarbital (110mg/kg) to sample cecal digesta, liver and loin area tissues (loin muscle plus back fat). Piglets fed FS diets had lower portal acetic acid (0.58 vs. 0.72, mmol/L; P = 0.05) and higher lactic acid (3.17 vs. 2.21, mmol/L; P = 0.04) compared with those fed non-FS diets. In the caecum, FS diets resulted in lower spermidine levels (0.65 vs. 0.98, PPM; P = 0.01) compared with non-FS diets. Flaxseed fed piglets had lower omega-6 to omega-3 fatty acid ratios in the liver and loin area (1.7 vs. 4.1, g/100g; P = 0.0001 and 3.5 vs. 6.6, g/100g; P = 0.0001, respectively) compared to non-FS diets. Pigs fed FS diet had lower (P = 0001) fecal fat digestibility compared with pigs fed non-FS diets. There tended to be an interaction between FS and CE in fat digestibility and tissue omega-3 fat deposition such that in FS fed

piglets CE supplementation resulted in higher fecal fat digestibility and tissue omega-3 fat deposition. In conclusion, feeding FS with or without CE supported lactic acid ferementors in the in the gastrointestinal tract. Although overall low fat digestibility was observed high omega-3 retention in FS fed piglets was evident.

W174 Biochemical profile of broilers fed diets supplemented with amylase from *Cryptococcus flavus* and *Aspergillus niger* HM2003. C. S. Minafra[2,1], J. H. Stringhini*[1], S. F. F. Marques[1], M. A. Andrade[1], C. J. Ulhoa[1], and G. H .K. Moraes[2], [1]*Universidade Federal de Goias*, *Goiania, Goias, Brazil*, [2]*Universidade Federal de Viçosa*, *Viçosa, Minas Gerais Brazil*.

In this experiment, the effect of alpha-amylase addition in broler rations on biochemical seru parameters was evaluated. The enzyme were produced by *Cryptococcus flavus* (CF) in Enzymology Laboratory Biological Sciences, (UFG) and by *Aspergillus niger* HM2003 (AN) in the Biotechnology Center (UFRS). 360 day-old male Cobb chicks were allotted in heated batteries in the Veterinary College, (UFG). Enzymes were added in the first week and from eight to 21 days in a completely randomized design with six treatments and five replications of 12 chicks each. Treatments consisted of pre-starter diets without enzyme (RPSS), with CF amylase (RPSCry) and with AN enzyme (RPSAsp), and starter diets without enzyme (RPS), with CF amylase (RSCry) and with AN enzyme (RSAsp). Statistical analyses were done with SAEG 9.1, using Tukey test 10% probability. Blood were collected at seven and 21 days and centrifuged at 6.000 rpm in 10 minutes to obtain serum. Serum analysis of minerals Ca, P, Cl, K, alkaline phosphatase, and protein was done. No effect in concentrations of K and AP were observed at seven days and for Ca, Cl or AP at 21 d. At 7 d, higher concentration of Ca in RPSCry, P in RPSAsp, Cl in PSV and Prot in RPSVAsp. At 21 d, higher concentrations of Ca, Prot and K in RSVAsp. These parameters indicate serum profile of broilers but didn't characterize the effect of enzymes addition in rations.

Table 1. Serum profile of Ca, P, Cl, K, TP and AP for broiler fed diets containing amylase from *Cryptococcus flavus* and *Aspergillus niger* HM2003

7 days	VPS	VPSCry	VPSAsp
Ca (mg/dL)	5.7b	6.9a	6.0ab

W175 Effects of graded levels of cottonseed cake on performance, haematological and carcass characteristics of broilers fed from day old to 8 weeks of age. G. O. Adeyemo* and O. G. Longe, *University of Ibadan*, *Oyo, Nigeria*.

Cottonseed cake (CSC) has been used as a cheaper alternative to soyabean cake (SBC) in livestock feeding and a source of dietary protein. There is, however, paucity of information on its nutritive value in chickens. This study evaluated the performance, haematological and carcass characteristics of chickens in which CSC replaced SBC in a nutritional experiment. One hundred and eighty day old chicks (DOC) were fed with 5 different diets, such that 0% (control), 25%, 50%, 75% and 100% of CSC replaced SBC from day old to 8 weeks of age. Average weekly gains (AWG), feed conversion ratio (FCR) and dressed weight (DWT) were monitored. Blood samples were collected and analyzed for differential white blood cell count (lymphocyte) and haemoglobin (Hb). Data were analysed using descriptive statistics and analysis of variance. Values of AWG and DWT ranged from 0.1kg to 0.4kg and 1.1kg to 1.8 kg respectively, with 100% CSC and control having the least and the highest values among the treatments. FCR ranged from 1.6 to 4.9. Values of lymphocyte and Hb ranged from 35.2 to 54.0 % and 8.5 to 11.1g/dl respectively. Birds on 75% CSC based diets had blood profile more comparable with the control than those of other diets. CSC can replace up to 75% SBC without adverse effects on performance, haematological values and carcass quality of the birds. This reveals CSC as a potent source of protein for meeting the CP requirements of chickens.

Key Words: Chicken, Cottonseed Cake, Performance

W176 Serum biochemistry profile of broilers fed an enzymatic complex from *Trichoderma harzianum*. S. M. F. Marques[1], C. S. Minafra[2,1], J. H. Stringhini*[1], P. M. Rezende[1], M. A. Andrade[1], M. B. Cafe[1], and C. J. Ulhoa[1], [1]*Universidade Federal de Goias*, *Goiania, Goias, Brazil*, [2]*Universidade Federal de Viçosa*, *Viçosa, MInas Gerais Brazil*.

This experiment were carried out to evaluate serum profile of broilers fed from 1 to 21 d diets with an enzymatic complex (EC) supplement produced by *Trichoderma harzianum*, composed by xylanase, amylase, cellulase and lipase. EC was produced in the Enzimology Laboratory of the Biological Sciences Institute of the Federal University of Goias (UFG). 480 day-old male chicks were allotted in heated batteries located in the Veterinary College (UFG). In the first experiment, EC supplementation was evaluated in pre-starter phase (1 to 7 days) and the second in starter phase (8 to 21 days) in a randomized block design with four treatments and five replicates of 12 chicks each. Treatments in Exp. 1 were: vegetable pre-starter diet non-supplemented (VPS), or supplemented (VPSE), animal by-products and vegetable diet non-supplemented (APS), or supplemented (APSE); in Exp. 2: vegetable starter diet non-supplemented (VS), or supplemented (VSE),

animal by-products and vegetable diet non-supplemented (AS), or supplemented (ASE). Feed and water were offered ad libitum. From one chick per treatment, blood was collected by heart puncture at 7 and 21 days of age for serum separation and analyzed for Ca, P, total protein, alkaline phosphatase, K, Cl. Data was analyzed using SAEG 9.1 and means compared as Tukey test (5%). Ay 7 days, higher concentrations for Ca; Cl and K IN APS, VPS and VPSE, respectively, and higher concentrations for P was observed for the two highest concentrations, APS and VPS. But, for PA, higher results were obtained for VPS, APSE and VPS. No significance occurred for TP concentrations at 7 d and Ca at 21 d of age. At 21 d, highest concentration for P, K and AP for AS. Rations VS, VSE and ASE showed reduced Pt, K and Cl, respectively. These parameters indicates serum profile of broilers but didn't characterize the effect of enzymes addition in rations.

Table 1. Serum profile of Ca, P, Cl, K, TP, AP in broilers fed an *Trichoderma harzianum* enzimatic complex

W177 Feeding performance in laying hens fed diets containing DAS-59122-7 maize grain compared with diets containing non-transgenic maize grain. C. M. Jacobs*[1], P. L. Utterback[1], C. M. Parsons[1], B. Smith[2], M. Hinds[2], D. Rice[2], M. Liebergesell[2], and T. Sauber[2], [1]*University of Illinois*, *Urbana*, [2]*Pioneer Hi-Bred International, Inc.*, *Johnston, IA*.

An experiment using 216 Hy-line W-36 pullets was conducted to evaluate the transgenic maize grain produced from a nonsegregating DAS-59122-7 line that contains the *cry*34Ab1 and *cry*35Ab1 genes from a *Bacillus thuringiensis (Bt)* strain, and the phosphinothricin acetyltransferase *(pat)*gene from *Streptomyces viridochromogenes*. Expression of the *cry*34Ab1 and *cry*35Ab1 genes confers resistance to corn rootworms, and the *pat* gene confers tolerance to herbicides containing glufosinate-ammonium. Pullets (20 wk of age) were placed in cage lots (3 hens/cage, 2 cages/lot) and were randomly assigned to one of three corn-soybean meal dietary treatments (12 lots/treatment) formulated with the following maize grains: near-isoline control (Control), conventional maize (Pioneer hybrid 3394), and transgenic test corn DAS-59122-7 (59122). The experimental diets were fed in mash form from 24 to 36 weeks of age. Differences between 59122 and Control group means were evaluated with statistical significance at $P<0.05$. Body weight and gain, egg production, egg mass, and feed efficiency for hens fed 59122 corn were not significantly different from the respective values for hens fed diets formulated with near-isoline maize grain. Egg component weights, Haugh unit measures, and egg weight class distribution were similar regardless of corn source. This research indicates that performance of hens fed diets containing 59122 maize grain, as measured by egg production and egg quality, was similar to that of hens fed diets formulated with the Control maize grain.

Key Words: *Cry*34Ab1, *Cry*35Ab1, Corn Rootworm

W178 Effects of supplemental humic substances on egg production and quality in laying hens. Q. Wang*, H. J. Kim, J. H. Cho, Y. J. Chen, J. S. Yoo, and I. H. Kim, *Dankook University*, *Cheonan, Choognam, Korea*.

The effects dietary of humic substances (HS) on egg production and egg quality were studied using 252 (55-wk old) ISA brown laying hens. They were divided into 21 groups of 12 hens each and seven groups (experimental units) were assigned to 1) CON (basal diet), 2) HS5 (basal diet + 5% humic substances) or 3) HS10 (basal diet +10% humic substances) in a completely randomized block design. Hens had free access to diets and water for 6 wk and egg production and egg quality were monitored over the 6-wk period. Results showed that 10% dietary HS decreased egg production and yolk diameter ($P<0.05$) compared to CON. Egg weight and yolk color were improved ($P<0.05$) in HS10 compared with CON. Egg shell breaking strength was increased ($P<0.05$) for hens fed HS5 diet compared with the others. There were no effects of treatments on egg shell thickness, yolk index, albumen height and haugh unit. The results suggested that the dietary supplementation of HS at 5 or 10% decreased egg production, but, HS5 could increase egg shell breaking strength. HS10 could increase egg weight and yolk color and decrease yolk diameter.

Key Words: Humic Substances, Egg Production, Egg Characteristics

W179 Enzyme complex containing NSP-enzymes and phytase improves the performance of broilers fed corn or wheat-based diets. A. V. Mori[1], M. Francesch[2], J. McNab[3], A. Knox[3], and P. A. Geraert*[1], [1]*Adisseo France SAS*, *Commentry, France*, [2]*Institut de Recerca i Tecnologia Agroalimentaries*, *Reus, Spain*, [3]*Nutrition Ltd.*, *Roslin, United Kingdom*.

Two experiments were conducted to investigate the benefits of a multi-enzyme complex containing carbohydrolase and phytase activities on the performance of Ross broiler chickens receiving corn or wheat-based diets. In Exp. 1, birds from 1 to 42 days were fed corn-based diets formulated to be phosphorus-restricted (reduction of 0.1% available phosphorus, [AP]) or phosphorus and energy-restricted (reduction of 0.1% AP and 60 kcal ME/kg), or phosphorus, energy and protein-restricted (reduction of 0.1% AP, 60 kcal ME/kg and 0.4% crude protein [CP]) in comparison to a positive control diet, meeting requirements for AP, ME and CP. In Exp. 2, birds from 1 to 40 days were fed wheat-based diets formulated to be phosphorus-restricted (reduction of 0.1% AP), or phosphorus and energy-restricted (reduction of 0.1% AP and 85 kcal ME/kg), or phosphorus, energy and protein-restricted

(reduction of 0.1% AP, 85 kcal ME/kg and 0.3% CP) in comparison to a positive control diet. In both experiments, the three reformulated diets were supplemented or not with RovabioTM Max at 100 g/t. This multi-enzyme complex provided 1,100 visco units of endo-β-1, 4-xylanase, 100 AGL units of endo-1,3(4)-β-glucanase, and 350 RPU of 3-phytase per kg of diet. Supplementation of the reformulated diets with the multi-enzyme complex improved ($P < 0.05$) weight gain of birds (4.0% and 4.6% in Exp.1 and 2, respectively), and weight gain values were comparable to those observed in the positive control groups. Additionally, in both studies, feed conversion of birds fed enzyme-supplemented diets did not differ ($P > 0.10$) from those of birds fed the positive-control diets. These results support that the dietary supplementation of multi-enzyme complex containing NSP-enzymes and phytase is efficient in reducing the phosphorus, energy and protein specifications of either corn or wheat-based diets without performance losses.

Key Words: Phytase, NSP-Enzymes, Broilers

W180 Effects of fermented wild-ginseng culture by-products on egg productivity, egg quality, blood characteristics and ginsenoside concentration of yolk in laying hens. H. D. Jang*, J. H. Cho, Y. J. Chen, J. S. Yoo, and I. H. Kim, *Dankook University*, *Cheonan, Choognam, Korea*.

The present study was to investigate the effect of fermented wild-ginseng culture by-product on egg production, egg quality and blood characteristics in laying hens. The animal used in the experiment were a total of 216 ISA brown laying hens(55 wk old). The experimental diets were basis diet (CON), 2.5% fermented wild-ginseng culture by-product replaced lupin in basis diet (WG1) and 5.0% fermented wild-ginseng culture by-product replaced lupin in basis diet (WG2). The laying hens were allotted into three treatments with six replicate pens per treatment by completely randomized design. Through the whole period of experiment, egg production was significantly increased in WG1 and WG2 treatments compared to CON treatment ($P<0.05$). Egg weight was significantly higher in WG2 treatment compared to CON treatment ($P<0.05$). Yolk color unit was greater in WG1 and CON treatments compared to WG2 treatment ($P<0.05$). Albumin height and haugh unit were significantly improved in WG1 treatment compared to WG2 treatment ($P<0.05$). Red blood cell was significantly lower in WG2 treatment than CON treatment ($P<0.05$). LDL cholesterol was significantly decreased in CON treatment compared to WG2 treatment ($P<0.05$). In conclusion, fermented wild-ginseng culture by-product could improve egg production and egg weight in laying hens.

Key Words: Fermented Wild-Ginseng Culture By-product, Egg, Layer

W181 Effects of enzyme addition to corn-soybean-meal-based diets on performance and processing yields of guinea fowl (*Numida meleagris*) broilers. H. L. Santiago*, J. A. Orama, and A. A. Rodríguez, *University of Puerto Rico*, *Mayagüez, Puerto Rico*.

Recent studies have demonstrated the benefits of supplementation with enzymes such as amylases and proteases to broiler diets based on corn and soybean meal. However, these benefits cannot be extrapolated to the commercial production of other species of domestic animals. The objective of this study was to determine the effects of diet fortification with Avizyme (AV) on guinea broiler growth performance and processing yields. A total of 600 guinea keets were randomly assigned to four dietary treatments with 10 replications of 15 birds per pen and reared until market age (84 d) in a conventional poultry house. Treatments consisted in diets containing 0 (control), 0.025, 0.050, and 0.075% of AV. Birds and feed were weighed weekly until 84 d of age to determine body weight (BW), feed intake (FI) and feed conversion ratio (FCR). At 84 d, 50 birds per treatment were processed to evaluate carcass composition. The weights of new york dressed (NYD), hot ready to cook (HRTC), cold ready to cook (CRTC), and fat pad (FP) were obtained and yields calculated as a percentage from live BW. No differences among treatments were observed for BW, FI, and FCR during the first 28 d of growth. However, from 28 to 84 d of age diet fortification with AV significantly improved FCR and reduced FI when compared to the control diet. At 84 d of age, birds fed diets containing 0.025 AV had significantly lower FI than controls; while birds fed diets with 0.050 and 0.075 % AV had FI similar to the rest of the dietary treatments. Birds fed diets containing 0.025 and 0.075 % AV obtained lower FC than that of controls. Diets containing 0.050% AV had FC similar to the other AV inclusion levels or the control. No significant differences in mortality and processing yields (NYD, HRTC, CRTC, and FP) were observed among treatments. The data obtained suggests that supplementation of corn and soybean meal diets with at least 0.025% improve FCR of guinea broilers without affecting BW at market age and processing yields.

Key Words: Guinea Fowl, Avizyme, Performance

W182 Dietary flaxseed supplementation affects broiler live performance. V. L. Carney*[1], M. J. Zuidhof[1], M. Betti[2], B. L. Schneider[1], R. A. Renema[2], F. E. Robinson[2], and D. R. Korver[2], [1]*Alberta Agriculture and Food*, *Edmonton, Alberta, Canada*, [2]*University of Alberta*, *Edmonton, Alberta, Canada*.

This experiment was conducted as a 2 X 8 factorial, with two dietary levels of ground flaxseed (10 and 17%) and eight durations of inclusion in the diet prior to processing (0 [Contro], 4, 8, 12, 16, 20, 24 and 35 d). Six hundred fifty-six Ross x Ross 308 mixed–sex broilers were evaluated in this study. Birds were weighed as a group each time feed was changed with each new duration. With more than 20 d of feeding duration, the diet containing 17% flaxseed significantly decreased BW and gain and increased feed conversion compared to the diet containing 10% ground flaxseed ($p<0.0001$). Feed intake was not significantly affected. A cost analysis showed that feeding flaxseed is costly due to production losses and increased feed costs. Feeding 10% flaxseed for 4 days increased cost per kg by $0.073/kg. Cost of production was more than $0.97/kg greater for the 17% flaxseed treatment fed for 35 days as compared to no dietary flaxseed. In conclusion, different levels and durations of flaxseed feeding significantly depressed broiler performance and increased associated costs of production.

Key Words: Flaxseed, Polyunsaturated Fatty Acids, Alpha-Linolenic Acid

W183 Effect of alternate lutein and flaxseed enriched diet combinations on production parameters in laying hens. D. Franco-Jimenez*[1,3], R. Renema[1], M. Zuidhof[2], and F. Robinson[1], [1]*University of Alberta*, *Edmonton, Alberta, Canada*, [2]*Alberta Agriculture, Food and Rural Development*, *Edmonton, Alberta, Canada*, [3]*California State Polytechnic University*, *Pomona*.

A total of (144) 56 wk old Lohman White layers were randomly selected and assigned to individual cages (24/diet) with 14L:8D. The hens were fed during 60 days with a regular wheat soybean control (C) diet or enriched diets: 500ppm Lutein diet (L), 10% Flaxseed diet (F) as a source of omega fatty acids, Lutein and flaxseed diet (LF), Alternate one diet (LF1) (Alternating L and F diets every other day), and Alternate two diet (LF2) (Alternating L and F diets every second day). Egg production (EP), feed intake (FI), egg weight (EW) and body weight (BW) data were collected over time and analyzed using repeated measures and proc Mixed of SAS in a completely randomized design. Bone strength, ovary morphology, fleshing (breast weight) and fatness (fat pad) and other carcass characteristics were assessed at 65 wk of age on all birds using proc mixed of SAS. The results showed not treatment effect on EP, poor shell eggs, settable eggs, Haught unit, bone strength, shank with, shank length, and ovary and oviduct weight. Yolk color (Roche® fan) was higher when lutein is added to any of the diets ($p<0.05$). Shell quality (specific gravity, shell weight and shell thickness) was significant reduced ($p<0.05$) on the LF1 and LF2 diets. Breast weight, liver weight and BW was significant reduced on diets containing flaxseed, while fat pad was lower on LF, LF1 and LF2 diets compared to control. Egg weight was lower for LF and LF2 diets and yolk weight was lower for all diets compared to C. Feed intake showed diet by time interaction with not specific pattern for diet over time; however, FI on LF1 and LF2 diets was higher during lutein feed days. These results indicate that using LF1 and LF2 diets do not affect EP, or reduce other production parameters dramatically, maintaining reproduction status and representing a good alternative for enrichment of the egg yolk with a possible reduction of the antagonistic effect observed for flaxseed over lutein incorporation.

Key Words: Laying Hens, Lutein, Omega Fatty Acids

W184 Impact of different sources of dietary unsaturated fatty acids on productive performance and immunological status of broiler chickens subjected to heat stress. M. N. Makled*, A. A. El-Sebaie, O. S. Afifi, and A. A. Nafady, *Assiut University*, *Assiut, Egypt*.

One hundred and eight unsexed one-day old Ross broiler chicks were equally allotted to three groups. Group1 (control) was fed a basal diet containing 4% palm oil which is poor in polyunsaturated fatty acids (PUFA); group2 was fed the basal diet after replacing palm oil with 4% linseed oil which is rich in linolenic acid (ω3); and group3 was fed the basal diet after replacing palm oil with 4% sunflower oil which is rich in linoleic acid (ω6). The experiment lasted for 7 weeks, and the birds were subjected to heat stress (HS) started from the age of 28 days at 35°C for eight hours daily. At 4 weeks of age, all birds were injected intravenously in the wing vein with 0.5 ml of 15% sheep red blood cells (SRBCs) suspension in saline solution of packed SRBCs. Thereafter, different criteria were estimated weekly: body weight, feed efficiency, mortality, blood picture, serum T3 and T4 concentration, and antibody titer response to SRBCs. Also, histopathological changes in bursa and thymus glands were examined at 7 weeks old. The obtained results indicated that different dietary sources of PUFA had no significant effect on the performance of broilers subjected to heat stress from 4 to 7 weeks of age. Meanwhile, their effects on immunological properties were variable. Sunflower oil caused significant increase of antibodies formation, RBCs count, and haematocrit at the first week of subjection to HS. After three weeks of HS, total leukocyte count in palm oil group was significantly lower than in linseed oil group or sunflower oil group. Lymphocytes % increased significantly in linseed oil group and sunflower oil group even before starting heat stress as compared with palm oil group, however, heterophils increased significantly in palm oil group as compared with the other groups. Hence, H/L ratio was significantly lower in linseed oil and sunflower oil groups. Histopathological examination indicated obvious increase in lymphocytes and thymocytes proliferation in bursa and thymus glands, respectively, in linseed oil and sunflower oil groups which may affect the immune potentiality of broilers.

Key Words: PUFA, Heat Stress, Immunity

W185 Dietary supplementation with *atractylodes macrocephala koidz* polysaccharides enhances growth performance and development of immune organs in ducks. L. L. Li*[1], Y. L. Yin[1], B. Zhang[2], G. H. Wen[1,2], A. K. Li[3], Z. P. Hou[1], P. Zhang[1], and G. Y. Wu[1,4], [1]*The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Hunan Agricultural University*, *Changsha, Hunan, China*, [3]*Academy of State Grain Administration of China*, *Beijing, China*, [4]*Texas A&M University*, *College Station*.

This study was conducted to determine the effects of dietary supplementation with *atractylodes macrocephala koidz* polysaccharides (AP) on growth performance and immune function in ducks. A total of 480 one-day-old Cherry Volley ducks were assigned randomly to one of 7 treatment groups, representing dietary supplementation with 0% (control), 0.2, 0.4, 0.6 or 0.8 AP or 0.02% terramycin (an antibiotic) to a corn- and soybean meal-based diet. There were 4 replicates for each treatment group, with 20 and 18 ducks per replicate in Phase I (d 1-14) and Phase II (d 15-28), respectively. All animals had free access to their respective diets and drinking water. In Phase I, dietary supplementation with 0.8% AP increased ADG by 10%, improved feed efficiency by 11%, and altered the ratios of the thymus and Bursa of Fabricius weights to BW ($P< 0.05$). No effect of AP supplementation was observed on the ratio of spleen to BW or serum concentrations of IGF-I and IGF-II ($P>0.05$). In Phase II, dietary supplementation with AP had no effect on ADG or the ratios of the spleen, thymus, and Bursa of Fabricius weights to BW ($P>0.05$), increased feed efficiency and serum concentrations of IGF-I ($P<0.05$), and reduced serum concentrations of IL-6. In both phases, dietary supplementation with other doses of AP had no effect on ADG ($P>0.05$), whereas the antibiotic treatment improved feed efficiency ($P<0.05$) without altering the measured parameters of the immune function. These results indicate that dietary supplementation with 0.8% AP resulted in a beneficial effect on growth performance and development of immune organs in ducks.

Key Words: Polysaccharides, Herbs, Ducks

W186 Production of low cholesterol eggs by dietary supplementation of probiotics and essential trace minerals in laying hen. S. J. You*, C. W. Kang, and B. Y. An, *KonKuk University*, *Seoul, Korea*.

For health-conscious consumers low cholesterol eggs may be an attractive and there were many efforts to reduce content of egg cholesterol using drugs, natural ingredients, mineral, etc. This experiment was conducted to develop dietary regimes for production of low cholesterol eggs by supplementing natural ingredients and trace minerals to laying hen feeds. Two hundred ten Hy-Line Brown layers, 53 weeks of age, used to investigate the effects of feeding diets containing various levels of probiotics and minerals such as copper and selenium on the content of egg yolk cholesterol. The layers were divided into seven groups and fed a commercial diet(control) or one of six experimental diets containing mixtures of various levels of probiotics(0.3, 0.5 and 0.7%), copper(100, 200 and 250 ppm) and selenium(0.3, 1.0 and 1.5 ppm) for 6 weeks. There were no significant differences in egg and eggshell qualities among the groups. The contents of egg yolk cholesterol of the birds fed the mixtures of various levels of probiotics, copper and selenium were significantly reduced by 13.9~25.6% as compared to those of the control($P<0.05$). The expression of 3-hydroxy-3-methylglutaryl coenzyme A reductase mRNA was decreased by the dietary treatments($P<0.05$). In conclusion, dietary mixtures of probiotics, copper and selenium were found to lower cholesterol contents of egg without any adverse effect on laying performance and egg qualities.

Key Words: Egg Cholesterol, Probiotics, Selenium

W187 A dose response comparison of MINTREX® Zn versus Zn-methionine in the presence of a Cu-Zn antagonism in 19 day-old broiler chickens. R. B. Shirley*, C. W. Wuelling, T. R. Hampton, J. J. Dibner, and C. D. Knight, *Novus International, Inc.*, *Saint Charles, MO*.

The following study evaluated the bioavailability of two zinc (Zn) sources, MINTREX® Zn (Mtx-Zn) and Zn-methionine (Zn-Met). The semi-purified basal diet contained 8.5 mg/kg (ppm) Zn and 10 ppm copper (Cu), to which Mtx-Zn or Zn-Met supplied up to 0, 15, 30, or 45 ppm total dietary Zn on an iso-nitrogenous, caloric and methionine-basis (seven treatments). Two additional treatments were added to the experiment by supplementing 250 ppm Cu from $CuSO_4 \bullet 5H_2O$ in diets that contained a dietary Zn level of 30 ppm from either Mtx-Zn or Zn-Met. Broilers were fed the Zn-deficient basal diet for 7 d, and then fed the respective dietary treatments until 19 d. Performance, foot pad development, as well as tibia and hepatic mineral status were measured; tibia histology and foot pad scores were also evaluated. Data were analyzed by ANOVA; and pair-wise comparisons were made to determine if there was a difference in Zn sources at each level of supplementation. Broilers fed the Zn-deficient basal diet consistently had the poorest body weight gain, feed intake, feed conversion, percent tibia ash and tibia ash Zn, and foot pad score ($p < 0.0001$). The addition of Mtx-Zn or Zn-Met resulted in a dose-dependent improvement in each of the latter parameters ($p \leq 0.0001$). There was no difference in the efficacy of Zn sources when compared across the three levels of supplementation. Adding Cu at 250 ppm in the presence of 30 ppm Zn, however, reduced body weight gain ($p = 0.0200$), tibia Cu ($p = 0.0026$) and hepatic Cu ($p = 0.0004$) in birds that consumed Zn-Met when compared to birds consuming Mtx-Zn. These data indicate no difference in the bioavailability of the two Zn sources under standard laboratory battery cage conditions. However, data indicate greater bioavailability of Mtx-Zn in the presence of excess dietary Cu, the conditions under which one would expect improved bioavailability of a chelated trace mineral.

MINTREX® Zn is a trademark of Novus International, Inc. and is registered in the United States and other countries.

Key Words: MINTREX® Zn, Zinc methionine, Mineral antagonism

W188 Use of enriched Selenium yeasts in laying hens diet: effects on production, metabolism, egg Se content and organ Se content. G. Invernizzi*, M. Ferroni, A. Agazzi, R. Rebucci, G. Savoini, A. Baldi, and V. Dell'Orto, *University of Milan*, *Milan, Italy*.

Sixty-four laying hens were assigned to four experimental treatments of 16 animals each allotted in cages per pair: C, control, SS, sodium selenite, Y1, treatment one, Y2, treatment two. All hens were fed the same basal diet (CP 18.30%, EE 6.03%, NDF 10.60%, Ca 3.34% on as-fed basis) without organic Se either than in the feedstuffs (C), plus 0.4ppm sodium selenite (SS), plus 0.4ppm of selenium and *S. cerevisiae* strain 1 (Y1), plus 0.4ppm of selenium and *S. cerevisiae* strain 2 (Y2) for eight weeks from starting laying. Productive performances were evaluate weekly, while egg samples for selenium content were collected on day 0, 18, 36 and 56 of laying period. Blood serum samples for metabolic profile (ALT, AST, ALP, NEFA, total protein, total bilirubin, albumin, cholesterol, glucose, urea content) and Se status were collected at slaughtering. Se organs content (liver, muscle, and skin) was determined on samples collected at slaughtering. No differences were detected on laying rate ($P>0.05$). Serum metabolites did not shown any statistical differences except for lower AST levels in Y1 (167UI/l) and in Y2 (170UI/l) than SS (249UI/l; $P<0.05$). Se egg content was significantly increased in Y1 and Y2 than C and SS (respectively: 1.6ppm, 1.4ppm, 0.5ppm and 0.9ppm on DM basis; $P<0.001$). Serum Se content was higher in Y1 and Y2 than other groups (Y1=0.33ppm, Y2=0.31ppm, C=0.15ppm, SS=0.21ppm on DM basis; $P<0.05$). In the same way liver Se content (Y1=1.92ppm, Y2=2.56ppm, C=1.36ppm, SS=1.65ppm; $P<0.01$), skin Se content (Y1=0.40ppm, Y2=0.43ppm, C=0.22ppm, SS=0.31ppm on DM basis; $P<0.05$), and muscle Se content (Y1=1.22ppm, Y2=0.94ppm, C=0.42ppm, SS=0.39ppm on DM basis; $P<0.05$) were higher in enriched Se yeast groups. The administration of Se enriched live yeasts in laying hens significantly increased the serum and organs Se content with no detrimental effect on productive performance.

Key Words: Selenium Yeast, Laying Hen, Sodium Selenite

W189 Performance of alternative meat chickens for organic markets: Impact of genotype, methionine level, and methionine source. A. C. Fanatico*, T. O'Connor-Dennie, C. M. Owens, and J. L. Emmert, *University of Arkansas*, *Fayetteville*.

Synthetic forms of the amino acid methionine (MET) will be banned from organic poultry diets in the future under the USDA National Organic Program. For organic producers possible alternatives include the use of slow-growing genotypes, which may have lower MET

requirements, and feed formulations utilizing only intact protein sources of MET (no synthetic MET). Three genotypes with different growth rates (Slow, Medium, and Fast) were given a low-MET basal diet or diets containing intermediate or high MET levels that were formulated with or without synthetic DL-MET; thus 5 experimental diets were fed to each genotype. Digestible MET levels (for the low, intermediate, and high MET diets) were 0.30%, 0.36%, and 0.42% in the starter phase, 0.26%, 0.30%, and 0.34% in the grower phase, and 0.22%, 0.26%, and 0.30% in the finisher phase. Twenty male birds were randomly assigned to pens with 5 replicate pens per treatment. Slow, Medium, and Fast birds were raised to 77, 63, and 49 d of age, respectively, and placement of the different genotypes was staggered in order to process all birds on the same day. Carcass and parts yield were calculated from 5 birds from each replicate. Genotype had a significant impact on weight gain, feed intake, feed efficiency, and yield ($P < 0.05$). The Fast birds had higher weight gain, feed efficiency, carcass and parts yield than slower-growing birds. Level of MET had a numerical but not significant impact on weight gain and feed efficiency. However, breast yield of all genotypes was affected by MET level, with higher breast yields from treatments with higher levels of MET ($P < 0.05$). The Slow genotype had lower breast yield than Fast but higher wing and leg yield ($P < 0.05$). Diet formulation without DL-MET (using intact-protein diets with higher crude protein levels) did not compromise growth or yield. These data exhibit the impact of genotype and MET level on performance of birds for organic markets, and demonstrate the use of intact-protein sources as an alternative to synthetic DL-MET.

Key Words: Organic, Methionine, Slow-Growing Poultry

W190 Fractional protein synthesis rate in breast muscle and liver tissues of broiler breeder hens before and after sexual maturity based on using ^{15}N-Phe, and LC-MS and GC-C-IRMS. M. K. Manangi* and C. N. Coon, *University of Arkansas*, *Fayetteville*.

Protein turnover is a continuous process of protein synthesis and degradation in the living system. The literature indicates that though whole body protein synthesis increases, the proportion of these proteins synthesized [i.e. the fractional synthesis rate (FSR), k_s] each day declines. The main objective of this study was to measure k_s for breast muscle and liver tissues in broiler breeder hens at 22 wk (before laying) and 26 wk (after first egg) of age. One hundred, 20 wk old, broiler breeder hens (Cobb500) of uniform body weight were placed in individual breeder cages and fed following breeders' recommendation. Seven birds of uniform body weight were selected each sampling time. Birds were injected with a flooding dose of L-Phe solution (150mM, 38 atom percent excess [^{15}N]Phe prepared from L-Phe (^{15}N, 98%+)) via wing vein at a rate of 10 mL/kg body weight. Plasma, muscle, and liver samples were collected after a 10 min isotopic incorporation period. Acid-soluble fraction, extracted in 2% (w/v) perchloric acid, containing free amino acids was separated from the protein precipitate, and the free and protein-bound Phe enrichment ratios (^{15}N:^{14}N) were measured using LC-MS (High Performance Liquid Chromatography Mass Spectrometry) and GC-C-IRMS (Gas chromatography-Combustion-Isotope Ratio Mass Spectrometry), respectively. The results indicate a decline ($P=0.1856$) in k_s from 38.96%/d at 22 wk to 32.84%/d at 26 wk for muscle and a significant ($P<0.05$) increase in k_s from 79.65%/d at 22 wk to 106.36%/d at 26 wk for liver. In conclusion, the decline in k_s for muscle and increase in k_s for liver at sexual maturity shows that breeders are changing tissue protein synthesis rate in conjunction with egg formation. A better understanding of breeder changes in breast muscle and liver FSR, protein degradation rates, and protein accretion may provide an opportunity to optimize the pullet rearing program, body composition, and breeder intake of nutrients for the purpose of increasing hatching egg production.

Key Words: FSR, Broiler Breeder Protein Degradation

W191 Effects of methionine versus cystine supplementation on egg production parameters and feather quality in Bovan strain laying hens from 20 to 70 weeks of age. S. E. Scheideler*, P. Weber, and S. Shields, *University of Nebraska*, *Lincoln*.

A study was conducted to test the effects of sulfur amino acid supplementation from either methionine (M)(DL-methionine) or cystine (C) (from feather meal) on feather quality and egg production parameters in laying hens from 20 to 70 wks of age. Hens were fed 7 dietary treatments in three phases. Phase I was an 18% protein (P) basal diet with .33% M and .37% C. Diets 2-4 had added M to .38, .40 and .42 % M and diets 5-7 had .41, .44 and .45% C added to the basal C levels. Phase II was a 16 % P basal diet with .28% M and .32% C. Diets 2-4, had added M to .32, .33 and .34% M and diets 5-7 had .32, .36 and .42% added C. Phase III was a 15% P basal diet with .28% M and .35% C. Diets 2-4, had added M to.32, .34 or .37% M and diets 5-7 had .38, .40 or .43% C. Diets were isocaloric and formulated to meet Bovan strain nutrient intake recommendations. Diet significantly affected egg production (EP) during all 3 phases of the trial. During P I, hens fed the highest levels of M (.42%) or C (.45%) had greater EP compared to the other levels of M and C supplementation. This trend was continued through P II and III. However, the lower levels of M and C supplementation did not benefit EP above the basal diet levels of M and C. Egg weights (EW) were only significantly affected during P II, during which time hens fed the highest level of M (.34%) had the greatest EW, followed by hens fed .32% C. C and M supplementation during P III inconsistently improved EW. Feather scores (FS) were conducted every 2 wks during the trial using 2 different scoring systems; a method developed by Tauson and the scales used by Webster and Hurnik. Results indicate no sig effects of diet M or C on feather scores, but sig effects of age (Phase) on FS, with rapid deterioration of FS during P II and III of the study. In summary, FS is more controlled by age than diet M or C during the first cycle of EP from 20-70 wks of age.

Key Words: Feather Score, Methionine, Cystine

W192 Comparison of various methods for endogenous ileal amino acid flow determination in broiler chickens. A. Golian*[1], W. Guenter[1], D. Hoehler[2], and C. M. Nyachoti[1], [1]*University of Manitoba*, *Winnipeg, MB, Canada*, [2]*Degussa Corporation*, *Kennesaw, GA*.

The purpose of this study was to compare estimates of ileal endogenous amino acid flow (IEAA) determined in broiler chicks with a nitrogen-free diet (NfD), diets containing intact casein or enzymatically hydrolyzed casein (EHC) and the regression method (RM). Male Ross broiler chicks were fed a commercial starter diet from d 1 to 15 of age and the following test diets from d 15 to 21: a NfD and diets containing 5, 10 or 15% casein or EHC as the sole protein source. All

diets contained chromic oxide as a digestibility marker. Each diet was assigned to six replicate cages, each with 10 birds. On d 21, birds were killed to sample ileal digesta. Compared with the NfD, the average IEAA values for the casein or EHC diets were higher (P<0.05) for all AA except for Arg, Phe and Pro whose values for casein and NfD diets were similar. The ileal flow of Met, Cys, Lys, Val and Ser in birds fed the casein or EHC diets were similar (P>0.10) but the flow of all other AA was higher (P<0.05) in EHC-fed birds than in those fed the casein diet. Feeding increasing levels of casein or EHC linearly (P<0.01) increased ileal AA flow. Estimates of IEAA obtained with the RM were similar (P>0.10) for all AA except for His (103 vs. 64 mg/kg DM) and Ser (418 vs. 577 mg/kg DM) whose values were higher and lower, respectively, for casein than for EHC (P<0.05). Compared with the NfD method, IEAA values obtained with the RM were similar for all AA except Met (69 vs. 77 mg/kg DM) with casein and Ile (209 vs. 321 mg/kg DM), Val (281 vs. 341 mg/kg DM) and Ser (357 vs. 577 mg/kg DM) with EHC that were higher (P<0.05). The present results show that IEAA values determined with NfD, EHC and casein diets are different for some AA and that, for most AA, values obtained with the NfD and the RM involving feeding graded levels of casein or EHC are comparable. Thus, using IEAA values obtained with either the NfD method or the RM to calculate standardized ileal AA digestibilities will give similar values.

Key Words: Ileal Endogenous Amino Acid Flow, Broilers

W193 Ideal ratio of Arg, Ile, Met, Met + Cys, Thr, Trp, and Val relative to Lys for 28 to 34-week-old laying hens. S. Roberts*[1], B. Kerr[2], D. Hoehler[3], and K. Bregendahl[1], [1]*Iowa State University*, *Ames*, [2]*NSRIC, USDA/ARS*, *Ames, IA*, [3]*Degussa Corporation*, *Kennesaw, GA*.

Seven separate experiments were conducted with Hy-Line W-36 hens to determine the ideal ratio of Arg, Ile, Met, Met + Cys, Thr, Trp, and Val relative to Lys for maximal egg mass (EM). The experiments were conducted simultaneously and were each designed as a randomized complete block design with 60 experimental units (each consisting of 1 cage with 2 hens) and 5 dietary treatments. The 35 treatment diets were made from a common basal diet (2,987 kcal/kg ME; 12.3% CP), formulated using corn, soybean meal, and meat and bone meal. The true digestible (TD) amino acid contents in the basal diet were determined using the total fecal collection precision-fed assay with adult cecectomized roosters. Crystalline L-Arg, L-Ile, L-Lys, DL-Met, L-Thr, L-Trp, and L-Val (all considered 100% TD) were added to the test diets at the expense of cornstarch to make the respective test amino acid first limiting and to yield 5 graded inclusions of the test amino acid. Hens were fed the treatment diets from 26 to 34 wk of age, with the first 2 wk considered a depletion period. Egg production was recorded daily and egg weight was determined weekly on 48-h eggs; EM was calculated as egg production × egg weight. The requirement for each amino acid was determined using the broken-line regression method and the ideal amino acid ratio was subsequently calculated. Consumption of Arg did not affect EM, thus an optimum ratio could not be derived. The daily TD amino acid requirements used to calculate the ideal amino acid ratio for maximum EM were 426 mg Ile, 538 mg Lys, 253 mg Met, 506 mg Met + Cys, 414 mg Thr, 120 mg Trp, and 501 mg Val. The ideal amino acid ratio for maximum EM was Ile 79%, Met 47%, Met + Cys 94%, Thr 77%, Trp 22%, and Val 93% on a TD basis relative to Lys.

Key Words: Ideal Amino Acid Ratio, Laying Hen, Egg Mass

W194 Carcass yield of modern vs 1970's heritage broilers fed drug free recommended and low protein diets. A. Golian*[2], T. A. Woyengo[1], C. Bennett[3], W. Guenter[1], and H. Muc[1], [1]*University of Manitoba*, *Winnipeg, Manitoba, Canada*, [2]*University of Ferdowsi*, *Mashhad, Iran*, [3]*Manitoba Agriculture, Food and Rural Initiatives*, *Winnipeg, Manitoba, Canada*.

Six hundred mixed sex day-old chicks from each of a modern (Ross, RS) and two 1970's heritage breeds (HB1 and HB2) broilers were randomly placed in 10 floor pens and fed two diets containing 3050 kcal ME/kg and either 22 or 19% crude protein (5 pens/diet/breed) from 1 to 30 d of age. All the birds were fed the diet containing 19% crude protein from 31 to 63 d of age. Comparisons of carcass yield cuts were carried out at 49 and 63 d of age. On the day of slaughter 10 birds from each pen were wing banded and deprived of feed at 4:00 AM, weighed at 8:00 AM, shipped and processed 9-10 h after feed removal. Carcasses were chilled on ice overnight, weighed and cut into parts. The level of dietary protein influenced (P<0.01) carcass yield and skinless breast fillet but not any other cuts at 49 d of age. Carcass yield of modern RS birds was greater (P<0.01) than for the HB1 and HB2 breeds (69.2, 65.8 and 65.6%, respectively). Skinless breast fillet as percent of carcass was 24.1, 18 and 17.5% for the RS, HB1 and HB2 breeds, respectively. Boneless skinless thighs were heavier (P<0.05) in RS vs. heritage breeds whereas thigh skin, thigh fat, drumsticks, wings and rack as a percent of carcass were smaller (P<0.01) for RS birds than the heritage breeds. A significant diet by breed interaction was only observed for carcass yield and breast fillet. At 63 d of age, diet had no effect (P>0.05) on carcass yield, however breast fillets were larger (P<0.01) for birds fed the 22% protein diet to 30 d of age. In general the breed response was the same as at 49 days. At 63 d of age carcass yield was significantly (P<0.01) greater for males than females whereas the opposite was true for breast fillet yield. Overall the modern day broiler is superior in carcass yield and breast fillet yield.

Key Words: Broiler, Breed, Carcass Yield

W195 Performance and carcass parameters of broiler chicken from 1 to 45 d fed with different levels and source of vitamin D. J. A. G. Brito[1], A. G. Bertechini*[1], J. C. C. Carvalho[1], R. L. Rios[1], J. O. B. Sorbara[2], and F. J. Piraces[2], [1]*Universidade Federal de Lavras, DZO*, *Lavras, MG, Brazil*, [2]*DSM Nutritional Products*, *Sao Paulo, SP, Brazil*.

Different levels and source of vitamin D were investigated in this study. 1500 male Cobb 700 were allocated in 100 wire cages with feed and water ad libitum. Ten programs of vitamin D supplementation according to the broiler chicken age were study (1-21 d; 22-38 d and 39-45 d) with four levels of vitamin D (20-16-10; 37,5-30-18,75; 87,5-70-43,75 and 137,5-110-68,75 mg/ton) another two treatments were add with both source of vitamin D\ (D3 and 25(OH)D3) and two treatments with both source of vitamin D (50 D3 + 37,5 25(OH)D3; 40 D3 + 30 25(OH)D3; 25 D3 + 18,75 25(OH)D3 and 50 D3 + 70 25(OH)D3; 40 D3 + 56 25(OH)D3; 25 D3 + 35 25(OH)D3 mg/ton). The experimental design was a complete randomized in a factorial arrangement (4 levels of vitamin D supplementation according to the bird age and 2 source of vitamin D) plus two treatments (with both source of vitamin D) with 10 replications. The feed were base in corn/soybean meal without growth promoter and with 500 FTU/ton feed of phytase. Performance parameters as body weight gain (BWG, g), feed intake (FI, g), and feed conversion were analyzed from 1 to

45 d. Carcass yield, breast yield and leg yield were evaluated at 45 d of age. Feed intake and body weight gain were statistical higher for the treatments with combined source of vitamin D. Carcass yield was proximally 1% higher when the 25(OH)D3 were used compared to vitamin D3. Feed conversion, breast yield, and leg yield were not affected by the level or source of vitamin D.

W196 Performance and bone characteristics of broiler chicken from 1 to 21 d fed with different levels and source of vitamin D. J. A. G. Brito[1], A. G. Bertechini*[1], J. C. C. Carvalho[1], E. J. Fassani[1], J. O. B. Sorbara[2], and F. J. Piraces[2], [1]*Universidade Federal de Lavras, DZO*, *Lavras, MG, Brazil*, [2]*DSM Nutritional Products*, *Sao Paulo, SP, Brazil*.

Different levels and source of vitamin D were investigated in this study. 1500 male Cobb 700 were allocated in wire cages with feed and water ad libitum. From 1 to 21 d four levels (800; 1500; 3500 and 5500 IU) of vitamin D were provided by two source of vitamin D (D3 or 25(OH)D3 known as HyD) another two treatments were add with both source of vitamin D 2000 IU by D3 + 1500 IU by Hy-D; and 2000 IU by D3 + 2800 IU by Hy-D.The experimental design was a complete randomized in a factorial arrangement (4 levels of vitamin D supplementation and 2 source of vitamin D) plus two treatments (with both source of vitamin D) with 10 replications. The feed were base in corn/soybean meal without growth promoter. Performance parameters as body weight gain (BWG, g), feed intake (FI, g), and feed conversion (FC, g/g) were analyzed from 1 to 21 d. Bone ash (%), calcium (%), phosphorus (%) and tibial dyschondroplasia (TD, %) were evaluated at 21 d of age. At 21 d-age the feed intake was affected just when the level of vitamin D was marginal with statistical higher feed intake with D3. The BW gain at 21 d were higher (P<0.05) when the two source of vitamin D were combined. The feed conversion at 21 d was statistical better when the highest levels of vitamin D were combined. The percentage of Ca on bone were statistical higher for 25(OH)D3 source just when the level of supplementation were between 25 and 37,5 mg of D3/ton feed. TD were lower (P<0.05) in the birds that received just Hy-D or when combined with D3.

W197 Performance and carcass yield of four quail genetic groups selected for meat production. C. Móri, E. A. Garcia, A. C. Pavan, A. Piccinin, C. C. Pizzolante, R. M. S. Emediato*, A. B. G. Faitarone, M. R. Scherer, D. A. Berto, and S. A. Maestá, *São Paulo State University*, *Botucatu, São Paulo, Brazil*.

The study aimed to evaluate the performance and carcass yield of four meat quail genetic groups. It was used one thousand and two hundred quail of 1 day of age until it have complete 42 days of age. The birds were allocated in a completely randomized design with four treatments (A, B, C and D) and five replicates of 60 birds each. The quails were weighted once a week in order to evaluate weight gain and feed consumption. Mortality rate was recorded daily. When the birds have completed 42 days of age, ten quails from each replication were identified and slaughtered in order to evaluate carcass and cuts yield. During the experimental period, the genetic group C has shown higher values for final weight and daily weight gain. No differences were observed among groups for feed consumption, feed efficiency, mortality, carcass weight, carcass yield and breast percentage. Genetic group D has shown higher values for wings, legs and breast meat percentage. In conclusion, there are differences of performance and carcass and cuts yield among quail genetic groups selected for meat production present on Brazilian market.

W198 Effects of genotype and plane of nutrition on performance and carcass composition of guinea fowl (*Numida meleagris*) broilers raised in the tropics. V. Díaz*, H. L. Santiago, and A. A. Rodríguez, *University of Puerto Rico*, *Mayagüez, Puerto Rico*.

Genetic selection of guinea stocks has improved production efficiency but studies directed to evaluate the nutritional requirements of new genotypes are limited. A total of 675 keets from three genotypes diverging in their genetic background; a native genotype (NG) and two commercial genotypes (CG1, CG2) were raised under three feeding regimes to market age. The three experimental diets provided a low

(LPN), intermediate (IPN), and a high (HPN) plane of nutrition based on the CP and ME of diets. Birds and feed were weighed at the end of the starter (35 d), grower (63 d), and finisher (84 d) periods to obtain body weight (BW), feed intake (FI), and feed conversion (FC). At 84d, 35 birds per treatment were randomly selected and processed to evaluate carcass composition. The weights of New York dressed (NYD), ready to cook (RTC), and fat pad (FP) were obtained and yields calculated as a percentage from live BW. A significant main effect of genotype for BW was found at 35, 63, and 84 d where both CG birds had similar but significantly heavier BW than NG birds. A significant effect of diet was observed at 35 and 84 d, where birds fed HPN diets had significantly heavier BW weights than those fed IPN and LPN diets. At all ages, CG1 and CG2 had similar but significantly lower FC compared to NG. However, no significant differences were observed for FI. There was a significant genotype and plane of nutrition interaction where birds of the CG1 fed HPN and IPN diets and CG2 fed IPN diet had significantly heavier NYD and RTC weights. Carcass RTC yields of CG were significantly higher compared to NG birds. Guineas of the NG had significantly lower percentage of FP than both CG evaluated. Birds raised under a HPN and IPN regime had significantly FP yield than those raised under a LPN regime. This investigation confirms that genetic selection has made significant improvements on performance and carcass traits of guinea broilers. The results showed that improvements in performance traits and processing yields may be obtained when CG are raised under a HPN regime.

W199 Influence of post-AI nutrition on blood urea nitrogen, progesterone, and pregnancy. G. A. Perry*, B. L. Perry, J. R. Nelson, and J. A. Walker, *South Dakota State University*, *Brookings*.

Research has shown that changes in nutrition can have an effect on reproductive performance. Our objective was to determine the effect of post-AI nutrition on BCS, blood urea nitrogen (BUN), progesterone, and pregnancy rates. Forage-developed Angus-cross heifers (n = 336) were synchronized with the Select Synch+CIDR protocol (d -7 100 µg GnRH and CIDR; d 0 25 mg PG and removal of CIDR; Estrus detected for 72 h and heifers bred 12 h after detection in estrus; heifers not in estrus were bred with an injection of GnRH at 72 h). Each breeding period was equally divided into three treatments: 1) heifers returned to feedlot (LOT), 2) heifers were moved to pasture (PASTURE), or 3) heifers were moved to pasture and supplemented with 2.22 kg/hd/d of dried distillers grains plus solubles (SUPP). Blood samples were collected on d -7, 0, 2, 14 and 42 (pregnancy determination; analyzed by repeated measures). BCS were determined on d -7 and 42. All heifers were in similar ($P = 0.78$) BCS (5.4 ± 0.05) on d -7, but on d 42 SUPP (5.9 ± 0.04) were in greater condition ($P < 0.01$) than LOT (5.8 ± 0.04) which were in greater condition ($P < 0.01$) than PASTURE (5.4 ± 0.04). All treatments had similar ($P > 0.14$) BUN concentrations on d -7 (129 ± 1), but on d 2, 14 and 42 SUPP had greater ($P < 0.01$) BUN concentrations compared to both LOT and PASTURE. There was no difference in BUN concentrations between pregnant and open heifers ($P = 0.37$). Progesterone concentrations were similar among all heifers ($P \geq 0.05$) on d 0 and 2. SUPP had greater progesterone on d 14 ($P = 0.02$) compared to LOT, and on d 14 and 42 PASTURE had greater progesterone ($P < 0.02$) compared to LOT. Progesterone was similar ($P > 0.16$) for open and pregnant heifers on d 0 and 2, but greater ($P < 0.04$) in pregnant heifers on d 14 and 42. There was no difference among treatments in pregnancy rates ($P > 0.64$; 57, 56, and 59% for SUPP, LOT, and PASTURE; analyzed by chi-square). In summary, supplementing forage-developed heifers after insemination increased BCS and BUN concentrations, but had no effect on pregnancy rates.

Key Words: Heifers, Fertility, Post-AI Nutrition

W200 Effect of dietary ω-3 polyunsaturated fatty acid supplementation on hormone and metabolite concentrations and corpus luteum size in beef heifers. S. Childs*[1,2], J. M. Sreenan[1], A. A. Hennessy[3], C. Stanton[3], M. G. Diskin[1], and D. A. Kenny[2], [1]*Teagasc Animal Production Research Centre*, *Athenry, Co. Galway, Ireland*, [2]*University College*, *Dublin, Ireland*, [3]*Teagasc Moorepark Food Research Centre*, *Co. Cork, Ireland*.

Supplementation of cattle diets with fishoil has been reported to improve fertility. Though the mechanisms involved remain unclear, it is thought that constituent ω-3 polyunsaturated fatty acids (ω-3 PUFA) eicosapentaenoic (EPA) and docosahexaenoic (DHA) acids may mediate this effect. The objective of this study was to examine the effect of level of a high ω-3 PUFA product on a number of important reproductive variables. Heifers (n=40) were randomly assigned to a concentrate and straw (80:20) based ration supplemented with one of four levels of a high ω-3 PUFA product to provide on a DM basis: (1) 0g (**C**); (2) 62g (**T2**); (3) 129g (**T3**) or (4) 273 g (**T4**) of EPA and DHA combined. Diets were offered for 45 days and were isolipid and isonitrogenous. Heifers were oestrous-synchronised and plasma samples were collected to determine progesterone (P_4) and oestradiol (E_2) concentrations on day of oestrus (0) and on days 4, 7, 10, 14 and 16 post oestrus. Corpus luteum (CL) size was measured on day 7. Samples for fatty acids (FA) and cholesterol analysis were collected on day 16. FA methyl esters were separated by gas chromatography. P_4 and E_2 were measured by RIA. Data were analysed using repeated measures ANOVA. There was a positive linear effect of dietary ω-3 PUFA on plasma EPA ($P<0.0001$) and both positive linear ($P<0.01$) and quadratic ($P<0.05$) components to the effect on plasma DHA. Plasma cholesterol was similar for C, T2 and T3, and higher ($P<0.05$) for T4 compared with C or T2. There was no effect of treatment ($P>0.05$) on E_2. CL diameter was greater ($P<0.05$) on T3 and T4 than C or T2. On day 14, P_4 concentrations were higher on T4 than on C and T2 ($P>0.01$) but did not differ between other treatment comparisons ($P>0.05$). Omega-3 PUFA supplementation may increase P_4 concentrations around the critical period of maternal recognition of pregnancy. This increase may be mediated through increased substrate availability and/or CL size.

Key Words: Omega-3 PUFA, Reproductive Hormones, Fertility

W201 Effect of level of dietary supplementation on concentrations of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) in selected tissues in cattle. S. Childs*[1,2], J. M. Sreenan[1], A. A. Hennessy[3], C. Stanton[3], and D. A. Kenny[2], [1]*Teagasc Animal Production Research Centre*, *Athenry, Co. Galway, Ireland*, [2]*University College*, *Dublin, Ireland*, [3]*Teagasc Moorepark Food Research Centre*, *Co Cork, Ireland*.

Increased intake of omega-3 polyunsaturated fatty acids (ω-3 PUFA) has been suggested to improve fertility in cattle. However, as long-chain PUFA are extensively hydrogenated in the rumen, this often results in poor transfer from diet to tissue. The objective of this study was to examine the effect of level of dietary ω-3 PUFA supplementation on concentrations of both EPA and DHA in blood plasma (PL), rumen fluid (RF), follicular fluid (FF) and uterine endometrial tissue (ET) in cattle. Heifers (n=40) were randomly assigned to a concentrate and straw (80:20) based ration supplemented with one of four levels of a partially rumen-protected high ω-3 PUFA product to provide on a DM basis: : (1) 0g (**C**); (2) 62g (**T2**); (3) 129g (**T3**) or (4) 273 g (**T4**) of EPA and DHA combined. Diets were offered on an individual basis and were isolipid and isonitrogenous. Heifers were slaughtered after 45 days on experiment. Blood samples for PL were collected on day 44 and RF, FF and ET samples were collected immediately post-slaughter for fatty acid analysis. Data were analyzed using ANOVA and multiple regression analyses. There was a positive linear effect of treatment on concentrations of EPA in PL ($P<0.0001$), FF ($P<0.05$) and ET ($P<0.0001$) but no effect in RF ($P>0.05$). There was a positive linear ($P<0.01$) effect of treatment on DHA concentrations in RF with a tendency towards a quadratic component ($P=0.07$). The effect of diet on PL and FF concentrations of DHA was positive with both linear ($P<0.01$) and quadratic ($P<0.05$) components while the effect on ET concentration was both positive and linear in direction ($P<0.05$). Blood plasma concentrations of EPA ($R^2=0.69$) and DHA ($R^2=0.28$) were the best predictors of their respective concentrations in ET. Tissue concentrations of ω-3 PUFA can be manipulated through rumen protection of dietary supplements. Blood plasma concentration may be a useful predictor of PUFA concentration in reproductive tissues.

Key Words: Omega-3 PUFA, Rumen Protection, Reproductive Tissue

W202 Nutritional and genetic effects on the follicular growth of the Nelore-Hereford heifers. J. O. J. Barcellos*, E. R. Prates, J. López, and J. Braccini, *Federal University of Rio Grande do Sul*, *Porto Alegre- RS - Brasil*.

The objective of this study was to evaluate the effects of growth rate during the post-weaning phase to puberty on the follicular growth of the two hundred beef heifers Nellore-Hereford crosses. The heifers were weaned in the six months old and allotted in the factorial experimental design 4 (weight gain daily) × 5 (crossbreed degree-CX) and treatments were: 50 heifers (25%N-75%H; 37.5%N-63.5%H; 43.7-56.3%H; 50%N-50%H and 75%N-25%H) submitted to an average growth rate (AGD) of 0.500 kg/day (G500); 50 heifers (25%N-75%H; 37.5%N-63.5%H; 43.7-56.3%H; 50%N-50%H and 75%N-25%H) with an ADG of 0.750 kg/day (G750); 50 heifers (25%N-75%H; 37.5%N-63.5%H; 43.7-56.3%H; 50%N-50%H and 75%N-25%H) with an ADG of 1.000 kg/day (G1000) and 50 heifers (25%N-75%H; 37.5%N-63.5%H; 43.7-56.3%H; 50%N-50%H and 75%N-25%H) with an ADG of 1.250 kg/day (G1250). The experimental diets were adjusted to achieve at puberty an 12-13 months of age. The diameter of the large follicle (DLF- mm) and the follicular area total (FA- mm2) at the 10, 11 and 12 months of age by real-time ovarian ultrasonography Aloka SD500 model, in the total heifers were evaluated. The data were analyzed by ANOVA and stepwise regression. The average age at puberty was at 338 ± 22 days. The general equation by DLF at 10 months were DLF=8.642*ADG-3.3615 (r2=0.70). At the 10 months, the results showed an interaction ($P<0.01$) between the ADGxCX with the higher effect of the ADG on the DLF in the heifers with minus of the 50%N. The effects of the nutritional levels were similar at 11 and 12 months ($P>0.06$). However, the G1250-75N showed higher variations ($P<0.05$) on the DLF from the 10 to 12 months (4.5mm × 10.6mm) than heifers 25, 35.5, 43.7 and 50% ones. The heifers 25, 35.5 and 43.7%N showed higher AF at 10, 11 and 12 months age and the effect were very important in the G1000 and G1250 ($P<0.01$). Therefore, the weight gain posweaning have the effect important on the follicular growth to puberty early in crossbreed heifers.

Key Words: Puberty, Beef Cattle, Reproduction

W203 Levels of serum progesterone in creole cows with and without corpus luteum treated with CIDR®, progesterone, β-estriadiol and $PGF_{2\alpha}$. J. P. Zarate Martinez*, J. A. Ramirez Godinez, and F. A. Rodriguez Almeida, *Universidad Autonoma de Chihuahua*, *Chihuahua, Chih. Mexico*.

Experiments were conducted to study the serum progesterone (P_4) levels in cows with ($P_4 \geq 1$ ng/mL) and without corpus luteum (CL), treated with two hormone protocols that used an intravaginal CIDR® device. Cows were assigned randomly to one of two treatments (T). T1 (n=14) received a CIDR® with 1.9 g of P_4 + IM injection of 1 mg β-estriadiol and 50 mg of P_4, and CIDR® was withdrawn on day 7, when an IM injection of 30 mg of $PGF_{2\alpha}$, and on day 8 1 mg IM of β-estriadiol was administered; T2 (n=13) was similar but IM injection contained 1 mg of β-estriadiol without P_4. To determine the concentrations of P_4, blood samples were taken on days (D) 0, 1, 2, 7, 8, and 9 after application of CIDR®. Serum concentrations were analyzed with PROC MIXED of SAS, adjusting a model with main effects of CL, T, D and their interactions, and random effects of cows within T*CL. Seventy-five percent of cows exhibited estrus. There were no differences ($P>0.05$) for P_4 concentrations between T1 (5.63±0.497 ng/mL) vs T2 (4.51±0.486 ng/mL). The presence of a CL at the beginning of hormone application protocols was not significant ($P>0.05$) for the average concentrations of P_4 in cows with CL (5.85±0.36 ng/mL) and cows without CL (4.31±0.59 ng/mL) during the days of treatment. The interaction T*D showed numerical differences in the P_4 concentrations. There were differences between T1 (10.90±0.921 ng/mL) and T2 (7.46±1.054 ng/mL) on day 1 and this trend continued until CIDR® was withdrawn; however differences were not significant ($p>0.05$). Higher values of P_4 concentrations for T1 cows, which received an IM injection of 50 mg of P_4 besides the CIDR®, than for T2 cows, which did not received P_4 injection, were as expected; however more observations are needed to confirm findings.

Key Words: Creole Cows, CIDR, Corpus Luteum

W204 Effect of progestin treatment on formation of persistent follicles in beef heifers. M. E. Heaton*, J. A. Atkins, J. F. Bader, C. L. Johnson, and M. F. Smith, *University of Missouri*, *Columbia*.

Effective estrous synchronization protocols frequently utilize progestins (melengestrol acetate [MGA] and Controlled Internal Drug Release [CIDR] inserts) to synchronize estrus. Previous research demonstrated that long-term treatment with MGA, in the absence of a corpus luteum, caused formation of persistent follicles and resulted in low fertility. The specific aims of this project were to determine if the presence of a new or used CIDR, in heifers without a corpus luteum, would induce the formation of persistent follicles and to compare the pattern of serum concentrations of progesterone in heifers treated with a new or used CIDR to luteal phase concentrations of progesterone (P4) in non-treated heifers. Normally cycling heifers were allocated by age, weight, and breed into four treatment groups: Control (n=8), MGA (n=4; 0.5 lbs-1hd-1day), new CIDR (n=7; 1.38 g P4), and used CIDR (n=8; new CIDR's previously inserted into cows for 7 d). Progestin treatment (MGA or CIDR) began on d 4 post-estrus and PG was injected on d 6 to induce luteolysis (d 0 = estrus). MGA or CIDR treatment continued for 14 d and length of a follicular wave was defined as the interval from follicular recruitment to ovulation or initiation of a new wave. Length of the first follicular wave (d) was 10.9^{a}, 18.0^{b}, 17.1^{b}, and 16.9^{b} ($^{ab}P \leq .05$) and maximum diameter (mm) of the dominant follicle was 14.4^{c}, 18.8^{d}, 16.0^{c}, and 18.5^{d} (Control, MGA, new CIDR, and used CIDR, respectively; $^{cd}P \leq .06$). Dominant follicle diameter was greater ($P \leq .05$) in the used CIDR group compared to the new CIDR group after d 10 of treatment but similar to the MGA group. Serum concentrations of progesterone in the new and used CIDR groups were similar ($P \geq .05$) throughout the 14 d treatment period but lower than in the control group. In summary, treatment with a new or used CIDR induced formation of persistent follicles in beef heifers and there was no difference in serum concentrations of progesterone between the two CIDR groups.

Key Words: Progesterone, Persistent Follicle, Estrous Synchronization

W205 Relationships between cortisol concentrations and cow temperament with calf exit velocity from 3 weeks of age through weaning. N. C. Burdick*[1], R. D. Randel[2], J. P. Banta[2], D. A. Neuendorff[2], J. C. White[2], J. G. Lyons[3], T. H. Welsh, Jr.[3], R. C. Vann[4], and J. C. Laurenz[1], [1]*Texas A&M University-Kingsville*, *Kingsville*, [2]*Texas A&M University Agricultural Research and Extension Center*, *Overton*, [3]*Texas A&M University*, *College Station*, [4]*Mississippi State University*, *Raymond*.

The relationship between cortisol concentrations and cow temperament with exit velocity (EV) in Brahman calves from 3 weeks of age through weaning was assessed. Blood samples were collected from calves (n=116) and their dams on d21-to-24 after birth and from the calves at weaning. Serum concentrations of cortisol (CS) were determined by RIA. Calf EV was determined on d21-to-24 of age and at 28-d intervals until weaning (d173±2) as a measure of temperament. Calves were ranked based on their EV on d21-to-24 (EV Rank) with calves 1 SD slower than the mean ranked 1 (calm; n=17), calves 1 SD faster than the mean ranked 3 (temperamental; n=19), and remaining calves ranked 2 (intermediate; n=80). A subjective measurement of cow temperament was assessed by individual observer with cows being ranked as calm, intermediate, or temperamental. Temperamental cows had greater concentrations of CS (7.2±0.7; $P<0.01$) than calm (3.9±0.4) and intermediate cows (4.2±0.3). Cow CS concentrations were not associated with calf CS concentrations early in life (d21-to-24; $P=0.91$) or at weaning ($P=0.63$). Cow temperament did not affect calf EV from d21-to-24 to weaning ($P=0.39$). However, calf EV was affected by calf EV Rank on d21-to-24, with temperamental calves having a greater EV (3.0±0.12; $P<0.01$) at all ages when compared with calm (1.7±0.2) and intermediate calves (2.1±0.1). Also, calf CS concentrations on d21-to-24 were associated with calf EV Rank on d21-to-24, with temperamental calves having greater concentrations of CS (5.2±0.8; $P<0.01$) when compared to calm (3.0±0.4) or intermediate calves (3.6±0.2). Calf CS at weaning, however, was not related to calf EV Rank on d21-to-24 ($P=0.22$), although temperamental calves had numerically greater concentrations than calm or intermediate calves. Collectively, these data suggest that although cow temperament is related to cow CS concentrations, and calf EV is associated with calf CS, calf EV is not affected by cow temperament. Calm and intermediate calf EV increased through d67 of age before reaching a plateau, while the EV of temperamental calves displayed little change over time.

Key Words: Temperament, Cortisol, Calves

W206 Microbial flora of normal and abnormal cervical mucous discharge associated with reproductive performance of cows and heifers in estrus. A. Ata, H. Turutoglu, M. Kale, M. S. Gulay*, and F. Pehlivanoglu, *Mehmet Akif Ersoy University*, *Burdur, Turkey*.

The aim of the present study was to describe whether abnormal cervical mucus discharge (A-CMD) or pathogens such as aerobic bacteria and fungi in cervical mucus discharge (CMD) have effects on reproductive performance (RP) of cows and heifers in estrus. For this purpose, CMD of 222 animals in estrus were evaluated visually before artificial insemination (AI). Animals having clear discharges (68 cows, 38 heifers) with normal viscosity and without bad odor were grouped as normal cervical mucous discharge (N-CMD) group. The other animals (84 cows, 32 heifers) were grouped as A-CMD group. CMD samples were submitted to cultural examination for *Campylobacter spp.*, *Brucella spp.*, aerobic bacteria and fungi. Microorganisms isolated from samples were divided three groups as uterine pathogens (UP), potential uterine pathogens (PUP) or opportunistic uterine pathogens (OUP). Presence of PUP was associated with A-CMD for both cows ($P<0.01$) and heifers ($P<0.02$). First service conception rates (FS-CR) were lower in cows positive for PUP ($P<0.01$). Moreover, presence of PUP and OUP affected FS-CR in heifers ($P<0.01$). Although A-CMD significantly affect FS-CR in cows ($P<0.04$), it did not affect FS-CR in heifers. Differences in average open day (OD) for cows and first service age (FSA) for heifers were significant between N-CMD ($P<0.02$) and A-CMD ($P<0.01$) groups, respectively. Our findings indicated that pathogens have a negative effect on reproductive performance of cows and heifers when it changes to appearance of CMD.

Key Words: Cervical Mucous Discharge, Reproductive Performance, Bacteria-Fungi

W207 *In vitro* production of bovine embryos in chemically defined serum-free media. A. Dhali, V. M. Anchamparuthy, S. P. Butler, R. E. Pearson, and F. C. Gwazdauskas*, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Embryo production and culture in serum supplemented media is a common practice. Nevertheless, several studies indicate the need to develop suitable serum-free conditions for *in vitro* embryo production and culture as serum can inhibit embryo development and can alter morphological and chemical properties of embryos. Moreover, *in vitro* embryos generated under chemically defined conditions can serve as a valuable model in many research applications. The objective was to develop a complete chemically defined serum-free system for in vitro production and culture of bovine embryos. Abattoir-derived oocytes were matured in TCM-199 supplemented with LH (0.02 U/mL), FSH (0.02 U/mL), estradiol (1 µg/mL) and BSA. The swim-up separation of motile spermatozoa for *in vitro* fertilization (IVF) was performed in BSA supplemented HEPES buffered synthetic oviductal fluid (SOF). Matured oocytes were fertilized in BSA supplemented SOF-IVF medium and presumptive zygotes were cultured for 8 d (in a humidified 5% CO_2 atmosphere at 38.5°C) in BSA supplemented SOF-in vitro culture (IVC) medium containing either epidermal growth factor (EGF, 10 ng/mL), stem cell factor (SCF, 50 ng/mL), or IGF-1 (100 ng/mL). Control embryos were cultured in BSA and fetal calf serum (FCS) supplemented SOF-IVC medium. The cleavage rate did not vary significantly among the treatments and control (EGF: 77.6%, SCF: 68.3%, IGF-1: 73.4% and FCS: 72.8%). Similarly, the blastocyst (EGF: 22.7%, SCF: 24.6%, IGF-1: 26.0%, FCS: 35.2%) and expanded blastocyst (EGF: 10.6%, SCF: 12.7%, IGF-1: 16.5% and FCS: 22.7%) formation rates based on total number of oocytes did not differ significantly among the treatments and control. In conclusion, an acceptable level of embryonic development could be achieved using the serum-free chemically defined conditions and growth factor supplementation in the culture medium.

Key Words: Embryo, Bovine, Serum-free Media

W208 Droplet vitrification method did not induce cytoskeletal damage in mouse embryos. A. Dhali, V. M. Anchamparuthy, S. P. Butler, R. E. Pearson, and F. C. Gwazdauskas*, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

The concept of ultra rapid vitrification has been emerging in recent years. This particular process increases cooling and warming rates that provide the opportunity to reduce cryoprotectant concentrations in vitrification solutions and reduce cytotoxicity. The objective was to document embryo survival and cytoskeletal damage when mouse embryos were vitrified using a modified ultra rapid vitrification method, the droplet vitrification. Mouse embryos (zygotes, 2-cell and morulae) were initially equilibrated for 3 min in 50% vitrification solution and then quickly washed 3 times in vitrification solution (17.5% ethylene glycol (EG), 17.5% DMSO, 0.5M sucrose and 4 mg/mL BSA in M2 medium). Subsequently a drop (5µL) of vitrification solution containing 10 to 12 embryos was formed, placed directly onto liquid nitrogen and liquid nitrogen was poured immediately over the drop. Warming and removal of cryoprectants were performed by placing the vitrified drop into dilution medium (0.3M sucrose and 4 mg/mL BSA in M2 medium) for 3 min and then into M2 medium for 5 min. Following vitrification, warming and culture, 57.9% of pronuclear stage, 59.2% of 2-cell stage and 86.3% of morulae developed into blastocysts. The corresponding figures for hatched blastocyst were 37.8, 40.7 and 73.5%, respectively. Still, the development of control embryos into blastocyst (70.2% of pronuclear stage, 75.5% of 2-cell stage embryos and 91.5% of morulae) and hatched blastocyst (58.5% of pronuclear stage, 62.9% of 2-cell stage and 77.7% of morulae) was significantly ($P < 0.05$) higher. Laser scanning confocal microscopy revealed no actin cytoskeletal damage in any of the 3 stages of mouse embryos either after vitrification and warming or following the development into blastocyst. The study reveals that droplet vitrification is an easy and potentially ultra rapid vitrification method, which may be utilized to preserve oocytes and embryos of other species as well.

Key Words: Embryo, Cytoskeleton, Vitrification

W209 Association of oviductal fluid (ODF) proteins with the bovine zona pellucida. E. Monaco*[1], B. Gasparrini[2], L. Boccia[2], A. De Rosa[2], L. Attanasio[2], G. Campanile[2], and G. Killian[1], [1]*The Pennsylvania State University*, *State College*, [2]*Federico II University*, *Naples, Italy*.

The objective of this study was to determine using confocal microscopy whether bovine serum albumin (BSA), osteopontin (OPN) and lipocalin-type prostaglandin D synthase (L-PGDS) were associated with the bovine zona pellucida (ZP) of immature bovine oocytes and after in vitro matured oocytes were incubated in ODF. Ampullary (A) and isthmic (I) non luteal (NL) ODFs from two Holstein cows were used. To investigate if BSA, OPN, L-PGDS bind to the ZP alone or to cumulus cells and plasma membrane, mature cumulus oocyte complexes, denuded and ZP-free mature oocytes were incubated in 1) TALP medium (without BSA, with 0.1% PVA) (control), 2) TALP medium and 50% ANL-ODF, 3) TALP medium and 50% INL-ODF. After 2.5 h the eggs were washed and incubated for 1 h with primary antibodies against one of the three proteins, washed again and then incubated for 30 min with goat anti-rabbit FITC labeled secondary antibody. Immature denuded oocytes were incubated for 1 h in 1) TCM (control), 2) TCM and primary antibody to one of the three proteins and then for 30 min with FITC-labeled secondary antibody. In all cases, the ZP of mature denuded eggs probed with primary and secondary FITC labeled antibodies fluoresced when eggs were pre-exposed to either TALP medium alone or TALP medium and ANL/INL-ODF. In no case did the cumulus cells or the plasma membrane have an affinity for any of the three proteins. However, L-PGDS distribution differed from that of BSA and OPN in that it was detected in the perivitelline space. These studies suggest the presence and in vivo binding of these proteins to the eggs before they reach the oviduct. Because the ZP of immature denuded oocytes incubated in TCM and probed with primary and secondary FITC labeled antibodies also fluoresced like the mature eggs, we suggest that BSA, OPN and L-PGDS are first acquired by the ZP from follicular fluid during follicular development. (USDA grant 2004-34437-15106).

W210 Decreased pulsatile LH secretion does not affect the function of the corpus luteum of pregnancy in cattle. H. T. Toriz*, H. Basurto, A. A. Porras, and C. G. Gutierrez, *Facultad de Medicina Veterinaria. UNAM*, *Mexico DF, Mexico*.

The objective of this study was to determine the corpus luteum (CL) dependence of pulsatile LH secretion in pregnant cattle. Twelve cows

with 90 days of pregnancy were either used as controls (n=6) or treated chronically with a GnRH agonist (n=6) (Buserelin; Hoechst Marion Roussel Ltd.). The chronic treatment with GnRHa was given with Buserelin acetate released continuously at 2.5 µg/h by an Alzet osmotic. This treatment has been previously shown to block LH pulses (Gong et al, 1996). The pump was replaced every 28 days with a new pump throughout gestation. Cattle were bled twice weekly from day 90 of to day 150 of gestation and every fortnight thereafter until parturition. The ability of the pituitary from the control and GnRHa treated cows to release LH was tested forty days after the start of the study (aprox. day 130 of gestation) by injecting them with 50ug of buserelin. Progesterone and LH were measured by RIA. All cows continue their pregnancy and calved normally. After the first GnRHa pump was inserted, treated cows developed a secondary CL. Progesterone concentrations were higher ($p<0.05$) in the GnRHa treated cattle (12.8 ng/ml) than in the control group (8.8 ng/ml) throughout the remaining of pregnancy. In the control group, all cows responded with LH release (≥ 4 ng/ml) after the buserelin challenge. However, LH released was significantly reduced ($p<0.01$) by GnRHa chronic treatment. The results of this study suggest that the corpus luteum of pregnancy does not depend on pulsatile release of LH for its maintenance and function.

Key Words: Corpus Luteum, Luteinizing Hormone, Pregnancy

W211 Protective effects of the antioxidant dithiothreitol (DTT) on preimplantation bovine embryos exposed to heat shock. L. A. de Castro e Paula* and P. J. Hansen, *University of Florida*, *Gainesville*.

Effects of heat shock (HS) on bovine embryos are greater in culture under high oxygen (20.95%) when compared to low oxygen (5%). It was hypothesized that HS effects involve reactive oxygen species (ROS) and DTT reduces these effects. For Experiment (Exp) 1 (culture in high oxygen), two-cell embryos were cultured at 38.5°C (control) or 41°C (HS) for 15 h with 0, 50 or 500 µM DTT. Embryos were then cultured at 38.5°C for 9 h in the same DTT treatment (trt) and then at 38.5°C without DTT until day 8. DTT increased the percent of control embryos becoming blastocysts ($P<0.05$) and heat shock reduced blastocyst development ($P<0.05$). This reduction was less for embryos treated with 500 µM DTT ($P<0.05$). For Exp 2, two-cell embryos were cultured at 38.5°C or 41°C for 15 h in high or low oxygen and with 0 or 500 µM DTT. Embryos were then cultured at 38.5°C for 9 h in either high or low oxygen in the same DTT trt and then cultured in low oxygen at 38.5°C without DTT until day 8. HS decreased blastocyst development in all trts except for the 0 µM DTT group cultured in low oxygen (temp × DTT; $P<0.05$). For Exp 3 (culture in high oxygen), embryos ≥16 cells were cultured at 38.5°C or 41°C for 15 h in the presence of 0, 50 or 500 µM DTT. Embryos were then cultured at 38.5°C for 9 h in their same DTT trts and then at 38.5°C without DTT until day 8. DTT increased the percent of control embryos becoming blastocysts ($P<0.05$). HS reduced blastocyst development ($P<0.05$) but the reduction was less for embryos treated with DTT ($P<0.05$). Exp 4 was conducted as for Exp 3 except that embryos were fixed 24 h after start of HS and analyzed by TUNEL assay. The percent of TUNEL-positive cells was increased by HS in the absence of DTT ($P<0.05$) but not in the presence of 50 or 500 µM DTT ($P>0.1$). In summary, DTT improved development of embryos cultured in high oxygen and conferred partial protection from HS. Protection was incomplete and it is likely that there are ROS-independent actions of HS. Since DTT was detrimental to HS embryos in low oxygen, there may be a ROS-dependent thermoprotective mechanism deployed by the embryo in low oxygen.

W212 Nylon mesh vitrification for cryopreservation of bovine oocytes. V. M. Anchamparuthy*, A. Dhali, S. P. Butler, R. E. Pearson, and F. C. Gwazdauskas, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Cryopreservation of oocytes is a challenge. The objective was to vitrify large numbers of cumulus intact bovine oocytes obtained from follicles of different diameter, ≤ 4 mm (Small) and 4 to 10 mm (Medium), after 15 h of in vitro maturation. Vitrification-warmed oocytes were in vitro fertilized using frozen semen from 2 bulls (Bull I and II). After maturation oocytes were first immersed in cryoprotectants consisting of 10% (v/v) ethylene glycol (EG), 4.5% (w/v) Ficoll-70 (F-70) and 0.075 M sucrose in Ca++ free PBS for 7 min followed by immersion in a solution consisting of 20% (v/v) EG, 9.0 % (w/v) F-70 and 0.15 M sucrose for 2 min, and finally in a solution of 40% (v/v) EG, 18% (w/v) F-70 and 0.3 M sucrose for 1 min. After equilibration, 15 to 20 oocytes were loaded onto nylon mesh, transferred to 2 mL pre-cooled cryovials, and directly plunging into liquid nitrogen. Thawing was conducted with a sequential series of 0.5, 0.25 and 0.125 M sucrose dilutions for 1, 2, and 3 min, respectively. After thawing, the oocytes were placed into maturation medium for an additional 9 h. Thawing resulted in 97% morphological survival with intact cumulus cells in both populations of oocytes. There was a difference ($P < 0.05$) in development rates between vitrified and control groups (39.6 ± 0.02 and 59.8 ± 0.02%, respectively, for cleavage compared with 6.5 ± 0.01 and 21.2 ± 0.01%, respectively, for blastocysts). Cleavage and blastocyst rates in oocyte populations from Small and Medium follicles were different ($P < 0.05$; 45.4 ± 0.02 and 53.9 ± 0.02% for cleavage; 11.6 ± 0.01 and 16.1 ± 0.01% for blastocyst, respectively). Sire did not affect cleavage rate ($P > 0.05$; 49.6 ± 0.02), but had an effect ($P < 0.05$) on blastocyst rate (10.0 ± 0.01 for Bull I vs. 17.8 ± 0.01% for Bull II). Our results show that nylon mesh is a useful method for vitrification of large numbers of matured bovine oocytes.

Key Words: Bovine, Vitrification, Oocyte

W213 Follicle numbers on the ovaries of cows selected for high and low IGF. L. Snellgrove[1], T. A. Hoagland*[1], G. W. Kazmer[1], M. E. Davis[2], D. Schrieber[1], and S. A. Zinn[1], [1]*University of Connecticut*, *Storrs*, [2]*The Ohio State University*, *Columbus*.

Post-partum lactating Angus beef cows (n = 10) divergently selected for greater (H; n = 6) or lesser (L; n = 4) IGF-I concentrations were subjected to rectal palpation and ultra-sonography to determine the influence of this divergent selection for IGF on follicular dynamics. Beef cows treated with bST have greater numbers of small and medium follicles. With these genetically diverse cows, the role of IGF on follicular development could be investigated. The cows were subjected to rectal examinations twice per week between 30 and 80 d post-partum. The number of follicles on each ovary were determined and classified as small (1 to 3mm), medium (4 to 6mm) or large (< 6mm). In addition, presence of corpora lutea, and length and width

of the ovaries were recorded. Total number of small, medium and large follicles were greater (P = 0.0068) in H IGF cows compared with L IGF cows. The H IGF group averaged 10.9 ± 0.76 follicles compared with the L IGF group which averaged 6.56 ± 0.93 follicles. On the right ovary, the number of small (3.87 ± 0.45 vs. 2.12 ± 0.55; P = 0.0389) and medium (1.28 ± 0.15 vs. 0.66 ± 0.18; P = 0.0284) follicles were greater in H IGF cows than L IGF cows. Similarly, on the left ovary, the number of medium follicles was greater (P = 0.046) in the H cattle (1.63 ± 0.21) compared with L cattle (0.84 ± 0.26); and the number of small follicles were greater at the P = 0.12 level in H (2.9 ± 0.35) then L (2.0 ± 0.42) cows. The average ovarian volume (4.8 ± 1.0 cc) or the number of large follicles (0.64 ± 0.1) on either the right or left ovary in the H or L IGF selected cows were not different (P < 0.12). In conclusion, cows selected for greater IGF had more follicles than cows selected for low IGF indicating that divergent selection for IGF subsequently plays a role in follicular recruitment.

Key Words: IGF, Beef Cows, Follicles

W214 Effect of insulin-like growth factor-1 during culture on blastocyst mRNA abundance and survival in utero to day 14 of bovine embryos produced in vitro. J. Block*[1], C. Wrenzycki[2], D. Herrman[2], T. M. Rodina[1], H. Niemann[2], A. D. Ealy[1], A. E. Fischer-Brown[3], and P. J. Hansen[1], [1]*University of Florida*, *Gainesville*, [2]*Institute for Animal Science*, *Neustadt, Germany*, [3]*University of Illinois*, *Urbana*.

Transfer of bovine embryos cultured with insulin-like growth factor–1 (IGF–1) can increase pregnancy rates in heat-stressed, lactating dairy cows. Two experiments were conducted to determine the effect of IGF–1 on the relative abundance of several developmentally important genes as well embryo survival to day 14 of gestation. In experiment 1, embryos were produced in vitro (n = 4 replicates) and cultured with or without 100 ng/mL IGF-1 for seven days. On day 7, grade 1 expanded blastocysts (n = 104 control and 96 IGF–1, respectively) were selected for semi-quantitative reverse transcription-polymerase chain reaction analysis. Treatment with IGF–1 increased (P < 0.02) the relative abundance of IGF binding protein 3 and desmocollin II and tended (P < 0.08) to increase sodium/potassium ATPase and Bax. In contrast, IGF–1 decreased (P < 0.05) the relative abundance of heat shock protein–70 and tended (P < 0.08) to decrease IGF-1 receptor. In experiment 2, non-lactating (n = 52) and lactating (n = 32) Holstein cows were selected as recipients following synchronization for timed-embryo transfer (n = 11 replicates). Embryos were produced as described in experiment 1. At Day 7 after anticipated ovulation (Day 0), a single embryo was randomly transferred to each recipient. Embryos were recovered at Day 14 and embryo length was recorded. Recovered embryos were cultured for 24 h and interferon-τ (IFN-τ) secretion was assessed using an anti-viral assay. Recovery rate at Day 14 for recipients that received IGF–1 treated embryos tended (P = 0.10) to be greater (16/37 = 43.2%) than for recipients that received control embryos (12/47 = 25.5%). However, there was no effect of IGF-1 on embryo length or IFN-τ secretion. Results indicate that IGF–1 treatment can alter the relative abundance of several developmentally important genes. Moreover, IGF–1 can increase embryo survival as early as day 14 of gestation. These effects may be important for the improved survival of IGF–1 treated embryos reported previously.

Key Words: Insulin-Like Growth Factor-1, Embryo, Bovine

W215 Effect of supplementation with Megalac-E on pregnancy rate in primiparous Nellore cows. C. N. Lopes[1], J. L. M. Vasconcelos*[1], T. P. B. Araujo[2], and L. O. F. Oliveira[3], [1]*FMVZ-UNESP*, *Botucatu, SP, Brazil*, [2]*Arm&Hammer*, *Brazil*, [3]*Propec Consultoria*, *Brazil*.

Fat supplementation has often positively influenced the reproductive status of the dairy cow. Linoleic acid is inhibitor of cyclooxygenase in endometrial tissue of dairy cows, which suppress endometrial secretion of PGF2α and potentially prevent early embryonic death (Staples et al, 1998). The objective was to evaluate effect of supplementation with Megalac-E® (40% linoleic acid; Arm&Hammer) on reproductive responses in primiparous Nellore cows after timed AI. The trial was conducted at a beef farm in Brazil from December 2006 to January 2007. Primiparous Nellore cows (n=411; 50 to 80 days post partum) received 0.4kg/day of concentrate plus minerals at pasture, from the beginning of the synchronization protocol until day 28 after timed AI and were randomly assigned to received or not the supplementation with Megalac-E: Control Group 100gr Kaolin (n= 211); Megalac Group 100 g Megalac-E (n= 200). Cows were synchronized with an intravaginal P4 device (CIDR®, Pfizer, Brazil) plus an injection of 2 mg of estradiol benzoate (Estrogin®, Farmavet, Brazil) on day 0. On day 9, 12.5 mg of dinoprost (Lutalyse®, Pfizer, Brazil) plus 0.5 mg of estradiol cipionate (ECP®, Pfizer, Brazil) were administered, CIDR® was removed, and the calves were removed until finishing TAI, that was performed 48 hours after CIDR® removal. Pregnancy rates were the percentage of cows diagnosed pregnant by ultrasonography (Aloka 500, probe 7.5 MHz) at Day 28 after TAI. Effects of treatment on pregnancy rates were analyzed by chi-square test. Pregnancy rates in the cows treated with Megalac-E (56.5%; 113/200) were higher (p=0.015) than in control group (45.6%; 94/211. The mechanism by which Megalac improves reproductive performance may be due to the Linoleic acid that has been demonstrated had inhibitory effect on the prostaglandin synthesis. This data suggests that Megalac-E at the beginning of the Timed AI protocol until day 28 after AI to lactating primiparous Nellore cows increased pregnancy rate, probably due its antiluteolytic effect.

Key Words: Conception, Megalac, Nellore Cows

W216 Progesterone postpartum determination and reproductive performance of crossbred cows. M. S. Arellano-Cornejo[1], J. C. Martinez-Gonzalez*[2], E. M. Romero-Trevino[1], F. Briones-Encinia[2], F. De la Garza-Requena[2], and M. Dominguez-Munoz[3], [1]*Instituto Tecnologico Superior de Altamira*, *Altamira, Tamaulipas, Mexico*, [2]*Agronomia y Ciencias, Universidad Autonoma de Tamaulipas*, *Ciudad Victoria, Tamaulipas, Mexico*, [3]*FMVZ, Universidad Autonoma de Tamaulipas*, *Ciudad Victoria, Tamaulipas, Mexico*.

This study was conducted to determine the effect of calving number (CN), body condition (BC), and days after calving (AC) on first progesterone postpartum rise (P4). Also first estrous postpartum (EP) and calving conception intervals (CC) were studied. Twenty one cows Brown Swiss × Zebu were divided into 4 groups according to CN: I) 3 (first-lactating); II) 9 (two calving); III) 7 (three calving), and IV) 2 (four calving). Cows grazed Cynodon nlemfuencis and Panicum maximum, and were protein supplemented (18% CP) with 2 kg/cow/d. Estrus was detected by daily visual observation at milking time and on pasture. Progesterone was determined by RIA, low plasma progesterone values (<0.5ng/mL) were consistent with ovarian inactivity, confirming

the true anestrus status of experimental animals. CC was confirmed by rectal palpation. BC was evaluated using a scale of 1 to 9, were 1 = very thin, and 9 = very fat. The study has duration of 60 days postpartum. The mean (P4P) was 1.07 ± 1.68 ng and were affected by BC and AC ($P < 0.001$). Cows with BC 3 and 4 failed to exhibit estrus and maintained low progesterone concentrations throughout the study (2.86, 1.89, 1.26, 0.61 and 0.04 ng for 7, 6, 5, 4 and 3 BC, respectively). The animals, high progesterone values from day 45 onwards suggested ovulatory estrus. It was concluded that BC and AC are the parameters that have more influence on ovarian activity ailed the duration of the anestrous postpartum period. To determine the factors that affect interval calving, it is necessary to study the overall herd fertility.

Key Words: Bovine, Progesterone, Anestrus

W217 Diagnosis of bovine freemartinism by fluorescence in situ hybridization using a bovine Y chromosome-specific DNA probe. S. H. Sohn, E. J. Cho, W. J. Son, and C. Y. Lee*, *Jinju National University*, *Jinju, Korea*.

A heifer born as a co-twin to a bull mostly becomes a sterile freemartin which needs to be screened out from the replacement stock during early development for efficient cattle production. Various methods are available for the diagnosis of freemartinism, but none of them are perfect in terms of the speed, sensitivity, or specificity. The present study was thus conducted to develop and validate a satisfactory fluorescence in situ hybridization (FISH) procedure for identifying the bovine XX/XY-karyotypic chimerism, the hallmark of the freemartinism. A FISH probe containing the 54-bp bovine male-specific BC1.2 DNA sequence was synthesized and labeled with digoxigenin by polymerase chain reaction. The FISH was performed on chromosome spreads and nuclei of blood lymphocytes on slides; karyotyping was done on the chromosome spread following G-banding. Upon FISH, the probe expectedly bound to the nucleus of the male cell or to a region of the Yp12 locus on the chromosome spread. Out of a total of 24 Holstein-Friesian and Korean Cattle heterosexual twins consisting of 13 heifers and 11 bulls which were analyzed in the present study, all but three exhibited the XX/XY-karyotypic chimerism to varying extents regardless of the breed or age of the animal in both FISH and karyotyping. One heifer was identified to have 100% XX-type cells by both analyses, whereas two bulls were judged as 100% XY- and XX/XY-chimeric karyotypes by karyotyping and FISH, respectively. Nevertheless, the ratios of the XY to XX cells in these two bulls and all the other animals were very similar between the two analyses. Results indicate that the present FISH is a rapid and reliable procedure which can be used for early diagnosis of bovine freemartinism.

Key Words: Freemartin, Karyotype, FISH

W218 Influence of insulin on plasma and hepatic composition, ovarian activity and estrous behavior in early lactation dairy cows. J. A. Casas*, M. F. Sa Filho, C. Narciso, F. Rivera, and J. E. P. Santos, *Veterinary Medicine Teaching and Research Center, University of California Davis*, *Tulare*.

Objectives were to determine the effects of increased plasma insulin under normoglycemia on blood and hepatic composition, ovarian activity and estrous behavior in dairy cows. Holstein cows at 1 d in milk (DIM) were randomly assigned to receive 0 (CON, n=38) or 75 IU of slow-release insulin (INS, n=38) and 30 g of glucose i.v. daily until 14 DIM. Ovaries were examined by ultrasonography 4 × weekly from 10 to 60 DIM. Estrous behavior was evaluated by a radiotelemetric heat mount device. Blood was sampled daily immediately before insulin injection in the first 14 DIM, and 4 × weekly thereafter. Plasma was analyzed for concentrations of glucose, insulin, nonesterified fatty acids, 3-hidroxybutyrate, insulin-like growth factor-I, growth hormone, estradiol and progesterone. Concentrations of glucose and insulin were also evaluated every 3 h during a 24 h after treatment. A liver biopsy was collected at 7 and 14 DIM and assayed for mRNA for bovine GH receptor and chemical composition. Yields of milk and components were measured for the first 90 DIM, and body condition (BCS) was scored at 1 and 60 DIM. Data were analyzed using the MIXED and Chi-square procedures of SAS (2001). In the first 24 h after treatment, concentrations of glucose in plasma were similar ($P=0.15$) and averaged 57.2 ±1.8 and 53.4 ±1.7 mg/dL for CON and INS cows. Rectal temperature was similar ($P=0.64$) for CON and INS during the first 10 DIM and averaged 39.3 oC. For CON and INS, respectively, yields (kg/d) of milk (40.7 vs 39.1), 3.5% fat-corrected milk (41.8 vs 41.5), energy corrected milk (37.8 vs 37.3), milk fat (1.50 vs 1.52) and true protein (1.17 vs 1.12) were similar ($P>0.10$). Similarly, mean and median BCS did not differ ($P>0.10$) for CON (2.75 and 2.84) and INS (2.63 and 2.71). All cows ovulated and DIM at first ovulation was similar ($P=0.80$) and averaged 20.5 d. Double ovulation was similar ($P=0.82$) between treatments and averaged 39.3%. Length of the first luteal phase did not differ between treatments and averaged 23.4 d. Treatment with insulin did not affect lactation performance or reproductive parameters evaluated.

Key Words: Dairy Cow, Follicle, Insulin

W219 Influence of parity on follicular dynamics and resumption of ovarian cycle in postpartum dairy cows. T. Tanaka*, M. Arai, S. Ohtani, S. Uemura, S. Kim, T. Kuroiwa, and H. Kamomae, *Tokyo University of Agriculture and Technology*, *Fuchu, Tokyo, Japan*.

The aim of the present study was to determine ovarian changes preceding the resumption of the ovarian cycle and their association with body energy status in postpartum dairy cows with different parities. In postpartum primi- (n=6), bi- (n=4) and multiparous (n=6) Holstein dairy cows, ovarian ultrasonographic observation starting at seven days after calving was performed every other day as a rule but daily after the confirmation of clinical signs of estrus for the detection of postpartum first ovulation. Blood samples were collected at ultrasonography and analyzed for estradiol and progesterone to monitor ovarian activity. To evaluate the nutritional condition of cows, body weight and body condition score (BCS, 1 = emaciated and 5 = obese) were measured weekly and blood samples for the analysis of glucose, insulin and non-esterified fatty acid (NEFA) were collected at the same time until postpartum second ovulation. The days to first ovulation after calving and the number of follicular waves preceding the first ovulation in primiparous cows were significantly greater than those in multiparous cows (31.8 ± 8.3 vs. 17.3 ± 6.3 days and 2.7 ± 0.8 vs. 1.3 ± 0.8 waves, $p<0.05$), but were not significantly different from biparous cows (28.8 ± 8.6 days and 2.0 ± 0.7 waves). Estradiol concentration on the day prior to the first ovulation in primiparous cows was significantly lower than that in multiparous cows (4.8 ± 2.3 vs. 9.6 ± 4.4 pg/ml, $p<0.05$). BCS was maintained at a

level of more than 2.5 during the postpartum period in all cows and the influence of parity on postpartum changes in BCS, glucose, insulin and NEFA was not found throughout the experiment. The present study demonstrated that the interval from calving to first ovulation in primiparous cows was longer than that in multiparous cows in association with the number of follicular waves under such similar body nutritional conditions.

Key Words: Parity, Postpartum First Ovulation, Dairy Cows

W220 Pregnancy loss in lactating Holstein cows diagnosed with twin versus singleton fetuses. N. Silva del Río*[1], J. D. Colloton[2], and P. M Fricke[1], [1]*University of Wisconsin*, *Madison*, [2]*Bovine Services LLC*, *Edgar, WI*.

Our objective was to characterize pregnancy loss (PL) for cows diagnosed with twin (T) vs. singleton (S) fetuses on a commercial dairy farm comprising 1,100 lactating Holstein cows. Records were collected by the herd veterinarian who performed weekly reproductive examinations using transrectal ultrasonography from January 2005 to February 2006. The initial data set included 2,048 pregnancy examinations (1,389 initial examinations and 659 re-examinations). The 730 observations with no recorded re-evaluation included 673 cows diagnosed not pregnant, 22 cows with nonviable fetuses, 33 cows diagnosed pregnant with a singleton fetus, and 2 cows diagnosed pregnant with twin fetuses. The remaining cows were either culled from the herd or were re-inseminated. Only records from cows diagnosed pregnant with a viable fetus from 27 to 40 d postbreeding that included a pregnancy re-evaluation from 48 to 82 d postbreeding were used to assess PL. Cows (n=13) identified with twin fetuses at the pregnancy re-examination but identified with singleton fetuses at the initial pregnancy examination were excluded from the data set. A total of 468 S cows and 74 T cows were included in the final data set. Pregnancies of S cows with 1 CL comprised 60.9% right horn with a CL on the right ovary and 39.1% left horn with a CL on the left ovary. Pregnancies of T cows with 2 CL comprised 26.1% unilateral right horn with 2 CL on the right ovary, 31.9% unilateral left horn with 2 CL on the left ovary, and 42.0% bilateral horn with one CL on each ovary. Overall, PL was greater ($P<0.01$) for T (25%) vs. S (4.9%) cows. For S cows with 1 CL, PL was 5.5 % (22/379), whereas PL for S cows with 2 CL was 1.5% (1/66). Among T cows, only 5 had 1 CL, and 3 of these cows lost 1 fetus and 1 lost both fetuses. For T cows with 2 CL, 8.6% (6/69) lost 1 fetus and 13.0% (9/69) lost both fetuses. We conclude that PL is greater for T compared to S cows and that spontaneous loss of one fetus and maintenance of the other can and does occur for T cows.

Key Words: Twinning, Pregnancy Loss, Dairy Cow

W221 Effects of twin pregnancy and prepartum diet on early postpartum ovarian activity in Holstein dairy cows. N. Silva del Río*, R. R. Grummer, and P. M. Fricke, *University of Wisconsin*, *Madison*.

To evaluate the effect of pregnancy type [singleton (S) vs. twin (T)], and prepartum feeding management [transition diet (NEL=1.54 Mcal/kg) for 3 (3TR) vs. 8 wk (8TR) before expected calving date (ECD)], on postpartum (PP) ovarian activity and periparturient traits, multiparous (n=39) and primiparous (n=8) Holstein cows were used in a 2×2 factorial randomized complete block design. All cows were feed a late lactation diet (NEL=1.58 Mcal/kg) from 90 to 60 d before ECD and the same early lactation diet (NEL=1.71Mcal/kg) after calving. At dry-off, cows were feed a transition diet for 8 wk before ECD (8TR) or far-off diet (NEL=1.32 Mcal/kg) for 5 wk followed by transition diet 21d before ECD (3TR). Thrice weekly (MWF), ovaries were evaluated with transrectal ultrasound, and blood samples were collected for serum progesterone (P4). Gestation length was shorter ($P<0.05$) for T than for S cows (276 vs. 281 d). Calf BW was greater ($P<0.05$) for twin vs. singleton calves (70.7 vs. 42.4 kg) and, for 5 of the twin pairs, the smaller calf was 24 % lighter than its cotwin. Numerically more retain placenta were recorded for T than for S cows (55 vs. 29 %), and more ($P<0.05$) T cows required calving assistance than S cows (70 vs. 30 %). Although prepartum serum P4 (-7 to 1 d relative to calving) was greater ($P<0.05$) for T than for S cows (2.5 vs. 1.9 ng/mL), no effect of treatment was detected for average d to first PP ovulation (40 ± 5 d); average d to first PP 10 mm follicle (15.0 ± 1.8 d); and diameter of the largest follicle at first PP ultrasound (7.0 ± 0.6 mm). No treatment effects were detected for the incidence of anovulation (9.1%) or short luteal phases (11.4 %). No treatments effects were detected on ovulation rate of the first PP dominant follicle (57.5%) or double ovulation rate at first (29.7%) or second PP ovulation (16.1 %). Thus, although T cows have a greater risk for negative periparturient traits than S cows, no effect of treatment was detected for PP ovarian activity.

Key Words: Twinning, Transition Diet, Early Postpartum Ovarian Activity

W222 Relationship between the occurrence of first ovulation in early postpartum and metabolic status in the cows that experiencing postpartum disease. M. Matsui*, E. Kaneko, M. Kataoka, C. Kawashima, N. Sudo, N. Matsunaga, M. Ishi, K. Kida, Y.-I. Miyake, and A. Miyamoto, *Obihiro University of Agriculture and Veterinary Medicine*, *Obihiro, Hokkaido, Japan*.

Our recent study showed that the cow with early first ovulation (1st OV) by 3 weeks postpartum (wk pp) has higher subsequent fertility, and that the metabolic status closely relates to the occurrence of early 1st OV. It is generally accepted that the cow with postpartum disease has delayed resumption of ovarian cycle and low fertility. In present study, the relationship between the occurrence of early 1st OV and metabolic status in cows experiencing postpartum disease was examined. We analyzed Holstein cows that had clinical record for postpartum paraplegia, retained placenta, abomasal displacement, mastitis and/or ketosis by 100 days pp. Weekly blood samples were obtained from 81 multiparous and 23 primiparous cows from 1st to 9th wk pp, and measured metabolites (glucose, non-esterified fatty acid: NEFA, aspartate aminotransferase: AST, γ-glutamyl transpeptidase: γ-GTP), metabolic hormones (growth hormone: GH, IGF-I, insulin) and progesterone (P4) concentrations. Increase in plasma P4 (≥ 1 ng/ml) by 3 wk pp was observed in 37 multiparous (45.7%) and 10 primiparous cows (43.5%), where those cows were confirmed as having early 1st OV. All data were evaluated by repeated measure analysis of variance. The average and values at each week by 3 wk pp were analyzed by Student's t-test. Multiparous cows with early 1st OV showed higher glucose at 3rd wk pp, lower AST at 2nd and 3rd wk pp, lower average of γ-GTP during 3 wk pp, lower GH at 3rd wk pp and higher average of insulin during 3 wk pp compared to the cows

having no ovulation. Lower NEFA at 1st wk pp, lower average of NEFA during 3 wk pp, and higher insulin at 3rd wk pp were observed in primiparous cows with early 1st OV. Data suggest that metabolic status in early pp influences the occurrence of early 1st OV in cows that experience postpartum disease. Hepatic function in multiparous cows and body fat mobilization in primiparous cows appear to relate to early 1st OV in pp. In addition, it may be common to these multiparous and primiparous diseased cows that insulin levels by 3 wk pp closely associate with early 1st OV.

Key Words: Dairy Cow, First Ovulation, Postpartum Disease

W223 Effects of dietary fats differing in proportion of unsaturated fatty acids on characteristics of preovulatory follicles in dairy cows. M. Katz*[1,2], A. Arieli[2], and U. Moallem[1], [1]*Agriculture Research Organization*, *Bet Dagan, Israel*, [2]*Faculty of Agriculture, Hebrew University*, *Rehovot, Israel*.

The objectives of this study were to examine the effects of dietary prilled fat containing low proportion of unsaturated fatty acids (LUFA) or calcium soap of fatty acids (FA) containing high proportion of unsaturated FA (HUFA), on characteristics of preovulatory follicles. Israeli-Holstein dry cows, 256 d pregnant, were divided into three treatments that continued until 100 d in milk: 1) Control - (n=14) were fed a dry cow diet and postpartum were fed a lactating cow diet; 2) LUFA - (n=13) were supplemented with 230 g/d per cow of prilled fat; 3) HUFA - (n=14) were supplemented with 215 g/d per cow of calcium soap of FA. At 40 d in milk the estrus cycle was synchronized. Fourteen d after behavioral estrus, cows were injected with $PGF_{2\alpha}$ and 48 h later > 7 mm follicles were aspirated (aspiration ranged 55 - 70 d in milk). Androstenedione (A_4), estradiol (E_2), progesterone (P_4), insulin and nonesterified FA concentrations in follicles were determined. Follicles with E_2/P_4 ratio higher than 1 were analyzed (n=39). Follicular A_4 concentrations were 69% higher in HUFA and 65% lower in LUFA than in control (181.3, 37.4 and 107.3 ng/ml, respectively, $P < 0.04$). Follicular E_2 concentrations were 40% higher in HUFA and 53% lower in LUFA than in control (1695.6, 572.5 and 1214.7 ng/ml, respectively, $P < 0.02$). Total A_4 and E_2 in follicles were higher in HUFA than in control with no differences between LUFA and control. No differences were observed in P_4 concentrations and content among groups. The E_2/P_4 ratio was 47% higher in HUFA and 41% lower in LUFA than in control (21.5, 8.7 and 14.7, respectively, $P < 0.05$). Nonesterified FA and insulin concentrations in follicles were not different among groups. In conclusion, the positive effect of dietary unsaturated FA on preovulatory follicle hormones may be beneficial to the oocyte, could improve estrus intensity and therefore contribute to fertility in dairy cows.

Key Words: Unsaturated Fatty Acid, Preovulatory Follicle

W224 Effects of endothelin-1 infused chronically adjacent the luteal-containing ovary or intrauterine in ewes on luteal function. C. W. Weems*, Y. S. Weems, D. Johnson, T. Uchima, E. Lennon, A. Raney, K. Goto, G. Bowers, J. Saldana, and J. Pang, *University of Hawaii*, *Honolulu*.

Endothelin-1 (ET-1) has been reported to mediate PGF2α-induced luteolysis (Hinckley and Milvae, Biol. Reprod. 64:1619, 2001). mRNA for ET-1 converting enzyme-1, pre-pro ET-1 and ET receptors increased in cow corpora lutea (CL) from D-1-10 postestrus, were similar on D-10 and D-17, were not increased by PGF2α on D-10, but were increased by PGF2α on D-17 when luteolysis was underway (Choudhary et al., Domest. Anim. Endocrinol. 27:63, 2004). PGE (PGE1 and PGE2) is antiluteolytic and luteotropic (C. Weems, Y. Weems, R. D. Randel. The Vet. J. 171:206, 2006). ET-1 increased PGE secretion by cow CL in vitro when estrus was not synchronized or when synchronized with PGF2α and did not affect CL PGF2α or progesterone (P4) secretion. This does not support ET-1 being luteolytic (Y. Weems et al.; Prostaglandins and Other Lipid Mediators 74:45, 2003). The objective of this experiment was to determine whether ET-1 infused every 6 h from 2400 h on D-10 to 1800 h on D-18 of the ovine estrous cycle into tissue of the ovarian vascular pedicle (IP-2μg) adjacent the CL ovary or intrauterine (IU-4 μg) was luteolytlc in ewes. Treatments were: Vehicle-IP (n=4); Vehicle-IU (n=4); ET-1-IP (n=5); or ET-1-IU (n=5). CL weights at 1800 h on day 18 were analyzed by a 2×2 Factorial Design for ANOVA. Jugular venous plasma at 0, 18, 42, 66, 90, 114, 138, 162, and 186 h was analyzed for P4 by RIA. P4 profiles were analyzed by a Split Plot Design for ANOVA for repeated measures. CL weights differed ($P \leq 0.05$) among treatment groups. CL weights (mg) at 1800 h on D-18 were: VEH-IP-247±38; VEH-IU-195±31; ET-1-IP-626±74; and ET-1-IU-542±69. CL weights were heavier ($P \leq 0.05$) in ET-1 IP or IU-treated ewes than Vehicle-IP or IU treatment groups and did not differ ($P \geq 0.05$) between ET-1 IP or IU groups. Profiles of P4 in jugular venous blood of Vehicle IP or IU were lower ($P \leq 0.05$) than in ewes treated with ET-1 IP or IU, which did not differ ($P \geq 0.05$) between ET-1 IP or IU treatment groups. In summary, ET-1 prevented the decrease in CL weights and the decline in P4 compared to controls. It is concluded that ET-1 may not be luteolytic, but antiluteolytic in ewes.

Key Words: Corpus Luteum, Endothelin-1, Progesterone

W225 Effect of extender on retention of viability and motility in hair sheep and goat semen stored at 4°C. J. L. Mook* and S. Wildeus, *Virginia State University*, *Petersburg*.

Liquid storage of chilled semen may provide an opportunity to expand the use of AI in small ruminants when used in conjunction with overnight shipping. This study evaluated the ability of various extenders to maintain motility and viability in hair sheep and goat semen. Ejaculates were collected via artificial vagina during the breeding season. For trial 1, two separate collections were used to generate pooled samples of 4 animals/species. Samples were extended in 2.9% sodium citrate, DPBS, DPBS with BSA, and TRIS with egg yolk (EY). Extended samples were initially kept at 25°C for 3 hand were then stored at 4°C for 24 h. Motility was assessed using a CASA system, and viability with eosin and Sybr14/PI staining at 0, 3, and 24 h. For trial 2, ejaculates from 6 animals/species were extended individually in TRIS, TRIS with BSA, TRIS with EY, non-fat milk, and a commercial 2-step extender (Continental Plastic Corp.). Extended samples were kept at 25°C for 6 h, and were then stored at 4°C until 48 h. Motility and viability were determined at 0, 3, 6, 24, and 48 h, and at 0, 12 and 48 h, respectively. For trial 1, total (Tmot) and progressive motility (Pmot) were influenced by an interaction of extender and storage time ($P<0.001$). Initial buck Tmot and Pmot, and ram Pmot were similar across all extenders. Ram samples in EY-containing extenders maintained higher motility and viability for the duration of storage ($P<0.05$). Buck samples demonstrated no change in viability

over time. In trial 2, initial Tmot and Pmot were higher ($P<0.05$) in TRIS with either EY or BSA over time. Ram samples extended in TRIS with EY had reduced ($P<0.05$) Tmot and Pmot initially compared to the other extenders, but maintained the highest motility over 48 h. No changes in viability were detected via eosin staining after 48 h, but Sybr14/PI staining indicated viability in rams was only maintained ($P<0.05$) in EY and milk. In both trials, effects on motility were usually notable within the first 3 h. These results show EY-based extenders maintained motility and viablity best, and should be evaluated further for long-term chilled storage of buck and ram semen.

Key Words: Semen, Hair Sheep, Goats

W226 Use of fecal progestin determinations to characterize the estrous cycle in captive female bontebok (*Damaliscus pygargus pygargus*). M. McGee*[1], A. Kouba[2], S. Bowers[1], R. Meek[2], B. L. Elliot[2], C. Horton[2], T. Hill[2], E. Piorkowski[2], and S. Willard[1], [1]*Mississippi State University*, *Mississippi State*, [2]*Memphis Zoo*, *Memphis, TN*.

The bontebok is an antelope that almost became extinct and is classified as "vulnerable". Information concerning their reproductive physiology is needed in support of propagation efforts. Our objective was to profile fecal progestins (PROG) of female bontebok to characterize the estrous cycle and reproductive season. Samples were collected from enclosures with positive identification of animal-fecal pairs. Fecal samples (n=1,132) were collected from n=6 female bontebok from July 2002 to Sept. 2005. Samples were stored at -20°C until extraction using 0.5 g of feces in 5 mL 80% Methanol with shaking for 12-14 h. Samples were centrifuged for 15 min and the supernatant analyzed for immunoractive fecal PROG in a progesterone RIA. Coefficients of variation (CV%) are reported as a statistical measure of variability among estrous cycles. Length of the estrous cycle was 20.7±1.4 d (range: 12-26 d; CV: 19.8%). For females that did not become pregnant, the number of estrous cycles exhibited in a season was 4.5±0.5 cycles (CV: 15.7%). Shifts in the seasonality of cycles were observed among individuals from year-to-year, attributed to environment (season) and/or previous reproductive status. As a representative example, a bontebok female (#L13871) gave birth in July 2002 and began cycling 137 d later from Dec. 4, 2002 to April 3, 2003 exhibiting n=5 estrous cycles (length: 22.4±1.5 d; CV: 14.6%) and did not become pregnant, shifting into anestrus. The next year #L13871 exhibited n=4 estrous cycles (length: 18.5±2.2 d; CV: 23.6%) that began and ended earlier than the previous year: Sept. 9, 2003 to Jan. 11, 2004. It is unclear whether lactational-induced anestrus resulted in a later reproductive season in 2002/2003 than 2003/2004, or whether a seasonal cue may have initiated the shift in cycles. In conclusion, this study has identified characteristics of the estrous cycle and reproductive season (possibly affected by previous reproductive status and/or environment) in captive bontebok. These data may assist in the reproductive management of this species to improve propagation efforts.

Key Words: Bontebok, Fecal Hormones, Estrous Cycle

W227 Cloning and characterization of chicken prostaglandin E receptor subtypes 2 and 4 (EP2 and EP4). A. H. Y. Kwok*, C. Y. Wang, Y. Wang, and F. C. Leung, *The University of Hong Kong*, *Hong Kong, HK-SAR, China*.

Prostaglandin E2 (PGE2) belongs to the eicosanoids and is an important chemical mediator regulating many vital physiological processes, including muscle relaxation, vascular homeostasis, gastrointestinal function and maintenance of pregnancy. Prostaglandin E receptor subtypes 2 and 4 (EP2 and EP4) are crucial mediators between its ligand, PGE2, and downstream intracellular cyclic AMP/protein kinase A (cAMP/PKA) signaling pathway. Both receptors were identified in mammals and zebrafish, but they have not been cloned in the avian species. In the present study, using reverse transcription-polymerase chain reaction (RT-PCR), the full-length cDNAs for chicken EP2 and EP4 receptors were cloned from adult chicken ovary and testis respectively. The full-length cDNA of EP2 gene encodes a precursor of 475 amino acids with a high degree of amino acid identity to that of mammals, including human (87%), mouse (86%), rat (84%), dog (85%), and cow (83%), and a low sequence identity to zebrafish (52%). Chicken EP4 is 356 amino acids in length and also shows high amino acid identity to that of mammals (human, 61%; mouse, 63%; rat, 61%; dog, 58%; cow, 59%) and a lower sequence identity to lower vertebrate (zebrafish, 41%). Using the pGL3-CRE-luciferase reporter system, we also demonstrated that PGE2 strongly induces luciferase activity of CHO/DF-1 cells expressing EP2 in a dose-dependent manner (EC50: <1 nM), confirming the functionality of the cloned EP2 receptor. The same experiment is also under way for EP4. The cloning and characterization of EP2 and EP4 receptors would help us to establish a molecular basis to elucidate the physiological roles of prostaglandin E2 in target tissues including their actions in chicken ovary.

Key Words: Chicken, PGE2, Prostaglandin E Receptors

W228 Pulmonary hemodynamic responses to intravenous prostaglandin E_2 in broiler chickens. S. Stebel and R. F. Wideman, Jr.*, *University of Arkansas*, *Fayetteville*.

Prostaglandin E_2 (PGE_2) affects pulmonary arterial pressure (PAP), pulmonary vascular resistance (PVR), and respiratory rate (RR) in mammals but no information previously was available regarding avian pulmonary responses to PGE_2. Two experiments were conducted in which 45 to 55 d old male broiler chickens were infused i.v. with PGE_2 at the lowest rate (30 µg/min for 4 min) that reliably reduced PAP by approximately 2 mm Hg during pilot studies. When compared with pre-infusion (Control) values in Experiment 1, PGE_2 reduced PAP from 19 ± 1 to 16 ± 1 mm Hg ($P<0.05$) and reduced mean systemic arterial pressure (MAP) from 111 ± 6 to 81 ± 5 mm Hg ($P<0.05$) but did not significantly reduce heart rate (HR) (Control: 338 ± 9 beats/min; PGE_2: 320 ± 12 beats/min; $P>0.05$). Infusing PGE_2 also reduced the respiratory rate (RR) from 57 ± 2 to 46 ± 4 breaths/min ($P<0.05$), and reduced the percentage saturation of hemoglobin with oxygen ($\%HbO_2$) from 85 ± 2 to 77 ± 3 % ($P<0.05$). The PAP, MAP, RR and $\%HbO_2$ all recovered to control levels after the PGE_2 infusion ceased. In Experiment 2 an ultrasonic flow probe was surgically implanted to measure cardiac output (CO). When compared with pre-infusion control values, PGE_2 reduced PAP from 25 ± 2 to 21 ± 1 mm Hg ($P<0.05$), reduced CO from 140 ± 6 to 111 ± 5 mL/kg BW × min ($P<0.05$), and reduced RR from 49 ± 4 to 35 ± 4 breaths/min ($P<0.05$). All of these variables recovered to control levels within 9 min after stopping the PGE_2 infusion. The reduction in CO was caused by a reduction in HR rather than stroke volume. The PVR, calculated as PAP/CO, was not altered by PGE_2 (Control: 0.180 ± 0.012 relative resistance units; PGE_2: 0.200 ± 0.017 relative resistance units; $P>0.05$). These results indicate that in broilers PGE_2 reduced PAP by reducing

CO rather than by acting as a pulmonary vasodilator to lower PVR. Reductions in CO, RR and blood oxygenation triggered by i.v. PGE_2 infusion previously have been reported for mammalian species in which specific PGE_2 receptors reside on parasympathetic neurons, suggesting parasympathetic inhibition of cardiac and respiratory function may play a role in the responses of broilers to PGE_2.

Key Words: Respiration, Hemodynamics, Cardiac Output

W229 Coordinate accumulation of the egg envelope glycoproteins during follicular development in Japanese quail (*Coturnix japonica*). T. Sasanami*[1], M. Ohtsuki[1,2], G. Hiyama[3], N. Kansaku[3], A. Tsukada[4], K. Tahara[4], T. Watanabe[4], T. Yoshimura[4], and M. Mori[1], [1]*Shizuoka University*, *Shizuoka, Japan*, [2]*Gifu University*, *Gifu, Japan*, [3]*Azabu University*, *Sagamihara, Japan*, [4]*Nagoya University*, *Nagoya, Japan*.

The extracellular matrix surrounding avian oocytes, termed as perivitelline membrane (PL), exhibit a three-dimensional network of coarse fiber between the granulosa cells and the oocyte. Our previous studies of Japanese quail have demonstrated that one of its components, ZPC, is synthesized in the ovarian granulosa cells. Another component, ZP1, which critically involves in triggering the sperm acrosome reaction in quail, is synthesized in the liver, and is transported to the surface of the oocyte in the follicles. We have previously isolated cDNAs encoding quail ZPC and ZP1, and now report the isolation of cDNA encoding quail ZPA. By RNase protection assay and *in situ* hybridazation with radio-labelled antisense probes to ZP mRNAs, we have demonstrated that ZPA transcripts are detected in the granulosa layer of small white follicles (SWF). Expression level of ZPA decreased progressively during follicular development (n=3, $P < 0.01$), and the highest expression was observed in SWF. On the other hand, ZPC transcripts increased as corresponding to follicular development (n=3, $P < 0.01$), but barely visible in SWF. Immunohistochemical analyses using specific antisera raised against ZP glycoproteins indicate that the immunoreactive materials recognized with anti-ZPA antiserum were detected in the apical side of the granulosa layers of SWF, and were also detected in the PL of small yellow follicles (SYF). However, the signal was not detected on the sections of SWF, which had been reacted with anti-ZPC as well as with anti-ZP1 antiserum. The intense staining with anti-ZPC antiserum was seen in the PL of SYF, whereas the weak signal was appeared when the section of 4th largest follicles was stained with anti-ZP1 antiserum. These results indicate that three PL glycoproteins are accumulated in a coordinate manner during the follicular development in quail, and the phenomena might contribute to the formation of the insoluble fiber of avian PL.

Key Words: Egg Envelope, Zona Pellucida, Japanese Quail

W230 Nicarbazin reduces egg production and fertility in White Pekin ducks via reducing ZP3 in the perivitelline membrane. V. P. Reinoso*, R. Katani, and G. F. Barbato, *The Pennsylvania State University*, *University Park*.

This study determined the dose-response relationship for the effect of nicarbazin in reducing egg production and/or hatchability in White Pekin ducks. Six dosages of nicarbazin were fed to female ducks with the range of doses being 0 ppm, 31.25 ppm, 62.5 ppm, 125 ppm, 250 ppm and 500 ppm for 14 days (n=12/dose group; N=72). Ducks were individually caged and artificially inseminated weekly with semen from untreated drakes. Control ducks had an average rate of lay of 93% with a mean fertility of 87%. Ducks receiving either 250 or 500 ppm nicarbazin had significantly reduced egg production within 2 days of treatment ($P<0.05$). The remaining groups had significantly reduced egg production by within 8 days of treatment ($P<0.05$). By the end of the treatment, all nicarbazin groups had significantly lower egg production than the control groups ($P<0.01$). Recovery of egg production after withdrawal of the nicarbazin treated diets occurred in reverse order of treatment dose, beginning 2 days after drug withdrawal, and completely recovering within 4 days. All nicarbazin groups had significantly lower fertility than the control group within 3 days ($P<0.05$). By seven days of nicarbazin treatment, the 500 ppm group had no fertile eggs (laying at 20%). The 125 and 250 ppm treatments eliminated fertility by day 27 (or 12 days post-treatment; $P<0.01$). Recovery of fertility followed the inverse of nicarbazin dose in the diet, preceding recovery of egg production by 2-3 days. Western blot analysis suggested a reduction in the presence of immunoreactive ZP3 (zona pellucida protein 3) in the perivitelline membrane of eggs laid by nicarbazin treated ducks. Furthermore, there were far fewer (<5%) sperm trapped in the perivitelline membrane of eggs from nicarbazin-treated ducks than in those from controls ($P<0.01$). The decreased fertility, western blots and dearth of trapped sperm in eggs of nicarbazin treated ducks implies a direct and negative effect of nicarbazin on ZP3, the putative sperm receptor, in the avian oocyte.

Key Words: Nicarbazin, ZP3, Ducks

W231 Isolation and culture of chicken oocytes. W. D. Berry*, S. S. Oates, L. M. Stevenson, and C. R. James, *Auburn University Poultry Science*, *Auburn, AL*.

A method of isolation and culture of chicken oocytes was needed to advance studies of oocyte development. The isolation of immature chicken oocytes was accomplished by enzymatic digestion of the chick ovary to disperse the immature oocytes. Ovaries were harvested from newly hatched chicks. The ovaries were collected into 4C calcium/magnesium free Hanks balanced salt solution (HBSS). The ovaries were washed 3 times in HBSS containing antibiotics/antimycotics, then finely minced in the HBSS. The minced tissue was then incubated with agitation for 60 minutes at 37C in a sterile enzymatic dispersal solution containing hyaluronidase, type 2 collagenase, and pronase. The dispersal solution containing the digested tissue was then filtered through a 100 micron filter and centrifuged at 25×g, at 4C, for 7 minutes. The cell pellet was then resuspended in minimal essential medium (MEM) and repelleted by centrifugation, followed by another resuspension step. The cell suspension was then cultured for 6 hours in MEM to remove contaminating fibroblasts by attachment. Alternatively, contaminating fibroblasts were removed by centrifuging the cell suspension through a Percoll gradient. Following fibroblast removal, the isolated oocytes were pelleted by centrifugation, resuspended in MEM and counted on a hemocytometer. Each chick ovary yielded 12,000 to 25,000 viable oocytes. The isolated and purified oocytes were cultured for up to one week in supplemented Dulbecco's MEM-Hams F-12 medium. Oocytes were also preserved at -20C in 95% ethanol. This work was supported by the Alabama Agricultural Experiment Station and the U.S. Poultry and Egg Association.

Key Words: Oocyte, Isolation, Chicken

W232 Gene expression of hen granulosa cell (GC) steroidogenic enzymes and gonadotropin receptors following a chronic heat stress (HS) episode. H. Taira*[1] and M. M. Beck[2], [1]*University of Nebraska*, *Lincoln*, [2]*Clemson University*, *Clemson, SC*.

This study was conducted to determine the effect of HS on gene expression of several key enzymes and hormone receptors in the steroidogenic pathway in GC of laying hens and to determine whether the hen responds like the rat. HS reduces synthesis of and circulating luteinizing hormone (LH), progesterone (P_4) and estrogen in hens, interfering with reproduction. In earlier studies, GC from hens subjected to HS synthesized less P_4 , even when stimulated by LH and 3β-hydroxysteroid dehydrogenase (3β-HSD) activity was reduced, while incubation with LH+FSH increased the activity. In this study, three strains of Hy-Line® laying hens (W36, W98 and CV20) were subjected to 35C (HS) for two wk or maintained in a thermoneutral (TN, 22C) environment. GC from the largest follicles were isolated and enzymatically dispersed. Aliquots of 100,000 viable cells were incubated with or without LH+FSH and the expression of mRNAs of steroidogenic acute regulatory protein (StAR), cytochrome P450 side-chain cleavage (P450scc), LH and FSH receptor (LH-R, FSH-R) and 3β-HSD were analyzed using real time RT-PCR normalized to 18s. Compared to TN, HS did not affect the expression of mRNA of P450scc, LH-R or FSH-R in any strain (P>0.1). Expression of StAR mRNA was reduced by HS in GC in W36 (P=0.0033) but not W98 or CV20 (P=0.6422, P=0.5275, respectively). Reduced 3β-HSD mRNA expression was observed only in CV20 (P=0.0589) and hormone incubation did not improve gene expression in any strain. This is somewhat inconsistent with earlier studies, in which HS reduced GC 3Î²-HSD activity and increased the number of apoptotic GC. The lack of a correlation between expression of 3β-HSD mRNA and enzyme expression under HS may suggest that HS interferes at translational but not the transcriptional level, that other factor(s) (e.g., increased PRL) maintain enzyme stability or receptor regulation, or that the effect of incubation times of hormones on different genes varies. A similar lack of correlation between mRNA and enzyme activity may be true for StAR and P450scc. Different methodologies made direct rat comparisons difficult.

Key Words: Steroidogenesis, mRNA

W233 Some observations on molting male Japanese quail. B. K. Biswas and K. L. Arora*, *Fort Valley State University*, *Fort Valley, GA*.

Molting is one of the important factors that cause significant changes in physiological and morphological characteristics in Japanese quail (*Coturnix japonica*). Our observations on **molting males** made during October 2006 and February 2007 are reported here. Each male (n=20; age 130-50 d) was housed in a separate cage (LD=16:8) with females. The birds were weighed regularly and blood was collected from the wing vein for determining PCV, glucose, and total plasma proteins. The cloacal gland was also measured. Some birds were euthanized to observe the size of testes. The birds started loosing feathers around the neck, then chest and back. The birds ceased crowing and lost some weight during molting. The testes were significantly reduced in size (4-5 vs 14+ mm) and weight (40-50 mg vs ~1.8 g). The cloacal gland was also significantly reduced from 14-19 mm to 6-8 mm. At the same time, the fertility in terms of fertile eggs laid by the cage-mate females was reduced to zero with the reduction of cloacal gland size. After molting the birds regained feathers starting around the neck, followed by chest and then extended backward toward the tail. The cloacal gland as well as testes also regained its normal size and weight. Fertility in male returned to 100% which have regained the size of cloacal gland to a minimum of 14 mm. The PCV of some male birds decreases (53.2% vs. 48.1%; p>0.05) and total plasma proteins increases (3.6 vs 4.2 mg/dl; p>0.05) during molting. Our observations indicate that the size of cloacal gland, testes and fertility in males are interrelated, and the cloacal gland size can serve as an indicator for male capability to fertilize eggs.

Key Words: Japanese Quail, Molting, Cloacal Gland

W234 Rooster semen cryopreservation: Effect of line and male age on sperm function. D. C. Bongalhardo*[1], J. Pelaez[1], J. E. Fulton[2], S. Saxena[2], P. Settar[2], N. P. O'Sullivan[2], J. Arango[2], and J. A. Long[1], [1]*Beltsville Agricultural Research Center*, *Beltsville, MD*, [2]*Hy-Line International*, *Dallas Center, IA*.

The fertility rates of cryopreserved poultry semen are highly variable and not reliable for use in commercial production or preservation of genetic stocks. Our objective was to evaluate the cryosurvival of semen from 8 pedigreed layer lines at the onset and end of production. Semen from 160 roosters (20/line) was frozen individually with 11% glycerol at 6 and 12 mths of age. Glycerol was removed from thawed semen by Accudenz gradient centrifugation. The viability of thawed sperm from each male was determined using SYBR/PI and flow cytometry. The fertilizing ability of thawed sperm was evaluated in vitro by assessing hydrolysis of the inner perivitelline layer. Hydrolysis data were grouped in 3 categories: <20 holes/mm^2; 21-80 holes/mm^2; and >81 holes holes/mm^2. Viability data were compared among lines and between age groups by repeated measures ANOVA. For hydrolysis data, logistic regressions were calculated to predict the natural log of the odds for males within lines to be in 1 of the 3 categories. The percentage of live sperm increased (p<0.0001) with age (6 mths, 35.6±0.8; 12 mths, 41.4±0.7%) and differed (p<0.0001) among lines, with 1 line consistently superior at both 6 and 12 mths. Hydrolyzing ability increased (p=0.0003) from 6 (54.5±6.1 holes/mm^2) to 12 mths (96.7±9.4 holes/mm^2) and differed among lines, with the odds of sperm hole category dependent upon line and age. Overall, viability was correlated with sperm hole number (r=0.24, p<0.0001) and category (r=0.25, p=0.0004); however, when the hydrolysis data were split by line and/or age, only 1 line consistently was correlated at both ages. These results demonstrate variability among pedigreed lines in withstanding glycerol-based semen cryopreservation. Further delineation of genotypic and phenotypic factors impacting sperm cryosurvival will be investigated in these genetic stocks.

Key Words: Chicken, Freezing, Fertilizing Ability

W235 Transcript profiling in mammary of ovariectomized pregnant gilts receiving progesterone and relaxin replacement therapy in late gestation. D. E. Graugnard*, J. J. Loor, E. A. Cutler, R. E. Everts, S. L. Rodriguez-Zas, and W. L. Hurley, *University of Illinois*, *Urbana*.

Relaxin-family peptides appear to have been important for the evolution and adaptation of lineage-specific physiologic processes (e.g.

lactation) during evolution. We previously determined that relaxin has a stimulatory effect on growth of mammary parenchymal tissue during late gestation (d 80-110) in the pig (Endocrinol. 128:1285-1290). To explore mammary genomic adaptations elicited by relaxin we used a swine oligoarray (70 mer) with 13,263 functional hits for transcript profiling of mammary tissue (n = 5/group) from control gilts sacrificed on d 110 of gestation (C110), gilts ovariectomized on d 100 and receiving progesterone (OP110), and gilts as in OP110, but also receiving porcine relaxin (OPR110). Annotation of the array was based on similarity searches using BLASTN and TBLASTX against human, mouse, and pig UniGene databases, the human genome, and pig TIGR. Cy3- and Cy5-labelled cDNA from mammary tissue and a reference standard were used for hybridizations. ANOVA ($P \leq 0.05$) identified 337 differentially expressed genes with OP110 or OPR110 vs. C110. Among these, there were 111 downregulated genes (ANGPT2, TAF12, NR1D2) by ≥2-fold with OP110 or OPR110 vs. C110. The extent of downregulation vs. C110 was more pronounced with OP110 (2-to-24-fold) than OPR110 (2-to-4-fold). Relaxin replacement therapy partially corrected downregulation of genes elicited by ovariectomy as shown by differences in expression between OP110 and OPR110, e.g. 102 genes with 2-fold (E2F5, AP2M1, TP53BP1) to 13-fold (LALBA, CSN1S2A, ANGPT2) upregulation due to OPR110 vs. OP110. Ingenuity Pathway Analysis of ≥2-fold upregulated genes with C110 and OPR110 vs. OP110 showed that molecular transport (19 genes), cell signaling (15 genes), cell growth/proliferation, and carbohydrate/lipid metabolism (10 genes in each) were among the most significant families of related genes. Overall, results demonstrate previously unrecognized genomic adaptations in the mammary gland elicited by relaxin.

Key Words: Mammary Gland, Relaxin, Micro Array

W236 Effect of boron supplementation on semen quality in mature boars. W. L. Flowers*[1], J. W. Spears[1], and F. H. Nielsen[2], [1]*North Carolina State University*, *Raleigh*, [2]*USDA-ARS, Grand Forks Human Nutrition Center*, *Grand Forks, ND*.

The objective of the study was to determine the effect of dietary boron on sperm production and semen quality in mature boars. Twelve crossbred boars (Landrace × Large White × Duroc × Hampshire) that were 2.5 ± 0.2 years of age and 215 ± 5 kg were randomly assigned to receive 0, 25, or 250 mg per head per day of supplemental boron for 8 weeks (n=4 per treatment). Boron was added to their basal diets and boars were fed 2.75 kg daily of a corn-soybean meal diet (14% crude protein). Concentrations of boron in the whole semen and seminal plasma fractions of ejaculates collected at the end of 7 weeks were different among treatments ($P<0.05$). The highest and lowest levels in semen and seminal plasma were measured in boars receiving 250 (708.7 and 692.0 ng/ml) and 0 mg of supplemental boron (88.9 and 76.5 ng/mL), respectively, while concentrations in boars receiving 25 mg (148.0 and 145.4 ng/mL) were in between the other two treatments. No effect of time or treatment on semen volume ($P>0.70$); total number of spermatozoa per ejaculate ($P>0.82$); or the proportion of spermatozoa exhibiting progressive forward motility ($P>0.89$) was observed. There was a tendency for a time by treatment interaction ($P=0.09$) for the proportion of spermatozoa with normal morphology. Normal morphology averaged 72.0% for control boars and did not change over time ($P>0.89$). In contrast, it tended to increase ($P<0.10$) from 74.7% and 76.1% during the first week of the study to 86.4% and 88.2% during week 8 in boars fed 25 and 250 mg of boron, respectively. Average path, straight line, and curvilinear velocities of motile spermatozoa increased over time ($P<0.05$) in boars receiving supplemental boron, but remained constant ($P>0.45$) in control boars (treatment × time; $P<0.05$). In conclusion, supplemental dietary boron enhanced sperm velocity characteristics and possibly, normal morphology, without influencing other measures of sperm production and semen quality.

Key Words: Boars, Boron, Spermatogenesis

W237 Transient transgene transmission to piglets by sperm-mediated gene transfer. Z. Wu[1], Z. Li[1,2], and J. Yang*[2], [1]*South China Agricultural University*, *Guangzhou, Guangdong, China*, [2]*University of Hawaii*, *Honolulu*.

An efficient and low-cost production of transgenic pigs has significant applications to the pig industry and biomedical science. Generation of transgenic pig by sperm-mediated gene transfer was inexpensive and convenient, but reported with inconsistent results. To test the method of sperm-mediated gene transfer in pigs, we employed deep post-cervical intrauterine insemination of incubated spermatozoa in this study. A test of sperm motility of semen from nine Landrace boars after incubation with radioactively-labeled DNA construct indicated that DNA uptake of the sperm were highly correlated with sperm motility at the time of collection. DNA concentration of 50 and 300 μg per one billion sperm was incubated with washed sperm at 17°C for 2h. Twenty-one hybrid gilts and sows of Meishan crossed with Large White were inseminated with transgene-incubated sperm and produced 156 piglets. Transgene DNA sequences were identified in 31 piglets by PCR amplification of genomic DNA isolated from piglet ears at the age of 3 days. The deep intrauterine insemination had a higher rate of positive transgenic piglets than regular insemination (29.6% of 98 piglets vs 3.4% of 58 piglets). However, the exogenous transgene DNA was not detected in all the piglets at the age of 70 to 100 days. Therefore, the results further demonstrated that that transgene through incubation with sperm was mostly transiently transmitted to the offspring at early growing stage and lost in adulthood, which may result from episomal DNA replications during germ cell division.

Key Words: Transgenic, Sperm-Mediated Gene Transfer, Episome

W238 Computer-assisted analysis of sperm parameters after selection of motile sperm by either percoll gradient, filtration or swim-up procedures. C. N. Person*, T. D. Lester, M. D. Person, and R. W. Rorie, *University of Arkansas*, *Fayetteville*.

A Hamilton-Thorne IVOS sperm analyzer (CASA) was used to compare sperm parameters of frozen-thawed semen from 10 bulls, before and after selection of motile sperm by either percoll gradient, filtration or swim-up procedures. Semen was thawed, washed in TALP medium and initial sperm parameters measured before assignment across selection methods. Sperm parameters measured at 0, 4 and 8 h after selection included motility, progressive motility, velocity distribution, path velocity (VAP), progressive velocity (VSL), track speed (VCL), lateral amplitude (ALH), beat frequency (BCF), straightness (STR), linearity (LIN), elongation and area. Percoll separation resulted in more total motile sperm recovered than either swim-up or filtration ($P=0.00$), while swim-up did not differ from

filtration (P=0.31). Percent motile, progressive, and rapid sperm did not differ (P=0.87, 0.91, and 0.94, respectively) across treatments. Across bulls, the percent motile sperm declined by ~50% from 0 to 4 h of culture, and by another ~33% from 4 to 8 h of culture. The VAP and VSL were similar (P≥0.09) across treatments, whereas VCL was greater (P=0.00) for both filtration and swim-up than for percoll. Sperm LIN and STR were similar across treatments (P=0.24 and 0.89). The ALH was greater for filtration and swim-up than for percoll (P≤0.01). The BCF for filter selected sperm was greater than that of either percoll or swim-up (P≤0.00). Sperm head elongation and area were also greater for filter selected than either swim-up or percoll (P≤0.00), whereas these parameters were similar for percoll and swim-up (P≥0.68). Based on total motile sperm recovered, percoll separation is superior to the other methods. Overall, results suggest that the method used for selection of motile sperm can influence some of the parameters related to motility and sperm head morphology. Further study is needed to determine if these differences are related to fertilization rate or developmental competence after IVF.

Key Words: Bovine, Sperm Parameters, CASA

Production, Management & the Environment - Livestock and Poultry III

W239 Effect of soaking dairy cows at the feed line on animal body temperature in a tunnel ventilated barn equipped with evaporative pads located in a tropical climate, Thailand. D. V. Armstrong*[1], M. J. VanBaale[1], S. Rungruang[2], V. Wuthironarith[2], M. J. Brouk[3], and J. F. Smith[3], [1]*The University of Arizona*, *Tucson*, [2]*Charoen Pokphand Group Co., Ltd.*, *Bangkok, Thailand*, [3]*Kansas State University*, *Manhattan*.

An experiment was conducted on ten lactating Holstein cows to evaluate the effect of soaking dairy cows at the feed line. The cows were housed in a two row tunnel ventilated free stall barn equipped with evaporative pads and a feed line soaker system. The free stall barn is 16 m by 113 m with a ceiling height of 2.6 m. The barn is equipped with 55.7 sq m of 2.4 cm thick evaporative pads on one end and eleven 130 cm fans on the opposite end of the barn. Air speed in the barn at animal shoulder height averages 9.7 km per hour. Air exchange is every 42 sec. Two treatments were utilized in this experiment: no feed line water spray (C) and feed line spray (FLS) from 1100 to 0600. Treatments were reversed every 4 days in a 2 × 2 Latin square design. The soaker cycle was 1 minute on and 4 minutes off. Water application was 2.8 liters of water per cow per cycle. Nozzles are located every 1.87 m on the line located at a height of 1.6 m from the floor. The average ambient temperature was 29.1°C, with relative humidity (RH) at 68%, and a temperature humidity index (THI) of 79. The average temperature inside the barn was 25°C, with the RH at 91% and a THI of 78. Individual cows were fitted with stainless steel temperature data loggers that recorded their core body temperature (CBT) at five-minute intervals throughout the study. Average CBT for the control group was higher, 39.08°C, than the cows with FLS, 38.99°C and is significant (P<0.01). The results of this trial suggest that feed line soaking has an additive effect for cooling cows in a tunnel ventilated barn located in a tropical climate. The difference between treatment CBT was from 06:00 to 09:00 when the ambient relative humidity is the highest and the difference between ambient and barn temperature is the lowest.

Key Words: Body Temperature, Feed Line Cooling, Tropical Climate

W240 Effect of soaking dairy cows at the feed line on animal behavior in a tunnel ventilated barn equipped with evaporative pads located in a tropical climate, Thailand. D. V. Armstrong*[1], M. J. VanBaale[1], S. Rungruang[2], V. Wuthironarith[2], M. J. Brouk[3], and J. F. Smith[3], [1]*The University of Arizona*, *Tucson*, [2]*Charoen Pokphand Group Co., Ltd.*, *Bangkok, Thailand*, [3]*Kansas State University*, *Manhattan*.

An experiment was conducted on ten lactating Holstein cows to evaluate the effect of soaking dairy cows at the feed line. The objective of the study was to observe if there are any changes in animal behavior for dairy animal that are soaked at the feed manger for 19 hours per day. The cows were housed in a two row tunnel ventilated free stall barn equipped with evaporative pads and a feed line soaker system. The free stall barn is 16 m by 113 m with a ceiling height of 2.6 m. The barn is equipped with 55.7 sq m of 2.4 cm thick evaporative pads on one end and eleven 130 cm fans on the opposite end of the barn. Total air exchange for the barn takes place every 42 sec. Treatments were no feed line water spray (C) and feed line spray (FLS) from 1100 to 0600 (19 hours). Treatments were reversed every four days in a 2 X 2 latin square design. The soaker cycle was 1 minute on and 4 minutes off. Water application was 2.8 liters of water per cow per cycle. Nozzles are located every 1.87 m on the line, which is at a height of 1.6 m from the floor of the feed line. Cow behavior data was collected every 15 minutes for 24 hours (96 observations per cow) over a 5 day period. Each pen of cows was on the C or FLS treatment for 5 days and then the groups were reversed. Twenty-four hour cow observation took place on day 5 of each period. The results would indicate three of the measurements of dairy animal behavior were changed with the addition of a feed line water soak for 19 hours per day. The time that cows spent eating was increased from 14.9% in the control group to 16.7% for the FLS. Standing time at the feed line was also increased to 6.2% for FLS compared with 4.4% for C. Time spent at the water trough was higher for C at 4.9% than 3.3% for FLS. All other observations were not measurably different.

Table 1.

Item	Control	% of time per day Feed line water soak	Remarks
Eating at manger	14.9	16.7	@
Standing at feed line	4.4	6.2	@
Lying at feed line	0.0	0.0	
Standing in free stall	17.8	16.1	
Lying in free stall	47.7	46.4	
At water trough	4.9	3.3	@
At milking area	10.9	11.3	

@ P<0.05

Key Words: Animal Behavior, Feed Line Cooling, Tropical Climate

W241 Thermal status for different breeds of dairy cattle exposed to summer heat stress in a grazing environment. J. N. Spain*[1], L. Parsons[1], R. Crawford[2], C. Brown[2], and D. E. Spiers[1], [1]*University of Missouri*, *Columbia*, [2]*Soutwest Research Center*, *Mt. Vernon, MO*.

There are few studies that have measured the long-term thermal status of different breeds of dairy cows maintained simultaneously in a pasture environment to determine differences in thermoregulatory responses to summer heat stress. A study was conducted to investigate thermal balance of lactating dairy cattle managed in an intensive managed rotational grazing system. The farm was located at the University of Missouri Southwest Research Center in Vernon County, MO. Thirty six lactating cows were blocked by parity, days in milk, milk production and breed. Cows were grouped by breed with 100% Holstein (H, n=8), 75%H:25% Jersey (J) (75H, n=5), 50%H:50%J (50H, n=8), 25%H:75%J (75J, n=7), and 100% J (J, n=8), and maintained on the same pastures from June 15 through August 1, 2006. Cows were rotated to paddocks to maintain ad libitum access to pasture. Ambient variables, including air temperature (Ta) and relative humidity, were measured continuously by a weather station at the Center. Ranges of Ta and calculated THI were 12 to 38C and 55 to 87, respectively. Thermal balance was evaluated prior to morning (0500) and afternoon (1600) milking by measuring rectal temperature (Tre), respiration rate (RR) and skin temperature on 16 days throughout the study during periods of maximum and minimum heat stress. Breed groups had different body weights ($p < 0.0001$) ranging from 530 kg (H) to 378 (J). However, body weight was similar for 75J and 75H (460 kg versus 501 kg, respectively). Although body weights were different across breed, change in rectal temperature with Ta ($r = 0.89$) and THI ($r = 0.92$) was predictable ($p < 0.0001$). Change in Tre with increasing Ta and THI was slowest for J and 75J, and highest for H and 75H. Change in Tre was influenced more by breed more than body weight. Respiration rate was highest for H and lowest for J at Ta below 30C. At Ta greater than 35C, J and 75J had RR similar to 50H. Cows with the highest percentage H (H and 75H) had lowest RR. These results suggest that breed selection can be used to improve thermal balance of cows managed in intensively managed rotational grazing systems.

Key Words: Heat Stress, Thermal Balance, Grazing

W242 Labor, housing, feeding, and bedding affects on herd turnover rate and mortality rates of Southeastern Pennsylvania dairy herds. C. D. Dechow[1] and R. C. Goodling*[2], [1]*The Pennsylania State University*, *University Park*, [2]*The Pennsylvania State University Cooperative Extension*, *University Park, PA*.

Various aspects of dairy operations were surveyed and compared to herd turnover rate and herd mortality rates. 269 Southeastern Pennsylvania dairy herds were surveyed to determine hours of full time and part time labor, type of facilities, bedding source, feeding system, and other herd management systems for each facility. Of these, 239 had viable 2005 DHI culling information to derive comparisons. Herd sizes ranged from 17 to 760 cows. Herds had at least nine test days, and at least ten cows per test day to be included in the analysis. Herd turnover rate groups were designated as low (≤0.20), low-to-moderate (0.21 to 0.30), moderate-to-high (0.31 to 0.40) and high (>0.40). Data were analyzed using the MEANS and GLM procedures of SAS version 9.1. Hours worked with lactating cows by part-time employees tended to be higher (P<0.03) in herds with higher turnover rates. Herds with higher turnover rates had more prevalent bST use (P<0.03). Lower turnover rate herds had greater access to pasture (P<0.007) and more ventilation (P<0.009). Lower mortality rate herds also tended to have greater access to pasture (P<0.07). Herds that fed lactating cows a TMR had moderately higher turnover rates than herds using component feeding (P<0.0001). No bedding types showed tendencies for higher or lower turnover and mortality rates. Further investigation into dry cow and heifer management, and potential confounding effects of herd size and production level with management type should be considered.

Key Words: Herd Turnover Rate, Mortality Rate, Management

W243 Body weight and condition score of four dairy genetic groups in summer or winter under low-input management. D. G. Johnson*[1], B. J. Heins[2], L. B. Hansen[2], A. J. Seykora[2], and J. G. Linn[2], [1]*University of Minnesota*, *Morris*, [2]*University of Minnesota*, *St. Paul*.

Holsteins selected for high production (H), Holsteins maintained at 1964 breed average level (C64), crossbreds including combinations Holstein, Jersey, and/or Montbeliarde selected for high production (HJM), and crossbreds including combinations of Holstein, Jersey, and/or Scandinavian Red selected for durability (HJS) were weighed and scored for body condition(1-5) on two consecutive months during summer and winter over three years. Groups studied were cows, bred heifers in second trimester, heifers being bred, and calves 8-10 months of ages. Animals within age group were fed and managed as a group. All groups were grazed during summer, only calves and lactating receiving cereal supplementation. Diets during winter were total mixed rations fed to requirements for growth and/or lactation and comprised of corn silage, alfalfa silage, grass hay, corn grain, soybean meal, distillers dried grains, and vitamin mineral supplements. Animals were housed on pasture or outdoor bedded packs during winter. All animals were located in west central Minnesota. Analysis by age group utilized SAS Mixed procedure with the model year, season, breed, year (breed), season (breed). Animal numbers were cows, 343; bred heifers, 298; breeding heifers, 269; and calf, 236; with 1 to 6 opportunities for an animal to appear in the data set. H and C64 cows were heavier then HJM or HJS, with cow weights higher in winter than in summer. Rank of condition scores was C64, 3.45, HJS, 3.15; HJM, 3.11; and H, 2.96.

Springer weights did not differ, but condition scores of H were lower than the other breeds. Breeding heifers and calves displayed a similar pattern. Winter weights tended to be higher than summer weights across all groups, but the pattern of condition scores was less consistent.

Key Words: Reduced Input, Dairy, Crossbred

W244 Phosphorus removal capacity of forages used on South Florida dairies. Y. C. Newman*, J. M. Scholberg, M. B. Adjei, and L. E. Sollenberger, *University of Florida*, *Gainesville*.

Excess accumulation of soil phosphorus (P) associated with intensively managed dairy operations has been linked to degradation of natural ecosystems. Warm-season perennial forages offer a complimentary and cost effective approach in remediation of soils with high P accumulation for livestock operations in the Lake Okeechobee region in South Florida. The objective of the study was to determine the P removal capacity, herbage production, and nutritive value of two warm-season species when managed for hay under intensive N fertilization. Bahiagrass (BG; Paspalum notatum) and limpograss (LG; Hemarthria altissima) were evaluated in an on-farm study during 2004 and 2005. Treatments were four levels of N fertilization rates (0, 50, 67, and 100 kg N ha^{-1} per harvest). Experimental units were 116-m^2 plots replicated four times in a randomized block design for each forage type. Data were analyzed using mixed model methodology through MIXED procedure of SAS and the nature of the N effects was assessed using orthogonal polynomial contrasts. Averaged across years, annual P removal of bahiagrass and limpograss had a linear ($P \leq 0.01$) increase with increasing N fertilization rate (26.2, 34.2, 40.5, and 39.4 kg P ha^{-1} yr^{-1} for bahiagrass, and 26.4, 40.0, 40.1, and 42.0 kg P ha^{-1} yr^{-1} for limpograss when fertilized with 0, 50, 67, and 101 kg N ha^{-1}, respectively). Herbage production and crude protein increased linearly ($P \leq 0.01$) with N fertilization treatment for both grasses in both years but crude protein values were consistently lower for LG compared to BG (average of 70 and 126 g kg^{-1}, respectively). Hay crop production using bahiagrass and limpograss is a feasible practice for removing excess soil P.

Key Words: Phosphorus, Bahiagrass, Limpograss

W245 Efficiency of use of imported magnesium, sulfur, copper, and zinc in Idaho dairy farms. A. N. Hristov*, W. Hazen, and J. W. Ellsworth, *University of Idaho*, *Moscow*.

Six commercial dairies from south central Idaho were surveyed to estimate the whole-farm surpluses of magnesium (Mg), sulfur (S), copper (Cu), and zinc (Zn). Mineral imports and exports were monitored in a 12-mo period and samples from the diets, feeds, feces, urine, and manure were collected at regular farm visits. Soils from manure-amended fields were sampled in the spring and fall. In all cases, the largest import of Mg, S, Cu, and Zn to the dairy was with purchased feeds, from 91 (S) to 97% (Zn) of all imports. The major mineral export item was manure (from 60%, S to 89%, Cu of all exports) and forages, in the case of a dairy with a large land base. Export with milk represented on average only 8.6, 25, 2.1, and 11% (Mg, S, Cu, and Zn, respectively) of all exports. Thus, the conversion of the imported feed Mg, S, Cu, and Zn into milk was rather low (on a whole-farm scale): 5.6, 11, 1.4, and 5.2%, respectively. Concentrations of Mg, Cu, and Zn in the lactating cow diets from the participating dairies exceeded current NRC recommendations on average by 85, 34, and 73%, respectively, which contributed to the inefficient use of imported minerals. Whole-farm Mg surplus varied from 4 to 54 t/yr (SD = 21.5; or 3 to 19 kg/cow per year). The efficiency of use of imported Mg varied from 27 to 88% (SD = 24.0). Sulfur surpluses were from 9 to 52 t/yr (SD = 18.0; or 12 to 40 kg/cow per yr). Copper and Zn surpluses were also significant (average of 59 and 585 kg/yr; SD = 59.9 and 711; or 0.05 and 0.4 kg/cow per year, respectively). The average efficiency of use of imported S, Cu and Mg was 44, 62, and 56% (SD = 12.3, 25.1, and 12.6), respectively and, as with Mg, varied significantly among the dairies. The results from this study suggest that reduction in the concentration of dietary Mg, Cu, and Zn is potentially the most efficient way of reducing overall excretions and whole-farm surpluses of these minerals.

Key Words: Dairy Farm, Nutrient Management

W246 Reproductive status of dairy herds in Alberta: An objective assessment based on milk progesterone (P4) concentrations. D. J. Ambrose*[1], M. G. Colazo[1], and J. P. Kastelic[2], [1]*Alberta Agriculture and Food*, *Edmonton, AB, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

To identify the factors contributing to poor reproductive efficiency 23 dairy herds were evaluated. Milk samples from 637 cows (26±2 cows/herd) were collected 2x/wk, from 7 to 120 d postpartum (pp), and P4 determined; health and reproductive records were also obtained. The interval from calving to first rise in P4 pp was 32.0±0.7 d. The % of cows cycling by 3, 6, 9, and >9 wk pp was 27, 75, 90, and 96, respectively. Only 4.4% of cows remained anestrus by 90 d pp. The first estrous cycle was short (<17 d), normal (17 to 24 d), or long (>24 d) in 42, 45, and 13% of the cows, respectively. Mean d from calving to first service was 88.5±1.4 (range 32 to 267 d). By 80, 100 and 125 d pp, 42, 62 and 77% of the cows, respectively, were inseminated. Based on milk P4 at AI (n=266) 89% of the cows were in a stage conducive (P4<1 ng/mL) to conception. Conception rate (CR) to first service (38.4%) was influenced by parity (P<0.03), with higher CR in young cows (1st+2nd: 46) than in mature cows (3rd+4th: 39; >4th: 32%). Cows that had their first rise in P4 within 3 wk pp had higher CR to first service than cows that had a delayed rise (46 vs. 31%; P<0.03). The % of cows pregnant by 80, 100 and 125 d pp was 18, 31, and 43%, respectively. Cows with reproductive disorders during the pp period had lower CR by 125 d (P<0.01; 26 vs. 49%). Parity affected (P<0.01) cumulative CR at 125 d pp: 50, 43, and 31%, for 1st+2nd, 3rd+4th, and >4 lactations, respectively. The mean d from first to second service (n=205) was 41.6±1.7 and that from second to third service (n=54) was 34.2±2.9. When whole-herd DHI records were analyzed, the mean (±SE) 21-d submission rate (SR), CR, and pregnancy rate (PR) was 36.9±0.54, 32.6±0.80, and 12.4±0.34, respectively, and differed among herds. The highest and lowest CR was during winter (45.7%) and fall (35.5%). The greatest % of abortions occurred from January to April (10.2); the least from September to November (3.0). Mature cows (≥3 lactations) had a higher risk of abortion than those in their second lactation.

Key Words: Dairy Herds, Reproductive Status, Milk Progesterone

W247 Incidence and interrelation of some common hoof problems in a Southeast US dairy herd. A. H. Sanders*[1], J. K. Shearer[1], L. C. Shearer[1], S. R. van Amstel[2], D. W. Webb[1], and A. De Vries[1], [1]*University of Florida*, *Gainesville*, [2]*University of Tennessee*, *Knoxville*.

Lameness is a costly problem affecting the US dairy industry. Besides the direct costs of treatment and culling, lameness can negatively effect production, reproduction, and udder health. This study quantified hoof problems identified on a large (>2100 cows) commercial dairy farm in Georgia. Data were collected during 33 months (April 2004 to December 2006). Cows identified as lame by staff were presented for treatment to hoof trimmers certified through the Master HoofCare program (University of Florida) and employed full-time on this farm. Defects were recorded using the system recommended by the American Association of Bovine Practitioners and included superficial diseases (e.g. hairy warts), whiteline disease (WLD; 3 hoof zones), ulcers (UL; 3 hoof zones), thin soles (TS), sole punctures (SP), laminitis, and mechanical defects. Each month, between 1 and 11% of cows were treated, and treated cows averaged 1.6 problems per year. Of problems seen, 31% were WLD, 26% UL, and 12% TS. All of these were more common in the summer (July-September) than the winter (January-March; odds ratios were 0.19, 0.15, and 0.16, respectively). This is contrary to reports of lameness by season in European herds. Wet conditions, most common in winter in Europe, are more common in summer in Georgia. Leg injury (6% of treated problems), is also associated with wet/slippery conditions and was also more common in the summer (OR = 0.48). Second and later parity cows were more prone to UL, WLD, and TS than fist parity cows (OR were 0.44, 0.28, and 0.42, respectively). Incidence of WLD and UL was increased among cows with TS earlier in the same lactation. In these cows, WLD was more likely to be reported in the toe (7% increase) than in the rest of the herd. Contrary to reports that a majority of WLD is in the posterior zone, in this herd, WLD was more common farther forward. Thin soles may have been a predisposing factor, but without causing observed lameness. These data summarize some aspects of hoof health under different climate and management conditions from previous studies. Further investigation of the relationship of hoof health to other production and reproduction functions is planned.

Key Words: Lameness

W248 Economic analysis of bovine somatotropin to increase pregnancy rates in lactating dairy cows. A. A. Bell*, P. J. Hansen, and A. De Vries, *University of Florida*, *Gainesville*.

The economic value of a single injection of bovine somatotropin (bST) for improving pregnancy rate in the hot season, cold season, or year round in Florida was evaluated. bST can increase pregnancy rates in cows subjected to timed artificial insemination. A dairy farm was modeled using DairyVIP (http://dairy.ifas.ufl.edu/tools) assuming typical conditions in Florida (seasonality in milk production and probability of conception) to estimate the economic benefit of bST. Service rate at first breeding was 100% and 50% afterwards. A single injection of bST ($6 a dose) was incorporated into the first breeding protocol during the cool season (November-May), the hot season (June-October), or year round. Modeling was performed assuming that bST increased the probability of conception by 8, or 16 percentage units. Each scenario was described as (response in hot season, response in cool season). Effects of three heifer prices ($1600±400) and three milk prices ($35±9per 100 kg) were evaluated. Base probability of conception was ±5 percentage unit to determine effects of different levels of reproductive management. Profit per slot per year was determined for incremental increases in probability of conception due to the use of bST to identify the breakeven point. Default profit per slot per year (no use, no use) was $338.11 and default pregnancy rate was 19%. The economic value of the use of bST ($1600 heifer price, $35 milk price) in the scenarios of (no use,8), (no use,16), (8,no use), (16,no use), (8,8), and (8,16) resulted in a profit over the default of $4.57, 12.50, 0.33, 1.09, 4.90, and 12.84, respectively. Changes in heifer price or decreasing milk price from $35 to $26 did not change trends for profit due to bST. When milk price was increased to $44, the profit due to bST was of reduced magnitude. Farms with greater probability of conception showed lower increased profit with bST use than farms with lower probability of conception. The breakeven point was determined to be an increased probability of conception of between 3 and 4 percentage units. Results showed a positive economic benefit of using bST to increase pregnancy rates.

Key Words: Bovine Somatotropin, Profit, Pregnancy Rate

W249 Performance of beef calves weaned by traditional, fenceline, and two-step methods. D. D. Buskirk, J. M. Siegford, and B. A. Wenner*, *Michigan State University*, *East Lansing*.

Abruptly weaning calves and isolating them from their dams introduces stressors which slow growth and suppress immune function. Gradual weaning methods may reduce acute stresses of weaning, resulting in improved animal performance and welfare. A total of 227 Angus-Simmental calves from two locations, averaging 173 d of age, were allocated by weight and gender into three weaning method treatments: 1) abrupt-weaned (AW); 2) fenceline-weaned (FW); and 3) two-step-weaned (TW). On d 0, all calves were assigned to one of nine pastures and prevented from nursing their dams. Dams of AW calves were moved to remote pastures, dams of FW calves were moved to adjoining pastures with fenceline contact, and TW calves had a plastic nose flap fitted. On d 5, TW calves had the nose flap removed, and all dams were moved to remote pastures. Body weights were obtained on d 0, 5, 14, 28, and 42 for all calves. Blood samples taken on d 0, 5, 14, 28, and 42 were analyzed for plasma haptoglobin, an acute-phase protein released in response to stress stimuli. There were no significant differences in weights through d 42. Although FW calves had greater ($P<0.001$) average daily gain (ADG) between d 0 and 14 than AW and TW calves, there was no significant difference in ADG from d 0 to 42 among treatments. Haptoglobin levels were greatest on d 5, and were higher ($P<0.001$) in both AW and TW calves than FW calves (827, 1019, and 409 μg/mL, respectively). Haptoglobin returned to baseline levels by d 14. Following backgrounding, 152 calves were transported to a feedlot and allotted by weaning treatment to 21 pens. Calves were fed for an average of 207 d. Initial and final body weights were not different ($P>0.63$) among weaning treatments, nor were there differences in ADG ($P=0.60$). There was also no significant difference in the percentage of calves that received one, or two or more medical treatments during finishing. Although FW calves gained more weight and had lower haptoglobin levels shortly after weaning, there were no sustained differences in performance due to weaning method.

Key Words: Weaning, Stress, Calf

W250 A comparison of visual and palpation-based body condition scoring systems. J. M. Bewley*[1], R. E. Boyce[2], D. J. Roberts[3], M. P. Coffey[3], A. Bagnall[3], and M. M. Schutz[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*IceRobotics Ltd.*, *Roslin, Scotland, UK*, [3]*3Scottish Agricultural College Dairy Research Centre*, *Dumfries, Scotland, UK*.

Body condition scoring (BCS) as an indirect measure of body fat in cattle has been widely adopted as a research and field management tool. Numerous BCS systems are utilized around the world. However, reports on how well the various systems correlate with each other are scarce. Two BCS systems were compared for assessing cows at the Scottish Agricultural College's Crichton Royal Farm. The weekly BCS were collected for a period of 12 weeks (9/5/2006-11/21/2006). Scores were obtained using the primary systems utilized within the United Kingdom (developed by Mulvany) and the United States (developed by Edmonson and Ferguson). The Mulvany (UKBCS) system involves palpation of specific body parts using a 0-4 scale. The Edmonson/Ferguson (USBCS) system is based entirely upon visual assessment using a 1-5 scale. The USBCS were obtained by the same observer each week, while UKBCS were obtained by two observers during alternate weeks. Individual scores were removed from the data set when the absolute differences with the preceding and subsequent scores were both greater than 0.25. Scores of 203 individual cows were obtained with a mean of 8.9 (±2.5) pairs of BCS per cow. Means were 2.11 (±0.36) and 2.91 (±0.39), modes were 2.25 and 2.75, and ranges were 1-3.5 and 1.5-4.5 for the UKBCS and USBCS, respectively (N=1809). The mean difference between paired observations was 0.80 (±0.26). The UKBCS and USBCS were highly correlated (r=0.766, P<0.0001). A regression equation to convert scores from the UKBCS to USBCS was developed using PROC GLM. The resulting equation was USBCS=1.6069+0.3912*UKBCS+0.1041*UKBCS^2 (R^2=0.59). This equation may be used to interpret scores within the literature obtained using these two BCS systems, though the equation should be corroborated with other scorers.

Key Words: Body Condition Scoring, International Comparison

W251 Effect of discontinuous roughage delivery in a feedlot diet on liveweight gain and feed efficiency of beef steers. M. Avila[3], J. I. Arroquy*[1,2], and J. J. Saravia[1], [1]*INTA Santiago del Estero*, *Santiago del Estero, Argentina*, [2]*Consejo Nacional de Investigaciones Científicas y Técnicas*, *Argentina*, [3]*Universidad Nacional de Santiago del Estero*, *Santiago del Estero, Argentina*.

The objective of this study was to evaluate the effect of feeding a total mixed ration compared to feeding the roughage portion of the diet once every 2-d and separated from the daily concentrate mix. Thirty beef steers (Braford, Criollo, and Braford × Criollo; initial body wt = 259 ± 27 kg) were used in a 69-d study. Treatments were: a total mixed ration (TMR) and the same proportion of ingredients but roughage offered once every 2-d and separated of the daily delivered concentrate portion of the diet (roughage every other day, REOD). Treatments were arranged in a completely randomized design (three pens/ treatment). Steers were fed ad libitum once a day. In both treatments diet had the following proportion of feedstuffs, 10% grass hay, 82% dry ground corn, 7% ground cottonseed, 0.65% urea, and 0.35% mineral-salt mix. But in REOD the amount of hay delivered once every 2-d was twice the quantity of hay daily offered in TMR. Final body weight did not differ between treatments (final liveweight = 331 ± 26 kg). Average daily gain did not differ among treatments (1013 vs. 1080 g/d for TMR vs. REOD respectively; SEM = 95 g/d). Intra-pen variability for ADG was similar between TMR and REOD. Dry matter intake was significantly greater in TMR compared to REOD (dry matter intake, 8.53 vs. 6.77 kg/d for TMR vs. REOD; $P < 0.01$). Gain to feed ratio tended to be better for REOD than TMR (0.15 vs. 0.13 kg of gain/ kg of DM for REOD vs. TMR; $P = 0.07$). The proportion of concentrate in the ingested diet did not differ between treatments (86.9 vs. 85.5% for TMR vs. REOD). However, steers in REOD adjusted the proportion of ingredients selecting grass hay (14.4% REOD vs. 13.0% TMR; $P < 0.01$). Steer in REOD selected a diet with a lower concentration of fiber (31.2 vs. 31.7% NDF for REOD and TMR respectively; $P < 0.01$) and a higher concentration of CP (14.6 vs. 14.2% CP for REOD and TMR respectively; $P < 0.01$). In conclusion, steers fed a separated roughage source once every 2-d had similar liveweight gain and tended to be more efficient in feedstuff use compared to a TMR delivered daily.

Key Words: Forage Delivery, Gain, Feed Efficiency

W252 Simulation model of fat deposition and distribution in beef steers: 1. Empirical models converting fat thickness to subcutaneous fat and KPH to visceral fat. M. J. McPhee*[1,2], J. W. Oltjen[1], J. G. Fadel[1], D. Perry[2], and R. D. Sainz[1], [1]*University of California*, *Davis*, [2]*NSW DPI*, *Armidale, Australia*.

Empirical models were developed to convert carcass characteristics into kilograms of fat or vice versa to be used in the Davis Growth Model of fat deposition and distribution in beef steers. Allometric equations ($y = ax^b$) that include frame size (1 to 9) were developed between: 12th-rib fat thickness (fat thickness, mm) and subcutaneous fat (kg); and between KPH (kg) and visceral fat (kg). The results of the non-linear regression were: subcutaneous fat, kg = (frame size × fat thickness, mm)$^{0.79}$ ($n = 12$; $P < 0.01$) with $R^2 = 0.99$ and SE = 0.36; and visceral fat, kg = $3.92 \times KPH^{0.87}$ ($n = 28$; $P < 0.01$) with $R^2 = 0.99$ and SE = 0.032. Several techniques were used to evaluate the model: (a) mean bias (observed – model-predicted); (b) modeling efficiency (values close to 1 indicate a perfect model and values < 0 indicate a very poor model); (c) Kolmogorov-Smirnov (KS) 2-sample test; and (d) linear regression. The KS was a test of the hypothesis that the observed and model-predictions have the same parent distribution. The linear regression tested slope = 1 intercept = 0 and bias using the simultaneous F-statistic for both slope = 1 and intercept = 0. The results were: mean bias of 2.90 and -1.65 kg; modeling efficiency of 0.59 and 0.85, for subcutaneous and visceral fat respectively; the KS test indicated that the observed and model-predicted values were from the same parent distribution for both subcutaneous and visceral fat and the linear regression indicated that there was some bias ($P = 0.02$ and $P < 0.01$, for subcutaneous and visceral fat, respectively). The inclusion of frame size is an important addition to the subcutaneous fat vs. fat thickness (mm) model. Further evaluation and improvements are required before the equations are incorporated into the Davis Growth Model.

Key Words: Cattle, Subcutaneous, Visceral

W253 Simulation model of fat deposition and distribution in beef steers: 2. Empirical models to initialize fat deposition models. M. J. McPhee*[1,2], J. W. Oltjen[1], J. G. Fadel[1], and R. D. Sainz[1], [1]*University of California*, *Davis*, [2]*NSW DPI*, *Armidale, Australia*.

Empirical models were developed to predict initial conditions for first-order differential equations to be used in the Davis Growth Model of fat deposition and distribution in beef steers. Allometric equations ($y = ax^b$) were developed between: empty body weight (EBW) for both DNA (g) and fat contribution (FC, %) for four fat depots: intermuscular (INTER), intramuscular (INTRA), subcutaneous (SUB), and visceral (VIS). The results for DNA were: INTER = $0.005\times(EBW)^{0.63}$; INTRA = $0.00000751\times(EBW)^{1.46}$; SUB = $0.000213\times(EBW)^{1.01}$ (n = 20; $P < 0.01$), and VIS = $0.12\times(RA)^{-0.11}$ (n = 20; P = 0.71) with $R^2 = 0.81$, 0.84, 0.74, and 0.04 and SE = 0.06, 0.13, 0.12, and 0.10, respectively; and FC were: INTRA = $155.66\times(EBW)^{-0.46}$; SUB = $3.24\times(EBW)^{0.39}$ (n = 21, 66; $P < 0.01$), and VIS = $52.22\times(EBW)^{-0.16}$ (n = 66; P = 0.89) with $R^2 = 0.66$, 0.55, and 0.09 and SE = 0.26, 0.12, and 0.17, respectively; INTER FC was found by difference. The models were challenged with independent data sets (INTER, INTRA, SUB, and VIS with n = 6, 5, 6, and 6 for DNA challenge; and n = 9, 9, 9, and 9 for FC challenge, respectively). Several techniques were used to evaluate the model: (a) mean bias (MB, observed – model-predicted); (b) modeling efficiency (MEF, values close to 1 indicate a perfect model and values < 0 indicate a very poor model); (c) Kolmogorov-Smirnov (KS) 2-sample test; and (d) linear regression. The KS was a test of the hypothesis that the observed and model-predictions have the same parent distribution. The linear regression tested slope = 1, intercept = 0, and bias using the simultaneous F-statistic for both slope = 1 and intercept = 0. The results for the DNA challenge were: MB of 0.03, -0.02, 0.02, and 0.02 g; the results for the FC challenge were: MB of 3.44, -1.72, -0.57, and -1.15 kg; and MEF of 0.64, 0.04, 0.84, and 0.68 for INTER, INTRA, SUB, and VIS, respectively; the KS test indicated that the observed and predicted values were from the same parent distribution. The linear regression for FC indicated that bias ($P < 0.01$) only existed for INTRA fat. These equations will be used to initialize the DNA and fat depot differential equations in our ongoing program for modeling beef cattle growth and carcass quality.

Key Words: Differential, DNA, Fat

W254 Pasturing to decrease greenhouse gas emissions from feedlot cattle operations: A whole system approach. H. Koknaroglu[1], T. Akunal[1], T. Purevjav*[2], and M. P. Hoffman[2], [1]*Suleyman Demirel University*, *Isparta, Turkey*, [2]*Iowa State University*, *Ames*.

A three-year study integrating pasture and drylot feeding systems was used to assess effect of pasturing on greenhouse gas emission from cattle operations. For this purpose, each year, 84 fall-born and 28 spring-born calves of similar genotypes were used. Fall-born and spring-born calves were started on test in May and October, respectively. Treatments were: 1) fall-born calves directly into feedlot; 2 and 3) fall-born calves put on pasture with or without an ionophore and moved to the feedlot at the end of July; 4 and 5) fall-born calves put on pasture with or without an ionophore and moved to the feedlot at the end of October; 6 and 7) spring-born calves put on pasture with or without an ionophore and moved to the feedlot at the end of October. In the feedlot, steers were provided an 82 % concentrate diet containing whole-shelled corn, ground alfalfa hay, ionophore and molasses. Pens of cattle were harvested at approximately 522 kg. Research conducted on greenhouse gas emission generally measures carbon dioxide (CO2), methane (CH4) and nitrous oxide (N2O) emissions in feedlot or on pasture. In this study we considered CO2 sequestered by pastures. CH4 production in the feedlot and on pasture was calculated by multiplying gross energy of feed consumed and percent of gross energy converted to CH4. N2O production on pasture was calculated by using the actual nitrogen fertilizer amount and percent of nitrogen converted to N2O on pasture. Fall-born cattle directly going into feedlot and spring-born cattle grazed for nearly a month had greenhouse gas emission of 2285 and 1029 kg per head CO2 equivalent, respectively. Cattle grazed until July and October sequestered more CO2 equivalent then they emitted meaning that they did not contribute to global warming. Net CO2 equivalent sequestered increased as time on pasture increased ($P<0.05$). Results show that pasturing is an important method to decrease greenhouse gas emission from cattle operations and when calculating the greenhouse gas emission from cattle operations, the amount of greenhouse gas sequestered by pastures should be taken into consideration.

Key Words: Global Warming, Greenhouse Gas, Feedlot Cattle

W255 Evaluation of a delayed-release anabolic implant in finishing steers. W. Nichols[1], J. Hutcheson[1], D. Yates[1], M. Streeter[1], D. Smith*[2], and M. Brown[2], [1]*Intervet, Inc.*, *Millsboro, DE*, [2]*West Texas A&M University*, *Canyon*.

Two experiments were conducted to evaluate the efficacy of a delayed-release implant. In Exp. 1, 360 yearling steers (177 d on feed) were assigned to either no implant, Revalor-IS (80 mg trenbolone acetate [TBA] and 16 mg estradiol [E]) on d 1 and a reimplant of Revalor-S (120 mg TBA and 24 mg E) on d 75 (IS/S), or Revalor-XS on d 1 only (XS; 200 mg of TBA and 40 mg of E). All cattle were removed from their home pen and moved through the handling facility on d 75. Overall ADG was 23.1% greater, DMI was 10.7% greater, and feed efficiency was improved by 10.1% ($P < 0.01$) for implanted steers. Dressing percent was greater ($P < 0.01$) for implanted than for non-implanted steers; implanting resulted in 38 kg more carcass weight ($P < 0.01$). Implanted steers had a larger LM area, greater rib fat thickness, more body fat, a higher average yield grade, but a lower marbling score ($P < 0.04$) than non-implanted steers. Growth performance and carcass characteristics did not differ between IS/S and XS ($P > 0.05$). Implanted steers produced fewer carcasses grading at least low Choice ($P < 0.01$; 45% vs 69%), but carcass quality did not differ among IS/S and XS. In Exp. 2, 720 steer calves at three locations were assigned to receive XS on d 1 only or sham implanting on d 1 (198 d on feed). Steer ADG was 19.9% greater and DMI was 10.5% greater ($P < 0.05$) for XS; feed efficiency was improved ($P < 0.05$) by 7.3% for XS. Dressing percent was similar across treatments (P = 0.16). Steers receiving XS produced carcasses that were 34 kg heavier, had a larger LM area, more external fat, a higher average yield grade, and more body fat ($P < 0.01$) than sham-implanted steers, but marbling score was similar across treatments. The number of carcasses grading at least low Choice was slightly reduced (P = 0.05) by XS (62% vs 69%). Steers receiving XS on d 1 only performed as well as steers given Revalor-IS/S. Implanting steers fed for 198 d on d 1 only with XS resulted in more carcass weight at slaughter, improved feed efficiency by 7%, and resulted in slightly fewer carcasses grading at least low Choice than non-implanted steers.

Key Words: Growth Promotant, Anabolic Implant, Implant Payout

W256 Temperament, assessed upon feedlot entry, did not impact performance of Texas A&M Ranch to Rail steers. K. O. Curley, Jr.*[1], J. J. Cleere[2], J. C. Paschal[3], T. H. Welsh, Jr.[1], and R. D. Randel[4], [1]*Texas Agricultural Experiment Station*, *College Station*, [2]*Texas Cooperative Extension*, *College Station*, [3]*Texas Cooperative Extension*, *Corpus Christi*, [4]*Texas Agricultural Experiment Station*, *Overton*.

As poor temperament negatively impacts multiple facets of cattle production an investigation of the linkage between cattle behavior and economic endpoints within the beef industry is warranted. The objective of this study was to identify any relationship of exit velocity (EV) measures obtained at entry to the feedlot with subsequent growth performance. Exit velocity measured during processing of 161 steers at a south Texas feedlot was utilized to identify calm (C; those slower than 0.5 SD below the mean EV; n = 55) and temperamental (T; those faster than 0.5 SD above the mean EV; n = 49) steers. At this time the cattle were weighed, tagged, implanted, vaccinated and sorted by weight (45 kg increments) into lots for feeding. Cattle were evaluated for USDA frame and muscle score and assigned an initial value. Animals were from various ranches (n = 6) and of variable breed types, both ranch of origin and Brahman influence (identified as greater than 1/8) were incorporated into statistical analyses. Linkage between temperament and stress physiology was confirmed as serum cortisol concentrations differed ($P < 0.01$; C = 6.40 ± 1.59, T = 11.77 ± 1.59 ng/ml) with temperament. Initial BW differed ($P < 0.01$) with temperament as the calm steers were heavier upon arrival to the feed yard (C = 310 ± 17, T = 256 ± 17 kg). The length of the feeding period differed ($P < 0.05$) with temperament as temperamental steers were fed longer (C = 207.0 ± 2.0, T = 214.0 ± 2.0 d). Weight gain of the steers differed with temperament ($P < 0.01$; C = 280 ± 15, T = 324 ± 15 kg), but the final BW did not ($P = 0.53$). While the initial value was greater for the calm steers ($P < 0.02$; C = $576.65 ± 27.30, T = $508.11 ± 27.30) the compensatory gain exhibited by the temperamental cattle contributed to no difference ($P = 0.94$) in the net income received from each of the temperament groups. Although temperament appraisals at weaning have been identified as a possible indicator of post-weaning growth, exit velocity measured upon arrival to the feedlot was not indicative of steer performance during the feeding period.

Key Words: Temperament, Exit Velocity, Feedlot Performance

W257 Effect of frame score on performance and carcass characteristics of steers finished in the feedlot or backgrounded for various time on pasture and finished in the feedlot. H. Koknaroglu[1], T. Akunal[1], T. Purevjav*[2], and M.P. Hoffman[2], [1]*Suleyman Demirel University*, *Isparta, Turkey*, [2]*Iowa State University*, *Ames*.

A three-year study integrating pasture and drylot feeding systems was used to examine effect of frame score on performance and carcass characteristics of steers. Each year, 84 fall-born and 28 spring-born calves of similar genotypes were used. Fall-born and spring-born calves were started on test in May and October, respectively. Treatments were: 1) fall-born calves directly into feedlot; 2 and 3) fall-born calves put on pasture with or without an ionophore and moved to the feedlot at the end of July; 4 and 5) fall-born calves put on pasture with or without an ionophore and moved to the feedlot at the end of October; 6 and 7) spring-born calves put on pasture with or without an ionophore and moved to the feedlot at the end of October. Frame scores were determined by taking steersâ€™ age and live weight into consideration. Cattle that grazed the same duration on pasture were regarded as the same treatment regardless of whether they received an ionophore or not. In the feedlot, steers were provided an 82% concentrate diet containing whole-shelled corn, ground alfalfa hay, and a protein, vitamin and mineral supplement containing ionophore and molasses. Pens of cattle were harvested at approximately 522 kg. Cattle having a higher frame score at the entry to pasture and grazed until July and October tended to have higher and lower daily gain on pasture than those having lower frame score, respectively ($P>0.05$). Fall-born and spring-born cattle grazed until October, which had higher frame scores at the entry to pasture tended to have higher daily gain in the feedlot showing a compensatory growth. In the feedlot, within each treatment cattle having higher frame score tended to have higher daily gain ($P>0.05$) and had higher dry matter intake ($P<0.05$). Results showed that cattle with higher frame scores had higher growth potentials in the feedlot and if the grazing season is extended then daily gain of cattle having higher frame score decreases.

Key Words: Feedlot Cattle, Frame Score, Pasture

Ruminant Nutrition III

W258 Biological treatment of peanut hay as ruminant feed. B. Borhami*[1], S. Soliman[2], M. EL-Adawy[1], E. Ghonaim[2], M. Yacout[3], and H. Gado[4], [1]*Department of Animal Production, Faculty of Agriculture, Alexandria Univ.*, *Alexandria, Egypt*, [2]*Central Lab for food and Feed (CLFF), Ministry of Agriculture, Dokki*, *Gizza, Egypt*, [3]*Animal Production Research Institute, Ministry of Agriculture, Dokki*, *Gizza, Egypt*, [4]*Department of Animal Production, Faculty of Agriculture, Ain Shams Univ.*, *Cario, Egypt*.

This work was carried out to evaluate the effect of two biological treatments on the nutritive value of peanut hay (PNH). Three Barki rams and three ewes (fitted with permanent rumen fistula) were used for the digestibility and rumen fermentation trials, respectively. Six crossbred Friesian cows were used for the lactation trial. All animal were fed a restricted amount of commercial concentrate and ad libitum PNH either untreated (control) or treated with Tricoderma viride or ZAD probiotic. Higher crude protein content and higher losses in fiber, except for hemicellulose, were observed with the treated PNH. Total digestible nutrients ranged between 55.8 and 64.62% for control or fungi treated diets, respectively. Highest values of nitrogen balance were observed with the ZAD probiotic diet and the lowest value was observed in sheep fed the control diet. Rumen ammonia concentration and its rates of production were significantly ($P<0.05$) higher with ZAD probiotic. VFA were significantly higher ($P<0.05$) with fungi treatment than other diets. Milk production was increased with the fungi and ZAD diet. Biological treatment leads to increase milk fat and total solids compared with the control diet. Long term feeding of such material with analysis of metabolites (blood and milk) of animals fed such material is necessary.

Key Words: Biological, Sheep, Peanut Hay

W259 Predicting intake of maize stover by sheep using near infrared reflectance spectroscopy. S. Fernandez-Rivera*, D. Negassa, J. Hanson, and G. Gebremariam, *International Livestock Research Institute*, *Addis Ababa, Ethiopia*.

Near infrared reflectance spectroscopy (NIRS) equations were developed to predict digestible organic matter intake (DOMI, g/kg $LW^{0.75}$) of maize stover by sheep. Stover or husk from eight maize cultivars grown in three field replicates in 2003 and stover from 12 cultivars grown in four field replicates in 2004 were used in three growth trials of 83-98 d. Diets consisted of 80% stover or husk and 20% supplement, contained 10.5% CP and were offered ad libitum to allow stover refusals of 20-25%. Nine or 12 individually fed sheep were used per cultivar (three sheep per field replicate). Sixty-eight diets were used for calibration and 28 for validation. Three samples were prepared for each diet: 1) WS, consisting of whole stover or husk; 2) SS, consisting of WS sieved to remove the exact proportion of stover refused in an attempt to account for the effect of diet selectivity; and 3) SS+S, made of SS and supplement in the proportions consumed by the sheep. Absorbance was determined from 1100 to 2498 nm at intervals of 2 nm in a FOSS NIR System Model 5000. Principal component analyses using a mathematical treatment 1, 4, 4, 1 were used for calibration. Best calibration parameters were obtained with WS (Table 1). Validation R^2 and SE of predictions (SEP) were 0.82 and 2.81 for WS; 0.82 and 3.04 for SS; and 0.87 and 2.34 for SS+S. DOMI of validation diets was predicted with acceptable levels of precision using WS. No gain in precision was observed by using SS, but R^2 increased by 0.05 and SEP decreased by 0.47 by sieving the residue and adding the supplement in the proportions consumed.

Table 1.

	WS	SS	SS+S
n	68	68	67
SEC	1.98	2.29	2.18
R^2	0.89	0.85	0.85

W260 Energy costs of steam-flaking corn with different chemical grain conditioning agents. A. T. Moore*[1], C. R. Richardson[1], J. M. Harris[2], G. V. Pollard[3], and D. C. Boyles[1], [1]*Texas Tech University*, *Lubbock*, [2]*Westway Feed Products, Inc.*, *Tomball, TX*, [3]*Texas State University*, *San Marcos*.

The effects of the addition of water only, or grain conditioning agents on the electrical and gas energy costs to steam-flake corn were determined in a randomized block design. Treatments were: A-water; B-Sur-Flake®; C-whey plus Sur-Flake; D-glycerol plus Sur-Flake; and E-whey plus glycerol plus Sur-Flake. Treatments were evaluated by time block during days (A.M. and P.M. blocks) and were randomly steam-flaked across five days, for a total of 50 determinations. U.S. No. 2 grade corn was obtained in one quantity through the local grain trade in the High Plains area of Texas. Corn was cleaned with a scalper cleaner prior to the conditioning and steam-flaking. All treatments were added to 45.5 kg batches of corn by mixing of six percentage points of moisture and left to stand for 18 h before steam-flaking. The conditioned grains were steamed for 20 min in a 15.24 cm diameter round chamber. Immediately after steaming, treatments were flaked and electrical energy usage was measured. Gas used for generating steam was the same ($.862 per 45.5 kg) for each treatment batch and was used to calculate total energy costs for processing. Electrical energy costs for flaking were not different (P = 0.845) as analyzed by SAS. In conclusion, type of grain conditioning agent may affect rate of moisture uptake, economics of the flaking process, and durability of flakes. Results from this experiment show that electrical energy costs of flaking varied by as much as 11%.

Table 1. Total electrical and gas cost ;per 45.5 kg

Treatment	Block A	Block B

W261 Determining optimum density of steam-flaked corn for feedlot heifers. M. L. May*, M. J. Quinn, B. E. Depenbush, and J. S. Drouillard, *Kansas State University*, *Manhattan*.

The purpose of the experiment was to determine optimum density (FD) of steam-flaked corn for beef finishing diets. Diets consisted of corn flaked to densities of 360, 411, or 462 g/L (28, 32 or 36 lb/bu, respectively). Cattle were randomly allotted to 48 feedlot pens (16 pens per treatment) with 6 to 8 animals in each pen (n=358; initial BW = 337 ± 1.22 kg). Animals were fed finishing diets for 115 d. There were no significant differences among treatments with respect to DMI; ADG; efficiency; carcass weight; dressing percent; quality grade; yield grade; fat over the 12th rib; kidney, pelvic, and heart fat; or longissimus muscle area (P > 0.10), though performance was numerically decreased when corn was less extensively processed. Mill efficiency improved as density of flaked grain increased (P < 0.01), which was driven primarily by increases in mill throughput. Particle size of processed corn and the complete diets increased as FD increased (P < 0.01). Percentages of available starch were 46.73, 39.27, and 34.87 for FD of 360, 411, and 462 g/L, respectively (P < 0.01). The increase in mill production would support increasing FD; however decreases in animal performance, though small, may offset economic benefits attributed to greater mill capacity.

Table 1.

Item	28	32	36	SEM	P-Value
DMI, kg	7.63	7.67	7.70	0.08	0.81

W262 Influence of dietary crude protein concentration on pancreatic α-amylase and trypsin activities in feedlot steers. K. C. Swanson*, H. Salim, Y. Wang, S. Holligan, M. Z. Fan, and B. W. McBride, *University of Guelph*, *Guelph, ON, Canada*.

Twenty-four yearling beef steers (initial BW=510±4.9 kg) predominately of Angus breeding were used in a randomized complete block design to determine the effect of dietary CP concentration on pancreatic α-amylase and trypsin activities. Treatment diets were formulated to contain 8.8, 11.0, 13.2, and 15.4% CP. Soybean meal and TOP SOY™ (bypass soybean meal) were used as supplemental protein sources to assure that metabolizable protein intake was increased with increasing dietary CP concentrations. Steers were individually fed at 2.5×NE_m requirement using Calan gates. Steers were penned in groups of four (1 per treatment) and fed experimental diets for 28 d before tissue collection. Four steers (1 pen) were slaughtered per wk. Pancreata were weighed, subsampled, frozen in liquid N, and stored at -80°C until analyses for protein, and α-amylase, and trypsin activities. Pancreatic weight (g and g/kg BW) did not differ between treatment groups. Pancreatic protein (mg/g and g/pancreas) increased linearly (P≤0.09) with increasing dietary CP concentration. Pancreatic α-amylase activity (U/g, U/g protein, U/pancreas, and U/g pancreas/kg BW) increased linearly (P≤0.01) with increasing dietary CP concentration. Pancreatic α-amylase activity (U/g, U/g protein, U/pancreas, and U/g pancreas/kg BW) also tended to respond quadratically (P≤0.15) with the greatest α-amylase activity observed in the 13.2% CP treatment. Pancreatic trypsin activity (U/g, U/g protein, U/pancreas, and U/pancreas/kg BW) increased linearly (P≤0.09) with increasing dietary CP concentration. These data indicate that increasing dietary CP concentration increases the concentration and content of pancreatic α-amylase and trypsin activities which may increase the capacity to digest starch and protein in the small intestine. However, this response may plateau for α-amylase as high dietary CP concentration (15.4% CP) did not elicit an additional increase in the concentration or content of α-amylase.

Key Words: Feedlot Cattle, α-Amylase, Trypsin

W263 Effects of dexamethasone administration and Revalor-S® on growth, carcass characteristics and visceral organ and fat mass of finishing beef steers. S. E. Kitts*, C. C. Taylor-Edwards, D. B. Edwards, J. B. Cannon, A. F. Beckemeyer, K. E. Earing, D. L. Harmon, E. S. Vanzant, and K. R. McLeod, *University of Kentucky*, *Lexington*.

Administation of dexamethasone (DEX), a synthetic glucocorticoid, has been shown to alter site and rate of fat accretion in several mammalian species, including cattle. Accordingly, this experiment was designed to determine the potential interaction between DEX and trenbolone acetate/estradiol (Revalor-S®) administration on growth performance, carcass characteristics and visceral organ and fat mass of finishing beef steers. One hundred forty-four crossbred steers (428 ± 4 kg) were assigned randomly to a 2 x 2 factorial arrangement of treatments consisting of either no implant or Revalor-S® implant on d 1 and either no or i.m. injection of 0.09 mg/kg BW DEX on d 1, 28, and 56. Steers received ad libitum amounts of a 90:10 concentrate-forage diet during the feeding period and were slaughtered (n=112) on d 84 for determination of carcass quality. A subset of steers (8/treatment) was slaughtered on d 84 and 86 for determination of visceral organ and fat mass. Over the feeding period, DMI (0.4 kg/d) and efficiency of gain (16%) were greater ($P \leq 0.05$) in steers receiving implant compared to those receiving no implant. In the presence of implant, DEX reduced ADG, whereas in the absence of implant, DEX had no effect (interaction, $P = 0.05$). There were no effects of treatment on carcass characteristics except DEX tended to increase ($P = 0.10$) dressing percentage. Steers receiving implants tended ($P = 0.10$) to have heavier rumen + reticulum weights as a percentage of empty BW compared to those receiving no implant. Administration of DEX increased ($P \leq 0.05$) liver and pancreas weights as a function of empty BW and increased omental fat mass for steers in the absence, but not the presence of implant (interaction, $P = 0.006$). In summary, Revalor-S® increased DMI and efficiency of gain; however, DEX partially attenuated the positive effects of implant on ADG and increased omental fat mass in the absence of implant.

Key Words: Cattle, Dexamethasone, Implant

W264 Effects of ractopamine HCl and steroid implants on feedlot performance and carcass characteristics of cull beef cows. K. W. Harborth*, T. T. Marston, J. A. Unruh, and B. J. Johnson, *Kansas State University*, *Manhattan*.

The marketing of cull cows can potentially contribute 10-25% of cow/calf operations gross income. Increasing the lean tissue and quality grade of cull cows could increase their market potential profitability. A study was conducted utilizing thirty-two open crossbred cows in a 2 × 2 factorial experiment to determine the effects of feeding ractopamine HCl (Optaflexx®, Elanco, at 300 mg•head- 1•d-1 for 28 d) and steroid implants (Revalor® 200, Intervet, 60d) on feedlot performance and carcass composition. Cows were blocked by weight (heavy and light) and randomly assigned to one of four serial slaughter groups. Following a warm-up period cows were individually fed an ad libitum 86% concentrate diet (CP = 14.63%, NEm = 2.12 Mcal/kg, NEg = 1.46 Mcal/kg) for 60 d. Within slaughter groups cows were allotted to treatment combinations. The combinations were: 1) Control (no implant or ractopamine HCl); 2) Implant (implanted only); 3) ractopamine HCl (ractopamine fed only); or 4) Combination (implanted and fed ractopamine). There were no significant differences in average daily. Implanted cows had greater dressing percentages (P = 0.06), and red meat yields 10 kg greater than non implanted cows (P = 0.06). Optaflexx treated cows had greater kidney, pelvic, heart fat percentages (P = 0.05). This study showed that implanting cull cows with Revalor-200 and/or feeding ractopamine HCl during the last 28 days on feed had minimal effects on performance and carcass characteristics of cull cows fed a high concentrate diet for 60 d.

Key Words: Cull Cows, Ractopamine, Steroid Implants

W265 Effect of age on feedlot performance and carcass characteristics of cull beef cows. K. W. Harborth*, T. T. Marston, J. A. Unruh, and B. J. Johnson, *Kansas State University*, *Manhattan*.

Data from thirty-one open crossbred cull beef cows fed a high concentrate diet for 60 d was used to investigate the effect of cow age on live animal performance, carcass composition, and subprimal yield. Cows were sorted into two age groups young (≤ 5 years of age, n= 16) and mature (≥ 6 years of age, n = 15). Mature cows were only slightly heavier than young cows initially. Young cows gained 0.9 kg/d more

than mature cows (P = 0.001). Young cows had greater DDMI, and feed efficiencies (P ≤ 0.05) during the duration of a 60 d feeding period. Young cows had heavier hot carcass weights (P < 0.001), and greater dressing percentages (P < 0.001) than older cows. Young cows had larger longissimus muscle area (P < 0.001) than mature cows. There were no differences between young and mature cows for adjusted 12th fat rib fat thickness and USDA yield grade. Young cows had greater quality grades (P = 0.001) primarily because of lower maturity scores (P < 0.01). Young cows also had greater ribeye roll, strip loin, tenderloin, inside round, outside round, eye of round, and knuckle weights when compared to mature cows. While there was no difference in lean trim weights (P = 0.51) between mature and young cows, young cows had significantly greater fat trim weights (P = 0.02) which may have influenced the difference in dressing percentage. Mature cows had greater initial values due to their weight advantage (P < 0.01), but younger cows had lower cost of gains (P < 0.01), greater final live market (P < 0.01) and net values (P < 0.01) when compared to the mature cows. These data indicate young cull cows were more profitable in a 60 d feeding period than older, mature cows.

Key Words: Cull Beef Cows, Age, Feedlot Performance

W266 Adding neem oil to a feedlot diet modulated proportions of volatile fatty acids and increased microbial protein synthesis in a continuous culture. W. Z. Yang*[1], J. Laurain[2], and B. Ametaj[3], [1]*Research Centre, Agriculture and Agri-Food Canada*, *Lethbridge, Alberta, Canada*, [2]*National Engineering School of Agronomy and Food Sciences*, *Nancy, France*, [3]*Department of Agricultural, Food and Nutritional Science, University of Alberta*, *Edmonton, Alberta, Canada*.

Neem oil is a commercialized product that has been shown to have antibacterial, antifungal and antiparasitic activities in different species. A dual effluent continuous culture system was used to investigate the effects of addition of neem oil in a feedlot diet on rumen fermentation, digestibility and microbial protein synthesis. The experiment was designed as a replicated 3 x 3 Latin square with the following treatments: control (no neem oil), low (3%) and high (6%) level of neem oil (DM basis). The experimental diet consisted of 84% barley grain, 9% barley silage, and 7% supplement (DM basis). Mean ruminal pH (6.08) and total VFA (82.1 m*M*) concentration were not affected by supplementation of neem oil. However, increasing the amount of neem oil tended to decrease ($P < 0.10$) proportion of acetate (45, 44, and 40%), increased ($P < 0.09$) proportion of butyrate (6.3, 6.9, and 9.5%) and had no affect on proportion of propionate (45%) for control, low and high levels of neem oil, respectively. As a result, the ratio of acetate to propionate decreased numerically ($P < 0.15$) with increasing the amount of neem oil. Ruminal digestibilities of DM (79, 77, and 70%), NDF (65, 64, and 56%) and starch (89, 85 and 82%) decreased ($P < 0.01$), whereas degradability of N (66, 82, and 74%) was increased ($P < 0.06$) in relation to the amount of neem oil added. Supplementing 3% neem oil increased microbial protein synthesis by 25% with no further increase with the addition of 6% neem oil. These results indicate that adding 3% neem oil in a feedlot diet modulated VFA profiles as well as increased ruminal N degradation and microbial protein synthesis. Increasing further the amount of neem oil (i.e., at 6%) had no beneficial effect on ruminal digestion.

Key Words: Neem Oil, Fermentation, Continuous Culture

W267 Fat tissue deposition and plasma hormone concentrations in early Angus–Nellore cattle treated with recombinant bovine somatotropin (rbST). C. L. Martins, R. C. Cervieri, M. D. B. Arrigoni, A. C. Silveira, C. A. Oliveira, D. D. Millen*, R. D. L. Pacheco, H. N. Oliveira, and L. A. L. Chardulo, *FMVZ/UNESP Botucatu*, *São Paulo, Brazil*.

The objective was to study the response of rbST on fat tissue deposition and plasma concentrations (PC) of thyroid hormones (T3 and T4), IGF–I and leptin (LE) in early Angus–Nellore cattle. We used 40 male calves, 20 d old, supplemented with creep feed until weaning (WE), and divided in two groups(n=20, 0.10mg/hd/d, every 14 d; n=20, not treated). The animals were weaned at 210 d old and fed in feedlot (FE), where they were housed and divided in four treatments keeping the same dose every 14 d until 100 d prior to slaughter (n=10, treated with rbST before and after WE; n=10, treated with rbST until WE; n=10, treated with rbST after WE; n=10, not treated with rbST). Back fat thickness (BFT) by ultrasound and PC were measured every 28 d. BFT did not differ (P>0.05) in the WE and FE periods (1.0 and 5.3mm, respectively). Treated calves presented higher (P<0.05) IGF–I and T4 PC (282.38 vs. 171.88ng/ml and 8.16 vs. 7.22µg/dL, respectively) than animals not treated in the end of the WE period, but PC in the FE period did not show significance for any treatments. For LE, no significant effect of the treatments and theirs interactions were observed (P>0.05), showing a constant PC during the experimental period. But, the LE concentration increased from the beginning to the end of the experiment (P<0.05), independent of treatments (3.098 vs. 7.996ng/mL) and fat tissue amount (P<0.05), from 18.7% (WE period) to 30.4% (FE period). T3 concentration did not differ (rbST=2.563 vs. Control=2.227µg/dL) in the WE period, but differed (P<0.05) in the FE period, when the animals which received rbST in the WE period presented a lower T3 concentration. We did not observe a correlation among BFT, T3, T4, IGF–I and LE in the periods tested. In the WE period the rbST showed advantage for not altering the fat tissue deposition. The hormones studied showed normal secretion as the animals got older, with increasing LE concentration as the BFT got thicker. Leptin showed to be a good metabolic indicator of animal adiposity, being able to be utilized to predict body condition score.

Key Words: Hormones, rbST

W268 Influence of concentrate supplements on performance of grazing growing steers during the dry season, in tropical pastures. R. H. T. B. Goes*[1], R. P. Lana[2], D. D. Alves[3], A. B. Mancio[2], and T. B. Freitas[2], [1]*Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*, [2]*Universidade Federal de Viçosa*, *Viçosa, MG. Brasil*, [3]*Universidade Estadual de Montes Claros*, *Janauba, MG, Brasil*.

The experiment was conducted to evaluated the effects of supplements on performance of growing cattle, in *Brachiaria brizantha* cv Marandu pasture during the dry season. Fifty-four crossbred, castrated steers, with initial weight of 271 kg, were distributed at random in five paddocks of 60.000 m^2. The supplements were fed at crescent levels of 0, 0.4, 0.80, 1.8 and 2.60 kg of supplement/animal/day, and were based in a mineral mixture (100, 16, 8.0, 4.0 and 2.0%), urea (0, 18, 17, 7 and 7 %), soybean meal and corn meal. The protein sources were used in the amount necessary to reach approximately a diet of 13% of crude protein. The animals were weighted at intervals of the 21 days. The average daily gain (ADG) in function of the supplement levels presented a linearly response (ADG = 0.132x + 0.151, $r^2 = 0.84$), with

the supplemetal levels affecting positively the average daily gain of the animals, in order of the 0.132 kg/animal/day. The supplement efficiency (kg of supplement as fed/kg of ADG), obtained by a reciprocal of the coefficients of the linear regressions, were 7.6:1. The pasture intake (IP) were linearly reduced by the crescent supplemental levels (IP = 4.87 - 3.10x, r^2 = 0.84), by the way the total dry matter intake didn't not influenced by the concentrated levels, with a medium value of 4.8 kg/animal/day. The high cost of concentrate feeds compared to the pasture and the low efficiency of the concentrated conversion in weight gain even under tropical pastures can explain the use of concentrate by Brazilian farmers, which can have a greater probability for a low cattle performance.

Key Words: Cattle, Concentrate Conversion, Growth Rate

W269 Energy levels in multiple supplements for finishing beef cattle grazing *Brachiaria brizantha* pasture during the rainy to dry transition season. M. F. L. Sales, M. F. Paulino, P. V. R. Paulino*, M. O. Porto, and S. de Campos Valadares Filho, *Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*.

The effects of increasing energy levels in multiple supplements for finishing beef cattle grazing *Brachiaria brizantha* cv. Marandu on performance and nutritional parameters were evaluated, during the rainy to dry transition season of the year 2004. For the performance trial, twenty four crossbred bulls, 18 month old and 330 kg of initial body weight (BW), were used, being distributed, randomly, into four paddocks of 1.5 ha each. Four treatments were evaluated: mineral salt (MS) and corn and whole soybean based supplements offered in 3 increasing allowance levels: 1.0; 1.5 and 2.0 kg/head/d, allowing TDN intake of, respectively, 0.832; 1.163 and 1.496 kg/head/d. There was detected a positive linear effect of the energy levels in the supplements on the average daily gain and on the final body weight (P<0.10). The nutritional parameters were assessed in a concomitant trial, in which four crossbred steers, 300 kg BW, fitted with esophageal, ruminal and abomasal cannula, and fed similar diets of those of the performance trial were used. There was not observed any effect of supplementation (P>0.05) on dry matter intake (DMI), although it was detected a linear reduction in forage intake (P<0.05) as the supplementation allowance increased. The organic matter intake of the pasture and the NDF intake of the total diet and of the pasture decreased linearly (P<0.05) as the energy level of the supplementation increased. There were no effects (P>0.05) of supplementation levels on the apparent digestibilities of any nutrients, except for crude protein (CP), which showed a quadratic response (P<0.05) to increasing level of supplementation. Additional weight gain, ranging from 20 to 30%, can be obtained in beef cattle supplemented with increasing amounts of energy during the period herein analyzed. However, those gains are due to substitution of supplement for forage.

Key Words: Beef Cattle, Supplementation, Pasture

W270 Effect of two buffers on nutrient digestibilities and rumina fermentation in Holstein steers. O. D. Montañez-Valdez*[1], E. O. Garcia-Flores[2], J. R. Barcena-Gama[3], S. S. Gonzalez- Muñoz[3], M. E. Ortega-Cerrilla[3], J. G. Peralta-Ortiz[3], and J. H. Avellaneda-Cevallos[4], [1]*Centro Universitario del Sur de la Universidad de Guadalajara*, *Ciudad Guzmán, Jalisco, México*, [2]*Centro Universitario del la Costa Sur de la Universidad de Guadalajara*, *Autlán, Jalisco, México*, [3]*Colegio de Postgraduados*, *Montecillos, Estado de México, México*, [4]*Universidad Técnica Estatal de Quevedo*, *Quevedo, Los Ríos, Ecuador*.

The effect of sodium bicarbonate (SB) and a commercial buffer (Acid Buf® AB; *Lithothamnium calcareum*; Celticsea Minerales. Srano Farm, Currabinny, Carrigaline, Co. Cork, Irlanda) on the *in situ* digestibility of DM, NDF and ruminal fermentation was evaluated. Five Holstein steers (BW 450±15 kg) fitted with rumen cannula were randomly assigned to a 5 × 5 latin square and housed in individual pens. Each period was 15 d, 10 d for adaptation to diets and 5 d for samples collection. Diet had 70% concentrate (47% ground sorghum, 8% soybean meal, 7% molasses cane, 6.8% corn gluten meal and 1.2% mineral premix) and 30 % forage (15% alfalfa hay and 15% corn silage) with addition of SB or AB. The treatments were: T1) control; T2) 1% SB; T3) 0.35% AB; T4) 0.50% AB; T5) 0.65% AB. There were no differences (P> 0.05) among treatments on *in situ* digestibility of DM, NDF or cellulolityc bacteria concentration. The ruminal pH was different among treatments (P≤ 0.05), the highest pH values were for T3 (6.35), as compared with T1 (5.98) and T2 (6.14). The rumen protozoa concentration was increased by AB (P≤ 0.05) in T3 ($7.71x10^6$) as compared with SB treatment (5.26×10^6) and control treatment (5.06×10^6). The use of these buffers on concentrate diets did not affect the *in situ* digestibility of MS and NDF, but improved ruminal pH and enhanced the rumen protozoa development.

Key Words: *In Situ* Digestibility, Diets, Buffers

W271 Phase feeding strategies to meet metabolizable amino acid requirements of calf-fed Holstein steers. R. A. Zinn[1], J. F. Calderón[2], L. Corona[3], A. Plascencia[2], M. F. Montaño[2], and N. Torrentera*[2], [1]*University of California, Davis*, *El Centro*, [2]*Universidad Autonoma de Baja California*, *Mexicali, B.C. Mexico*, [3]*Universidad Autonoma de Mexico*, *Mexico, D.F.*

One hundred eight Holstein steer calves (114 kg) were used to evaluate effects of phase feeding metabolizable amino acids (**MAA**) on growth performance and carcass characteristics. Three feeding strategies were evaluated: 1) control, single phase feeding (single urea-based growing finishing diet that meets MAA requirements for the overall feeding period); 2) two-phase feeding (diet formulated to meet the average MAA requirements for the first 112 d on feed, and thereafter, finished on the control urea-based diet) and 3) three-phase feeding (two diets during the first and second 56-d feedlot feeding periods, and thereafter cattle were finished on the urea-based diet). Growth performances among different phases were not different (P > 0.20). Multiple-phase feeding increased ADG (18%, P< 0.01), DMI (4%, P<0.05) and observed/expected dietary NE (16%, P<0.01) during the first 112 d of the study. From d 112 to slaughter there were no treatment effects (P > 0.20) on growth performance. However, multiple-phase feeding increased overall (351-d) ADG (6.3%, P < 0.01), DMI (3.7%, P < 0.10), gain efficiency (2.8%, P < 0.01), and observed/expected dietary NE (3.4%, P < 0.01). Multiple phase-feeding increased hot carcass weight (5.2%, P < 0.01), dressing percentage (1.0%, P < 0.10), fat thickness (25%, P < 0.05) and longissimus muscle (LM) area (8.8%, P < 0.05). Thus, observed dietary NEg was similar (96%) to expected for the two- and three-phase programs during the first 112 d, while it was only 83% of expected for the single-phase program. It is concluded that a two-phase feeding program, where diets for calf-fed

Holstein steers are formulated to meet the average MAA requirements for optimal growth rate, until 280 kg live weight, and from 280 kg until slaughter will enhance overall ADG, gain efficiency, and energetic efficiency compared with a conventional single-phase feeding program. Methionine, lysine and histidine appear to be the first limiting amino acids during the first feeding phase. During the second phase (280 kg to slaughter), supply of all MAA acids will exceed requirements, even where urea is the sole source of supplemental N.

Key Words: Amino Acid, Holstein Steer, Phase Feeding

W272 Relationships between feed efficiency, carcass and ultrasound traits in Angus beef cattle divergently selected for serum IGF–I concentration. F. R. B. Ribeiro*[1], G. E. Carstens[1], P. A. Lancaster[1], L. O. Tedeschi[1], and M. E. Davis[2], [1]*Texas A&M University*, *College Station*, [2]*The Ohio State University*, *Columbus*.

Objectives of this study were to characterize feed efficiency traits and examine phenotypic correlations with carcass and ultrasound traits in Angus bulls and heifers divergently selected for serum IGF–I concentration. Individual DMI were measured in Angus bulls (n = 27) and heifers (n = 29) fed a corn-based diet (ME = 2.85 Mcal/kg) for 70 d using Calan gates. Body weight was measured at 14–d intervals. Ultrasound back fat (**UBF**) and *longissimus* muscle area (**ULMA**) were measured on start and end of test. Cattle were harvested at the end of the test and carcass longissimus muscle area (**CLMA**) and back fat (**CFT**) were collected. Residual feed intake (**RFI**) was computed as the residuals from the linear regression of DMI on mid-test $BW^{0.75}$ and ADG with gender and interactions in the model. Overall mean (± SD) ADG, DMI and RFI were 1.78 ± 0.26, 10.47 ± 1.22, and 0.0 ± 0.70 kg/d for bulls and 1.30 ± 0.15, 9.43 ± 1.14, and 0.0 ± 0.64 kg/d for heifers, respectively. There were no significant differences in ADG, DMI, BW or feed efficiency traits between low and high IGF–I lines. Calves selected for low IGF–I had less (P<0.05) UBF, but similar ULMA at the end of the test than high IGF–I calves. As expected, heifers consumed less feed, grew slower, had a greater feed conversion ratio (**FCR**), and were fatter than bulls. Residual feed intake was correlated with DMI (0.57), and FCR (0.53) but not ADG. Initial BW (0.50) and UBF (0.29) were correlated with FCR, but not RFI, suggesting that calves with lower FCR were lighter and leaner at the start of the test. Final UBF and ULMA were not correlated with RFI or FCR, however carcass marbling score (0.44) was correlated to FCR. These results suggest that RFI was less influenced by rate and composition of growth, and BW compared to FCR. Divergent selection for serum IGF–I had no effect on performance or feed efficiency in Angus calves.

Key Words: Ultrasound, Residual Feed Intake, Feed Conversion Ratio

W273 Feed efficiency of beef cows and its progeny during the preweaning interval[1]. T. Z. Albertini[2], S. R. de Medeiros[3], R. A. de A. Torres, Jr.[3], A. R. D. L. Sousa[3], F. A. Biberg[3], and D. P. D. Lanna*[2], [1]*Fapesp, Embrapa*, [2]*ESALQ-USP*, *Piracicaba, SP, Brazil*, [3]*Embrapa Beef Cattle*, *Campo Grande, MS, Brazil*.

In this experiment the feed efficiency of non-pregnant lactating beef cows and their progeny was determined. Cow/calf pairs were individually fed from just after birth (17±5 d SD) to weaning at 211 d. Adult cows evaluated were 10 Caracu × Nelore and 10 Angus × Nelore that were bred to Red Angus and Canchim (5/8 Charolais) bulls, respectively. The diet (2.30±0.04 Mcal ME/kg and 12.4±0.9% CP) was fed in variable amounts and adjusted every 28 d in order to maintain weight and body scores. The same diet was offered *ad libitum* to the calves. Milk production was determined by milking each cow at 47, 75, 104, 132, 160, 188 and 216 d postpartum. Correlations among efficiency indexes were evaluated using MANOVA option of Proc GLM in SAS. The model included the effects: time at start of feeding period, genetic group, sex and age of calf at beginning of the experiment. Metabolizable energy intake (MEI) means for the progeny, derived from milk and from the solid diet, were 1504.3 (± 170.5 SD; 11.3% CV) and 595.0 Mcal (± 121.8 SD; 20.5% CV), respectively. Efficiency of calves was 85.1 g LWG_{210d}/Mcal of total MEI (milk+solid diet; ± 6.8 SD; 8.0% CV). Efficiency of cow/calf pairs was 34.9 g LWG_{210d}/Mcal MEI (± 4.3 SD; 12.3% CV) using total cow and calf solid diet intake. Phenotypical correlations showed association between the efficiency of calves and MEI from milk (r=-0.73; P<0.01) and between progeny efficiency and total MEI (intake of milk+solid diet; r=-0.74; P<0.01). Moreover, there was correlation (y = -0.0548x + 60.95) between the live weight of cows and the efficiency of cow/calf (r=-0.69; P<0.01). There was correlation between ME for maintenance (Mcal ME/$BW^{0.75}$) and BW of cows (r=0.58; P<0.05). In conclusion, heavier cows were associated with greater maintenance requirements and lower cow/calf pair efficiencies. It was also demonstrated a negative association between calf milk consumption and calf efficiency.

Key Words: Growth, Bioenergetics, Milk

W274 Body composition and net protein and energy requirements of steers from four zebu and zebu × B. taurus crossbreds[1]. R. Silva Goulart[2], E. Benno Pott[3], M. Mello de Alencar[3], G. Maria da Cruz[3], R. Tullio[3], and D. Pazzanese Duarte Lanna*[2], [1]*FAPESP, USP, Embrapa*, [2]*ESALQ/USP*, *Piracicaba, SP, Brazil*, [3]*Embrapa*, *Sao Carlos, SP, Brazil*.

The objective of this study was to determine body composition and net protein and energy requirements of four genetic groups: purebred Nelore (NE) and Aberdeen Angus × Nelore (AN), Canchim (5/8 Charolais) × Nelore (CN) and Simmental × Nelore (SN) crossbreds. Forty seven steers, 22 mo of age and 310 kg of BW, were evaluated in a completely randomized design. The comparative slaughter method was used with 16 animals slaughtered for baseline. EB composition was estimated from the 9-11th rib cut composition using specific equations developed for each genetic group. Diet was based on corn silage, corn and soybean meal, with 13.3% CP and 68.7% TDN, and was fed for a 101-d period. Data were analyzed by proc GLM of SAS, with effects of genetic groups. Results are presented in Table. There was no difference (P>0.05) between AN (428±9 kg) and SN (410±12 kg) in final empty body weight; also weight of CN (389±10 kg), NE (390±11 kg), and SN (410±12 kg) were similar. Steers of AN and SN groups had a greater proportion of ether extract and a smaller percentage of water in the empty body at slaughter. Cattle from SN and AN groups presented greater protein requirements than CN and NE. Steers of the AN group had the highest requirements of net energy for gain. Aberdeen Angus x Nelore cattle needed more energy and more protein than purebred Nelore steers.

Table 1. Empty body composition of Nelore (NE) and crossbreds (Angus, AN; Canchim, CN; and Simmental, SN) steers

Variables	AN	CN	NE	SN	Standar Error
Composition					
Water (%)	56.8[b]	58.1[a]	58.3[a]	55.5[b]	.46
Ether extract (%)	22.6[a]	20.6[b]	20.4[b]	22.3[a]	.54

W275 Relationship between residual feed intake, water intake and ultrasound body composition traits in Angus bulls. G. R. Hansen*[1], G. E. Carstens[2], and D. G. Riley[3], [1]*University of Florida NFREC*, *Marianna*, [2]*Texas A & M University*, *College Station*, [3]*USDA-ARS STARS*, *Brooksville, Fl.*

The objective was to examine the relationship between residual feed intake (RFI), water intake (WI), feed conversion ratio (FCR), initial feed consumption (IFC—total intake for first 2 wk prior to 70-d trial) and real time ultrasound body composition traits (RTUS) in 9-mo-old Angus bulls (n=126). Bulls were produced using embryo transfer at a private farm and moved to a GrowSafe feeding facility in summer 2006. Individual daily feed intake (DMI), daily WI and BW (every 2 wk) were obtained during a 70-d feeding trial. RTUS were measured on d 70. RFI was calculated by regressing dry matter intake on ADG and mid-test $BW^{.75}$. Bulls were assigned to high (bull RFI > mean + 0.5 SD), medium (bull RFI between mean ± ? 0.5 SD) and low (bull RFI < mean – 0.5 SD) RFI groups. ADG, DMI and RFI were 1.54 ± 0.28 kg/d, 10.63 ± 1.73 kg/d and 0.00 ± 1.39, respectively. Low, medium and high RFI groups differed (P<0.05) for IFC. Low RFI bulls consumed 19.9 % less feed (P<0.001) and 32.4 % less water (P<0.001) than high RFI bulls. There were no differences for ADG, % IMF, or ribeye area among RFI groups. Beginning scrotal circumference (d -14) was greater (P<0.05) in high RFI bulls than low or medium groups. Residuals were generated for traits by adjusting for pen, age, sire and dam effects. Residual correlations were calculated using residual values. FCR was associated with RFI using simple (0.61) and residual (0.40) correlations.

Table 1. Correlations among traits for Angus bulls

	RFI	WI	Ribfat	DMI	IFC
RFI	--	0.43	0.44	0.73	0.59
WI	0.33	--	0.23	0.40	0.23
Ribfat	0.33	0.29	--	0.33	0.38
DMI	0.52	0.40	0.27	--	0.71
IFC	0.38	0.24	0.37	0.58	--

Simple correlations above diagonal and residual correlations below diagonal

Key Words: Feed Efficiency, Residual Feed Intake, Carcass Traits

W276 Effect of yeast culture on 28-day performance of newly weaned, low-stress beef calves. C. R. Belknap*[1], R. R. Scott[2], and J. C. Forcherio[2], [1]*Diamond V Mills*, *Cedar Rapids, IA*, [2]*LongView Animal Nutrition Center*, *Gray Summit, MO*.

The objective of this study was to determine the effect of yeast culture (Diamond V XPC™ Yeast Culture, Diamond V Mills) on 28-d post-weaning performance when fed to ranch-weaned calves that had previously received creep feed for 111 d. Seventy-four Angus x Charolais calves were removed from their dams, weighed, vaccinated and held in dry lot overnight with access to hay and water. The next morning, calves were reweighed and assigned to one of five weight blocks. Within weight blocks, calves were equally distributed to one of two treatment pens based on sex and age of dam. Treatments consisted of: Control (C) or 0.25% Diamond V XPC Yeast Culture (YC). The basal diet consisted of a coarse textured complete feed (88% DM) containing cracked corn, cottonseed hulls and supplemental pellet. Both treatments contained chlortetracycline and sulfamethazine (Aureo S-700®, Alpharma Animal Health) at 77 g/ton and 0.0084% respectively. Yeast culture was provided in the supplemental pellet for the YC treatment. Calves were fed twice daily and brought up on feed the initial 5 d, then allowed to consume feed ad libitum. DMI was recorded daily. Initial and final weights (28 d) were averaged from two consecutive weights. After the 5-d step-up period, calves fed YC had numerically higher DMI the remaining days on trial (data not shown) and DMI tended to be increased (P<0.19) compared to C (Table 1). Final BW and ADG were increased (P<0.01) by the addition of YC to the weaning diet. These data indicate that Diamond V XPC Yeast Culture will increase ADG of low-stress, ranch-weaned calves when fed in conjunction with chlortetracycline and sulfamethazine.

Table 1. Effect of yeast culture on 28-d post-weaning performance.

	Control	Yeast Culture	P <
Initial BW, kg	270	270	NS
Final BW, kg	319	323	0.01
DMI, kg/d	6.70	7.07	0.19
ADG, kg/d	1.67	1.81	0.01
F/G, kg/kg	4.00	3.91	NS

Key Words: Beef Cattle, Yeast Culture, ChlortetraCycline

W277 Effects of an intratracheal challenge with *Mannheimia haemolytica* on intake and N balance in fed or fasted steers. L. O. Burciaga-Robles*[1], C. R. Krehbiel[1], D. L. Step[2], B. P. Holland[1], M. Montelongo[2], A. W. Confer[2], J. N. Gilliam[2], and C. L. Goad[3], [1]*Department of Animal Science*, [2]*Center for Veterinary Health Sciences*, [3]*Department of Statistics. Oklahoma State University*, *Stillwater*.

The objective was to determine acute (5 d) and longer-term (2 wk) effects of an intratracheal challenge with *Mannheimia haemolytica* on DMI and N balance in fed or fasted steers. Twenty-two steers (BW = 320±24 kg) were assigned to one of four treatments: 1) fed ad libitum and not challenged (FED/CON); 2) fed ad libitum and challenged (d 0) with *M. haemolytica* (FED/CH); 3) fasted for 72 h and not challenged (FAST/CON); or 4) fasted for 72 h and challenged (d 0) with *M. haemolytica* (FAST/CH). Feed, total urine and feces were collected for three (d -3, -2, and -1), five (acute response on d 0, 1, 2, 3, and 4;

wk 1), three (d 6, 7, and 8; wk 2), and three (d 14, 15, and 16; wk 3) days. Challenge with *M. haemolytica* increased (P < 0.05) antibody concentration of the whole bacteria on day 15. In the acute model, DMI responded with a diet*challenge*day interaction (P = 0.02). After the 72 h fast, FAST/CON steers consumed a similar amount of DM as FED/CON. Steers challenged with *M. haemolytica* had lower (P < 0.05) DMI during the first 2 (FED) and 4 (FAST) d. In the long-term model a diet*challenge*week interaction was observed (P = 0.002). FED/CON steers generally had constant DMI in comparison with FAST/CON and FED/CH. No difference was observed (P > 0.10) in DMI among FED/CON, FAST/CON, and FED/CH during wk 2 and 3 of the experiment. FAST/CH steers had lower (P < 0.05) N retention than FED/CON steers 4 d after the challenge (diet*challenge*day interaction, P = 0.09). Nitrogen retention of FAST steers was lower (P = 0.006) compared with FED steers. Steers challenged with *M. haemolytica* tended (P = 0.10) to retain less N during the acute response. For the longer-term model no statistical difference was observed (P = 0.20) for N balance. Our data suggest that cattle that are fasted and challenged with a bovine respiratory pathogen retain less N for up to 4 d following the insult.

Key Words: Diet, *M. haemolytica*, N Balance

W278 Feedlot performance and rumen parakeratosis incidence in *Bos indicus* type bullocks fed high-grain diets and monensin or polyclonal antibody preparations against rumen bacteria. D. D. Millen*, R. D. L. Pacheco, M. D. B. Arrigoni, M. Parrili, S. A. Matsuhara, M. V. Fossa, L. M. N. Sarti, C. L. Martins, J. P. S. T. Bastos, and T. M. Mariani, *FMVZ/UNESP–Botucatu*, *São Paulo, Brazil*.

Oral dosing of polyclonal antibody preparations (PAP) against *Streptococcus bovis* or *Fusobacterium necrophorum* enhanced feedlot performance of *Bos taurus* cattle. This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to test PAP against *S. bovis*, *F. necrophorum*, and several strains of proteolytic bacteria (RMT) on performance and parakeratosis incidence of *Bos indicus*-based types. The experiment was designed as a 3 X 2 factorial, replicated thrice (4 bullocks/pen), in which 24 9-mo-old bullocks (297 kg) of each of three *Bos indicus*-based types: 3-way cross (1/2 Brangus, 1/4 Angus, 1/4 Nellore; TC), Canchim (5/8 Charolais, 3/8 Nellore; CC), or Nellore (NE) were fed one of two diets containing either monensin (MO) at 300 mg/d or RMT at 10 mL/d. Bullocks were fed ad libitum twice daily and, at harvest, rumen parakeratosis was scored on the entire washed rumen using a scale of 0 (no lesions noted) to 10 (severe ulcerative parakeratosis). Diets contained 50% high moisture corn, 21% cracked corn, 10% soybean meal, 10% sugarcane bagasse, 5% corn silage and 4% supplement (DM basis). There were no interactions (P > 0.05) between breed type and feed additive. Bullocks fed RMT had similar (P > 0.05) ADG (1.34 vs. 1.30 kg), DMI (8.28 vs. 8.02 kg/d) and DM required/kg gain (6.17 vs. 6.17 kg) as those fed MO. When analyzed as percentage of BW, bullocks fed RMT consumed (P< 0.05) more feed than those fed MO (2.20 vs. 2.14%). Bullocks fed RMT tended (P = 0.09) to have lesser rumen parakeratosis scores than those fed MO (55.6% vs. 45.7% of the rumens from bullocks fed RMT and MO scored between 0 and 1, respectively). Crossbred cattle (TC and CC) had greater (P < 0.05) DMI and ADG, and better (P < 0.05) feed conversion than purebred NE. Rumens from NE bullocks had greater (P < 0.05) parakeratosis scores than those of crossbreds. Feeding RMT enhanced intake of *Bos indicus*-based bullocks fed high-grain diets while maintaining rumen health, and permitting performance similar to that of bullocks fed monensin.

Key Words: PAP, Monensin, Performance

W279 Effects of a saccharin-containing additive (SUCRAM) on total tract digestibility, plasma metabolites, and urine organic acid excretion by steer calves. C. H. Ponce*[1], M. S. Brown[1], J. C. Silva[1], P. Schlegel[2], and W. Rounds[3], [1]*West Texas A&M University*, *Canyon*, [2]*Pancosma, SA*, *Geneva, Switzerland*, [3]*Prince Agri Products*, *Quincy, IL*.

Previous data suggest that SUCRAM C-150 (97% sodium saccharin; Pancosma SA) may improve growth performance by stressed beef calves. Fifteen steers (261 +/- 28 kg BW) were used to evaluate the effects of SUCRAM C-150 on total tract digestibility, plasma metabolite concentrations, and urine monoamine metabolite concentrations. Treatments included ad libitum access to a 60% concentrate diet (NC), ad libitum access to NC + 180 g of SUCRAM C-150/ton of DM (AS), and NC + 180 g of SUCRAM C-150/ton of DM with feed intake paired to NC (PS). Steers were adapted to treatments for 28 d before a 5-d collection of total feces and urine excreted. Jugular blood samples were collected on the last day of collection period. Steer DMI during the metabolism period did not differ (P > 0.15) between PS and NC (93 and 97 +/- 4 g/kg of $BW^{0.75}$, respectively), but DMI tended (P = 0.14) to be greater for AS (105 g/kg of $BW^{0.75}$) than for NC. Treatments did not alter (P > 0.15) apparent total tract DM, OM, CP, or NDF digestibility. Plasma homocysteine concentration was reduced (P < 0.03) by feeding PS or AS (0.57, 0.39, and 0.44 +/- 0.04 ug/mL for NC, PS, and AS, respectively). No differences were detected (P > 0.15) in plasma concentrations of tryptophan, large neutral amino acids, branched chain amino acids, or in the ratio of tryptophan to either large neutral or branched-chain amino acids. Urinary concentration (mmol/mol creatinine) of ethylmalonic acid, vanillymandelic acid (0.68, 1.65, and 1.47 +/- 0.23 for NC, PS, and AS, respectively), and 5-hydroxyindolacetic acid were greater (P < 0.06) for steers receiving AS than for steers receiving NC; steers fed PS had a greater (P = 0.02) urine vanillymandelic acid concentration than steers fed NC and tended (P < 0.12) to have a greater urinary concentration of ethylmalonic and 5-hydroxyindolacetic acid. The volume and mass of urine excreted did not differ (P > 0.32). Data suggest that saccharin-specific alterations in metabolism by calves may include reduced plasma homocysteine and increased excretion of vanillymandelic acid.

Key Words: Saccharin, Sweetener, Monoamine Metabolites

W280 Evaluation of feeding behavior of young cattle from different genetic groups fed with high concentrate diets with different NDF levels. L. M. N. Sarti, R. D. L. Pacheco*, D. D. Millen, M. D. B. Arrigoni, M. V. Fossa, S. A. Matsuhara, M. Parrili, C. L. Martins, H. N. Oliveira, T. M. Mariani, J. P. S. T. Bastos, and L. F. S. Niero, *FMVZ/UNESP–Botucatu*, *São Paulo, Brazil*.

The objective was to evaluate the feeding behavior of young cattle from different genetic groups (GG) with different zebu percentage in their compositions fed high concentrate diets with different NDF levels. The study had 3 GG (3 way cross – 1/2 Braunvieh, 1/4 Angus,

1/4 Nellore (TC); Canchim – 5/8 Charolais, 3/8 Nellore (CC) and Nellore (NE)) evaluated with four different diets (DD) with varying concentrate and NDF levels (Concentrate (%) = 58, 73, 82 and 85; NDF (%) = 38.1, 30.9, 27.7 and 23.0; respectively). We evaluated grams per hour feeding efficiency of dry matter (FEDM) and NDF (FENDF) and rumination efficiency of dry matter (REDM) and NDF (RENDF). The experiment was conducted at the experimental feedlot of the Veterinary Medicine and Animal Science College, São Paulo State University, Botucatu campus (UNESP), Brazil. Twelve 8–month–old TC, CC and NE bulls (297±84 kilos) were fed from creep feeding for 135 d, with 4 animals per group tested. For FEDM (g/hour) we found an effect (P<0.05) for GG and DD (TC=4183.66^{b}, CC=3037.81^{a}, NE=2280.24^{a}; 1=2482.99^{c}, 2=2511.20^{c}, 3=3385.01^{d}, 4=4289.74^{d}) but there was no interaction among them. Regarding FENDF, REDM and RENDF, we found effects for GG, DD and an interaction. TC was more efficient (P<0.05) than NE and CC for FENDF in the diets tested (TC=1354.12, CC=954.33, NE=713.70). For REDM, the TC was better (P<0.05) when compared to NE, but the CC did not differ when compared to TC and NE in the four diets tested (TC=1668.54, CC=1378.20, NE=1149.80). For RENDF, the TC was more efficient (P<0.05) than NE, but the CC did not differ when compared to TC and NE for all diets evaluated (TC=526.58, CC=440.47, NE=366.08). In conclusion, the TC and NE were more and less efficient, respectively, regarding the feeding behavior efficiencies evaluated. As zebu percentage in the GG composition gets lower, the concentrate level of the diets could be increased and vice versa, showing a grain adaptation in animals with low zebu percentage in GG composition.

Key Words: Feeding Behavior, FDN, Efficiency

W281 Beet pulp as a non-roughage fiber source in a total concentrate diet fed growing heifers. A. D. Faleiro, A. Ferret*, X. Manteca, J. L. R. de la Torre, and S. Calsamiglia, *Universitat Autonoma de Barcelona*, *Bellaterra, Spain*.

Eight rumen fistulated Holstein heifers (140 ± 24 kg, initial BW) were used to study the effect of using beet pulp as a non-roughage fiber source in a high concentrate diet. The variables studied were intake, ruminal fermentation and growth. All heifers were fed *ad-libitum* a concentrate composed of (DM basis) barley (31.4%), corn (32.2%), soybean meal (8%), corn gluten feed (9%), beet pulp (16%), and a mineral and vitamin compound (3.4%). The chemical composition of the concentrate was: 2.9 Mcal/kg ME, 14.9% CP, 24.2% NDF, 11.4% ADF, on DM basis. Four animals received barley straw as a roughage supplement (Diet A), while the other 4 did not (Diet B). The experiment was performed in six 28-d periods, and sampling was carried out in the last week of each period. Intake was recorded during five consecutive days. Feed and refusal samples were taken to determine DM, CP and NDF content. Ruminal samples were collected over 3 d at 0, 4, 8, and 12 hours post-feeding to measure pH, and VFA and NH3-N concentrations. Body weight was recorded on 1 d of each period. Data were analyzed using the generalized mixed model adequate for repeated measures. The model contained the effect of diet, period, and their interaction as fixed effects. Period was used as a repeated factor, and animal as a random effect. Barley straw intake in heifers fed diet A was 0.5kg/d. There were no statistical differences in concentrate DM intake (6.8 ± 0.42 kg/d) or CP intake (1.1 ± 0.07 kg/d). In contrast, there were statistical differences (P < 0.001) in ADF intake (kg, Diet A = 0.852, Diet B = 0.582), ruminal pH (Diet A = 6.0, Diet B = 5.5), total VFA (mM, Diet A = 134.3, Diet B = 153.4), propionate proportion (mol/100 mol, Diet A = 21.7, Diet B = 33.4), and acetate to propionate ratio (Diet A = 2.6, Diet B = 1.4). The ruminal concentration of NH3-N was not different (5.2 ± 0.84 mg/100 mL). Diets had no effect on ADG, (1.3 ± 0.06 kg/d). Results indicate that beet pulp as a non-roughage fiber source affected ruminal fermentation but did not change performance in a feedlot compared to a high-concentrate diet supplemented with barley straw.

Key Words: Beet Pulp, Concentrate Diet, Growing Heifers

W282 Post weaning performance of Holstein dairy heifers fed diets differing in forage quality and supplemented with a low moisture block. H. Chester-Jones*[1], D. Ziegler[1], R. Larson[2], B. Ziegler[2], J. Linn[3], M. Raeth-Knight[3], and G. Golombeski[3], [1]*University of Minnesota Southern Research and Outreach Center*, *Waseca*, [2]*Hubbard Feeds*, *Mankato, MN*, [3]*University of Minnesota Southern Research and Outreach Center*, *St. Paul*.

Ninety-six dairy heifers were used in a 112-d study to evaluate feed intake and performance from 9 to 25 weeks of-age. Heifers (92.3 ± 0.93 kg BW) were randomly assigned to 1 of 4 grower diets (6 heifers/pen, 4 pens/treatment). Heifers were each fed a cracked corn and pellet grain mix (16%CP) limit-fed to 2.72 kg/d (as fed) from d 1 to 14 and to 1.82 kg/d from d 15 to 112 with free choice hay. Treatments were: 1) LOW: alfalfa hay (19.3% CP; 100 RFV); 2) LOWB: alfalfa hay and low moisture molasses-based block (30% CP); 3) MED: alfalfa hay (19.6 % CP; 130 RFV); and 4)HIGH: alfalfa hay (18.6 % CP; 154 RFV). Using the low moisture block increased ADG by 4.0% and feed efficiency (FE) by 2.3% for the LOWB as compared to the LOW treatment. Feeding a higher quality hay increased ADG by 9.0% and FE by 3.0% for the MED compared to the LOW and LOWB treatments. Heifers receiving the highest quality hay (HIGH) had increased ADG (1.4%) and FE (5.9%) compared to heifers fed the MED treatment. Final BW for heifers fed LOW (188.9 kg) and LOWB (193.1 kg) were lower (P < 0.05) than heifers fed MED (198.9 kg) and HIGH (202.0 kg), respectively. Over the 112 d study, ADG (kg/d), grain DMI (kg), hay DMI (kg/d) and FE (kg feed/kg gain) were 0.87, 1.70, 2.41, 4.78; 0.91, 1.70, 2.36, 4.62; 0.96, 1.70, 2.68, 4.59; 0.97, 1.70, 2.49 and 4.33 kg for heifers fed LOW, LOWB, MED, and HIGH treatments, respectively. Under the conditions of the study, performance of all heifers was acceptable and an economic comparison should be the criteria to select the hay of choice when limit feeding grain mixes. The study demonstrated that feeding up to 2.72 kg daily of a 16% CP grain mix for the first 14 d followed by 1.82 kg/d from d 15 to 112 with access to FC alfalfa hay provides sufficient energy and protein for acceptable heifer growth.

Key Words: Dairy Heifers, Grain Mixes and Forage Quality, Performance

W283 Performance of Holstein dairy heifers fed whole-shelled corn and protein pellet diets differing in protein levels. D. Ziegler*[1], M. Raeth-Knight[2], J. Linn[2], G. Golombeski[2], R. Larson[3], B. Ziegler[3], and H. Chester-Jones[1], [1]*University of Minnesota Southern Research and Outreach Center*, *Waseca*, [2]*University of Minnesota*, *St. Paul*, [3]*Hubbard Feeds*, *Mankato, MN*.

Ninety-six dairy heifers (93.8 ± 0.77 kg BW) were used in a 112-d study to evaluate feed intake and performance from 9 to 25 weeks of age when offered limit (LF) or full-fed (FF) whole-shelled corn and pellet (WCP) diets varying in protein level, with or without access to free choice (FC) hay. Heifers were randomly assigned to 1 of 4 grower diets (6 heifers/pen, 4 pens/treatment). Treatments from d 1 to 56 were 1) 16LF: 16% CP WCP, LF to 2.72 kg/calf (as-fed) and FC alfalfa hay (19.7% CP, DM basis); 2) 13FF: 13% CP WCP, FF with no hay; 3) 16FF: 16% CP WCP, FF with no hay; and 4) 19FF: 19% CP WCP, FF with no hay. Day 57 to 112 all heifers were LF their respective WCP up to 2.27 kg daily with FC hay. Day 1 to 56, heifers fed 16LF had the lowest (P <0.05) daily gain (1.01 kg/d) and highest feed/gain (3.64) vs. FF diets, which averaged 1.25 kg/d and 3.13 kg feed/kg BW gain, respectively. From d 57 to 112, heifers fed 16LF had 10.2% higher (P <0.05) ADG (1.08 kg/d) compared to the 13FF, 16FF and 19FF diets which averaged 0.97 kg/d. Total gain over 112-d for 16LF heifers (116.6 kg) was 6.2% lower than the other treatments which averaged 124.4 kg. Daily gain (kg/d) and feed/gain for the 112-d study were 1.04, 4.42; 1.10, 4.29; 1.11, 4.11; 1.13, and 4.03 kg for 16LF, 13FF, 16FF, and 19FF heifer groups, respectively. Initial hip heights (HH) averaged 105.3 cm with similar (P > 0.05) HH gains (20.8 cm) for all heifer groups over the 112-d. Body condition score gain for 16LF heifers was +0.77 being 9.4% less than the other heifer groups (+0.85). Under the conditions of this study, all treatments resulted in adequate heifer growth. The results will allow for further refinement of protein levels to use in grain mixes.

Key Words: Dairy Heifers, Concentrate Protein Levels, Performance

W284 Effects of amount and composition of concentrate on silage and total DM intake of dairy cows. P. Huhtanen*[1], M. Rinne[2], and J. Nousiainen[3], [1]*Cornell University*, *Ithaca, NY*, [2]*MTT-Agrifood Research*, *Finland*, [3]*Valio Ltd*, *Finland*.

Dry matter intake (DMI) explains most of the variation in nutrient supply and milk production. DMI is regulated by animal, diet and management factors and their complex interactions. Our objective was to develop a DMI model describing the relative intake potential of the diet. A data set of 960 diets from 204 production trials with dairy cows was collected. The effects of concentrate feeding on silage DMI were investigated in 168 comparisons including 610 diets. The data was further divided into sub-sets: level of concentrate, and CP, NDF and fat concentration of concentrate. Within each comparison the same forage was fed ad libitum. A mixed model regression analysis was used to estimate the relationships between silage DMI (SDMI) and independent variables. SDMI decreased quadratically with increased concentrate DMI (CDMI). The substitution rate increased with increasing relative SDMI potential. An increase in concentrate CP concentration in response to replacement of energy substrates with protein feeds (e.g. soybean or rapeseed meal) was associated with quadratic increases in silage and total DMI. Replacement of starchy ingredients with fibrous by-products in concentrate slightly increased DMI, whereas fat supplementation had a negative effect on DMI. The effects of different components (CDMI, CP, NDF and fat concentration and interaction CDMI Ã— SDMI potential) were combined to create a relative CDMI index. Relative CDMI index predicted the intake responses within a study precisely as indicated by a low mean squared prediction error (MSPE = 0.33 kg) between predicted and observed DMI adjusted for random study effect. The total DMI (TDMI) index calculated as CDMI + SDMI indexes predicted TDMI within a study precisely (MSPE = 0.37 kg, n = 960). One TDMI index point corresponded to a 0.103 kg DMI, i.e. very close to the default value of 0.10. Marginal responses in TDMI of grass silage based diets to changes in diet composition can be predicted accurately and precisely, but predicting absolute intakes needs a better characterization of the animal's intake potential.

Key Words: Intake Prediction, Grass Silage, Modelling

W285 Please see abstract # 278.

W286 Effects of feeding monensin and brown midrib corn silage on milk production and rumen fermentation. C. R. Mullins*, A. M. Gehman, P. J. Kononoff, and B. N. Janicek, *University of Nebraska*, *Lincoln*.

An experiment was conducted to compare rations including brown midrib corn silage (*bm3*) and a control dual purpose hybrid (DP) on milk production and rumen fermentation. The effect of monensin in these rations was also examined. Twenty multiparous Holstein cows (4 ruminally cannulated) averaging 101 ± 34 DIM (mean ± SD) and 674 ± 77 kg BW were assigned to one of five 4 × 4 Latin squares, using a 2 X 2 factorial arrangement of treatments. Cows were fed one of four treatments during each of the four 28-d periods: 1) C-*bm3*, 0 mg/d monensin and *bm3*, 2) C-DP, 0 mg/d monensin and DP, 3) M-*bm3*, 300 mg/d monensin and *bm3*, and 4) M-DP, 300 mg/d monensin and DP. Diets were formulated to maintain energy, neutral detergent fiber, and non-fiber carbohydrate concentrations across treatments. Diets containing *bm3* contained more corn silage than those containing DP (54 vs. 49 % DM). *In vitro* 30 h neutral detergent fiber digestibility was higher for *bm3* than DP (61.0 vs. 49.1 ± 0.62 %). Monensin tended ($P = 0.07$) to increase rumen pH (5.89 vs. 5.79 ± 0.07) compared to the control treatment. In addition, diets containing *bm3* resulted in a decrease ($P < 0.01$) in rumen pH (5.72 vs. 5.98 ± 0.07). Monensin had no effect on molar concentration of acetate, propionate, or butyrate. In contrast, monensin increased ($P < 0.01$) branched chain volatile fatty acids. Diets containing DP resulted in a higher ($P < 0.01$) concentration of propionate (27.4 vs. 26.3 ± 1.77 mol/100 mol) and tended to have a higher ($P = 0.07$) acetate concentration (56.0 vs. 55.2 ± 1.30 % mol/100 mol). Cows consuming diets containing *bm3* tended ($P = 0.08$) to have higher dry matter intake (21.3 vs. 20.2 ± 0.63 kg/d) but was not affected by monensin. No differences were observed in 3.5% fat-corrected milk, averaging 38.0 ± 2.09 kg/d. In addition, no differences were observed for fat and protein yield, averaging 1.34 ± 0.08 and 1.13 ± 0.06 kg/d respectively. Monensin supplementation increased rumen pH, without affecting dry matter intake or milk production. Diets containing *bm3* were consumed in greater amounts but did not affect milk production or composition.

Key Words: Brown Midrib Corn Silage, Monensin, Dairy Cow

W287 Effects of mixing red clover silage with grass silage on the fatty acid and sensory properties of milk from dairy cows. J. M. Moorby*[1], D. R. Davies[1], W. J. Fisher[1], N. M. Ellis[1], N. D. Scollan[1], and G. R. Nute[2], [1]*Institute of Grassland and Environmental Research*, *Aberystwyth, UK*, [2]*University of Bristol*, *UK*.

Twenty-four multiparous mid-lactation Holstein-Friesian dairy cows were used in a replicated 4×4 Latin square changeover design experiment to test the effects of changing from ryegrass silage to red clover silage in graded proportions on milk fatty acid (FA) profiles and organoleptic qualities. Four diets were offered comprising ad libitum access to 1 of 4 forage mixes plus 4 kg dairy concentrates per d. The forage mixes were, on a DM basis: 1) 100% ryegrass silage (GS), 2) 66% GS:34% red clover silage (RCS), 3) 34% GS:66% RCS, and 4) 100% RCS. Each experimental period comprised 21 d for adaptation to diets and 7 d of measurements. Milk FA profiles were hardly affected by diet, with no significant effects on $C_{18:2}$ and $C_{18:3}$ FAs. Similarly, and perhaps because of this, there was little effect of diet on organoleptic qualities of pasteurised milk as assessed by taste panel analysis, with no effects on milk aroma, aftertaste, or overall liking. The appearance of milk was thicker ($P < 0.001$ linear effect) and more cream-coloured ($P < 0.001$ linear effect) when cows were fed GS compared to when fed RCS. The flavour of milk was largely unaffected by diet, apart from a quadratic ($P < 0.05$) effect of diet on the sour flavour characteristic, with milk from cows on the two extreme diets scoring higher than milk from cows on the two mixed silage diets, and a small but significant ($P = 0.010$) linear effect of treatment on the boiled milk flavour, with an increasing score as the proportion of RCS in the diet increased. In conclusion, increasing the proportion of RCS in the diet of dairy cows had little effect on milk FA profiles or on milk organoleptic characteristics.

Key Words: Red Clover Silage, Milk Fatty Acids, Taste Panel

W288 Effects of mixing red clover silage with grass silage on feed intake and milk output from dairy cows. J. M. Moorby*, D. R. Davies, W. J. Fisher, N. M. Ellis, and N. D. Scollan, *Institute of Grassland and Environmental Research*, *Aberystwyth, UK*.

Twenty-four multiparous mid-lactation Holstein-Friesian dairy cows were used in a replicated 4×4 Latin square changeover design experiment to test the effects of changing from ryegrass silage to red clover silage in graded proportions on feed intakes, milk production, and milk composition. Four diets were offered comprising ad libitum access to 1 of 4 forage mixes plus 4 kg dairy concentrates per d. The forage mixes were, on a DM basis: 1) 100% ryegrass silage (GS), 2) 66% GS:34% red clover silage (RCS), 3) 34% GS:66% RCS, and 4) 100% RCS. Each experimental period comprised 21 d for adaptation to diets and 7 d of measurements. Total dry matter intakes ($P < 0.001$) increased linearly as the proportion of RCS in the diet increased (16.7, 17.8, 18.3, 19.0 kg/d, SED = 0.024). Milk yields also increased with inclusion of RCS in the diet (25.2, 26.1, 26.5, 26.1 kg/d, SED = 0.47, $P < 0.05$ linear effect, $P < 0.05$ quadratic effect) but the increase was not as great as the DMI increase so that the efficiency of milk production (kg milk/kg DMI) decreased linearly ($P < 0.001$). Concentrations of milk fat and protein decreased linearly ($P < 0.001$) as the proportion of RCS in the diet increased, but yields of fat were unaffected. There was a significant ($P < 0.01$) quadratic effect on protein yield, with the highest yields from the two mixed diets. In conclusion, increasing the proportion of RCS in the diet of dairy cows increased feed intakes and milk yields, with the highest milk and milk protein yields from the 34% GS:66% RCS diet. However, including RCS in the diet decreased milk fat and protein concentrations and milk production efficiency.

Key Words: Red Clover Silage, Milk Production, Feed Intake

W289 Intake, digestibility and milk production and composition of dairy cows fed sugar–cane based diets corrected with soybean meal or different levels of urea. A. H. do Nascimento Rangel*[1], J. M. de Souza Campos[2], S. de Campos Valadares Filho[2], A. Barbosa[2], and P. V. R. Paulino[2], [1]*Universidade Federal Rural do Semi–Árido*, *Mossoró, RN, Brazil*, [2]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*.

The mixture of sugar–cane and urea was been widely used by dairy cattle producers in Brazil, mainly during the dry season of the year. However, more research is needed in order to determine the most appropriate level of urea to be included in this kind of diet. Thus, the objective of this work was to evaluate the effect of sugar–cane based diets, corrected with soybean meal based concentrate (SM) or different levels of urea, on the intake, digestibility and milk production and composition of dairy cows. Twelve pure and crossbred Holstein cows were used, being arranged in three 4 × 4 Latin squares, distributed according to lactation period. The diets were formulated to be isonitrogenous, containing 14% crude protein on the dry matter (DM) basis. The daily supply of concentrate was fixed at 0.5 kg for each kg of milk produced. The urea levels tested were 0.4, 0.8 and 1.2%, on the natural matter basis. Following the analysis of variance, it was performed the decomposition of sums of squares for treatments into non–orthogonal contrasts, comparing the sugar cane diet corrected with SM based concentrate with the diets in which the different urea levels were used. Linear and quadratic effects of the three urea levels were also tested. There were no differences among the diets ($P > 0.05$) in the intakes of dry matter (DM), organic matter (OM), ether extract (EE), total carbohydrates (CHO), non–fiber carbohydrates (NFC) and neutral detergent fiber (NDF). A decreasing linear effect ($P<0.05$) was found for NDF intake among diets containing different urea levels. No effect of diet was observed ($P > 0.05$) for the apparent digestibility coefficients of DM, OM, CP, EE, NDF and NFC. A linear effect was detected ($P<0.05$) for the total carbohydrates digestibility and for the TDN content of the diet, which increased as the urea level increased. Milk production, corrected or not for 3.5% of fat, and milk composition did not differ ($P>0.05$) among the diets tested. The mean value of milk production, corrected for 3.5% of fat, was 20.07 kg/d. The diets containing urea were more profitable than the diet containing soybean meal, justifying its use by the producer in order to reduce feeding costs of the herd.

Key Words: Holstein, Sugar-Cane, Urea

W290 Performance and nutritional parameters of replacement dairy heifers fed corn silage or sugar–cane based diets supplemented with increasing concentrate levels. A. H. do Nascimento Rangel*[1], J. M. de Souza Campos[2], P. V. R. Paulino[2], A. J. de Assis[2], and A. S. de Oliveira[2], [1]*Universidade Federal Rural do Semi–Árido*, *Mossoró, RN, Brazil*, [2]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*.

This study evaluated the response of replacement dairy heifers to a corn silage based diet, supplemented with 1.3 kg/day of concentrate, and to three sugar–cane based diets, corrected with 1% of the mixture urea and ammonium sulphate (9:1), and supplemented with 1.3; 2.0 and 2.7 kg/d of concentrate, respectively. Twenty animals were used (12 Holstein and 8 Brown Swiss heifers), with initial body weight (BW) of 176 kg. The experiment was arranged in a randomized block design, with 5 blocks, considering each animal as an experimental unit and the blocks formed on the basis of initial BW and breed. Dry matter

intake (DMI), organic matter (OM) intake and neutral detergent fiber (NDF) intake did not differ (P>0.05) among the diets. Higher intake of ether extract (EE) (P<0.05) was found for the corn silage based diet compared to the sugar–cane based diets. There was detected difference in the total carbohydrate (CHO) intake and in the non–fiber carbohydrate (NFC) intake between the corn silage diet and the sugar–cane based diets supplemented with 1.3 and 2 kg of concentrate. The heifers fed the sugar–cane diet supplemented with 2.0 kg of concentrate had the lowest TDN intake (2.89 kg/d) whereas the animals fed the corn silage diet had the highest (3.62 kg of TDN/d). Dry matter, organic matter and non–fiber carbohydrates digestibilities were not different (P>0.05) among diets. The digestibility of the crude protein (CP) of the corn silage diet was lower (P<0.05) than the CP digestibility of the three sugar–cane based diets (62.93 vs 75.10 %). No significant difference was detected (P>0.05) for total weight gain (TWG, kg) and average daily gain (ADG, kg/d) between the corn silage based diet and the sugar–cane diet supplemented with 2.7 kg of concentrate, with mean values of 71.22 kg and 0.847 kg/d. The other two sugar–cane based diets provided the lowest ADG (0.629 kg/d). Rumen pH, measured at 0 and 3 hours after feeding, did not differ (P>0.05) among the experimental diets. N-NH_3 , measured three hours after feeding, was lower (P<0.05) for the animals fed corn silage based diet compared to those fed sugar–cane based diets.

Key Words: Dairy Heifers, Rumen, Sugar-Cane

W291 Use of NutriDense corn variety for corn and corn silage in diets fed to high producing dairy cows. J. Sampson and J. Spain*, *University of Missouri*, *Columbia*.

This study evaluated a hybrid corn variety for corn silage and corn grain fed to high producing dairy cattle. Sixty-three lactating Holsteins were paired based on parity, stage of lactation, milk production, and body weight and randomly assigned to one of three dietary treatments. Control (CC) cows received total mixed ration (TMR) containing control corn silage (CS) and control corn grain. Group NDC received TMR containing NutriDense (ND) CS and control corn grain. Group NDND received TMR containing ND CS and ND corn grain. All three dietary treatments were formulated to meet NRC requirements for a 636 kg cow producing 41 kg milk/day containing 3.75% fat. Cows were fed twice daily with weights and feed refusals recorded. Cows were fed using electronic feeding gates (Calan Gates, American Calan, Inc.). Cows were fed assigned diets for 50d. Cows were milked twice a day and milk samples were taken weekly and submitted to DHIA to measure fat, protein, MUN and SCC. Body weights and condition scores were measured and recorded weekly. Blood samples were collected weekly to measure plasma glucose and urea nitrogen (PUN). A second experiment was conducted to evaluate ruminal fermentation of dietary treatments. Diets were subjected to digestion using standard in situ and in vitro techniques. Data collected were ruminal pH, optical density, and NH3-N concentrations as well as dry matter and nitrogen disappearance. Data were analyzed by Proc Mixed procedures of SAS. Average daily DMI was different (P=0.05; 22.03, 21.02, and 20.22 kg for CC, NDC, and NDND, respectively). FCM, milk fat, protein and SCC were not different (P=0.36, P=0.70, P=0.26, P=0.40, respectively). MUN and PUN were different by treatment (P=0.01, P<0.05, respectively) and by treatment over time (P=0.1, P<0.05, respectively). In situ N disappearance was also different due to treatment (P=0.0383), with higher values for NDND than CC or NDC (73.3%, 71.4%, and 71.9%, respectively). Ruminal NH3 concentrations were higher (P=0.02) for NDND than CC or NDC with values of 6.6, 5.9, and 6.2, respectively. Milk production efficiency was improved by ND hybrid.

Key Words: Corn Silage, Hybrid, Milk Production Efficiency

W292 Comparative effects of wild-type, *bmr*-6, *bmr*-12 and stacked sorghum: Sorghum stover digestibility. H. M. Dann*[1], A. M. DiCerbo[1], J. F. Pedersen[2], and R. J. Grant[1], [1]*William H. Miner Agricultural Research Institute*, *Chazy, NY*, [2]*USDA, ARS, NPA Wheat, Sorghum and Forage Research, University of Nebraska*, *Lincoln*.

Samples of wild-type 'Atlas' and its brown midrib near-isolines containing *bmr*-6, *bmr*-12, and stacked *bmr*-6 and *bmr*-12 genes were used to assess the effect of *bmr* mutations on in situ digestion kinetics of sorghum stover. Forage sorghum was grown in 2004 at Mead, Nebraska. Panicles were removed from sorghum before harvest. Wild-type, *bmr*-6, *bmr*-12, and stacked sorghum stovers had a neutral detergent fiber (NDF) content of 52.7, 53.1, 50.9, and 53.9%, respectively and a lignin content of 5.3, 3.8, 3.6, and 3.6%, respectively. Ruminal in situ digestion kinetics of dry matter (DM) and NDF of sorghum stover were determined with 4 ruminally cannulated multiparous lactating Holstein cows used in a 4×4 Latin square design. Samples of sorghum stover were incubated in N-free polyester in situ bags (5 g sample/bag) for 0, 6, 12, 24, 48, and 96 h and removed simultaneously at 0 h. Residues were analyzed for DM and NDF with residual ash (using α-amylase and without sodium sulfite). Digestion kinetics [lag, fractional rate of digestion (k_d), and potential extent of digestion (PED)] for DM and NDF were calculated. Data were analyzed by ANOVA. Dry matter lag (2.0 h), DM k_d (0.036 h_{-1}), NDF lag (2.8 h), and NDF k_d (0.036 h_{-1}) were similar ($P > 0.10$) among sorghum stovers. The PED of DM and NDF differed ($P < 0.05$) among sorghum stovers. The PED of DM was 52.1, 55.6, 64.3, and 73.2% and the PED of NDF was 53.1, 54.7, 65.3, and 74.1% for wild-type, *bmr*-6, *bmr*-12, and stacked sorghum stovers, respectively. Digestibility of NDF (% of NDF) was higher for stacked than wild-type sorghum stover at 24 h ($P < 0.10$; 49.0 vs. 39.1%) and 48 h ($P < 0.05$; 65.0 vs. 52.8%). In summary, there was more digestible DM and NDF in *bmr*-6, *bmr*-12, and stacked sorghum stovers than wild-type sorghum stover. The stacked *bmr*-6 and *bmr*-12 mutations had the greatest positive impact on digestibility.

Key Words: Sorghum, *bmr*, Digestibility

W293 Impact of the brown midrib (BMR) mutant gene on the nutritive value of sudangrass fed as forage to lactating dairy cows. D. N. Ledgerwood*, E. J. DePeters, P. H. Robinson, S. J. Taylor, and J. M. Heguy, *University of California*, *Davis*.

The BMR gene causes changes in lignin concentration and composition that have been demonstrated to increase fiber digestion in ruminants. Our objective was to assess potential benefits of the BMR mutant of Sudangrass, compared to the Piper variety, on production performance and digestibility in lactating dairy cows. The total mixed rations (TMR) contained 18% shredded Sudangrass hay, 18% sliced alfalfa hay with the remaining 64% representing the concentrate portion. The proportion of Piper to BMR in the TMR was varied as: 100:0, 66:34,

34:66, or 0:100. Four lactating dairy cows (251 ± 30 days in milk), fitted with ruminal and duodenal cannulas, were used in a 4x4 Latin square design with 14d adjustment and 7d sample collection phases. Individual feed intake and milk yield were measured daily during the collection phase, with fecal and duodenal samples collected 5 times over the last 3d of the collection phase. As the proportion of Piper to BMR decreased in the TMR, yields of milk and milk protein were highest at intermediate inclusion levels (Q: P=0.06/0.07), but milk fat, protein, and lactose contents, as well as dry matter intake, did not vary. Ruminal and total tract digestibility of ash-free NDF, organic matter, and cellulose did not vary as well. The optimal Piper:BMR Sudangrass ratio in this TMR with 18% Sudangrass was 66:34.

Table 1. Yield and NDF Digestibility

Diet [1]	100:0	66:34	34:66	0:100	S.E.	L[2]	Q[3]
Yield (kg/d)						P	P
Milk	29.9	32.3	30.8	30.3	0.68	0.91	0.06
Protein	0.95	1.02	0.97	0.95	0.03	0.68	0.07
NDF digestibility [4]							
Ruminal	53.6	54.8	52.2	57.3	3.93	0.64	0.63
Total Tract	60.4	60.3	61.9	64.9	2.55	0.23	0.56

[1] Piper : BMR = Proportion of Piper Sudangrass to BMR Sudangrass.
[2] L = Linear effect. [3]Q = Quadratic effect. [4] % of ash-free NDF intake.

W294 Use of computer simulation model to teach systems approach to metabolism. H. A. Johnson*, C. C. Calvert, and R. L. Baldwin, *University of California*, *Davis*.

Using a systems approach as embodied in the computer simulation model of a dairy cow, Molly (Baldwin, 2005) is ideal for teaching nutrition because there are many quantitative interactions among nutrients supplied and metabolic processes. Using Molly, undergraduate animal science students are able to observe effects of changing diets, altering genetic potential (e.g., milk production potential) and manipulating metabolism on whole cow metabolism. The objective is to show how Molly can be used in the classroom to teach a systems approach to nutrition using example simulations with and without administrating bovine somatotropin (BST) to cows at 2 levels of milk production (high and low), fed two different diets (Diet1 and Diet2). The table below shows results of the 8 simulations. BST increases milk production approximately 3000 kg, increases milk protein output 90-100 kg and increases milk fat yield 120-130 kg over 308 days. Diet2 results in higher milk production (300-400 kg) and higher milk protein (12-26 kg) compared to Diet1. Diet2 is higher in starch (2%) and insoluble protein (2%) which contributes to higher lactose (GlLmV) production increasing milk production and milk protein production. Higher producing cows respond less to BST in milk and milk protein production than lower producing cows. Diet causes little change in milk fat synthesis (AcTmV) relative to BST and increasing milk production. But, both increasing milk production potential and BST decrease lipogenesis (AcTsF, FaTsF) and increase adipose breakdown (TsFaF1) increasing the availability of fatty acids for milk fat synthesis (FaTmV). Therefore, BST increases udder synthetic capacity for milk lactose (GlLmV), milk protein (TAaLaV, TAaPmV) and milk fat (AcTmV and FaTmV). From these simulations, students are able to observe how manipulation of metabolism through diet, BST and genetic potential to produce milk changes milk production and whole body metabolism. Classroom handouts describing model settings, model output and the model program (Windows 98, 2000 or XP) are available at http://animalscience.ucdavis.edu/research/molly.

Table 1. Molly simulation results at 84 days

Parameter (mole/d)	Diet1, low, no BST	Diet2, low, no BST	Diet1, high, no BST	Diet2, high, no BST	Diet1, low, BST	Diet2, low, BST	Diet1, high, BST	Diet2, high, BST

W295 Energy dilution of growing heifers' diet as a tool for induced negative energy balance in cattle. A. Arieli*[1], O. Eshel[1], U. Moallem[2], and Z. Uni[1], [1]*Hebrew University of Jerusalem*, *Rehovot, Israel*, [2]*Agricultural Research Organization*, *Bet Dagan, Israel*.

Our objective was to determine if energy dilution of growing heifers' diet is an appropriate model for inducing NEB in cattle. Four non-pregnant, non-lactating Holstein heifers (initial BW = 410 kg) were used in a 4 × 4 Latin square design trial with 21d periods to evaluate the effects of dietary energy dilution on: feed intake, energy balance and metabolic traits. Diets were based on a heifers mix (HMIX, 13% CP, 53% NDF, 1.35 Mcal NEL/kg DM). Control heifers (CON) were fed with diet containing 65% HMIX, 31% wheat straw and 4% SBM. The other diets contained 55% HMIX, 27% wheat straw, 3% SBM and 15% of either corn grains, barley grains or soy hulls supplements (COR, BAR and SOH diets, respectively). Blood samples were obtained weekly, 2 hours before morning feeding. Feed intake was monitored daily. Total tract digestibility was assessed by using indigestible NDF as a digestive marker, and energy values were based on DE. Intakes of DM and BW changes were similar among treatments and averaged 9.7 and 0.35 kg/d, respectively. Intake of DE, dietary concentration of DE, and ME intake above maintenance requirements were higher ($P < 0.05$) in supplemented diets than in CON (26.8 vs. 21.8 Mcal/d, 2.65 vs. 2.45 Mcal DE/kg of DM, and 11.9 vs. 7.3 Mcal ME/d). Blood NEFA and PUN were lower ($P<0.001$) and blood glucose was higher ($P<0.04$) in COR than in CON cows (105 vs. 185 meq/l, 8.3 vs. 9.9 mg/dl, and 85 vs. 80 mg/dl, respectively). Intermediate values were obtained for the corresponding blood metabolite concentration of BAR and SOH cows. Blood BHBA was similar among treatment, averaging 2.6 mg/dl. Significant correlations were found between ME intake above energy requirements and dietary DE concentration ($r = 0.75$. $P< 0.001$), and blood NEFA ($r = 0.68$, $P < 0.01$), indicating that NEB balance could be reached with diets diluted to less than 2.0 Mcal DE/kg of DM. These data indicate that energy dilution of growing heifers diet can be used as a tool for induced NEB in cattle.

Key Words: Heifers, Energy Balance, Dietary Energy Dilution

W296 Negative exponential models to predict dry matter intake of dairy heifers. P. C. Hoffman*, K. A. Weigel, and R. R. Wernberg, *University of Wisconsin*, *Madison*.

Daily pen dry matter intakes (DMI, n=9273) were collected over a 28 month period at the Integrated Dairy Research Facility of the University of Wisconsin-Madison. Forty, 4.5 × 9.0 m pens containing eight Holstein or Holstein × Jersey crossbred heifers were bedded with sawdust and provided access to 0.75 m of bunk space/heifer. Diets were formulated bi-monthly and fed to a common bunk score, with dietary nutrient densities, ambient temperature, and nutrient intakes recorded daily. Heifers were weighed at 60 d intervals, and mean pen body weights (BW) were adjusted for the number of days between the weigh intervals using average daily gain during the interval as a regression coefficient. Prediction of DMI was evaluated using first and second order random effects mixed models or non-linear models using the MIXED or NONLIN procedures of SAS, respectively. The effects of breed, BW, temperature and NDF deviation (from predicted mean dietary NDF for that BW) were considered as independent variables. Dietary NDF deviation was considered because dietary nutrients densities are codependent with BW. Preliminary mixed models suggested that NDF deviation was an independent source of DMI variance. The best DMI prediction was achieved with negative exponential non-linear models for Holstein and crossbred heifers. For Holsteins (R^2=0.87), the prediction equation was: DMI (kg/d) = 15.7930 * (1 - exp(-0.00210 * BW)) - 0.0820 * NDF deviation, where: NDF deviation = (dietary NDF as a % of DM) - (22.07020 + (0.08714 * BW) - (0.00007383 * $(BW)^2$)). For crossbred heifers (R^2=0.87), the prediction equation was: DMI (kg/d) = 13.4770 * (1 - exp(-0.00271 * BW)) - 0.0824 * NDF deviation, where: NDF deviation = (dietary NDF as a % of DM) - (23.11235 + (0.07968 * BW) - (0.00006252 * $(BW)^2$)). Alternative negative exponential DMI models when dietary NDF is unknown were also developed. The Holstein DMI equation (R^2=0.83) was: DMI(kg/d) = 15.3642 * (1 - exp(-0.00220 * BW)), where as the crossbred DMI equation (R^2=0.82) was: DMI(kg/d) = 12.9139 * (1 - exp(-0.00295 * BW).

W297 Impact of corn particle size and forage source on nitrogen digestibility and partitioning in lactating Holstein dairy cows. N. E. Brown*, V. A. Ishler, T. W. Cassidy, K. Heyler, and G. A. Varga, *The Pennsylvania State University*, *University Park*.

The utilization of dietary nitrogen and the efficiency in which it is converted into milk protein has tremendous implications on productivity, profitability and environmental stewardship of dairy operations. A replicated 4 × 4 Latin square design was conducted to evaluate the effects of forage source and corn particle size on N digestibility, N partitioning and ammonia (NH_3) volatilization from manure in mid-lactation Holstein dairy cows. The four treatments were: 1) grass silage (G) with fine (F) ground corn (GF), 2) G with coarse (C) ground corn (GC), 3) alfalfa silage (A) with F (AF) and 4) A with C (AC) in diets for lactating cows. Diets were 50% forage on a DM basis with the treatment forage comprising 50% of the forage DM and corn silage making up the remaining forage. Approximately 40% of the coarse corn and 100% of the fine corn was able to pass through or remaining on a 16 inch sieve screen. Cows that were fed A based rations consumed and deposited greater N in milk (780 and 176 g/d respectively) compared to cows consuming G based rations (612 g/d and 142 g/d). The A based ration showed a trend (P < 0.09) for greater CP digestibility (57%) compared to grass based rations (53%); fecal N excretion for cows fed A based rations (347 g/d) was greater than cows fed G silage based rations (291 g/d). A trend (P<0.07) was observed for greater urinary N excretion for cows fed A based rations (272 g/d) compared to G based rations (243g/d). More of the dietary N was converted into milk protein for the G based rations (26%) compared to the A based rations (22%). Corn particle size had no significant impact on the digestibility or the partitioning of N into milk. Based upon NH_3 emissions measured, a total of 655 animals and 569 animals could be maintained on the G and A based rations respectively, resulting in the production of 100 lbs of ammonia, the threshold upon which dairy operations may be regulated.

Key Words: Corn particle Size, Nitrogen Partitioning, Ammonia Emission

W298 Evaluation of a corn replacement product in diets fed to lactating dairy cows. D. J. Rincker*[1], N. A. Janovick Guretzky[1], P. H. Doane[2], and J. K. Drackley[1], [1]*University of Illinois*, *Urbana*, [2]*ADM Animal Nutrition Research*, *Decatur, IN*.

Our objective was to determine the efficacy of a prototype product designed to replace corn grain in diets for lactating cows. The corn replacement product (CRP) was prepared by treating corn stover with CaO and water in an enclosed twin screw continuous mixer (Readco® Continuous Processor). The treated stover then was mixed with distillers grains (3:1 ratio) and pelleted. Multiparous and primiparous Holsteins (n = 13 per diet) were used in a complete randomized design trial with a 14-d standardization period and 33-d experimental period. Diets contained (DM basis) 40.0% corn silage, 10.0% alfalfa silage, 5.5% soybean hulls, and concentrates. Replacement of approximately 50% (Low; LCRP) or nearly all (High; HCRP) corn grain resulted in diets containing 11 or 22% of DM as CRP. Diets were isonitrogenous and isocaloric (if CRP was effective) with the control diet, which contained 16.5% CP and 1.71 Mcal NEL/kg. Dietary NDF was 33.3, 38.2, and 42.5% of DM for control, LCRP, and HCRP, respectively. The DMI decreased linearly (P < 0.001) as CRP increased (19.8, 16.7, and 14.3 kg/d for control, LCRP, and HCRP). Intake of NDF was similar for all diets (6.8, 6.1, 6.3 kg/d). Milk yield decreased (P =0.05) when CRP was fed (27.1, 23.6, 23.7 kg/d). Milk fat percentage was not affected by treatment (P > 0.20), but milk protein percentage and yields of milk solids decreased linearly with CRP (P < 0.01). Body weight was less for cows fed LCRP and HCRP versus control (P < 0.05), probably because lower DMI for CRP diets decreased gut fill. Calculated energy balance decreased linearly with CRP inclusion. Total tract apparent digestibilities of DM and energy were greater (P < 0.05) for LCRP than for control or HCRP. A combination of chemically treated corn stover and DDGS was not an effective replacement for corn grain in diets fed to mid-lactation cows.

Key Words: Corn Replacement, Corn Stover, Dairy Cows

W299 Effect of feed energy source on milk components in dairy cattle. M.-C. Ferland*[1], D. Lefebvre[2], and K. M. Wade[1], [1]*McGill University*, *Montreal, QC, Canada*, [2]*Valacta*, *Ste. Anne de Bellevue, QC, Canada*.

The objective of this study was to evaluate the effect of three different energy sources on the milk composition of dairy cattle. These energy sources were corn grain (CG), high-moisture corn (HMC) and Commercial concentrate (CONC). A total 9,163,240 test-day records from 570,083 Holstein cows from 5191 different herds, and 434,018 test-day records from 27,110 Ayrshire cows from 652 different herds covering a period of five years were obtained from the Québec dairy herd improvement agency (Valacta). In addition to test-day records, information on lactation, feed composition and feeding systems was also available. Diets with only one of the three sources as the sole source of energy supplement were included. For both breeds, cows consuming diets with HMC and CG tended to have higher milk yield, higher fat and protein content and lower MUN concentration then cows consuming diets with a CONC. Milk yield averages were 28.92 kg/day, 27.34 kg/day and 26.22 kg/day (for Holsteins) and 23.64 kg/day, 22.51 kg/day and 21.70 kg/day (for Ayrshires) for HMC, CG and CONC respectively. The equivalent fat % values were 3.87%, 3.87% and 3.76% (for Holstein) and 4.09%, 4.03% and 4.02% (for Ayrshires) for HMC, CG and CONC respectively. Milk protein % in Holsteins was higher on HMC and CG diets (3.35% and 3.34% respectively) compared to CONC diets (3.25%). There were negligible differences in the overall milk-protein values for Ayrshires; however, similar trends to those seen in Holsteins were observed from 75 to 305 DIM. The MUN content was higher for CONC compared to HMC and CG in both breeds. Holstein averages of MUN were 10.51 mg/dL, 10.86 mg/dL and 11.93 mg/dL while Ayrshire averages of MUN were 11.04 mg/dL, 11.20 mg/dL and 13.03 mg/dL for HMC, CG and CONC respectively.

Key Words: Feed Energy Source, Milk Components, Dairy Cattle Nutrition

W300 The effect of dry chopped alfalfa hay content on eating behavior, milk yield and components, and rumen fermentation in lactating dairy cows. D. D. Maulfair* and A. J. Heinrichs, *The Pennsylvania State University*, *University Park*.

The objective of this experiment was to evaluate the inclusion of dry chopped alfalfa hay in lactating dairy cow rations on eating behavior, milk yield and components, and rumen fermentation. Eight multiparous Holstein cows (79 ± 18 DIM initially; 660 ± 87 kg BW) were randomly assigned to replicated 4 × 4 Latin Squares. One square consisted of cannulated cows and the other, non-cannulated cows. During each of the four periods, cows were fed one of four diets that were chemically similar but varied in dry chopped alfalfa hay level. The forage DM content of each ration consisted of 50% corn silage and 5, 10, 20, or 40% dry chopped alfalfa hay. The remaining forage DM content was alfalfa silage (45, 40, 30, and 10% respectively). The other ingredients of the ration included: ground corn, canola meal, roasted soybeans, bypass protein blend, and a mineral/vitamin mix. The forage level for each ration was between 58 and 59% and the total ration DM was 49, 50, 52, and 56% for the 5, 10, 20 and 40% rations respectively. No significant differences ($P< 0.05$) were found in feed sorting, milk yield and components, DMI, and rumen pH among the four rations. This experiment indicates that there is opportunity to include dry chopped alfalfa hay in lactating dairy cow rations at rates up to 40% of the forage DM content (approximately 23% of total ration DM) without adverse effects on eating behavior, milk yield and components, and rumen fermentation.

Key Words: Forage Level, Feed Sorting, Ruminal pH

W301 Evening feeding improves nutrient digestibility and nitrogen balance in lactating cows. A. Nikkhah*, J. C. Plaizier, C. J. Furedi, A. D. Kennedy, G. H. Crow, and K. M. Wittenberg, *Department of Animal Science*, *Winnipeg, MB, Canada*.

The primary objective was to evaluate the impact of feed delivery at either 2100 h or 0900 h on nutrient digestibility and nitrogen (N) partitioning. Four multiparous and four primiparous midlactation Holsteins were used in a cross-over design with two 6-week periods. Each period consisted of 3-wk adaptation. Cows were offered a TMR containing 50% concentrate (DM basis). Total fecal and urine were collected during week-4 to determine the total tract nutrient digestibility and N partitioning. Dry matter intake and milk yield were also recorded. Data were analyzed as a Mixed model with the fixed effects of feeding time, parity, and the interaction. Compared with morning feeding, evening feeding improved ($P<0.05$) the apparent total tract digestibility of dry matter (63 vs. 60), N (65.5 vs. 63%), NDF (49 vs. 44%), and ADF (44 vs. 41%). Provision of fresh TMR at 2100 h instead of 0900 h increased N intake by primiparous cows (562 vs. 510 g/d). Urinary and milk N outputs, % of digested N, were lower ($P<0.05$) with evening vs. morning feeding suggesting improved body N retention. Consequently, N balance was improved by providing fresh TMR at 2100 instead of 0900 h (55 vs. -3.5 g/d). Milk protein percent (2.82 vs. 3.12%, $P<0.10$) and not yield (1.0 vs. 1.1 kg/d) was numerically lower in multiparous, but not in primiparous, cows fed at 2100 vs. 0900 h. Treatments did not significantly affect rumen microbial protein synthesis. Results suggest beneficial impacts of evening feeding on nutrient digestibility and N retention in lactating cows. Reduce N excretion via urine and feces by evening feed delivery may have environmental implications.

Key Words: Evening Feeding, Digestibility, Nitrogen Balance

W302 Time of feed delivery: A determinant of post feeding patterns in feed intake of lactating cows. A. Nikkhah*, J. C. Plaizier, C. J. Furedi, G. H. Crow, and A. D. Kennedy, *Department of Animal Science*, *Winnipeg, MB, Canada*.

We examined the effects of providing a higher (HC) or a lower concentrate (LC) total mixed ration at either 2100 h or 0900 h on post feeding patterns in feed intake of dairy cows. Four primiparous and four pluriparous tie-stall-housed Holsteins were used in a 4×4 Latin square design with four 3-week periods. Cows were not heat stressed at any time during the experiment. Each period consisted of 2-week adaptation. The concentrate portion was 62% for HC and 51% for LC diet (DM basis). Feed intake was monitored continuously for the entire trial using a data acquisition system (Grow-Safe 4000 Hardware). Data for week-3 of each period were analyzed as a Mixed Model. Time of feed delivery had no effects on total feed consumed. Feeding at 2100 h instead of 0900 h, however, remarkably increased the amount consumed within 3-h post feeding from 26 to 37% of total daily intake ($P<0.01$). The amount consumed within 6-h and 9-h post feeding were similar in 0900 h- and 2100 h-fed cows. By 12-h post feeding, however, 0900 h-fed cows had eaten 75% of their daily intake compared with 68% in 2100 h-fed cows ($P<0.01$). This difference remained significant at 21-h post feeding (83 vs. 76%), as well. Parity and diet did not interact with feeding time on diurnal feed intake patterns. Results introduce the time of feed delivery as a main determinant of post feeding patterns in feed intake of lactating cows.

Key Words: Feed Delivery Time, Feed Intake Pattern, Lactating Cow

W303 Feed sorting in dairy cattle: effects of forage content and dietary change. T. J. DeVries*[1], K. A. Beauchemin[1], and M. A. G. von Keyserlingk[2], [1]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*, [2]*University of British Columbia*, *Vancouver, BC, Canada*.

The objective of this study was to determine whether the amount of forage in a TMR influences feed sorting by cows and whether the extent of this sorting changes as they adapt to a new diet. Six lactating Holstein cows, individually fed once per day, were provided in a crossover design with 2 diets (DM basis): 1) high forage diet (HF; 62.3% forage), and 2) low forage diet (LF; 50.7% forage). DMI, feeding behavior, and sorting activity were monitored for each cow on each diet for 7 d. Fresh feed and orts were sampled daily for each animal and subjected to NDF and particle size analysis. The particle size separator contained two screens (18 and 9 mm) and a bottom pan resulting in 3 fractions (long, medium and short). Sorting activity (for each fraction, NDF and physically effective fiber: peNDF) was calculated as the actual intake expressed as a percentage of the predicted intake. To determine if sorting occurred, each variable was tested for a difference from 100%. Cows on the LF diet had higher DMI (22.2 vs 19.9 kg/d; P=0.03), but they spent less time feeding (193.3 vs 220.5 min/d; P=0.02), which translated into a higher intake rate (0.15 vs 0.11 kg/min; P=0.02) compared with cows on the HF diet. Overall, sorting activity was greatest on the LF diet (P<0.001) with cows sorting for short particles (106.1%; P< 0.001), but against long particles (74.2%; P<0.001), medium particles (98.3%; P=0.001), NDF (97.1%; P<0.001), and peNDF (90.1%; P<0.001). On the HF diet, cows sorted against long particles (93.7%; P=0.07), NDF (98.9%; P=0.009), and peNDF (96.8%; P=0.03) and sorted for short particles (103.5%; P=0.001). Treatment*day interactions (P<0.1) occurred for sorting for short particles and against peNDF because it took cows 1 d to adjust their sorting behavior to the LF diet. These results indicate that cows rapidly adjust their sorting behavior when subjected to a dietary change and they exhibit more sorting for short particles and against long particles, NDF and peNDF when fed a LF diet.

Key Words: Sorting, Forage, Particle Size

W304 Understanding feed sorting by dairy cows. W. Z. Yang* and K. A. Beauchemin, *Research Centre, Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

The sorting behaviour of lactating dairy cows was examined by compiling results from various studies. The diets in these studies contained alfalfa silage (AS), barley silage (BS) or corn silage (CS) cut coarsely or finely and mixed with either barley- or corn-based concentrate. Particle size of each TMR was determined using the Penn State Particle Separator with a top sieve (19-mm, long particles), middle sieve (8-mm) and pan. The physical effectiveness factors (pef; top + middle fractions) for the TMRs containing fine and coarse silages were (DM basis): 0.36 and 0.53 for AS diets, 0.33 and 0.41 for BS diets, and 0.30 and 0.56 for CS diets. The difference in the proportion of long particles between the TMR and the orts indicates whether cows select against or in favor of long forage particles. For AS diets, the proportion of long particles in the orts (19 and 25%) was higher (P < 0.01) than in the original TMR (6 and 10%) containing coarse or fine silages, respectively. The pef was also greater (P < 0.01) for orts (0.64 and 0.44) than for TMRs containing coarse and fine silages, respectively. However, for BS diets, the proportion of long particles (0.9 and 0.5%) and the pef (0.33 and 0.28) of the orts were smaller (P < 0.05) than in the original TMRs. For CS diets, the proportion of long particles in the orts (6.3 and 0.2%) was smaller (P < 0.01) than in the TMR (8.6 and 7.0%) for coarse and fine cut silages, respectively, when barley grain was fed. In contrast, the proportion of long particles in the orts (13.6 and 3.7%) was greater (P < 0.01) than in the TMR (7.6 and 2.3%) for coarse and fine silage, respectively, when corn grain was fed. Mean ruminal pH, measured using indwelling probes, was 6.29 for AS, 5.65 for BS, 5.49 for CS with barley grain and 6.04 for CS with corn grain diets. Dairy cows sort against long particles when fed AS or corn grain-based diets, but not when fed diets that lower ruminal pH. In the case of low ruminal pH, cows intentionally select long particles to meet their need for physically effective fiber.

Key Words: Physically Effective Fiber, Sorting, Dairy Cow

W305 Susceptibility of lactating dairy cows to ruminal acidosis depends on the proportion of forage in the diet. F. Dohme[1], T. J. DeVries[2], K. A. Beauchemin*[2], K. M. Krause[3], and K. S. Schwartzkopf-Genswein[2], [1]*Agroscope Liebefeld-Posieux, Research Station ALP*, *Posieux, Switzerland*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*, [3]*West Virginia University*, *Morgantown*.

An experiment was conducted to determine the effects of the physically effective fiber content of the diet on susceptibility of cows to ruminal acidosis. Eight lactating ruminally cannulated cows were assigned to one of 2 diets (DM basis): high fiber (HF, 60% forage) or low fiber (LF, 45% forage). Following a 2-wk adaptation, ruminal pH was measured continuously for 9 d to determine the effects of an acidosis challenge. Total acidosis was defined as pH < 5.8 and moderate acidosis as pH < 5.5. After a 3-d baseline measurement period, feed was restricted to 50% *ad libitum* intake for 24 h. Following this restriction period, cows were provided with 4 kg of ground barley/wheat followed by *ad libitum* allocation of TMR (challenge day). Throughout the experiment, pH profiles were higher (P < 0.05) for cows fed HF compared with LF. During the baseline period, cows fed HF had higher mean pH (6.28 vs 5.85; P = 0.01) and shorter duration of total (2.2 vs 9.5 h/d; P = 0.003) and moderate acidosis (0.6 vs 3.1 h/d; P = 0.05). Both groups responded to the challenge in a similar manner as there were no day × diet interactions (P > 0.05) for any of the pH variables measured. Relative to the baseline period, pH drastically dropped on the challenge day, recovering 2 days later. On the challenge day, mean pH dropped by 0.25 pH units (P < 0.001), duration of total acidosis increased by 6.4 h/d (P < 0.001) and moderate acidosis increased by 5.9 h/d (P < 0.01) relative to baseline. Higher baseline ruminal pH profiles of cows fed HF helped reduce the extent of pH depression during the acidosis challenge. These results suggest that diets containing higher levels of physically effective fiber help maintain a higher ruminal pH, which helps prevent severe acidosis from occurring as a result of improper feed delivery.

Key Words: Acidosis, Ruminal pH, Physically Effective Fiber

W306 Diagnosis of acidosis in dairy cattle using milk fatty acid profiles. M. Craninx*[1], A. Beeckman[1], H. Van Laar[2], J. Martin-Tereso[2], and V. Fievez[1], [1]*Laboratory for Animal Nutrition and Animal*

Product Quality, Ghent University, *Ghent, Belgium*, [2]*Nutreco Ruminant Research Centre*, *Boxmeer, The Netherlands*.

Acute and/or subacute ruminal acidosis (SARA) manifests with low-roughage high-concentrate diets and sudden changes in diet or dry matter intake pattern. SARA is characterised by prolonged periods of depressed ruminal pH, which can be linked to a modified rumen microbial population. Previous experiments showed that the milk fatty acid (MFA) pattern can be used to assess rumen function, particularly the odd and branched-chain MFA as they are of microbial origin. Further, accumulation of biohydrogenation intermediates are dependent of rumen conditions. Results from experiments with high concentrate diets showed a rapid increase in trans-10 C18:1 (> 5 g / kg milk fat) when the average daily ruminal pH drops below 5.8. Milk C17:0 + C17:1 cis-9 and C15:0 are negatively, whereas iso C14:0 and iso C15: 0 are positively correlated with the rumen pH. This was applied for the interpretation of the MFA pattern of a cow in a feeding trial that became sick in the 3rd week of lactation, because of a severely disturbed roughage and concentrate intake pattern. The animal was fed a diet high in concentrate and ad libitum a forage mixture containing grass and hay silage. MFA (g/kg milk fat) in weekly pooled samples of the first 4 weeks showed a peak concentration of trans-10 C18:1 (0.31, 0.25, 2.55, 0.47) and trans-10 cis-12 CLA (0.008, 0.009, 0.035, 0.012) in week 3, which rapidly decreased when the cow was offered a standard Dutch dairy diet based on concentrate/grass silage/maize silage in week 4. Apparently, these MFA show potential as indicators of acute acidosis. The odd and branched-chain MFA pattern already showed changes in terms of an increased C17:0 + C17:1 cis-9 (0.83, 1.42, 0.94, 0.97) and a decreased iso C14:0 (0.076, 0.034, 0.033, 0.038) concentration before clinical symptoms of digestive disorders were obvious. These results are currently further explored for the development of an early-diagnosis-model for acidosis, based on the MFA.

Key Words: Acidosis, Milk Fatty Acids, Detection

W307 Subacute ruminal acidosis increases milk fat depression with diets supplemented with polyunsaturated fatty acids. O. AlZahal*, M. R. Or-Rashid, S. L. Greenwood, M. S. Douglas, and B. W. McBride, *University of Guelph*, *Guelph, Ontario, Canada*.

The objective of this study was to investigate the effect of subacute ruminal acidosis (SARA) and dietary soybean oil (SBO) interaction on milk fat content and yield. Six rumen-fistulated lactating Holstein dairy cows (639 ± 51 kg body weight) were used in the study. Cows were allocated into blocks based on DIM (early 80 d, moderate 135 d, and late lactation 206 d). Two dietary treatments, control diet (% DM, 40% corn silage, 27% mixed haylage, 7% alfalfa hay, 18% protein supplement, 4% ground corn, and 4% wheat bran) and SARA diet (% DM, 31% corn silage, 20% mixed haylage, 5% alfalfa hay, 15% protein supplement, 19% ground wheat, and 10% ground barley) were randomly assigned to each block. The trial consisted of a 4-wk pre-SBO period, a 3-wk SBO period, and a 3-wk post-SBO period. The control (n=3) and SARA (n=3) diets were fed throughout the trial and SBO (2% of previous week average DM intake) was added into the rumen through the fistula during the SBO period. Ruminal pH was continuously recorded and milk samples were taken 3 d per wk. Milk yield and DM intake were recorded daily. Data were averaged by week and analyzed by SBO period using PROC MIXED of SAS with repeated measures. The effect of SBO was tested by the contrast describing time (wk) and time by diet interaction. During pre-SBO period, time below pH 5.8, pH 6.0, and pH 6.2 and mean pH was different ($P < 0.05$) between control and SARA cows. Soybean oil addition depressed milk fat for both SARA and control cows (table 1). However, the significant interaction (table 1) denoted that the SARA cows had a greater milk fat depression. By wk 3 of SBO; milk fat % dropped 21% and 42% and fat yield dropped 21% and 49% for control and SARA cows; respectively.

Table 1. Effect of SBO on milk fat % and milk fat yield

W308 The effect of buffering dairy cow diets with limestone, Acid Buf or sodium bicarbonate + limestone on production response and rumen parameters. C. W. Cruywagen*[1], S. J. Taylor[2], and M. M. Beya[1], [1]*Stellenbosch University*, *Stellenbosch, South Africa*, [2]*Celtic Sea Minerals*, *Cork, Ireland*.

A high concentrate TMR, formulated to be potentially acidotic, was used to construct three dietary treatments in which Acid Buf, the skeletal remains of the seaweed *Lithothamnium calcareum*, was compared against limestone (Control) and sodium bicarbonate plus limestone. The diets contained 4 g/kg of Acid Buf or 3.5 g/kg limestone (Control) or 3.7 g/kg of limestone plus 8 g/kg of sodium bicarbonate, respectively. The response to treatment was measured using 6 rumen cannulated lactating Holstein cows allocated to treatments according to a 3 × 3 (n=2) balanced Latin square design, with three treatments and three periods. The total experimental period was 66 days in which every cow received each diet for a period of 15 days prior to a data collection period of 7 days. Rumen pH was monitored continuously every 10 minutes for 2 days using a portable data logging system and in-dwelling electrodes. During each data collection period, milk was collected and analysed for its solids and mineral content. Feed dry matter consumption was also recorded. The impact of treatment on rumen acidity was clearly visible, especially during the period from mid day to midnight when pH dropped to below 5.5 for a longer period (13 h) in the Control (limestone) treatment than in the Sodium Bicarbonate (7.7 h) and Acid Buf (4 h) treatments. The minimum rumen pH was lower for the Control (5.19) than for the Acid Buf treatment (5.42), while the pH for the Sodium Bicarbonate treatment (5.37) did not differ from the other treatments. Daily milk yield was 27.6^{a}, 29.1^{a} and 31.6^{b} liters/cow for the Control, Sodium Bicarbonate and Acid Buf treatments, respectively, with milk containing 38.6^{a}, 41.8^{b} and 42.1^{b} g/kg fat and 34.3, 33.8 and 34.7 g/kg protein. The trial indicated that supplementing the diet of dairy cows with approximately 90 g/day of Acid Buf may have a greater impact on rumen acidity and milk production than 180 g/day of sodium bicarbonate and that sub-clinical rumen acidosis could reduce daily milk output by 4 liters/cow.

Key Words: Acid Buf, Buffers, Rumen Parameters

W309 Ruminal temperature may aid in the detection of subacute ruminal acidosis. O. AlZahal*[1], E. Kebreab[1], J. France[1], M. Froetschel[2], and B. W. McBride[1], [1]*University of Guelph*, *Guelph, Ontario, Canada*, [2]*Edgar L. Rhodes Center for ADS, University of Georgia*, *Athens*.

Subacute ruminal acidosis (SARA) is a common condition in early lactating cows that is difficult to diagnose. The objective of this study was to investigate the relationship between ruminal pH and temperature (T) and to develop a predictive equation that may aid in the diagnosis of SARA. Six rumen-fistulated lactating Holstein dairy cows (639 ± 51 kg body weight) were used in the study. Cows were randomly allocated to one of two dietary treatments, control diet (%DM, 40% corn silage, 27% mixed haylage, 7% alfalfa hay, 18% protein supplement, 4% ground corn, and 4% wheat bran) and SARA diet (%DM, 31% corn silage, 20% mixed haylage, 5% alfalfa hay, 15% protein supplement, 19% ground wheat, and 10% ground barley). The trial consisted of 1 wk of adaptation and 1 wk of collection. During wk 2, ruminal pH and temperature were continuously recorded (every minute) for 4 d by an indwelling system. Daily average ruminal pH and temperature (table 1) was analyzed using PROC MIXED of SAS with repeated measures. The relationship between lowest pH point of the day and associated temperature was investigated using PROC MIXED considering intercept and slope for each cow as random effects and with repeated measures. SARA cows had greater ($P < 0.05$) average daily ruminal temperature and time (min/d) above 39.2 and 39.0 °C than control cows. Ruminal temperature had a negative relationship with ruminal pH and the random effect of cow was not significant:
pH = (16.9 ± 2.04) + (– 0.29 ± 0.052 T), $R^2 = 0.77$, n = 22, $P < 0.0001$.

W310 Evaluation of an intraruminal pH probe. B. A. Crooker*[1], W. J. Weber[1], S. C. Denham[2], and J. L. Vicini[2], [1]*University of Minnesota*, *St. Paul*, [2]*Monsanto Company*, *St. Louis, MO*.

Studies were conducted to compare rumen pH measurements from an intraruminal pH probe (IRP) to those obtained from a standard pH meter (M). Functional life and ability of IRP to detect changes caused by alterations in diet and feeding management were evaluated. The IRP (Well Cow, LTD, Bedford, UK) were calibrated prior to insertion and the M (Thermo Electron Corp., Beverly, MA) was calibrated before each use. Frequency (1 or 10 min) of measurement and data download from IRP were controlled through software on an external computer. The IRP (n = 2 or 3) were placed in the reticulum (R) or rumen of 3 lactating and 1 non-lactating cows for up to 28 d (Study 1). Measurements by M were obtained from R and ventral (V), caudal-ventral (CV) and caudal-dorsal (CD) sacs on d 0 to 5, 11, 23, and 27. Study 2 had three, 3-wk periods in which cows were fed a basal diet with sodium bicarbonate (B) 1X/d (continuous access to feed) and pH in R was compared with that of cows fed a) B with extra starch 1X/d, b) B as two discrete (3h) meals/d, or c) B without bicarbonate 1X/d. Each period had a 7 d transition (all cows fed B) and 14 d of treatment. The IRP (n = 2) were placed in R of 12 lactating cows blocked (n = 3) by DIM and milk yield. Results from IRP and M were compared using restricted maximum likelihood mixed model analysis. Means differed if $P < 0.05$. Mean pH by M differed by site (6.37, 6.28, 6.19, and 6.13 ± 0.04 in R, V, CV and CD, respectively) and time with no interaction (Study 1). When IRP functioned correctly, IRP and M values differed by less than 0.1 units but this was significant. Life of IRP was shorter (24.8 ± 1.5 and 28.6 ±3.6 d for Study 1 and 2, respectively) and overall failure (50% by 28 d) greater than expected. Daily mean pH was not altered by treatment. Mean daily decline in pH after feeding was greater in cows not fed bicarbonate (-0.57 vs. -0.44 ± 0.01). The minimum pH per day was less for cows fed 1X/d than 2X/d (6.29 vs. 6.44 ± 0.07). The IRP have potential to provide accurate, prolonged measurements of pH but their functional life needs to be increased.

Key Words: Intraruminal Probe, pH, Cow

W311 Role of effective fiber in reducing milk fat depression in lactating cows fed Rumensin. D. R. Mertens*, *U.S. Dairy Forage Research Center*, *Madison, WI*.

It is unclear how Rumensin (R) and effective fiber interact with high concentrate diets that lead to milk fat depression (MFD). Goals were to determine the effects of R when added to a milk fat-depressing diet and the role of effective fiber in alleviating MFD. Sixty-five cows were fed a typical dairy ration for one week, and then given a ration that was low in fiber for four weeks. After four weeks, 60 cows were blocked into fifteen groups based on parity, days in lactation, MFD, 4.0% FCM, and body weight. Cows were assigned diets in a randomized complete block design with a 2×2 factorial arrangement of treatments: two levels of NDF in the ration each fed with 0 or 14.6 g of R per ton of ration DM for 12 weeks. Low-fiber diets contained high moisture corn (HMC) and were formulated to contain 27% aNDF and 19% peNDF. Added effective fiber was 5% wheat straw, which was substituted for HMC. Amylase and sodium sulfite were used to measure amylase-treated NDF (aNDF). Physically effective fiber (peNDF) was calculated as (aNDF) × (fraction of DM retained on sieves with 1.18mm or greater apertures). Cows were milked twice daily and fed individually. Milk samples were taken every 3 to 4 days. Chewing activity was recorded during weeks 4, 9, and 12. Data was analyzed using PROC MIXED. Added fiber increased (P=.003) and R decreased (P=.039) milk fat. A fiber by R interaction (P=.022) was related to R having minimal effect on milk fat when the low-fiber diet was fed and adding 5% chopped wheat straw increasing milk fat less when R was fed. Compared to low-fiber diets, adding 5% chopped straw did not alleviate milk fat depression, with (2.61 vs 2.85%) or

without (2.69 vs 3.30%) R. Neither added fiber nor R affected milk yield, 3.5% FCM, SCM, weight gain, or DMI. Minutes of chewing per day were increased by added fiber. Rumensin decreased eating time, but increased rumination time. In conclusion, low-fiber diets (27% aNDF and 19% peNDF) containing >27% readily fermentable starch from HMC require more than 23% peNDF in the diet to achieve normal milk fat, especially with Rumensin.

Key Words: Monensin, Effective Fiber, Milk Fat

W312 Validation of an on-farm tool (Z-Box) for determining a physical effectiveness factor using a bioassay based on chewing activity and ruminal fermentation in lactating dairy cows. H. M. Dann*[1], K. W. Cotanch[1], M. P. Carter[1], C. S. Ballard[1], T. Eguchi[2], and R. J. Grant[1], [1]*William H. Miner Agricultural Research Institute*, *Chazy, NY*, [2]*Zen-Noh National Federation of Agricultural Co-operative Associations*, *Tokyo, Japan*.

A study was conducted to determine 1) the agreement of on-farm and laboratory methods for determining a physical effectiveness factor (pef) and 2) the effects of pef and physically effective neutral detergent fiber (peNDF) content of diets on intake, chewing activity, and ruminal fermentation in dairy cows. Sixteen lactating Holstein cows (4 ruminally fistulated) were fed diets (control, fine, medium, and coarse) in a replicated 4×4 Latin square design with 14-d periods. Diets varied in pef and peNDF content by altering the particle size and inclusion level of oat hay. The pef of the diets was determined with a laboratory dry vertical sieving method (standard) and an on-farm, as-fed method (Z-Box). The $pef_{Z\text{-}Box}$ was in agreement with the $pef_{Standard}$ with no mean bias ($P = 0.55$) or slope bias ($P = 0.65$) with regression analysis. Based on ANOVA, intake of peNDF, chewing time, and eating time differed among diets ($P < 0.05$). The relative change in cow chewing response between the control and treatment diets resulted in a pef (pef_{Chew}) that agreed with the sieving-derived pef for the fine and coarse diets. Diet did not affect > 0.05) mean ruminal pH (6.1) or ruminal concentration of total volatile fatty acids (132 m*M*). In summary, the Z-Box method provides pef values that are similar to the standard method and appears to be useful for predicting cow chewing response.

Table 1.

Item	Control	Fine	Medium	Coarse
$pef_{Standard}$	0.58	0.55	0.60	0.63
$pef_{Z\text{-}Box}$	0.53	0.56	0.58	0.61

W313 Use of a caliper to measure skinfold thickness in multiparous Holstein cows and its relationship to body condition score. H. M. Dann* and J. K. Drackley, *University of Illinois*, *Urbana*.

Skinfold thickness measurement is a quick, inexpensive, and commonly used technique for indirectly measuring subcutaneous fat in humans and might be useful for indirectly measuring subcutaneous fat in dairy cows. Seventy-four multiparous Holstein cows were used to 1) evaluate changes in skinfold thickness at seven locations from dry-off to 8 wk postpartum and 2) compare skinfold thickness to body condition score (BCS). Skinfold thickness (mm) was determined weekly with a caliper (The Body Caliper; The Caliper Company, Inc., Las Vegas, NV) on the thigh region of the leg, rear udder attachment, tailhead, 12th rib, shoulder, neck, and dewlap. All measurements were made on the left side of the cow except for the udder measurement. Hair was clipped with a size 40 surgical blade to eliminate variation associated with hair coat thickness. Body condition score was determined weekly. Skinfold thickness measurements and BCS were analyzed by ANOVA using the MIXED procedure of SAS to evaluate the effect of time. The CORR procedure of SAS was used to determine Pearson correlation coefficients between skinfold thickness measurements and BCS. Skinfold thickness of the dewlap, rib, shoulder, and tailhead and BSC changed ($P < 0.01$) from dry-off to 8 wk postpartum with higher values prepartum than postpartum. Skinfold thickness of the leg and neck did not change ($P > 0.05$). Skinfold thickness of the udder increased around parturition and then decreased as lactation progressed ($P < 0.01$). Measurements of skinfold thickness at the rib (r = 0.11), shoulder (r = 0.26), and tailhead (r = 0.46) were correlated positively with BCS ($P < 0.01$). Skinfold thickness measurements of the dewlap, leg, and neck were not correlated with BCS ($P > 0.05$). A skinfold thickness score, calculated as the sum of the skinfold thickness of the rib, shoulder, and tailhead, was correlated positively with BCS (r = 0.48; $P < 0.01$). Skinfold thickness is an objective measurement that can be used in addition to BCS to assess the body fat reserves of dairy cows.

Key Words: Skinfold Thickness, Body Condition Score, Dairy Cow

W314 Development of a method for measuring forage fragility. K. W. Cotanch*[1], R. J. Grant[1], J. Darrah[1], H. M. Wolford[1], and T. Eguchi[2], [1]*William H. Miner Agricultural Research Institute*, *Chazy, NY*, [2]*Zen-Noh National Federation of Agricultural Co-operative Associations*, *Tokyo, Japan*.

A method to determine forage fragility was developed using a ceramic ball mill to elucidate the relationship among resistance to physical breakdown, neutral detergent fiber digestibility (NDFd) and animal chewing response of various forages. The objective of this study was to 1) develop a ball mill method to quickly and accurately determine forage fragility based on particle size reduction and 2) investigate the relationship between forage fragility and NDF digestibility at 24 h ($NDFd_{24}$). A series of preliminary tests were run to determine optimal sample size relative to jar volume, amount of ceramic balls, and the length of milling time. Fragility was determined as percentage reduction in the physical effectiveness factor (pef), percentage of dry matter larger than 1.18 mm after ball milling, as determined by dry vertical sieving compared to that of the original sample. The final ball mill method required 600 ml of sample dried overnight at 55°C, 900 g of ceramic balls (n = 40) in a 5.5 L jar for 6 h of milling. A set

of 10 forages was assayed for NDF, acid detergent fiber (ADF), acid detergent lignin (ADL), and $NDFd_{24}$using the Ankom system. Samples included two corn silages, three haycrop silages, alfalfa hay stems, grass hay first and second cut, oat hay and wheat straw. Forage fragility (x) was moderately related to $NDFd_{24}$ (y) with $R^2 = 0.34$ and regression equation of y = 1.04x + 11.74. Forage fragility as determined with this ball mill method is moderately related with NDFd but has yet to be compared with actual cow chewing data.

Key Words: pef, peNDF, Forage Fragility

W315 Near infrared spectroscopy can be used to predict pH and concentrations of volatile fatty acids in fermented feeds. D. P. Casper*, D. Spangler, J. Horst, S. Gravert, and K. Thompson, *Agri-King, Inc.*, *Fulton, IL*.

The concentrations of volatile fatty acids (VFA's) and pH of ensiled feeds are routinely measured to determine the extent and quality of the ensiling process. Measurement of pH and VFA's in ensiled feeds can be slow and time consuming using wet chemistry methods. This preliminary study was conducted to determine if NIRS technology could be used to rapidly predict pH and concentrations of VFA's in ensiled feeds. Samples being submitted to Agri-King's analytical laboratory for determination of pH and VFA's via wet chemistry techniques (pH meter and capillary electrophoresis) were selected for this study. Samples were forced air dried at 55°C and ground through a .8 mm screen before being scanned by a Foss NIRS 5000 instrument. The paired data were subjected to a *t*-test using the proc means procedure of SAS. This preliminary study demonstrated that NIRS technology can be used to rapidly determine the pH and VFA concentrations in fermented feeds (Table 1).

Table 1. The wet chemistry (Lab) and NIRS predicted measurements of pH and VFA's in different ensiled feeds

W316 Effect of lignin type, acid detergent lignin or Klason lignin, on rate and extent of NDF digestion. E. Raffrenato*, M. E. Van Amburgh, J. B. Robertson, and P. J. Van Soest, *Cornell University*, *Ithaca, NY*.

Lignification is widely known to negatively affect the extent of NDF digestion. However, it is not well known if lignin affects the rate of NDF digestion and further there is little known about the effect of soluble phenolics on the rate of NDF digestion. Therefore the objective of this study was to determine the relationship between acid detergent lignin (ADL) and Klason lignin (KL) with in vitro NDF digestion (IVNDFd) and rates of degradation (IVNDFd kd) among various forage types. Eighty five forages of various families (alfalfa, corn silage and grasses) were analyzed for NDF, ADL, KL and IVNDFd. Digestibility was measured at 6, 24, 30, and 96 hr. Correlations were estimated for all forage types between lignin type, lignin and extent of IVNDFd, and lignin type and IVNDFd kd and tested for significance ($P < 0.05$). Among all forage types, the correlation between ADL and KL was high and positive (0.77 to 0.90, $P < 0.05$). Within and among all forages, only ADL was consistently negatively correlated with IVNDFd at 24, 30 and 48 hours (-0.54 to -0.94). Results varied when relationships were analyzed between KL and IVNDFd. Correlation among forages for IVNDFd kd and lignin type were not consistent. Among all forages, KL was negatively correlated with IVNDFd and IVNDFd kd, and this was particularly true for bmr corn silages and mature grasses and less for conventional corn, early cut grasses, and alfalfa. The correlation between IVNDFd and ADL increased, as fermentation time increased among all forages (0.24 to 0.90), however, the correlation of KL and IVNDFd was greater early in the fermentation period (especially for Alfalfa and mature grasses), suggesting that the soluble phenolics affected both the rate and extent of IVNDFd. Compared with ADL, KL disappeared during IVNDF fermentation in alfalfas and grasses compared to corn silages. This data suggests that the acid soluble lignin potentially dilutes the NDF solubles and might impact the apparent energy content of the forage and will vary by forage type and maturity.

Key Words: Lignin, Digestibility, Neutral Detergent Fiber Rate of Digestion

W317 Estimating NDF rate of digestion: a comparison of different approaches for use in a first order model application. E. Raffrenato*, M. E. Van Amburgh, P. J. Van Soest, and J. B. Robertson, *Cornell University*, *Ithaca, NY*.

Digestion in ruminants can be empirically and mechanistically described by models of varying complexity. In models like the Cornell Net Carbohydrate and Protein System (CNCPS), rate of NDF digestion (kd) is an input variable in the feed library. However, estimation of kd as a commercial laboratory procedure has not been achieved, in part, because of lengthy analyses and statistical interpretation of fiber digestion. Most rates of NDF digestion have been computed assuming that digestion is complete at 96 hours and using nonlinear models. However, Chandler et al. (1980) estimated the indigestible NDF fraction as lignin times 2.4/NDF ($U_{2.4}$), after fermentation up to 120 d. The objective of this work was to compare non-linear and linear regression (ln-linear) approaches using the same time point fermentations, with and without estimation of the unavailable pool, and to present a mathematical approach for determining rates of digestion using a minimum of time points for commercial laboratory application. Data used for rate estimations were in vitro NDF fermentation residues, fermented for 6, 24, 30, 36, 48 and 96 hr from 90 forages. The ln-linear regression was applied to the data using 96 hr residue as the endpoint or the $U_{2.4}$ as the unavailable NDF fraction. The non-linear model resulted in simultaneous estimation of all parameters (lag, rate, available and

indigestible pools) when using 96 hr as an endpoint or was constrained to rate and lag when forced through $U_{2.4}$. The Levenburg-Marquardt algorithm was used to derive estimates for the non-linear models and uses the Gauss-Jordan procedure for the matrix inverse required in each iteration. The nonlinear approach was considered the least biased and correlations were compared to the nonlinear solutions. The correlation was high between the two nonlinear approaches (0.88) and ranged between 0.31 to 0.93 between the non-linear and ln-linear approaches. The single time point ln-linear approach provided the highest correlation with the non-linear approach when $U_{2.4}$ was used to estimate the available pool.

Key Words: Neutral Detergent Fiber Rate of Digestion, Modeling

W318 Urinary creatinine concentration during the periparturient period and the effect of correcting urinary creatinine concentration for DM content on the ability to predict total urinary output. G. Chibisa*[1], G. B. Penner[2], G. N. Gozho[1], and T. Mutsvangwa[1], [1]*University of Saskatchewan*, *Canada*, [2]*University of Alberta*, *Canada*.

The objectives of this study were to characterize changes in urinary creatinine excretion during the periparturient period and to determine if correcting urinary creatinine excretion for DM content improves the prediction for urine output. Sixteen pregnant cows were randomly assigned to one of two diets: 1. control (total mixed ration, TMR); and 2. TMR top-dressed with 600 ml/d of propylene glycol. Diets were fed from d -14 to d 49 relative to calving. Total urine output was collected using Foley catheters for 5 d starting on d -14 ± 5, d 15 ± 0, and d 38 ± 0 relative to calving. There were no effects of diet on any of the dependent variables measured (($P > 0.05$); therefore, the data were pooled to characterize changes relative to calving. Body weight decreased ($P < 0.01$) throughout the duration of the study, with mean values of 754, 658, and 635 kg at d -14, d 15 and d 38, respectively, relative to calving. An interaction between parity and day relative to calving was detected for urine output ($P = 0.01$) as both primiparous and multiparous had similar pre-partum urinary output (12.7 vs. 16.3 kg/d), whereas multiparous animals had greater urinary output at d 15 (26.7 vs. 18.1 kg/d) and d 38 (30.8 vs. 19.5 kg/d) compared to primiparous cows. Urinary DM content (mean 6.42%) was not affected by day relative to calving. Urinary creatinine concentration (mg/dl) corrected for DM was highest ($P < 0.01$) pre-partum and decreased until d 38 relative to calving. When urinary creatinine concentration was corrected for urinary DM content pre-partum, we observed a higher correlation coefficient ($r^2 = 0.50$) between creatinine concentration and total urine output when compared to using uncorrected (as-is) creatinine concentration ($r^2 = 0.35$). However, correlation coefficients at d 15 (0.73 vs. 0.69) and d 38 (0.72 vs. 0.69) postpartum were not different. These data indicate that physiological state affects creatinine excretion and that correcting creatinine excretion for DM content improves the ability to predict urinary output in cows.

Key Words: Urinary Output, Creatinine, Periparturient Period

W319 New analytical method indicates that purine metabolites may interfere in estimates of microbial flow. S. M. Reynal* and G. A. Broderick, *US Dairy Forage Research Center*, *Madison, WI*.

A new HPLC method was developed to determine concentrations of the purines adenine (A) and guanine (G) and their metabolites xanthine (X) and hypoxanthine (HX) in omasal digesta and bacterial samples and to assess the effect of using either purines or purines plus metabolites as microbial markers for estimating flows of N fractions from the rumen of dairy cows. Four ruminally-cannulated lactating dairy cows (mean DMI 25.6 kg/d) were assigned to a 4x4 Latin square and fed 16.7% CP diets supplemented with increasing amounts of sucrose (0, 2.5, 5, and 7.5% of DM) and decreasing amounts of starch (7,5, 5, 2.5, and 0% of DM). Digesta flow from the rumen was quantified using an omasal sampling technique and a triple-marker method. Individual purines and metabolites were separated using a C18 column with gradient flow rate and two mobile phases. The CV within assay ranged from 0.6 to 3.1%. Recovery of 4 purine bases from added nucleosides averaged 101% (nucleoside hydrolysis), 103% (bacterial isolates), and 104% (omasal digesta). Mean concentrations of A, G, X, and HX were, respectively, 53, 58, 2.8, and 3.5 µmol/g of DM in omasal bacteria and 10, 12, 7.5, and 7.5 µmol/g of DM in omasal digesta. Omasal N flows were not significantly affected by diet. Omasal flows of microbial and non-microbial N (g/d), and true ruminal digestibility of N (%) averaged, respectively, 284, 467, and 32 when estimated using purines; 449, 302, and 56 when estimated using purines plus metabolites; and 413, 209, and 69 when predicted by the NRC model. These results suggest that when total purines are used as a microbial marker, both purines and their metabolites should be determined and used in the calculations. Due to substantial differences in their extinction coefficients, concentrations of purines and metabolites should be determined individually by HPLC, precluding the use of the most common Zinn and Owens (1986) method. However, a portion of these compounds may be of dietary origin and their use as markers may result in biased estimates of microbial flow.

Key Words: Microbial N, Purines, Omasal Flow

W320 Comparative characterization of reticular and duodenal digesta in dairy cows and possibilities to estimate microbial outflow from the rumen based on reticular sampling. A. N. Hristov*, *University of Idaho*, *Moscow*.

The objective of this experiment was to investigate the possibility of estimating outflow of nutrients and microbial protein from the rumen based on sampling reticular contents as an alternative to duodenal sampling. Microbial protein flow estimates were also compared to a third method based on sampling of ruminal contents. Reticular and duodenal digesta and ruminal contents were recovered from 4 cows used in a 4×4 Latin square design experiment, in which the ruminal effects of four exogenous enzyme preparations were studied. Large and small particulate and fluid markers were used to estimate digesta flow in a triple-marker model; ^{15}N was used as a microbial marker. Reticular and duodenal digesta was segregated into small and large particles (SP and LP) and fluid phase and ruminal digesta - into particulate and fluid phases. Compared with digesta recovered at the duodenum, reticular digesta had lower OM ($P < 0.001$) and higher NDF content ($P < 0.001$ and $P = 0.031$; SP and LP, respectively). The proportion of microbial N was notably greater in the fluid phase of reticular digesta (by 78%; $P < 0.001$). Ruminal outflow of DM and OM were greater (by 17 and 28%; $P = 0.034$ and 0.028) and that of NDF lower (by 14%; $P = 0.020$) when estimated from duodenal than from reticular samples. There was no difference ($P = 0.315$ to 0.501) in the estimated flow of starch and non-ammonia and microbial N

(305 and 325 g/d, respectively) between the reticular and duodenal techniques. Microbial N flow estimated based on ruminal sampling was similar (P = 0.315) to those based on duodenal and reticular sampling. The ruminal method, however, grossly overestimated flow of DM, OM, and NDF. This study supports the concept that microbial protein outflow from the rumen can be measured based on sampling of ruminal or reticular digesta. The reticular sampling technique can also provide reliable estimates for ruminal digestibility of OM, N, and fiber fractions.

Key Words: Dairy Cow, Reticular Digesta, Microbial Protein Synthesis

W321 Kinetics of milk production as a function of energy and protein supplementation. R. P. Lana*[1,2], D. C. Abreu[1,2], P. F. C. Castro[1], B. Zamperline[1], and B. S. B. C. Souza[1], [1]*Universidade Federal de Viçosa*, *MG, Brazil*, [2]*CNPq*, *Brasília, DF, Brazil*.

Three experiments aimed to evaluate the effects of energy and protein supplementation on milk production by cows at the end of lactation, with suckling calves and consuming tropical grasses (6% CP and 2 Mcal ME/kg DM) during the dry season. Twelve-crossbred Holstein-Zebu cows (520 kg) were allotted in three-4×4 Latin squares, in four periods of seven days. The treatments consisted of increased levels of corn meal-CM (0.0, 0.85, 1.7 and 3.4 kg/cow/day), soybean meal-SM (0.0, 0.65, 1.3 and 2.6 kg) and grinded soybean grain-SG (0.32, 0.65, 1.3 and 2.6 kg). The concentrate supplements were fed twice a day, at milking time, and mineral salt was offered free choice. The experiments were analyzed as Latin square design including effects of treatments, animal and period. Although there were no treatment effects (P>.05), the mean data of milk production presented a curvilinear response to supplement levels, following a Michaelis-Menten relationship of enzyme systems, according to the next equations of Lineweaver-Burk:

Exp. 1: $1/Milk = 0.0384*(1/CM) + 0.168$ $r^2 = 0.91$

Exp. 2: $1/Milk = 0.0181*(1/SM) + 0.1956$ $r^2 = 0.99$

Exp. 3: $1/Milk = 0.0140*(1/SG) + 0.1165$ $r^2 = 0.98$

The theoretical maximum milk production (1/a) were 5.9, 5.1 and 8.6 kg/animal/day and the calculated amounts of supplements to reach marginal cost-benefit zero were 0.95, 0.6 and 0.9 kg for CM, SM and SG, respectively. The marginal increase in milk production reduced with increasing supplementation (0.97, 0.41 and 0.37 kg of milk/kg of CM; 0.79, 0.42 and 0.15 kg of milk/kg of SM; and -0.56, 0.81 and 0.37 kg of milk/kg of SG). The 2001 dairy NRC considers linear response of 2.3 kg of milk/kg of concentrate for both net energy of lactation and metabolizable protein supplementation, but models of saturation kinetics are more appropriate to explain these effects and to make nutrient recommendations.

Key Words: Energy, Protein, Supplement

W322 Effects of inoculation of ryegrass at ensiling on production of milk from dairy cows and whole body N partitioning. J. M. Moorby*, D. R. Davies, W. J. Fisher, and N. M. Ellis, *Institute of Grassland and Environmental Research*, *Aberystwyth, UK*.

To investigate the effect of inoculating grass at ensiling on subsequent feed intake and production characteristics of dairy cows, 18 multiparous mid-lactation Holstein-Friesian cows were used in a 3×3 Latin square design changeover experiment. Two silages were prepared from a single ryegrass dominated sward, with alternate trailer loads at harvest being left untreated or treated with an inoculant comprising a blend of bacteria and cellulytic enzymes before being used to fill two separate bunkers. Three dietary treatments were investigated, based on ad libitum access to ryegrass silage with 4 kg dairy concentrate/d: 1) the untreated grass silage, 2) a 1:1 mix (fresh) of the two silages, and 3) the inoculated grass silage. Of the 18 cows, half also underwent procedures to measure whole animal N partitioning and apparent whole-tract diet digestibilities. Results are in order of untreated, mixed, and inoculated silage treatments. There was very little difference in the composition of the forages (DM: 29.3, 28.4, 28.2 %; CP in DM: 21.3, 21.2, 21.3 %; NDF in DM: 48.1, 49.9, 49.9 %). Silage (and thus total) DM intakes were highest ($P < 0.05$) on the untreated silage (15.4, 14.7, 14.9 kg silage DM/d), although milk yields were not significantly affected by treatment (mean 26.8 kg/d). Milk fat % was lowest ($P < 0.05$) on the mixed diet (4.03, 3.92, 4.02 %), while protein % was highest ($P < 0.05$) on the inoculated silage diet (3.11, 3.15, 3.19 %). Nitrogen intake was highest ($P < 0.01$) on the untreated silage diet (644, 618, 594 g N/d) but daily outputs of N in urine, faeces and milk were all unaffected by treatment. Nitrogen balance was very significantly ($P < 0.001$) affected by treatment (121, 96, 58 g N/d). In conclusion, cows offered the inoculated silage ate slightly less food but produced the same amount of milk (with a higher protein %) as cows offered the untreated silage, while those offered the untreated silage accreted significantly more body N. Results from cows offered the mixed silage diet generally fell between the two extremes.

Key Words: Diary Cows, Ryegrass Silage, Inoculation

W323 Nitrogen utilization and nutrient digestibility in dairy cattle fed brown midrib corn silage and monensin. A. M. Gehman*, P. J. Kononoff, and B. N. Janicek, *University of Nebraska*, *Lincoln*.

Twenty Holstein cows (101 ± 34 DIM and 674 ± 77 kg BW) were used to compare rations containing brown midrib corn silage (*bm3*) to a control dual purpose hybrid (DP) on N intake and utilization. The effect of monensin in these rations was also examined. Animals were assigned to one of five 4 x 4 Latin squares with treatments arranged in a 2 x 2 factorial. Cows were fed one of four treatments during each of the four 28-d periods: 1) C-*bm3*, 0 mg/d monensin and *bm3*, 2) C-DP, 0 mg/d monensin and DP, 3) M-*bm3*, 300 mg/d monensin and *bm3*, and 4) M-DP, 300 mg/d monensin and DP. Indigestible acid detergent fiber was used as an internal fecal marker to determine nutrient digestibility, and urinary purine derivatives were used to estimate rumen microbial protein synthesis. N digestibility was ($P < 0.01$) lower for *bm3* compared to DP (61.9 vs. 65.6 %). Dry matter, acid detergent fiber, ether extract digestibility were ($P < 0.05$) and organic matter digestibility tended to be ($P = 0.07$) lower for *bm3* than DP. Neutral detergent fiber digestibility was not different (40.5 ± 2.42 %). There was no effect of hybrid on purine derivative:creatinine ratio (1.68 ± 0.07) or microbial protein synthesis (1140.1 ± 56.1 g/d). Cows consuming *bm3* tended to have ($P = 0.06$) higher N intake than those on DP (630.4 vs. 587.9 g/d). More ($P < 0.01$) fecal N was excreted by cows consuming *bm3* (240.5 g/d and 38.2 % N intake) than those consuming DP (204.1 g/d and 34.4 % N intake), however urinary N

(211.1 g/d and 35.8% N intake) and total manure N (431.5 g/d and 71.9% N intake) were not different. There was no effect of monensin or hybrid x monensin interaction on any measurements. The reduction in the digestibility of nutrients for *bm3* was probably attributed to increased dry matter intake observed for cows consumed *bm3*. This increase in dry matter intake appeared to have negatively affected N digestibility but not neutral detergent fiber digestibility. This resulted in a greater amount of N excreted in feces but did not affect total manure N excreted.

Key Words: Brown Midrib Corn Silage, Monensin, Nitrogen

W324 Effect of carbohydrates or amino acid infusions on plasma ghrelin in early and late lactating cows. I. Schei*[1,2] and H. Volden[1], [1]*Department of Animal and Aquacultural Sciences, Norwegian University of Life Sciences*, *Ås, Norway*, [2]*TINE BA*, *Ås, Norway*.

The objective was to study the effect of abomasal or intravenous infusions of wheat starch, glucose (CHO) or a mixture of amino acids (AA) on plasma ghrelin concentrations of dairy cows with different genetic capacity. Eight cows from two genetic lines selected for low (L) and high (H) milk production were used in a 4×4 Latin square design. The mean differences in pedigree index between the two groups were 1639 kg milk and 55 kg protein yield based on 305 d lactation. Infusions were: 1) starch in the abomasum (SP), 2) glucose in the blood (GB), 3) AA in the abomasum (AP), and 4) AA in the blood (AB). The experiment was conducted in early lactation (start: 57±4 and 52±2 d postpartum, 31.3±2.8 and 34.7±1.4 kg milk for L and H cows, respectively) and repeated with the same animals and treatments in late lactation (start: 168±4 and 162±2 d postpartum, 21.0±1.9 and 23.8±0.7 kg milk for L and H cows, respectively). Average daily amounts infused were 354 and 258 g in early and late lactation, respectively. The cows were fed a basal diet consisting of concentrate and grass silage (55:45 on DM basis) fixed to 95 % of the energy requirements for milk yield. Blood samples from the jugular vein were drawn at 0500, 0800 and 1200. Genetic group or genetic group × infusion interaction showed no effect (P>0.10) on plasma ghrelin concentration in early or late lactation. Across genetic group, average concentrations in early and late lactation were 560 (±17.2) and 512 (±19.7) pg\ml, respectively. In early lactation, the GB infusion tended to (P=0.10) be lower in plasma ghrelin concentration compared to the SP and AP infusions, but no effect (P>0.10) of infusion was found in late lactation. On restricted feed intake, plasma ghrelin concentration was similar for all cows when they were infused with starch or AA post-ruminal or intravenously but ghrelin concentration was slightly lower when glucose was infused intravenously in early lactating dairy cows.

Key Words: Genetic Capacity, Glucose, Starch

W325 Depression in feed intake by a highly fermentable diet is related to plasma insulin concentration and insulin response to glucose infusion. B. J. Bradford* and M. S. Allen, *Michigan State University*, *East Lansing*.

Effects of dietary starch fermentability on feed intake and nutrient digestibility were evaluated in a crossover study designed to identify factors that predict individual variation in feed intake response to starch fermentability. Thirty-two multiparous Holstein cows (121 ± 48 d in milk, 44 ± 7 kg/d milk yield; mean ± SD) were fed a diet intermediate to the treatments during a preliminary period and assigned randomly to treatment sequence. Treatments were dry ground corn grain (DG) and high moisture corn (HM) harvested from the same field. Treatment periods were 14 d, with the final 4 d used for data and sample collection. Diets included corn silage and alfalfa silage at a 2:1 ratio and were ~26% neutral detergent fiber, 17% crude protein, 32% starch, and 3.5% fatty acids. HM decreased dry matter intake (DMI) by 8% ($P < 0.001$), but did not significantly alter digestible DMI. Individual DMI responses to treatment were highly variable, ranging from an increase of 0.9 kg/d to a decrease of 6.0 kg/d when starch fermentability was increased. Variables from preliminary period propionate challenge tests, glucose tolerance tests, and hepatic mRNA analysis were assessed as potential predictors of DMI depression from increased dietary starch fermentability. Of the covariates tested, only plasma insulin concentration and insulin response to glucose tolerance test were significant predictors of DMI response to treatment. Higher plasma insulin concentration was related to greater depression in DMI with increased fermentability ($r^2 = 0.28$, $P < 0.01$); conversely, greater insulin secretion in response to glucose infusion was related to lower depression in DMI ($r^2 = 0.32$, $P < 0.01$). These insulin variables were independent predictors of DMI response ($r^2 = 0.001$). Consistent with past results, increased dietary starch fermentability decreased DMI. Significant correlations between insulin variables and individual DMI response warrant further investigation.

Key Words: Starch Fermentability, Insulin, Feed Intake

W326 Effect of weaning age on calving age, milk yield, and milk composition in the first lactation. J. A. Elizondo Salazar*, S. I. Kehoe, G. I. Zanton, C. D. Dechow, and A. J. Heinrichs, *The Pennsylavania State University*, *University Park*.

Average weaning age of dairy calves in the United States is approximately 8 wk. However, with proper management it has been shown that calves can be weaned as early as 3 to 6 wk saving time, labor, and cost. Research from many labs has shown that calves weaned at 4 to 6 wk were not different from calves weaned conventionally in feed intake, average daily gain, and feed efficiency. However, little is known about any effects that this could have on milk yield and composition. A retrospective analysis was used to determine effects of early weaning on calving age, milk production, and milk composition. The database included 40 Holstein heifer calves from 2 trials that studied effects of weaning age and milk feeding frequency on calf growth, health, and rumen parameters. Treatments consisted of weaning at 3, 4, 5, or 6 wk. In trial 1, calves were fed at 5% of birth BW, twice daily until 1 wk prior to weaning; and 5% once daily during the wk before weaning. For trial 2, calves were fed at 5% of birth BW twice daily until 14 d of age, then fed 10% of birth BW in the morning until 1 wk prior to their respective weaning age, at which time milk replacer was reduced to 5% of birth BW. After this time, calves were raised in the PSU Dairy Herd under a standard protocol. For the data analysis, DHIA records were compiled for age at calving, milk production and composition. Data were analyzed using the GLM procedure of SAS. Least squares means were calculated using sire, dam PTA fat%, and PTA fat% as covariates. No differences were detected in calving age or first lactation performance of calves weaned at 3 to 6 wk or fed once or twice daily. We conclude that weaning age or feeding system did not have any long term impacts on calving age or production.

Table 1. Calving age, milk yield, and milk composition in the first lactation of dairy cows in relation to weaning age

Item	Weaning Age (wk) 3	4	5	6	SEM	*P*
Number of calves	9	10	12	9	-	-
Age at calving, mo	24.1	23.2	23.1	23.2	0.40	NS
Milk, kg (305 ME)	13,212.6	12,771.2	13,856.2	14,754.3	545.7	NS

Key Words: Dairy Cows, Weaning Age, Milk Production

W327 Effects of dietary AflaDetox on aflatoxin M1 residue in milk of dairy cows. M. Denli*[1], J. C. Blandon[1], S. Salado[2], J. F. Perez[2], and S. Calsamiglia[1], [1]*Animal Nutrition, Management and Welfare Research Group, Universitat Autònoma de Barcelona*, *Barcelona, Spain*, [2]*Adiveter S.L. Agro-Reus*, *Tarragona, Spain*.

This study was conducted to evaluate the efficacy of a dietary mycotoxin adsorbent (AflaDetox, ADIVETER, S.L.) in reducing the excretion of aflatoxin M1 (AFM1) in milk of lactating dairy cows. Twenty five lactating Holstein cows from a commercial dairy farm were fed aflatoxin B1 (AFB1) contaminated feed in three experimental periods. AFB1 concentration in the total mixed ration (TMR) was 21 ppb. In Periods 1 and 3, animals were fed the TMR without AflaDetox, and in Period 2 animals were supplemented with AflaDetox at 1% (DM basis). Each experimental period consisted in 15 days adaptation and 3 days for sampling. Animals were fed a 55:45 forage (corn and triticale silage) to concentrate diet (17.9% CP, 32% NDF), respectively. Differences were declared at $P < 0.05$. Most of parameters studied were not affected by the inclusion of AflaDetox ($P>0.05$). Following values are average for the three periods; DM intake (21.9 kg/animal/day), milk production (27.9 ± 0.32 L/day), fat (3.85 ± 0.24%), protein (3.19 ± 0.27%) or somatic cell counts (290,700 ± 134.7 cells/mL), and serum activities of alanine amino transferase (33.8 ± 9.1 U/L), aspartate amino transferase (108.0 ± 19.4 U/L) and glutamly-transferase (16.9 ± 3.7 U/L). However, the addition of AflaDetox to the AFB1 contaminated diet reduced the concentration of AFM1 in milk from 250 to 100 ppt. Results from our experiment demonstrated that 1% AflaDetox in the diet can reduce up to 60% the concentration of AFM1 into milk of lactating cows fed AFB1 contaminated feed.

Key Words: Aflatoxin M1, Mycotoxin Adsorbent, Carry-Over

W328 *In vitro* aflatoxin binding efficiency of several sequestering agents in water or rumen fluids. F. Masoero[1], A. Gallo[1], D. E. Diaz*[2], G. Piva[1], and M. Moschini[1], [1]*Catholic University of Piacenza*, *Piacenza, PC, Italy*, [2]*Utah State University*, *Logan*.

The aflatoxins (AFs) are a group of mycotoxin produced primarily by *Aspergillus flavus* and *A. parasiticus*. Aflatoxin B1 (AFB1), the most frequently occurring and most studied of the AF is a Group 1 carcinogen and a potent hepatotoxin. Aflatoxin M1, a direct metabolite of AFB1, appears in milk of lactating dairy cows soon after consumption of AFB1 contaminated diets. The objective of this experiment was to measure the *in vitro* AFB1 binding efficiency of several sequestering agents used at different level of inclusion in water or rumen solutions. Three commercial sequestering agents, two clay based (clay 1 and clay 2) and a yeast cell wall derivate (CWD), were used at three different ratio with AFs (1:5000, 1:50000 and 1:500000 AFs:B) in water (CTR) or in rumen fluid (RF). The AFB1 was extracted from a natural contaminated corn meal (82.21±0.01 ppm), then added (0.205µg) to the binder suspension. Samples were incubated at 39°C for one hour under a light shake. Then, three 10 mL sub-samples were obtained, cooled down at 4°C to stop fermentation activity and centrifuged at 3500g for 15 minutes. The supernatant was recovered and the precipitate was suspended into 10 mL water before centrifugation. The step was cycled three times and the recovered supernatant was analyzed by HPLC for AFB1 content. Data were analyzed with factorial arrangement. Main effects (agent, substrate, dose), agent × dose and agent × substrate first order interactions and agent × dose × substrate second order interaction were significant at $P<0.01$.

Table 1. Sequestering agent (B) efficiency at different ratio with AFB1 (AFs:SA - 1:5000, 1:50000, 1:500000) in water (CTR) and rumen fluid (RF)

Solution	AFs:B	B Clay 1	Clay 2	CWD	SE	B	Main effect (P) Solution	AFs:B

W329 Early lactation production, body condition, and incidence of disease in multiparous Holstein cows fed a low potassium diet supplemented with SoyChlor®16-7 prepartum. J. Siciliano-Jones[1], P. W. Jardon[2], M. Kucerak[2], and M. B. de Ondarza*[3], [1]*F.A.R.M.E. Institute*, *Homer, NY*, [2]*West Central®*, *Ralston, IA*, [3]*Paradox Nutrition, LLC*, *West Chazy, NY*.

The objective of the trial was to determine if feeding a chloride and protein supplement (SoyChlor 16-7) with a low potassium diet (<1.20% DM) for three weeks prior to calving would effect production, body condition, and incidence of disease during the first 90 DIM. Two hundred multiparous Holstein cows were paired based on expected calving date and estimated mature equivalent 305-day production and assigned to: 1) control treatment consisting of a low potassium diet with a forage base of straw and corn silage or 2) a low potassium diet with a forage base of straw and corn silage supplemented with SoyChlor16-7 (5.3-7.6% DM). Cows were housed in separate pens and fed differing rations for the prepartum period (-21 to 0 DIM) but were co-mingled after calving. Mean urine pH during the prefresh period was 6.61 and 8.02 for SoyChlor 16-7 and control cows, respectively. Plasma calcium levels in presumptively normal cows were significantly higher ($P<0.05$) for SoyChlor 16-7 cows than for the low potassium controls at 0 and 7 DIM (9.12 and 8.78 mg/dl serum, respectively). SoyChlor 16-7 supplementation had no effect on disease incidence

or body condition loss (P>0.20). SoyChlor 16-7 positively affected production of milk, milk protein, and milk solids (P<0.10). Significant treatment by parity interactions were noted for milk production, protein yield, and milk solids yield (P<0.10). These results suggest an improved transition for cows fed a SoyChlor 16-7 anionic ration compared with a low potassium control especially for third and greater lactation cows.

Table 1.

	Treatment Mean			P-value	
	Control	SoyChlor	SEM	Treatment	Trt*Parity
Milk, kg/d	41.2	41.8	0.346	0.0674	0.0712
Fat, %	3.60	3.59	0.037	0.7537	0.9478
Protein, %	2.79	2.79	0.017	0.9752	0.1299
Protein, kg/d	1.13	1.15	0.008	0.0218	0.0011
Milk Solids, kg/d	2.59	2.64	0.021	0.0980	0.0358

W330 Intake of oral histidine does not alter milk or milk component production in dairy cattle. N. G. Purdie*, A. Krueger, V. R. Osborne, and J. P. Cant, *University of Guelph*, *Guelph, Ontario, Canada*.

This experiment was designed to test the hypothesis that a sufficient proportion of amino acid included in the drinking water of lactating cows will bypass the rumen to have an effect on milk or milk component production. Histidine was selected as the amino acid to investigate as it has previously been shown to affect milk synthesis and it is an essential amino acid so that an increase in absorption of it from the intestine will be mirrored in its plasma concentration. Eight high-producing, early lactation, dairy cows were assigned to either 0 or 2.5 g/L histidine in the drinking water in a crossover design of 2 seven day periods. Cows were offered a corn and alfalfa silage-based TMR for ad libitum intake. Water was provided ad libitum to each cow in an individual automatic drinking bowl with a flow meter attached. Based on previous estimates of rumen bypass of ingested water, the histidine treatment was calculated to supply a bypass of 30 g/d histidine. Water intakes and milk yields were recorded, and milk samples were collected for compositional analysis, on each of the last 3 d of each period. Plasma samples were obtained on the last day of each period. Water intakes increased from 83 to 94 L/d (P = 0.014). Plasma histidine concentrations increased from 14.6 to 21.6 μM (P = 0.060) by the addition of histidine to the drinking water. Though inclusion of histidine in the drinking water elevated plasma histidine concentrations, there were no effects on milk, fat, protein or lactose yields or percentage composition of milk. The 7 μM increase in plasma histidine concentration indicates a lower rumen bypass of the drinking water than expected.

Key Words: Histidine, Rumen Bypass, Water

W331 Meta-functional genomics of the rumen biome. S. C. Fernando[1], H. T. Purvis, II[1], F. Z. Najar[2], G. Wiley[2], S. Macmil[2], L. O. Sukharnikov[2], T. G. Nagaraja[3], C. R. Krehbiel[1], B. A. Roe[2], and U. DeSilva*[1], [1]*Oklahoma State University*, *Stillwater*, [2]*University of Oklahoma*, *Norman*, [3]*Kansas State University*, *Manhattan*.

Microorganisms within the rumen play an important role in nutrient digestion. The synergistic relationship between the microflora and the animal provides the animal with nutrients that are not available to monogastric animals. The interaction between the animal and rumen microflora is a complex relationship which directly impacts the animal's efficiency and performance. Hence, understanding the relationships between the host animal and rumen microflora as well as understanding the functional role of these bacteria within the rumen is of critical importance. However, the current understanding of the functional role of rumen bacterial species is very limited. As a first step towards understanding the relative abundance of rumen microbial mRNA species and thus the putative function of rumen bacteria, we have sequence analyzed ~58,000 individual rumen microbial mRNA species. Initial sequencing results demonstrate a complex metabolic function within the rumen with <18% redundancy and only 11% of the transcripts with valid functional annotation suggesting significant diversity in microbial metabolism within the rumen. Out of the 11% transcripts that could be annotated, 57% show association with metabolic function where transcripts associated with carbohydrate metabolism, amino acid metabolism and glycan biosynthesis/metabolism predominate. Further, analysis of the poly-adenylated mRNA species reveals the functional role of eukaryotes within the rumen. This approach should greatly facilitate future studies of the rumen microbial function.

Key Words: Rumen, Functional Genomics, Bovine

W332 A meta-analysis on the effects of feeding malate to ruminants. E. M. Ungerfeld* and R. A. Kohn, *University of Maryland*, *College Park*.

Malate is an intermediate of propionate formation in the rumen. Malate addition to ruminant diets can benefit production by decreasing methane production in the rumen through the incorporation of reducing equivalents in its conversion to propionate. In addition, malate stimulates the uptake of lactate by *Selenomonas ruminantium*, which can result in an amelioration of lactic acidosis that occur when rapidly fermentable diets are offered to ruminants. The objective of this study was to examine the effects of malate on ruminant digestion, metabolism and performance through a meta-analysis of published studies where malate was added to beef, dairy or sheep diets. Random effects of experiment and its interactions with main effects were included in models, and data were weighted by the reciprocal of their coefficient of variation scaled to one. There were no effects of malate supplementation on DM intake. Average daily gain increased with malate addition until about 0.5% malate in DM and then declined. Gain over feed tended to slightly decline with more than 0.4% malate in DM. Total VFA concentration in the rumen tended to increase with malate, although the opposite response was observed in one experiment. Acetate molar percentage tended to increase and propionate unexpectedly to decrease with malate supplementation, and butyrate was unaffected. Also unexpectedly, high levels of malate supplementation increased ruminal lactate concentration, even though its addition increased ruminal pH as well as DM and ADF digestibility. There were no effects on N digestibility. There was a tendency toward lower blood glucose concentration with malate supplementation,

and no effects on blood urea-N or lactate concentrations. From this analysis, malate amelioration of rumen acidosis may not always be explained by lower lactate or VFA concentration. Changes in VFA profile differed from in vitro results and make it doubtful that added malate could have been a quantitatively important electron sink in vivo. Research is needed on mechanisms by which malate affects pH, and on the metabolism of added malate in the rumen.

Key Words: Rumen, Fermentation, Malate

W333 A multiple regression approach to explore the contribution of 2-hydroxy-4-methylthio butanoic acid or ruminally protected DL-methionine to production parameters for lactating dairy cows reported in the literature. G. R. Bowman*[1], M. Vázquez-Añón[1], and L. M. Rode[2], [1]*Novus International, Inc.*, *St. Louis, MO*, [2]*Sage Biosciences, Inc.*, *Alberta, Canada*.

A vast amount of research has been conducted on lactating dairy cow response to supplemental 2-hydroxy-4-methylthio butanoic acid (HMTBa) and ruminally protected DL-methionine (RPM). The objective of the study was to compile the research over the past 40 years and utilize a nutrient modeling program to explore predictive response equations for milk production, fat corrected milk (FCM), milk component constituents, and dry matter intake (DMI). There were 46 total studies in the database; 23 studies with 62 treatment comparisons used HMTBa and 23 studies with 48 treatment comparisons evaluated RPM. A step-wise multiple regression analysis was used to identify variables that significantly ($P < 0.1$) contributed to the prediction equation. Variables found to be significant were used to predict final equations for HMTBa and RPM independently using mixed model procedures. The average milk production, FCM, and DMI responses over control for HMTBa and RPM were; 0.23 kg, 0.83 kg, and 0.05 kg; and -0.28 kg, 0.09 kg, and 0.03 kg, respectively. HMTBa and RPM supplementation increased milk fat % (0.14 and 0.06 % units), milk fat production (0.05 and 0.01 kg), milk protein % (0.02 and 0.06 % units) and milk protein production (0.02 and 0.01 kg) over the control. Supply of HMTBa in the diet positively contributed ($P < 0.1$) to predicting FCM production, milk fat %, fat production, and protein production responses over control. Supply of RPM ($P > 0.1$) in the diet did not contribute to predicting any production responses. Dietary ether extract significantly improved ($P < 0.1$) and physically effective fiber ($P < 0.1$) and non-fiber carbohydrates ($P < 0.1$) significantly reduced HMTBa and RPM production parameters. In conclusion, HMTBa supplementation improved milk, FCM, milk fat and protein yield, where as RPM predicted production responses were not influenced by amount of RPM supplemented.

Key Words: HMTBa, DL-Methionine, Multiple Regression Analysis

W334 Effect of a phytase on *in vitro* digestibility and finishing Criollo lambs fed a high sorghum diet. G. Buendía–Rodríguez[1], G. D. Mendoza–Martínez[2], S. S. González*[1], E. Aranda–Ibáñez[1], L. Miranda–Romero[3], L. Melgoza–Contreras[2], and J. H. Avellaneda–Cevallos[4], [1]*Colegio de Postgraduados*, *Montecillo, Edo. México, México*, [2]*UAM Xochimilco*, *México D.F.*, [3]*Universidad Autónoma Chapingo*, *Chapingo, Edo. México, México*, [4]*Universidad Técnica Estatal de Quevedo*, *Quevedo, Ecuador*.

The objective of this trial was to evaluate the effect of a phytase (Natuphos-5000G, BASF Mexicana) on *in vitro* digestibility and performance of finishing Criollo lambs. For the *in vitro* digestibility trial a completely randomized design was used and treatments (0 or 0.15 mg phytase/g sorghum or corn) were compared with Tukey test ($P \leq 0.05$). For the *in vitro* digestibility trial, results for residual phosphorus concentration were as follows ($P \leq 0.05$): a) 0.061a, 0.055a sorghum, and 0.129a, 0.030b corn (for 0 and 0.15 mg phytase, respectively) at 24 h; b) 0.059a, 0.033b sorghum, and 0.093a, 0.032b corn (for 0 and 0.15 mg phytase, respectively) at 48 h. For the finishing trial, treatments (0, 150, 300, 450 g phytase/t DM) were randomly allotted to 32 Criollo lambs (21.47 ± 2.24 kg initial BW) fed a 70% sorghum grain diet and housed in individual metabolic cages during 60 d. Treatment means were compared with Tukey test. There were no significant differences ($P \geq 0.05$) between treatments for ADG (201, 220, 194, 198 g/d), DMI (995, 1166, 1078, 1149 g/d) or feed conversion (5.02, 5.39, 5.69, 6.03). It may be concluded that phytase improved only *in vitro* phosphorus availability but it did not change finishing lamb performance.

Key Words: Phytase, *In Vitro* Digestibility, Criollo Lambs

W335 Digestibility and blood parameters in growing goats offered high concentrate diets with different rice straw particle size. X. G. Zhao[1], B. Zeng[1], S. X. Tang[1], Z. H. Sun[1], Z. L. Tan*[1], Z. H. Cong[1], and G. O. Tayo[1,2], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, P.R.China*, [2]*Babcock University*, *Ikeja Lagos, Nigeria*.

This work had the objective of evaluating the effect of different particle sizes of rice straw (geometric mean: 0.97cm, SRS; 1.98 cm, MRS1; 3.93 cm, MRS2; 7.79 cm, LRS) on the total tract digestibility of NDF, ADF and CP, and blood variables of growing goats. Four goats at 6 months of age and an average weight of 24.5 kg were used in a 4 × 4 Latin square experimental design with 4 periods of 16 d each. The diets consisted of 40.0, 37.0, 9.4, 8.0, 2.0, 0.8, 0.2, 2.0 and 0.6% rice straw, corn grain, soybean meal, wheat bran, rapeseed meal, urea, salt, vitamin premix and dicalcium phosphate (DM basis), respectively. All goats were offered the feed at 90% of ad libitum intake to maintain no orts during the experimental period. About 20 ml of blood were collected from the jugular vein at the end of each experimental period for each goat. Apparent digestibility of NDF (P=0.04) and ADF (P=0.05) were higher for MRS1 than for SRS and LRS. Total tract digestibility of CP was not influenced by the particle size of rice straw. Goats offered the SRS diet had higher (P=0.02) serum insulin when compared with goats offered MRS1 and LRS (36.8 vs 28.0 and 28.4 μU/ml). Serum glucagon concentration was lower in goats fed MRS1 diet than those fed MRS2 (258.4 vs 319.4 pg/ml). There were no differences in blood glucose, urea nitrogen and growth hormone concentrations among the four treatments (P >0.05). It was concluded that the particle size of dietary rice straw probably affected fiber digestion but did not influence serum biochemical parameter concentrations.

Acknowledgements: The work was partially funded by CAS (KSCX2-YW-N-49).

Key Words: Digestibility, Blood Parameter, Particle Size

W336 Effect of acetylated soybean peptides on ruminal fermentation and nitrogen metabolism in sheep. Z. J. Cao*, L. S. Li, Y. J. Wang, and M. Ma, *China Agricultural University*, *Beijing, China*.

The objective of this experiment was to determine the effect of acetylated peptides on rumen fermentation and nitrogen metabolism in sheep. Six adult Poll Dorset cross sheep, fitted with permanent rumen and duodenum fistulas, were used in a replicated 3×3 Latin design experiment. Three basic diets, balanced to similar nitrogen intake, were supplemented with 100 g soybean meal (ST), 60 g soybean peptides (PT), or 80 g acetylated soybean peptides (AT). Experimental periods were 15 d in duration (10 d of treatment adaptation and 5 d of data collection). The crude protein of soybean peptides and acetylated peptide powder were 66.8% and 51.0% (based on DM). The acetylatic degree was 88.9%. PT had the highest pH value (6.94), followed by AT and ST (6.74 and 6.58, $P < 0.01$). Ruminal ammonia concentrations were affected by treatment (8.25, 10.18 and 14.98 mg/dL for AT, PT and ST, respectively, $P < 0.05$). AT had higher free amino acid (FAA) concentrations compared to ST and PT ($P < 0.01$). Peptide amino acid (PAA) concentrations were higher (522.36 vs 122.81 mg/ L, $P < 0.01$) for sheep fed AT than ST. Methionine in total amino acids (TAA) was higher in AT compared to ST (0.45 vs 0.26 g/d, $P < 0.05$). Blood urea nitrogen (BUN) of ST had the highest value compared to PT and AT (5.96, 4.14, and 2.90 mmol/L, $P < 0.05$). Nitrogen losses from the feces of AT were less than that of ST (4.54 vs 6.44 g/d, $P < 0.05$). Similarly, nitrogen losses from the urine were higher for ST than for PT or AT (7.68 vs 5.19 and 5.01 g/d, $P < 0.05$). Apparent nitrogen digestibility of PT and AT (70.53 and 73.51%) was significantly higher than that of ST (62.85%, $P < 0.01$). Based on the results of this study, acetylation of the N-terminus of peptides can protect dietary peptides from rumen degradation. Ruminants might benefit more from acetylated peptides supplementation because of low degradability in the rumen and high digestibility in the intestine.

Key Words: Acetylated Peptides, Nitrogen Metabolism, Sheep

W337 Effects of rearing system on performance of weaned Pelibuey lambs. E. Gonzalez*[1,2], J. Arece[2], O. Cáceres[2], and P. P. Gomarín[2], [1]*INRA Antilles-Guyane*, *Domaine Duclos, Petit Bourg, Guadeloupe, France*, [2]*Estación Experimental de Pastos y Forrajes 'Indio Hatuey'*, *Central España Republicana, C.P., Matanzas, Cuba*.

A silvopastoral grazing system was compared with confinement (CF) for growth and general performance of weaned Pelibuey lambs. Lambs were from the EEPF 'Indio Hatuey' flock of Matanzas, Cuba (22°48′N, 81°2′W; 60 m above sea level). Ewes lambed in October and November and grazed at 12 to 14 per ha in a rotational silvopastoral system composed of three grasses distributed by plots ((*Panicum maximum*, *Brachiaria decumbens* and *Andropogon gayanus*) and three fodder trees (*Leucaena leucocephala*, *Albizia lebbeck* and *Bauhinia* spp.) randomly distributed in the 4.5 ha of pasture. Ewes were supplemented during drought with dehydrated citrus pulp (dcp) and sugarcane molasses containing 2% urea. The trial began with weaning in March and April about 3 months after lambing, with the lambs weighing 13 to 15 kg, and continued for 125 days. After being drenched with Levamisol, 25 lambs were grown on the silvopastoral system described above (SP) with 18 to 21 lambs/ha and 25 lambs were grown in confinement (CF). A rustic shed was used for CF with 1.5 to 1.8 m^2 per animal and *ad libitum* fresh water. The CF lambs were fed cut and carried chopped forage (60% *Pennisetum purpureum*, 40% *Morus alba*) and dcp at 0.8 to 1.0 kg/lamb per d. Data were analyzed by one-way analysis of variance. For the whole experimental period differences ($P < 0.0001$) were obtained for ADG (48.2 vs. 88.5 g/d) and incidence of gastrointestinal parasitism, mainly from *Haemonchus contortus* (2117 vs. 144 EPG of feces) for SP and CF feeding systems, respectively. Morbidity rate (data not available) was explicitly higher in SP (*i.e.* worse lamb external appearance), and consequently, the survival level was better under CF conditions (8% mortality in SP vs. 0% in CF). Advantages of the CF feeding system were mainly related to reduced *Trichostrongyle* numbers, which influence feed intake and efficiency, morbidity, growth rate, and survival. These results suggest that CF of lambs is a good alternative for improving the growth and welfare of lambs in the tropics.

Key Words: Lambs, Silvopastoral System, Confinement System

W338 Evaluation of growth and carcass characteristics of pure Pelibuey sheep and their cross with Dorper and Katahdin breeds. J. G. Canton* and J. A. Quintal, *Instituto Nacional de Investigaciones Forestales Agricolas y Pecuarias*, *Merida, Yucatan*.

Growth and carcass characteristics of purebred Pelibuey ram lambs were compared with those of Dorper $/times; Pelibuey and Katahdin × Pelibuey ram lambs. Thirty-four Pelibuey, 25 Dorper × Pelibuey and 20 Katahdin × Pelibuey lambs were included in a completely randomized experiment. Lambs were feed a diet composed of 27% of DM as orange pulp silage, 12% of DM as cut and carried Taiwan pasture, and 61% of DM as concentrate. At the end of the 68-d experiment, 3 animals of each breed group were slaughtered to measure carcass characteristics. Estimated DMI were 1143, 1266, and 1180 g/d and final BW ($P > 0.05$) were 40.9, 41.9, and 40.3 ± 1.1 kg, for Pelibuey, Dorper × Pelibuey, and Katahdin $/times; Pelibuey, respectively. No significant differences were detected for ADG, carcass weight, or dressing percentage. The average values obtained for all breeds were 232 g/d, 21.6 kg, and 55.1%, respectively. A higher ($P < 0.05$) percentage of loin and rib weight was observed in Pelibuey and Dorper × Pelibuey, compared with Katahdin × Pelibuey breeds (9.2 and 9.4 vs. 8.9 ± 0.5 %, respectively). There was no breed effect on area of the loin eye, or on proportions of neck, shoulder, leg, or total fat of the carcass. From these results, we conclude that pure Pelibuey sheep have growth rates and carcass characteristics similar to F1 crosses with Dorper and Katahdin breeds.

Key Words: Sheep, Growth, Hair Sheep

W339 Growth and feed efficiency of F1 Pelibuey lambs crossbred with specialized breeds for commercial production of meat. J. G. Canton*[1], R. F Bores[1], J. J. Baeza[1], J. A. Quintal[1], R. H. Santos[2], and C. A. Sandoval[2], [1]*Instituto Nacional de Investigaciones Forestales Agricolas y Pecuarias*, *Mérida, Yucatán*, [2]*Universidad Autónoma de Yucatán*, *Mérida, Yucatán*.

Growth and feed efficiency were evaluated for F1 crossbred ram lambs from different genotypes: Pelibuey × Pelibuey (PbPb), Black Head Dorper × Pb (BHDPb), White Dorper × Pb (WDPb), Katahdin $/times; Pb (KdPb) and Ile de France x Pb (IFPb). Forty-five lambs were distributed in a randomized block design with a factorial arrangement of 5 genotypes and 3 concentrations of dietary ME at 2.2, 2.5 and 2.8 Mcal/kg DM. There were two periods representing the initial (33 d) and the final phases (42 d) the growth, with 18 and 14% dietary crude protein, respectively. The IFPb lambs had a higher ($P < 0.05$) DMI than PbPb, BHDPb and WDPb lambs, but no differences were found ($P > 0.05$) between IFPb and KdPb. The values were 75, 76, 79, 80 and 86 g/kg$^{0.75}$ per d, for the PbPb, BHDPb, WDPb, KdPb and IFPb lambs, respectively. No effect on DMI was detected for the level of energy in either the interaction of genotype or main effect. There was a higher DMI ($P < 0.05$) in the final phase of growth (74 vs 84 g/kg$^{0.75}$ per d). No genotype effect was observed for ADG, total weight gain, or feed conversion. A linear effect ($P < 0.05$) was detected for ADG with increasing level of ME. The values obtained were 157, 193 and 240 g/d, for 2.2, 2.5 and 2.8 Mcal ME/kg DM, respectively. Lambs fed the medium and high ME levels had better ($P < 0.05$) feed conversions (4.3 and 5.0, respectively) compared to lambs fed at the lowest level of ME (6.5). Lambs had a lower ($P < 0.05$) total gain (5.6 vs. 8.1 kg) but better ($P < 0.05$) feed conversion (4.9 vs. 5.7) in the initial period than in the final period. Pelibuey lambs have growth and feed efficieny values similar to those of the specialized meat breeds, indicating that the Pelibuey breed can be used for commercial production of meat.

Key Words: Sheep, Crosses, Growth

W340 Introduction to Merino breeding resource flocks at Rafter 7 Ranch in Nevada. T. Wuliji*[1], H. Glimp[1,2], W. Jesko[2], and W. Rauw[1], [1]*University of Nevada*, *Reno*, [2]*Rafter 7 Ranch, The Edwin L Wiegand Trust*, *Yerington, NV*.

A Merino breeding resource flock was established at Rafter 7 Ranch through cooperation of the College of Agriculture, Biotechnology and Natural Resources, UNR and The Edwin L Wiegand Trust in 1990. Initially, 500 Rambouillet ewes were purchased from two established breeders in 1990. These ewes were bred naturally or by AI to imported rams from Australia and to rams selected within the flock. Over the 16 years, 16 rams and semen from 41 rams have been imported from Australia. Selection was based on objective wool measurements and phenotypic performance traits. Merino crossbred ewes showed that wool fiber density, clean wool yield, staple length, and grease fleece weight were increased by 41% per unit area of skin, 15%, 2.5 cm, and 1.14 kg per head shorn, respectively. The current flock wool fiber diameter was reduced by 3 micron on average compared with the foundation flock (23 micron). The flock was expanded to 1200 ewes and was bred in 30 single sire mating groups in 2006. Presently, the Merino flock is managed in two breeding lines, one as a registered Merino flock (n = 600) and the other as Rafter 7 line (n = 600), which is selected for wool, lambing, and meat production traits. Wool sales from Rafter 7 Ranch won 7 consecutive annual shears for the highest price in US grown wool. The 5 finest bales of wool clips in 2006 averaged 16.9 um fiber diameter. Sheep producers from 17 states and Canada have purchased breeding rams and ewes from Rafter 7 ranch over the past 10 years. These resource flocks have made significant progress over the foundation ewe flock during the crossbreeding and upgrading phase in major selection traits and are now becoming the flagship Merino flocks in the western states. Wool industry experts project that wool fiber diameter and its associated wool characteristics will continue to dominate wool price and textile use. Therefore, genetic improvement in wool and meat traits will increase sheep industry profits, and Rafter 7 ranch is poised to contribute genetic advantages to region-wide wool and sheep enterprises.

Key Words: Merino, Wool, Breeding

W341 Evaluation of Saint Croix ram lambs for growth, feed efficiency, blood urea nitrogen, and glucose levels by multivariate analysis. J. Simroth-Rodriguez*[1], E. Gutierrez-Ornelas[1], H. Bernal-Barragan[1], H. Morales-Treviño[1], J. Colin-Negrete[1], and V- Torres[2], [1]*Facultad de Agronomia, Universidad Autonoma de Nuevo Leon*, *Marin, Mexico*, [2]*Instituto de Ciencia Animal*, *Apartado Postal 24, San Jose de las Lajas La Habana, Cuba*.

Seventeen Saint Croix ram lambs were evaluated using a combination of growth and feed intake responses, and blood urea N (BUN) and glucose (BG), using multivariate analysis to identify and select those more efficient rams. The growth period was 102 d. Ram lambs (initial body BW: 13.7 ± 1.9 kg) were allocated into individual pens and fed a diet containing 18.7% CP and 2.65 Mcal of ME/kg, composed of ground sorghum grain (53.6%), soybean meal (15.2%), alfalfa hay (5%), wheat bran (15%), cane molasses (6%), tallow (1.5%), urea (1%), and vitamin-mineral premix (2.7%). Blood samples were obtained every 14 d and blood serum was analyzed to obtain BUN and BG levels. Five groups were discriminated by the hierarchical cluster method (Table 1). Group 4, with only one animal, was considered as the best. It had better data for birth type, birth weight, and weaning weight, as well as scrotal circumference, daily feed intake, ADG, feed/gain, and average BUN and BG levels measured throughout the growth period. The use of this method as a selection technique may represent a practical and useful tool for ram lamb selection in situations where scarce information is available.

Table 1. Characteristics of discriminate groups

Discr. group:	1	2	3	4	5

W342 Effect of dried distillers grains substituting for corn-soybean meal on growth and feed intake of Pelibuey sheep. A. Estrada-Angulo*[1], G. Contreras[1], A. Perez[1], G. Gamez[1], O. Lozano[2], F. G. Rios[1], and E. Vazquez[1], [1]*FMVZ - UAS*, *Culiacán, Sinaloa, Mexico*, [2]*Ganadera Flexi*, *Culiacán, Sinaloa, Mexico*.

To determine the effect of four levels of dried distillers grains (DDG) substituting for corn-soybean meal on growth of sheep, 32 Pelibuey ram lambs (BW= 19.0 kg) were fed for 84 d in a randomized block experiment. The animals were weighed and blocked by weight in 16 groups of two, placed into 16 (2 x 3 m) floor pens, and assigned to one of 4 diets: 1) Control had 17.3% CP and 3.48 Mcal DE/kg, and contained 12.5% corn straw, 62% whole corn grain, 15% soybean meal, 8% sugarcane molasses, and 2.5% mineral premix; 2) like Control, DDG15 had 17.3% CP and 3.50 Mcal of DE/kg, but contained 15% DDG, 56% whole corn grain, and 6% soybean meal; 3) like Control, DDG25 had 17.3% CP and 3.53 Mcal of DE/kg, but contained 25% DDG and 52% whole corn grain; and 4) like Control, DDG35 had 18.4% CP and 3.53 Mcal DE/kg, but contained 35% DDG and 42% whole corn grain. Feed was offered twice daily under free access conditions. In the first 28 d of the experiment, diet had no effect on ADG (245, 240, 244, 202 g/day), DMI (865, 821, 838, 828 g/day), or feed/gain (3.55, 3.52, 3.46, 4.14) for Control, DDG15, DDG25, and DDG35, respectively. Also, for the entire 84-d period, ADG (224, 217, 199, 184 g/d), final weight (38.6, 38.2, 36.4, 36.4 kg), and feed/gain (4.17, 4.54, 4.79 4.82) were similar ($P > 0.05$) for Control, DDG15, DDG25, and DDG35 diets, respectively. It is concluded, that DDG can substitute for a mix of whole corn grain and soybean meal in diets for Pelibuey sheep.

Key Words: Dried Distillers Grains, Soybean Meal, Pelibuey Sheep

W343 Effect of dried distillers grains substituting for corn-soybean meal on apparent digestibility and energy concentration of feed in growing Pelibuey sheep. A. Estrada-Angulo*[1], G. Contreras[1], M. Osuna[1], A. Perez[1], O. Lozano[2], and E. Vazquez[1], [1]*FMVZ - UAS*, *Culiacán, Sinaloa, Mexico*, [2]*Ganadera Flexi*, *Culiacán, Sinaloa, Mexico*.

To determine the effect of four levels of dried distillers grains (DDG) substituting for corn-soybean meal on apparent digestibility in sheep, four male Pelibuey sheep (15.0 kg) were used in a 4 × 4 Latin square with the following diets: 1) Control had 17.3% CP and 3.48 Mcal DE/kg, and contained 12.5% corn straw, 62% whole corn grain, 15% soybean meal, 8% sugarcane molasses, and 2.5% mineral premix; 2) like Control, DDG15 had 17.3% CP and 3.50 Mcal of DE/kg, but contained 15% DDG, 56% whole corn grain, and 6% soybean meal; 3) like Control, DDG25 had 17.3% of CP and 3.53 Mcal of DE/kg, but contained 25% DDG and 52% whole corn grain; and 4) like Control, DDG35 had 18.4% of CP and 3.53 Mcal of DE/kg, but contained 35% DDG and 42% whole corn grain. The DM excreted in feces was higher ($P = 0.01$) for DDG35 (88.8 g/d) compared to Control, DDG15, and DDG25 (66.1, 75.3, and 76.1 g/d, respectively). The apparent digestibility of DM for Control, DDG15 and DDG25 (84.8, 82.7, 82.4, respectively) was better than for DDG35 (79.8%, $P = 0.10$). The DE concentration was lower ($P = 0.01$) for DDG35 (3.42 Mcal/kg of DM) than for Control, DDG15, and DDG25 (3.64, 3.54, and 3.53, respectively). The observed/calculated DE ratio was lower for DDG35 (0.97) while it was higher or equal (1.05, 1.01, and 1.0) for Control, DDG15, and DDG25, respectively. It is concluded that a whole corn grain-soybean meal mixture can be substituted with DDG at 15 or 25% of the diet without an effect on apparent digestibility of DM and energy concentration, but the inclusion of 35% of DDG reduces the apparent digestibility of DM and DE concentration in diets for growing Pelibuey sheep.

Key Words: Dry Distillers Grains, Apparent Digestibility, Pelibuey Sheep

W344 Quantitative carcass characteristics of different sheep categories. R. S. B. Pinheiro, A. G. Silva Sobrinho, R. M. S. Emediato*, and S. M. Yamamoto, *São Paulo State University*, *Botucatu, São Paulo, Brazil*.

Thirty-six 1/2 Ile de France, 1/2 Polwarth sheep (12 ram lambs, 12 culled ewes and 12 culled wethers) were used to evaluate carcass quantitative characteristics of different sheep categories. Animals were grazed on Tifton-85 pasture and supplemented with concentrate. Lambs were weaned at 17 kg and slaughtered at 32 kg of live weight, at around 5 mo of age. Ewes and wethers were slaughtered at 55 kg and 60 mo of age. Sheep categories did not affect dressing percentages of hot or cold carcass, but chilling losses were higher in carcasses from young (3.67%) than adult animals (2.35%). The percentages of leg, rib and shoulder cuts did not differ among animal categories, but neck percentages were higher in wethers (9.29%) and loin percentages were higher in lambs (14.56%). In conclusion, sheep categories influenced carcas chilling losses, without alterations on carcass yield.

Key Words: Carcass Yield, Dressing Percentage, Sexual Condition

W345 Measurements of *Longissimus dorsi* muscle cross-section and leg muscularity index of sheep from different categories. R. S. B. Pinheiro, A. G. Silva Sobrinho, A. M. Jorge, R. M. S. Emediato*, and S. M. Yamamoto, *São Paulo State University*, *Botucatu, São Paulo, Brazil*.

The objective of this experiment was to compare measurements of *Longissimus dorsi* muscle cross section at the 13th rib, fat depth, and leg muscularity index of different categories of sheep. Thirty-six 1/2 Ile de France 1/2 Polwarth animals (12 ram lambs, 12 culled ewes and 12 culled wethers) were used. Animals were raised on Tifton-85 pasture and were supplemented with concentrates. Lambs were weaned at 17 kg and slaughtered at 32 kg live weight, at about 5 mo old. Ewes and wethers were slaughtered at 55 kg and about 60 mo of age. Measurements of *Longissimus dorsi* muscle cross section were different among all animal categories, except for the maximum linear dimension of the muscle cross section, with an average value of 5.4 cm. Maximum depth of muscle was higher for adult animals (3.4 cm) than lambs (3.0 cm); consequently, the loin eye area of lambs was also smaller than for adult ewes and wethers. Maximum fat thickness of wethers was 2.6 cm. This was higher than for ewes (1.9 cm) and lambs (0.8 cm). Leg muscularity index was different among animal categories, with higher values (0.46) for adults (ewes and wethers) and lower values (0.40) for lambs. In conclusion, sheep categories affected measurements of *Longissimus dorsi* muscle cross-section and leg muscularity index.

Key Words: Carcass, Sheep, Muscle

W346 Yield of wholesale cuts and non-carcass components of Morada Nova and Somális Brasileira × Morada Nova ram lambs. R. S. B. Pinheiro[1], A. G. Silva Sobrinho[1], A. M. Jorge[1], R. M. S. Emediato*[1], S. Gonzaga Neto[2], and S. M. Yamamoto[1], [1]*São Paulo State University*, *Botucatu, São Paulo, Brazil*, [2]*Paraíba Federal University*, *Areia, Paraíba, Brazil*.

The objective of this experiment was to evaluate carcass cut percentages and non-carcass component yields of Morada Nova and Somális Brasileira × Morada Nova lambs grown in a feedlot. Lambs were fed a diet containing 40:60 forage:concentrate ratio. Sixteen ram lambs averaging 15 kg initial BW were included in each genetic group. Morada Nova lambs had higher percentages of neck (9.7%) and loin (13.3%) cuts than crossbred lambs (8.0 and 10.4%, respectively). Leg and rib cut yields were higher for crossbred lambs (35.1 and 27.0%, respectively) than Morada Nova lambs (32.7 and 25.0%, respectively). There was no breed effect for shoulder blade percentage, which averaged 19.4%. Except for the liver and tongue, with no breed effect and average values of 2.29% and 0.35%, respectively, non-carcass component percentages were influenced by breed. Crossbred lambs had higher percentages of skin (8.96), head plus foot (10.68), heart (0.88), and kidney (0.93) than purebred lambs (7.15, 9.69, 0.56 and 0.35, respectively). In conclusion, Somális Brasileira × Morada Nova lambs had different percentages of carcass cuts as well as non-carcass components compared with Morada Nova lambs.

Key Words: Commercial Cuts, Crossbreeding, Sheep

W347 Effect of rumen-protected fat in diets of Bergamasca ewes on lamb growth, ewe weight gain, and milk production. M. M. Stradiotto, E. R. Siqueira, R. M. S. Emediato*, S. A. Maestá, and A. Piccinin, *São Paulo State University*, *Botucatu, São Paulo, Brazil*.

The amount and quality of milk may be reduced if the ewe diet is improperly balanced. At the beginning of their development, lambs rely almost uniquely on ewe milk. If the ewe diet limits milk production, lamb development is limited, with low weight at weaning. The objective of this project was to determine the effect of rumen-protected fat on milk production and weight gain of Bergamasca milk ewes and their lambs. The experiment was carried out at the Ewe Milk Production Research Unit of the School of Veterinary Medicine and Animal Science of the São Paulo State University (UNESP), with 80 Bergamasca ewes allocated at random to one of two diets: 1) a concentrate and corn silage diet; and 2) diet 1 with rumen-protected fat added to the concentrate at 35 g/ewe per d starting 20 d prior to lambing. In both groups, lambs were kept with their dams on pasture during the day and separated at night. After the morning milking, lambs were returned to their mothers. Lambs were weaned at 45 d of age. Ewes were mechanically milked for 60 d. Ewe and lamb ADG, milk protein, milk fat, milk lactose, and total milk solids were analyzed by t-tests. Added fat did not influence ($P > 0.05$) lamb birth weight, weight weaning, or ewe or lamb ADG. Adding protected dietary fat to the diet of lactating ewes did not affect lamb growth or ewe milk production or weight gain.

Key Words: Energy, Weight Gain, Sheep Milk

W348 Effect of weaning system on composition and yield of milk of Bergamasca ewes. L. S. Serrão, E. R. Siqueira, R. M. S. Emediato*, E. O. Queiroz, C. C. Boucinhas, M. M. Stradiotto, and S. A. Maestá, *São Paulo State University*, *Botucatu, São Paulo, Brazil*.

The objective of this experiment was to study the effects of three weaning systems on milk production and composition and somatic cell count (SCC) of Bergamasca ewes. Prior to parturition ewes were allocated to one of the following three treatments: 1) ewes weaned from their lambs at 48 h postpartum, and their lambs raised artificially (D1); or 2) beginning 48 h postpartum, ewes separated from their lambs for 17 h during the evening, ewes machine milked once daily in the morning, lambs allowed to suckle for 7 h during the day; lambs weaned at 45 d of age (MIX); or 3) ewes not machine milked and exclusively suckled by their lambs during first 30 d and then lambs were weaned (DY30). During the 90 d of the trial, ewes in all treatments were milked once a day after weaning of their lambs. Milk yield was recorded daily and samples of milk were collected weekly for milk composition analysis. Differences among weaning systems for milk yield and milk fat percentage were significant while ewes were nursing their lambs, and final average milk production was higher for D1 followed by MIX and D30, with 0.400, 0.351 and 0.293 kg/ewe per day, respectively. Although the experimental period was 90 d, D1 had a longer lactation (84 d) than D30 and MIX (71 and 70 d, respectively). No difference ($P > 0.05$) was observed for SCC (249, 164 and 188 x 10^3 cells/mL for D1, MIX and D30, respectively) or milk protein percentage, but higher milk fat percentage was observed for D1 (5.24%) and D30 (5.00%) than MIX (3.55%). The weaning system can be an important variable when the objective of the herd is intensive milk production. The D1 system will result in higher milk yield while the MIX system will result in a lower milk fat percentage as long as the lambs are nursing. This lower fat percentage could have a detrimental effect for cheese manufacturing.

Key Words: Dairy Ewe, Milk Constituents, Sheep Milk

W349 Effect of use of bypass fat in the feeding of Bergamasca milk ewes on gastrointestinal nematode infections. M. M. Stradiotto, E. R. Siqueira, R. M. S. Emediato*, A. F. T. Amarante, S. A. Maestá, and A. Piccinin, *São Paulo State University*, *Botucatu, São Paulo, Brazil*.

The goal of this trial was to evaluate the effect of bypass fat added to ewe diets on gastrointestinal nematode infections. The experiment was carried out at the Ewe Milk Production Research Unit of the School of Veterinary Medicine and Animal Science of the São Paulo State University (UNESP). Eighty Bergamasca ewes were submitted to two feeding systems. The randomized block experimental included two treatments: 1 – balanced diet (concentrate + corn silage) and 2 – same diet as 1 however with bypass fat (35 g/ewe per d) added to the concentrate. In both groups, lambs were kept with their mothers on pasture during the day, being separated at night. After morning milking, lambs were returned to their mothers, being weaned at 45 days of age. Ewes from both groups were mechanically milked for 60 days. Every fourteen days, blood samples and feces were collected to determine packed cell volume (PCV), total plasma protein levels (TPP), peripheral eosinophil counts, fecal nematode egg counts (FEC) and worm cultures. Data were analyzed by one-way analysis of variance,

with statistical significance between treatment means determined at $P < 0.05$. There was no effect of diet on any variable studied. *Haemonchus* spp, followed by *Trichostrongylus* spp were the predominant nematodes in the worm cultures. Protected fat added to diets of dairy ewes did not affect gastrointestinal nematode infections.

Key Words: Energy, Gastrointestinal Nematodes, Lactation

W350 Sheep mastitis: Pathogens and susceptibility to antimicrobial agents. L. S. Serrão, E. R. Siqueira, R. M. S. Emediato*, P. F. Domingues, E. O. Queiroz, C. C. Boucinhas, M. M. Stradiotto, and S. A. Maestá, *São Paulo State University*, *Botucatu, São Paulo, Brazil*.

A total of 655 samples of Bergamasca ewe milk were examined for subclinical mastitis by the California Mastitis Test and assigned scores of 1+, 2+ and 3+. The same samples were examined by bacteriological culture on blood agar and MacConkey agar. The isolated microorganisms were identified by Gram stain and taxonomy tests. Soon afterward, each microorganism was tested for in vitro antibacterial susceptibility. In total 49 microorganisms were isolated in pure culture distributed as follows: *Staphylococcus* sp (n=39; 79.6%), *Streptococcus* sp (n=4; 8.16%), *Mannheimia haemolytica* (n=2; 4.1%), *Bacillus* sp (n=2; 4.1%), *Corynebacterium* sp (n=1; 2.05%), and *Escherichia coli* (n=1; 2.05%). In antibiotic susceptibility tests for *Staphylococcus* sp and *Streptococcus* sp, the agents isolated with highest frequency, florfenicol, gentamicin and cefalexin were the drugs of best efficacy.

Key Words: Mastitis, Microorganism, Antibiotics

W351 Postpartum ovarian activity of Santa Ines lactating ewes fed soybean hulls replacing coastcross hay. R. C. Araujo[1], A. V. Pires*[1], I. Susin[1], C. Q. Mendes[1], G. H. Rodrigues[1], F. S. Urano[1], C. A. Oliveira[2], and P. Viau[2], [1]*ESALQ/University of São Paulo*, *Piracicaba, SP, Brazil*, [2]*FMVZ/University of São Paulo*, *São Paulo, SP, Brazil*.

Available data about the duration of anestrus postpartum of Santa Ines ewes are scarce. The objective of this experiment was to evaluate the effects of replacing coastcross hay NDF with soybean hull (SH) NDF on postpartum ovarian activity measured by progesterone (P_4) profiles. Fifty-six lactating ewes (initial BW 56.1 ± 6.8 kg) were penned individually and used in a complete randomized block design according to parity, type of rearing, offspring gender and lambing date. Hay NDF from a 70% roughage-based diet was replaced with SH NDF by 0 (SH0), 33 (SH33), 67 (SH67), and 100% (SH100), resulting in 0, 25, 54 and 85% of SH in the diet DM, respectively. Diets provided a similar NDF (56%) and CP (16%) content. BCS (1 to 5 scale) was assessed at the second and eighth week(weaning date) after lambing. Blood samples were collected by venipuncture twice a week, from the first to the twelfth week after lambing. Serum P_4 concentration was determined by RIA. Intra-assay and inter-assay coefficients of variation were 9.6% and 3.8%, respectively. The assay sensitivity was 96.1% for a minimal concentration of 0.01 ng/mL. Ovarian activity resumption was defined as six days prior to the date when P_4 concentration was ≥ 1 ng/mL. A linear increase ($P < 0.01$) for final BCS was observed with SH addition (3.09, 3.24, 3.34, and 3.36). Determined P_4 concentration ≥ 1 ng/mL and estimated mean ovarian activity resumption were 40.5 ± 15.6 and 34.5 ± 15.6 days after lambing, respectively, showing no difference ($P > 0.10$) among treatments. A quadratic effect ($P < 0.05$) was observed for NEFA concentration with values of 0.323, 0.244, 0.204, and 0.216 mEq/L for SH0, SH33, SH67, and SH100, respectively. Average ovarian activity resumption in Santa Ines ewes is attained earlier than two months postpartum.

Key Words: Hair sheep, Postpartum, Progesterone

W352 Multivariate analysis of within-litter birth weight variation, litter weight and litter size in the Ripollesa ewe. J. Casellas*, G. Caja, and J. Piedrafita, *Grup de Recerca en Remugants, Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

Birth weight plays a central role in lamb survival and growth, and the knowledge of its genetic determinism has become essential in worldwide selection programs. Within this context, within-litter birth weight variation (BWV) has been suggested as an attractive trait to homogenize litters in prolific species, although it has not been analyzed in sheep. The objective of this study was to ascertain whether maternal additive genetic variance exists for BWV in Ripollesa ewes, and to study its genetic, permanent and residual relationships with litter weight (LW) and litter size (LS) at birth. Data were recorded in the Ripollesa experimental flock of the Universitat Autònoma of Barcelona (Spain), between 1986 and 2005, and included 1,662 litters from 380 ewes, with 712 records of BWV and 1,530 records of LW. Traits were analyzed with a multivariate animal model solved through Bayesian methodologies, and with a threshold characterization of LS. Additive genetic variance was observed for BWV ($h^2 = 0.061$), as well as for LW ($h^2 = 0.200$) and LS ($h^2 = 0.141$). Nevertheless, genetic correlations among those traits were not substantial and suffered from a high degree of uncertainly, with the null correlation included within the highest posterior interval at 95%. Within-litter birth weight variation and LS showed a negative and large permanent environmental correlation (-0.872), and LW and LS were negatively correlated due to residual (-0.762) and permanent environmental (-0.449) random sources of variation. The low heritability found indicates that slow genetic progress may be expected from selecting for BWV. Close to zero genetic correlations suggest that this selection will probably not affect LS and LW, although some significant permanent and residual correlations must be taken into account. Further studies are needed to better understand the genetic architecture among these three reproductive traits.

Key Words: Birth Weight, Litter Size, Ripollesa Breed

W353 The influence of maternal and fetal breed on vascularity of the placenta in sheep. P. P. Borowicz*, A. T. Grazul-Bilska, D. A. Redmer, K. A. Vonnahme, J. S. Caton, and L. P. Reynolds, *Center for Nutrition and Pregnancy, and Department of Animal and Range Sciences, North Dakota State University*, *Fargo*.

The aim of the experiment was to determine the influence of fetal and maternal breeds on fetal placental (cotyledonary, **COT**), and maternal

placental (caruncular, **CAR**) vascularity in sheep. Previously we have reported the profound effect of maternal and fetal breed on placental and fetal weights (Borowicz et al., 2006). We hypothesized that the vascularity of placentas of highly prolific Romanov (**R**) sheep (litter-bearing, small birthweight) differs from that of Columbia (**C**) sheep (traditional, large birthweight). We also hypothesized that not only the maternal but also the fetal genome determines the size and vascularity of the placenta. Straight-bred (controls) and reciprocal pregnancies were established by transferring embryos from R or C ewes to R or C recipients (n = 1 embryo per dam; n = 4 to 11 total dams per group; groups: R×R, R×C, C×C, and C×R, where the first letter is the embryo breed and the second is the ewe breed). Gravid uteri were collected on d 130 of gestation and separate placentomes were fixed with Carnoy's solution by perfusion of the main arterial vessels supplying the CAR or COT, embedded in paraffin, sectioned, and stained, and vascularity was determined by image analysis (Image-Pro Plus) using 15 micrographs/placentome. For each CAR and COT, we determined: the capillary area density (**CAD**, total capillary area as a proportion of tissue area), capillary number density (**CND**, total number of capillaries per unit of tissue area), and capillary surface density (**CSD**, total capillary circumference per unit of tissue area). For CAR, CND and CSD were not different between fetal or maternal breeds. CAD was greater in the R dams regardless of the embryo breed ($P<0.05$). For COT, CND and CSD were greater in C×C and R×R vs. R×C ($P<0.06$). These data suggest minimal effects of fetal and maternal breed on placental vascularity in sheep with different prolificacies. Supported by *NIH grant HL64141 to LPR and DAR; and NIH grant P20 RR016741 from INBRE.*

W354 Genetic resistance to nematode parasites in sheep: Use of Box-Cox transformation in QTL mapping. M. V. B. Silva*[1], C. P. Van Tassell[1], T. S. Sonstegard[1], J. Mugambi[2], S. Nagda[2], S. McClintock[2], M. Malek[3], P. Boettcher[3], S. Kemp[2], J. F. Garcia[3], F. Iraq[2], and O. Hanotte[2], [1]*United States Department of Agriculture, Agricultural Research Service*, *Beltsville,MD*, [2]*International Livestock Research Institute*, *Nairobi, Kenya*, [3]*Atomic Energy Agency*, *Vienna, Austria*.

Fecal egg count (FEC) is used to quantify gastrointestinal parasite infestations. However, FEC values are not distributed normally, and a small percentage of the herd is often responsible for a majority of parasite transmission. Non-normality is a possible source of error when (co)variance components and genetic parameters are estimated, as well as decreasing likelihood of quantitative trait loci (QTL) detection. Typically, the distribution of FEC is right-skewed with a long tail and a high frequency of zero values (zero-inflated distribution). Nearly all QTL studies to date have used logarithmic transformations of FEC data before QTL analysis. In our study, six first cross (F1) Red Maasai x Dorper rams were mated to both Red Maasai (R) and Dorper (D) ewes to produce 1342 reciprocal backcross progeny. These six resource families were used to identify QTL controlling resistance to gastro-intestinal (GI) nematode parasites (particularly Haemonchus contortus). FEC measures were determined for 361 animals from 1 to 6 months old. In this study, original data were transformed using an extension of the Box-Cox transformation to approach normality and to estimate the position and variance components of the QTL in 19 of the 26 ovine autosomes. QTL detection was done using QxPak. Transformation of ovine FEC data utilizing the Box-Cox were effective in reducing the coefficients of asymmetry and kurtosis for the variable studied, which improved estimates of variance components of the QTL. Significant QTL for FEC were detected in chromosomes 7, 8, 9, 13, 14, 15, 16, 22, and 23. These results indicate that after transforming data by the Box-Cox procedure the genetic parameters in relation to QTL were more exact.

Key Words: QTL, Parasites, Sheep

W355 Effect of HCl-Zilpaterol and HCl-ractopamine on non-carcass components of hair sheep grown in the feedlot. F. G. Rios*, J. C. Robles, A. Estrada-Angulo, J. F. Obregon, G. Contreras, and A. B. Perez, *FMVZ - UAS*, *Culiacan, Sinaloa, Mexico*.

To determinate the effects of beta-agonists clorhidrate of zilpaterol (HCL-Z) and clorhidrate of ractopamine (HCL-R) on non-carcass components of hair sheep grown in the feedlot, 60 ram lambs (35.81 ± 3.05 kg initial weight) were used in a randomized complete block experiment where block was initial weight. The lambs were assigned to one of three diets fed ad libitum: 1) control diet with 17% CP and 3.62 Mcal of DE/kg consisting of 11.9% Sudan grass hay, 62% whole corn grain, 14% soybean meal, 2.0% meat meal, 5.0% cane molasses, 2.0% animal fat, 2.5% mineral premix and 0.6% sodium bicarbonate; 2) diet similar to control but with the addition of 15.5 ppm of HCL-R; and 3) diet similar to control but with addition of 3.75 ppm of HCL-R. Hot carcass (HCW), full gut (FGW), empty gut (EGW), and mesenteric fat weights (MFW) were recorded. The data were analyzed by one-way ANOVA with the 2 df for diet fitted as orthogonal contrasts comparing: 1) control with the average of HCL-Z and HCL-R; and 2) HCL-Z with HCL-R. The hot carcass weight was increased 5.54% ($P < 0.05$) for lambs fed diets with beta agonists, but the dressing percentage was improved 1.31% only for lambs fed the diet with HCl-Z compared with lambs fed the diet with HCl-R. Diets with beta agonists increased ($P < 0.05$) empty body weight (38.98 vs. 37.71 kg; 0.78 SEM) and EGW (3.16 vs. 2.82 kg; 0.076 SEM). A similar effect ($P < 0.05$) was observed for the percentage of empty gut weight (7.45 vs. 6.89% of HCW; 0.10 SEM), but there was no effect for FGW, which averaged 6.77 kg and 16.04% of HCW. MFW averaged 819 g and was not affected by diets. These data show that addition of HCl-Z and HCl-R to diets of hair sheep increased hot carcass, empty body, and empty gut weights.

W356 Nutritional value of sticky coffee hull silage on starting pigs diets. I. Moreira*[1], P. L. O. Carvalho[1], D. Paiano[2], L. M. Peñuela Sierra[3], L. M. Piano[1], and M. E. O. Girola[1], [1]*Universidade Estadual de Maringá*, *Maringá, Paraná, Brazil*, [2]*Universidade Estadual de Mato Grosso do Sul*, *Aquidauana, MS, Brazil*, [3]*Universidad Del Tolima*, *Ibagué, Tolima, Colombia*.

These experiments were conduct to study the use of sticky coffee hull (SCH) silage (SCHS) on starting pigs feeding. SCH (caffeine = 0.59%; tannin = 0.82%, as-fed-basis) is a by-product obtained from coffee processing (conversion the raw fruit of the coffee plant (cherry) into the commodity green coffee) and may represent an environmental threat. In Brazil there is a great supply of this cheap by-product. SCH was ground (4 mm screen-opening diameters) before ensilaging. There were at least 30 days of ensilage period before using it. Chemical composition (as-fed-basis) of SCHS is: DM= 66.48%; CP= 6.79%; GE= 2,753 kcal/kg; CF= 10.48%; ADF= 15.97%; NDF= 19.23%; hemicelulose= 3.26%; lignin= 3.77 %; ash= 4.587%; Ca= 0.20 %; P= 0.07%. Experiment I consisted of a digestibility trial using 15 piglets (Initial BW= 20.78±2.86 kg). In the Experiment II, 60 piglets (BW = 15.52±2.19 to 32.52±3.51 kg) were used in a performance study. Piglets were allotted to treatments with six replicates of two pigs per replicate in a randomized complete block design. Treatments consisted of a corn-soybean meal basal diet (0%) and four diets with sticky coffee hull (4, 8, 12, and 16%). Experimental diets were formulated to meet the same nutrients levels (NRC, 1998). From Experiment I it was obtained: Digestibility coefficient of energy of SCHS= 57.49%, which means 1,583 kcal of DE/kg (as-fed-basis). Performance data (Experiment II) were, respectively for 0, 4, 8, 12 and 16 % of SCHS inclusion: DFI = 1.345, 1.359, 1.304, 1.222 and 1.264 kg; DWG = 0.665, 0.671, 0.643, 0.592 and 0.640 kg; F: G ratio: 2.027, 2.031, 2.028, 2.056 and 1.976. The regression analysis indicates no effects (P≥0.05) of sticky coffee hull silage inclusion on piglet performance (DFI, DWG and F: G ratio). The results indicated 1,583 kcal of DE/kg of SCHS and suggest that it is feasible to use up to 16% of sticky coffee hull silage on starting piglet diet.

W357 Use of sticky coffee hull silage on growing pigs feeding. I. Moreira*[1], P. L. O. Carvalho[1], D. Paiano[2], G. C. Oliveira[1], I. S. Kuroda Júnior[1], and F. L. Mourinho[1], [1]*Universidade Estadual de Maringá*, *Maringá, Paraná, Brazil*, [2]*Universidade Estadual de Mato Grosso do Sul*, *Aquidauana, Mato Grosso do Sul, Brazil*.

Two experiments were carried out to evaluate nutritional value of sticky coffee hull (SCH) silage (SCHS) on growing pigs feeding. SCH (caffeine = 0.59%; tannin = 0.82%, as-fed-basis) is a by-product obtained from coffee processing (conversion the raw fruit of the coffee plant (cherry) into the commodity green coffee) and may represent an environmental threat. In Brazil there is a great supply of this cheap by-product. SCH was ground (4 mm screen-opening diameters) before ensilaging. There were at least 30 days of ensilage period before using it. Chemical composition (as-fed-basis) of SCHS is: DM= 63.71%; CP= 6.56%; GE= 2,708 kcal/kg; CF= 10.14%; ADF= 15.55%; NDF= 18.62%; hemicelulose= 3.07%; lignin= 3.64%; ash= 4.37%; Ca= 0.20%; P= 0.07%. Experiment I consisted of a digestibility trial using 15 pigs (Initial BW= 43.09±4.12 kg). In the Experiment II, 60 pigs (BW = 32.52±3.21 to 59.58±4.01 kg) were used in a performance study. Pigs were allotted to treatments with six replicates of two pigs per replicate in a randomized complete block design. Treatments consisted of a corn-soybean meal basal diet (0%) and four diets with sticky coffee hull (4, 8, 12, and 16%). Experimental diets were formulated to achieve the same nutrients levels (NRC, 1998). From Experiment I it was obtained: Digestibility coefficient of energy of SCHS = 49.87%, which means 1,351 kcal of DE/kg (as-fed-basis). Performance data (Experiment II) were, respectively for 0, 4, 8, 12 and 16% of SCHS inclusion: DFI = 1.919, 1.834, 1.831, 1.742 and 1.703 kg; DWG = 0.823, 0.744, 0.775, 0.764 and 0.738 kg; F: G ratio: 2.340, 2.456, 2.361, 2.274 and 2.312. No effects (P≥0.05) of sticky coffee hull silage inclusion on piglet performance (DFI, DWG and F: G ratio) were showed by regression analysis. It can be concluded that using up to 16% of sticky coffee hull silage (1,351 kcal of DE/kg) on growing piglet diet is feasible.

W358 Evaluating varied periods of water deprivation on body weight and feed intake in 50 to 70 kg pigs. A. D. Quant*, M. D. Lindemann, G. L. Cromwell, H. J. Monegue, J. S. Monegue, and B. G. Kim, *University of Kentucky*, *Lexington*.

Water deprivation can occur in swine production for various reasons (e.g., transport, water line breakage or freeze, power outage, etc.). A study was conducted to examine short and long-term effects of various water deprivation periods on pig performance. Crossbred pigs (n = 80; initial BW: 59.07 ± 3.93 kg) were blocked by gender and BW and allotted to 5 treatments with 4 replications of 4 pigs/pen. Pigs were weighed and observed twice daily for 5 d during and following the period of deprivation (0, 10, 13, 24, and 48 h deprivation), then weighed weekly for 7 wk. Minimum and maximum ambient temperatures during deprivation were 20.51 and 22.25°C. Pigs were allowed ad libitum access to water (except during deprivation) and feed for the entire experimental period. Backfat depth and longissimus muscle depth were measured by ultrasonography at the conclusion of the experiment. As duration of water deprivation increased, BW loss during deprivation increased (0.00, 1.22, 1.85, 2.56, and 4.06 kg) linearly ($P < 0.01$) and quadratically ($P < 0.01$). Body weight gain in the first 24 h immediately following water restoration increased (0.88, 2.41, 2.93, 4.01, and 5.74 kg) linearly ($P < 0.01$) and quadratically ($P < 0.05$) as water deprivation increased. Feed intake 24 h post deprivation was not affected by treatment (2.76, 2.74, 2.74, 2.72, and 2.93 kg; $P = 0.73$). During the 5-d observation period, BW gain decreased linearly (4.49, 3.89, 3.72, 3.52, and 2.95 kg; $P < 0.01$) as deprivation time increased, but 7-wk BW gain was not affected by treatment (49.66, 49.89, 50.37, 49.46, and 51.85 kg; $P = 0.61$). The length of water deprivation had no effect on backfat depth (17.44, 17.94, 16.38, 17.31, and 18.69 mm; $P = 0.59$) or longissimus muscle depth (56.63, 60.81, 59.25, 58.06, and 58.44 mm; $P = 0.73$). Therefore, based on growth performance and carcass characteristics, we conclude that water deprivation in grower pigs for durations less than 48 h

results in no detrimental effects to the pigs. The BW changes associated with the period of deprivation would seem to be largely those of dehydration, rehydration, and gut fill.

Key Words: Pigs, Water Deprivation

W359 Evaluation of pigs raised on two types of pasture-based and a confined grow-finish systems for production efficiency. K. Nadarajah*, D. L. Kuhlers, and W. F. Owsley, *Auburn University*, *Auburn, AL*.

Two independent grow-finish (G-F) trials with 2 pasture-based stocking systems (rotational (RP) and continuous (CP)) along with a confined (CF) system each with 2 replicates were conducted in spring and fall of 2004, to evaluate production efficiency of pigs. Each pasture based G-F stocking system utilized 0.2 hectares of electrical fenced plot with shade, and feed and water available *ad libitum*. In the CP system, pigs for a replicate had access to entire 0.2 hectares; however, a replicate for pigs in the RP system had access to one-fourth of the 0.2 hectares paddock, and remained in it for 2 wk and were rotated to next sub paddock. Each pen in the CF was about 12.5 m^2. A replicate is the experimental unit that consisted of 8 feeder pigs for a total of 48 pigs/trial. Pigs were evaluated for growth rate, feed efficiency, hot carcass wt and incidence of parasitic infestation (liver scores 1- 6: <10 spots with incremental increase of 10, where 6 =>50 spots; lungs scores 0-5: no damage with increasing increments of 20%, where 5 => 80% damage). Growth performance data of pigs (off test wt, ADG, and hot carcass wt) were analyzed using a mixed model fitting the effects of covariate for initial entry wt and trial, system, sex and their interactions as fixed effects and replicate nested within trial and system as a random effect. Differences ($P < 0.05$) for trial, system and sex were observed for all growth performance traits. Initial entry wt influenced off test wt and hot carcass wt ($P < 0.001$). Compared to RP and CP systems, pigs from CF systems grew faster (ADG: 0.67 and 0.66 vs. 0.78 kg; $P = 0.06$), and were heavier at off test (108 and 107 vs. 122 kg; $P = 0.02$) and for hot carcass wt (81 and 81 vs. 93 kg; $P = 0.02$).There was no difference in growth rate of pigs between the RP and CP systems. Difference between trials for growth performance may have been due to effect of season. Pen G:F for pigs in the CF system was more efficient than RP and CP systems (0.30 vs. 0.26 and 0.28; $P < 0.05$). Liver and lung scores did not differ between trials or systems. Pigs on sustainable outdoor pasture environments were equally healthy as in CF.

Key Words: Pigs, Pasture, Growth

W360 An analysis of the effect of age and weaning status on gastrointestinal characteristics and microbiota of young pigs. J. C. Miguel*, P. J. Laski, R. I. Mackie, and J. E. Pettigrew, *University of Illinois*, *Urbana*.

A 3 wk experiment was conducted to evaluate the effect of age and weaning status on gastrointestinal characteristics and microbiota of young pigs. Thirty pigs were weaned at 21.2 d of age and 5.95 kg BW and allotted to one of three euthanasia dates. Six pigs were euthanized at weaning and the remaining 24 pigs were separated into two groups of 12 pigs and euthanized on d 7 or 21 post-wean. At euthanasia, tissue segments were taken from the small intestine for morphology. The stomach, small intestine, cecum, and large intestine were emptied and wet weights recorded. Luminal contents and mucosal scrapings from the pars esophagea, fundus, jejunum, ileum, proximal colon, and distal colon were collected for genomic DNA isolation. The variable 3 (V3) region of 16S rDNA was amplified by PCR and denaturing gradient gel electrophoresis (DGGE) was utilized to generate microbial profiles. Bands generated following PCR-DGGE were enumerated and Sorenson′s pairwise similarity coefficients (C_s) were analyzed. Pigs at 7 d post-wean had reduced ($P < 0.05$) villus height in the duodenum and ileum and a smaller ($P < 0.05$) villus height:crypt depth and villus cross-sectional area in all 3 segments. Pigs at wean had a smaller ($P < 0.05$) crypt depth in all 3 segments. As the pigs aged, there was an increase ($P < 0.01$) in digestive organ weight as a percent of body weight. Analysis of PCR-DGGE band numbers indicated differences ($P < 0.05$) among age groups but no consistent pattern according to age or weaning status. Pigs at wean had more bands in jejunal luminal contents and mucosa and fewer band numbers in distal colonic luminal contents compared to pigs at 7 and 21 d post-wean. Comparisons of microbial diversity indicated similarity among pigs within age groups was greater ($P < 0.05$) than between age groups ($P < 0.05$), signifying age-dependent alterations in microbial banding patterns. Age and weaning status appear to influence the gastrointestinal environment of young pigs.

Key Words: Pigs, GastrointesFinal, 16S rDNA PCR-DGGE

W361 Effect of bacitracin supplementation on lactation management, neonatal piglet performance, and subsequent reproductive performance of sows. F. B. Turner*[1], L. M. Thompson[1], K. J. Kinney[1], S. E. Shute[1], W. L. Flowers[1], R. A. Schlutz[2], and B. Pratte[3], [1]*North Carolina State University*, *Raleigh*, [2]*Avoca Veterinary Clinic*, *Avoca, IA*, [3]*Alpharma Animal Health Division*, *Fort Lee, NJ*.

A study was conducted to examine the effect of supplementation of bacitracin in sow diets on lactation management and neonatal growth and mortality of piglets on a 2400-head commercial sow farm with a yearly average of 24 pigs per sows per year. There were no clinical signs of clostridial enteritis at the onset of the study. Females were housed in pens of 8 to 10 animals during gestation and moved into individual farrowing crates by day 112 of gestation. Sows (n=130 per treatment) were randomly assigned to receive feed supplemented with either 0 or 250 grams of BMD®/ton from day 100 of gestation through weaning. Piglets (n= 2767) received ear tags and were weighed within 2 days of birth and at weaning. Weaning age decisions were made by farm personnel independent of the study. Fecal samples from a subset of sows (n=30 per treatment) indicated that BMD® significantly reduced ($P < 0.05$) the clostridial load. No differences ($P > 0.30$) were observed in neonatal mortality or piglet weight within 2 days of birth. The proportion of litters in which piglets were crossfostered during lactation was lower ($P < 0.05$) in BMD® than control sows. Crossfostering tended to reduce ($P < 0.08$) the growth of piglets in a litter independent of treatment. There was no difference ($P > 0.12$) in unadjusted weaning weights of piglets between treatments. However, piglets nursing sows receiving BMD® were weaned an average of 2.3 days earlier ($P < 0.05$) than piglets nursing control sows which resulted in a higher ($P < 0.05$) weight per day of age during lactation. This was particularly evident for piglets whose weight at 2 days of age was less than 1.3 kg. Subsequent reproductive performance of sows was not affected by treatment ($P > 0.25$). In summary, supplementation of

gestation and lactation diets with bacitracin decreased the need for crossfostering and improved neonatal growth of piglets.

Key Words: Bacitracin, Lactation, Swine

W362 Comparing histopathological scores and exterior data for phenotyping pigs to address leg weakness. C. Rudolph, E. Tholen, M. Mielenz, G. Breves*, K. Schellander, and H. Sauerwein, *University of Bonn*, *Bonn, Germany*.

Leg weakness is one of the most serious problems in the pig industry. Herein we aimed to establish a classification modus from a histological evaluation of four joint cartilage surfaces in pigs and to relate the findings to exterior data. From 139 pigs of a F2 crossing of pietrain (Pi) x Duroc (Du) and Du × Pi, the stance in angle and position of fore- and hind legs was assessed and linearly scored (1 to 5, 3 is optimal). After slaughter, femur and humerus were dissected, each the distal and the proximal ends were cut into longitudinal slabs and histological sections were prepared from the joint surfaces. Two sections per joint surface were microscopically evaluated whereby the following criteria were recorded and then classified: Score 1: no pathohistological alterations, only marginally rough surface or weakly eosinophilic matrix or fibrillation; score 2: marginal histophathological alterations comprising fibrillation and hyperplasia and minor vascularization of the joint cartilage; score 3: severe alterations of the surface structures and the deeper layers; score 4: massive alterations of the cartilage including necrotic or ossified areas. All joints were accordingly scored and summarized for each animal. Data of exterior and histology were linked by the procedure FREQ of the SAS programme. According to their exterior data, only 12.2% of the pigs had consistently optimal scorings. By histology, no animal was without any aberrations; 15.5% of the animals had large-scale changes on each of the joints assessed. Significant ($p \leq 0.055$) analogies with medium contingency factors ($c = 0.23$ to 0.32) were found between individual exterior and histology data, e.g. between the exterior scores for hindleg stance and the histological scores from proximal and distal femur joint surface. Consideration of histological traits thus extends the repertoire available to characterize alterations associated with leg weakness and can therefore be used as an additional tool when aiming to comprehensively phenotype animals for genetic approaches.

Key Words: Pig, Leg Weakness, Histology

W363 A novel freezing-thawing device for porcine semen using a detachable catheter. G. Rocha-Chavez[1], M. A. Pinto-Jacobo*[2,1], L. Pinal-Suazo[1], and J. G. Michel-Parra[1], [1]*CUSUR Univ de Guadalajara*, *Cd Guzman Jalisco Mexico*, [2]*URPJ*, *Guadalajara Jalisco Mexico*.

Current freezing protocols for porcine semen require at least 2 billion spermatozoa packed in either several 0.5 cc straws, or one maxi straw of 5cc. Thawing protocols require the use of a minimum of 50 ml of extender for re-suspension of semen under a strictly controlled procedure. The objective of this study was to determine motility readings of thawed semen packed either in traditional .5 cc straws or in a novel separable intrauterine device. The sperm-rich fraction of three boars of known fertility was collected using the gloved hand technique. The semen was pooled, diluted 1:1 centrifuged (900g for 15 min) and the supernatant was resuspended in freezing extender and packed in either five straws of 0.5 cc (treatment 1) or two special maxi tubes (treatment 2). Maxi tubes are plastic tubes 37 cm long, 4 mm inside diameter and 0.7 mm wall thickness. For each treatment, a minimum of 2 billion spermatozoa per dose was used independently of the volume used for freezing. After gradual thawing, semen of treatment one was resuspended in a 27°C extender whereas semen on maxi tubes (treatment two) was thawed directly in a 27°C water bath and the two tubes were coupled using the pre designed steel connector. A special tip was connected in one end of the device and semen was forced out using isothermal extender at the other end. Semen was recovered in a prewarmed test tube and motility readings were made at 37°C using videorecording technology on both treatments. Ten replicates were made for each treatment and all readings were made in triplicate. Readings of 38 ± 7.3 and 42 ± 8.5 % on motility were found for treatment one and two respectively with no significant differences ($p<0.05$). It was concluded that after-thaw motility is the same for both treatments; however, the device can easily be used for direct deposition of semen at the uterine lumen of he sow using the right technique. Further in vivo studies are needed to validate the usefulness of the technique under field conditions.

Key Words: Frozen, Semen, Detachable

W364 Analysis of the association of factors associated with stillbirth in breeding sows. S. S. Anil*, L. Anil, J. Deen, S. K. Baidoo, and R. D. Walker, *University of Minnesota*, *St. Paul*.

The number of pigs weaned per litter and the number of pigs weaned per sow per year are adversely affected by a high stillborn rate and therefore it is important to analyze the risk factors associated with stillbirth in swine breeding herds. The objective of the present study was to analyze the association of the parity of the sow (categorized into ≤ 3 or ≥ 4), number of piglets born alive, number of mummies (0 or ≥ 1), litter birth weight, gestation length (categorized into ≤ 115 or ≥ 115 days) and farrowing induction (induced or not induced) with stillbirth (0 or ≥ 1) using logistic regression analysis (Proc logistic, SAS V 9.1). Data on 5290 parity records of sows were collected from the PigCHAMP database of the swine research unit of the University of Minnesota, Waseca, MN. Results indicated that the risk of having stillborn piglets was lower ($P \leq 0.05$) among sows of parity ≤ 3 compared to higher parity sows (Odds ratio, OR = 0.57). As litter birth weight increased the likelihood of having stillborn piglets decreased (OR 0.957, $P \leq 0.05$). Sows with no mummies were 29% less ($P \leq 0.05$) likely to have stillborn piglets. A higher number of piglets born alive and a gestation length of ≤ 115 days increased ($P \leq 0.05$) the risk of having stillborn piglets (OR 1.056 and 1.204 respectively). Sows that were not induced for farrowing had a higher ($P \leq 0.05$) risk of having stillborn piglets (OR 1.327). Results indicated that the factors associated with higher still births include, higher parity sows, sows that farrow in ≤ 115 days of gestation and sows that were not induced. These sows required special attention in order to minimize the risk of stillbirth.

Key Words: Stillbirth, Sows

W365 Influence of sex and terminal sire line on fresh meat quality, fatty acid profile of backfat, and ham weight losses during ripening of Iberian pigs reared under intensive production systems. M. P. Serrano[1], D. G. Valencia[1], R. Lázaro[1], A. Fuentetaja[2], and G. G. Mateos*[1], [1]*Universidad Politécnica de Madrid*, *Spain*, [2]*Copese*, *Segovia, Spain*.

Iberian (IB) pig is a native breed of Spain originally reared under free range conditions and sacrificed at 160 to 180 kg BW. Quality of cured products from IB pigs is high but productivity is low. During ripening of hams (15 d salting, 60 d postsalting, 31 d drying, and 639 d cellar phase), lipid changes occur and as a consequence the aroma and flavour of the products are improved. We studied the influence of sex (EF, gilts; CM, barrows) and terminal sire line (DD, Danish Duroc; SD, Spanish Duroc; RIB, Retinto Iberian) on fresh meat quality, fatty acid (FA) profile of backfat (BF), and ham weight losses during ripening in 180 pigs sacrificed at 145 kg BW. The female line used was pure RIB in all cases. Treatments were arranged factorially (2 x 3) with five replicates (six pigs) per treatment. Meat samples were taken at m. *Longissimus dorsi*. Samples of BF were taken at tail insertion from the two Duroc sire lines, but no samples were taken from the RIB sire line. Meat from CM had more lightness (42.1 vs. 40.0; $P < 0.05$) and more fat (8.6 vs. 6.1%; $P < 0.01$) but less protein (21.5 vs. 22.1%; $P < 0.01$) than meat from EF. No differences were detected between Duroc sire lines for any trait studied. Meat from RIB sired pigs was redder (11.3 vs. 7.8; $P < 0.001$) and had more intensive colour ($P < 0.01$) than meat from Duroc sired pigs. Also, meat from pure RIB pigs had more fat (8.8 vs. 6.8%; $P < 0.05$) and less protein (21.0 vs. 22.1%; $P < 0.001$) than meat from Duroc sired pigs. Treatment did not affect FA profile of BF. Weight losses during ripening were lower for CM than for EF (32.2 vs. 33.1%; $P < 0.01$) but were not affected by sire line. We conclude that entire females are an alternative to castrated females for production of Iberian pig and that Danish Duroc can be successfully used as sire line for this type of production.

Key Words: Iberian Pig, Duroc Pig, Quality

W366 Influence of gender on growth and carcass quality of pigs slaughtered at the same age destined to the production of high quality dry-cured hams. M. A. Latorre[1], L. Ariño[2], E. García[3], and R. Lázaro*[4], [1]*Centro de Investigación y Tecnología Agroalimentaria de Aragón*, *Zaragoza, Spain*, [2]*Integraciones Porcinas S.L.*, *Teruel, Spain*, [3]*Jamones y Embutidos Alto Mijares S.L.*, *Teruel, Spain*, [4]*Universidad Politécnica de Madrid*, *Spain*.

High quality dry-cured hams under the protection and designation of Teruel hams trademark are produced from heavy pigs in a specific area of Spain. For Teruel ham production the fat at Gluteus medius level should be at least 20 mm because lower fat levels impair the ripening process and ham quality. A total of 300 Landrace*Large White sows was crossed with Duroc boars. Forty hybrid pigs, with an average age of 182 d (50% castrated males with 110.1 kg BW and 50% entire females with 104.1 kg BW), were chosen at random. They were fed a commercial wheat, barley, and soybean meal diet containing 2,430 kcal NE/kg and 0.80% total lysine until slaughter age at 210 d. The effects of gender (castrates and females) on growth and carcass quality of pigs destined to the production of Teruel hams were studied. Each treatment was replicated twenty times (one pig per replicate). No effect of gender on average daily gain, carcass weight or dressing percentage was detected ($P > 0.05$). Castrates had more backfat (29.3 vs. 24.2 mm) and fat at Gluteus medius muscle (28.5 vs. 22.8 mm) than females ($P < 0.001$). In consequence, the percentage of carcasses with a Gluteus medius fat depth equal or greater than 20 mm was higher in castrates than in females (100 vs. 77.8%; $P < 0.05$). Gender did not influence carcass length nor pH or temperature at 45 min postmortem ($P > 0.05$). The weight of trimmed primal cuts (loins+shoulders+hams) was not affected by gender ($P > 0.05$), but the trimmed primal cut yield was higher in females than in castrates (46.9 vs. 44.5%; $P < 0.001$). It is concluded that castrated males are more adequate than entire females when sacrificed at the same age for the production of Teruel hams.

Key Words: Gender, Teruel Ham, Pigs

W367 Influence of slaughter weight on performance and carcass quality of pigs destined to the production of high quality dry-cured hams. M. A. Latorre[1], L. Ariño[2], E. García[3], and G. G. Mateos*[4], [1]*Centro de Investigación y Tecnología Agroalimentaria de Aragón*, *Zaragoza, Spain*, [2]*Integraciones Porcinas S.L. Teruel*, *Spain*, [3]*Jamones y Embutidos Alto Mijares S.L.*, *Teruel, Spain*, [4]*Universidad Politécnica de Madrid*, *Spain*.

High quality dry-cured hams under the designation of Teruel hams trademark are produced from heavy pigs in a specific area of Spain. For Teruel ham production the fat at Gluteus medius level should be at least 20 mm because lower fat levels impair the ripening process and ham quality. Two hundred (Landrace x Large White) × Duroc pigs, 50% castrated males and 50% entire females, with an average weight of 107 kg were used to study the effect of slaughter weight (SW; 120, 125, 130, 135 or 140 kg BW) on performance and carcass quality of pigs destined to the production of Teruel hams. Each treatment was replicated four times (ten pigs penned together). Animals were fed a commercial wheat, barley, and soybean meal diet containing 2,430 kcal NE/kg and 0.80% total lysine. Average daily gain and average daily feed intake were not affected by SW ($P > 0.05$), but feed conversion increased linearly ($P < 0.05$) at a rate of 0.08 kg for every 10 kg of BW increase. A linear relationship between SW and dressing percentage, backfat depth, and fat over the Gluteus medius muscle was detected suggesting increases by 0.5 percentage unit, 2.1 mm, and 2.0 mm, respectively, for every 10 kg extra BW at slaughter ($P < 0.001$). Weight of trimmed loins, shoulders, and hams increased with weight ($P < 0.001$). However, trimmed shoulder yield was not affected by SW ($P > 0.05$). Also, there was a linear relationship between SW and trimmed loin and ham yields ($P < 0.001$), indicating 0.17 kg and 0.30 kg decreases, respectively, for every 10 kg increase in SW. It is concluded that an increase in slaughter weight impaired productive performance of pigs, but might improve carcass quality. Slaughtering at more than 125 kg BW might help to optimize carcass characteristics of pigs destined to production of Teruel hams.

Key Words: Slaughter Weight, Teruel Ham, Pigs

W368 Change of characteristics of rib eye with cut section of pork using computer image analysis. M. Oishi*, Y. Furumoto, S. Hidaka, and K. Kuchida, *Obihiro University of A & VM*, *Obihiro, Hokkaido, Japan*.

The objective of this study was to determine how shape, color and marbling change with the cut section of pork loin. Rib loins

between 4-5th and the last rib of 6 barrows and 6 gilts of 3-way crossbred([Landrace × Large White] × Duroc) were cut into 18 slices with 2.5cm interval. Slice 1 was for 4-5th rib and slice 18 was for the last rib. High quality digital images of each section were taken by a mirror type camera for carcass cross section. For each section, nine traits were measured using an image analysis software (i.e., rib-eye area, fat area ratio, index of overall marbling coarseness, minor-major axis ratio, complexity of rib-eye shape, and RGBY values for rib eye color). At the same time, rib eye color (L*, a* and b* value) was measured with a colorimeter, and then the crude fat contents in rib eye was determined by chemical analysis for each slice. Correlation coefficients between Y and L* value, between the crude fat and fat area ratio were 0.825 and 0.740, respectively. The sections were classified into six positions by three slices backward from the front (e.g., position 1 = slices 1-3, position 6 = slices 16-18). Analysis of variance was performed by the SAS program for the image analysis traits as dependent variables and positions as fixed effects. Least square means (LSM) of the minor-major axis ratio for positions 1-6 were 0.62, 0.61, 0.58, 0.57, 0.49 and 0.39, respectively. Those of the fat area ratio were 3.80, 2.78, 2.13, 2.48, 2.50 and 3.24. Corresponding LSM of Y values were 121.59, 116.23, 112.06, 113.95, 115.19, and 117.72. From these results, rib-eye shape became flat toward the last position. Also the fat area ratio decreased in middle positions and then increased toward the last position. Marbling coarseness had the same trend with the fat area ratio. Brightness of rib eye was decreased in middle positions and then increased toward the last position.

Teaching/Undergraduate & Graduate Education

W369 Evaluation of Mississippi State University equine curriculum. M. Nicodemus* and K. Slater, *Mississippi State University*, *Mississippi State*.

With the growth of the equine industry, the demand for more university equine programs is increasing. Faculty has a challenge of trying to address the needs of the equine student as they prepare for jobs in a very diverse equine industry. To better develop a curriculum that meets the needs of the equine student, a survey was given to students (n=78) currently enrolled in equine classes at Mississippi State University. Questions addressed the students' background and interests concerning horses. The majority (74%) of students were Animal & Dairy Sciences majors with a science concentration with only 15% pursuing an equine management/production concentration. The majority of students had participated in or attended a horse show or clinic (69%) and had owned or family members had owned a horse (83%). 68% were planning on pursuing a career in the equine industry with 61% of those students choosing a veterinary career. Horse Science ranked first (41%) in equine classes that the students were currently taking or had taken followed by Equine Conformation & Performance Evaluation (20%). The majority (68%) of students indicated that they were taking equine classes because the classes "fulfilled a degree requirement" and the students "enjoyed horses", while 15% were taking classes just because they "enjoyed horses". Horse Science (17%) and Advanced Horsemanship (17%) were ranked as students' favorite equine classes in which both have a hands-on component. Equine Behavior & Training ranked the highest (23%) in equine classes the students wanted to take in the future followed by Western Equitation (19%) and Equine Reproduction (19%). Riding classes ranked the highest (58%) for recommended equine classes to add to the curriculum followed by an advanced horse science (35%). Overall, a hands-on component to the equine classes was a motivation for students taking an equine class. Laboratory components have been recently added to several of the equine classes to meet students' needs. Additionally, both Equine Reproduction and Advanced Horsemanship are only offered as a special topics class, but with favorable responses from this survey, these classes are currently being added to the curriculum.

W370 Development of an animal science managerial mentoring program. J. S. Pendergraft and B. T. Gutierrez*, *Sul Ross State University*, *Alpine, TX*.

The main goal of this project was to develop a managerial mentoring program for incoming animal science students. A model was developed to create a realistic workplace experience for animal science students outside of the classroom. The equine science program was divided into four specialized managerial areas: stables, nutrition lab, reproduction lab, and exercise physiology lab. One manager position with several specialized assistant manager positions were created. Additional staff positions were created under each assistant manager's area of responsibility. The equine science coordinator interviewed and hired the barn manager who in turn interviewed and hired the assistant managers. All hiring of positions were supervised by the equine science coordinator. All manager positions were renewable each year and staff positions were renewed each semester allowing for more diversity in a student's experience. A mentoring program for incoming equine science students was incorporated into the managerial model. The manager and assistant managers were responsible for mentoring their staff. Each incoming equine science student participating in the mentoring program committed 30 hours to each specialized area. Students successfully completing the mentoring program could choose to continue for a second semester of mentoring to gain more experience or apply for a mentoring position. During the first semester of the managerial mentoring program in the fall of 2006 three students participated as mentees. Two of these students are continuing the mentoring program during their second semester. One mentee chose to become a mentor during her second semester. The head manager/mentor obtained employment after graduation as a mare manager for a Thoroughbred farm in New Zealand. Eight new students entered the mentoring program during the spring of 2007. The main outcome from the Hispanic Serving Institute grant project was the development of a managerial mentoring model that can be used for any livestock program. The impact from this model was students were able to gain viable realistic workplace experience for the development of life skills that will be desired by future employees. Project progress can be found at: http://faculty.sulross.edu/jeffp/Equine/HSI.htm.

W371 Animal welfare assessment scenarios as a tool for animal production industries. J. M. Siegford*, C. Daigle, M. Tubbs, T. Bernardo, C. R. Heleski, R. Malinowski, and R. Snider, *Michigan State University*, *East Lansing*.

Hypothetical comparative scenarios depicting welfare of animals in various scenarios have been developed at Michigan State University (MSU) to teach students to assess animal welfare. These welfare assessment scenarios have been used in collegiate Animal Welfare Judging Contests and in courses at MSU and other institutions. In addition to teaching students about animal welfare, the scenarios foster development of critical thinking skills and problem solving abilities. Scenario development begins by identifying a species or situation of interest and collecting scientific and management information from experts, in industry and academia, and through searches of the literature. The information is synthesized into a PowerPoint-type presentation with images and video to develop two realistic, yet fictitious situations which can then be compared. Animal industries could proactively address animal welfare issues by developing and using welfare assessment scenarios with a production emphasis. Such scenarios could help identify animals or situations where animal welfare could be improved and offer staff education in an area of increasing public concern. The scenarios can be tailored to emphasize management practices, facility design, veterinary care, or nutritional regimes for a particular species or production setting to identify areas for improvement and expansion. Welfare assessment scenarios could thus provide an unbiased internal assessment of current practices and conditions to facilitate any necessary internal changes directed at an individual worker, production unit, or entire facility. Scenarios could also be helpful in training new stockpersons by reinforcing proper animal practices related to meeting the needs of the animal physically, mentally and psychologically. By collaborating with industry to develop production-based animal welfare assessment scenarios, a positive relationship between the industry and MSU can be strengthened. The goals of such collaboration are to improve welfare of animals in production, support education for staff, and produce MSU students able to assess animal welfare based on scientific research and reasoning.

W372 Poultry production demonstration: The effects of breeder hen's age on incubation, broiler growout and processing of broilers. G. M. Pesti*, R. I. Bakalli, and M. Y. Shim, *University of Georgia*, *Athens*.

The objectives of this laboratory exercise were to demonstrate: 1) the effects of the breeder's life cycle on fertility, hatchability and embryonic mortality patterns; 2) to compare the growth, feed efficiency and mortality of broilers hatched from large and small eggs laid by older and younger hens; and 3) to compare carcass characteristics of male and female chicks from two feedings programs. Average results from of 5 years of laboratories starting with 1080 eggs each from older hens (avg age = 63 weeks) and younger hens (avg age = 28 weeks) were: egg weight, 67 vs 54g; fertility, 80 vs 94%; hatch of eggs set, 71 vs 86%; chicks weight, 47 vs 38g; and mortality 7 vs 6%; for old hens vs young hens respectively. For the broiler grow out project, 30 chicks from each hen's age and chick gender were placed in 4 replicate pens (120 per treatment),and fed either a least cost diet (LC) with 16% protein and maximum profit (MP) diet with 24% protein. Average duration of broiler experiments was 40 days. Main effects means for chicks from old vs young hens were: body weight gain (BG), 2.35 vs 2.24 kg; feed conversion ratio (FCR), 1.74 vs 1.73 g feed/g gain; and mortality (M), 2.64 vs 4.17 %. Main effects of male vs females: BG, 2.45 vs 2.13 kg; FCR, 1.71 vs 1.75 g/g; and M, 4.19 vs 2.61. Main effects of diet were: BG, 2.26 vs 2.32 kg; FCR, 1.82 vs 1.64 g /g; and M, 4.03 vs 2.78%. Three chickens from each pen were randomly selected for processing. Main effects chicks source (old vs young hens) where: chilled carcass weight (CHCW) 72.5 vs 71.6%; abdominal fat (FP) 2.0 vs 1.8%; breast meat yield (BMY) 25.1 vs 24.8%; and leg quarters (LGW) 30.8 vs 30.7 %. Main effects male vs female where: CHCW, 72.7 vs 71.4%; FP, 1.7 vs 2.1%; BMY, 25.2 vs 24.6%; and LGW, 31.3 vs 30.2%. Main effects LC vs MP diets where: CHCW, 70.6 vs 73.5%; FP, 2.3 vs 1.5%; BMY 23.4 vs 26.4%; and LGW 31.3 vs 30.2%. The laboratory exercise described allows students to learn various techniques of incubation and husbandry while observing how breeder age, gender and type of feed influence incubation, broiler production and processing parameters.

W373 Effect of management type, conventional versus organic, on production and culling in Southeastern Pennsylvania dairy herds. K. E. Griswold*[1], H. Karreman[2], and J. Mylin[3], [1]*Pennsylvania State University Cooperative Extension*, *University Park*, [2]*Penn Dutch Cow Care*, *Gap, PA*, [3]*Lancaster DHIA*, *Manheim, PA*.

The effect of management type, conventional versus organic, on production, health and culling was evaluated using Dairy Herd Improvement Association (DHIA) data from 68 dairy cattle herds in Southeastern Pennsylvania. Initially, 34 organically-managed (OM) herds were recruited for the study. Then, each OM herd was matched with a conventionally-managed (CM) herd of similar size and breed geographically located within a one-mile radius of the OM herd. These 34 matched pairs were selected to limit the effects of herd size, breed, local weather patterns and soil type on the results of the study. All herds used Lancaster DHIA services, and monthly DHIA 202 report data from 2006 were used for the study. Herds ranged in size from 22 to 105 cows with a mean size of 47 ± 6. Data were analyzed using PROC MIXED within SAS. While the majority of herds were Holstein, several (n = 9) of the OM herds were classified in DHIA as crossbred. As a result, the model included the fixed effect of management type with breed (Holstein versus Crossbred) nested inside management type. LS means with standard errors are presented in the table below. The results would indicate that OM herds produced less milk of poorer quality compared to CM herds. However, OM herds had greater milk component percentages, and lower culling rates compared to CM herds. The reduced culling rate resulted from less culling for reproduction and injury/other. Within OM herds, crossbreeding significantly lowered milk production and quality, but improved milk components and pregnancy rate. These results suggest that OM dairy herds face different production and health challenges compared to CM dairy herds, and the breed of cattle can further impact the production and health challenges in OM herds.

Table 1. Effect of management & breed on production & health

Item	Mgmt			Breed			P-value	
	Conv	Organic	SE	Holstein	Cross	SE	Mgmt	Breed
Milk, kg/cow/d	31.4	22.6	0.63	25.5	19.7	0.91	<0.0001	<0.0001

685 Gene expression of alpha-toxin and *Clostridium perfringens* colonization in the development of necrotic enteritis disease in broiler chickens. W. Si[1], J. Gong[1], Y. Han*[2], H. Yu[1], H. Zhou[1], and S. Chen[3], [1]*Food Research Program, Agriculture and Agri-Food Canada*, *Guelph, Ontario, Canada*, [2]*Maple Leaf Foods Agresearch*, *Guelph, Ontario, Canada*, [3]*Labotory Service Division, University of Guelph*, *Guelph, Ontario, Canada*.

Alpha-toxin produced by *Clostridium perfringens*(CP) is considered one of the major virulence factors for necrotic enteritis (NE). This study was conducted to study alpha-toxin production at the gene expression level and its relationship to CP proliferation in the development of NE lesions in broiler chickens. 600 d-old birds were reared in 12 pens (50 birds/pen) and were fed either a medicated diet (55ppm bacitracin) or a non-medicated diet. The birds were challenged with a type A CP inoculum at a concentration of 10^7 CFU/ml on day 18. Two birds per pen were then humanely killed daily for 4 consecutive days. Ileal digesta was collected to analyze CP counts and alpha-toxin gene expression. NE lesions were scored on days 20, 21, and 22. The gene expression of alpha-toxin was quantified by two-step q-RT real-time PCR analysis. The birds fed the medicated control diet showed no NE lesions, undetectable alpha-toxin gene expression, and a mean CP counts of 0-13 CFU/g of digesta. In contrast, birds fed the non-medicated diet developed visible NE lesions 2 days after the infection (day 20). The average CP counts in the digesta of birds fed the non-medicated diet were 7 CFU/g before, and 1.3 x 10^4-2.0 x 10^7 CFU/g after the infection. Birds fed the non-medicated diet also had higher numbers of infected birds, NE scores, ileal CP counts, and alpha-toxin gene expression on day 20. Alpha-toxin gene expression reached a peak on day 20 and started to decline on day 21. All the infected birds fed the non-medicated diet demonstrated a highly positive correlation between the gene expression of alpha-toxin and cell proliferation of CP (R^2=0.7606, $P < 0.0001$). It appears that there was a threshold of counts of the alpha-toxin producing CP for the development of the disease.
