Triennial Growth Symposium: Interface Between Growth and Immunology

1 Brain-immune-periphery cross talk: Shared signals that link pathogen sensing and growth biology. J. L. Burton*, *Michigan State University*, *East Lansing*.

Animal survival depends upon the dual ability to modify metabolism according to environmental cues and mount effective immune reactions against pathogens. Both appear to rely on coordinated cross talk between the brain, immune system, and peripheral tissues such as the liver, skeletal muscle and fat. For example, recent work from our group has shown that stress hormone elaborated during brain-adrenal axis activation modifies the transcriptome of innate immune cells such that they forgo their traditional pathogen fighting behaviors in favor of higher priority metabolic activities such as tissue remodeling and repair. Other researchers have shown that myofibers and adipocytes share striking similarities with immune cells, allowing them to respond to and actively participate in pathogen sensing and local inflammatory responses but modifying their metabolic status to promote protein and fat mobilization in support of the higher priority immune reactions. This coordinated response is possible because the cells of each system express a variety of shared pathogen recognition molecules, receptors, and secreted cytokines/hormones that co-regulate inflammation and metabolism through the ability to influence activities of NF-kappaB and PPAR-gamma, key transcription factors which are also shared by the cells. As such, the brain, immune cells, skeletal muscle, and adipose tissue are both targets of and active participants in inflammation that helps clear pathogens but also modifies protein and fat accretion and thus animal growth.

Key Words: Immunity, Inflammation, Growth

2 Interleukin-15: A cytokine which modulates fat:lean body composition. L. S. Quinn*[1,2], [1]*University of Washington*, *Seattle*, [2]*VA Puget Sound Health Care System*, *Seattle, WA*.

Recent progress in understanding the hormonal control of fat:lean body composition has been made through identification of proinflammatory cytokines and other circulating factors produced by adipose tissue which affect body composition. Adipose-derived factors such as leptin, TNF-alpha, resistin, and adiponectin have been shown to affect muscle protein accretion and insulin sensitivity by direct actions. This talk reviews recent data which demonstrate the existence of a reciprocal muscle-to-fat signaling pathway involving release of the cytokine interleukin-15 (IL-15) from muscle tissue. Data are presented from transgenic mouse models, cell culture studies, short-term in vivo studies, and human genotype association studies which all support the model that muscle-derived IL-15 can decrease fat deposition and insulin sensitivity via a muscle-to-fat endocrine pathway. Fat:lean body composition is an important factor determining the efficiency of meat production, as well as the fat content of meat products. The information presented contributes to an increasing body of literature linking immune and inflammatory factors to growth and control of body composition.

Key Words: Interleukin-15, Muscle, Adipose Tissue

3 Regulation of muscle growth by pathogen associated molecules. R. A. Frost* and C. H. Lang, *The Pennsylvania State University*, *Hershey*.

Skeletal muscle demonstrates great plasticity in response to environmental and hormonal factors including pathogen-associated molecules, inflammatory cytokines and growth factors. These signals impinge on

muscle by forcing individual muscle fibers to either grow or atrophy. We have recently demonstrated that skeletal muscle cells express multiple Toll-like receptors (TLRs) that recognize bacterial cell wall components such as lipopolysaccharide (LPS). Exposure of muscle cells to LPS and other TLR ligands stimulates an inflammatory response characterized by the autocrine production of cytokines and nitric oxide (NO) by nitric oxide synthase (NOS)-2.

The TLRs signal through protein kinases that phosphorylate and promote the degradation of an inhibitory protein that normally retains the transcription factor nuclear factor kappa B (NFκB) in the cytoplasm. Phosphorylation and degradation of IκB allows for translocation of NFκB to the nucleus and activation of inflammatory genes. Overexpression of a constitutively active IκB kinase in skeletal muscle causes severe wasting and we find that inhibitors of either the phosphorylation of IκB or its proteolytic degradation prevent TLR ligand-induced expression of cytokines and NOS2.

The combination of LPS and IFNγ dramatically enhances the magnitude and duration of LPS-stimulated NOS2 expression and reduces protein translation by 80%. LPS/IFNγ also down regulates signaling from the mammalian target of rapamycin (mTOR) a kinase that directs changes in cell size. NOS inhibitors block the fall in muscle cell protein synthesis and restore translational signaling suggesting that activation of the NOS2-NO pathway is responsible for the observed decrease in muscle protein synthesis.

Our work provides a molecular explanation for reduced muscle growth during infection. Muscle is largely self-sufficient as it expresses receptors, signaling pathways, and effectors to regulate its own size. Prolonged activation of NFκB and NOS2 has emerged as detrimental facets of the immune response in muscle. The interplay between inflammatory components and growth factor signaling clearly places muscle at the interface between growth and immunity.

Key Words: Muscle, Growth, Cytokines

4 Insulin resistance by TNF-alpha in skeletal muscle and fat. M. Lorenzo*, S. Fernandez-Veledo, R. Vila-Bedmar, L. Garcia-Guerra, and I. Nieto-Vazquez, *Biochemistry Department, Pharmacy Faculty, Complutense University*, *Madrid, Spain*.

Insulin resistance, defined as the diminished ability of a cell to respond to the action of insulin, is an important contributor to the pathogenesis of type 2 diabetes. Obesity is a risk factor for development of type 2 diabetes, due in part to the fact that adipose tissue secretes proteins called adipokines that may influence glucose homeostasis and insulin sensitivity. Among these molecules, tumor necrosis factor (TNF)-alpha has been proposed as a link between obesity and insulin resistance because TNF-alpha is overexpressed in adipose tissues of obese animals and humans, and obese mice lacking either TNF-alpha or its receptors showed protection for developing insulin resistance. We have investigated how the direct exposure to TNF-alpha induces a state of insulin resistance on glucose uptake in myocytes and brown adipocytes by affecting insulin receptor substrate (IRS) proteins through activation of pro-inflammatory pathways. In this regard we identified the residue Ser 307 in IRS-1 as a site for TNF-alpha-impaired insulin-signaling in myotubes, being p38MAPK and IKB kinase involved in the phosphorylation of this residue. Conversely, serine phosphorylation of IRS-2 mediated by activation of p38- and p42/p44-MAPK by TNF-alpha was the mechanism found in brown adipocytes. Protein-tyrosine phosphatase (PTP)1B acts as a physiological negative regulator of insulin signaling by dephosphorylating the phosphotyrosine residues of the insulin receptor and IRS-1, and PTP1B expression is increased in muscle and adipose tissue of obese and diabetic humans and rodents. We have recently found that TNF-alpha up-regulated PTP1B expression. Accordingly, immortalized myocytes and primary brown adipocytes have been generated from PTP1B-deficient and wild-type neonatal mice. Cells deficient on PTP1B were protected against insulin resistance by this cytokine. In conclusion, the lack of PTP1B in muscle and adipose cells increased insulin sensitivity and glucose uptake and could confer protection against insulin resistance induced by adipokines.

Key Words: TNF-alpha, Insulin Resistance, Muscle and Fat

5 Proinflammatory changes in adipose tissue: Effects of diet-induced obesity. D. K. Brake, H. Wu, C. M. Ballantyne, and C. W. Smith*, *Baylor College of Medicine*, *Houston, TX*.

Obesity is associated with chronic inflammation, which may contribute to the high risk for type 2 diabetes, cardiovascular disease and metabolic syndrome with elevated markers of systemic inflammation. In obesity, macrophage accumulation in adipose tissue is increased, and monocyte chemoattractant protein 1 (MCP-1, CCL2) and its receptor, CC chemokine receptor-2 (CCR2), are up-regulated. Using a diet-induced mouse obesity model, we examined the expression of adhesion molecules, chemokines, inflammatory cytokines and leukocyte subsets in adipose tissue. Six week old C57BL/6J mice were fed a high fat diet (41% Kcal from milk fat) for 3, 10 and 24 weeks. After 3 weeks, CD54, IL-6 (but not TNF) and CCL2 were expressed in adipose tissue; two populations of CD11b+, CD54+ macrophages significantly increased in the stromal-vascular fraction of adipose, one of which also expressed CD11c and CD14. These changes were seen in male but not female mice. After 10 weeks on the diet, CD54 and IL-6 were further increased in adipose, and TNF expression was detected. The CD11c+ macrophages were still evident and increases in CD3+ cells (T lymphocytes) were evident. In addition to CCL2, CCL5 (RANTES) expression was detected. After 24 weeks, serum levels of soluble CD54 were elevated and positively correlated with fat mass in both male and female mice, though expression was significantly greater in males. CCL5, CCR5 and CD3+ cells were significantly elevated in obese male but not obese female mice. CCL5 mRNA levels were negatively correlated with adiponectin in adipose tissue, but positively correlated with CD3+ and CD11b+ cells. These observations reveal a progressive increase in proinflammatory changes in adipose tissue in dietary obesity that is pronounced in male mice, but minimal in female mice over a 24 week feeding period.

Key Words: Adipose, Inflammation, Mice

6 Critical control points in the impact of proinflammatory immune response on growth and metabolism. T. H. Elsasser*[1], S. Kahl[2], and J. L. Sartin[2], [1]*USDA-ARS-Growth Bio Lab*, *Beltsville, MD*, [2]*Auburn University*, *Auburn, AL*.

Growth is dependant on the assimilation of nutrient precursors into the structured components of all tissues. Where in the larger context of species survival, the growth and maturation of young animals into the adult constitutes the processes necessary to reproduce, nurture, and protect following generations. In production situations where we have assumed oversight of many of these life processes for the animals we raise, we have come to define growth largely in terms of production criteria. Intrinsic in the equation for successful animal production is the efficiency of nutrient use for assimilation into useful animal-derived product. However, in many management scenarios there develop time periods during which animals will experience levels of proinflammatory response (PR) as mediated through components of the immune system. The efficiency of nutrient use will proportionally decrease for growth rate at the expense of the redirection of nutrient use to support immune response tissues and processes. These PR events can develop in association with infectious disease and infestation but also are a part of the response to vaccination and the natural and management processes of birth, parturition, and weaning. If growth patterns are tracked during these periods of PR, growth deficits are often apparent, some relatively transient in duration and others quite long lasting, persisten though traditional clinical markers of PR are no longer evident. Recent evidence suggests that the PR cascades initiated by cytokines like tumor necrosis factor-α play a major role in these growth deficits in concert with the functions of Toll-like- and CD14 receptors, NF-κB proteins, nitric oxide synthase isoforms and superoxide anion generation; where the cascade tends to over-respond, the generation of free radicals and reactive nitrogen intermediates causes the nitration and nitrosylation of select amino acids in many metabolic regulatory and signal transduction proteins altering their functionality. The potential for dietary strategies to moderate PR-affected perturbations in growth are discussed.

Key Words: Proinflammatory Response, Growth, Metabolism

7 Bi-directional communication: Growth and immunity in domestic animals. J. A. Carroll*, *USDA-ARS Livestock Issues Research Unit*, *Lubbock, TX*.

Evidence continues to mount supporting the existence of bi-directional communication pathways between the animal's growth axis and immune system. For more than three decades, researchers have sought, and identified, linkages between the somatotrophic axis and health in domestic livestock. Early investigations were particularly interested in the various effects of exogenous growth hormone (GH) on both *in vitro* and *in vivo* aspects of immunity in domestic livestock. During an immunological insult, an uncoupling of the GH/insulin-like growth factor I (IGF-I) axis occurs resulting in elevated concentrations of GH in the presence of low circulating concentrations of IGF-I. Typically, sick animals experience a period of anorexia, thus requiring nutrient repartitioning and nutrient sparing to liberate nutrients for the production of proteins such as the pro-inflammatory cytokines and acute phase proteins that are critical for re-establishing homeostasis. While the energy liberating effects of GH are well-recognized, the significance of elevated GH during times of sickness-induced anorexia may be more profound due to its stimulatory actions on immune cells. In addition to GH, IGF-I and its associated binding proteins (IGFBP) have also generated significant interest with regard to their interactions with various pro-inflammatory cytokines and the overall effect on muscle growth and repair. For example, recent studies have demonstrated that the pro-inflammatory cytokines interleukin 1-beta (IL-1β) and IL-6 can impair IGF-I stimulated muscle growth, and may alter IGFBP profiles thereby indirectly altering the bioactivity of IGF-I (Broussard et al., 2004). In contrast to the catabolic actions of IL-1 β and IL-6 on muscle tissue, IL-15, a cytokine produced in various tissues including placenta, skeletal muscle, kidney, lung, heart, and macrophages, has been reported to act in an additive fashion with IGF-I on muscle fiber growth (Quinn et al., 1995). Further elucidation of the cross-communication that takes place among the endocrine, neuroendocrine, immune, and nutritional processes within the body will undoubtedly continue to be unveiled as researchers pursue the complexities associated with the regulation of the immune system.

Animal Behavior & Well-Being - Livestock and Poultry I

M1 Analysis of the association of parity, body condition and lactation feed intake with claw lesions in breeding sows. S. S. Anil*, L. Anil, and J. Deen, *University of Minnesota*, *St Paul*.

Severe claw lesions can cause lameness in pigs. It is important to identify and analyze the association between claw lesions and various risk factors in order to minimize the incidence of such lesions to reduce removal of sows for lameness. The objective of this study was to analyze the association of factors such as parity, body condition (BC) score and average lactation feed intake (LFI) with lesion scores (< median vs. ≥ median) on different claw areas in breeding sows using separate univariate logistic regression models (Proc logistic, SAS V 9.1). Claws of 771 sows in a breeding herd in Minnesota were examined for lesions on day 110 of gestation. Areas on the claw were classified as side wall (SW), heel (H), overgrown heel (OGH), sole (S), heel-sole junction (HSJ), white line (WL) and toe (T). Lesions were scored on a scale of 0 (no lesions) to 4 (severe). The final score on each area was obtained by multiplying the number of lesions by the severity of these lesions. Data on the parity of the sow and LFI were collected from the sow cards and BC was scored visually on a 5 point scale. For analysis, parity was categorized as parities 1 and 2, 3-5 and ≥ 6. The BC scores were categorized as ≤ 2 and ≥ 3. Average LFI was included in the model as a continuous variable. Sows of parity 1 and 2 had a higher likelihood of ≥ median scores for WL and HSJ lesions than sows of parity ≥ 6 (Odds ratio, OR 4.34 and 1.94 respectively) and lower likelihood of ≥ median scores for H lesions and OGH (OR 0.56 and 0.58 respectively, P ≤ 0.05 for all). Sows of parity 3-5 had lower (P ≤ 0.05) likelihood of ≥ median scores for OGH (OR 0.60) and higher (P ≤ 0.05) likelihood of ≥ median scores for WL lesions (OR 2.23) and HSJ lesions (OR 1.57). The odds of having ≥ median lesion scores were 58% and 43% higher (P ≤ 0.05) for sows with BC score of ≤ 2 compared to sows with a condition score of ≥ 3 on SW and WL respectively. The likelihood of ≥ median H lesion scores increased (P ≤ 0.05) by approximately 50% with every kg increase in average LFI. Results indicated that claw lesions were associated with parity, body condition and lactation feed intake.

Key Words: Claw Lesions, Sows

M2 Analysis of the association of claw lesions with lameness in breeding sows. L. Anil*, S. S. Anil, and J. Deen, *University of Minnesota*, *St Paul*.

Claw lesions are very common in pigs. Severe claw lesions can cause lameness, a welfare concern, and a major reason for early removal of sows from breeding herds. Housing conditions and management practices may be associated with the development of claw lesions. It is important to understand the association between claw lesions and lameness in order to minimize the incidence of such lesions and to reduce removal of sows for lameness. The objective of this study was to analyze the association of different types of claw lesions with lameness. Claws of 771 sows in a commercial breeding herd in Minnesota were individually examined for lesions on day 110 of gestation when sows were in the farrowing stalls. Lesions included erosions, cracks, and overgrowths. Areas on the claw were classified as side wall, heel, overgrown heel, sole, heel-sole junction, white line and toe. Lesions were scored on a scale of 0 (no lesions) to 4 (severe). The final score on each area was obtained by multiplying the number of lesions by the severity of these lesions. A multivariate logistic regression analysis was performed (Proc logistic) to assess the association of lesion scores (less than median vs. ≥ median) on different claw areas with lameness (lame vs. non-lame). The lesion scores on different claw areas of lame and non-lame sows were compared using Kruskal-Wallis test. Lesions on the heel and the white line were associated with lameness whereas overgrown heel, lesions at heel-sole junction and sole lesions were not associated with lameness. Sows with less than median heel lesion scores had 34% lower (P ≤ 0.05) likelihood of being lame. Similarly, sows with less than median white line lesion scores were less (P ≤ 0.05) likely to be lame (Odds ratio 0.689). Sows with less severe side wall lesions were less likely (Odds ratio 0.686) to be lame (P = 0.06). The comparison of lesion scores indicated higher (P ≤ 0.05) scores on side wall and white line in lame sows. Though not significant (P = 0.06), sole lesion scores tended to be higher in lame sows.

Key Words: Lameness, Sow, Claw Lesions

M3 Analysis of the association of periparturient risk factors with sow longevity. L. Anil*, S. S Anil, and J. Deen, *University of Minnesota*, *St Paul*.

Premature removal of sows in breeding herds is a reason for both economic and welfare concerns. Removal of younger parity females means that they are removed before they attain peak production performance. Farrowing is a high risk event in the life of a breeding female. The objective of the present study was to analyze the association of factors including parity, number of piglets born alive, lactation length, lactation feed intake and incidence of lameness during periparturient period (including lactation) with likelihood of sow

removal (cull, death or euthanasia) within 35 days post farrowing or before the next farrowing using multivariate logistic regression models (Proc logistic, SAS v 9.1). Data were (n =1357) collected from a commercial herd in Minnesota. Risk factors found significant ($P \leq 0.05$) in the univariate analyses were only included in the multivariate model. For analysis, lameness was categorized as lame or non-lame and parity as parities 1 and 2, 3-5 and ≥ 6. Other variables were included in the model as continuous variables. The results indicated that the likelihood of removal from the herd within 35 days post-farrowing decreased ($P \leq 0.05$) by approximately 19% with every additional piglet born alive. The risk of removal from the herd before 35 d post-farrowing decreased ($P \leq 0.05$) by 34 % with every additional kg increase in average lactation feed intake. Sows that did not have lameness during periparturient period had a lower ($P \leq 0.05$) likelihood of removal from the herd before 35 d post-farrowing (Odds ratio 0.260) compared to the other sows. Sows of parity 1 and 2, and 3 to 5 had lower ($P \leq 0.05$) likelihoods of removal from the herd before 35 d post-farrowing compared to sows of parity ≥ 6 (Odds ratios 0.181 and 0.285 respectively). Number of piglets born alive (Odds ratio 0.916), incidence of lameness (Odds ratio 0.626) and parity (Odds ratio 0.548 and 0.558 respectively for parities 1 and 2 and parities 3-5 respectively) appeared to influence the likelihood of removal of sows from the herd before next parity as well ($P \leq 0.05$ for all).

Key Words: Longevity, Sows, Periparturient Risk Factors

M4 Stress level of steers in long distance transport in Japanese four seasons. T. Ishiwata*, K. Uetake, Y. Eguchi, and T. Tanaka, *Azabu University*, *Sagamihara, Kanagawa, Japan*.

The objectives of this study were to investigate transportation conditions and behavioral and physiological responses of beef steers in long distance commercial transport in Japan. Japanese black × Holstein steers aged 8 mo were transported by truck in spring (n = 8), summer (n = 5), autumn (n = 8) and winter (n = 5). Transport distances (time) were 1,020.6 km (25 h including lairage periods): 615.4 km (6.4 h) on expressways, 163.2 km (3.7 h) on arterial roads and 242.0 km (10.5 h) by ferry. Internal temperatures of the truck were 14.7 ± 4.7°C in spring, 27.9 ± 2.6°C in summer, 24.4 ± 2.8°C in autumn and 9.2 ± 4.3°C in winter. During transport, more steers were lying during moving on expressways (chi square test, $P < 0.001$). The reason for this should be that vibration acceleration (m/s^2) of the truck in the lateral direction was smaller on the expressways (0.29 ± 0.36) than on arterial roads (0.31 ± 0.16) (Tukey's studentized range test, $P < 0.05$). Blood glucose, plasma cortisol, serum triiodothyronine (T_3) and ALT (reflecting liver function) concentrations were higher in spring (Tukey's studentized range test, all $P < 0.05$). This could be explained by that vibration acceleration (m/s^2) of the truck in the longitudinal direction was bigger in spring (-0.19 ± 0.43) than in the other seasons (-0.14 ± 0.09 in summer, -0.15 ± 0.20 in autumn and -0.15 ± 0.13 in winter) (Tukey's studentized range test, all $P < 0.01$). Furthermore, internal airflow velocity (m/s) of the truck was lower in spring (0.75 ± 0.70) than in summer (1.72 ± 1.88) and winter (1.31 ± 1.33) (Tukey's studentized range test, both $P < 0.01$). Heart rate, serum concentrations of T_3 , cholesterol, protein, AST (reflecting liver function) and ALT were higher just after transport than 1 wk after transport (Tukey's studentized range test, all $P < 0.05$). However, level of transport stress should be low, since no difference between before and after transport was shown on concentrations of plasma cortisol, blood lactate and serum NEFA, and serum pH and BW.

Key Words: Beef Cattle, Transport, Stress

M5 Welfare assessment of cattle transported in Japan. K. Uetake*, T. Ishiwata, Y. Eguchi, and T. Tanaka, *Azabu University*, *Sagamihara, Kanagawa, Japan*.

The objective of this study was to assess cattle welfare during transportation. Vehicle inspection and observation of cattle behavior were conducted at major livestock markets (T and M) in Japan. Market T provided young cattle (Wagyu and crossbred aged 6.8 to 9.0 mo) mainly for regions farther than 1,500 km. Market M provided young cattle (Wagyu aged 6.6 to 11.2 mo) and small calves (crossbred and Holstein aged 21 to 47 d) for nearby regions less than 500 km. Market T had loading platforms 1.0 m high, whereas market M did not have them and forced transporters to load cattle from the ground. Requirements to be met by vehicles were inspected according to the welfare standards for beef cattle of the RSPCA. Number of vehicles inspected was 36 and 31 in markets T and M, respectively. Cattle hesitations (kneeling down, slipping, balking, backing down, turning around, jumping and eliminating) were observed at the loading ramp. Vehicles inspected at the markets complied with most requirements of the welfare standards, but non-compliance was found in two requirements: In market M, 71.0% of vehicles had the loading ramp at more than a 20% incline, whereas 17.1% of vehicles did in market T (chi square test, $P < 0.001$). Slope of the loading ramp was steeper in market M than in market T (median 35.9% vs. 14.5%; Mann-Whitney test, $P < 0.001$). Market M had higher proportion of vehicles that did not comply with the requirement 'Both loading ramps and tail boards must be appropriately designed and covered with litter, to prevent animals from falling off or slipping' compared with market T (83.9% vs. 17.1%; chi square test, $P < 0.001$). Higher frequencies were observed in some hesitations in market M than in market T (Mann-Whitney test, all $P < 0.05$): Median frequencies (times/head) of slipping, balking and jumping were 1.0, 1.1 and 0.1 in market M, and 0.0, 0.8 and 0.0 in market T, respectively. Steeper loading ramp was correlated with higher frequencies of kneeling down ($r = 0.53$), slipping ($r = 0.59$), balking ($r = 0.45$) and backing down ($r = 0.42$) in market M (Pearson's correlation coefficient, all $P < 0.05$).

Key Words: Beef Cattle, Transportation, Welfare

M6 Spirit of humane. J. M. Regenstein*[1], J. Moses[2], and L. Jacoby[2], [1]*Cornell University*, *Ithaca, NY*, [2]*Shepherd Song Farms*, *Downing, WI.*

The recent emphasis in the US and Europe on animal welfare often presents a challenge for small meat processors and on-farm slaughter operations (where permitted by law) to meet modern animal welfare slaughter standards such as those of the Food Marketing Institute and the National Council of Chain Restaurants. This can especially be the case for the special slaughter needs of the religious communities, particularly the Muslim community, where all adult Muslim ideally slaughter a sheep or goat at least once a year. It may also be a challenge for small scale slaughter in the Jewish community, where only a trained slaughterman is used. Other ethnic groups wanting freshly slaughtered meat may not be knowledgeable about current animal welfare standards. As one looks at the developing world, there is an even greater need to educate people about animal welfare, ideally presenting them with a workable solution. Working with Dr. Temple Grandin (Colorado State Univ.), a small scale, low-cost sheep/goat slaughter pen has been designed that builds on her double rail animal support system. An appropriate commercially available slaughter knife with a long straight blade has been identified that is ideal for religious

slaughter and for the slaughter of un-stunned animals, giving an easily handled, calm animal. This assures that the full humane benefits of un-stunned slaughter can be realized. In addition an educational poster on humane animal handling has been prepared for both religious and non-religious slaughter and this poster has been translated into a number of other languages including: Arabic, Malay, Persian, Spanish, Somali, Turkish and Urdu. The original pen design for sheep and goats has been modified to make it efficiently shippable and easily assembled without any special tool requirements. An alternate pen for larger animals is being designed with the same criteria, but obviously requiring a sturdier structural framework.

Key Words: Humane Slaughter, Sheep, Goats

M7 Comparison of beak trimming methods on early broiler breeder performance. S. N. Henderson*[1], J. T. Barton[2], W. J. Kuenzel[1], A. D. Wolfenden[1], S. E. Higgins[1], J. P. Higgins[1], C. A. Lester[1], G. I. Tellez[1], and B. M. Hargis[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Tyson Foods*, *Springdale, AR*.

Beak trimming is necessary in commercial broiler breeders to prevent aggressive trauma as they mature. Two common methods were evaluated by early performance comparison with non-trimmed chicks (NBT). The robotic electrocautery device (ECD) trims and cauterizes the beak tip, while the robotic infrared beak trimming device (IBT) applies an infrared light beam to destroy the live basal tissue while leaving the hard corneum intact for the first ~10 days. On day-of-hatch, 900 Ross 708 byproduct chicks were obtained from a local hatchery, and 1/3 of the chicks were trimmed using IBT. All 900 chicks were then transported to another hatchery where 1/3 were trimmed using ECD. Personnel at each hatchery were highly experienced and skilled with their respective technique. All chicks were then transported to UA facilities where chicks were co-mingled, provided ample feeder and water space, and age-appropriate environment on fresh wood shavings. Prior to placement, chicks were individually neck tagged, weighed, and beaks were measured using a digital caliper: from the rostral point of the nares to either the beak tip (NBT and IBT) or amputated line (ECD). Initial beak measurements of NBT group (6.3 mm) were significantly ($p<0.05$) longer than ECD (3.8 mm) and the intact beak of IBT (5.8 mm). No significant ($p>0.05$) differences in body weight gain (BWG) were observed among treatments at 4 d (NBT: 35.5g; ECD: 32.3g; IBT: 32.7g) or 7d (NBT: 81.2g; ECD: 81.2g; IBT: 82.9g) post-placement. Effects of treatments on BWG through 6 wks will be reported. These results suggest that when beak trimming is performed on day-of-hatch by skilled and experienced personnel, little measurable effects on performance are observed during this critical first 7 day period when ample feeder and water space are provided.

Key Words: Beak Trimming, Early Performance

M8 Analysis of the incidence of claw lesions in breeding sows. S. S. Anil*, L. Anil, and J. Deen, *University of Minnesota*, *St Paul*.

A painful lesion in the claw can cause lameness in pigs. Housing conditions and management practices may be associated with development of claw lesions. Measures to minimize the incidence of claw lesions and lameness must be preceded by attempts to understand the pattern of the incidence of claw lesions. The objective of this study was to characterize claw lesions in breeding sows. Claws of 771 sows in a commercial breeding herd in Minnesota were individually examined for lesions on day 110 of gestation when sows were in the farrowing stalls. Lesions included erosions, cracks, and overgrowths. Areas on the claw were classified as side wall (SW), heel (H), sole (S), heel-sole junction (HSJ), white line (WL) and toe (T). Lesions were scored on a scale of 0 (no lesions) to 4 (severe). The final score on each area was obtained by multiplying the number of lesions by the severity of these lesions. The proportions of sows with and without lesions on different areas in the lateral and medial claws of front and hind limbs and the proportions with severe (≥ 4 score) and less severe (≤ 3 lesion score) were compared using 1-sample and 2 sample proportion tests. The proportions of sows with overgrown heel (OGH), and lesions on SW, H and WL were higher than the proportions without lesions ($P \leq 0.05$, 1- sample proportion test). However, a higher ($P \leq 0.05$) proportion of sows had no lesions on the T. There was no difference in the proportion of sows with and without lesions on the S and HSJ. A higher proportion of sows had lesions on the SW, WL, HSJ, S and T in the front limbs compared to the hind limbs ($P \leq 0.05$, 2-sample proportion test). A higher proportion of sows had H lesions and OGH in the hind limbs than in the front limbs ($P \leq 0.05$). In both front and hind limbs, the proportions of sows with lateral claw lesions were higher than those with medial claw lesions ($P \leq 0.05$, 2-sample proportion test). The proportions of sows with ≤ 3 lesion scores in all claw areas except the SW were higher ($P \leq 0.05$, 1-sample proportion test) than the proportions with ≥ 4 lesion scores. The study indicates a high prevalence of claw lesions, especially severe SW lesions.

Key Words: Claw Lesions, Sows

M9 Effect of the presence of hungry conspecifics in the stress and weight gains of recently weaned lambs. J. Rojas, R. Vázquez, F. I. Flores-Pérez, V. Aguirre, and A. Orihuela*, *Universidad Autónoma del Estado de Morelos*, *Morelos, México*.

Newly-weaned lambs were exposed to feed in the presence of hungry conspecifics to determine if socially-facilitated feeding behavior would help to alleviate stress and improve weight gains during the period immediately following weaning. Twenty-two (Dorper X Santa Cruz) single lambs, were assigned to two groups at 60 days of age. No lambs were added to the control group, while in the experimental group, a total of fifteen hungry weaned lambs were added daily with a 90 min interval between introduction of each group of five hungry lambs starting at the time of mother young separation (08:00). These hungry lambs were fasted for 12 h previous to their use. Significant ($P<0.05$) increases in the number of visits to the feeders and serum cortisol concentration were observed daily during four days in the experimental lambs in comparison with the controls. Lambs in the experimental group vocalized less ($P<0.05$) frequently than controls during the third and fourth day of separation, while no differences ($P>0.05$) were found between groups or days in the number of animals lying and individual weight gains. It was assumed that the increased number of visits to the feeder by the experimental lambs was a socially facilitated behavior in response to the continuous use of the feeders achieved by the hungry lambs. As a consequence of this increase in locomotor activities, fewer experimental animals were observed lying. In addition, the reduction in vocalizations in the experimental group on days three and four may reflect a reduction in separation distress or habituation to the test procedure. The higher cortisol concentrations of the experimental group may have been induced by the constant changes in social

environment and handling that the experimental group experienced. It was concluded that social facilitation increased the number of visits to the feeders, but had no effect on the stress and weight gain of recently weaned lambs.

Key Words: Welfare, Weaning, Lambs

M10 Bone quality, behavioural repertoire, and physical condition of laying hens housed in conventional, modified and furnished colony battery cages. M. J. Jendral*[1], D. R. Korver[1], J. S. Church[2], and J. R. Feddes[1], [1]*University of Alberta*, *Edmonton, Canada*, [2]*Alberta Agriculture, Food and Rural Development*, *Edmonton, Canada*.

The welfare of White Leghorn hens housed in conventional (CON) (30cm x 45cm) (n=84), modified (MOD) (n=84) (60cm x 45cm) and furnished colony (120cm x 110cm) (n=24) cages was investigated by evaluating bone quality, behavior and physical condition. All cages provided 450cm^2 floor space/hen. CON and MOD each housed 3 hens, and MOD contained a perch (30cm x 5cm) and nestbox (NB) (24cm x 45cm), providing an additional 360cm^2 of nest area/bird. Colony units, which housed 26 hens, contained a perch (120cm x 5cm), NB (60cm x 55cm) and were furnished with (CWDB) or without (CWODB) a dustbath (DB) (60cm x 20cm), providing each hen with 126cm^2 NB space, and in CWDB, 46cm^2 DB area. Video recordings at 35 and 60 wks were examined for locomotory behavior, and hen physical condition was scored at 31 and 65 wks. At 65 wks, hens were euthanized and right femur, tibia and humerus were excised for analysis. Data were analyzed using GLM for mixed effects, and scored condition values were compared by chi-square analysis. Effects were significant at $P<0.05$. CON hens exhibited lower femoral and tibial total mineral density and mass, cortical area and mass, and breaking strength than CWDB, CWODB or MOD hens, but higher density and cross sectional area of bone in the trabecular space. Total and cortical humeral density, mass and breaking strength were higher in CWDB and CWODB than in CON and MOD. Birds in CON cages exhibited more pacing, standing and escape behaviors, but fewer bouts of walking, wing flapping, stretching and ruffling than hens in furnished cages. CWDB and CWODB hens perched, jumped and walked more than hens in MOD. Average and total feather condition scores were higher for MOD and CON hens, as were the proportion of hens with higher scores for individual body regions, and head and vent wounds. Foot and claw condition were improved in furnished cages, and keel bone scores were lowest for MOD hens. These finding suggest that while group size impacts hen welfare, MOD and colony cages provide amenities that encourage movement, performance of natural behaviours and improved bone condition.

M11 Osteopontin expression during the periparturient period in dairy cows naturally infected with *Mycobacterium avium* subsp. *paratuberculosis* infection. E. L. Karcher*[1], D. C. Beitz[1], and J. R. Stabel[2], [1]*Iowa State University*, *Ames*, [2]*USDA-ARS-National Animal Disease Center*, *Ames, IA*.

Investigation of the role of osteopontin (Opn) in Johne's disease is of interest based upon its ability to influence cytokine expression and to improve host defense against mycobacterial infections. The objective of this study was to characterize Opn expression and secretion by peripheral blood mononuclear cells (PBMCs) isolated from periparturient dairy cows naturally infected with Mycobacterium avium subsp. paratuberculosis (MAP). Twenty-five multiparous Holstein cows were assigned to 3 groups based upon their infection status: 1) noninfected healthy cows (n = 8), subclinically infected cows (n = 10), and clinically infected cows (n = 7). Blood was collected from the jugular vein from 3 wks pre- through 5 wks post-calving. PBMCs were isolated from the buffy coat fractions of whole blood. PBMC were cultured for 24 h with and without MAP whole cell sonicate (MPS). RNA was extracted from cells, and converted to first-strand cDNA. Real-time PCR was performed on each sample to evaluate the expression of Opn. RT-PCR data was evaluated using $2^{-(\Delta\Delta Ct)}$ with samples calibrated within treatment to mean ΔΔCt value at one day after calving. Immunoblot analysis was performed for detection of Opn protein from cultured PBMCs. PBMCs isolated from subclinical cows expressed greater amounts of Opn mRNA compared with control ($P<0.06$) and clinical ($P<0.05$) cows. Expression was higher prepartum, followed by a decline at calving that was consistent until 21 days postpartum. MPS-stimulated PBMCs from subclinical cows expressed less Opn mRNA than control and clinical cows ($P<0.05$). There was no effect of parturition on expression from stimulated cells, regardless of treatment group. Immunoblot analysis of Opn detected a predominant band at 50 kDa and three minor bands at 62, 37, and 24 kDa. The data indicate an ability of MAP infection and parturition to modulate Opn expression.

Key Words: Periparturient, Osteopontin, *Mycobacterium avium* subsp. *paratuberculosis*

M12 Development of a novel enzyme-linked immunosorbent assay for the diagnosis of Johne's disease. S. Eda*[1], A. J. Branscum[2], Y. Kaneko[1], M. C. Scott[1], and C. A. Speer[1], [1]*University of Tennessee*, *Knoxville*, [2]*University of Kentucky*, *Lexington*.

Johne's disease (JD), caused by *Mycobacterium avium* subsp. *paratuberculosis* (MAP), has a significant economic impact on the US dairy cattle industry. Use of enzyme-linked immunosorbent assays (ELISA) to identify cattle for further fecal culture testing or for culling is listed as a recommended method for JD control in dairy and beef herds. However, several recent reports estimated diagnostic sensitivities of currently available ELISAs to be only 13.5 to 27.8%. For example, by using a Bayesian non-gold standard analysis, the diagnostic sensitivities of two current ELISAs were estimated to be 26-27%. Recently, it was predicted that if the diagnostic sensitivity of currently available ELISAs could be improved to 80%, then their use could result in an effective reduction of JD prevalence, higher level of milk production, and higher annual net revenue per cow. We developed a novel ELISA, called EVELISA, for the detection of MAP infections in cattle and is highly sensitive identifying 97.4% of fecal-culture positive cattle compared to a currently marketed ELISA that identified 50%. However, when 37 serum samples from a herd with a high rate of false-positives were tested by the EVELISA as well as a currently available ELISA, both ELISAs found more than 70% of the samples to be positive for JD. The false-positive rate of the

EVELISA was reduced significantly to 26.1% when the serum samples were pre-absorbed with *M. phlei*. By using the fecal culture method as the gold standard, empirical diagnostic sensitivity of the EVELISA using *M. phlei* absorption (absorbed EVELISA) was 97.1%, whereas that of a current ELISA was 48.5%. Moreover, a Bayesian non-gold standard analysis revealed that the absorbed EVELISA had a significantly higher level of diagnostic sensitivity (82%) than that of a current ELISA (22%). These data indicate that this novel ELISA is a rapid, inexpensive, specific, and highly sensitive test for JD which may improve the effectiveness of JD control measures.

Key Words: *Mycobacterium avium* subsp. *paratuberculosis*, Johne's disease, Enzyme-linked Immunosorbent Assay

M13 Effect of pasteurization on bacterial count and immunoglobulin G levels of bovine colostrum. J. A. Elizondo Salazar*, S. C. Donaldson, B. M. Jayarao, and A. J. Heinrichs, *The Pennsylvania State University*, *University Park*.

On-farm pasteurization of colostrum has received considerable attention in recent years, primarily to reduce bacterial pathogens present in colostrum. Application of this practice has been reported to result in significant health benefits for calves and economic returns for producers, however little information is available on the effect of pasteurization on immunoglobulin G (IgG) concentration. A study was conducted to determine the effect of low-temperature long-time pasteurization on the bacteriology and IgG levels in colostrum. First milking colostrum was collected from 28 primiparous and multiparous Holstein cows. Each sample was thoroughly mixed and two 10mL aliquots were analyzed. The first aliquot served as the control while the second aliquot was heated for 30 min at 62.8°C. The treated and untreated colostrum samples were examined for standard plate count (SPC), preliminary incubation count (PIC), coagulase-negative staphylococci (CNS) count, environmental streptococci (ES) count, coliform (CC) count, gram-negative noncoliform (NC) count, Streptococcus agalactiae (SAG) count, and Staphylococcus aureus (SA) count. IgG1 and IgG2 levels were measured using radial immunodiffusion. The results of the study showed that pasteurization resulted in a significant reduction of SPC, CC, NC, ES, CNS, SA, and PIC. Pasteurization also resulted in denaturation of 24% of colostral total IgG. The preliminary findings of the study suggest that gram-negative bacterial numbers (CC, NC) and gram-positive mastitis pathogens such as SA, CNS, and ES are considerably reduced.

Table 1. Bacterial count and immunoglobulin G levels of bovine colostrum before and after pasteurization.

	Unpasteurized	Pasteurized	SEM	*P*

M14 Measuring bovine colostrum specific gravity using two hydrometers at various temperatures. A. J. Heinrichs*, S. A. Belegundu, C. M. Jones, and J. A. Elizondo Salazar, *The Pennsylvania State University*, *University Park*.

An indirect measure of colostrum IgG quantity has been to measure specific gravity of colostrum and apply the data to a predetermined equation. This method has been used to some degree on farms for the past 25 years, utilizing a glass hydrometer with a specific calibration chart for colostrum at 22°C. While it is known that the relationship between specific gravity and IgG is variable, this method remains one of the few rapid, on-farm means to evaluate colostrum quality. Two different hydrometers were studied in this experiment, one a standard glass hydrometer fitted with the colostrum IgG calibration chart, the other a plastic hydrometer with a similar specific gravity range. Holstein colostrum samples (n = 146) were analyzed at 15.6, 21.1 and 26.7°C to determine correlations between the 2 hydrometers over a temperature range that is frequently observed when samples are tested on-farm. Specific gravity measurements for the glass hydrometer were calculated from IgG values recorded from the instrument's scale. The correlation for specific gravity between glass and plastic hydrometers was 0.96 over all temperatures and was 0.94, 0.97 and 0.98 at 15.6, 21.1 and 26.7°C, respectively. Specific gravity was different between 15.6 and 26.7°C for both glass and plastic hydrometers. This study shows that a plastic hydrometer can be equally effective in estimating colostrum specific gravity as a glass instrument, making it a viable option for on-farm use. The potential for improved durability of this tool may encourage expanded use of the hydrometer to estimate colostrum IgG content and thus improve passive transfer in calves.

M15 Changes in protein expression in *Escherichia coli* as a consequence of growth in milk whey. J. D. Lippolis* and T. A. Reinhards, *National Animal Disease Center / ARS/ USDA*, *Ames, IA*.

Understanding changes in protein expression by bacteria as they adapt to their environment and the pressures exerted by the host immune system to eliminate the bacteria will become a foundation to research into better therapeutics for treatment of bacterial infections. Shotgun Proteomics, using amine-reactive isobaric tags (iTRAQ) was used to quantify protein changes in Escherichia coli (mastitis isolate) grown in either Luria-Bertoni broth or milk whey. Changes in expression for over 264 proteins were obtained, 74 proteins that were down-regulated when the bacteria were grown in whey, 66 that were up-regulated and the rest were unchanged. Several proteins of immediate interest were those involve in iron transport. Iron(III) dicitrate transport protein (FECA) and Iron(III) dicitrate-binding periplasmic protein (FECB) were both up-regulated in E. coli when grown in whey by approximately 3.0 fold. An innate mechanism to limit bacterial growth is the sequestration of free iron by proteins such a lactoferrin. Therefore, necessary for successful growth in milk, bacteria must increase expression of proteins that bind and internalize iron. Our proteomic profiling suggests E. coli responded to the milk environment by increasing its own iron-binding proteins. Two proteins associated with osmotic regulation were also up-regulated when the E. coli was grown in whey. Osmotically-induced protein Y (OSMY) and Osmotically-inducible lipoprotein E (OSME) were up-regulated 4 and 5 fold respectively. There is evidence that osmotic regulation plays an important role in bacterial virulence by either affecting expression

of virulence genes or affecting bacterial growth in vivo. These data demonstrate that quantitative shotgun proteomics has great potential to provide new insights into how bacteria thrive in milk and may provide new insights into antibiotic therapies.

M16 Results of milk samples submitted for *Mycoplasma* spp examination from California dairies between 1999 and 2005. D. F. Resende*, R. G. S. Bruno, P. V. Rossito, K. Glenn, and J. S. Cullor, *University of California*, *Davis*.

The objective of this study was to study the prevalence of *Mycoplasma* spp in California, utilizing data from milk samples submitted to the Milk Quality laboratory located at the Veterinary Medicine Teaching and Research Center (VMTRC - UC Davis) in Tulare - CA with the majority of milk samples representing San Joaquin Valley. A total of 350,412 records of microbiological testing of individual animal milk samples (n=267,357) and bulk tank milk samples (n=83,055) submitted for screening of *Mycoplasma* spp between 1999 and 2005, including milk samples obtained from mastitis cases, routine herd checks and routine creameries samples, were reviewed. Bulk milk samples represent approximately 1100 dairies, and individual cow samples represent approximately 120 dairies. Samples were cultured on Mycoplasma agar plates (UC Davis media lab) and results were recorded as no growth, contaminated and positive. In a subset of samples Fluorescent Antibody Staining was performed for *Mycoplasma*spp identification. All data was analyzed using Minitab software (Minitab 14). 9,167 bulk tank milk samples, 6,405 individual cow samples and about 40% of the dairies tested positive for *Mycoplasma* spp. *Mycoplasma* spp prevalence in bulk milk tank samples was higher in 1999 (P<0.005) when compared to the other years (2000-2005), and prevalence in individual cow samples was higher in 2001(P<0.01). There was no difference among the other years (P<0.005). Incidence of *Mycoplasma* spp was not influenced by season (P>0.20). *Mycoplasma bovis* was the most common isolated species when compared to other *Mycoplasma* species (581 vs. 126 cases /year; P<0.005).The vast majority of both bulk milk tank samples and individual cow samples were characterized as no growth. In summary, among years, 1999 had the highest incidence of *Mycoplasma* spp and season did not affect this incidence. *Mycoplasma bovis* was the most abundant isolated species of *Mycoplasma* in bulk tank milk and individual cow samples.

Key Words: Mycoplasma, Milk Quality, Milk Samples

M17 Evaluation of Direct Fecal PCR and Serum ELISA for the Detection of *Mycobacterium avium* subsp. *paratuberculosis*. D. L. Clark*, J. J. Koziczkowski, R. P. Radcliff, R. A. Carlson, and J. L. E. Ellingson, *Marshfield Clinic*, *Marshfield, WI*.

Mycobacterium avium subsp. *paratuberculosis* (MAP) is the etiologic agent of Johne's disease in cattle. The disease causes diarrhea, reduced milk production, poor reproductivity, emaciation, and eventually death. Culture on Herrold's egg yolk agar (HEYA) is considered the gold standard for diagnosis of Johne's in cattle. Although sensitive and specific, the method can take up to 16 weeks due to slow growth of MAP. Currently serum ELISA is used to screen herds for Johne's disease but positive tests must be confirmed with culture or PCR. The current research sought to evaluate an in-house direct fecal PCR procedure and directly compare it to ELISA using culture as the gold standard. Serum and fecal samples were collected from cows (n=250) with unknown Johne's status. Fecal samples were processed for culture on HEYA and direct PCR. Serum samples were tested using the Parachek™ serum ELISA. Overall 67/250 (26.8%, 95% CI 21.4-32.8) animals were culturally confirmed as being infected. PCR and ELISA detected 74/250 (29.6% 95% CI 24-35.7) and 25/250 (10% 95% CI 6.6-14.4) respectively. Culture and PCR were able to detect more positive animals than ELISA ($P < 0.0001$). Overall, direct fecal PCR was 70.2% sensitive and 85.3% specific when using culture as the gold standard. The ELISA method was 31.3% sensitive and 97.8% specific. When culture reported < 10 CFU, the sensitivity and specificity of PCR and ELISA were 57.1% and 85.3%, and 4.8% and 97.8% respectively. When culture reported 11-39 CFU, the sensitivity of PCR and ELISA were 75% and 50% respectively. When culture reported > 40 CFU, the sensitivity of PCR and ELISA were 100% and 88.2% respectively. Specificity could not be calculated at these levels because there were no negative samples. Direct PCR out performed ELISA in diagnosing infected animals and was not significantly different when compared to culture. The direct fecal PCR method described here is economical, easy to use, and more accurate than the ELISA method. These data support the use of PCR as an alternative to culture for screening herds for prevalence and diagnosis of Johne's disease.

Key Words: Johne's, PCR, Paratuberculosis

M18 Effect of vitamin E and selenium administration on concentration of malondialdehyde in udder milk. P. Wicheanson[1], V. Harnpanichpun[2], V. Chupia[3], P. Vinitchaikul*[3], and W. Suriyasathaporn[3], [1]*Sixth year student, Faculty of Veterinary Medicine, Chiang Mai University*, *Muang, Chiang Mai, Thailand*, [2]*Dairy Product Research and Development Unit, Chiang Mai*, *Muang, Chiang Mai, Thailand*, [3]*Faculty of Veterinary Medicine, Chiang Mai University*, *Muang, Chiang Mai, Thailand*.

In response to mastitis, phagocytes generate superoxide to kill invading microorganisms, causing an increase of oxidative reaction in the udder. Although essential for survival, the undesirable repercussion of inappropriate or excessive oxidative reaction, the so-called oxidative stress, can cause tissue degeneration and consequently decrease in milk production. To reduce oxidative stress, it is possible that external administration of antioxidants might decrease oxidative stress in udder. The objective of this research was to determine the effect of vitamin E and selenium administration (Vit E-Se), an antioxidant, on concentrations of malondialdehyde (MDA), a oxidative stress marker, in udder milk. Fifty-eight dairy cows from six small holder farms in Chiang Mai were used. Milk samples were collected at morning milking. Twenty ml of commercial Vit E-Se with concentrations of 17 mg/ml of vitamin E and 1.67 mg/ml of selenium were administered after morning milking. Milk samples were collected at 6, 24, 72 hour after Vit E-Se administration. The samples was measured MDA with modified Smith's method. Due to data collected from the same cow, repeated measure analysis was used (Proc Mixed, SAS 8.0). MDA after Vit E-Se were compared with MDA before administration. Cow factor was defined as a repeated factor. Result shown that mean and SEM of MDA at before and after administration at 6th, 24th and 72nd hours were 1,370 +45, 1,133+28, 1,232+18 and 1,252+23 ppb, respectively. Concentration of MDA at before was higher than those after administration (p<0.05) There was no significant difference

of MDA between 24 and 72 hour after Vit E-Se. In conclusion, vitamin E and selenium administration result in decrease oxidative stress in udder.

Key Words: Vitamin E and Selenium, Dairy Milk, Malondialdehyde (MDA)

M19 Effect of feeding an immunostimulatory feed supplement (OmniGen-AF) during the dry period on somatic cell scores (SCS) in early lactation Holstein cows. H. T. Ballantine*[1], J. D. Chapman[2], Y.-Q Wang[4], and N. E. Forsberg[3,4], [1]*Ballantine Consulting*, *Hiram, GA*, [2]*Prince Agri Products*, *Quincy, IL*, [3]*Oregon State University*, *Corvallis*, [4]*OmniGen Research*, *Corvallis, OR*.

In previous studies, the feeding of a proprietary ingredient blend, OmniGen-AF (OG), (OmniGen-AF; Prince Agri Products) has been observed to increase the expression of markers of innate and acquired immunity. The goal of this study was to assess the hypothesis that OG, when fed to dry cows, had potential to reduce somatic cell scores (SCS) of cows in the subsequent lactation. The study was conducted on a commercial dairy in the southeast and included 114 Holstein cows. Cows were randomly assigned to one of two dry cow feeding regimens which consisted of a control ration program (0 g/h/d; n=46 cows) or a treatment ration program which consisted of feeding OG at 28 g/h/d to far-off dry cows and 56 g/h/d to close-up cows (n=68 cows). Animals were assigned to treatments as they entered the dry period over a period of 8 months. At freshening, all animals were managed similarly (i.e., no OmniGen-AF was fed during lactation). Milk production and SCS values were evaluated from monthly DHIA records and differences between treatment groups were assessed using ANOVA including treatment and parity as main effects. Addition of OG to the rations of dry cows had no effect on summit milk ($P>0.05$) which averaged 34.8 kg/day. SCS at the first DHIA test were not different ($P>0.05$) between the control (SCS=4.75) and OG-fed cows (SCS=4.45). SCS differences were detected between treatments at the second ($P=0.008$) and third ($P=0.022$) DHIA tests between control (SCS=5.31 and 4.78) and OG-fed cows (SCS=4.16 and 3.88). No differences in SCS were noted ($P=0.13$) between control and OG-fed dry cows animals at the fourth DHIA test. These results suggest that feeding OG during the dry period may be of benefit in reducing SCS in fresh cows in the subsequent lactation.

Key Words: OmniGen-AF, Somatic cells, Immunity

M20 Effect of intramammary treatment with Pirlimycin hydrochloride on antibiotic sensitivity of Gram-positive subclinical mastitis pathogens. M. D. Apparao, L. Oliveira, C. Hulland, and P. L. Ruegg*, *University of Wisconsin*, *Madison*.

The objective of this study was to evaluate the effect of intramammary treatment with pirlimycin hydrochloride on antibiotic sensitivity of subclinical mastitis pathogens. Cows (n = 254) from six WI dairy herds were screened for subclinical mastitis using the California Mastitis Test (CMT). Cows with at least one CMT positive quarter (n = 211) were randomly assigned to receive 50 mg intramammary pirlimycin in each positive quarter once daily for two consecutive days (labeled treatment) or no treatment. Duplicate aseptic milk samples were collected from all CMT positive quarters before treatment (pre-treatment) and 21 days after treatment (post-treatment). Target pathogens (Staphylococci spp and Streptococci spp.) isolated from milk samples were identified to the species level using laboratory procedures as defined by the NMC (1999). Treatment failures were defined as recovery of the same pathogen from pre and post-treatment milk samples. Cure was defined as absence of the causative pathogens or recovery of a different pathogen from the post treatment sample. Minimum Inhibitory Concentrations (MIC) were determined for Gram-positive pathogens using broth microdilution. Statistical analysis was done using PROC Univariate of SAS 9.1. Resistance was observed in 31% and 24% of pre and post treatment isolates, respectively. There was a significant difference between the pre- and post treatment MIC values for control quarters but no significant difference was observed for treated quarters. Microbiological cures were 37% and 52% for control and treated quarters, respectively. There was no association between results of antibiotic sensitivity testing and microbiological cures. Labeled usage of intramammary Pirlimycin had little short-term effect on the antibiotic sensitivity of Gram-positive subclinical mastitis pathogens but the outcomes of the sensitivity tests were poor predictors of microbiological cure of Gram-positive mastitis pathogens.

Key Words: Mastitis, Sensitivity Test, Antibiotics

M21 The effect of uterine infusion of ceftiofur in the immediate postpartum on lactation and reproduction in dairy cows. R. G. Bruno*, M. F. Sa Filho, F. S. Lima, V. J. A. Magalhaes, and J. E. P. Santos, *Veterinary Medicine Teaching and Research Center, University of California Davis*, *Tulare*.

Objectives were to evaluate the effect of intrauterine antibiotic treatment on lactation and reproduction in dairy cows. Holstein cows, 379, were randomly assigned to no treatment (CON, n=188), or a single uterine infusion (INF, n=191) of 500 mg of ceftiofur hydrochloride (Spectramast DC, Pfizer Animal Health) at 2 d in milk (DIM). Cows were presynchronized with two PGF2a injections at 37 and 51 DIM. Cows observed in estrus after the second PGF2a were inseminated, and those not in estrus received timed AI at 75 DIM. Ovaries were examined by ultrasonography at 35 and 42 DIM to determine cyclicity by the presence of a CL in at least one of the two examinations. Pregnancy was diagnosed at 38 and 66 d after the first AI. Yields of milk and milk components were measured once a month for the first 200 DIM. Survival and reproductive performance were evaluated for the first 240 DIM. Treatment did not affect ($P>0.10$) yields of milk and milk components and they were 39.5 and 39.0 Kg/d for milk, 1.39 and 1.35 kg/d for fat, and 1.18 and 1.17 Kg/d for true protein for CON and INF, respectively. Cows at high risk for uterine disease (retained placenta, milk fever, assisted calving, or twin calving) produced less ($P<0.01$) milk, fat and true protein than those at low risk. Infusion did not influence ($P=0.14$) prevalence of cyclic cows (50.9 vs 58.6%). Pregnancy rates at first AI were 30.4 and 29.7% for CON and INF ($P=0.88$). The median days open were similar ($P=0.18$) for CON and INF (170 vs 183 d). Similarly, survival time did not differ ($P=0.12$) between treatments and averaged 209 and 208 for CON and INF, respectively. Cows with subclinical endometritis had marked reduction ($P=0.02$) in first AI pregnancy rate (22.5 vs 34.3%) and extended ($P=0.01$) interval to pregnancy (189 vs 164 d). In summary, a single intrauterine infusion with 500 mg of ceftiofur did not improve lactation performance, resumption of ovulation, pregnancy rate at first AI and time to pregnancy, but cows with subclinical uterine inflammation had smaller pregnancy rate and extended interval to pregnancy.

Key Words: Ceftiofur, Dairy Cow, Reproduction

M22 Association of milk antimicrobial proteins with mastitis in dairy cattle. M. D. Person*, C. N. Person, T. D. Lester, and R. W. Rorie, *University of Arkansas*, *Fayetteville*.

Dairy cattle vary considerably in their susceptibility to mastitis, perhaps due to innate levels of milk antimicrobial proteins. This study evaluated the relationship between level of antimicrobial proteins in milk and incidence of mastitis. Milk samples were collected from 81 Holstein cows with at least three consecutive months of DHI records for somatic cell count (SCC). Composite milk samples were analyzed for the antimicrobial proteins, lysozyme, glucosaminidase, lactoferrin and lactoperoxidase. Based on SCC history and criteria established by DHIA, mastitis status of each cow was categorized as either new (SCC > 200,000 for the first time during current test date), chronic (SCC > 200,000 on two or more consecutive test dates), previous (classified as chronic previously, but current test SCC < 200,000), or no infection (SCC < 200,000). Levels of each of the milk antimicrobial proteins were then compared for cows in the four mastitis categories. Cows with new or chronic mastitis infections had higher (P = 0.0002) glucosaminidase levels (18.82 and 16.25 U, respectively) than cows with previous or no infection (9.31 and 9.26 U, respectively). Likewise, lactoferrin levels were higher (P = 0.008) for cows with new or chronic mastitis than for those with previous or no mastitis (141.78 and 99.92 versus 74.94 and 79.55 mg/L, respectively). No correlation was found between either lactoperoxidase (range of 970.77 to 1124.17 U/L) or lysozyme (range of 86.48 to 94.17 U/L) milk levels, and the mastitis categories (P = 0.6248 and 0.6830, respectively). Results suggest that glucosaminidase and lactoferrin increase in response to mastitis infection, rather than innate high levels of these proteins prevent mastitis since cows without mastitis had lower levels of these proteins than cows with infection. It is possible that a cow's ability to produce these proteins quickly in response to mastitis might reduce the severity and duration of infection.

Key Words: Mastitis, Cattle, Antimicrobial proteins

M23 Reduction of mortality and morbidity and increase in milk production in dairy livestock by plasmid-mediated growth hormone releasing hormone treatment during a period of high temperatures and humidity. P. A. Brown*, A. S. Khan, and R. Draghia-Akli, *ADViSYS Inc*, *Woodlands, TX*.

South Texas dairy farmers usually use a seasonal calving program to avoid the heat stress during the summer months. Pregnant Holstein heifers were relocated from South Dakota to Texas and calved June through September. The average temperatures and relative humidity (RH%) in South Texas resulting in high heat indexes (Table 1). In South Dakota, the climatic conditions would have been more favorable for calving (Table 1), We evaluated the potential of a plasmid-mediated growth hormone releasing hormone (GHRH) treatment to mitigate heat stress and its effects on the morbidity, mortality and milk production of treated animals and their offspring. In the third trimester of their pregnancy, thirty–two of the 52 heifers received 2.5 mg of a myogenic plasmid expressing a GHRH analog with increased half-life (pSP-HV-GHRH), while 20 heifers were used as controls. Body condition scores of treated animals vs. controls were statistically significantly better (3.55 vs. 3.35 at 60-80 days in milk (DIM), P < 0.0001), correlating with maintenance of IGF-I levels (P < 0.04) and body weights (r = 0.63). Hoof pathology was reduced with treatment. Involuntary culling of the pSP-HV-GHRH-treated animals was reduced by 40%. Mortality of heifers was significantly decreased (3% vs. 20% in controls, P < 0.003), while calves from treated heifers were 25% less likely to die at birth (18.8% vs. 25%), and from birth-to-260 days (0% vs. 20%). Overall calf mortality was reduced by 47%, P < 0.02. Calves from treated heifers were heavier at 260 days post-natal (P < 0.05). Milk production was increased by 10 to 22% (27.45 ± 0.89 kg/d vs. 23.2 ± 1 kg/d) in GHRH-treated animals compared to non-treated controls up to 300 DIM. This study demonstrates that treatment with a GHRH-expressing plasmid during the third trimester of pregnancy greatly improved the production, viability and general welfare of dairy cattle exposed to a four month period of high temperatures and humidity during late gestation and calving.

M24 Factors affecting death rate of lactating cows in Dairy Herd Improvement herds. R. H. Miller, H. D. Norman*, M. T. Kuhn, and J. R. Wright, *Agricultural Research Service, USDA*, *Beltsville, MD*.

Frequencies of deaths of lactating cows of all breeds from 2001 through 2005 were estimated from an approximate 10% sample of US Dairy Herd Improvement herds (based on units position of herd code). Herds with <400 lactations across years were excluded. Because the trait is binomially distributed (0 = live; 1 = dead), PROC GENMOD of SAS was used. To prevent failure to converge, herds with a death rate of <0.3% were excluded. Data from 998,599 lactations (793 herds) were analyzed. The model included herd, year that lactation ended, month that lactation ended, and parity (1, 2, …, 7, ≥8). Actual death rate was 3.9% per lactation. All effects were significant ($P < 0.0001$). Chi-square values for herd, year, month, and parity were 14,826, 1,447, 209, and 6,990, respectively. Parameter estimates from GENMOD were expressed as least squares means on the binomial scale. Differences among months were small, but frequencies were slightly higher for lactations that ended in February and March. Death rate steadily increased with parity; estimates of parity differences relative to first parity were 0.8, 2.1, 3.1, 3.8, 4.3, 4.5, and 5.8% for parities 2, 3, 4, 5, 6, 7, and ≥8, respectively. Cows were 4 times more likely to die during eighth lactation and later than during first lactation. Death rates increased from 2001 to 2005; estimates of year differences relative to 2001 were 0.1, 0.5, 1.9, and 2.1% for 2002, 2003, 2004, and 2005, respectively. The sharp increase in frequency from 2003 to 2004 may have resulted from changes in regulations for disposal of downer cows.

Key Words: Death Rate, Longevity, Herdlife

M25 Identification of Monascus purpurea (red yeast) contamination of silages in the mid-West. G. Seiler[1], Y. Wang[2], and N. E. Forsberg*[2,3], [1]*Heartland Veterinary Services*, *Goddard, KS*, [2]*OmniGen Research*, *Corvallis, OR*, [3]*Oregon State University*, *Corvallis*.

The goal of this study was to identify a red mold common in silages on dairies in the mid-West and to determine whether it had potential to account for health challenges on dairy farms. This type of red mold is widely reported by dairy practitioners and can achieve sizes exceeding one foot in diameter. The red aspect of the mold is found in the interior of the ball and may not be visible from the exterior. The rationale for completing this study was that appearance of the mold coincided with appearance of several clinical signs which might be attributed to the presence of this mold. Clinical signs included multiple births, birth deformities, early embryonic mortality and toxic metritis. No changes in milk production were associated with the mold. A sample of molded silage was recovered and applied to Sabouraud culture plates containing antibiotics. Red-colored colonies were recovered and DNA was isolated using a Qiagen kit procedure. DNA from the isolated mold was amplified using pan-fungal primer sequences which specified a 550 bp fragment extending from the 16S ribosomal DNA to the 28S ribosomal subunit. The product spanned both the ITS-1 and -2 domains. The PCR product was sequenced and identified via a BLAST search. Identity of the DNA was Monascus purpurea (100% match to database), also known as "red yeast". Implications to the feeding of M. purpurea-infected silage are not certain but a review of the literature indicates that this yeast secretes citrinin (a nephrotoxin and mild hepatotoxin). Red yeast has been used as a nutritional supplement for humans to reduce cholesterol. Several cholesterol-lowering compounds are present in the yeast (monocolins) some of which are patented for cholesterol-lowering properties. These have been reported to effectively reduce liver HMG-CoA reductase activity. Others have also reported a similar mold in silages known as Monascus ruber. M. ruber lies within the same clade as M. purpurea and, like M. purpurea, produces citrinin and monocolins. Implications of Monascus spp. to livestock health warrant additional study.

Key Words: Silage, Monascus, Mold

M26 *Neotyphodium coenophialum* exposure reduces carcass mass and ribeye area, but not meat quality of growing steers grazing high versus low endophyte infected forages. K. R. Brown*[1], R. B. Cox[1], G. A. Anderson[1], G. K. Rentfrow[1], L. P. Bush[1], J. R. Strickland[2], J. A. Boling[1], and J. C. Matthews[1], [1]*University of Kentucky*, *Lexington*, [2]*Forage-Animal Production Research Unit, USDA-ARS*, *Lexington, KY*.

Steers that graze toxic endophyte-infected tall fescue before undergoing a finishing feed regimen generally have compromised growth during finishing and carcass characteristics at slaughter. The potential effects of consumption of toxic endophyte-infected tall fescue on growth, carcass quality, and postmortem parameters of growing Angus steers slaughtered off of pasture were examined. Steers were randomly allotted by weight to either a low-endophyte (LE; 6.8% infection) mixed grass fescue pasture (n = 9; BW = 266 ± 10.9 kg; 5.7 ha) or a high endophyte (HE; 62.8% infection) fescue pasture (n = 10; BW = 267 ± 14.5 kg; 5.7 ha) for at least 85 d. Shrunk BW was measured at d 0, 36, 57 and 85, and carcass parameters taken at slaughter (d 89, 91, 98, 103, or 105). ADG was greater ($P < 0.01$) for LE than for HE (0.40 vs -0.05 kg, respectively) from d 0 to 36, but no treatment difference was observed for ADG or BW for the overall 85 d period. However, BW at slaughter ($P < 0.05$; 338 vs 313 kg), hot carcass BW ($P < 0.01$; 172 vs 148 kg), and dressing percentage ($P < 0.01$) of LE steers were greater than for HE. Although 12th rib backfat thickness did not differ between LE and HE, the REA of LE steers was greater ($P < 0.01$; 60.3 vs 51.7 cm^2). No differences in pH, a^* , b^* , or shear force of REA steaks were observed between LE and HE on d 7, 14, or 21 postmortem. Although no treatment effects were observed for hue angle and chroma values, REA steak L^* values of LE steers were 1.3 to 2.0 units higher ($P < 0.04$) than for HE at d 7, 14, and 21. These results indicate that steers grazing fescue pastures with a high percentage of endophyte infection have reduced carcass mass and REA, but not indices of meat quality after 85–105 d of exposure.

Key Words: Endophyte, Fescue, Growing Steers

M27 Plasma metabolite and mineral levels of dry cows out–wintered on brassica forages. P. Gazzola*[1,2], L. Boyle[1], P. French[1], A. Hanlon[2], and F. Mulligan[2], [1]*Teagasc*, *Fermoy, County Cork, Ireland*, [2]*University College Dublin*, *Belfield, Dublin, Ireland*.

Maintaining cows on plots of brassica forages during the winter (out–wintering) is an attractive low–cost management system. The aim of this study was to evaluate plasma metabolite and mineral levels of dry cows out-wintered on kale (Maris Kestrel) and swedes (Marian) to cows housed indoors fed grass silage. Cows (n=22 per treatment) were blocked according to parity, liveweight, body condition score (BCS) and calving date, and randomly assigned to treatment. Cows were scored for BCS fortnightly. Blood samples were collected from cows within 1 wk of their expected calving date, and then again 1 wk post–calving. Non–esterified fatty acids (NEFA), beta–hydroxy butyrate (BHB) and glucose were evaluated from blood plasma to measure metabolic status. Minerals measured include calcium (Ca), phosphorous (P), magnesium (Mg), copper (Cu) and glutathione–peroxidase (GSH–Px). Data was tested for normality using SAS (9.1) and analyzed using a mixed model which included the number of days prior to/post bleeding as a factor, block as a random variable and the pre–calving values as a co–variate for post–calving values. Indoor cows had a higher BCS (3.67) prior to calving compared to cows on swedes (3.32) but not to kale (3.40; SE 0.125; $P<0.05$). No difference in NEFA, BHB or glucose was detected at either the pre or post calving stage. Out-wintered cows on kale had lower plasma Cu levels (15.0 µmol/L) compared to swedes (19.1) and indoor cows (20.2; SE 0.93; $P<0.001$). Alternatively, cows on kale had a higher ($P<0.05$) GSH–Px levels (96.4 units / g HB) compared to swedes (80.7) but not indoor cows (86.4; SE 5.4). No difference was detected for Ca, P or Mg at the pre or post stage. Metabolite levels did not indicate any negative effects of out-wintering cows on kale or swedes. Cows out-wintered on kale are at risk of copper deficiency copper.

Key Words: Brassicas, Dry Dairy Cow, Metabolic and Mineral Status

M28 Grazing high versus low endophyte-infected tall fescue reduces contractility of bovine lateral saphenous veins. J. L. Klotz*[1], K. R. Brown[2], L. P. Bush[2], J. C. Matthews[2], J. A. Boling[2], and J. R. Strickland[1], [1]*USDA-ARS, FAPRU*, *Lexington, KY*, [2]*University of Kentucky*, *Lexington*.

Cattle that graze toxic endophyte-infected tall fescue are continuously exposed to a myriad of toxins that are known to negatively affect cardiovascular tissues. As part of a larger study documenting the physiologic impact of grazing endophyte-infected tall fescue in growing cattle, the objective was to examine the vasoconstrictive activities of 5-hydroxytryptamine (5HT), α-methylserotonin (ME5HT; a $5HT_2$ receptor agonist), D-lysergic acid (LSA), and ergovaline (ERV) as affected by consumption of 2 levels of toxic endophyte infected tall fescue. Segments (2-3 cm) of the cranial branch of lateral saphenous vein were collected at time of slaughter from steers following an 89-105 d grazing period of either a low endophyte-infected (LE) mixed grass pasture (6.8% infection; n=8; BW=336±9 kg) or a high endophyte-infected (HE) tall fescue pasture (62.8% infection; n=8; BW=317±9 kg). Veins were sliced into 2-3 mm sections and suspended in a myograph chamber containing 5 mL of oxygenated Krebs-Henseleit buffer (95% O_2/5%CO_2; pH=7.4; 37°C) and allowed to equilibrate at 1 g of tension for 90 min. Increasing concentrations ($1x10^{-11}$ to $1x10^{-4}$ *M*) of 5HT, ME5HT, LSA, and ERV were administered every 15 min. Data were normalized (%) to contractile response induced by a reference dose of norepinephrine ($1x10^{-4}$ *M*) and data for each treatment were analyzed for effects of concentration and endophyte level. Maximal contractile intensities ($1x10^{-4}$ *M*) were greater ($P<0.05$) for steers grazing LE pastures than HE pastures for 5HT (73.3 vs 48.9±2.1%), ME5HT (52.7 vs 24.9±1.5%), and ERV (65.7 vs 49.1±2.6%). Onset of contractile response did not differ for 5HT and ERV, but onset of ME5HT contraction was delayed ($P<0.05$) in HE steers to 10^{-4} compared to 10^{-5} *M* in LE grazing steers. Grazing of HE pastures for 89-105 d appears to induce functional alterations in blood vessels, as evidenced by reduced contractile capacity and altered serotonergic receptor activity.

Key Words: Bovine, Fescue, Vasoconstriction

M29 Ergocryptine and ergonovine induced contractile responses in fescue naïve bovine lateral saphenous veins. J. L. Klotz*[1], B. H. Kirch[1], G. E. Aiken[1], L. P. Bush[2], B. C. Arrington[2], and J. R. Strickland[1], [1]*USDA-ARS, FAPRU*, *Lexington, KY*, [2]*University of Kentucky*, *Lexington*.

α-Ergocryptine (ERP; ergopeptine alkaloid) and ergonovine (ERN; ergoline alkaloid) are two alkaloids found in endophyte-infected tall fescue. Various alkaloids found in endophyte-infected tall fescue have been shown to elicit different effects in the grazing animal. As part of an ongoing characterization of vascular response generated by different alkaloids, the objective this study was to examine the vasoconstrictive potentials of ERP and ERN using bovine lateral saphenous veins (cranial branch) biopsied from fescue naïve cattle. Segments (2-3 cm) of vein were surgically biopsied from healthy cross-bred yearling cattle (n=6; 280 ±26 kg). Veins were trimmed of excess fat and connective tissue, sliced into 2-3 mm sections and suspended in a myograph chamber containing 5 mL of oxygenated Krebs-Henseleit buffer (95% O_2/5% CO_2; pH = 7.4; 37°C). Tissue was allowed to equilibrate at 1 g of tension for 90 min prior to initiation of treatment additions. Increasing doses of ERP or ERN ($1x10^{-11}$ to $1x10^{-4}$ *M*) were administered every 15 min following buffer replacement. Data were normalized as a percent of contractile response induced by a reference dose of norepinephrine ($1x10^{-4}$ *M*). Exposure of vein segments to increasing concentrations of ERP and ERN did not result in appreciable contractile response until $1x10^{-7}$ *M*. The two alkaloids did not differ in potency, but did in contractile intensity, with the $1x10^{-4}$ *M* response to ERN and ERP reaching maximums of 68.5 ±7.7% and 42.9 ±7.9%, respectively. The contractile response to increasing concentrations of ERN and ERP were opposite from previous evaluations of ergoline (e.g. lysergic acid) and ergopeptine (e.g. ergovaline) alkaloids using this bioassay, where the ergopeptine generated the greatest contractile intensity. This experiment demonstrates two additional causative agents that may be involved in the loss of vascular plasticity concomitant with consumption of toxic endophyte-infected tall fescue.

Key Words: Alkaloid, Bovine, Vasoconstriction

M30 Defining cutoff points for subclinical endometritis at different stages of lactation. K. N. Galvão*, S. B. Brittin, M. Frajblat, and R. O. Gilbert, *Cornell University*, *Ithca, NY*.

The objective was to define cutoff points for subclinical endometritis at different stages of lactation based on uterine cytology. Holstein cows (555), from 7 different herds, had uterine cytology performed at 21, 35, and 49±7 d in milk (DIM) and the proportion of each leukocyte type out of 200 cells counted, including epithelial and excluding erythrocytes, was recorded. Receiver operating characteristic (ROC) curves were performed at each time point to select the best cutoff point, for each leukocyte type, to predict pregnancy by 150 DIM. After selection of a cutoff point for significant predictors, time to conception was evaluated using Kaplan-Meier survival analysis. A Cox model including the effects of parity, BCS, PGF2a treatment before first AI, cyclicity by 49 DIM, plus each significant leukocyte predictor separately, was performed for 382 cows with complete information. Open cows were censored at 300 DIM. At 21 DIM, none of the leukocytes were significant predictors of pregnancy. The proportion of neutrophils (PMN) at 35 and 49 DIM tended to be a significant ($P=0.08$) predictor of pregnancy and the cutoff point was 3.0% PMN in both time points. This cutoff point resulted in significant ($P<0.01$) differences in time to conception at 35 DIM and in a tendency ($P=0.10$) at 49 DIM. Median d to conception was longer for cows with more than 3% PMN at 35 DIM (151 vs 121 d) and at 49 DIM (159 vs 131 d). For the Cox model that included PMN cutoff points, cyclicity by 49 DIM was the only significant variable and cyclic cows had increased ($P=0.01$) hazard of conceiving. The mere presence of one macrophage (LMN) was a significant ($P=0.04$) predictor at 49 DIM. The median d to conception was longer ($P<0.01$) for cows having LMN (169 vs 130 d) and resulted in lower ($P<0.01$) hazard of conceiving using the Cox model. Lymphocytes (SMN) were not significant ($P>0.15$) predictors at any stage. We infer from these data that leukocytes at 21 DIM, LMN at 35 DIM, and SMN at any stage are not diagnostic for subclinical endometritis and that the cutoff point for diagnosing subclinical endometritis should be 3% PMN at 35 and 49 DIM or the presence of LMN at 49 DIM.

Key Words: Endometritis, Dairy cow

M31 Effects of selection for post-weaning BW gain on carcass characteristics of *Bos indicus* and tropical adapted *Bos taurus* breeds. S. F. M. Bonilha*[1,2], L. O. Tedeschi[1], I. U. Packer[2], A. G. Razook[3], G. F. Alleoni[4], F. D. Resende[5], R. F. Nardon[4], and L. A. Figueiredo[3], [1]*Texas A&M University*, *College Station*, [2]*ESALQ/USP*, *Piracicaba, SP, Brazil*, [3]*Instituto de Zootecnia*, *Sertãozinho, SP, Brazil*, [4]*Insituto de Zootecnia*, *Nova Odessa, SP, Brazil*, [5]*APTA*, *Colina, SP, Brazil*.

A genetic program for selecting post-weaning growth performance of *Bos indicus* and tropical adapted *Bos taurus* (Caracu) breeds was initiated in 1976 at Sertãozinho Experimental Station (São Paulo, Brazil). Several studies have found a significant effect of genetic selection on ADG and body size, but few studies have thoroughly evaluated the impact of this genetic selection on carcass characteristics and meat quality. Therefore, the objective of this work was to evaluate carcass characteristics of the selected progenies. Adjusted BW at 378 days of 414 bulls of genetic selected herds (Caracu, Ca; Nellore, NeS; Guzerah, GuS; and Gir, Gi) and unselected herd (Nellore, NeC), born from 1992 to 1999, were used. Animals across years were fed different diets (TRT) either under feedlot or grazing conditions and were slaughtered, on average, with 653 days of age. Data were analyzed using a random coefficients model, considering herd as fixed and TRT within year and year as random effects. Initial BW was used as a covariate. The table below shows the least-square means of ADG; empty BW (EBW); KPH; HCW, dressing percentage (DP), hindquarter percentage (HQP), rib-eye area (REA), fat thickness (FT), and Warner-Bratzler shear force (WBSF). We concluded that despite a greater ADG, EBW, HCW for Ca and NeS compared to NeC and Gi ($P < 0.05$), KPH and carcass characteristics (REA, FT, and WBSF) did not differ ($P > 0.05$). This indicated the genetic selection of Nellore increased HCW without affecting carcass deposition, composition and meat quality.

M32 Gene expression analysis of pig muscle associated to cholesterol and fat parameters. A. Cánovas[1], J. Casellas*[1], L. Varona[1], I. Díaz[2], R. Quintanilla[1], and R. N. Pena[1], [1]*Genètica i Millora Animal. IRTA-Lleida*, *Lleida, Spain*, [2]*Tecnologia dels Aliments. IRTA-Monells*, *Monells, Spain*.

The objective of this study is to detect and identify genes involved in lipid metabolism in pigs. With this purpose, we have used a microarray approach over muscle samples. The animal material came from an experimental Duroc population of 370 castrated males distributed in five half-sib families. A total of 70 *Gluteus medius* (GM) muscle samples were processed, belonging to animals with the most extreme levels (HIGH and LOW lines; 35 animals per line) for cholesterol and fat parameters such as plasma lipoprotein and triglycerides concentration, percentage of intramuscular fat and fatty acid composition in muscle. Each sample was individually hybridized using *GeneChip Porcine Genome*® arrays (*Affymetrix*). After normalizing data with the RMA algorithm, comparison between lines was performed with two different analyses: a standard t-test and a Bayesian analysis by means of a mixed model with heterogeneous residual variances. The t-test results showed a total of 1,007 genes whose expression levels differed significantly (p-value$<10^{-7}$) between the HIGH and LOW lines. Among these significant genes, 140 had a ratio of expression between the two lines superior to 1.5. The mixed model analysis resulted in a total of 500 genes differently expressed at a significant level (p-value$<10^{-9}$), 158 of which showed a ratio between classes greater than 1.5. It is worth mentioning the high coincidence of genes detected with both analyses. The great majority of these 158 genes (95.5%) have a known human homonymous with biological functions related to a variety of processes such as: transcription factor, lipid metabolism and RNA processing.

Key Words: Cholesterol, Gene Expression, *Gluteus Medius*

M33 Positive association between porcine PTHLH gene and teat number in a F_2 Meishan and Iberian crossbreed. M. Martinez*[1], J.L. Noguera[1], O. Ramirez[2], E. Alves[3], and R.N. Pena[1], [1]*Genètica i Millora Animal. IRTA-Lleida.*, *Lleida. Spain*, [2]*Departament de Ciència Animal i dels Aliments. UAB.*, *Bellaterra. Spain*, [3]*Departamento de Mejora Genética Animal. SGIT-INIA.*, *Madrid. Spain*.

The differentiation factor PTHLH (parathyroid hormone-like hormone) has an established role as a local modulator of epithelial-mesenchymal interactions such as those of bone, teeth, mammary gland and nipple development. PTHLH is expressed in placenta and in a variety of tissues at embryonic stages; however its role in adult tissue has not been well reported. PTHLH-knock out mice die at birth from complications of a chondrodysplastic syndrome, while reduction of PTHLH receptor expression decreased mammary gland and nipple development. A QTL was observed for teat number in chromosome 5, where the PTHLH gene is located. Based on this, we are investigating the PTHLH gene as a candidate gene for nipple development in a Meishan × Iberian (Ms×Ib) F_2 experimental intercross. These breeds differ substantially in teat number. A C>T non-synonymous polymorphism has been characterized in the coding region of pig PTHLH gene. An allelic discrimination assay was carried out in parental, F_1 and F_2 Ms×Ib animals. Statistical analysis was performed with a fixed effects model which included genotype (3 levels) and generation (2 levels). Iberian boars were all homozygous for allele C while the SNP was found to segregate in Meishan sows being allele C the most frequent. For the association study we have used the first two generations (F_1 and F_2) of the crossbred because we lack teat number information in parental generation. We observed significant differences between homozygous for allele C (13.40±0.08) and the other two genotypes: heterozygous (13.80±0.10; P=0.0004) and homozygous for allele T (14.21±0.36; P=0.025). This result must be confirmed with alternative statistical

models that included the information provided by neutral markers. This study has been financed by the project AGL2004-08368-C03/GAN.

Key Words: Swine, Teat Number, Parathyroid Hormone-Like Hormone

M34 Rapid characterization of radiation hybrid panel DNA by SYBR® Green I-based dissociation curve analysis and application for river buffalo gene mapping. K. J. Kochan[1], M. E. J. Amaral[2], and P. K. Riggs*[1], [1]*Texas A&M University*, *College Station*, [2]*IBILCE, UNESP*, *São José do Rio Preto, Brasil*.

High quality genome maps are essential for identification of genes affecting economically important traits in domestic animals, yet genomic resources remain scarce for many agriculturally important livestock species, including the river buffalo (*Bubalus bubalis*). Meat and milk production from river buffalo is a valuable world commodity, but its genetic map has not been well characterized. Radiation hybrid DNA mapping panels are widely-used tools for the generation of gene maps in numerous vertebrate species. A radiation hybrid panel was recently developed for river buffalo, and a framework map is under construction. Efficient utilization of available resources is necessary for completion of this map, so the objective of this project was to reduce reagent and labor cost by adaptation of SYBR® Green-based real-time PCR and dissociation curve analysis methods for map construction. SYBR® Green I chemistry has been employed extensively in other real-time PCR applications, including quantification of gene expression, detection of mRNA splice variants and DNA sequence polymorphisms, and detection of bacterial and viral pathogens. Differences in fragment length or sequence composition of the PCR products can be distinguished by analysis of the dissociation curve. As an initial test of the application of this method, 30 bovine microsatellite markers were selected from the cattle genome map for analysis. These markers were tested by PCR amplification of DNA samples from a *Bos taurus* bull (positive control), river buffalo bull, and Chinese hamster A23 fibroblast cells. Of these markers, 26 (87%) amplified in river buffalo DNA and exhibited dissociation curves that were distinguishable between river buffalo and hamster, and were used to generate a map of chromosome 20 (BBU 20). Thus, this method can be used for fast and efficient mapping, and the necessity of gel electrophoresis and photodocumentation of gels has been eliminated, reducing overall cost. This technique can be employed for mapping of additional chromosomes to generate a whole genome river buffalo framework map.

Key Words: River Buffalo, Radiation Hybrid Mapping

M35 Comparison of ribosomal protein gene distribution between full-length enriched cDNA libraries from multiple stages of porcine early embryo. R. S. Wu*, E. -C. Lin, C. C. Hsu, and W. T. K. Cheng, *Department of Animal Science and Technology, National Taiwan University*, *Taipei, Taiwan*.

Preimplantation stage influences porcine early development. Ribosomal proteins are responsible for some basic functions to support the normality of embryogenesis during this period. In order to compare ribosomal protein gene expression between different stages of early embryo, the expressed sequence tags (ESTs) of ribosomal protein genes were extracted from porcine multiple embryonic stages: 4-cell, 8-cell, morula and early blastocyst. The strategy of the library construction is to generate full-length enriched cDNA library in early embryogenesis. Furthermore, the percentages of cDNA clones annotated were calculated as eighty ribosomal protein genes in the four libraries for statistical comparison of distribution for each ribosomal protein genes (4-cell vs. 8-cell; morula vs. early blastocyst). After cleaning those clones of low quality, short insertion and low complexity, the remaining sequences of high quality (N=31,339) were clustered into groups according to sequence similarity (≥ 95% identity and 90 bp minimum overlapping) to produce 1,378 clusters and 2,139 singletons. The ESTs of different ribosomal protein genes contained in the four libraries were different (4-cell: 10%, 8-cell: 6%, morula: 30% and early blastocyst: 63%). The ESTs frequency for 7 kinds of ribosomal protein genes were found to be significantly different between 4-cell and 8-cell embryos with R statistics from 12 to 47 (4-cell > 8-cell: 6 ; 8-cell > 4-cell: 1). As well, the ESTs frequency for 37 kinds of ribosomal protein genes were found to be significantly different between morula and early blastocyst with R statistics from 9 to 134 (morula > early blastocyst: 2 ; early blastocyst > morula: 35). The results described above showed that several ribosomal protein genes might be responsible for certain biological functions in the early embryogenesis in pigs.

Key Words: Ribosomal Protein, Early Embryogenesis, Pigs

M36 Use of random regression model in the milk yield analysis of water buffaloes. A. A. Ramos*[1], C. V. Araújo[2], S. I. Araújo[2], and D. C. P. Pereira[2], [1]*Sao Paulo State University*, *Botucatu, SP, Brazil*, [2]*Federal Rural University of Amazonia*, *Belém, PA, Brazil*.

Data comprising 1,719 milk yield controls of 357 females (predominantly Murrah breed) daughters of 110 sires, with births from 1974 to 2004, obtained from the Programa de Melhoramento Genético de Bubalinos (PROMEBUL) and also from records of EMBRAPA Amazónia Oriental - EAO herd, located in Belém, Pará State, were used to compare random regression models, for estimating variance components and predicting breeding values of the sires. Data of milk yield were analyzed by different random regression models using the Legendre's orthogonal polynomials functions of second, third and fourth orders. The random regression models included the effects of herd-year, month of parity date of the control; regression coefficients for age of females (in order to describe the fixed part of the lactation curve) and random regression coefficients related to the direct genetic effects and the permanent environment. The comparisons among the models were based on the Akaike Criteria Infromation. The random regression model that used the third order Legendre's polynomials and four class of the environmental effect was the one which better described the additive genetic variation of milk yield.The heritability estimates varied from 0.08 to 0.40. The genetic correlation between milk yields in younger ages was close to the unit, but in older ages was low.

Key Words: Genetic Evaluation, Murrah Breed, Milk Yield

M37 Effects of cytoplasmic line on scrotal circumference and semen quality traits in Angus bulls. A. G. Garmyn* and D. W. Moser, *Kansas State University*, *Manhattan*.

The purpose of this study was to estimate the heritability of semen traits, genetic correlations between scrotal circumference (SC) and

semen quality parameters, and the effect of cytoplasmic line on semen traits. Breeding soundness exam (BSE) data was collected on registered Angus bulls at four ranches over seven years. The American Angus Association provided historical pedigree information to estimate the effect of cytoplasmic line on SC and semen quality traits. After editing, the evaluated dataset contained 1,281 bulls with BSE data that traced to 100 founder dams. Data were analyzed using a two-trait animal model to obtain heritability, genetic correlation between SC and semen quality traits, as well as the effect of cytoplasmic line as a random effect for SC, percent motility (MOT), percent primary abnormalities (PRIM), percent secondary abnormalities (SEC), and percent total abnormalities (TOT) using MTDFREML. Fixed effects included source ranch and birth year, and test age was used as a covariate. Estimates of heritability for SC, MOT, PRIM, SEC and TOT were 0.46, 0.05, 0.27, 0.24, and 0.25, respectively. Genetic correlations between SC and MOT, PRIM, SEC, and TOT were 0.37, -0.20, -0.13, and -0.25, respectively. The proportions of phenotypic variance accounted for by cytoplasmic line for SC, MOT, PRIM, SEC, and TOT were <0.001, 0.013, 0.022, 0.0023, and <0.001, respectively. Genetic correlations between SC and semen quality traits were low to moderate and favorable. Cytoplasmic line may have a marginal effect on MOT and PRIM, but is likely not a significant source of variation for SC, SEC, or TOT.

Key Words: Bulls, Cytoplasmic Line, Semen

M38 Effect of temperature and humidity on gestation length. H. D. Norman, J. R. Wright*, and J. B. Cole, *Agricultural Research Service, USDA*, *Beltsville, MD*.

High temperature and humidity have been shown to suppress daily milk and component yields of dairy cows, but their effects on most other performance traits have not been investigated. To determine if monthly differences in GL are caused by temperature and humidity, meteorological data since 1997 recorded at 238 weather stations was used in conjunction with national data for nearly 7 million calvings from 1999 through 2005. Temperature and relative humidity recorded at the weather station closest to the herd were combined into temperature-humidity indexes (THI): THI = (1.8T + 32) – (0.55 – 0.0055H)(1.8T – 28), where T is temperature in °C and H is relative humidity expressed as a percentage, for the week prior to calving and for calving day. Effect of weekly and calving-day THI on GL were compared with a model that accounted for THI, calving day, calving year, calving herd-year, calving month, age-parity, calf birth code (gender and multiple-birth status), lactation length, milk yield, service sire, sire, and cow. All effects were fixed except service sire, sire, and cow. Effect of THI on GL without calving month in the model also was examined. When weekly THI was 36 to 40, 56 to 60, and 76 to 80 with calving month in the model, GL was 279.7, 279.5, and 279.1 d, respectively; without calving month in the model, GL was 280.2, 279.8, and 278.6 d. Excluding calving month from the model resulted in greater variation in GL, which became shorter at an accelerated rate as THI increased. Calving-day THI were less effective than weekly THI in accounting for GL differences. Although the benefit of including THI in the model was rather limited if calving month was already considered, GL still became noticeably shorter when THI was >70. Either calving month or THI can be effective in helping to predict calving dates.

Key Words: Gestation Length, Heat stress, Temperature-Humidity Index

M39 Relationship of gestation length to stillbirth. R. L. Powell*, H. D. Norman, and J. R. Wright, *Agricultural Research Service, USDA*, *Beltsville, MD*.

Gestation length (GL) has economic and management effects, but its relationship to stillbirth (SB) has not been well documented. Mean Holstein SB rate by GL was examined using >800,000 Holstein calvings with SB data from 1999 through 2005. Data were limited to calvings with a GL of 260 to 295 d from herds with ≥15 calvings with SB data that included ≥3 reported SB. The SB rate was 17.8% for GL of <270 d, 5.0% for GL of 278 to 282 d, and 8.1% for GL of >290 d. Genetic parameters for SB were estimated with a linear model that included fixed effects for calving year, calving herd-year, age-parity, calf birth code (gender and multiple-birth status), lactation length, and milk yield and random effects for service sire, sire, and cow. Effect of calving year on SB rate was small. The SB rate was 1.5% higher for calvings in December and January compared with April to June, 2% higher for lactations of >500 d compared with <250 d, and 2% higher for milk yield of <6,000 kg compared with >16,000 kg. Multiple birth tripled SB rate. Heritability estimates for SB were 0.6% for service sire and 1.2% for sire (2.3% and 4.6%, respectively, when transformed to an assumed underlying scale); heritabilities for February 2007 USDA SB evaluations, which are calculated with a threshold model, were 3.0% for service sire and 5.8% for sire. Correlations of calculated service-sire and sire SB predicted transmitting abilities (PTA) with corresponding February 2007 USDA SB PTA were 0.77 and 0.82 for bulls with >100 daughters with SB data. Correlations of GL PTA, which accounted for the same effects as for SB PTA, with February 2007 USDA SB PTA were 0.20 for service-sire traits and 0.03 for sire traits for bulls with ≥100 observations for each trait (1,613 service sires; 1,040 sires). Of those bulls that were in active artificial-insemination service (132 service sires; 109 sires), corresponding correlations were 0.38 and 0.09. Linear regression of SB PTA on GL PTA showed a 0.07% increase in service sire SB PTA ($P > 0.05$) and a 0.14% increase in sire SB PTA ($P < 0.0001$) for each 1-d increase in corresponding GL PTA.

Key Words: Genetic Evaluation, Stillbirth, Gestation Length

M40 Genomic structure and polymorphisms of the bovine c21orf66 gene. K. R. Wunderlich*, C. A. Abbey, and C. A. Gill, *Texas A&M University*, *College Station*.

The c21orf66 gene is a putative transcription factor with no known function that lies within the polled interval on BTA1. In humans, this gene spans approximately 37,000 bp and alternative splicing results in at least 4 variant isoforms. The objective of this study was to evaluate this gene as a positional candidate for polled and characterize the genomic structure of this gene in bovine. In order to characterize c21orf66, we assembled bovine whole-genome shotgun, bacterial artificial chromosome, expressed sequence tag, and in-house sequence data into a contig spanning over 50,000 bases to include c21orf66, its promoter, and its 3' end. As in humans and mice, and based on this sequence information, this gene has 18 exons. The contig also served as a reference sequence for SNP discovery through the sequencing of 93 animals from within a breed panel consisting of Angus, horned Hereford, polled Hereford, Ankole, Brahman, Nelore, and Simmental. Single nucleotide polymorphisms within breeds were identified using polyPHRED followed by manual verification in Consed, and then consensus sequences were compared between breeds. The number of confirmed SNPs within c21orf66 for each individual breed varied from

29 to 98 with a total of 145 SNPs discovered across all breeds. The average spacing between SNPs was 363 bp and the average ratio for transitions vs. transverions was 1:2.6. Additionally, 7 indels were also discovered. However, no single SNP or insertion/deletion discovered is consistently different between the horned and polled consensus sequences and thus cannot be attributed as the causative mutation for polled.

Key Words: c21orf66, Bovine, SNP

M41 Application of the Sleeping Beauty transposon system to avian cells. B-W. Kong*[1], L. K. Foster[2], and D. N. Foster[2], [1]*University of Arkansas*, *Fayetteville*, [2]*University of Minnesota*, *St. Paul*.

The Sleeping Beauty (SB) transposon system is a member of the Tc1/mariner superfamily of DNA transposable elements which have been reconstructed from inactive elements found in salmonids fish. The SB system was developed for gene therapy and mutagenesis in human and mouse species, and until now, has not been shown to function in chicken and turkey cells as a molecular tool for avian transgenesis and chromosome engineering. The transposon construct was generated using the antibiotic (puromycin) selectable marker flanked by the Sleeping Beauty repeat sequences in the improved transposon vector, pT2 (pT2/Puro). To test the ability of SB-mediated transposition in avian species, immortal DF-1 chicken embryo fibroblast (CEF), breast-derived CEF (BCEF) and turkey turbinate-derived (TT-1) cell lines were transfected with a selectable transposon (pT2/puro) vector with or without the transposase (pCMV/SB) vector. Following antibiotic selection, resistant foci were stained and counted to determine relative transposition frequencies. DF-1 CEF cells co-transfected with the transposon and SB vector (pT2/puro + pCMV/SB) showed an approximate 1300-fold increase in the number of foci, compared to the non-transposon vector control (pCMV/puro). When SB mediated transposition was compared to non-SB mediated transposition, the SB co-transfected immortal TT-1, BCEF, and DF-1 CEF cells showed approximately 15-, 20-, and 40-fold increases in the number of puromycin resistant colonies, respectively. This suggests that the ″cut and paste″ manner of foreign gene insertion into genomic DNA using SB system possibly could be more effective than the nicking mechanism for the incorporation of a non-transposable expression vector. Of interest, primary CEF cells did not show significant increased SB-mediated transfection or transposition efficiencies, suggesting that a more efficient transfection method is needed in order to apply SB-mediated transposition in primary avian cells. In conclusion, we have demonstrated that the SB transposon system can be utilized for the mutagenesis of avian cultured cells.

Key Words: Sleeping Beauty Transposon, Mutagenesis, Avian Cell Lines

M42 Evaluation of growth traits of Brazilian herefords using multivariate analysis. J. C. Souza*[1,2], L. T. Campos[3], J. A. Freitas[2], R. Weaber[4], and W. R. Lamberson[4], [1]*Scholarship of CNPq*, *Brazil*, [2]*Parana Federal University*, *Palontina, Brazil*, [3]*Engenheiro Agronomo*, *Brazil*, [4]*Univeristy of Missouri*, *Columbia*.

The objective was to evaluate growth and conformation of Brazilian Herefords using principal component (PC) analysis. Traits analyzed included birth weight (BW); weaning weight (WWT); weight adjusted to 205 d (W205); daily and total gain birth to weaning (DGBW, TGBW); observed yearling weight (OW365); weight adjusted to 365 d (W365); daily and total gain weaning to yearling (DGWY, TGWY) and scores of conformation (CS); maturity (MAT); muscle (MS); and frame (FS). Eigenvalues of the first three PC were 5.33 (41%), 3.75 (29%) and 2.03 (16%). The correlations among W205, DGWT and W365 were high and positive as were those among CS, MAT, MS, and FS, but were near zero between these sets of traits. Traits contributing most to the first PC were W365 (0.40) and W205 (0.38), to the second PC were CS (0.48), MAT, MS and FS (0.47). Genetic parameters for W205, W365 and PC1 were estimated with MTDFREML using a univariate animal model fitting contemporary group (year, herd, management, season and sex) and age of dam (linear and quadratic covariate) as fixed effects and direct and maternal genetic, their covariance, and uncorrelated maternal permanent environment (c^2) as random effects. For W205, W365 and PC1, respectively, estimates of direct h^2 were 0.22 ± 0.14; 0.50 ± 0.02; 0.44 ± 0.03; of maternal h^2 were 0.13 ± 0.02; 0.13 ± 0.02; 0.14 ± 0.04; and c^2 were 0.07 ± 0.10; 0.07 ± 0.01; 0.09 ± 0.02 and correlations between direct and maternal genetic effects were -0.67 ± 0.04; -0.80 ± 0.03;-0.64 ± 0.06. Both direct and maternal heritabilities were of expected magnitude as was the negative direct-maternal correlation. The first principal component, weighted heavily toward growth traits, had similar estimates of genetic parameters. Principal components can be used to consolidate correlated traits into a simpler set of groupings.

Key Words: Beef Cattle, Growth, Heritability

M43 Molecular evidence that turkey varieties belong to a single breed. E. Smith*, J. Xu, X. Guan, T. Geng, and D. Kamara, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Using a total of 250 birds from seven varieties, we investigated the relatedness among and within different populations of the domestic turkey, Meleagris gallopavo. The molecular markers used in the investigation were obtained from both nuclear and mitochondrial genome. From the nuclear genome, the markers used were microsatellite, SNP, and RAPD-based. The mitochondrial-based markers, developed from the whole genome sequence obtained for this work and submitted to GenBank (Accession number assigned is EF_153719) were d-loop and 16S rRNA-based. In addition to variants in the mitochondria, a total of 15 markers formed the basis of the analyses. Together, the analyses suggest that except for the Royal Palm, the turkey varieties are very closely related with a higher genetic variation within than among the populations. The Royal Palm appears to be distant from all the varieties including the commercial turkey as alleles of several distinct markers and marker-types were absent in other varieties but fixed in the Royal Palm populations. The Royal Palm appears to be distant from all the varieties including the commercial turkey, as alleles of several distinct markers and marker-types were absent in other varieties but fixed in the Royal Palm populations. However, consistent with morphological reports, results suggest that turkey varieties originated from a single breed.

Key Words: Turkey, Varieties, Molecular Phylogeny

M44 Evaluation of nucleolar proliferating protein 1 as a candidate gene for beef carcass characteristics. J. H. Bosques-Méndez*[1], M. Pagan[1], E. Casas[2], A. Casas[1], and D. Cianzio[1], [1]*University of Puerto Rico*, *Mayagüez, Puerto Rico*, [2]*Roman L. Hruska USDA MARC*, *Clay Center, NE*.

Single nucleotide polymorphisms (SNP) identified in four regions of nucleolar proliferating protein 1 (Nol1: A, B, C and D) were evaluated for associations with carcass traits. Genotyping was performed in a group of 42 Senepol x Charolais and Angus × Charolais crossbred bulls grazing tropical grass from weaning to harvest. Nol1-A was associated (P<0.05) with shrinkage percentage (SH), Obliquous muscle weight (OM; kg), trimmed fat (TF; kg), and dressing percentage (DP). Animals inheriting the TT and CT genotype had greater SH, OM and DP than those inheriting the CC genotype. Nol1-B was associated (P<0.05) with SH, left hindquarter weight (LHQ; kg), OM, hindquarter percentage (HQP), frontquarter percentage (FQP), total muscle weight (TMW; kg), and slaughter weight (SW; kg). Animals with the CC and CT genotypes were heavier than those inheriting the TT genotype. Associations (P<0.05) between Nol1-C and SH, Gastrocnemius muscle weight (GM; kg), TF, LHQ and TMW were detected. Animals having the AA genotype had greater values for SH and GM compared with animals with the AG and GG genotypes. Animals inheriting the GG genotype had greater TF than the other genotypic groups. For Nol1-D, associations where ascertained for HQP, FQP, LHQ, TMW. No animals inherited the AA genotype, but AG animals had greater values for HQP, LHQ and TMW. Although larger studies need to be conducted, results from this study indicate that markers at the nuclear proliferating protein 1 gene are associated with important carcass traits for beef cattle in the tropics.

Key Words: Nol1, SNP, Carcass

M45 Application of Wilmink's function to Bayesian inference of heritability for monthly test day milk yields in Iranian Holsteins. H. Farhangfar*, *Birjand University*, *Birjand, Iran*.

To estimate heritability of individual monthly test day milk yields in Iranian Holstein heifers, a total of 32854 test day records collected from 3842 first lactation Holsteins (progeny of 466 sires) calving from 2001 to 2005 and distributed in 125 herds of Razavi Khorasan province of Iran was used. Bayesian statistical method via Gibbs sampling technique in a random regression test day animal model was applied. In the random regression model, fixed environmental effect of herd-year-month of test-milking times (as contemporary group with 1359 levels), covariables (linear and quadratic) of cow age at calving, linear covariable of Holstein gene as well as random effects of direct additive genetic and permanent environment were included. Wilmink's function ($y = a + bt + c(Exp(-0.05t))$) was also included in the random regression test day model as a sub-model to take account of milk yield variation over the course of the lactation at two genetic and environmental levels. Heterogeneous environmental variance was assumed over the course of lactation. The analysis was undertaken using RRGIBBS software in which Bayesian heritability estimates of test day milk yields were obtained through 50000 rounds Gibbs sampling from which the first 10000 chains was considered as burn-in period. The lowest and greatest heritabilities were obtained for months 2 (0.236) and 10 (0.361) of the lactation period respectively. The results of the present research also showed that permanent environmental variance as a proportion of the phenotypic variance were maximum (0.625) and minimum (0.337) for the first and fourth month of the lactation course.

Key Words: Wilmink's Function, Bayesian Estimate, Iranian Holstein

M46 Bivariate genetic analysis of monthly test day milk yield and protein percentage for Holstein heifers in Khorasan province of Iran. H. Farhangfar*, R. Lotfi, and H. Naeemipour, *Birjand University*, *Birjand, Iran*.

In this study a bivariate animal model was used to estimate genetic parameters of monthly test day milk yield and protein percentage for Holstein heifers in Khorasan province of Iran. The data was 27673 monthly test day records obtained from 4125 first lactation cows (representing 430 sires and 3744 dams) calving between 2002 and 2005 in 113 herds. The average milk yield and protein percentage over the course of the lactation were 28.69 Kg and 3.27% respectively. In the repeatability test day model, the environmental factors were the combined effect of herd-year-season of production (as contemporary group), stage of lactation, milking times, covariables of Holstein gene (linear) and age of cow at recording (linear and quadratic). Random effects of direct additive genetic as well as permanent environment were also included in the model. Genetic and environmental variance and covariance components were estimated by AI-REML algorithm implemented in DMU package. The results obtained in the present study showed that the heritabilities of milk yield and protein percentage were 0.100 and 0.048 respectively. Additive genetic, permanent and temporary environment correlations between the traits were -0.147, -0.713 and -0.069 respectively. Repeatability estimate of monthly test day milk yield was found to be 0.601 while the corresponding estimate for monthly test day protein percentage was 0.092.

Key Words: Animal Model, Heritability, Iranian Holstein

M47 Insemination of Holstein cows with sexed sperm. J. L. Schenk*[1] and R. W. Everett[2], [1]*XY, Inc.*, *Fort Collins, CO*, [2]*Cornell University*, *Ithaca, NY*.

Most research with sex-sorted sperm has been limited to heifers. The objective of this field trial was to determine pregnancy rates in lactating dairy cows following AI of frozen-thawed X-chromosome-bearing sperm. Sperm were sorted with a MoFlo® SX flow cytometer on the basis of DNA content, targeting 90% purity of X-sperm. Holstein cows (N=2197), lactations 1 - 4 and 20 - 140 DIM were inseminated 12 or 24 h after synchronized ($PGF_{2\alpha}$ or Ovsynch) or natural estrus. Three experimental treatments, unsorted control (20 x 10^6 sperm/dose) in 0.25 mL straws and sex-sorted (2 x 10^6 sperm/dose) in 0.25 mL or 0.5 mL straws, were balanced over 3 Holstein bulls. Equal numbers of straws of each treatment x bull combination were distributed to 7 commercial dairies. AI services were limited to two per cow and performed by multiple technicians. Pregnancy was determined via rectal palpation at ~60 d after insemination. Data were analyzed with a mixed model ANOVA that included environmental and biological variables known to influence pregnancy rates in cows. Pregnancy rates from sexed sperm were similar (P>.05) for 0.25 mL (25.0%) and 0.5 mL (24.4%) straws, but different (P<.001) from controls (37.7%). Pregnancy rates with sexed sperm were >12 percentage points lower than those for unsexed sperm (64% of controls). Pregnancy rates for

sexed sperm after 84 - 98 DIM were 7.9 percentage points higher than earlier in lactation and >6 percentage points lower in 3rd and 4th lactation cows compared to 2nd lactation cows. The range of differences between bulls (6.7 percentage points; P<.001) was consistent across treatments. Pregnancy rates were similar between cows synchronized with $PGF_{2\alpha}$ or Ovsynch (P>.05), but 15 percentage points higher for natural estrus compared to Ovsynch (P<.001). Use of sexed sperm will reduce pregnancy rates ~12 percentage points compared to unsexed sperm in lactataing cows. Limiting use of sexed sperm to 1st and 2nd lactation cows after an elective postpartum waiting period of >100 DIM will yield the highest pregnancy rates with sexed and unsexed sperm.

Key Words: Dairy Cows, Pregnancy, Sexed Sperm

M48 Genetic trends for dairy traits in the Holstein x Other Breeds multibreed dairy cattle population in tropical central Thailand. S. Koonawootrittriron[1], M. A. Elzo*[2], and T. Tongprapi[3], [1]*Kasetsart University*, *Bangkok, Thailand*, [2]*University of Florida*, *Gainesville*, [3]*Dairy Farming Promotion Organization*, *Saraburi, Thailand*.

There has been a concerted effort to increase milk production in Thailand over the past 35 years. This effort has been a combination of government policies, importation and widespread use of Holstein semen, and extensive use of high percent Holstein sires generated in Thailand. This mating strategy has resulted in a multibreed dairy population where 90% of animals are 75% Holstein or greater. Central Thailand is the most important dairy region. The objective of this research was to assess genetic variability and genetic trends for 305-d milk yield (MY), 305-d fat yield (FY), and average 305-d fat percent (FP) in Central Thailand from 1991 to 2005. Data consisted of 15,260 monthly test-day records from 1,377 first-lactation cows collected in 92 farms from 1991 to 2005. Dairies in Thailand maintain cows in open barns, and less than 10% use fans to reduce heat stress. Estimates of variance and covariance components and breeding values (EBV) were obtained using a multiple-trait animal model. Fixed effects were contemporary group (herd-year-season), calving age, and additive genetic group as a function of Holstein fraction. Random effects were animal and residual. Program ASREML was used to perform computations. Estimates of heritabilities were 0.39 ± 0.10 for MY, 0.26 ± 0.10 for FY, and 0.21 ± 0.11 for FP. Although the difference between the mean MY for cows in 2005 and 1991 was 79.3 kg, the regression of mean cow EBV for MY on year was only 0.9 kg/yr. Differences between mean cow EBV for FY and FP in 1991 and 2005 and their corresponding regressions of mean FY and FP on year were all near zero. Similarly, mean EBV for sires and dams of cows also showed near zero trends during these years. The absence of genetic trends suggests that high percent Holstein cows are not reaching their production potential under the management, nutrition, and hot and humid climatic conditions in this tropical region.

Key Words: Multibreed, Cattle, Tropical

M49 Multi-trait evaluation for calving ease and stillbirth with separate genetic effects by parity. G. R. Wiggans, J. C. Cole, and L. L. M. Thornton*, *Agricultural Research Service, USDA*, *Beltsville, MD*.

Genetic evaluations for calving ease and stillbirth were calculated with Holstein and Brown Swiss data from 14,164,522 calving reports in the USDA national dairy database. Calving ease was measured on a scale of 1 (no difficulty) to 5 (difficult birth); stillbirth status was designated as live or dead within 48 hr. Calving-ease scores were transformed separately for first and later parities and calf gender. The score used in the analysis was on a unit standard deviation scale in the middle of the range for each score. Stillbirth status was present for 53% of calving-ease observations. Variance components were estimated from a 103,909-record Holstein sample with no missing observations, which represented the 2,999 bulls with the most data. For calving ease and stillbirth in first and later parities, a multitrait sire-maternal grandsire (MGS) linear model included fixed effects for year-season, gender, sire birth year, and MGS birth year and random effects for herd-year interaction, sire, and MGS was applied. For later parities, gender effects were separated by parity. The correlation between first and later parities was 0.69 for sire and 0.19 for MGS solutions for calving ease and 0.84 for sire and 0.78 for MGS solutions for stillbirth. For first-parity, the correlation between calving ease and stillbirth was 0.86 for sire and 0.34 for MGS solutions. To calculate national evaluations for Holstein and Brown Swiss, a fixed effect for breed was added to the model. Correlations between solutions on the underlying scale from the current evaluation with those from this analysis averaged 0.85 for sire and 0.80 for MGS for calving ease and 0.67 for sire and 0.70 for MGS for stillbirth. The multitrait analysis provided stillbirth evaluations for bulls with missing observations based on correlated calving-ease data and accounted for genetic differences in calving performance between first and later parities. Evaluation stability should be improved as the portion of observations from different parities changes. Accuracy of the net merit index can be improved by adjusting weights to use evaluations for separate parities optimally.

Key Words: Calving Traits, Dystocia, Stillbirth

M50 Estimation of genetic parameters for milk and fat yields in Holstein cattle of Khorasan province of Iran. H. Naeemipour*[1], H. Farhangfar[1], H. Moravej[2], M. Rokoei[3], and M. B. Sayyadnejad[4], [1]*Birjand University*, *Birjand, Khorasan, Iran*, [2]*Tehran University*, *Tehran, Tehran, Iran*, [3]*Zabol University*, *Zabol, Sistan va Bluchestan, Iran*, [4]*Animal Breeding Center*, *Karaj, Tehran, Iran*.

In order to estimate genetic parameters for milk and fat yields in Holsteins of Khorasan province of Iran, a total of 17791 records belonging to 26078 cows calving from 1990 to 2003 and distributed in 133 herds was used. The data was recorded by animal breeding center of Iran. Two separate analyses consisting of bi-variate (first lactation milk and fat yields) and four-variate (first and second lactation milk and fat yields) animal models were undertaken. In the models, fixed effect of herd-year-season of calving, age at first calving (linear and quadratic covariates) as well as the random effect of additive genetic were included. Additive genetic and environmental (co)variance components were estimated for the traits under consideration applying restricted maximum likelihood method based upon derivative-free algorithm. The results obtained in the present study indicated that heritability estimates of milk and fat yields were 0.28 and 0.23 respectively in bi-variate model. In four-variate model, the heritability estimates of milk yield were 0.29 (at first lactation) and 0.23 (at second lactation) while the corresponding figures for fat yield were found to be 0.24 and 0.21 respectively.

Key Words: Genetic Parameters, Holstein, Khorasan Province of Iran

M51 REML heritability and repeatability estimates of net energy for lactation trait for Holstein heifers in Khorasan province of Iran. H. Farhangfar*[1], H. Naeemipour[1], R. Lotfi[1], and M. Pajaz[2], [1]*Birjand University*, *Birjand, Iran*, [2]*Jihade Agriculture of Razavi Khorasan*, *Mashhad, Iran*.

In this study, a total of 24473 monthly test day records of net energy for lactation (NEL in terms of Mcal/kg) obtained from 3805 Iranian Holstein heifers (representing 423 sires and 3474 dams) calving between 2002 and 2005 and distributed in 112 herds was used to estimate heritability and repeatability. A repeatability fixed regression test day animal model was fitted to the data. In the model, fixed environmental effects of herd-year-season of calving-milking times-stage of lactation, age at calving (linear and quadratic covariates), Holstein genes (linear and quadratic covariates) and daily milk yield (linear and quadratic covariates), and random direct additive genetic and permanent environmental effects were included. Restricted maximum likelihood (REML) estimates of heritability and repeatability of NEL were obtained by DFREML software. The results showed that NEL had a heritability of 0.05 indicating that there was low direct genetic variation among cows to be selected in a genetic evaluation. For this trait the same figure was also observed for repeatability suggesting that non-significant permanent environmental variation was found during the course of lactation.

Key Words: Net Energy for Lactation, Genetic Parameters, Iranian Holsteins

M52 Genetic evaluation of lactation persistency estimated by best prediction for Ayrshire, Brown Swiss, Guernsey, and Milking Shorthorn dairy cattle. J. B. Cole and D. J. Null*, *Animal Improvement Programs Laboratory, USDA*, *Beltsville, MD*.

The objectives of this study were to calculate (co)variance components and breeding values for best predictions of persistency of milk (M), fat (F), protein (P), and SCS in Ayrshire (AY), Brown Swiss (BS), Guernsey (GU), and Milking Shorthorn (MS) dairy cattle. Cows with high persistency tend to milk less than expected at the beginning of lactation and more than expected at the end. Persistency was calculated as a function of a trait-specific standard lactation curve and the linear regression of a cow's test day deviations on days in milk. Heritabilities represent the additive genetic variance of persistency that is independent of yield and defined to have a phenotypic variance of 1. Available data ranged from 27,964 (MS) to 159,898 (BS) records for cows calving since 1997. The number of active AI sires receiving evaluations for persistency ranged from 4 (MS) to 39 (BS). Results from the four breeds were similar; only BS results are presented (Table 1). Sire EBV for persistency of M, F, and P were similar and ranged from -0.36 to 0.67 for M; EBV for persistency of SCS ranged from -0.40 to 0.42. Regressions of sire EBV on birth year were near zero ($P < 0.0001$) but in favorable directions for all breeds and traits. Genetic correlations of persistency of M, F, and P with SCS were moderate and negative for all breeds, indicating that persistency of SCS decreases as persistency of yield increases. Genetic correlations among yield and persistency were low to moderate and ranged from 0.01 (SCS) to 0.08 (F). As expected, selection for improved yield has not affected persistency of yield. Heritabilities and repeatabilities were similar to those previously reported for US Holsteins with the exception of SCS, which were larger in the colored breeds.

Table 1. Heritabilities, repeatabilities, and genetic and phenotypic correlations among persistency traits in Brown Swiss.

Trait	M[1]	F	P	S
M	**0.10 (0.19)**	0.84	0.88	-0.52
F	0.76	**0.08 (0.17)**	0.80	-0.50
P	0.91	0.79	**0.08 (0.17)**	-0.44
S	-0.21	-0.15	-0.17	**0.06 (0.12)**

[1]Heritabilities (repeatabilities) on diagonal, genetic correlations above diagonal, and phenotypic correlations below the diagonal.

Key Words: Best Prediction, Persistency, Test Day Model

M53 Phenotypic and genetic analysis of days open for Japanese Holstein cows. H. Abe*, M. Suzuki, and Y. Masuda, *Obihiro University of A & VM.*, *Obihiro, Japan*.

The objectives of this study were to analyze phenotypic change and to estimate genetic parameters of days open for Japanese Holstein cows. Days open for cows that calved between 1990 and 2002 were calculated from reproduction records obtained from Hokkaido Dairy Milk Recording & Testing Association. Phenotypic change of records from first to fifth parities was investigated. Descriptive statistics were calculated by categories of herd size and average yield of herd. Days open of first and second parities were analyzed by a two-trait animal model. The model included the fixed effects of herd-year, month of calving and age of calving, and random additive genetic effect of animal. The numbers of records were 592,294 and 494,944 for the first and second parities, respectively. Records with less than 22 d or greater than 500 d were deleted. At least 5 records were required per herd-year. The numbers of edited records were 338,440 and 249,702 for the first and second parities, respectively. Five subsets of records were extracted by random sampling of herds, and means of estimates on each subset were used as final estimates. Genetic parameters were estimated by the AIREMLF90 program. The mode on days open was nearly 75 d for each year. However, over the years, the average increased from 120 d to nearly 140 d. For all the categories of the herd size and average yield of herd, the modes were nearly constant, whereas the averages and standard deviations increased every year. As the average yield of herd increased, the averages and standard deviations for days open decreased. Moreover, as the herd size increased, the averages, standard deviations, and modes decreased. Estimates of heritability were 0.056 and 0.049 for the first and second parities, respectively. Estimates of phenotypic, genetic and environmental correlation were 0.11, 0.93 and 0.062, respectively.

Key Words: Days Open, Genetic Parameters, Japanese Holstein Cows

M54 Performance and egg quality of four quail genetic groups. C. Móri[1], E. A. Garcia[1], A. C. Pavan[1], C. C. Pizzolante[2], R. M. S. Emediato*[1], S. A. Maestá[1], and D. A. Berto[1], [1]*São Paulo State University*, *Botucatu, São Paulo, Brazil*, [2]*São Paulo Agency of Agribusiness Tecnology*, *Brotas, São Paulo, Brazil*.

The study aimed to evaluate the performance and egg quality of four genetic groups selected for meat production. Two hundred and eighty eight quails of 42 days of age were used. The experiment design was the completely randomized blocks with four treatments (genetic groups A, B, C and D) and six replications of 12 birds each. In the first week it was given 14 hour of light with increases of 30 minutes per week until it reaches 17 hours of light. Eggs and feed were weighted once a week to determine egg weight and feed consumption. Three eggs from each replication were collected and analyzed after each 28 days period during 3 consecutive days to evaluate their quality. There were significant differences ($p<.05$) among the genetic groups for egg weight and egg mass with higher values for the genetic group B. Treatment D has shown higher means for specific gravity and shell percentage. Quails used for meat production have shown as good for egg production with good quality of eggs.

Key Words: Egg Production, Meat Quail, Performance

M55 Relationship between calpastatin activity and lamb carcass characteristics. J. A. Gevin*[1], H. N. Zerby[1], P. S. Kuber[1], S. J. Moeller[1], M. P. Wick[1], D. R. Notter[2], T. D. Leeds[3], and M. R. Mousel[3], [1]*The Ohio State University*, *Columbus*, [2]*Virgina Polytechnic Institute and State University*, *Blacksburg*, [3]*USDA-ARS, U.S. Sheep Experiment Station*, *Dubois, ID*.

The purpose of this study was to determine if calpastatin activity (CALP) was related to the amount of intramuscular fat (IMF) and Warner-Bratzler shear force (WBS) in lamb carcasses. Market wethers representing three sire lines (n = 40, average live weight of 68.9 kg) were harvested at the OSU Meat Science Laboratory. *Longissimus thorasis* (L) samples were taken 24 h postmortem (PM) for determination of CALP and IMF (Caviezel® method). Standard carcass measurements were collected to assess relationships among traits. Nine (2.5 cm) chops were removed from the L at approximately the 7th through the 12th rib location, utilizing both the left and right side of the rack. Chops were randomly assigned to one of three (24 h, 72 h, and 7 d PM) aging periods and WBS was measured. Correlations between CALP, IMF, WBS and carcass traits were calculated. Using a mixed model with fixed sire line, aging and a sire line by aging interaction and a random animal within sire line effect, the force to shear samples decreased ($P < 0.01$) over time (24 h, 72 h and 7 d), with least squares means of 4.7 kg, 4.2 kg, and 2.7 kg, respectively. Percent intramuscular fat ranged from 2.9% to 8.5% with a mean of 5.8% (std. dev. 1.2%). Calpastatin was significantly ($P < 0.03$) and positively correlated with 24 h, 72 h, and 7 d WBS, $r = 0.35$, 0.40, and 0.40, respectively. Simple correlations of CALP with IMF ($r = -0.22$, $P = 0.17$), backfat ($r = -0.07$, $P = 0.68$) and body wall ($r = .0002$, $P = 0.99$) were not significant. Furthermore, IMF was not significantly correlated with 24 h ($r = 0.08$, $P = 0.63$), 72 h ($r = 0.13$, $P = 0.41$), or 7 d ($r = 0.06$, $P = 0.72$) WBS. These results are consistent with previous literature in lamb and beef reporting that CALP is positively correlated with WBS and in beef that IMF is not directly related to WBS. The correlation between CALP and IMF warrants further investigation.

Key Words: Calpastatin, Lamb, Intramuscular Fat

M56 Effect of salt, trisodium phosphate, BHA/BHT and CLA on sensory, quality and instrumental color characteristics of beef strip loins of different quality grades. C. W. Rowe*, F. W. Pohlman, A. H. Brown, Jr., and Z. B. Johnson, *University of Arkansas*, *Fayetteville*.

USDA Select and Choice (n=22) striploins were enhanced with trisodium phosphate in combination with salt, BHA/BHT and CLA to determine the impact of sensory and quality attributes. There were 10 Choice and 12 Select striploins used and analyzed in an oneway ANOVA. Treatments were: Choice control (n=5) (non-inject) (CC), Choice inject (n=5) (0.4% trisodium phosphate, 0.5% salt and 0.006% BHA/BHT) (CI), Select inject (n=4) (0.4% trisodium phosphate, 0.5% salt and 0.006% BHA/BHT) (SI), Select inject + CLA (n=4) (0.4% trisodium phosphate, 0.5% salt, 1.3% CLA and 0.006% BHA/BHT) (CL), and a Select control (n=4) (non-inject) (SC). All injected treatments were injected to 110% of their original weight. Injected treatments allowed for lower ($P < 0.05$) WBS, cooking loss, and lower retail purge. Injected treatments also allowed for greater ($P < 0.05$) myofibrillar and overall tenderness values, and lower ($P < 0.05$) connective tissue values when sampled by trained panelist. The injected treatments were also juicer ($P < 0.05$) than the two controls. There was a general decline during retail display for all of the instrumental color measures except for hue angle which had a general increase in value. There were no treatment differences ($P > 0.05$) in regards to b*, a*, hue angle, and saturation index. There were differences however in L* values where CL had the highest mean and was different ($P < 0.05$) from CI and SI. Treatment CL was not different ($P > 0.05$) from any of the other treatments for 630/580 nm, however, SI and CI did not differ ($P > 0.05$), but both were different ($P < 0.05$) from CC and SC. Marbling scores differed among the treatments with CC, SC, and SI not differing ($P > 0.05$) and CI and CC not differing ($P > 0.05$). However, CL differed ($P < 0.05$) from all other treatments having a higher score due to the CLA adding artificial marbling. This data suggest that through enhancement, overall palatability and marbling scores can be improved.

Key Words: Beef, CLA, Sensory

M57 Predicting beef tenderness using proteomic analysis of 36 hour postmortem muscle. M. S. Updike*, I. Zapata, H. Zerby, and M. Wick, *The Ohio State University*, *Columbus*.

Inconsistency in tenderness has been described as the biggest factor negatively impacting beef palatability, significantly harming the beef industry. Currently, carcasses are sorted into palatability classes using quality grade, a score based on physiological age and intramuscular fat, which is slightly correlated to tenderness. A method that would rapidly and accurately predict tenderness would be an advantage to the beef industry. The long term goal of our laboratory is to create an immunochemical test strip which can accurately predict tenderness for consumers (7-14 d postmortem) when the carcasses move from the cooler for fabrication (24-48 h postmortem). Previous research from our lab used bovine myofibrils from 36 h to predict 7 d tenderness as proof of principle. To expand upon that research, 34 Angus cross steers were harvested at The Ohio State University meat lab. Samples of Longissimus dorsi were taken at 36 h postmortem for proteomic analysis and sarcomere length determination. Steaks were assayed for tenderness using Warner Bratzler sheer (WBS) force at 7 and 14 d

postmortem. Sarcomere length determination samples were dissected and fixed in a glutaraldehyde/cacodylic acid buffer. Samples were homogenized in cacodylic acid buffer, mounted on glass slides, observed by phase contrast microscopy and images captured with a CCD camera. Proteomic analysis samples underwent principle component fractionation using a high salt extraction. Both the high salt soluble fraction and the high salt insoluble fraction were solublized and run on SDS-PAGE using 5-20% gradient polyacrylamide gels. The resulting images were analyzed and the percent that each band contributed to the total was used in a reverse step wise regression on the WBS force value and on the sarcomere length. Ten bands from 36 h samples were identified that are associated with and predictive of 7 and/or 14 d tenderness ($r^2 = 0.76$, $p \leq 0.01$). Five bands were identified that are associated with the sarcomere length ($r^2 = 0.66$, $p \leq 0.01$). These results suggest that an immunochemical test strip could accurately predict tenderness of beef when it is consumed at 7 to 14 d postmortem.

Key Words: Beef, Tenderness, Proteomics

M58 Evaluation of different fatty acid methyl ester preparation procedures for analysis of egg fat with emphasis on omega-3, omega-6 and conjugated linoleic acids. G. Cherian*, A. S. Abd El-Hakim, and M. P. Goeger, *Oregon State University*, *Corvallis*.

With the availability of different brands of fatty acid modified eggs on the market, accurate methods to measure fatty acid content in eggs is needed. Fatty acids are usually analyzed as their methyl esters (FAME). In the current study, three different FAME preparation procedures were compared using regular, omega-3, or conjugated linoleic acid (CLA)-enriched eggs. Lipids from egg yolk were extracted with chloroform:methanol (2:1) and an aliquot (0.5 ml) dried under N2 at 40C. In Method 1, methanolic HCl (1 ml) was added to the lipid extract and heated at 60C for 40 min. In Method 2, hexane (2 ml), methyl acetate (0.04 ml) and methylating reagent (0.04 ml) [1.75ml methanol, 0.4 ml sodium methoxide (5.4 mol/L)] were added to the lipid extract, allowed to stand 10 min at room temperature then combined with stopping reagent (0.06 ml) [0.1g oxalic acid in 3.0 ml diethyl ether] and centrifuged at 2400 × g for 5 min. In Method 3, lipid extract and methylating reagent (2 ml) [45% methanol, 35% boron trifluoride, 20% hexane] were heated at 90-100C for 60 min. FAME was extracted with distilled water and hexane. An internal standard (C19:0) was used for quantification. Highest recovery of alpha-linolenic acid (18:3n-3), linoleic (18:2n-6), cis9, trans11 and trans10, cis12 CLA was obtained with Method 3 ($P<0.05$). No difference was found in the docosahexaenoic acid (DHA, 22:6n-3) content of regular eggs with the three methods tested. Recovery of DHA for omega-3 eggs was best with Method 3 ($P<0.05$). Lowest recovery of DHA for CLA-enriched eggs was obtained with Method 1 ($P<0.05$). The current study shows that FAME preparation methods should be based on the egg type and the experimental objectives.

Key Words: Egg, Fatty Acid Methyl Ester, Omega-3

M59 Effect of animal, transportation, and slaughterhouse variables on beef behavior at the slaughterhouse. N. Mach*[1], A. Bach[2,1], A. Velarde[3], and M. Devant[1], [1]*IRTA*, *Barcelona, Spain*, [2]*ICREA*, *Barcelona, Spain*, [3]*IRTA*, *Girona, Spain*.

To evaluate the influence of factors related to animal, transportation and animal handling at the slaughterhouse, as well as their interactions, on behavior of beef cattle at the slaughterhouse, a total of 1,633 beef cattle were monitored. A scan sampling of 182 pens (9.13 ± 3.94 animals/pen) with a 30-min interval was conducted 3 times per pen, to study the lying, drinking, exploring, and ruminating behaviors. Mounting behavior was registered continuously during 15 min. A Poisson regression model was conducted with 5 variables to identify the main factors, and their interactions, affecting the incidence of each studied behavior at the slaughterhouse. Lying, drinking, exploring behaviors were not affected by the factors studied, and no statistical interactions were observed. Average incidence of animal mountings and ruminating behavior were 0.9 ± 0.12, and 0.66 ± 0.04 cases per pen, respectively. The incidence rate ratio (IRR) of mountings was 4.54 times greater ($P < 0.001$) in males than in females. Furthermore, the IRR of mountings was 1.28 times greater ($P < 0.01$) in medium (0.19 to 0.35 animal per m^2) and 0.57 times lower in high (≥ 0.27 animal per m^2) than in the low (≤ 0.19 animal per m^2) stocking densities at slaughterhouse. In contrast, ruminating behavior was greater ($P < 0.001$) in females than in males (IRR = 1.68), and slightly decreased ($P < 0.05$) as waiting time at the slaughterhouse increased from 4 to above 12 h (IRR = 0.66), being reduced 34% when animals waited over 12 h at slaughterhouse. Handling decisions such as optimizing stocking densities and waiting time at the slaughterhouse may reduce the incidence of mountings and improve rumination time. Additionally, both behaviors were affected by gender.

Key Words: Beef, Behavior, Pre-slaughter Handling

M60 Effects of dietary vitamin A on growth and beef quality traits of Limousin × Chinese Luxi steers. J. Q. Wang*, F. C. Wan, D. P. Bu, H. Y. Wei, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

Thirty two (11±0.5mo; 310±10.35 kg) Limousin × Chinese Luxi steers were allotted to one of four dietary treatments(n=4) in two trials with a randomized complete design to evaluate the effects of supplementation of vitamin A on growth, carcass trait, beef quality and chemical composition. Steers were fed a basal diet supplemented with 0 (A0),1100 (A1100), 2200 (A2200), or 4400 IU (A4400) of vitamin A (palmitate retinyl ester, IU /kg DM) for 90d(Exp 1) or 180d(Exp 2). At the end of finishing , 3 steers of each treatment were transported to a commercial slaughter facility. HCW(Hot carcasses weight) were measured and marbling scores(MS) were recorded according to JMGA grading system. Samples of longissmus muscle(LM) were taken at 7-12 ribs of each right side carcass and water holding capacity(WHC) was measured. Warner-Bratzler shear force(WBSF) was evaluated using 7- to 8-cm thick steaks. Chemical composition of intramuscular fat, moisture, protein, and ash of LM were determined according official methods. Lipid oxidation determined as thiobarbituric acid-reacting substances (TBA).HP (heme pigment) and DL (drip loss) of steaks were measured at 168h of aging period. No treatment difference($p>0.05$) were observed for dry matter intake(DMI),average daily gain(ADG),feed gain ratio (F/G) and chemical compositions of LM. MS for carcass in Exp 2 were 6.00^{ab},$7,33^{a}$,5.00^{b} and 5.67^{b}in A0,A1100,A 2200 and A 4400($p=0.04$) respectively.Decreased dietary vitamin A concentration improved the drip loss (DL), antioxidant ability of the fat and water holding capacity(WHC) in Exp 1. However, dietary VA level had no apparent effect($p>0.05$) on most meat quality traits.

M61 Effects of supplemental fat on growth performance and quality of beef from steers fed corn finishing diets. M. L. Nelson*, J. R. Busboom, C. F. Ross, and J. V. O'Fallon, *Washington State University*, *Pullman*.

To measure effects of dietary fat on feedlot performance, carcass characteristics, and beef appearance, moisture binding, shelf life, palatability and fatty acid content, 126 crossbred beef steers (321.1 ± 0.57 kg) were allotted to a randomized complete block design with a 3 × 2 + 1 factorial arrangement of dietary treatments. Main effects were level of yellow grease (0, 3 or 6%) and alfalfa hay (3.5 or 7%) in corn-based diets containing 15% potato byproduct (PB). The added treatment was 6% tallow and 7% alfalfa in a barley-based diet containing 15% PB. Dry matter intake and ADG were not affected by diet, however G/F and diet NE content increased linearly ($P \leq 0.10$) as yellow grease increased. Kidney, pelvic, and heart fat (2.0 to 2.3 ± 0.07) and yield grade (2.8 to 3.1 ± 0.09) increased linearly ($P \leq 0.05$) as yellow grease increased. Yellow grease fed steers had lower ($P \leq 0.05$) beef firmness and beef texture scores but greater ($P \leq 0.01$) fat color score than those fed tallow. Moisture retention of beef was not affected by dietary treatment except purge score during retail storage was decreased linearly ($P \leq 0.01$) 2.1 to 1.6 ± 0.06 by level of yellow grease. Steaks from barley plus tallow fed steers had greater ($P \leq 0.05$) shear force than those from steers fed corn plus yellow grease. But beef flavor increased linearly ($P \leq 0.05$) from 6.2 to 6.7 ± 0.11 as yellow grease increased. Level of yellow grease decreased linearly ($P \leq 0.01$) vaccenic acid but increased linearly ($P \leq 0.01$) transvaccenic acid (TVA) and CLA content of beef. Beef from corn plus yellow grease-fed steers had lower ($P \leq 0.05$) palmitoleic and oleic acids and greater ($P \leq 0.05$) linoleic, TVA, and CLA than beef from barley-tallow fed steers. Feeding yellow grease increased diet energy content which increased carcass fatness, altered beef fatty acid content which increased beef flavor without affecting moisture retention, shelf-life, or cooking properties of the beef. Additionally, beef from corn plus yellow grease-fed steers was more tender and had more unsaturated fatty acid content and CLA than of beef from barley plus tallow-fed steers.

Key Words: Beef Cattle, Yellow Grease, Fatty Acid

M62 Influence of β-adrenergic agonist (Metaproterenol) and lysine on growth, carcass quality in broiler chickens. A. M. Tahmasbi*[1], E. Kasefi[2], G. Moghadam[2], A. Taghizadeh[2], and H. A. Ghasemi[2], [1]*University of Mashhad*, *Iran*, [2]*University of Tabriz*, *Iran*.

An investigation was made to find out the importance of β-adnergenic and lysine on carcass characteristics and blood metabolite of 648 broiler chickens from 21–42 days of age. Effect of metaproterenol (a β2- adrenergic agonist) and lysine were assessed by mixing them in feed at 0.0, 0.25, 0.50 and 1.00 ppm metaproterenol sulfate and 100%, 115% and 130% of NRC recommended lysine in a 4–3 factorial arrangement of treatments. Chickens were reared under normal condition to 3 week of ages and then randomly allocated to treatments. Each treatment contained 3 pens with 18 birds/pen. Body weight gains (BWG), feed conversion ratio (FCR) abdominal fat pat (AFP) breast weight (BW) were measured. Result indicate that during 4th and 5th week of study using metaproterenol (0.5 ppm), compare to control group, improved BWG (5.1%), carcass efficiency (3.4%) and breast weight (2.2%), breast and thigh muscle protein and depressed abdominal fat (P<0.05). Increasing lysine levels lead to significant increase in body weight gain, carcass weight, carcass efficiency, breast muscle weight (P<0.5), but it has no effect on feed intake, feed conversion ratio, blood metabolites. Data from this experiment suggested that both adding 0.5 ppm β-adrenergic agonist metaproterenol sulphate significantly improved birds performance and their carcass quality and the most efficient lysine level for broiler chickens was proved to be 115% NRC recommended.

Key Words: Broiler, Adrenergic Agonis, Carcass Composition

M63 Effect of deboning time and muscle type on dielectric properties of uncooked chicken breast meat at 5°C. H. Zhuang*, S. Nelson, S. Trabelsi, and E. Savage, *Agriculture Research Service, USDA*, *Athens, GA*.

Color, pH, water-holding capacity and texture (or tenderness) are the most commonly-used quality indicators for chicken meat, and they can be significantly affected by deboning time and muscle type. So far, little attempt has been made to assess and monitor these quality indicators during processing at a refrigerated temperature by using rapid and non-destructive instrumental methods. Dielectric properties measurements have potential to assess raw meat quality nondestructively. The objective of this study was to determine the effects of muscle type and deboning time on dielectric properties of uncooked chicken breast meat at 5°C. The dielectric properties, consisting of the dielectric constant and loss factor, were measured with an open-ended coaxial-line probe and impedance analyzer for uncooked chicken breast muscle Pectoralis major and Pectoralis minor, deboned at 2- and 24-h postmortem, at frequencies of 10, 26, 900 and 1800 MHz and 5°C. The quality indicators were also measured. Our study shows that there are no differences in the dielectric constant and loss factor values for the two deboning times or for the two muscle types. However, the deboning time significantly ($p < 0.1$) affects the average values of the loss tangent (dielectric loss factor/dielectric constant) at frequencies 26, 900 and 1800 MHz, and the muscle type significantly ($p < 0.1$) affects the loss tangent at 900 MHz. The deboning time and/or muscle type have also significant effects ($p < 0.05$) on the quality indicators, color (L* value), pH, water-holding capacity, drip loss, and texture (Warner-Bratzler shear force value). These results suggest that there is a potential for using dielectric

properties measurements, or specifically the loss tangent, to assess the quality, deboning time, and/or muscle types of chicken meat at a refrigerated temperature during the processing. Further studies are needed to determine the relationships between dielectric property measurements and the quality indicators, deboning time and muscle types.

Key Words: Chicken Breast Muscle, Dielectric Property, Deboning

M64 Rabbit meat quality as affected by feed containing coconut meal. D. V. Souza[1], J. F. F. Zapata*[1], E. R. Freitas[1], D. S. Garruti[2], E. M. C. Silva[1], T. F. Vidal[1], and A. L. F. Pereira[1], [1]*Universidade Federal do Ceará*, *Fortaleza, CE, Brasil*, [2]*Embrapa Agroindústria Tropical*, *Fortaleza, CE, Brasil*.

The objective of this work was to assess the effect of feeding rabbits (White New Zeeland × Californian) with diets containing coconut meal (CM) on meat proximal composition (moisture, protein, fat and ashes), pH, color (components L*, a* and b*), water holding capacity (WHC), cooking losses (CL), shear force (SF) and fatty acid profile. The experiment utilized 60 rabbits in a complete randomized design with diets containing five levels of CM: 0% (control diet), 6.25, 12.5, 18.75 and 25.00%) and 12 animals per treatment. Increasing levels of CM in the diet did not affect ($p \geq 0.05$) meat proximal composition, pH or CL, but it showed a quadratic effect on meat WHC and a linear effect on meat SF. Diets containing 25.00% CM produced meat with lower ($p \leq 0.05$) WHC and those containing 18.75 and 25.00% CM produced meat with higher ($p \leq 0.05$) SF than that from the control diet. Meat color component a* in meat from diets containing 12.5, 18.75 and 25.00% CM was higher ($p \leq 0.05$) than that from the control diet. Meat color component b* was linearly affected by CM levels and all diets containing CM produced meats with higher ($p \leq 0.05$) b* values than that from the control diet. The levels of palmitoleic, stearic, and linolenic acids in the meat were linearly affected by CM levels in the diets. When compared to the levels of fatty acids in the meat from the control diet, palmitic acid was lower ($p \leq 0.05$) in the meat from all diets containing CM; myristic acid and stearic acid levels were higher ($p \leq 0.05$) and palmitoleic acid level was lower ($p \leq 0.05$) in the meat from the diet containing 25.00% CM; and linolenic acid level was lower ($p \leq 0.05$) in meats from diets containing 18.75 and 25.00%. The relation P/S in the meat decreased ($p \leq 0.05$) when rabbits were fed the 18.75 and 25.00% CM diets suggesting that these levels of inclusion increase the saturated fatty acid content in rabbit meat.

Key Words: Fatty Acids, Shear Force, Water Holding Capacity

M65 Fatty acid profile of *Longissimus* by steers finishing at *Brachiaria brizantha* cv. Stapf. pasture, under tropical conditions. D. M. Lambertucci*[1], R. H. T. Buschinelli de Goes[2], A. B. Mancio[1], C. Mistura[3], and R. P Lana[1], [1]*Universidade Federal de Viçosa*, *Viçosa, Minas Gerais, Brasil*, [2]*Universidade Federal da Grande Dourados*, *Dourados, Mato Grosso do Sul, Brasil*, [3]*Universidade do Estado da Bahia*, *Juazeiro, Bahia, Brasil*.

The chemical composition and the fatty acids profile of *Longissimus* muscle of Nellore steers (NL) and its crossbreeds with Simental (SI) and Santa Gertrudis (SG) finished in pastures of *Brachiaria brizantha* cv Stapf, were evaluated. They were studied 14 animals carcasses, with live weight of 481+30 kg, receiving 1.1 kg of supplement/day, containing 24% of CP. Among to 12nd and 13rd rib, a sample of the *Longissimus* muscle was removed. The pasture of *Brachiaria brizantha* presented low tenor of saturated fatty acids (29.69%), high tenor of omega 3 acid (28.21%). The crossbreed with Santa Gertrudis presented smaller saturated fatty acid tenor (SFA), of (45.47%), if compared with Nellore and Simental, 48.15 and 47.96%, respectively. The tenors of the linoleic conjugated acid (CLA) and omega-3 acid (mg/100g muscle) were higher in Nellore steers, presenting values of 1.27% of CLA and 2.09% of omega-3 acid, while the animals Santa Gertrudis and Simental presented values of 1.03 and 1.16% of CLA and 1.81 and 1.56% of omega-3 acid, respectively. There was no difference among the genetic groups for the polyunsaturated acids (PUFA) and monounsaturated acid (MUFA), as well as for the omega-6 acid. The average for the PUFA was of 7.7%. The average of the tenor of observed SFA was of 47.19%, and the relationship among PUFA/SFA was of 0.16. The total CLA was significant ($P < 0.05$) for the Santa Gertrudis steers (64.22%) in relation to the Simental (46.69%) and Nellore steers (41.68%). The linoleic conjugated acid (18:2 c-9, t-11; 18:2 c-11, t-13 and 18:2 t-10, c-12) followed a similar behavior, being verified the CLA 18:2 c-9, t-11 for samples of muscle of the Santa Gertrudis steers were 61.92% higher to Nellore steers; for the CLA 18:2 c-11, t-13, the difference was of 56.32%; and for the CLA 18:2 t-10, c-12 the difference was of 52.11%.

Key Words: Linoleic Conjugated Acid, Fatty Acids, Genetic Group

M66 Phenotypic correlation of egg weight and egg morphometric measures. O. T. F. Abanikannda[1], A. O. Leigh[1], O. Olutogun[2], L. A. Ajayi*[1], and M. Orunmuyi[3], [1]*Lagos State University*, *Ojo, Lagos State, Nigeria*, [2]*University of Ibadan*, *Oyo State, Nigeria*, [3]*Ahmadu Bello University*, *Zaria, Kaduna State, Nigeria*.

Weight and morphometric measurements were taken on table eggs from Harco heavy breed layers in the humid tropics of Lagos, Nigeria. Statistical descriptive measures and relationships between egg weight (EGGWT), egg length (EGGLT), egg width (EGGWD) and egg shape index (SHPINDX) were studied. A total of 2951 eggs were obtained from layers at five different age groups in lay. The descriptive statistics are presented in the table below. Egg weight and egg width exhibited similar pattern in their distribution across the different age groups, with steady increase from age group A (22 - 32 weeks), peaked at age group D (55 - 65 weeks) before a decline afterwards. Egg length consistently increased with increasing age of hen, while shape index consistently decreased with increasing age of hen. Correlation between egg weight & egg length, egg width and shape index was 0.78, 0.84 and -0.07 respectively, while the correlation between egg length & egg width and shape index was 0.53 and -0.60 respectively, and between egg width and shape index was 0.37. The fitted model of the study was EGGWT = -124.72 + 1.65EGGLT + 1.32EGGWD + 0.43SHPINDX. All coefficients obtained were significant ($P<0.05$), however, it was observed that egg length and egg width were better predictors of egg weight when compared to shape index. Analysis of variance revealed that effects of all factors studied (age group, egg length, egg width, shape index and egg length × egg width interaction) were highly significant ($P<0.01$) on egg weight except for shape index which was significant ($P<0.05$). A further separation of the means for all the variables studied across the five age groups was done using Tukey's method. Morphometric measures studied were good predictors of egg weight.

Table 1. Mean ± S.E. of the Correlates Studied Across Age Groups

Age Group (Weeks)	N	Egg weight (g)	Egg length (mm)	Egg width (mm)	Shape Index (%)
A (22–32)	596	49.94±0.20^{c}	53.86±0.09^{d}	40.91±0.06^{d}	76.02±0.12^{a}

M67 Effect of vitamin D_3supplementation on plasma and muscle calcium levels, tenderness and sensory characteristics of crossbred grazing steers in the tropics. J. Gutierrez, L. Machado, O. E. Moron-Fuenmayor, O. E. Araujo-Febres*, and S. Pietrosemoli, *La Universidad del Zulia*, *Maracaibo, Estado Zulia, Venezuela*.

Sixty large framed, *Indicus* × *Continental*, crossbred beef steers grazing in a tropical dry forest environment, were used to investigate the effect of supplementing diets with various levels of vitamin D_3 (VITD) to provide 0, 6, and 10 million IU/(steer×d) for 8 d before slaughter on plasma (PCa) and *Longissimus lumborum* muscle Ca^{2+} (MCa) concentrations, texture analysis (TX), and sensorial analysis of the organoleptic qualities, in which appearance (A), odor (O), flavor (F), juiciness (J), amount of connective tissue (CT), and tenderness (T). Steers were slaughtered using an approved humane technique. A randomly subsample of five steers of the three individual VITD treatments (n = 15) was chosen for meat quality and palatability analyses. Following a 24-h chilling period -4°C, carcasses (a randomly selected subsample n=15) were ribbed, one strip loin of *Longissimus lumborum* (LL) muscle was removed from each carcass. Steaks were vacuum-packed. The data were analyzed in a completely randomized design using the General Linear Models procedures. Warner-Bratzler shear force (WB) was measured on strip loin at 7 d postmortem. Steaks for WB and sensory evaluation were thawed to 2°C. Blood plasma Ca^{2+} and muscle Ca concentration of cattle treated with VITD were higher ($P < .05$) than controls. VITD supplementation did not ($P > .05$) affect TX. Sensory traits of appearance, odor, flavor, juiciness, connective tissue, and tenderness were improved ($P < .05$) by all VITD treatments in LL steaks. Treatment with VITD will effectively improve tenderness in grazing zebu cattle in tropical conditions.

Key Words: Beef, Vitamin D, Tenderness

M68 Evaluation of freshness of egg yolks and shell eggs stored under the super chilled temperature through analyses of changes of volatiles and lipoprotein conformation. T. Yanagisawa*[1], C. Watanuki[1], M. Ariizumi[1], Y. Shigematsu[1], H. Kobayashi[1], M. Hasegawa[1], and K. Watanabe[2], [1]*Q.P. Corporation*, *Tokyo, Japan*, [2]*Tokyo University of Agriculture*, *Kanagawa, Japan*.

This study evaluated freshness of egg yolks and shell eggs stored under the super chilled temperature range (-5-0°C) by analyzing changes in volatiles affecting their flavors and lipoprotein conformation affecting their emulsifying characteristics. As the samples, 10% salted egg yolks were stored at -30, -20, -15, -5 and 5°C, and shell eggs were stored at 0, 10, 20°C with different carbon dioxide concentrations in packages. To analyze volatiles, those samples were incubated and generated headspace gas was absorbed on solid phase microextraction (SPME) fiber and obtained volatiles were analyzed using gas chromatography-mass spectrometry (GC-MS). The analyses demonstrated that amount of volatiles such as hexanal considered to generate by lipids oxidation was the smallest in the samples stored at the super chilled temperatures for both salted egg yolks (-5 and 5°C) and shell eggs. Generation of volatiles in shell eggs was also suppressed at higher carbon dioxide levels. For salted egg yolk samples, conformational changes of lipoproteins were observed using ^{31}P nuclear magnetic resonance (NMR) spectroscopy, as the changes of peaks of phosphorus atoms of phospholipids in the lipoproteins. The alterations of the peaks of the super chilled egg yolks were smaller than those of egg yolks stored at the lower temperatures. The results suggested that there are less conformational changes of lipoproteins at the super chilled temperature (-5°C). It has been also confirmed that the shell egg samples stored at the super chilled temperature range maintained high freshness from the Haugh Unit values and the pH values of their egg white. This study demonstrated effectiveness of super chilling storage for maintaining freshness of salted egg yolks and shell eggs by new analytical methods.

Key Words: Egg, Super Chilling Storage, Freshness

M69 StockPlan: Decision support tools for exploring management options for drought. M. J. McPhee*[1], G. Meaker[1], P. M. Graham[1], B. L. Davies[1], and M. B. Whelan[2], [1]*NSW DPI*, *Armidale, Australia*, [2]*Southern Cross University*, *Lismore, NSW, Australia*.

StockPlan® is a suite of activities that can be undertaken during workshops and subsequently at home. It is highly recommended that StockPlan® is taken as a workshop. The StockPlan® resources include: StockPlan® Basics-Producer Manual; StockPlan® Extras – Home Study Guide; the Resources CD; StockPlan® CD and the StockPlan® User Manual. This study describes the 3 StockPlan® decision support tools (DST; Drought Pack, Feed Sell Agist (FSA) Pack, and ImPack) that include the StockPlan® User Manual to assist producers and extension staff test out management strategies for sheep or cattle through a projected period of limited pasture or drought. **Drought Pack** can help producers or extension staff choose between different strategies when faced with a period of limited or severely reduced pasture supply. The DST assesses the likely financial consequences of various strategies and looks at the impact of each strategy by varying the length of time that pasture may be limited. The DST also estimates the likely cost to repurchase stock when the drought ends. **FSA Pack**

is designed to assist producers or extension staff select the best option: to feed, sell, or agist. FSA also provides the user with the opportunity to calculate the expected costs of each option available based on the probability of each event occurring. **ImPack** is designed to assist the producer or extension staff test breeding, selling, and buying strategies for any beef breeding herd or sheep flock. ImPack will evaluate what will happen to the herd or flock age structure, animal production, and cash flow on an annual basis over an 11-year period. The models implemented in ImPack were developed to explore the consequences of a drought-forced reduction. The DST can also cater for other management changes e.g., flock reductions due to disease. The ImPack models are designed to represent a year where flock or herd numbers are reducing followed by a recovery period over the next ten years. ImPack also illustrates the long-term consequences of a one-year herd or flock reduction. Drought Pack, FSA Pack, and ImPack are valuable management tools that can be used for drought risk management plans.

Key Words: Drought, Management, Risk

M70 Characterization of claw lesions associated with lameness in the University of Arkansas sow herd. C. L. Bradley*[1], J. W. Frank[1], C. V. Maxwell[1], Z. B. Johnson[1], J. G. Powell[1], S. R. Van Amstel[2], and T. L. Ward[3], [1]*University of Arkansas*, *Fayetteville*, [2]*University of Tennessee*, *Knoxville*, [3]*Zinpro, Inc.*, *Eden Prairie, MN*.

Claw lesions that have been associated with lameness were evaluated for three successive breeding cycles in 201 multiparous sows (Monsanto Choice Genetics: GPK348, GPK348 × GPK4, and GPK35) to characterize lesion frequency. Each sow was evaluated in a modified calf table and flipped on her side, where both claws of each foot were evaluated by the same technician. The lesions evaluated were: heel erosions, Fischer's Cracks, excessive growth of the soft tissue, axial (inner) and abaxial (outer) white line cracks or separation on the sole, horizontal and vertical wall cracks, hardship grooves in the hoof wall, hemorrhages, and abscesses of the soft and hard tissue. Lesions were evaluated on a scale of 1 to 3, with 1 representing a mild lesion, 2 representing a moderate lesion, and 3 representing a severe lesion. Overall, greater than 95% of sows had at least one type of lesion during the study. Heel erosions (43.8%) were the most common type of lesion, followed by abaxial white line cracks (17.6%), Fischer's Cracks (11.0%), vertical wall cracks (8.6%), hemorrhages (6.5%), and axial cracks (5.2%), with the frequency of each of the remaining lesion types at less than 2.2% of total lesions. The rear outer claws had the largest occurrence of a noted lesion (49.3% of total lesions), followed by the front outer claws (26.1% of total lesions). Of all the lesions noted, 57.0% were scored a 1, 28.5% a 2, and 14.5% a 3. The likelihood of an axial white line crack, a Fischer's Crack, heel erosion, or hemorrhage was related to sow parity ($P < 0.05$). Within lesions identified as heel erosions, parity 1 sows had the highest frequency (25.0%), followed by parity 3 (14.8%), parity 5 or greater (13.0%), parity 4 (11.1%), parity 0 (8.3%), and parity 2 (8.4%; $P < 0.05$). The majority of lesions observed in this herd were mild, with heel erosions being the most predominant. Our data also indicate that the rear outer claws had the greatest number of lesions associated with lameness in sows.

Key Words: Sows, Lesions, Lameness

M71 Maryland dairy producer education needs assessment study. R. R. Peters*, K. M. Wilson, M. R. Bell, R. A. Erdman, S. W. Fultz, J. E. Hall, R. A. Kohn, W. D. Lantz, J. W. Semler, and M. A. Varner, *University of Maryland*, *College Park*.

The number of Maryland dairy farms has been steadily declining over the last several decades as many areas of the state have made a demographic shift from rural to suburban. To identify current demographics, practices and potential educational needs of dairy producers in Maryland, a 15-page questionnaire was constructed. The questionnaire was sent to a sample of 629 licensed dairies in Maryland using a multi-wave mail strategy with a response rate of 49%. The objectives of this study were 1) to determine what program topics are of current interest to dairy producers and 2) to identify their preferential media type and informational sources. Statistical analyses were conducted using SPSS software. The survey indicated that the responding dairy producers often have dairy-production related questions and are moderately to very interested in obtaining more information about such topics. The topic areas that most interested dairy producers include mastitis and milk quality, reproductive management, nutrition and feeding, and transition cow management. Topics of least interest primarily included recent technologies and non-conventional dairying methods. Dairy producers tended to utilize local sources of information including veterinarians, local farm/feed suppliers and other dairy producers in the area. The most valued characteristics in these sources included individuals that had general knowledge about many topics, had quick access to a specialist when needed, could provide a quick response and were willing to visit their farms. Producers most frequently obtained information from dairy and cattle/farm magazines, observations of other producers and county extension newsletters. Respondents also indicated that University of Maryland Extension, industry sponsored events, dairy organizational events, and regional dairy trade shows were most useful for providing educational information. The survey helped Cooperative Extension to identify topics, media type and information sources that dairy producers value most for future educational programming.

Key Words: Dairy, Needs Assessment, Survey

M72 Trends in Maryland dairying and future prospects. R. R. Peters*, K. M. Wilson, M. R. Bell, R. A. Erdman, S. W. Fultz, J. E. Hall, R. A. Kohn, W. D. Lantz, J. W. Semler, and M. A. Varner, *University of Maryland*, *College Park*.

Maryland's dairy industry faces the constraints of urban growth and reduced milk prices currently affecting the dairy industry nationwide. To identify potential educational needs, practices and demographics of dairy producers in Maryland, a 15-page questionnaire was constructed and sent to a sample of 629 licensed dairies in Maryland using a multi-wave mail strategy, with a response rate of 49%. The objective of this study was to identify characteristics of Maryland dairy operations including, 1) strategies for remaining competitive, 2) constraints of growing the dairy operation and 3) the projected outlook of dairy producers. Statistical analyses were conducted using SPSS software. Respondents indicated their role in the farm business as sole proprietor (64%), business partner (11.4%), renting (9.8%), corporation (9.8%) and other (4.9%). The average herd size was 108 cows with 84 replacements and calves. Respondents reported having predominantly Holstein (92%), Jersey (19%) and crossbred cattle (15.6%). Most survey respondents indicated they operated the following type of dairy: whole herd (72%); free stall (68%); and grade cattle (59%) with an

average of 124 hectares of tillable cropland. Non-conventional types of dairy included grazing (31%), value added (4%), agro-tourism (4%), and organic dairy (3%). Respondents indicated that business management practices including keeping cost of production, up-to-date business records, herd health records and accurate production records as their top priorities. The five most important limiting factors to improving and/or growing the dairy operation were land costs, low profits, encroachment of development, labor availability and government regulations. Ninety-four percent of all survey respondents plan to be in the dairy business in 5 years with an average herd size of 127 cows. Results of this study indicate that some dairy producers in Maryland have adapted to a changing economy with non-conventional operations. Nearly all producers plan to stay in dairying in the next 5 years with larger size herds.

Key Words: Dairy, Needs Assessment, Survey

M73 Field evaluation of laboratory assays to assess starch and fiber digestibility in corn grain and silage. M. D. Tassoul*[1], R. D. Shaver[1], J. A. Barmore[2], D. Taysom[3], and P. C. Hoffman[1], [1]*University of Wisconsin, Madison*, [2]*Five-Star Dairy Consulting LLC, Verona, WI*, [3]*Dairyland Laboratories, Inc., Arcadia, WI*.

Objectives of this field trial were to evaluate laboratory assays to assess starch digestibility in dry (DC) and high-moisture corn (HMC) and starch and fiber digestibility in corn silage (WPCS). Samples (n = 11, 16 and 29 for DC, HMC and WPCS replicate samples, respectively) were obtained from inventories fed on 25 dairy farms during two farm visits in summer. All samples were analyzed for nutrient composition, Degree of Starch Access (DSA), modified in vitro starch degradation (rumen fluid in vitro on 6 mm grind samples (MRSD) followed by enzymatic digestion (MPRSD) on the residue), and particle size. Kernel processing score (KPS) was determined on WPCS. In vitro NDF digestibility (IVNDFD) of WPCS was determined at 48- and 24-h. DM contents of HMC and WPCS were 73.7 ± 3.7% and 35.8 ± 4.7%, respectively. NDF and starch contents of WPCS were 40.6 ± 2.8% and 31.6 ± 3.6%, respectively. R-square value from multiple regression of DSA on DM content and mean particle size for HMC was 61% ($P < 0.0001$). For WPCS, DSA and MRSD were 93.7 ± 2.3% and 89.7 ± 5.4%, respectively. Total-tract in vitro starch degradability (MRSD+MPRSD) varied minimally (98.0 ± 1.1% of starch) for WPCS. DSA was positively ($r = 0.43$) correlated ($P < 0.05$) to KPS for WPCS. Whole-plant DM was unrelated ($P > 0.10$) to DSA or in vitro starch degradation parameters. Average 24-h IVNDFD was 19%-units lower than average 48-h IVNDFD (46% vs. 65% of NDF). R-square value from regression of 24-h on 48-h IVNDFD was only 33% ($P < 0.05$). Correlation ($P < 0.05$) between wet chemistry lignin (% of NDF) and IVNDFD was lower for 24-h than 48-h IVNDFD ($r = -0.28$ vs. -0.49). Results from this relatively small sample set indicate that 24-h IVNDFD was more variable and less related to lignin than 48-h IVNDFD, and that data from the two IVNDFD time points were not highly correlated. Recent assays to assess starch digestibility of corn grain and silage can aide our evaluation of these feeds in the field. More comparative research of these assays and research to validate their results relative to in vivo digestibility data is needed before they can be used with confidence in the field.

Key Words: Corn Silage, Starch, NDF

M74 Job satisfaction and interest in testing more cows: A survey of DHIA supervisors. J. C. Dalton*, *University of Idaho, Caldwell*.

Between 2003 and 2005, the number of dairy cows in Idaho increased by 45,000. During the same time period, twenty Idaho DHIA supervisors tested, on average, 114,784 cows (2003) and 119,120 cows (2005) and processed these records with a DRPC. In December 2005, Idaho had 472,000 dairy cows. To determine the level of interest of DHIA supervisors to test more cows, two surveys were conducted. DHIA supervisors (2003: n = 18; 2005: n = 17) in attendance at the 2003 and 2005 Annual Idaho DHIA Supervisor Conference were asked questions regarding length of time working as a supervisor, job satisfaction, number of cows tested per week, number of hours worked per week, and interest in testing more cows. For the years 2003 and 2005, respectively, 67% and 82% of supervisors reported being on the job greater than five years. When asked how satisfied they were with their job as a DHIA supervisor, the majority of supervisors responded that they were somewhat to very satisfied (56% and 65% for 2003 and 2005, respectively). Results showed that 72% and 75% of supervisors (for 2003 and 2005, respectively) tested more than 500 cows per week, while 100% and 86% of supervisors (for 2003 and 2005, respectively) reported working less than 60 hours per week. When asked if they were interested in testing more cows, 39% of supervisors responded yes, 28% responded no, and 33% were unsure according to the 2003 survey. In contrast, 17% of supervisors responded yes, 71% responded no, and 12% were unsure when asked in 2005 if they were interested in testing more cows. The results of these surveys suggest that although greater than half the supervisors expressed a high degree of job satisfaction, less than half the supervisors expressed an interest in testing more cows. Lastly, with continued dairy industry growth (Idaho had 500,000 dairy cows in December 2006 and was the fourth-largest milk producing state in the United States) and only 20 DHIA supervisors in Idaho, it is apparent that opportunities exist for current and future supervisors interested in testing cows.

Key Words: Dairy, DHIA Supervisor, Survey

M75 Use of real-farm case studies to teach nutrient management planners the value of feed management as part of whole farm nutrient management. R. A. White*[1], G. E. Erickson[2], R. K. Koelsch[2], R. E. Massey[3], V. R. Bremer[2], M. Fox[4], and J. H. Harrison[1], [1]*Washington State University, Puyallup*, [2]*University of Nebraska, Lincoln*, [3]*University of Missouri, Columbia*, [4]*KLA Environmental Services, Inc., Salina, KS*.

Feed management is an optional component of a Comprehensive Nutrient Management Plan (CNMP) and may be a viable option to decrease excess nutrients such as N and P on animal operations. The National Feed Management Education Project has developed assessment tools to facilitate development and implementation of a feed management plan (FMP) into a CNMP. The two audiences for the education program are animal nutritionists and nutrient management planners (planners). In most cases, collaboration between these two individuals is needed for successful completion of a FMP. The focus of this paper will be on the planner. The project team has chosen real-farm case studies as a teaching aid to illustrate and document the benefits of feed management. These case studies are used in separate, four hour education workshops to teach nutrient management planners about the five step process for development and implementation of a FMP. The goals of the workshops are to educate planners on the value of

feed management, encourage incorporation of a FMP into CNMP, and facilitate collaboration with animal nutritionists. Two feed management case studies were developed for Kansas feedlots (35,000 and 59,000 animal capacities). Both feedlots utilize nutritionists and private nutrient management planners. The case studies were developed by their planners who had previous knowledge of the operations. The objectives of the case studies were to 1) test practical use of the assessment tools in the field, and 2) use completed case studies as an educational resource when conducting feed management workshops. Feedback from the planner was used to improve the assessment tools for ease of use. Case study information was evaluated with a new software tool for assessing the dietary impact on land application and nutrient distribution costs. The completed FMP were used in a CNMP feed management workshop to instruct participants on how to use materials, illustrate the value of FMP, and what could be completed by someone with a similar background and knowledge of the material.

Key Words: Case Study, Education, Feed Management

M76 Comparison of somatic cell counts from fresh and frozen milk samples using the DeLaval DCC. W. D. Gilson*, L. O. Ely, and S. P. Nickerson, *University of Georgia*, *Athens*.

Milk somatic cell counts and culture results are valuable tools in determining the infection status for making decisions regarding further therapy or culling. Samples are often frozen before analysis. Freezing is generally regarded as harmful to somatic cells. There are limited reports comparing the results from fresh and frozen samples. Previous research indicates that fresh and frozen samples analyzed using fluoro-opto-electronic principles compare favorably. New equipment has been introduced based on the same principles. Aseptic quarter and composite milk samples were collected for microbiological culturing and refrigerated at 5 degrees C until processing. The samples were warmed to ambient temperature and plated to determine the microbiological status. Samples were vortexed and analyzed for somatic cells using the DeLaval DCC. The samples were subsequently frozen at -20 degrees C for a minimum of 2 weeks. Samples were thawed, allowed to warm to ambient temperature, vortexed and analyzed using the DeLaval DCC. Statistical analysis was performed using SAS to compare cell counts before and after freezing. Natural logarithmic transformation of the data was also performed to approximate a normal distribution. The mean SCC and LN SCC for fresh and frozen samples was 466,564, 454,918, 4.68 and 4.75, respectively. Differences were not statistically different. The correlations between the fresh and frozen samples were .914 and .934 for actual and LN. The data were further grouped according to the relative time in the lactation cycle the sample was collected. The actual SCC's for samples collected during the first 3 days following parturition were statistically different (P>.002) while the LN was not significantly different. No statistical differences were found for any of the other groups. These results indicate that cell counts determined by the DCC from frozen samples may be useful in evaluating infection status. Log transformation normalizes the data resulting in more accurate information. Further research is necessary to confirm the relationship between cell counts on fresh and frozen milk samples.

Key Words: Somatic Cell Count, Milk Quality

M77 A milk quality management survey of Minnesota DHI dairies with consistently low somatic cell counts. J. K. Reneau*, T. Bartholomay, and J. M. Lukas, *University of Minnesota*, *St Paul*.

A milk quality survey was professionally designed to assess the milk quality attitudes and management practices among Minnesota DHI herds with the lowest average somatic cell counts. Seventy-seven of the 104 surveys mailed were completed and returned. Five were eliminated not meeting SCC criteria of < 160,000. For the remaining 72 herds the mean herd size was 107 cows with a range of 32 – 415 cows. Bulk tank Somatic cell counts (BTSCC) mean and variation was 118,000 & 19,700 respectively. The average was standard plate count was 3,400. Rolling herd average milk production was 10,412 kgs. Questions reflecting the seven habits of highly effective people were asked. Responses indicate: 87% are proactive, 79% have vision, 84% put first things first, 79% seek win-win relationships with employees and farm consultants, 53% try to understand then be understood, 73% value synergy, clear communications and teamwork, Only 50% indicate they value personal improvement for themselves and employees yet 92% report keeping up to date on latest SCC issues. 99% think that doing the job right is more important than getting done fast. 76% report that their milkers enjoy milking. By self assessment cow composite hygiene score (scale 1-5) for lower rear legs and udders was 2.12. 91% remove manure and soiled bedding at each milking; 76% using organic bedding re-bed daily and 64% use more than 1 inch of bedding; 83% using sand re-bed weekly 94% keeping sand at minimum level to curb; 72% use full 10-20 seconds per cow pre-milking teat prep; 75% fore-strip; 82% report they always or almost always achieve complete pre-dip coverage and 93% report achieving complete post dip coverage; 91% dry cow treat all cows all quarters and 67% use internal sealers for all dry cows; 78% provide formulated dry cow diets. Responses indicating need for improvement: 56% indicate milking machine checks only when needed or once per year and although 52% indicate they keep some clinical mastitis treatment records only 19% keep detailed treatment records.

Key Words: Milk Quality, Attitudes, Management Practices

M78 Poultry nutrition and disease knowledge in California exhibition poultry owners: A survey. B. A. McCrea*[1], T. Y. Morishita[2], and F. A. Bradley[1], [1]*University of California*, *Davis*, [2]*Western University of Health Sciences*, *Pomona, CA*.

Survey responses from California exhibition poultry owners were collected using a set of questions developed in a previous study at Ohio State University. Our objective was to determine the perception and level of knowledge in this group with regard to poultry health management and nutrition topics. Surveys were given to adult and youth (i.e., 4-H and FFA) exhibitors. Surveys were handed out at exhibition poultry shows between October 2006 and March 2007. Show locations attended include the central valley, central coast, and north coast regions. In general, participants, both young and old, were more knowledgeable about poultry health management topics than nutrition topics. Our results indicate that there is a distinct lack of knowledge regarding antibiotic use and vaccination. Participants had little knowledge of poultry digestive anatomy. These topics may be more effectively communicated if the basic level of understanding can be determined. Poultry extensionists can use the information from this survey to develop materials and continuing education programs incorporating poultry health and nutrition.

Key Words: Exhibition Poultry, Health Management, Nutrition

M79 Cull cow and calf marketing methods employed by Idaho dairies. M. Chahine and J. B. Glaze, Jr.*, *University of Idaho*, *Twin Falls*.

To assess the awareness, knowledge, understanding, and implementation of beef quality assurance (BQA) principles on Idaho dairies, a survey of dairy farmers in Idaho was conducted. Each of the 736 known dairies operating in Idaho received copies of the survey. Two-hundred, thirty six dairies returned the survey for an overall response rate of 37%. One section of the survey inquired about the cull cow and calf marketing methods employed by Idaho dairies. The marketing questions offered auction market, order buyer, forward contract, and private treaty, as marketing options for cull cows and calves. An additional marketing option listed for cull cows was direct market to the packer. To determine which marketing methods were most used by dairies, survey participants were asked to select any or all of the marketing options used by their dairy. The selections were compiled and used to assign use percentages. As dairies market their cull cows, they use auction markets most often (64%), followed by order buyers (17%), direct to the packer (17%), private treaty sales (16%), and forward contract (1%). The most used calf marketing method was private treaty sales (52%), followed by auction markets (42%), order buyers (14%), and forward contracts (1%). When the selections were compiled based on dairy size, results indicated that large dairies (more than 1000 cows) used auction markets most often (62%) to market their cull cows, followed by order buyers (33%), private treaty sales (23%), and direct to the packer (23%). Medium-sized dairies (200-1000 cows) favored auction markets (61%) over direct to the packer (17%), private treaty sales (15%), and order buyers (14%) when marketing cull cows. Small dairies (less than 200 cows) chose auction markets (66%) to market their cull cows more often than direct to the packer (15%), private treaty sales (14%), and order buyers (13%). Regardless of size, dairies chose private treaty sales over auction markets, order buyers, and forward contracts to market their calves.

Key Words: Marketing, Cull Cow, Calves

M80 Financial performance of dairies in Florida and Georgia in 2005. L. O. Ely*[1], R. Giesy[2], B. Broaddus[2], C. Vann[2], A. Bell[2], and A. deVries[2], [1]*University of Georgia*, *Athens*, [2]*University of Florida*, *Gainesville*.

The Dairy Business Analysis Project (DBAP) includes an annual survey of the financial performance of dairies primarily located in Florida and Georgia. Its objective is to document the dairies' financial success using standardized, accrual accounting methods in order to calculate benchmarks and provide feedback on the dairies financial strengths and weaknesses. Twenty-six dairies submitted financial data in 2005. Twenty-one dairies were included in the summary results. Of these, 15 were located in Florida, and 6 in Georgia. The average herd size was 1,045 cows and 538 heifers with 18322 lbs. milk sold per cow. The average culling rate was 36%. There was an average of 19 FTE workers per farm and 0.93 million lbs milk sold per FTE worker. Total revenue per cwt. was $20.73 / cwt with $18.24 / cwt milk income. The average total expense was $20.20 / cwt. The largest expense items were purchased feed ($7.22 / cwt), labor ($3.50 / cwt), livestock ($2.01 / cwt) and milk marketing ($1.22 / cwt). Net farm income from operations was $0.53 / cwt and net farm income was $0.07 / cwt. The debt to asset ratio was 0.39, the rate of return on assets was 0.04, the rate of return on equity was 0.02, the operating profit margin ratio was 0.02. Total expenses decreased and returns increased with herd size in 2005. Herds >670 cows had the middle total revenue ($20.44 / cwt) and the lowest expenses ($17.65 / cwt) resulting in the highest net farm income ($2.79 / cwt). The herds with the highest milk production (>19,500 lbs / cow / year) had the middle total revenue ($20.29 / cwt) and the lowest expenses ($18.98 / cwt) resulting in the highest net farm income ($1.19 / cwt).

Food Safety - Livestock and Poultry

M81 Preventing *Salmonella* colonization in cement using Bio Deep Seal. K. S. Macklin*, J. B. Hess, and D. E. Conner, *Auburn University*, *Auburn, AL*.

Salmonella is an important foodborne pathogen that is often associated with poultry. Unfortunately, the ability to properly clean and disinfect an area to remove this pathogen and/or other bacteria can be difficult. This is especially true in a constantly wet environment, such as that typically found in a poultry processing plant. In this study a commercial product (Acon Bio Deep Seal) that claimed to kill, encapsulate or displace bacteria was tested. This product was tested on cement blocks that had been impregnated with *Salmonella typhimurin*. To test the product an experiment was designed to include four treatments that were tested in five blocks each. The four treatments were an unchallenged group (CON), a challenged untreated group (CHAL), a challenged/pre-challenged treated group (PRE), and a challenged/post-challenge group (POST). The PRE group was treated with the product according to the manufacturer specifications. After 1 h, the PRE, CHAL, and POST blocks were placed in a broth that contained approximately 5 x 10^9 cfu/mL of a *S. typhimurin*. After 24 h, the blocks were removed and the POST group was treated. After 6 h from removal from the broth, swabs were taken of the surface from each block. After the external swabs were taken, internal swabs were also obtained. Swabs were taken in duplicate with one swab being placed in TTB Hajna and the other being used for direct plating onto XLT4. After 24 and 48 h of incubation, the XLT4 plates were examined for presence of *Salmonella*. The TTB blocks were incubated for 48 h before being streaked onto XLT4. *Salmonella* counts (cfu/cm^2) for the XLT4 plates were transformed using log10. The data were analyzed using the GLM procedures of SAS with $P < 0.05$ and the means were separated using Tukey's HSD. *Salmonella* was detected on the block's exterior from treatments CHAL and PRE, but not from the CON and POST treatments. *Salmonella* was detected on the interior of the blocks only from the CHAL group. The results showed that Bio Deep Seal is an effective cement treatment to eliminate *Salmonella* when it is applied either before or after the cement was exposed to the pathogen.

Key Words: *Salmonella*, Disinfection, Cement

M82 Effects of transport stress on subclinical infection in an *Escherichia coli-Listeria monocytogenes* challenge model. G. R. Huff*[1], W. E. Huff[1], V. Dutta[2], R. Nannapaneni[3], and M. G. Johnson[3],

[1]*USDA/ARS/PPPSRU*, *Fayetteville, AR*, [2]*University of Arkansas*, *Fayetteville*, [3]*Center for Food Safety & Microbiology-IFSE, University of Arkansas*, *Fayettevile, AR*.

We hypothesized that stress-induced subclinical infection of turkeys with *Listeria monocytogenes* (Lm) may be a source of contamination in processing plants and we have shown that concurrent *Escherichia coli* challenge can increase Lm colonization. The objective of this study was to determine effects of transport stress on isolation of Lm in an *E. coli*-Lm challenge model. Thirteen-wk-old male turkeys housed in floor pens were challenged by exposure to *E. coli* and Lm Scott A using coarse spray and feed inclusion. Positive controls were given an immunosuppressive dose of dexamethasone (Dex) during challenge. At 15 wk, a sample of birds was subjected to 12 h transport stress and all birds were bled and necropsied the following morning. Leukocyte numbers and percentages and hematological indices were determined. Knee and hip joints were sampled using transport swabs and cultured using pre-enrichment in University of Vermont medium and Fraser broth, and isolation of Lm on Listeria selective agar plates. Challenged birds, challenged-transported birds, and challenged-Dex or Dex treated birds had lower ($P < 0.05$)BW than the controls. Isolation of Lm was achieved from the knee or hip joints of 71% of challenged-Dex treated birds, 44% of challenged birds, and 23% of challenged-transported birds. Peripheral blood leukocyte count and percentage of heterophils (H) increased ($P < 0.05$) by Dex and by Transport. Dex decreased ($P < 0.05$) percentage of lymphocytes (L). The H/L ratio increased ($P < 0.05$) by Dex. Total erythrocyte counts, hematocrit, and hemoglobin decreased by Dex ($P < 0.05$) and by Transport ($P < 0.09$). The data suggested that subclinical infection with Lm can result from environmental exposure and Dex treatment could increase incidence of Lm colonization. Transport stress also tend to decrease Lm isolation from hip joints relative to unstressed challenged birds and this effect may be related to an increase in heterophil numbers.

Key Words: Turkeys, *Listeria monocytogenes*, Transport

M83 A dual system based on the use of electronic identification and molecular markers to ensure lamb traceability. G. Caja*, J. J. Ghirardi, M. Hernández-Jover, and A. Sánchez, *Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

As a part of a European Union project (FAIR5 QLk1-2001-02229: EID+DNA Tracing) the efficiency of a dual traceability system based on animal electronic identification (e-ID), by radiofrequency boluses (Rumitag, Barcelona, Spain) containing low-frequency (LF, 134.2 kHz) transponders of 32 mm, and genetic fingerprinting (DNA) by analyzing specific sets of ovine microsatellites (n = 12) in biopsies, was evaluated. A high-frequency (HF, 13.56 MHz; Tiris, Almelo, Holland) read-write inlay transponder (45 × 76 mm) was used for transferring e-ID code to the carcass. All animals also had visual ear tags (VE). Lambs (n = 1,908) on seven farms (Badajoz and Barcelona, Spain) were e-ID during suckling by using two LF mini-boluses (B1 [9 g; 10 × 39 mm; n = 1,091] and B2 [20 g; 11 × 56 mm; n = 817]). At bolus administration, biopsying ear tags (BE) were also attached (n = 980; Biopsytec, Rheinbach, Germany). Lambs were slaughtered before 3 mo of age in two commercial abattoirs. Mini-boluses were automatically read just before evisceration by a LF transceiver interfaced with a HF recorder. Bolus LF code was transferred to HF labels which were attached on the shank of the carcass after recording. Carcass samples (n = 868) were taken by using sampling tubes (Biopsytec). Ear and carcass samples were frozen until DNA analysis. On-farm traceability was lower for VE (96.8%) than for BE (99.7%), B1 (98.4%) and B2 (100%). Semi-automatic data transfer to carcasses was 98.9% successful. Abattoir traceability as well as total traceability differed between B1 (97.7 and 96.1%) and B2 (99.9 and 99.9%), respectively. When tracing back of carcasses to lambs in 50 random samples, one pair did not match (2.0%), showing 98.0% lamb traceability. In conclusion, the dual e-ID and DNA tracing system showed high traceability efficiencies (98%) under practical conditions, although improvement in label design and reading equipment is needed.

Key Words: Traceability, Transponder, Fingerprinting

M84 Reduction of cecal *Campylobacter* spp. in broiler chickens by egg powder, mannobiose, or their combination. Y. Han, G. I. Page*, and J. J. Brennan, *Maple Leaf Foods Agresearch*, *Guelph, Ontario, Canada*.

Fresh chicken is the main risk factor for human Campylobacteriosis. Two trials were conducted to study effects of dietary addition of egg powder (EP) or mannobiose (MB) on number of *Campylobacter* spp. in broiler chickens. In Exp. 1, 240 birds were fed the same medicated diet until d 34. From d 35 to 42, four different diets were fed to six pens (replications) per treatment (10 birds/pen). The following test material was added into the medicated (55 ppm bacitracin) control diet: 5% EP, 130 ppm MB, or 13 ppm MB. On d 29, 37, 39, and 42, two birds per pen were sacrificed for cecal *Campylobacter* counts. In Exp. 2, five experimental diets were fed to six pens (replications) per treatment (15 birds/pen) of 450 d-old chicks for 2 wk, followed by a common feed until d 41. The following product was added into a medicated control diet, 5% EP, 130 ppm MB, 5% EP + 130 ppm MB, or 2.5% EP + 65 ppm MB. On d 14, 21, 28, and 41, two birds per pen were analyzed for cecal *Campylobacter* counts and cecal total IgA. In both experiments, the test materials did not affect ($P > 0.05$) growth performance or mortality of the birds. In Exp. 1, all birds were positive for *Campylobacter* by d 29. No differences ($P > 0.05$) in cecal *Campylobacter* counts were found on d 37 or 39. However, on d 42, birds fed the 5% EP had lower ($P < 0.05$) *Campylobacter* counts than those fed the Control or the 13 ppm MB diet (0.94 vs 2.50 or 2.69 log cfu/g), but not different ($P > 0.05$) from those fed the 130 ppm MB diet (2.09 log cfu/g). In Exp. 2, the test materials did not prevent the newly placed birds from being colonized by *Campylobacter* by day 14. By d 41, the cecal *Campylobacter* counts in the control birds were numerically higher ($P > 0.05$) than those in the birds fed the 5% EP, the 130 ppm MB, the combination of both, or the 2.5% EP + 65 ppm MB diets (2.61, .98, 1.03, 1.27, or 1.20 log cfu/g, respectively; $P = 0.09$). Cecal total IgA concentrations on d 41 were higher ($P < 0.05$) in the birds fed the EP, the MB, or the combination diets than in those fed the control diet. It was concluded that egg powder and mannobiose could be used to reduce *Campylobacter* colonization in broiler chickens.

Key Words: *Campylobacter* spp., Egg Powder, Mannobiose

M85 Development of a polymerase chain reaction-based method to identify poultry, ruminants, and equine components in fish meal. A. Heravi Moussavi*[1], M. Nassiri[1], G. Pourseifi[1], M. Soltani[1], A. Javadmanesh[1], and R. Noorbakhsh[2], [1]*Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavy, Iran*, [2]*Standards*

and Industrial Research, Khorasan Razavy Head Office, *Mashhad, Khorasan Razavy, Iran*.

Fish meal is a widely used feedstuff for poultry and ruminants. The objective of this study was to develop a polymerase chain reaction (PCR)-based method to identify poultry, ruminants, and equine components in fish meal. In this experiment, 10 different available commercial fish meals were used. The nitrogen contents were measured using the Kejeldal method to investigate the correlation between nitrogen contents and the possible non-fish species components. Mitochondrial DNA extraction was carried out using a commercial kit based on phenol-chloroform method. Specific primers for every species were designed and calibrated to generate exclusively a PCR product with a specific size when DNA for each species was present in the sample. Blood samples of hen, cow, sheep, and horse were run as the positive controls. The results demonstrated that only two products were not contaminated and the others were contaminated with at least one of the species. The correlation between nitrogen content and possible non-fish species components was not significant ($P = 0.57$; $r = 0.2$). The results demonstrated that evaluation of fish meal by measuring its CP content is not accurate and it should be evaluated by other methods such as PCR-based methods. It is recommended that PCR methods to be considered for feedstuff standards as tools to assure quality.

Key Words: Fish Meal, PCR, Adulteration

M86 Detection of *Escherichia coli* O157:H7 using Au nanoparticles mediator on an electrochemical amperometric immunobiosensor. S.-H. Chen*[1], Y.-H. Lin[1,2], Y.-C. Chuang[1], Y.-R. Lin[1], C. A. Chang[1], T. Y. Shen[2], and C.-S. Lin[1], [1]*National Chiao Tung University*, *Hsinchu, Taiwan, R.O.C*, [2]*Apex Biotechnology Corporation*, *Hsinchu, Taiwan, R.O.C*.

A screen-printed carbon electrode (SPCE) immunobiosensor, based on 13-nm Au nanoparticles (AuNPs) as mediator for amplifying electronic conduction and detection signal, was used for real-time detection of *Escherichia coli* O157:H7. We investigated the impact of electronic conduction using horseradish peroxidase (HRP) reacted to hydrogen peroxide (H_2O_2) through an AuNPs-modified SPCE surface. The AuNPs were used to increase electron conductivity and surface area of SPCE for amplifying detection current in developing immunobiosensing system. In the assembling process of SPCE, the AuNPs-mediator was first addressed onto the SPCE surface and immobilized the first specific antibody against *E. coli* O157:H7. The modified SPCE was then used to detect the samples containing *E. coli* O157:H7. After the procedures of detection and washing, the SPCE was treated with the second *E. coli* O157:H7 specific antibody conjugated with HRP, and reacted to H_2O_2, the free electron generated could be detected by an electrochemical amperometric biosensor. The detection results demonstrated that the 13-nm AuNPs, as in an immunobiosensor mediator, could enhance the current around 60 folds compared with those without AuNPs-modified electrodes. The AuNPs-modified SPCE developed in this study enabled the detection of *E. coli* O157:H7 at a low concentration of 10^2 cfu/strip within 1 h and the reproducibility reaches 85%, which shows that this technique is more efficient than traditional culture plate methods. The SPCE immunobiosensing system has potential for further applications and lays the groundwork for incorporating the method into an integrated system for rapid pathogen detection.

Key Words: *Escherichia coli* O157:H7, Screen-printed Carbon Electrode, Immunobiosensor

M87 Effect of heat treatments on stability of β-lactams in milk. M. Roca[1], M. A. Zorraquino[2], C. Igualada[3], R. L. Althaus[4], and M. P. Molina*[1], [1]*Universidad Politecnica de Valencia*, *Valencia, Spain*, [2]*Universidad Publica de Navarra*, *Pamplona, Spain*, [3]*Generalitat Valenciana*, *Valencia, Spain*, [4]*Universidad Nacional del Litoral*, *Esperanza, Republica Argentina*.

The presence in milk of residues of antimicrobial substances may have serious toxicological and technical consequences. Studies referring to the influence of heat treatments on antimicrobial residues in milk are very scarce. The objective of the study was to analyze, using HPLC assays, the effect of different heat treatments (60, 70, 80, 90, and 100°C at six different times) on milk samples fortified with 5,000 μg/kg of penicillin, amoxycillin, ampicillin, cloxacillin, cephalexin, cephalonium, cefquinome, cefoperazone, cephapirin, and cephuroxime. The half-life (losses of 50% of the initial concentration) calculated for β-lactams showed that penicillins are more stable molecules than cephalosporins. Using the obtained prediction equations, the thermal loss percentages in concentration for the frequent heat treatments carried out in the control laboratories and dairy industry, are calculated. The results showed that the sample homogenization (40°C for 10 min) caused no inactivation in most of the β-lactams, whereas heating to 83°C for 10 min to inactivate the natural milk inhibitors, caused a small reduction in penicillin concentrations, around 6%, but a higher one in cephalosporins (15 to 53%). The LTLT pasteurization (60°C for 30 min) caused less degradation (3 to 6%), somewhat higher in the cephalosporins (16 to 43%). The HTST pasteurization (72°C for 15 s) produced very small losses in all β-lactams (< 1%). In contrast, sterilization (120°C for 20 min) produced a marked heat degradation ranging between 47% (amoxicillin) and 93% (ampicillin) for the penicillins and greater than 90% for most cephalosporins. In turn, the inactivation percentages of the treatment at 140°C for 10 s (UHT) are low for nearly all β-lactams, being situated between 1 and 8%, and moderate for cephuroxime (19%) and cefoperazone (37%). In conclusion, only sterilization produced a high inactivation level of β-lactams in milk. The other treatments were no guarantee that these molecules would lose their antimicrobial activity.

Key Words: Antibiotics, Milk, Thermostability

M88 Effects of feed withdrawal times prior to slaughter on cecal fermentation and *Salmonella* shedding at the abattoir. S. Martín-Peláez[1], E. Creus[1], B. Peralta[2], J. F. Pérez*[1], E. Mateu[2], and S. M. Martín–Orúe[1], [1]*Animal Nutrition, Management and Welfare Research Group, Universitat Autònoma de Barcelona*, *Spain*, [2]*Departament de Sanitat i Anatomia Animals, Universitat Autònoma de Barcelona*, *Spain*.

The objective of this study was to determine whether different times of feed withdrawal in pigs prior to slaughter have any effect on cecal fermentation and *Salmonella* shedding. One commercial farm subclinically infected with *Salmonella* (prevalence of carriers = 13%) was studied. Two groups of pigs (45 each) were either deprived of feed for 15 or 30 h before slaughter. Fecal samples were collected the day before slaughter at the farm. The weight of the gastrointestinal tract (GIT) was recorded and fecal samples from the rectum were collected for *Salmonella* detection. Cecal samples were also collected to evaluate possible changes in pH, concentrations of short chain fatty acids (SCFA) and NH_3, and numbers of lactobacilli and enterobacteria by means of qPCR. The GIT weight decreased ($P < 0.05$) with increasing feed withdrawal time (6.76 vs 6.39 kg) whereas cecal pH (5.9 vs 6.4)

increased ($P < 0.05$). Concentration of total SCFA (89.5 vs 77.8 mM) decreased ($P < 0.05$) with increasing feed withdrawal time but the percentage of branched SCFA (1.9 vs 3.1%) increased ($P < 0.05$). The NH_3 concentration (366.6 vs 769.3 mg/L also increased ($P < 0.05$) with increasing feed withdrawal time. The numbers of enterobacteria (8.7 vs 9.1 log 16 S rDNA copies/g FM) increased ($P = 0.08$) with increasing feed withdrawl time whereas the numbers of lactobacilli (9.6 vs 9.0 log 16 S rDNA copies/g FM) decreased ($P < 0.05$). The percentage of pigs with *Salmonella* in the rectal contents was higher ($P < 0.05$) in the group that was fasted for 30 h (18 vs 33%). The results suggested feed withdrawl for a short period of time (e.g., 15 h) to have the potential to decrease presence of *Salmonella* in the GIT of pigs arriving at the abattoir.

Key Words: Swine, *Salmonella*, Feed withdrawal

M89 Efficacy of a micro-encapsulated or non-encapsulated blend of lactic and formic acid to reduce the prevalence of *Salmonella* in finishing pigs. J. dos Santos[1], E. Creus[1], J. F. Pérez*[1], E. Mateu[2], and S. M. Martín–Orúe[1], [1]*Animal Nutrition, Management and Welfare Research Group, Universitat Autònoma de Barcelona*, *Spain*, [2]*Departament de Sanitat i Anatomia Animals, Universitat Autònoma de Barcelona*, *Spain*.

Micro-encapsulated acids in the feed have been proposed to increase acid concentrations in the posterior sections of the gut. The objective was to examine if an economically affordable dose of protected acid could improve efficacy of a non-protected blend in reducing *Salmonella* in finishing pigs. One commercial farm subclinically infected was selected. A total of 261 pigs were allocated to three dietary groups that included a control (CTR), the CTR with a blend of lactic and formic acids added at 0.4% each (NPB), and the CTR diet with a lipid microencapsulated blend of each acid (0.14% each) added (PB). The pigs had ad libitum access to the diets for 5 wk. Blood samples for ELISA were taken before starting the diets (d-0) and immediately after slaughter (d-36), and fecal samples were collected on d-0 and d-36 for microbiology tseting. Cecal contents were also collected for measuring pH, short chain fatty acids (SCFA), and both formic and lactic acids. No change was detected in cecal pH but increased concentrations ($P < 0.05$) of formic and lactic acids were detected with feeding the NPB diet (3.2 and 12.9 mM, respectively) and the PB diet (4.0 and 11.6 mM, respectively) compared with feeding the CTR diet (2.0 and 4.8 mM, respectively). Concentrations of SCFA were higher ($P < 0.05$) with feeding the PB diet (233 mM) than with feeding the CTR (177) or the NPB (173) diets. Five weeks of feeding the NPB diet decreased ($P < 0.05$) seroprevalence (from 59.4 to 8.8%) but not the rest of diets. No change in *Salmonella* shedding was detected from d-0 to d-35. However increases ($P < 0.05$) were found after transport to the abattoir with feeding the CTR (12.5 vs 77.4%) and the PB (0 vs 17.4%) diets, but not with the NPB diet (0 vs 3.3%). The results suggested that inclusion of a non-protected blend of formic and lactic acids in finishing diets could decrease *Salmonella* seroprevalence in swine. The microencapsulated blend, however, did not decrease *Salmonella* prevalence.

Key Words: Swine , *Salmonella*, Acidifiers

M90 Effects of feed withdrawal and lairage time prior to slaughter on the gut environment and cecal *Enterobacteriaceae* in finishing pigs. S. Martín–Peláez[1], S. M. Martín–Orúe[1], J. F. Pérez*[1], A. Dalmau[2], E. Fàbrega[2], A. Velarde[2], J. Tibau[2], and J. Gasa[1], [1]*Animal Nutrition, Management and Welfare Research Group, Universitat Autònoma de Barcelona*, *Spain*, [2]*IRTA*, *Monells, Girona, Spain*.

The objective of this study was to determine effects of different feed withdrawal and lairage times prior to slaughter on the gut environment of pigs and also on growth of *Enterobacteriaceae* as a possible marker of *Salmonella* shedding. Two groups of finishing pigs (36 each) were deprived of feed for 2 or 12 h before their lairage at the slaughterhouse. Each group was divided into three subgroups and held in different holding pens for 0, 5, or 10 h before slaughter. The weight of the gastrointestinal tract (GIT) was determined and samples of cecal contents were collected to measure pH, short chain fatty acids (SCFA), and the numbers of lactobacilli and enterobacteria by means of qPCR. The GIT weight decreased ($P < 0.05$) with feed withdrawal (6.8 vs 5.7 kg) but not with increasing lairage time. Similarly cecal pH increased ($P < 0.05$) only with feed withdrawal (6.14 vs 6.55). Cecal concentration of total SCFA decreased ($P < 0.05$) with feed withdrawal (165 vs 125 mM) and increasing lairage time (182, 147, and 105 mM for 0, 5, and 10 h, respectively). Lactobacilli population decreased ($P < 0.05$) with increasing lairage time (10.0, 9.3, and 8.6 log 16 S rDNA copies/g FM for 0, 5, and 10 h, respectively) whereas *Enterobacteriaceae* increased ($P < 0.05$) with feed withdrawal (9.0 vs 9.5 log 16 S rDNA copies/g FM) and increasing lairage time (8.9, 9.4, and 9.6 log 16 S rDNA copies/g FM for 0, 5, and 10 h, respectively). The results showed that antemortem feed depriviation time can have a significant impact on intestinal environment and potential growth of pathogens of the *Enterobacteriaceae* family.

Key Words: Swine, Pathogens, Feed Withdrawl

M91 The relationship between *Salmonella* detection from milk filters and bulk milk and fecal shedding of *Salmonella* in a dairy herd. J. S. Van Kessel*[1], J. S. Karns[1], D. R. Wolfgang[2], E. Hovingh[2], and Y. Schukken[3], [1]*USDA-ARS-EMSL*, *Beltsville, MD*, [2]*The Pennsylvania State University*, *University Park*, [3]*Cornell University*, *Ithaca, NY*.

Although dairy cattle are known reservoirs for *Salmonella*, cattle that are shedding this pathogen are often asymptomatic and difficult to identify. A dairy herd experiencing an outbreak of *Salmonella enterica* subsp. *enterica* Cerro was monitored for 2 yr. Fecal samples from lactating cows were collected every 6 to 8 wk and were tested for presence of *Salmonella* using traditional culture methods. Fecal shedding of *Salmonella* fluctuated throughout the test period and the prevalence ranged from 8 to 88%. During this period, bulk milk and milk filters were also tested for *Salmonella* on a weekly basis. *Salmonella* was detected in 15% of milk samples (n = 109) and in 78% (n = 107) of milk filters. Results of weekly bulk milk quality testing (i.e. bulk tank somatic cell score, standard plate count, and preliminary incubation count) were typically well within acceptable ranges. The recovery of *Salmonella* from milk filters and to a lesser extent from bulk milk, closely matched that from the feces. Analysis of in-line milk filters has been used previously as a useful method to detect presence of zoonotic bacteria entering bulk tanks. It is concluded that milk filter analysis could be used as a convenient method for monitoring *Salmonella* shedding in dairy herds.

Key Words: *Salmonella*, Dairy Cattle, Pathogens

M92 Validation of peracetic acid as an antimicrobial for poultry chillers. S. R. McKee*, L. J. Bauermeister, and J. W. Bowers, *Auburn University*, *Auburn, AL*.

Spectrum™ (peracetic acid; PAA) has been approved as an antimicrobial for use in poultry chillers. To validate its effectiveness, laboratory and commercial trials were conducted. In the laboratory trials, 200 poultry carcasses were inoculated with *Salmonella* (10^6 cfu) and were randomly allocated into chill water containing chlorine (30 ppm) or PPA (25, 100, or 200 ppm). The results illustrated that PPA concentrations of 100 or 200 ppm to effective in reducing *Salmonella* when compared with the chlorine treatment. A sensory study was also conducted with another set of 200 carcasses (not inoculated) treated with water, chlorine (30 ppm), or PPA (100, 150, or 200 ppm). Sensory panels and microbial data were collected weekly on randomly sampled carcasses that were stored at 4°C for 21 d. The PAA-treated carcasses at 150 and 200 ppm had an extended shelf life that ranged from 3 to 4 d beyond those treated with water or chlorine. On d 15, the only treatments that could be served to sensory panelists were the carcasses treated with 150 or 200 ppm PAA. The carcasses treated with water, chlorine, or 100 ppm PPA had off-colors, off-odors, and high microbial counts. In another trial, 65 ppm PPA was compared with the 30 ppm chlorine treatment in a commercial setting. In this trial, 100 carcasses were sampled for *Salmonella* prior to the chiller and 100 were sampled after chilling. In all, 400 carcasses were sampled using 65 ppm PPA in the chiller and 400 carcasses were sampled using the chlorine treatment. *Salmonella* was reduced by 90% using the 65 ppm PPA treatment and it was reduced by 55% using the chlorine treatment. Peracetic acid appears to be an effective antimicrobial in poultry chillers. It also appears to have the potential to extend the shelf-life of poultry when used at concentrations of 150 or 200 ppm.

Key Words: *Salmonella*, Poutlry Chilling, Peracetic Acid

M93 Evaluation of rep-PCR and denatured gradient gel electrophoresis (DGGE) in identifying *Salmonella* serotypes isolated from processed turkeys. P. N. Anderson*[1], M. E. Hume[1,2], J. A. Byrd[1,2], and D. J. Caldwell[1], [1]*Texas A & M University*, *College Station*, [2]*USDA-ARS, FFSRU*, *College Station, Texas*.

Salmonella has been reported as the leading foodborne pathogen in the U.S. Researchers are continually evaluating different molecular typing methods to identify the most suitable technique that is able to discriminate among *Salmonella* serotypes. A study was conducted to compare the use of automated repetitive extragenic palindromic (rep-PCR) and denaturing gradient gel electrophoresis (DGGE) as diagnostic tools for identifying *Salmonella* serotypes. The interspersed conserved repetitive sequence of the bacterial genome and the 16-23S rDNA intergenic spacer region were amplified for rep-PCR and DGGE, respectively. Fifty-three *Salmonella* isolates from two turkey processing plants (A and B) were used for this comparison: Brandenburg, Derby, Hadar, and Typhimurium with n = 6, 21, 12, and 15, respectively. The rep-PCR was fully automated, while DGGE was run on an acrylamide gel and the image was captured digitally and the dendrograms were created using the unweighted pair group method with arithmetic average. There were more variations in percentage similarity in DGGE when compared with rep-PCR. The banding patterns were more distinct and uniform in the rep-PCR group than with DGGE group. The results from the rep-PCR were generated within an hour, while the DGGE required nearly a day to run. The data suggested that DGGE and rep-PCR are useful tools for identifying *Salmonella* serotypes. In addition, rep-PCR is more rapid, may have a higher discriminatory power, but may be less cost effective than DGGE.

Key Words: *Salmonella*, Detection, Molecular Methods

M94 Association between on-farm milk and wash water temperature variations and bulk milk coliform counts. J. C. F. Pantoja, C. Hulland, G. J. M. Rosa, D. J. Reinemann, and P. L. Ruegg*, *University of Wisconsin*, *Madison*.

The objective was to determine the impact of temperature variations during milk storage and wash procedures on bulk milk coliform counts. Data were collected from two dairy farms between July and December, 2006. Farm A had 1,110 lactating cows that produced 42,184 kg milk/d with a log somatic cell counts (SCC) of 5.01. Farm B had 400 lactating cows that produced 13,607 kg milk/d with a log SCC of 5.04. Cows in both farms were housed in freestalls and were milked in parallel parlors. Both farms cooled milk using plate coolers, loaded milk directly into tankers, and had temperature recording charts for monitoring milk and wash water temperatures with sensors located in the milk line between the chiller and the tanker entry. The farms were visited monthly and daily somatic cell, standard plate, coliform, and laboratory pasteurized counts were downloaded from the processor website. Temperature charts were examined to detect minor temperature failures (temperature recorded between 7.2 and 10.0°C), major temperature failures (>10°C) and failure to reach 60°C during wash cycles (wash failures). The association between the occurrence of failures and coliform spikes (values above 100 cfu/mL) was analyzed using SAS. The distribution of failures, was minor (n = 101), major (n = 49), and wash failure (n = 11). Coliform counts varied between 0 and 1,500 cfu/mL and there were 32 occurrences of spikes. The occurrence of temperature failures was associated with occurrence of coliform spikes (P = 0.001) and the risk of a coliform spike was 3.58 higher when > 1 temperature errors occurred within a 2-d interval. Coliform spikes and temperature errors decreased from summer to winter. For the two farms investigated, there was an association between coliform count spikes and temperature variations. The results contribute to increasing the understanding of the complex factors impacting microbial ecology of raw milk.

Key Words: Milk Quality, Milking, Bcteria

M95 Meat quality and microbial shelf life of chicken breast fillets from air or immersion chilled processing systems and packaged under modified atmospheres. D. Monsalve*[1], H. Thippareddi[1], and S. Russell[2], [1]*University of Nebraska*, *Lincoln*, [2]*University of Georgia*, *Athens*.

The effects of modified atmosphere packaging (MAP) on microbial shelf life, lipid oxidation, and color stability of chicken breast fillets were determined during refrigerated storage. Chicken breast fillets were obtained from an air-chill and an immersion-chill establishment. Fillets were packaged aerobically (tray-pack) or under vacuum or flushed with nitrogen. Breast fillets for each packaging system were stored at 1 or 5°C. Changes in color, TBARS (2-thibarbituric acid-reactive substances), and microbiota were determined at 1, 7, 14, and 21 d of storage. Storage of breast fillets at 1°C and under a modified atmosphere (vacuum and nitrogen flush) extended the shelf life of the breast fillets, with lower microbial populations throughout the storage period. Vacuum and nitrogen flush packaged samples had

lower ($P < 0.001$) TBARS values (2,688 and 3,319 µg MDA/kg) than the aerobically-packaged samples (4,752 µg MDA/kg). Color values for lightness (L*), redness (a*), and yellowness (b*) were lower ($P < 0.001$) in air-chilled samples than in the immersion-chilled samples. The results indicated that modified atmosphere packaging of breast fillets can improve lipid stability and may extend shelf life.

Key Words: Storage, Modified Atmosphere, Shelf Life

M96 Characterization and potential human health risks of Shiga toxin-producing *Escherichia coli* isolated from California dairy cattle over one year. L. M. Bollinger*[1], H. S. Hussein[1], M. R. Hall[1], and E. R. Atwill[2], [1]*University of Nevada*, *Reno*, [2]*University of California*, *Davis*.

Worldwide awareness of Shiga toxin-producing *Escherichia coli* (STEC) increased in recent years due to tracing many human illness outbreaks to consumption of foods contaminated with cattle feces. Pathogenic STEC strains produce toxins responsible for causing (Shiga toxin 1 and/or Shiga toxin 2) or increasing (α-hemolysin and/or enterohemorrhagic *E. coli* [EHEC]-hemolysin) the severity of illnesses. These toxins are encoded by stx_1, stx_2, *hlyA*, and EHEC-*hlyA* genes, respectively. Because dairy cattle are STEC reservoirs, they can impose significant health risks to humans. The objective was to examine STEC prevalence in four dairy farms (averaging 712 cows) in California and to assess potential pathogenicity of the isolates. Analysis of 1,268 fecal samples from heifers (n = 261) and cows (n = 1,007) over one year resulted in detection of 33 isolates that belonged to 16 STEC serotypes (O15:H^- [nonmotile], O116:H^-, O125:H20, O127:H19, O128:H20, O136:H10, O136:H12, O136:H19, O136:HUT [untypeable H antigen], O157:H7, O157:H^-, O166:H6, OX13 [new provisional O antigen]:H19, OX13:H20, OUT [untypeable O antigen]:H7, and OUT:H^-) and were lethal to Vero (African green monkey kidney) cells. Of these isolates, 17, 4, and 12 had stx_1, stx_2, or both genes, respectively. Except for one (belonging to the O128:H20 serotype, having both genes, and expressing only stx_2), all isolates expressed these genes. Only one isolate (belonging to the O166:H6 serotype) had and expressed the *hlyA* gene whereas 18 isolates had the EHEC-*hlyA* gene but only five expressed it. Of the 16 serotypes, three (O157:H7, O157:H^-, and OUT:H^-) cause hemolytic uremic syndrome, two (O15:H^- and OUT:H7) cause other human illnesses, and eight (O125:H20, O127:H19, O128:H20, O136:H10, O136:H19, O166:H6, OX13:H19, and OX13:H20) have not been reported previously in cattle. Because our STEC isolates produced one (n = 18), two (n = 13), or three (n = 2) virulence factors, their pathogenic potential to humans should not be ignored. Our results demonstrate the potential health risks of O157 and non-O157 STEC isolates from dairy cattle origin.

Key Words: Shiga Toxins, *Escherichia coli*, Dairy Cattle

M97 Characterization and potential human health risks of Shiga toxin-producing *Escherichia coli* isolated from feedlot cattle. H. S. Hussein*[1], L. M. Bollinger[1], M. R. Hall[1], S. F. Khaiboullina[1], and E. R Atwill[2], [1]*University of Nevada*, *Reno*, [2]*University of California*, *Davis*.

Since tracing two outbreaks of human illnesses to consumption of beef contaminated with Shiga toxin-producing *Escherichia coli* (STEC) in 1982, the concerns with beef safety have been on the rise. The illnesses included bloody diarrhea, hemorrhagic colitis, and hemolytic uremic syndrome (HUS). The ability of STEC to cause (Shiga toxin 1 and/or Shiga toxin 2) or increase (α-hemolysin and/or enterohemorrhagic *E. coli* [EHEC]-hemolysin) the severity of these illnesses is directly related to production of virulence factors. The genes coding for these factors are stx_1, stx_2, *hlyA*, and EHEC-*hlyA*, respectively. Because beef cattle are STEC reservoirs, they continue to impose significant health risks to humans. The objective was to examine STEC prevalence in four feedlots (ranging from 13,000 to 46,000 Holstein steers) in California and to assess potential pathogenicity of their isolates. To achieve this, 642 fecal samples (approximately 40 samples per feedlot per season) were collected from 321 growing and 321 finishing steers over one year. A total of 21 isolates belonging to 14 STEC serotypes (O86:H19, O114:H2, O125:H19, O127:H19, O136:H12, O136:H^- [nonmotile], O153:H^-, O157:H7, O165:H7, OUT [untypeable O antigen]:H5, OUT:H12, OUT:H20, OUT:H^-, and OUT:HUT [untypeable H antigen]) were detected and were toxic to Vero (African green monkey kidney) cells. Of these isolates, 12, 5, and 4 had stx_1, stx_2, or both genes, respectively. Except for two (belonging to the O157:H7 and O165:H7 serotypes, having both genes, and expressing only stx_2), all isolates expressed these genes. None of the recovered isolates had the *hlyA* gene whereas 14 isolates had the EHEC-*hlyA* gene but only five expressed it. Of the recovered serotypes, two (O157:H7 and OUT:H^-) cause HUS, two (OUT:H12 and OUT:HUT) cause other human illnesses, and seven (O86:H19, O114:H2, O125:H19, O127:H19, O165:H7, OUT:H12, and OUT:H20) have not been reported previously in cattle. The results showed these beef cattle isolates to produce one (n = 14) or two (n = 7) virulence factors and demonstrated the potential health risks of O157 and non-O157 STEC isolates.

Key Words: Beef Cattle, Shiga Toxins, *Escherichia coli*

M98 Prevalence and pre-harvest control factors affecting Shiga toxin-producing *Escherichia coli* in cattle grazing rangeland forages. L. M. Bollinger*[1], H. S. Hussein[1], and E. R. Atwill[2], [1]*University of Nevada*, *Reno*, [2]*University of California*, *Davis*.

Shiga toxin-producing *Escherichia coli* (STEC) caused numerous outbreaks of human illnesses ranging from mild diarrhea to hemolytic uremic syndrome (HUS). Beef cattle are STEC reservoirs and impose health risks to humans through fecal contamination of beef. To minimize this risk, it is essential to identify and implement pre-harvest control measures that decrease fecal shedding of STEC. The objective was to determine effects of pre-harvest factors on STEC prevalence in California cattle grazing rangeland forages. In six cow/calf operations (ranging from 65 to 225 cows), 774 fecal samples (approximately 32 samples per operation per season) were collected from 463 cows, 40 heifers, and 271 calves (16 to 121-d-old) over one year. Prevalence of STEC was higher ($P < 0.05$) for calves and heifer (8.1 and 15%) than for cows (3.7%) and in the winter than in the other seasons (13.6 vs an average of 3.0%). The STEC isolates belonged to 38 serotypes (O1:H2, O5:H^- [nonmotile], O26:H11, O39:H^-, O84:H1, O84:H2, O84:H^-, O86:H2, O96:H19, O111:H16, O111:H^-, O116:H2, O116:H36, O125:H2, O125:H16, O125:H19, O125:H27, O125:H28, O125:H^-, O127:H2, O127:H19, O127:H28, O128:H2, O128:H16, O128:H20, O146:H21, O157:H7, O157:H19, O157:H^-, O158:H16, O158:H19, O158:H28, O166:H2, O166:H6, O166:H20, OUT [untypeable O antigen]:H2, OUT:H19, and OUT:H^-). Of these, 10 (O5:H^-, O26:H11, O84:H^-, O111:H^-, O125:H^-, O128:H2, O157:H7, O157:H^-, OUT:H2, and OUT:H^-) cause HUS, three (O1:H2, O84:H2, and

OUT:H19) cause other illnesses, and 19 have not been reported previously in cattle. Lower ($P < 0.05$) STEC prevalence was associated with animal factors such as decreasing stock density (≤ 1.0 cow/acre), early separation of calves (≤ 6 mo), increasing the size of calving pasture (> 120 acres), and absence of diarrhetic calves 2 to 4 mo prior to fecal sampling. Of the dietary factors tested (e.g., supplementation of pregnant cows with alfalfa, molasses, or selenium), only molasses decreased ($P < 0.05$) STEC prevalence from 6.7 to 0%. Thus, decreasing fecal shedding of STEC by range cattle appears possible by altering management practices.

Key Words: Shiga Toxins, *Escherichia coli*, Beef Cattle

Forages and Pastures - Livestock and Poultry: Forage Quality and Nutritive Value

M99 Mineral concentrations of tropical forages in the regions of San Vicente de Caguan, Colombia. R. Vargas, L. R. McDowell*, R. Van Alstyne, and N. S. Wilkinson, *University of Florida*, *Gainesville*.

In the San Vicente Zone of Colombia, South America, south of Llanos Orientales, beef cattle have been dying of a disease linked to nutrient deficiencies. Botulism is the major disease linked to the bovine mortality with 4000 deaths from 1995 to 2003. Animals were observed with abnormal appetite (pica) consuming old bones and bones from decaying carcasses. Mineral deficiencies, particularly P, are the suspected reason for the large consumption of bone. An experiment was designed to determine the mineral status of forages in relation to cattle requirements from eight ranches in the region of San Vicente de Caguan, Colombia. Forage samples (64) were collected equally between the rainy (September–December, 2002) and dry (January–March, 2003) seasons. The major forage was Brachiaria decumbens, with other important grasses including Axonopus pursuii, Tachypogan vestitus and Leersia hexandra. Samples were collected, dried, ground and analyzed by standardized procedures for 12 minerals. Significant ($P<0.05$) forage concentrations were found among farms and there were season differences ($P<0.05$) for K, Co and Zn. Potassium and Co were higher in the rainy season and Zn higher in the dry season. Forage macromineral concentrations (%) for rainy and dry seasons were as follows: Ca (0.18, 0.15); P (0.07, 0.07); Na (0.04, 0.04); K (5.5, 1.3); Mg (0.22, 0.14) and for trace minerals (ppm); Cu (6.7, 8.3); Co (0.09, 0.34); Se (0.07, 0.08); Zn (15, 34); Fe (108, 136); Mn (173, 238); Mo (0.08, 0.08). In relation to beef cattle requirements almost all samples were severely deficient in P, Na and Ca. Cobalt was deficient only in the rainy season. Potassium, Mg, Fe and Mn were not deficient and Mo was not in excess. The minerals most deficient and most likely causing death and botulism are P, Na, Ca, Se, Cu and Zn.

Key Words: Cattle, Botulism, Minerals

M100 Effect of selenium fertilizer on forage selenium content. S. J. Filley*, A. Peters, and C. Bouska, *Oregon State University*, *Corvallis*.

The objective of this experiment was to determine the effect of source and rate of Se applied as fertilizer on forage Se content. Low-Se pasture plots (three per treatment) containing perennial ryegrass (*Lolium perenne*) and subterranean clover (*Trifolium subterranean*) were assigned randomly to treatments of 0.0 (control), 0.6, 1.1, and 2.2 kg/ha sodium selenite, and 0.6 kg/ha sodium selenate. Plots were protected from grazing by use of electric fence, and total forage DM production and Se concentrations were measured after the spring growing season in year one. Pastures were grazed by sheep over the fall growing season, but then protected from spring grazing to enable sampling of residual forage Se concentrations during year two. Differences among treatments within year were analyzed with a Kruskal-Wallis non-parametric test. Welch's t-tests were conducted for each two-way comparison between the four active treatments and the control. The significance level was adjusted using a Bonferroni correction. Fertilization with 0.6 kg/ha selenate provided the highest ($P<0.01$) average forage Se content in year one (8.44±0.08 mg/kg). Plots treated with 0.6 and 2.2 kg/ha selenite contained greater ($P<0.01$) forage Se content (1.17±0.05 and 4.24±0.35 mg/kg, respectively) than control (0.09±0.06 mg/kg), whereas the 1.1 kg/ha selenite treatment only tended ($P=0.06$) to increase forage Se content (3.11±0.79 mg/kg). The second year after treatment, forage Se concentrations for the 0.6 kg/ha selenate and 2.2 kg/ha selenite application (0.43±0.04 mg/kg and 0.51±0.06 mg/kg, respectively) were greater ($P=0.04$ and $P=0.01$, respectively) than control (0.06±0.03 mg/kg). Fertilization with Se had no effect ($P=0.37$) on forage yield during year one. These data suggest that selenite and selenate fertilization increases forage Se concentrations for up to two years, and is a cost-effective method of supplying Se for grazing livestock.

Key Words: Selenium, Fertilization, Forage

M101 Effect of organic and chemical nitrogen fertilization on mulberry (*Morus alba*) fodder production. J. A. Elizondo Salazar* and C. Boschini Figueroa, *Estación Experimental Alfredo Volio Mata. Facultad de Ciencias Agroalimentarias*, *Universidad de Costa Rica, Costa Rica.*

Feeding woody plants as a supplement in dairy and beef systems has been widely used in Costa Rica and many other areas of the world. However, high fodder yields and adequate crude protein levels require application of large doses of chemical N, increasing production costs and pollution risk. To reduce cost, producers are utilizing organic fertilizers from manure without knowing the impact on production. For this reason, a study was conducted to evaluate the application of 150 kg/ha per yr of N from 2 organic fertilizers: vermicompost and compost; and from 1 chemical fertilizer: ammonium nitrate (33.5% N) on fodder production. A 12-yr-old mulberry plantation planted at spacings 0.9 × 0.40 m (27,777 plants/ha) was utilized in a randomized block design with 4 treatments: 2 organic fertilizers, ammonium nitrate, and a control (no fertilizer). All plots were uniformly pruned at 0.6 m from the ground at the beginning of the trial. Fertilizers were applied in 2 doses during the rainy season. For a 365-d period, plants were pruned consecutively every 90 d. Leaves and stems were separated and analyzed for dry matter and crude protein content. Dry matter production was 23% higher for the chemical fertilizer. Crude protein content was also significantly higher for the chemical nitrogen, while dry matter content was lower. The amount of N in the soil was sufficiently high for the control treatment to yield fodder and crude protein levels similar to those of organic fertilizers.

M102 The economics of liming coastal dairy pastures. T. W. Downing* and J. Hart, *Oregon State University*, *Corvallis*.

Soil acidity is a universal problem for crop production in high rainfall environments. Research has shown for many crops that low soil pH can significantly reduce plant productivity. Consequently, applying lime to increase soil pH is a common practice. Coastal Oregon pasture managers continue to question the economic returns and benefit from lime application even with low soil pH values. The objectives of this study were to: 1) measure soil pH change from different rates and method of lime application in coastal-pastures, 2) calculate the economic returns of lime application by measuring increases in pasture productivity and feed value. Twenty four plots measuring 1.5m x 6m were planted in the fall in perennial ryegrass. Lime treatment levels were at 2.4, 4.8 and 9.6 tons per hectare. Each treatment was replicated three times in both the incorporated and top dress blocks. Three control plots were also included in each lime treatment block. For two years, plots were harvested 6 times annually, yield data was recorded and samples of each treatment were collected and analyzed for protein, TDN, NDF, Ca, P and other trace minerals. Soil samples were taken from each treatment block and rate at the end of each growing season. Data were statistically analyzed to understand any differences in yield, treatment method, treatment rate, and any interactions. Lime increased soil pH and extractable Ca ($P<0.01$). No interaction between method and rate was measured. Method of application did not influence yield. Liming had no significant effect on forage quality parameters measured. Lime treatments increased soil pH from 5.1 up to 6 in the highest lime treatments ($P<0.01$). However, the total increase was only around 500 kg of forage per hectare per year. The increased forage production would take four years to cover the costs of lime. This project has improved our understanding of the economic returns of liming coastal pastures. Coastal soils that are high in organic matter and low in pH appear to respond differently to lime application than other acidic soils reported in the literature.

Key Words: Acidic Soils, Liming, Economics of Liming

M103 Nitrogen fertilization and weather influence winter yield and nutritive value of stockpiled bermudagrass. J. A. Guretzky*, J. B. Ball, B. J. Cook, S. L. Norton, and F. J. Motal, *The Samuel Roberts Noble Foundation, Inc.*, *Ardmore, OK*.

Management strategies that extend the grazing season and reduce hay demands may improve the profitability of cow-calf operations. Our objective was to evaluate the yield and nutritive value of fall stockpiled bermudagrass (*Cynodon dactylon* (L.) Pers.) in response to N fertilization rate, N application time, and winter harvest date. Research was conducted on a fine, sandy loam soil near Burneyville, OK from 2000 to 2003. Nitrogen rates included 0, 56, 112, and 168 kg ha^{-1} applied 15 Aug, 1 Sep, 15 Sep, 1 Oct, and 15 Oct. Dry matter yield was measured ten days after the first killing frost. Samples were collected every 15 days from 6 Dec through 20 Feb to evaluate CP and TDN. The experiment design was a split-plot with repeated measures over years and harvest dates. Nitrogen application dates served as whole plots and N rates as subplots. Forage yields were 123, 3735, 5541, and 4021 kg ha^{-1} in 2000, 2001, 2002, and 2003, respectively. In the latter three years, N affected yields in a quadratic manner. Yields averaged 3864, 4480, 4645, and 4738 kg ha^{-1} with 0, 56, 112, and 168 kg N ha^{-1}. Although interactions of year, N rate, application date, and harvest date occurred, nutritive value from 2001 to 2003 was largely affected by N rate. Of 17 winter harvest date-year combinations, CP increased in a linear or quadratic manner 16 times as N rate increased and exceeded 71 g kg^{-1} DM on most harvest dates with 112 kg N ha^{-1}. Total digestible nutrients increased from 565, 555, and 582 g kg^{-1} DM at 0 kg N ha^{-1} to 571, 563, and 585 g kg^{-1} DM at 168 kg N ha^{-1} in 2001, 2002, and 2003, respectively. Drought limited the accumulation of fall stockpiled bermudagrass and inflated nutritive values in 2000. As a consequence, N fertilization is not recommended during dry falls. In years of favorable fall precipitation, 112 kg N ha^{-1} will produce 4645 kg ha^{-1} of forage with CP and TDN concentrations that meet the nutrient requirements of beef cows during the middle third of pregnancy. Nitrogen application date and winter harvest date had minimal effects on yield and nutritive value.

Key Words: Forage Management, Beef Cow Nutrition, Forage Quality

M104 Macro and micro mineral concentrations of annual cool season pasture forages in north Florida–a four year summary. R. O. Myer*, G. Chelliah, J. N. Carter, L. R. McDowell, N. S. Wilkinson, and A. R. Blount, *University of Florida*, *Gainesville*.

Concentrations of selected macro (Ca, P, Na, K, Mg) and trace (Cu, Fe, Zn, Mn, Co, Se) minerals were determined from annual pasture forages over four winter-spring grazing seasons (2001-2005). Forage samples were taken from eight experimental pastures per year used in beef cattle grazing studies. Two, 2-yr experiments were done; animal and pasture data were reported previously. Each experiment was of a similar 2×2 design comparing clean tilled vs. sod-seeded pastures with two different forage combinations (Exp. 1, rye + oats vs. rye + oats + ryegrass (Lolium multiflorum L.); Exp. 2, oats + ryegrass vs. ryegrass only). Pastures were planted in Oct or Nov, and grazed (and sampled) starting Nov, Dec, Jan or Feb and ending Apr or May. Overall, forage type or pasture planting method had little effect on pasture forage mineral concentrations except for Zn ($P<0.01$). Year effected ($P<0.01$) forage P, K, Mg, Cu, Fe and Zn. Month during the grazing season had a large effect ($P<0.01$) on P, K, Fe, Mn and a smaller effect ($P<0.05$) on Mg, Cu, Zn and Co concentrations. Overall pasture forage mean

concentrations and S.D. for macro minerals (% of DM) were Ca, 0.31 ± 0.05; P, 0.38 ± 0.03; Na, 0.035 ± 0.005; K, 2.9 ± 0.2; and Mg, 0.21 ± 0.03; and for micro minerals (ppm of DM) were Cu, 5.7 ± 0.7; Fe, 78 ± 14; Zn, 40 ± 5; Mn, 110 ± 18; Co, 0.06 ± 0.04; Se, 0.05 ± 0.01. Results indicate that year and month within year can influence concentrations of various macro and micro minerals of annual cool season pastures in the southeastern USA. Of the minerals evaluated, Na, Cu, Co and Se would be deficient for beef cattle.

M105 Nutritive value of low DCAD timothy forage produced with Cl fertilization. G. F. Tremblay*[1], S. Pelletier[1], G. Bélanger[1], P. Seguin[2], R. Drapeau[1], and G. Allard[3], [1]*Agriculture and Agri-Food Canada*, *Québec, QC, Canada*, [2]*McGill University*, *Ste-Anne-de-Bellevue, QC, Canada*, [3]*Université Laval*, *Québec, QC, Canada*.

To prevent hypocalcaemia, dairy producers feed dry cows a ration with a low dietary cation-anion difference [**DCAD**=(Na+K)-(Cl+S)]. Because anionic salts used to decrease the ration DCAD may reduce DM intake, low DCAD forages should be fed to dry cows. We have shown that Cl fertilization decreased the DCAD of timothy forage by as much as 266 meq/kg DM with no effect on DM yield. Here, we assessed the effect of Cl fertilization on the nutritive value of timothy forage at four locations in Québec, Canada, in 2003 and 2004. Ten fertilizer treatments were applied (0, 80, 160, and 240 kg Cl/ha as $CaCl_2$; 160 kg Cl/ha as NH_4Cl; all combined with 70 or 140 kg N/ha) in a split application: 60% in spring and 40% after the first harvest. A split-split-plot design was used with locations assigned to main plots, fertilizer treatments to sub-plots, and harvests to sub-sub-plots. Concentrations of crude proteins (**CP**) and neutral detergent fibers (**NDF**), in vitro true DM digestibility (**IVTDMD**), and NDF digestibility (**dNDF**) were measured in forage samples. Average values across harvests and locations were used because of no significant interactions with Cl fertilization. At the lowest N fertilization rate (70 kg N/ha), Cl fertilization had no effect on the four measured parameters of nutritive value. At the highest N rate (140 kg N/ha), increasing Cl fertilization did not affect CP concentration but it increased NDF concentration (+10 g/kg DM) and decreased IVTDMD (-10 g/kg) and dNDF (-12 g/kg NDF); this effect, however, was small and would most likely be of no biological importance. Decreasing DCAD with Cl fertilization would not significantly affect the timothy forage nutritive value.

M106 Nutritive quality of a species-rich, extensively managed pasture exposed to elevated ozone in a free-air fumigation system. J. C. Lin*[1], K. Nadarajah[1], M. Volk[2], R. B. Muntifering[1], and J. Fuhrer[2], [1]*Auburn University*, *Auburn, AL*, [2]*Swiss Federal Research Station for Agroecology and Agriculture*, *Zurich, Switzerland*.

Effects of tropospheric ozone (O_3) on nutritive quality of O_3-sensitive species grown as monocultures or in simple mixed cultures are well established, but its effects on complex, species-rich plant communities are unknown. A 5-year field experiment was conducted near Le Mouret, Switzerland to investigate the effects of exposure to elevated O_3 on nutritive quality of an extensively managed, semi-natural pasture containing a diverse mixture of grasses, legumes and forbs. Using a free-air fumigation system, six circular plots (7-m diam.) were randomly exposed to either ambient air (control) or to air containing approximately 1.5 × ambient O_3 concentration (n = 3). Six subplots (0.5 m^2) in each ring were harvested each year in mid-June, early August and late October. Compared with controls, annual biomass yields from elevated-O_3 plots decreased by 23% over the 5-yr period. Except for year and seasonal differences, there was no effect of elevated O_3 on forage N concentration. However, there were differences ($P < 0.001$) between control and O_3-enriched plots in forage concentrations of NDF and ADF, but not lignin, and in relative feed value (RFV). Changes in proportions of grasses, legumes and forbs followed a similar pattern within treatments, but the magnitude of these changes was greater ($P < 0.05$) for the elevated-O_3 than control treatment. Between the first harvest (spring, 1999) and spring of 2003, forbs increased ($P < 0.05$) from 23.4 to 36.2%, grasses decreased ($P < 0.001$) from 67.6 to 60.5%, and legumes decreased ($P < 0.01$) from 8.9 to 3.3% of total plant DM within the O_3-enriched plots. Compared with control plots, forage from O_3-enriched plots had lower concentrations of NDF (46.9 vs. 49.9%) and ADF (27.2 vs. 28.2%), and higher RFV (136 vs. 126, by reference to a mature legume forage of RFV = 100). Unlike earlier reports of negative effects of elevated O_3 on nutritive quality resulting from altered leaf chemistry in individual plant species, this is the first report of altered nutritive quality associated with O_3-driven shifts in proportions of plant functional groups in a complex, species-rich pasture.

Key Words: Pasture, Nutritive Quality, Ozone

M107 Evaluation of forage quality, grazing capacity and intake of cool season grasses. C. I. Ward*[1] and H. A. Lardner[1,2], [1]*University of Saskatchewan*, *Saskatoon, Canada*, [2]*Western Beef Development Center*, *Humboldt, Saskatchewan, Canada*.

An experiment was conducted to evaluate the effects of cool season grass varieties on forage quality, animal grazing days (AGD), total beef production (TBP) per hectare and dry matter intake (DMI) of yearling cross-bred steers. Grass varieties were crested wheatgrass (CWG) (*Agropyron cristatum*) cv. 'AC Goliath', meadow bromegrass (MBG) (*Bromus riparius*) cv. 'Paddock', smooth bromegrass (SBG) (*B. inermis*) cv. 'Carlton', hybrid bromegrass (HBG) (*B. riparius* X *B. inermis*) cv. 'AC Knowles' and tall fescue (TF) (*Festuca arundinacea*) cv. 'Courtenay'. A long established CWG stand acted as a control pasture. Each variety was replicated (n=2) in paddocks measuring 0.8 ha. Forage samples clipped at start, end and mid-grazing period were analyzed for neutral detergent fiber (NDF), acid detergent fiber (ADF), crude protein (CP) and *in vitro* organic matter digestibility (IVOMD). In 2004 and 2005, all paddocks were grazed once (averaged 26 and 32 days of grazing, respectively) except in 2004 when the TF and CWG control paddocks were not grazed. In 2006, regrowth allowed for two grazing periods on all paddocks (averaged 35 and 16 days of grazing, respectively) except for the TF and CWG control paddocks, which were only grazed once. MBG and CWG control paddocks had the lowest CP content at the start of grazing ($P<0.05$). CWG paddocks had greater NDF and ADF content compared to TF and MBG ($P<0.05$). The CWG control paddocks had the lowest AGD in 2005 and 2006 while TF had the greatest AGD ($P<0.05$). Total beef production per hectare was similar among grass varieties ($P>0.05$). Results indicate

that new grass varieties have greater potential forage quality and animal production compared to long established CWG pastures. Dry matter intake was measured using the *n*-alkane technique in both grazing periods of 2006.

Key Words: Forage Quality, Beef Production, Intake

M108 Productivity and nutritive quality of dallisgrass (*Paspalum dilatatum*) as influenced by rate of fertilization with poultry litter or commercial fertilizer. E. J. Bungenstab*, J. C. Lin, J. L. Holliman, A. C. Pereira, and R. B. Muntifering, *Auburn University*, *Auburn, AL*.

Dallisgrass (*Paspalum dilatatum*) is well adapted to the clayey and loamy soils and warm, humid climate of the Black Belt physiographic region of the southeastern US, but poor soil fertility can be a major limitation to forage production in the region. In 2006, an existing pasture dominated by dallisgrass was clipped to a height of 10 cm on July 17 and subdivided into 48 cells of 9.3 m^2 each. Each cell received the equivalent of 34 (34N), 67 (67N), 101 (101N) or 134 (134N) kg N/ha from poultry litter (PL; 2.75% N, DM basis) or commercial fertilizer (CF; 35% N as NH_4NO_3), and forage regrowth from each was clipped on August 21 and then again on September 25 (n = 6 cells/treatment). Forage DM yield was not different between CF and PL treatments in the August harvest (836 and 763 kg DM/ha, respectively), but was greater ($P < 0.001$) for CF than PL treatments in the September harvest (436 vs. 346 kg DM/ha). Yields of CF-amended forage from both harvests were lower for the 101N rate than other rates of CF application, whereas yield of PL-amended forage was greater for the 134N rate in August but not different among rates of PL application in September (fertilizer source × rate interaction, $P < 0.05$). Forage concentration of CP was greater ($P < 0.001$) for CF than PL treatments in August (10.4 vs. 9.3%) and September (10.6 vs. 9.3%), and increased in both treatments at both harvests with increasing rates of N application. Forage concentrations of cell-wall constituents were not different between CF and PL treatments, but forage amended with CF at the 134N rate had lower concentrations of NDF ($P < 0.04$) and ADF ($P < 0.05$) in August than did forage amended with CF at the 34N rate (67.5 vs. 70.0% and 33.3 vs. 34.7%, respectively). Forage amended with PL at the 34N rate had higher ($P < 0.02$) concentration of ADF (34.3%) in September than did forage amended with PL at the 67N (32.9%) and 134N (33.0%) rates. Results indicate that poultry litter offers potential as a cost-effective alternative to commercial fertilizer for supporting productivity of dallisgrass on sub-fertile soils.

Key Words: Dallisgrass, Nutritive Quality, Poultry Litter

M109 Effect of clipping on the stolon elongation rate and stolon survival of cultivars *Chloris gayana* Kunth in conditions of salinity. M. V. Cornacchione*[1], H. E. Pérez[2], and A. F. Fumagalli[1,3], [1]*Instituto Nacional de Tecnología Agropecuaria*, *Santiago del Estero, Argentina*, [2]*Instituto Nacional de Tecnología Agropecuaria*, *Leales, Tucumán, Argentina*, [3]*Universidad Nacional de Santiago del Estero*, *Santiago del Estero, Argentina*.

The objective of this trial was to evaluate the effect of clipping on stolon elongation rate (SER) and stolon survival of four cultivars of *Chloris gayana* Kunth, in a moderate saline soil (from 0 to 60 cm depth, the avg. ECe=9.6 dS/m and avg. pH=7.95). Three tetraploid (Callide, Boma and experimental line; EL, INTA-PEMAN) and one diploid cultivar (Topcut) were planted in February of 2005. The initial stolon density (n°/m^2) was evaluated in a completely randomized block design with four replicates. The elongation stolon (L=cm) and stolon survival were measured on 40 stolons identified for cultivar when 20 stolon were clipped every seven weeks to approximately 12 cm of this base including to the first knot. The stolon elongation rate was calculated as SER= L-12/days among cuts. Stolon survival was calculated for each cultivar as follow: %S=(n° of live stolons/20)×100. Initial stolon density was significantly greater in EL ($P<0.01$; 57±12 stolons/m^2), intermediate in Boma and Callide (46±12 and 45±9 stolons/m^2), and lowest in Topcut (24±9 stolons/m^2). EL tended to have greater SER with regards to Topcut ($P=0.06$; 0.50±0.26 vs. 0.15±0.10 cm/d for EL and Topcut respectively). The SER of Callide and Boma were intermediate and did not differ with the previous ones. The % of S in Callide and Topcut was affected negatively by clipping treatment ($P<0.05$; clipping: 27.5% and non-clipping: 67.5%). All cultivars under clipping had low %S (avg. 30%). However clipping affected Callide and Topcut ($P<0.05$) than LE and Boma. In conclusion, in conditions of intermediate salinity, the tetraploid cultivars showed better performance due to: greater initial density of stolon and capacity of growth under clipping (principally EL) with respect to Topcut. The survival stolons in Topcut and Callide was better when they were not cut.

Key Words: *Chloris gayana*, Saline Soil, Stolon Elongation

M110 The effect of wide swathing on wilting times and nutritive value of alfalfa haylage. L. Kung, Jr., E. C. Stough*, E. E. McDonell, R. J. Schmidt, M. W. Hofherr, L. J. Reich, and C. M. Klingerman, *University of Delaware*, *Newark*.

At three separate cuttings, alfalfa (*Medicago sativa*) from a single field was mowed with a John Deere 946 mower-conditioner (4 m cut width) to leave narrow swaths (NS) with widths between 1.2 to 1.52 m (4-5 ft) and wide swaths (WS) ranging 2.44 to 2.74 m (8-9 ft). Samples were collected from windrows and DM was monitored during wilting until a target of 43-45% DM was obtained. Forage from random windrows (n = 4 to 6 depending on cutting) was then chopped and ensiled in replicated vacuum sealed bags for about 65 d. Data were analyzed for the main effects of swath width (NS vs. WS), cutting (1 to 3) and swath width × cutting interaction. There was no swath width × cutting interaction for any parameter tested. Over all cuttings, the resulting silage DM was not different between NS (43.8%) and WS (44.9%). However, wide swathing greatly reduced the time of wilting before making silage. The hours of wilting time for NS and WS at cuttings 1, 2 and 3 were 50 vs. 29, 54 vs. 28, and 25 vs. 6, respectively. On average, wide swathed alfalfa was chopped 22 h earlier than narrow swathed alfalfa. At the time of ensiling, WS had more water soluble carbohydrates (5.1%, $P < 0.05$) than did NS (3.7%). Silages made from WS had a lower pH (4.58, $P < 0.05$) than did NS (4.66) but swath width did not affect fermentation end products (lactic acid, acetic acid and ethanol). Silage made from NS had more NH3-N (0.26%, $P < 0.05$) than WS (0.21%). Swath width did not affect the concentration of ash, NDF or the digestibility of NDF but it lowered the N content of the resulting silage (NS = 3.45%, WS = 3.23%, $P < 0.05$). For the main effect of cutting, the concentrations of N and water soluble carbohydrates decreased and the digestibility of NDF decreased, whereas the concentration of NDF increased with progressive cuttings.

Wide swathing can markedly reduce the time that alfalfa must wilt before it can be chopped for silage but under good conditions, the resulting silage quality was generally not improved.

Key Words: Alfalfa, Swath Width, Wilting

M111 Effects of harvest timing on estimates of rumen degradable protein from alfalfa forages. W. K. Coblentz*[1], G. E. Brink[2], N. P. Martin[2], and D. J. Undersander[3], [1]*US Dairy Forage Research Center*, *Marshfield, WI*, [2]*US Dairy Forage Research Center*, *Madison, WI*, [3]*University of Wisconsin*, *Madison*.

Alfalfa (*Medicago sativa* L.) proteins ingested by dairy cows typically degrade at rapid rates, resulting in low percentages of dietary crude protein (CP) that escape the rumen intact. Our objectives were to determine rumen degradable protein (RDP) for alfalfa managed in a four-harvest system that was clipped on five dates within each harvest. During 2004 and 2005, ″Affinity″ alfalfa was harvested four times (spring, early and late summer, and fall) at Prairie du Sac, WI; within each harvest, plots were clipped initially (d 0) when plants were at least 30 cm tall, but did not exhibit any evidence of buds. Additional sampling dates were scheduled at 5-d intervals for the next 20 d, resulting in a total of five clipping dates (0, 5, 10, 15, and 20 d) within each individual harvest. Forages were evaluated for CP, neutral-detergent soluble CP (NDSCP), and neutral-detergent insoluble CP (NDICP); in addition, RDP and rumen undegradable protein (RUP) were determined by the *Streptomyces griseus* protease method. For 2004, there were no interactions ($P \geq 0.372$) between harvest number and clipping date for any protein component. Crude protein, NDSCP, and RDP declined in a quadratic ($P \leq 0.026$) relationship with clipping dates. A quadratic ($P = 0.002$) pattern also was observed for RUP, but the overall range was small (6.04 to 6.65% of DM); similarly, NDICP exhibited only a quadratic trend ($P = 0.077$) and a small overall range (2.63 to 2.90% of DM). On a percentage of CP basis, RDP declined linearly ($P < 0.001$) from 72.0 to 65.9% of CP during 2004. For 2005, there were interactions ($P \leq 0.020$) of harvest number and clipping date within harvest for all response variables. Although less consistent than in 2004, trends for individual CP pools generally were similar over clipping dates within harvest. Concentrations of RDP (% of CP) declined ($P \leq 0.042$) with clipping date during three of four harvests, but specific polynomial effects varied with harvest number. Overall, RDP (% of CP) declined as alfalfa plants aged, but these responses were due primarily to reduced concentrations of CP within the highly degradable cell-soluble fraction.

Key Words: Alfalfa, Rumen Degradable Protein, Plant Age

M112 Effects of planting density, cultivar and growing day on the dry matter yield and forage quality of Kenaf (*Hibiscus Cannabinus* L.) in the northern area of South Korea. B. W. Kim* and K. I. Sung, *Kangwon National University*, *Chuncheon, Kangwon-Do, South Korea*.

This study was conducted to evaluate the dry matter (DM) yield and forage quality of Kenaf in relation to planting density (10×10 and 10×20 cm^2) and growing days (Day 53, Day 62, Day 73, Day 84, Day 93, Day 104 and Day 115) in the northern area of South Korea from May 20 to September 12, 2005. The experiment was laid out in a split plot design with three replications. The main plots consisted of planting density and growing days with three cultivars of Kenaf as sub-plots; Dowling, Everglade and Tainung. The DM yield increased with maturity in all three cultivars, especially Dowling showed the highest DM yield at each harvest time. The crude protein (CP) contents of all three cultivars decreased with maturity. Especially, the decrease in the CP contents was greater in the early stage than in the late stage. The planting density did not affect the CP contents, even though they are little higher in 10×20 cm^2 compared to 10×10 cm^2. Among cultivars, the higher CP contents were observed in Dowling at each growing day. No difference in the neutral detergent fiber and acid detergent fiber contents was observed in the planting density and cultivars, although the increasing tendency was found with maturity. These results suggest that Kenaf can be a good potential forage crop in the northern area of South Korea, especially Dowling which had the greatest DM yield (29.5 ton/ha) and best forage quality (67.1% NDF and 55.8 % ADF) when harvested on Day 104 at 10×20 cm^2 planting density.

Key Words: Kenaf, Planting Density, Forage Quality

M113 The effect of cutting height on yield and quality of alfalfa/reed canarygrass in northern New York. E. D. Thomas, C. S. Ballard*, K. W. Cotanch, H. M. Wolford, and S. A. Flis, *W.H. Miner Agricultural Research Institute*, *Chazy, NY*.

Reducing cutting height when harvesting alfalfa has been shown to increase yield, however forage quality may be compromised by inclusion of more lignified stem material and soil contamination. The objective of this study was to evalulate forage quality and yield of alfalfa/reed canarygrass harvested at 5 and 10 cm. A 2nd year alfalfa/reed canarygrass stand was divided into four plots. Three 61×91 cm areas within each plot were selected randomly for hand–harvest (**HH**) at 5 cm. The HH forage was composited within plot and separated by species to determine sward composition. To simulate 10 cm cutting height, 5 cm was cut from stem of all plants after separation. Each species and removed stem were weighed, dried and ground for analysis. Forage yield and quality were calculated based on sward composition, analysis of species and removed stem for each cutting. From the same field plots, strips within plot were randomly assigned to a theoretical cutting height of 5 and 10 cm and mechanically harvested (**MH**). Actual cutting height was determined by measuring stubble at 15 random locations within each strip. Yield was estimated and chopped forages were dried and ground for analysis. All samples were analyzed for NDF, ADF, lignin, ash, in vitro 24–h DM and NDF digestibility. Procedures were followed for three consecutive cuttings and data were analyzed as a randomized block. The percent alfalfa in the sward was higher in the 2nd and 3rd (74 and 70%) compared to the 1st cutting (42%). Dry matter yield was higher for HH alfalfa/grass at 5 versus 10 cm ($P<0.01$). The 10 cm HH alfalfa/grass was higher in CP and DMd and lower in NDF, ADF and lignin (%DM) compared to the 5 cm ($P<0.05$). Average actual cutting height for MH forage was 8 and 11 cm for 5 versus 10 cm ($P<0.001$). The MH alfalfa/grass had similar numerical differences as the HH for all parameters except ash which tended to be lower in forages MH at 10 versus 5 cm (8.6 and 8.3 %DM, respectively; $P=0.06$), indicating an increase in foreign material obtained during MH. Overall, increases in forage quality were offset by lower yields when alfalfa/grass was harvested at 10 versus 5 cm.

Key Words: Alfalfa, Cutting Height, Forage Quality

M114 Lineweaver-Burk data transformation to evaluate interaction between nutrients in fertilization of tropical forages. H. J. Fernandes[1,4], R. P. Lana[2], C. E. S. Baroni[2], L. M. Paiva[1,4], and J. C Souza*[3,5], [1]*University of Mato Grosso do Sul*, *Brazil*, [2]*Federal University of Vicosa*, *Brazil*, [3]*Parana Federal Univeristy*, *Palotina, PR Brazil*, [4]*Scholarship of FUNDECT*, *Campo Grande, MS, Brazil*, [5]*University of Missouri*, *Columbia*.

This study evaluated the use of a Lineweaver-Burk data transformation to evaluate the effect of potassium (K) fertilization and the productive response to nitrogen (N) fertilization. Forty observations of the Panicum, Cyndom and Penisetum genera in Brazil were obtained from three published studies. A Lineweaver-Burk transformation was used to predict the maximum dry forage mass production (RESPmax) and the amount of nutrient needed to reach half maximum response (NUTR50). The model adequacy was evaluated by the coefficient of determination (R2) and the simultaneous test of the intercept and slope. In all equations, this test accepted the null hypothesis (P>0.10), and the R2 were greater than 0.80. When another limiting nutrient is supplied at same time as the N, the capacity of the forage to convert N in dry matter is increased (and RESPmax too). The differences between the forages may cause differences in NUTR50 responses. When the NUTR50 did not change, the marginal efficiency (kg increase in DM production / Kg of N) increased at all rates of N fertilization. A decrease in the NUTR50 indicates an increase in the efficiency of use of N at small rates of fertilization. When the rates of K fertilization increase an increase in NUTR50 resulted for Cynodom and a decrease in NUTR50 (until 234 kg/ha) result for the Panicum, with an increase in NUTR50 at higher levels. The NUTR50 was not altered in the Pennisetum. It's possible to use the Lineweaver-Burk transformation to evaluate the interaction between the K fertilization and the response of the tropical forages to the N fertilization. The metabolic differences between genera cause different responses at the interaction between nutrients.

Key Words: Mathematical Models, Nutrient Interaction, Tropical Forages

M115 Lineweaver-Burk data transformation to evaluate the production of tropical forages. H. J. Fernandes[1,5], R. P. Lana[2], C. E. S. Baroni[2], L. M. Paiva[1,5], and J. C. Souza*[3,4], [1]*State University of Mato Grosso do Sul*, *Brazil*, [2]*Federal University of Vicosa*, *Brazil*, [3]*Parana Federal University*, *Brazil*, [4]*University of Missouri*, *Columbia*, [5]*FUNDECT*, *Campo Grande, MS, Brazil*.

This study evaluated the use of the Lineweaver-Burk transformation to estimate the kinetic parameters of growth and the responses of forages to nitrogen (N) fertilization. Data included 43 observations of the principal genera of forages used in Brazil (Brachiaria, Panicum, Cyndom and Penisetum) obtained from published studies considered a random study effect. Linear regressions of the reciprocal of the each 'genus' plant responses (Y) as a function of the reciprocal of N fertilization (X) were developed as the model: $1/Y = a + b\ (1/X)$. The maxima of dry forage mass production were obtained by the reciprocal of the intercept (RESPmax=1/a) and the amount of nutrients needed to reach half maximum response (NUTR50), by dividing the coefficient of the linear regression by the intercept (b/a). The R2 of model of the equations to the genera Brachiaria, Panicum, Cyndom e Penisetum were 0.756, 0.865, 0.994 and 0.703, respectively. Marginal responses of the forages decreased as the N rates increased. This behavior can be explained by saturation of the enzymatic systems. The Penisetum genus had a linear response until the maximum rate of N each (400 Kg N/ha/year). In this case, the maximum rate of fertilization was less than that necessary to reach RESPmax. The kinetics parameters estimated for Brachiaria, Panicum,Cyndom and Penisetum were 8.04, 118.3, 25.3 and 80.8 ton DM/ha/year (RESPmax); and 30.5, 380.8, 105.6 and 176.8 kg N/ha/year (NUTR50). The lower the NUTR50, they greater is slopes of response and the greater the responses to small rates of N. The Lineweaver-Burk transformation efficiently explained the kinetics parameters of growing plant. The Brachiaria genus had the greatest response to small rates of N fertilization and the Penisetum had the capacity to respond at high rates.

Key Words: Mathematical Models, Forage, Fertilization

M116 Effect of planting date on starch accumulation of whole crop barley. L. E. McKeown*[1], M. A. Bal[1], M. Oba[1], and V. S. Baron[2], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lacombe, AB, Canada*.

The objective of this study was to evaluate effect of planting date on rate of starch accumulation and free sugar concentration of whole-plant barley (*Hordeum vulgare*). Two barley varieties (AC Lacombe and Vivar) were planted on either May 5, 2005 (BM) or June 7, 2005 (BJ). Samples of whole plants (n=6) were collected twice weekly after the plant reached the heading stage, until the harvest at late dough stage. Samples were collected on July 5, 8, 12, 15, 19, and 22 for BM and July 26, 29, August 2, 5, 9, 12, 16, 19, and 23 for BJ. The BM took 62 days to reach the heading stage, which was longer than BJ that only took 50 days. However, the period from heading to harvest was shorter for BM (18 d) compared to BJ (29 d). For both BM and BJ, starch concentration increased over time and sugar concentration decreased over time. The final starch concentration of BM at late dough stage was 29.5 and 27.9% for AC Lacombe and Vivar, respectively, and that of BJ was 25.4 and 22.9% for AC Lacombe and Vivar, respectively. Free glucose concentration for BM and BJ were 1.3 and 1.6%, respectively for AC Lacombe, and 1.8 and 1.0% for Vivar. Greater final starch concentration for BM, compared to BJ, might be attributed to lower average temperature throughout the growing period of BM, when compared to the relatively higher average temperature throughout the growing period of BJ. It was also noted that rate of starch accumulation of whole crop barley is decreased regardless of planting date when the daily mean temperature deviated greatly from 15°C. These observations indicate that the ambient temperature during the growing season can affect starch concentration of whole crop barley. Planting dates of barley can alter its growing environment, and affect rate of starch accumulation and its final concentration. Altering planting date may allow for increased management options to harvest whole-crop barley with greater starch concentration, decreasing the amount of supplemental grains fed in dairy diets.

Key Words: Planting Date, Starch, Whole Crop Barley

M117 Seed quality effects on yield, stover nutritional value, and maize grain. C. Perez-Mendoza[1], M. R. Tovar-Gomez*[2], G. Garcia-Santos[1], A. Hernandez-Livera[1], and A. Carballo-Carballo[1], [1]*Colegio de Postgraduados*, *Texcoco, State Mexico, Mexico*, [2]*INIFAP-CEVAMEX*, *Texcoco, State Mexico, Mexico*.

The objective of this study was to evaluate the effect of seed quality on yield, nutritional value of stover and maize (Zea mays L.) grain.

The research was done in 2002 in the Texcoco and Zumpango, State of Mexico and consisted of three phases: 1) seed physical quality and its characterization by form, size and weight was evaluated (flat, large, and medium), 2) seed physiological quality was determined in a microtunnel and 3) yield and nutritional value of maize harvested at physiological maturity were evaluated. Experiments were established using a randomized block design with four replications and a factorial array of treatments. Nine varieties of maize with forage potential were used to study: weight per thousand seeds (W1000S); seed length (LS), width (WS) and thickness (TS); velocity of emergence (VE); dry weight aerial part (DWAP); stover yields (SY) and grain (GY); stover protein (CPS) and grain starch (ST). Significant differences ($P<0.001$) were observed among varieties for all the evaluated parameters; location had a significant effect on SY, GY and ST. Seed size affected W1000, LS, WS, and CPS. Landrace Campen, VS-2000, and VS-22 had the best physical qualities with W1000S and LS of 427.9, 338.6 and 221.4 g; 1.7, 1.4 and 1.3 cm, respectively. With respect to the physiological quality, Landrace Campen had the highest values for VE and DWAP (4.1 and 11.3 g, respectively). Yields of SY for the varieties oscillated between 10.6 and 15 t ha-1 MS and for grain between 4.3 and 10.6 t ha-1. Landrace Campen (7.1%) and VS-22 (6.3%) contained more CPS while VS-2000, H-157, H-358 and Campen had higher concentrations of starch (76.1, 74.8, 74.2, 73.8%, respectively). It was concluded maize seed quality is more affected by the variety than by the seed size. Varieties Campen, HS-2, Promesa and VS-22 showed the best physical and physiological quality. Variety was the most important factor afffecting SY with Campen, VS-22 and VS-2000 having the higher SY. Promesa, H-157 and HS-2 had the higher GY.

Key Words: Maize Stover, Varieties, Seed Size

M118 Evaluation of experimental and commercial maize hybrids for silage in the Highland Valleys Region. M. R. Tovar-Gomez*[1], J. L. Arellano-Vazquez[1], C. Perez-Mendoza[1], A. Peña-Ramos[2], and G. Nuñez-Hernandez[3], [1]*INIFAP-CEVAMEX*, *Texcoco, State Mexico, Mexico*, [2]*INIFAP-CAEPAB*, *Pabellon, Aguascalientes, Mexico*, [3]*INIFAP-CAELALA*, *Toreon, Coahuila, Mexico*.

A study was conducted to determine the productivity and nutritional value of maize cultivars for silage. Twenty experimental and commercial maize (Zea mays L.) hybrids adapted to different areas were evaluated in the Highland Valleys Region. The experiment was done during irrigation cycle PV-2004 in the Texcoco of the State of Mexico. The experiment used a randomized complete block design with three replications. The measured variables were: days to silk (DS), plant height (PH), lodging (LG), common corn rust (Puccinia sorghi Schw.,CCR), green matter yield (GMY) and dry matter yield (DMY), crude protein (CP) and in vitro DM digestibility (IVDMD). Significant varietal differences were observed for variables. Days to silk varied fro, 84 to 109 days and PH ranged from 190 to 283 cm. Cultivars with subtropical and tropical germplasm had higher occurrences of CCR. Fresh forage yeild (GMY) varied from 37.1 to 80 t/ha and DMY ranged from 12.8 to 24.8 t/ha. Across varieties, CP varied from 7.9 to 9.6% and IVDMD ranged from 68.2 to 76.2%. Multivariate analysis indicated that PH, CCR, GMY, IVDMD were most important in this study. The hybrids with subtropical × tropical germplasm were more susceptoble to rust and had lower yield potential. The hybrids with Highland Valleys × Tropical germplasm excelled in this study. Of this group, hybrids H-157E, H-161E, H-159E and H-165E were better.

Key Words: Maize Forage, Yield, Nutritive Value

M119 Green-chop maize forage production in temperate Mexico. H. Crespo-Lira[1], R. D. Améndola-Massiotti*[1], and J. A. Burgueño-Ferreira[2], [1]*Universidad Autónoma Chapingo*, *Chapingo, México, México*, [2]*CIMMYT*, *El Batán, México*.

Green chop maize is used during summer and autumn in dairy farms of temperate Mexico; however, there is little information on maize forage production under this utilization strategy which could imply the use of high levels of N (nitrogen) fertilization and sowing densities. The aim of this experiment was to evaluate forage yield of green chop maize under two levels of N fertilization, during summer and autumn. The study was carried out at Chapingo, Mexico (central area of the country), using an intermediate to late local hybrid (San Jose). The levels of fertilization were 150 (N1) and 200 (N2) kg of N/ha. The sowing density was 178571 seeds/ha. Experimental plots of 66 m^2 were used, in a randomized block design with two treatments (N1 and N2) and six replicates. At 50 (D1), 86 (D2), 122 (D3) and 158 (D4) days after sowing, per plot six systematically chosen samples of one m maize row each were harvested at 20 cm height above ground level. Analysis was performed using a mixed model, considering fixed effects of fertilization, sampling date and their interaction, and random effects of blocks and their interaction with treatment. Means were compared using Tukey's test. Plant density was not affected ($p>0.05$) by fertilization but was higher ($p<0.05$) in D1 (142188 plants/ha) than in the other dates (on average 125521 plants/ha), meaning that with such high plant densities about 12% of the plants were lost in early stages due to intra-specific competition. Forage yield was not affected ($p>0.05$) by fertilization, and increased ($p<0.05$) until D3 (3126, 16110, 23854 and 23480 kg of DM/ha for D1, D2, D3 and D4, respectively), meaning that with the lower level of N fertilization, an average forage accumulation of about 200 kg of DM/ha/d could be achieved in about 120 days. This result shows that green chop maize could be an alternative for dairy farmers at the end of the summer and beginning of autumn, since that level of production can not be achieved with other forage species in temperate Mexico.

Key Words: Plant Density, Nitrogen Fertilization, Days After Sowing

M120 Identification of ATP binding cassette transporter G2 (ABCG2) gene in mammary gland of Xinong Saanen Goat and its expression profile during lactation. H. J. Wu[1], J. Luo[1], N. Wu*[2], K. Matand[2], L. J. Zhang[1], B. J. Yang[1], X. F. Han[1], H. B. Wang[1], N. Zhang[1], G. Yu[1], and C. Y. Shan[1], [1]*Northwest A&F University*, *Yangling, Shanxi, P. R. China*, [2]*Langston University*, *Langston, OK*.

The ABCG2 gene codes for a protein that belongs to a trans-membrane proteins superfamily that mediates the ATP-dependent translocation of a variety of lipophilic substrates. The effect of ABCG2 gene on milk yield and composition has been reported in dairy cattle. However, there is limited information on ABCG2 gene structure, expression or functional analysis in dairy goats. This is the first report on ABCG2 gene coding region nucleotide sequence and expression pattern during the lactation period of the Chinese Xinong Saanen goats. The full sequence of this goat's gene coding region was sequenced and deposited into the GenBank nucleotide database (Accession number - DQ904356). This gene's complementary DNA contained an open reading frame of 1977 nucleotides that encoded a putative protein of 658 amino acids. The similarities between the nucleotide and peptide sequences of goat ABCG2 gene and putative protein compared with the bovine, human, and mouse homologs were 96%, 89%, 85% and 96%, 85%, 79%, respectively. Further, bioinformatical analysis showed that most of the goat ABCG2's virtually translated polypeptide sequence were predictably similar to those of bovine's and human's. However, the significant differences that were observed in coil-helix structures and optional motifs were species specific. When Real-time reverse transcription-polymerase chain reaction analysis was employed to explore the gene expression profile during lactation, the result showed a five-fold increase in expression level during peak yield, compared with the onset of lactation. Overall the results suggested that ABCG2 gene might be involved in goat milk synthesis probably by mediating lipophilic substrates translocation during early, peak, and mid-lactation stages.

Key Words: ABCG2, DNA, Polypeptide

M121 Differentially expressed gene profile during dairy goat whole lactation period. H. J. Wu[1], J. Luo*[1], N. Wu[2], K. Matand[2], L. J. Zhang[1], B. J. Yang[1], X. F. Han[1], H. B. Wang[1], N. Zhang[1], G. Yu[1], and C. Y. Shan[1], [1]*Northwest A&F University*, *Yangling, Shanxi, P. R. China*, [2]*Langston University*, *Langston, OK*.

The profile of mammary gland differentially expressed genes during the whole lactation of Chinese Xinong Saanen goat was determined by using suppression subtractive hybridization (SSH) approach. Mammary gland-subtracted cDNA libraries of different lactation stages were also constructed to facilitate target genes isolation. Real-time reverse transcription-polymerase chain reaction was applied to validate SSH results. Five target genes coding for serum amyloid A3 (SAA3), ATP-binding cassette subfamily G2 (ABCG2), heart fatty acid-binding protein (hFABP), xanthine dehydrogenase (XDH) and zinc-finger Ubi-d4 proteins (ZNP) were identified and analyzed. The expression level of ABCG2 and hFABP genes showed a significant increase from early to peak lactation stages. The results showed that their expression trends were similarly highest during peak yield and gradually decreased through mid, late and end of lactation. The results also reflected active functional involvement of proteins that were profiled in this study. ABCG2 and hFABP gene proteins seem to be involved in the mediation of ATP-dependent translocation of a variety of lipophilic substrates and lipid metabolism, respectively, during the peak of lactation; whereas XDH, a major constituent of the milk fat globule membrane, showed the expression trend similar to that of ABCG2 and hFABP, but with a mild increase during early and peak lactation stages. The expression pattern of SAA3, a lipid metabolism and cell proliferation protein, increased during early and late lactation, with a subsequent decline to baseline at the end of the lactation. Unlike other genes, ZNP gene expression increase began at the end of the middle lactation stage, with the highest point at the end of lactation. This results suggest a potential role of this gene′s protein in cell apoptosis.

Key Words: ABCG2 Gene, hFABP Gene, Polymerase Chain Reaction

M122 Initial gene expression analysis of Chinese Xinong Saanen goat mammary gland. X. F. Han[1], J. Luo[1], N. Wu[2], K. Matand*[2], B. J. Yang[1], H. J. Wu[1], L. J. Zhang[1], and H. B. Wang[1], [1]*Northwest A&F University*, *Yangling, Shanxi, P. R. China*, [2]*Langston University*, *Langston, OK*.

Goat is a major source of income and animal nutrients, primarily in developing countries. It is also an important animal research bio-system, but genomic studies are scarce in this species. This has resulted in a lower pace for genomic resources generation that could be used for goat production improvement. This pioneering study on goat mammary gland genomics was designed to construct and assess the functional quality of the mammary gland cDNA library and clones on Chinese Xinong Saanen goat. The results showed that the cDNA library was of high quality and contained 1.4×10^7 cfu with an average insert size of 1000 bp and recombinant rate of 96%. Sequencing analysis revealed that about 55.7% of sequenced clones were redundant, whereas 25% of them or 56.9% of the clone clusters represented novel genes. Functional analysis also showed that, although milk proteins which included beta-lactoglobulin, beta-casein, αs2-casein, kappa-casein and prealpha-lactalbumin were the most abundant. Other proteins involved in ribosomal structure, metabolism, immune response, and translation were also identified through sheep, cow and human cross-species genomic comparisons.

Key Words: cDNA, Genome, Goat

M123 Lactation curve characteristics of the Sarda goat breed. R. Steri[1], N. Bacciu[1], P. Fresi[2], A. Cappio-Borlino[1], and N. P. P. Macciotta*[1], [1]*Dipartimento di Scienze Zootecniche, Universitá di Sassari*, *Sassari, Italia*, [2]*Associazione Nazionale della Pastorizia*, *Roma, Italia*.

The Sarda is the largest Italian goat breed . Its main feature is represented by a high fitness to difficult environmental conditions that make this breed able to produce in areas that cannot be exploited with other species. A consistent strategy of genetic improvement should be preceded by a deepening of the knowledge on main productive characteristics of the animal and of main factors that affect these traits. In this study, 10,150 test day records for milk yield of 1,832 Sarda

breed goats were fitted with the incomplete gamma function of wood (WD) in the log-linear form and (logY = log a + b log t + ct) The WD model was fitted both to individual lactation curves and average lactation curves of goats with different parity (1st to 5th), kidding season (winter and spring) type of kidding (single or twins) and altitude of the flock (mountain, hill or plain).Estimated individual curves were ranked according to five levels of adjusted R-squared (ADJRSQ) and were classified as standard or atypical (presence or absence of the peak) on the basis of the signs for parameter b. Goodness of fit showed a wide range of variation, although about 38% of individual curves had and ADJRSQ>0.80. About 42% of individual curves show an atypical shape. The days in milk at which the peak occurs tends to increase with parity (from about 33 for first kidding goats to 23 for goats at the fifth kidding), with the number of kids born (15 vs 27 for one and two kids, respectively),with the season of kidding (25 vs 39 for winter ad spring) and with the altitude of location of flocks (14, 23 and 28 in flocks located on plain, hill and mountain, respectively). Milk yield at peak tend to increase with parity (from 1,32 liters for first kidding goats to 1.56 lt for goats at the fifth kidding), number of kids born (1.46 vs 1.55 for one and two kids , respectively), with the season of kidding (1.46 vs 1.60 for winter ad spring) and with the altitude of location of flocks (1.63, 1.43, 1.07 in flocks for plain, hill and mountain, respectively).

Key Words: Dairy Goats, Lactation Curve, Wood Model

M124 Milk production in goats supplemented with different levels of ruminally protected methionine. G. A. Flores, R. E. Gutierrez, D. D. Ruiz, F. X. Plata*, A. A. Ramirez, S. Vega, and G. D. Mendoza, *Universidad Autónoma Metropolitana Xochimilco*, *Mexico, D.F., Mexico*.

Twelve lactating multiparous Saanen goats (55.9 ± 5.6 kg) were fed a basal diet (14.4% CP, 26.71% RUP, 2.44 Mcal ME) with alfalfa, wheat bran, soybean meal, sorghum grain, corn grain, molasses, corn silage and oat straw (forage:concentrate ratio, 67:33). Goats were randomly assigned to the treatments, which consisted of three levels of ruminally protected methionine (RPM): 0, 2.5 or 5.0 g/d (Mepron M85 Degussa Co). Experiment was conducted for 30 days with measurements of milk production, composition and changes in body weight. Milk production was reduced ($P \leq 0.05$) with higher doses of RPM (1441^{ab}, 1698^{a}, 1390^{b} g/d for 0, 2.5 and 5.0 g/d respectively). Milk protein was reduced with 2.5 g of RPM (3.18^{a}, 2.86^{b}, 3.01^{ab}). No treatment effects were observed in milk fat or body weight. Higher doses of ruminally protected methionine affects negatively milk production in dairy goats presumably because the ratio lysine:methionie was reduced. More research is needed to determine optimum doses of ruminally protected methionine in lactating goats.

Key Words: Goat, Methionine, Milk

M125 *In vivo* prediction of body composition in goat dams 2) Relationship between IGF-I, body weight and body composition. C. A. Mejia*[1,2], G. Dominguez[2], E. Villagomez[1,3], M. Montaño[1,2], R. Basurto[1,2], H. Jimenez[1,2], and H. Vera[1,2], [1]*Cenid-Fisiologia INIFAP*, *Queretaro, Mexico*, [2]*FESC-UNAM*, *Queretaro, Mexico*, [3]*Cenid-Microbiologia INIFAP*, *D.F., Mexico*.

The objective of this research was to establish if plasma concentrations of IGF-I are related to weight and body composition of goat dams. A total of 64 goats from 2 genetics (Saanen and Creole) and 3 to 4 years of age, were used. Dams were divided in three groups according to their body score (BS, 1-5): LOW (1.5 - 2), MID (2.5 - 3) or HIGH (>3). Each of these groups received an integral diet for 12 weeks varying the offered amount to keep or establish these differences. At the end of this period (day 0), live weight (LW) and BS were registered. LW and BS were recorded 42 days later. This same day, a blood simple was obtained in the morning and another one in the afternoon. Plasma concentrations of IGF-I were determined by RIA, using a commercial kit. Dams were slaughtered at day 43 and inner fat was registered, and carcasses were weighed and stored in a cold chamber at 4°C. After 24 h, the left half of each carcass was dissected in fat (FAT), muscle (MUS), and bone tissue (BT). Data were analyzed by ANOVA and correlation using SAS software. There were no differences in plasma concentrations of IGF-I related to day time ($P>0.30$). Saanen dams had higher ($P<0.001$) IGF-I concentrations than Creole dams (262 vs 113 ± 15 ng/ml, respectively). The average of the two daily measures was used to make the correlation analyses. Despite the group (n=64), IGF-I correlations to LW (r=0.68), FAT (r=0.64), MUS (r=0.69; $P<0.001$) and BT (r=0.24; $P<0.07$) were meaningful. When data were analyzed by group, the correlation values of IGF-I to LW, FAT,and MUS continued being meaningful (r=0.57 a 0.77; $P<0.03$) for HIGH (n=21), MID (n=21) and LOW (n=22). However, correlation of IGF-I to BT was not meaningful in any of the three groups (r=0.05 a 0.20; $P>0.15$). We conclude that plasma concentrations of IGF-I are positively associated to body weight and body composition of goat dams.

Key Words: Body Composition, Goat, IGF-I

M126 Evaluation of the FAMACHA© system in lactating goats. M. Rovai*[1], T. A. Gipson[1], and L. J. Dawson[1,2], [1]*E (Kika) de la Garza American Institute for Goat Research, Langston University*, *Langston, OK, USA*, [2]*Oklahoma State University. College of Veterinary Medicine*, *Stillwater*.

The FAMACHA system has been adopted as a useful tool in meat goats for identifying clinical anemia associated with parasitism. However, the applicability of this method in dairy goats remains uncertain. The relation between FAMACHA system (FAM; scale based on the ocular conjunctiva color; 1–2 healthy, 3 border line, and 4–5 pale), fecal egg counts (FEC) and blood packed cell volume (PCV) were studied in 24 Alpine dairy goats measured every 2 wk throughout 7 month of lactation. All does were drenched with an anthelmintic at kidding. Samples for FEC were determined using modified McMaster method and classified as: low (≤750) and high (>750) eggs per gram feces. For PCV, measured by the microhaematocrit method, values of ≤19, 20–25, and > 25 were considered anemic, border line, and healthy, respectively. A false positive result was defined as animals with FAM 4–5 but not anemic and a false negative as animals with FAM 1–2 but anemic. The FEC values, log transformed, were affected by FAM ($P < 0.05$) where scores 4 and 5 showed low FEC (2.42, 2.49, and 2.23 for scores 1–2, 3, and 4–5, respectively). Moreover, high FEC had a tendency ($P= 0.07$) for low PCV values (2.52, 2.37, and 2.24 for anemic, border line, and healthy, respectively). For low FEC, 37% of animals were classified as FAM 4–5, 48% as border line, and only 15% FAM 1–2. The relation between FEC and PCV also presented a negative tendency ($P = 0.07$) which reaffirms the presence of high FEC with low PCV and, consequently, anemia. About 8.5% of goats would have been correctly treated with eye scores of 4–5 and low PCV values. However, 21% of the goats were false positive and would have

been treated unnecessarily. Although there is a physiological relation between FEC and PCV, the FAM system was not sufficient in itself for identifying anemia in dairy goats. Other causes (e.g., lactation stress) can be responsible for anemia, therefore FAM scores of 4–5 should be validated with FEC analysis.

Key Words: Dairy Goat, FAMACHA, Fecal Egg Count

M127 Protein and/or energy supplementation does not change forage digestibility in growing meat goat kids. J. M. Patterson*[1,2], B. D. Lambert[1,2], and J. P. Muir[1], [1]*Texas Agricultural Experiment Station*, *Stephenville*, [2]*Tarleton State University*, *Stephenville, TX*.

The nutritive value of supplements may affect feed intake and weight gains in growing goats. Our objectives were to determine the effects of protein and energy supplementation on growth, forage intake, forage apparent digestibility, and nitrogen retention in meat goat kids. In Experiment 1, an 18% crude protein complete goat grower was added to the diet of wethers eating coastal bermudagrass (CB) (12.2% CP, 67.5% NDF, 37.5% ADF), Tifton 85 bermudagrass (T85) (6.8% CP, 78.2% NDF, 45.1% ADF), or sorghum-Sudan (SS) (8.3% CP, 73.7% NDF, 47.9% ADF) hays. This experiment used seventy-two wether goats and measured the effects of the supplement on average daily gain (ADG) of goats fed one of three grass hays with or without supplemental levels (1% body weight daily) or *ad libitum* access to a complete goat grower. In Experiment 2, four wether goats were used in a 4×4 Latin square design and fed a SS basal diet (8.3% CP, 73.7% NDF, 47.9% ADF). Goats were confined to metabolic crates to facilitate total urine and fecal collection. Treatments consisted of no supplement, supplemental urea (200mg•(kg BW)$^{-1(d-1)}$), supplemental dextrose (0.2% BW^{-d}), or urea + dextrose ((200mg•(kg BW)$^{-1(d-1)}$), 0.2% BW^{-d}, respectively). In Experiment 1, ADG were -3.80, -4.97, and -6.56 for CB, T85, SS, respectively. ADG for hay plus supplement were 69.22, 61.62, and 58.12 for CB, T85, SS, respectively. Supplementation in Experiment 1 increased (P< 0.01) ADG for all hays by a factor of 5 over hay-only diets. Additionally, goats with *ad libitum* access to the complete feed had increased ADG compared to all treatments. In Experiment 2, protein and energy supplementation increased (P< 0.01) nitrogen retention. However, no differences (P>0.05) were shown for digestibility of dry matter, organic matter, acid detergent fiber, or neutral detergent fiber. We conclude that the beneficial effects of supplements in Experiment 1 and the increase in nitrogen retention in Experiment 2 cannot be explained by improvements in ruminal fiber utilization and could be due to post-ruminal energy and/or protein supply to the animal.

Key Words: Coastal Bermudagrass, Sorghum-Sudan, Tifton 85 Bermudagrass

M128 *In situ* dry matter degradation of cacti and fruits commonly selected by goats in the semi-arid region of North México. M. Guerrero-Cervantes[1], R. G. Ramírez-Lozano[2], R. Montoya-Escalante[1], A. S. Juárez-Reyes[1], and M. A. Cerrillo-Soto*[1], [1]*Universidad juárez del Estado de Durango*, *Durango, Durango, Mexico*, [2]*Universidad Autónoma de Nuevo León*, *Monterrey, Nuevo León, Mexico*.

The aim of this study was to determine the parameters of *in situ* DM degradability of cacti and fruits commonly selected by range goats in the semiarid region of North Mexico. Immature pods of *O. leucotricha*, *O. imbricata* and *O. leptocaulis*, and fruits of *O. leucotricha* and *O. imbricata* were collected, burned and milled. To determine the parameters of degradability, 5 g DM of samples were incubated in nylon bags for 0, 3, 7, 12, 24, 48, 72 and 96 h, in the rumen of 3 sheep fed alfalfa hay:concentrate (75:25). Results of DM degradability were fitted to exponential equation $P = a + b\ (1 - e^{-ct})$; where **a** is the intercept, **b** is slowly degradable fraction, **c** is the rate constant of disappearance of **b** fraction, and **a+b** is the potentially degradable fraction. Data were analyzed by analysis of variance for a completely randomized design. The DM degradability was different among species (P<0.05). The values for the fraction **a** were 20.9% higher in the fruit of *O. leucotricha* (white prickly pear) than the fruit of *O. imbricata*. The slowly degraded fraction **b** ranked the species *O. imbricata* higher and the fruit of *O. leucotricha* lower. *O. leucotricha* ranked intermediate (P<0.05). No differences (P>0.05) were recorded in the constant rate **c**. However, a numerical increment was observed in white prickly pear. The potential gas production **a+b** was 16.7% higher (P>0.05) in *O. imbricata* and *O. leucotricha* than the lowest counterpart (Fruit of *O. imbricata*). A similar trend was observed with effective degradability. Results indicated that white prickly pear, which is the fruit of *O. leucotricha* and *O. imbricata* represent valuable scarcity feeds in hot semiarid environments.

Table 1. *In situ* degradation of cacti and fruits commonly consumed by goats in the semiarid region of Mexico

	Parameters				
Species	a (%)	b (%)	c (% $^{-h}$)	a+b (%)	ED (%)
O. leucotricha	54.2^{b}	36.2^{b}	0.042	90.4^{a}	70.7^{a}
O. leptocaulis	55.5^{b}	31.4^{c}	0.059	87.0^{ab}	72.6^{a}

M129 *In vitro* gas production parameters of fruits commonly selected by grazing goats. M. Guerrero-Cervantes[1], R. G. Ramirez-Lozano[2], R. Montoya-Escalante[1], A. S. Juárez-Reyes[1], and M. A. Cerrillo-Soto*[1], [1]*Universidad Juárez del Estado de Durango*, *Durango, Dgo., Mexico*, [2]*Universidad Autónoma de Nuevo León*, *Monterrey, N.L., Mexico*.

The objective of the study was to determine the *in vitro* gas production parameters of fruits commonly selected by range goats in the semiarid region of North Mexico. Fruits from *P. leavigata*, *Opuntia leucotricha* (white prickly pear), *O. leucotricha* (red prickly pear), *O. imbricata* and *O. leptocaulis* were collected. Triplicate samples (500 mg DM) were incubated in 100 ml glass syringes. The gas production was registered at 3, 6, 9, 12, 24, 48, 72, and 96 h. Data were fitted to the equation: $p = a + b\ (1 - e^{-ct})$, were ***p*** represents gas volume at time ***t***, ***a*** is the gas produced (ml) from the soluble fermentable feed fraction, ***b*** is the gas produced (ml) from the insoluble but fermentable feed fraction, ***a + b*** is the potential gas production (ml), ***c*** is the the constant rate of gas production (% h^{-1}). Data were analyzed by ANOVA for a completely randomized design. Gas produced from the soluble ***a***

fraction was highest for red and white prickly pear ($P < 0.05$) whereas the fruits of *O. imbricata* and *P. leavigata* were lowest. The gas produced from the slowly degradable fraction ***b*** followed the same pattern than the ***a*** fraction. White prickly pear from *O. leucotricha* resulted in higher values; *P. leavigata* recorded the lowest ($P < 0.05$). The constant rate of gas production ***c*** was highest for white and red prickly pears, whereas fruits from *P. leavigata*, *O. leptocaulis* and *O. imbricata* were lower ($P < 0.05$). The highest potential gas production ***a+b*** was recorded in white prickly pear, and the lowest in *O. imbricata*. Data supported the fact that fruits from *O. leucotricha* represent a valuable source of food in harsh conditions in semi arid regions.

Table 1. *In vitro* gas production parameters of fruits

	Parameters			
	a	***b***	***c***	***a+b***
Fruits	ml/500 mg DM	ml/500 mg DM	% h^{-1}	ml/500 mg DM
P. leavigata	23.3^{c}	81.1^{c}	0.049^{b}	104.4^{d}
O. leptocaulis	36.1^{b}	83.7^{c}	0.040^{b}	119.9^{c}
O. imbricata	23.2^{c}	81.9^{c}	0.053^{b}	105.2^{d}
O. leucotricha **(red prickly pear)**	43.3^{a}	96.1^{b}	0.083^{a}	139.5^{b}

M130 Effects of dietary concentrate level on tissue and organ mass of Alpine does at different stages of lactation. A. T. Ngwa[1], L. J. Dawson[2], R. Puchala[1], G. Detweiler[1], R. C. Merkel[1], T. Sahlu[1], C. L. Ferrell[3], and A. L. Goetsch*[1], [1]*American Institute for Goat Research, Langston University*, *Langston, OK*, [2]*College of Veterinary Medicine, Oklahoma State University*, *Stillwater*, [3]*US Meat Animal Research Center*, *Clay Center, NE*.

Multiparous Alpine does (42) were used to determine how dietary concentrate level and stage of lactation affect mass of organs and tissues. Initial measures were conducted with six does a few days after kidding (0 wk). Eighteen does were fed a 60% concentrate diet (C) and 18 received one based on forage (20% concentrate; F) for 8, 16, or 24 wk of lactation. Intake of DM was greater ($P < 0.05$) for F vs C (2.23, 2.14, 2.10, 2.42, 2.81, and 2.55 kg/d), ADG was affected ($P < 0.07$) by an interaction between diet and time (0, 24, 121, -61, 46, and 73 g), and 4% fat-corrected milk was less ($P < 0.05$) in wk 17-24 than earlier (3.60, 2.78, and 2.45 kg/d for C and 3.02, 3.00, and 2.14 kg/d for F in wk 1-8, 9-16, and 17-24, respectively). Measures at 0 wk in % empty BW (EBW) included 51.1% carcass, 2.01% liver, 14.88% internal fat, and 6.57% gastrointestinal tract (GIT). Carcass mass was greater ($P < 0.05$) for F vs C and similar among times (50.8, 52.1, and 51.2% EBW for C and 52.6, 53.0, and 52.2% EBW for F at 8, 16, and 24 wk, respectively). Liver mass was similar between diets ($P = 0.13$) and greatest among times ($P < 0.05$) at 8 wk (2.87, 2.46, and 2.23% EBW for C and 2.81, 2.63, and 2.58% EBW for F at 8, 16, and 24 wk, respectively). Internal fat mass was greatest among times ($P < 0.05$) at 24 wk and greater for C vs F (11.40, 14.27, and 18.59% EBW for C and 9.39, 11.43, and 13.70% EBW for F at 8, 16, and 24 wk, respectively). Mass of the GIT was less ($P < 0.05$) for C than for F and decreased ($P < 0.05$) with increasing time in lactation (9.26, 7.56, and 6.21% EBW for C and 9.24, 8.50, and 7.87% EBW for F at 8, 16, and 24 wk, respectively). In conclusion, though milk production was not affected by diet partially because of greater DMI for F vs C, based on tissue mass more energy was expended by the GIT of F vs C does. In this regard, it appears that considerable internal fat is mobilized in early lactation particularly with forage-based diets, with more rapid and a greater magnitude of repletion by does consuming diets with high vs moderate or low concentrate levels.

M131 Effects of dietary starch sources on intake, growth and blood variables in growing goats. S. P. Wang, W. J. Wang, B. Lin, Z. L. Tan*, S. X. Tang, Z. H. Sun, and J. Y. Zeng, *Institute of Subtropical Agriculture, The Chinese Academy of Science*, *Changsha, P.R.China*.

The effects of dietary starch sources on feed intake, growth and blood variables were investigated in growing goats. Sixteen Liuyang black wether goats (Local breed; 15.0 ± 2.5 kg) were randomly allocated to four dietary treatments (4/treatment) for 54 d feeding period. The rations consisted of maize stover and concentrate containing soybean meal, fish meal, fat meal, rice husk, and a vitamin and mineral premix. Extra dietary starch was supplied, respectively with wheat grain, maize grain, sorghum grain, or paddy grain, all grounded and mixed with the concentrate to form four treatment diets with the same CP, starch and DE level. Goats were fed maize stover ad libitum, and the concentrate was provided daily in two equal portions at 0800 and 1700 h. The feed offered and orts were weighed daily, while animals were weighed at the beginning and end of feeding trail. About 20 ml blood samples were collected from the jugular vein at day 53 from each goat. Dry matter intake (DMI) of maize stover and concentrate, and daily weight gain of goats did not differ ($P > 0.05$) among treatments. Dietary starch sources affected ($P < 0.05$) the leucocyte numbers, the numbers and percentage composition of lymphocyte, intermediate cell and neutrophilic granulocyte, and the distribution dispersion of thrombocyte volume in whole blood. However, treatment did not affect ($P > 0.05$) the erythrocyte numbers, haemoglobin mass, haematocrit, average volume of erythrocyte, the distribution dispersion of erythrocyte volume, the thrombocyte numbers, the average volume of thrombocyte and packed thrombocyte in whole blood. Although these data suggest that dietary starch sources from cereal grains have no effect on DMI and growth, it affected the blood cell numbers.

M132 Effects of dietary starch sources on meat quality and serum hormonal concentrations in growing goats. S. P. Wang, W. J. Wang, B. Lin, Z. L. Tan*, S. X. Tang, Z. H. Sun, and J. Y. Zeng, *Institute of Subtropical Agriculture, The Chinese Academy of Science*, *Changsha, P.R. China*.

The objective of this study was to examine the effects of different dietary starch sources on serum hormone concentrations and meat quality of growing goats. Sixteen wether goats (15.0±2.5 kg) were randomly allocated to four dietary treatments (4/treatment). Ration

consisted of maize stover and concentrate. The concentrate contained soybean meal, fish meal, fat meal, rice husk, and a vitamin and mineral premix. Extra dietary starch was supplied respectively by wheat grain, maize grain, sorghum grain and paddy grain which were grounded and mixed with the concentrate to form four treatment diets with the same CP, starch and DE level. Goats were fed maize stover ad libitum while concentrate was provided daily in two equal portions at 0800 and 1700 h. The feeding period lasted for 54 days. Blood samples were taken from the jugular vein on d 55 before the morning feeding to determine hormone concentrations. Thereafter the goats were slaughtered and about 350 g of longissimus dorsi from each goat were sampled for meat quality measurement. Dietary starch sources did not affect (P>0.05) the concentrations of insulin, growth hormone, T4, leptin, gastrin, and motilin in the serum. No significant differences (P>0.05) were observed in pH at 24 h after slaughter, drip loss for days 1, 3, 5, 7, 9, 14 and 21, cooked meat ratio, percentage of water loss between treatments. The pH at 45 min after slaughter, the content of total pigment and myoglobin were higher (P<0.05) in goats fed the paddy grain diet than the other diets. Crude protein content in the meat was higher (P<0.05) in goats fed the wheat diet than in goats fed the sorghum or the paddy diet. The current study demonstrated that different dietary starch sources could affect the pigment sediment and protein content of muscle tissues.

M133 Evaluating associative effects of different proportions of mixed forage species using gas production technique. S. X. Tang, Z. L Tan*, Z. H. Cong, Y, Hu, Z. H. Sun, and M. Wang, *Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, P.R. China*.

The objective of this study was to investigate the associative effects of different forage species mixed with the mixture of *Rumex* and *Trifolium* (50:50, RT) at the proportions of 0:100, 25:75, 50:50, 75:25 and 100:0 respectively. The forage species included *Pennisetum Purpureum×P. americanum* (PPPA), *Guimu No.1* (GM), *Secale carele L* (SCL), *Pennisetum Purpureum Schum. Cvmott* (PPS), *Hemarthria japonica* (HJ), *Lolium perenne* (LP), and *Sorghum sudanens* (SS). Three goats (20±2 kg) were used. The goats were fed a diet consisting of 500 g kg^{-1} concentrate and 500 g kg^{-1} forage containing DE (3.15Mcal/kg DM) and CP (140 g/kg DM) and used as ruminal fluid donors for the preparation of inoculums. The gas production (GP) of the above forage combinations were measured in each vial after 12, 24 and 48 h of incubation. The associative effects were evaluated using their measured GP at 12, 24 and 48 h incubation time and their predicted GP. The predicted GP of combinative proportions was calculated according to GP of single RT and forage. The results were analyzed using completely randomized design in each incubation time with Duncan's multiple range test used for the comparison of means. The major combinations of RT and forages expressed significant positive associative effects (P<0.05) in gas production at different proportions. The negative associative effect (P>0.05) was only observed for the mixture of 25% RT and 75% GM at 12 h incubation time. The results indicated that the in vitro fermentation of forages could be improved through changing their combinative proportions.

M134 Ingestive behavior of goats fed with urea in the diet. L. S. Amorim*[1,4], C. A. A. Torres[1], E. A. M. Amorim[1,4], J. F. Fonseca[2], J. H. Bruschi[3], and M. T. Rodrigues[1], [1]*Federal University of Vicosa*, *MG, Brazil*, [2]*Embrapa Small Ruminant Research Center*, *Sobral, CE, Brazil*, [3]*Embrapa Dairy Cattle Research Center*, *Juiz de Fora, MG, Brazil*, [4]*Colorado State University*, *Fort Collins, CO*.

True protein supplements are the most expensive ingredients in diets. Therefore, substitution of a true protein supplement with a non-protein N source may significantly reduce the diet costs. However, studies have demonstrated that urea addition in the diets is related to increases in the ammonia concentrations in the serum and plasma blood, therefore has diminished the reproductive performance. A trial was conduced with 20 Toggenburg goats, not pregnant and nonlactating, averaging 48.55 ± 7.87 kg BW, 2.97 ± 0.5 ECC and 34.33 ± 20.80 months old distributed in five randomized blocks to evaluate the effect of the addition of high urea levels on the diet on feeding behavior. The goats were fed with two diets (TRT) contend 0 and 2.2% of urea in the total DM basis of the ration. Diets consisted of 60% of Tifton hay (Cynodon ssp.) and 40% of concentrate, formulated to be isonitrogenous (14% CP, DM basis). Treatments consisted of 0 (TRT1) and 2.2% of urea in the total DM basis of the ration (TRT2), that it was substituted by the meal corn in the concentrated mixture. The animals were allotted to individual pens. The data measured was time spent eating (TSA), time spent ruminating (TRU), time spent idle (TID), time spent on foot (TFO), time spent lying down (TLY), chewing time (TCH) and ruminating chewing by number bolus (RCB), was determined by means of the visual observation of the animals, at intervals of ten minutes, for a period 24 hour. During the nocturnal collection of the data, the environment was kept with artificial illumination. Data were analyzed by ANOVA using the glm procedure of SAS (version 8.7). No statistical difference was observed between treatments (TRT1 and TRT2, respectively) on TSA 283.4 vs. 290.86 min, TRU 392.16 vs. 399.62 min, TID 748.86 vs. 756.32 min, TLY 835.67 vs. 843.13 min, TFO 586.77 vs. 594.23 min, TCH 41.38 vs. 48.84 min and RCB 54.49 vs. 61.95. The urea in the diet did not change the feeding behavior of animals.

Key Words: Behavior, Goats, Urea

M135 Lysophosphatidic acid (LPA) stimulates activiation of ERK-1/2 and proliferation of C_2C_{12} cells but does not result in a significant increase in total DNA. J. M. Scheffler*, A. K. Batie, and S. J. Jones, *University of Nebraska*, *Lincoln*.

Lysophosphatidic acid (LPA) plays an important role in modulating cell survival, proliferation and apoptosis in a variety of cell lines. LPA's possible role in proliferation makes it a candidate to be a component used in defined cell culture media. Skeletal muscle expresses all four LPA receptors, however, the role LPA plays in skeletal muscle has not been clearly defined. This study investigated the effect of LPA on proliferating C_2C_{12} cells by a variety of means. Serum starved C_2C_{12} cells were treated with serum free Dulbecco's Modified Eagle Medium (DMEM) with either 5% fetal bovine serum or 50, 25, or 12.5 μm LPA. Total DNA, proliferation (thymidine incorporation), cell cycle analysis (flow cytometry), and ERK were measured. The FBS treatment stimulated ($P<.05$) an increase in DNA, LPA did not stimulate ($P<.05$) an increase in total DNA. During a 48 h period, there was an increase in [3H]thymidine incorporation after 24 h. Treatment with LPA did result ($P<.05$) in the phosphorylation of ERK-1/2 within 5 min, however, phosphorylation was not maintained to the extent seen with serum addition. Cell cycle analysis by flow cytometry revealed that LPA stimulated a transient increase in proliferation which abated by 24 h. These results indicate that LPA stimulates proliferation of C_2C_{12} cells and activation of ERK-1/2, however, these responses are transient. A significant increase in DNA could be detected after 48 h.

Key Words: LPA, ERK1/2, DNA

M136 Phospho-MAPK as a marker of myogenic satellite cell responsiveness to growth factors. D. C. McFarland* and J. E. Pesall, *South Dakota State University*, *Brookings*.

Previous studies identified variation in the mitogenic response of subpopulations of turkey myogenic satellite cells to growth factor stimuli. Further work determined that this was not due to differences in growth factor receptor numbers or affinity between the subpopulations. In order to determine if the differential response to growth factor stimuli was due to variation in the levels of activated intracellular signaling proteins, a Western blotting procedure was utilized to measure the levels of phospho-MAPK (phospho-ERK 1/2). Confluent cultures of turkey satellite cells were rinsed and administered serum/growth factor-free medium for 3 hrs. Following this, treatment media were applied to the cells for 3 min. Cells were then scraped from the wells, extracted, and the supernatant subjected to Western blotting with anti-phospho-ERK 1/2 antibodies and visualized by chemiluminescence. Initial measurements using serum mitogenic stimuli showed differences in phospho-MAPK levels between the clonal subpopulations, but the responses did not correlate with proliferation rates of the individual clones ($P > 0.05$). IGF-I alone did not increase phospho-MAPK levels compared to non-growth factor controls ($P > 0.05$), whereas fibroblast growth factor (FGF) did result in increased levels ($P < 0.05$). A synergistic response was seen in cells administered both IGF-I and FGF. When administered FGF and IGF-I, 2 of the slow growing clones exhibited lowest levels of phospho-MAPK ($P < 0.05$). One of the slow growing clones had similar levels of phospho-MAPK to the three fast growing clones ($P < 0.05$). Similar results were seen with cells administered FGF, IGF-I, platelet-derived growth factor BB and hepatocyte growth factor. The results suggest that variation in the responsiveness of some satellite cell subpopulations may be due to differences in phospho-MAPK generation.

Key Words: Muscle, Satellite Cells, Turkey

M137 Mapping the glucocorticoid responsive element of the growth hormone gene in chicken embryonic somatotrophs. K. A. Heuck* and T. E. Porter, *University of Maryland*, *College Park*.

Normal expression of growth hormone (GH) in the chicken pituitary occurs around embryonic day (e) 14 and can be induced earlier by the glucocorticoid (GC), corticosterone (CORT). Induction of GH gene expression by CORT can be blocked by the protein synthesis inhibitor, cycloheximide, indicating an indirect effect requiring translation of an intermediary protein(s). Furthermore, no consensus glucocorticoid response element (GRE) exists within 10 kilobase (kb) upstream and 5 kb downstream of the GH gene, only several imperfect GRE half sites. Therefore, the objective of this study was to identify the GC-responsive region of the GH gene. A previous report indicated that reporter constructs containing 1.7 kb of the chicken GH gene 5′-flanking region were minimally responsive to GC (two-fold) in rat pituitary cell line. In the present study, luciferase reporter constructs were tested containing 1.4 and 1.7 kb of the GH promoter. Chicken e11 pituitary cells were used to avoid effects of heterologous cell lines. Constructs were evaluated in 5 separate experiments, and luciferase activity compared by analysis of variance. Reporter activity of the 1.7 kb construct showed a mean twelve-fold increase over basal when treated with CORT. Deletion of the 1.7 kb region to 1.4 (-1467) kb resulted in ablation of reporter activity ($P<0.05$; $n=5$). Preliminary experiments with constructs with 1.6 (-1620) kb and 1.5 (-1544) kb of the GH promoter recapitulated the 1.7 kb response in reporter activity ($n=1$), indicating that a GRE resides in a region between 1.5 kb and 1.4 kb upstream of the chicken GH gene. Inspection of this region reveals potential binding sites for Ikaros, ELF2, HNF1 and CREB, which are known to be regulated by GC or involved in cell differentiation. We conclude that the chicken GH gene is responsive to GC without a classical GRE and that this response is most likely indirect due to other GC-responsive transcription factors binding upstream of the GH gene.

Key Words: Growth, Pituitary, Gene Expression

M138 Intestinal morphology and gene expression differences between broiler chicken lines selected for divergent growth rates. E. R. Feierstein*[1], E. R. Gilbert[2], M. E. Persia[1], E. A. Wong[2], W. W. Saylor[1], and C. J. Schmidt[1], [1]*University of Delaware*, *Newark*, [2]*Virginia Polytechnic Institute and State University*, *Blacksburg*.

Modern broilers have been selected for rapid growth, and a reasonable hypothesis is that this selection may have affected intestine development or function. The objective of this study was to compare intestinal gene expression patterns between two strains of broilers that exhibit different growth properties. For this study, a broiler strain Ross-708 (Allen Poultry Company) was compared with strain IL50, an inbred strain maintained at the University of Illinois that exhibits growth

properties similar to those seen in broilers in the early 1950's. At 35 d post hatch, the mass of the IL50 birds was 60% of the size of the Ross birds. Also, the intestine of the IL50 birds contributes 3.1 (± 0.1)% of the bird mass, while the intestine of the Ross line contributes 2.4 (± 0.1)%. The growth of the duodenum, jejunum and ileum was monitored during that period by sacrificing birds at weekly intervals and measuring the mass and length of the individual intestinal segments. The increase in length was complex, with both strains exhibiting a plateau in all three segments between d 7 and 14. During this period the segments continued to increase in mass. RNA was prepared from d 2 and 14 post-hatch duodenal segments and quantitative real time PCR used to determine the expression levels of various nutrient transporters. For example, ANOVA analysis indicates the mRNA encoding peptide transporter 1 (PepT1) mRNA decreased ($P < .05$) between d 2 to d 14. In addition, we have used microarrays to evaluate global patterns of gene expression in this segment. This study may be useful for identifying candidate genes that have played a role in improving production traits during the past 50 years.

Key Words: Poultry, Intestine, Gene

M139 Cloning of chicken ras-dva: Glucocorticoid regulation in the embryonic anterior pituitary. L. E. Ellestad*[1,2], S. A. Jenkins[1], and T. E. Porter[1,2], [1]*Department of Animal and Avian Sciences, University of Maryland*, *College Park*, [2]*Molecular and Cell Biology Program, University of Maryland*, *College Park*.

Understanding mechanisms involved in initiating pituitary growth hormone (GH) expression during embryogenesis should aid in developing strategies for improving growth in broiler chickens. Circulating corticosterone (CORT) increases GH production between embryonic day (e) 12 and e14 in the chicken through a mechanism involving a Ras protein. This study was aimed at characterizing chicken Ras-dva, a candidate gene that may mediate CORT induction of GH during development. Through random sequencing of a cDNA library, we identified and sequenced in its entirety a putative Ras-dva clone. Comparison of chicken Ras-dva with GenBank and with vertebrate genomes indicated that homologs are present only in non-mammalian vertebrates. Phylogenetic comparison of our nucleotide sequence (1276 bp) with that in fish and frogs indicated an overall identity of 52-62%, and the predicted amino acid sequence of chicken Ras-dva (208 aa) is 74-76% identical to Ras-dva in other non-mammalian vertebrates. Pituitary expression of Ras-dva in the chicken was confirmed with RT-PCR, and ontogenic analysis indicated that pituitary Ras-dva mRNA increases between e10 and e17 in a manner similar to GH ($P<0.05$; n=4). CORT treatment increased Ras-dva mRNA in e11 anterior pituitary cells in vitro ($P<0.05$; n=4). Although the increase was less than that in cells receiving CORT alone, Ras-dva mRNA was induced by CORT in the presence of a protein synthesis inhibitor ($P<0.05$; n=4), indicating that it may be a direct target of the glucocorticoid receptor (GR). Analysis of potential regulatory regions of the chicken Ras-dva gene identified three putative GR binding sites within 5 kb upstream and one within 4.2 kb downstream of its transcription start site. Six potential binding sites for the pituitary-specific factor Pit-1 were also identified within 5 kb upstream, indicating that Ras-dva may be expressed in Pit-1 expressing cells such as GH-producing somatotrophs. We conclude that Ras-dva is a glucocorticoid-induced gene in the chicken anterior pituitary gland that may play a role in initiating GH expression during embryonic development.

Key Words: Growth Hormone, Somatotroph, Corticosterone

M140 Identification of potential feed efficiency biomarkers. C. P. Ojano-Dirain*[1], N. R. Pumford[1], T. Wing[2], M. Cooper[2], J. Lay[3], R. Liyanage[3], and W. G. Bottje[1], [1]*Center of Excellence for Poultry Science, University of Arkansas*, *Fayetteville*, [2]*Cobb-Vantress, Inc.*, *Siloam Springs, AR*, [3]*State Wide Mass Spectrometry Laboratory, University of Arkansas*, *Fayetteville*.

Our previous research has reported that certain mitochondrial proteins were differentially expressed in breast muscle, liver and duodenum in broilers with high or low phenotypic expression of feed efficiency (FE, gain to feed). The objective of this study was to identify proteins that are expressed differently in readily accessible tissue, such as lymphocytes or plasma, from broilers with high or low FE. In Experiment 1, lymphocytes were isolated from whole blood of broilers with a continuum of FE (n = 25 to 48) using density gradient Histopaque-1077. Results of Western blot assay showed a significant correlation ($P<0.05$) between FE and the levels of vinculin and cytochrome c in lymphocytes. Using the level of these two potential biomarkers, we found that we could identify the bottom 30% of birds in terms of FE with ~90% accuracy. In Experiment 2, plasma was separated by 2D electrophoresis and four separate gels from each group of high or low FE broilers were analyzed for significant differences. Ten proteins from the plasma proteome were expressed differently ($P<0.05$) between the high and low FE broilers. Of these 10 proteins, 4 have been identified using MALDI-TOF MS, namely transthyretin, histone deacetylase 1 and 2, adipophilin and albumin. Although the mechanism behind the association of plasma proteins to FE is yet unknown, results of this study indicates that some mitochondrial and extramitochondrial proteins are potential candidates for developing a biomarker assay that could aid in identifying low FE birds for exclusion from the breeding line.

Key Words: Feed Efficiency, Broilers, Potential Biomarkers

M141 Physiological function of butoxybutyl alcohol a novel compound in broilers. S. Inada*, A. Ohtsuka, and K. Hayashi, *Kagoshima University*, *Kagoshima city , Korimoto, Japan*.

We have shown that sweet potato shochu distillery by-product (SDBP) contains growth promoting factor. Butoxybutyl alcohol (BBA) is a new compound which may be responsible for the growth promotion. The ether extract of SDBP was first fractionated by a Sephadex column (Sephadex LH-20), purified by HPLC (high performance liquid chromatography) and the chemical structure was determined by NMR (nuclear magnetic resonance) and MS (mass spectrometry). In the present study, chemical synthesis of BBA was carried out using butanol, butyric aldehyde and *p*-toluenesulfonic acid as the catalyst. After the fractionation by a Sephadex column, BBA was verified by HPLC. Then physiological function of BBA was investigated *in vivo* (broiler) and *in vitro* (chick muscle cells). Birds (Cobb strain, male) were raised under 24 ±1° C in wire bottom cages for 20 d from 15 d of age. Feed (CP 23%; 3200 kcal ME/kg) and water were given *ad libitum* during the experimental period. BBA was mixed into the feed at the level of 70 ppm. Body weight was recorded every 3 d and feed intake was recorded daily. At 35 d of age, all the birds were killed and dissected to measure muscle and organs weights. Blood was collected to measure GOT (glutamate oxaloacetate transaminase) as an index of liver function. In the case of *in vitro* experiment, BBA was added to the culture medium at the levels of 1, 10 and 100 ppm, and cells were cultivated for seven days. BBA increased feed intake ($P<.05$) and growth was facilitated. Feed conversion, abdominal fat weight, liver

weight, spleen weight and serum GOT were not changed by BBA. Muscle TBARS (thiobarbituric-acid reactive substances) as an index of lipid peroxidation was significantly decreased by BBA. Protein content of the cultured muscle cell was increased (P<.05) by 1 and 10 ppm BBA, but decreased by 100 ppm BBA.

Key Words: Broiler, Growth Promotor, Distillery By-product

M142 Bone mineralization in nine pedigree lines of meat-type chickens. P. Talaty*[1], M. N. Katanbaf[2], and P. Y. Hester[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*Cobb-Vantress, Inc.*, *Monticello, KY*.

The variability of bone mineral density (BMD) and bone mineral content (BMC) of the tibia, ulna, and radius of 9 Cobb pure lines (L) of chickens were accessed at 6 wk of age. Bone mineralization of 9 birds/line/sex was determined using dual energy X-ray absorptiometry. Using the mixed model of SAS, data for BMC, bone length, and bone area were analyzed using an analysis of covariance with BW as the covariant. An ANOVA was used for BMD and bone width as BW was nonsignificant as a covariant. Bone within bird (used a subplot), line of chicken, and sex of the bird were considered fixed effects. The BMD did not differ among pedigree lines. Interactions with sex and bone were nonsignificant indicating that the BMD response was the same for all 9 pedigree lines with respect to the sex of the bird and the type of bone scanned. However, all other traits measured in this study including BW, BMC, bone length, bone width, and bone area were different among lines ($P < 0.001$). The two pedigree lines (L 7 and L8) with the lightest 6-wk-old BW (2033 and 2055 g, respectively) had diverse skeletal traits. Birds of L7 had the lowest BMC (1.05 g), shortest bone length (69.2 mm) and smallest bone area (8.0 sq cm); however, the other pedigree line low in BW (L8) showed the opposite trend in that bones from these birds were the highest in BMC (1.38 g), bone length (74.6 mm), and area (9.2 sq cm) when compared to all of the other lines. It was the BMC of the tibia and not the radius and ulna that caused the differences in BMC among pedigree lines of chickens (line × bone interaction, $P < 0.0001$). The BMD of L8 was also the highest of all pedigree lines that were compared, but the difference was non-significant ($P = 0.12$). The overall CVs calculated for skeletal traits across all genetic lines were high with BMD at 51% and BMC at 80%. It is concluded that large differences in skeletal traits exist among pedigree lines of meat-type chickens.

Key Words: Bone Mineralization, Bone Mineral Density, Pedigree Chickens

M143 The expression of neutral amino acid transporter B^0 and mTOR proteins along the gut mucosal crypt-villus axis in the formula-fed neonatal pig. C. Yang[1], X. Yang[1], D. Lackeyram[1], Y. L. Yin[2], K. Swanson[1], F. Verrey[3], and M. Z. Fan*[1], [1]*University of Guelph*, *Guelph, ON, Canada*, [2]*Institute of Subtropical Agriculture, the Chinese Academy of Sciences*, *Changsha, Hunan, China*, [3]*Institute of Physiology, University of Zurich*, *CH-8057 Zurich, Switzerland*.

The intestinal apical Na+-neutral amino acid (AA) transporter B^0 is believed to be the primary transporter for the uptake of luminal neutral AA across the apical membrane. Our previous work demonstrated a high level of apical B^0 transporter activity along the jejunal crypt-villus axis in fed neonatal pigs. However, the B^0 gene (mRNA) expression is low in proliferating crypt cells and increases with cell differentiation in the villus cells. This study was conducted to examine how B^0 protein is expressed along the jejunal crypt-villus axis in fed neonatal pigs. Six Yorkshire gilts were removed from sows at d 5 of age and fed a milk protein-based liquid formula till 14-16 d of age before being sacrificed for tissue collection. Three major intestinal epithelial cell fractions from the jejunum, representing cells from the upper villus, the middle villus and the crypt regions, were sequentially isolated, with cell viability of 92-95%, as assessed by trypan blue exclusion, by the distended sac method. Western blot analyses were used to examine the protein abundance of Na+-neutral amino acid (AA) transporter B^0 and the mammalian target of rapamycin (mTOR) protein phosphorylated (Pi). No differences ($P>0.05$) were observed in B^0 protein abundance among the cell homogenate, soluble, and the apical membrane along the three cell fractions. A higher ($P<0.05$) mTOR protein-Pi was observed in the middle villus cells. The crypt cell also expressed relatively high level of the activated mTOR protein. The results suggest that the B^0 protein expression along the gut crypt-villus axis may be regulated at posttranscriptional level and the mTOR-signaling pathway may be involved in the regulation in the fed neonate.

Key Words: Na+-Neutral Amino Acid Transporter B^0, Neonates, The Mammalian Target of Rapamycin (mTOR)

M144 Modulation of protein synthesis by somatotropin and insulin in skeletal muscle of growing pigs. F. A. Wilson*, H. V. Nguyen, A. Suryawan, R. A. Orellana, J. G. Fleming, A. S. Jeyapalan, and T. A. Davis, *Childrens Nutrition Research Center, Baylor College of Medicine*, *Houston, TX*.

Chronic treatment of pigs with porcine somatotropin (pST) for 7 days increases feed efficiency by both promoting whole body protein synthesis in the fed state and reducing whole body protein degradation during fasting. pST-treated pigs have higher plasma insulin levels than vehicle-treated controls. This study aims to determine whether the increase in protein synthesis of pST-treated pigs is mediated through an insulin-induced stimulation of translation initiation. Growing pair-fed, weight-matched pigs were treated with pST (150 μg/kg/day, n=18) or vehicle (n=18) for 7 to 10 days. Pancreatic glucose-amino acid clamps were performed in overnight fasted pigs to attain plasma insulin levels of 5, 25 and 50 μU/ml, equivalent to reported insulin levels in 1) fasted control and fasted ST-treated, 2) fed control, and 3) fed-pST treated pigs, respectively. Amino acid and glucose levels were maintained at fasting levels. Skeletal muscle protein synthesis was measured with the flooding dose method and western blotting was used to identify changes in the abundance and activation of translation initiation factors in muscle. Statistical analysis was performed using ANOVA. Plasma levels of urea nitrogen were lowered ($P<0.001$) and insulin-like growth factor-1 levels increased ($P<0.005$) in pST-treated pigs indicating effectiveness of pST treatment. Insulin increased protein synthesis in muscle of control ($P=0.01$) and pST-treated ($P=0.07$) pigs. Treatment with pST also increased muscle protein synthesis ($P<0.05$). The abundance of the active translation initiation complex eIF4G-eIF4E and the phosphorylation of eIF4G in muscle mirrored the changes in muscle protein synthesis in response to insulin, however there was no clear effect of pST. We conclude that both insulin and pST stimulate protein synthesis in skeletal muscle of growing pigs.

M145 Impact of different doses of ractopamine in swine carcass and meat characteristics from Large White and Duroc breeds. E. F. Leonardo[1], I. L. Stella[1], A. C. M. S. Pedreira[2], G. B. Mourão[1], and E. F. Delgado*[1], [1]*Escola Superior de Agricultura "Luiz de Queiroz"*, *Piracicaba, SP, Brazil*, [2]*Agência Paulista de Tecnologia do Agronegócio*, *Piracicaba, SP, Brazil*.

Lean meat production has been an important issue for health and economical reasons in swine meat industry. Sixty animals (30 castrated males and 30 females) being 30 Large White (LW) and 30 Duroc (DU) were randomly assigned to different doses of ractopamine (RAC): 0 (control), 10 ppm and 20 ppm in the diet. The experiment started when animals reached 85 kg of live weight and ended after 4 weeks when animals were 110 kg. The *L. dorsi* muscle samples were collected 24 h postmortem (PM) from the left carcass side in a commercial abattoir. The WB shear force (WBS) was measured 24 h PM (d 1) and 5 d after slaughter (d 5). Rib eye area (REA) and fat thickness (FT) were measured 24 h PM. WBS on d 1 were higher (P≤0.01) for LW (7.58±0.32 kgf) than DU breed (6.09±0.38 kgf). Differences in WBS remained on day 5 (P≤0.01) for LW and DU breeds (4.83±0.21 and 3.86±0.25 kgf, respectively). The WBS for d 1 were not different between RAC doses but higher than control diet (0: 6.12±0.44; 10 ppm: 6.86±0.43; 20 ppm: 7.51±0.44 kgf; P≤0.05). On d 5, WBS was different between RAC doses and also compared to the control diet (0: 3.74±0.29; 10 ppm: 4.23±0.28; 20 ppm: 5.07±0.29 kgf; P≤0.05). LW animals had greater REA (P≤0.05) than DU breed (37.7±1.0 and 34.3±1.2 cm^2, respectively). Rib-eye area for females and males were different (37.7±1.1 and 34.3±1.2 cm^2, respectively). There was a FT interaction between breeds and sex condition (P=0.083). FT were different between RAC doses (P≤0.05) and also compared to the control diet (P=0.054) (0: 2.62±0.13 cm; 10 ppm: 2.53±0.12 cm; 20 ppm: 2.10±0.13 cm). The results confirmed the leaner carcass production when RAC is added to diet. However, in those pure breeds doses of RAC did not modified REA. The negative effect of increased RAC dose on swine meat tenderness was also observed.

Immunology - Livestock and Poultry I

M146 Pro-inflammatory response of chicken thrombocytes to lipopolysaccharide. T. R. Scott* and M. D. Owens, *Clemson University*, *Clemson, SC*.

Thrombocytes (10^7) from blood of SCWL chickens were cultured 1 hr in the presence of lipopolysaccharide (LPS). LPS concentrations of 0, 0.1, 1 and 10 µg/ml were used. Following culture, thrombocytes and culture media were separated by high speed centrifugation. Cell pellets were resuspended in RNA*later*™. RNA was extracted from cells for real-time PCR of GAPDH, Toll-like receptor 4 (TLR4), IL-1β, IL-6 and IL-12. Culture media supernatant histamine (H) and prostaglandin E2 (PGE2) concentrations were determined with homologous time-resolved fluorescence assays. GAPDH was used as the housekeeping gene, and the expression of this was unaffected by any concentration of LPS used in culture with the thrombocytes. TLR4 was found to be constitutively expressed by thrombocytes and its expression was not altered by any concentration of LPS. Expression of IL-1β, IL-6 and IL-12 were all increased by LPS stimulation of thrombocytes in culture. H release by thrombocytes in culture was not affected by LPS. PGE2 concentrations in culture supernatants were found to be increased following LPS treatment. Although different from the 0 µg/ml control, the expressions of cytokines and PGE2 concentrations were not different among 0.1, 1 and 10 µg/ml LPS used in culture. Chicken thrombocytes express TLR4 and respond to LPS stimulation with increased pro-inflammatory cytokine expression and PGE2 release.

Key Words: Thrombocyte TLR4, Pro-inflammatory Cytokines, Prostaglandin E2

M147 Pro-inflammatory response of broiler chick thrombocytes. F. Ferdous*, D. V. Maurice, and T. R. Scott, *Clemson University*, *Clemson, SC*.

Broiler chicks at 4 weeks of age were bled to obtain thrombocytes for in vitro stimulation with lipopolysacchardie (LPS). The chicks had been fed a chick starter diet or the same diet supplemented with either corticosterone (CS) or vitamin C plus corticosterone (VitC). The diets were fed to the chicks from 2 to 4 weeks of age in order to induce body conditions indicative of stress. After 2 weeks of feeding, the chicks exhibited differences in feathering and body weight with the control chicks being largest and well-feathered while the VitC chicks were intermediate in both features and the CS chicks were small and poorly feathered. Isolated thrombocytes (10^7) were cultured for 1 hour with 0 or 10 µg/mL LPS. Following culture the cells were separated from the supernatants by high speed centrifugation. The thrombocyte pellets were resuspended in RNA*later*™, and RNA was extracted with the RNeasy Kit. RNA samples were processed for real-time PCR of GAPDH, IL-1β, IL-6 and IL-12. GAPDH was used as the housekeeping gene, and its expression was not affected by any dietary treatment nor concentration of LPS. The thrombocyte pro-inflammatory cytokines were unaffected by the diets, but 10 µg/mL LPS significantly induced greater expression of these above 0 µg/mL LPS. Although dietary induced stress can affect other physiological parameters in broiler chicks, the LPS induced expression of thrombocyte IL-1β, IL-6 and IL-12 are not altered.

Key Words: Thrombocytes, Pro-inflammatory Cytokines, Stress

M148 Identification of antimicrobial peptides in avian heterophils using whole cell MALDI-TOF. L. Kannan*[1,2], N. C. Rath[1], R. Liyanage[2], and J. O. Lay[2], [1]*USDA/Agricultural Research Service*, *Fayetteville, AR*, [2]*University of Arkansas*, *Fayetteville*.

Mass spectrometry (MS) is a rapidly emerging tool not only to characterize specific biomolecules but also to characterize and identify prokaryotic cells using whole cell MALDI-TOF-MS (matrix assisted laser desorption ionization time of flight). In order to study the potential of this technique to explore the eukaryotic cell associated peptides we isolated heterophils from the peripheral blood of chickens and turkeys and subjected to whole cell MALDI-TOF in the mass range of 1-20kDa. The mass-spectrum obtained showed a prominent peak at m/z 3915 in chicken and at m/z 4132 in turkey heterophils. Since heterophils occur abundantly in bone marrow, we isolated these peptides from the bone marrow extracts of both the species using

reverse phase liquid chromatography. Edman sequencing and peptide mass fingerprinting followed by fragmentation data obtained for a couple of tryptic peptides using post source decay experiment were used in MASCOT database search and it yielded 3915 to be gallinacin-2. Similarity database search found a corresponding significant hit for turkey heterophil peptide-2 (THP-2) which is in agreement with the MALDI-TOF observed nominal mass 4132 Da. These are antimicrobial peptides which serve as natural defense mechanism in many species of animals. Peptide search indicate that gallinacin-2 and THP-2 consist of 36 amino acids and contain 6 invariant cysteines that form three disulfide bonds thereby sharing more than 90% of sequence homology. However with the sequence obtained we noticed that THP-2 consist more number of arginine which shows that THP-2 is more cationic compared to gallinacin-2. These results demonstrate that, development of a rapid method to prospect for cell associated factors or bioactive peptides using 'whole cell MALDI' may be a viable method to study their physiology.

Key Words: Heterophils, Antimicrobial Peptides, Mass Spectrometry

M149 Adjuvants containing diverse peptidoglycan structures modulate hen antibody response to immunization. D. L. Trott*, E. M. Hellestad, and M. E. Cook, *University of Wisconsin*, *Madison*.

Hen egg yolks are utilized as a commercial source of polyclonal antibody, and adjuvant modifications have been shown to modulate hen antibody response to vaccination. Previous work showed that the addition of killed gram-positive *Staphylococcus aureus* or *Clostridium perfingens* to Freund complete adjuvant (FCA) consistently increased egg antibody titers to a test antigen, phospholipase A_2 (PLA_2), as compared to unmodified FCA. We tested the hypothesis that the increased titer due to adjuvant modification was due to the presence of lipoteichoic acid (LTA). Eight hens per treatment were injected with either FCA plus PLA_2 (FCA) or FCA/LTA from S. aureus (modified FCA) plus PLA_2. The vaccine composed of FCA was prepared by emulsifying 0.5 ml phosphate buffer saline containing 6 mg PLA_2 with in 0.5 ml adjuvant. The FCA/LTA vaccine was the same composition plus 2 mg purified LTA. In each hen, the 1 ml vaccine was injected i.m. into 4 injection sites. All hens received a second vaccination 7 days later with 3 mg/ml PLA_2 emulsified in Freund incomplete adjuvant administered in same manner as described above. Egg yolk antibody titer to PLA_2 was determined by ELISA. Results showed that *S. aureus* LTA modification of FCA decreased antibody titer 45% as compared to unmodified FCA. To determine the importance of peptidoglycan structure (PGS) as an adjuvant, a second study was conducted to determine if modification of FCA with killed bacteria containing diverse PGSs had added adjuvant effects. The killed bacteria added to the adjuvant were based on the diamino acid at position 3 of the PGS within the muramyl dipeptide (the smallest unit in FCA known to have an adjuvant effect). Using *Corynebacterium*, *S. aureus*, and *Streptococcus suis* combinations with FCA it appeared that the addition of stem peptides different than found in FCA increased the adjuvant effect (as much as 1.7 fold). These results would suggest that the adjuvant effects of FCA can be improved, and that attention to the PGS may offer insight into successful modifications.

Key Words: Egg Yolk Antibody, Adjuvants

M150 Immunocytochemical demonstration of neuroendocrine cells in chicken Peyer's Patches. C. H. Chen* and L. R. Berghman, *Texas A&M University*, *College Station*.

Peyer's patches (Pp), the secondary gut-associated lymphoid organ of the mucosal immune system, was named after the Swiss anatomist Hans Conrad Peyer in 17th-century. Because the chicken gastrointestinal tract lumen is exposed to the external environment, much of it is populated with potentially pathogenic microorganisms. Thus, chicken Peyer's patches (C-Pp), characterized by aggregations of lymphoid tissues, serve an important site for monitoring immunological and inflammatory responses against enteric pathogens. The novel staining method developed by L. E. Vaughn et al. (Avian Dis. 2006) was used for accurate identification the C-Pp from fresh intestine tissue specimens of White Leghorn chickens (SCWL) (ages ranging from 3 weeks to 2 years) and 7-week old broilers. Typical C-Pp were found in 7-week old broilers and 3-4 week old SCWL. Macroscopically, C-Pp were observable as elongated thickenings of the intestinal epithelium measuring from 3 milimeters to 1 centimeter in length. Light microscopic evaluation of H&E stained C-Pp tissue slides revealed oval lymphoid follicles located in the mucosa and extending into the submucosa of the ileum. M-cells that were located in a unique pocket-like structure on the basolateral side of the lumen were also observed. Chromogranin A (CgA)-positive cells were found exclusively in C-Pp, but not in the intestinal segments adjacent to the C-Pp. C-Pp play an important role in the immunological surveillance of the intestinal lumen and in facilitating the generation of the immune response within the mucosa. Interestingly, our observations provide morphological evidence for the potential involvement of neuroendocrine cells in the immune function of the C-Pp. Future studies will focus on determining the nature of the neuropeptides produced locally by the diffuse neuroendocrine system in the C-Pp.

Key Words: Peyer's Patches, Neuroendocrine Cells, Chromogranin A

M151 Altered monocyte/macrophage numbers in blood and organs of chickens injected i.v. with LPS. O. T. Bowen*, R. F. Wideman, and G. F. Erf, *University of Arkansas*, *Fayetteville*.

We recently reported peak circulating levels of nitric oxide (NO) 5h post–lipopolysaccharide (LPS) injection (i.v.) in chickens. To examine the ability of monocytes from in vivo LPS injected (1 mg) chickens to produce NO in vitro, young adult male chickens were injected i.v. with LPS and peripheral blood mononuclear cells (PMNC) were collected 5h later. PMNC were cultured with and without LPS and NO in the culture supernates assessed by nitrite assay at 1, 6, 12, 18, and 24h of incubation. Exposure to LPS in vivo attenuated further LPS stimulation in vitro (24 h NO level: 9.1 ± 3.8 μM vs. 39.1 ± 6.5 μM, in vivo LPS vs. control; $P<0.001$). When NO production was examined in PMNC cultures established at 5h and 48h post–in vivo LPS injection, in vitro LPS stimulated NO production again was attenuated in cultures established 5h after in vivo LPS ($P=0.03$), but not in cultures established 48h after in vivo LPS (NO level: 26.6 ± 3.5 μM vs. 22.1 ± 3.7 μM, in vivo LPS vs. control; $P=0.46$). Cell population analyses of the PMNC cultures established 5h post–in vivo LPS revealed reduced monocytes levels compared to controls (KUL01+: 3.6 ± 0.9% vs. 9.3 ± 1.1%, respectively; $P<0.001$). Hence, the lower in vitro LPS–stimulated NO production observed in these PMNC cultures is likely due to a reduction in monocytes in the blood. To gain insight into the potential redistribution of monocytes from the blood into tissues, the presence

of macrophages in the lung, spleen, and liver collected 0, 1, 3, 6, and 48h after LPS injection was examined. Compared to controls, the % area occupied by KUL01+ cells in tissue sections of lung, spleen, and liver decreased 1 h post–in vivo LPS injection (lung: 7.7 ± 1.0% vs. 5.0 ± 0.7%, P=0.004; spleen: 9.2 ± 0.4% vs. 2.2 ± 0.3%, P<0.001; and liver: 5.4 ± 0.7% vs. 2.4 ± 0.5%, P=0.002, respectively) and returned to normal or above normal by 48h in all tissues but the lung. Further studies are needed to determine whether the observed decrease in monocytes/macrophages is due to death of cells and/or redistribution to other tissues or specific locations in tissues.

Key Words: LPS, Chicken, Macrophage

M152 Oxidative stress and immune response in the chicken. S. Bush*[1,2], K. Gyenai[1], X. Guan[1], and T. Geng[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*University of North Dakota*, *Fargo*.

Oxidative Stress (OS) occurs when an organism has higher levels of oxidants than antioxidants. In this research, OS and Immune Response (IR) are analyzed in chickens. We are evaluating OS and IR to determine if a higher oxidative state would induce a higher or lower immune response in the birds. Oxidative stress occurs when there is an imbalance between an organism's free radicals and their antioxidants. When in excess, free radicals damage cellular macromolecules including DNA, lipid and protein. Here, we hypothesized that lowered immune response is one consequence of the macromolecular damage. Therefore the objective of this summer internship investigation was to evaluate the correlation between immune response and oxidative stress. Biomarkers used as indicators for OS were Thio Barbiturate Acid Reactive Substances (TBARS) and Malondialdehyde (MDA). Chickens were classified as either high or low immune response based on antibody titers produced in response to a challenge with sheep red blood cells. Based on both TBARS and MDA, high immune response birds had a significantly higher level of oxidative stress than low antibody producing chickens. The results appear to support earlier reports in the mouse that immune response was associated with immune response. The work provides a foundation for further investigating the role of oxidative stress in the general well-being of chickens.

Key Words: Chickens, Oxidative Stress, Immune Response

M153 Effects of immunoglobulin binding on signal transduction in bovine polymorphonuclear neutrophils. M. J. Paape* and Y. Wang, *Bovine Functional Genomics Laboratory, USDA-ARS*, *Beltsville, MD*.

Immunoglobulins are major molecules that mediate humoral immune responses. Their functional effects on leukocytes are mediated by the cell surface receptors for the Fc domain of immunoglobulins (FcR). Ligation of FcR on human polymorphonuclear neutrophils (PMN) is capable of triggering a wide range of biological activities, including phagocytosis, secretion of granules, generation of respiratory burst, antibody-dependent cellular cytotoxicity (ADCC), and production of proinflammatory mediators and cytokines. Bovine immunoglobulins IgG_2 and IgM but not IgG_1 bind to bovine PMN. The immunoglobulin binding pattern of bovine PMN is consistent with the major opsonic roles of IgG_2 and IgM for phagocytosis by bovine PMN. In this study, changes in intracellular free calcium concentrations ($[Ca^{2+}]_i$) and protein tyrosine phosphorylation (PTP) induced by immunoglobulin binding to bovine PMN were investigated. Purified bovine IgG, IgG_1, IgG_2, IgM and heat aggregated IgG (aIgG) were used. IgG_1 alone or crosslinked with a second antibody did not induce changes in $[Ca^{2+}]_i$ and PTP. IgG_2 alone or crosslinked with a second antibody and aIgG induced a strong PTP response without changes in $[Ca^{2+}]_i$. Crosslinking of IgG caused a rapid $[Ca^{2+}]_i$ increase of 91 nM without a PTP response. IgM did not induce $[Ca^{2+}]_i$ influx or PTP responses. However, crosslinking IgM with anti-bovine-IgM resulted in an increase of 115 nM in $[Ca^{2+}]_i$ and a strong PTP response on 45, 55, 100 and 115 kD proteins. Anti-bovine-IgM antibody alone induced a similar $[Ca^{2+}]_i$ influx and PTP response, indicating a high occupancy of IgM on bovine PMN surfaces. The immunoglobulin binding pattern of bovine PMN is consistent with the major opsonic roles of IgG_2 and IgM for phagocytosis by bovine PMN. Binding of these opsonic antibodies may trigger pathways for effective PMN phagocytosis and oxidative burst activity.

Key Words: Neutrophil, Bovine, Immunoglobulin

M154 Evaluation of a bovine respiratory pathogen exposure model on immune response and short-term performance of finishing cattle. B. McLaughlin*[1], L. O. Burciaga-Robles[1], D. L. Step[2], C. R. Krehbiel[1], M. Montelongo[2], A. W. Confer[2], R. W. Fulton[2], C. J. Richards[1], U. DeSilva[1], and G. Zhang[1], [1]*Department of Animal Science, Oklahoma State University*, *Stillwater*, [2]*Center for Veterinary Health Sciences, Oklahoma State University*, *Stillwater*.

The objective was to determine effects of an intratracheal *Mannheimia haemolytica* (Mh) challenge following short-term exposure (72 h) to Bovine Viral Diarrhea (BVD) persistently infected calves on white blood cell (WBC) count and differentials, DMI and performance in feedlot steers (BW = 305±20 kg). Treatments included: 1) steers not challenged with BVD or Mh (CON); 2) steers intratracheally challenged with Mh only (MH); 3) steers challenged with BVD, no Mh (BVD); and 4) steers challenged with BVD and Mh (BVD+MH). Feed, total urine and feces were collected during the first 2 wk post challenge. In addition, blood samples were collected at -72, 0, 7, 18, 36, 72, 96, 168, 336, and 672 h post challenge. Rectal temperature was greater ($P < 0.001$) for BVD+MH and MH during the first 24 h after the Mh challenge. For BVD+MH and MH, total WBC count was greater ($P < 0.01$) at 36 h post *M. haemolytica* challenge compared with CON, whereas in BVD steers, WBC count was lower ($P < 0.01$). Total lymphocyte count was lower ($P = 0.004$) during the first 72 h post BVD exposure for both the BVD and BVD+MH groups compared with MH and CON, and this difference remained at 96 h post *M. haemolytica* challenge. An increased ($P < 0.001$) total neutrophil count was observed during the first 36 h for the MH group and for 72 h for the BVD+MH challenge group. Although data were not significant ($P > 0.10$), ADG was 1.29, 1.04, 0.88 and 0.75 kg/d and G:F was 0.180, 0.122, 0.110 and 0.092 kg/kg for CON, BVD, BVD+MH, and MH steers, respectively, during the first 17 d post challenge. We conclude that the challenge model was successful at inducing bovine respiratory disease (BRD) associated with BVD and *M. haemolytica*. Understanding the physiological changes in morbid animals will lead to improved strategies for decreasing severity and economic losses associated with BRD.

Key Words: Bovine Viral Diarrhea, *Mannheimia haemolytica*, Steers

M155 ***In vivo*** **characterization of the recall response to antigen in chickens vaccinated with attenuated** ***Salmonella*** **mutants expressing M2e protein.** S. E. Higgins*, S. L. Layton, A. D. Wolfenden, K. Cole, B. M. Hargis, and G. F. Erf, *University of Arkansas*, *Fayetteville*.

We recently developed attenuated Δ*aro*A *Salmonella enteritidis* strains (ΔSE) that express the Influenzavirus epitope M2e, with or without a 10 aa CD154 (CD40 ligand) sequence. These mutants were orally administered to broiler chicks (10^7cfu/chick day-of-hatch, boosted with 10^8cfu at 32d). Mutants evaluated were ΔSE, ΔSE expressing M2e, ΔSEM2e and CD154, or ΔSE expressing multiple copies of M2e with CD154. Serum antibodies against M2e were detectable by 11d post-vaccination and steadily increased to day 20. To evaluate cell-mediated immune activity, we injected antigen on day 44 into the pulp of small growing feathers of five chickens per vaccination group. Three different antigen injections (sterile saline, M2e peptide conjugated with BSA (M2e-BSA), and ΔSE constructs homologous to the initial vaccine strain)(10μL) were made into separate feathers on each chicken. Feathers were collected 24h post-injection, and hematoxylin and eosin stained sections were prepared. Each sample was evaluated for the extent of leukocyte infiltration into the feather pulp (score 0-3; none to high level, respectively). Mean leukocyte-infiltration (MLI) scores following saline injection were ≤1 in all vaccination groups. The MLI score in response homologous ΔSE constructs was higher ($P<0.05$; 2.00-2.50) than that of saline controls in all groups. However, MLI scores following M2e injection in birds vaccinated with ΔSE expressing M2e were not different from those of saline controls. M2e-BSA injection into feathers of ΔSE (without M2e) vaccinated chickens (not M2e-sensitized) resulted in a MLI score of 2.6, which was higher than MLI scores observed in response to saline or M2e-BSA injection in birds vaccinated with ΔSE expressing M2e ($P<0.05$). Considering the low recall response to M2e-BSA in M2E sensitized birds, together with the observed antibody response to M2e in serum, it appears that the M2e-containing ΔSE constructs favor initiation of a humoral response over a cell-mediated immune response.

Key Words: Salmonella, M2e, Leukocyte

M156 Immune responses of dairy calves vaccinated at 2 versus 6 weeks of age. J. J. R. Patlola* and J. M. Smith, *University of Vermont*, *Burlington*.

Dairy calf raisers are implementing vaccine protocols with little documented evidence of efficacy in young calves. In this project, immune responses of calves vaccinated at different ages (2 wk vs. 6 wk) were determined. Twenty Holstein heifer calves on a custom replacement raising operation were enrolled. Calves were assigned to 1 of 2 groups based on their age. Of 10 age-matched calves in Group 1, 7 were vaccinated at 6 wk of age and 3 (unvaccinated controls) were not. Of 10 age-matched calves in Group 2, 7 were vaccinated at 2 wk of age and 3 were not. Vaccinated calves received 2 ml of a modified-live virus vaccine against infectious bovine rhinotracheitis (IBR), bovine viral diarrhea 1 and 2, parainfluenza-3, and bovine respiratory syncytial virus (BRSV). Blood was collected immediately before and 3 wk after vaccination. Calves were sampled at 6 and 9 wk of age in Group 1, and at 2 and 5 wk of age in Group 2. Lymphocyte proliferation was measured by thymidine incorporation after stimulation with various antigens (Vista 5 vaccine, IBR and BRSV antigens). Total serum IgG and Vista 5-specific IgG were measured by ELISA. Proliferative responses in 6-wk-old calves were greater than in 2-wk-old calves. The intensity of proliferation with Vista 5 was more pronounced than with other antigens. Three wk after vaccination, Vista 5-specific IgG were higher in calves vaccinated at 6 wk of age. There was no effect of vaccination on body weights and total serum IgG. The results of this study demonstrated that vaccination produces greater cell mediated and humoral responses in 6-wk-old calves as compared to 2-wk-old calves. Elucidation of the type of cells responding to early vaccination and demonstration of efficacy against challenge are needed to fully evaluate the usefulness of vaccinating calves at 2 wk of age.

Key Words: Dairy Calf, Vaccination, Lymphocyte Proliferation

M157 Campylobacter infection in day-old chickens. K. J. Genovese*, H. He, D. J. Nisbet, and M. H. Kogut, *USDA-ARS, FFSRU*, *College Station, TX*.

Intra-abdominal *Campylobacter* infection facilitates the characterization of peripheral blood leukocyte dynamics and abdominal cell infiltrates. Day-of-hatch leghorn chickens were injected intra-abdominally with *Campylobacter jejuni* [(CJ) 10^8 colony-forming units (CFUs)]. Peripheral blood leukocyte numbers were monitored at 0, 2, 4, 8, and 24 hours post-injection. In mortality studies, birds were injected intra-abdominally with 1 x10^8 CFUs CJ and mortalities were recorded for 72 hours post-injection. In CJ-injected chicks, total white blood cell (WBC) numbers began increasing by 2 hours post-injection, peaking at 4 hours post-injection, with the predominant cell type being polymorphonuclear leukocytes (heterophils). Total WBCs declined after 8 hours and this decline continued, with total WBC numbers approaching control values at 24 hr. Injection of CJ into the abdominal cavity caused a rapid rise in abdominal cell infiltrates, with the predominant infiltrating leukocytes being heterophils. Peak abdominal heterophil infiltrates were observed at 8 hours post-injection, declining only slightly by 24 hours post-injection. Chick mortality in the CJ challenge groups reached 30%. Mortality in the *Salmonella enteritidis* positive control groups was greater than 50%. The data suggest that *Campylobacter* infection does stimulate the innate immune response in chickens, however the response and infection is not characterized with the high levels of pathogenesis observed with a Salmonella infection. The present studies provide a foundation for the study and characterization of the avian immune response to *Campylobacter* and for the study of intervention strategies to prevent infection and colonization of poultry.

Key Words: Campylobacter, Heterophil, Innate Immunity

M158 Genetic and phenotypic factors influencing milk, protein and fat yields of dairy cows in Tasmania, Australia. S. A. Adediran[1], P. Nish[2], D. J. Donaghy[1], J. R. Roche[1], and A. E. O. Malau-Aduli*[1], [1]*University of Tasmania*, *Hobart, Tasmania, Australia*, [2]*Tasherd Pty Ltd*, *Hadspen, Tasmania, Australia*.

The Australian State of Tasmania enjoys a cool, temperate climate that remains the backbone of its pasture-based dairy production system. In this study, 330,366 lactation records from 428 Tasmanian dairy herds collected between 2000 and 2005 were analysed. The objective was to determine the influence of genetic and non-genetic factors on milk, protein and fat yields of pasture-based dairy cows. The data were statistically subjected to analyses of variance using general linear mixed model procedures with repeated measures. State-wide average milk yield per lactation over a standard 305-day lactation length was 5200.7 ± 1239.7 litres (ranging from 1107 to 13256 litres), while fat and protein yields averaged 205.5 ± 47.0 kg (ranging from 53 to 385 kg) and 166.2 ± 41.5 kg (ranging from 47 to 297 kg), respectively. Highly significant ($P<0.001$) effects on milk, protein and fat yields attributable to variation in herd size, cow's parity, breed, season and year of calving were detected. Milk yield increased linearly with increase in parity (means of 3482.4, 4019.5, 4615.4, 4826.1 and 5018.8 litres per lactation for parities 1, 2, 3, 4 and >4, respectively). Milk, fat and protein yields were highest in cows calving during the spring season (4769.8 litres, 215.2kg and 168 kg respectively), Holstein-Friesian genotypes produced the most milk (5211 litres), protein (171 kg) and fat (210kg) yields per lactation. Herd sizes of more than 1110 cows produced the most milk, fat and protein. Productivity per cow increased with calving year except in 2003 when total milk yield was lower than in 2002. We conclude that herd size, breed, parity, season and year of calving were among the main factors driving production of dairy cows in Tasmania and adjustments for these factors would be mandatory for any unbiased comparison of lactation performance within and between pasture-based dairy production systems.

Key Words: Milk Protein, Fat, Tasmania

M159 Impact of Warana Dairy Cooperative on the socio-economic status of farmers in Maharashtra, India. R. A. Patil*[1] and T. R. Dhiman[2], [1]*Warana Milk Cooperative*, *Warananagar, Maharashtra, India*, [2]*Utah State University*, *Logan*.

Warananagar is a cooperative complex established in 1958 with the objective of socio-economic development of rural Warana, Maharashtra, India. A milk cooperative was established under this complex during 1969-70 with 200 employee and procurement of 4000 liters of milk per day from 36 nearby villages. The objective of this study was to quantify the changes in structure of a rural cooperative from 1970 to the present and its influence on the Socio-economic development of rural people in Maharashtra, India. During 2006 milk cooperative collected daily 280,000 liters of milk, has 57,000 members, 1750 employee, a milk processing and a dairy product manufacturing facility. The data related to socioeconomic status of members between 1970 and 2006 was statistically analyzed. The annual turnover of the cooperative has grown significantly from $3 million in 1970 to $50 million in 2006. Interestingly, the women membership in the cooperative has changed significantly from 16% in 1970 to 46% of total members in 2006. Out of total 1250 societies in the cooperative, 161 are managed by women members. Milk cooperative in 1970 was selling milk locally and today exporting cheese, butter, ice cream and other dairy products to large cities in India and to Gulf, Africa and Asian countries. The cooperative currently has 126 full time artificial insemination technicians that perform 90,000 inseminations per year. Societies are connected with cooperative complex through an internet for procurement, payment and other record keeping. Cooperative supplies fodders seed and cattle feed to the members at non-profit basis and provides extension education. As a result of improved animal management and feeding, the milk yield of cows has increased significantly from 2.2 liters/d in 1970 to 4.0 liters/d in 2006. The present per capita income of cooperative members is $360. Our study concluded that a high technology dairy cooperative is managed successfully by producers with a significant role of women and having a positive impact on the animal productivity and per capita income of members.

Key Words: Dairy, Milk, Extension

M160 Metabolizable energy content and *in vitro* gas production characteristics of subtropical grasses of Northeastern Mexico. H. Bernal-Barragán[1], E. Gutiérrez-Ornelas[1], E. M. Romero-Treviño[2], J. Colin-Negrete[1], M. A. Cerrillo-Soto*[3], and A. S. Juárez-Reyes[3], [1]*Universidad Autónoma de Nuevo León*, *Monterrey, Nuevo León, México*, [2]*Instituto Tecnológico*, *Altamira, Tamaulipas, México*, [3]*Universidad Juárez del Estado de Durango*, *Durango, Durango, México*.

The objective of this study was to determine the *in vitro* gas parameters and to estimate the metabolizable energy (ME) content of subtropical grasses used for beef cattle production in Northeastern Mexico. Samples of Guinea (*Panicum maximum*), Pangola (*Digitaria decumbens*), Bermuda (*Cynodon dactylon*), Tanzania (*Panicum maximum* var Tanzania), Pretoria 90 (*Dichantium annulatum*) and Buffel (*Cenchrus ciliaris*) were collected at bloom stage and analyzed. Triplicate samples (500 mg DM) were incubated in calibrated 100 ml glass syringes. Ruminal fluid, used as inoculum was obtained from two sheep fed alfalfa hay:concentrate (75:25). Gas production was recorded at 0, 3, 6, 9, 12, 24, 48, 72 and 96h. Data were fitted to the equation: $p=a+b(1-e^{-ct})$. The ME content (Mcal kg^{-1} DM) of samples was calculated by: ME = (2.20 + 0.136GP24h + 0.057CP + 0.0029CF2)/4.184. Statistical analysis was performed by ANOVA for a completely randomized design, and means were separated by the Tukey test. Content of ME was highest for Pangola, lowest for Buffel and intermediate for Guinea, Bermuda, Tanzania and Pretoria 90; extreme ME values were 3.2 for Pangola and 1.8 Mcal ME kg^{-1} DM for Buffel ($P<0.05$). Pangola showed the highest value for the **b** fraction ($P<0.05$) and Guinea and Bermuda the lowest. The highest constant rate **c** was for Guinea, whereas the values were 30% and 45% lower for Pretoria and Buffel ($P<0.05$). The **a+b** fraction was highest for Pangola and Pretoria 90, intermediate for Tanzania and Buffel, and lowest for Guinea and Bermuda. Ranking of subtropical grasses using *in vitro* gas parameters (**b** and **a+b**) was similar to results obtained for ME content. Combinations of the studied variables allowed to recognize the potential of Pangola grass for grazing cattle in Northeastern Mexico.

Table 1. ME content (Mcal/kg DM) and *in vitro* gas production parameters of subtropical grasses of Northeastern Mexico incubated in rumen fluid *in vitro* (ml/500 mg DM)

	ME	b	c	a+b

M161 Evaluation of the center costs methodology sensibility by technologies introduction in the cow-calf production system. R. P. Oaigen, J. O. J. Barcellos*, T. E. Oliveira, E. R. Prates, and L. F. Christofari, *Federal University of Rio Grande do Sul*, *Porto Alegre- RS - Brasil*.

A bioeconomical simulation model was developed in a traditional production system in cow-calf (TPS) for the application of cost center methodology with the objective of evaluating its sensibility by the introduction of technologies of early weaning in primiparous cows (EWS), improved natural pasture for primiparous cows and half the lot of secundiparous cows (INP) and protein supplementation for replacement heifers in the first winter (PSS). All technologies were used to increasing the pregnancy rate in this system (TPS). Data on biological performance was obtained from a bibliographic review on production indicators and cost and economic values were obtained from market. The inputs of the model were: herd structure, production costs and production technology. The outputs of the model were: operational cost (OC); spented cost (SC); production costs per centers (PCC); unitary cost per calf (UCC); weaned kilo cost (WC/kg); annual cost per cow (ACC); financial break-even (FBE), operational margin (OM), pregnancy rate (PT), calf crop (CC), productivity/cow (P/C), number of weaned calves (NWC), calves break-even (CBE) and total production in kilos (TP/kg). The use of the methodology of cost centers was sensitive in identifying variations in the technical economic indicators and in the costs of each productive center. The introduction of EWS, INP and PSS showed in the increase of technical indicators and in the operational margin, presented a straight relation with the changing in the cost centers, proving the sensibility of the costs methodology in relation to the impact in TPS.

Key Words: Modeling, Cow-Calf, Production Cost

M162 Quality of vetch lines for hay and spring grazing. A. Larbi*[1], S. Rihawi[1], and S. Hassan[2], [1]*International Center for Agricultural Research in the Dry Areas*, *Aleppo, Syria*, [2]*General Commission for Scientific Agricultural Research*, *Damascus, Syria*.

Vetches (*Vicia* spp) are important feed legumes for production of hay, grain and straw, and early spring grazing; but data on nutritive value of high-yielding and disease tolerant vetches (elite lines) selected by the International Center for Agricultural Research in the Dry Areas (ICARDA) to replace low-yielding local cultivars in the non-tropical dry areas is scanty. Two experiments were conducted in Syria to compare the nutritive value of elite lines of common vetch (*V. sativa*, line 2566) and bitter vetch (*V. ervilia*, line 2520) with a released cultivar of common vetch 'Baraka' as control. In Experiment 1, the vetches were grazed by weaned Awassi lambs for 31 and 42 days in 2005 and 2006 respectively to compare their potential for spring grazing. Forage-on-offer (FOF) and average daily gain (ADG) were monitored. Experiment 2 compared hay from the vetches as a protein supplement to low-quality cereal straw basal diets. Four adult Awassi rams were fed barley straw supplemented with hay from the vetches for 28 days. Voluntary dry matter intake of vetch, organic matter digestibility (OMD) were determined from data from the last 7 days of the trial. The vetches differed (P<0.05) in FOF, ADG, voluntary intake and OMD. Average values were - FOF:3.34, 4.31, 3.42 t/ha; ADG: 147, 116, 159 g/head; voluntary intake of vetch: 44.4, 48.4, 37.7 gDM/W$^{0.75}$; and OMD: 696, 667, 747 g/kg for common vetch line 2556, bitter vetch line 2520 and the released common vetch cultivar 'Baraka' respectively. The study showed that common vetch line 2566 has similar forage potential as the released cultivar for spring grazing and hay production based on forage yield and ADG.

Key Words: Vicia Hay, Sheep Grazing, Nutritive Value

M163 Utilization of pruning waste of cactus pear orchards as a forage source for sheep in Temascalapa, Mexico. C. A. Flores-Valdez, G. Aranda-Osorio*, and M. Cruz-Miranda, *Universidad Autonoma Chapingo*, *Chapingo, Mexico*.

An establish cactus pear orchard can produce as much as 10 ton of cladodes ha-1 year-1 of pruning waste in the Pyramid's Region of Mexico State, representing approximately 175,000 ton of succulent material suitable for use as fodder. The objective of the present study was to evaluate the inclusion of pruning waste in sheep diets during winter to improve sustainability and profitability of the agricultural production systems. Seventy five heads (4 rams, 48 ewes, and 23 lambs) of the local "Criollo" breed were used. They were divided into four groups (one ram, 12 ewes and their six lambs) and randomly assigned to one of the following treatments: T1, total confinement with a complete diet (diet 1, 2 kg hd-1 day-1), T2, total confinement with a complete diet (diet 2, 1.6 kg plus 4.0 kg of cactus pear hd-1 day-1) fed at 08:00 and 16:00 h, T3, sheep ranged from 10:00 to 16:00 h, confined overnight and supplemented with 0.8 kg of diet 2 plus 2.0 kg of cladodes hd-1 day-1, T4, sheep ranged as T3 but supplemented with 2.0 kg of corn stover head-1 day-1 (traditional system). The experiment lasted 124 days. Average initial live weight was 549.5 ± 7.1 kg, and final live weight varied from 680.0 to 943.0 kg, treatments 4 and 1, respectively. The change in live weight was due to the increase in live weight of the adults and lambs as well as the new borns. However, the lowest feed cost resulting in T3 and T2, where cactus pear was included. It was concluded that the inclusion of cactus pear may represent an important alternative to utilize agricultural resources and increase animal production.

Key Words: Cactus Pear, Pruning Waste, Sheep

M164 Effects of the addition of *Saccharomyces cerevisiae* to sheep diets on productive performance and ruminal fermentation. I. Mejia-Haro*[1], E. Ortega-Perez[1], G. Tirado-Estrada[1], J. Mejia-Haro[2], and I. Castillo-Zuñiga[1], [1]*ITEL, AGUASCALIENTES*, *Aguascalientes, Ags. Mexico*, [2]*Universidad de Guanajuato*, *Irapuato, Gto. Mexico*.

The objective of this study was to evaluate the effects of the addition of *Saccharomyces cerevisiae* to sheep diets on productive performance, and ruminal fermentation. The study was carried out in two experimental periods. In period I, average daily gain, and feed efficiency were evaluated in 15 wethers sheep assigned to a completely randomized design where *Saccharomyces cerevisiae* was added to diet in three concentration- treatments (T1, 0%; T2, 1% and T3, 1.5% DM). In period II, the effects of the addition of *Saccaromyces servisae* to the experimental diet on in situ digestibility in six times of ruminal fermentation (0, 8, 12, 24, 48, and 72 h), free fatty acids, and NH3-N concentrations were evaluated. Data were analyzed by GLM procedure of SAS using ANOVA and Tukey test. In period I, T2 and T3 were higher (P<.05) than T1 in ADG (195, 226 and 115 for T2, T3, and T1, respectively, CV = 15%) and feed efficiency (kg of feed / kg BW of gain) was lower in T2 (4.7) than T1, and T3 (7.2 and 5.8, respectively). Values of in situ digestibility were higher in T2 and T3 (84, and 84%) than T1 (82%) at 72 h. The VFA and acetic and propionic concentration were higher (P<.05) in T3 (186, 124, and 33 mM for VFA, acetic, and propionic acid, respectively) than T1 (109, 69, and 20 mM, respectively) and T2 (115, 77, 20 mM, respectively); however, in the butyric acid concentration, the addition of Saccharomyces c. did not have any significant effect (20, 18, and 28 mM for T1, T2, and T3, respectively). In the NH3-N concentration, T3 was higher (53 mg/dL, P<.05) than T1 and T2 (22, and 30 mg/dL, respectively), which presented no differences. As a conclusion, the addition of *Saccharomyces cerevisiae* to sheep diets improved ADG and feed efficiency and produced changes in ruminal fermentation.

Key Words: ADG, Feed Efficiency, Digestibility

M165 Rumen fermentation parameters in sheep fed oat and bean straw-based diets. C. A. Anderson-Huerta, G. Nevarez-Carrasco, R. Montoya-Escalante, A. S. Juárez-Reyes, and M. A. Cerrillo-Soto*, *Universidad Juárez del Estado de Durango*, *Durango, Durango, México*.

Sheep represent an important potential for meat production in the semiarid regions of North Mexico. Common agricultural by-products in such areas are oat and bean straw which are utilized after prolonged dry periods. Thus, a study was conducted to estimate the effect of oat and bean straw-based diets on rumen VFA, Ammonia-N and pH. Five rumen cannulated criollo sheep (45 ±4.5 kg BW) were used to obtain rumen fluid samples at 0, 2, 4, 6, 8 an 10 h after feeding. Treatments consisted of 70% oat straw (T1); 40% oat straw (T2), 70% bean straw (T3); 40% bean straw (T4); and a control with 50% oat straw and 50% bean straw (T5). Other ingredients were alfalfa hay, ground corn and cotton seed meal. Diets were isonitrogenous (11% CP). Each period of the trial consisted of a 14-day adjustment and a 5-day collection phases. Ammonia-N concentrations were determined by the hypochlorite procedure using spectrophotometry. Volatile fatty acid concentrations were estimated by gas chromatography. Data were analyzed using Proc GLM for a Latin Square Split-Plot Design. Ammonia-N concentrations ranged from 5.38 to 7.61 mg/dl for T3 and T5, respectively and were similar between treatments (P>0.05). Values for pH were also similar in animals fed the treatments (mean 6.56: P>0.05). Treatments resulted in marginal differences in VFA concentratios among treatments (P=0.056). A numerical increment (P<0.10) in acetate concentrations was registered in sheep fed T5 which produced 27.5% more acetate than their counterparts fed T1. No differences in propionate concentrations were registered between treatments (P>0.05), although animals fed T5 produced 32.5% more propionate than the animals receiving T1. Butyrate levels followed the same trend (P>0.05). Data indicated that the diets produced enough ammonia-N to ensure an adequate microbial synthesis. Mean pH concentrations might not jeopardize ruminal cellulolysis. Volatile fatty acid concentrations in diets containing equal proportions of oat and bean straws, might evidence the importance of such by products when other source of food are scarce for sheep production.

Rumen fermentation parameters of sheep fed oat and bean straw-based diets.

M166 Effects of supplementation of two selenium sources in productive performance of growing sheep. I. Mejia-Haro*[1], A. R. Rodriguez-Murillo[1], G. Tirado-Estrada[1], R. Bañuelos-Valenzuela[2], J. Mejia-Haro[3], and J. A. Nungaray-Ornelas[1], [1]*ITEL, Ags.*, *Aguascalientes, Ags., Mexico*, [2]*Unidad Academica de Medicina veterinaria y Zoot., UAZ*, *Calera, Zac., Mexico*, [3]*Universidad de Guanajuato*, *Irapuato, Gto., Mexico*.

The objective of this study was to compare the supplementation of two sources of selenium in response to sheep performance. Twenty-four Pelibuey sheep (X= 20.5 kg of body weight), after the adaptation period were assigned in a completely randomized design to 1 of 3 treatments for a three-month study; T1, basal diet without selenium supplementation; T2, basal diet plus 1 ppm of organic selenium (Sel-Plex of All Tech lab) and T3, basal diet plus 1 ppm of selenium- yeast (Vitamin World, used in human nutrition). The evaluated variables were average daily gain, feed conversion and selenium content in hair samples. Data were analyzed by GLM procedure of SAS using ANOVA and comparison of means by tukey test. The treatment containing the diet supplemented with Selenium-yeast (T3) had higher (p<.05) daily gain (211 g) than the control group (162 g) and T2 (193 g). Feed conversion was lower (P<.05) in T3 (4.9 kg of feed/ kg gain of weight) than T2 and T1 (5.3 and 6.3 kg of feed/kg BW, respectively). Selenium content of hair was higher (P <.05) in T3 (.83 ppm) than T2 and T1 (.65 and .56 ppm, respectively). It was concluded that source of selenium supplementation influences average daily gain and feed conversion and supplementing selenium-yeast produced a better response in these parameters than not supplementing or supplementing Sel-Plex.

Key Words: Selenium, Minerals, Deficiency

M167 Toxicological study of gandul forage (Cajanus cajan). M. Duron-Velazquez[1], G. Tirado-Estrada*[1], I. Mejia-Haro[1], F. Jaramillo-Juarez[2], R. Larios-Gonzalez[1], H. Silos-Espino[1], and F. Nieto-Muñoz[1], [1]*ITEL, Ags., El Llano, Ags. Mexico*, [2]*Universidad Autonoma de Aguascalientes*, *Aguascalientes, Ags., Mexico*.

The objective of this study was to evaluate the toxicological content of gandul forage in vitro and in vivo in wethers sheep, two stages were carried out, the first one consisted in the in vitro evaluation of gandul forage, in which tannins (colorimetric method of Folin-Dennis and saponines (level of color intensity, method of thin layer chromatography) were analyzed in four sampling sites (S1, S2, S3 and S4) dividing the plant in three vegetative strata in each site (bottom = EB, medium = EM, top = EA), and three different ages (young plants = PJ, medium = PM and mature = PA). The saponines analysis also was carried out in flowers of the sites 2, 3 and 4 (FS2, FS3 and FS4). The second stage consisted in observe signs of toxicity in 20 sheep (18 kg BW) fed diets with different concentrations of gandul (0, 15, 30, 45 and 60 % of DM for T1, T2, T3, T4 and T5, respectively) and assigned to one of five treatments in a completely randomized design and evaluated by GLM of SAS using ANOVA and tukey tests. Blood samples were collected to determine albumin and transaminases concentrations (aspartate aminotransferase = GOT, and alanine aminotransferase = GTP). Also, liver samples were collected to carry out a histological study, for which, five wethers, one of each treatment were sacrificed. The results indicated no toxicity. In the first stage, the highest value of tannins (gTA equivalents) was for PM (12.52), followed by S1EB (11.86) and the lowest value for PJ (2.71), the average value (7.9) was below 8, which is considered a marginal value of toxicity . For saponines, the highest value was for S1EB and S1EM, otherwise, in FS4 and PJ, saponine presence was not observed. T5 obtained the highest serum albumin concentration (7.084 u/l). For GOT, T3 obtained the highest value (38.72 u/l) and the lowest value for T4 (25.4 u/l), likewise, for GTP, the highest value was obtained by T3 (61.7 units) and the lowest by T2 (21.1 units). In liver, all samples presented a normal histological organization. In the in vivo study, no toxicity was present; ADG, and feed intake were adequate for all treatments. Gandul forage did not present toxicity in in vivo and in vitro studies.

Key Words: Saponines, Tannins

M168 Characterization of a negative halothane gene commercial multibreed swine population for growth and conformation traits in tropical western Thailand. S. Koonawootrittriron[1], M. A. Elzo*[2], and T. Suwanasopee[1], [1]*Kasetsart University*, *Bangkok, Thailand*, [2]*University of Florida*, *Gainesville*.

The Thai market demands lean pork. Producers are attempting to meet this demand by breeding pigs of larger size and lean content. Pietrain is one of the major breeds used to achieve this goal. Unfortunately, Pietrain has a high frequency of halothane (i.e., porcine stress syndrome) genes that can produce low quality meat and death by heat stress under conditions of high temperature and humidity. The objective of this research was to evaluate a large commercial negative halothane gene multibreed swine population in western Thailand for growth and conformation traits. Breeds represented were Pietrain (P), Large White (LW), and Landrace (L). Boars from all breeds were mated to P sows. LW females were only used to produce replacement boars. This mating strategy resulted in 4 breed groups of piglets: P, L, F1 LW×P, and F1 L×P. Pigs were kept in open barns, and received the same nutrition, management, and health care. Data consisted of 37,628 birth weights (BW) and 12,404 weaning weights (WW), and 2,980 body lengths (BL), shoulder widths (SW), hip widths (HW) and ages at first estrus (AE) from pigs born from 2003 to 2006. Genetic parameters and estimated breeding values were computing using multivariate animal models (BW-WW and BL-SW-HW-AE). Fixed effects were contemporary group (year-month), sex, parity of dam, direct heterosis, and animal genetic group. Random effects were animal, dam (BW-WW only), and residual. Computations were performed using ASREML. All fixed effects were important for all traits ($P < 0.001$). Estimates of heritabilities for direct genetic effects were 0.09 ± 0.02 for BW, 0.08 ± 0.02 for WW, 0.13 ± 0.03 for BL, 0.18 ± 0.04 for SW, 0.15 ± 0.04 for HW, and 0.33 ± 0.06 for AE. Maternal heritabilities were 0.22 ± 0.01 for BW and 0.20 ± 0.01 for WW. Monthly phenotypic means tended to increase for BW, BL, and HW, and to decrease for AE. Monthly genetic means tended to increase for HW and to decrease for AE.

Lactation Biology: Mechanisms Regulating Lactation and Mammary Function

M169 Effects of dietary supplementation with flax during prepuberty on mammary development and circulating prolactin and estradiol concentrations. C. Farmer*[1], H. V. Petit[1], and A. V. Capuco[2], [1]*Agriculture and Agri-Food Canada*, *Sherbrooke, QC, Canada*, [2]*USDA-ARS*, *Beltsville, MD*.

The possible role of dietary flax on mammary development of prepubertal gilts was investigated. Fifty-seven gilts were fed one of four diets from 88 d of age until slaughter (day 212 ± 1). Diets were: standard, CTL (n=14); 10% flaxseed supplementation, FS (n=13); 6.5% flaxseed meal supplementation, FSM (n=15); and 3.5% flaxseed oil supplementation, FSO (n=15). All diets were isonitrogenous, isolipidic and isocaloric. Jugular blood samples were obtained on days 78 and 210 and assayed for prolactin and estradiol. At slaughter, mammary glands were excised, parenchymal and extraparenchymal tissues were dissected and composition of parenchymal tissue was determined. Histochemical analyses of mammary parenchyma were performed and fatty acid profiles in extraparenchymal tissue were evaluated. Dietary flax increased ($P \leq 0.001$) the concentrations of polyunsaturated fatty acids (PUFA) and decreased those of saturated (SFA, $P < 0.01$) and monounsaturated (MUFA, $P < 0.001$) fatty acids in mammary extraparenchymal tissue. This was largely due to the inclusion of FS or FSO ($P < 0.01$), but not FSM. Circulating concentrations of prolactin and estradiol were unaltered by treatments ($P > 0.1$). Dry matter content of parenchymal tissue was the only mammary compositional value affected, showing an increase with flax addition ($P < 0.05$). Diet did not alter ($P \geq 0.1$) BrdU labelling index or estrogen receptor localization. Within mammary parenchyma, estrogen receptors were present in epithelial cells but not adipocytes, a novel demonstration of potential estrogen targets in gilt mammary gland. Dietary supplementation with flax as seed, meal or oil, brought about expected changes in fatty acid profile in mammary extraparenchymal tissue but neither the alteration in fatty acid profile nor the presence of lignans had beneficial effects on hormone concentrations or mammary development.

Key Words: Flax, Mammary Development, Swine

M170 Developmental changes in the milk fat globule membrane proteome during the transition from colostrum to milk. T. A. Reinhardt* and J. D. Lippolis, *National Animal Disease Center, ARS, USDA*, *Ames, IA*.

Shotgun Proteomics, using amine-reactive isobaric tags (iTRAQ) was used to quantify protein changes in milk fat globule membranes (MFGM) that were isolated from day 1 colostrum and compared to MFGM from day 7 milk. Eight Holstein cows were randomly assigned to 2 groups of 4 cow sample pools for a simple replication of this proteomic analysis using iTRAQ. iTRAQ labeled peptides from the experiment sample pools were fractionated by strong cation exchange chromatography followed by further fractionation on a micro-capillary high performance liquid chromatograph connected to a nanospray-tandem mass spectrometer. Data analysis identified 138 bovine proteins in the MFGM with 26 proteins up-regulated and 19 proteins down-regulated in day 7 MFGM compared to colostrum MFGM. Mucin 1 and 15 were up-regulated greater than 7 fold in MFGM from day 7 milk compared to colostrum MFGM. The tripartite complex of proteins of adipophilin, butyrophilin and xanthine dehydrogenase were individually upregulated in day 7 MFGM 3.4, 3.2 and 2.6 fold respectively compared to colostrum MFGM. Additional proteins associated with various aspects of lipid transport, synthesis and secretion such as acyl-CoA synthetase, lanosterol synthase, lysophosphatidic acid acyltransferase, and fatty acid binding protein were up-regulated 2.6 -5.1 fold in day 7 MFGM compared to colostrum MFGM. In contrast, apolipoproteins A1, C-III, E and A-IV were down-regulated 2.6-4.3 fold in day 7 MFGM compared to colostrum MFGM. These data demonstrate that quantitative shotgun proteomics has great potential to provide new insights into mammary development.

Key Words: Proteomics, Milk Fat Globule Membrane, Lactation

M171 Temporal effect of *trans*-10, *cis*-12 conjugated linoleic acid on mammary lipogenic gene expression. J. K. Kay[1,2], C. E. Moore[1], D. E. Bauman[3], R. P. Rhoads[1], S. R. Sanders[1], A. F. Keating[1], and L. H. Baumgard*[1], [1]*University of Arizona*, *Tucson*, [2]*Dexcel*, *Hamilton, New Zealand*, [3]*Cornell University*, *Ithaca*.

Trans-10, *cis*-12 conjugated linoleic acid (CLA) reduces milk fat synthesis and mammary lipogenic gene expression in lactating dairy cows. It is unknown however, if these genes are collectively down regulated by a global nuclear transcription factor or if one key enzyme is directly affected and reduction in other lipogenic genes is due to lack of substrate (i.e. malonyl CoA) availability/requirement, or an alternative indirect mechanism. We investigated the temporal effects (0, 12, 24 and 72 h) of intravenous (IV) *trans*-10, *cis*-12 CLA infusion (13.1 g *trans*-10, *cis*-12 CLA/d) on mammary acetyl CoA carboxylase (ACC), fatty acid synthetase (FAS), Δ*9*-desaturase (SCD), and fatty acid binding protein (FABP) mRNA abundance. Dry matter intake, milk yield and yield and content of milk protein and lactose were not affected by CLA infusion. However, CLA infusion progressively reduced milk fat content and maximum milk fat depression (MFD; 49%; $P<0.05$) occurred at 72 h. Overall mRNA expression of ACC and FAS decreased ($P<0.05$) and SCD tended to decrease ($P<0.09$) but FABP was not altered by CLA infusion. By 24 h post infusion initiation, ACC mRNA abundance was reduced ($P<0.05$) by 44% while FAS and SCD tended to be reduced ($P<0.08$) by 47 and 46%, respectively. At 72 h, magnitude of reduction and level of significance did not alter from the 24 h time point even though MFD continued to progress. The similar temporal effects of *trans*-10, *cis*-12 CLA on ACC, FAS and SCD mRNA abundance suggests these lipogenic genes are down regulated collectively by *trans*-10, *cis*-12 CLA, probably via a global modulator, rather than inhibition of a specific key lipogenic gene.

Key Words: CLA, Milk Fat, Gene Expression

M172 Expression profiling of proteins involved in CLA metabolism in mammary tissue and mammary gland epithelial cells. Y. C. Jin[1], H. G. Lee*[1], J. A. Han[1], J. H. Li[1], K. H. Kim[1], N. K. Lee[1], Y. J. Kim[2], M. K. Song[3], and Y. J. Choi[1], [1]*School of Agricultural Biotechnology, Seoul National University*, *Seoul, Korea*, [2]*Department of Food Science & Biotechnology, Korea University*, *Chochiwon*, [3]*Department of Animal Science, Chungbuk National University*, *Chungbuk, Korea*.

This study was conducted to observe proteins involved in CLA metabolism comparing the difference of protein expression among control (no additional fatty acid), vaccenic acid (trans-11 C18:1, a precursor for CLA biosynthesis) and CLA i.v. infusion in the abdomen of 9 lactating rats. The rats were perfused with 120ml of heparinized DMEM. The mammary tissue samples were biopsied by surgical biopsy instrument in lactating rats. Likewise we sought to compare the difference of protein expression among control (BSA), vaccenic acid and CLA added to the medium of differentiated HC11 cells. The protein samples of the mammary tissue and epithelial cells were analyzed by two-dimensional electrophoresis. We identified the specific spots using ESI-Q-TOF and a protein search engine. In rats, vaccenic acid treatment increased the level of cis-9, trans 11 CLA and vaccenic acid in mammary tissue. In addition, CLA treatment increased the level of trans-10, cis-12 CLA and cis-9, trans-11 CLA in mammary tissue ($P<0.05$). The most striking differences in protein abundance between the control and vaccenic acid treatment were seen in 5 specific spots, and 7 spots were detected between saline and CLA treatment. Likewise in HC11 cells, the most striking differences in protein abundance between the control and vaccenic acid treatment were seen in 3 specific spots and 2 spots were detected between BSA and CLA treatment. So we examined the expression of mRNA in the mammary tissue and epithelial cells by real-time PCR, which substantiated 4 genes differentially expressed overall in mammary tissue and epithelial cells. Our results suggest that the identified proteins may be related to CLA biosynthesis and apoptosis of the mammary tissue induced by CLA.

Key Words: Conjugated Linoleic Acid, Mammary Gland, Proteomics

M173 Effects of heat stress vs. underfeeding on milk fatty acid composition. M. D. O'Brien*, J. B. Wheelock, A. J. La Noce, M. L. Rhoads, R. P. Rhoads, M. J. VanBaale, R. J. Collier, and L. H. Baumgard, *University of Arizona*, *Tucson*.

Determining heat stress (HS) effects on lactation variables is complex as they are confounded with reduced nutrient intake. To separate the differences between HS and decreased feed intake on milk fatty acid composition, we conducted two HS experiments (EXPS) where a thermal-neutral (TN) control group was pair-fed to match nutrient intake with the heat-stressed cows. In both EXPS, the diet was similar and consisted primarily of alfalfa hay and steamed-flaked corn. HS conditions were cyclic to mimic an AZ July day, with temperatures

ranging from 29.7 to 39.2°C. After a TN period of ad libitum feed intake, cows entered HS or underfeeding (UF) periods which lasted for either 9 d (exp 1; n = 12) or 7 d (exp 2; n = 24). In both EXPS rectal temperature increased during HS (averaging 40.5°C at 1400 hr) while DMI decreased by ~30%. By design, UF cows had similar intakes while still producing more milk (> 7 kg/d) indicating UF accounts for only ~50% of HS-induced decreased milk yield. There were little differences in milk fatty acid parameters between experiments, therefore main effects of HS and UF are presented. Milk fat content did not differ (3.73) between treatments. Compared to UF, HS decreased (>10%) the MUFA and PUFA content and increased the saturated fatty acid content of milk fat. Specifically, HS decreased the content of 18:2, 18:3, 18:1 *trans*-6-8, 18:1 *trans*-9 and 18:1 *trans* -11 and increased biohydrogenation end products (18:0 & 16:0), but had no effect on 18:1 *trans*-10 and 18:1 *trans*-12. HS decreased the Δ^9-desaturase index (34.9 vs. 39.4) and reduced the milk fat *cis*-9, *trans*-11 CLA content (2.97 vs. 5.16 mg/g). On a fatty acid origin basis (as a % of total molar yield), HS increased the contribution of 16:0 and 16:1, but *de novo* and preformed derived fatty acids did not contribute differently between treatments. Independent of reduced feed intake, HS markedly effects milk fatty acid composition and this is characterized by a decrease in PUFA and most biohydrogenation intermediates with a corresponding increase in the resulting saturated end products.

Key Words: Heat Stress, Milk Fatty Acids, Biohydrogenation

M174 Stearoyl-CoA desaturase gene expression and fatty acid concentrations in bovine tissues. E. Mosley, B. Hatch, K. Hunt, A. Morrison, C. Roberts, D. Sevier, and M. McGuire*, *University of Idaho*, *Moscow*.

The stearoyl-CoA desaturase (SCD) enzyme is important in maintaining lipid fluidity. However, the relationship between the level of gene expression and activity of the SCD enzyme is not well defined. The objective of this study was to determine if there was an association between the basal gene expression of SCD and occurrence of the products of SCD (14:1c9, 16:1c9, 18:1c9, and 18:2c9t11) in various tissues. Samples were obtained from animals (2 lactating Holstein cows and 2 mixed breed market steers) at slaughter. Heart, skeletal muscle, liver, lung, rumen, large intestine, small intestine, intestinal adipose, and mammary (cows only) samples were frozen in liquid nitrogen and stored at -80°C. RNA was extracted and converted to cDNA for quantitative real time PCR analysis of the SCD gene. Extracted lipid was converted to fatty acid methyl esters and analyzed by gas chromatography. In descending order, intestinal adipose, mammary, lung, heart, and small intestine tissues had the highest expression of SCD (3,037,718 ± 1,989,208; 1,468,529 ± 199,409; 1,319,235 ± 403,596; 1,123,247 ± 345,633; and 931,783 ± 250,632 copies/100 ng RNA, respectively), while skeletal muscle, large intestine, rumen, and liver tissues contained lower levels of expression (519,809 ± 142,239; 385,048 ± 232,297; 359,063 ± 54,836; and 354,244 ± 156,812 copies/100 ng RNA, respectively). Considerable variation was detected among animals independent of gender (cow vs steer). The desaturase indices for each substrate of SCD (product/(substrate+product)) were similar across tissues. There was an inverse correlation ($r = -0.79$, $P < 0.0001$) between total PUFA and total SCD product concentrations across all tissues. No relationship was detected between the level of gene expression and occurrence of SCD fatty acid products in tissues or desaturase indices. A greater understanding of the regulation of tissue fatty acids is necessary.

Key Words: Stearoyl-CoA Desaturase, Real Time PCR, Fatty Acid

M175 Expression of PPAR and LXR nuclear hormone receptor families are not modified during milk fat depression induced by diet or treatment with trans-10, cis-12 conjugated linoleic acid (CLA). K. J. Harvatine* and D. E. Bauman, *Cornell University*, *Ithaca, NY*.

Milk fat synthesis can be inhibited by intermediates of ruminal fatty acid biohydrogenation including trans-10, cis-12 CLA. These biohydrogenation intermediates signal a coordinated down-regulation of genes involved in mammary fatty acid synthesis, transport and esterification. We have previously reported decreased expression of SREBP1, SREBP1 activating proteins and Spot 14 during diet-induced milk fat depression and treatment with trans-10, cis-12 CLA. Regulation of nuclear hormone receptors (NR) during milk fat depression is of interest as NR are key regulators of lipogenic genes and CLA is known to modify expression and activation of some NR. Tissue profiling identified only LXRalpha as responsive to lactation with increased expression in lactating compared to nonlactating mammary tissue. Expression of NR and NR responsive genes during milk fat depression was investigated by Real-Time PCR using mammary tissue of cows during diet-induced milk fat depression (low forage, high oil diet: LF/HO) and 3d intravenous infusion of trans-10, cis-12 CLA (10 g/d). The LF/HO diet and CLA treatment reduced milk fat yield by 38 and 24%, respectively. Expression of PPARalpha, beta and delta was not modified by treatment. Expression of mitochondrial fatty acid oxidation enzymes (CPT1a and ACADVL) was increased approximately 50% by LF/HO treatment but expression of a peroxisomal oxidation enzyme (ACOX) was unaffected. Expression of LXRalpha and beta and the LXR responsive gene ABCA1 was not modified by treatment. Some members of the LXR and PPAR gene families are expressed in the lactating mammary gland; however, their expression is not modified during diet or trans-10, cis-12 CLA induced milk fat depression.

Key Words: Nuclear Receptors, Milk Fat Synthesis, Lipogenesis

M176 Production and physiological indicators to select pasture-based dairy cows suitable for extended lactations. J. K. Kay, P. W. Aspin, C. V. C. Phyn, J. R. Roche, D. A. Clark*, and E. S. Kolver, *Dexcel*, *Hamilton, New Zealand*.

In pasture-based systems cows are traditionally managed to calve seasonally and annually in order to maximize pasture utilization. Increased productivity and declining reproductive performance has led to the incorporation of longer calving intervals and extended lactations, however, individual cows vary in their ability to maintain milk production for an extended lactation. Identifying production and physiological markers to predict suitable cows for extended lactations would allow dairy farmers to make early decisions to withhold mating or to continue milking specific non-pregnant cows through the typical dry months. Fifty-six genetically divergent North American and New Zealand Holstein Friesians were allocated to three pasture-based dietary treatments (0, 3 and 6 kg concentrate DM/cow/d), and breeding was withheld to target a 600 d lactation. Within each treatment (genotype × diet), milk solids (MS; protein + fat) yield during the extended lactation (>296 DIM) was positively correlated with MS yield from the previous season ($P < 0.05$; $r^2 = 0.15$), MS yield from the first 296 DIM ($P < 0.01$; $r^2 = 0.19$) and daily MS yield at a theoretical dry-off date (~296 DIM; $P < 0.01$; $r^2 = 0.43$). In contrast, MS yield during the extended lactation was negatively correlated with BCS at theoretical dry-off ($P < 0.01$; $r^2 = 0.37$). Hormone and metabolite data from wk

1-10 post-partum demonstrated a positive association ($P < 0.01$; $r^2 = 0.24$) between NEFA levels and extended lactation MS production, whereas glucose, insulin, and IGF-I were negatively associated ($P < 0.01$; $r^2 = 0.23, 0.37, 0.26$, respectively) with extended lactation MS production. Overall, milk production, BCS and early lactation hormone and metabolite data may be useful criteria to identify animals that will undergo a successful extended lactation.

Key Words: Extended Lactation, Predictors

M177 Milk from cows at involution reduces MAC-T cell survival. G. Tremblay*[1], P. Bernier-Dodier[1], L. Delbecchi[2], G. F. Wagner[3], B. G. Talbot[1], and P. Lacasse[2], [1]*Université de Sherbrooke*, *Sherbrooke, QC, Canada*, [2]*AAFC-Dairy and Swine R&D Center*, *Sherbrooke, QC, Canada*, [3]*University of Western Ontario*, *London, ON, Canada*.

Several data indicate that mammary gland involution is under a local control. However, the exact nature of this control is still unknown. The objective of this experiment was to verify the presence of factors in milk that can reduce mammary cell survival during milk stasis. Milk samples were obtained from nine Holstein cows in late lactation that received a unilateral milking for 14 days. Left forequarter and right hindquarter were milked twice a day while the two other quarters were dried off (d 0). Milk samples were taken from forequarters on d -7, 1, 2, 7, and 14 for an *in vitro* assay. In the *in vitro* assay, milk samples were added to DMEM/F12 medium at a final concentration of 10% and incubated for 9 h with confluent MAC-T cells. Survival was quantified by the metabolic turnover of tetrazolium salt (XTT). The assay showed a ~98% survival for each milk sample except those from dry quarters on d 7 and 14, which showed a reduction of cell survival to 83.7% ($P < 0.001$) and 74.8% ($P < 0.005$), respectively, in comparison with cells incubated with milk from milked quarters at d 14. These results suggest that milk from dry quarters contains a factor able to reduce cell survival. Among the factors present in milk, stanniocalcin (STC) increased ($P < 0.001$) 2.5- and 3.2-fold after 7 and 14 d of milk stasis, respectively. There was a negative correlation (Pearson coefficient of -0.605) between STC concentration in milk and cell survival. Stanniocalcin is involved in the homeostasis of calcium and has been reported to induce apoptosis in chondrocytes *in vitro*. Even if the exact contribution of this hormone in the involution process is not known, its role in cell death has to be further investigated.

Key Words: Stanniocalcin, Mammary Gland, Involution

M178 Different milking frequencies alter stanniocalcin content in cow's milk. P. Bernier-Dodier*[1], P. Lacasse[2], G. F. Wagner[3], B. G. Talbot[1], and L. Delbecchi[2], [1]*Université de Sherbrooke*, *Sherbrooke, QC, Canada*, [2]*AAFC-Dairy and Swine R&D Center*, *Sherbrooke, QC, Canada*, [3]*University of Western Ontario*, *London, ON, Canada*.

Several lines of evidence suggest that there is a factor in milk that exerts a local control on lactation and mammary gland involution. Previously, we have shown that estradiol reduces milk production and increases the expression and concentration of stanniocalcin (STC) in the mammary gland of cows. We hypothesized that this hormone may be implicated in the involution process. To verify this hypothesis, we modulated the involution rate by manipulation of the milking frequency. Ten Holstein cows in mid-late lactation were differentially milked, two quarters being milked once daily and the two others thrice daily for 8 weeks. Milk samples were taken from forequarters every week to determine the STC content (RIA), the BSA content (colorimetric assay), and the protease activity (zymography). A significant difference in milk yield ($P < 0.0001$) was observed during the treatment between the thrice daily milked glands (increase) and the once daily milked glands (decrease). Milk yields (kg/d) were 12.6, 8.0, 6.5, and 8.8 for once daily milked glands, and 13.5, 16.3, 16.2, and 14.6 for thrice daily milked glands, on weeks 0, 4, 8, and 10 (week 2 post-treatment) respectively. At week 4, a higher rate of apoptosis was observed in the glands milked once daily compared with the glands milked thrice daily (0.83% and 0.38% respectively; $P < 0.05$), as detected by TUNEL analysis. This effect on apoptosis was not detected at week 8. In the majority of the cows (7 out of 10), zymographic analyses showed an increase in protease activity only in the milk from once-daily milked quarters, indicating an active remodelling of these glands. Milk BSA concentration was significantly increased in the once-daily milked quarters ($P < 0.001$), an augmentation possibly caused by an opening of the tight junctions in those quarters. Finally, milk STC concentration increased in all quarters during the treatment ($P < 0.001$); however, this increase was higher in the once-daily milked quarters than in the thrice-daily milked ones ($P < 0.01$). Our data indicate that milking frequency alters milk STC concentration and that this effect may be related to gradual involution of the mammary gland.

Key Words: Mammary Gland, Involution, Stanniocalcin

M179 Reduced nursing frequency decreases milk output and alters SOCS and TPH1 gene expression in the mouse mammary gland. W. Olea*, D. Torres, J. George, and D. L. Hadsell, *Baylor College of Medicine*, *Houston,TX*.

Reduced milking frequency in cows lowers milk production. In rats decreased nursing frequency below 4 times daily causes mammary involution. The mechanism by which this effect occurs is poorly understood. Recent studies in cows have shown that suppressors of cytokine signaling (SOCS) are regulated by milking frequency. The hypothesis for this study was that decreased nursing frequency in lactating mice would decrease milk production and increase mammary expression of SOCS genes and other negative feedback regulators of lactation. To test this hypothesis milk output and mammary gene expression was measured in dams that were allowed to nurse either ad-libitum (AL) or four times daily (4X). On day 1 of lactation, groups of CD-1 dams (10 mice /treatment) were given weight-normalized litters of 10 pups each. On day 8 postpartum the interval nursing was started in the 4x group. For this group the dams were given 4 1-hour nursing periods with their litters over a 24 hour period (5am, 11am, 5pm, and 11pm). Litter weight was measured daily. On day 14 post partum, milk production was measured in both groups by the weigh-suckle-weigh method after a 5 hour period of separation from the litters. Mammary tissue was then collected for analysis. Total RNA prepared from the inguinal mammary gland was analyzed for α-lactalbumin, lactoferrin, SOCS1, SOCS2, SOCS3, Cish, and TPH1 mRNA abundance using RT-qPCR. Milk output was lower ($P<0.05$) in 4X than AL (0.45±0.12g and 1.09±0.15g, respectively) but mammary morphology appeared similar between 4X and AL. Abundance of the mRNAs for α-lactalbumin, lactoferrin, SOCS2, and TPH1 was higher ($P<0.05$) in 4x than AL. Abundance of the mRNAs for SOCS1 was lower ($P<0.05$) in 4X than AL. Abundance of the mRNAs for SOCS3

and Cish were similar among 4X and AL. These results suggest that altered gene expression for SOCS1, SOCS2 and TPH1 in the mammary gland may mediate the loss of milk production that occurs with reduced nursing frequency in mice.

Key Words: Lactation, Milking Frequency, SOCS

M180 Gene expression profiling in bovine mammary gland during onset of lactation. K. A. Finucane[1], T. B. McFadden[1], J. P. Bond[1], J. J. Kennelly[2], and F.-Q. Zhao*[1], [1]*University of Vermont*, *Burlington*, [2]*University of Alberta*, *Edmonton, Alberta, Canada*.

The mammary gland undergoes dramatic functional and metabolic changes during the transition from late pregnancy to lactation. To better understand the molecular events underlying these changes, we analyzed expression profiles of approximately 23,000 gene transcripts in bovine mammary gland at day 5 before parturition and day 10 after parturition. A total of 1531 transcripts were significantly up-regulated while 2910 transcripts were down-regulated ($P < 0.05$). Gene ontology analysis showed that the main up-regulated genes were associated with transport activity (amino acid, nucleotide, glucose and ion transporters), lipid and carbohydrate metabolism (lipoprotein lipase, acetyl-Coenzyme A synthetase and carboxylase, 6-phosphofructo-2-kinase, etc.), and regulation of transcription and translation (transcription factor-like 1, CBP/p300-interacting transactivator, tRNA synthetase, etc.) while the main down-regulated genes were associated with cell cycle and proliferation (cyclins, cyclin-dependent kinase, etc.), protein and RNA degradation (proteasomes, thiolesterase, pinin, RNA binding motif protein, etc.), DNA replication and chromosome organization (histone, histone deacetylases, DNA polymerase accessory subunit, etc.) and microtubule-based processes (microtubule associated protein tau, kinesin, tubulins, etc.). The increased ($P < 0.05$) expression of glucose transporter GLUT1 mRNA during lactation was verified by quantitative reverse transcription/PCR. GLUT1 protein also tended to increase during lactation ($P = 0.13$). Furthermore, GLUT1 protein was primarily localized in mammary ductal epithelia and blood vessel endothelia before parturition, but was predominantly localized in the basolateral and apical membranes of mammary alveolar epithelial cells during lactation. Our microarray data provide insights into the molecular events in the mammary gland at the onset of lactation, indicating the up-regulation of genes involved in milk synthesis concomitant with the inhibition of those related to cell proliferation.

M181 Co-localization of glucose transporter-1 and hexokinase-1 in response to lactogenic hormones and media glucose concentration in bovine mammary epithelial cells. M. Dai* and J. P. Cant, *University of Guelph*, *Ontario, Canada*.

Hexokinase (HK) catalyzes the first step in intracellular glucose metabolism. Prior experiments revealed that glucose transport across the plasma membrane of bovine mammary epithelial cells appears to involve translocation into an intracellular compartment to which HK has access. The glucose transporter GLUT1 is the primary glucose transporter isoform expressed in bovine mammary gland during lactation. However, the isozyme of HK expressed in the bovine mammary gland remains unknown to date. Four isoforms of HK have been identified, and tissue-specific patterns of expression for the isozymes suggest unique roles for each in metabolism. In the present work, we tested the hypothesis that HK1 is expressed in bovine mammary gland, and co-localizes with GLUT1 in the presence of glucose and lactogenic hormones. Western blotting of mammary tissue with anti-HK1 revealed a band in the 75kDa region that is smaller than what has previously been reported for HK1 in other species. Confocal immunofluorescent microscopy of mammary epithelial cells revealed that co-localization of GLUT1 and HK1 is induced by lactogenic hormone complex (insulin, prolactin and hydrocortisone) at varied media glucose concentrations. Without lactogenic hormones, the immunofluorescent density of GLUT1 was low, and HK1 appeared not to co-localize with GLUT1 when media glucose concentration was increased to 25 mM. These results demonstrate that changes in GLUT1 expression and the co-localization of GLUT1 and HK1 in response to lactogenic hormones are consistent with the regulation of mammary glucose uptake and metabolism.

Key Words: Hexokinase, Glucose Transporter, Co-localization

M182 Presence of functional phosphodiesterases in dairy cow's mammary gland. V. Dostaler-Touchette*[1], C. Guillemette[2], F. J. Richard[2], and P. Y. Chouinard[1], [1]*Institut des nutraceutiques et des aliments fonctionnels, Université Laval*, *Québec, Québec, Canada*, [2]*Centre de recherche en biologie de la reproduction, Université Laval*, *Québec, Québec, Canada*.

One possible way to improve the secretion of milk constituents is to modulate cyclic nucleotide (cAMP, cGMP) pathways. Intracellular cyclic nucleotides are degraded by the enzyme family called phosphodiesterases (PDE). Previous studies have shown that using non-specific PDE inhibitors like caffeine improved milk production. The objective of this study was to investigate the critical role of PDEs in the lactation of dairy cows. In order to understand the enzymatic expression pattern in the mammary gland, tissue samples were taken randomly from an udder obtained from a local slaughterhouse. Using 1 μM of cAMP, PDE essays (n=5) reported a total activity of 45.5±5.5 fmol/min per μg of total protein. Rolipram, a specific PDE4 inhibitor, showed a sensible activity of 15.9±5.5 fmol/min/μg of total protein, supporting that PDE4 is responsible for one third of the total enzymatic activity in the mammary gland. Transcript analysis using RT-PCR revealed that PDE4D was amplified from specific primers designed from rat, mouse, human and validated with bovine. Expected size fragment was obtained in a 1% agarose gel. Sequence analysis of the amplicon resulted in 99% homology to PDE4D. It is therefore possible to give this subfamily the credit for the Rolipram-sensitive PDE activity in the cow's udder. Moreover, western blotting using a specific PDE4D antibody has confirmed that the protein of this isoenzyme is present. In conclusion, these results not only demonstrate the presence of PDE4D transcript and protein, but also show an active enzyme, suggesting a functional role of PDE4D in bovine mammary gland.

Key Words: Dairy Cow, Mammary Gland, Phosphodiesterase

M183 Modulation of cellular activity of glutathione peroxidase by L-selenomethionine in primary cultures of bovine mammary gland epithelial cells. S. G. Miranda*[1,2], Y. J. Wang[2], N. G. Purdie[2], V. Osborne[2], B. L. Coomber[2], and J. P. Cant[2], [1]*University of Zulia*,

Maracaibo, Zulia, Venezuela, [2]*University of Guelph*, *Guelph, Ontario, Canada*.

Cytosolic glutathione peroxidase (GPx1; E.C. 1.11.1.9) is a selenoenzyme that catalyzes the reduction of hydrogen peroxide, or organic hydrogen peroxides, and protects cells from oxidative damage. We have hypothesized that selenium supply influences mammary epithelial cell (MEC) survival by increasing GPx1 activity. A study was designed to evaluate the effect of L-selenomethionine (SeMet) on the activity of GPx1 in bovine MEC. Six Holstein lactating cows with udders free of infection were slaughtered and parenchymal tissue was harvested to prepare cells for primary culture. MEC were enzymatically monodispersed and collected by filtration. Western Blotting analysis detected GPx1 in the mammary parenchyma and MEC. Secretory cells were plated on collagen gel matrix in 24-well plates and fed with media which was replaced every 24 h. After reaching 80% confluence, MEC were incubated with media containing 0, 10, 20 or 50 nM SeMet for 3 d. GPx1 activity, total MEC and cell viability were recorded daily. Statistical analysis was carried out using one-way ANOVA with significance declared at $P<0.01$. Enzymatic activity of GPx1 in MEC increased linearly ($P<0.01$) as SeMet increased in the medium. Cells cultured in 20 and 50 nM SeMet had significantly higher ($P<0.01$) activity of GPx1 (46.3 ± 4.0, 46.3 ± 4.0 nmole NADPH/min per mg protein, respectively) than those in 0 and 10 nM SeMet (30.5 ± 4.0, 38.9 ± 4.0 nmole NADPH/min per mg protein, respectively). The total number of MEC (4.5×10^5) and their viability (91.7%) were significantly increased ($P<0.01$) in 50 nM SeMet *vs.* 0, 10, and 20 nM SeMet (2.4, 2.4, and 2.5×10^5, respectively, and 77.2, 79.4, and 80.5%, respectively). Results suggest that SeMet can increase the GPx1 activity, number and viability of lactating bovine MEC.

Key Words: Selenomethionine, Glutathione Peroxidase, MEC

M184 Prostaglandins A1 (PGA1) and E1 (PGE1) alter heat shock protein 70 (HSP-70) gene expression in bovine mammary epithelial cells (BMEC). J. L. Collier*[1], M. B. Abdallah[1], L. L. Hernandez[1], J. V. Norgaard[2], and R. J. Collier[1], [1]*University of Arizona*, *Tucson*, [2]*Danish Institute of Agricultural Sciences*, *Tjele, Denmark*.

PGA1 is known to induce heat shock protein (HSP) synthesis in a wide variety of mammalian cells resulting in protection against cellular stresses while PGE1 is associated with alteration of hypothalamic set point during fever. We tested the effects of PGA1 and PGE1 on HSP-70 gene expression in BMEC at thermoneutral (TN, 37°C) and during heat shock (HS, 42°C). Primary BMEC were cast in collagen gels using Dulbecco's Modified Eagle's media (DMEM) containing 10 ng/ml insulin, 25 ng/ml epidermal growth factor, 75 ng/ml insulin-like growth factor-1, 0.1% BSA and antibiotic/antimycotic at 37°C in 5% CO2. Cultures grew into ductal structures for 8 days with media changes at 48 hour intervals. On day 9 cultures were divided into 3 groups with Controls (C) receiving the growth media, another group received growth media containing 8ug/ml PGA1 and the final group received growth media containing 8ug/ml PGE1. Cultures were then equally divided and moved to TN or HS incubators for up to 16 h with samples removed at 0, 1, 2, 4, 8 and 16h. At each time point, 4 collagen cultures were pooled and immediately placed in TRIzol and stored at -80°C until extracted for RNA. Isolated RNA was evaluated by Nanodrop and was reverse transcribed into cDNA. Expression of HSP-70 was measured by real time-PCR using a Bio Rad IQ5 system with analysis by the delta delta CT method. Hypoxanthine phosphoribosyltransferase 1 (HPRT-1) was used as the housekeeping gene. Addition of PGA1 increased HSP-70 expression in both TN and HS at all time points with much greater expression differences detected during HS. Peak fold increases in HSP-70 expression over time zero for C and PGA1 in HS at 8 h were 16.3 vs. 122.3 ($P<0.0001$). Addition of PGE1 significantly reduced HSP-70 gene expression compared to C and PGA1 in both TN and HS at all time periods except 16h ($P<0.001$). At 16h, HSP-70 expression was higher in cultures containing PGA1 or PGE1 compared to C (2.2 and 0.8 vs. 0.5 fold over time zero; $P<0.03$). We conclude that PGA1 and PGE1 alter HSP-70 expression in BMEC in TN and HS environments.

Key Words: Heat Shock Protein 70, Gene Expression, Prostaglandins

M185 Suitability of foremilk somatic cell counts to estimate total quarter somatic cell count. O. Wellnitz[1], M. Woloszyn[2], and R. M. Bruckmaier*[1], [1]*University of Bern*, *Bern, Switzerland*, [2]*DeLaval International AB*, *Tumba, Sweden*.

In dairy practice, testing of quarter foremilk for the detection of mastitis (by California Mastitis Test (CMT) or by determination of somatic cell count (SCC)) is well established. However, the use of foremilk SCC to estimate total quarter SCC as a basis for calculation of whole udder and bulk tank SCC has not been systematically investigated. Therefore, a study was conducted in 19 dairy cows during 10 consecutive days, i.e. 20 consecutive milkings. Foremilk samples were taken from each quarter after a 1 min udder preparation for SCC measurement by a DeLaval cell counter (DCC). During machine milking, the whole milk of each quarter was collected separately and the SCC of each quarter milk was also determined and 1512 pairs of quarter recordings were evaluated by various linear regression analyses. Quarter milk SCC ranged from 2 to 3100 while foremilk SCC ranged from 5 to 5400 × 1000 cells/ml, respectively. The linear regression of foremilk and total quarter milk measurements of all quarters based on log10 SCC had a slope of 0.43 (R2=0.70). To characterize the predictability of total quarter milk SCC by foremilk measurements at different SCC levels, the samples were classified into different foremilk SCC (<20 (n=217), 20-50 (n=419), 50-100 (n=300), 100-300 (n=373), 300-500 (n=99), and > 500 (n=111) × 1000 cells/ml). The percentage of quarters with numerically higher SCC in the total milk than in the foremilk were 70.5, 46.3, 42.0, 23.3, 19.2, and 6.3% in the groups with foremilk levels of <20, 20-50, 50-100, 100-300, 300-500, and >500 × 1000 cells/ml, respectively. The regression coefficients ($p<0.001$) in these groups were 1.54, 1.05, 1.01, 0.75, 0.67, and 0.44, respectively. In conclusion, whole quarter SCC is higher than foremilk SCC at very low SCC levels. At higher foremilk SCC, whole quarter SCC is mostly lower with an increasing difference between foremilk and whole quarter values.

Key Words: Somatic Cell Count, Foremilk

M186 17β-hydroxysteroid dehydrogenase and β-casein transcripts detected in bovine milk somatic cells. D. A. Pape-Zambito*[1], C. A. Gifford[2], T. L. Ott[1], and R. S. Kensinger[1], [1]*The Pennsylvania State University*, *University Park*, [2]*University of Idaho*, *Moscow*.

Bovine milk contains 17β-Estradiol (E2) but the origins of this E2 in milk are undefined. Because E2 is fat-soluble, E2 in milk may be due to passive diffusion of E2 from plasma. However, we showed

that milk E2 concentrations were lower than plasma concentrations in early pregnancy, but were higher than plasma E2 concentrations in late pregnancy. Limited literature is available on enzymes with the ability to convert estrone (E1) to E2 in the mammary gland. The objective of this study was to determine if somatic cells obtained from milk generate 17β-hydroxysteroid dehydrogenase (17β-HSD) mRNA. Production of β-casein (β-CN) mRNA was used to verify presence of mammary epithelial cells (MEC) in somatic cell samples. Primers specific for bovine β-CN, 17β-HSD 7 and 17β-HSD 12 were designed from known and predicted sequences in the NCBI database. Milk was collected from 9 Holstein cows: 3 from each trimester of pregnancy. Milk was centrifuged, fat removed, and the supernantant decanted. The cellular pellet containing somatic cells was washed with PBS and resuspended in Trizol reagent (Invitrogen). RNA was extracted and RT-PCR utilized to determine presence of transcripts for β-CN, 17β-HSD 7, and 17β-HSD 12. The PCR conditions were as follows: 95C for 5 min, 40 cycles of 95C for 30 s, 64C for 30 s, and 68C for 45 s, a final extension step at 68C for 10 min, followed by agarose gel electrophoresis. Milk somatic cells from all 9 cows expressed β-CN, indicating a MEC population. In addition, 17β-HSD 7 and 17β-HSD 12 sequences were detected in cells of cows from all trimesters of pregnancy. The PCR products were cloned, sequenced, and verified against the NCBI database. These data are consistent with the hypothesis that cells within the mammary gland are capable of converting E1 to E2. Additional experiments are needed to determine which cell type(s) express 17β-HSD transcripts from milk-derived somatic cells.

M187 Estimation of heritability, repeatability and genetic trend for milk yield of Iranian buffalo in Khuzestan province of Iran using a univariate repeatability animal model. H. Farhangfar*[1], B. Zinvand[2], and F. Amirlou Abolfathi[3], [1]*University of Birjand*, *Birjand, Iran*, [2]*Azad University of Shooshtar*, *Shooshtar, Iran*, [3]*Jihade Agriculture of Khuzestan*, *Iran*.

In order to estimate heritability, repeatability and genetic trend for milk yield (adjusted to 305,2x) a total of 1214 records from lactation 1 through 5 of 795 Iranian buffaloes calving from 1993 to 2003 and distributed in 189 herds in Khuzestan province was used. A univariate repeatability animal model was applied to analyze the records. In the model, fixed environmental factors were herd-year-month of calving (contemporary group), lactation order and age linear covariate nested in the lactation. Additive genetic and permanent environmental random effects were also included in the model. Additive genetic relationship among animals was partially complete due to major lack of sire or dam identification. Restricted maximum likelihood estimates of variance components were obtained (via Average Information algorithm) using WOMBAT software. The results obtained in the present study showed that heritability and repeatability of milk yield were 0.071 and 0.075 respectively. This indicates that there was not only low additive genetic but also low permanent environmental variation among animals over the first 5 lactations suggesting that temporary environmental variation made up a large proportion of total phenotypic variance. Based upon regression of average predicted breeding value of animals with records on year of first calving it was also revealed that there was no statistically significant genetic trend over the period of time.

M188 Effect of feeding two forages at two levels with and without Rumensin to high producing Holstein cows on animal performance. C. M. Martinez*, Y. H Chung, T. W. Cassidy, V. Ishler, K. S. Heyler, and G. A. Varga, *The Pennsylvania State University*, *University Park*.

Two studies were conducted to evaluate the effects of feeding corn silage (study I) or grass silage (Study II) based diets at two levels with and without Rumensin on DMI, milk production and composition and blood metabolites. In both studies, 8 multiparous high producing Holstein cows were used (BW=698 kg±16 and DIM=194 d±3 for study I; BW=656 kg±16 and DIM=124 d±3 for study II) in a replicated 4x4 Latin square design with a 2x2 factorial treatment arrangement to evaluate the effects of forage level with and without Rumensin supplementation (300 mg/cow/d, top dressed). In study I, diets were formulated to contain 50 or 60% forage (DM basis) in which corn silage comprised 70% and western hay comprised 30% of the total forage in the diet. In study II, diets were formulated to contain 50 or 55% forage (DM basis) in which grass silage comprised 55% and corn silage comprised 45% of the total forage in the diet. The length of each period was 4 wks and samples were collected during the last wk. Results from study I (corn silage based diet) showed that DMI was higher ($P < 0.01$) for the 50% forage diets (29.6 kg/d) compared to the 60% forage diet (28.3 kg/d). In study II, DMI was lower ($P < 0.05$) for cows that were supplemented with Rumensin when compared to cows with no supplementation (25.9 vs. 24.7 kg/d, respectively). Milk total solids% was reduced ($P < 0.05$) with Rumensin supplementation (11.8%) versus no Rumensin supplementation (12.3%). Milk urea nitrogen was higher ($P < 0.059$) for cows consuming the 55% forage diet (10.1 mg/dL) than for cows provided the 50% forage diet (8.81 mg/dL). Within each forage source, milk yield and fat corrected milk were not affected by forage level source or Rumensin in the diet (40.9 and 42.4 kg/d, for study I; 41.6 and 41.7 kg/d for study II, respectively). Data from these studies showed that higher forage inclusion in dairy rations can be attained without affecting milk production or major components such as milk fat or protein % for either corn silage or grass silage based diets. Rumensin supplementation may affect milk components and DMI depending on the level and type of forage fed.

Key Words: Rumensin, Forage Level, Silage

M189 Conjugated linoleic acids attenuate lymphocyte proliferation and interleukin-4 production in bovine peripheral blood mononuclear cells challenged with concanavalin-A. C. Caldari-Torres*, W. R. Collante, and L. Badinga, *University of Florida*, *Gainesville*.

During the perinatal period, immune functions such as lymphocyte response to mitogens and production of antibodies are depressed in dairy cows. The objective of this study was to examine the short-term effects of *cis*-9,*trans*-11 and *trans*-10,*cis*-12 isomers of conjugated linoleic acid (CLA) on lymphocyte proliferation, tumor necrosis

factor-α (TNF-α) and interleukin-4 (IL-4) production by mitogen-stimulated bovine peripheral blood mononuclear cells (PBMCs). In preliminary studies, bovine PBMCs were incubated in the absence (Control) or presence of concanavalin-A (ConA, 10 μg/mL), lipopolysaccharide (LPS, 10 μg/mL), or phytohemagluttinin A (PHA, 10 μg/mL) for 24 or 48 h. Proliferative and cytokine responses were measured using thymidine incorporation and enzyme-linked immunosorbent assays, respectively. Compared to untreated cells, proliferation and cytokine production were maximally stimulated ($P < 0.05$) by ConA within 48 h. Tumor necrosis factor-α (range 53 to 84 pg/mL; $P < 0.01$) and IL-4 (range 16 to 197 pg/mL; $P < 0.01$) concentrations increased linearly between 0 and 15 μg/mL of ConA. Co-incubation with linoleic acid (LA) and CLA greatly decreased lymphoproliferative (448 cpm > 239 cpm; $P < 0.01$) and IL-4 (580 pg/mL > 272 pg/mL; $P < 0.05$) responses to ConA in cultured PBMCs. There were no apparent differences in TNF-α response to ConA due to fatty acid treatment (119 pg/mL; $P = 0.68$). These in vitro studies provide no evidence for LA or CLA-mediated improvement of immune functions in cattle. Whether these findings reflect the physiological effects of these fatty acids in vivo warrants further investigation.

Key Words: CLA, Immune Response, Cattle

M190 Evaluation of *in situ* indigestible neutral detergent fiber as an internal marker to determine digestibility of nutrients. L. O. Chow*, C. Silveira, and M. Oba, *University of Alberta*, *Edmonton, Alberta, Canada*.

The efficacy of *in situ* indigestible neutral detergent fiber (ISIDF) as an internal marker was compared to the external marker ytterbium (Yb) in determining apparent total tract digestibility of nutrients. It was hypothesized that the *in situ* method would provide repeatable indigestible NDF measurements, and would be a reliable marker to estimate digestibility. In the first study, ISIDF concentrations were determined with triplicate samples of concentrate mix, silage, TMR, and feces incubated for 120h in the rumen of 3 lactating and 3 dry cows. The overall intra- and inter-assay CVs for ISIDF measurements were 2.9 and 6.9%, respectively. The inter-assay CV was lower for samples incubated in the rumen of early dry cows as compared to those at peak lactation (3.5 vs. 7.2%), which may be due to lower diurnal variation in ruminal fermentation. In the second study, apparent total tract digestibility using ISIDF was compared with that using Yb as an external marker. Feed and fecal samples were collected from a study evaluating two lots of barley grain cultivars at two dietary grain allocations using 8 cows in a duplicated 4x4 Latin square design with a 2x2 factorial arrangement of treatments. Apparent total tract DM digestibility estimated by Yb was greater than that estimated by ISIDF (65.8 vs. 61.1%; $p < 0.05$), suggesting that nutrient digestibility was either overestimated by the Yb method, underestimated by ISIDF, or both. However, standard errors of means for DM digestibility were smaller when ISIDF was used as a digestibility marker compared with Yb (0.9 vs. 1.3%), suggesting that fecal DM flow was estimated more precisely using an 120h ISIDF as a marker. Though external markers such as Yb are used extensively to estimate flow of duodenal digesta or feces, their use requires extra labor for the frequent dosing of markers. The alternative of using the in situ method provides repeatable ISIDF measurements and is a reliable marker to estimate nutrient digestibility.

Key Words: *In Situ* Indigestible Neutral Detergent, Internal Marker, Apparent Total Tract Digestibility

M191 Producer perceptions of feed management software. B. G. Cox*, R. E. James, K. F. Knowlton, M. L. McGilliard, and C. C. Stallings, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Nine Virginia dairy farmers were surveyed in December 2006 to ascertain satisfaction with feed management software after at least 2 mo of use. Each received a subsidy (20%), installed feed management software (TMR Tracker ™, Digi-Star LLC, Fort Atkinson WI), and participated in a 24-question personal interview addressing installation, operation, and satisfaction with the software. Herd size ranged from 135 to 450 lactating cows, averaging 271 lactating cows producing 30 kg/cow/d. Number of TMR mixer operators per farm varied from 1 to 5, with 2 or 3 on 5 farms. Number of feeding groups per farm ranged from 1 to 3; 5 farms feeding 2 groups and 3 farms feeding 1 group. All participants reported that the software met expectations and, if given the choice, they would invest again. Despite satisfaction, 4 of 9 were uncertain or would not purchase the software without the subsidy provided by the project. All but one perceived feed management software as economically beneficial. All farms utilized the software to monitor operator performance and saw no change in quantity of feed purchased. Five producers noted improvements in ration consistency following use. Change made to the feeding program due to TMR Tracker correlated (r=0.80) with improvement in ration consistency. More than half (5 of 9) claimed employee training as the most challenging aspect of implementing TMR Tracker. The obstacle to viewing reports was dedication of adequate time. Forty-four percent of respondents attributed most problems to operator error. Overall, producers perceived feed management software as a beneficial subsidized investment with most problems arising from inexperience.

Key Words: Feed Management Software, Precision Feeding, Survey

M192 Out wintering pad design affects woodchip condition. K. O'Driscoll*[1,2], L. Boyle[1], P. French[1], B. Meaney[1], and A. Hanlon[2], [1]*Moorepark Dairy Production Research Centre*, *Fermoy, Co. Cork, Ireland*, [2]*University College Dublin*, *Dublin, Ireland*.

This study evaluated woodchip hygiene in 3 out-wintering pad (OWP) designs for spring calving dairy cows; uncovered [UP] and sheltered [SP] OWP where cows fed grass silage at a concrete feedface, and an OWP where cows self-fed silage on the woodchips [SF]. Cows were accommodated on each treatment in two replicates from Nov 05 until calving (mean=21 Feb 06). Cows on UP and SP had a woodchip space allowance of 12m^2 and on concrete of 2.52 m^2. The concrete was scraped 6 times per day. SF cows had a woodchip space allowance of 14.52m^2. OWPs were managed so that each cow had a minimum clean lying area of 2.2 m^2. OWPs were scored weekly using a visual dirt scale (DS) (1-4; 1=clean, 4=dirty) and composite woodchip samples were taken from the surface. Samples were analysed for dry matter (DM) and pH. Presence of bacteria (staphlococci, streptococci, coliforms) and bacterial load (no. colonies/agar plate) from each sample were determined using selective media. Data were analysed using SAS V9.1. A mixed model was used to analyse DS, DM and pH. Correlations between DS, no. weeks in use, and DM were investigated. Fishers exact test was used to investigate differences in species present and bacterial loads (low=<40 colonies, medium=>40, <200 colonies, high=>200 colonies) between treatments. UP and SF had higher DS scores than SP ($P<0.01$). DS increased with weeks in use ($P<0.001$). Woodchip DM was lower in UP and SF than in SP ($P<0.01$) and DM decreased with weeks in use ($P<0.001$). There was no effect

of treatment on pH, and although the effect of time was significant (P<0.05) there was no discernable pattern over time. There was a positive correlation between DS and weeks in use (P<0.001; r=0.764) and a negative correlation between DS and DM (P<0.001; r=-0.633). There was no difference between treatment samples in either presence or load of Staphylococci sp or in the number of samples per treatment that contained Streptococci spp, but SF had more samples with a high load (P<0.01). More samples from SF contained Coliform spp (P<0.05), due to a higher number of samples with a low and medium bacterial load. It is likely that the higher bacterial presence in SF is due to lack of manure removal at the feedface.

Key Words: Dairy, Housing, Hygiene

M193 Effect of metabolizable protein and energy intake on amino acid metabolism in growing dairy calves. A. G. Rius*[1], J. Cyriac[1], B. J. Bequette[2], and M. D. Hanigan[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*University of Maryland*, *College Park*.

The objective of this study was to examine the relationship between dietary energy and protein on free amino acids (AA) metabolism. Twenty-four newborn Holstein heifer calves where assigned to each of four treatments: 24/17 (24% CP, 17% fat fed at 350 g/d); 32/17 (32% CP, 17% fat fed at 764 g/d); 31/24 (31% CP, 24% fat fed at 782 g/d); and 31/24+ (fed at 1177 g/d) in a complete randomized block design. Diets were fed for 63 d. Blood samples were collected at wks 1, 5, and 9. Heifers were sacrificed at the end of the study and analyzed for body composition. Within 5 min of slaughter liver and muscle samples were collected. Plasma, liver and muscle AA concentrations were determined by gas chromatography-mass spectrometry. Data were analyzed using the GLM procedure of SAS. Calves fed 32/17 had the greatest lean gain as compared to the 24/17 and 31/24 diets and also had a higher N as a percent of EBW (reported elsewhere). There were no significant effects of treatment on total essential amino acid concentrations in muscle (P=0.342) or liver (P=0.721). In muscle, there was a tendency for a significant treatment effect for aspartate (P=0.103) 128.3, 79.9, 99.1, 122.1 µmol/L (SEM =20.1), leucine (P=0.127) 107.8, 131.6, 98.7, 97.6 µmol/L (SEM =14.7), serine (P=0.106) 369.6, 241.2, 269.1, 290.1 µmol/L (SEM =51.9), and methionine (P=0.066) 16.8, 35.0, 28.6, 31.5 (SEM =6.7) µmol/L for the 24/17, 32/17, 31/24 and 31/24+ treatments, respectively. There was a significant treatment effect for liver alanine (P=0.021) 3330.1, 2463.8, 1848.4, 1901,4 µmol/L (SEM=485.2) and serine (P=0.003) 1915.7, 1517.6, 1124.2, 1184.2 µmol/L (SEM =205.2), and a trend for glutamate (P=0.061) 5735.2, 4851.6, 4240.6, 3860.3 µmol/L (SEM =678.8) and histidine (P=0.082) 436.2, 508.8, 344.3, 388.8 (SEM =58.8) for the 24/17, 32/17, 31/24 and 31/24+ treatments, respectively. Overall, the 32/17 treatment supported the greatest methionine concentration in muscle whereas treatment 24/17 supported the greatest concentrations of alanine and serine in liver.

M194 Evaluation of antimicrobial effects on monogastric gut microflora by plant waste products. S. Stella, D. Tedesco*, C. Barbieri, L. Garavaglia, and D. Cattaneo, *University of Milan*, *Italy*.

EU is focusing on effective alternatives to antibiotics in order to reduce the incidence of potential pathogenic bacteria in the gastrointestinal tract of monogastrics. The aim of the present study was to evaluate the effects of plants and their post-processing derivative waste products, recognized as safe for human or animal health (SAFEWASTES, EU project n. 513949), on growth and viability of gut intestinal microbiota in weaning piglets. A total of 28 plant by-products have been tested. Five strains of Escherichia coli, Clostridia and Lactobacilli were isolated from faecal samples of healthy piglets (60–70 days of age), by inoculation of specific culture media. Aliquots of 0.1 mL of bacterial suspension of each selected strain (10^8 CFU/mL) were inoculated onto the surface of agar plates containing the specific culture media. The effects of plant extracts on gut bacteria have been studied using the paper disc agar diffusion (Kirby-Bauer) method. Samples were solubilized into deionized water or ethanol (10 mg/mL) and sterilized by filtration. Sterile paper discs were moistened with extract solution and dried before use. A test paper disc moistened with the extract, a positive control (a disc with Ampicillin or Apramycin) and a negative control (a disc moistened with sterile deionised water or ethanol) were placed under aseptic conditions onto the surface of inoculated culture medium. After incubation, plates were observed in order to find the presence of growth inhibition areas. Four of the 28 tested substances showed an inhibitory effect on E. coli strains, without influence on Clostridia growth. It was not observed any negative effect on commensal microbiota beneficial to the host. None of tested substances showed an inhibitory effect on Lactobacilli growth. On the basis of this preliminary screening, further investigations will be performed in order to confirm the antimicrobial activity of these potential feed additives also in in vivo trials with target species.

Key Words: Plant Waste Products, Gut Microflora, Antimicrobial Effects

M195 Microlocalization of digestion-resistant aromatic lignin and cellulosic compounds in feeds at cellular and subcellular levels with the synchrotron: A novel approach. P. Yu*, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

The objective of this study was to micro-localize the distribution of digestion-resistant aromatic lignin and cellulosic compounds in feeds at cellular and subcellular levels using advanced synchrotron-powered FTIR microspectroscopy (SFTIRM) as a novel approach. The SFTIRM is a newly emerging and non-destructive analytical technique and can reveal molecular chemistry (structural-chemical make-up) of biological samples at highly spatial resolutions (3-10 µm) without destruction of the feed internal structures. The experiment was performed at the National Synchrotron Light Source in Brookhaven National Laboratory (NSLS-BNL, US Department of Energy, New York). The exampled feeds used for this pilot study were corn (cv. Pioneer) and barley (cv. Harrington). The results show that with SFTIRM, the images of the aromatic lignin and cellulosic compounds could be generated to be able to show the distribution and intensity across the feeds tissues. The digestion-resistant aromatic lignin compound only presented in the pericarp region and no lignin has been found in seed coat, aleurone layer and endosperm. The cellulosic compounds presented most in the

pericarp region, less in the seed coat, aleurone layer, and endosperm. The agglomerative hierarchical cluster analysis (CLA) and principal component analysis (PCA) showed the distinct differences of the chemical make-up between the two feeds (corn vs. barley) and between the different structures (pericarp vs. aleurone) within a feed. Even in the same structural regions (such as aleurone layer, and endosperm), the structural make-up were different between the corn and barley. This may explain why digestive behaviors are different between the barley and corn. The implication of this study is that with extremely bright synchrotron light, we can localize and characterize internal feed digestion-resistant compounds in a chemical sense with cellular dimensions.

Key Words: Digestion-Resistant Compounds, Structural Chemistry, Synchrotron

M196 Effects of feeding lactic acid bacteria-based direct-fed microbial complex on growth performance, diarrhea appearance and blood characteristics in pigs. J. S. Yoo*[1], Y. J. Chen[1], J. H. Cho[1], B. C. Park[2], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Choognam, Korea*, [2]*CJ Feed Inc*, *Incheon, Gyeonggi, Korea*.

This study was conducted to investigate the effects of direct-fed microbial(DFM: *Lactobacillus casei, L. plantarum casei, L. salivarus casei, Saccharomyces cerevisiae*) complex on the growth performance and fecal score in nursery pigs and growing pig. In exp.1, a total of 96 nursery pigs with an average initial BW of 15.00±1.67 kg were used in five weeks experiment trial. There were six pens per treatment with four pigs per pen. Dietary treatments included 1) NC(basal diet; antibiotics free diet), 2) PC(NC diet with 0.1% antibiotics; chlortetracycline 0.05% +neomycin 0.05%), 3) NDFM0.1(NC diet with 0.1% DFM) and 4) NDFM0.2 (NC diet with 0.2% DFM). During the entire experimental period, ADG was increased in PC, NDFM0.1 and NDFM0.2 treatments compared with NC treatment(P<0.05). ADFI was also increased in PC treatment compared with NC treatment(P<0.05). Gain/feed was increased in NDFM0.1 and NDFM0.2 treatments compared with NC treatment(P<0.05). Diarrhea appearance was decreased in PC and NDFM0.2 treatments compared with NC treatment at 5 weeks. In exp. 2, total of 72 growing pigs with an average initial BW of 24.64±2.46 kg were used in 28 days experiment trial. There were six pens per treatment with three pigs per pen. Dietary treatments included 1) NC(basal diet; antibiotics free diet), 2) PC(NC diet with 0.1% antibiotics; chlortetracycline 0.05% +neomycin 0.05%), 3) DFM0.1 (NC diet + 0.1% DFM) and 4) DFM0.3 (NC diet + 0.3% DFM). During the entire experimental period, ADG was increased in NC treatment compared with NDFM0.1 and NDFM0.3 treatments. However, there was no significant treatment effets (P>0.05). Also, there was no significant difference in ADFI among the treatments. Blood characteristics(RBC, WBC and IgG) tended to be improved, however, no significant differences were observed(P>0.05). In conclusion, feeding DFM affected growth performance, diarrhea appearance and blood characteristics in nursery and growing pig.

Key Words: Direct-Fed Microbial(DFM), Growth Performance, Pig

M197 Cupric methionate affect nutrients digestibility and fecal pH and Cu concentration. Y. Huang*[1], Q. Wang[1], Y. Wang[1], J. H. Cho[1], Y. J. Chen[1], J. S. Yoo[1], Y. K. Han[2], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Choognam, Korea*, [2]*Sungkyunkwan University*, *Suwon, Korea*.

This study was conducted to investigate the effects of organic and inorganic copper on performance in growing pigs. A total of 100 pigs with an average initial weight of 21.46±1.13kg were assigned to five treatments. Dietary treatments include 1) CON (basal diet, 0 ppm Cu), 2) T1 (basal diet with 67 ppm Cu as cupric sulfate, $CuSO_4$), 3) T2 (basal diet with 134 ppm Cu as cupric sulfate, $CuSO_4$), 4) T3 (basal diet with 67 ppm Cu as cupric methionate, CuMet), 5) T4 (basal diet with 134 ppm Cu as cupric methionate, CuMet). During the entire experimental period, ADG, ADFI and GF ratio had no significant differences. Dry matter digestibility of T1, T2, T3 and T4 treatments was improved (P<0.05) compared with the CON. Nitrogen digestibility was improved in T3 treatment compared with control treatment (P<0.05). Compared with T1 treatment, fecal pH value was increased in CON, T3 and T4 treatments (P<0.05). Fecal Cu concentration was significantly lower in CON, T3 and T4 treatments than this of T1 and T2 treatments (P<0.05). Diarrhea appearance was decreased when pigs fed T2, T3 and T4 diets compared with CON. In conclusion, diets supplemented with 67 or 134 ppm Cu as CuMet may be effective for improving nutrient digestibility and fecal pH value in grower pigs and fecal Cu concentration may be decreased by CuMet supplement.

Key Words: Cupric Methionate, Nutrients Digestibility, Growing Pigs

M198 Gain of weight in rabbits of initiation using two commercial diets. M. C. Rubio Robles*, J. M. Beltrán, M. Millán, B. E. Romero, and J. A. Sauceda, *Universidad Autonoma de Sinaloa*, *Culiacan, Sinaloa, Mexico*.

With the objective to determine the gain of weight in rabbits of initiation using Purina commercial food and the district; 12 domestic rabbits were used, of 21 days of age, with a weight average of 276.66±1.3 g.; Two treatments, identified were used like: treatment “A” commercial food the district (Protein 18 %, Fat 2 %, Crude Fiber 14 %, Ash 10 %, And L. N. 44 %, Humidity 12 %) and treatment “B” Purina commercial food (Protein 14,50 %, Fat 2 %, Crude Fiber 18 %, Ashes 10 %, Calcium 1 %, Phosphorus 0,55, And L. N. 43.50 %, Humidity 12 %). Each treatment consist of two repetitions with three rabbits each one; for each repetition; were provided to them food of their respective treatments during 15 d that were the period of the study, it was collected and it weighed the food leftover to know the daily consumption by treatment, also provided new food to them; the weight of the animals was made at the beginning and aim of the study, having itself for the treatment A a weight average of 273.33±2.16 g. and for treatment B 280±1.26 g. Being a final weight for the treatment A from 398.33±1.63g. and 395±2.09 g. for treatment B. In all the period, the gain of weight average by animal, went for the treatment A of 125 g. whereas Treatment B gain in average 115 g. with which it is appraised that the treatment A had in average by animal 10 g. (8%) but gain of weight that the B. with respect to the food consumption the treatment A was of 730 g. and 760g for treatment B, being a nutritional conversion from 5,84 for the treatment A and 6,61 for treatment B. concluding that the animals that fed with the treatment A: commercial food the district had one better answer with a 8% but gain of weight, a food consumption 3,95% less and 11,65 % better nutritional conversion with respect to the Purina commercial food.

Key Words: Rabbit, Weight, Commercial Food

M199 Effects of Bio-Mos® on growth and survival of channel catfish challenged with *Edwardsiella ictaluri*. B. C. Peterson*[1], S. Quiniou[1], B. B. Manning[2], and T. C. Bramble[3], [1]*USDA/ARS*, *Stoneville, MS*, [2]*MSU*, *Stoneville, MS*, [3]*Alltech Biotechnology*, *Nicholasville, KY*.

A major problem in the catfish farming industry has been high disease loss to enteric septicemia of catfish (ESC), caused by the bacterium *Edwardsiella ictaluri* (*E. ictaluri*). Methods to control this disease include antibiotic therapy, vaccinations, and management strategies such as taking the fish off feed. Alternative methods such as feeding yeast-derived mannans in the form of Bio-Mos® may prove beneficial in improving growth performance and immune function. Research was conducted to examine the effects of Bio-Mos® on growth and immune function in channel catfish. One hundred fish (45.8 ± 1.2 g) were randomly assigned to two treatments with five replicates each: 1.) Control (36% CP catfish diet) and 2.) Bio-Mos® (36% CP catfish diet with Bio-Mos® supplemented at 2 g/kg). The fish were fed for 6 wks and then challenged with *E. ictaluri*. Mortality was recorded daily for 3 wks. Levels of lysozyme activity were determined pre- and post-challenge. At the end of the 6 wk growth study, weight gain and FE was similar between treatments. Survival was higher ($P < 0.05$) in fish fed Bio-Mos® compared to Controls (90 ± 7.3% vs 55 ± 6.4%). Plasma levels of lysozyme activity were similar ($P > 0.10$) between treatments. The results of this study suggest that Bio-Mos® can be supplemented into catfish diets without negatively affecting growth or FE. The results also show that Bio-Mos® improves resistance to *E. ictaluri* without significantly altering lysozyme activity. Supplementing Bio-Mos® into diets may provide another strategy to control ESC in channel catfish.

Key Words: Bio-Mos®, Disease, Catfish

M200 The effect of plant tannins and yucca extracts on in vitro ruminal fermentation and methane gas production. B. R. Min*[1], W. E. Pinchak[1], R. C. Anderson[2], and R. Puchala[3], [1]*Texas Agricultural Research Center*, *Vernon, TX*, [2]*USDA/ARS*, *College Station, TX*, [3]*E (Kida) dela garza American Institute for Goat Research*, *Langston, OK*.

The overall objective was to quantify in vitro, the effect sources of tannin and yucca extract at 2 dose levels on rate of gas production, ruminal fermentation and protease enzyme activity. Pine bark was used as a non-extracted plant tannin source for negative control. In vitro gas and methane production were measured from 0 to 6 h rumen incubation periods. In vitro rate of gas and potential gas production were linearly decreased ($P < 0.01$) in a dose dependent manner for quebracho (QT), mimosa (MT), chestnut tannins (CTT), and pine bark (PB) addition. In the presence of QT ($P < 0.03$), MT ($P < 0.02$), CTT ($P < 0.02$), yucca ($P = 0.06$), and PB ($P = 0.11$), methane production was linearly decreased. Cumulative hourly total in vitro ruminal gas production was similar between control, yucca and PB after 6 h rumen fermentation at 5 mg extracts/ml, but cumulative ruminal gas production was lower for QT ($P < 0.01$), MT ($P < 0.001$), and CCT ($P < 0.001$) after 3 - h fermentation from control treatment. Total average VFA concentration was not affected by CCT and yucca extracts treatments, but total VFA was linearly decreased for QT ($P < 0.04$), MT ($P < 0.01$) and PB ($P < 0.01$) tannins treatments. Acetate and propionate (A/P ratio) molar ratios for QT ($P <0 .01$), MT ($P < 0.01$), yucca ($P = 0.11$), and PB ($P = 0.001$) decreased linearly in a dose dependent manner. Hydrolysis of azocasein, used to estimate ruminal protease enzyme activity, was decreased linearly for all tannins and yucca extracts. It is concluded that addition of commercial tannins and yucca extracts changed in vitro rumen fermentations and VFA profiles. Addition of tannins and yucca extracts, except chestnut tannins, decreased A/P ratios, indicated that plant tannins and yucca extracts may be nutritionally benefit in terms of increased VFA efficiency with either dose level of those plant extracts.

Key Words: Methane Gas, Rumen Fermentation, Tannins

M201 Evaluation of the efficacy of a commercial purified phylosilicate to reduce the estrogenic effects of zearalenone in gilts. B. Malone[1], C. Bond[1], C. Maue[1], Z. Scheitegger[1], and D. Zaviezo*[2], [1]*Trilogy Analytical Laboratory*, *Washington, MO*, [2]*Special Nutrients*, *Miami, FL*.

An experiment was conducted to study the efficacy of a very low inclusion of commercial purified phylosilicate (Myco-Ad A-Z) in preventing the deleterious estrogenic effects of zearalenone (ZEA) in prepubertal gilts. Eighteen 20-d old recently weaned Yorkshire Cross gilts individually housed were randomly distributed into 3 dietary treatments with 6 replications each. After a 4-d pretrial adaptation period, pigs were fed a commercial basal diet containing or exceeding NRC recommended nutrients levels for 30 d. The feed was experimentally contaminated with crystalline ZEA, determined to be over 99% pure. Treatments were: (1) control basal diet; (2) control + 750 ppb ZEA; and (3) control + 750 ppb ZEA + 1 kg/mt Myco-Ad A-Z. At the end of the experiment all pigs were sacrificed and the internal reproductive organs weighed. Results indicated no significant differences in body weight (wt) gain, feed intake and feed conversion ratio among treatments. Gilts fed 750 ppb ZEA contaminated diet showed significant heavier ovary + bursa wt (40%), uterus wt (93%), cervix wt (260%) and total reproductive organs wt (98%) than gilts fed the control diet. The addition of Myco-Ad A-Z to the contaminated diet resulted in gilts with a statistically significant reduction in ovary + bursa wt (12%), uterus wt (25%), cervix wt (32%) and total reproductive organs wt (24%) than those fed 750 ppb ZEA. Even though the addition of 1 kg/mt of Myco-Ad A-Z to a gilt diet contaminated with 2 to 3 times the ZEA level producing problems in the field did reduce the abnormal growth of the reproductive organs; they were still heavier than those from gilts fed the control diet. These results indicate that Myco-Ad A-Z at 1 kg/mt was effective in reducing the estrogenic effects of ZEA in prepubertal gilts.

Key Words: Myco-Ad A-Z, Zearalenone, Gilts

M202 Response of market turkey toms to dietary protein and threonine levels in diets containing corn distillers dried grains. S. L. Noll* and J. Brannon, *University of Minnesota*, *St. Paul*.

The response of market turkey toms to diet threonine level was examined during 8 to 19 wks of age. Diets were formulated to contain 90, 94, 100, and 106% NRC digestible thr from intact protein. In addition, supplemental thr was used to reach 100 or 106% NRC thr. Diets were composed primarily of corn, soybean meal, poultry by-product meal (PBM, 10%) and corn distillers dried grains with solubles (DDGS, 20%). Large White male turkey poults (Nicholas strain) were randomly assigned to pens (10/pen) at 8 wks of age. The treatments were (T): 1. Corn soy control, 100% NRC thr; 2. PBM-DDGS 106% NRC thr; 3. As T2, plus 6% NRC thr; 4. As T2, 100% NRC thr; 5. As T4, plus 6% NRC thr; 6. As T4, plus 12% NRC thr; 7. As T2, 94% NRC thr; 8. As T7 plus 6% NRC thr; 9. As T7 plus 12% NRC thr; 10. As T2, 90% NRC thr; 11. As T10 plus 10% NRC thr. All diets were supplemented as needed with lys and met to meet the specific NRC recommendations for these amino acids. The ratio of calcium: inorganic phosphorus was maintained at 2:1. Each diet was fed to 8 replicate pens. The experimental design was a completely randomized block design. Dietary treatment affected body weight at all ages (P<.0001). BW at 19 wks of age was similar for T 1, 2, 3 and 4. Decreasing diet NRC thr to 94 and 90% significantly decreased BW while supplementation with thr improved body weight but not to the level of the control at 100% NRC. Increased average daily gain response to supplemental thr (6% NRC thr) was observed for 100, 94, and 90% NRC thr treatment groups during 8-11 and 11-14 wks of age; and, only in the 90% NRC thr treatment during 14-17 and 17-19 wks of age. Improved feed efficiency in response to supplemental thr (6% NRC thr) was observed for the 94% NRC treatment during 8-11 wks; and, for the 90% NRC thr group during 8-11 and 17-19 wks of age. In diets containing a large amount of alternative protein (10% PBM and 20% DDGS), a gain response to supplemental thr was observed when diet thr from intact protein was less than 106% NRC during 8-11 wks, less than 100 % NRC during 11-14 wks, and less than 94% NRC during 14-19 wks of age.

Key Words: Turkey, Distillers Grains with Solubles, Threonine

M203 Influence of feed form and fiber inclusion in the diet on performance of broilers from one to twenty one days of age. E. Jiménez-Moreno[1], J. M. González-Alvarado[1,2], A. P. Bonilla[1], R. Lázaro[1], and G. G. Mateos*[1], [1]*Universidad Politécnica de Madrid*, *Spain*, [2]*Universidad Autónoma de Tlaxcala*, *México*.

We studied the effects of feed form and the inclusion of fiber in the diet on productive performance of broilers from 1 to 21 d of age. There were twelve treatments arranged factorially with two feed forms (mash and pelleted) and six diets consisting in the combination of three insoluble fiber sources (OH; oat hulls, RH; rice hulls, and SFH; sunflower hulls) and two levels of fiber source inclusion (2.5 vs. 5%). In addition, a control diet without additional fiber was formulated and offered either in mash or pellet form. The diameter of the pellets was 2–mm. The control diet was based on rice, soy protein concentrate, fish meal, and fat, and had 3,200 kcal AME_n/kg, 1.4% total lysine, and 1.6% crude fiber. The fiber source was included in the experimental diets at expenses (wt/wt) of the whole diet. Each treatment was replicated six times (a cage with 12 chicks). Body weight (BW) and feed consumption (ADFI) were recorded per replicate at 0, 4, 8, 14, and 21 d of age. No interactions between main effects were observed. For the entire experiment, broilers fed pellets had better BW gain, higher ADFI, and lower feed conversion ratio (FCR) than broilers fed mash ($P \leq 0.001$). Fiber inclusion tended to improve BW gain ($P \leq 0.1$) and improved FCR ($P \leq 0.05$) but no differences were observed between diets containing 2.5 or 5% fiber source for any trait studied. From 0 to 4 d of age, broilers fed SFH had better FCR than broilers fed OH or RH (0.844 vs. 0.870 and 0.876; $P \leq 0.05$) but the effect disappeared with age. We conclude that pelleting improves productive performance of broilers from 1 to 21 d of age. Also, the inclusion of fiber source at levels of up to 5% (from 1.61% crude fiber in the control diet to 4.24% crude fiber in the 5% RH containing diet) improves productive performance in chicks fed low–fiber diets. Therefore, chicks might have a requirement for a minimum amount of fiber in the diet.

Key Words: Pellet, Fiber Sources, Broiler Performance

M204 Nutritional value of corn distiller dried grains with solubles (DDGs): Influence of solubles addition. S. L. Noll*[1], J. Brannon[1], and C. Parsons[2], [1]*University of Minnesota*, *St. Paul*, [2]*University of Illinois*, *Champaign*.

Batches of corn distiller dried grains were produced with varying levels of solubles (syrup) added back to the wet grains (mash) in cooperation with a Minnesota ethanol plant. The batches produced contained syrup added at approximately 0, 30, 60, and 100% of the maximum possible addition of syrup to mash. Actual rates of syrup addition were 0, 12, 25, and 42 gal/minute. The different combinations of mash and syrup were dried at the plant with a lag of 60 minutes in between the changes for the different rates of syrup addition. Samples of each lot of material were taken and were chemically analyzed. Digestible amino acid content was determined with cecectomized roosters. True metabolizable energy (TMEn) was determined in intact young growing turkeys. Regression analyses and correlation coefficients (Pearson) were conducted to determine the extent of the relationship between the level of solubles added and the resulting nutrient content. Particle size was greatly affected with larger and more variable particle size with the highest level of solubles addition. The larger particles ("syrup balls") were readily apparent in the 100% batch and are of concern for product quality for poultry feeds. Content of fat and ash increased with solubles addition. Fat content increased from 8% in the dried grains to 10.5% (as fed basis) where 100% of the solubles were added back. The TMEn content also increased with solubles addition from 2712 kcal/kg for the dried grains to 3743 kcal/kg where 100% of the solubles were added back. Mineral content, especially for magnesium, sodium, phosphorus, potassium, chloride, and sulfur increased as the level of solubles addition increased. Protein and amino acid content showed very little change in the various products. True amino acid digestibility coefficients of the essential amino acids tended to be negatively correlated with solubles addition. The results indicate that solubles addition has the largest effect on particle size, color, and; content of fat and minerals.

Key Words: Distillers Grains, Solubles, Energy

M205 Metabolizable energy value of crude glycerin for laying hens. K. Bregendahl*[1], P. Lammers[1], B. Kerr[2], M. Honeyman[1], K. Stalder[1], T. Weber[1], W. Dozier, III[3], K. Dion[1], M. Neal[1], and S. Mottet[1], [1]*Iowa State University*, *Ames*, [2]*USDA/ARS*, *Ames, IA*, [3]*USDA/ARS*, *Mississippi State, MS*.

An experiment with laying hens was conducted to determine the AMEn value of crude glycerin, a coproduct of biodiesel production. Crude glycerin (86.95% glycerol, 9.22% water, 0.03% methanol, 1.26% Na, 3625 kcal/kg gross energy) was obtained from AG Processing Inc., Sergeant Bluff, IA. A total of 48 40-wk-old laying hens (Hy-Line W-36) were placed in metabolic cages (2 hens/cage) in a light-controlled (16:8 L:D) room and given free access to the experimental diets. A basal diet (19% CP; 2922 kcal/kg AMEn) was formulated using corn, soybean meal, and meat and bone meal with 15% glucose and 1% Celite (to increase the content of acid-insoluble ash used as an indigestible marker). The 4 treatment diets were created by substituting 0, 5, 10, or 15% crude glycerin for glucose (3640 kcal/kg AMEn). After 7 d of dietary adaptation, excreta was collected twice daily for 3 d, freeze-dried, and analyzed for contents of DM, Kjeldahl N, acid-insoluble ash, and gross energy. Egg production was recorded daily, and eggs collected on Day 7 and 8 of the experiment were weighed for calculation of egg mass (egg production × egg weight). Feed consumption was measured over the entire 13-d-long experiment. Egg-production data were analyzed using ANOVA with 4 treatments and 6 replications in a completely randomized experimental design. The AMEn value of the crude glycerin was estimated as the slope of the linear relationship between the inclusion rate of dietary crude glycerin and the glucose-corrected AMEn value of the experimental diets. There were no treatment effects ($P > 0.05$) on the hens' egg-production rate (93.0%), egg weight (56.1 g), egg mass (52.2 g/d), or feed consumption (104 g/d). Linear regression analysis ($P < 0.001$, $r^2 = 0.92$, $n = 24$) showed that the AMEn value of the crude glycerin used in this study was 3805 ± 238 kcal/kg (mean ± SE; as-is basis) for laying hens. The results of this study show that the energy in crude glycerin is utilized with high efficiency by laying hens.

Key Words: Crude Glycerin, Metabolizable Energy, Laying Hens

M206 Nutrient digestibility of high protein corn distillers dried grains with solubles, dehydrated corn germ and bran. A. Batal*, *University of Georgia*, *Athens*.

Sectors of the ethanol industry are starting to use a new bio-refining production technology which separates the corn into three fractions: fiber, germ and endosperm, prior to ethanol production. These fractions are then converted into new co-products, high protein distillers dried grains with solubles (HP-DDGS), dehydrated corn germ meal, and bran cake. Studies were conducted to determine the nutritional parameters of these new co-products. A chick experiment was conducted to determine the phosphorus (P) bioavailability based on tibia ash. In addition, conventional and cecectomzied precision-fed rooster assays were conducted to determine TME_n and amino acid digestibility. For the chick assay, a P-deficient corn-soybean meal diet containing 0.13% non-phytate P was supplemented with 0, 0.05, 0.10, and 0.15% from KH_2PO_4 or 7 and 14% DDGS, HP-DDGS, and corn germ. Cobb 500 chicks were fed the experimental diets to 18 d of age and bioavailability of P was estimated using the slope-ratio method where tibia ash was repressed on P intake. The total P content and P bioavailability of the DDGS, HP-DDGS, and corn germ were 0.77 and 60, 0.35 and 47, and 1.18 and 31%, respectively. The average protein, fiber, and fat % for DDGS was 27, 7, and 10, for HP-DDGS 44, 7, and 3, for corn germ 15.5, 4.5, and 17, and for bran 11.6, 4.5, 7.8. The average TME_n was 2,829, 2,700, 2,965, and 2,912 kcal/kg (as-fed basis) for the DDGS, HP-DDGS, corn germ, and bran, respectively. Bran had a higher TME_n value than expected, which is likely due to the high fat content. Total concentration and percent availability, of lysine for the DDGS, HP-DDGS, corn germ, and bran was 0.79 (81), 1.03 (72), 0.83 (80) and 0.43% (68%), respectively. The total lysine as a % of CP was 3% for the conventional DDGS and only 2% for the HP-DDGS, however these products had a similar TME_n. New bio-refining techniques result in co-products that have unique nutritional qualities compared to conventional DDGS. Thus, confirmatory analyses should be conducted prior to utilizing these new co-products of ethanol production.

Key Words: Distillers Dried Grains with Solubles, Corn Germ, Amino Acid Digestibility

M207 Effects of sorghum variety on growth and subsequent egg production in layers reared in West Africa. S. Issa*[1,2], J. D. Hancock[1], M. R. Tuinstra[1], I. Kapran[2], and S. Kaka[2], [1]*Kansas State University*, *Manhattan*, [2]*National Institute for Agricultural Research in Niger*, *Niamey, Niger*.

A total of 450 1-d-old layer chicks (Harco line with an initial body weight of 29 g) were used in an 18-month experiment to determine the effects of sorghum variety on growth and egg production. There were 50 chicks/pen and three pens/treatment with feed and water consumed on an ad-libitum basis. The control diet was corn based with fishmeal and peanut cake used as the primary protein supplements. The control was formulated to exceed recommendations for all nutrient concentrations as suggested in the 1994 NRC for poultry. Sorghum was used to replace the corn on a wt/wt basis so that treatments were: 1) corn (imported from Nigeria)-based control; 2) a locally adapted landrace variety of sorghum (Mota Galmi) with red seed, purple plant, and 0.3 mg catechin equivalents/100 mg of grain DM; and 3) an agronomically improved variety of sorghum (IRAT 204) with white seed, tan plant, and no detectable tannins. For d 0 to 126, there were no differences ($P > 0.12$) in average daily gain (ADG) and gain to feed ratio (G:F) among birds fed the corn and sorghum treatments. However, the numerical advantage in ADG for birds fed the agronomically improved sorghum resulted in a 79 g advantage ($P < 0.001$) in body weight at the beginning of the laying period compared to birds fed the locally adapted sorghum. For the laying period, birds fed the sorghum grains took fewer days to come into production ($P < 0.007$), ate more feed ($P < 0.02$), and produced more eggs ($P < 0.001$) than birds fed the corn-based diet. There were no differences in average egg weight and egg:feed ratio among birds fed corn and the sorghums. Means for corn, locally adapted sorghum, and improved sorghum were 1,855, 1,840, and 1,919 g body weight at 126 days, 141, 135, and 133 d to reach 20% production, and 47, 56, and 55% production for the entire laying period. In conclusion, sorghum grain was equal (if not superior) to corn as a feedstuff in diets for layers reared in West Africa.

Key Words: Sorghum, Corn, Layer

M208 Dietary inclusion of a dairy processing plant by-product on performance and processing yields of broilers. H. L. Santiago*, L. J. Pérez, J. A. Orama, and A. A. Rodríguez, *University of Puerto Rico*, *Mayagüez, Puerto Rico*.

Dairy processing wastes resulting from the manufacture of Latin white cheese have nutrient profiles similar to grains used in poultry diets and can become potential feed sources at reasonable prices. The objective of this study was to evaluate the dietary inclusion of a dairy industry by-product (DIBP) on growth performance and processing yields of broilers. The dried DIBP incorporated into diets had a 50.6% crude protein and 1.9 % fat content. A total of 540 d-old chicks were randomized in three treatments with six replicate pens of 30 birds each. Treatments consisted of diets containing 0 (control), 3, and 6% DIBP. Feed and birds were weighed weekly up to 42 d of age to determine body weight (BW), feed intake (FI), and feed conversion (FC). At market age (43 d), a total of 180 birds were processed to evaluate carcass composition and to determine processing yields. The dietary inclusion of DIBP had no effect on growth performance of broilers. At all ages, broilers fed a 3 and 6% of DIBP had similar BW, FI, and FC than that of controls. Although, no significant differences among dietary treatments were observed for FC, birds fed diets containing 6% DIBP tended to have better FC when compared to birds fed control and 3% DIBP diets. Mortality and the percentage of culled birds were similar for all dietary treatments. No differences among treatments were observed in yields of carcass, abdominal fat, mayor cuts, and breast meat. Fat pad yield declined from 1.14 to 0.97 % as the percentage of DIBP inclusion in the diet increased. The results of this study indicate that the DIBP evaluated could be a valuable feed ingredient to supply part of the dietary protein and metabolizable energy requirements of broilers. The results showed that DIBP could be used in broiler diets up to 6% without compromising growth performance, health, and processing yields.

Key Words: Broilers, Growth, Dairy By-Product

M209 The researches for the functional components in fish meal for broiler chickens. K. Nakagawa*[1], T. Akazawa[2], M. Tamura[2], and H. Sato[1], [1]*Ajinomoto Co., Inc.*, *Tokyo, Japan*, [2]*Itochu Feed Mills Co., Ltd.*, *Tochigi, Japan*.

In our previous studies, we found that the broiler chickens grew faster when birds were fed a diet containing fish meal than when fed all-vegetable diet or a diet containing chicken meal. However, there was no effect of sole supplementation of the specific components in fish meal (ex. fish oil, creatine, glycine or taurine). Two broiler trials were conducted to identify what components in fish meal have key roles for growth. In the initial trial, 240 male Cobb broiler chicks of 0-d-old were allocated to one of four treatments with six replicates of 10 birds each. The experimental diets were all-vegetable diet (VEG as control, a diet containing 5% fish meal (FM), 5% soluble fraction (SF) or 5% insoluble fraction (IF) of fish meal, respectively. Both SF and IF were prepared by separating the slurry of fish meal into the solid and liquid parts, drying up the solid as IF, and freeze-drying the liquid as SF. Chicks were fed each experimental diet for two weeks, with individual body weight and feed intake per replicate measured on day 7 and 14. On day 14, body weight ($P<0.01$) and feed intake ($P<0.01$) were significantly improved by feeding FM, SF and IF comparing with feeding VEG. In the subsequent trial, we focused on the effect of the soluble fraction and conducted an experiment with the similar procedures with the initial one. The experimental diets were VEG, a diet containing 4% SF, 1.7% low MW fraction of SF (LMW) or 2.3% high MW fraction of SF (HMW). The inclusion of LMW and HMW in the diets was determined based on their proportion (weight %) in the whole SF. LMW and HMW were prepared from SF by using a membrane filter for 1,000 MW. On day 14, body weight ($P<0.01$), feed intake ($P<0.01$) and feed conversion ratio ($P<0.10$) were significantly improved by feeding SF and HMW comparing with feeding VEG, and not improved by feeding LMW. These results suggest that several components in fish meal have beneficial functions, and they are included in the insoluble fraction and the soluble fraction of high MW.

Key Words: Fish Meal, Fraction, Broiler Chicken

M210 Evaluation of NutriDense® corn compared to conventional corn fed to laying hens. P. Utterback*[1], E. Kim[1], C. Jacobs[1], C. Utterback[1], C. Parsons[1], J. Snow[2], and J. Weigel[2], [1]*University of Illinois*, *Urbana*, [2]*BASF Plant Science*, *Research Triangle Park, NC*.

A 12-week experiment was conducted using 360 Hy-Line W-36 hens (24 wk of age) to compare NutriDense® (ND) corn, supplied by BASF Plant Science, to conventional (CONV) corn when used in laying hen diets. Treatment 1 utilized conventional corn formulated to meet NRC (1994) requirements for layers, and the diet was formulated to contain 17% crude protein and 2900 kcal of MEn. Treatment 2 also used conventional corn, but the diet was formulated to contain lower nutrient levels to reduce feed costs. The Treatment 2 diet was formulated to contain 15% crude protein and 2800 kcal of MEn. Treatments 3 & 4 were the same as 1 & 2, respectively, but with ND corn added in place of CONV corn. The final treatment was a least-cost formulated diet containing the same nutrient levels as Treatment 1 but using ND corn instead of CONV corn. The latter treatment was included to compare the economic value of ND corn compared to the CONV corn. Diets were fed for 12 weeks, and data were summarized at two-week intervals. There were no differences among any of the treatments at any time period for body weight, hen-day egg production, egg weight, egg mass, egg specific gravity, or mortality. Feed consumption showed statistical differences among treatments ($P< 0.05$) at Week 6, 10, 12, and cumulatively, with feed intake being highest for Treatment 2 and lowest for Treatment 3. There were also significant differences in feed efficiency (egg mass divided by feed intake) among treatments at Weeks 8, 10, 12, and cumulatively due to Treatment 2 being significantly ($P<0.05$) lower than all other treatments. The results of this study indicate that the egg production performance of laying hens fed ND corn is equal to or superior to that of hens fed CONV corn and that feeding ND corn may reduce feed costs.

Key Words: Laying Hens, NutriDense® Corn, Conventional Corn

M211 Comparison of broiler performance and carcass parameters when fed diets containing combined trait insect-protected and glyphosate-tolerant corn (MON 89034 × NK603), control, or conventional reference corn. M. L. Taylor*[1], G. F. Hartnell[1], D. M. Lucas[1], M. A. Nemeth[1], and S. W. Davis[2], [1]*Monsanto Company*, *Creve Coeur, MO*, [2]*Colorado Quality Research*, *Wellington, CO*.

A 42-d floor pen study was conducted to compare broiler (Ross × Ross 308) performance and carcass measurements when fed diets containing lepidopteran protected corn combined with glyphosate tolerant corn (MON 89034 × NK603) with those of broiler fed diets containing corn grain from the conventional control and 6 conventional corn hybrids. MON 89034 produces the Cry1A.105 and Cry2Ab2 insecticidal

proteins that protect corn plants from feeding damage caused by European corn borer (Ostrinia nubilalis) and other lepidopteran insect pests. The combination of the Cry2Ab2 and Cry1A.105 insecticidal proteins in a single plant provides outstanding insect control and offers an effective insect-resistance management tool. NK603 produces the 5-enolpyruvylshikimate-3-phosphate synthase protein from Agrobacterium sp. strain CP4 (CP4 EPSPS), which confers tolerance to glyphosate, the active ingredient in Roundup$|reg; agricultural herbicides. MON 89034 × NK603 was produced by traditional breeding of plants that express the individual traits. Broilers were fed starter diets (approximately 57% wt/wt corn grain) from d 0 to d 21 and grower/finisher diets (approximately 59% wt/wt corn grain) from d 21 to d 42. The study utilized a randomized complete block design with 8 dietary treatments assigned randomly within 5 blocks of 16 pens each (8 male and 8 female) with 10 birds per pen. There were 10 pens per treatment group (5 male and 5 female). Weight at d 0 and d 42, feed intake, and feed conversion, and all measured carcass and meat quality parameters were not different (P > 0.05) for birds fed MON 89034 × NK603 and control corn diets. In addition, comparisons of the MON 89034 × NK603 diet to the population of the control and 6 reference corn diets showed no difference (P > 0.05) in any performance, carcass, or meat quality parameter measured. In conclusion, the diets containing MON 89034 × NK603 were nutritionally equivalent to diets containing the control or conventional reference corn grain when fed to broilers.

Key Words: Broiler Performance, Carcass Yield, Genetically Modified Corn

M212 Comparison of broiler performance and carcass parameters when fed diets containing soybean meal produced from glyphosate-tolerant (MON 89788), control or conventional reference soybeans. M. L. Taylor*[1], G. F. Hartnell[1], D. M. Lucas[1], M. A. Nemeth[1], and S. W. Davis[2], [1]*Monsanto Company*, *Creve Coeur, MO*, [2]*Colorado Quality Research*, *Wellington, CO*.

A 42-d floor pen study was conducted to compare broiler (Ross × Ross 308) performance and carcass measurements when fed diets containing meal produced from glyphosate-tolerant soybeans (MON 89788) with those of broilers fed diets containing meal produced from control soybean (A3244) that has similar genetic background to MON 89788. Soybean meal produced from 6 conventional soybean varieties were included in the study to provide comparison measurements for broilers fed meal derived from conventional soybeans. MON 89788 produces the 5-enolpyruvylshikimate-3-phosphate synthase protein from Agrobacterium sp. strain CP4 (cp4 epsps), which confers tolerance to glyphosate, the active ingredient in Roundup® agricultural herbicides. Broilers were fed starter diets (approximately 33% wt/wt dehulled soybean meal) from d 0 to d 21 and grower/finisher diets (approximately 30% wt/wt dehulled soybean meal) from d 21 to d 42. The study utilized a randomized complete block design with 8 dietary treatments assigned randomly within 5 blocks of 16 pens each (8 male and 8 female) with 10 birds per pen. There were 10 pens per treatment group (5 male and 5 female). No treatment differences (P > 0.05) were detected among dietary treatments for feed intake, weight gain, feed conversion, adjusted feed conversion, or any measured carcass and meat quality parameters. Comparison of all performance, carcass, and meat quality parameters measured showed no differences (P > 0.05) between birds fed the MON 89788 soybean meal diet and the population of birds fed the control and 6 conventional reference soybean meal diets. It is concluded that the diets containing soybean meal produced from MON 89788 were nutritionally equivalent to diets containing soybean meal produced from the control and conventional reference soybean varieties when fed to broilers.

Key Words: Broiler Performance, Carcass Yield, Genetically Modified Soybean

M213 Broiler chicken performance as affected by diets containing cashew nut meal submitted to different storage conditions. I. R. V. Lopes[1], M. F. F. Fuentes*[1], E. R. Freitas[1], J. R. Lima[2], R. B. Silva[1], R. C. Lima[1], and R. M. Bezerra[1], [1]*Universidade Federal do Ceará*, *Fortaleza, CE, Brazil*, [2]*Embrapa Agroindústria Tropical*, *Fortaleza, CE, Brazil*.

Cashew nut meal (CNM) is an abundant sub product from the cashew nut processing industry in Northeast Brazil and it contains about 47.8% ether extract and 22% crude protein. This experiment was conducted to evaluate the performance of broiler chickens fed diets containing CNM which had been stored with or without addition of butylated hydroxytoluene (BHT) as an antioxidant additive. A 400kg batch of freshly produced CNM was divided into five portions. One portion was stored without BHT and the others were added of 500 ppm BHT at 0, 7, 14 and 21 days of storage. Total storage time was 35 days. Weekly samplings of CNM were taken for peroxide index (PI) determination. At the end of the storing period five isoproteic and isocaloric diets were formulated as to contain 15% CNM from each of the five different storage conditions described above. A feeding trial was then carried out with 480 day old chicks males Ross x Ross. Birds were randomly distributed among the five treatments with eight repetitions of twelve birds each. The variables studied were weight gain, feed intake and feed conversion. PI values in stored CNM, with or without BHT, increased with storage time. However, diets containing CNM with or without BHT and stored for 35 days did not affect (P≥0.05) the variables studied. CNM stored for 35 days without BHT can be used in broiler diets with no effect on bird performance.

Key Words: Weight Gain, Feed Conversion, Peroxide Index

M214 Broiler performance and carcass characteristics when fed diets containing Lysine maize (LY038 or LY038 × MON 810), control or conventional reference maize. D. M. Lucas*[1], M. L. Taylor[1], G. F. Hartnell[1], M. A. Nemeth[1], K. C. Glenn[1], and S. W. Davis[2], [1]*Monsanto Company*, *St. Louis, MO*, [2]*Colorado Quality Research*, *Wellington, CO*.

Lysine maize, LY038, was developed through the application of modern biotechnology to accumulate free lysine (Lys) in the germ portion of maize grain and provide an alternative to direct addition of supplemental Lys to poultry diets. Maize LY038 × MON 810 was produced by conventional breeding of LY038 with MON 810, which provides the maize plant protection against feeding damage from the European corn borer. A 42–d broiler feeding study (10 pens of 10 male Cobb × Cobb 500 broilers/treatment) was conducted to compare the feeding value of grain from LY038 or LY038 × MON 810 to that of a conventional control (similar genetic background to the test maize) and 5 conventional maize hybrids. LY038 and LY038 × MON 810 diets, and control and conventional reference maize diets supplemented with L–Lys HCl were formulated to a Lys level below that required for

optimal bird performance; whereas, all other essential amino acids were present at levels, relative to Lys, above those required for optimal bird performance [1.05% and 0.90% total Lys (as-fed) for d 0 to 21 and d 21 to 42, respectively]. Total Lys level in control and reference maize based diets without supplemental L–Lys HCl were formulated to be 0.079% lower than supplemented diets. Weight gain, feed efficiency, and carcass yield and composition of broilers fed diets containing LY038 or LY038 × MON 810 were not different ($P \geq 0.05$) from that of broilers fed L–Lys HCl supplemented diets and were superior ($P \leq 0.05$) to that of broilers fed conventional maize diets without supplemental L–Lys HCl. Both broiler performance and carcass data demonstrate that the bioefficacy of the incremental Lys in LY038 or LY038 × MON 810 grain was not different from that of Lys in conventional maize diets supplemented with L–Lys HCl. LY038 and LY038 × MON 810 can be considered as wholesome as and more nutritious than conventional maize due to its higher than average Lys content.

Key Words: Broiler Performance, Lysine, Maize

M215 Effects of selection for mold resistance on nutritional value of sorghum grain in broiler chicks. C. R. Monge*[1], J. D. Hancock[1], C. Feoli[1], W. L. Rooney[2], S. R. Bean[1,3], and S. Beyer[1], [1]*Kansas State University*, *Manhattan*, [2]*Texas A&M University*, *College Station*, [3]*USDA/ARS*, *Manhattan*.

A total of 264 broiler chicks (Cobb x Cobb, 14 d of age, and average initial body weight of 403 g) was used in a 7-d metabolism experiment to determine the effects of selection for mold resistance on nutrient utilization. A reference diet with 50% cornstarch was formulated to meet or exceed all nutrient concentrations recommended in the 1994 NRC for poultry. Sorghum grain was then substituted for cornstarch in the reference diet. Treatments were sorghums selected from a plant-breeding program that were susceptible and resistant to mold and weathering. These sorghums were grown at four locations in Texas (Corpus Christi, Beeville, College Station, and Halfway) and one location in Kansas (Manhattan). The chicks were adjusted to treatment for 4 d followed by 3 d collection of excreta. The excreta were dried, ground, and analyzed for DM, N, and GE with Cr2O3 used as an indigestible marker. Analysis of variance suggested there were no interactions ($P > 0.66$) among location and sorghum type for average daily gain (ADG), gain to feed ratio (G:F), and retention of DM and GE. Also, there were no effects of location or sorghum type on ADG and G:F ($P > 0.37$). However, there were trends ($P < 0.06$) for location effects on retention of DM and N and these trends were in agreement with the greater retention of GE ($P < 0.02$) for chicks fed sorghums produced in Beeville vs the other locations. There was a trend ($P < 0.06$) for greater retention of DM among chicks fed the susceptible vs the resistant sorghum, but retention of N and GE were not affected by sorghum type ($P > 0.3$). Means for the susceptible and resistant sorghums were 44 and 46 g/d for ADG, 707 and 710 g/kg for G:F, 72 and 70% for retention of DM, 47 and 49% for retention of N, and 77 and 76% for retention of GE, respectively. In conclusion, selection for mold resistance had minimal and inconsistent effects on the nutritional value of sorghum grain for broiler chicks.

Key Words: Sorghum, Mold Resistance, Poultry

M216 Influence of fish meal processing on performance of broilers from 1 to 28 days of age. A. P. Bonilla, A. de Coca-Sinova, E. Jiménez-Moreno, R. Lázaro, and G. G. Mateos*, *Universidad Politécnica de Madrid*, *Spain*.

Bacterial contamination and particularly Salmonella spp. contamination limits the use of fish meal (FM) in prestarter diets for broilers. In consequence, FM processing plants apply severe heat conditions (100° C for 120 min) during rendering to reduce bacterial load. However, an increase in time and temperature conditions during processing might reduce amino acid availability and FM quality. We studied the effect of processing FM under different time and temperature conditions on productive performance of broiler from 1 to 28 d of age. There were six dietary treatments that differed in the type of FM used to replace 5% of the crude protein of the diet. There were a control diet (SFM) that included 8.0% standard FM (100° C for 120 min) and a positive control diet (FMLT) that included 7.1% of spray dried FM (70° C). The remaining four diets included the same original fresh FM that the control SFM diet but in which the FM was processed according to a factorial combination of temperature (80 vs. 90° C) and time (50 vs. 90 min). Each treatment was replicated eight times (10 chicks caged together). The experimental design was completely at random and data were analysed by a protected t–test. In addition two extra non–orthogonal contrasts were included; 1) FMLT vs. SFM and 2) main effects of temperature (80 vs. 90° C) and time (50 vs. 90 min) applied during processing and their interaction. The best BWG and FCR were obtained for broilers fed FMLT or FM processed at 80° C during 50 min but the differences with respect to broilers fed SFM were not significant. The temperature applied during processing had little effect on broiler productivity ($P > 0.10$) but an increase in processing time from 50 to 90 min tended ($P \leq 0.10$) to reduce BWG (52.16 vs. 50.57 g/d) and to impair FCR (1.44 vs. 1.47). We conclude that an aggressive thermal process with an increase in time from 50 to 90 min to reduce microorganism load and Salmonella spp. counts in feed might reduce the quality of fish meal in diets for broilers.

Key Words: Fish Meal, Heat Processing, Broiler Performance

M217 Improved phosphorus utilization in broilers fed phosphorus deficient diets early in life. R. Angel*[1] and C. M. Ashwell[2], [1]*University of Maryland*, *College Park*, [2]*North Carolina State University*, *Raleigh*.

Land application of poultry litter, that is comparatively high in P due to poor utilization of phytin P (PP) by poultry, is of increasing concern in areas of intensive poultry production in the United States. Several strategies have been developed to address this issue, but with variable effectiveness and often increasing production costs, therefore alternative strategies must be explored. To determine the effects of early P nutrition on performance and P utilization male Ross 308 chicks were fed either a control (C) (1.11% Ca and 0.50% PP) or a low (L) (0.59% Ca and 0.25% PP) diet from hatch to 4 d of age (90hr). All birds were then fed a C diet (NRC Ca and P) until d 22. From d 22 to 38 birds were either maintained on a C diet (0.7% Ca and 0.3% P) or an L diet (0.4% Ca and 0.12% P). The three treatments (Trt), C-C-C, C-C-L, and L-C-L met all other NRC (1994) nutrient recommendations. Data were collected for each phase including weight gain, feed conversion, bone ash, and specific nutrient retention. All diets and ileal contents were analyzed for dry matter, P, Ca, PP, and acid insoluble ash. Diet non-PP was determined by subtracting analyzed PP from analyzed P. Apparent ileal absorption of P and Ca, and disappearance of PP were

calculated using an indigestible marker. Broilers fed the L diet to 90 hr were better able to handle a deficiency in P in the grower/finisher phase (22 to 38 d of age) than those fed a C diet in the first 90 hr. Not only were the broilers fed the L diet early heavier (P<0.05) at 38 d of age (2275.6 vs 2235.4 g for the L-C-L and the C-C-L Trt, respectively), but they had better feed efficiency (1.76 vs 1.89 in the L-C-L and C-C-L Trt, respectively), had higher tibia ash and higher P retention (56.54 vs 45.39% for the L-C-L and C-C-L Trt, respectively) than those fed the C diet in the first 90 hr of life. This clearly establishes that "imprinting" or permanent modifications are occurring post-hatch that are long term and allow for improved P utilization when P deficient diets are fed in the grower/finisher phases.

Key Words: Phosphorus, Conditioning, Imprinting

M218 Calcium and available phosphorus levels at 2:1 ratio for growing broiler chickens. S. Bunzen, H. S. Rostagno*, L. F. T. Albino, L. R. Nery, and C. R. Silva, *Viçosa Federal University*, *Viçosa, MG, Brazil*.

The reduction of phosphorus (P) levels in broiler chickens diets will certainly help to decrease costs and P excretion with reduced effect on the environment. There are many interrelationships between calcium (Ca) and P suggesting that nutritional studies should be run evaluating Ca:available P (aP) levels at a constant ratio of 2:1. A study was carried out with the objective of determining the best %Ca:%aP level for broiler chickens from 22 to 35 days of age. A floor pen trial with 1,440 broilers (Cobb 500; 720 males and 720 females) was conducted using a completely randomized block design, in a 2 x 6 factorial arrangement (Gender x 6 %Ca:%aP levels) with eight replicates and 15 birds per experimental unit (pen). The experimental diets were based on corn (0.03% Ca / 0.08% aP) and soybean meal (0.24% Ca / 0.18% aP), supplemented with dicalcium phosphate (24.5% Ca / 18.5% aP) and limestone (38.4% Ca) to obtain 6 %Ca:%aP levels (0.40 / 0.20, 0.50 / 0.25, 0.60 / 0.30, 0.70 / 0.35, 0.80 / 0.40 and 0.90 / 0.45). Weight gain, feed consumption, feed conversion and bone (tibia) parameters (ash, Ca and P from three birds per pen) were evaluated. Feed consumption was not affected (P>0.05) by the experimental treatments. Weight gain improved linearly (P<0.05) to the dietary Ca:aP levels (gain males = 1095.26 + 102.286 aP; R2= 0.64, and gain females = 895.90 + 153.143 aP; R2=0.57) with an improvement of 36 g/male and 44 g/female (highest - lowest gain). Feed conversion of males and females broilers showed a quadratic response (P<0.05) described by the equations; Y = 1.86068 - 0.675337 aP + 0.85 aP 2 (R2 = 0.87) for males, and Y = 1.99459 - 1.44471 aP + 2.01429 aP 2 (R2 = 0.75) for females. Based on feed conversion and using a 95% confidence limit, the recommended levels are: 0.377% aP / 0.754% Ca for broiler males and 0.341% aP / 0.682% Ca for broiler females.

Key Words: Available Phosphorus, Broilers, Calcium

M219 The effects of Quantum™ phytase on broiler chick live performance and tibia ash percentage. M. E. Persia* and M. R. Bedford, *Syngenta Animal Nutrition*, *RTP, NC*.

Chick tibia ash percentage (TAP) is a sensitive measure of the phosphorus adequacy of poultry diets. Three experiments were conducted to determine the effects of two doses of Quantum™ phytase (QP) on TAP and live performance of chickens fed reduced nonphytate phosphorus (NPP) diets. Four experimental diets were utilized including a positive control diet (PC) that met or exceeded all NRC (1994) recommendations, a negative control diet (NC) similar to the PC but deficient in NPP (0.20% NPP) and the same NC diet supplemented with either 250 or 500 FTU of QP/kg (250 and 500, respectively). In all experiments, 12 blocks of either 6 or 12 Cobb x Cobb broiler chicks were assigned to each of the four treatments utilizing a randomized complete block design. Chicks were raised on experimental diets from 0 to 21 d in Petersime battery pens located in an environmentally controlled room. Weight gain and feed intake were recorded for the 21 d period. At the conclusion of the experiment, chicks were sacrificed and the right tibia was collected from four chicks per replicate group for fat-free TAP determination. Data were analyzed using ANOVA and means separated using specific pre-planned contrasts. Over all experiments, chick weight gain and feed intake was reduced 162 and 171g, respectively, when birds were fed the NC compared with PC rations. Phytase supplementation significantly increased weight gain and feed intake of the NC ration, resulting in overall increases of 95 and 128 g for weight gain and 96 and 137 for feed intake with 250 and 500 FTU/kg, respectively. Tibia ash percent was reduced by 8.3, 8.9 and 7.6% units between the NC and PC fed chickens in experiments 1, 2 and 3, respectively. Supplementation of the NC ration with 250 and 500 FTU/kg significantly increased TAP restoring 2.9, 2.3 and 2.7% units and 4.9, 4.3 and 4.8% units, respectively. These data demonstrate the consistent ability of QP to liberate P and increase weight gain, feed intake and TAP of chicks fed NPP deficient diets.

Key Words: Tibia ash, Phytase, Broiler

M220 Dietary nucleotides supplementation improves growth performance of early weaned pigs. D. Martinez-Puig*[1], J. Morales[2], E. Borda[1], C. Piñeiro[2], and C. Chetrit[1], [1]*Bioiberica S.A.*, *Palafolls, Barcelona, Spain*, [2]*PigChamp Pro-Europa*, *Segovia, Spain*.

In the weaning period, transition from sow's milk to the postweaning diet causes the withdrawal of milk nucleotides. Dietary nucleotide are known to be important for the maturation of the gastrointestinal tract and in the development of immune function (Carver et al., 1991). The objective of the present experiment was to study the effect of dietary supplementation of a nucleotide preparation (Nucleoforce Piglets™) on the productive performance of early weaned pigs. 192 suckling piglets of 14 days of age were distributed into two treatments according to the litter and fed with two creep feed diets, one supplemented with the nucleotide preparation (1000 ppm) and the other no supplemented. Piglets were weaned at 21 days of age and consumed the experimental diets till day 35. From day 35 until day 56 all piglets were fed with the same diet. Performance was determined on days 21, 28, 35 and 56. Mortality and faecal consistency were also assessed. During the prestarter period (21 to 35 d), the average daily gain of pigs fed the nucleotide preparation was numerically higher (76.7 g/d; P=0.12) than that of the pigs fed the control diet (53.5 g/d), although no differences were detected on the feed conversion ratio. During the starter period (35-56d), the nucleotide supplementation significantly improved

average daily gain by 20% (P=0.02) and numerically improved feed conversion ratio by 23.7% (P=0.14). There were no significant effects on mortality and faecal consistency, but were numerically better on the nucleotide supplemented group. The overall results suggest that dietary nucleotide supplementation at 1000 ppm significantly improves the performance of early weaned pigs.

Key Words: Dietary Nucleotides, Productive Performance, Weaning Pigs

M221 The effect of soybean oil, tallow and coconut oil supplementation on growth performance, serum lipid changes and nutrient digestibility in weaned pigs. J. H. Cho*[1], H. J. Kim[1], Y. J. Chen[1], J. S. Yoo[1], B. J. Min[1], J. D. Kim[2], and I. H. Kim[1], [1]*Dankook Univ*, *Cheonan, Choong nam, Korea*, [2]*CJ Feed Co. Ltd*, *Incheon, gyeong gi, Korea*.

This experiment was conducted to determine the effect of soybean oil, tallow and coconut oil supplementation on growth performance, serum lipid changes and nutrient digestibility in weaned pigs. One hundred twenty cross-bred [(Yorkshire×Landrace)×Duroc, 6.92±0.01kg average initial BW] were used in a 35 d growth trial. Dietary treatments included CON (5% soybean oil), T0.5 (4.5% soybean oil + 0.5% tallow), C0.5 (4.5% soybean oil + 0.5% coconut oil) and C1.0 (4.0% soybean oil + 1.0% coconut oil). For the whole period and from d 14 to 35, G/F was increased in C0.5 and C1.0 treatments compared with T0.5 treatment(P<0.05). ADG and ADFI were not affected by treatments. On d 14, C1.0 treatment was higher in serum HDL-cholesterol than C0.5 treatment and atherogenic index was increased in C0.5 treatment compared to T0.5 and C1.0 treatments(P<0.05). Digestibility of fat was improved for pigs fed C1.0 diet compared with those fed T0.5 diet on d 35(P<0.05). However, there were no significant differences in digestibilities of DM, N and DE. In conclusion, feeding diets containing soybean and coconut oils in weaned pigs increased feed efficiency and fat digestibility than feeding those containing soybean oil and tallow.

Key Words: Coconut Oil, Tallow, Weaned Pigs

M222 Dietary supplementation with *atractylis macroceohala koidz* polysaccharides enhances growth performance in weaned pigs. Z. Bin*[1], L. L. Li[2], Y. L. Yin[2], H. Z. Peng[1], K. M. Yang[3], T. J. Li[2], Z. P. Hou[2], P. Zhang[2], and G. Y. Wu[1,4], [1]*Hunan Agricultural University*, *Changsha, Hunan, China*, [2]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [3]*Hunan Zhenghong Science and Technology Co.*, *Changsha, Hunan, China*, [4]*Texas A&M University*, *College Station*.

This study was conducted to evaluate the effects of *atractylis macroceohala koidz* polysaccharides (AP) on growth performance in weaned piglets. A total of 120 piglets (Landrace x Yorkshine) weaned at 28 d of age (average BW of 7.5 kg) were assigned randomly to 1 of the 5 treatment groups, with 3 replicates and 8 pigs per replicate. The treatments represented dietary supplementation with 0% (control), 0.3%, 0.6% or 0.9% AP, or 0.02% aureomycin (an antibiotic) to corn- and soybean meal-based diet. All pigs had free access to their diets and drinking water. In the first 14-d (28 to 42 d of age) and second 14-d (42 to 56 d of age) phases, dietary supplementation with all dosages of AP did not affect (P>0.05) feed intake bur with 0.6% AP increased (P<0.05) ADG by 7.6% and 18.5%, respectively, compared with the control pigs. In the second phase, the gain:feed ratio was 14.0% higher (P<0.01) in pigs supplemented with 0.6% AP, and the value was 7.4% higher (P<0.05) in piglets supplemented with 0.9% AP, compared with the control and antibiotic-supplemented pigs. In both phases, growth performance did not differ (P>0.05) statistically among pigs supplemented with the 3 dosages of AP. These results indicate that dietary supplementation with 0.6% AP resulted in a most favorable effect on growth performance in weaned piglets. We suggest that AP is an effective alternative to a feed antibiotic for post-weaning growing swine. (Supported by NSFC, CAS, and Hunan Natural Science and Technology Foundation)

Key Words: Polysaccharides, Herbs, Weaned Pigs

M223 Dietary supplementation with Chinese herbal formula affects serum concentrations of amino acids in weaned pigs. X. F. Kong*[1], Y. L. Yin[1], F. G. Yin[1], H. J. Liu[1], F. F. Xing[1], T. J. Li[1], R. L. Huang[1], and G. Y. Wu[1,2], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Texas A&M University*, *College Station*.

This experiment was conducted to determine the effects of dietary supplementation with Chinese herbal formula (CHF) on serum concentration of amino acids (AA) in weaned pigs. Sixty piglets weaned at 21 d of age were randomly assigned to one of the three treatment groups, representing supplementation with 0 (control) or 0.2% CHF, or 0.02% colistin (an antibiotic) to a corn- and soybean meal-based diet (n = 20 pigs/group). On d 7, 14, and 28 after initiation of CFH supplementation, venous blood samples were obtained for the analysis of serum protein and AA using an Auto-Blood Biochemical Analyzer and an Auto-AA Analyzer, respectively. The results indicated that dietary supplementation with CHF increased (P < 0.05) serum concentrations of total protein and albumin as well as ADG, compared with the other two groups of pigs. On d 7, serum concentrations of Phe were higher (P<0.05), but serum concentrations of Ala, Pro, Lys, Arg, Met, branched-chain AA, aromatic AA, and total AA were lower (P<0.05) in CHF-supplemented piglets than in the other two groups of pigs. On d 14, the CHF treatment increased (P<0.05) serum concentrations of Ile, Ala, Glu, aromatic AA, and total AA, compared with the control group and increased (P<0.05) serum concentrations of Asp, Cys, His, Lys, Thr and Met, compared with colistin-supplemented piglets. On d 28, serum concentrations of Ala, Met, branched-chain AA, aromatic AA, and total AA were higher (P<0.05) in CHF-supplemented than in control pigs, and serum concentrations of His and Tyr were higher (P<0.05) in CHF-supplemented pigs, compared with the other two groups of pigs. These results suggest that dietary supplementation with CHF may affect the digestion of dietary protein or whole-body amino acid metabolism, thereby improving growth performance in weaned pigs. (Supported by NSFC and CAS)

M224 Effects of feeding resistant starch on glucose and hormone levels in plasma of weaned pigs. X. Wu*[1], S. Y. Bin[1], G. Y. Wu[1,2], X. F. Kong[1], Y. L. Yin[1], T. J. Li[1], and R. L. Huang[1], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Texas A&M University*, *College Station*.

Two experiments were conducted to determine effects of feeding resistant starch (RS) on concentrations of glucose, insulin, growth hormone (GH), thyroid hormones (T3 and T4), in plasma of the weanling piglet as an model for studying infant nutrition. In Experiment 1, 12 pigs (Duroc×Landrace×Yorkshire) weaned at 28 d of age (BW of 8.8 ± 1.0 kg) were randomly assigned into one of the four treatments, representing control, isonitrogenous (20%), isocaloric (16 MJ/kg), and iso-starch (39%) diets. The four diets were formulated with corn, brown rice, sticky rice and RS as starch sources, with their RS content being 2.29%, 0.94%, 0.00% and 20.64%, respectively. On d 25 of the feeding trial, venous blood samples were obtained at time zero and every 1 h for 12 h. Plasma was analyzed for glucose, insulin, GH, T3 and T4. The results indicated that feeding RS decreased (P<0.05) postprandial plasma concentrations of glucose, insulin, GH, T3 and T4, while sticky rice increased plasma concentrations of glucose and insulin (P<0.05) at 1 h post feeding, compared with the other groups of pigs. Plasma concentrations of insulin in piglets fed the sticky rice diet was 69.2 μU/ml at 1 h post feeding, which was 59%, 74% and 161% higher (P<0.05) than those in pigs fed the corn, brown rice and sticky rice diets, while plasma concentrations of glucose at 1, 2, 3, 6, and 8 h post feeding were lower (P<0.05) than those in the other three groups of pigs. These results suggest that RS is potentially beneficial for improving insulin sensitivity in young pigs. (Supported by NSFC and CAS)

Key Words: Resistant Starch, Weaned Pigs, Plasma Parameters

M225 Effect of adding a wheat dextrin on growth performance of nursery pigs. H. Yang[1], J. Less[2], D. Holzgraefe[1], M. Cecava[1], T. Radke[1], M. Franklin*[1], and C. Sparks[3], [1]*ADM Animal Nutrition Research*, *Decatur, IL*, [2]*ADM Specialty Feed Ingredients*, *Decatur, IL*, [3]*ADM Alliance Nutrition*, *Quincy, IL*.

Two studies were conducted to evaluate whether a wheat dextrin (PremiDex™) improves performance of nursery pigs. In Exp 1, weanling pigs (n=180; BW=4.82 kg) were blocked by initial BW to one of two dietary treatments (TRT), with 18 pens per TRT and five pigs per pen. The TRT were PremiDex (PD) at 0.0 or 0.2% of diet. In Exp 2, weanling pigs (n=150; BW=4.15 kg) were blocked by initial BW to one of five dietary TRT, with six pens per TRT and five pigs per pen. Dietary levels of PD were 0.0, 0.1, 0.2, 0.3, and 0.6%. ADG, ADFI and G/F were measured throughout four phases ending at d 6, 13, 27 and 35 in Exp 1, and d 7, 14, 28, and 42 in Exp 2. Feeds were pelleted in the first two phases and were meal thereafter in both studies. Antibiotic, mannanoligosaccharide (CitriStim™), and acidifier were included in all diets. Addition of 0.2% PD did not affect overall ADG (411 vs. 418 g; P > 0.10) or ADFI (563 vs. 554 g; P>0.10) of nursery pigs in Exp 1, but tended to improve G/F (0.72 vs. 0.74; P=0.076). In Exp 2, increasing PD from 0.0 to 0.6% did not affect ADG, ADFI or final BW (P>0.10). However, pigs fed 0.2% PD were 0.91 kg heavier than pigs fed no PD at the end of the study. PremiDex improved feed efficiency in a quadratic (P=0.01) and cubic (P=0.03) manner. In summary, the test wheat dextrin (PremiDex) improved feed efficiency of nursery pigs.

Table 1.

	% PremiDex						P value		
Exp 2	0.0	0.1	0.2	0.3	0.6	SE	Lin	Quad	Cubic
ADG, g (d 0 to 42)	425	433	444	422	423	14	0.91	0.24	0.83
ADFI, g (d 0 to 42)	670	623	650	618	638	19	0.40	0.19	0.76
G/F (d 0 to 42)	0.64	0.69	0.68	0.68	0.66	0.01	0.54	0.01	0.03
End weight, kg	22.16	22.30	23.07	22.60	22.19	0.50	0.94	0.24	0.85

Key Words: Dextrin, Pig, Prebioitc

M226 Effects of δ-aminolevulinic acid on growth performance, nutrients digestibility, blood characteristics and immune responses of weanling pigs challenged with lipopolysaccharide. Y. J. Chen*[1], J. H. Cho[1], Y. Wang[1], Y. Huang[1], Y. Hyun[2], T. G. Ko[2], and I. H. Kim[1], [1]*Dankook University*, *Cheonan, Choognam, Korea*, [2]*Easy Bio System Inc*, *Cheonan, Choognam, Korea*.

Eighty pigs (BW=7.21 kg) were allotted to 4 dietary treatments with 4 pens per treatment and 5 pigs per pen. Diets were supplemented with 0, 5, 10, or 15 ppm δ-aminolevulinic acid (ALA) of diet and fed for 35 days. Subsequently, 20 pigs were selected from 0 and 10 ppm ALA added treatments (10 pigs in each treatment) and half of those pigs which from same dietary treatment (n=5) were injected with either LPS (50 μg/kg BW) or sterile saline, resulting to a 2×2 factorial arrangement. Blood sample and rectal temperature date were collected at 0, 2, 4 and 12 h after challenge. Growth performance was not affected by treatments during feeding period. Digestibilities of DM and N were improved in 15 ppm ALA added treatment at d 35 (P<0.05). Serum haemoglobin and iron concentrations were increased in 10 ppm ALA added treatment (P<0.05). At d 35, RBC and WBC counts were affected with 5 and 10 ppm ALA supplemented treatments had greatest level (P<0.05). During challenge period, rectal temperature was elevated by LPS injection at 2 and 4 h postchallenge (P<0.05). Plasma cortisol concentration was increased by LPS injection at 2 and 4 h postchallenge and an ALA alleviate effect was exhibited at 2 h postchallenge (P<0.01). Concentration of plasma IGF-I was higher in ALA included treatments at 2 h postchallenge (P<0.05). Injection of LPS elevated plasma TNF-α concentration at 2, 4 and 12 h (P<0.01) while ALA alleviate effect was observed at 2 and 4 h postchallenge. Challenge of LPS decreased WBC counts in blood at 2 and 4 h postchallenge (P<0.01). At 12 h postchallenge, blood cell counts were influenced by LPS challenge while an ALA supplemented effect was only observed on WBC count (P<0.05). In conclusion, dietary supplementation of ALA can improve DM and N digestibilities and attenuate inflammatory response by improving iron status of weanling pigs.

Key Words: Delta-Aminolevulinic Acid, Lipopolysaccharide, Weanling Pigs

M227 Animal performance as influenced by organic acid supplementation into the diet of post-weaning piglets. C. Lückstädt*[1], S. Nitsch[1], N. Kvietkute[2], A. Stupeliene[2], V. Sasyte[2], and R. Gruzauskas[2], [1]*Biomin GmbH*, *Herzogenburg, Austria*, [2]*Veterinary Academy of Lithuania*, *Kaunas, Lithuania*.

During weaning pigs are exposed to a large variety of physiological and environmental stressors. Intensive research has therefore been directed to the potential of natural growth promoters, like organic acids. They have been shown to be effective in reducing the incidence of gastrointestinal disorders, thereby improving growth performance in pigs. Moreover, due to a decrease in gastric pH, acidification of the diets creates favorable conditions for nutrient digestibility, especially in young piglets. The objective of this study was to evaluate the potential of an organic acid blend in post-weaning pig diets regarding its effect on BW, daily weight gain and gain:feed ratio. The trial was conducted in a commercial pig farm under surveillance of the Veterinary Academy of Lithuania. The aim of the trial was to test the acidifier Biotronic®, an organic acid blend consisting of formic acid, propionic acid and their salts on a sequential release medium (3 kg per t of feed), against a commercial piglet diet containing no acidifying additive. Feed and water were available ad libitum. 52 piglets (Pietrain × Yorkshire × Landrace hybrid), 35 days of age, were randomly selected and litter wise allocated to 2 treatment groups. The trial lasted over a period of 28 days. Performance data were measured on a bi-weekly basis. Piglets in the acidifier group weighed 30.77 kg compared with 29.31 kg in the negative control group and the final BW of 63 day old piglets differed numerically (P=0.186). Based on average daily weight gain, a numerical enhancement of more than 11% could be monitored (708 g vs. 634 g for treatment and control, respectively; P=0.115). The G:F was improved by approximately 3% (0.60 and 0.58 for treatment and control, respectively). It can be concluded that the use of the organic acidifier Biotronic® increased numerically performance data of piglets under European production conditions.

Key Words: Organic Acidifier, Piglet Growth, Gain:Feed Ratio

M228 Evaluation of an extruded wheat and milk by–product mixture in diets for early–weaned pigs. B. Vicente, M. P. Serrano, D. G. Valencia, R. Lázaro, and G. G. Mateos*, *Universidad Politécnica de Madrid*, *Spain*.

Condensed lactoserum (CL) is a by-product of the cheese and milk protein industry that results from the ultrafiltration and pasteurization of liquid whey. In a previous study we observed that the inclusion in the diet of 49% of an extruded mixture of CL and wheat (20:80 on DM basis) had little effect on productive performance but increased the incidence of diarrhea (ID). It was hypothesized that the high electrolyte content of CL (2.1% Na and 6.1% K on DM basis) was responsible for the high ID. After ultrafiltration, the electrolyte content of the original CL was reduced by approximately 30%. The ingredient tested in current trial was an extruded mixture (18:82 on DM basis) of CL low in electrolytes and wheat (CL-W). The CL used had 62.5% lactose and 7.7% CP on DM basis. We studied the effect of increasing levels of CL-W (0, 15, 30, 45, and 60%) in the diet on performance of pigs from 24 to 50 d of age and on apparent total tract digestibility (ATTD) of nutrients at 36 d. All diets were isonutritive except for electrolyte content that increased with increasing levels of CL-W (0.27 to 0.39% for Na, 0.51 to 0.71% for Cl, and 1.04 to 1.12% for K for the control and the 60% CL-W containing diets, respectively). Each treatment was replicated seven times (six piglets) and the trial lasted 26 d. From 24 to 34 d of age an increase in CL-W content of the diet increased ADG (L; P<0.05) and tended to improve ADFI and FCR (L; P<0.10). Inclusion level did not affect productive performance from 34 to 45 d of age but from 45 to 50 d reduced ADFI and improved FCR (L; P<0.05). For the entire experiment no differences were found among treatments for any trait studied. An increase in the level of CL-W increased digestibility of all nutrients (P<0.01) except CP. We conclude that reducing the electrolyte content of the condensed lactoserum will allow its use at levels of up to 10.8% in diets for young pigs.

Key Words: Electrolytes, Milk By–Product, Pig Performance

M229 Relationship between texture and preference of cereal based diets in piglets. D. Solà-Oriol[1], E. Roura*[2], and D. Torrallardona[1], [1]*IRTA, Mas de Bover*, *Constantí (Tarragona), Spain*, [2]*Lucta SA*, *Barcelona, Spain*.

We have reported that diet palatability in piglets depends on the cereal source used and its inclusion level. Although the perception of flavor is a combination of taste and smell, texture could be a sensory input that may play an important role in modifying palatability. In the present study we evaluated the relationship between the preference for different cereals and their textural properties as indicator of mouth feel during eating. A series of double choice preference trials was conducted to evaluate the palatability of different cereals compared to a common reference diet (REF) containing 60% rice. A total of 63 diets were tested (5 trials with 3 cereals at 3 inclusion levels and 3 trials with 3 cereals at 2 inclusion levels). In each trial 144 piglets in 36 pens were given simultaneous access to two diets in two feeding hoppers; one with the REF diet and the other with a diet in which different proportions (15, 30 or 60%) of rice were replaced by the different cereals. Preference in each pen was calculated as the percentage contribution of the cereal diet to total feed intake. Additionally, hardness, fragility, chewing work and adhesiveness of each diet were also measured with a texture analyzer. Pearson's correlation coefficients between preference and texture parameters were analyzed using the CORR procedure of the statistical package SAS. Hardness, fragility and chewing work were negatively correlated with preference (Pearson's correlation coefficients: r = -0.51, -0.52 and -0.38, respectively; P<0.01). On the other hand, no correlation was observed between preference and adhesiveness (P>0.1). In conclusion, reducing the hardness and fragility of feed, as well as reducing its chewing work is a way of improving its acceptability in piglets.

Key Words: Cereal Texture, Palatability, Piglet

M230 Effect of processing cereals on feed digestibility and meal retention in piglets. D. Solà-Oriol* and D. Torrallardona, *IRTA. Mas de Bover*, *Constantí (Tarragona), Spain*.

Cereals with a high nutrient digestibility are recommended for piglet diets. Processing of cereals may improve nutrient availability and digestive function. The present trial studied the effect of cereal processing on the digestibility and proximal GIT digesta flow. Eight diets containing 60% of white rice (raw or cooked), whole oats (raw or steam-rolled with hull removal) whole oats (raw or cooked) or naked oats (raw or micronized) were studied. The apparent digestibilities

for CP (ileal) and DM and OM (ileal and faecal) were measured in 24 pigs fitted with an ileal T-cannula in four consecutive 7d-periods, using TiO_2 as indigestible marker (n=12). The fractional meal retention (FMR) in the proximal GIT (estimated from ileal DM flow) was measured in 16 pigs (4 periods) for 28 h after feeding (n=8). FMR as a function of time was fitted with a modified power exponential function $(y(t)=1-(1-e^{-kt})^b)$ for each pig using the NLIN procedure of the statistical package SAS. The emptying rate (k, %/min) and the extrapolated y-intercept (b) from the terminal portion of the curve were obtained, and used to calculate $T_{1/2}$ (minutes to empty half of the contents) and the lag time (T_{lag}, min) by solving t from $\ddot{y}(t)=0$. The effects of cereal and technological process were analyzed using the GLM procedure of the statistical package SAS. Steam rolling with hull removal of whole oats improved (P<0.001) fecal DM (75.1 *vs*. 83.9) and OM digestibilities (78.6 *vs*. 89.1). Moreover steam rolling of whole oats reduced b (P<0.01), $T_{1/2}$ (783 *vs*. 568; P<0.05) and T_{lag} (639 *vs*. 398; P<0.05). Cooking whole oats reduced the ileal digestibilities of DM (61.4 *vs*. 57.2; P<0.01), OM (64.4 *vs*. 61.0; P<0.05) and CP (77.1 *vs*. 72.7; P<0.001). Cooking rice or micronizing naked oats did not affect digestibility or proximal GIT DM flow (P>0.1). It is concluded that the response to cereal processing depends on both the characteristics of the cereal and the technological treatment considered.

Key Words: Piglet, Processed Cereals, Digestibility

M231 Storage affects the palatability of protein sources in piglet diets. D. Solà-Oriol[1], E. Roura*[2], and D. Torrallardona[1], [1]*IRTA. Mas de Bover*, *Constantí (Tarragona), Spain*, [2]*Lucta SA*, *Barcelona, Spain*.

We have shown previously that protein source affects palatability in piglets. Proteins may be affected during storage due to chemical reactions that alter their composition and the release of volatile compounds. Palatability for skimmed milk (SM), soybean protein concentrate (SPC) and potato protein (PP), before or after storage (300d) was evaluated using a double choice preference test vs. a reference diet (REF). Stored SM was used beyond its expiry date, which was not the case for SPC and PP. Each pen (4 pigs) was offered the choice between the REF diet and a protein source diet (in mash form). Protein sources were included at 5, 10 and 20% by replacing a soy protein product (56% CP) from the REF diet. Each pen was offered the same protein source in three consecutive 4d periods testing the inclusions levels of 5, 10 and 20%, respectively. Preference (percentage contribution of the tested protein diet to total intake) was measured for each pen. The preference values were analyzed taking into account the effects of protein source (P), inclusion level (L), storage (S) and their interactions using the GLM procedures of the statistical package SAS. Significant effects for P (P<0.0001), L (P<0.05), S (P<0.0001), PxS (P<0.001) and LxS (P<0.001) were observed (n=9; SD = 14.4). The preferences of the three protein sources were: SM=39, SPC=32 and PP=12%. Preference decreased with increasing inclusion level: 31, 27 and 24%. Storage reduced preference from 37 to 17%. The interaction PxS indicated different reductions in preference due to S for the different proteins: SM (55 vs. 23 %), SPC (42 vs. 22%) and PP (16 vs. 7%). Finally, the interaction LxS indicates that whereas L affected the preference of the non-stored proteins (45, 39 and 30% at 5, 10 and 20%), it did not affect that of the stored ones (18, 15 and 19% at 5, 10 and 20%). It is concluded that storage reduces the palatability of proteins and that the magnitude depends on the protein source independently of its level of inclusion.

Key Words: Piglet, Protein Sources, Palatability

M232 Cereal nutrient composition correlates with feed oro-sensorial perception in piglets. D. Solà-Oriol[1], E. Roura*[2], and D. Torrallardona[1], [1]*IRTA, Mas de Bover*, *Constantí (Tarragona), Spain*, [2]*Lucta SA*, *Barcelona, Spain*.

The taste sensory system provides information on major nutrients such as carbohydrates or proteins, whereas the olfactory sensory system detects feed volatiles. The combination of both will provide the basis for the diversity of flavors found in the diet. Piglet diets are formulated taking into account the nutritional value of feed ingredients from a proximal analysis. Feed oro-sensorial perception can be related with the nutrient availability or composition. In the present work we studied the direct relationship between cereal nutritional values and feed preference. Eight double choice preference trials (36 pens; 4 animals/pen) were conducted using a diet with 60% of white rice as reference (REF). In each trial, three cereals were tested and a double control test (rice vs. rice) was included. Overall, the preference for a total of 24 cereal based diets was obtained. In the test diets all the rice from the REF diet was replaced by the cereal to be tested. Preference was calculated as the percentage contribution of the test diet to total feed intake. For each cereal, dry matter (DM), ash (ASH), crude fibre (CF), ether extract (EE), gross energy (GE) and crude protein (CP) were measured and digestible energy (DE) content was calculated. The relationship between the preference and the nutritional values measured was determined as a Pearson's correlation coefficients using the CORR procedure of the statistical package SAS. No significant (P>0.1) Pearson's correlation coefficients between preference and DM, ASH, EE, GE and CP were observed, however, CF and DE showed linear relationships with preference (r = -0.61 and -0.54; P<0.01, respectively). In conclusion, DE and CF of cereals are directly associated with their palatability. Further studies are required to assess the role of mouth feel associated with CF. Other nutrient-related compounds may better explain the oro-sensorial perception of feed.

Key Words: Cereals Nutrients, Piglet, Palatability

M233 The body weight-related differences of leptin and neuropeptide Y (NPY) gene expression in pigs. T. Z. Shan*, Y. Z. Wang, J. X. Liu, and Z. R. Xu, *Institute of Feed Science*, *Hangzhou, Zhejiang, China*.

To determine if the body weight change is directly related to allered leptin and neuropeptide Y (NPY) gene expression, we assessed the adipose tissue weight, adipose deposition rate, leptin and NPY mRNA levels, serum leptin concentration in pigs weighted 1, 20, 40, 60, and 90 kg. The results indicate that the weight of adipose tissues and the adipose deposition rates of pigs significantly increased and correlated with BW from 1 kg to 90 kg (P < 0.01). Serum leptin concentration and leptin mRNA levels in omental adipose tissue (OAT) increased from 1 to 60 kg, then decreased from 60 to 90 kg. At 60 kg, the serum leptin concentration and leptin mRNA level significantly increased by 33.5% (P < 0.01) and 98.2% (P < 0.01) respectively as compared with the levels at 1 kg. At 60 kg, the amount of leptin mRNA in

subcutaneous adipose tissue (SAT) was significantly higher than that of 1 and 40 kg animals ($P < 0.05$). NPY gene expression also changed with BW and at 60 kg, the NPY mRNA level significantly decreased by 54.0% ($P < 0.05$) as compared with that in 1 kg. Leptin mRNA in OAT correlated with serum leptin concentrations ($r=0.98$, $P < 0.01$), the body weight ($r=0.82$, $P < 0.05$) and fat deposition rate ($r=0.81$, $P < 0.05$). Our results first reported that the developmental expression of leptin in porcine OAT, PAT and SAT, and first proved that the expression of leptin in OAT was the primary source of circulating leptin. These results could provide some information for gene therapy to manipulate leptin secretion, which will lead to practical methods of controlling appetite and growth in farm animals, thereby regulating and improving efficiency of lean meat production and meat production quality.

Key Words: Pig, Leptin, Neuropeptide Y

M234 *In vitro* screening of plant materials as anti-adhesive agents against *E. coli* K88. S. Galletti[1,2], P. G. van Wikselaar[2], D. Tedesco[1], and P. M. Becker*[2], [1]*University of Milan*, *Milan, Italy*, [2]*Animal Sciences Group of Wageningen UR*, *Lelystad, The Netherlands*.

Due to the ban of antibiotics in feeds, alternative ways are needed to improve animal health and performance. A promising strategy is to supply animals with feed ingredients that act as alternative adhesion sites, thus facilitating bacterial shedding from the gut and reducing colonization and infection. In order to screen the ability of different materials as anti-adhesion agents, a microplate-based *in vitro* method was developed. In this test, different feed/food ingredients and plant by-products from the EU project Safewastes were tested for their binding ability towards the pig pathogen *E. coli* K88. ELISA microplates were coated with suspensions of powdered test ingredients in PBS buffer (Safewastes by-products SW1 to SW11, coffee grounds, konjac gum, locust bean gum, sesame seed expeller, tomato, yeast product) and incubated overnight at 4°C. Quenching was done with 1% BSA in PBS as blocking solution. BSA-coated wells were included as control. After filling with BHI broth, plates were incubated at 37°C in the reading chamber of a photometer. The O.D. was automatically read at a wavelength of 650 nm at 15 min intervals. All OD data were processed by non-linear regression analysis (P-NLIN, SAS). Parameters of the sigmoidal growth curves obtained were analysed by GLM procedure (SAS). The test principle was based on an inverse relationship between initial cell densities and the appearance of growth: The higher adhering cell numbers are, the shorter are the detection times of bacterial growth. Testing of different ingredients resulted in rankings according to their adhesive capacity towards *E. coli* K88, the sorting being based on the respective detection time of cell growth. Detection times ranged from 2.43 h (SEM=0.103 h) for the first position (yeast product) to 5.76 h (SW6) for the last one, being 4.47 h for BSA as a control. The yeast product, SW11, sesame seed expeller and SW7 had significantly lower detection times with respect to control ($P<0.05$), and therefore were considered promising anti-adhesive agents against *E. coli* K88. These ingredients were destined for further testing and validation in an *in vivo* trial on challenged pigs.

Key Words: Anti-Adhesion, *E. coli* K88, Plant Materials

M235 Dose response trials of an enhanced milky flavor in a pig nursery program 1: linear and quadratic effects on piglet performance. E. Roura*[1], I. R. Ipharraguerre[1], and D. Torrallardona[2], [1]*Lucta S.A.*, *Barcelona, Spain*, [2]*IRTA*, *Centre Mas de Bover, Constantí, Spain*.

Two trials were conducted in newly weaned 26d-old pigs to study the effect of the addition of an enhanced milky flavor to feed with and without its water-soluble formulation applied to drinking water. In trials 1 and 2 respectively, 192 and 132 piglets (*Landrace* × *Pietrain*) were distributed in four or three blocks of 12 pens according to initial body weight. Pigs were offered free access to 1 of 6 diets differing only in the flavor dose (trial 1: 0, 250, 500, 750, 1000 and 1500 ppm and trial 2: 0, 1000, 2000, 3000, 4000 and 5000 ppm). Additionally, half of the pens were offered flavored water during the first 28 (trial 1) or 14 (trial 2) days postweaning. Single effects of feed treatments for the non-flavored water groups are reported here. At the end of the pre-starter phase (0-14 d postweaning) of trial 1, animals in the 1500 ppm group had the numerically highest ADG (121 g/d) and ADFI (180 g/d). When compared to the control diet, all diets treated with flavor improved ($P < 0.05$) feed efficiency during the starter phase (14-28 days postweaning), but overall (0-28 d postweaning) only the diet treated with 1500 ppm of flavor improved ($P < 0.05$) ADG. However, when only equidistant doses were analyzed (0, 500, 1000 and 1500 ppm), a significant ($P < 0.10$) linear effect was observed for ADG throughout the 28 days. In trial 2 flavor addition in feed resulted in increases in ADG in the pre-starter phase ($P < 0.01$) and overall ($P < 0.05$). At the end of the trial, feed treated with 1000, 2000, 3000 and 5000, but not 4000, ppm of flavor increased ($P < 0.05$) ADG by 21, 21, 19 and 26% respectively compared with the control. In trial 2, the response to increasing flavor dosage was quadratic ($P < 0.01$). It is concluded that adding the enhanced milky flavor to feed results in higher ADG in weanling pigs and that such response is linear at low doses (up to 1500 ppm) but becomes quadratic for the high doses (1000 through 5000 ppm).

Key Words: Flavor, Feed Intake, Piglet

M236 Dose response trials of an enhanced milky flavor in a pig nursery program 2: benefits of flavoring water up to 14 d. E. Roura*[1], I. R. Ipharraguerre[1], and D. Torrallardona[2], [1]*Lucta S.A.*, *Barcelona, Spain*, [2]*IRTA*, *Centre Mas de Bover, Constantí, Spain*.

Two trials were conducted in newly weaned 26-d-old pigs to study the effect of the addition of an enhanced milky flavor to feed and water. In trial 1 and 2 respectively, 192 and 132 piglets (*Landrace* × *Pietrain*) were distributed in four or three blocks of 12 pens according to initial body weight. Pigs were offered free access to 1 of 6 diets differing only in the flavor dose (trial 1: 0, 250, 500, 750, 1000 and 1500 ppm and trial 2: 0, 1000, 2000, 3000, 4000 and 5000 ppm). In addition, half of the pens were offered flavored water (3000 ppm) during the first 28 (trial 1) or 14 (trial 2) days postweaning. In trial 1, adding flavor to water numerically increased ADG by 6% in the pre-starter phase (0-14 d postweaning). However, during the starter phase (14-28 days postweaning) an interaction for ADG ($P < 0.1$) and ADFI ($P < 0.08$) between the addition of flavor to water and feed was observed. In this phase offering flavored water to animals that consumed non-flavored feed increased ADG by 18% and ADFI by 20% compared with pigs offered non-flavored water and feed (negative control). However, offering flavored water to animals that consumed flavored feed did not improve further these parameters. A similar interaction ($P < 0.09$) was

observed for ADFI for the overall trial (0-28 days postweaning). In trial 2, water treatment did not result in significant effects or interactions. Nevertheless, among the water flavored groups, ADG was numerically higher for dietary low doses 0, 1000 and 2000 and lower for dietary high doses 3000, 4000 and 5000 when compared to the non-flavored water groups. It is concluded that addition of an enhanced milky flavor to feed and/or water improves piglet growth in the pre-starter phase. Furthermore, benefits from flavoring feed and water for 14 d postweaning appear to be additive at doses not higher than 2000 ppm in feed.

Key Words: Flavor, Water Intake, Piglet

M237 Response of enterotoxigenic *Escherichia coli* K88 infected piglet jejunal segments to extracts derived from degradation of soybean and canola meal polysaccharides by carbohydrase enzymes. E. Kiarie*, B. A. Slominski, and C. M. Nyachoti, *University of Manitoba*, *Winnipeg, MB, Canada*.

Enterotoxigenic *E. coli* K88 (ETEC) infection results in fluid secretion and electrolyte losses in piglet small intestine. In the present study, effect of perfusing extracts from soybean (SBM) and canola (CM) meals containing polysaccharide hydrolysis products on net absorption was investigated using ETEC-infected jejunal segments. Extracts were generated by incubation of ethanol-extracted SBM and CM with a combination of polysaccharide degrading enzymes including pectinase, cellulase, mannanase, xylanase, glucanase and galactanase activities. Following incubation, the slurries were centrifuged and the supernatants were mixed with absolute ethanol to produce 2 fractions: 80% ethanol-solubles (ES) and 80% ethanol insolubles (EI). Eight pigs weaned at 21 d of age and fed a commercial starter diet for 7 d were held under anesthesia and 10 segments were prepared in jejunum of each pig. Extracts from SBM and CM were studied in 2 independent experiments involving 4 piglets each in which 2 factors were studied: extract type (EI vs. ES) and time of ETEC infection (before perfusion vs. 30 min after perfusion). Pairs of jejunal segments (1 noninfected and the other ETEC-infected) were perfused simultaneously with different extracts during a 7.5 h. In each piglet 1 pair of segments was perfused with saline as a control. Net absorption of fluid and solutes was determined. In both Experiments ETEC-infected segments perfused with saline had the lowest ($P < 0.05$) net fluid and solutes absorption compared with SBM and CM extract. Interaction ($P < 0.001$) between extract type and time of infection was only evident for SBM in which case perfusing ES extracts 30 min before infection resulted in high fluid (835±22 vs. 428±51 µl/cm^2) and solutes (259±7.1 vs. 133±16 µOsmol/cm^2) absorption compared with ETEC infection before perfusion. In conclusion, SBM and CM polysaccharide hydrolysis products were beneficial in maintaining fluids and solutes balance during ETEC infection.

Key Words: Carbohydrase Enzymes, Enterotoxigenic *E. coli* , Piglet

M238 Performance, immune response and intestinal microbial populations of weanling pigs fed diets containing a specially prepared potato protein. Z. Jin[1], Y. X. Yang[1], J. Y. Choi[1], P. L. Shinde[1], T. W. Hahn[1], H. T. Lim[1], Y. K. Park[2], K. S. Hahm[2], and B. J. Chae*[1], [1]*Kangwon National University*, *Chuncheon, Kangwon-Do, Republic of Korea*, [2]*Chosun University*, *Kwangju, Republic of Korea*.

A total of 280 weanling pigs (Landrace × Yorkshire × Duroc) were used in a 28-d growth study to investigate the effects of feeding a potato protein (PP) on growth performance, immunity, and bacterial populations in large intestine. These weanling pigs (initially 6.42±0.74kg and 23±3 d of age) were randomly allotted to five treatments on the basis of their body weight, each treatment comprised of four pens and each pen had 14 piglets. Dietary treatments included: NC (negative control; basal diet); PC (positive control; basal diet + 0.15% apramycin and 0.10% colistin sulfate); PP (basal diet added with 0.25, 0.50 and 0.75% of potato protein). PP was extracted from a special potato breed (*Solanum tuberosum* L cv. Gogu) containing antimicrobial peptides (Potamin-1). PC treatment showed significantly ($P<0.05$) higher ADG than PP, but PP showed linear improvement ($P<0.05$) in ADG and ADFI. The feeding of PP to weanling pigs had no effect ($P>0.05$) on their immune response. The total anaerobic bacteria in caecum and rectum, *Staphylococcus* in caecum and *E. coli* in colon were significantly ($P<0.05$) lower in PC than PP. Similarly, PP had lower (linear, $P<0.05$) total anaerobic bacteria and *Staphylococcus* in caecum, rectum and colon, and *E. coli* in colon than NC, respectively. These results suggest that PP used in this experiment can be a candidate as an animal growth promoter in weanling pigs.

M239 Decreasing postnatal skeletal muscle protein synthetic activity is associated with a reduction in the expression of S6K1 in fed young pigs. X Yang* and M. Z. Fan, *Centre for Nutrition Modeling, University of Guelph*, *Guelph, Ontario, Canada*.

The objective of this study was to investigate the association between developmental changes of fractional protein synthesis rates (FSR) and the expression of ribosomal protein S6 kinase 1 (S6K1) in the skeletal muscle of fed young pigs. Thirty-six purebred Yorkshire gilts were used at the ages of d 1, 4, 6, 12, 20 and 28 (1 wk post-weaning). Piglets were given intraperitoneally a flooding dose of Phe containing L-[ring-2H5]Phe in saline. Plasma and loin muscle samples at 30 min post-injection were collected for the determination of tracer Phe enrichment by GC-MS. Total and phosphorylated (Thr 389) forms of S6K1 were examined by Western blot. The FSR of skeletal muscle decreased linearly ($P<0.05$) from d 1 (20.8 %/d) to day 28 (5.3 %/d). Linear (total and the phosphorylated forms) and quadratic (phosphorylated form) decreases in S6K1 abundances ($P<0.05$) were observed, and the changes were correlated ($P<0.05$; $r= 0.69$ and 0.59 for total and phosphorylated S6K1, respectively) with FSR at the ages of d 1 to 28. Furthermore, the ratio of the phosphorylated S6K1 to total S6K1 abundance was linearly and quadratically decreased ($P<0.05$) from d 1 to 28 in the fed young pig. These results indicate that the decreasing FSR in skeletal muscle is associated with a reduced expression of S6K1 in fed pigs during the early postnatal growth.

M240 Effect of plant extracts on growth performance and immune status in weaning pigs. H. J. Jung*[1], J. C. Park[1], Y. H. Kim[1], S. Y. Jee[1], S. D. Lee[1], H. D. Jang[1], H. J. Kim[2], I. H. Kim[2], H. K. Moon[1], S. W. Kim[3], I. C. Kim[1], and S. J. Lee[1], [1]*National Livestock Research Institute*, *Cheoan, Chungnam, Republic of Korea*, [2]*Dankook*

University, *Cheoan, Chungnam, Republic of Korea*, [3]*Texas Tech University*, *Lubbock*.

This study was conducted to investigate the effects of plant extracts on growth performance, immune status in weaning pigs. A total of 125 crossbred ([Landrace×Yorkshire]×Duroc) pigs with an initial body weight of 7.05 ± 0.07 kg were used in this 6-weeks experiment. Pigs were allotted to five treatments (five replicates per treatment and five pigs per pen) according to a randomized complete block design. Dietary treatments were : 1) NC (negative control; basal diet), 2) PC (positive control diet; NC diet + 0.1% antibiotics), 3) PL 1 (Control diet + 0.2% Mistole), 4) PL 2 (Control diet + 0.2% Stevia), 5) PL 3 (Control diet+0.2% SMUS®). In overall trial, ADG was increased PL 3 treatment compared with NC and other PL treatment ($p<0.05$). However, blood traits were not affected by treatments. The morphology of small intestine was not affected by pigs fed diets with plant extracts, but villi height and crypt depth of small intestine improved significantly in PL 3 treatment compared with other treatments ($p<0.05$). In conclusion, plant extracts tended to improve growth performance, morphology of small intestine compared with the pigs fed the NC and PC diets.

Key Words: Plant Extracts, Immune, Weaning Pigs

M241 Effect of probiotics in lactating sows diets on sows and litter performance. A. Castellanos A*[1], J. A. Renteria F[2,1], J. A. Cuaron I[2,1], and C. A. Mejia G[2,1], [1]*FES-C UNAM*, *Ajuchitlan, Qro*, [2]*CENIDFA-INIFAP*, *Ajuchitlan, Qro*.

To evaluate the effect of two probiotics on sow and litter performance, 562 sows (257 ± 33 kg) were fed four lactation diets. A Control diet (C) formulated to satisfy the requirements of lactating sows (NRC, 1998) based on sorghum-soy bean meal, a 2nd diet (B) similar to C with the addition of 0.5 kg of a probiotic containing the combination of two bacteria Bacillus Licheniformis and B. subtilis, a 3rd diet (Y) similar to C plus the addition of 3 kg of a probiotic containing Saccharomyces cerevisiae, a 4th diet (BY) similar to C plus the addition of both probiotics. Sows were fed the diets starting on day 100 of gestation and until weaning. Response variables were; feed intake during lactation (total TFI and ADFI), number and weight of born pigs, number and weight of weaned pigs, and weight lose during lactation. Experimental design was a CRB whit factorial arrangement 2x2, the experimental unit was the sow and its litter, and block was the maternity building. Data were analyzed using the GLM of SAS (9.1.3). In TFI during lactation an interaction yeast*bacteria was found ($P < 0.05$, SEM= 2.54) 99.2, 93, 95.2, 101.3 kg for C, B, Y, and BY respectively. For litter weight at weaning an interaction yeast*bacteria was observed ($P = 0.09$, SEM = 1.8375) 54.3, 53.8, 53.3, 60 kg, for C, B, Y and BY respectively. For the number of pigs wean a B effect was observed, ($P < 0.04$, EEM = 0.137) 9.62 vs. 9.12. While for the average weight of wean pigs a Y effect was observed ($P < 0.001$, SEM= 0.079) 6.2 vs. 5.6. For sow weight lose during lactation an interaction yeast*bacteria was observed ($P<0.06$, SEM= 5.45) 19.18, 42.01, 22.42, 28.86 kg; C, B, Y and BY respectively. In conclusion, the combination of both probiotics used in this experiment resulted in an improved litter performance, without affecting sow performance. The inclusion of bacteria probiotic in lactating sows diets increased the number of weaned pigs. The inclusion of yeast in lactating sows diets increasedthe average weight of weaned pigs.

Key Words: Sow, Probiotics, Performance

M242 Evaluation of Concept PR 100 in diets for nursery pigs. J. M. DeRouchey*[1], E. J. Wiedmann[1], M. D. Tokach[1], R. D. Goodband[1], J. L. Nelssen[1], S. S. Dritz[1], and J. Whitehead[2], [1]*Kansas State University*, *Manhattan, KS*, [2]*Concept Nutrition, Ltd*, *Preston, UK*.

Concept PR 100 (CNPR), a plant based protein ingredient with added synthetic amino acids and nucleic acids, was compared to spray-dried animal plasma (SDAP) in nursery pig diets. Two separate experiments, each utilizing 180 weanling pigs (initially 5.51 and 5.15 kg for Exp. 1 and 2, respectively and 21 d of age) were used in 28-d feeding trials. In Exp. 1, five experimental diets were fed which included: 1) Control (no specialty protein source); 2) 2.5% SDAP; 3) 5.0% SDAP; 4) 2.5% CNPR; and 5) 5.0% CNPR. In Exp. 2, diets 1, 2, and 3 were similar to Exp. 1, while a modified CNPR was used at 2.5% and 5.0%, respectively for the 4th and 5th treatment diets. In Exp. 1 from d 0 to 14, pigs fed increasing levels of SDAP or CNPR had improved (linear and quadratic, $P<0.001$) ADG and ADFI. Pigs fed increasing levels of SDAP or CNPR also had improved (linear, $P<0.001$) G:F. When comparing the mean of pigs fed diets containing SDAP versus CNPR, pigs fed SDAP had greater ($P<0.002$) ADG, ADFI, and BW at d 14 compared to pigs fed CNPR. Overall, (d 0 to 28), pigs fed increasing SDAP or CNPR had greater ADG, ADFI and final BW (linear, $P< 0.004$) than pigs fed the control diet. There was no overall growth differences between pigs fed SDAP and CNPR ($P>0.11$). For Exp. 2 from d 0 to 14, pigs fed increasing SDAP had improved (linear, $P<0.01$) ADG, ADFI, G:F. Pigs fed increasing CNPR had improved (quadratic, $P<0.001$) G:F. However, pigs fed SDAP had greater ($P<0.03$) ADG, ADFI, and BW at d 14 compared to those fed CNPR. Overall (d 0 to 28), pigs fed increasing levels of SDAP had greater ($P<0.03$) ADG and tended to have improved ($P<0.08$) ADFI and G:F. Also, pigs fed increasing levels of CNPR had improved (quadratic, $P<0.009$) G:F. There was no overall differences in growth between pigs fed SDAP and CNPR ($P>0.22$). These data indicate that pigs fed SDAP compared with CNPR generally had greater performance during the test period, however these differences were not found at the conclusion of the studies.

Key Words: Swine, Protein Source, Growth

M243 The effect of American alligator (*Alligator mississippiensis*) serum on growth performance of weanling pigs. J. T. Compton*, M. E. Merchant, T. S. Shields, and F. M. LeMieux, *McNeese State University*, *Lake Charles, LA*.

Antibiotic use in the food animal industry is a major concern. The use of antibiotics in animal feed is a common practice. Of the total antibiotic production for both human and animal purposes, approximately 25% is used for food animals and 90% of that portion has been reported as being used in subtherapeutic concentrations (Lehenbauer et al., 2002). Subtherapeutic use in these animals is mainly for improved feed efficiency and growth. Subtherapeutic use in farm production animal diets has been a common practice since 1946 when the addition of subtherapeutic levels of antimicrobials was found to enhance growth in poultry (Moore et al., 1946). Today, consumers are concerned of the potential of bacteria resistance to these antibiotics. If a cost efficient antimicrobial substitute for these traditional antibiotics can be found producers and consumers will benefit. Alligator serum has exhibited antimicrobial properties in vitro (Merchant et al., 2003, 2004, 2005) decreasing bacterial and *Escherichia coli* growth. To our knowledge no in vivo research had been performed to date. The objective of this study was to evaluate the effect of 0.5% alligator serum (AS) on growth

performance of nursery pigs fed diets with or without antibiotics. Weanling pigs (n = 100; 7.44 kg BW) were assigned to one of four dietary treatments with six replications per treatment and three, four, or five pigs per pen. The ADG, ADFI, and G/F were measured at d 7, 14, and 21. Pigs fed diets containing AS had increased ($P < 0.05$) ADG from d 0 to 7 and d 14 to 21, and overall when compared with pigs fed diets without antibiotic.

Key Words: Pigs, Alligator, Antibiotic

M244 Post–weaning development of the microbiota composition and activity in piglets fed diets with wheat bran, wheat middlings or sugar beet pulp. F. Molist*, A. Gómez de Segura, E. G. Manzanilla, J. Gasa, R. G. Hermes, and J. F. Pérez, *Universitat Autònoma de Barcelona*, *Spain*.

To determine the effect of dietary fibrous ingredients on intestinal microbial population and activity, 48 early–weaned (24–25 days) pigs were divided into six dietary treatments: a standard diet (STD) based on corn, barley and soybean protein; or high fibrous diets obtained by replacing some major ingredients of STD with 8% Wheat bran (WB), 8% Wheat middlings (WM), 6% Sugar beet pulp (SBP), 4% Wheat bran and 3% Sugar beet pulp (WB–SBP), or 4% Wheat middlings and 3% Sugar beet pulp (WM–SBP). After 10 and 15 days receiving ad libitum the experimental diets, animals were weighed, sacrificed, and digesta samples from the caecum, colon and rectum were taken. Short–chain fatty acid (SCFA) concentration was determined and microbial counts for enterobacteria and lactobacilli were determined by quantitative–PCR. Inclusion of WB promoted increases in the weight gain of the animals at day 15 (142, 1256, 136, 1164, 700, 1187 g for STD, WB, WM, SBP, WB–SBP, WM–SBP). Wheat bran, either at 8% or 4% promoted a decrease in enterobacteria counts in the caecum (11.1, 9.9, 11.7, 10.8, 8.2 and 11.6 log 16 S rDNA gene copies/g FM) and feces (10.3, 9.2, 11.5, 10.9, 8.7, 11.9 log 16 S rDNA gene copies/g FM for STD, WB, WM, SBP, WB–SBP, WM–SBP, respectively, $P \leq 0.001$) of piglets 15 days after weaning. No significant differences were observed on the lactobacilli counts at d15 or on the microbial counts at d10. The SCFA concentrations increased significantly from d10 to d15 in the caecum and feces. Diets supplemented with SBP decreased the isoacids (isobutyrate and isovalerate) proportions in the caecum of piglets at day 10 after weaning ($P \leq 0.003$) and in the feces at day 15 post–weaning ($P \leq 0.004$), while the inclusion of WB significantly increased the percentage of butyrate in the caecum at d15 (7.14, 14.22, 5.39, 4.63, 12.36, 11.48 % for STD, WB, WM, SBP, WB–SBP, WM–SBP, respectively, $P \leq 0.001$). Results suggest a beneficial shift in the composition and activity of the hindgut microbial population of early weaned piglets fed on diets supplemented with WB.

Key Words: Piglets, Dietary Fiber, Microbial Population

M245 Dietary preference for methionine sources in 8 to 25-kg nursery pigs. T. Ettle[1], M. Rademacher[2], F. X. Roth[3], and R. L. Payne*[2], [1]*BOKU University*, *Vienna, Austria*, [2]*Degussa*, *Hanau, Germany*, [3]*Technical University of Munich*, *Munich, Germany*.

Feed intake during the nursery period of growth is crucial to a pig's growth and development. As such, there is considerable interest about how the ingredients used in a typical nursery pig diet influence feed intake, and if a pig can demonstrate a preference for a particular ingredient. Therefore, the objective of this study was to investigate the dietary preferences of nursery pigs given the choice of diets supplemented with either DL-Met (DLM, 99%) or liquid Met hydroxy analogue (MHA-FA, 88%), which are the commonly used sources of supplemental Met. Mixed-sex pigs with an initial body weight of 8.1 ± 1.0 kg were randomly subdivided into 8 groups of 12 animals each for a 5-wk choice feeding trial. Groups 1 through 4 were fed one of the following treatments: 1) a Met-deficient basal diet (0.25% Met, 0.32% Cys, and 1.36% Lys); 2-3) diet 1 plus 0.1 or 0.2% DLM; or 4) diet 1 plus 0.113% MHA-FA. Treatment groups 5 through 8 were able to choose from pairs of treatment diets, and their treatments were: 5) diet 1 plus 0.1% DLM or 0.113% MHA-FA; 6) diet 1 plus 0.1% DLM or 0.152% MHA-FA; 7) diet 1 plus 0.2% DLM or 0.225% MHA-FA; or 8) diet 1 plus 0.2% DLM or 0.305% MHA-FA. Pigs fed treatments 5 and 6 had higher ($P < 0.05$) ADFI than those fed the Met-deficient basal diet. Pigs in treatment groups 2 through 8 had improved ($P < 0.05$) ADG and feed:gain compared with those fed the Met-deficient basal diet. In the non-choice groups (treatments 1 through 4), feed intake was not influenced ($P > 0.05$) by Met source or concentration. However, in the choice-fed groups, pigs fed treatments 5, 7, and 8 consumed a higher percentage ($P < 0.05$) of their total feed intake from the diets containing DLM than they did from the diets containing liquid MHA-FA. In this trial, pigs expressed a dietary preference for DL-Met when given a choice of supplemental Met sources. Furthermore, this preference may be the result of sensory properties of the diets offered to the nursery pig.

M246 Hormonal response of bulls to glucose challenge in a segregating family structure. R. Pfuhl*, O. Bellmann, F. Schneider, C. Kühn, and K. Ender, *Research Institute for the Biology of Farm Animals (FBN)*, *Dummerstorf, Germany*.

Cattle of the accretion type (Charolais) and the secretion type (Holstein) differ in their hormonal regulation of nutrient utilization. To deepen the insight in the physiological backgrounds, 65 F_2 cross bulls from five Charolais grandfathers and Holstein grandmothers were investigated to test a potential segregation of their glucose-induced insulin response. Growing bulls showed the highest hormonal activity at the age of eight months due to the onset of puberty. Thus, bulls of five families were subjected to a glucose challenge test at this age. Every bull received a glucose solution intravenous (1g/kg $BW^{0.75}$) via catheter into the jugular vein. Blood samples were taken in the same way before and 7, 14, 21 and 28 minutes after glucose administration. Serum insulin and glucagon concentrations as well as the glucose concentration in the whole blood were recorded. The data were evaluated with the GLM procedure of SAS. All tested bulls showed a characteristic glucose clearance curve ($P=0.9832$). In contrast, the insulin response curve differed and showed high variation between and within the five families. The average serum insulin concentration of family 4 reached greatest values and decreased slower, than in the other families.

Significant differences between the families were found in the serum glucagon concentrations before (P=0.025) as well as 21 minutes (P=0.0098) and 28 minutes (P=0.0063) after glucose infusion. Family 4 showed also the highest average serum glucagon levels before (P=0.05), 7 minutes (P=0.0806), 21 minutes (P=0.0098) and 28 minutes (P=0.0063) after glucose infusion. In conclusion, glucose-challenge test revealed a segregation of energy utilizing mechanisms in F_2 cross bulls. Of particular concern are the bulls of family 4, which shows criteria of a possible insulin resistance and will be subjected to further investigations.

Key Words: Glucose, Insulin, Cross Bulls

M247 Growth hormone on metabolic profile of Nellore bulls of two different ages. L. S. Amorim*[1,4], C. A. A. Torres[1], E. A. M. Amorim[1,4], J. M. Silva Filho[2], J. D. Guimaraes[1], M. M. N. F. Oliveira[3], K. Zorzi[1], and G. R. Carvalho[1], [1]*Federal University of Vicosa*, *MG, Brazil*, [2]*Federal University of Minas Gerais*, *Belo Horizonte, MG, Brazil*, [3]*University of Diamantina*, *MG, Brazil*, [4]*Colorado State University*, *Fort Collins*.

The objective of this study was to evaluate the effects of Growth Hormone (recombinant bovine Somatotropin (r-bST)) on the profiles of blood metabolites from two different ages of Nellore bulls. Sixteen bulls were allocated in a factorial arrangement 2 × 2 (ages: young and adults; and r-bST: 0 and 500 mg) with four animals per treatment. The mean age of the young and adult animals was of 13.37 and 20.62 months. Four animals per treatment received every 14 days, saline solution or 500 mg of r-bST, with a total of nine injections per animal, during a 120 day experiment. Bulls were fed corn silage and concentrated diet on the base of corn crumb and soy, twice a day, supplied in individual stalls. Blood was collected every three days for metabolic evaluation. The datas were analized by ANOVA using Tukey test for to compare medias. The statistical analyses of the data were done for three applications, considering three periods (period 1, 2 and 3). The non-esterified fatty acid (NEFA) concentrations were analyzed by week. Serum cholesterol, total protein and glucose levels were affected by period and by treatment (P<0.05). The NEFA levels were affected by the weeks of collection (P <0.05) but not by r-bST treatment (P>0.05). The GH change blood metabolic of young and adult bulls.

Key Words: Bulls, Growth Hormone, Metabolic

M248 Leptin expression in early- and late-maturing *Bos indicus* heifers. L. F. P. Silva*[1], A. Vaiciunas[1], and L. L. Coutinho[2], [1]*University of São Paulo*, *Pirassununga, SP, Brazil*, [2]*University of São Paulo*, *Piracicaba, SP, Brazil*.

The process of maturation of the hypothalamus and the metabolic signal that triggers puberty are not well understood. Clearly, body weight and adiposity influence age at puberty, and leptin has been proposed to have a permissive role on puberty. Our objective was to test whether early-maturing *Bos indicus* heifers had a higher expression of leptin mRNA in adipose tissues. Among a population of 500 heifers between 20 and 25 months of age, 100 heifers were selected based on breed attributes (Nelore), month of birth, and body weight (280 to 300 kg). These 100 heifers were scored as prepubertal or pubertal according to the presence or not of a palpable corpus luteum (CL). Ten heifers without a CL and ten heifers with a CL received a prostaglandin injection, and according to visual observation of heat and rectal palpation, 6 prepubertal and 6 pubertal heifers were selected for the experiment. These 12 heifers were slaughtered and samples of subcutaneous, omental and perirenal adipose tissues were collected and frozen in liquid nitrogen. Expression of leptin was quantified by real-time PCR using the ribosomal protein RP-L19 as a reference gene. Heifers that attained puberty earlier had significant higher expression of leptin by the adipose tissues ($P<0.05$), and there was a significant treatment by tissue interaction. On average, leptin expression was increased 14.7-fold in early-maturing heifers. Early-maturing heifers had higher leptin expression in the omental fat depot (90-fold increase) and in the subcutaneous fat depot (39-fold increase), while there was no effect on leptin expression in the perirenal fat depot (1.5-fold increase). Regardless of the treatment effects, leptin expression was higher in the perirenal fat depot than in the other two tissues ($P<0.01$). Leptin expression was 115-fold higher in the perirenal fat depot then in the other two depots. These results support the idea that circulating levels of leptin is an important signal for the initiation of puberty, and suggest that heifers with higher leptin expression in the adipose tissue could attain puberty earlier, with a lighter body weight.

M249 Changes in antioxidant status in beef cows during weight loss and weight maintenance. K. M. Brennan*, J. J. Michal, R. Collins, and K. A. Johnson, *Washington State University*, *Pullman*.

To investigate the impact of β-oxidation on the enzymes, metabolites and genes that are involved in regulation of mitochondrial antioxidant status, Angus and Angus-cross cows (n=26) were examined during weight loss and weight maintenance or small weight gain. The weight maintenance (M) period occurred after weaning. The weight loss and fat mobilization period (L) occurred during lactation. Cows were weighed and condition scored weekly during the 60d period. Tail vein blood samples were collected at both intake levels at the end of the period and immediately processed to yield serum and red blood cell lysate. Serum nonesterified fatty acid (NEFA) concentrations were measured spectrophotometrically using NEFA-C (HR) kit (Wako Chemicals). Superoxide dismutase activity (SOD), an antioxidant enzyme, in red blood cell lysate was measured spectrophotometrically using a Cayman chemical assay kit. During L, cows lost approximately 77 kg of body weight (P>.0001). At the M level of intake cows maintained or gained a slight amount of body weight (approximately 13 kg). Serum NEFA concentration was significantly higher during L than M (P <.001). Average serum NEFA levels at L and M were 0.511± 0.167 and 0.102 ± .031, respectively. SOD activity in red blood cell lysate was greater in L than M (P<.025). Mobilization of body fat, as reflected by body weight loss and serum NEFA levels, results in greater antioxidant activity in red blood cells.

Key Words: Beef Cattle, Antioxidants, Oxidative Stress

M250 Plasma ghrelin concentrations of beef cattle consuming a similar amount of dietary energy supplied by different dietary ingredients. A. E. Wertz-Lutz*[1], J. A. Clapper[1], J. S. Thurlow[1], D. C. Beitz[2], and A. Trenkle[2], [1]*South Dakota State University*, *Brookings*, [2]*Iowa State University*, *Ames*.

Previous research demonstrated that varying caloric intake by manipulating DMI of high-grain diet influenced plasma ghrelin concentrations in cattle. To determine if dietary ingredient composition influenced plasma ghrelin, insulin, NEFA, and GH concentrations when caloric intake was similar, five steers (589±18.1kg) were used in a crossover design. Dietary treatments were 50% hay-50% concentrate **(HAY)** offered at an amount that met the steer′s maintenance requirement plus supplied an additional 3.5 Mcals of NEg daily, or a diet composed of 10% hay-90% concentrate but limit-fed to achieve a caloric intake similar to that of the HAY steers **(LFC)**. On d 21 following initiation of the dietary treatment, serial blood samples were collected via indwelling jugular catheter at 15-min intervals. Following period 1, steers were weighed, dietary treatments were switched between groups, and intake amounts were recalculated. Sampling period 2 was initiated as described for period 1. Plasma samples were assayed for ghrelin, insulin, GH, and NEFA, and, subsequent to analyses, data were pooled by hour for statistical analyses. Hormone data were analyzed statistically as repeated measures in time using the MIXED procedure of SAS. The NEg was similar between treatment groups (3.5 ± 0.04 Mcals NEg/d). However, a higher DMI (P≤0.001) was required by HAY steers compared with LFC steers (9.4 vs. 7.2± 0.06 kg) to achieve the same caloric intake. Plasma ghrelin concentrations were similar (P=0.12) for HAY and LFC steers (115 vs. 107±3.3 pg/mL), and plasma GH, NEFA, and insulin concentrations were similar regardless of dietary treatment. These data are consistent with the hypothesis that ingredient composition and quantity of DM consumed do not influence plasma ghrelin concentrations of steers when caloric intake is similar and steers are in positive energy balance.

Key Words: Beef Cattle, Energy Intake, Ghrelin

M251 Impact of metabolic acidosis on amino acid metabolism in lambs. S. L. Greenwood*[1], T. C. Wright[1], J. Gilmore[1], J. E. Las[1], N. E. Odongo[1], O. AlZahal[1], A. K. Shoveller[1], J. C. Matthews[2], and B. W. McBride[1], [1]*University of Guelph*, *Guelph, Ontario, Canada*, [2]*University of Kentucky*, *Lexington*.

Feeding high amounts of concentrate to ruminants commonly leads to increased production of volatile fatty acids (VFAs) and lactate in the rumen. Metabolic (systemic) acidosis occurs in ruminants as a result of increased absorption of these VFAs and lactate. Furthermore, metabolic acidosis results in high levels of protein degradation of the skeletal muscle in many species, a response thought to alter the concentration of plasma L-amino acids to increase plasma buffering capacity and renal catabolism of glutamine. The objective of this study was to characterize the effect of metabolic acidosis on plasma amino acids of lambs. Ten fully fleeced Rideau-Arcott wether lambs (54.3 ± 6.7 kg body weight) were randomly allocated to balanced treatment groups that were fed diets that contained either 1) a canola meal supplement (control; CS) or 2) a HCl-treated canola meal (NutriChlor) supplement to induce metabolic acidosis (AS). Lambs were fed daily at 0700 and 1100 h. Blood samples were collected daily between 1100 and 1130 h throughout the experimental period (d 0 to d 10) via jugular catheters and were pooled within animal from d 4 to d 10 for analysis. Lambs were slaughtered on d 11 and kidney, liver, and muscle samples were collected from each animal. Plasma serine (19%), glycine (32%), and glutamine (14%) concentrations were increased (P<0.05) in acidotic lambs compared to control animals. This pattern and magnitude of altered plasma amino acid profiles suggests that protein degradation was increased in acidotic sheep. Ongoing Northern blot analyses to identify altered expression of components of the ubiquitin protein degradation system by kidney, skeletal muscle, and liver should reveal tissue-specific mechanisms responsible for the observed shifts in intra-organ amino acid metabolism. These findings suggest that future formulation of high-starch diets need to compensate for metabolic acidosis-induced shifts in amino acid metabolism.

M252 Palmitate and CLA isomer effects on gene expression in MDBK cells. B. J. Thering*, M. Bionaz, and J. J. Loor, *University of Illinois*, *Urbana*.

A time course experiment was conducted to evaluate effects of 150 µM of Wy-14643 (WY, PPARα specific agonist) and 16:0 on CPT1A, ACADVL, ACSL1, LPIN1, PPARGC1A, SREBF1, and RPS9 (reference gene) expression by qPCR. Two replicate cultures were harvested at 0, 6, 12, 18, and 24 h. ANOVA using MIXED was used for statistical analysis. In a second experiment cells were treated for 18 h with 16:0 (150 µM), c9t11CLA (200 µM), and t10c12CLA (200 µM) plus control (CTR). Each duplicate treatment was pooled for microarray analysis using a 13K-gene bovine oligoarray platform using a dye-swap design. Microarray data were analyzed with a ≥2-fold change cut-off relative to CTR. In the time course experiment, expression of all genes except SREBF1, increased ($P < 0.05$) over time with both WY and 16:0. ACSL1 and LPIN1 experienced a treatment × time effect, such that expression of both genes peaked between 6 and 12 h with 16:0, and at 18 h with WY. CPT1A and ACADVL reached peak expression at 18 h and PPARA and PPARGC1A at 24 h. Except for CPT1A and PPARGC1A, expression of all other genes was higher with 16:0 vs. WY, particularly LPIN1 (7-fold at 6 h). Compared to CTR, microarray data showed 29, 47, and 43 genes with ≥2-fold difference due to 16:0, c9t11CLA, and t10c12CLA, respectively. Ingenuity Pathway analysis showed that genes affected by c9t11CLA were associated with lipid metabolism (6 genes, e.g. ADFP (up), SCD (down), FABP3 (down)) and cell signaling and morphology (7 genes, e.g. SPP1 (up), ITGA2 (up)). Genes affected by t10c12CLA were associated with lipid transport and metabolism (11 genes, e.g. ADFP (up), SCD (down), HMGCS1 (down), SC4MOL (down)) and cellular growth (9 genes, e.g. SPP1 (up), IGF1 (up)). Palmitate affected genes involved primarily in cellular growth and among these, SPP1 and G1P2 had the highest difference (≥10-fold). Results suggest 16:0 activated genes through PPARA, and had greater potency in stimulating expression than WY. Marked stimulation of LPIN1 and SPP1 by 16:0 revealed an unknown, PPARA-independent mechanism on gene expression. CLAs affected expression of unpredicted genes involved in pathways of lipid metabolism and cellular growth/morphology.

Key Words: Genomics, Nutrition, Lipids

M253 Transcriptional regulation of mammary and adipose tissue gene expression in dairy cows fed a milk fat-depressing or milk fat-enhancing diet. B. J. Thering*, D. E. Graugnard, P. Piantoni, R. L. Wallace, R. E. Everts, S. L. Rodriguez-Zas, H. A. Lewin, and J. J. Loor, *University of Illinois*, *Urbana*.

To better characterize mammary (MG) and adipose (AT) tissue gene networks regulating lipid synthesis and other cellular processes that

might be responsive to dietary lipid, we biopsied MG (n = 6/diet) at 0, 7, and 21 d, and AT (n = 3/diet) at 21 d of feeding mid-lactation cows (n = 6/diet) a milk fat-depressing (MFD, fish/soybean oil (1:2) at 3.5% of DM), milk fat-enhancing (MFE, EnergyBooster100, 3.5% of DM), or control (no added lipid) diet for 28 d. Milk composition was examined daily. A 13,257 bovine oligonucleotide (70-mers) array and qPCR were used for transcript profiling. Annotation was based on similarity searches using BLASTN against human, mouse and bovine RefSeq, human, mouse, and bovine UniGene, and bovine TIGR. Cy3- and Cy5-labelled cDNA from MG or AT and a reference standard were used for hybridizations. Milk yield was not affected by diets (29 ± 1.7 kg/d), but milk fat % (FP) decreased ($P < 0.001$) gradually (3.73% to ~2.50%) with MFD and reached a nadir essentially by d 13 of feeding. MFE did not increase FP above controls and averaged 3.71%. ANOVA (FDR-adjusted P ± 0.10) identified 797 differentially expressed genes in MG over time due to MFD, and 378 genes in AT due to diet. Among genes in MG, we found 74 downregulated and 171 upregulated by ≥1.5-fold on d 21 vs. 0. In AT, MFD and MFE compared with control resulted in 57 and 35 genes with ≥2-fold up or downregulation. Ingenuity Pathway Analysis of d 21-upregulated MG genes identified cell growth/proliferation (35 genes), molecular transport (22), cell assembly/organization (18), and cell signaling (15) as modified families of related genes. Overall, results suggest that milk fat depression is associated with previously-unknown adaptations in gene networks both in MG and AT. Gene expression in AT seemed responsive, via direct or indirect mechanisms, to both dietary lipids and reduced energy output in milk.

Key Words: Genomics, Lipid, Nutrition

M254 Effect of growth hormone on expression of metabolic genes in adipose tissue of dairy cows. M. Baik[2], J. L. Liesman[1], B. E. Etchebarne[1], J. Bong[2], and M. J. VandeHaar*[1], [1]*Michigan State University*, *East Lansing*, [2]*Chonnam National University*, *Gwangju, South Korea*.

We recently developed a new bovine specific microarray that is targeted for studies on metabolic regulation in cattle. This array (BMET) is a long oligo spotted array of 2400 genes with 4 replicate spots per gene. Our objective in this study was to determine the influence of bovine growth hormone (GH) on the expression of individual genes and gene pathways associated with metabolism and metabolic regulation in adipose tissue of lactating cows. Primiparous Holstein cows were treated with 0 or 29 mg of GH per day, and omental fat was collected at slaughter on day 60. RNA was isolated from adipose tissue of 3 cows treated with GH and from 3 matched controls. Direct comparisons of the treatments were made using two arrays for each cow comparison with a reversal of dye assignments for the second array; a total of 6 arrays were performed. Approximately 9% of the genes were altered at the $P < 0.05$ level, and the distribution of P-values was highly skewed toward the lower P values, indicating a significant treatment effect. Approximately 100 genes were down-regulated. These included several genes associated with glucose transport and activation, fatty acid synthesis, the TCA cycle and NADPH generation, as well as steroyl-CoA desaturase, LDL receptor, and leptin. Approximately 120 genes were up-regulated. These included several genes for protein modification for several signaling pathways, zinc fingers, as well as PPAR alpha, SOCS1 and 5, and IGFBP3. In addition, several genes associated with insulin signaling were altered by GH. Pathway analysis is ongoing. The overall effects of GH were consistent with previously published results. GH decreased activity of many enzymes that would explain the major decrease in fatty acid synthesis and esterification that occurs in adipose tissue during GH administration.

Key Words: Gene Expression, Growth Hormone, Metabolism

M255 Growth hormone receptor expression in two dairy breeds during the periparturient period. C. S. Okamura, J. F. Bader, T. C. Cantley, and M. C. Lucy*, *University of Missouri*, *Columbia*.

The somatotropic axis is implicated in the profound physiological and metabolic changes that accompany parturition and the onset of lactation in dairy cattle. In Holstein cows, the expression of the primary growth hormone receptor (GHR) mRNA in liver, GHR1A, declines dramatically within one week after calving. When Angus beef cows were sampled, however, GHR1A mRNA amount did not change after calving. The present study tested whether the decrease in GHR1A was a characteristic of the Holstein breed alone or whether a second dairy breed (Guernsey) also experienced a decrease in GHR1A after calving. Holstein (n = 9) and Guernsey (n = 9) cows were paired by parturition date. Liver biopsies were taken prepartum (d -20±1) and postpartum on d +3, and d +14±1. Liver RNA was isolated and reverse transcribed (RT) into cDNA. A quantitative RTPCR assay was used to measure the amount of GHR1A, GHR1B and IGF-I mRNA. Heterogeneous nuclear RNA (hnRNA; precursor of mRNA) was also measured to infer rates of transcription for GHR transcripts. There was no effect of breed on GHR1A, GHR1B or IGF-I mRNA amount ($P > .10$). Both Holstein and Guernsey cows underwent a decrease and subsequent increase in GHR1A and IGF-I mRNA from d -20 to +14 [15.6, 2.8, and 8.4 (±1.4) for GHR1A and 12.3, 2.2, and 5.9 (±.9) for IGF-I on d -20, +3, and +14, respectively; effect of day, $P<.001$]. There was no effect of day on hnGHR1A. The change in GHR1B was opposite to GHR1A because GHR1B increased on d+3 [12.8, 25.8, and 15.1 (±3.8); day, $P<.05$]. The hnGHR1B also increased on d+3 (day, $P<.05$). The decrease in GHR1A expression after calving occurred in two dairy breeds that have undergone independent selection for milk production. Reduced GHR1A after calving may be an inherent characteristic of dairy cows that enables nutrient partitioning for greater milk production. The decrease in GHR1A mRNA may arise from a mechanism involving enhanced mRNA turnover because the amount of its precursor mRNA (hnGHR1A) did not change in periparturient cows.

Key Words: Growth Hormone Receptor, Dairy

M256 Effects of milk replacer composition on selected blood metabolites and hormones in pre-weaned Holstein heifers. K. M. Daniels*, S. R. Hill, K. F. Knowlton, R. E. James, R. E. Pearson, M. L. McGilliard, and R. M. Akers, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

We investigated the effects of increasing dietary protein and energy on the concentrations of selected blood metabolites and hormones in Holstein heifer calves. Twenty-four heifers were fed one of four milk replacer (MR) diets (n=6/diet): 20:20 (20% CP, 20% fat MR fed at 450 g/d), 28:20 (28% CP, 20% fat MR fed at 970 g/d), 28:28L (28% CP, 28% fat MR fed at 970 g/d), and 28:28H (28% CP, 28% fat MR fed at 1460 g/d). Calves arrived at the Virginia Polytechnic Institute and State University Dairy Center August 20, September 10, or September 25, 2005. Calves were fed twice daily; water and starter (20% CP)

were available at all times, and any orts were recorded daily. Serum and plasma aliquots from blood samples collected twice weekly after a 12 h fast were analyzed for insulin-like growth factor-I (IGF-I), growth hormone (GH), insulin, glucose, NEFA, triglycerides (TRI), and plasma urea nitrogen (PUN). Calves fed 20:20 had the lowest overall glucose concentration (83, 103, 107, and 107±2 mg/dl for 20:20, 28:20, 28:28L, and 28:28H). Calves on treatments 28:20, 28:28L, and 28:28H increased linearly in blood IGF-I (53 to 126 ng/ml) and decreased in TRI (0.20 to 0.13 mmol/l) over time. Calves fed 20:20 however, demonstrated quadratic IGF-I and TRI responses over time, with lowest values reported at week 4 for IGF-I (20 ng/ml) and week 6 for TRI (0.14 mmol/l). Change in insulin over time was quadratic with the lowest value (0.16 ng/ml) occurring at week 6; GH decreased linearly from 9.8 to 3.8 ng/ml. No differences were detected in PUN concentrations (mean = 7.35 mg/dl of urea N). Plasma NEFA decreased over time in all calves (0.42 to 0.37 mmol/l). Overall, the blood parameters measured here did not depend on treatment diet composition; differences in body composition and calf growth (reported elsewhere) in these animals may likely be explained by variables not measured here.

Key Words: Blood Metabolite, Calf, Milk Replacer

M257 Circulating glucose responses in early lactation dairy cows to dietary restriction and rbST treatment. A. Basson and N. H. Casey*, *University of Pretoria*, *Pretoria, South Africa*.

Galactopoietic effects of somatotropin are the result of IGF-I and require high-quality nutrient intake. This study investigated short-term partitioning effects during recombinant bovine somatotropin (rbST) administration in high yielding early lactation dairy cows. Administration of rbST has been shown generally to alter results of metabolic tests in the face of unchanged basal glucose and insulin concentrations. Ten multiparous Holstein cows were subjected to rbST (LactotropinÒ) and/or feed intake restriction to 80% of predicted ME requirement (80% ME). Responses to insulin challenge (0.1 IU canine insulin/kg BW, 210 min) and hyperglycemic clamp (+50 mg/dL whole blood, 120 min) were tested during weeks 8 (control), 9 (rbST), 11 (80% ME) and 12 (rbST + 80% ME) post partum. Plasma and whole blood samples were assayed for glucose concentrations. The rbST treatment decreased fasting glucose concentration by 10.0% ($P<0.0001$), which was likely a remnant of control hyperglycemia. Maximum glucose response was 4.0 mg/dL lower ($P<0.0148$) and took 6.5 min longer to attain ($P<0.0112$). Steady state glucose infusion rate (SSGIR) decreased by 8.1% ($P<0.0001$). The 80% ME treatment decreased glucose availability by 4.9% ($P<0.0001$), while no glucose responses were affected. Restricted energy intake during treatment with rbST resulted in plasma glucose increase by 5.5% ($P<0,0001$). Peripheral uptake and utilization of glucose increased by 5.1% ($P<0,0001$). Compared to energy restriction, 80% ME + rbST did not alter effects of nutrient restriction on responses to exogenous insulin challenge. Effects were small and inconsistent. SSGIR decreased by 5% in the 80% ME + rbST compared to the 80% ME period ($P<0.0001$) and the change in the hyperglycemic clamp in the absence of an effect in the insulin challenge may be due to differences in endogenous insulin secretion. The conclusion was that rbST treatment resulted in altered glucose metabolic responses, even with restricted energy intake.

Key Words: Glucose, rbST, Dairy Cows

M258 Alterations in hepatic gene expression profiles in dairy cows in response to L-carnitine and feed restriction. D. B. Carlson*, J. K. Drackley, M. Bionaz, S. L. Rodriguez-Zas, N. A. Janovick Guretzky, R. E. Everts, H. A. Lewin, and J. J Loor, *University of Illinois*, *Urbana*.

Previously we showed that abomasal carnitine infusion increases hepatic fatty acid oxidation and decreases liver lipid accumulation during acute feed restriction (J. Dairy Sci. 89:4819-4834). Further, carnitine has been shown to stimulate hepatic gluconeogenesis in nonruminants. Our objectives were to determine global gene expression patterns in liver using a microarray consisting of 7,872 bovine cDNA inserts and qPCR. Eight lactating Holstein cows were used in a replicated 4 × 4 Latin square design with 14-d periods. Treatments were factorial combinations of dry matter intake (DMI) restriction and abomasal carnitine (20 g/d) infusion: water infusion + ad libitum DMI (WA), water infusion + restricted DMI (WR), carnitine infusion + ad libitum DMI (CA), carnitine infusion + restricted DMI (CR). Annotation was based on similarity searches using BLASTN against human, mouse and bovine RefSeq, human, mouse, and bovine UniGene, and bovine TIGR. Cy3- and Cy5-labelled cDNA from liver tissue and a reference standard were used for hybridizations. ANOVA (FDR-adjusted $P \leq 0.10$) identified 248, 655, and 362 differentially expressed genes due to L-carnitine infusion, feed restriction, and their interaction, respectively. Hierarchical clustering indicated that L-carnitine infusion resulted in 26% difference and feed restriction in 37% difference in global gene expression patterns. The CR treatment affected gene expression patterns by 20% relative to WR. qPCR confirmed downregulation ($P \leq 0.05$) of CPT1A, ADIPOR2, and PCK1 by carnitine infusion. In addition, qPCR confirmed ≥2-fold upregulation ($P \leq 0.05$) of PC by feed restriction compared with ad libitum-fed cows, whereas PDK4 expression increased in WR but not CR cows. Gene expression and in vitro liver metabolism data indicate that L-carnitine altered hepatic responses to feed restriction, likely by effects on acute regulatory mechanisms of enzymes associated with fatty acid oxidation and gluconeogenesis.

Key Words: Liver, Microarray, L-carnitine

M259 Hepatic gene expression profiling in postpubertal Holstein dairy heifers. J. Doelman*, N. G. Purdie, H. Cao, L. E. Wright, N. A. Karrow, and J. P. Cant, *University of Guelph*, *Guelph, Ontario, Canada*.

The liver is central to the nutritional response of animals to nutrient supply. The objective of this study was to evaluate the effects of a negative energy balance on hepatic gene expression in Holstein heifers. One-hundred postpubertal heifers between 9 and 13 months of age were randomly assigned to a fed or a 24-hour feed withdrawal treatment under a randomized block design. Liver biopsies and blood samples were taken to obtain RNA for microarray analysis and blood plasma for metabolite and hormone analyses. Spectrophotometric assays were used to quantify plasma concentrations of non-esterified fatty acids (NEFA) and beta-hydroxybutyrate (BhB); statistical analysis was conducted using one-way ANOVA. Plasma NEFA concentrations were significantly higher in fasted heifers ($P<0.0001$), while BhB levels were significantly lower ($P<0.0001$) with the 24-hour feed withdrawal. A cDNA microarray consisting of 8800 oligonucleotide inserts was used to identify hepatic transcript profiles. Array elements were selected from a database of bovine ESTs. A reference design was employed to compare Cy-5 labelled RNA from liver to Cy-3 labelled

RNA from reference standard (derived from bovine liver, spleen and placenta). Gene Spring analysis software was used for LOWESS normalization procedures and statistical analysis (ANOVA, P = 0.05). Sixty-six differentially expressed genes were found using Benjamini and Hochberg's False Discovery Rate (P = 0.05). Forty-two genes were found to be 4.0 to 1.5 fold lower and twenty-four were 1.5 to 2.6 fold greater with feed withdrawal. Down-regulated genes were associated with cell cycle progression or cytolysis, endocytosis, cholesterol synthesis, TCA cycle, immune response and the protein synthetic pathway. Genes associated with gluconeogenesis and fatty acid synthesis suppression, fatty acid transport, TCA cycle, cell structure and transport, and immune response were up-regulated with restricted energy intake. These results are indicative of a hepatic gene response to energetic status in postpubertal dairy heifers.

Key Words: Liver, Gene Expression, Dairy Heifer

M260 Effects of feed restriction on lipogenic gene expression in liver of broiler chickens. H. K. Kang, E. J. Chae, I. S. Jang, S. H. Sohn, and Y. S. Moon*, *Jinju National University*, *Jinju, Korea*.

Ross male broiler chickens were used to determine the effect of either energy restriction (ER) or quantitative feed restriction (QFR) on hepatic expression of the lipogenic genes. Diet restriction in all experiments was accomplished by providing chicks with 70% or 85% energy level of control (ER70, ER85), and 70% or 85% feed intake of control (QFR70, QFR85). Diet restriction groups of chickens were restricted for 7days, starting at 8 days of age. Ad libitum feeding was resumed after the restriction periods, and continued through the end of the experiment at 35 days of age. A control group was fed ad libitum throughout the experiment. Chickens were sacrificed and samples of liver were collected at 14 and 35 days of age. After completion of feed restriction, the body weights of QFR70 and ER70 were the lowest and followed by QFR85 and ER85 ($P<0.05$). However, complete compensatory growth by feed restricted birds relative to controls was achieved by 35 days of age in all treatment groups. Hepatic expression of fatty acid synthase (FAS) gene from QFR70 and QFR85 was 2.7 and 2.1-fold lower than that of control at 14 days of age whereas ER groups were not different from the control group. The FAS gene expressions in QFR groups and ER70 were not completely caught up the control group at 35 days of age while its expression of ER85 was 26% higher than that of control. CEBP/α and PPARγ were the potent transcription factors to stimulate FAS gene at 35 days of age. The expression levels of SREBP-1 were not different between treatment and control groups after compensatory growth. The results of this study indicated that feeding regimen alters expression of lipogenic genes in liver and may influence lipid metabolism of broilers.

Key Words: Feed Restriction, Hepatic Gene Expression, Broilers

M261 Purification of Japanese quail prolactin and detection of multiple glycosylated isoforms. N. Kansaku*[1], G. Hiyama[1], T. Murata[2], T. Sasanami[2], and D. Zadworny[3], [1]*Azabu University*, *Sagamihara, Japan*, [2]*Shizuoka University*, *Shizuoka, Japan*, [3]*McGill University*, *Ste. Anne de Bellevue, Canada*.

Prolactin (PRL) is mainly produced in the cephalic lobe of the anterior pituitary gland and affects a variety of physiological functions in birds. We previously cloned and sequenced PRL cDNA of Japanese quail (AB162003). Since galliform PRL has no consensus sequence for N-linked glycosylation (Asn-X-Ser), an alternative glycosylation site (Asn-X-Cys) for N-glycosylation has been proposed. In Japanese quail, this site is located at position 56 of mature PRL. In general, receptor binding and activation is greatly reduced by glycosylation. However, it is unkown if PRL is glycosylated in the Japanese quail. Accordingly, this study examined the purification of PRL from laying Japanese quail. Anterior pituitary glands were collected from 6 month old Japanese quails (n=500), homogenized and PRL was purified by affinity chromatography using monoclonal antibody against recombinant chicken PRL. The purified PRL was separated by SDS polyacrylamide gel (SDS PAGE) and visualized by Coomassie brilliant blue G-250 staining. Japanese quail PRL consisted of at least three protein bands with molecular sizes estimated to be between 23 to 25 kDa. Western blot analysis using polyclonal antibody against chicken PRL detected similar bands to Coomassie brilliant blue staining. Interestingly, different signal intensity was obtained using various lectins (ConA, DBA, LCA, PHAE4, RCA120, UEFA-I, and WGA). However, no signal was detected when using PNA. These results indicate the presence of multiple forms of glycosylated PRL in the anterior pituitary gland of Japanese quail.

Key Words: Prolactin, Quail, Isoform

M262 Developmental gene expression of preprocholecystokinin (CCK) in lines of chickens divergently selected for high or low juvenile body weight. J. C. Gould*, C. R. Miller, P. B. Siegel, and E. A. Wong, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

This study was designed to measure developmental gene expression of preprocholecystokinin (CCK), a satiety inducing peptide, in the small intestine of chickens that have undergone long-term genetic selection for high (HWS) or low (LWS) 8-wk body weight. HWS chickens are hyperphagic, while LWS chickens are hypophagic. Chicks were reared in batteries with ad libitum access to feed and water. Chicks were weighed and killed on embryonic d 20 (e20), d of hatch (DOH with no access to feed), and d 3 (D3) and 7 (D7) post hatch. RNA was extracted from duodenum, jejunum, and ileum from four males from each line and time point. The abundance of CCK mRNA was assayed by real time PCR using the relative quantification method with GAPDH as the endogenous control. LWS males had a 2.4-fold higher CCK mRNA abundance than HWS males ($P = 0.009$), with abundance of CCK mRNA higher in the ileum ($P < 0.001$) than the duodenum and jejunum. There was an effect of age ($P = 0.037$) with gene expression of CCK increasing through D3 and decreasing slightly by D7. These results indicate that long term selection for high or low 8-wk body weight has affected gene expression of CCK in the small intestine of chickens. Higher expression of CCK in LWS males compared to HWS males suggests a role for CCK in the hypophagia observed in LWS chickens.

Key Words: Chicken, Small Intestine, Preprocholecystokinin

M263 Incremental dietary conjugated linoleic acid (CLA) mixture inclusion has non-linear effects on atherosclerosis in cholesterol-sensitive Japanese quail. C. K. Reynolds*, M. S. Lilburn,

S. G. Velleman, V. L. Cannon, J. A. Lynch, D. L. Hartzler, and W. L. Bacon, *The Ohio State University, OARDC*, *Wooster*.

Our objective was to determine the incremental effect of dietary CLA on the development of atherosclerosis in Japanese quail selected for cholesterol-induced aortal plaque deposition. At 19 wks of age 120 male quail were randomly assigned to one of 10 pens (12 birds/pen) and fed for ad libitum intake one of 5 diets (2 pens/diet). Diets were a negative control containing 1.25% soybean oil and no cholesterol and 4 diets containing 0.5% cholesterol and one of 4 levels of CLA oil (40% *cis*-9, *trans*-11 CLA, 40% *trans*-10, *cis*-12 CLA; replacing soybean oil) providing 0, 0.25, 0.5, or 1.0% CLA (DM basis). After 14 wks a jugular vein blood sample was taken and quail were euthanized. A score (0 to 4) was assigned for aortal lesions and samples were frozen for later analysis of plasma cholesterol and triglyceride (TAG) concentration and fatty acid concentrations in abdominal fat. Treatments had no effects on body wt (108 g) or plasma TAG, but liver wt was increased (linear, $P < 0.07$) by CLA (Table). Plasma cholesterol was increased ($P < 0.02$) by cholesterol and decreased (linear, $P < 0.07$) by CLA. Aortal lesions were increased by cholesterol ($P < 0.01$) and decreased by CLA (quadratic, $P < 0.02$), with the greatest reduction for 0.5% CLA. Feeding cholesterol increased C18:1 and C16:0 and decreased *cis*-9, *cis*-12 C18:2 and C18:3 concentrations in abdominal fat ($P < 0.05$). Abdominal fat concentrations of CLA, C16:0, and C18:0 were increased and concentrations of *cis*-9, *cis*-12 C18:2 and C18:3 were reduced (linear, $P < 0.01$) by dietary CLA. Consumption of a CLA mixture lessened the severity of cholesterol-induced atherosclerosis in Japanese quail, in part through reduced plasma cholesterol concentration. Reasons for the reduced response at the highest CLA inclusion level are not apparent, but differential effects of the individual isomers fed should be investigated.

Table 1.

Item	Control	0% CLA	0.25% CLA	0.5% CLA	1.0% CLA	SEM
Cholesterol, mg/dl	233	1364	1216	1108	1111	62
Triglyceride, mg/dl	151	335	342	475	312	58
Liver wt, g	1.86	2.35	2.60	2.81	2.79	0.14
Aorta score	1.16	3.75	3.49	2.77	3.56	0.20

Key Words: Atherosclerosis, Conjugated Linoleic Acid, Cholesterol

M264 Effects of feeding blends of grains naturally contaminated with Fusarium mycotoxins on small intestinal morphology of turkeys. C. K. Girish* and T. K. Smith, *University of Guelph*, *Guelph, Ontario, Canada*.

An experiment was conducted to investigate the effects of feeding turkeys grains naturally contaminated with Fusarium mycotoxins on morphometric indices of duodenum, jejunum and ileum, and the possible preventative effect of feeding a polymeric glucomannan mycotoxin adsorbent (GMA, Mycosorb®, Alltech, Inc., Nicholasville, KY). Three hundred 1-d-old male turkey poults were fed wheat, corn and soybean meal-based starter (0-3 wk), grower (4-6 wk), developer (7-9 wk), and finisher (10-12 wk) diets formulated with uncontaminated grains (C), contaminated grains (CONT) and contaminated grains + 0.2 % GMA (CONT+GMA). The morphometric indices were measured at the end of each growth phase and included villus height (VH), crypt depth (CD), villus width (VW), thicknesses of submucosa and muscularis, crypt to villus ratio and apparent villus surface area (AVSA). At the end of the starter phase, feeding CONT significantly (p=0.01) decreased the VH (968.44 vs 782.68µm) in duodenum and feeding CONT+GMA prevented this effect (782.68 vs 991.28µm) (p=0.002). The feeding of CONT also reduced VH (448 vs 380µm) (p=0.04) and AVSA (29944 vs 23604 µm2) (p=0.01) in jejunum, whereas none of the variables were affected in the ileum. VW (41.62 vs 36.23µm) (p=0.04) and AVSA (29342 vs 22057µm2) (p=0.03) of duodenum, VH (738.64 vs 582.27µm) (p=0.02) and AVSA (56346 vs 41129µm2) (p=0.01) of jejunum and submucosa thickness of ileum (31.94 vs 24.69 µm) (p=0.04) were significantly reduced when birds were fed CONT compared to C at the end of the grower phase and the feeding of CONT+GMA prevented ($p<0.05$) these effects in jejunum and ileum. The feeding of CONT did not significantly ($p>0.05$) affect the morphometric variables at the end of the developer and finisher phases. It was concluded that consumption of grains naturally contaminated with Fusarium mycotoxins results in adverse effects on intestinal morphology during the early growth phase of turkeys and GMA can prevent many of these effects.

Key Words: Fusarium mycotoxin, Duodenum, Jejunum

M265 Age-specific species variation in oxidative stress in birds. X. Guan*, K. Gyenai, C. Larson, and E. Smith, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Aging reduces the ability of livestock and poultry to sustain reproductive ability, especially egg-laying in birds. Delaying aging thus has economic benefits in poultry and other livestock species. Understanding the biochemical and molecular mechanisms that underlie the aging process could help develop approaches including selection that will slow the aging process in birds. Here, our objective was to test if birds with different longevities differ in oxidative stress levels associated with aging. The species evaluated were the 20 budgies, 15 guinea fowls, 30 Japanese quails and 30 domestic turkeys. Biomarkers used to estimate oxidative stress were thiobarbituric acid reacting substance (TBARS), an oxidant, and plasma uric acid (PUA) and glutathione (GSH), both antioxidants. Biomarkers were determined at 10, 30, 55 and 80 wks-of-age within each species. In the Guinea fowl, PUA (from 4.78 mg/dL to 8.28 mg/dL) and TBARS (0.22 to 0.57 mg/L) increased significantly with age while GSH (1074.43 to 613.63 uM) decreased significantly over the same period. Though changes in the levels of the biomarkers with age were inconsistent in the Japanese quail, the oxidant levels increased while the antioxidants decreased with age. In the turkey, PUA (6.85 to 4.69 mg/dL) decreased significantly from 10 to 55 wks-of-age while TBARS (0.31 to 0.56 mg/L) increased. In the budgie, antioxidant level decreased with age though not as rapidly as in the other species. Though changes in the oxidative stress were inconsistent and showed no clear pattern, it appears that the decline in oxidant and antioxidant status varies with species, suggesting a genetic basis to this biologically important characteristics.

Key Words: Oxidative Stress, Poultry, Biomarkers

M266 Effect of maternal stress on the stress hormone and growth response of pigs to a lipopolysaccharide (LPS) challenge. P. N. Williams*[1], J. A. Carroll[2], J. W. Dailey[2], and T. H. Welsh, Jr.[3], [1]*Texas A&M University-Kingsville*, *Kingville*, [2]*USDA-ARS, Livestock*

Issues Research Unit, *Lubbock, TX, USA*, [3]*Texas A&M University*, *College Station*.

This study assessed the effect of maternal stress on the stress hormone and growth response of the progeny following an endotoxin challenge. Sows were assigned to one of two treatments (n = 10 per treatment) and subjected to either a daily 5-min restraint stress (stressed; S) from d 84 to d 112 of gestation or managed per current industry standards (non-stressed; NS). All sows were then managed similarly through farrowing and lactation. At weaning (20.0 ± 0.3 d) pigs from S and NS sows (n = 40 per treatment balanced for litter and gender) were selected, transferred to a climate controlled facility where they were placed into individual pens and allowed ad libitum access to feed and water. Pigs were allowed to acclimate for 14 d before LPS challenge. On d 14 pigs were weighed and non-surgically fitted with jugular catheters. On d 15 pigs were infused i.v. with LPS (25 µg/kg BW) and blood samples collected every 30 min for 1 h prior to and 6 h following LPS challenge. Serum was analyzed for cortisol (CS), norepinephrine (NE), and epinephrine (E). Weekly weights were taken and average daily gain (ADG) prior to and following LPS challenge calculated. Baseline (pre-LPS) CS, E, and NE were not affected ($P > 0.05$) by maternal treatment. Consistent with previous reports, CS, E and NE increased ($P < 0.01$) in a time-dependent manner following LPS with peak values at 3, 1 and 0.5 h post-infusion. Although not affecting the temporal pattern, S pigs had a decreased ($P < 0.01$) CS response and tended ($P = 0.07$) to have a greater E response following LPS. Furthermore, there was a tendency ($P = 0.08$) for S pigs to have greater NE then NS pigs post-LPS. Maternal treatment did not affect ($P > 0.40$) ADG prior to or following LPS challenge. However, there was a positive relationship between ADG prior to the LPS challenge and peak NE following LPS ($r = 0.29$; $P<0.01$) and a negative relationship between peak E and ADG following LPS ($r = -0.23$; $P<0.05$). Collectively, these results indicate that maternal stress alters the stress hormone response of the progeny to an endotoxin challenge.

Key Words: Maternal Stress, LPS, Pig

M267 Expression of porcine intestinal alkaline phosphatase during the early postnatal development. T. Li[1,2], C. Yang[2], D. Lackeyram[2], Y. L. Yin[1], C. F. M. de Lange[2], and M. Z. Fan*[2], [1]*The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*University of Guelph*, *Guelph, Ontario, Canada*.

The small intestinal alkaline phosphatase (IAP) is responsible for hydrolyzing phosphoric ester bonds of organic phosphorus compounds and plays a role in absorption of triglycerides. To understand factors affecting early postnatal IAP expression, we examined IAP hydrolytic kinetics (Vmax, Km), digestive capacity (Vcap), jejunal IAP protein and mRNA abundances and their associations with hormonal factors in 36 ad libitum fed pigs. Six pigs were sacrificed at 1, 4, 6, 12, 20 and 28 d of age, respectively. Vmax was significantly high in jejunum and low in duodenum and distal ileum for all the age groups. Km was significantly high in jejunum, intermediate in the duodenum and low in distal ileum for all the age groups. There were postnatal decreases ($P<0.05$) in Vmax for all the small intestinal segments and Vcap, while significant changes in Km were only observed in jejunum. Pearson analysis showed that Vcap was correlated ($P<0.05$; $r=0.62$ and 0.64) with jejunal Vmax, however, poorly related ($P=0.13$; $r=0.27$) to duodenal Vmax. There were up to the quartic pattern of age effects ($P<0.05$) on the proximal jejunal homogenate and apical membrane IAP protein abundances, while a quadratic age effect was observed ($P<0.05$) in the proximal jejunal IAP relative mRNA abundance measured by real time RT-PCR. Jejunal IAP Vmax was correlated ($P<0.05$; $r=0.59$-0.65) with IAP protein abundance, however, poorly related ($P=0.66$; $r=0.08$) to IAP mRNA abundance. Furthermore, jejunal homogenate and apical IAP protein abundances were poorly correlated ($P=0.91$ or 0.73; $r=-0.02$ and -0.06) with IAP mRNA abundance. In conclusion, there were dramatic reductions in IAP maximal activity and digestive capacity during early postnatal development in the pig, likely regulated at the levels of post-transcriptional IAP protein processing and post-translational IAP affinity modifications.

Key Words: Gene Expression, Intestinal Alkaline Phosphatase, Pigs

M268 Changes of physiological and biochemical parameters in weaned pigs. X. F. Kong*[1], Y. L. Yin[1], F. G. Yin[1], H. J. Liu[1], F. F. Xing[1], Q. H. He[1], T. J. Li[1], R. L. Huang[1], P. Zhang[1], M. Z. Fan[2], S. W. Kim[3,4], and G. Y. Wu[1,4], [1]*The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*University of Guelph*, *Guelph, Ontario, Canada*, [3]*Texas Tech University*, *Lubbock*, [4]*Texas A&M University*, *College Station*.

This study was conducted to determine the values of serum biochemical parameters in piglets weaned at 21 d of age. On d 0, 7, 14 and 28 post weaning, venous blood samples were obtained randomly from 5five piglets for analysis. With increasing age, the numbers of leukocytes, lymphocytes and granulocytes increased ($P < 0.05$) progressively. The erythrocyte volume, the platelet distributing width, serum concentrations of phosphorus, urea, total cholesterol and glucose, as well as serum activities of lipase, creatine phosphokinase and glutamate-pyruvate transaminase decreased ($P < 0.05$) on d 7 and increased ($P < 0.05$) thereafter. Serum activity of alkaline phosphatase increased ($P < 0.05$) progressively between d 0 and 14 post weaning and declined thereafter ($P < 0.05$). Concentrations of erythrocyte hemoglobins increased ($P < 0.05$) progressively between d 0 and 14, and the elevated values remained until d 28. In contrast, serum concentrations of ammonia, Zn, Na and Cl increased ($P < 0.05$) on d 7 and decreased ($P < 0.05$) thereafter. Serum concentrations of triglycerides on d 14 and 28 were lower ($P < 0.05$) than those on d 0 and 7. Serum concentrations of all amino acids, except for glutamate, glutamine, ornithine, citrulline and arginine, increased ($P < 0.05$) on d 7 and decreased ($P < 0.05$) thereafter. The ratio of kidney weight to BW decreased ($P < 0.05$) progressively until d 28, the ratios of stomach, lymph nodes, and liver weights to BW were the highest ($P < 0.05$) on d 7, and the ratio of spleen weight to BW was the highest ($P < 0.05$) on d 14. These results indicate that serum metabolite concentrations and organ growth undergo marked changes in post-weaning piglets. (Supported by NSFC and CAS)

Key Words: Weaned Pigs, Serum Parameters, Growth

M269 Omega-3-fatty acid supplementation and the IGF system in early pregnancy in pigs. A. Brazle*, T. Rathbun, B. Johnson, and D. Davis, *Kansas State University*, *Manhattan*.

The IGF system of growth factors, receptors and binding proteins functions from early in pregnancy. Recent evidence indicates improved embryo survival in gilts fed supplemental omega-3 fatty acids

beginning before conception. Here we report effects of supplementing a corn-soybean meal diet (Control) with a marine source of protected omega-3 fatty acids (PFA, 1.5% of diet) on mRNA expression for IGF-I, IGF-II, IGFBP-3 and IGFBP-5 in the porcine gravid uterus. The PFA (Fertilium™365) contained equal amounts of eicosapentanoic (EPA) and docosahexanoic (DHA) acids and replaced corn in the diet beginning when gilts were approximately 170 d old (n=13/treatment). Gilts were artificially inseminated at approximately 205 d of age. Conceptus and endometrial samples were collected at d 11, 15, and 19 of gestation. All gilts were pregnant. In the conceptus, message for IGF-II and IGFBP-3 increased ($P < 0.001$) from d 15 to d 19 while there was an increase ($P < 0.001$) in IGF-I and IGFBP-5 from d11 to 15 and a decrease ($P < 0.001$) to d 19. In the endometrium, message for IGF-I was stable over the interval but message for IGF-II and IGFBP-5 were increased by d 15 and IGFBP-3 by d 19 ($P < 0.01$). There were trends for omega-3-fatty acid supplementation to increase endometrial IGF-II ($P = 0.09$) and IGFBP-5 ($P = 0.12$) on d 15. In the d-19 conceptus, embryonic but not extraembryonic IGF-I mRNA tended ($P = 0.13$) to be greater for PFA compared to Control gilts. During d 11 to 19 the conceptus is elongating, attaching to the uterus, and the embryonic disc is differentiating from a homogenous tissue to form the tissues and organs of the adult. One mechanism for omega-3 fatty acid effects in early pregnancy could involve epigenetic effects on mRNA expression for the IGF and IGFBP proteins.

Key Words: Pig, IGF, Omega-3 Fatty Acids

M270 Serum and anterior pituitary (AP) concentrations of IGF-I and relative amounts of AP IGF binding proteins throughout the estrous cycle in gilts. A. R. Taylor* and J. A. Clapper, *South Dakota State University*, *Brookings*.

It has been established that components of the circulating and anterior pituitary IGF system vary in response to steroids in the pig. However, whether serum and anterior pituitary concentrations of the IGF system vary throughout the estrous cycle has not been determined. To further examine this relationship the following experiment was performed. Forty gilts of similar age and weight (180 d; 120 kg) were injected with PG 600 to induce the gilts into puberty. Fifteen days later all gilts were fed 15 mg Matrix for 15 d to synchronize estrus. Gilts were checked twice daily for expression of estrus beginning 3 d after the end of Matrix treatment and continuing for 7 d. The first day each gilt exhibited estrus was designated as d 1 of the estrous cycle. Blood samples were obtained by jugular venipuncture on d 1, 4, 7, 10, 13, 16, 19, and 22 of the estrous cycle. On d 7, 13, 19, and 22 of the estrous cycle 10 pigs were killed and anterior pituitary glands (AP) were collected. Serum concentrations of IGF-I and AP concentrations of IGF-I were determined by RIA. Relative amounts of AP IGF-binding proteins (IGFBP) were determined by Western ligand blot analysis. Serum concentrations of IGF-I fluctuated throughout the estrous cycle. Mean serum concentrations of IGF-I decreased ($P<0.02$) from d 1 through d 10, then increased ($P<0.02$) on d 13 through 16, then decreased ($P<0.02$) from d 19 through 22. Mean AP concentrations of IGF-I were greater ($P<0.03$) on d 19 compared to all other days, while no difference was detected ($P>0.05$) in mean anterior pituitary concentrations of IGF-I on d 7, 13, and 22. Western ligand blot analysis identified 33 kDa IGFBP-2 and 29 kDa IGFBP-5 in the AP. Mean relative amounts of AP IGFBP-2 and -5 were each greater ($P<0.02$) in gilts on d 19 compared to all other days while no difference was detected in mean relative amounts of AP IGFBP-2 and -5 among pigs on d 7, 13, and 22 of the estrous cycle. Anterior pituitary gland function in the pig may be influenced by the IGF system during the estrous cycle.

Key Words: Pig, Estrous Cycle, IGF

M271 Growth performance and muscle protein, RNA and DNA content in juveniles of *Pseudoplatystoma fasciatum* (Teleostei, Pimelodidae) fed lyophilized bovine colostrum. P. Pauletti, L. Kindlein, A. R. Bagaldo, A. P. O. Rodrigues, E. F. Delgado, J. E. P. Cyrino, and R. Machado-Neto*, *Escola Superior de Agricultura "Luiz de Queiroz" – ESALQ/USP*, *Piracicaba, SP, Brazil*.

Little information is available on the physiology and growth performance of speckled catfish, *Pseudoplatystoma fasciatum*, an important Brazilian freshwater food-fish. Muscle DNA, RNA, total protein (TP) contents and RNA:DNA ratios are good indexes of fish growth and condition. The IGF-I plays a central role in the growth regulation system, and the defatted lyophilized bovine colostrum (BC) is a rich source of IGF-I. The objective of this study was to evaluate effects of diets with partial replacement of protein source by BC on growth performance, body composition, and muscle TP, RNA, and DNA contents of juvenile speckled catfish (35.14 ± 2.23^{-1}) fed ad libitum for 30 or 60 days with five diets (45% crude protein; 4000 kcal kg^{-1}) with increasing levels of BC (0, 5, 10, 15 and 20%) (n=3). BC positively influenced weight gain, specific growth rate, and feed conversion only at 30 d. Carcass lipid contents were higher above 10% dietary BC levels. DNA concentration increased ($P\leq0.05$) between 30 and 60 d; all levels of BC elicited higher DNA concentration at 60 d, except for diets 5 and 10% BC, while the RNA concentration decreased ($P\leq0.05$). Higher ($P\leq0.05$) TP concentrations were registered at 30 d when dietary BC levels were 15 and 20%. At 60 d, diets 0, 5, 10 and 20% BC induced reduction of RNA:DNA ratio comparatively to 30 d ($P\leq0.05$). Increased DNA muscle content indicate that fish fed diets containing BC present additional hyperplasic growth.

Key Words: Siluriformes, Biochemical Indicators, Growth

M272 Feeding juveniles of *Pseudoplatystoma fasciatum* (Teleostei, Pimelodidae) with lyophilized bovine colostrum: Growth and protein, RNA and DNA content in liver and intestine. P. Pauletti, L. Kindlein, A. R. Bagaldo, A. P. O. Rodrigues, E. F. Delgado, J. E. P. Cyrino, and R. Machado-Neto*, *Escola Superior de Agricultura "Luiz de Queiroz" – ESALQ/USP*, *Piracicaba, SP, Brazil*.

The knowledge about the physiology and growth performance of speckled catfish, *Pseudoplatystoma fasciatum*, is strategic to the Brazilian freshwater food-fish industry. Concentrations of DNA, RNA and total protein (TP) in body tissues provide reliable indicators of feeding regime changes. The contribution of visceral tissues, namely liver and gut, to whole-body energy expenditures is related to protein synthetic activity. The liver plays an important role in the regulation of fish energy metabolism and growth, and IGF-I plays vital role in growth regulation and tissues differentiation. The defatted lyophilized bovine colostrum (BC) is a rich source of growth factors, such as IGF-I. The objective of this study was to evaluate effects of diets with partial replacement of protein source by BC on growth and TP, RNA and DNA contents in liver and intestine of juvenile speckled catfish ($35.14 \pm 2.23\ g^{-1}$) fed ad libitum for 30 or 60 days with five diets (45%

crude protein; 4000 kcal kg^{-1}) with increasing levels of BC (0, 5, 10, 15 and 20%) (n=3). Liver and intestine DNA concentrations increased (P≤0.05) between d 30 and 60 indicating a hyperplasia process, but no significant differences (P≥0.05) for RNA concentration in the same period were registered. Liver TP did not differ (P≥0.05) between diets, but decreased (P≤0.05) with time; significant effect of diet and period was observed for intestinal parameters, BC 5% being superior to others diets. Intestine TP decreased (P≤0.05) between d 30 and 60. Diets did not influence RNA/DNA rations in both liver and intestine, but decreased (P≤0.05) markedly between 30 and 60 d. Liver and intestine growth was characterized by a major contribution of hyperplasia compared to hypertrophy, as confirmed by linear increases in total DNA and a decrease in RNA/DNA and protein:DNA ratio.

Production, Management & the Environment - Livestock and Poultry I

M273 Effect of ProAgri™ amendment, before and after cleanout, on broiler litter moisture, calcium, nitrogen, and total and soluble phosphorus. N. G. Zimmermann*[1], R. Angel[1], and W. Saylor[2], [1]*University of Maryland*, *College Park*, [2]*University of Delaware*, *Newark*.

Nutrient pollution is a serious problem whenever animal production is concentrated and too little land is available for manure application. A 60 pen broiler experiment was conducted where diet and litter management were used concurrently to reduce nutrient pollution. A single flock (Ross 308) was grown on fresh pine shavings. The experiment was a 3 × 2 × 2 factorial design with unequal replication. Main effects were sex, feeding regimen, and litter amendment. The sex main effect was female, male, or straight run; number of birds per 1.52 × 2.44 m pen was 55, 45, and 50, respectively. Four and six phase diets were the feeding regimen main effect. The litter amendment main effect was ProAgri™ Activator followed by ProAgri™ 8-26-2 sodium silicate solutions sprayed onto litter (2.54 and 0.76 l/m^2, respectively). Total number of birds was 2880. At the end of the trial samples of litter from each pen, including cake, were collected to measure percent moisture, available water (A_w), N, Ca and total (tP) and soluble P (sP). Furthermore, a subsample of litter was treated with ProAgri™ Activator solution, 1:1(w:v) then ProAgri™ 8-26-2 sodium silicate solution, 2.4:1 (w:v). After oven drying, N, Ca, and tP and sP were measured. Only the effects of the litter amendment are reported here except for main effect interactions. Application of the litter amendment prior to bird placement did not have an effect on percent moisture, A_w, N, Ca, tP, or sP in clean out litter. However, clean out litter treated with the amendment had reduced (P>.05) sP (486 vs 271 mg/g) and N. Furthermore, a significant interaction of litter amendment with diet regimen was observed. The litter amendment reduced (P>.05) sP in litter when diets containing higher levels of tP were fed.

Key Words: Litter Amendment, Phosphorus, Nitrogen

M274 Genotype analysis of *Campylobacter* spp. isolated from various internal organs and unabsorbed yolks of commercial broiler and roaster chickens. K. L. Hiett, R. J. Buhr*, N. A. Cox, L. J. Richardson, P. J. Fedorka-Cray, J. S. Bailey, and J. K. Northcutt, *USDA-ARS, Russell Research Center*, *Athens, GA*.

Campylobacter spp. are presently believed to be the leading bacterial etiological agent of acute gastroenteritis in the human population. Evidence implicates poultry as a significant source of the organism for human illness; however, the pathways involved in *Campylobacter* spp. contamination of poultry flocks remain unclear. In an effort to further understand the dissemination of naturally occurring *Campylobacter* spp. through commercial broiler and roaster chickens, *Campylobacter jejuni* isolates previously recovered from the liver/gallbladder, spleen, ceca, and unabsorbed yolks of broiler and roaster chickens were genotyped using *flagellinA* Short Variable Region (*flaA*-SVR) DNA sequence analysis. All isolates recovered from broilers were of one *flaA*-SVR subtype regardless of the site of recovery. Isolates recovered from roasters comprised two subtypes. The predominant subtype (*flaA*-SVR type 1) contained isolates recovered from all locations tested. Additionally, this same *flaA*-SVR subtype was recovered from both broilers and roasters. This investigation demonstrated that very closely related subtypes of *C. jejuni* were naturally present within the internal organs and unabsorbed yolks of commercial broilers and roasters from different flocks, companies, and breeder strains. Further investigations of these subtypes are needed to understand their involvement in intestinal tract microbiology and the subsequent contamination of the final food product.

Key Words: *Campylobacter*, Genotyping, Tissues

M275 Recovery of naturally occurring *Campylobacter* from the circulating blood of market age commercial broilers. L. J. Richardson[1], N. A. Cox[1], R. J. Buhr*[1], and M. A. Harrison[2], [1]*USDA-ARS-PMSRU, Russell Research Center*, *Athens, GA*, [2]*Department of Food Science and Technology, University of Georgia*, *Athens*.

Campylobacter species have recently been recovered from several primary and secondary lymphoid tissues and internally from the spleen of poultry. The objective of this study was to determine whether naturally occurring *Campylobacter* can be recovered from the circulating blood of market age commercial broilers utilizing aseptic techniques. Broilers (n=100) were acquired from two commercial processing facility's live haul area on 10 separate days. The feathers where removed from the ventral surface of the humerous and alcohol was sprayed on the skin, then Betadine was applied to the area and allowed to sit for 1 min before vena-puncture (brachial vein) with a sterile needle. Five mL of circulating blood was collected and added to 45 mL of Bolton's broth without antibiotics and incubated at 42 C in microareophilic conditions for 48 h and then streaked onto Campy-Cefex plates. For flocks 9 and 10, direct plating onto aerobic plate count agar was also performed to verify that the skin had been disinfected. Standard laboratory procedures for *Campylobacter* were performed on ceca contents collected from all broilers sampled. *Campylobacter* were not recovered from the blood (0/60) nor the ceca (0/60) from flocks 1-4, 6, or 7. From flocks 5 and 8-10, *Campylobacter* were recovered from the blood (11/40) and the ceca (28/40). From aerobic plate counts performed in flocks 9 and 10, no growth was observed suggesting that the method utilized results in aseptic sampling of the circulating blood. With *Campylobacter* being recovered from the circulating blood, this provides insight to a possible means by which this organism is able to rapidly disseminate to tissues within the bird and suggests that *Campylobacter* is not strictly limited to the

digestive tract. Further research will determine whether *Campylobacter* resides in the blood for prolonged periods of time or if the organism's presence is merely transitory.

Key Words: *Campylobacter*, Blood, Broilers

M276 Effect of a *Lactobacillus spp*-based probiotic culture product on broiler chick performance under commercial conditions. A. D. Wolfenden*[1], J. L. Vicente[1,2], L. Aviña[2], A. Torres-Rodriguez[3], G. Tellez[1], and B. M. Hargis[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Sigrah Zellet de Mexico S.A. de C.V.*, *Cuernavaca Morelos, Mexico*, [3]*Cobb-Vantress*, *Siloam Springs, AR*.

Concern about antimicrobial resistance has led to increased attention to alternatives for controlling infections and increasing performance in animal production. Probiotics and organic acids have gained attention as options in poultry industry. Our laboratory has been working in the selection of lactic acid bacteria, mainly from the genus *Lactobacillus*, as potential probiotic candidates. Previous data indicates that these selected probiotic bacteria are able to reduce *Salmonella* infection and improve performance in broiler and turkey under experimental and commercial trials in the USA. The selected probiotic organisms were used in field trials to evaluate their efficacy in commercial conditions in Mexico. In the present report, the probiotic culture (n= 6 broiler houses) significantly reduced mortality (P<0.01) compared to 6 control houses (5.87% vs. 6.72%). Also, a consistent, albeit non-significant, improvement of body weight, 2.06% (Control: 2.429 ± 0.157kg vs. Treated: 2.479 ± 0.164kg) and reduction of FCR (3.5%) was observed in the treated flocks. Average daily gain was improved by 1.8% in the treated flocks (50.4 ± 1.98g) compared to the control (49.5 ± 1.88g) with p=0.06. The results of this report suggest that this *Lactobacillus*-based probiotic culture could be useful to reduce mortality and improve performance in commercial poultry farms.

Key Words: *Lactobacillus*, Broiler, Performance

M277 Factors affecting the eggshell thickness on laying hens in Tepatitlan, Jalisco. R. G. Ramírez*, A. J. Zárate, M. G. Alcorta, and J. A. C. Meneses, *Universidad Autónoma Chapingo*, *Texcoco, Estado de México, México*.

The eggshell quality is a very important trait in laying hens, due to the losses by broken eggs. The objectives of this research were to evaluate genetic and environmental factors affecting eggshell quality in Leghorn type hens in the Tepatitlan, Jalisco area, and to determine the relationship between Eggshell Thickness (ET) and Eggshell Stiffness (ES). A total of 6,157 eggs of 24 poultry farms were sampled and their eggshell thickness and eggshell stiffness values were measured. The Laying Strain (LS), Laying Age (LA) and Feed Type (FT) were registered for each egg measured. Data analysis included a linear correlation (ET-ES), regression for ET (n=2626) and ES (n=6151) with LA as a covariate of LS, and means tests to determine differences among LS, LA and FT on their ET and ES values. There were differences within Laying strains and Feed Types (P<0.05) for both, ET and ES. Linear correlation coefficient between ET and ES was 0.67 in this research. Means and standard deviation for ET and ES was 0.324 ± 0.0308 mm and 3481 ± 850.9 g/cm2 respectively.

Key Words: Eggshell Quality, Strain, Feed

M278 Effects of feeding blends of grains naturally contaminated with Fusarium mycotoxins on performance, hematology and blood chemistry of turkeys. C. K. Girish*, T. K. Smith, H. J. Boermans, and N. A. Karrow, *University of Guelph*, *Guelph, Ontario, Canada*.

An experiment was conducted to investigate the effects of feeding blends of grains naturally contaminated with Fusarium mycotoxins on performance, hematology and blood chemistry of turkeys. The efficacy of polymeric glucomannan mycotoxin adsorbent (GMA, Mycosorb®, Alltech, Inc., Nicholasville, KY) in preventing the adverse effects of Fusarium mycotoxins was also evaluated. Three hundred 1-d-old male turkey poults were fed wheat, corn and soybean meal-based starter (0-3 wk), grower (4-6 wk), developer (7-9 wk), and finisher (10-12 wk) diets formulated with uncontaminated grains, contaminated grains and contaminated grains + 0.2 % GMA. Feeding contaminated grains to turkeys significantly decreased body weight gains during the grower and developer phases. Feeding contaminated grains did not, however, alter feed intake or feed efficiency. GMA supplementation prevented the effects of contaminated grains. The feeding of contaminated grains reduced (p<0.05) total lymphocyte counts at wk 3. Supplementation with GMA increased plasma total protein concentrations compared to controls and birds fed the contaminated diet. Plasma uric acid concentrations in birds fed contaminated grains were increased at the end of the experiment compared to controls and the feeding of GMA prevented this effect. The feeding of contaminated grains for 12 wk increased the relative weights of gizzard and bursa of Fabricius. Dietary supplementation with GMA in contaminated diet prevented the effects on the bursa of Fabricius. It was concluded that turkey performance, some blood parameters and organ weights were affected by feed borne Fusarium mycotoxins, and that GMA prevented many of these effects.

Key Words: Fusarium Mycotoxin, Performance, Hematology

M279 Impacts of raising season and phytase addition to standard and vegetable diets on broilers performance and litter physical characteristics. N. Bergeron*[1], A. Ouyed[2], and M. Lefrançois[1], [1]*Université Laval*, *Québec, Québec, Canada*, [2]*Centre de recherche en sciences animales de Deschambault*, *Deschambault, Québec, Canada*.

Two experiments were conducted in summer and winter, respectively, to assess the effects of phytase (PHY) addition to conventional (CON) and all vegetable (VG) diets on broilers performance and litter physical characteristics as dry matter content. To this end, 3080 Ross × Ross male broilers were allotted to 40 pens in each assay, according to a complete randomized block design with diets (CON vs VG) and PHY (0 vs 100 g/t liquid Natuphos 5000™) as main factors. CON diets contained animal fat (Sani-Santé™) and meat meal (54.35% CP) which were replaced with micronized soybean in the VG diets. Broilers were submitted to a four phases feeding program respecting the following nutritional specifications for CP (%), ME (kcal/kg), aP (%) and Ca (%) : starter from 0-15 d (21.9; 3039; 0.45; 0.96), grower from 16-21 d (19.9; 3139; 0.40; 0.85), finisher 1 from 22-32 d (17.9; 3193; 0.37; 0.80), and finisher 2 from 33-38 d (16.9; 3216; 0.32; 0.71). Broilers fed the CON diets had greater final body weights when results from both assays were combined (2905 vs 2853 g; P<.01), whereas PHY addition had no effects (2883 vs 2875 g with PHY). Overall feed efficiency (FE) was improved (1.667 vs 1.615; P<.0001) when broilers were fed the VG diets. PHY addition had no effects on FE (1.642 vs 1.641 with PHY). FE was also better (P<.05) in winter (1.631) than

in summer (1.651). Apparent litter density (kg/m^3) was not influenced (P>.05) by the dietary treatments (CON/-PHY:350.38; CON/+PHY: 350.24; VG/-PHY: 360.11; VG/+PHY:353.80) but increased (P<.0001) in winter (375.56 vs 331.70). In summer, litter dry matter content was higher with CON diets (70.06 vs 64.14% ; P<.0001) and without added PHY (68.67 vs 65.44% ; P<.01). CON fed broilers showed better feed efficiency and final body weight than VG fed broilers. VG fed broilers produced a more humid litter in summer only. PHY addition increased litter moisture but did not influence broilers performance. These results suggest that VG diets and dietary phytase addition had significant but limited negative impacts on broilers performance and litter characteristics.

Key Words: Broiler Performance, Phytase Vegetable, Litter

M280 Reduction of emissions from in vitro swine manure using monensin. T. R. Whitehead* and M. A. Cotta, *USDA-ARS-NCAUR, Peoria, IL*.

Storage of swine manure is associated with the generation of malodorous compounds and emissions. These are produced as a result of anaerobic degradation of materials present in manure and include sulfides, methane, organic acids, ammonia, and other volatile compounds. Because odor emission from livestock creates a nuisance and may be regulated, there is considerable interest in devising methods to control these emissions. Previous research in our laboratories has demonstrated that the primary microbial populations in stored swine manure are low (G+C), Gram positive anaerobic bacteria. One approach for reducing emissions production would be to target these populations. Monensin has been used to alter the bacterial population and metabolic end products in the rumen of domestic animals for improved animal performance, largely through its effect on Gram positive bacteria. Therefore, it was decided to test the effects of monensin on stored swine manure. Fecal and manure pit slurry were collected from a local swine production facility. Manure slurry (20% final concentration) was combined with 20% (w/v) feces and buffer and mixed under gas. The mixture was aliquoted into glass bottles under gas. Monensin (10 mM) was added to three bottles, and three bottles without monensin were used as controls. Gas production was measured over time, and aliquots were removed for chemical analyses and determination of viable bacterial numbers. Gas production in the monensin samples was greatly reduced within 24 hr (<10% of controls), and this reduction was maintained over a 28 day test period. Methane production was also reduced (<5% of controls). However, no detectable hydrogen was observed in any sample. Volatile fatty acid production was only slightly decreased in the monensin samples, while butyrate production increased 3 fold. These results are quite different from those observed in the rumen. The results of this study suggest that addition of antimicrobial compounds may prove useful for reducing gaseous, odorous emissions from swine facilities. Evaluation of other microbial inhibitors in addition to monensin appears warranted.

Key Words: Swine, Odor, Manure

M281 The relationship of animal, production, and carcass traits to consumer acceptability of grass-fed steaks. E. L. Steinberg*, J. W. Comerford, and V. H. Baumer, *The Pennsylvania State University, University Park*.

Twenty grass-fed steers and 10 grass-fed heifers were evaluated for the relationship of wintering growth rate, grazing daily weight gain, sex, grazing period, frame size, final weight, and carcass traits (fat thickness, ribeye area, marbling score, yield grade and shear force) to consumer evaluation of tenderness, juiciness, flavor, and acceptability of cooked steaks. All of the cattle were wintered for a targeted weight gain of 0.73 kg/d for 156 d, and then were grazed in rotationally-grazed paddocks containing primarily cool-season grasses. Cattle were harvested at a constant age (532.9 d ± 5.7 d) in 6 harvest groups ranging from 124 d to 187 d of grazing and carcass data were collected. Final quality grade ranged from low Select to low Choice. Longissimus muscle steaks were thawed, cooked, and offered to trained panelists. Steaks were evaluated for Warner-Bratzler shear force, and analysis of covariance evaluated the relationship of carcass traits with growth and animal traits, and consumer evaluations were compared with all traits. There was a significant covariance of yield grade with frame size and with fat thickness and grazing days ($P < 0.05$). Animal, growth, and carcass traits were not related to panelist evaluations of tenderness, flavor, juiciness, meat texture, or overall desirability for grass-fed cattle harvested at 532 d of age ($P > 0.05$). The relationship of marbling score and consumer evaluation of juiciness was not significant ($P = 0.21$). There was no significant covariance among frame size, juiciness, flavor, tenderness, texture or overall acceptability ($P > 0.05$) except for yield grade with juiciness ($P = 0.01$). Mean panel scores for grass-fed steaks were moderate for overall acceptability (4.6 out of 9), flavor (5.1 out of 9), and juiciness (3.1 out of 7), while scoring them slightly tough (4.4 out of 9). Significant variation in scores for tenderness, juiciness, flavor, and overall acceptability were found, indicating post-harvest interventions may be more effective in increasing consistency for consumers of grass-fed meat compared to production and carcass traits.

Key Words: Grass-Fed Beef, Carcass, Production

M282 Differentiation of fecal alkane and fatty alcohol markers of diet composition of cattle and sheep grazing a complex heathland sward. J. M. Moorby*, M. D. Fraser, V. J. Theobald, and S. M. Morris, *Institute of Grassland and Environmental Research, Aberystwyth, UK*.

To investigate inter- and intra-species differences in foraging strategy, two breeds of each of cattle (Welsh Black, WB, and a continental crossbreed, CX) and sheep (Welsh Mountain, WM and Scottish Blackface, SB) were rotationally grazed on four adjacent 1 ha plots of a *Calluna vulgaris*-dominated heathland community. In each of two sampling sessions in 2005, late July and late September, after adaptation for 21 d, fecal samples were collected from each animal and bulked over 7 d. These were dried and analyzed for alkane and long-chain fatty alcohol (LCFA) concentrations, which are of plant (diet) origin and are largely undigested. Their profiles in plants differ between species and thus their profiles in feces depend on diet composition. Data were analyzed by principal components (PC) analysis and hierarchical cluster analysis. A scatter plot of PC1 v. PC2 showed differentiation between cattle and sheep and within-species segregation of the sampling sessions, indicating different diets for cattle and sheep. This also indicated that diets differed by session, or at least that the marker profiles differed within the diets in different sessions. Analysis of variance of PC1 (accounting for 90.6% of data variation) with species, breed and month as treatment factors were significant ($P < 0.001$) for each factor. Similarly, HCA showed clear

clustering of species and sample months, with some overlap of breed within sample month. There was greater spread (PC variation and HCA heterogeneity) among the sheep data (SD of PC1 = 1451 for all sheep data, 1423 for WM, and 1258 for SB) than among the cattle data (SD of PC1 = 415 for all cattle data, 553 for WB, and 229 for CX). This indicates that cattle, and in particular CX, chose more consistent diets than sheep and perhaps while the cattle consumed diets dependant on plant availability, different breeds of sheep chose more varied diets. In conclusion, this work found greater variation in diet composition of sheep than of cattle given equal selection opportunities, and that diets differed in their alkane and LFCA concentrations at different times of the year.

Key Words: Grazing, Diet Selection, Alkanes

M283 Predicting the retention of ruminal boluses for the electronic identification of goats. S. Carné*, G. Caja, J. J. Ghirardi, and A. A. K. Salama, *Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

A total of 1,725 boluses were used to build-up a model for predicting the long-term retention of boluses into the forestomachs of adult goats under on-farm conditions. Animals belonged to Murciano-Granadina (dairy) and Blanca de Rasquera (meat) Spanish autochthonous goat breeds. Boluses consisted of 15 capsules made of different materials (ceramic, concrete, plastic with or without metallic balast) for achieving a wide range of physical features: length (37 to 84 mm), o. d. (9 to 22 mm), weight (5 to 110 g), volume (2.6 to 26 mL) and specific gravity (1 to 4.3). Each bolus contained an ISO half-duplex glass encapsulated transponder (32 × 3.8 mm). Boluses were administered by trained operators using adapted balling guns. Full-ISO handheld transceivers working at a frequency of 134.2 kHz were used to perform static readings. When a bolus loss (bolus not readable) was detected, a heavier bolus was applied. Retention rate (RR = 100 × read/applied) was calculated from data recorded from 2 to 24 mo post-application. No application problems or apparent behaviour alterations were observed for any bolus type. Bolus RR ranged 0 to 100% depending on their physical features. Only the largest bolus (26 ml; 110 g; and SG = 4.23) showed RR > 99%. Data allowed fitting a logistic model for predicting bolus retention from their volume (V, ml) and weight (W, g). The model (R^2 = 0.956; P < 0.001) was: RR (%) = 100 / (1 + 0.8086 e $^{0.879\ V\ -\ 0.283\ W}$). An exponential relationship (r = –0.84; P < 0.01) was found between specific gravity and W for the predicted values of bolus retention. Estimated weight and specific gravity for producing a standard size bolus (22 mL) with RR > 99% are greater than 95 g and 4.32, respectively. Further research is required for improving prediction accuracy.

Key Words: Electronic Bolus, Electronic Identification, Goat

M284 Effects of age and rearing method on long-term retention of different electronic identification devices in goat. S. Carné*, G. Caja, J. J. Ghirardi, and A. A. K. Salama, *Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

A total of 70 Murciano-Granadina kids were used for evaluating the use of visual ear tags and 3 types of electronic identification (ID) devices (injectable, ear tag and bolus) in replacement goats. Kids were ID after birth with 2 types of plastic ear tags (V1, n = 42; V2 = 25) in the left ear, and raised as a single group with ad libitum milk substitute, concentrate and straw until 60 d of age (7.7 ± 0.8 kg BW). Four kids (5.7%) died during this period. Half of the kids (n = 33) were weaned and a daily single milk feeding was maintained thereafter in the other half (n = 33) up to 5 mo of age. Kids were also ID at d 60 with 1 electronic ear-tag in the right ear (ET, n = 66; half-duplex double button tag, 6 g) and 1 electronic mini-bolus (B1,13.7 g, 51 × 11 mm, n = 66; half-duplex) containing a 32 × 3.8 mm half-duplex transponder. Additionally, kids were ID at d 90 with 2 injectable transponders in each metacarpus (IM1, 12 × 2.1 mm, n = 50; IM2, 15 × 2.1 mm, n = 75; full-duplex B glass encapsulated). Lost B1were replaced by larger bolus (B2, 20.1 g, 56 × 11 mm). Retention rate (read/applied × 100) of ID devices was recorded weekly up to18 mo of age. Intermediary retention at mo 5 varied between devices (V1, 85.4%; V2, 100%; E1, 100%; E2, 100%; B1, 77.3%; B2, 100%; IM1, 92.0%; IM2, 98.0%; P < 0.05). Extended milk-fed rearing tended to increase B1 losses (84.8 vs 69.7%; P = 0.148), which should be confirmed with a larger kid number. V1 were removed at 1 yr of age. Lost B1 during the experiment were replaced with B2 boluses (n = 21). Finally, at 18 mo of age, average retention rate of devices were: bolus, 62.5% (B1, 68.2%; B2, 78.6%; P = 0.087); injectable, 93.3% (IM1, 91.4%; IM2, 96.0%; P = 0.333); and, electronic ear tag, 100% (E1, 100%; E2, 100%). Mini-bolus showed the lowest retention (P < 0.05) when compared to ear tag and injectable. In conclusion, only electronic ear tags proved to be efficient devices for the identification of goats from suckling to adult, and new bolus designs are required for the electronic identification of goat in practice.

Key Words: Ear tag, Electronic Identification, Goat

M285 Performance of milk recording procedures based on visual or electronic identification in dairy goats. A. Ait-Saidi, G. Caja*, S. Carné, and A. A. K. Salama, *Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

A group of 24 Murciano-Granadina dairy goats at early-mid lactation (60 to 120 DIM; 1.44 to 2.41 L/d) was used to compare labor time and data collection efficiency of using manual or semi-automated systems for milk recording on-field conditions. Goats were milked in a 2 × 12 parallel platform with 6 milking units by side (3 units/operator), automatic head lockers and manual concentrate feeding and goat releasing. Manual (M) system used visual identification (48 × 38 mm plastic ear tags recorded with 3 digits), on paper data recording (ear tag number, milk yield and observations) and typing for uploading data to a computer. Semi-automated (SA) system used electronic identification (75 g boluses, 21 × 68 mm; containing HDX transponders, 32 × 3.8 mm, Rumitag, Barcelona, Spain) and reading (hand-held reader with stick antenna; Smart-reader, Rumitag), data recording by typing on reader keyboard (milk yield and observations) and automatic data uploading to computer by blue-tooth connection. Data were collected by groups of 12 goats in 10 milk recordings of each system done during an interval of 55 d. Although there was no difference between M and SA in milk recording time corrected by milk yield (0.72 ± 0.04 min/L/goat, on average), a marked difference was observed for time needed for transferring data of series of 24 goats to the computer (M, 0.22 ± 0.02 min/goat; SA, 0.05 ± 0.01 min/goat; P < 0.001). Total milk recording time corrected by yield and per goat was lower (P < 0.01) in SA than in M (0.77 vs 0.93 min/L/goat). Time necessary for transfering milk recording data of groups 24 goats was 5.24 and 1.25 min for M and SA, respectively. Data transfer time increased by 0.2 min for each additional 24 goats in the SA system. Consequently,

differences in estimated labor time for downloading data between both systems increased with number of goats recorded in the same test day, being: 4.0, 14.2, 29.4, 44.7, 59.9, and 75.2 min; for: 24, 72, 144, 216, 288, and 360 goats, respectively. Differences in labor time cost ($15/h) ranged from $1.0 to $18.8 per milk recording, in favour of using electronic identification.

Key Words: Electronic Identification, Milk Recording, Dairy Goats

M286 Is ethanol production sustainable? An animal science approach. H. Koknaroglu[1], T. Purevjav*[1], T. Akunal[2], and M. P. Hoffman[1], [1]*Suleyman Demirel University*, *Isparta, Turkey*, [2]*Iowa State University*, *Ames*.

A three-year grazing and feedlot finishing trial was conducted to examine the inclusion of condensed corn distillers solubles (CCDS) on sustainability of cattle feeding program. Cultural energy (CE) is the energy other than solar energy needed to produce food and fiber and energy output/input ratios is one of the most useful methods to examine the potential long-term sustainability of various agricultural practices and this analysis is performed to quantify the energy return from products produced relative to the CE invested to produce the product. CCDS is a by-product of ethanol production and is a valuable feed resource that can be used with corn stalks to feed cattle. In our research, we assumed that CCDS and corn stalks have no CE embedded. Each year, calves (n=112) were assigned to four treatment groups by weight and color pattern. Treatments 1 and 2 were pasture (P) rotational grazing (May-September) followed by feedlot finishing (FL) on chopped alfalfa hay and corn (P/FL) or corn, corn stalks and CCDS (P+CCDS/FL), respectively. Cattle in treatments 3 (FL) and 4 (FL+CCDS) were fed in the feedlot from May until harvested. The FL included chopped alfalfa hay and corn, and FL+CCDS included corn, corn stalks, and CCDS. Cattle were weighed every 28 days, and about 586 kg live weight, they were harvested. CE used for pasture establishment, feed consumption, and maintenance were calculated using the actual inputs and corresponding energy values from the literature. FL had higher total CE expenditures and pasturing decreased total CE expenditures ($P<0.01$). Feed energy comprised more than half of the total CE and was highest for FL and was lowest for P+CCDS/FL ($P<0.01$). Kilocalories of CE required to produce kilocalories of protein energy was lower for cattle receiving CCDS ($P<0.05$). Results showed that including CCDS and corn stalks into cattle feeding programs saved 480.5 Mcal CE expended per head corresponding to more than 10% of total CE expended. Thus this shows that CCDS and corn stalks are an effective way to reduce CE expenditure of cattle feeding and this amount will help to increase sustainability of ethanol production.

M287 Impact of producing low DCAD forage on chloride farm-gate balance. O. Soucy*, D. Pellerin, E. Charbonneau, and G. Allard, *Universite Laval*, *Quebec, Canada*.

The addition of chloride (Cl) to prepartum dairy cow diets can reduce incidence of milk fever by reducing their dietary cation-anion difference (DCAD). Chloride can be added in the ration as anionic salts or be included through forage produced on the farm and fertilized with $CaCl_2$. Both practices have an impact on the Cl farm balance. The objective of this study was to model the Cl cycle on dairy farms and to compute their farm-gate Cl balances according to two scenarios: 1- actual farm data; 2- actual farm data with production of low DCAD forage. The N-CyCLE model has been modified to describe the Cl cycling and to compute the farm-gate balance for Cl. The model was run with data from 18 farms from two different areas of the Quebec province. In scenario 2, a 160 kg / ha application of $CaCl_2$ was added on each 3.7 ha necessary to feed 50 lactating cows. Average Cl farm-gate balance is 2559 kg. It varies from -705 kg to 5441 kg. The high variability can be linked to the Cl in purchased feed, which varies from 1187 to 6260 kg Cl, and the Cl in crops sold, which varies from 1153 to 3380 kg Cl. On a milk production basis, Cl input by feed purchased is quite stable with an average of 5.7 kg Cl /hL. A larger variability is observed with Cl sold as crops, it accounts for 4.4 kg Cl /hL, varying from 2.9 to 12.2 kg Cl /ha. The environmental impact, predicted using the Cl balance expressed on a land basis, is, on average, 17.1 kg Cl / ha but varies from 5.3 to 29.9 kg Cl /ha. The production of low DCAD forage leads to an average farm-gate balance of 2969 kg Cl, varying from -457 to 6092 kg Cl, this represents a mean increase of 16 %. As expected, such an increase depends on the existent Cl global farm balance: for the farm with the minimum global balance, -705 kg Cl, the increase is 35% but it is only a 12% increase for the farm with the maximum balance of 5441 kg Cl. In order to predict the environmental impact of a management practice such as Cl fertilization, our data suggest that the Cl balance should be computed for every farm since a high variability exists between farms.

Key Words: Chloride, Balance, Model

M288 The effect of dehorning at twenty-eight days of age on calf growth and health. B. L. Miller*, T. J. Earleywine, and T. E. Johnson, *Land O'Lakes, Inc.*, *Webster City, IA*.

Three hundred seventy two (372) 3 to 5 day old Holstein bull calves (mean BW=45.3 kg) were employed in two 42 day trials. These animals were employed to understand the impact of de-horning on performance and health. Not dehorned (NDH) or dehorned (DH) were stratified across different dietary treatments by initial weight and blood IgG status. No interactions were noted thus only main effects for dehorning treatments are presented. Calves were fed an average 359 g of a milk replacer twice daily. The milk replacer contained 20% fat and either 22% or 25% protein. Milk replacer was not medicated. Calf starter (18% CP) was fed throughout these trials. Calves assigned to the DH treatment were dehorned at 28 days of age via hot-iron method. Total gain, intake, respiratory and treatments costs were not impacted by dehorning ($P>.05$). Dehorning of calves at twenty eight days of age does not appear to influence calf growth or health.

Table 1.

Item	NDH	DH
No. calves	188	184
D 28-42 gain, kg	9.34	9.26
D 28-42 milk replacer intake, kg	7.51	7.49
D 28-42 starter intake, kg	8.90	9.31
D 28-42 respiratory days	.27	.33
D 28-42 treatment cost, $	.84	.91

all means NS ($P>.05$)

M289 Temperament and chute exit velocity scores of Senepol calves after weaning. R. W. Godfrey and R. C. Ketring*, *University of the Virgin Islands, Agricultural Experiment Station*, *St. Croix, US Virgin Islands*.

The objective of this study was to evaluate the temperament and chute exit velocities (EV) of weaned Senepol calves. Bull (n =14) and heifer (n= 30) calves were evaluated at an age of 8.7 ± 0.4 mo (d 0) using chute score (CS) and EV as indicators of temperament. All calves were fire branded with the herd identification on d 0, after the initial CS and EV were measured, and a second EV was recorded at this time (BRND). On d 49 CS and EV were measured again for all calves. The CS was determined on a 1 to 5 scale with 1 being calm and 5 being extremely agitated. Chute exit velocity, reported in m/sec, was measured as the animals exited the chute using an electric timing system. There was no difference ($P > 0.10$) in any trait measured between bulls and heifers so data were pooled across sex. There was no difference ($P > 0.10$) in CS of calves measured at d 0 or d 49 (2.1 ± 0.1 vs. 2.2 ± 0.2, respectively). Only 6.8 % of the calves had a CS greater than 3 ($P < 0.006$). Calves had a greater EV at BRND ($P < 0.0009$) than at either d 0 or d 49 (3.1 ± 0.1 vs. 2.4 ± 0.1 vs. 2.4 ± .01 m/sec, respectively). At d 0 calves with a CS of 1 had a lower ($P < 0.03$) EV compared to calves with a CS of 2, 3 or 4 (1.7 ± 0.3 vs. 2.3 ± 0.2 vs. 2.6 ± 0.2 vs. 3.0 ± 0.5 m/sec, respectively). At d 49 EV of calves with a CS of 1 was lower ($P < 0.01$) than that of calves with a CS of 2, but not different ($P > 0.10$) from calves with a CS of 3 or 4 (1.9 ± 0.2 vs. 2.7 ± 0.2 vs. 2.3 ± 0.2 vs. 2.9 ± 0.6 m/sec., respectively). There was no difference ($P > 0.10$) in weaning weight among calves that received CS of 1, 2, 3 or 4 at day 0 or d 49. Overall CS and EV had a moderate correlation ($P < 0.002$, $r = 0.359$). At d 0 CS and EV had a moderate correlation ($P < .004$, $r = 0.446$) but not at d 49 ($P > 0.10$, $r = 0.209$). There was no correlation ($P > 0.10$) between weaning weight and EV at d 0 or d 49. At BRND EV tended to have a negative correlation with weaning weight ($P < 0.07$, $r = -0.298$). These results show that the temperament of Senepol calves does not change significantly over time after weaning.

Key Words: Temperament, Cattle, Behavior

M290 The effect of calf ear infection (otitis media) on calf growth and health. B. L. Miller*, T. J. Earleywine, and T. E. Johnson, *Land O'Lakes, Inc.*, *Webster City, IA*.

The Land O'Lakes Research facility in Webster City, IA conducts trials with over 1500 three-to-five day old Holstein bull calves annually. These calves are co-mingled sale barn calves purchased from Wisconsin. Upon the completion of research trials, these calves have been sold to local producers. However, during the last six years *Micoplasma bovis* infection has reduced the value and number of saleable calves. To better understand the full impact of ear infection (otitis media), calf performance, health and total treatment costs were examined. One hundred thirty-one (131) Holstein bull calves (mean BW=45.2 kg) were employed in this 42 day trial. All calves were fed 340 g of a 20% all-milk protein, 20% fat milk replacer (MR) twice daily. Milk replacer was not medicated. Calf groups were formed by treatment for ear infection (1. no clinical signs, no antibiotic treatment; 2. clinical signs with antibiotic treatment for 1 - 6 days; or 3. clinical signs with antibiotic treatment for over 6 days). Daily antibiotic (AB) treatment was approved extra-label use of Lincomycin (.45 g/d) and Spectomycin (.33 g/d) intramuscular injection. Antibiotic treatment was not related to initial weight or blood gamma globulin status. Calf starter (18% CP) was fed throughout this trial. Total gain, MR intake and starter intake were reduced ($P<.05$) for calves having clinical signs of ear infection and treated for more than six days compared with non-clinical, non-treated calves. Total calf treatment cost increased with number of treatment days.

Table 1.

Item	No clinical/ No AB	Clinical/ 1-6 d AB	Clinical/ 6+d AB
No. calves	77	33	21

M291 Feeding behavior and weight gain of calves fed low or high quantities of milk using an automated feeding system. T. F. Borderas*[1,2], A. M. dePassillé[1], and J. Rushen[1], [1]*Agriculture and Agri-Food Canada*, *Agassiz, B.C., Canada*, [2]*University of British Columbia*, *Vancouver, B.C., Canada*.

There is interest in feeding unweaned calves more milk but little is known about feeding behavior in group-housed calves fed with an automated feeder. In two experiments, we examined the effect of low and high milk allowances on behavior and weight gain of Holstein calves fed on an automated feeder. In Exp. 1, we fed calves either 4L/d milk replacer (N=25) or to ad libitum intake (N=25) to 42d of age. In Exp. 2, calves were fed 4L/d (N=14) or 12L/d (N=14) of whole milk to 32d. Calves were housed in dynamic groups of 3 to 15. Results were analysed using a mixed model with calf, treatment and age as factors. Differences were significant at P=0.05. Calves with a high milk allowance consumed more milk (Mean±SD Exp 1: 13.4 ± 1.9 L /d, Exp 2: 8.9 ± 0.7) than calves fed 4L/d. Low milk fed calves made more visits to the milk feeder than high milk fed calves (Exp 1: 22.9 ± 5.1 vs. 11.4 ± 3.5; Exp 2: 22.3 ± 5.8 vs. 11.7 ± 2.4). To d14, calves ate less than 200 g/d of concentrate and there were no differences between treatments (P>0.10) After d14, high fed calves ate less grain (Exp 1 : 17.3 ± 4.7 g/d; Exp2: 110.1 ± 33.4 g/d) than low fed calves (Exp 1: 793.8 ± 87.9 g/d ; Exp2: 581.5 ± 149.1). At 2 wk of age, there were no differences in time spent resting between treatments, but in wk 4 and 5, high milk-fed calves rested for 21.6 ± 10.7 min/d longer than low milk-fed calves. In Exp. 1, weight gains of ad lib fed calves from d0 to d21 were higher (21.96 ± 1.3 kg) than for low milk-fed calves (10.1 ± 0.9 kg). From d21 to weaning, low milk-fed calves gained more than high milk-fed calves (24.8 ± 1.9 vs. 18.1 ± 0.55 kg) but at 42d weaning, body weights of high milk-fed calves were higher (86.9 ± 2.6 vs. 77.6 ± 2.3 kg). Feeding calves more milk improved weight gain until d21 and improved the efficiency of use of the automated feeder. However, feeding more milk reduces concentrate consumption after 14 d and growth advantages after 21 d of age.

Key Words: Dairy, Calf, Feeding

M292 Effect of palm kernel meal plus urea on finishing of Brown Swiss young bulls. J. H. Avellaneda-Cevallos*[1], T. A. Cedeño-Cedeño[1], A. Suárez-Chiquito[1], O. Montañez-Valdez[2], C. D. Cepeda-Cantos[1], R. Luna-Murillo[1], I. Espinoza-Guerra[1], J. Quintana-Zamora[1], and L. Casanova-Ferrín[1], [1]*Facultad de Ciencias Pecuarias, Unidad de Investigación Científica y Tecnológica, Universidad Técnica Estatal de Quevedo*, *Quevedo, Los Rios, Ecuador*, [2]*División de Bienetar y Desarrollo Regional, Departamento de Desarrollo Regional, Universidad de Guadalajara*, *Ciudad Guzmán, Jalisco, México*.

The supplementation of the palm kernel meal (PKM) was evaluated plus urea (U) in 16 castrated cross breed Brown Swiss young bulls with initial average weight 283.75 kg, fed with grass Saboya (Panicum maximum Jacq). The research lasted 90 days. The daily gain of weight (DGW) and total gain (TGW) was evaluated, as was consumption of grass (CG), palm kernel meal (CPKM), total dry matter (TDMC: PKM+CG+U), and the nutritious conversion (NC). A completely random design was used with four treatments and four replications. The treatments were: T0 (control): shepherding; T1: T0+ 1.5 kg DM PKM + 50 g urea/animal; T2: T0 + 2.5 kg DM PKM + 50 g urea/animal; T3: T0 + 3.5 kg DM PKM + 50 g urea/animal. The DGW and TGW, didn't show differences ($p>0.05$) between the animals supplemented, but there were differences between these and T0 ($p<0.05$). The DGW improved when adding PKM+U to the diet, obtaining the best value with T3. The CG didn't present differences ($p>0.05$) between the treatments. The TDMC presented differences ($p<0.05$), the T3 had the most consumption. The NC between the supplemented treatments (T1, T2, and T3) didn't present differences ($p>0.05$), but it was differences were observed ($p<0.05$) when comparing them with the T0.

Table 1.

	T0	T1	T2	T3	SEM	p<
Initial weight, kg	284.25[a]	279.75[a]	290.50[a]	280.75[a]	3.08	0.68
Final weight, kg	316.75[b]	341.50[ab]	348.50[a]	351.75[a]	0.02	0.01

M293 Effect of heat processing on ruminal and post-ruminal disappearance of individual amino acids of Iranian whole soybeans. M. H. Fathi Nasri*[1] and M. Danesh Mesgaran[2], [1]*University of Birjand*, *Birjand, Iran*, [2]*University of Mashad*, *Mashad, Iran*.

The effect of heat processing (roasting and steep-roasting) on ruminal degradability and intestinal digestibility of individual amino acids (AA) in two Iranian whole soybean cultivars (Sahar and Williams) was determined using the mobile nylon bag technique. The seeds were roasted at 140 to 145ºC using a drum roaster (for 1.5-2 min). A fraction of the seeds were cooled immediately and the rest were held in isolated barrels for 45 minutes (steeping). The ruminal degradability of all AA of heat processed soybeans was reduced significantly ($P<0.001$) compared to raw seeds, however, among the individual AA there was variation in ruminal degradation, so that, in both raw and heat processed seeds Arg, Lys, Glu, Asp were degraded to a relatively high degree, whereas Leu, Ile, Met, Phe, Tyr, Thr, and to some extent, Val, Ala were degraded to a relatively low degree. Roasting increased the intestinal digestibility of total and individual AA in residues after rumen incubation, significantly ($P<0.001$), and steeping intensified it, showing beneficial effects of steeping beyond roasting (12.3 % and 18.5 % for total AA, respectively), however, variations in digestibility of the individual AA were found. Total tract disappearance of total AA was higher for raw than roasted seeds, due to higher AA degradability of raw seeds. Among individual AA, some had the higher total tract disappearance in raw seeds and some in heated seeds. There was no significant difference between the two soybean cultivars in respect to AA ruminal degradability, intestinal digestibility and total tract disappearance. The interaction between cultivar and heat processing was not significantly different either. Roasting and steep-roasting were effective methods of changing the site of digestion from rumen to small intestine and therefore the amount of digestible undegraded AA in small intestine was increased.

Key Words: Whole Soybean, Amino Acid, Mobile Nylon Bag

M294 *In situ* ruminal degradability of dry matter and crude protein of cottonseed meal containing different fat concentrations. M. Danesh Mesgaran*, A. Heravi Moussavi, and S. Danesh Mesgaran, *Department of Animal Science (Excellence Center for Animal Science), Ferdowsi University of Mashhad*, *Mashhad, Iran*.

The objective of this study was to determine *in situ* ruminal degradability of DM and CP of 3 cottonseed meals containing different fat concentrations [low (CSl), medium (CSm) and high (CSh); 5, 30 and 60 g/kg, respectively) produced in various Iranian oil industries. Cottonseed CP levels ranged from 288 (CSh) to 395 (CSl) g/kg DM. Four ruminally fistulated steers (400±20 kg, body weight) were used. Bags (12×19 cm, pore size of 48 tμm) containing 5 g DM of each sample was incubated in the rumen (4 replicates per each animal) for 0.0, 2, 4, 8, 16, 24, 48 and 72 h. Ruminal DM and CP disappearance rates was analyzed using a negative exponential model. Relative to the other cottonseed meals, CSl had the highest *in situ* quickly degradable (a) DM fraction (0.39). No difference in (a) fraction of DM was observed between CSm (0.33) and CSh (0.30). In situ (a) fraction of CP ranged from 0.33 for CSh to 0.41 for CSl. Slowly degradable (b) fraction of DM and CP was not similar among the cottonseed meals (CSl= 0.39 and 0.42, CSm= 0.34 and 0.31, CSh= 0.31 and 0.34, respectively). CSh had a lower rate of degradation (c) of DM and CP (0.04 and 0.05, respectively) compared with CSl (0.06 and 0.08, respectively). It was concluded that differences in ruminal degradable parameters exist between cottonseed meals with different fat levels, with more variations observed for ruminal CP than for DM degradability.

Key Words: Cottonseed Meal, Degradability, Crude Protein

M295 The effect of fat content on ruminal and post-ruminal protein disappearance of cottonseed meal using *in situ* mobile bag and alternative enzymatic procedures. M. Danesh Mesgaran*, M. Vatandoost, H. Jahani Azizabadi, and A. Heravi Moussavi, *Department of Animal Science (Excellence Center for Animal Science), Ferdowsi University of Mashhad*, *Mashhad, Iran*.

Ruminal, post-ruminal and total tract crude protein (CP) disappearance from various cottonseed meals [low (CSl), medium (CSm) and high (CSh) fat; 5, 30 and 60 g/kg, respectively) were evaluated using the in situ mobile nylon bag technique, an *in vitro* enzyme procedure and a three-step *in situ/in vitro* enzyme procedure. Results from the current study using different procedures showed relatively lower ruminal and post-ruminal digestibility values for CSh and CSm compared with CSl. Mean ruminal CP disappearance of CSl (0.68) was higher (P < 0.05) than CSm and CSh (0.59 and 0.57, SEM=0.03, respectively). There was a significant effect (P < 0.05) of fat content of cottonseed meal on post-ruminal CP disappearance (CSl= 0.94, CSm= 0.88, CSh= 0.76, SEM= 0.03). Total tract CP disappearance of CSl (0.96) was also significantly higher (P < 0.05) than CSm and CSh (0.88 and 0.79, SEM= 0.04, respectively). Ruminal, post-ruminal and total tract protein disappearance of various cottonseed meals followed non significant patterns with the different procedures used in this study. The coefficient of determination (r2) for the relationship of total tract CP disappearance between the mobile nylon bag technique and *in vitro* and three-step procedures was 0.67 and 0.69, respectively. It may be concluded that the different ruminal and post-ruminal diappearance of CP of cottonseed meal, using different procedures, might be due to the fat content of the samples evaluated in the present study.

Key Words: Protein Disappearance, Three-Step Procedure, In Vitro

M296 A comparison of synchrotron and globar Fourier transform infra-red microspectroscopy (FTIRM) use in predicting cereal grain rumen degradation characteristics. A. M. Walker*, C. R. Christensen, D. A. Christensen, P. Yu, H. C. Block, and J. J. McKinnon, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

The DM, CP, and starch degradation characteristics of one corn and four barley grain varieties were evaluated in two *in situ* nylon bag trials. Trial 1 was a 2 × 2 factorial comparing ground or rolled Harrington barley and Pioneer 39P78 corn. Trial 2 was a 2 × 4 factorial comparing ground or rolled CDC Bold, CDC Dolly, Harrington, and Valier barley. Spectra from reflectance mode globar-based FTIRM were collected on five seeds from each grain using the mid-IR end station at CLS (Saskatoon, SK). Spectra from transmission mode synchrotron-based FTIRM were collected on five seeds from Harrington and Valier barley and Pioneer 39P78 corn grain using the U2B beam line at NSLS-BNL (Upton, NY). Carbohydrate (CHO):amide I spectra peak area ratios were compared to in situ results to determine if FTIRM spectra related to degradation rate differences, and if globar and synchrotron based FTIRM differed. Trial 1 had grain x processing interactions (P<0.01) with Harrington barley degradation rates increasing more (P<0.05) with grinding. Trial 2 had barley variety x processing interactions (P<0.05) with the greatest (P<0.05) degradation rate differences occurring with ground CDC Bold and CDC Dolly vs. Harrington and Valier barley. Both globar- and synchrotron-based FTIRM found CHO:Amide I peak area ratios were greater (P<0.05) for corn than Harrington barley. This suggests high CHO:Amide I peak area ratios indicate reduced degradation rates. However, this relationship reversed when comparing barley varieties with globar FTIRM where varieties with higher (P<0.05) CHO:Amide I peak area ratios generally had higher (P<0.05) degradation rates. Synchrotron FTIRM comparison of Harrington and Valier barley failed (P=0.41) to identify differences in CHO:Amide I peak areas. These results suggest FTIRM spectral features may relate to cereal grain degradation characteristics, but additional research is required to characterize these relationships and compare spectra collection methods.

Key Words: Synchrotron, Infra-Red Spectra, Rumen Degradation

M297 *In situ* ruminal disappearance of acid detergent insoluble nitrogen (ADIN) of various feeds. H. Jahani-Azizabadi, M. Danesh Mesgaran*, R. Valizadeh, and H. Nasirimoghadam, *Ferdowsi University of Mashhad*, *Mashhad, Iran*.

In situ ruminal disappearance of acid detergent insoluble nitrogen (ADIN) of alfalfa hay, alfalfa silage, corn silage, corn grain, barley grain, cottonseed meal and canola meal was determined. Two rumen fistulated Holstein steers (450±50 kg, body weight) were used. Steers were fed 5.1 kg of alfalfa hay, 1.2 kg of corn silage and 2.7 kg of concentrate (150 g CP/kg of DM). Approximately, 6 g of each sample (DM) was placed in each bag [polyester nylon bag (9×17 cm, pore size of 52 µm) and incubated in the rumen for 0.0, 12, 24, 48 and 96 h. After removal of the bags from the rumen, they were washed using cold water and dried in a forced air oven (60 0C, 48 h), weighed to determination DM disappearance, and ADIN of the samples determined. Data in each time were statistically analyzed using a completely randomized design. ADIN value for alfalfa hay, alfalfa silage, corn silage, corn grain, barley grain, cottonseed meal and canola meal was 1.6, 3.4, 1.03, 2.25, 0.8, 2.8 and 4.5 g per kg of DM, respectively. Ruminal ADIN disappearance of alfalfa hay, alfalfa silage, corn silage, corn grain, barley grain, cottonseed meal and canola meal after 24 and 96 hours incubation was 0.3 & 0.4, 0.4 & 0.5, 0.3 & 0.5, 0.6 & 0.9, 0.6 & 0.7, 0.3 & 0.5, 0.2 & 0.3 (SEM= 0.02 & 0.02), respectively. The ruminal ADIN disappearance of the corn and barley grains was significantly higher compared with the other feed samples (P <0.05). Results of the present experiment indicated that a part of the ADIN of the feed samples analyzed in the present experiment disappeared in the rumen and the relative disappearance increased when incubation time was increased.

Key Words: ADIN, Disappearance, Rumen

M298 Feed intake and digestibility response of ram lambs fed olive cake ensiled with different feed supplements. F. T. Sleiman*[1], R. E. Issa[1], S. H. Ibrahim[2], M. G. Uwayjan[1], S. K. Hamadeh[1], I. Toufeili[1], and M. T. Farran[1], [1]*American University of Beirut*, *Beirut, Lebanon*, [2]*University of Dohuk*, *Dohuk, Kurdistan, Iraq*.

Previous research (J. Dairy Sci. 89. Suppl.1,P-371) has shown that ensiling high levels (≥ 72%) of olive cake (OC) with different levels of ground yellow corn (GYC), wheat bran (WB), molasses (M) and urea (U) improved apparent digestibility of fiber fractions and silage (S) DMI when fed to goat kids. In this study lower levels of OC were ensiled with the above feed ingredients in order to evaluate feed DMI, apparent digestibility and performance of ram lambs. The experiment utilized 12 lambs in a completely randomized design and consisted of a 4-wk trial including a 1-wk collection period using the following silage treatments: I) 58.55% OC + 21.3% GYC + 10.0% M + 10.0%

water + 0.15% U; II) 65.3% OC + 10.6% GYC + 6.0% WB+ 10.0% M + 8.0% water + 0.1 U; and III) 46.3% OC + 10.6%GYC + 6.0% WB +20% M+ 17.0% water +0.1% U. Each lamb received 0.5 kg/d concentrate (14% CP on DM basis) in addition to ad libitum feeding of the experimental silages. Means were separated using Duncan Multiple Range test. S DMI was not significantly different (P>0.05) among treatments and averaged 261, 220 and 308g/h/d for treatments I, II, and III, respectively. Change in BW was not significantly different (P>0.05) and averaged 112, 105 and 137 g/h/d for the respective treatments. Apparent digestibility of DM, NFE and NDF of treatment I was significantly higher (P<0.05) than that of treatment III (74.0 Vs 58.7%; 88.4 Vs 77.3%; 50.1 Vs 12.9%, respectively). CP, EE, CF and ADF digestibility was not significantly different (P>0.05) among the silage treatments, with treatment I having the highest digestibility coefficients of these fractions (72.0, 59.5, 36.5 and 40.5%, respectively). Results of this study indicated that ensiling OC with the used levels of feed supplements resulted in acceptable DMI, digestibility and animal performance.

Key Words: Ram Lambs, Olive Cake, Apparent Digestibility

M299 Effects of microwave irradiation on protein degradation of safflower meal in the rumen. P. Shawrang*[1] and A. A. Sadeghi[2], [1]*Animal Science Research Section, Research Center for Agriculture and Medicine, Atomic Energy Organization of Iran*, *Karaj, Iran*, [2]*Department of Animal Science, Faculty of Agriculture, Science and Research Branch, Islamic Azad University*, *Tehran, Iran*.

This study was completed to evaluate effects of 1000 W microwave irradiation for 1, 2 and 3 min on protein degradability and intestinal digestibility of safflower meal (SM) by using nylon bags and SDS-PAGE techniques. Duplicate nylon bags of untreated and microwave irradiated SM were suspended into the rumen of four non-lactating Holstein cows from 0, 2, 4, 6, 8, 12, 16, 24 and 48 h, and data was fitted to exponential model to calculate degradation parameters of CP. Increasing irradiation time decreased (P<0.05) the water soluble fraction and increased (P<0.05) the potentially degradable fraction of CP. The degradation rate of the b fraction decreased (P<0.05) with increases in irradiation time. The effective CP degradability of 1, 2 and 3 min microwave irradiated SM at a rumen outflow rate of 0.05/h decreased (P<0.05) by 10, 17 and 20 %, respectively, compared to untreated SM. SDS-PAGE analysis revealed that SM proteins were composed of two major components A and B, accounting for approximately 34 and 51 percent of the total meal protein, respectively. Both proteins were multi-subunits. The molecular weights of 31.9, 26.0, 21.4, 19.5 kDa for A subunits and 8.0, 9.6 kDa for B subunits were observed in this study. Electrophoretic and densitometric analysis of untreated SM protein residues revealed that B subunits were degraded completely within 4-h, whereas the four subunits of A were not degraded after 12-h of incubation. In microwave irradiated SM, B subunits were resistant until 12-h incubation and four subunits of A were not degraded until 24-h of incubation. Mobile bag CP digestibility linearly (P<0.001) increased as irradiation time increased. Intestinal CP digestibility of untreated, 1, 2 and 3 min microwave irradiated SM at 16-h of ruminal incubation period were 807, 838, 855 and 876 g/kg, respectively. Irradiation at this dose for 4 min induced burning of SM. In conclusion, microwave irradiation of SM at power of 1000 W for 3 min appeared to be an effective means of increasing digestible rumen undegradable protein content.

Key Words: Safflower Meal, Microwave Irradiation, SDS-PAGE

M300 Optigen® is a sustained release source of non-protein nitrogen in the rumen. R. Garcia-Gonzalez*[1], J. M. Tricarico[1], G. A. Harrison[1], M. D. Meyer[1], K. R. McLeod[2], D. L. Harmon[2], and K. A. Dawson[1], [1]*Alltech Inc.*, *Nicholasville, KY*, [2]*University of Kentucky*, *Lexington*.

A trial was conducted to study the N release characteristics of Optigen® (Alltech Inc.) in the rumen. Four ruminally-cannulated steers (277 kg average BW) were fed a 60% corn silage, 30% high moisture corn, and 10% supplement diet at 2% of BW in two daily meals. Steers were assigned to urea (0.11 g/kg BW) or Optigen® (0.12 g/kg BW) in cross-over design. Supplements were top-dressed at feeding. Each period consisted of a 21-d adaptation period and a 3-d sample collection period. On day 22, jugular blood and ruminal samples were collected for up to 8 h post-feeding. Ruminal fluid was analyzed for ammonia, pH and VFA content and blood plasma for ammonia, urea and glucose content. On day 23, disappearance of Optigen® NPN in the rumen was studied *in situ*. Bags with residue were not washed after *in situ* incubation but were placed in acidified water, sonicated, and analyzed for residual urea. On day 24, ruminal and blood samples were collected after intra-ruminal administration of Optigen® or urea prior to the morning feeding. Non-linear modeling of *in situ* NPN disappearance resulted in 7% NPN available at time 0h and a disappearance rate of 0.237 h^{-1} for the NPN fraction released over time. No differences in ruminal pH, VFA, or blood glucose concentrations were observed after urea or Optigen® administration. Ruminal ammonia concentrations were lower in steers fed Optigen® vs. urea (5.3 vs. 6.6 mg/dL, $P<0.05$) on day 22. Differences were greater when Optigen® or urea were administered intra-ruminally on day 24, possibly due to differential eating behavior between steers on day 22. Ruminal ammonia concentrations (mg/dL) were lower ($P<0.05$) in steers receiving Optigen® vs. urea at 2 (16.3 vs. 28.4) and 4 h (1.9 vs. 9.3). Jugular plasma ammonia concentrations peaked at 2 h post-administration of urea (0.216 mM) while they remained constant (0.069 mM average) throughout the same 8-h period in steers receiving Optigen®. Jugular blood plasma urea concentrations were lower ($P<0.05$) in steers receiving Optigen® vs. urea at 4 (4.00 vs. 4.82 mM) and 6 h (3.24 vs. 4.26 mM). This study suggests that Optigen® is a protected source of NPN with sustained release characteristics in the rumen.

Key Words: NPN, Urea, Ammonia

M301 Effects of Optigen® on fermentation, digestion, and N partitioning in rumen-simulating fermenters. G. A. Harrison*, J. M. Tricarico, M. D. Meyer, and K. A. Dawson, *Alltech Biotechnology*, *Nicholasville, KY*.

The effects Optigen® (blended, controlled-release urea) on ruminal fermentation, digestion, and N flow were investigated in single-flow rumen-simulating fermenter cultures. Data from 10 experiments were included in this meta-analysis (all-natural protein: 52 cultures; Optigen: 52 cultures). Cultures were fed diets with a forage base of corn silage and alfalfa hay, 45 to 50% forage (DM basis) and NPN from Optigen at 0.44 to 0.66% dietary DM. NPN from Optigen replaced 6.0 to 9.8% of dietary N. Cultures were fed 12.5 g as fed of experimental diets twice daily for six days. Target dilution rate with McDougall's artificial saliva solution diluted 70:30 with tap water was 0.045 h^{-1}. Samples were collected from all cultures immediately prior to morning feeding during the last 3 days of experiments for fermentation analysis. Effluent weights were recorded each day and a composite sample

for each fermenter was used for DM, OM, and NDF disappearance determination. Nitrogen flow measures were estimated by using purine to N ratios for effluent DM and bacteria. Data were analyzed using the PROC MIXED Model of SAS. Culture fluid pH was not affected by diet (6.42 vs. 6.45; $P>0.10$). Cultures fed all-natural protein diets had higher total VFA concentrations (75.5 vs. 69.1 mM, $P<0.05$) than Optigen-fed cultures. Ammonia (prior to morning feeding) was similar between culture diets (4.24 vs. 4.43 mg/dl, $P>0.10$). Apparent and true DM digestion were not affected by culture diet ($P>0.10$). Cultures receiving Optigen had higher protein degradability (63.5 vs. 65.3% of CP, $P<0.05$) and less undegraded feed N (0.239 vs. 0.228 g/d, $P<0.05$) than all-natural protein cultures. Bacterial N yields (0.323 vs. 0.324 g, $P>0.10$) and efficiency (23.3 vs. 23.3 g bacterial N/kg DM truly digested, $P>0.10$) were not altered by culture diet. We conclude that Optigen can replace up to 9.8% of dietary N in rumen-simulating fermenter cultures without negative effects on fermentation, digestion, or N partitioning.

Key Words: Non-Protein Nitrogen, Optigen, Ruminal Metabolism

M302 The effect of fat content of sodium hydroxide treated sunflower meal on *in situ* dry matter and crude protein degradation parameters. T. Mohammadabadi, M. Danesh Mesgaran*, A. R. Heravi Moussavi, H. Nasiri Moghadam, and M. Chaji, *Ferdowsi University*, *Mashhad, Iran*.

This study was conducted to evaluate *in situ* dry matter (DM) and crude protein (CP) degradation parameters of sunflower meals (containing 25 (SFM25) or 150 (SFM150) g fat/kg DM). Samples were untreated (SFM25U or SFM150U) or sodium hydroxide (40g/kg DM) treated (SFM25T or SFM150T, respectively). CP content of sunflower meals ranged from 232 (SFM150T) to 338 (SFM25U) g/kg DM. Four ruminally fistulated Holstein steers (400±12 Kg, body weight) were used. Approximately, 5 g DM of each sample were placed into bags (12x19 cm), made of polyester cloth with 52 µm pore size (4 replicates per each treatment). Bags were incubated in the rumen for 0.0, 2, 4, 6, 8, 16, 24, 48, 72 and 96 h. The degradable parameters of DM and CP were determined using the equation of P=a + b (1 - e^-ct). SFM150T had the highest rapidly degradable fraction (a) of DM (0.43) compared with the other samples. There was no difference in (a) fraction of DM between SFM150U (0.39), SFM25T (0.32) and SFM25U (0.33). In situ (a) fraction of CP of SFM150U was the lowest, but there was no difference in (a) fraction CP between SFM150T (0.39) and SFM25T (0.38). Slowly degradable fraction (b) of DM of SFM25T was the highest (0.42) and SFM150T was the lowest (0.31) compared with the other samples and (b) fraction of CP ranged from 0.32 for SFM25U to 0.63 for SFM150U. No difference in (b) fraction of CP of SFM150T (0.59) and SFM25T (0.57) was observed. SFM150T had the lowest of fractional degradation rate (c) of DM (0.05) and CP (0.04) and SFM25U had the highest of (c) fraction of DM (0.16) and CP (0.11) compared with the others. It was concluded that the potential degradation of SFM might be affected by the fat content and sodium hydroxide treatment.

M303 Pistachio hull tannin affected digestibility of soybean meal and alfalfa during *in vitro* digestion. A. Bohluli and A. A. Naserian*, *Ferdowsi University*, *Mashhad, Iran*.

Due to binding tannin with protein and cellulose, it was hypothesized that pistachio hull tannin can decrease the digestibility of soybean meal (47% CP and 19% NDF) and alfalfa (18% CP and 34% NDF). Pistachio Hull (PH) is the main pistachio by-product produced from the pistachio dehulling process. PH consisted of 12.7, 5.7, 16.6, 25, and 20% ash, EE, CP, NDF, and ADF, respectively; also it contained a 9.6% total phenolic component and 4.5% tannin determined using Folin-Ciocalteu reagent with a calorimetric method. Poly Ethylene Glycol (PEG) was used as a tannin binder for its ability to counteract the action of PHT on digestibility of SBM and alfalfa. The SBM and alfalfa were incubated separately, with PH in 50:50 ratios or by adding PEG into the mixtures. Dry Matter and Organic Matter Digestibility (IVDMD and IVOMD) of the treatments were determined using a in vitro 2-step digestion technique (48h incubation in a rumen microbial culture and 48h digestion after HCl-pepsin solution addition). PEG enhanced dry matter and organic matter digestibility of the PH+SBM and the PH+alfalfa mixture ($P<0.05$) and its effect was higher for the PH+alfalfa ($P<0.01$). These results suggest pistachio hull tannin prevented digestion of high protein and structural carbohydrate feed sources. In this study, PHT inhibited fiber more than protein digestion. It is maybe because of the addition of HCl-pepsin solution in the second step of in vitro digestion, which may have eased the tannin-protein complex and improved protein digestion in the second step of digestion by pepsin; whereas the structural carbohydrate can only be digested in the first step.

Table 1.

Item	SBM	Alfalfa	PH	SEM
IVDMD	89.0	70.1	62.5

M304 Comparison of ruminal *in situ* crude protein degradability of selected feedstuffs in growing goats. Y. Hu*[1], Z. L. Tan[1], S. X. Tang[1], Z. H. Sun[1], M. Wang[1], and G. O. Tayo[1,2], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, P.R. China*, [2]*Babcock University*, *Ikeja Lagos, Nigeria*.

The objective of this study was to update the feed database on ruminal crude protein (CP) degradability in China. Ruminal in situ CP degradability of three classes of feedstuffs, namely cereal grain (barley, buckwheat, rice and millet), legume (horse bean, pea, mung bean and jequirity), and tuber (potato, sweat potato and cassava) were determined using the *in situ* nylon bag technique. All feed samples were collected from the main production regions in China. Three wether goats (20±1 kg) were used and fed a diet consisting of 500 g kg^{-1} concentrate and 500 g kg^{-1} forage containing DE (3.15 Mcal/kg DM)

and CP (140 g/kg DM). Ruminal CP degradability of each feedstuff was measured at 0, 2, 4, 8, 12, 24 and 36h in duplicate for each goat. The in situ CP disappearance data were fitted to the equation p=a+b (1-e^{-ct}). For cereal grain feedstuffs, the rapidly soluble fraction (a), potentially degradable fraction (b), and degradation constant rate (c) of fraction b was highest for barley, rice, and barley or buck wheat, respectively. For legume feedstuffs, Pea had the highest value of 'a', while 'b' and 'c' values were highest for soybean and horse bean. For tuber feedstuffs, potato had the highest values of 'a' and 'c', and the lowest value of 'b'. Results indicated that ruminal in situ CP degradability of these classes of feedstuffs varied widely. These data could be practically applied in formulating total mixed rations for ruminant production in China.

M305 Effect of replacing soybean meal with *Mucuna pruriens* on growth performance, carcass characteristics and meat safety. S. K. Chikagwa-Malunga*[1], A. T. Adesogan[1], M. Huisden[1], S. C. Kim[1], S. C. Phatak[2], N. J. Szabo[1], and R. C. Littell[1], [1]*University of Florida*, *Gainesville*, [2]*University of Georgia*, *Tifton*.

The harmful effects of the L-dopa in *Mucuna pruriens* (M, Velvet bean) seeds have limited its use as a protein supplement for monogastrics and humans. This study determined how replacing soybean meal (SB) with M affects the performance of lambs and meat safety. Twenty-seven Rambouillet lambs (RM; initial BW = 33.8 ± 5.4 kg) and twelve Florida Native (FN; initial BW = 24.9 ± 8.6 kg) lambs were assigned to four treatments and fed a basal diet of coastal bermudagrass hay, corn, and molasses for 42 (FN) or 49 d (RM) and then harvested. Dietary supplements were formulated by substituting 0 (SB), 33 (Lo), 67 (Med) or 100 (Hi) % of SB with rolled M seeds. Body weight was measured weekly and carcass characteristics and concentrations of L-dopa and its metabolites in rumen fluid, blood and the longisimuss dorsi muscle were measured at harvest. Lambs fed SB had greater ($P < 0.05$) ADG than those fed M (0.20 vs. 0.15 kg/d for RM; 0.18 vs. 0.13 kg/d for FN), and FN lambs had greater ($P < 0.01$) final BW (33.9 vs. 30.3 kg) and hot carcass weights (16.2 vs. 15.1 kg; ($P < 0.10$, tendency) than those fed M. However, supplementary protein source did not affect ($P > 0.05$) dressing percent and concentrations of BUN, blood glucose, cerruloplasmin, and haptoglobin, or concentrations of L-dopa and its metabolites in rumen fluid, blood and muscle. Therefore although SB is a better protein supplement than M, acceptable growth rates and carcass characteristics can be achieved with M supplementation in lambs. Mucuna L-dopa was extensively metabolized in lambs and did not elicit an inflammatory stress response or accumulate in muscle tissue. Therefore, feeding mucuna to lambs as described does not affect meat safety.

Key Words: *Mucuna pruriens* L-dopa, Soybean, Weight Gain

M306 Urea-nitrogen recycling in growing lambs fed diets differing in rumen degradable protein and carbohydrate. D. Kiran* and T. Mutsvangwa, *University of Saskatchewan*, *Saskatchewan, Canada*.

The objective of this study was to determine the interactions between dietary ruminally-degradable protein (RDP) level and ruminally-fermentable carbohydrate on urea kinetics and nitrogen efficiency in rapidly growing lambs fed high N diets. Four Suffolk ram lambs (34.8 ± 0.5 kg BW) were used in a 4 × 4 latin square design with 21-d periods and a 2 × 2 factorial arrangement of dietary treatments. The dietary factors studied were: 1) dry-rolled vs pelleted barley as the principal source of ruminally-fermentable carbohydrate; and 2) dietary levels of RDP of 60 vs 70%. All diets contained 28.8 g N/kg DM. Nitrogen balance was measured from d 15 to d 20, while urea-N kinetics were measured from d 15 to d 19 using intra-jugular infusions of [^{15}N^{15}N]urea. Nitrogen intake ($P = 0.001$), and fecal ($P = 0.002$) and urinary ($P = 0.034$) N excretion increased as the dietary RDP level increased; however, barley processing had no effect. Feeding dry-rolled barley compared to pelleted barley ($P = 0.04$), and feeding 60% RDP compared to 70% RDP ($P = 0.04$) resulted in higher N digestibility. Endogenous production of urea-N and its recycling to the gastrointestinal tract (GIT) did not differ among dietary treatments; however, endogenous production of urea-N was high (45.8 to 50.9 g/d), exceeding N intake (42.3 to 47.9 g/d) across dietary treatments. Similarly, across dietary treatments, 30.6 to 38.5 g/d of urea-N was recycled to the GIT, representing 66.9 to 74.2% of endogenous urea-N production; however, 63.6 to 75.6% of urea-N recycled to the GIT was returned to the ornithine cycle. In summary, although dietary treatment did not alter urea-N kinetics, substantial amounts of hepatic urea-N output were recycled to the GIT under the dietary conditions employed in this study, and additional research is required to determine how this recycled urea-N can be efficiently captured by bacteria within the GIT.

Key Words: Urea Recycling, Sheep, Degradable Protein

M307 Ruminal and intestinal protein and amino acid digestibility of feather meal and feather meal with blood products. K. W. Cotanch*[1], R. J. Grant[1], J. Darrah[1], M. E. VanAmburgh[2], D. A. Ross[2], and J. Haid[3], [1]*William H. Miner Agricultural Research Institute*, *Chazy, NY*, [2]*Cornell University*, *Ithaca, NY*, [3]*U.S. Poultry & Egg Association*, *Tucker, GA*.

Ruminal and intestinal protein and amino acid digestibility of feather meal (FM) with and without blood was determined using the 3-step in vitro procedure of Calsamiglia and Stern (1995) as modified by Gargallo et al. (1996). Thirteen samples of FM were selected for analysis: 6 without blood, 4 with blood added pre-hydrolyzation and 3 with blood added post-hydrolyzation. Hydrolyzation parameters varied

in time, (5 to 150 min), temperature (88 to 163°C) and pressure (30 to 75 psi). Samples were subjected to 12 and 18 h in situ (IS) incubation and 18 h in vitro (IV) incubation with rumen fluid buffer (Goering and Van Soest, 1970) comparing the 3 ruminal incubation methods. Ruminal residues were subjected to in vitro intestinal digestion with 0.1 N HCl and pepsin for 1 h, and then buffered pancreatin for 24 h. Residues were analyzed for total nitrogen (N) and essential amino acid (EAA). The GLM procedure of SAS was used to perform the ANOVA of the EAA content of the whole, buffer insoluble residue and undigested residues. Three soy products, a solvent-extracted soybean meal and two processed soy products were analyzed as controls with the FM through all procedures. Soy product N digestion was similar between products (98.2 to 99.3%) and among the IV intestinal digestion of the IS and IV ruminal residues. These values are consistent with previous data for these feeds and methods. Feather meal in vitro total N digestion did not significantly differ by product (P>0.05). Average total N digestibility for product without blood, with blood added pre-hydrolyzation and blood added post-hydrolyzation, were 57.6%, 64.1% and 66.6% respectively. These results support the 3-step methodology for protein and amino acid digestion as a viable means of estimating ruminal and intestinal digestion of FM product.

Key Words: Feather Meal, Digestibility, Protein

M308 Milk production, milk composition, digestion, and feed intake of cows fed different concentrations of flaxseed meal. H. V. Petit*[1] and P. S. Mir[2], [1]*Agriculture and Agri-Food Canada*, *Sherbrooke, QC, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

Thirty-two lactating multiparous Holstein cows averaging 620 kg of BW were used from week 33 to 37 of lactation to determine the effects of different concentrations of flaxseed meal in the diet on milk production, milk composition, digestion, and feed intake. Cows were blocked for similar DIM. Cows within groups were assigned randomly to one of four treatments. The four TMR consisted of a control diet (CON) with no fat supplement or diets containing either 5, 10 or 15 % flaxseed meal (FM) on a DM basis. Diets were designed to yield similar CP and NEL concentrations. Diets were fed twice daily for 10% orts. Feed consumption and milk yield were recorded daily. Milk samples were obtained from each cow for two consecutive milkings on the fifth week of the experiment and they were analyzed separately to determine milk composition. Total collection of feces and urine was carried out on the fifth week of the experiment. Milk production averaged 22.0 kg/d and was similar among treatments. Milk concentrations of protein and fat, and yields of protein, lactose, and fat were not affected by diet. Intake of DM averaged 17.3 kg/d and was similar among treatments. Digestibilities of DM, ADF, NDF, and N were similar among treatments. Dietary concentrations of flaxseed meal had little effect on milk concentrations of fatty acids (FA). However, feeding FM increased milk concentrations of C18:3n3 and decreased the omega 6 to omega 3 FA ratio in milk fat. These results suggest that flaxseed meal is a good protein source for late lactating dairy cows and that it is possible to feed as much as 15% of the DM in the total diet with little effect on feed intake, milk yield and milk composition.

Key Words: Dairy Cow, Flaxseed, Fatty Acid

M309 Interactions between oilseed supplementation and barley grain processing on urea-nitrogen recycling and nitrogen metabolism in dairy cows. G. N. Gozho*, M. Hobin, and T. Mutsvangwa, *University of Saskatchewan*, *Saskatchewan, Canada*.

The objective of this study was to determine how interactions between oilseed supplementation and barley grain processing alter urea-N transfer to the gastrointestinal tract (GIT) and the utilization of this recycled urea-N in lactating dairy cows. Four Holstein cows (656.3 kg BW; 79.8 days-in-milk) were used in a 4 × 4 Latin square design with 21-d periods and a 2 × 2 factorial arrangement of dietary treatments. The dietary factors studied were: 1) dry-rolled or pelleted barley as the principal source of ruminally-fermentable carbohydrate; and 2) whole canola or whole flaxseed as supplemental fat sources, such that experimental diets contained 6% total fat. Nitrogen balance was measured from d 15 to d 19, while urea-N kinetics were measured from d 15 to d 19 using continuous intra-jugular infusions of [$^{15}N^{15}N$]urea. Nitrogen retention was unaffected (P > 0.05) by diet; however, fecal N excretion was higher (P < 0.001) in cows fed dry-rolled barley compared to those fed pelleted barley. Source of supplemental fat did not affect (P > 0.05) urea-N kinetics. Urea-N production (468.7 vs 371.4 g/d; P = 0.03) was higher, and urea-N entering the GIT (299.4 vs 239.9 g/d; P = 0.07) and the amount of GIT urea-N entry that was returned to the ornithine cycle (230.3 vs 189.6 g/d; P = 0.06) tended to be higher in cows fed dry rolled barley compared to those fed pelleted barley. Despite differences between cows fed dry-rolled barley or pelleted barley in the amounts of urea-N entering the GIT, the amounts of recycled urea-N that were used for anabolic purposes were similar (60.0 vs 42.8 g/d; P = 0.39). The proportion of endogenous urea-N production that was transferred to the GIT, and the proportion of urea-N GIT entry that was used for anabolic purposes, or was lost in the urine or feces were unaffected (P > 0.05) by diet. In consequence, even if barley grain processing altered endogenous urea-N production and urea-N entry into the GIT, this did not result in increased utilization of recycled urea-N for microbial production as the additional urea-N which entered the GIT was returned to ureagenesis.

Key Words: Dairy Cow, Urea Kinetics, Nitrogen Metabolism

M310 Influence of carbohydrate source on nitrogen metabolism and microbial protein synthesis in dairy cows. G. N. Gozho* and T. Mutsvangwa, *University of Saskatchewan*, *Saskatchewan, Canada*.

Nitrogen balance and microbial protein synthesis were examined in four ruminally-fistulated dairy cows (676.3 kg BW; 120.5 DIM). The experiment was a 4 × 4 Latin square design with 21-d periods during which TMR containing barley, corn, oats or wheat as the major carbohydrate source were fed. In western Canada, dairy cow diets typically contain barley, corn, wheat or oats as the principal source of energy, and these cereal grains differ in their starch content and in their ruminal starch degradation. Our hypothesis was that these cereal grains would differ in their ability to support ruminal microbial protein production. Dry matter intake was unaffected by diet; however, cows fed wheat tended (P = 0.08) to consume less DM compared to those fed barley, corn or oats. Milk yield was unaffected by diet; however, 3.5% fat-corrected milk yield for cows fed wheat was lower (P = 0.02) compared to cows fed barley, corn or oats. Total N intake, urinary N output, urinary urea-N output and N retention were all unaffected (P > 0.05) by diet. Cows fed oats tended (P = 0.09) to have a lower fecal N output compared to those fed wheat, barley or corn. Cows fed barley or

corn had higher N output in milk ($P = 0.03$) compared with those fed wheat or oats; however, when expressed as a percentage of N intake, milk N output averaged 25% and was unaffected by diet. Overall, N balance was not affected ($P = 0.10$) by diet. Urinary uric acid excretion was unaffected by diet, but urinary allantoin excretion tended ($P = 0.08$) to be higher in cows fed barley or corn compared to those fed wheat or oats. Urinary excretion of purine derivatives (PD; uric acid + allantoin) were higher ($P = 0.04$) in cows fed barley (436 mmol/d) or corn (427 mmol/d) compared to those fed wheat (397 mmol/d) or oats (379 mmol /d). Microbial protein synthesis, calculated from PD excretion, was higher ($P = 04$) for cows fed barley (324 g N/d) compared to those fed wheat (291 g N/d) or oats (275 g N/d). These data suggest that commonly-fed carbohydrate sources differ in their ability to support ruminal microbial protein production.

Key Words: Dairy Cow, Nitrogen Metabolism, Microbial Protein Synthesis

M311 Supplementation of lactating cows receiving high citrus pulp diets with heated soybeans. G. S. Dias Júnior[1], A. van Vugt[2], G. Warringa[2], C. A. Mello, Jr.[3], and M. N. Pereira*[1], [1]*Universidade Federal de Lavras*, *Brazil*, [2]*Wageningen University*, *Holland*, [3]*Nutron Alimentos*, *Brazil*.

Total or partial replacement of corn by citrus pulp has decreased milk protein production. We tried two strategies to avoid such a depression: Increasing diet RUP content by replacing raw soybeans by heated soybeans, and decreasing diet forage content by replacement of corn silage by pellets of citrus pulp. Twenty-one Holsteins were assigned to a sequence of three treatments in seven 3x3 Latin Squares with 21-day periods. All diets contained 10.7% of DM of mature and finely ground flint corn, 13.0% of soybean meal and 11.0% of whole soybeans. Diet corn silage content was 46.9% for the high forage treatments with heated (HFHS) or raw (HFRS) soybeans. The low forage diet contained 34.2% of corn silage and raw soybeans (LFRS). Two single degree of freedom orthogonal contrasts were tested: LFRS *vs.* HFRS and HFRS *vs*. HFHS. Nutrient composition of the consumed diets were: 16.4% CP, 33.1% NDF, 19.3% forage NDF, and 5.1% EE for LFRS; 15.9% CP, 36.4% NDF, 26.6% forage NDF, and 5.1% EE for HFRS; and 16.6% CP, 37.3% NDF, 26.4% forage NDF, and 5.3% EE for HFHS. Intake was 17.6 ($P<0.01$), 19.1 and 19.5 ($P=0.51$) kg/d for LFRS, HFRS and HFHS. Milk yield was increased from 29.1 kg/d to 30.2 when heated soybeans replaced raw soybeans ($P=0.06$), while the replacement of forage with byproduct was not so effective (29.8, $P=0.18$). Lactose secretion were (kg/d): 1.364 for LFRS ($P=0.09$), 1.330 for HFRS, and 1.391 for HFHS ($P=0.03$). Plasma glucose were: 52.5 ($P=0.08$), 54.8 and 51.4 ($P=0.01$) mg/dl for LFRS, HFRS and HFHS. Diets that increased lactose secretion, decreased plasma glucose. Dietary manipulation did not affect the daily secretion or the content of fat and protein in milk ($P>0.22$). Diet LFRS had greater secretion of milk energy per unit of digestible organic matter intake than diet HFRS (1.53 vs. 1.49 Mcal/kg, $P=0.06$). Chewing time was decreased by the low forage diet ($P<0.01$), but plasma lactate did not change ($P>0.20$). Substitution of raw by heat treated soybeans increased milk yield and had no effect on milk composition, the mechanism may have involved a larger drive of plasma glucose to milk lactose synthesis.

M312 Comparison of protein disappearance of alfalfa hay and barley grain by *in vivo*, mobile bag and 3-step methods. H. Jahani-Azizabadi, M. Danesh Mesgaran*, R. Valizadeh, and H. Nasirimoghadam, *Ferdowsi University of Mashhad*, *Mashhad, Iran*.

Ruminal, post-ruminal and total tract crude protein (CP) disappearance of alfalfa hay and barley grain were measured using in vivo, mobile bag and three-step *in situ* / *in vitro* enzyme procedures. For in vivo, eight Baluchi lambs (49.4 ± 3.5 kg, body weight) were used. Experimental diets were made of two alfalfa hay:barley grain ratios (DM basis) as 1.0:0.0 and 0.50:0.50. Diets were fed to animals for 28 d, with 7 d of feces collection. For the mobile nylon bag technique, two Holstein steers (450 ± 50 kg, body weight) fitted with ruminal fistulae and T-shaped intestinal cannulae were used. Steers fed 5.1 kg of alfalfa hay, 1.2 kg of corn silage and 2.7 kg of concentrate (150 CP/kg of DM). Three-step procedure was followed by rumen incubation of samples for 12 h and enzymatic incubation of ruminal-undegradable samples. Data were analyzed using completely block randomized design. In vivo total tract CP disappearance of alfalfa hay and barley grain (0.74 and 0.69, respectively) was significantly ($P< 0.01$) lower than in situ mobile nylon bag (0.89 and 0.96, respectively) and three-step procedure (0.81 and 0.89, respectively). Total tract CP disappearance from mobile nylon bag was significantly ($P< 0.01$) higher than three-step technique. Post-ruminal disappearance of ruminal undegradable CP from alfalfa and barley grain in the mobile nylon bag method (0.69 and 0.86, respectively) was significantly ($P< 0.01$) higher than the three-step enzymatic method (0.49 and 0.56, respectively). Results of the present study showed that there is significant difference between in vivo, mobile bag and the 3-step method when total tract CP disappearance of barley grain and alfalfa hay is evaluated.

Key Words: Protein, Three-Step Procedure, Mobile Bag

M313 Evaluation of a rumen undegradable soybean product for lactating dairy cattle. S. S. Donkin*[1], S. L. Koser[1], E. M. Barnes[1], P. H. Doane[2], J. L. Dunn[2], and M. J. Cecava[2], [1]*Purdue University*, *West Lafayette, IN*, [2]*ADM Animal Nutrition Research*, *Decatur, IN*.

Increasing the bypass protein content of soybean meal can be accomplished by applying moist heat and additives in a controlled reaction process. The objective of this study was to determine the effects of feeding a specially-processed high bypass soybean meal on performance of dairy cows. Thirty-six multiparous Holstein cows from the Purdue University Dairy Cattle Research and Education Center were used in the study. Cows were 123 ± 4 days and produced 37.2 ± 1.1 kg/d of milk at study initiation. The base diet consisting of corn silage, legume haylage, legume hay, cottonseed hulls, soyhulls, soybean meal, corn gluten meal, high moisture corn, and a mineral/vitamin supplement was fed during a two-week covariate adjustment period. During the following six weeks, cows were fed the diets containing soybean meal (Negative control; NC), Aminoplus® to replace soybean meal and increase dietary RUP content (Positive control; PC), or the specially-processed bypass soybean meal as a replacement for soybean meal (RUPSBM). All diets contained equal amounts of protein and the PC and RUPSBM diets contained equal quantities of RUP. Cows were milked twice daily and weekly milk samples were analyzed for fat, protein, lactose, total solids, milk urea N, and somatic cells. Body weights and body condition scores were obtained at the beginning and the end of the study. Milk production was 37.4, 36.6, 37.8 ± 1.7 kg/d and feed intake was 25.6, 25.8, 26.3 ± 0.7 kg/d for NC, PC, and RUPSBM, respectively, and did not differ ($P > 0.05$). Milk composition

was not affected by treatment. When averaged across all treatments, DMI was 25.9 kg/d, or approximately 4.3% of body weight. The high DM and consequent high RUP intake likely diminished the ability to determine the value of bypass protein for lactating dairy cows. Both AminoPlus and RUPSBM were acceptable for lactating dairy cow diets based upon no observed detrimental effects on feed intake and milk yield or milk composition.

Key Words: Rumen Undegradable, Protein, Dairy

M314 The effects of controlled feeding a high concentrate or high forage diet at four nitrogen intakes on digestibility in dairy heifers. G. I. Zanton* and A. J. Heinrichs, *The Pennsylvania State University*, *University Park*.

The hypothesis of this experiment is that a high concentrate ration (**HC**) will be utilized with a greater efficiency than a high forage ration (**HF**) by postpubertal dairy heifers and that the response will be affected by level of N intake. To test this hypothesis, 8 Holstein heifers (beginning at 362 ± 7 kg and 12.3 ± 0.4 mo) were fed eight rations according to a split-plot, 4 x 4 Latin square design. Treatments were formulated to contain 75% or 25% forage (corn silage and chopped wheat straw) and 4 levels of N intake (0.94, 1.62, 2.30, 2.96 g N/kg $BW^{0.75}$ per d) and were fed to maintain equal ME intake. Feces were collected for 8 d/ 28 d period. Organic matter intake was greater for heifers fed HF, but, due to increased OM digestibility of HC (74.0 vs 67.6% ± 0.9; $P < 0.001$), digestible OMI was unaffected by forage level ($P > 0.40$). OM digestibility was affected by an interaction between forage level and N intake ($P < 0.013$); increasing to a plateau of 77.5% at 2.30 g N/kg BW0.75 for HC and 69.0% at 1.62 g N/kg $BW^{0.75}$ per d for HF fed heifers. Apparent N digestibility was greater for heifers fed HC and increased from 47.7% to 80.8% between 0.94 and 2.96 g N/kg $BW^{0.75}$ per d. Analysis of covariance revealed a strong linear relationship between apparently digested N and N intake, however the response differed between forage levels ($P < 0.05$). Predicted true digestibilities were 97.4 and 94.4% and non-dietary fecal N excretion was 0.45 and 0.47 g N/kg $BW^{0.75}$ per d for HC and HF fed heifers, respectively. Due to these relationships, less N appeared in the feces of heifers fed HC than HF (0.50 vs 0.57 g N/kg $BW^{0.75}$ per d). It is concluded that increasing N intake increases the digestibility of OM, the magnitude of which depends on the level of dietary forage provided. It is further concluded that the digestion of N by dairy heifers is high and nearly complete and that the majority of N appearing in the feces is not of dietary origin and may be differentially affected by the level of forage intake.

Key Words: Dairy Heifer, Forage:Concentrate, N Intake

M315 Evaluation of the fermentation dynamics of the soluble protein fraction of three protein sources in continuous culture fermenters. M. Ruiz Moreno*[1], A. Bach[2,3], M. Thrune[1], and M. D. Stern[1], [1]*University of Minnesota*, *Saint Paul*, [2]*ICREA*, *Barcelona, Spain*, [3]*IRTA-Unitat de Remugants*, *Barcelona, Spain*.

Six dual-flow continuous culture fermenters were used to assess differences in degradation pattern and ability to promote bacterial growth from the soluble CP fractions of canola meal (CM), soybean meal (SBM) and fish meal (FM) using a completely randomized design with two 9-d experimental periods. All fermenters received the same basal diet (58% ground corn, 40% canary grass hay, 0.4% vitamin-mineral premix, 1% CaCO3, 0.6% salt on a DM basis). During sampling on the last 3-d of each period, 90-mL doses containing soluble proteins were infused into fermenters 30 min after the beginning of the first and last feedings of the day at a rate of 3 mL/min, using a constant-infusion pump. These doses were prepared from samples of FM, SBM and CM that were ground and soaked in distilled water (1:4 wt/vol, 38C, 1h) under continuous stirring. The solutions were centrifuged and the supernatant vacuum-filtered through a N-free filter paper. Equal N concentrations were achieved by diluting filtrates with the higher N content to match the one with the lowest N content using distilled water. Normalized filtrates (1.8% CP as is) were frozen in 90-mL doses and were gently thawed prior to infusions into the fermenters. The total amount of soluble CP supplied by the infusions of FM, CM and SBM was 3.2 g/d, representing 27% of daily dietary CP intake. Each sampling day at 0, 0.5, 1, 3, and 6 h following the morning infusion of soluble CP fractions, a 10-mL aliquot from each fermenter flask was collected to determine NH_3-N concentrations. Infusion of FM resulted in the greatest ($P < 0.05$) NH_3-N concentrations (4.5±0.08 mg/dL) compared with the other treatments (0.42±0.08 mg/dL). Bacterial N flow (g/d) was also greatest ($P < 0.05$) with FM (1.47±0.07) compared with the other soluble CP fractions (1.09±0.07). Results indicate that microbial degradation of the soluble CP fraction of FM appears to be higher than the soluble CP fractions of CM or SBM.

Key Words: Soluble Protein, Rumen, Dual Flow Fermenters

M316 Supplementation of grazing dairy cows with high-fat dietary protein sources. R. Nyoka*, A. R. Hippen, and K. F. Kalscheur, *South Dakota State University*, *Brookings*.

The effect of supplementing cows on pasture with partial Total Mixed Rations (pTMR) containing different high-fat protein sources on milk yield and milk components was investigated. The objective of the experiment was to investigate the effect of using distiller's grains, soybean meal, and fishmeal as supplements to cows grazing an alfalfa/grass pasture on milk yields and milk components. Multiparious Holstein (n = 18) and Brown Swiss (n = 9) cows were blocked by milk yield and assigned to three dietary treatments in a complete randomized design for an 8 wk experimental period. The first 2 wk were a covariate period in which all 27 cows were fed a common diet. After the covariate period, nine cows in each dietary treatment were fed Soybean (SB), Fishmeal (FM), or Dry Distillers grain (DDG) in a partial TMR. The partial TMR was fed in the morning at a rate to provide 50% of estimated energy intake determined during the covariate period and cows grazed ad libitum on alfalfa pasture from the afternoon till the morning milking. Milk was sampled at all three milkings each day on the last 2 d of the covariate period, every third day during the first 9 d of the grazing period, and the last day of each week for 6 wk. There were no significant ($P > 0.05$) dietary effects observed in milk yield and milk components. Significant ($P < 0.05$) time differences were observed in milk yield and milk MUN content. Significant time*diet interactions ($P < 0.01$) were observed in milk yield with the decline in milk yield greatest in FM followed by DDG and the least in SB based TMR (40%, 34%, and 29% respectively). This research demonstrated that soybean-based supplement supports greater milk production in grazing cows than the lesser ruminally degradable protein sources distillers grains and fish meal.

M317 Effects of pure essential oil compounds on the digestion of nitrogen in dairy cows. V. Noirot[1] and C. Bayourthe*[2], [1]*Phodé, Albi, France*, [2]*Ecole Nationale Supérieure d'Agronomie de Toulouse, Castanet-Tolosan, France*.

An *in vivo* study was carried out to evaluate the effect of oral pure essential oil compounds (EOc) on nitrogen (N) digestion. Four non-lactating cows with ruminal, duodenal and ileal cannulas were used in a 4 × 4 Latin square design. EOc was given daily in two equal doses at feeding times with a total dose of either 1 g / head for carvacrol (Cv) and cinnamaldehyde (Cn) or 2 g / head for Cv + Cn (1:1). Each experimental period lasted 21 days, including 14 days of adjustment and 7 days of collection. There was a 3-day interval between two experimental periods during which all the cows received the control (C) diet to return them to the initial state. The markers Cr-EDTA, $YbCl_3$ and purines were used for liquid, particulate matter, and bacteria, respectively. Effects of treatments were determined (PROC MIXED, SPSS) and orthogonal contrasts were used: (C + Cn) *vs* (Cv + [Cv + Cn]). Significance was declared at $P \leq 0.05$ and tendency at $P \leq 0.10$. Compared with C and Cn, Cv and Cv + Cn increased significantly passage of non ammonia N (NAN) to the small intestine (159.8 *vs* 146.4 g / d) and duodenal N (percentage of NAN) of bacterial origin (64.3 *vs* 56.2 %). They also tended to slightly increase the apparent ruminal digestion of feed N ($P = 0.08$) compared with C and Cn. Bacterial synthesis efficiency was significantly improved by Cv treatments (16.6 *vs* 13.9 g N / kg of OM truly digested in the rumen).

Table 1.

	Treatment					P	
	C	Cn	Cv	Cv + Cn	SEM	Treatment	C+Cn *vs* Cv+ [Cv+Cn]
N Intake, g/d	163.0	164.9	166.7	165.2	2.1	0.80	-
Duodenal flow, g/d							
Total N	159.5	160.2	175.6	177.5	5.2	0.05	0.01

M318 Effects of garlic and juniper berry essential oils on site and extent of digestion by dairy cows. W. Z. Yang*[1], C. Benchaar[2], A. V. Chaves[1], M. L. He[1], and T. A. McAllister[1], [1]*Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada*, [2]*Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Lennoxville, QC, Canada*.

An experiment was conducted to evaluate the effects of garlic (GAR) and juniper berry (JUN) essential oils (EO) and monensin (MO) on feed intake, site and extent of digestion, and microbial N synthesis in the rumen. Four mid-lactating Holstein cows with ruminal and duodenal cannulas were used in a 4 × 4 Latin square design (21-d periods) with four treatments: control (no additives), GAR (5 g/cow/d), JUN (2 g/cow/d) and MO (330 mg/cow/d). Cows were fed ad libitum a TMR consisting of 40% forage and 60% barley-based concentrate. Data were analyzed using the PROC MIXED procedure of SAS to account for effects of period, cow and treatments (feed additives). Feed intake averaged 20.4 kg/d and was not affected by the dietary additives. Digestibilities of DM and OM in the rumen were similar between GAR and JUN supplementation, and were increased by 13% ($P < 0.02$) compared to the control and MO. This increase was mainly attributed to the increase in ruminal CP ($P < 0.03$) and starch ($P < 0.15$) digestion. However, GAR and JUN supplementation had no effects ($P > 0.15$) on total-tract digestibilities of DM, OM, NDF, starch and CP. Supplementation of MO reduced ruminal digestibilities of CP (-11%; $P < 0.03$) and NDF (-16%; $P < 0.15$) compared with the control, but did not alter the total digestibility of other nutrients. Flow (g/d) of microbial N to the duodenum was similar ($P > 0.15$) among treatments, whereas the proportion of microbial N in the duodenum (% of intake) was higher ($P < 0.09$) for GAR and JUN (59.8%) than for the control (46.6%) or the MO (47.1%). These results suggest that at the doses evaluated, supplementing dairy cows with GAR and JUN had potential to improve feed digestibility in the rumen but not in the total tract.

Key Words: Essential Cil, Digestion, Dairy Cow

M319 Effect of vegetal extracts on rumen microbial fermentation in batch culture. M. Ruiz Moreno*[1], A. Bach[2,3], J. van Eys[4], and M. D. Stern[1], [1]*University of Minnesota, Saint Paul*, [2]*ICREA, Barcelona, Spain*, [3]*IRTA-Unitat de Remugants, Barcelona, Spain*, [4]*Global Animal Nutrition, Paris, France*.

An experiment using 24 h batch culture incubations was conducted in two consecutive periods to evaluate the effect of four different vegetal extracts on rumen microbial fermentation. Treatments consisted of 300 mg of *Acacia concinna* (AC), *Sapindus mukorossi* (SM), *Yucca schidigera* (YS) or *Sapindus rarak* (SR) extracts, added to 500 mL sealed bottles. An additional set of bottles without vegetal extract was utilized as a control (C) group. Each treatment was randomly assigned in triplicate to the incubation bottles. Three grams of DM (60% forage: 40% concentrate) were provided as substrate for microbial fermentation. Three hundred mL of a 1:4 rumen fluid + buffer mix were anaerobically transferred to each bottle and incubated in an agitation bath at 39 C. At each of the following incubation times, 0, 3, 6, 9, 12 and 24 h, gas pressure was monitored using a digital pressure meter, pH was recorded, and a 10 mL aliquot was anaerobically removed for ammonia and VFA analyses. Cumulative pressure throughout the experiment was calculated by adding individual pressures. Results were analyzed as repeated measures using mixed model by SAS. The control group had a higher pH ($P < 0.05$) than the rest of the treatments (C=6.63; vs SM=6.57; AC=6.58; SR=6.59; YS=6.6). There was a trend ($P < 0.1$) for pH with YS to be higher compared with SM. The SR and YS treatments attained lower ($P < 0.05$) ammonia concentrations (21.4 and 21.3 mg/100 mL, respectively) compared with C (22.6 mg/100 mL), AC (22.2 mg/100 mL) and SM (22.3 mg/100 mL) treatments. No differences in cumulative gas pressure were obtained between treatments ($P > 0.05$). Lower ammonia release after the addition of SR and YS extracts suggests a beneficial use of these extracts in altering ruminal protein degradability.

Key Words: Vegetal Extracts, Rumen, Batch Culture

M320 Adding rare earth elements to beef cattle diets improved in situ digestibility in the rumen and digestibility in the total tract. Q. Liu[1], W. Z. Yang*[2], C. Wang[1], Y. X. Huang[1], K. H. Dong[1], and H.

Wang[1], [1]*College of Animal Sciences and Veterinary Medicines, Shanxi Agricultural University*, *Taigu, Shanxi, China*, [2]*Research Centre, Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

Rare earth elements have been used as feed additives for many years in China and recently shown to improve growth performance of pig in Europe. A study was conducted to evaluate the effects of addition of Lanthanum (La) to beef cattle diet on in situ ruminal degradation and digestibility in the total tract. Eight ruminally cannulated steers were used in a replicated 4 × 4 Latin square experiment. Treatments were control, low, medium and high dose of La with 0, 450, 900 and 1800 mg/steer/day $LaCI_3$, respectively. Diets consisted of 60% corn straw and 40% concentrate (DM basis). Corn straw and soybean meal were ground (2-mm) and measured for in situ ruminal digestibility. The duplicated bags were suspended in the rumen of each steer for 0, 4, 8, 12, 24, 36, 48 and 72 h. Increasing the dose of La quadratically ($P < 0.02$) increased ruminal soluble (0.11, 0.19, 0.27 and 0.12) and potential degradable fractions (0.70, 0.72, 0.73 and 0.88), and effective degradability (ED; 39.9, 40.1, 42.1 and 30.3% for control, low, med and high dose of La, respectively) of DM for corn straw. The soluble fraction (0.44, 0.42, 0.42 and 0.38) and ED (58.3, 56.9, 55.0 and 51.3%) of DM were linearly ($P < 0.01$) decreased but the potential degradable fraction (0.52, 0.52, 0.56 and 0.60 for control, low, med and high dose of La, respectively) was linearly ($P < 0.04$) increased with increasing La supplementation for soybean meal,. Digestibilities of OM (72.1, 75.0, 77.9 and 74.5%), NDF (59.4, 62.6, 67.2 and 63.1%) and CP (72.1, 76.2, 77.3 and 75.4% for control, low, med and high dose of La, respectively) in the total tract were quadratically improved ($P < 0.05$). These results indicate that $LaCI_3$ supplementation potentially improved digestibility in the rumen and in the total tract of beef cattle with a dose-dependent manner.

Key Words: Rare Earth Elements, Digestibility, Beef Cattle

M321 Ethanolic extract of propolis in lactating cows. J. A. De Freitas*[1], J. C. De Souza[1], R. P. Lana[2], R. P. Antonangelo[1], A. A. De Freitas[2], and R. T. S. De Santana[1], [1]*Federal University of Parana*, *Palotina, PR, Brazil*, [2]*Federal University of Viçosa*, *Viçosa, MG, Brazil*.

Propolis is a natural product that contains several powerful substances like the flavonoids which have important therapeutic properties. Propolis also seems to have effects upon the rumen bacterial membrane and can be considered as ionophore agent. This study aimed to evaluated the effect of ethanolic extract of propolis (EEP) upon milk and 4% fat corrected milk (FCM) production, milk fat and milk protein in dairy cows. The research was conducted in Federal University of Parana - Brazil. Twenty Holstein cows with an average weight of 600 kg and production of 6000 kg of milk/year were used. The animals were fed ad libitum a diet formulated using the 2001 dairy NRC recommendations. The experiment was analyzed as completely randomized design and two treatments, with 10 animals per treatment, were used: T1 - control treatment - the animals were fed ad libitum a diet formulated to supply energy, protein, minerals and vitamins requirements plus 100 gr of finely ground corn; and T2 - T1 plus 50 mL of 30% EEP. The data were submitted to the analysis of variance and means of treatments were compared at 5% probability. The addition of EEP resulted in increased milk production but did not influence FCM (Table 1). Propolis probably acts upon the Gram-positive bacteria, reducing their growth and methane production, thereby reducing loss of energy in the rumen and increasing the total available energy for metabolism. Milk fat and protein were greater (3.14 vs 3.03 and 2.93 vs 2.80, respectively) in the treatment with EEP addition.

Table 1. Effect of propolis addition upon milk and 4% FCM production

Treatment	Milk (kg/cow/day)	Standard error	4% FCM (kg/cow/day)	Standard error
1 – Control	22.63a	1.30	19.48 ns	1.21
2 – EEP	25.92b	0.91	22.20 ns	0.85

ns – non significative ($p>0.05$).

Key Words: Animal Nutrition, Performance, Ruminal Fermentation

M322 Ruminal bacterial diversity in cattle grazing wheat and supplemented with condensed tannins. B. R. Min*[1], W. E. Pinchak[1], M. E. Hume[2], and R. C. Anderson[2], [1]*Texas Agricultural Research Center*, *Vernon, TX*, [2]*USDA/ARS, Food and Feed Safety Research Unit*, *College Station, TX*.

The objectives of this study were to 1) ascertain relative changes in ruminal bacterial diversity associated with transition from a Bermuda grass hay to a grazed wheat diet, 2) determine relative changes in diversity over 90 days of grazing winter wheat, and 3) bacterial populations response to supplementation with condensed tannin (CT) through the developmental stages of wheat associated peak bloat risk in stocker cattle. Eighteen rumen-cannulated steers were randomly allocated to CT treatments (0, 10, and 20 g CT/kg dry matter intake). Ruminal bacterial diversities were visualized by polymerization chain reaction (PCR)-denaturing gel gradient electrophoresis (DGGE). Dendograms were constructed based on similarity coefficients (% SC) among bands patterns. On day - 30, after steers had been fed Bermuda grass hay for 30 days, ruminal bacterial populations clustered ranging from 82 to 96% SC and exhibited animal to animal variation. Following 30 days (referred as to day 0) adaptation to grazing wheat, variability in bacterial populations within and among animals increased from 68 to 92%. After day 20 day CT supplementation and 50 days grazing wheat, ruminal bacterial similarity (83 to 98% SC) was comparable (82 to 92% SC) to day 0. In contrast, CT supplementation caused ruminal bacterial populations to become more dissimilar (56 to 84% SC). These results clearly document changes in ruminal bacterial populations associated with wheat grazing, animal to animal variation, and CT supplementation over time. The results of this study suggest that molecular-based DGGE facilitated rapid and cost effective visualization of diverse in vivo ruminal bacterial communities among animals, between diets and through time

Key Words: Bacterial Population, Plant Tannins, Wheat Forage

M323 *In vitro* manipulation of rumen fermentation by propolis flavonoids and monensin. S. M. J. Yaghoubi*[1], G. R. Ghorbani[1], H. R. Rahmani[1], and A. Nikkhah[2], [1]*Isfahan University of Technology*, *Isfahan, Iran*, [2]*University of Manitoba*, *Winnipeg, MB, Canada*.

Human health concerns as to the use of ionophore antibiotics in ruminant diets have promoted research on natural plant extracts. Flavonoids are plant pigments comprising polyphenolic compounds

with antimicrobial activity. The primary objective was to determine the effects of 1) the flavonoid extract from propolis (FE) and 2) monensin (MO) on batch culture rumen fermentation in three experiments. The three *in vitro* experiments determined fermentation properties of three diets with forage to concentrate ratios of 1) 100:0, 2) 50:50, or 3) 20:80. Rumen fluid was collected from two fistulated Naeini sheep fed for maintenance and adapted for 14-d to the same diet used as the substrate during the in vitro experiment. The FE doses of 17, 35, 70, and 140 µg/ml and a MO dose of 2.5 µg/ml were added to the three cultures (i.e., three forage to concentrate ratios). Within each forage to concentrate ratio, there was a control culture with no FE and MO. The increasing levels of FE linearly reduced ($P < 0.05$) in vitro 24-h dry matter disappearance in the 50% and 100% forage cultures but increased it in the 20% forage culture. The in vitro ADF disappearance, gas production, and ammonia concentrations were also decreased ($P < 0.05$) by the increasing levels of FE. Both FE and MO decreased pH with 20% but not with 50% dietary forage. With 20% and 50% forages, MO decreased ($P < 0.05$) ammonia and gas production. Also, MO reduced ($P < 0.05$) ADF digestibility with 20% and 100% forages but not with 50% forage culture. Monensin, however, increased ($P < 0.05$) 24-h dry matter digestibility with 20 and 50% but not with 100% dietary forage. The protozoa populations were decreased ($P < 0.05$) by MO and in a dose-dependent manner by FE with 50% and 20% forage diets. Results demonstrated that FE can manipulate the batch culture rumen fermentation. The effects of FE on rumen fermentation were reasonably comparable to that of MO. Therefore, findings offer the perspective that FE may be considered as an alternative for MO. Future in vitro and in vivo studies are essential before such a perspective could turn into an on-farm potential.

Key Words: Batch Culture, Flavonoid, Propolis

M324 Effects of zeolites and monensin on *in vitro* dry matter disappearance, pH change, and volatile fatty acid proportions. B. F. Domeniconi*[1,2], J. P. McMeniman[1], J. T. Vasconcelos[1], and M. L. Galyean[1], [1]*Texas Tech University*, *Lubbock*, [2]*FMVZ-UNESP*, *Botucatu, Brazil*.

Two experiments were conduced to determine the effects of 2 different zeolites and monensin on IVDMD and VFA proportions (Exp. 1) and in vitro pH changes over time measured with a reduced buffer fermentation (Exp. 2) of a 90% concentrate diet. Dietary treatments in both experiments were: 1) biolite (BIO); 2) maxibond (MAX); 3) monensin (MON); and 4) control (CON). All products were included in a 90% concentrate steam-flaked corn-based diet. The BIO and MAX additives were included at 2% of DM, and the MON and CON diets contained 2% (DM basis) of an inert substance (sand). Monensin was added to the cultures in 100 µL of ethanol to provide 4 µg/mL of culture, with an equal volume of ethanol added to other cultures. For Exp. 1, diet substrates (approximately 0.5 g in duplicate) were incubated with 35 mL of a 4:1 McDougall's buffer-to-ruminal fluid mixture for 0, 2, 4, 8, 24, and 36 h at 39°C, followed by a 48-h incubation in acidified pepsin solution. For Exp. 2, the same procedures were followed, except that the McDougall's buffer was diluted to 25% strength with 0.9% (wt/vol) saline, and culture pH was measured with a combination electrode at 0, 0.5, 2, 4, 8, 12, and 24 h. Ruminal fluid was obtained approximately 4 h after feeding from 2 ruminally cannulated steers fed a 75% concentrate diet. Both experiments were replicated in 2 separate runs. The IVDMD differed only at 8 h of incubation, being greater for MON than for BIO ($P = 0.03$) and MAX ($P = 0.02$). No differences ($P > 0.10$) in pH at the various incubation times were observed among treatments. For VFA in culture fluid after the 36-h incubation period of Exp. 1, MON increased propionate compared with MAX ($P = 0.01$) and BIO ($P = 0.03$), whereas proportions of acetate were greater for MAX ($P = 0.01$) and BIO ($P = 0.05$) than for MON. No differences in VFA proportions were observed between the 3 treatments and CON for either acetate ($P = 0.43$) or propionate ($P = 0.84$). Data suggest that adding 2% of these 2 zeolites to a high-concentrate diet did not markedly alter IVDMD or changes in pH compared with monensin, but both zeolites increased acetate relative to monensin.

Key Words: IVDMD, Monensin, Zeolites

M325 Preservation of enzymatic activities in a liquid extract obtained after *Agaricus bisporus* growth. M. Ayala–Martínez[1], S. S. González*[2], G. D. Mendoza–Martínez[3], C. Vázquez–González[1], M. Meneses–Mayo[2], O. Loera[4], and J. H. Avellaneda–Cevallos[5], [1]*UNAM*, *México D.F.*, [2]*Colegio de Postgraduados*, *Montecillo, Edo. México, México*, [3]*UAM Xochimilco*, *México D.F.*, [4]*UAM Iztapalapa*, *México D.F.*, [5]*Universidad Tecnica Estatal de Quevedo*, *Quevedo, Ecuador*.

The objective of this study was to evaluate lignocellulolytic enzymes and soluble protein in a crude extract from a compost after harvesting *Agaricus bisporus* body fruits at 50, 60 and 90 days culture times. Then crude extract was subjected to preservation treatments: refrigeration (R); R + benzoic acid (RB); freezing (F); F + B (FB); F + glycerol (FG); F + G + B (FGB); liophilization (L). Residual enzymatic activities were measured at 1, 7, 14, 28, 56 and 101 days after preservation. The experimental design was completely randomized, an ANOVA was performed and means were compared with Tukey test ($P \leq 0.01$). A difference ($P \leq 0.01$) was found according to culture times (50, 60 and 90 days) for xylanases (4361a, 3124b, 587c IU/g), cellulases (17b, 25a, 9c IU/g|), laccases (2502b, 3279ab, 4657a IU/g) and soluble protein (0.62a, 0.64a, 0.41b mg/g), with the highest values at 50 and 60 days. For conservation treatments the best results were for FB for xylanases (1323 IU/g), F for cellulases (9.09 IU/g), FG for laccases (3714 IU/g), and FB for soluble protein (0.75 mg/g).

Key Words: Fibrolytic Enzymes, Preservation Methods, *Agaricus Bisporus*

M326 Activity of fibrolytic enzymes by *Trametes sp.* EUM1, *Pleurotus ostreatus* IE8 and *Aspergillus niger* AD96.4 in solid-state fermentation. A. T. Márquez-Araque[1], G. D. Mendoza-Martínez[2], S. S. González*[3], S. E. Buntinx-Dios[4], and O. Loera[5], [1]*UNAM and UCLA*, *México D.F. and Caracas, Venezuela*, [2]*UAM Xochimilco*, *México D.F.*, [3]*Colegio de Postgraduados*, *Montecillo, Edo. México, México*, [4]*UNAM*, *México D.F.*, [5]*UAM Iztapalapa*, *México D.F.*

The objective of this study was to determine the activity of fibrolytic enzymes (xylanases, celullases and laccases) from the fungi *Trametes sp.* EUM1, *Pleurotus ostreatus* IE8, and *Aspergillus niger* AD96.4 at 14 and 19 d of fermentation on sugar cane bagasse. The fibrolytic activity was expressed as IU/g DM and as specific activity (IU/mg protein). The experimental design was completely randomized with four replicates per treatment, and means were compared with Tukey test ($P \leq 0.01$). *Trametes sp.* EUM1 showed higher activity ($P \leq 0.01$) of xylanases (141.77 IU/g DM and 1073.8 IU/mg protein) and celullases

(9.04 IU/g DM and 69.16 IU/mg protein) as compared to *P. ostreatus* IE8 and *A. niger* AD96.4. The higher (P≤0.01) laccases activity was expressed by *P. ostreatus* IE8 (15.54 IU/g DM and 128.75 IU/mg protein) at 14 and 19 d (11.75 IU/g DM and 102.88 IU/mg protein). For *Trametes sp*. EUM1 the laccases activity was similar at both fermentation times (3.45 and 2.03 IU/g DM) and lower (P≤0.01) than *P. ostreatus* IE8. For *A. niger* AD96.4 the laccases activity was significantly low. The activity of fibrolytic enzymes by *Trametes sp.* EUM1 suggests a potential for biotechnological applications in ruminant nutrition.

Key Words: Fungus, Fibrolytic Enzymes, Times of Fermentation

M327 Feed intake, nutrient digestibility and animal growth performance in sheep and goats fed wheat straw *ad lib*. in presence of ZADO as direct feed of anaerobic enzymes and bacteria. A.-F. Salem*[1], M. El-Adawy[1], H. Gado[2], and M. Khalil[3], [1]*Department of Animal Production*, *Faculty of Agriculture (El-Shatby), Alexandria University, Alexandria, Egypt*, [2]*Department of Animal Production*, *Faculty of Agriculture, Ain Shams University, Cairo, Egypt*, [3]*Animal Production Research Institute*, *Ministry of Agriculture, Dokki, Gizza, Egypt*.

Six crossbred sheep (32 kg BW) and six Baladi goats (18 kg BW) were used to evaluate the effect of ZADO (new probiotic, patent No. 22155) as feed direct microbials on feed intake, apparent digestibility and animal growth performance. Sheep and goats were randomly divided into two groups of three animals and fed wheat straw *ad lib*. as a basal diet and commercial concentrate with or without 10g/animal/d of ZADO. A growth performance trial of 65-days was ended by a digestibility trial of 21-days for each individual animal within each group. Feed intake was not affected (P>0.05) by ZADO addition neither in sheep nor goats but it improved the nutrients digestibility coefficients as well as total digestible nutrient of feed in sheep and goats. ZADO significantly increased (P<0.001) the neutral detergent fiber digestibility of diet. The improvement (P<0.001) was more in goats than sheep. Average daily gain and feed efficiency were improved (P<0.05) by addition of ZADO, and the improvement was more in goats than sheep. Calculated net energy required for one kg gain was decreased (P<0.05) by inclusion of ZADO in diets and the decease was more in goats than sheep. Improving the animal performance by addition of ZADO was as a consequence to the improvement in digestibility in sheep and goats. In conclusion, ZADO had improved the nutritive value of wheat straw, as a basal diet in sheep and goats and suggested that its useful roles in activating the ruminal fiber degrading enzymes.

Key Words: Feed Intake, Growth Performance, Sheep

M328 Performance of Holstein cows fed diets containing either alfalfa hay or Tifton 85 bermudagrass with or without a cellulase enzyme. J. K. Bernard*[1], J. W. West[1], and A. T. Adesogan[2], [1]*The University of Georgia*, *Tifton*, [2]*The University of Florida*, *Grainesville*.

Forty-four lactating Holstein cows were used in an 8-wk completely randomized trial with a 2 × 2 factorial arrangement of treatments to determine the effect of forage source and supplemental cellulase enzyme on performance. Diets were based on two forage combinations (corn silage plus 12.5 % DM from either alfalfa hay (**AH**) or Tifton 85 bermudagrass haylage (**T85**)) with (+) or without (-) a commercial cellulase enzyme (Promote N.E.T.-L, Agribrands Purina Canada, Inc., Woodstock, Ontario, Canada). Diets were formulated to provide similar concentrations of protein (16.5% of DM), energy (1.63 Mcal NE_L /kg of DM) and NDF (41.7 % of DM) and were fed once daily as a TMR behind Calan doors for ad libitum intake. The cellulase enzyme was applied at the rate of 4 gram hd^{-1} d^{-1} to the TMR and allowed to mix for 5 min before feeding. The cellulase enzyme provided 1,200 cellulase units of activity per gram. Before beginning the trial, all cows were trained to eat behind Calan doors and then fed the alfalfa hay based diet for 2 wk. Data collected during wk 2 were used as a covariant in the statistical analysis. At the beginning of the 6 wk experimental period, cows were assigned randomly to one of the four experimental diets. No interactions were observed among forage and enzyme for any measures. Daily DMI, milk yield, concentrations milk fat, true protein, lactose, and SNF, 3.5% FCM yield, and dairy efficiency were similar among treatments: 24.3, 41.3, 3.76, 2.81, 4.69, 8.41, 43.0 and 1.78; 24.2, 40.4, 3.70, 2.81, 4.66, 8.37, 41.8 and 1.73; 24.9, 42.1, 3.63, 2.75, 4.65, 8.32, 43.0 and 1.73; 24.6 kg/d, 41.6 kg/d, 3.68% , 2.81%, 4.68%, 8.41%, 42.8 kg/d and 1.74 for AH-, AH+, T85-, and T85+, respectively. These results indicate that Tifton 85 bermudagrass can replace alfalfa hay in rations fed to high producing lactating dairy cows when rations are balanced for NDF. Although cellulase enzymes have been shown to improve ration digestibility and animal performance, there were no advantages observed in the current trial.

Key Words: Tift 85 Bermudagrass, Alfalfa Hay, Milk Yield

M329 Effects of enzyme formulations on roasted grains and rations that contain them. K. F. Wilson*[1], G. V. Pollard[2], and C. R. Richardson[3], [1]*Animal Feed Technologies*, *Greeley, CO*, [2]*Texas State University*, *San Marcos*, [3]*Texas Tech University*, *Lubbock*.

The efficacy of enzymes for improving the nutritional valve over a broad spectrum of feedstuffs is evident and established. However, due to different feeding practices and processing methods, the affects of enzyme formulations are vague and constantly needing evaluation. Thus, an IVDMD study was conducted to determine and establish what effects Cattle-Ase™ C (corn specific) or Cattle-Ase™ S (sorghum specific) enzyme formulations could have on roasted grains and rations that contain them. Samples for corn and sorghum were collected at two different locations, however both feeding operations fed similar ration formulations with the exception of the grain source. The feedstuffs evaluated included roasted corn or roasted sorghum and subsequent rations formulated for starter and finishing cattle. Dry-matter disappearance was evaluated utilizing the Moore modification of the Tilley-Terry procedure at fermentation times of 24 h and 48 h. Results showed that at 24 h, Cattle-Ase treated samples had enhanced digestion. Yet, only the roasted corn, finished corn ration, and the roasted sorghum samples were improved (P = 0.0004, 0.020, and 0.018). At 48 h, the Cattle-Ase treatment still enhanced digestion, but only the roasted sorghum rations were improved (P = 0.007 and 0.005). On average, regardless of substrate and enzyme formulation, the Cattle-Ase treatments enhanced digestion by 17.8% at 24 h and 17.6% at 48 h. Moreover, the results appeared to show that Cattle-Ase C treated substrates responded best at 24 h vs. 48 h, and Cattle-Ase S treated substrates responded best at 48 h vs. 24 h. These responses most likely are attributed to the starch solubility of corn vs. sorghum.

Therefore, it is likely that Cattle-Ase has more of an affect on the rate vs. extent of digestion. As seen in other invitro studies, high-energy feedstuffs show their greatest response within the first 24 h, but tend to level off and show minimal returns to Cattle-Ase′s inclusion at longer periods.

Key Words: Enzyme, Roasted Grain, In Vitro

M330 Effects of monensin, virginiamycin and sodium bicarbonate on rumen fermentation of beef cattle fed medium concentrate. H. Y. Wei, J. Q. Wang*, C. H. Li, D. P. Bu, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition,Institute of Animal Science,Chinese Academy of Agricultural Sciences*, *Beijing, China*.

To assess potential of preventing chronic acidosis in beef cattle fed medium concentrate, effects of monensin, virginiamycin and sodium bicarbonate on ruminal fermentation and fecal pH were studied in a 4×4 Latin-square trial over 64d with four ruminal cannulated steers. The basal diet (8.9 kg DM/hd/d) was fed for control(C), monensin (M; 180 mg/d), virginiamycin (V; 180 mg/d) or sodium bicarbonate (N; 120 mg/d) treatments. The basal diet included 40% Chinese wildrye hay and 60% concentrate. Ruminal pH at 0, 2, 4, 6, 9 and 12h after morning feeding was not different and when averaged was 6.44, 6.51, 6.49 and 6.50 for C, M, V and N, respectively. Also, ruminal total VFA at 0, 2, 4, 6, 9 and 12h after morning feeding were not different and averaged 88.29, 88.18, 95.38 and 92.79 mMol for C, M, V and N, respectively. Average acetate for C, M, V and N was 58.89, 55.63, 62.83 and 61.69 mMol, respectively and that of M was significantly less (p=0.03) than that of V. Average propionate for M (22.41mmol/L) was significantly higher (p=0.0002) than C, V and N (17.45, 17.87 and 18.45 mMol, respectively). Average L-lactic acid for C, M, V and N was 5.12, 4.63, 4.19 and 4.46 mMol (p=0.012) respectively. The potential for L-lactic acid accumulation in vitro was different (p=0.001) for C, M, V and N (6.56,5.98,5.33 and 6.35 mMol). Fecal pH for C, M, V and N was 6.39, 6.85, 6.84 and 6.58 (p=0.0001) respectively. For beef cattle fed medium concentrate, these results indicated that 1) supplementation of monensin and virginiamycin can inhibit lactic acid accumulation in rumen liquid, while virginiamycin tended to be more potent and sodium bicarbonate had little effect; 2) monensin and virginiamycin play a role not only in the rumen but in hind gut, whereas sodium bicarbonate mainly works in the rumen.

Key Words: Ionophores, Sodium Bicarbonate, Beef Cattle

M331 Effects of monensin and *Yucca schidigera* extract on metabolism by ruminal microbes in dual flow continuous culture fermenters. M. Ruiz Moreno* and M. D. Stern, *University of Minnesota*, *St. Paul*.

The effects of Monensin (M) and *Yucca schidigera* extract (YSE) on rumen fermentation were evaluated using a dual flow continuous culture system. Eight fermenters were inoculated with ruminal fluid from a dairy cow in early lactation on day 1 of two 10-d experimental periods. A 58:42 concentrate:forage diet (DM basis) was formulated with 0 (YS0) or 80 ppm (YS80) of YSE as substrate for fermentation. Two concentrations of Monensin, 0 (M0) and 5 ppm (M5), were continuously infused into the fermentation vessels via the artificial saliva. The YS0, YS80, M0 and M5 treatments were randomly assigned in a 2 × 2 factorial arrangement of treatments with two replicates per period. Apparent and true OMD were not affected ($P > 0.05$) by M (42.2 vs 39.6% and 56.1 vs 53.2% for M0 vs M5, respectively) or by YSE (39 vs 42.8% and 52.8 vs 56.6% for YS0 vs YS80, respectively). Maximum pH attained in fermenters was lower ($P < 0.05$) for YS80 than for YS0 (6.14 vs 6.32). Total VFA (140.9 vs 102.7 mM) and propionate concentrations (21.2 vs 36.9 mol/100 mol) were greater ($P < 0.05$) while acetate (63.4 vs 53.9 mol/100 mol), butyrate (10.3 vs 5.3 mol/100 mol), isovalerate (0.28 vs 0.13 mol/100 mol) and 2-methylbutyrate (1.19 vs 0.34 mol/100 mol) were lower ($P < 0.05$) for M5 vs M0 treatment. Total branched chain VFA were greater ($P < 0.05$) with M5 than M0 (1.8 vs 0.7 mol/100 mol), while the A:P ratio was greater ($P < 0.05$) with the M0 treatment (3.11 vs 1.48). Supplementation with YS80 increased ($P < 0.05$) isovalerate (0.29 vs 0.13 mol/100 mol), isobutyrate (0.36 vs 0.20 mol/100 mol) and decreased ($P < 0.01$) 2-methylbutyrate (0.16 vs 0.37 mol/100 mol) compared with YS0. Ammonia N concentration, bacterial N flow, efficiency of microbial protein synthesis and CP degradation were not affected ($P > 0.05$) by the addition of M or YSE. Monensin had substantial effects on total VFA concentration and VFA proportions, while YSE supplementation at 80 ppm only affected branched chain VFA concentrations and maximum pH.

Key Words: Rumen, Monensin, *Yucca Schidigera*

M332 Effects of Yea-Sacc1026 supplementation on rumen pH of loose-housed dairy cattle. A. Bach*[1] and S. Andrieu[2], [1]*Institut de Recerca i Tecnologia Agroalimentàries (IRTA)*, *Barcelona, Spain*, [2]*Alltech Biotechnology Centre*, *Dunboyne, Ireland*.

The aim of this study was to determine the effects on rumen pH of live yeast supplementation in loose-housed dairy cows. Four multiparous lactating rumen-cannulated cows were supplemented (YS) or not (C) with live yeast for 2 periods of 6 wk each, following a cross-over design. The live yeast was top-dressed on the TMR with a single dose of 10 g/d (equivalent to 5x10E10 CFU/d) of Saccharomyces cerevisiae strain 1026 (CBS 493.94, Alltech). The 4 cows were in a group of 50 cows in total, with access to 28 feeding places. During the last 8 d of each period, rumen pH was monitored every 15 min. pH was recorded with an automatic pH meter, placed inside a custom-made PVC pipe with 300 g of lead to ensure that the device remained in the ventral part of the rumen throughout experiment. The rumen was only accessed once every 2 days during samplings. The data were analyzed using a mixed model with repeated measures accounting for the random effect of each cow, and fixed effects of yeast, day of sampling, time since last TMR eating bout, time since previous concentrate consumption, and interaction of yeast with the remaining fixed effects. Yea-Sacc (YS) supplementation did not affect any of the studied feeding behaviors nor DMI. Rumen pH was numerically (P = 0.32) greater for YS than for Control (6.65 vs 6.48. respectively). The coefficient of variation (CV) was numerically lower for YS than for Control (4.91 vs 6.27%, respectively). The average minimum pH for YS (6.53) was numerically greater than the average minimum pH of Control (5.40). Conversely, and in line with the greater variation in rumen pH, the maximum average rumen pH of YS cows was 7.53, whereas the average maximum rumen pH for the C cows was 7.68. YS cows had only 11.1% of their rumen pH below the threshold of 6.2, whereas 26.2% of the rumen pH values were below 6.2 in the C cows. The area under the pH 6.2 for the Control was 0.76±0.09 pH x h/d, whereas the area under the pH 6.2 for YS was 0.67±0.09 pH x h/d (P < 0.05). The results indicate

that live yeasts may have a beneficial effect on rumen pH with cows kept in loose-house conditions receiving rations similar to the one of this study

Key Words: Ruminant, pH, Live Yeast

M333 Rumen fermentation patterns of dairy heifers fed restricted amounts of high, medium, and low concentrate diets and the addition of *Saccharomyces cerevisiae*. G. J. Lascano* and A. J. Heinrichs, *The Pennsylvania State University*, *University Park*.

The objective of this experiment was to investigate ruminal fermentation and *in situ* digestibility of 3 levels of forage:concentrate in diets fed at restricted levels. Three cannulated post-pubertal Holstein heifers (age 18 ± 1 mo; BW 450 ± 20 kg) were fed corn silage (CS)-based diets in a 3-period (35 d) Latin Square Design. Heifers were fed diets for 21 d with no yeast addition, followed by 14 d where yeast culture (YC) was added (1 g/kg as fed basis). A high concentrate (HC) TMR (40% CS, 60% grain; 12.6% CP, 25% NDF), a medium concentrate (MC) TMR (60% CS, 40% grain; 12.3% CP. 28% NDF), and a low concentrate (LC) TMR (80% CS, 20% grain; 12.4% CP, 35% NDF) were fed once/d on a restricted basis to provide 0.22 Mcal ME intake/kg $EBW^{0.75}$. Actual N intake was 165.99 HC, 181.69 MC, 175.21 LC ± 4.3 g ($P > 0.05$). Rumen fluid was sampled on d 18 and d 32 of each period; rumen contents were removed on d 21 and d 35. In situ digestibility was determined on d 15 to 17 and on d 30 to 32. MC diets were incubated with each diet as a control. HC rations had increased in situ rate of DM disappearance (DMD) compared to LC (4.8 vs. 3.4 ± 0.4%/h; $P < 0.06$), but no differences when compared to MC (4.8 vs. 4.0 ± 0.4%/h; $P > 0.1$). No differences were observed in MC in situ digestibility. Mean rumen pH was not different between treatments (6.32, 6.30, 6.30 ± 0.07; $P > 0.1$) and no YC effect was detected. Mean rumen NH3-N concentration was not different among treatments (4.5, 4.7, 4.5 ± 0.7 mg/dL; $P > 0.1$), but YC addition decreased NH3-N in all treatments ($P < 0.01$). Total wet and dry rumen contents, and DM turnover were different between all treatments ($P < 0.01$). From these results we conclude that feeding HC diets in restricted amounts increases DMD rate while having minimal effects on rumen fermentation patterns between different forage:concentrate diets. YC modified NH3-N utilization in the rumen in all 3 diets in this study.

Key Words: Forage:Concentrate, Rumen Fermentation, Yeast Culture

M334 Addition of three yeast cultures to diets for dairy cows in mid-lactation. K. E. Cowles*[1], M. R. Murphy[1], and J. W. Jones[2], [1]*University of Illinois*, *Urbana*, [2]*Western Yeast Co.*, *Chillicothe, IL*.

Our objective was to compare the effects of three concentrated yeast cultures fed with a totally mixed ration to dairy cows in mid-lactation. Eight multiparous Holstein cows (averaging 155 DIM at the start of the trial) were assigned to one of two 4 × 4 Latin squares, blocked by average daily milk yield for the previous week. Cows received a basal diet composed of corn silage, alfalfa silage, chopped alfalfa hay, ground corn, soybean meal, whole cottonseed, wet brewers grain, vitamin-mineral mix, and monensin. The four treatments included: control (14 g of cornmeal), 14 g of Western Yeast Cel-Con, 14 g of Western Yeast Cel-Con-5, or 14 g of Diamond V-XPC yeast. Dosages were according to tag instructions and treatments were topdressed daily at 1000 h. Experimental periods were 21-d long. Cows were milked twice daily at approximately 0600 and 1600 h. Milk composition was analyzed once weekly. Cows were administered Cr_2O_3 twice daily for the last 10 d of each period. Fecal grab-samples were collected twice daily for the last 5 d of each period, composited, and subsampled for Cr_2O_3 analysis. Data were analyzed using the MIXED procedure of SAS. One cow was removed after period 1 because of teat injury. Dry matter intake, 3.5% FCM yield, milk fat percentage and yield, milk protein percentage and yield, FCM:DMI, and apparent total-tract digestibility of DM were unaffected by treatment. Yeast cultures did not affect measured variables; however, stage of lactation and increased variation because of heat stress likely reduced experiment sensitivity.

Table 1.

	Treatment					
	Control	Cel-Con	Cel-Con5	DV-XPC	SE	*P*-value
DMI, kg/d	21.9	20.8	20.8	22.1	1.60	0.898

Key Words: Yeast Culture, Dairy Cow, Digestibility

M335 Effects of dietary yeast culture supplementation on milk production and somatic cell counts at a commercial dairy. C. R. Richardson*[1,3], D. W. Boyles[2], D. B. Wester[3], H. P. Hagaman[1,3], J. E. Vander Dussen[1,3], and G. V. Pollard[4], [1]*The Center for Feed Industry Research and Education*, *Lubbock*, [2]*LDJ Nutrition*, *Lubbock, TX*, [3]*Texas Tech University*, *Lubbock*, [4]*Texas State University*, *San Marcos*.

Sixteen pens of lactating Holstein cows were utilized in a 64 d yeast culture supplementation experiment to determine the effects of yeast source on milk production, somatic cell counts, feed intake, and health status. Treatments evaluated were: control, GRO-TEC, yeast, Diamond V yeast, and Western yeast. Upon initiation of the trial, 3,600 cows were utilized. As the daily cow husbandry protocol demanded, cow pen movements reduced the final number of cows used in the statistical evaluation of this experiment to 2,213 hd. Cows that did not remain in the same pen throughout the duration of the experiment were eliminated. Pen was the experimental unit for statistical comparison. Milk test days for variables being studied were: initial on August 7, month one of September 11, and month two on October 9. Means for variables were calculated by treatment for all cows in treatment pens (n=2,213) and also for those cows in mid-lactation (n=1,014). Mid-lactation cows were those over 60 d in milk or less than 230 d in milk. There were no differences among yeast sources across treatments for milk production (P=0.2656 for all cows and P=0.2180 for mid-lactation cows), or for somatic cell counts (P=0.1926 for all cows and P=0.4846 for mid-lactation cows). Milk production ranged from 32.1 kg/d to 34.8 kg/d, while somatic cell counts varied from

83,700 to 186,000.Milk production and somatic cell counts differed by month for all cows (P = 0.0001 and P = 0.008) and for mid-lactation cows P = 0.0001 and P = 0.080), respectfully. This study indicates possible benefits from yeast supplementation in high lactation Holstein cows and may be related to somatic cell counts.

Key Words: Lactation, Milk Production, Yeast Culture

M336 Blood metabolites in Holstein steers fed diets with different concentrate to alfalfa hay ratios. A. R. Vakili, M. Danesh Mesgaran*, A. Heravi Moussavi, and R. Valizadeh, *Ferdowsi University*, *Mashhad, Khorasan, Iran*.

In dry and semiarid regions, because of low pasture availability, ruminant diets are based on concentrates. The objective of the present experiment was to investigate the effect of diets providing different concentrate to alfalfa hay ratios on blood metabolites in Holstein steers. Four Holstein steers with initial body weight of 300±15 kg fitted with ruminal Fistulae were used in a 4×4 Latin square design (28 days of each period). Animals were fed 7 kg of DM of diets differing in concentrate [155 g CP kg-1 of DM; consisted of maize, barley, soybean meal, sugar beet pulp, wheat bran, cottonseed meal, CaCo3, mineral and vitamin premix, salt (30, 34, 8, 5, 10, 12, 0.3, 0.5, and 0.2 g/100g DM; respectively)] to alfalfa hay ratios as 60:40 (C_{60}:L_{40}), 70:30 (C_{70}:L_{30}), 80:20 (C_{80}:L_{20}) and 90:10 (C_{90}:L_{10}). Steers fed the experimental diets as total mixed ration twice daily at 0800 and 2000 h. At day 24 of the each experimental period, blood samples were taken from jugular vein before the morning feeding, 2, 4 and 6 h post feeding. Serum samples were measured for glucose and urea N by Spectrophotometer (CE 1021, England). Data were analyzed using the GLM procedure of SAS and the means compared by the Duncan test (P <0.05). Blood glucose was similar among diets but blood urea N was affected by treatments. The results of this study indicated that the blood glucose values were not significantly influenced by the concentrate to alfalfa hay ratios but urea N values were influenced significantly.

Table 1. Blood glucose and urea N (mg/dl) in Holstein steers fed diets differing in concentrate: alfalfa hay ratios

Item	Time (h)	Concentrate: alfalfa hay ratio[1]				
	Treatment effect

M337 Effects of corn and alfalfa particle size on ruminal fermentation, digestibility and chewing activity of dairy cows in midlactation. Z. J. Cao*, S. L. Li, M. Ma, and L. L. Wang, *China Agricultural University*, *Beijing, China*.

This study evaluated the effects of, and interactions between, corn particle size and alfalfa particle size on dry matter intake (DMI), milk production, milk composition, ruminal fermentation, microbial yield, chewing activity and nutrient digestibility in midlactating dairy cows. Four multiparous Holstein cows with ruminal cannulas, averaging 595 kg (SD =52) of body weight and 121 DIM (SD= 21) at the start of the experiment, were assigned randomly to a 4 × 4 Latin square design. Experimental periods were 21 d in length (14 d of treatment adaptation and 7 d of data collection). All diets were fed as TMR and were formulated to meet or exceed the requirements of a 600 kg multiparous cow producing 20 kg milk/ d with 4.0% fat. The ratio of concentrate to forage was 40:60 (DM basis). Treatments were arranged in a 2 × 2 factorial design; two levels of alfalfa particle size (2.54 cm and 6.22 cm) were combined with concentrates based on either ground corn (711 µm) or cracked corn (1755 µm). Corn and alfalfa particle size did not affect DMI, milk production and milk fat percentage. Milk protein percentage increased when corn particle size was decreased (P=0.04). Milk urea nitrogen was lower for cows fed ground corn compared to cracked corn (118 vs 134 mg/ l, P=0.05). Estimated microbial N supply increased 41.9 g/d for ground corn compared to cracked corn. Cows fed long alfalfa hay spent more time ruminating compared with cows fed short alfalfa hay ranging from 293 to 336 min/d (P<0.001). Total time spent on chewing by cows increased from 505 to 574 min/d (P=0.002) for short alfalfa and long alfalfa, respectively. Based on the results from this study, dairy cows can be fed diets that contain ground corn and short alfalfa hay without leading to negative effects on rumen pH or nutrient digestibility.

Key Words: Corn Particle Size, Alfalfa Particle Size, Ruminal Fermentation

M338 Effect of feeding pistachio by-product on milk yield, apparent nutrient digestibility and chewing activity of early lactation Holstein cows. A. Bohluli, A. A. Naserian*, R. Valizadeh, and F. Eftekharshahroodi, *Ferdowsi University*, *Mashhad, Iran*.

Eight multiparous Holstein cows in early lactation (57 ± DIM) were assigned into a replicated 4 × 4 Latin square design with 3-wk periods to study the effect of Pistachio By-product (PB) on their performance. Control diet consisted of 60% concentrate, 20% alfalfa, 5% cottonseed, and 15% corn silage. Pistachio by-product was substituted with corn silage at 0, 5, 10, and 15% in DM of control diet according to treat 1 to 4. DMI, daily milk yield and composition were not affected by treatments, although fat daily yield, Economically Corrected Milk (ECM) and 4% FCM were decreased linearly (P<0.1) and daily milk protein yield was increased quadratically (P<0.15) by increasing PB level in the diet. Milk urea nitrogen and Blood concentration of glucose, urea, and Hb were not affected by treatments. Urine pH was increased from 7.7 to 8.0 linearly (P<0.01) from T1 to T4. Crud protein digestibility was similar for all diets (P<0.15), but by increasing PB level in the diet, digestibility of DM, OM, NDF and ADF were decreased linearly (P<0.05). Daily rumination and chewing activity alone or per DM, NDF or ADF daily intake were linearly decreased when PB level increased in the diet (P<0.05). It seems the reduction in milk fat might be due to decrease in structural carbohydrate digestion and chewing activity by increasing PB in the lactating cow diet. The

results show the pistachio by-product can be used as a part of forage in the lactating cow diet; however it cannot be a perfect substituting for roughages in the diet.

M339 Probiotics in growing pre-ruminant calves. J. B. Cannon*[1], D. L. Harmon[1], K. R. McLeod[1], and A. J. Gallegos[2], [1]*University of Kentucky*, *Lexington*, [2]*synBios*, *SA de CV Queretaro, Mexico*.

This study evaluated the addition of a Bacillus-based probiotic to milk replacer and starter for preruminant calves. Thirty-four dairy calves (1 to 4 d old) were housed individually and blocked by sex and birthdate with treatments assigned randomly within blocks. The treatments were probiotic (Bacillus subtilis + Bacillus licheniformis; 10^9 cfu/day) added to the milk replacer and starter or control (no additive). During the study, probiotic treated calves received a commercial starter containing 10^6 cfu/g starter while control calves were offered starter with no additive. All calves received a milk-based milk replacer containing their treatment during the initial 14 days on the experiment. On d 15, they were abruptly switched to a soy-based milk replacer. All calves remained on the soy-based milk replacer and their respective treatment until weaning. Weaning occurred when starter consumption exceeded 1% of body weight for three consecutive days. After 42 days on the study, unweaned calves were reduced to one feeding of milk replacer daily to promote increased starter intake. Weaned calves were maintained on their respective treatments through the total of 56 days on experiment. Dry matter intake (sum of the two food sources) was recorded daily and fecal output was scored (fecal scoring: fluidity, 1=normal, 2=soft, 3=runny, 4=watery; Consistency, 1=normal, 2=foamy, 3=mucus, 4=sticky, 5=constipated; Odor, 1=normal, 2=slightly offensive, 3=highly offensive). A scour day was recorded if fluidity=3 or 4, consistency=3, and odor=2 or 3. Calves were weighed weekly and measured for hip and wither height, hip width and heart girth. Blood samples were collected weekly for determination of hematocrit. Treatment did not affect days to weaning, however calves receiving the probiotic treatment had numerically greater ADG and BW gain (24.6 vs. 22.0 kg). There were no differences between treatments in feed efficiency, scour days per calf, hematocrit, hip and wither height or heart girth. Probiotic treated calves tended (P=0.07) to gain more in hip width. These results indicate that calves housed indoors in a temperature controlled environment with little added stressor may not benefit from probiotic feeding.

Key Words: Probiotic, Calf, Stress

M340 The performance of calves fed starter feeds containing distillers grains. A. B. Chestnut* and D. L. Carr, *Vigortone Ag Products*, *Hiawatha, IA*.

The value of dried distillers grains with solubles (DDGS) as an ingredient in calf starter feed was evaluated in two trials using Holstein bull calves that averaged 5 days of age (+/- 3 d) with a mean BW of 43.9 kg (Trial 1) or 41.6 kg (Trial 2). For each trial 106 calves were randomly assigned to treatments and weighed on d 1, 35, and 56 (Trial 1) or 60 (Trial 2). Each calf received 284 g commercial milk replacer twice daily from d 1 to 28 and once daily from d 29 to 35. Starter feeds were offered ad libitum beginning d 1. All starters were fortified with the same vitamin/mineral premix and formulated to contain 18% CP. The texturized control starter (CON) in both trials was composed of steam-flaked corn, oats, roasted soybeans, molasses, and a pellet containing soybean meal (SBM), fish meal, blood meal, corn gluten meal, and premix. Trial 1 compared CON with 3 pelleted starters composed of ground-corn, SBM, molasses, premix and DDGS. Treatments containing DDGS were: DG10 (10% DDGS), DG10L (10% DDGS + 0.1% L-lysine HCl), and DG20L (20% DDGS + 0.1% L-lysine HCl). From d 1 to 35 ADG was 475 g and did not differ among treatments (P>0.20). From d 35 to 56 ADG was 825, 765, 726, and 689 g for calves on treatments CON, DG20L, DG10L, and DG10, respectively. The CON supported more weight gain (P<0.05) than either DG10L or DG10. DG20L was not different (P>0.05) from either the CON or the DG10L and DG10 treatments. Trial 2 compared CON to a whole-corn/SBM/DDGS starter with 20% DDGS (DG) and a whole-corn/SBM starter (SB). All starters were formulated to 18% CP. The ADG from d 1 to 35 was 438, 427, and 343 g and from d 1 to 60 was 600, 565 and 501 g for CON, DG and SB treatments, respectively. The CON and DG treatments supported similar ADG. The SB treatment supported less (P<0.05) ADG than CON and DG treatments at d 35 and less (P<0.05) ADG than CON at d 60. In these trials starters with 20% DDGS supported ADG similar to a traditional texturized calf starter.

Key Words: Distillers Grains, Starter Feed, Calves

M341 Effect of feeding yeast culture on performance, health, and immunocompetence of dairy Calves. V. J. A. Magalhaes*[1], F. Susca[1], A. F. Branco[2], I. Yoon[3], and J. E. P. Santos[1], [1]*Veterinary Medicine Teaching and Research Center, University of California Davis*, *Tulare*, [2]*Univesidade Estadual de Maringa*, *Maringa, Brazil*, [3]*Diamond V Mills, Inc.*, *Cedar Rapids, IA*.

Objectives were to determine the effects feeding yeast culture (Diamond V XP, Diamond V Mills, Inc.) on performance, health and immunocompetence of calves from 2 to 70 d of age. Holstein calves (n = 512; 2±1 d of age) were randomly assigned to receive 0 (CON; 223 females and 34 males) or yeast culture at 2% of grain DM (YC, 218 females and 37 males). Calves were housed in individual hutches and received 3 feedings of 1.9 L of colostrum in the first 24 h, and pasteurized milk thereafter to 60 d of age. Grain intake was measured 5 d each week for each calf, while BW was measured on d 5, 30 and

68. Attitude and fecal consistency were scored daily. Incidence and duration of health disorders and treatments were recorded. Neutrophil phagocytic and killing activities and antibody response to immunization with ovalbumin were evaluated. Data were analyzed using the LOGISTIC, MIXED, and LIFETEST procedures of SAS. Grain intake did not differ (P = 0.54) between treatments and averaged 908 g/d. Body weight change was similar (P > 0.10) for YC and CON between d 5 and 30 (212 and 229 g/d) and d 30 and 68 (772 and 780 g/d). Glucose (76.1 vs. 71.9 mg/dL) and 3-hydroxybutyrate (0.343 vs. 0.344 mM) concentrations did not differ (P = 0.92) between YC and CON. Attitude scores were similar between treatments throughout the study, but calves fed YC had improved (P = 0.06) mean (1.44 vs. 1.47) and median (1.2 vs 1.3) fecal scores and fewer (P < 0.01) days with diarrhea (4.6 vs. 5.9%). Incidence of fever tended to be reduced (P = 0.08, 34.1 vs. 41.6%) and the risk of health disorders (cases/1000 calf days at risk) was reduced (P = 0.03, 40 vs. 49) with YC in the diet. Minor effects on neutrophil function were observed, and YC tended to improve (P < 0.10) killing of phagocytized bacteria. Yeast culture improved (P = 0.06) survival of calves (92.5 vs. 87.9%) because of a decline (P = 0.05) in mortality rate after 15 d of age. Incorporation of YC in the grain did not alter intake and weight gain, but improved health and survival of dairy calves.

Key Words: Calves, Yeast Culture, Health

M342 The effect of feeding different milk replacer programs on calf growth, health and serum glucose. T. J. Earleywine*[1], T. E. Johnson[1], B. J. Nonnecke[2], and B. L. Miller[1], [1]*Land O'Lakes, Inc.*, *Webster City, IA*, [2]*USDA, ARS, National Disease Center*, *Ames, IA*.

Twenty-six (26) Holstein bull calves (mean=45.6 kg) were employed in a 63 day trial to evaluate milk replacer (MR) feeding programs. Calves were allotted to treatment based upon weight and blood gamma globulin status. Calves were fed a conventional product (20% protein / 20% fat) to provide 227 g or an intensified product (28% protein / 20% fat) to provide 568 g of MR powder twice daily. Milk replacers contained all-milk protein and were medicated with neomycin and terramycin. The conventional and intensified products were fed through days 35 and 49, respectively. Calf starter (18% CP for conventional or 22% for intensified) was fed throughout this 63 day trial. Total gain, MR intake and F/G were improved (P<.05) for calves fed intensive product when compared with calves fed conventional product. Calves fed the conventional product had lower serum glucose levels than those fed the intensified product during the milk replacer feeding phase. After weaning, serum glucose levels of conventional product calves increased to that of intensified product fed calves.

Table 1. Serum Glucose, mg / dL

Diet	Day 14	Day 28	Day 35	Day 49	Day 61
Intensified	119.6	95.7	106.0	85.2	115.7
Conventional	71.7	60.1	72.0	73.2	120.8
P-value	.0003	.0041	.0011	.076	>.10

Key Words: Calf, Milk Replacer, Glucose

M343 First lactation milk yield and fertility of Holstein heifers reared using three milk replacer feeding regimes. P. C. Aikman*[1], M. Gould[2], and E. C. L. Bleach[3], [1]*University of Reading*, *UK*, [2]*Volac International Ltd*, *Royston, UK*, [3]*Writtle College*, *Chelmsford, UK*.

Holstein heifer calves previously used to study effect of pre-weaning feeding regime on calf growth rates were monitored until their second calving to assess effects on milk yield and reproductive performance. Calves were blocked according to birthweight and parity of dam then assigned 48 h after birth to warm ad libitum milk replacer (WA; n = 25), cold ad libitum milk replacer (CA; n = 25) or 4 l/d of warm milk replacer offered in 2 equal feeds (WR; n = 25). The same milk replacer (crude protein 260 g/kg, oil 160 g/kg, ash 70 g/kg; 100 g/l water) was used for each treatment. Ad libitum water, calf concentrate and barley straw were available pre-weaning. All animals were managed identically from weaning at six weeks of age until their second calving. WR animals tended to have lower daily liveweight gains from birth until 12 months of age and lower first parity pre-calving bodyweight. Age at first AI (420 ±7 d) and the number of services per conception as maiden heifers were similar. Age at first (720 ±13 d) and second (1108 ±28 d) calving, total first lactation milk yield (9146 ± 565 kg) and daily milk yield were not affected by treatment. Animals on the WA treatment tended to require less intervention for reproductive problems during the first lactation, hence calving interval and lactation length were numerically shorter. In conclusion, animals allocated to the WA treatment tended to have improved pre-breeding growth rate and reproductive performance in the first lactation, though the limited numbers of animals in the treatment groups prevented significant differences being detected.

Table 1.

	WR	CA	WA	SED	P

Key Words: Heifers, Rearing Period, Fertility

M344 Effects of early intensified nutrition on growth and metabolism of neonatal dairy calves. C. C. Williams*[1], D. T. Gantt[1], C. F. Hutchison[1], C. C. Stanley[1], and M. A. Froetschel[2], [1]*Louisiana State University Agricultural Center*, *Baton Rouge*, [2]*University of Georgia*, *Athens*.

A study was conducted to determine if early intensified nutrition would improve performance of neonatal dairy calves in southeast Louisiana. Thirty-one calves (19 male; 12 female) were assigned to one of two dietary treatments. Treatments included an accelerated feeding program or the conventional feeding program in use at the LSU Dairy Farm. The accelerated feeding treatment (ACC) consisted of milk replacer (Cow's Match, Land O'Lakes, 28% CP, 20% fat) and

22% CP calf starter, and the conventional treatment (CON) consisted of milk replacer (20% CP, 20% fat, Land O′Lakes) and 18% CP calf starter. Both treatments were fed according to recommended procedures. On day 42 milk replacer was reduced by 50%, and on day 49 all calves were weaned. Body weights were measured at birth and weekly through weaning. Additionally, hip height, wither height, and body length were measured weekly. Feed intake and fecal scores were recorded daily. Beginning on day 7 and continuing weekly through weaning, blood samples were collected prior to morning feeding for analysis of IGF-I. On day 25 and again on days 56, 84, 112 rumen fluid was collected for analysis of pH and short chain VFA to evaluate possible differences in rumen development. Calves on the ACC treatment had greater ($P < 0.01$) body weight gain and fecal scores and decreased starter intake when compared to CON calves. There was a treatment by week interaction ($P < 0.01$) for ADG, with calves on ACC having higher ADG through week 5 and CON calves having higher ADG from weeks 6 through 8. Wither height, hip height, and body length were greater ($P < 0.05$) in ACC calves. There were no effects ($P > 0.05$) of treatment on pH, IGF-I or VFA concentrations. However, there were treatment by week interactions ($P < 0.05$) for rumen concentrations of acetate, propionate, and total VFA. There was an effect of week ($P < 0.01$) on IGF-I concentrations and on rumen pH. These data indicate that early intensified nutrition does improve growth in young dairy calves. However, rumen development may be affected due to decreased starter intake and the effects on rumen VFA concentrations.

Key Words: Calves, Early Intensified Nutrition, Growth

M345 Partial replacement of whole milk with soymilk stimulates early calf starter intake, saves milk, and reduces weaning age and costs. G. R. Ghorbani[1], R. Kowsarzar*[1], M. Alikhani[1], and A. Nikkhah[2], [1]*Isfahan University of Technology*, *Isfahan, Iran*, [2]*University of Manitoba*, *Manitoba, Canada*.

Evidence has been accumulating that cow's milk must not be considered undesirable for human health simply because of its cholesterol and saturated fatty acids. Milk, instead, contains bioactive substances that may reduce the risk of cancer and cardiovascular diseases. Partial replacement of whole milk with soymilk was hypothesized to stimulate starter intake, hasten rumen development, and reduce weaning age, thereby reducing feed costs and saving more milk. The primary objective of the current study was to determine the effects of partial replacement of whole milk with soymilk on pre-weaning calf performance and feed costs. Following 3-d of colostrum and transition milk feeding, twenty seven neonatal Holstein calves (41.6 ± 1.6 kg body weight; mean ± SE) were assigned in a completely randomized design to three treatments: 1) whole milk (M), 2) 75% M + 25% soymilk (S25), or 3) 50% M + 50% soymilk (S50), fed at 10% of body weight, on a wet basis. The weaning criterion was defined as the calf age at a daily intake of 900 g starter concentrate lasting for two weeks. During the first two weeks of the trial, treatments did not differ in starter intake and fecal score; however, the M- and S25-fed calves gained more weight ($P<0.05$) than did S50-fed calves. By 49 days of age, S25-fed but not S50-fed calves gained competitively similar body weight as M-fed calves. The S25- and S50-fed calves achieved a minimum daily starter intake of 900 g respectively about 10 and 12 d earlier than did M-fed peers ($P<0.01$). As a result, soymilk fed calves consumed about 20% less milk than M-fed calves to meet the weaning criterion ($P<0.05$). Because M was about 50% more expensive than both soymilk and starter concentrate, feed-related weaning costs dropped by about 35% when soymilk was fed ($P=0.06$). Saving more milk will have nutritional implications as to the increasing human demands for milk products.

Key Words: Calf, Soymilk, Weaning

M346 Evaluation of Jersey calves fed milk replacers and starter of varying protein and fat composition. E. H. Jaster*, J. L. Beckett, and D. G. Peterson, *California Polytechnic State University*, *San Luis Obispo*.

The objective of this study was to evaluate the growth and performance of Jersey calves fed milk replacer and starter with different amounts of protein and fat. Three day old Jersey calves (n=24) were assigned to one of three diets. From d 3 to 42, calves in treatment 1 were fed a standard MR (20% CP and 20 % fat) and an 18 % CP pelleted starter. Calves in treatment 1 were fed 236 g of milk replacer and fed at constant rate of 1.89 L of warm water per feeding with a nipple bottle. Milk replacer was fed twice daily in two equal feedings at 0600 and 1800 h. Treatment 2 calves were fed a MR (22 % CP and 22 % fat) and 18 % CP starter. Treatment two calves were fed the same amounts of milk replacer and schedule as treatment 1. Treatment 3 calves were fed a MR (30 % CP and 25 % fat) and 25 % CP starter. The CP content of each milk replacer was derived from all-milk sources and the fat content was choice white grease. During wk 7, calves in all treatments were fed half the daily amount offered during wk 2-6 and weaned at the end of wk 7. During the experiment, calves were offered ad libitum intake of a starter from wk one to ten; intake was measured weekly between wk 1 to 3 and daily from wk 4 to 10. Calves weights, fecal consistency scores, heart girth, height at withers and body length were measured weekly. A blood sample was drawn by jugular venipuncture wk 1 (start) and wk 2, 4, 6, 8, and 10. Samples were assayed for glucose and serum urea nitrogen. Increasing levels of dietary protein and fat resulted in greater overall body weight ($P<0.05$), though body weight was not different at week 10 between treatment 2 and 3 ($P>0.50$). Plasma glucose was similar across all groups with no effect of diet ($P>0.50$). Urea nitrogen was not different between treatments 1 and 2, but elevated in animals fed treatment 3.

Key Words: Dairy, Calves, Milk Replacer

M347 Pre- and post weaning performance and health of dairy heifer calves fed milk replacers supplemented with oligosaccharides. B. Ziegler*[1], R. Larson[1], S. Hayes[2], H. Chester-Jones[3], D. Ziegler[3], J. Linn[4], M. Raeth-Knight[4], and G. Golombeski[4], [1]*Hubbard Feeds*, *Mankato, MN*, [2]*Milk Products*, *Chilton, WI*, [3]*University of Minnesota Southern Research and Outreach Center*, *Waseca*, [4]*University of Minnesota*, *St. Paul*.

One-hundred one 2 to 4 day-old dairy heifer calves were randomly assigned to one of 4 non-medicated, all-milk protein (20% protein:20% fat) milk replacers (MR) with supplemental treatments to evaluate their effect on pre- and post weaning calf performance and health. Calves were housed from July to September in 2.29 x 1.17 m individual calf pens, within a frame-steel curtain side-wall, naturally ventilated barn. Initial BW averaged 40.4 kg ± 0.69 kg. Treatments were: 1) MR control; 2) MR with mannan oligosaccharides (Bio-mos®, fed at 2 g/calf daily); 3) MR with fructo-oligosaccharides (inulin, fed at 5.67

g/calf daily) and, 4) MR with a combination of Bio-mos® (2 g/calf daily) and inulin (5.67 g/calf daily). Milk replacers were fed at 0.284 kg (as-fed) in 1.99 L water 2× daily for the first 35 d, and then 1X daily from d 36 to weaning at 42 d. Calves were offered a 20.4% CP (DM basis) texturized calf starter (CS) and had access to fresh water at all times. Total DMI from MR for 42 d averaged 20.58 kg/calf. There were no pre- and post weaning performance differences by treatments (P > 0.05). Pre-weaning CS DMI, total DMI, total gain and feed/gain averaged 17.32, 37.90, 22.81 and 1.67 kg, respectively. Post weaning CS DMI, total gain, and feed/gain averaged 26.51, 12.75 and 2.08 kg, respectively. Overall 56-d daily gain and feed/gain averaged 0.64 and 1.79 kg, respectively. Pre-weaning fecal scores for the control MR calves tended (P = 0.07) to be lower than calves fed the other treatments. Health treatment costs/calf averaged $3.24, $3.17, $3.88 and $3.97 for calves fed treatments 1, 2, 3 and 4, respectively. Under the conditions of this study, feeding a MR supplemented with oligosaccharides did not affect pre- and immediate post weaning calf performance.

Key Words: Dairy Calves, Milk Replacer Supplements, Performance

M348 Pre- and post weaning performance and health of dairy heifer calves fed milk replacers with different protein sources. S. Hayes*[1], B. Ziegler[2], R. Larson[2], H. Chester-Jones[3], D. Ziegler[3], J. Linn[4], M. Raeth-Knight[4], and G. Golombeski[4], [1]*Milk Products*, *Chilton, WI*, [2]*Hubbard Feeds*, *Mankato, MN*, [3]*University of Minnesota Southern Research and Outreach Center*, *Waseca*, [4]*University of Minnesota*, *St. Paul*.

One-hundred twenty-four 2 to 4 d-old dairy heifer calves were randomly assigned to 1 of 5 medicated (20% CP:20% fat) milk replacers (MR) with 4 MR partially replacing milk protein with plant-based sources to measure pre- and post weaning performance and health. Calves were housed in 2.29 x 1.17 m individual calf pens within a frame-steel, curtain side-wall, naturally ventilated, barn. Initial BW averaged 40.9 ± 0.79 kg. Treatments were: 1) MR with all-milk protein (CON); 2) MR with hydrolyzed wheat gluten protein replacing 50% of the milk protein (50WG); 3) MR with soybean protein concentrate replacing 50% of the milk protein (50SPC); 4) MR with WG replacing 30% of the milk protein (30WG); and 5) MR with 25% WG and 25% SPC replacing milk protein (25SPCWG). Milk replacers were fed at 0.284 kg (as-fed) in 1.99 L water 2× daily for the first 35 d, and then 1X daily from d 36 to weaning at 42 d. Calves were offered a 20.2% CP calf starter (CS) and had access to fresh water. Total DMI from MR averaged 21.8 kg/calf. Calves fed CON had 4.09 kg greater (P < 0.05) pre-weaning gain compared to other groups. Overall ADG and feed/gain were 0.78, 1.80; 0.71, 1.85; .70, 1.98; 0.69, 1.88; 0.68 and 1.93 kg for calves fed CON, 50WG, 50SPC, 30WG and 25WGSPC, respectively. Health treatment costs/calf averaged $2.09. Under the conditions of this study, feeding an all-milk protein MR with CS resulted in excellent growth. The use of WG and SPC as a partial replacement for milk protein reduced calf performance due mainly to CS intake differences. Plant-based MR protein sources do have the potential to reduce feed costs to weaning.

Key Words: Dairy Calves, Milk Replacer Protein Sources, Performance

M349 Comparison of three analytical methods to assess urea nitrogen in colostrum. N. E. Lobos*[1], M. A. Wattiaux[1], and G. A. Broderick[1,2], [1]*University of Wisconsin*, *Madison*, [2]*US Dairy Forage Research Center*, *Madison, WI*.

Recent research has suggested that milk urea nitrogen is correlated with feed efficiency (FCM/DMI) and thus the cow's metabolic status in early lactation. Colostral urea nitrogen (UN) may provide useful information for early lactating cow management. Thus, we studied three methods to determine colostral UN. Starting 2 wks before calving, 27 Holstein cows were fed a 13.2% CP diet. Colostrum samples were collected and preserved frozen with bronopol until analysis. After thawing, three sub-samples were obtained. The first one was analyzed in a commercial laboratory by near infrared spectroscopy (NIR) using a Foss 6000 instrument calibrated for milk. The second sub-sample was centrifuged to remove fat and analyzed using a colorimetric urease-based assay with sodium nitroprusside as catalyst (Berthelot reaction (BR)). After deproteinization, the third sub-sample was analyzed by an automated colorimetric assay using the Diacetyl Monoxyme method (DAM) adapted to a flow-injection analyzer (Lachat QuikChem 8000). Data were analyzed using Proc REG of SAS. Linear models assumed no intercept. Average and (standard deviation) of colostral UN were 20.9 (14.8), 9.5 (4.5), and 11.1 (4.3) mg/dL for the NIR, BR, and DAM methods, respectively. Values ranged from 0.6 to 62.5, from 1.2 to 18.0 and from 4.2 to 23.3 mg/dL for the NIR, BR, and DAM methods, respectively. Regressions were as follow: NIR-UN = 1.69 (standard error (se) = 0.34) x BR-UN (r^2 = 0.49, root MSE = 18.6); NIR-UN = 1.66 (se = 0.27) x DAM-UN (r^2 = 0.60, root MSE = 16.5), and BR-UN = 0.84 (se = 0.06) x DAM-UN (r^2 = 0.89, root MSE = 3.5). For each regression, the slope differed from 1.0 (P<0.05). Because true colostral UN was not known, the most accurate technique could not be established, but the NIR-UN was the least precise. The NIR-UN was poorly correlated with BR-UN and DAM-UN, but the latter two methods were in close agreement. The wide variation in colostral UN most likely reflected metabolic differences among cows at parturition.

Key Words: Colostrum, Urea, Nitrogen

M350 Influence of fish/soybean oil supplementation on milk conjugated linoleic acid and mammary gland SCD gene expression in dairy cows. D. P. Bu[1], J. Q. Wang*[1], T. R. Dhiman[2], and S. J Liu[1], [1]*State Key Laboratory of Animal Nutrition,Institute of Animal Science,Chinese Academy of Agricultural Sciences*, *Beijing, China*, [2]*Department of Animal, Dairy and Veterinary Sciences, Utah State University*, *Logan*.

The objective of this study was to examine the effect of adding fish oil and soybean oil to dairy cows on milk fat C18:2 cis-9 trans-11 conjugated linoleic acid (CLA) and mammary gland SCD gene expression. Eighteen Chinese Holstein dairy cows (176 ± 16 DIM) in a randomized design were fed a basal diet (CTL), or basal diet supplemented with either 2% fish oil (FO) or a combination of 2% fish oil and 2% soybean oil (SBFO). The basal diet contained 40% forage and 60% concentrate mix. Oils were added by replacing the corn in the diet. Experimental duration was 9 wk. Diets contained an average 16.6 ± 0.3% CP and had 1.56, 1.64 and 1.72 Mcal NEL/kg DM in CTL, FO and SBFO, respectively. Milk yields were recorded daily and milk samples were collected weekly from 3 consecutive milkings and analyzed for composition and fatty acid (FA) profile. Within each treatment, 3 cows were used for mammary gland biopsy sampling.

Mammary gland tissues were taken from a rear quarter at the end of the treatment period. Relative gene expression data were calculated by $2^{-\Delta\Delta CT}$ method. β-actin was used as the reference gene. Analysis of variance for variables was conducted using the MIXED procedure of SAS. Significance was declared at $P < 0.05$. Feed DMI and milk yields were not different among treatments. Cows in FO and SBFO treatments had 2.50^{b} and 2.86^{b} % fat in milk, respectively compared to 3.63^{a} % in CTL. The proportions of vaccenic acid (VA) and cis-9 trans-11 CLA isomer were 0.75^{b} , 7.88^{a} , and 8.54^{a} , 0.56^{b} , 3.20^{a} and 4.15^{a} percent of total FA methyl esters in CTL, FO and SBFO, respectively. The proportions of unsaturated FA were increased in FO and SOFO treatments compared to CTL. The abundance of SCD mRNA in the mammary gland was reduced by 50% in FO and 57% SOFO compared to CTL. Feeding 2% fish oil (FO) or 2% fish oil plus 2% soybean oil (SBFO) to dairy cows increased the content of VA and CLA in milk by 560% and decreased the milk fat content by 26% compared to CTL without oil.

Key Words: Fish Oil, Conjugated Linoleic Acid, SCD

M351 Flow of fatty acids to the duodenum and fatty acid profile of milk from cows fed diets differing in forage fiber level. D. P. Bu[1], J. Q. Wang*[1], T. R. Dhiman[2], S. C. Li[1], and S. J. Liu[1], [1]*State Key Laboratory of Animal Nutrition,Institute of Animal Science,Chinese Academy of Agricultural Sciences*, *Beijing, China*, [2]*Department of Animal, Dairy and Veterinary Sciences, Utah State University*, *Logan*.

A study was conducted to evaluate the effects of diets differing in forage NDF (fNDF) on the flow of fatty acids (FA) to the duodenum and milk FA profile. Four Holstein cows (483±21kg BW; 175±6 DIM) fitted with permanent ruminal and simple T-shaped cannulae in the proximal duodenum were used in a 4×4 Latin square design experiment. Each period was 21 d. First 2 wk were considered as adaptation to the diets and measurements were made during the last week in each period. Diets in 4 treatments had fNDF content of 46.71(Trt-1), 37.01(Trt-2), 26.43 (Trt-3) and 18.50% (Trt-4) on dry matter basis. The different levels of fNDF in diets were achieved by varying the ratio of forage and concentrate and type of forage. The forages used to formulate diets were corn silage, Chinese wildrye or Alfalfa hay. The diets were formulated to be low-fat. The FA content of the diets was 0.86, 1.14, 1.46 and 1.71 in treatments 1 through 4, respectively. During the last week in each period samples of the rumen fluid and duodenal chyme were collected to study the flow of FA. Milk samples were analyzed for FA profiles. Ruminal fluid pH was 6.56^{a} , 6.55^{a} , 6.45^{a} and 6.26^{b} in treatments 1 through 4, respectively. Decreasing fNDF content of the diets tended to increase the flow of C18:1 trans-11 (VA; $P < 0.09$). The flow of C16:0, C18:0, C18:1 cis-9 and C18:2 to the duodenum increased significantly with decreasing fNDF in the treatment diets. The flow of C18:2 cis-9 trans-11 isomer of conjugated linoleic acid (CLA) was not affected by dietary treatments. Varying the fNDF in the present study had no influence on milk fatty acid profile including CLA content. The results suggest that varying forage NDF content from 46.7 to 18.5 % of diet DM in low fat diets (< 2% of diet) had little effect on milk fatty acid profile

Key Words: Forage, Fatty Acids, Dairy Cow

M352 Fatty acids composition of milk from cows fed oilseeds. S. J. Liu[1], J. Q. Wang*[1], D. P. Bu[1], and T. R. Dhiman[2], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*, [2]*Department of Animal, Dairy and Veterinary Sciences, Utah State University*, *Logan*.

The objective of this study was to examine the influence of oilseeds supplementation on milk fatty acid (FA) profile and plasma parameters in dairy cows. Forty Holstein dairy cows (150 ± 25 DIM) were randomly assigned to four treatments. Cows in four treatments were fed a basal diet (CTL) or basal diet supplemented with either whole soybeans (FS), expanded soybeans (ES), or a mix of whole cottonseed, whole soybeans and expanded soybeans (MIX). Diets contained 1.57, 1.59, 1.60 and 1.64 NEL/kg DM in CTL, FS, ES and MIX treatments. All diets were iso-nitrogenous and contained an average 16.50% CP. Experimental duration was 6 week. Measurements were made during the last 3 weeks. Daily feed intake and milk yield were recorded. Weekly milk samples were analyzed for composition and fatty acid profile. Blood samples were taken from the coccygeal vein or artery at 3h post-feeding on the last day of experiment and analyzed for blood chemistry. Statistical analysis was conducted using the MIXED procedure of SAS for a completely randomized design with repeated measures. Yields of milk, fat and protein were not different among treatments. The proportions of short and medium chain (C4:0 – C12:0) were decreased and long chain FA increased in cows fed oil seeds compared with cows in CTL. Feeding expanded soybeans to cows in ES treatment increased the C18:2 cis-9 trans-11 isomer of CLA in milk by 84% compared with CTL treatment. The concentrations of CLA in milk were the same in CTL, FS and MIX treatments. Mean concentration of plasma cholesterol, lipoprotein cholesterol, NEFA, Leptin, glucose, triglyceride, insulin and β-hydroxybutyric acid was not different among treatments. Results suggest that feeding expanded soybeans to dairy cows enhances the C18:2 cis-9 trans-11 isomer of CLA without influencing feed intake, milk yield, milk composition and blood parameters.

Key Words: Oilseeds, Milk Fatty Acids, Hormones

M353 Please see abstract #282.

M354 Yields of fatty acids in milk of dairy cows fed a high- or low- forage diet supplemented with either flaxseed or flaxseed oil. C. Benchaar*[1], H. V. Petit[1], T. A. McAllister[2], and P. Y. Chouinard[3], [1]*Agriculture and Agri-Food Canada*, *Dairy and Swine R&D Centre, Sherbrooke, QC, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*, [3]*Université Laval*, *Quebec, QC, Canada*.

The objective of this study was to examine the effect of whole flaxseed (FS) and flaxseed oil (FO) supplementation (10 and 3%, respectively; DM basis) on yields of fatty acids in milk of dairy cows fed high- (H) or low- (L) forage diets (70 and 30%, respectively; DM basis). Four lactating cows (BW = 647 kg; DIM = 96 d) used in a 4x4 Latin square design were fed: H+FS (HFS), H+FO (HFO), L+FS (LFS), and L+FO (LFO). Orthogonal contrasts (PROC MIXED, SAS) were used to test the effects of forage level (F), flaxseed source (FLA), and their interaction (F x FLA). Significance was declared at $P < 0.05$. Yields of C18:0 (147.3 vs. 190.8 g/d) and *cis*-9, *trans*-11, *cis*-15 C18:3 (CLNA; 0.78 vs. 1.16 g/d) were lower, and those of C10:0 (37.9 vs. 30.7 g/d), C12:0 (45.2 vs. 33.6 g/d), C14:0 (158.6 vs. 136.1 g/d), C14:1 (14.4 vs. 10.8 g/d), C15:0 (17.4 vs. 14.2 g/d), and *trans*-15 C18:1 (12.9 vs.

9.48 g/d) were higher in milk of cows fed L than in milk of cows fed H diets. Cows fed FS had higher yields of C6:0 (27.8 vs. 24.2 g/d), C8:0 (16.8 vs. 14.3 g/d), C10:0 (37.9 vs. 30.7 g/d), C12:0 (43.4 vs. 35.4 g/d), C16:0 (341.9 vs. 292.8 g/d), C18:0 (179.6 vs. 158.4 g/d), and *cis*-9, *cis*-12, *cis*-15 C18:3 (8.75 vs. 5.74 g/d), and lower yields of *cis*-15 C18:1 (4.67 vs. 7.84 g/d), *trans*-9 C18:1 (3.40 vs. 6.05 g/d), *trans*-11 C18:1 (16.5 vs. 37.7 g/d), *trans*-15 C18:1 (10.1 vs. 12.3 g/d), *cis*-9, *cis*-12 C18:2 (5.21 vs. 14.4 g/d), and *cis*-9, *trans*-11 C18:2 (CLA; 6.10 vs. 14.2 g/d) than cows fed FO. Yield of *trans*-10 C18:1 was 6.83, 3.83, 27.8, and 5.54 g/d for HFO, HFS, LFO, and LFS, respectively (F x FLA). Cows fed FS had higher transfer of *cis*-9, *cis*-12, *cis*-15 C18:3 from feed to milk than cows fed FO (1.63 vs. 1.24%). Feeding L diets modified the pathway of biohydrogenation, leading to higher production of *trans*-10 C18:1 in milk and this effect was of greater magnitude when FO was added in the diet as compared to FS. Feeding FS increased yield and transfer efficiency of *cis*-9, *cis*-12, *cis*-15 C18:3 and decreased the concentration of *trans* intermediates of ruminal biohydrogenation as compared with FO.

Key Words: Flaxseed Oil, Milk Fatty Acid Yield, Dairy Cows

M355 Abomasal infusion of butterfat increases milk fat in lactating dairy cows. A. K. G Kadegowda*, L. S. Piperova, and R. A. Erdman, *University of Maryland*, *College Park*.

Our objective was to compare the effects of abomasal infusion of short and medium chain FA (SCFA) with long chain fatty acids (LCFA) on milk fat synthesis. Eight rumen fistulated Holstein cows, beginning in early lactation (49±20 DIM) were used in a replicated 4x4 Latin square design. Treatments were: 1) Control (C) (no infusion); 2) abomasal infusion of 400g/d butterfat (B); 3) 245 g/d LCFA using a blend of 60% cocoa butter, 30% olive oil, and 10% palm oil that provided equivalent amounts of LCFA found in 400g of B; and 4) CLA (negative control). The CLA mixture provided equal proportions of c9t11 and t10c12 CLA (18% of total CLA; 7.5g/d of t10c12 CLA). Fat supplements were infused in equal portions 3 times daily at 0800, 1400, and 1800 h during the last 2 wks of each 3 wk experimental period. Milk samples for milk composition by infrared analysis were collected from 5 consecutive milkings at the end of wk 3. Daily dry matter intake (DMI) and milk production were unaffected by treatment. Butterfat infusion increased milk fat percentage by 14% ($P < 0.03$) to 4.26% and milk fat yield by 15% ($P < 0.07$) to 1351 g/day compared with Controls (3.74 % and 1175 g/day). CLA infusion decreased milk fat percentage and fat yield by 43% ($P< 0.001$). However, milk protein percentage was higher (3.70%; $P < 0.01$) in CLA infused cows than in Controls (3.30%), butterfat (3.28%) or LCFA (3.27%). While LCFA had no effect on fat synthesis, abomasal infusion of butterfat containing both LCFA and SCFA suggested that the availability of short and medium chain FA may be a limiting factor for milk fat synthesis.

Table 1.

	Treatments					Contrasts (*P*

M356 Evaluation of LYSOFORTE™ PF brand biosurfactant toward enhancing digestion of supplemental dietary fat in animal diets. D. Sapienza[1], F. R. Valdez*[2], A. S. Suleman[2], and W. Rounds[2], [1]*Sapienza Analytica LLC*, *Slater, IA*, [2]*Kemin Industries, Inc.*, *Des Moines, IA*.

Emulsifiers as feed additives improve total-tract digestibility of dietary fats and are especially important in improving fat digestibility when dry distillers grains solubles (DDGS) are fed. An objective of this evaluation was to quantify the increase in the quantity of DDGS that could be digested with the synergistic effects of supplemental emulsifiers. Three different emulsifiers, namely LYSOFORTE™ brand PF (LPC) Biosurfactant, LYSOPRIN, and de-oiled lecithin were evaluated in an *in vitro* anaerobic system with proteases and a lipase. LPC is more effective than either de-oiled lecithin or LYSOPRIN as an aid to digestion of DDGS. The beneficial effects of LPC appear to be more consistent across dosages and levels of DDGS incubated than either de-oiled lecithin or LYSOPRIN. The data suggest that there may be limited benefit in adding an emulsifier when soy oil or tallow is the dietary source of fat but at certain dosages the production of free fatty acids (FFA) was increased when choice grease was incubated with LPC. The concentrations of DDGS ranged from the equivalent of 5 to 30% of the ration dry matter. At the inclusion rate of 5%, the data show that DDGS can be digested (%FATD) above 95% without the aid of an emulsifier. But at inclusion percentages above 14%, %FATD can decrease to 72.2% at the 30% rate. The comparisons of %FATD by dosage reveals that LPC at 250 g/T is significantly better ($P>0.1$) in the number of incidences in which %FATD is equal to or greater than 95%. In contrast, de-oiled lecithin at 250 g/T and LYSOPRIN at 250 g/T have significantly lower instances above 95% and their average %FATD are also significantly lower at 90.4% and 90.8%, respectively. LPC averages 95.7% across all three of its dosages. These data suggest that LPC may be a viable fat digestibility enhancer when DDGS are fed to animal diets greater than 14% of the diet compared to de-oiled lecithin and LYSOPRIN.

Key Words: Dry Distillers Grains Solubles, Fat Digestibility, Lysoforte

M357 Optimizing the levels of linseed oil in grazing cow diets to maximize conjugated linoleic acid in milk. G. D. Flowers*[1], A. A. AbuGhazaleh[1], and S. Ibrahim[2], [1]*Southern Illinois University Carbondale*, *Carbondale*, [2]*North Carolina Agricultural and Technical State University*, *Greensboro*.

In the recent past, there has been considerable interest in the potential health-promoting properties of conjugated linoleic acid (c9t11 CLA), a fatty acid produced naturally in ruminant animals. Previous studies have shown that milk c9t11 CLA increased when cows grazed or fed vegetable oils, however, feeding vegetable oils at higher level can be detrimental to cows. The primary objective of this study was to determine optimum dietary level of linseed oil to increase milk c9t11 CLA for grazing dairy cows. Twelve Holsteins cows in mid lactation were placed on alfalfa based pasture and assigned into four treatment groups using a 4 X4 Latin square design with 3 wk experimental periods. Treatment groups were: 1) control grain supplement; 2) control grain supplement containing 167g linseed oil; 3) control grain supplement containing 333g linseed oil and 4) control grain supplement containing 500g linseed oil. Grain supplements were offered at 7kg/d in two equal feedings after the a.m. and p.m. milking. Additional 100g/day of algae (high in C22:6n3, 40% of total fatty acids) were

added to treatment diets. Milk samples were collected during the last three days of each period and analyzed for composition and fatty acids profile. Treatment diets had no effect on milk production (19.9, 18.8, 19.3, and 20.3 kg/day for diets 1 to 4, respectively), milk fat percentages (3.23, 3.35, 3.36, and 3.31) and milk protein percentages (3.02, 3.1, 3.11, and 3.07). Milk c9t11CLA (1.10, 1.23, 1.43, and 1.65 g/100g fatty acids for diets 1 to 4, respectively), t11 C18:1 (3.28, 3.59, 4.30, and 4.79 g/100g), and C18:3n3 (0.59, 0.78, 1.02, and 1.03 g/100g) concentrations were linearly ($P < 0.05$) increased with linseed oil supplementations. In conclusion, adding linseed oil to grazing dairy cows diet at 500g/d can improve the nutritional value of milk by increasing the levels of milk c9t11 CLA and C18:3n3 without adversely affecting cows milk production or composition.

Key Words: CLA, Linseed Oil, Grazing

M358 Effect of ruminal infusion of sunflower oil (SO) or seeds (SS) combined or not with fish oil (FO) on conjugated linoleic acid (CLA) in milk. G. A. Gagliostro*[1], M. A. Rodriguez[2], P. Pellegrini[2], G. Muset[2], P. Gatti[2], D. A. Garciarena[1], H. H. Fernández[1], M. Oporto[1], A. Ferlay[3], and Y. Chilliard[3], [1]*Instituto Nacional de Tecnología Agropecuaria (INTA)*, *Balcarce, Argentina*, [2]*Instituto Nacional de Tecnología Industrial (INTI)*, *Buenos Aires, Argentina*, [3]*Institut National de la Recherche Agronomique (INRA)*, *Theix, France*.

Four rumen cannulated Holstein cows grazing a pasture (Avena sativa, L.) received according to a 4×4 Latin square design four corn silage-based diets supplemented with sunflower seeds (SS, 1.9 kg DM/cow/d); sunflower oil (SO, 0.8 kg/cow/d); SS plus fish oil (SS-FO, SS + 0.24 kg/cow/d FO) or SO-FO (SO + 0.24 kg/cow/d FO). Corn silage and corn grain were fed at 5.6 and 1.3 kg DM/cow/d. SO treatments were balanced for CP by adding 0.89 kg DM/cow of sunflower meal. Oils and seeds (coarsely ground) were introduced via ruminal cannulae. Statistical analysis included effects of cow, period, linoleic source, FO supply and the interaction. Duncan's Multiple Range Test was used to compare (SS + SS-FO) vs (SO + SO-FO) and (SS +SO) vs (SS-FO + SO-FO). Pasture, SO and FO represented 39, 5.6 and 1.6% of total DMI. . Interaction effects were not detected. Milk yield tended ($P<0.07$) to increase with SO (9.9 vs 8.7 kg/d). FCM (8.01 vs 6.37 kg/d) and milk fat (270 vs 191 g/d) yields increased ($P<0.04$) with SO. Content (40.5 vs 37.0 g/kg) and yield (397 vs 322 g/d) of milk protein were higher ($P<0.01$) in SO treatments. Parameters of pasture NDF degradation did not differ. Soluble CP fraction of pasture increased ($P<0.04$) from 31.3% up to 49.6 % when FO was fed. Ruminal pH was higher ($P<0.05$) in SS-FO (6.07) compared to SO-FO (5.77). SS or SO alone or combined with FO decreased concentrations (g/100g FA) of de novo synthesized saturated FA (-1.59 for C12:0, -4.79 for C14:0 and -8.29 for C16:0, vs pre-experimental period). C18:0 was 14.1 in SS and SO vs 6.42 g/100g FA in SS-FO and SO-FO ($P<0.002$). Trans-C18:1 was higher ($P<0.001$) in FO groups (30.7) compared to SS and SO (13.9) and particularly with SS-FO (33.5; $P<0.05$). Cis-9 C18:1 decreased (-12.6 g/100g FA) with FO ($P<.0001$). Increase of 9-cis 11-trans CLA over baseline averaged 2 g/100g FA across treatments. FO supply increased CLA content from 2.86 up to 3.92 g/100g FA ($P<0.04$) and increased the C18:3n-3 (+0.34 g/100g FA, $P<0.0003$). Unsaturated FA supply had a marked effect on milk FA profile. However the increase in trans-C18:1 isomers with FO and their implications on human health need to be determined.

Key Words: Conjugated Linoleic Acid, Sunflower, Fish Oil

M359 Effects of high oil corn grain supplementation on milk yield and composition and milk fatty acid profile in grazing dairy cows in early lactation. F. Luparia[1], D. A. Garciarena[1], C. A. Cangiano[1], P. Pellegrini[2], M.A. Rodriguez[2], H. H. Fernández[1], and G. A. Gagliostro*[1], [1]*Instituto Nacional de Tecnología Agropecuaria, INTA*, *Balcarce, Buenos Aires, Argentina*, [2]*Instituto Nacional de Tecnología Industrial, INTI*, *Buenos Aires, Argentina*.

The objective was to evaluate the effect of high oil corn grain (HOC, 6.6% ether extract) vs conventional corn (CC, 2.25 % ether extract) at two feeding levels (4 and 8 kg/cow/d) on yield, composition and fatty acid (FA) profile of milk in grazing dairy cows. Four ruminal cannulated Holstein cows in early lactation (30 days in milk) grazed a pasture in 4x4 Latin square design with a 2x2 factorial arrangement of treatments. Each experimental period lasted 14 days (d). The first 10 d were used for adaptation to diets with the last 4 d for data collection. Herbage allowance was fixed at 11 and 17 kg pasture DM/cow/d when 8 and 4 kg of grain were consumed. Cows received 2 kg/d of soybean meal and 0,15 kg/d of a mineral-vitamin premix. Milk yield (25.5 kg/cow/d), FCM (21.9 kg/cow/d), milk fat (30.8 g/kg) and milk protein contents (31.2 g/kg) did not differ between treatments. Concentration of C12:0 and C14:0 in milk-fat resulted lower ($P<0.01$) in HOC (2.70 and 24.51 g/100 g FA) than CC (3.15 and 25.85 g/100 g FA). A significative corn level x genotype interaction was detected for C16:0 concentration. It was lower in HOC groups (24.51 g/100 g FA) compared to CC (25.85 g/100 g FA) and particularly to HOC8 (24.04 g/100 g FA). Concentration of vaccenic acid (trans-11 C18:1) in milk-fat was higher with 4 kg (3.20 g/100 g FA) instead of 8 kg (2.81 g/ 100g FA) feeding level of corn grain without genotype effect. Content of 9c, 11t CLA resulted higher ($P<0.02$) in cows that ingested 4 kg (1.28 g/100 g FA) instead of 8 kg (1.08 g/ 100g FA) of corn grain. Neither the level nor the genotype of supplemental corn grain affected yield and composition of milk. Feeding HOC grain slightly reduced the concentration of C12, C14 and C16 FA in milk without effects on milk CLA content. Milk CLA concentration was decreased with the highest corn grain intake.

Key Words: High Oil Corn, Conjugated Linoleic Acid, Grazing Dairy Cows

M360 Evaluation of the effects of dietary fat supplement on conjugated linoleic acid (CLA) in milk fat of dairy cows: A meta-analysis approach. A. Nudda, C. Dimauro, A. Mereu, N. P. P. Macciotta*, and A. Cappio-Borlino, *Dipartimento di Scienze Zootecniche - University of Sassari*, *Sassari, Italy*.

Diet has been widely recognized as the most important factor influencing milk CLA content in ruminant milk. However results of experiments carried out the effects of dietary fat supplementation on milk CLA content in dairy cows are remarkably variable. In this work, a meta-analysis has been carried out to analyze the results from different studies designed to evaluate the effects of different fat sources and different amount of dietary fat on milk CLA content in dairy cows. Data were extracted from 51 feeding trials published in Pubmed, ScienceDirect and proceedings of scientific meetings, updated through January 2007. Data on milk CLA content were analyzed with a linear mixed model that included the content of fat supplemented in the diet, the type of fatty acid predominant in the fat source, the physical form of the supplemented fat, the forage/concentrate ratio as fixed effects. Moreover, the study has been included as a block random variable. Results highlighted a significant effect on milk CLA content of the

type of fatty acid predominant in the dietary fat source and of the physical form of the lipid supplement. In particular, the fish oil results in the highest CLA concentration in milk, whereas the saturated fatty acids (C18:0+C16:0) are the less efficient. As far as the physical form of supplement is concerned, the highest milk CLA content is observed when oil and mix of oil with other fat are used. Finally, the content of fat in the diet and the forage/concentrate ratio does not show significant effects on milk CLA content. In conclusion, results of the meta-analysis confirms the assessed knowledge about main nutritional factors that influence the milk CLA content but some points are raised on the usefulness of some nutritional strategies that have been recommended to obtain appreciable increases of milk CLA content.

Key Words: CLA, Dairy Cow, Meta-Analysis

M361 Milk conjugated linoleic acid response to fish oil and sunflower oil supplementation to dairy cows managed under two feeding systems. D. O. Felton* and A. A. AbuGhazaleh, *Southern Illinois University*, *Carbondale*.

Conjugated linoleic acid (CLA) is a generic term used to describe positional and geometric isomers of octadecadienoic fatty acids (FA) containing conjugated double bonds. CLA have been of keen interest since it was discovered that some have potential human health benefits. Earlier research has showed that cis-9, trans-11 CLA level in milk fat is highest when cows diets are supplemented with a blend of fish oil (FO) and linoleic acid-rich oil. The objective of this study was to determine the effect of FO and sunflower oil (SFO) supplementation to dairy cows fed fresh or conserved forage-based diets on milk cis-9, trans-11 CLA. Fourteen cows in midlactation were split into two treatment groups and fed the treatment diets for 3 wk. Cows in group one were fed corn silage-alfalfa hay mix ad libitum (L) while cows in group two grazed on alfalfa-grass pasture (P). Both groups were supplemented with 8kg grain supplement containing 640g of FO and SFO (1:3 w/w). Grain supplement was fed in two equal feedings after the AM and PM milkings. Milk samples were collected during the last 3 days. Compared with the L group, the P group saw a large decrease ($P < 0.05$) in milk production (25.8 and 16.8kg/d for L and P, respectively). Milk fat percentages (2.18 and 3.16) were lower ($P < 0.05$) in L compared with P treatment, however, milk fat yield (0.55 and 0.52kg/d) was similar ($P > 0.05$) for both treatments. Milk protein percentages were not affected ($P > 0.05$) by treatment diets (3.27 and 3.41) but protein yield (0.80 and 0.55kg/d) was lower ($P < 0.05$) for P compared with L treatment. Concentrations and yields of vaccenic acid (2.15 and 4.52g/100g of FA; 10.8 and 18.3g/d for L and P, respectively) and cis-9, trans-11 CLA (0.84 and 1.52g/100g FA; 4.0 and 6.1 g/d for L and P, respectively) in milk fat were higher ($P < 0.05$) with P compared with L treatment. Milk fat trans-10 C18:1 concentration (4.99 and 1.69g/100g FA) and yield (23.4 and 7.4g/d) were higher ($P < 0.05$) with L compared with P treatment. In conclusion, milk cis-9, trans-11 CLA content was higher when FO and SFO were supplemented with fresh forage-based diet.

Key Words: CLA, Oil, Forage

M362 Effects of feeding increasing amounts of a lipid-encapsulated conjugated linoleic acid (CLA) supplement on periparturient cows. J. W. Wheelock*[1], L. L. Hernandez[1], S. R. Sanders[1], M. J. de Veth[2], and L. H. Baumgard[1], [1]*University of Arizona*, [2]*BASF AG*, *Germany*.

Compared to established lactation, *trans*-10, *cis*-12 CLA is less effective at reducing milk fat synthesis during the first few weeks postpartum. Therefore, to induce milk fat depression and improve bioenergetic variables a much larger CLA dose is necessary. Objectives of this small preliminary trial were to evaluate the transfer of dietary *trans*-10, *cis*-12 CLA into milk fat and utilize those concentrations to predict effects on mammary lipid metabolism and production variables. Multiparous Holstein cows (n = 15) were randomly assigned to one of four supplemental CLA doses (0, 50, 250 and 500 g/d) with each dose providing either 0, 5, 25, or 50 g of *trans*-10, *cis*-12 CLA/d, respectively. *cis*-9, *trans*-11 was the only other CLA isomer in the supplement and was at a similar content as the *trans*-10, *cis*-12 CLA isomer. Each group received treatments (top-dressed) from -10 to 21 d relative to calving. Milk yield and feed intake were recorded daily, and milk samples obtained from each cow on 2, 4, 6, 8, 10, 15 and 20 DIM. Milk samples from 2, 8 and 20 DIM were analyzed for milk fatty acid composition. Results were analyzed as repeated measures using PROC MIXED of SAS. There were no overall differences in milk yield (35.6 kg/d), DMI (17.1 kg/d), protein% (3.61), lactose% (4.43), SNF (9.01) or SCC (355 x 1000). The 50 g/d dose did not significantly effect milk fat levels, but the two largest CLA doses decreased overall milk fat content by >17%. Milk fat *trans*-10, *cis*-12 CLA content averaged 0.13, 0.27, 0.76 and 1.42 mg/g fatty acids and milk *cis*-9, *trans*-11 followed a similar dose responsive ($P< 0.05$) pattern. Milk fat 18:1 *trans*-10 content averaged 3.35, 3.43, 3.48 and 4.57 mg/g, but treatment had no effect on other 18:1 trans-monoenes. Both CLA isomers and the 18:1 *trans*-10 milk fat content were temporally independent. Data from this small preliminary trial indicate a large dose of lipid-encapsulated CLA supplement delivers an amount of *trans*-10, *cis*-12 CLA necessary to reduce milk fat synthesis during the transition period.

Key Words: CLA, Transition Cows

M363 Effect of diets enriched with oleic, trans-octadecenoic, linoleic, or linolenic acids on gene expression of liver tissue from early postpartum lactating Holstein cows. B. C. do Amaral*, C. R. Staples, L. Badinga, S. A. Sennikov, and W. W. Thatcher, *University of Florida*, *Gainesville*.

The objective was to evaluate how dietary fat sources of oleic, trans-octadecenoic, linoleic, or linolenic acids affected gene expression of pyruvate carboxylase (PC), phosphoenolpyruvate carboxykinase (PEPCK), IGF–2, IGFBP–2, and IGFBP–3 in the liver of Holstein primiparous (n = 12) and multiparous (n = 20) cows during the summer season. Fat supplements were the following: 1) sunflower oil (SFO; Trisun, Humko Oil, 80% C18:1), 2) Ca salt of trans-octadecenoic acids (TRANS; EnerG TR, Virtus Nutrition, 57% trans 6–12 C18:1), 3) Ca salt of vegetable oils (CaVeg; Megalac–R, Church & Dwight Co, 29% C18:2), and 4) linseed oil (LSO; Archer Daniels Midland, 56% C18:3 and 16% C18:2). Supplemental fats were fed at 1.35% of dietary DM beginning at 30 ± 7 d prior to expected calving date. After calving, fat supplements were fed at 1.5% (oils) and 1.75% (Ca salts) of dietary DM for 15 wk. Liver samples were taken via biopsy on 2, 14 ± 1, and 28 ± 1 DIM. Abundance of PC mRNA decreased linearly whereas that

of PEPCK mRNA increased linearly over time across diets. Abundance of PC and PEPCK mRNA increased over time in livers of cows fed LSO but decreased in those of cows fed CaVeg. Primiparous cows had a greater abundance of IGF–2 and IGFBP–2 mRNA in the liver compared to multiparous cows. Hepatic content of IGF–2 mRNA did not change over DIM in cows fed LSO but was maximal at 14 DIM in cows fed CaVeg (LSO vs. CaVeg by DIM interaction). Expression of IGFBP–2 increased from 2 to 14 DIM but decreased at 28 DIM, with the decrease being greater for liver of cows fed the monounsaturated fats (MUFA) compared to the polyunsaturated fats (PUFA) (MUFA vs. PUFA by quadratic DIM interaction). Likewise, hepatic expression of IGFBP–3 was only different at 28 DIM with cows fed MUFA expressing less IGFBP–3 than those fed PUFA. Supplemental fat source influences hepatic gene expression of the gluconeogenic enzymes as well as the IGF system.

M364 Please see abstract #279.

M365 Effects of abomasal infusion of water linseed oil or tallow on responses to glucose and insulin challenges in feed restricted Holstein cows. J. A. A. Pires*, J. B. Pescara, N. Silva del Rio, A. P. Cunha, and R. R. Grummer, *University of Wisconsin*, *Madison*.

The objective was to test the effects of abomasal infusion of water (**W**), linseed oil (**L**) or tallow (**T**) on responses to i.v. glucose tolerance tests (**IVGTT**; 0.25g dextrose i.v. bolus/kg BW) and insulin challenges (**IC**; 0.1 IU insulin i.v. bolus/kg BW) in feed restricted Holstein cows. Six non-lactating, non-gestating cows were assigned to a replicated 3 × 3 Latin square design, and infused with W, L or T at a rate of 0.54 g/d per kg BW, for 5.5 d. Cows were fed to meet maintenance requirements for the first 72 h of each period, and were feed restricted thereafter to stimulate body reserve mobilization. IVGTT were performed on d 5, 50 h after initiation of feed restriction, followed by IC 12 h later. Contrasts were: 1) W vs. fat; 2) L vs. T. Before IVGTT, plasma glucose was 58, 61 and 58 ± 1.3 mg/dL (L vs. T; $P = 0.09$), serum insulin was 12.3, 11.8 and 12.5 ± 1.3 µIU/mL, and plasma NEFA was 548, 612 and 508 ± 44 µEq/L (L vs. T; $P = 0.09$) for W, L and T respectively. There were no treatment differences in glucose or insulin response to IVGTT. NEFA clearance rate was 2.6, 2.8 and 2.5 ± 0.1 %/min (L vs. T; $P = 0.06$), time to reach half concentration was 27, 25 and 29 ± 1.3 min (L vs. T; $P = 0.04$), and NEFA response area under the curve (**AUC**) was -52187, -64150 and -46402 ± 5871 (\mu;Eq/L)*180 min (L vs. T; $P = 0.04$) for W, L and T, respectively. Before IC, plasma glucose was 59, 60 and 60 ± 1.5 mg/dL, serum insulin was 10.1, 8.7 and 9.6 ± 1.3 \mu;IU/mL, and plasma NEFA was 689, 764 and 664 ± 72 \mu;Eq/L for W, L and T respectively. There were no differences in glucose and insulin response after IC. NEFA AUC was -16338, -18275 and -13817 ± 5034 (µEq/L)*30 min (L vs. T; $P = 0.12$) for W, L and T respectively. Supplementation of L, rich in C18:3, may enhance insulin antilipolytic effects in adipose tissue of Holstein cows as compared to T. However, plasma NEFA immediately before IVGTT and IC was approximately 100 µEq/L greater for L than T for unknown reasons.

Key Words: Linseed Oil, NEFA, Insulin Resistance

M366 Effect of vitamin E or vitamin C on *in vitro* biohydrogenation of linolenic and linoleic acid in the presence of unesterified DHA. C. Boeckaert*[1], K. Ardvisson[2], N. Boon[1], and V. Fievez[1], [1]*Ghent University*, *Melle, Belgium*, [2]*Swedish University of Agricultural Sciences*, *Umeå, Sweden*.

Unesterified DHA was shown to inhibit the production of C18:0 in the rumen from dietary linolenic (C18:3 n-3) or linoleic (C18:2 n-6) acid. The current study investigated whether supplementation of vitamin E or C could prevent this inhibition. *In vitro* incubations with 50 ml buffered rumen fluid were performed to study the effect of unesterified DHA (21.5 mg) either or not supplemented with lipid soluble vitamin E or water soluble vitamin C on rumen biohydrogenation of C18:3 n-3 from grass silage (0.8 g) and C18:2 n-6 from sunflower oil (20 mg). Vitamin E was supplemented as DL-all-rac-α-tocopherol (5 mg) and vitamin C as ascorbic acid (5 mg). After 6 h of incubation, DHA supplemented flasks contained significantly ($P < 0.05$) higher amounts of C18:3 n-3, C18:2 t11c15, CLA c9t11 and C18:1 t11 whereas C18:3 c9t11c15 and C18:0 significantly decreased. No significant difference in C18:2 n-6, CLA t10c12 and C18:1 t10 concentrations were observed between control and DHA supplemented treatments. Vitamin addition did not prevent DHA to inhibit rumen biohydrogenation as the accumulation of hydrogenation intermediates did not significantly differ between DHA supplemented incubations either with or without vitamin addition. DHA also shifted rumen fermentation, significantly depressing acetate and CH_4 productions whereas propionate and butyrate productions significantly increased in comparison to the control treatment without DHA supplementation. The overall volatile fatty acid production was not affected by DHA. The relative CH_4 productions for incubations supplemented with vitamin E or vitamin C were intermediate ($P < 0.05$) between the control and the DHA treatments. This indicates that the inhibition of rumen methanogenesis induced by DHA can partially be prevented by both vitamins. In conclusion, vitamin E or vitamin C supplementation could not prevent the inhibitory effect of unesterified DHA on rumen biohydrogenation, which indicates that the latter effect is not provoked by oxidation of DHA.

Key Words: Biohydrogenation, DHA, Vitamin

M367 Effect of dietary polyunsaturated fatty acids on the expression of genes involved in prostaglandin biosynthesis in the bovine uterus. S. M. Waters[1], S. Childs[1,2], J. M. Sreenan[1], A. A. Hennessy[2], C. Stanton[2], and D. A. Kenny*[3], [1]*Teagasc, Animal Production Research Centre, Mellows Campus*, *Athenry, Co. Galway, Ireland*, [2]*Teagasc Dairy Products Research Centre*, *Fermoy, Co. Cork, Ireland*, [3]*School of Agriculture, Food Science & Veterinary Medicine, University College Dublin*, *Belfield, Dublin 4, Ireland*.

Nutrition plays a critical role in the regulation of cow fertility and there is emerging evidence that dietary omega-3 polyunsaturated fatty acids (ω-3 PUFA) may act as potent regulators of the reproductive process. *In-vitro* studies have demonstrated that the ω-3 PUFAs, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) play pivotal roles in the suppression of uterine derived prostaglandin F2α synthesis, a critical regulator of embryo survival, though the biochemical mechanisms involved are as yet unclear. The objective of this study was to determine the effect of dietary supplementation of ω-3 PUFA on mRNA expression of key uterine endometrial genes involved in PGF2α biosynthesis. Beef heifers were fed either a high or low ω-3 PUFA diet, generating, in turn, combined uterine endometrial

concentrations of EPA and DHA which were more than two-fold higher (P <0.05), and EPA concentrations alone that were more than fourfold higher (P < 0.01) in the high and low supplemented animals, respectively. Total RNA was isolated from endometrial tissue and real-time RT PCR was carried out to measure the relative expression of 10 genes known to be involved in the prostaglandin biosynthetic pathway. Expression of mRNA for prostaglandin E synthase (PGES) and the peroxisome proliferator-activated receptors, PPAR α and δ was increased in animals fed the high compared with low ω-3 PUFA diet (P<0.05). There was a tendency for the mRNA expression of phospholipase A2 (PLA2), to be down-regulated (P=0.08). In conclusion, bovine endometrial gene expression of PGES, PPAR α, PPAR δ and PLA2 is differentially regulated in response to long chain ω-3 PUFA supplementation, suggesting a possible mechanism by which PUFAs may influence uterine function and in turn embryo survival.

Key Words: ω-3 PUFA, Gene Expression, Bovine Endometrium

M368 Effect of electron beam irradiation on ruminal DM and NDF degradation characteristics of wheat and barley straws. A. A. Sadeghi*[1] and P. Shawrang[2], [1]*Department of Animal Science, Faculty of Agriculture, Science and Research Branch, Islamic Azad University*, *Tehran, Iran*, [2]*Animal Science Research Section, Research Center for Agriculture and Medicine, Atomic Energy Organization of Iran*, *Karaj, Iran*.

The present study was designed to evaluate the effects of electron beam irradiation at doses of 100, 200 and 300 kGy on ruminal DM and NDF degradation characteristics of wheat straw (WS) and barley straw (BS). Duplicate nylon bags of untreated and treated straws were suspended into the rumen of four non-lactating Holstein cows for 0, 8, 12, 24, 48, 72 and 96-h. Immediately after submersion of the 0 h bags of substrate into the ruminal fluid, all bags were removed and rinsed with an automatic washing machine. Bags were then freeze dried, weighed and analysed for chemical composition. Data were fitted to exponential model to calculate degradation parameters of DM and NDF. The degradability parameters for the nylon bags analyzed as a randomized complete block design, using cows as blocks. Data were analyzed with the general linear model of SAS (1996). Differences among treatments were separated using polynomial orthogonal contrasts to determine linear, quadratic, and cubic responses. Electron beam had no effect on CP, ash and ether extract contents, but decreased NDF and ADF contents of both straws as irradiation dose increased. There was a linear increase (P<0.001) in the wash-out fraction and a linear decrease (P<0.001) in the potentially degradable fraction of DM and NDF. The degradation rate of the latter fraction increased linearly (P<0.001) as irradiation dose increased. The effective DM and NDF degradability of 100, 200 and 300 kGy irradiated WS at an outflow rate of 0.05/h increased by 18 and 15; 31 and 27; and, 43 and 38%, compared to untreated WS, and for 100, 200 and 300 kGy irradiated BS increased by 21 and 19; 36 and 33; and, 48 and 43% compared to untreated BS, respectively.

Key Words: Electron Beam, Wheat and Barley Straws, Ruminal Degradability

M369 Delta 9 desaturase gene expression in muscle, adipose tissue and liver of beef heifers following supplementation of grass with a concentrate containing sunflower seed and fish oil. S. A. McGettrick*[1], A. P. Maloney[2], F. J. Monahan[1], T. Sweeney[1], and F. J. Mulligan[1], [1]*Veterinary Sciences Centre, School of Agriculture, Food Science and Veterinary Medicine*, *University College Dublin, Belfield, Dublin 4, Ireland*, [2]*Teagasc, Grange Research Centre*, *Dunsany, Co. Meath, Ireland*.

In ruminant tissues delta 9 desaturase is involved in the endogenous synthesis of conjugated Linoleic acid (CLA) from vaccenic acid (VA), formed during rumen microbial biohydrogenation of Linoleic and Linolenic acid. Previous experiments have shown that dietary sunflower and fish oil inclusion increase CLA levels in bovine tissue. The objective of this experiment was to examine the effects of grazed grass or concentrates either alone or supplemented with sunflower seed (SFS) and fish oil (FO) on the expression of the delta 9 desaturase gene in liver, adipose tissue and muscle of fattening beef heifers. Forty Charolais or Limousin crossbred heifers of similar nutritional history were assigned to two outdoor and two indoor groups (n=10). The outdoor animals were offered unsupplemented pasture (*Lolium Perenne*), or restricted pasture with 2.5kg of a supplement containing SFS (29%) and FO (6%). Indoor groups were fed a basal concentrate rich in linolenic acid (32% of total fatty acids) or restricted basal concentrate with 2.5kg of the SFS and FO based supplement. Animals were slaughtered after 150 days on experimental treatments. Samples of subcutaneous adipose, liver and muscle were collected within 45 minutes of slaughter and stored at -70°C before total RNA extraction using RNAeasy kits (Qiagen). RNA extracts were quantified spectrophotometerically and c-DNA was synthesized using Invitrogen Superscript III First-Strand Synthesis System for RT-PCR. Quantities of mRNA were determined relative to 18S-RNA using quantitative real time-RT PCR and analysed using the GLM procedure of SAS. Delta 9 desaturase mRNA levels were lower (P<0.05) in muscle and subcutaneous adipose of grass-fed animals compared to concentrate-fed animals but were unchanged in liver (P>0.05). Supplementation of the diet with SFS and FO had no effect on delta 9 desaturase gene expression in any tissue. These results show that grass-based diets result in lower delta 9 desaturase gene expression in muscle and adipose tissue of beef animals despite increasing overall CLA levels in the tissues.

Key Words: CLA, Delta 9 Desaturase, Beef

M370 Effect of level and duration of dietary ω-3 polyunsaturated fatty acid supplementation on Δ-9 desaturase gene expression in muscle of beef cattle. S. M. Waters[1], J. P. Kelly[2], P. O Boyle[1], A. P. Moloney[3], and D. A. Kenny*[2], [1]*Teagasc, Animal Production Research Centre, Mellows Campus*, *Athenry, Co. Galway, Ireland.*, [2]*School of Agriculture, Food Science & Veterinary Medicine, University College Dublin*, *Belfield, Dublin 4, Ireland*, [3]*Teagasc, Grange Beef Research Centre*, *Dunsany, Co. Meath, Ireland.*

Supplementation of cattle diets with a blend of oils rich in omega-3 polyunsaturated fatty acids (ω-3 PUFA) and linoleic acid has a synergistic effect on the accumulation of ruminal and tissue concentrations of vaccenic acid, the main substrate for tissue synthesis of the cis9, trans11 isomer of conjugated linoleic acid (CLA), via Δ-9 desaturase. However, concentrations of CLA in muscle of beef animals have not always been increased. The objective of this study was to investigate the effect of level and duration of feeding a high ω-3

fishoil (FO) supplement in combination with soyaoil (SO) on the gene expression of Δ-9 desaturase in muscle. Beef bulls (n=48) were assigned to one of four isolipid and isonitrogenous dietary treatments. Diets contained one of the following: (i) 6% SO (CON); (ii) 6% SO + 1% FO (FO1); (iii) 6% SO + 2% FO (FO2) or (iv) 8% palmitic acid for first 50 days and 6% SO + 2% FO for the latter 50 days (FO2(50)). Samples of *M. longissimus dorsi* were harvested. Concentrations of a range of fatty acids were measured. Total RNA was isolated and the relative expression of mRNA for Δ-9 desaturase was determined. Expression of mRNA for Δ-9 desaturase was decreased 2.6, 4.1 and 4.6 fold in FO1, FO2(50) and FO2 treatment groups compared with CON, respectively ($P<0.05$). Increasing the level of dietary FO from 1% to 2%, resulted in a further repression of Δ-9 desaturase mRNA expression ($P=0.09$). Extending the duration of supplementation by 50 days did not affect mRNA expression ($P=0.24$). Regression analysis displayed a negative relationship between tissue concentration of ω-3 PUFA and Δ-9 desaturase gene expression ($P<0.05$). Simultaneous enhancement of both CLA and ω-3 PUFA concentrations in bovine muscle may be hindered by negative interactions between dietary ω-3 PUFA supplementation and tissue Δ-9 desaturase gene expression.

Key Words: Δ-9 Desaturase, Gene Expression, Bovine Muscle

M371 Body condition score and day of lactation affect lipogenic mRNA abundance and transcription factors in adipose tissue of beef cows fed supplemental fat. C. M. Murrieta*, S. L. Lake, E. J. Scholljegerdes, B. W. Hess, and D. C. Rule, *University of Wyoming*, *Laramie*.

We hypothesized that BCS at parturition and postpartum dietary fat supplementation will alter transcription factors and mRNA abundance of adipose tissue lipogenic and lipolytic enzymes during lactation in beef cows. Our objective was to determine abundance of mRNA for acetyl-CoA carboxylase (ACC), hormone-sensitive lipase (HSL), and lipoprotein lipase (LPL), and transcription factor levels in adipose tissue of 3-yr old Angus × Gelbvieh beef cows nutritionally managed to achieve a BCS of 4 ± 0.07 (BW = 479 ± 36 kg; n = 18) or 6 ± 0.07 (BW = 579 ±53 kg; n = 18) at parturition. Beginning 3 d postpartum, cows within each BCS were assigned to isonitrogenous and isocaloric diets of hay plus low-fat control supplement, or supplements (5% of DMI as fat) with either cracked high-linoleate or cracked high-oleate safflower seeds until d 60 of lactation. At d 30 and d 60 of lactation, s.c. adipose tissue biopsies were collected for RNA extraction, quantitative RT-PCR determination of transcript abundance, and Western blot analysis for STAT-5 and PPAR-γ. Adipose tissue of BCS 4 cows had less mRNA for LPL ($P = 0.001$) and HSL ($P = 0.09$) compared with BCS 6 cows. Abundance of LPL mRNA was lower ($P = 0.002$) at d 30 postpartum compared with d 60; whereas, HSL mRNA was greater at d 30 ($P = 0.001$). Cow BCS did not affect ($P = 0.35$) ACC mRNA; however, it tended to be higher ($P = 0.13$) at d 60 compared to d 30 of lactation. Abundance of PPAR-γ tended ($P = 0.13$) to be lower in adipose tissue of BCS 4 cows compared with BCS 6 cows. Both STAT-5 ($P = 0.0001$) and PPAR-γ ($P = 0.05$) were higher at d 30 compared to d 60 postpartum. We conclude that abundance of adipose tissue mRNA for LPL and HSL are influenced by cow BCS, and changes in mRNA abundance during lactation indicates a shift in nutrient partitioning away from the mammary gland to s.c. adipose tissue. Furthermore, STAT-5 and PPAR-γ likely play a role in the transcription regulation of LPL and HSL in adipose tissue during lactation in beef cows.

Key Words: Adipose, mRNA, Lactation

M372 Modeling fatty acid kinetics in plasma and immune cells of neonatal calves in response to increasing levels of dietary fish oil. M. A. Ballou*, J. G. Fadel, and E. J. DePeters, *University of California*, *Davis*.

Mathematical descriptions of the changes in FA composition of immune cells and plasma were determined in calves fed a commercial milk replacer supplemented with additional lipid. 15 Jersey calves (6 ± 1 d old) were completely randomized to one of 3 treatment diets, which were altered by supplementing 2% of a milk replacer with FA from various sources. Treatments included a control (3:1 blend of corn and canola oils), a 1:1 mix of fish oil (FO) and the control blend, and FO only. On d 0, 7, 14, 21, and 42 blood was collected and plasma and peripheral blood mononuclear cells (PBMC) were fractionated for FA analyses of phospholipids. Parameter estimations, the rate of incorporation and the proportional change in the FA composition when a relative asymptote was reached, were determined for each calf using non-linear procedures of SAS. ANOVA of parameter estimates were performed and simple linear regression analyses were carried out to describe the dose response relationship to dietary FO. All data are reported from the PBMC pool as arachidonic acid (AA), eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA). In control calves, AA, EPA, and DHA all decreased during the neonatal period. Concentrations at d 0 (19.4, 0.46, and 1.47 g / 100 g FA), the proportional decrease from d 0 to asymptote (19.3, 66.6, and 35.5 %), and the relative half lives (6.0, 3.2, and 4.0 d) are reported. Supplementing FO to neonatal calves increased EPA and DHA incorporation into PBMC; linear regression analyses of EPA ($r^2 = 0.825$) and DHA ($r^2 = 0.861$) revealed the linear relationship between concentration in diet and PBMC. Supplementing FO tended ($P < 0.08$) to linearly decrease AA. The relative half lives of AA, EPA, and DHA did not differ with level of dietary FO; however, across FO treatments the half lives were markedly different (6.2, 30.5, and 8.4 d). The impacts of decreased polyunsaturated FA composition of neonatal PBMC are unknown. These data demonstrate that dietary strategies to alter immune cell FA composition by supplementing FO require adaptation periods of weeks to months to reach a new steady state.

Key Words: Immune, Fatty Acid, Kinetic

M373 Effects of soybean oil plus additional forage and anabolic implant on performance, carcass quality, and meat CLA content in finished steers. V. Poulin*[1], A. Fournier[2], J. Jacob[3], C. Gariépy[4], C. Avezard[4], N. Durand[4], J. Fortin[4], and P. Y. Chouinard[1], [1]*Institut des nutraceutiques et des aliments fonctionnels, Université Laval*, *Québec, Qc, Canada*, [2]*MAPAQ*, *Nicolet, Qc, Canada*, [3]*MAPAQ*, *St-Narcisse, Qc, Canada*, [4]*CRDA, Agriculture and AgriFood Canada*, *St-Hyacinthe, Qc, Canada*.

One hundred twenty crossbred steers (9 mo of age; 336 kg BW) were allotted to six weight replicates. Within each replicate, steers were allotted to one of four pens in a randomized complete block design (5 head per pen, 24 total pens). Treatments were low forage control diets (LFC) or high forage diets supplemented with soybean oil (HFO), without (NI) or with anabolic implant (Revalor S) (I) in 2x2 factorial arrangement. Growing diets fed for 63 d were based (DM basis) on wet grass hay (22.9 and 33.7% for LFC and HFO, respectively) corn silage (19.3 and 27.9%), ground corn (52.7 and 28.5%), soybean meal (3.0 and 3.4%), and soybean oil (0 and 4.6%). Finishing diets fed from day 64 to slaughter (4-10 mm backfat, 600 kg BW) were based on wet grass hay (14.0 and 21.2%) corn silage (14.2 and 21.5%), ground corn

(66.9 and 47.3%), soybean meal (2.9 and 3.6%), and soybean oil (0 and 4.3%). Steers were implanted at the beginning of the growing and the finishing phases. The HFO diets resulted in 12.6% lower ADG, 2.2% lower carcass yield, and 19.4% lower s.c. fat thickness at slaughter (P<0.01). Implant increased ADG by 26%, feed efficiency by 16%, carcass yield by 2.1%, BW at slaughter by 5.4%, and carcass weight by 7.5% (P<0.01), but decreased s.c. fat thickness by 13% (P=0.02). Warner-Bratzler shear force of the longissimus dorsi (l.d.; 3 steers per pen) was 33% higher (P<0.01) for I than for NI, which was confirmed by a 23% higher firmness score for I than for NI (P<0.01) as rated by a trained sensory panel (8 steers per treatment). Total fatty acid (FA) content of l.d. (2 steers per pen) were lower (P<0.01) with HFO as compared to LFC (-21%), and with I as compared to NI (-41%). Conjugated linoleic acid (CLA) concentration (% by weight of total FA) in intramuscular fat was 140% greater in HFO than in LFC. The CLA content of l.d. was also higher for HFO than for LFC, but the increase was of higher magnitude for NI (11 vs. 5 mg/g meat) than for I (6 vs. 3 mg/g meat) (interaction, P=0.03). This trial shows several interactions between diet and anabolic implant on carcass quality and FA composition in finished steers.

Key Words: Beef, Implant, CLA

M374 Effects of flunixin meglumine on pyrexia, production, and bioenergetic variables in post-parturient dairy cows. G. Shwartz*[1], S. R. Hartman[1], J. D. Earnest[1], A. L. Debold[1], K. L. Hill[2], M. J. VanBaale[1], and L. H. Baumgard[1], [1]*The University of Arizona*, *Tucson*, [2]*Schering Plough Animal Health*, *Kenilworth, NJ*.

Multiparous cows (n=26) were randomly assigned to one of two treatments beginning at parturition. Treatments were flunixin meglumine (Banamine®, 50 mg/mL, Schering Plough Animal Health, Kenilworth, NJ) at a dose of 2cc/45.5 kg BW and control (saline) at 2cc/45.5 kg BW. All treatments were administrated I.V. via a jugular catheter daily for the first 3 DIM. Individual milk yield (MY) and DMI were recorded daily. Body temperature (BT) was measured daily at 0700 h and 1600 h for the first 7 DIM. Milk composition was determined on 2, 7, 14, 21, 28, and 35 DIM. Blood plasma was harvested on 1, 2, 3, 4, 7, 14, 21, 28, and 35 DIM. BW and BCS were determined on -7, 1, 7, 14, 21, 28, and 35 DIM. BT did not differ between treatments during the first 7 DIM (38.87°C), and there was no treatment differences in overall MY (35.2 kg/d), 3.5% FCM (37.6 kg/d), or ECM (37.7 kg/d). Compared to controls, flunixin meglumine had no effect on DMI (2.97% of BW), or overall energy balance (-2.32 Mcal/d). There were no treatment differences in milk fat (3.91%), milk protein (3.32%), milk lactose (4.57%), and milk SCC (532 × 1000/mL). Treatment had no effect on plasma glucose (66.5 mg/dL) or plasma NEFA (553 μEq/mL), but circulating PUN tended to be lower in flunixin meglumine treated cows (16.4 vs. 14.5 mg/dL). Irrespective of treatment, when separated into a BT hierarchy (warmest 50% vs. coolest 50%; 39.21 vs. 38.64°C) cows with a higher body temperature during the first 7 DIM had an overall lower PUN (13.8 vs. 16.6 mg/dL), higher plasma NEFA (642 vs. 493 μEq/mL), and tended to have a lower energy balance (-4.09 vs. -1.19 Mcal/d). Warmer cows also had increased milk SCC (955 vs. 200 × 1000/mL), but BT had little or no effect on other milk components and production parameters. Daily flunixin meglumine administration for the first 3 d after parturition had little or no effect on production or energetic variables, but tended to decrease PUN levels in transition dairy cows.

Key Words: Flunixin Meglumine, Transition Cow, Pyrexia

8 Effects of protein sources on growth and hormonal status of weaned dairy calves. C. A. Sissell*, C. C. Williams, C. F. Hutchison, D. T. Gantt, L. R. Gentry, A. J. Bridges, and J. E. Chandler, *Louisiana State University Agricultural Center*, *Baton Rouge*.

Eight weaned Holstein calves approximately 6 months of age (mean BW 185.15 ± 16.16 kg) were used in a replicated 4 x 4 Latin Square designed experiment to study the effects of protein sources on performance of weaned dairy calves. Dietary treatments consisted of 16% CP diets with three sources of ruminally undegradable protein (RUP). Experimental diets were corn-silage based, with soybean meal (SBM) as the source of ruminally degradable protein (control) and 3 sources of RUP including heat treated SBM (SoyPlus), animal protein blend (ProLak), and extruded-expelled SBM, all included at 45% of the dietary CP. The animals were fed their respective diets twice daily at ad libitum levels during each 14-d adjustment period and 4-d sample collection period. Animals were housed in individual stalls for 14 days for dietary adjustment and feed intake measurements. Steers were housed in metabolism crates during the last 4 days of each experimental period for sample collection. Total fecal and urine output was collected, weighed, and sub sampled for laboratory analysis of nitrogen during the 4-d collection period. On day 4 of the collection period, animals were fitted with jugular catheters. Blood samples were collected at 15-minute intervals for 6 hours for analysis of growth hormone (GH). Also on day 4, blood samples were collected at the beginning of the 6 hours for plasma urea nitrogen (PUN) and at 30-minute intervals for analysis of IGF-I and insulin. On day 18 of each experimental period body weight, wither height, hip height, and body length were measured. Treatment did not affect dry matter intake ($P > 0.05$). There were also no effects ($P > 0.05$) of protein source on nitrogen balance, PUN, or on any growth parameters measured. There was a treatment effect ($P < 0.01$) on GH, with calves fed extruded-expelled SBM having the lowest concentrations. Plasma IGF-I concentrations were greater ($P < 0.05$) in calves consuming extruded-expelled SBM and Prolak. Treatment did not affect ($P > 0.05$) insulin concentrations. These data suggest that feeding diets with sources of RUP does not improve performance in weaned dairy calves.

Key Words: Weaned Calves, Rumen Undegradable Protein, Hormones

9 Impact of feed management software on whole farm nutrient balance and feeding management. B. G. Cox*, R. E. James, K. F. Knowlton, M. L. McGilliard, and C. C. Stallings, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

The impact of precision feeding utilizing feed management software on whole farm nutrient balance (**WFNB**) and feeding management was assessed from January through December 2006. Nine treatment and six control farms were selected in four regions of the Chesapeake Bay Watershed of Virginia. Herd sizes averaged 271 and 390 lactating cows for treatment and control farms while milk yield averaged 30 and 27 kg/d per cow, respectively. Crop hectares grown averaged 309 and 310 ha for treatment and control farms, respectively. Treatment farms purchased and installed feed management software (TMR Tracker™, Digi-Star LLC, Fort Atkinson WI) between May and October 2006. Data were collected for calendar year 2005 and 2006 to compute WFNB using software from the University of Nebraska. On treatment farms, up to five feed samples were obtained monthly including each total mixed ration fed to lactating cows. Control farms submitted total mixed ration samples every 2 mo. Standard wet chemistry analysis of samples was performed. Data stored in the software were collected monthly from each treatment farm concurrent with feed sampling. Daily overfeeding of all ingredients across treatment farms averaged 1.25% ± 5.86, ranging from –67.28% to +54.57%. This corresponded to average daily overfeeding of CP and P of 2.26% ± 6.88 and 1.91% ± 6.39, respectively. Whole farm nutrient balance did not differ between treatment and control farms. In conclusion, WFNB was not reduced after 3 to 6 mo of using feed management software; however, the large variation in daily over or under feeding indicates potential for future reductions through reduced variability.

10 Nutrient synchrony: Sound in theory, elusive in practice. M. B. Hall*, *U.S. Dairy Forage Research Center, USDA-ARS*, *Madison, WI.*

The concept of improving animal performance through synchronizing ruminal availability of nutrients has been with us for at least 3 decades. Though theoretically appealing, research and field results have not supported this approach to diet formulation. Why? Essential to successful ruminal synchrony is the ability to predict available amounts and fates of diverse substrates. The substrates come from varied sources; their efficiencies of use and yields of products are affected by inherent properties, interactions, transformations, and passage. Substrate quality and availability is affected only in part by diet: for example, NPN, true protein, and peptides are contributed by diet and intraruminal recycling, with additional endogenous NPN contributions by the cow. Conversion of the ruminally degraded N sources to AA available to the cow depends greatly upon availability of fermentable carbohydrates and other nutrients that support microbial growth. However, changes in factors that alter rate or extent of substrate fermentation such as rate of passage or ruminal pH can alter nutrient yield from the rumen, and must be accounted for for synchrony to work. Yield of microbial protein from carbohydrate can be altered by type of N source available, but these may be available from intraruminal recycling and diet. Conversion of some carbohydrates such as sucrose and fructan to stored microbial α-glucan alters the prediction of carbohydrate available in the rumen. Our ability to estimate ruminally available substrate is also challenged by normal variation in feed composition and imprecision in component and digestibility analyses. To have any effect on performance, ruminal synchronization of nutrients needs to be in concert with specific nutrient demands of the animal. "Synchrony" implies a greater deliberate precision than may be currently possible to effect. Perhaps we should consider balance: Within the rumen and cow, can we generate conditions so that needed substrates or nutrients are concurrently available or accessible from endogenous resources to enhance productivity and efficiency? This approach brings a broader view than focusing on the rumen and feed we offer to the cow.

Key Words: Diet Formulation, Fermentation, Rumen

11 Nitrogen recycling and the nitrogen economy of ruminants – asynchronous symbiosis. C. K. Reynolds*[1] and N. B. Kristensen[2], [1]*The University of Reading*, *England*, [2]*University of Aarhus*, *Denmark*.

The extensive development of the ruminant forestomach sets apart their nitrogen economy from that of nonruminants in a number of respects. Extensive pre-gastric fermentation dramatically alters the profile of protein reaching the small intestine, largely through the transformation of dietary protein and nitrogenous compounds into microbial protein. This process is fueled primarily by carbohydrate fermentation, and includes extensive recycling of nitrogen between the body and gut lumen pools. Nitrogen recycling occurs via blood and gut lumen exchanges of urea and ammonia, as well as endogenous gut and secretory nitrogen entry into the gut lumen, and the subsequent digestion and absorption of microbial and endogenous protein. Factors controlling urea transfer to the gut from blood, including the contributions of urea transporters, remain equivocal. Ammonia produced by microbial degradation of urea and dietary and endogenous amino acids is utilized by microbial fermentation, or reabsorbed and primarily converted to urea. Therefore, microbial growth and carbohydrate fermentation impact on the extent of ammonia absorption and urea recycling and excretion. The extensive recycling of nitrogen to the rumen represents an evolutionary advantage of the ruminant in terms of absorbable protein supply during periods of dietary protein deficiency, or asynchronous carbohydrate and protein supply, but incurs a cost at higher nitrogen intakes, especially in terms of excess nitrogen excretion. Efforts to improve the efficiency of nitrogen utilization in ruminants by synchronizing fermentable energy and nitrogen availability through feedstuff selection, or the manipulation of urea or protein degradation, have generally met with limited success as regards production responses, but may influence nitrogen excretion. The microbial symbiosis of the ruminant is inherently adaptable to asynchronous nitrogen and energy supply. To synchronize, or not to synchronize: that is the question.

Key Words: Ammonia, Rumen Synchrony, Urea

12 Opportunities to enhance performance and efficiency through nutrient synchrony in forage-fed ruminants. M. J. Hersom*, *University of Florida*, *Gainesville*.

Increasingly, the need for optimized nutrient utilization to address increasing costs of production and environmental considerations will necessitate opportunities to improve nutrient synchrony. Historical attempts at synchronizing nutrient supply in ruminants, particularly in cattle consuming high-forage diets, has met with variable results. The success of nutrient synchrony has been measured primarily in ruminants by increases in microbial yield, microbial efficiency, nutrient utilization, and to a lesser extent animal performance. Successful synchrony of nutrient supply to cattle consuming forage-based diets faces several challenges. From a feed supply aspect, the challenges to nutrient synchrony include accurately measuring forage intake and consumed forage chemical composition. The issue of forage intake and chemical composition is perhaps the most daunting for grazing cattle. Indeed, for forage-fed cattle the availability of forage protein and carbohydrate can be the most asynchronous aspect of the diet. In most grazed forages, digestion rates of the carbohydrate fractions are much slower than that of the corresponding protein fractions. Additionally, the forage-supplement interaction exerts a large impact on the synchrony of nutrients. The supplemental feedstuffs comprise the component of the nutrient synchrony scenario that is most often manipulated to influence synchrony. The supplement type (starch vs. fiber, dry vs. liquid), nutrient profile (DIP vs. UIP), and degradation rates are often prime considerations associated with nutrient synchrony on high-forage diets. Other considerations that warrant attention include temporal intake patterns of the forage and supplement, increased use and types of co-product supplements, and an assessment of the success of nutrient synchrony. Synchronization of nutrient utilization by forage-fed ruminants has and will continue to encounter challenges for successful outcomes. Ultimately it is the improvement of animal performance and optimization of nutrient utilization efficiency that dictates whether nutrient synchrony is a successful strategy.

13 Opportunities to enhance performance and efficiency through nutrient synchrony in concentrate-fed ruminants. N. A. Cole*, *USDA-ARS-CPRL*, *Bushland, TX*.

Synchronization of the ruminal degradation of carbohydrates and CP is projected to increase ruminal microbial protein synthesis, and improve N use efficiency. Attempts to synchronize the fermentation of dietary carbohydrates and CP have met with mixed results, suggesting that either ruminal nutrient synchrony is not important, or that N recycling to the rumen can offset a lack of synchrony. We hypothesized that in high-concentrate diets N utilization could be improved by synchronizing the supply of nutrients in one segment of the gut with those in another segment (i.e., synchronize a ruminal N deficiency with a lower gut N excess, etc.) via oscillating the dietary CP between deficient and adequate concentrations. With corn-based diets and oil-seed based natural protein supplements, N retention has been greater in lambs or steers fed oscillating CP concentrations (at 48-h intervals) than in animals fed a constant CP percentage. Effects of oscillating CP on cattle performance have been variable, and may depend upon the fermentability of the carbohydrate source (e.g., forage vs. grain, grain processing). In agreement with our hypothesis, Archibeque et al. (2007) reported that net portal uptake of urea was greater in lambs fed oscillating CP than in lambs fed constant CP concentrations. Nutrient intakes also need to be synchronized with the animal's requirements. One method to adjust nutrient intake with requirements is via phase- feeding. Results of studies with dry-rolled corn-based diets indicate that dietary CP concentrations can be decreased late in the feeding period with no adverse effects on animal performance; however, results of studies using steam-flaked corn-based diets are less consistent, possibly due to differences in the aggressiveness of the implant program used. In conclusion, ruminal nutrient synchrony is theoretically a sound principle; however, it seems that N recycling may mitigate effects of asynchrony. Thus, methodologies that increase N recycling and(or) increase the utilization of recycled N may benefit animal performance and the environment.

Animal Behavior & Well-Being - Livestock and Poultry I

14 Does flavored sow's milk matched with the same flavored post-weaning feed improve performance, reduce post-weaning aggression, and establish an odor preference in piglets? N. Krebs* and J. J. McGlone, *Texas Tech University*, *Lubbock*.

Odor conditioning has been shown in utero and post-partum in rodents. The objective of this study was to determine the effects of post-partum conditioning of piglets to onion given in the sow diet (and through the milk) on behavior and performance of piglets weaned onto onion-flavored feed. Sows (n = 24) and piglets (N = 96) were assigned (N = 12 experimental units/treatment) to treatments: onion (ON), added to the sows′ diet before and after parturition (during lactation), or control diet (CON). Before weaning, the ON and CON piglets were tested in a Y-maze for 1 minute to determine if they were attracted to onion smell. Pigs were .more attracted to the left side than the right side (Preference Index: 55% ± 4.03 vs 38.6 ± 4.28) but there was no effect of the odor treatment ($P > 0.05$). At weaning, ON and CON pigs were kept in treatment groups and given an onion-flavored diet. Aggressive behavior was recorded by 5 min scan samples over 24h after weaning. Performance was recorded for 4 weeks post-weaning. Pigs on the east side (EA) of the room (regardless of the treatment) fought less than the pigs that were on the west side (WE) (3.13 % of the time based on 5 min scan samples over 24h ± 0.84 vs 6.43 % ± 1.10). CON pigs had a greater percentage time engaged in aggressive behaviors ($P < 0.05$) than the ON pigs (5.99 % of the time over 24h ± 0.767 vs 3.64 % ± 0.767). The weight at d 0 (day of weaning) significantly ($P < 0.0001$) affected the weight at d 1, 7, 14, 21, and 28 after weaning. Weight gain and feed efficiency were calculated. Treatments did not influence ($P > 0.10$) pig performance, although the treatment by barn-side interaction ($P < 0.05$) may have masked main effects. Odor conditioning had no effect on ON preference in a Y-maze, or on post-weaning performance, but odor conditioning reduced piglet post-weaning aggressive behavior.

Key Words: Pigs, Conditioning, Behavior

15 Sex differences in the septal-hypothalamo-pituitary-adrenal axis and distribution of arginine vasotocin and cortocotropin releasing neurons in the domestic fowl. F. N. Madison*, A. Jurkevic, and W. J. Kuenzel, *University of Arkansas*, *Fayetteville*.

Stress is a common stimulus faced by birds in the poultry industry and a better insight into a bird's response to a stressor could lead to improvements in productivity and well-being. In domestic fowl, males have been shown to have higher corticosterone (CORT) levels in response to acute stressors and to be more fearful than females. This suggests that males are more responsive to stress. Sexually dimorphic regions of the brain have been found in a few avian species, yet little is known about sex differences in the septo-hypothalamic region of the brain of the chicken, nor in the neuroendocrine release of stress hormones. We studied sex-related responses to intracerebroventricular injections of neuropeptides. Our past studies showed that male birds had significantly lower basal levels of plasma CORT than females, however males injected with arginine vasotocin (AVT) and corticotropin releasing hormone (CRH) had higher plasma CORT release than females (148% and 90% greater increase at peak response, respectively). Immunocytochemical studies were performed on sexually mature male and female chickens to determine the distribution of AVT and CRH anatomical profiles within the septo-hypothalamic region. Sexually dimorphic differences were observed in the medial bed nucleus of stria terminalis (BSTM), lateral septum (SL), and paraventricular nucleus (PVN). Co-localization of AVT and CRH neurons and fibers were present in the BSTM and SL of males, not females. There were more CRH perikarya in the PVN of female birds compared to males. A significant number of CRH fibers formed baskets around AVT neurons in the supraoptic nucleus of both males and females. Our results demonstrate that females have a higher number of CRH neurons in the PVN, higher baseline levels of plasma CORT, but are less responsive to ICV injections of CRH. Supported in part by NSF grant #IBN 01111006 and NRI grant #2005-35203-15850 from USDA, CSREES.

Key Words: Stress Response, Corticosterone, BSTM and PVN

16 Changes in feeding and standing behavior of transition cows predict risk of sole hemorrhages and ulcers. K. L. Proudfoot*[1], D. M. Veira[2], D. M. Weary[1], and M. A. G. von Keyserlingk[1], [1]*University of British Columbia*, *Vancouver, BC, Canada*, [2]*Pacific Agri-Food Research Centre*, *Agassiz, BC, Canada*.

The development of sole hemorrhages and ulcers in dairy cows has been associated with environmental and systemic events related to calving, but the nature of these relationships is unclear. The aim of this study was to identify the relationship between cow behavior around the calving period and the development of lesions later in lactation. The claws of 55 multiparous and 23 primiparous Holstein dairy cows were scored for sole hemorrhage severity and presence of ulcers 2 wk before calving, 3 wk after calving and every 4 wk thereafter until 15 wk. Individual dry matter intake and inactive standing time were recorded from 2 wk before calving to 2 wk after calving. Following data collection, cows were grouped into those with no/low hemorrhage scores throughout the study (healthy), high hemorrhage scores after 3 wk post-calving and ulcers after 3 wk post-calving. Differences in dry matter intake and inactive standing time between the groups and within the periods -2 wk, +2 wk and +24 hr relative to calving were then analyzed using a SAS mixed model where group, parity and body weight were fixed effects and cow was a random effect. Multiparous and primiparous cows were analyzed separately. Multiparous cows that developed ulcers (n=6) ate more in the 2 weeks leading up to calving (17.50±0.72 vs. 15.32±0.43 kg/d P=0.01) and first 24 h after calving (16.88±1.97 vs. 11.93±1.13 kg/d P=0.04) compared to healthy cows. High hemorrhage score cows (n=12) stood longer (not eating) in the 2 wk before calving (653±44 vs. 540±33 mins/d P=0.05) and 24 h after calving (632±43 vs. 801±54 mins/d P=0.02) compared to healthy cows. No differences in feeding or standing behavior were found between healthy and high hemorrhage score first-lactation heifers. These data indicate that changes in feeding and standing behavior of multiparous transition cows are associated with the development of sole hemorrhages and ulcers later in lactation.

Key Words: Lameness, Behavior, Claw Horn Lesion

17 The effect of light intensity on broiler behavior and welfare. R. A. Blatchford*, J. A. Mench, P. S. Wakenell, and G. S. Archer, *University of California*, *Davis*.

Broilers are typically raised commercially in dim lighting. It has been suggested that providing brighter diurnal light intensity could improve bird health and provide opportunities for more normal behavioral rhythms. We examined the effects of three light intensities (5, 50, and 200 lux) on behavior and leg condition of broilers (N = 455, with 4 replicate pens/treatment). Broilers were reared under these intensities from 1-6 wk of age; photoperiods consisted of 16L: 8D with 1 lux intensity during the scotophase for all treatments. General activity was measured continuously using passive infra-red detection, and feeding activity measured by the amount of feed consumed per hour, during one 24-hour period per pen each week. At 6 weeks of age, all broilers were gait scored using a 0-5 scoring system, weighed, euthanized, and evaluated for the occurrence of leg abnormalities. There were no significant differences between treatments for body weight (mean = 2.32±0.01kg; P = 0.58), feed conversion ratio (0.18±0.004; P = 0.77), or feeding activity (0.94±0.04 kg/hr; P = 0.98). There were no significant differences in gait score, but broilers reared with 50 lux had more (P = 0.002) hock erosions (32 broilers) than those reared with either 5 or 200 lux (17, 10). There was also a trend for broilers reared with 5 lux to show less (P = 0.08) general activity during the day than 50 or 200 lux and show less (P = 0.001) change in activity between day and night than 50 or 200 lux. Thus, rearing broilers with dim light (5 lux) appeared to decrease activity, while intermediate light intensity (50 lux) was associated with poorer leg health but not increased lameness.

Key Words: Broiler, Lighting, Welfare

18 Separating the effects of group size, stocking density and pen size in broilers. E. H. Leone* and I. Estevez, *University of Maryland*, *College Park*.

In examining stocking density (SD), group size (GS), or pen size (PS) there is inadvertent confounding between two or more variables. While traditionally a three factor analysis is required to separate the confounded effects our design maximized replication use, reducing the number of treatments required. We used GS of 10, 20, and 30 birds in 1.5m^2, 3.0m^2 and 4.5m^2 PS to study broiler movement and space use. GS 10 was placed in all PS, GS 20 in 3.0m^2 and GS 30 in 4.5m^2 PS. This enabled us to look at increasing PS at constant GS (10) and SD (0.15 m^2/ bird) and across constant PS where GS/SD increased (GS 10 vs. 20 in 3.0m^2 and GS 10 vs. 30 in 4.5m^2 PS). Five focal birds were randomly chosen in each pen and their locations recorded via scan sampling. While the total area utilized by the birds increased with PS both for constant GS and SD ($p<0.05$), the percentage of space utilized decreased ($p<0.05$). When SD remained constant broilers were more active in larger PS ($p<0.05$) and birds in similar PS were more active at higher GS/SD ($p<0.05$). Interactions with a greater number of group members may have a more profound effect on activity levels than PS alone. At a constant PS movement patterns became more complex for larger GS/SD ($p<0.05$). While nearest neighbor distances increased with PS ($p<0.05$), differences were more pronounced across constant GS than SD. Although net displacement, defined as the distance between the first and last observed location, lengthened with growing PS at constant GS ($p<0.05$), SD was most likely the contributing factor. In equal PS displacement and total distance traveled dropped at higher GS/SD ($p<0.05$). Overall PS, SD, and GS had significant and individual influences on movement patters in broilers. PS had the strongest effect on the average distance traveled, whereas SD and GS heavily impacted activity levels, complexity of movement, net displacement, and total distance traveled.

Key Words: Movement, Use of Space, Broiler

19 Reducing stress at the packing plant using prior training and conditioning to odors in finishing pigs. N. Krebs*, M. A. Sutherland, and J. J. McGlone, *Texas Tech University*, *Lubbock*.

Finishing pigs are infrequently handled on some farms and can be difficult to handle when experiencing novel situations. This study aimed to determine the effects of minimal training and conditioning of finishing pigs to a novel odor (maple syrup, MS) on the ease of handling in a novel environment (simulated processing plant pre-stun area). Pigs were assigned one of four treatments organized with a 2 × 2 factorial arrangement: training and odor exposure at the barn for 10 d (trained-TR or not trained-NOTR) and odor at the plant or not (MS or NO). Trained (TR) pigs (n = 140) were allowed out of their home pens and could chew on MS-soaked flags. NOTR pigs (n = 140) were

not handled nor exposed to MS. The day of the experiment, TR and NOTR pigs were loaded, transported, unloaded, rested, then they experienced a novel simulated pre-stun area. For the MS-pigs, MS was put in the simulated CO2 stun box. The NO-pigs were not exposed to MS. Trained pigs (TR) unloaded faster ($P < 0.05$) than NOTR pigs (TR: 5.61 s/pig ± 1.79; NOTR: 13.8 s/pig ± 1.79). Trained (TR/MS and TR/NO) and NOTR/MS pigs received more ($P < 0.05$) paddle hits in the first part of the pre-stun than the NOTR/NO pigs (TR/MS: 0.010 hits/pig/s ± 0.0015; TR/NO: 0.012 hits/pig/s ± 0.0015; NOTR/MS: 0.015 hits/pig/s ±0.0015; NOTR/NO: 0.00 hits/pig/s ±0.0015) but MS pigs received less ($P < 0.05$) hits in the second part of the pre-stun compared to NO pigs (0.039 hits/s/pig ± 0.0051 vs 0.074 ± 0.0051). TR pigs spent less ($P < 0.05$) time backing up than NOTR pigs (0.082 % ± 0.68 vs 2.43 % ± 0.68 of the time). TR pigs had lower ($P < 0.05$) neutrophils (TR: 41.1 % ± 1.4; NOTR: 47.6 % ± 1.4) and lower ($P < 0.05$) neutrophil:lymphocyte ratio (TR: 0.89 ±0.05; NOTR: 1.13 ±0.05) than NOTR pigs. Cortisol levels increased ($P < 0.01$) with the total time spent in the chute. Adapting facilities and routine management to allow pigs free time outside the finishing home pen with a unique taste and/or odor that is also present at the processing plant may improve the welfare of pigs, the ease of handling, and the time required to move pigs at harvest.

Key Words: Pigs, Stress, Conditioning

20 The efficacy of Meloxicam at relieving the pain response to dehorning in dairy calves. A. Heinrich*[1,3], T. Duffield[1,3], K. Lissemore[2,3], E. J. Squires[1,3], and S. T. Millman[1,3], [1]*Ontario Veterinary College*, *Guelph, ON, Canada*, [2]*Ontario Agricultural College*, *Guelph, ON, Canada*, [3]*University of Guelph*, *Guelph, ON, Canada*.

The objectives of this study were (1) to describe the duration of pain when calves were dehorned using a local anesthetic and (2) to determine if Meloxicam (Metacam®, Boehringer Ingelheim, Germany) is effective at mitigating the pain response to the procedure. Meloxicam is a preferential COX-2 inhibiting NSAID with a half-life of approximately 26 hours in bovines. In this study 60 Holstein heifer calves, age 6 to12 weeks, were blocked by age and randomly assigned to Meloxicam and control treatments. Ten minutes prior to dehorning, calves received a lidocaine cornual nerve block and an I.M injection of either Meloxicam (0.5 mg/kg) or saline. Calves were dehorned using heat cauterization. Twenty-four hours prior to dehorning calves were sham dehorned using the unheated dehorner. Blood samples were taken via indwelling jugular catheters 0, 0.5, 1, 1.5, 2, 4, 6 and 24 hours following sham and actual dehorning in order to measure serum cortisol. Cortisol was measured using human radioimmunoassay kits validated for use with bovine blood (Coat-a-Count®, DPC, Markham, ON). Pain sensitivity was measured 4 hours after treatment using an algometer. Digital videorecording was used to collect behavior data for 24 hours following sham and 48 hours following dehorning. Data was analyzed using the Mixed procedure in SAS (version 9.1.3; SAS Institute Inc., Cary, NC, USA) with responses during the sham procedures used covariates. Meloxicam treated calves displayed significantly less pain sensitivity than Controls ($p=0.012$). Meloxicam treated calves also had significantly lower serum cortisol than Controls at all time periods except at 24 hours after dehorning ($p<0.05$). Preliminary behavior results suggest that Meloxicam treated calves performed less ear flicking and head shaking for at least 28 hours following dehorning. There was also a visible circadian pattern to behavior, with calves demonstrating the majority of pain-related behaviors in the late afternoon. In conclusion, dehorning causes long-term pain and the prolonged action of Meloxicam is effective in alleviating the chronic pain associated with dehorning.

Key Words: Dehorning, Pain, Behavior

21 Removal of sub-therapeutic antibiotics from nursery pigs diets: influence on behavior, performance and physiology. C. Goldsmith*, L. Sadler, K. Stalder, L. Karriker, M. Honeyman, and A. Johnson, *Iowa State University*, *Ames*.

Sub therapeutic use of feed grade antibiotics for food animals is being debated. The objective of this study was to determine the effects on nursery pig behavior, physiology and performance of removing sub-therapeutic antibiotics from nursery feeds. Nursery pigs (224 crossbred; 17 - 20 d of age) were assigned to pens (4 pigs/pen) in a completely randomized design arrangement of dietary treatments (with and without feed grade antibiotics). Sub-therapeutic antibiotics used were carbadox and tiamulin/CTC at approved levels. The treatment without antibiotics had additional dietary fat (choice white grease) added at a level of 50%. All pigs were housed in pens (0.36 m^2/pig; 2 gilts/2 barrows per pen) with slatted plastic flooring. Pigs were provided ad lib access to feed and water during three dietary phases from 6 to 23 kg BW. Proc Mixed of SAS was used to implement a fixed and random effects model. When dietary phases changed, the time required for all pigs in a pen to initially visit the feeder was recorded. Pigs fed diets without antibiotics visited the feeder more quickly ($P = 0.004$) than pigs fed diets with antibiotics (575 ± 210 vs. 1454 ± 210 s). Respiration rates and rectal temperatures were taken weekly on one barrow and gilt per pen and there were no treatment differences ($P > 0.05$). Pigs fed diets containing no antibiotics had better ($P < 0.01$) ADG (0.44 vs. 0.37 ± 0.01 kg/d) and had improved ($P = 0.015$) Feed to Gain than pigs fed diets containing antibiotics (1.48 vs. 1.66 ± 0.04 kg/d), respectively. There were no differences ($P < 0.05$) in total nursery feed intake for either dietary treatment. In conclusion, adding 50% more fat to nursery pig diets may allow removal of sub-therapeutic antibiotics when fed to pigs whose health status is not compromised without adversely affecting behavior, physiology or performance.

Key Words: Antibiotics, Behavior, Pigs

22 Effects of ractopamine on transport losses in market weight pigs. J. E. Swan, M. H. Gillis, K. D. Miller, J. D. Muegge, D. H. Mowrey, T. A. Armstrong, W. C. Weldon, and M. J. Ritter*, *Elanco Animal Health*, *Greenfield, IN*.

Data on 192 trailer loads of market weight pigs were collected from two different regions (Midwest and Southeast) over one year under U.S. commercial conditions to determine the effects of feeding ractopamine for 21 to 35 d prior to slaughter on transport losses (dead and non-ambulatory pigs). A randomized complete block design was utilized with farm as the blocking factor. Within each region, effects of ractopamine were evaluated on 96 trailer loads of pigs from four different farms with each farm marketing pigs from four different sites to a common slaughter plant. Within a site, ractopamine treatments (0, 5 or 10 ppm) were randomly assigned to the experimental units, barns, and two trailer loads of pigs were used to evaluate the effect per barn. Pigs were loaded and unloaded according to standard commercial

procedures. The number of dead, non-ambulatory, injured (NAI), and non-ambulatory, non-injured (NANI) pigs were recorded during loading, unloading, and the final drive. Data were analyzed using a generalized mixed effects model (GLIMM, SAS® macro GLMM800). Effects of ractopamine on total losses (dead + NAI + NANI) were dependent upon region. Ractopamine had no impact on total losses (1.35% vs. 0.85% vs. 1.55%, respectively for 0, 5, and 10 ppm) in the Southeast. However, in the Midwest, pigs fed ractopamine had higher total losses than control pigs (1.33% vs. 2.63% vs. 2.26%, respectively for 0, 5, and 10 ppm). It is possible that differences in transport times and conditions across the two regions may have contributed to these conflicting results. On average, pigs in the Midwest had 61 min longer journeys, 24 min longer waiting times prior to unloading, 33 min longer unloading times, and 194 min shorter lairage times than pigs in the Southeast. Also, electric prods were used on 52% and 97% of the loads during unloading and during the final drive in the Midwest, while electric prods were not used at these stages in the Southeast. These data suggest that the effects of ractopamine on transport losses are dependent upon other factors such as transport times and conditions.

Key Words: Pig, Ractopamine, Transport losses

23 Value of anesthesia in the dehorning of dairy calves. K. N. Patel*, A. L. Magliaro, J. R. Werner, D. A. Pape-Zambito, and R. S. Kensinger, *The Pennsylvania State University*, *University Park*.

Dehorning calves is a common management practice in the dairy industry. Both producers and the public would like dehorning to have as little impact on calf growth and health as possible. Studies have suggested using anesthetics with dehorning to improve calf performance; but there is little objective data on which to base these recommendations for this age group. The purpose of this study was to determine if the use of xylazine and lidocaine in dehorning would affect growth rate, calf health and haptoglobin concentrations. Ninety Holstein heifer calves (6-8 wk old, 64.85 ± 8.1 kg BW) were blocked by age and randomly assigned to: sedative and anesthesia (SA) or control (C) treatment groups. SA calves received 0.2 mg/kg of xylazine IM and cornual nerve blocks with 3 mL of 2 % lidocaine in each cornual cleft. C calves received no drugs. Calves were dehorned by a veterinarian with an electrical iron at 600 C with a mean contact time of 35 s per horn bud. Calves were fed farm-pasteurized milk twice daily and were given calf starter ad libitum. BW was determined using a digital scale equipped with an averaging function (Arlyn 320-LLA). Fecal scores were recorded on days 0, 1, 3, 7, 14, and jugular blood samples were collected on days 0, 1, 3 and 7 relative to dehorning. Calves were observed on each experimental day and a fecal score between 1 (normal) to 4 (watery) was assigned for each calf. Data were analyzed using PROC MIXED in SAS. Health of calves during the study was generally good with 0% mortality, normal respiratory function and average fecal score of 2. Average daily gain from d 0 to d 14 of the study averaged 1.0 kg/d for both SA and C calves and was not affected by treatment. Hematocrit averaged 28 %; and plasma protein averaged 4.7 g/dL for all calves, and neither was affected by treatment. Use of sedative and anesthesia prior to dehorning in the current study provided no detectable change in growth of the calves.

24 Over-supplementation of Vitamin D as a risk factor for chronic heart failure in fast growing commercial broilers. S. Nain*, B. Laarveld, and A. A. Olkowski, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

Broiler diets are frequently fortified with Vitamin D (D3) above the recommended levels to prevent commonly occurring leg problems. Over-supplementation with D3 has been shown to have detrimental effects on the heart. In order to evaluate the risk of D3 over-supplementation on the incidence of chronic heart failure in fast growing broilers, we examined the effects of high dietary D3 in commercial male broilers. 364 Ross male chicks were randomly assigned to six pens and offered a commercial broiler diet (vitamin D 5,000 IU/kg) or a vitamin D enriched diet (80,000 IU/kg). The birds were housed in floor pens in an environmentally controlled room. During the first 7 days the temperature was maintained at 34°C followed by a gradual decrease to a level approximately 30% lower than that set for normo-thermal brooding. Feed and water were provided ad-lib. All birds were monitored several times daily for overt signs of disease and periodically electrocardiographic measurements were obtained. Morbidity and mortality data were collected daily. Electrocardiographic examination revealed a numerically larger number of birds with cardiac arrhythmia and negative QRS axis on lead-II (an indication of left heart failure) in the D3 fed group in comparison to the control group. The blood gas analysis revealed marked hypoxemia, hypercapnia and lower Hb O2 saturation percentage, with the incidence of cyanosis being 33.0% in the D3 fed group vs control group 24.8% ($P<0.05$). The risk of ascites was 3.33 fold higher ($P<0.05$) in birds fed the D3 enriched diet, with the incidence of ascites being 3.3 % in the control and 11.0 % in D3 group. The present findings indicate that over-supplementation of vitamin D increases the risk of chronic heart failure in broilers.

Key Words: Broilers, Heart Failure, Vitamin D

25 Evaluation of Vitamin U on *Salmonella typhimurium* in broilers. A. L. Shaw*, K. S. Macklin, and J. P. Blake, *Auburn University*, *Auburn, AL*.

Vitamin U (DL-methionine methylsulfonium chloride) is a sulfur-containing methionine derivative previously shown to modulate the immune system and protect intestinal membrane cells in humans and swine. Two 28-day trials were conducted to evaluate the effect of Vitamin U on controlling *Salmonella typhimurium* in broilers. Each trial utilized day-old straight-run broilers that were randomly allotted to one of four dietary treatments (3 reps/trt) employing a corn-soy basal diet (21.5% CP, 3142 kcal/kg). Cecal samples were collected from 12 birds and cultured to ensure they were negative for salmonellosis. On day 1, all birds were challenged with 1 ml of *Salmonella typhimurium* (10^8 cfu/ml) via oral gavage. Cecal samples (3 birds/trt in Trial 1;

6 birds/trt in Trial 2) were collected weekly to derive colonization counts. Liver samples were also collected and enriched to determine if birds were septic. In Trial 1, treatments consisted of the basal diet containing no feed additive (control), Bio-Mos (900 mg/kg), low Vitamin U (300 mg/kg), or high Vitamin U (600 mg/kg). Significant differences in salmonella colonization increased among all treatments compared with the control during week 2. Treatments for Trial 2 were comprised of the basal diet containing no feed additive (control), Bio-Mos (900 mg/kg), BMD (50 mg/kg), or Vitamin U (300 mg/kg). Intestinal tissue samples were collected and measured from four birds per treatment on day 14. Results indicated that Salmonella colonization during week 1 was lower ($P<0.05$) for Bio-Mos than Vitamin U, and during week 3 Vitamin U was lower ($P<0.05$) than BMD. The villi length of the jejunum and ileum, and crypt depth of the duodenum and ileum were significantly longer ($P<0.05$) in the control in comparison to the three treatments tested. It was concluded that the overall effects of Vitamin U on salmonella colonization and septicemia are comparable to Bio-Mos. Vitamin U was not found to have an effect on intestinal tract integrity.

Key Words: Vitamin U, Bio-Mos, *Salmonella typhimurium*

26 Arginine and vitamin E modulate the subpopulations of T-lymphocytes in broiler chickens. S. T. Abdukalykova* and C. A. Ruiz-Feria, *McGill University*, *Montreal, QC, Canada*.

We examined the effects of vitamin E (VE) and ARG (ARG) on the subpopulations of T lymphocytes in peripheral blood after an IBDV vaccination. Broiler chickens were fed diets with normal levels of ARG (NARG) or high levels of ARG (HARG, 1% added to the feed); and three levels of VE (40, 80, or 200 IU / kg of feed) in a factorial arrangement of treatments. Fifty four broiler chickens were vaccinated at 20d of age. The percentages of T-helper (Th) and T-cytotoxic (Tc) cells 9d after vaccination were not different in birds fed the HARG or NARG feed, but they were higher in birds fed the VE80 diet than in birds fed the VE40 diet. Birds fed the VE200 feed had similar levels of Th and Tc cells than birds fed the VE40 diet ($P=0.02$). However, 19 after vaccination, the percentage of Th cells were higher in birds fed the HARG (43.93±1.05;$P=0.045$) diet than in birds fed the NARG diet (41.14±1.05; $P=0.045$), and in birds fed the VE80(44.1±1.28; $P =0.003$) diet as opposed to the VE40 (39.04±1.28; $P =0.003$), yet similar to that of VE200 (44.42±1.28; $P =0.003$) diet. The percentage of Tc cells was highest in birds fed the HARG and VE80 feed compared with all the other ARG and VE combinations. The B-cell:T-cell ratio was higher in birds fed the HARG (0.27±0.009; $P=0.01$) diet than in birds fed the NARG diets (0.24±0.009; $P=0.01$) and birds fed the VE40(0.32±0.01; $P <0.001$) than in birds fed VE80(0.22±0.01; $P<0.001$) and VE200 (0.23 ±0.01;$P <0.001$) diet 9 d after vaccination. Neither ARG nor VE had an effect on the Th:Th cell ratio, and on the percentage of immature (CD4+CD8+) T-lymphocytes. These results suggest that ARG and VE have synergistic effects on cellular immune function and may enhance the resistance of broilers to infectious diseases.

Key Words: Arginine, Vitamin E, Cell-mediated Immunity

27 Effects of arginine and vitamin E on antibody production against sheep red blood cells and immune bursal disease virus. S. T. Abdukalykova* and C. A. Ruiz-Feria, *McGill University*, *Montreal, QC, Canada*.

The objective of this study was to evaluate the combined effects of arginine (ARG) and vitamin E (VE) on antibody response to sheep red blood cell (SRBC, agglutination assay) inoculation, and antibody titers (ELISA) to the infectious bursal disease virus (IBDV) before and after vaccination. Broiler chickens were fed diets with normal levels of ARG (NARG) or high levels of ARG (HARG, 1% added to the feed); and three levels of VE (40, 80, or 200 IU / kg of feed) in a factorial arrangement of treatments. The antibody titers to SRBC were higher in birds fed the HARG diet than in birds fed the NARG ($P < 0.013$), and in birds fed the VE80 diet compared with birds fed the VE200 ($P<0.001$) diets at 5, 8, and 12 d after inoculation. Antibody titers (log_{10}) to the IBDV 2d before and 19d after vaccination were higher in birds fed the HARG diet compared with birds fed the NARG diet ($P < 0.001$), whereas birds fed the VE80 diet showed a higher antibody titers compared with birds fed the VE40 diet ($P<0.001$), but similar to those of the VE200 birds. However, the antibody titers against IBDV 5d after vaccination were higher in birds fed the NARG (963.3±8.9; $P<0.001$) diet than in birds fed the HARG (857.1±8.9; $P<0.001$), and in birds fed the VE40 (953.7±10.1; $P<0.001$) diet as opposed to the VE80 (841.1±10.1; $P<0.001$), yet similar to that of VE200 (935.8±10.1; $P<0.001$) diets. In summary, birds fed HARG and VE80 diets showed the best response against SRBC and IBDV vaccination, which may enhance the resistance of broilers to infectious diseases in the field.

Key Words: Arginine, Vitamin E, IBDV

28 Effect of tribasic copper chloride on performance of broiler chickens facing health challenges. J. I. Cohen*, *Micronutrients*, *Indianapolis, IN*.

Two experiments were conducted to evaluate the role of tribasic copper chloride (TBCC) in mitigating the detrimental effects of health challenges. In Experiment 1, 96 1-day-old Ross broiler chicks were divided into the four groups (three replicates each of 8 broiler chicks); Control (basal diet), AF (1 ppm), TBCC (200 ppm copper as TBCC) and AF plus TBCC (1 ppm aflatoxin plus 200 ppm copper as TBCC). The chicks were maintained on these treatments for 42 days. Serum biochemical analyses were performed at the end of the experiment and growth performance parameters of chicks were evaluated weekly during the experiment. The AF-induced changes in the levels of albumin, total protein and total cholesterol, and in the activities of serum ALT, LDH and ALP were detrimentally altered by AF, and significantly improved by adding TBCC to the AF-containing diet. While supplementation of TBCC to the AF containing diet did not improve the BWG, adverse effects of AFs on FCR were reversed by TBCC supplementation. Experiment 2 was a 21-day floor pen study conducted with 300 Cobb chicks divided into five groups (five replicates each of 10 chicks) inoculated with Candida albicans and Coccidia to induce crop mycosis at 3 days of age and fed a corn-soybean meal diet supplemented with 0, 125 or 250 ppm Cu from either feed-grade Cu sulfate or TBCC. As measured by disease scores for spread of infection in crop membranes and for number of observed intestinal lesions, both copper sources at both treatment levels gave a significant improvement over untreated, infected birds, with 250 ppm Cu being statistically better than 125 ppm. Only TBCC at 250 ppm gave crop mycosis scores equal to the negative control. Body weight gain and feed conversion were significantly improved versus the positive control at both 125 and 250 ppm added Cu, regardless of

source. A linear regression of the data showed TBCC to be 112% as bioavailable as copper sulfate. Both studies suggest that TBCC is effective in preventing performance reduction often associated with toxins which challenge broiler health.

29 Detection of bacteria in the vas deferens and testes of broiler breeder roosters. C. R. James*, L. M. Stevenson, S. S. Oates, S. Martin, K. S. Macklin, R. A. Norton, and W. D. Berry, *Auburn University Poultry Science*, *Auburn, AL*.

There have been relatively few studies characterizing the microflora of the rooster reproductive tract with respect to effects on fertility. The ultimate objective of this study is to determine whether fertility of the broiler breeder rooster is affected by reproductive tract microorganisms. Four broiler breeder roosterswer e euthanized by CO2 inhalation. The left vas deferens of each rooster was ligated at its attachment to the cloaca. The vas deferens and the left testis of each rooster was then excised en bloc, rinsed in 70% alcohol, followed sterile .85% saline and placed in a vial of ice cold sterile saline until used for culture. Samples of the vas and testes were minced in phosphate buffered saline. The samples were plated out onto MacConkey agar, blood agar, and plate count agar, and cultured at 37C in an aerobic incubator to detect the presence of aerophilic bacteria; chocolate agar cultured at 37 C in a C02 incubator to detect the presence of microaerophilic bacteria; blood agar, and prereduced blood agar cultured at 37C in an anaerobic chamber to detect the presence of anaerobic bacteria; and potato dextrose cultured at room temperature and atmosphere to determine if fungi were present. These plates were incubated for 24 hours and counted. In both trials a second set of the samples underwent enrichment in BPW prior to culture as above to ensure that any bacteria present would grow. Bacterial colonies grown in this trial were collected and streaked for isolation. They were then fixed onto slides, Gram stained and examined. Aerophilic bacteria, anaerobic, and microaerophilic bacteria were identified, with the majority of the bacteria identified as Gram positive cocci. No fungi were evident. This experiment demonstrates that a complex bacterial community consisting of aerophilic, anaerobic, and microaerophilic bacteria exists in the rooster reproductive tract. Further studies are underway to identify individual bacterial species and their potential effects on reproduction. This work was supported by the Alabama Agricultural Experiment Station and the U.S. Poultry and Egg Association.

30 Acquisition of immunity to *Eimeria maxima* in newly hatched chickens reared on new or reused litter. S. Rayavarapu* and H. D. Chapman, *University of Arkansas*, *Fayetteville*.

The acquisition of immunity by chickens infected 18 hours post-hatch with 100 oocysts of *E. maxima* and reared in floor-pens in contact with their droppings was investigated. In the first experiment birds were placed on new litter and immunity was measured at 2, 3, 4, and 5 weeks of age. Immunity had developed in birds challenged at 3, 4, and 5 weeks, judged by weight gain and oocyst production, but at 2 weeks immunity was not complete. In the second experiment birds were placed on new litter or reused litter from the first experiment and challenged at 1, 2, and 3 weeks of age. Immunity had developed in birds challenged at 1, 2, and 3 weeks measured by either criterion. In both experiments birds produced small numbers of oocysts in their feces following challenge. Judged by weight gain following challenge, no significant difference in the acquisition of immunity was observed whether birds were reared on new or reused litter.

Key Words: Eimeria, Immunity, Litter

31 Evaluation of Coccivac-B® and Bio-Cox® (salinomycin) for control of 3 species of *Eimeria* in broilers. C. Brown*[1], R. G. Teeter[1], A. Beker[1], M. Singh[1], C. Broussard[2], S. Fitz-Coy[2], and J. Radu[2], [1]*Oklahoma State University*, *Stillwater*, [2]*Schering-Plough Animal Health*, *Union, NJ*.

An experiment was conducted utilizing Cobb x Cobb males to evaluate coccidiosis control in 6 treatments: control-nonchallenged (CNC); control-challenged (CC); Bio-Cox®-nonchallenged (60g/ton; 0-35 days; SNC); Bio-Cox®-challenged (SC); vaccinated-nonchallenged (Coccivac-B® at hatch; VNC); and vaccinated-challenged (VC). Challenge consisted of an oral dose of sterile saline or a mixture of 3 *Eimeria* species administered as oocysts at 14, 21, 28, 35, and 42 days. Variables examined six days post challenge included live weight, FE, gross lesion scores (upper small intestine: USI; mid small intestine: MSI; ceca: C), and microscopic lesion scores (*E. maxima; E. tenella; and E. acervulina*). CNC birds exhibited higher live weight than CC birds at all ages ($P<0.01$) while results for other treatments are age dependent; VNC birds were similar to VC birds except on 20 and 41 days where VNC exceeded VC ($P=0.05$); SNC birds were similar to SC birds to 35d ($P>0.10$) but exceeded SC live weight thereafter ($P<0.05$). Live weights for CNC, VNC, and SNC birds post challenge were similar for all ages with the exception that SNC birds were depressed on day 48 ($P<0.05$). VC and SC birds were superior to CC birds ($P<0.05$) post 20d. The VC bird weights were similar to SC bird weights to 35d ($P>0.10$), superior post 35d ($P<0.05$) and markedly superior ($P<0.01$) for challenge period live weight gain. Feed efficiency (FE) of challenged birds favored SC only on day 34, while VC birds exhibited a marked superiority post 34d. Indeed, FE following oocyst challenge at 42d was -0.04 for SC and 0.41 for VC on day 48. Lesion scores (0=none; 4=high) for CNC, VNC, and SNC birds did not differ from zero ($P>0.10$) throughout the testing period, while other scores were inversely correlated ($P<0.01$) with live weight, weight gain, and FE. Results demonstrate the importance of time dependency on coccidiosis control.

Key Words: Eimeria, Vaccination

32 Benefits of the broiler feed additive Roxarsone. G. Mathis*[1] and M. LaVorgna[2], [1]*Southern Poultry Research, Inc.*, *Athens, GA*, [2]*Alpharma Animal Health*, *Fort Lee, NJ*.

As early as 1946, it was demonstrated that the feed additive 3-nitro-4 hydroyphenlarsonic acid (Roxarsone) (ROX) improved growth rate and feed conversion and had some anticoccidial activity. Over the years studies were performed examining these findings. A coccidial battery study showed that ROX was particularly effective against E. tenella. The NMI coccidial lesion score was 3.2 and ROX 45. 4 g/t was 1.3. An Anticoccidial drug sensitivity test demonstrated that the addition of ROX to ionophore anticoccidial drugs improves total anticoccidial control. Lesion scores for NMI 2.3, salinomycin 60 g/t

1.7 and salinomycin 60 g/t plus ROX 45.4 g/t 0.4. An improvement in performance of coccidial vaccinated broiler chickens was demonstrated in a 42 day floor pen study. Weight gain for nonmedicated birds was 1.873 kg compared to 1.992 for ROX 34.5 g/t vaccinated birds. In a salmonella challenge study, pens had less salmonella when ROX was fed compared to NM. As the early research indicated, 3-Nitro is beneficial for broiler production especially due to it's anticoccidial activity.

Key Words: Roxarsone, 3-Nitro, Anticoccidial

33 A comparison of performance of coccidia vaccinated broilers fed RepaXol, AciXol, or Bacitracin Methylene Disalicylate. G. Mathis*[1] and N. Scicutella[2], [1]*Southern Poultry Research, Inc.*, *Athens, GA*, [2]*SODA Feed Ingredients*, *Monaco*.

The objective of the two studies was to determine the influence of RepaXol, a blend of double coated essential oils, AciXol, an encapsulated blend of organic and inorganic acids along with RepaXol or Bacitracin Methylene Disalicylate (BMD), an antibiotic, on the performance of coccidial vaccinated broiler chickens reared to 42 days of age. Both studies had a similar experimental design. The second study used built up litter with a higher level of coccidial oocysts and Clostridium. The stocking density was 0.77 sq. ft. per male bird. All chicks were spray vaccinated with a commercial coccidial vaccine. A randomized block design with 8 replications was used. The test treatments were nonmedicated, RepaXol 50 ppm (study 1) and 100 ppm, AciXol 500 ppm (study 1), or BMD 55 ppm. Results showed a significant improvement in Day 42 performance, both feed conversion and weight gain with RepaXol 50 and 100 ppm, AciXol 500 ppm, and BMD 55 ppm compared to the nonmedicated controls. The feed conversion and weight gain for RepaXol and BMD were not significantly different in either study. No matter the background challenge level, RepaXol, AciXol, and BMD improved performance of coccidial vaccinated broiler chickens.

Key Words: RepaXol, AciXol, BMD

34 Identification of *Eimeria* species using Denaturing Gradient Gel Electrophoresis. A. Martynova-Van Kley[1], A. Syvyk*[1], A. Nalian[1], I. Teplova[1], and M. Hume[2], [1]*Steven F. Austin State University*, *Nacogdoches, TX*, [2]*USDA, ARS, SPARC, Food and Feed Safety Research Unit*, *College Station, TX*.

The avian protozoan disease known as coccidiosis causes economic losses to the poultry industry worldwide and costs the U.S. economy an estimated $700 million per year. The causative agent of coccidiosis in the domestic fowl is the protozoan *Eimeria*. Although it is not usually life threatening, coccidiosis has a significant negative impact on growth and feed utilization in chickens. Chickens are known to be infected with at least eight species of *Eimeria*. Application of appropriate preventive and treatment measures depends upon correct identification of the *Eimeria*species affecting a flock. The goal of this project was to identify an appropriate genetic marker and to develop a rapid, accurate, and highly discriminating assay for *Eimeria* species in chicken fecal samples. A multiple sequence alignment of full-length 18S rDNA sequences from seven *Eimeria* species conserved regions were compared for primer design. The theoretical melting profiles of the sequences were overlaid on the alignment to identify a single melting domain which provides the best temperature differentiation. DNA from a live oocyte vaccine (Advent, Viridus, Inc.) was used to create a Novel Ladder-Marker. PCR-DGGE analysis was performed on ~200 fecal samples collected from vaccinated birds, experimentally infected birds, and control birds. The results showed that the proposed approach based on PCR/DGGE analysis can be used for *Eimeria* species detection and identification. The designed primers were shown to be specific for amplification of *Eimeria* species from fecal DNA extracts as well as directly from oocysts. This PCR-based technique offers a rapid and highly discriminating assay for *Eimeria* species identification and with the potential for fast-response strategic intervention targeting coccidia at distinct locations along the digestive tract.

Key Words: Coccidiosis, Eimeria Identification, DGGE

35 Eimeria acervulina and E. mivati: Are they one and the same? S. Fitz-Coy*, *Schering-Plough AH*, *Summit, NJ*.

An experiment was conducted using Cobb x Cobb broiler chickens in cages. At 2 days of age, one group was inoculated with E. acervulina, a second group was given E. mivati and the third group kept coccidian-free, given robenidine in the feed at 33ppm for two weeks. Chickens were inoculated with E. acervulina or E. mivati three times per week, for three weeks. At 28 days of age, birds were randomized into challenge cages. Each bird received 500,000 sporulated oocysts of either E. mivati or E. acervulina by gavage. Trial terminated on day 6 post challenged; weight, gross lesions and microscopic parasite burden evaluated. Birds immunized with E. acervulina or E. mivati, challenged with homologous species grew at comparable rates, 420g and 389g, respectively ($P>0.05$). Birds immunized with E. mivati or E. acervulina and challenged with heterologous species grew at comparable rates, 313g and 264g, respectively ($P>0.05$). Control birds challenged with E. acervulina or E. mivati gained 278g and 91g, respectively; less ($P<0.05$) than birds immunized and challenged with homologous species. Gross lesions for controls-challenged with E. acervulina or E. mivati were highest among the groups (<0.05). Birds immunized with E. acervulina or E. mivati and challenged with homologous species had good protection. But E. acervulina or E. mivati immunized birds and challenged with heterologous species demonstrated no protection, 2.42 and 1.42, respectively. Microscopic parasite load for controls-challenged with E. mvati and E. acervulina immunized E. mivat-challenged birds had the highest scores, 10.73 and 10.5, respectively, ($P<0.05$). Birds immunized with E. acervulina or E. mivati and challenged with homologous species had good protection. Birds immunized with E. mivati or controls-challenged with E. acervulina had similar levels of parasitism, 5.5 and 6.33, respectively ($P>0.05$). Control birds challenged with E. mivati has 18% mortality. E. mivati was more pathogenic than E. acervulina, caused greater growth suppression, higher gross lesions and microscopic parasitism and caused mortality.

Key Words: Eimeria, Acervulina, Mivati

Bio Ethics - Livestock and Poultry: The Ethics of Food Animal Production, Processing and Marketing

36 Introduction. R. D. Reynnells*, *USDA/CSREES/PAS*, *Washington, DC*.

Food animal production systems that supply food and fiber to society have been directly affected by societal demands from the beginning of history. This is true whether most people were directly engaged in food production, or for our current approximately 2 percent of the population. Societal expectations for food products and animal welfare have changed over these years. Today's ethical concerns of animal production and processing reflect our current understanding of the significance of animal sentience, our abundance of food, and the desires of some to control the actions of others without personal risk or responsibility versus using educational programs that create market demand to thus change the food animal system. Speakers for the first of two bioethics symposia discuss topics around the theme "The Ethics of Food Animal Production, Processing and Marketing". The first presentation covers the range of ethical arguments for and against animal use by humans (e.g., philosophy; maximizing genetic potential; realities of alternative systems; stewardship responsibilities of all size farmers). The changing social dynamics and related questions of ethics related to our food choices and marketing ethics are discussed by the second speaker. The current system was created in part by societal demand for cheap food, has altered the rural social structure, and is viewed by some as negatively impacting animal welfare. How should our society and food production system create a mutually beneficial relationship that includes concerns for animal welfare? Are there viable options to accommodate societal demands that do not create unfair burdens on farmers? The ethical aspects of controlling food animal production and processing include voluntary and involuntary options (e.g., certification programs; regulations), which the third speaker will discuss. An often-used argument against commercial animal production is harm to the environment (e.g., potential for surface and ground water contamination, ammonia, odor, worker safety, insect pests) and related societal costs, to be discussed in the final presentation. This is followed by a general discussion.

Key Words: Animal Welfare , Bioethics, Food Animals

37 The end of husbandry. B. E. Rollin*, *Colorado State University*, *Fort Collins*.

Civilization is ultimately based on agriculture, historically a contract with animals and the earth. We discuss the manner in which modern agriculture has cavalierly broken that contract. This violation ramifies in dire ethical and prudential consequences. The industrialization of agriculture has unintentionally but clearly undercut sustainability, animal welfare, and husbandry in ways we discuss in detail, and has also raised serious questions of environmental preservation, well-being of farmers and rural communities, and loss of what can be called ancestral local wisdom of the soil.

Key Words: Husbandry, Ethics, Sustainability

38 Ethical aspects of regulating production. J. C. Swanson*, *Kansas State University*, *Manhattan*.

Polls and surveys conducted within the United States show general agreement that there is public support for the protection of farm livestock and poultry. Concurrent with the growing public sentiment, is the recent adoption of socially responsible corporate policies by major food retailers relative to animal welfare. The animal welfare assurance and audit programs developed by the private sector are an attempt to assure consumers that best practice measures and independent oversight result in a reasonable quality of life for food producing animals. These programs represent voluntary self-regulation and arguably a market-based approach to secure the welfare of food producing animals. Animal advocacy organizations historically sought regulatory oversight of animal care practice. Legislative routes that require government promulgation and enforcement of animal care regulations represent an involuntary form of animal welfare assurance. There are ethical considerations concerning the employment of voluntary or involuntary regulation of the welfare of food producing animals. For example, impact on food price, viability of small to medium producers, food abundance and quality, taxpayer and government burden, and food security are prominent among the ethical considerations in deliberating involuntary regulated production. In either approach the public must be convinced that the welfare of food producing animals can be secured in a transparent and convincing manner.

Key Words: Livestock, Production, Regulation

39 Environmental aspects of ethical animal production. J. M. Siegford* and W. J. Powers, *Michigan State University*, *East Lansing*.

Livestock and poultry producers face a number of challenges including pressure from the public to be good environmental stewards and adopt welfare-friendly practices. In both arenas, producers often implement practices beyond those required for regulatory compliance in order to meet consumer demands. However, environmental stewardship and animal welfare may have conflicting objectives. Examples include pasture-based dairy and beef cattle production where high fiber diets increase methane production and subsequent release to the atmosphere compared to grain feeding practices in confinement. Grazing systems contribute to nitrate leaching to groundwater in some areas of the world where grazing is the predominant land use. Surface water impacts are of issue when grazed animals have unrestricted access to streams. Similarly, hoop housing for sows, as an alternative to indoor gestation crates, increases the risk of nutrient leaching into soil and groundwater contamination if sites are not suitably prepared. Air emissions may also increase as a result of less opportunity to trap and treat emissions. Increasing cage space and providing greater surface area per mass of excreta in any production system can increase emissions from the excreta surface. Coupling welfare-friendly and organic production practices may require greater nutrient inputs in order to reach the same production endpoint, resulting in less efficient nutrient use and greater losses to the environment. Dual systems might additionally increase environmental contamination by pathogens. When swine were housed in huts, Salmonella cycled between swine and their environment; however, population numbers of pathogenic bacteria were not different between the indoor and outdoor systems evaluated. Alternatively, these dual purpose systems may reduce antibiotic and hormonal

contaminants. When considering ethical animal production practices, consideration needs to be given to the system impacts. In most situations, welfare-friendly production requires more land units per animal or per unit of product. Consideration of energy inputs into the system may be needed as energy use profoundly affects the ecological footprint left by an operation.

Key Words: Environment, Welfare, Organic

Breeding and Genetics - Livestock and Poultry: Poultry

40 Genetic variations in chicken aggressive behavior: the role of serotonergic system. R. L. Dennis*[1,2], Z. Q. Chen[3], and H. W. Cheng[1], [1]*Livestock Behavior Research Unit, USDA-ARS*, *West Lafayette, IN*, [2]*Purdue University*, *West Lafayette, IN*, [3]*Zheijiang University, School of Animal Science*, *Hangzhou, Zhejiang Province, China*.

Serotonin (5-HT) regulates aggressive behavior via binding to its receptors, such as 5HT-1A and -1B, in humans and rodents. This study was designed to test if 5-HT regulating aggressiveness has a heritable component in chickens. Chickens from two divergently selected lines KGB and MBB (low and high aggressiveness, respectively) and DXL (Dekalb XL, an aggressive out-group) were used in the study. Hens were paired within the same strain. At 24 wk of age, the subordinate of each pair received i.p. injection of either NAN-190 (1mg/kg, a 5HT-1A antagonist, NAN), GR-127935 (1mg/kg, a 5HT-1B antagonist, GR) or saline (control) for 5 days (n= 10 per strain). Frequency of aggressive behaviors were increased in the hens of DXL and MBB treated with NAN ($P<0.05$) and in the KGB hens treated with GR ($P<0.05$), respectively. GR treated KGB hens ($P<0.05$) and NAN treated MBB hens ($P<0.05$) also displayed an increased feather pecking (FP); but neither antagonist had an effect on FP of DXL hens ($P>0.05$). This may suggest the possibility of multiple mediating factors altering FP behaviors. Among the controls, MBB hens have higher epinephrine (EP) levels than KGB or DXL hens, indicative of the inferior stress coping ability of MBB hens. Treatment with GR significantly reduced EP levels in MBB hens ($P<0.05$), but not in DXL or KGB hens, suggesting a role of 5HT-1B in stress regulation in MBB hens. Hens of all strains treated with GR but not NAN exhibited reduced weight gain and increased plasma 5-HT concentrations compared to controls ($P<0.05$), suggesting a negative feedback system altering stress coping ability. The results provide evidence for different heritable serotonergic mediation of stress coping, aggression, and FP behaviors in chickens with high and low aggressive propensities. The data also indicates that, similar to humans and rodents, 5-HT-1A and -1B have different functions in the regulation of aggressive behaviors in chickens.

Key Words: Serotonin, Aggression, Hen

41 Association between SNPs and mortality in commercial broilers: a machine learning approach. N. Long*[1], D. Gianola[1], K. A. Weigel[1], G. J. M. Rosa[1], and S. Avendaño[2], [1]*University of Wisconsin*, *Madison*, [2]*Aviagen Ltd.*, *Newbridge, Scotland*.

Genome-wide association studies using single nucleotide polymorphisms (SNPs) can identify genetic variants related to complex traits. An objective is to find sets of relevant SNPs, and to combine them in a model that predicts phenotypes of individuals or groups. Typically, there are thousands of SNPs genotyped, but the number of phenotypes is smaller. An efficient method of selecting influential SNP markers is required; subsequently, more elaborate statistical modeling work can be conducted. A 2-step feature selection method for binary traits was developed, which consisted of filtering (using information gain), and wrapping (using naïve Bayesian classification). The filter reduces the large number of SNPs to a much smaller size, to facilitate the wrapper step. Also, an approach based on discretization for dealing with continuous phenotypic values in a classification framework was developed, to enable feature selection. The methods were applied to chick mortality rates on progeny from 201 sires in a commercial broiler, with the goal of identifying SNPs (over 5000) related to progeny mortality. To mimic a case-control study, sires were clustered into two groups, low and high, according to two arbitrarily chosen mortality cut points. By varying these thresholds, 11 different "case-control" samples were formed, and the 2-step feature selection procedure was applied to each. To compare the 11 sets of chosen SNPs, an ANOVA was carried out, and p-value of overall model fit and the predicted residual sum of squares (PRESS) were used as end-points. The 2-step method improved greatly the naïve Bayesian classification accuracy over the case without feature selection (from around 50% to above 90% without and with feature selection in each case-control sample). There was consistency over the 11 case-control samples between the patterns of selected SNPs and the mutual information. The best case-control group (63 sires over or below the thresholds) had a small p-value (< 0.0001) and a relatively small PRESS value (0.59). The 17 SNPs selected using this group accounted for 36% of the variation in mortality rates across all sire groups.

Key Words: SNP-mortality Association, Machine Learning

42 Non-major histocompatibility complex effects on the outcome of Rous sarcoma virus in Arkansas Progressor and Regressor chicken lines. M. Spanakos*[1], S. M. Sullivan[1], L. K. Stamps[1], R. Kopulos[2], J. Thompson[1], G. F. Erf[1], and N. B. Anthony[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Northern Illinois University*, *DeKalb, IL*.

The *B* complex, or the major histocompatibility complex (MHC) in chickens, has a direct effect on the development of Rous sarcoma virus (RSV)-induced tumors. Certain erythrocyte (*Ea*) alloantigen systems have also been shown to influence the regression of RSV-induced tumors. The objective of this study was to determine the effects of the *Ea-A* and *Ea-I* systems on the development of RSV-induced tumors within and between the Arkansas Progressor (AP) and Regressor (AR) chicken lines. The interactions between the *Ea-A* and *Ea-I* loci and the *B* complex were also examined. The AP line (B^{13}) has two segregating alleles at the *Ea-A* (A^4 and A^5) and *Ea-I* (I^2 and I^8) loci, while the AR line (B^{13} and B^{221}) is fixed at the *A* locus (A^4). Tumors were scored three times a week for a 10-week period. Pattern of response to the tumor was evaluated using tumor score (TS), tumor profile index (TPI), and mortality. Birds with the AP B^{13}, AR B^{13}, and AP B^{13}/AR B^{13} backgrounds and I^2I^8 haplotype had higher TS, TPI and mortality compared to those with the homozygous *Ea-I* combinations. A similar effect was seen with the *Ea-A* heterozygotes as compared to homozygotes in the AP B^{13}, and AP B^{13}/AR B^{13} backgrounds. Tumor

regression efficiency declined even further when an individual was heterozygous at both the *Ea-A* and *Ea-I* loci in the AP B^{13}, and AP B^{13}/AR B^{13} backgrounds. The observed decline in the efficiency of tumor regression as heterozygosity at the *Ea-A* and *Ea-I* loci increased suggests a dosage effect of the *Ea-A* and *Ea-I* systems. However the effects of the *Ea-A* and *Ea-I* loci seemed to be suppressed when the B^{221} allele was present. This suggests that the *B* locus has an epistatic effect on the *Ea-A* and *Ea-I* systems. Hence, in the AP and AR lines the effects of the *Ea-A* and *Ea-I* loci on the response to RSV challenge are expressed in the presence of the B^{13} allele.

Key Words: MHC, Erythrocyte Alloantigen Systems, Rous Sarcoma Tumor

43 Animal model estimation of (Co) variance components and genetic parameters for most important economic traits in Iranian native fowl. A. Ghazi Khani Shad*[1], A. Nejati Javaremi[2], and H. Mehrabani Yeganeh[2], [1]*Azad University of Science and Research*, *Tehran, Iran*, [2]*University of Tehran*, *Iran*.

(Co)Variance components and genetic parameters for economic traits in Iranian native fowls were estimated using multivariate animal model analysis with DFREML procedure. The data of four stations of native fowls breeding (Mazandaran:n= 49536, Esfahan:n= 23108, West Azarbaijan:n= 24890 and Fars: n=30279) was containing records of cocks and hens collected during period of 1988 to 2006. The recorded traits were body weight (at 8 weeks or 12 weeks), ge at first egg, egg number at 12 first weeks of production and mean egg weight between 28 to 32 weeks. The most estimated heritabilites, except egg number, were more than 0.20. The highest heritabilites for all traits were related to Fars station, whereas most heritabilites in West Azarbaijan were less than other stations. The heritability for egg number was estimated 0.099 ± 0.018 for Esfahan to 0.322±0.012 for Fars. The estimated heritabilities of body weight were medium to high and varied from 0.228 ± 0.014 for Esfahan to 0.548 ± 0.014 for Fars, While, the heritabilities of mean egg weight were high and ranged from 0.223 ± 0.021 for West Azarbaijan to 0.638 ± 0.013 for Fars. The heritability for Age at first egg was estimated 0.270 ± 0.021 for Esfahan to 0.520 ± 0.014 for Fars. The most estimated genetic correlations, except between Body weight and Egg weight and between age at first egg and egg weight, were negative.The direct genetic correlations between maturity age and egg number were high and negative, ranging from -0.384 ± 0.033 to -0.987 ± 0.003 for Mazandaran and Fars, respectively.

The estimated Heritabilites ± standard errors for BW, AFE, EN12 and MEW

	Mazandaran	Fars	West Azarbaijan	Esfahan
BW	0.279±0.009	0.548±0.014	0.254±0.014	0.228±0.014
AFE	0.346±0.012	0.520±0.014	0.276±0.027	0.270±0.021
EN12	0.158±0.009	0.322±0.012	0.099±0.018	0.185±0.019
MEW	0.458±0.012	0.638±0.014	0.223±0.021	0.246±0.022

BW, AFE,EN12 and MEW are body weight, age at first egg,egg number and mean egg weight, respectively

Key Words: Economic Traits, Heritability, Genetic Correlation

44 Effects of competition on expected response to selection for ADG. C. Y. Chen*[1], R. K. Johnson[1], S. D. Kachman[1], and L. D. Van Vleck[1,2], [1]*University of Nebraska*, *Lincoln*, [2]*ARS, USDA, U.S. Meat Animal Research Center*, *Clay Center, NE*.

The objective was to investigate the importance of competition effects on expected response to selection for average daily gain (ADG, g) of boars. A total of 9,720 records from dam lines (1 and 2) and sire lines (3 and 4) were available with 15 boars per pen. Gains (ADG) were measured from about 71 to 161 d of age and weight from 31 to 120 kg. Four models for EBV were compared; each included initial age on test as a covariate and fixed effect of contemporary group (farm-year-season). Direct genetic (d) and competition genetic (c) effects were included in models as random effects. Pen (pn) was included in some models as fixed and in other models as random factors. Models were: Model 1 (d, c, pn random) as full model, Model 2 (d and c), Model 3 (d and pn random), and Model 4 (d, pn fixed). Estimates of direct heritability with Model 1 obtained with MTDFREML for ADG were 0.31, 0.39, 0.21, and 0.26 for lines 1-4. Estimates of heritability of competition effects were near zero. Model 2 produced slightly larger estimates of competition variances ($P<0.05$ for lines 1-3). Expected responses to selection were calculated under the assumption that estimates of parameters from Model 1 were unbiased. For response of one genetic SD for both components (d and c), the proportions of expected total gain due to competition effects (with economic weights of 1 for each with pen size of 14) were 53, 19, 62, and 58% for the 4 lines. Rank correlations within lines were: 0.87-0.95, 0.51-0.99, and 0.36-0.97 between Model 1 and Models 2, 3, and 4. Genetic gains were calculated with pigs ranked on reduced models, but with EBV calculated with the best model (Model 1). Average total breeding values ($TEBV=EBV_d +14EBV_c$) for the top 10% of boars selected with Model 1 were 83, 110, 42, and 102 g for lines 1 to 4, respectively. For rankings based on Model 3, but EBV calculated with Model 1, average TEBV for the top 10% were 76, 110, 18, and 95 g and for rankings based on Model 4 were 66, 108, 12, and 87 g. Further study of correlated responses with models including competition effects seems warranted.

Key Words: Competition, Response to Selection, Swine

45 Effect of sex and sire on the intramuscular fatty acid profile in pigs. S. De Smet*[1], M. Ntawubizi[1], K. Raes[1,3], and N. Buys[2], [1]*Laboratory for Animal Nutrition and Animal Product Quality, Department of Animal Production, Ghent University*, *Melle, Belgium*, [2]*Centre for Animal Genetics and Selection, Catholic University Leuven*, *Heverlee, Belgium*, [3]*University College of West-Flanders, Department PIH*, *Kortrijk, Belgium*.

Intramuscular (IM) fatty acid (FA) composition is affected by dietary and genetic factors. The aim of this study was to investigate the effect of sex and sire on the IM FA profile of pork. Indices reflecting activities of desaturase and elongase enzymes involved in FA metabolism were calculated as ratio's of product to precursor FA proportions. The *Longissimus dorsi* from 123 animals (n = 61 castrates and 62 females) originating from 5 boars (n = 24-26 per boar) was analysed for FA composition. Pigs were all fattened on the same diet, and were slaughtered at a live weight of approximately 110 kg. The results of the FA proportions (g/100g FAME) were analysed using a General Linear Model with sex and sire as fixed effects (sex x sire interaction term not significant), and IM fat content as covariate to account for variation in the FA proportions due to differences in fatness. The IM fat

content had a highly significant effect on all individual polyunsaturated FA (PUFA) proportions, except C18:3n-3. The sum of n-6 and n-3 PUFA proportions were higher in females compared to castrates ($P<0.05$). Sire had no effect on the sum of n-6 PUFA, but affected the sum of n-3 PUFA ($P<0.001$). An effect of sire ($P<0.05$) but not of sex was observed for several indices reflecting de('Δ');9-desaturase activity. A significant ($P<0.001$) effect of sire was observed for most indices reflecting desaturase and elongase activities involved in the n-3 PUFA metabolism. A moderate effect of sex was found, with a higher capacity of females compared to castrates to elongate and desaturate C18:3n-3 to longer chain FA. The effects of sex and sire on the indices calculated within the n-6 PUFA series were less marked. The data suggest considerable genetic variability for the long chain PUFA metabolism independent of the level of fatness.

Key Words: Polyunsaturated Fatty Acids, Elongase/Desaturase Activity, Pig Muscle

46 Assessing hepatic gene expression in response to xenobiotic exposure. S. Boorgula*, D. J. Blodgett, M. Carlidge, S. Blevins, J. Boothe, and R. M. Lewis, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Xenobiotics from plant derived foreign chemicals are metabolized in liver when ingested. Phase I liver enzymes may change non-polar xenobiotics into reactive metabolites, thereby increasing toxicity. Phase II enzymes help inactivate these metabolites by addition of water-soluble groups and by their excretion in urine or bile. Some genes affecting expression of phase I enzymes are cytochrome P450 (Cyp) 1a2 and flavin mono-oxygenase (FMO) 1; and phase II enzymes are glutathione-S-transferase mu (Gstm) 1 and quinone reductase (Nq) 02. Xenobiotics of interest are ergotamine (ET), associated with fescue toxicosis, and sulforaphane (SFN), considered a phase II enzyme inducer. Although effects of SFN on phase I genes are unclear, ET is generally metabolized by phase I enzymes. Our objective was to test whether predicted variation in liver enzyme activity and gene expression occurred with exposure to these xenobiotics. Polymorphic mice (ICR, Harlan Sprague Dawley) were orally dosed for 2, 5, 8 or 11 d with either SFN (2.5 mg•mouse^{-1}•d^{-1}) or ET (0.6 mg•mouse^{-1}•d^{-1}) or control ($n \geq 5$ for each period and treatment). Control was a 50:50 mix of dimethyl sulfoxide and water, a vehicle used for diluting SFN and ET. Mice were killed 24h after last dosing and livers collected. Real time PCR revealed increase in expression ($P \leq 0.05$) of Cyp1a2 in both treatments relative to control on d 5, while FMO1 expression increased ($P \leq 0.05$) on d 11 in only SFN treated mice. Increase ($P < 0.05$) in expression of transcription factor, Nuclear factor-erythroid 2 p45-related factor 2 (Nrf2) and Nq02 ($P < 0.05$) gene on d 5 was followed by increase in Gstm1 expression ($P < 0.05$) on 8 and 11 d in SFN treated mice. Activity of Nq enzyme was decreased ($P < 0.05$) on d 8 in ET treated mice. Although, the down stream metabolism of FMO1 is not well documented, previous studies showed that Cyp1a2 inducers are deactivated in the presence of Gstm1. Thus, polymorphic mice, showing similarity in phase I gene (Cyp1a2) expression, but disparity in phase II gene (Gstm1 and Nq02) induction and enzyme activity, exhibited variable liver enzyme expression when challenged with different xenobiotics.

Key Words: Xenobiotics, Phase I and II Enzymes, Real Time PCR

47 Characterization of newly developed chicken 44K Agilent microarray. X. Y. Li*, H. I. Chiang, J. Zhu, and H. Zhou, *Texas A&M University*, *College Station*.

The development of high quality, reliable microarray resources for the chicken scientific community is an important step for avian functional genomics study. A new chicken 44K 60-mer oligonucleotide microarray featuring entire Marek's disease virus, avian influenza virus genomes, 150 chicken microRNAs and all gene models for the chicken genome has been developed on the Agilent platform. This new array provided a platform with four independent 44K arrays per slide. To characterize this array, four major tissues: liver, spleen, cecal tonsil, and ileum were collected from 6 commercial broilers and total RNA was isolated for hybridization to the microarray. A loop design was used to compare between every two tissues with dye swap and there were four biological replicates for each comparison. In total, 24 arrays were used in the current study. The signal intensity of each gene was normalized using LOWESS implemented in the R programming environment. More than 95% of spots had high signal to noise ratio (more than 10). A mixed model including fixed effects for tissue and dye was used to identify differentially expressed genes. There were 3710, 3355, 3208, 2886, 2660, and 358 genes significantly differentially expressed between spleen and ileum, liver and ileum, liver and cecal tonsil, liver and spleen, spleen and cecal tonsil, as well as cecal tonsil and ileum ($P<10^{-7}$) with corresponding false discovery rate (FDR) of 4.46×10^{-7}, 4.14×10^{-7}, 4.37×10^{-7}, 5.02×10^{-7}, 7.39×10^{-7} and 9.11×10^{-6}, respectively. Three to four hundred differentially expressed genes were more than 10-fold different for each comparison, except between cecal tonsil and ileum (18 genes). There existed 560, 108, 96, and 71 genes specifically expressed in liver, spleen, cecal tonsil, and ileum, respectively ($P<10^{-7}$). The results showed that this newly developed chicken oligonucleotide array is very informative and tissue-specific. This powerful genomic tool will provide a solid foundation for the further investigation in the areas of immunology, genetics, nutrition, and food safety in chickens.

Key Words: Chicken, Microarray, Functional Genome

48 Sources of variation in meat and carcass quality of pigs. E. F. Knol*, K. A. Engelsma, and J. W. M. Merks, *Institute for Pig Genetics (IPG)*, *Beuningen, The Netherlands*.

Predictable uniform pork quality is the goal for slaughter plants. 2526 animals of six sire lines and four dam crosses were born and raised on a Western European commercial farm and slaughtered and dissected in a large commercial slaughter plant to represent a standard situation. Phenotypic variation in 16 meat and 2 carcass quality traits was analyzed with ASReml and attributed to day of slaughter, weight, feeding system, sex, sire line, dam cross, litter and individual genetic variation. Heritabilities in strict sense were in line with literature values. Ratio between influence of sire line*dam cross and influence of slaughter day differed between 0.3 (Japanese color scale (JCS)) and 3.0 (drip loss) for meat quality. Recorded traits (h^2 ±SE) were: JCS loin (0.20 ±0.05), JCS inner ham (0.12 ±0.05), JCS outer ham (0.22 ±0.06), Minolta L (0.37 ±0.06), Minolta a (0.34 ±0.06), Minolta b (0.25 ±0.06), pH loin (0.23 ±0.05), pH ham (0.17 ±0.05), IMF (0.54 ±0.17), marbling loin (0.24 ±0.05), marbling ham (0.10 ±0.04), drip weight (0.23 ±0.06), drip score (0.15 ±0.05), drip loss (0.17 ±0.05), purge (0.18 ±0.06) and conductivity (0.27 ±0.06). For the two most relevant carcass traits (h^2 ±SE): deboned loin weight (0.28 ±0.06) and deboned ham weight (0.36 ±0.06). Genetic correlations between meat

quality traits show opportunities for indirect measurements (Minolta, pH and conductivity), they also show possibilities for simplified measurements (drip score). Heritabilities are interestingly high. Repeated meat quality measurements will further decrease the error term and increase the effective heritability. Uniformity in meat quality can be improved by using uniform sire line*dam cross, standardized shipping and processing, and genetic selection.

Key Words: Meat Quality, Variation, Heritability

49 Using a web-based economic model to examine investment decisions in the turkey industry for both integrated and non-integrated companies. B. J. Wood* and N. Buddiger, *Hybrid Turkeys*, *Kitchener, Ontario, Canada*.

An economic model for both integrated and non-integrated turkey production companies was created for use as a web-based management tool. Modeling turkey production was possible as all variables, from the supply of parent stock (PS) through to carcass processing and sale of final product, were readily quantified. Costs of production included PS and hatching costs related to poult production, feed, housing and labor for both the poult and commercial live production and finally manufacturing costs in the processing plant. Returns were generated though the sale of processed final product. At each level manipulation of PS strain, feed, labor, housing and processing had an effect on profitability and to accurately access the impact of each, the model should reflect the change in profitability of the system when production parameters were altered. Parameters higher in the production chain such as commercial poult cost and PS selection affected lower elements in the model such as the live production cost which ultimately affects the gross margin. Price volatility in feed and breast meat price were modeled with Gompertz-type growth and feed intake equations. This allowed optimal slaughter age or weight windows to be calculated based on feed price and processed product value. As feed price decreased or processed breast meat price increased the optimal slaughter weight also increased, conversely, with increased feed or lower breast meat price, the opposite was true, with a decrease in the optimal slaughter weight because of lower feed efficiencies at later ages. In each case, a decision on investment in feed and facilities must be made. Economic modeling can increase profitability via the ability to identify areas in which changes in management or investment can be made to improve performance. By examining the profit to investment ratio, investment may be made in an economically rational manner with funds channeled to areas that best increase the profit to investment ratio.

Key Words: Economic Model, Turkeys, World Wide Web

50 Quantitative and biological issues of feed utilization efficiency. S. E. Aggrey*, *University of Georgia*, *Athens*.

Most parametric statistical tests assume an additive rather than proportional error model. Since FC and BWG do not have similar distributions, the ratios of the two tend to be asymmetric (skewed). This violates the normality assumption the normality assumption of most statistical tests. The central limit theorem affords little protection for most skewed distributions, and when the sample size is small, the P-values associated with parametric tests like the t-test and ANOVA is incorrect. Summary statistics of FCR and FE yield different quantities. Log (any base) transformation of FE and FCR has the advantage of transforming the error model from a proportional to an additive one because log (FC/BWG)=log (FC) – log (BWG). Distributions of log values and consequently log ratios tends to be normal. Summary statistics of log ratios yield the same quantities, regardless of numerator/denominator assignments. The difference in sign of the means reflects whether on average the numerator is larger [+] or smaller [-] than the denominator. Taking the antilog of the average log ratios returns the data to a fold-metric.

Key Words: Feed Conversion Ratio, Feed Efficiency, Log Transformation

Egg and Meat Science and Muscle Biology - Livestock and Poultry: Meat Packaging and Shelf Life

51 Overview of meat life cycle from harvest to consumer. R. D. Huffman*[1] and J. C. Brooks[2], [1]*American Meat Institute Foundation*, *Washington, DC*, [2]*Texas Tech University*, *Lubbock*.

The harvest, processing and distribution of perishable meat products presents myriad challenges with respect to maintaining optimum quality and safety attributes. Frequently, the marketing term ″fresh″ is used to describe desirable product attributes and conversely, the term ″spoiled″ may be used to describe product that is no longer desirable for consumption. Product safety however is an attribute that should be decoupled from these product quality descriptors. When livestock are harvested, there exists an intrinsic potential for shelf life of the products derived from the carcass. The meat processing sector has developed numerous innovative means of protecting the integrity of raw meat products and maximizing potential shelf life of each product type. The processing steps and appropriate application of technology will determine how closely potential shelf life is maximized. This paper will describe the life cycle of meat products from the point of slaughter to the point of consumption, and attempt to clarify the meaning of the terms “fresh” and “spoiled.” The history of meat preservation dates back centuries and involves such important innovations as the first uses of salt in ancient times and the advent of mechanical refrigeration in the 1930’s. No doubt, these innovations were critical to the evolution of meat preservation; however, the most important recent innovation for increasing raw product shelf life is widespread adoption of vacuum packaging. Recent innovations have enabled the processing sector to further maximize fresh shelf life. Three major factors contribute to raw meat deterioration, 1) microbiological growth, 2) oxidation of lipids and 3) enzymatic activity. These factors are not mutually exclusive and in fact may interact to ultimately determine the end of shelf life. Optimum refrigeration at critical points in the harvest process, time and temperature controls throughout processing and distribution, reduction or elimination of oxygen exposure through packaging, and reduction of UV light exposure are all control methods that will mitigate the three factors that lead to product deterioration.

Key Words: Meat, Packaging, Shelf Life

52 Defining spoilage: What is shelf life and how is it determined? T. L. Brown[1], S. L. Jaax[1], M. M. Brashears[2], and S. J. Eilert*[1], [1]*Cargill Meat Solutions*, *Wichita, KS*, [2]*Texas Tech University*, *Lubbock*.

The objective of this review paper is to discuss the definitions and methods used to determine the shelf life of meat products. Predicting shelf life accurately impacts multiple facets of the food industry, including production, consumers and regulatory compliance. The economic impact of shelf life on consumer confidence and market position can be dramatic. The effort spent on modifications to formulation and packaging in attempt to maximize shelf life and product quality can be staggering. Shelf life is defined as the length of time that food and other perishable items are given before they are considered unacceptable for sale from a sensory, nutritional or safety perspective. Microbial growth or predictive microbiology is widely used to determine shelf life. To use microbial data requires making the assumption that a product has reached the end of its shelf life when the microbial count reaches a predetermined level. This assumption is usually made based on historical knowledge of the product. Even with an abundance of historical product knowledge, statements regarding shelf life based on microbial data may not hold true. Microbial growth rates are affected by product type, formulation, packaging, storage conditions, beginning microbial load, and many other variables. Some products will be considered spoiled at a low microbial load due to physical characteristics like odor, color or gas production. However, other products containing an excessive microbial load will still be acceptable referring to the definition of shelf life. Traditional microbial counts or predictive microbiology does not determine if a product is spoiled. Shelf life or product acceptability is a measure of product quality not microbial counts. Microbial counts may give an indication about the product stability but will not determine shelf life. Chemical or physical measurement is a more accurate gauge of shelf life by observing nutritional degradation or sensory acceptability.

Key Words: Shelf Life, Spoilage, Meat

53 Is there a link between food safety and food spoilage? J. C. Brooks*, M. M. Brashears, and M. F. Miller, *Texas Tech University*, *Lubbock*.

Microbial food safety is a general term that refers to the presence of harmful or pathogenic bacteria in foods that could cause human illness if consumed. Spoilage is a subjective measurement of quality and includes chemical and/or physical changes in color, texture, odor, taste, and microbial counts. Some researchers believe controlling microbial growth is the most important factor in controlling the spoilage of meat and choose to measure spoilage by quantifying bacteria. This practice of measuring bacteria as an indicator of spoilage has resulted in a perceived relationship between spoilage bacteria counts and pathogenic bacteria counts. This perception has been supported by several research scientists who have documented their concern that certain packaging techniques, namely Modified Atmosphere Packaging, may inhibit the growth of microorganisms that are typical indicators of spoilage to consumers and promote the growth of food pathogens. To determine if a link exists between food safety and spoilage, studies were conducted to measure the spoilage (trained and consumer panels for color and odor; total aerobic plate counts, coliforms, and lactobacillus bacteria; and oxidative rancidity) and safety (Escherichia coli O157:H7 and Salmonella spp inoculated samples) characteristics of ground beef and poultry packaged under low-oxygen and high-oxygen modified atmospheres. Results indicate food pathogen levels are not related to food spoilage (microbial and sensory traits) in ground beef patties packaged under high-oxygen and low-oxygen (with 0.4% CO) modified atmospheres. Similar results were observed for chicken drums and breast meat packaged in low-oxygen environments containing 0.4% CO. The lack of data to support a relationship between food safety and food spoilage is likely the result of several factors affecting the chemical and physical changes that occur during the storage of meat products. Storage temperature, package atmosphere, light intensity, meat constituents, initial microorganism loads, indigenous enzyme activity and consumers collectively define food spoilage and appear to have little effect on the growth and survivability of food pathogens under controlled conditions.

Key Words: Spoilage, Safety, Packaging

Food Safety - Livestock and Poultry: Current and Future Salmonella Challenges

54 Gastrointestinal microbial ecology and the safety of our food supply as related to *Salmonella*. T. R. Callaway*, T. S. Edrington, J. A. Byrd, R. C. Anderson, R. B. Harvey, K. J. Genovese, J. L. McReynolds, and D. J. Nisbet, *Food and Feed Safety Research Unit*, *College Station, TX*.

Salmonella causes an estimated 1.3 million cases of human illnesses and more than 500 deaths annually in the U.S. This was estimated at an annual cost to the economy of approximately $2.9 billion. *Salmonella enterica* is comprised of more than 2,500 serotypes. With this genetic and environmental diversity serotypes are adapted to live in a wide variety of hosts using non-pathogenic and pathogenic lifestyles depending on environmental conditions. Thus *Salmonella* presents a multi-faceted threat to food production and safety. *Salmonella* have been isolated from all food animals and can cause morbidity as well as mortality in swine, cattle, sheep, and poultry. The link between human salmonellosis and host animals is most clear in poultry. During the early part of the 20th century a successful campaign was waged to eliminate fowl typhoid caused by *Salmonella* Gallinarum/Pullorum. Microbial ecology is much like macroecology; environmental niches are filled by adapted and specialized species. Elimination of *S.* Gallinarum cleared a niche in the on-farm and intestinal microbial ecology that was quickly exploited by *S.* Enteriditis and other serotypes that live in other hosts, such as rodents. In the years since, human salmonellosis cases linked to poultry have increased to the point that uncooked chicken and eggs are regarded as toxic in the zeitgeist. Salmonellosis caused by poultry products have increased significantly in the past 5 yr, leading to federal efforts that target reducing the incidence of *Salmonella* in chickens below the current 19% rate. Prevalence of *Salmonella* in swine and cattle is lower, but still poses a threat to food safety and production efficiency. Thus, approaches to reducing *Salmonella* in animals must bear in mind that the microbial ecology of the animal is a critical factor that must be accounted for when designing intervention strategies. Competitive exclusion, sodium chlorate, vaccination, are bacteriophage are all strategies that can reduce *Salmonella* in the live animal, but it is vital to understand how they function.

Key Words: *Salmonella*, Preharvest Strategies, Food safety

55 Current and future *Salmonella* challenges: Background, serotypes, pathogenicity, and drug resistance. S. L. Foley*, *Marshfield Clinic Research Foundation*, *Marshfield, WI*.

Salmonellosis is a worldwide health problem and *Salmonella* infections are the second leading cause of bacterial foodborne illnesses in the U.S. Approximately 95% of human salmonellosis cases are associated with consumption of contaminated foods such as meat, poultry, eggs, milk, seafood, and fresh produce. *Salmonella* can cause a number of human illnesses that include enterocolitis, bacteremia, and typhoid fever, with the most common being enterocolitis. Enterocolitis is often characterized by abdominal pain, nausea and vomiting, diarrhea, and headache. Typically the illness is self-limiting, but antimicrobial therapy is often needed to treat more severe infections. Currently, there are over 2,500 identified serotypes of *Salmonella*. A smaller number of these serotypes are significantly associated with animal and human illnesses. These include Typhimurium, Enteritidis, Newport, Heidelberg, Muenchen, and Montevideo. Isolates from these serotypes are more frequently detected demonstrating resistance to multiple antimicrobial agents, especially third generation cephalosporins that are recommended for treatment of severe infections. Many of the genes encoding resistance are located on transmissible elements such as plasmids to allow for potential transfer of resistance among strains. Plasmids are also known to harbor virulence factors that contribute to *Salmonella* pathogenicity. Several serotypes of medical importance such as Typhimurium, Enteritidis, Newport, Dublin, and Choleraesuis are known to harbor virulence plasmids containing genes encoding for fimbriae, serum resistance, and other factors. Additionally, many *Salmonella* contain pathogenicity islands scattered throughout their genomes to encode factors essential for bacterial adhesion, invasion, and infection. *Salmonella* have evolved several virulence and antimicrobial resistance mechanisms that allowed for continued challenges to our public health infrastructure.

Key Words: *Salmonella*, Pathogenesis, Antimicrobial Resistance

56 Current and future *Salmonella* challenges: Prevalence of *Salmonella* in beef and dairy cattle and potential pathogenicity of their isolates. C. R. Jackson*, P. J. Fedorka-Cray, J. Haro, and B. M. McGlinchey, *USDA-ARS*, *Athens, GA*.

Salmonella is a leading cause of foodborne illnesses that spread to humans from different sources. While all *Salmonella* serotypes have the potential to cause illnesses, certain serovars appear to be responsible for various illnesses in animals and humans. *Salmonella* Typhimurium, *S.* Enteritidis, and *S.* Newport are in the top five serotypes implicated in human infections whereas *S.* Dublin is a common cause of cattle infections. As a part of the National Antimicrobial Resistance Monitoring System (NARMS), prevalence, antimicrobial susceptibility, and pulsed-field gel electrophoresis of *Salmonella* serotypes in beef and dairy cattle collected from 1997 to 2005 were examined. A total of 10,228 and 4,584 *Salmonella* isolates from beef cattle and dairy cattle, respectively, were tested. For beef cattle, the clinical status of the isolates included slaughter (n = 6,813; 61.3%), diagnostic (n = 3,415; 30.7%), and on-farm (n = 883; 8.0%). For dairy cattle, the clinical status included diagnostic (n = 3,036; 66.2%) and on-farm (n = 1,548; 33.8%). For samples from beef cattle at slaughter, the top three serotypes were *S.* Montevideo (13.9%), *S.* Anatum (8.9%), and *S.* Newport (7.6%). For diagnostic isolates, the top three serotypes from both beef and dairy cattle were the same, but were ranked differently: *S.* Typhimurium var. 5- (15.8%), *S.* Newport (13.6%), and *S.* Typhimurium (13.1%) from beef cattle and *S.* Newport (24.3%), *S.* Typhimurium (19.7%), and *S.* Typhimurium var. 5- (18.6%) from dairy cattle. Regardless of the source, 51.9% of all *Salmonella* from cattle were pan-susceptible in 2005. Through 2005, 45.4% of *S.* Typhimurium, 24.6% of *S.* Newport, and 13.4% of *S.* Typhimurium var. 5- from slaughter samples were pan-susceptible. Multidrug resistance (resistance to two or more antimicrobials) was 80.2% for *S.* Typhimurium var. 5-, 74.8% for *S.* Newport, and 52.0% for *S.* Typhimurium. Using PFGE, the most common pattern for all cattle isolates was for *S.* Newport (n = 165). The results demonstrated the differences between beef and dairy cattle in prevalence of *Salmonella* serotypes.

Key Words: *Salmonella*, Cattle, Serotypes

57 Current and future *Salmonella* challenges: Prevalence in swine and poultry and potential pathogenicity of their isolates. S. L. Foley*, *Marshfield Clinic Research Foundation*, *Marshfield, WI*.

Salmonella infections are the second leading cause of bacterial foodborne illness in the U.S. The great majority of these infections are associated with consumption of foods such as meat, poultry, eggs, milk, seafood, and fresh produce contaminated with *Salmonella*. The per capita consumption of meat and poultry in the U.S. has increased significantly over the past century. This increase is especially evident with poultry products, where there has been a nearly six-fold increase in chicken consumption and 17-fold increase in turkey consumption since 1909. The annual per capita consumption of pork has also increased over that time from 18.7 to 21.7 kg. With these increases in consumption, the dynamics of animal production and consumer exposure have changed leading to new challenges in limiting salmonellosis. To meet the high demand of consumers, more intensive agricultural practices have been adopted. This has likely changed the population characteristics of *Salmonella* present among poultry and swine populations. With regard to *Salmonella* isolated from swine in the U.S., Typhimurium has replaced Choleraesuis as the predominant serovar in recent years. Among isolates collected from turkeys in 2004, serovars Senftenberg and Hadar were most common. However, Heidelberg was most common from clinical sources, potentially indicating increased virulence. Heidelberg was also the most commonly detected serovar in clinical and non-clincal isolates from chickens. A high percentage of isolates from many of these prominent serovars are resistant to antibiotics. Public statistics suggested that antimicrobial use in the U.S. has increased at least 30-fold over the past 50 yr. This increase has likely provided selective pressure to drive proliferation of antimicrobial resistance and potentially select for transfer of virulence factors. This can be physically associated with resistance genes that lead to increased pathogenicity among *Salmonella* strains.

Key Words: *Salmonella*, Swine, Poultry

58 Temporal variables of the Quarter Horse hunter trot and canter. M. Nicodemus*, *Mississippi State University*, *Mississippi State*.

American Quarter Horse (QH) is the largest breed in the United States with hunter under saddle (HUS) ranking as one of the highest in number of entries for rail classes. However, kinematic research on stock-type horses and on HUS horses is lacking. Research has studied the kinematics of nationally ranked stock-type western pleasure horses finding horses won at competitions while performing gaits that did not follow breed association guidelines. This research assisted in changes to improve upon the gait definitions of the western pleasure horse. Therefore, objectives of this study were to measure the temporal variables of the trot and canter of the QH HUS horse and to define using measured gait variables the gaits that are winning at competitions. 6 registered QH showing in a HUS class were filmed at 60 Hz. Camera was set perpendicular to horse's plane of motion at a distance of 399.2 cm. Horses were filmed throughout the class along one of the long sides of the arena. Trot and canter strides judged as desirable by carded QH judges under breed standards were evaluated using frame-by-frame analysis. Judging guidelines are documented in the 2006 QH rulebook under the HUS section. Strides not considered "desirable" were not included as the study objectives were to only define the locomotion of those horses winning at competitions. Means (SD) were determined for 5 strides for each horse for each gait with stance and limb support given as % of stride. Fore (Right=40±2%, Left=40±3%) and hind (Right=40±3%, Left=40±2%) stance were balanced in the trot, while the diagonal limbs of the canter were balanced (Trailing Fore=46±5%, Leading Hind=46±5%;Trailing Hind=41±3%, Leading Fore=42±4%). Along with suspension and bipedal support, the canter demonstrated periods of single fore (27±4%), single hind (20±3%), tripedal with 2 hind (20±4%), and tripedal with 2 fore (15±4%) supports (Table 1). In conclusion, the understanding of kinematics of the QH HUS horse can assist in performance evaluation. The measured variables from this study can be used to better define the HUS gaits according to QH breed association guidelines.

Table 1: Means (SD) of the temporal variables of the Quarter Horse hunter trot and canter.

	Trot	Canter
Velocity (m/s)	2.83±0.31	3.22±0.33
Stride Duration (ms)	773±43	623±27
Stride Length (m)	2.19±0.25	2.01±0.23
Stride Rate (stride/s)	1.30±0.07	1.61±0.07
Suspension (%)	19±1	7±4
Bipedal Support (%)	81±1	10±5

59 Survey of working conditions and management of donkeys in Niono and Segou. M. M. Diarra[1], A. Doumbia[1], and A. K. McLean*[2], [1]*Institut Polytechnique Rural de Formation et de Recherche Appliquèe*, *Katibougou, Mali*, [2]*Michigan State University*, *East Lansing*.

Donkeys, *Equus asinus*, play a vital role in the agriculture based economy of Mali, where they are used primarily by low income farmers for traction and to generate additional income by providing transportation of crops to market and a source of manure for fertilizer. The breakdown of donkeys caused by adverse conditions and poor health can lead to their unavailability for periods lasting from one to six months, often leading to abandonment due to the cost of care and lack of productivity. The objective of this survey was to identify the most common existing causes of poor health and reduced ability to work that could be rectified by better management strategies. The maintenance procedures of 2,656 donkeys in two locations in Mali, Niono (n=1448, 6 mo. duration) and Segou (n=1208, 8 mo. duration) were recorded by a veterinarian. Donkeys were examined monthly and evaluated with respect to their ability to work. Variables analyzed included the number of donkeys per owner, the use of the donkey, quality of harness, daily distance traveled, type of goods transported, hours worked per day, feed and watering practices, problems treated by the owner such as lesions caused by poor harnesses or lameness that impaired ability to work. The most prevalent causes of reduced work output were poorly constructed and fitting harnesses (76%), overloading (51% carried loads over 500 kg, the FAO recommends 400 kg), traveling long distances (79% traveled over 20 km/day), and for long hours (82% worked longer than 6 hr). In Segou (67%) and Niono (75%) of the donkeys had adverse health conditions such as lesions on the withers and shoulders, lameness, parasites, tetanus, trypanosomiasis and inanition. No medical care was provided to 72% of these animals especially with parasites and lesions. Harness quality is believed to be directly related to frequency of the lesions and wounds. These data highlight the need for education on donkey work practices, harnessing, and husbandry to improve the quality of life and work of these essential animals.

Key Words: Donkeys, Mali, Survey

60 11 β- hydroxysteroid dehydrogenase type 1 activity in equine adipose tissue. F. H. G. Farias*, P. J. Johnson, V. K. Ganjam, and D. H. Keisler, *University of Missouri*, *Columbia*.

Enzymatic 11βHSD1 amplification of glucocorticoid concentration in adipose tissue has been associated with obesity, diabetes, hypertension, dyslipdemia, and cardiovascular disease in humans and mice. Furthermore, mice that over-express 11βHSD1 activity in adipose tissue exhibit characteristics of visceral obesity and metabolic syndrome. Analogous to the growing problem of obesity and related problems in humans, the incidence of obesity and related problems are on the rise in the horse industry. In horses, obesity predisposes to greater risk for laminitis, infertility, insulin resistance, and equine metabolic syndrome. Our objective was to determine if 11βHSD1 activity exists in horse adipose tissue and, if present, to quantitate the amount of activity in abdominal vs. subcutaneous fat depots. Our hypothesis was that 11βHSD1 is present in horse adipose and that its activity is more abundant in abdominal vs. subcutaneous fat depots. Thus, samples of abdominal (retro-peritoneal) and subcutaneous (base of the tail) adipose tissue were collected from 23 horses. Horse body condition scores were categorized as obese (7-9), subtle overweight (6), normal (4-5), and thin (1-3). Fat samples from each adipose depot were submitted for immuno-histochemistry procedures to detect the presence of 11βHSD1 in abdominal and subcutaneous adipose tissue. In addition, radiometric assay procedures were also used to reaffirm the presence and quantitate the activity of 11βHSD1 in abdominal and subcutaneous

adipose tissue locations. Data were analyzed by PROC GLM and PROC MIXED of SAS, significance was set at P<0.05. We found no difference in 11βHSD1 activity between subcutaneous and abdominal adipose tissue nor did its activity correlate with body condition scores. These data provide evidence that 11βHSD1 activity is present in horse subcutaneous and abdominal adipose tissue, but these data fail to provide evidence that body condition score and 11βHSD1 activity are correlated as reported to occur in humans.

Key Words: Horses, 11β-HSD

61 Glucose/insulin responses of weanling horses fed forage based total mixed ration cubes versus hay/concentrate rations. S. L. Ralston*[1], H. Anderson[2], and R. Johnson[3], [1]*Rutgers*, *New Brunswick, NJ*, [2]*IdleAcres*, *Cokato, MN*, [3]*Nutrena*, *Minnetonka, MN*.

Insulin resistance (IR), resulting in hyperinsulinemia, has been documented in young horses fed high starch/sugar feeds (NSC 20% or higher). Hyperinsulinemia has been reported to be correlated with an increased incidence of developmental orthopedic disease(DOD). To test the hypothesis that rations with low NSC (<20%) such as forage based total mixed ration (TMR) cubes or Safe Choice® (SF, Nutrena ®(Minnetonka, MN) may reduce IR in weanling horses, a series of three trials were conducted (2004-2006). Each year 12 weanlings were fed either TMR cubes (Next Generation, IdleAcres, Cokato, MN) free choice (TMR, n=6 per year) or Nutrena ®(Minnetonka, MN) Life Design ®Youth ® (HS:2004, 2005) or SF (LS:2006) to provide 50% of the calories recommended for growth with adlib grass/alfalfa hay (n=6 per year) for 6 weeks. Hay and cube orts were recorded. Horses were fed in individual stalls overnight and turned out in dry lot paddock 0830-1600h daily. Horses were visually monitored for epiphysitis and flexure deformities, rated in a scale of 0-4, and radiographs were taken if indicated. Insulin sensitivity was assessed with a low dose oral dextrose challenge (LDOD: 0.25 gm dextrose/kg BW) before treatments were initiated and after 6 weeks on treatments (PostTX). Glucose/insulin responses to equicaloric amounts of TMR and concentrates were measured PostTX in all years. Glucose/insulin data were compared within and between years by ANOVA for repeated measures factoring effects of treatment, individual and year where appropriate (Statistixs for Windows, Analytical software) and Students T-test where appropriate. Nutrient content of the rations differed between and within years (Table 1). No DOD>1 was observed in 2004. In 2005 two IR horses had DOD>2 before the treatments were initiated, one was placed on TMR, the other on HS. The one on TMR had a DOD score of <2 within 2 weeks of feeding, the one on HC had a score>2 throughout the study. In 2006 2 horses had DOD>2 but only one was IR. Bothe were fed TMR but had no change in DOD score. Glucose responses to the PostTX LDOD did not differ between treatments in the first two years but insulin responses tended (P<0.1) to be higher in HS fed horses, suggesting reduced insulin sensitivity. Glucose/insulin responses to HS were higher than TMR or LS. In 2006 TMR fed horses had higher (P<0.05) glucose and insulin responses those fed LS but both tended (P<0.1) to be lower than in previous years. Restriction of NSC may increase insulin sensitivity in weanling horses but will not prevent or resolve all DOD. Young horses with DOD are not always IR.

Table 1. Nutrient Content of Rations consumed (DM basis)

	HC04*	TMR04	HC05*	TMR05	HC06*	TMR06
Mcal/kg	2.4	2.2	2.2	2.2	2.6	2.4
%CP	14.0	18.7	11.0	16.7	14.7	15.6
%NSC	20.0	16.5	20.0	13.0	15.4	15.0

*based on total hay/concentrate consumed per day

62 Metabolic and digestive profiles of horses grazing spring pasture. B. McIntosh*[1,2], D. Kronfeld[1], R. Geor[1], W. Staniar[1], and P. Harris[3], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*Blue Seal Feeds, Inc*, *Londonderry, NH*, [3]*WALTHAM Centre for Pet Nutrition*, *Melton Mowbray, United Kingdom*.

Laminitis often occurs in the spring and may be associated with dietary nonstructural carbohydrates (NSC). A 36 h study in April 2005 took examined the effects of forage NSC on grazing horses in Virginia. Fourteen mares were randomly assigned to grazing (housed on a 5-ha pasture predominantly tall fescue; n = 10) or control (stabled and fed timothy/alfalfa hay; n = 4) groups. The mares were 11±5 yr old, weighed 596.0±14.5 kg, and body condition scores ranged from 4.5 to 7.5 (on a scale of 1 to 9). Plasma glucose, insulin and L-lactate concentrations, and fecal pH and volatile fatty acids (VFA) were measured hourly. Hay samples and hourly pasture samples were analyzed (Dairy One, Ithaca, NY) for starch and sugar, where sugar is water soluble carbohydrates (and includes fructans), and NSC was the sum of starch and sugar. Data were tested for normality and repeated measures ANOVA with post tests were performed. The NSC content of the hay was 8.9±0.05 % DM, and pasture NSC content ranged from 15.8 to 25.3 % DM. Grazing horses had higher overall insulin and glucose than control horses (P < 0.05). Mean insulin concentrations in grazing horses displayed a circadian pattern that correlated to NSC levels in the forage (r = 0.60, P = 0.008). Plasma L-lactate was higher in grazing horses (0.64 mmol/L) than control horses (0.40 mmol/L) (P < 0.001). Fecal pH was lower in grazing horses (pH 6.9) than control horses (pH 7.2) (P = 0.008). Fecal VFA, including acetic acid, butyric acid, D- and L-lactic acid were higher in grazing horses compared to control horses (P < 0.05). The alterations in metabolic and digestive variables observed in grazing horses may reflect increased intake and digestion of hydrolysable and rapidly fermentable carbohydrates that were present in spring forages. Changes in carbohydrate metabolism and digestion in grazing horses during spring may increase risk of laminitis via exacerbation of insulin resistance and rapid fermentation in the hindgut.

Key Words: Horse, Forage, Laminitis

63 Fatty acid content of grass and legume hays commonly fed to horses. L. K. Warren* and J. Kivipelto, *University of Florida*, *Gainesville*.

Recent interest in supplementing equine diets with omega-3 (n-3) fatty acids (FA) for their potential anti-inflammatory benefits has generated the need to better characterize the FA composition of basal feeds. While flaxseed and marine-derived oils are potent sources of n-3 FA,

a limited amount of data suggest that forages may be a reasonable source of alpha-linolenic acid (C18:3). However, the FA composition of different forages is not well described. The objective of this study was to characterize the FA composition of several grass and legume hays commonly fed to horses. Different sources of each of the following 5 hays were examined: timothy (n=8), orchardgrass (n=6), Coastal bermudagrass (n=10), alfalfa (n=8) and perennial peanut (n=6). Hays were analyzed for FA composition, total fat, crude protein, NDF and ADF. Data were analyzed by ANOVA to compare differences between individual hay varieties, grass vs. legume hays and warm- vs. cool-season grass hays. Across all hays, C18:3 made up the greatest ($P<0.01$) portion of the total fat content of hay (39.1±1.9 g/100 g fat), followed by C16:0 (23.8±0.9 g/100 g fat) and C18:2 (21.2±0.9 g/100 g fat). Other FA detected in all hays included C18:0, 18:1, 20:0, 22:1 and 24:1, each ranging from 0.02 to 4.1 g/100 g fat. Grass hays tended to contain a higher ($P<0.10$) proportion of C18:0 than legume hays, but no other differences in FA content were detected between these hays. The total fat content of legume hays (6.9±0.6%) was higher ($P<0.05$) than that observed for grass hays (3.8±0.3%), suggesting that while the FA composition of legume hays does not differ greatly from grass hays, legume hays may provide a greater total quantity of C18:3. Warm-season grass hay tended to be higher ($P<0.10$) in C16:0 and C18:0 and lower ($P<0.10$) in C18:3 than cool-season grass hays. Individual grass hay varieties did not differ in total fat content. Across all hays, a negative correlation was found between C18:3 and ADF content ($r=-0.58$; $P<0.05$), which indicates n-3 FA content of hay may decline when forage is harvested for hay at a more mature stage. Ultimately, consumption of commonly available hays of good to moderate quality will result in a greater intake of n-3 FA (C18:3) over omega-6 FA, regardless of the type of hay.

Key Words: Omega-3 Fatty Acids, Alpha-Linolenic Acid, Forage

64 Effect of season, forage maturity and grazing on the fatty acid composition of bahiagrass pasture. L. K. Warren* and J. Kivipelto, *University of Florida*, *Gainesville*.

Although low in total fat, a limited amount of data suggest forage may serve as a significant source of alpha-linolenic acid (C18:3) in equine diets. However, the fatty acid (FA) composition of common pasture forages has not been widely described. The objectives of this study were to characterize the FA composition of bahiagrass pasture selected by grazing horses and to determine the effect of season and cumulative growth on pasture FA composition. Over a 24-mo period, 3 replicates of each of 3 types of pasture samples were obtained at 1-mo intervals: grasses on or near areas where there was recent evidence of grazing by horses (GRAZE), grasses obtained from the same plots each month (MONTH), and grasses obtained from different plots each month that were allowed to accumulate up to 12 mo of growth (ACCUM). Both MONTH and ACCUM samples were obtained from areas on pasture that were restricted from grazing. MONTH was used to assess change in FA composition for new growth occurring in each 1-mo interval. ACCUM was used to determine changes in FA content as pasture forage grew and matured. All samples were obtained from an 8.1-ha, mixed-cultivar bahiagrass (*Paspalum notatum*) pasture that continually housed the same 6 mature geldings. Differences in FA content between sample types and with season were determined by ANOVA. On average pasture contained 4.1±0.2% total fat. Across all months and sample types, C18:3 made up the largest proportion of the total fat in forage ($P<0.01$), followed by C16:0 ($P<0.01$) and C18:2 ($P<0.01$). Other FA detected in pasture included C17:0, 18:0, 18:1, 20:0, 22:1 and 24:1, each ranging from 0.1 to 5 g/100 g fat. On average C18:3 was higher ($P<0.01$) in GRAZE (56.4±2.2 g/100 g fat) and MONTH (54.7±2.3 g/100 g fat) than ACCUM (39.8±4.2 g/100 g fat), whereas C18:2 made up a greater ($P<0.01$) proportion of the fat in ACCUM (21.5±1.1 g/100 g fat) compared to GRAZE (15.2±0.6 g/100 g fat) and MONTH (16.8±0.6 g/100 g fat). Season ($P<0.05$) affected C18:3 and C18:2 content of MONTH and ACCUM samples, with higher levels observed from April to July. ACCUM samples contained higher ($P<0.01$) C17:0, 18:0, 18:1 and 20:0 than GRAZE and MONTH, indicating a rise in these FA as bahiagrass pasture matures.

Key Words: Alpha-linolenic acid, Omega-3 fatty acids, Warm-season forage

Immunology - Livestock and Poultry I

65 An initial evaluation of the pathogenesis of Turkey-origin avian reovirus in poults. C. Stephens*[1], M. Pantin-Jackwood[2], E. Spackman[2], and J. M. Day[2], [1]*University of Georgia*, *Athens*, [2]*Southeast Poultry Research Labs, USDA*, *Athens, GA*.

Enteric disease causes poor performance in turkey flocks and, consequently, production losses in the industry. The pathogenesis of enteric viruses is not well understood and needs to be studied to further understand the nature of enteric disease. A virus isolated in 2003 from the intestines of poorly performing commercial turkeys in North Carolina (NC/SEP-R44/03) was selected for this study. In a previous study, this virus induced both humoral and cell-mediated immunosuppression in two-day-old poults. Three-week-old Broad Breasted White turkeys were inoculated by oral gavage with NC/SEP-R44/03, and the sham inoculated birds were inoculated with sterile phosphate buffered saline. Both the sham inoculated birds and the infected birds were weighed at days 0, 9, and 16 days post inoculation (DPI) to evaluate body weights. At 8 and 15 days PI, ten sham birds and 10 inoculated birds were selected to study the cutaneous basophil hypersensitivity (CBH) response; a measure of cell-mediated immunity. Another 20 birds were selected to study the humoral immune response by evaluating their antibody titers to Newcastle disease vaccine. Serum was collected from these birds at 21 and 42 DPI, and the antibody titers were determined by ELISA and were compared between the sham inoculated birds and the virus inoculated birds. Poults were periodically necropsied and examined for clinical signs of enteric disease. The spleen, bursa, and thymus were collected for histopathological analysis. No clear differences between the treatment groups in bodyweight, CBH response, and antibody response were observed; however, gross lesions consistent with enteric disease were observed at 8 and 15 days PI. Gross lesions included gas-filled, fluid filled intestines with undigested feed, and ceca with frothy contents. Enlarged bursas of fabricius with bursal 'cores' were also observed. In conclusion, older turkeys, in contrast with younger turkeys, do not appear to suffer immunosuppression with reovirus; however, enteric disease is observed.

66 Characters and functions of anterior pituitary progenitor cells that are identified by a novel monoclonal antibody. Y. Nagai*, H. Aso, H. Ogasawara, S. Tanaka, K. Watanabe, S. Ohwada, and T. Yamaguchi, *Laboratory of Functional Morphology, Graduate School of Agricultural Science, Tohoku University*, *Sendai, Japan*.

In anterior pituitary gland, inflammatory mediators such as cytokines modulate the cell function through immuno-endocrine pathway. Our previous study showed that proinflammatory cytokine, IL-18 was localized in the cell layer of Rathke′s pouch that has been proposed to embody stem/progenitor cell compartment in the anterior pituitary gland of cattle. We established a stem/progenitor cell line (BAPC-1) from the anterior pituitary gland. BAPC-1 expressed the mRNA of stem/progenitor cell-associated factors and inflammatory cytokines including IL-1, IL-6, IL-8, IL-12 and IL-18. However, the nature and behavior of anterior pituitary progenitor cells remains unclear. The present study was conducted to produce monoclonal antibodies (mAbs) specific for the membrane protein of BAPC-1 and to detail anterior pituitary progenitor cells. It was revealed that the mAbs termed 12B strongly reacted with BAPC-1 and recognized 4Ig-B7-H3 molecule, which is a costimulatory molecule and a negative regulator in T-cell activation. The 12B-immunoreactive cells (12B-ir cells) were localized around the Rathke′s pouch in young and adult cows. However, the number of 12B-ir cells was less in adult cows compared with young cows. The 12B-ir cells were also observed around the pars tuberalis, which lie closely to median eminence and have blood supply via the primary portal plexus in anterior pituitary gland. In the intermediate lobe, 12B-ir cells were sporadically observed around the Rathke′s pouch in both cows. The 12B-ir cells corresponded with the cells immunoreactive for IL-18 around the Rathke′s pouch. Thus, 12B was available to detect anterior pituitary progenitor cells. These results suggest that anterior pituitary progenitor cells are localized in the layer of Rathke′s pouch and function as immunomodulatory cells.

67 Effect of photoperiod on immune function in broiler chickens. S. Dalal*, K. Schwean-Lardner, B. Laarveld, H. L. Classen, and A. G. Van Kessel, *University of Saskatchewan*, *Saskatoon, SK, CANADA*.

Three experiments were conducted to investigate the effect of lighting program on immunity in broiler chickens. In experiment 1, 560 day-old male chicks were placed in 8 rooms (70 birds/pen) on used litter and assigned to 14, 17, 20 or 23 hours continuous light. Sixteen chickens were selected from one pen in each room and intraperitoneally administered 400 μg of lipopolysaccharide (LPS) in 1ml saline or saline every second day for 10 days beginning at day 17. Experiment 2 was a replicate experiment except that LPS or saline were administered beginning at 27 days of age. Weight gain during LPS administration and relative organ weight at the end of LPS administration were recorded. In experiment 3, 6264 day-old chickens were placed on fresh litter in one of 9 rooms at a housing density of 30 kg/m^2 and assigned to one of 3 lighting programs including intermittent (15h light: 3.5h dark: 2h light:3.5h dark), 17h light:7h dark (17L) and 23h light:1dark (23L). One bird was selected from each pen per room and administered (i.m.) on days 10 and 21 a commercial *E.coli* (K88) vaccine (0.2 mL/bird). On day 39, antibody titre was assayed in serum and heterophil phagocytic and free radical production was assayed in whole blood. LPS administration reduced ($P < 0.001$) weight gain in experiment 1 and increased ($P< 0.05$) relative liver and spleen weight in experiment 1 and 2. No interaction was found between lighting program and response to LPS. In Experiment 3, serum anti-K88 titre was highest ($P<0.05$) in birds on a 1 hour dark period compared with birds on other lighting treatments ($P<0.05$). Blood phagocytic activity was highest ($P<0.05$) in birds exposed to a 7 hour continuous dark period compared to an intermittent 7 hour dark period or a 1 h dark period. We conclude that lighting program did not markedly influence the magnitude of the inflammatory response to LPS. Short dark exposure appeared to support the highest serum antibody response, whereas a long continuous dark exposure supported the highest whole blood phagocytic activity.

68 Gene expression profiling in heterophils from *Salmonella*-resistant and -susceptible chicken lines using a chicken 44K Agilent microarray. H. I. Chiang*[1], C. L. Swaggerty[2], M. H. Kogut[2], X. Y. Li[1], and H. Zhou[1], [1]*Texas A&M University*, *College Station*, [2]*United States Department of Agriculture*, *College Station, TX*.

Large-scale expression profiling is a promising tool for ascribing complex biological function and interactions between genes with available genomic sequence data. To determine the transcriptional response to *Salmonella* enterica serovar Enteritidis (SE) infection, a newly developed chicken 44K Agilent array was used to analyze RNA of heterophils from SE-resistant (line A) and SE-susceptible chickens (line B), treated with in vitro infection of SE (I) or non-SE medium (N). A dual-color balanced design was used to provide a direct comparison between SE-infected and non-infected groups (A-I vs. A-N, B-I vs. B-N) and between line A and line B (A-N vs. B-N, A-I vs. B-I). Each comparison includes four biological replicates with a dye swap. The medium signal intensity was normalized using locally weighted linear regression (LOWESS) method, and followed by a mixed model analyses using SAS program. The results indicated that: for the comparisons of SE infection with non-infection, 3096 genes in line A and 3312 genes in line B were differentially expressed ($P < 0.05$), while 67 and 56 genes were related to immune function, respectively. In the comparison of lineage (line A and line B) difference, 4377 genes in the non-infected and 4333 genes in the infected groups showed differential expression ($P < 0.05$), whereas 71 genes and 69 genes were immunologically related, respectively. Interestingly, more differentially expressed genes were identified in the comparison of the lineage difference than in the comparison of SE infected to non-infected group, however, there were more genes that achieved a 4-fold change (up- or down-regulated) in the latter comparison. The results discovered in the present study have laid a solid foundation to elucidate cellular and molecular mechanisms of SE infection in chickens.

69 Relationship between growth performance and immuno-competence measurements in broiler strains under high ambient temperatures. M. M. Fathi*, A. Galal, S. A. El-Safty, and S. S. Al-Rishan, *Faculty of Agric., Ain Shams Univ.*, *Cairo, Egypt*.

An experiment was conducted to quantify the growth performance and immunological parameters of broiler strains under high ambient temperatures. Three different genetic strains of broiler chicks (125 Hubbard, 125 Ross and 125 Arbor Acres) were reared under similar managerial, environmental and hygienic conditions during summer

season of Egypt. The high and low ambient temperatures recorded during the experimental period were 33 and 28C, respectively. The birds were weighed weekly. Feed consumption and feed conversion ratio were determined on a week basis. At 4 weeks of age, 20 birds from each strain were randomly assigned to determine cell mediated response and relative weight of lymphoid organs. Also, at 5 weeks of age, 5 birds from each strain were randomly taken to determine the phagocytic ability. The results of the current study revealed that the Ross broiler chicks had significantly heavier body weight than that of Hubbard chicks. However, the Arbor Acres broiler chicks were intermediated. There were no significant differences among strains for feed consumption, feed conversion ratio and rectal temperature. With respect to cutaneous basophil hypersensitivity (CBH) response, it could be observed that the Hubbard strain had a greater dermal swelling response to phytohemagglutinin-P (PHA-P) followed by Ross one when compared to Arbor Acres strain at 72 hours post injection. Also, the Arbor Acres strain exhibited greater bursa and spleen (as a percentage of live body weight) compared to the remaining strains. On the other hand, the Ross strain showed smaller relative weight of thymus compared to the other strains. Concerning the phagocytic activity, the Ross strain had significantly lower level of carbon particles in their blood circulation as compared to Hubbard and Arbor Acres chicks. We concluded that although there was no significant difference for productive performance traits among strains, the Ross broiler chicks strain is hyper responder to phytohemagglutinin-P (PHA-P), had a better phagocytic ability and lower mortality rate compared to other strains.

Key Words: Broiler Strains, Immunocompetence, Growth Performance

70 The feather as an *in vivo* test tube for tissue immune responses. G. F. Erf*, B. Lockhart, K. Bateman, R. Finley, and O. T. Bowen, *University of Arkansas*, *Fayetteville*.

While the blood serves as an excellent window into humoral immune activity, it is much more difficult to monitor and assess qualitative and quantitative aspects of tissue immune responses. To determine the presence of cell-mediated immunity (CMI) to an antigen (Ag) *in vivo*, the Ag is injected into the wattle, wing-web or toe-web and the swelling response (SR) measured over a 12 to 72h period. However, the SR does not provide direct information on Ag-induced immune activities. Through our work on autoimmune loss of feather pigment cells (vitiligo) in Smyth line chickens, we have studied CMI extensively and noted that growing feathers, like other integumental tissues, are immunologically active sites. For our vitiligo studies we used growing feathers (5-10 mm living pulp) for histology, immunohistochemistry, cell isolation and gene-expression studies. Considering that the growing feather is a defined, accessible, living unit that can easily be removed for down-stream analyses, we examined the suitability of feathers for study of *in vivo* tissue immune responses. In Study 1, growing feathers of 12-wk-old roosters were injected with LPS, PHA, or vehicle. The feathers were collected 6h later. Histological examination revealed infiltration of heterophils, and heterophils, macrophages and lymphocytes, when LPS and PHA were injected, respectively. Vehicle injection was not associated with leukocyte infiltration. To test Ag-specific CMI, *Mycobacterium butyricum* was injected into feathers of *M. butyricum*-sensitized and -unsensitized chickens. Feathers were collected 4, 24, 48, and 72h later. Conventional histology and immunohistochemistry revealed leukocyte infiltration profiles in feathers identical to those reported previously for wattle tissue. Therefore, the feather is highly suitable for monitoring and assessing various aspects of CMI in an individual bird. Knowledge gained by studying tissue immune responses *in vivo* will find direct application in the design of vaccines and strategies to optimize immune system development and function.

Key Words: Cell-mediated Immunity, LPS, PHA

71 Risk factors for avian developmental immunotoxicity (DIT): potential role of sex, hormone status, and age. R. R. Dietert*, *Cornell University*, *Ithaca, NY*.

Recent research has suggested that the developing immune system is far more sensitive to environmental modulation than that of the fully-mature adult. Both quantitative differences in dose-response sensitivity as well as qualitative differences in the nature and extent of environmentally-induced immune alterations have been linked to the age of exposure. But a surprising observation is that age alone may not be the only risk factor warranting consideration. The sex of the embryo and hormone balance at the time of exposure may also help to determine subsequent immunotoxicity and as a result, later-life health risk. In fact, differential immunotoxic risk based on sex may be even greater in early life than in the adult. Even in cases where there is not necessarily a dose-sensitivity difference between the sexes, the nature of immunotoxic alterations may differ among the sexes. Hormone alteration at the time of exposure seems to influence risk even when the toxicant is not a potent endocrine-disruptor. Additionally, immune impairment may not be readily apparent until post-hatch stress and/or disease challenges occur. As a result, unpredicted post-hatch immune responses, particularly when they are restricted to a subpopulation, may not be readily identified in term of early-life cause/later-life effect. For this reason, it is important to recognize the potential for differential sex-determined and hormone-influenced immunomodulatory responses following both intended (vaccine and/or adjuvant exposures in poultry) and unintended in ovo exposure. This presentation will review recent results in birds concerning heavy metals, and other toxicants relative to early life-insult and subsequent immunotoxic risk. Supported by USDA Grant Regional Project NE-1016.

Key Words: Developmental Immunotoxicity (DIT), Avian, Risk Factors

72 Antibody response against bovine red blood cells in major histocompatibility (*B*) complex recombinant *R13*. N. G. Wilkinson[1], L. M. Yates[2], R. T. Kopulos[2], W. E. Briles[2], and R. L. Taylor, Jr.*[1], [1]*University of New Hampshire*, *Durham*, [2]*Northern Illinois University*, *DeKalb*.

Recombination within the chicken major histocompatibility complex (MHC) has enabled more precise identification of genes controlling immune responses. Chicken MHC genes that are closely linked on chromosome 16 include *B-F*, MHC class I; *B-L*, MHC class II; and *B-G*, MHC class IV. Six congenic lines, each containing a single unique MHC recombinant, achieved 99.9% genetic uniformity through ten backcross generations to inbred Line UCD 003 genotype *B17B17*. Recombinant *R13* (*BF17-BG23*), arose in a single male from the tenth backcross generation for *R1* (*BF24-BG23*). An additional backcross to the Line UCD 003 background increased the number of *R13*

individuals. This new recombinant was tested for antibody production against the T-dependent antigen, bovine RBC (BRBC). Fifty-one progeny segregating for *R13R13* (n = 10), *R13B17* (n = 26), and *B17B17* (n = 15) genotypes were produced by a single *R13B17* male mated to five *R13B17* dams. One mL of 2.5% bovine BRBC was injected intravenously into all genotypes at 4 and 11 weeks of age to stimulate primary and secondary immune responses, respectively. Blood samples were collected 7 days post-injection. Serum total and mercaptoethanol (ME)-resistant antibodies against BRBC were measured by microtiter methods. Titers were expressed as the $\log_2$ of the reciprocal of the highest dilution giving visible agglutination. The least squares ANOVA used to evaluate all primary and secondary antibody titers included hatch and *B* genotype as main effects. Significant means were separated by Fisher's Protected LSD at $P < 0.05$. *R13R13* chickens had significantly lower primary total and ME-resistant antibodies than did the *R13B17* and *B17B17* genotypes. Secondary total and ME-resistant antibodies were significantly lower in *R13R13* chickens compared with *R13B17* but not *B17B17* chickens. Gene differences generated through recombination impacted the antibody response of *R13* compared with *B17*. Secondary antibody titers were not substantially higher than the primary titers suggesting that the memory response had waned in the 7 week interval between injections.

73 Use of HTST pasteurization combined with other nonthermal processes to improve fluid milk shelf life. Z. P. Caplan* and D. M. Barbano, *Cornell University*, *Ithaca, NY*.

Our objective was to develop a process using minimum HTST pasteurization in combination with other nonthermal processes to achieve 60 to 90 days of fluid milk shelf life at 6°C. Microfiltration of raw skim milk and different methods of reducing the total bacteria count of milk fat sources for production of 2% milk were evaluated. Microfiltration (MF) and HTST pasteurization were used to reduce total bacteria, spores, and coliforms in 2% milk made from MF skim milk and various milk fat sources. Raw skim milk was microfiltered at 51°C using a Tetra Alcross M7 Pilot Plant equipped with a ceramic Membralox membrane (pore size: 1.4 micron). MF skim milk plus 3 different milk fat sources were heated to 51°C, and pumped, by weight, into separate containers of MF skim milk to create different 2% milks. These milks were compared to a MF skim milk control without fat added. Each 2% milk was homogenized at 500/2500 psi before undergoing HTST processing (73°C, 15 sec). Total bacteria counts of raw and pasteurized MF skim milks, and pasteurized 2% milks, were determined with most probable number and standard plate count (SPC) methods. Average (n=4) raw skim milk SPC was reduced from 1690 cfu/mL to 0.13 cfu/mL by MF, and further reduced to 0.08 cfu/mL by HTST processing, demonstrating an average 4.3 log reduction from the raw skim milk count due to the combination of MF and HTST. The SPC for all of the pasteurized 2% milks averaged <100 cfu/mL. The pasteurized MF skim milk and pasteurized 2% milks were then stored at 6°C, and the SPC was determined weekly over a 90 d period using a Foss Bactoscan™ FC. Different fat sources did not have a large impact on shelf life. Across 3 replicates, 9 of 9 one liter containers of the pasteurized MF skim milk, and 23 of 27 one liter containers of the pasteurized 2% milks, remained below 20,000 cfu/mL at 70 d. Minimum HTST pasteurization combined with other nonthermal processes was used to successfully extend refrigerated fluid milk shelf life beyond 60 d at 6°C.

Key Words: Microfiltration, Shelf Life, HTST

74 Manufacture of pasteurized process cheese spread from milk concentrated by microfiltration. H. Somni*, V. V. Mistry, K. Muthukumarappan, and K. R. Nauth, *Midwest Dairy Foods Research Center, South Dakota State University*, *Brookings*.

The objective was to replace base cheese in pasteurized process cheese (PC) spread making with microfiltered (MF) milk. Earlier studies focused on PC manufacture from ultrafiltered (UF) milk. With microfiltration, milk proteins are fractionated and offer unique opportunities in process cheese making. Raw skim milk was microfiltered using 0.1µm membrane to approximately 5.7X casein concentration (MFC). Casein in the MFC was 95, 94 and 77% of true protein, total protein and total solids, respectively. MFC was used to substitute base Swiss cheese in PC spread formulations at 33% (T1), 66% (T2) and 100% (T3) by weight of cheese. Total solids, fat, and salt were targeted to 59, 21.5, and 1.5%, respectively, and pH at 5.75. Control (C) was made from Swiss cheese without any substitution. Swiss cheese flavor concentrate was added at 0, 0, 1.85 and 3.5 % levels to C, T1, T2 and T3, respectively. The cheese spread was pasteurized at 71°C for 2 min. The treatments were replicated three times using a randomized block design. Cheeses were analyzed for composition, sensory and rheological properties. Spreadability was measured as percent increase in area after 2.5 and 5.0 min at 25°C. Means were compared using PROC GLM procedure of SAS at p=0.05. With increase in the level of MFC in the spreads, total protein decreased and minerals increased significantly. Control differed from treatments and had minimum viscosity. The bulk and elastic moduli differed for the treatments but did not correlate to level of MFC. A panel of seven expert judges rated T1 above C and the difference was significant for overall flavor, body and texture, and overall acceptability on 1-9 scale (9-liked most and 1-extreme dislike). Substitution of base Swiss cheese with MFC significantly affected rheological properties of the PC spread. This could be because of differences in the protein and minerals levels within the treatments. Thus, microfiltration offers opportunities for developing spreads with consistency and acceptable quality.

Key Words: Microfiltration, Process Cheese Spread

75 Effect of different stabilizers on the textural and rheological properties of cream cheese. M. Brighenti*[1], S. Govindasamy-Lucey[2], J. J. Jaeggi[2], M. E. Johnson[2], and J. A. Lucey[1], [1]*University of Wisconsin*, *Madison*, [2]*Wisconsin Center for Dairy Research*, *Madison, WI*.

Stabilizers are added during cream cheese manufacture to help prevent syneresis during storage. The objective of this study was to determine the impact of different stabilizers on the texture and rheology of cream

cheese. Cream cheeses were manufactured with 0.33% of xanthan gum, locust bean gum or guar gum, and a combination (CBN) of these three stabilizers (0.11% of each). The rheological properties of solutions of these gums, under conditions similar to the aqueous phase of cream cheese (0.6% gum, 1.8% NaCl and pH 5.00), were also tested. Dynamic small amplitude rheological properties were measured during heating from 5 to 80°C at 1°C/min and cooling at the same rate and the parameters measured were storage modulus (SM) and loss tangent (LT). Hardness was determined by texture profile analysis (TPA). A trained sensory panel used spectrum descriptive analysis to determine firmness, stickiness, and spreadability. Lower LT values (indicating higher elasticity) were observed in several regions of the heating and cooling curves for the CBN cream cheeses compared to the cream cheeses manufactured with the individual gums. The CBN cream cheeses gave significantly ($P<0.01$) higher hardness values than the cream cheeses manufactured with the individual gums. A similar trend was observed for firmness and spreadability obtained from sensory analyses while stickiness gave the opposite trend. Due to small differences in the moisture contents of the experimental cream cheeses further replicates will be performed. Rheological tests on the CBN solutions also indicated that they had higher SM values than the individual gums. Differences were also observed among the solutions containing individual gums with locust bean gum solutions having the lowest SM followed by guar gum and xanthan. The higher hardness and lower LT values observed for the CBN cheese samples could be due to the synergistic interaction that exists between xanthan and the galactomannans present in guar gum and locust bean gum. This study shows that the stabilizers used in cream cheese manufacture impacted the texture and rheology of cream cheese.

Key Words: Texture, Cream Cheese, Stabilizers

76 Effect of stabilizers on fat agglomeration and melting resistance of ice cream. I. Herlambang*[1], W. J. Harper[1], and B. W. Tharp[2], [1]*The Ohio State University*, *Columbus*, [2]*Tharp's Food Technology*, *Wayne, PA*.

Hydrocolloid stabilizers are commonly used in ice cream to improve smoothness of body, increase melting resistance and maintain stability during storage. Fat network is one essential element in development of ice cream infrastructure. The mechanism in which the stabilizers affect the fat agglomeration is not yet well understood.

The first objective of this study was to examine the particle size distribution and melting properties of ice creams varying in emulsifiers and gums. Eight commercial ice creams were analyzed for particle size and melting properties. Another objective of the study was to understand the effect of carboxymethyl cellulose (CMC) on fat agglomeration during freezing in the presence and absence of an emulsifier. Ice cream mix was formulated to contain 10% milk fat, 10% milk solids-not-fat, 12% sucrose, 6% corn syrup solids, and 0.15% CMC. The formulations also included mixes with and without 0.15% mono-and di-glycerides (MDG). Fat aggregation was indicated by D[4.3] and % particles above 10 µm as measured by a Malvern Mastersizer. Melting rate was defined as the amount of drip loss divided by melting time. The commercial ice cream analysis showed that ice cream with egg yolks (EY) without any stabilizers had no fat aggregates. Particle size distributions varied between ice cream brands. Ice creams with MDG or those with gums in addition to EY showed an increased aggregation. Ice cream without stabilizer, which also had no fat aggregates, melted at the fastest rate. Gums decreased the melting rate and the melting properties were independent from particle size. Ice cream with only CMC showed the highest amount of fat aggregates and highest resistance to melting. The effect was followed by ice cream made with both CMC and MDG, and only MDG. The amount of fat aggregates was highly correlated to the melting resistance of the ice creams. Ice cream with most melting resistance had greater amount of fat aggregates. The results indicated that stabilizers in ice cream affected fat agglomeration by somewhat modifying the fat structure. These results are useful to better understand the functionality of stabilizers in ice cream.

Key Words: Fat Agglomeration, Stabilizers, Ice Cream

77 Optical measurement of curd shrinkage during cheese manufacturing. C. C. Fagan*[2,1], M Castillo[1], C. P. O'Donnell[2], D. J. O'Callaghan[3], and F A Payne[1], [1]*University of Kentucky*, *Lexington*, [2]*University College Dublin*, *Ireland*, [3]*Moorepark, Teagasc*, *Cork, Ireland*.

There is currently a drive towards continuous monitoring and automation in the cheese processing industry. Control of the process through real time analysis of critical quality parameters can improve product quality and consistency. Full automation of the manufacturing process is dependent on developing technologies for monitoring critical unit operations such as syneresis. The objective of this study was to determine if the response of an optical sensor detecting light backscatter in a laboratory scale cheese vat was related to physicochemical changes occurring in the curd and whey mixture during syneresis. A three-factor (coagulation temperature, calcium chloride addition level, cutting time), randomized, central composite design comprising 20 runs was carried out in triplicate. A prototype sensor collected scattered light during coagulation and syneresis which was conducted through a fibre optic cable to a miniature spectrometer. Upon cutting the gel, stirring commenced and samples of curd and whey were removed at 10 min intervals up to 85 min after cutting and analyzed for moisture and fat. The sensor output during syneresis at each sampling point was shown to have a significant relationship with curd moisture and whey fat content ($P < 0.001$). The rate of change of the optical sensor response was also significantly ($P < 0.01$) correlated with the kinetic rate constants for changes in curd moisture and whey fat content during syneresis. In conclusion, these results showed that light backscatter measured during syneresis was sensitive to physicochemical changes resulting from curd shrinkage and provided information required for curd moisture content control. This optical technique has the potential to be developed as a unique sensor for monitoring syneresis, providing a key enabling technology for improving process control during cheese manufacture.

Key Words: Light Backscatter, Syneresis, Curd Shrinkage

78 Impact of different curd-washing methods on the insoluble Ca content and rheological properties of Colby cheese. M.-R. Lee*[1], M. E. Johnson[2], S. Govindasamy-Lucey[2], J. Jaeggi[2], and J. A. Lucey[1], [1]*University of Wisconsin*, *Madison*, [2]*Center for Dairy Research*, *Madison, WI*.

A curd-washing step is used in the manufacture of some cheese varieties (e.g. Colby) to decrease the residual lactose content and to reduce the formation of lactic acid during ripening. Curd washing

may also alter the levels of Ca, which may influence cheese rheology. The objective of this study was to investigate the impact of different washing methods on the Ca equilibrium and rheological properties of Colby cheese. Four different methods of curd-washing were performed including batch washing (BW) where water (10°C) was added to the vat, with and without stirring, where curds were in contact with water for 5 min. The other method used was continuous washing (CW), with or without stirring, where curds were rinsed with continuously running water for ~15 min and water was allowed to drain immediately. The rate of acid development during manufacturing was similar in all 4 treatments. The insoluble (INSOL) Ca content of cheese was measured by cheese juice method and rheological properties were measured by small amplitude oscillatory rheology. The levels of lactose in cheese at 1 d were significantly ($P<0.05$) higher in both CW cheeses (0.08%) than in both BW cheeses (0.02%). The levels of lactic acid at 2 and 12 wk were significantly ($P<0.05$) higher in both types of CW cheese compared with both BW cheeses. The INSOL Ca content of all cheeses decreased during the first 4 wk and this occurred concomitantly with an increase in cheese pH from 5.1 to 5.4. The INSOL Ca content of cheese during ripening was significantly ($P<0.01$) affected by washing method but not by stirring. The INSOL Ca content of BW cheeses was significantly higher ($P<0.05$) than that of CW cheeses at all time points during the first mo. At 1 d and 1 wk of ripening the maximum loss tangent values during heating of cheese were significantly higher ($P<0.05$) in CW cheeses compared to BW cheeses. In conclusion, different curd washing methods had a significant impact on the levels of lactose, lactic acid, INSOL Ca and meltability of Colby-type cheese during ripening.

Key Words: INSOL Ca, Curd Washing, Cheese Meltability

79 Preference mapping of commercial strawberry drinkable yogurt among African-American, Caucasian and Hispanic consumers. J. L. Thompson*, K. Lopetcharat, and M. A. Drake, *North Carolina State University*, *Raleigh*.

The drinkable yogurt marketplace is a competitive and growing category in the dairy industry. Drinkable yogurts vary widely in flavor, variety, texture, and other sensory properties. Understanding these sensory differences is critical for understanding the product and ultimately consumer preference. Little is known about differences in preference among Caucasian, African-American, and Hispanic consumers within the United States. The objective of this study was to identify and define the sensory characteristics of commercial drinkable yogurts and identify consumer preferences among Caucasian, African-American, and Hispanic consumers in the United States. Focus groups with each ethnic group (3 groups/ethnicity) were conducted to gain insight into perceptions of drinkable yogurts. A descriptive sensory language was developed to document the sensory properties (visual, flavor, and mouthfeel) of strawberry drinkable yogurts. Thirteen commercial products (strawberry flavor) were evaluated by a trained panel using the sensory language. Five representative yogurts were chosen for consumer testing by African-American (n=83), Caucasian (n=88) and Hispanic (n=88) consumers. Univariate and multivariate analyses were conducted to identify differences in product liking among the consumer groups. Drinkable yogurts were differentiated by descriptive analysis in visual, flavor and mouthfeel attributes ($p<0.001$). Three distinct clusters of consumers were identified and ethnic membership within the clusters was distinct ($p<0.05$). Key drivers for all three consumer clusters were natural fruit flavor and sweet taste. The impact of changes in these attributes on liking differentiated two of the three consumer clusters while the third consumer cluster was characterized by these attributes along with other fruit flavors, artificial sweetener, and color intensity as key drivers. Acceptability varied widely among consumers and consumer ethnicities and drinkable yogurts with specific flavor and physical properties could be marketed to specific target market segments.

Key Words: Drinkable Yogurts, Preference Mapping, Sensory Analysis

80 Classification of cheddar cheese based on flavor quality using Fourier transform infrared spectroscopy. A. Subramanian*, J.W. Harper, and L.E. Rodriguez-Saona, *The Ohio State University*, *Columbus*.

Flavor quality of cheddar cheese significantly influences its acceptance and price. Cheese flavor is directly affected by the changes that occur during maturation. Cheese flavor is currently determined using trained sensory panels. This process is time consuming and very expensive. Hence there is a need for rapid and simple instrumental methods. Fourier transform Infrared (FT-IR) spectroscopy, which monitors the light absorbing properties of chemical compounds, combined with an efficient sample preparation method, can be used as a rapid, inexpensive, and sensitive method to analyze cheese flavor. The objective of this research was to develop a sample preparation method and FT-IR technique to rapidly predict flavor quality of cheddar cheese. Fifteen cheddar cheese samples obtained from a local manufacturer were ground into powders using liquid nitrogen. The water-soluble compounds from the cheese powder, without interfering compounds such as fat and protein, were extracted using water and organic solvents. Aliquots (10 μL) of the extract were placed onto a FT-IR sample crystal, dried and scanned in the spectrometer (4000 to 700 cm^{-1}). The spectra were matched with the flavor quality to build multivariate classification models. The developed extraction method yielded extracts, whose FT-IR spectra were highly consistent within each sample and distinct from other samples. The multivariate model showed a 3D plot in which all the 15 cheese samples formed well separated clusters. The orientation of the clusters in 3D space correlated well with the cheese flavor. All the cheese samples could be classified based on their flavor quality attributes (fermented, unclean, low flavor, sour, good cheddar, etc.). The discrimination of the samples was due to organic and fatty acids and their esters (1500 to 900 cm^{-1}), which are known to contribute significantly to cheese flavor. The total analysis time, including the sample preparation time, was less than 20 min per cheese sample. This technique can be a rapid, inexpensive, high-throughput and simple tool to the cheese industry for predicting the flavor quality of cheese.

Key Words: Cheddar Cheese, Flavor, Infrared Spectroscopy

81 Perfusing egg yolk antibodies in enterotoxigenic *Escherichia coli* K88 infected piglet jejunal segments reduces fluid and electrolyte losses. E. Kiarie*, B. A. Slominski, D. O. Krause, and C. M. Nyachoti, *University of Manitoba*, *Winnipeg, MB, Canada*.

Effects of anti-K88 egg yolk antibodies (EYA) on fluid and electrolyte losses were studied using an *in situ* model of secretory diarrhea in which jejunal segments of 4 anaesthetized piglets were infected with enterotoxigenic *E. coli* K88 (ETEC) and perfused with either EYA or conventional anti-diarrhea agents carbadox (C), zinc oxide (ZO) and fumaric acid (FA). Pigs were weaned at 21 d of age and fed a commercial starter diet for 7 d. In each pig, the first segment (20 cm) was prepared at 300 cm caudal from the stomach and fitted with inflow and outflow PVC tubing at cranial and caudal sites, respectively. Caudal from and adjacent to the first segment 9 other segments were similarly prepared to give a total of 10 segments per pig. Treatments in deionized water suspension were: FA (20 mg/l), ZO (3 g/l), C (55 mg/l), EYA (5 g/l), with saline (S) as a control. In each piglet, a pair of segments (1 non-infected and the other ETEC-infected) were perfused simultaneously with 60 mL of each treatment at 4 mL for every 30 min for a total of 7.5 h. Outflow contents were collected; 2h after the last perfusion, solutions remaining in the segments were emptied into respective containers and then the pig was killed. Net fluid and electrolyte absorption were calculated from the difference between the volume and concentration of inflow and outflow divided by the surface area of each segment. Net loss was calculated as the difference between net absorption in non-infected and infected segments. ETEC infection reduced ($P < 0.05$) fluid absorption in S perfused segments (105 ± 12 µl/cm^2) compared with segments perfused with EYA (760 ± 64 µl/cm^2) C (605 ± 53 µl/cm^2), ZO (624 ± 61 µl/cm^2) and FA (298 ± 34 µl/cm^2). High ($P < 0.05$) Na and Cl losses were observed in ETEC-infected segments perfused with S, FA and ZO compared with those perfused with EYA and C. In conclusion, EYA enhanced fluid absorption and protected against electrolyte losses in piglets challenged with ETEC.

Key Words: Egg Yolk Antibodies, Enterotoxigenic *E. coli*, Piglet

82 Dietary addition of mannobiose, beta glucan, or mannan-oligosaccharides on growth performance and immune response in early-weaned pigs raised at two locations. Y. Han*[1], J. J. Brennan[1], and M. Vignola[2], [1]*Maple Leaf Foods Agresearch*, *Guelph, Ontario, Canada*, [2]*Maple Leaf Foods Agresearch*, *St-Romuald, Quebec, Canada*.

A two-location trial was conducted in early-weaned pigs to study the influence of dietary mannobiose, yeast beta glucan, or mannan-oligosaccharides (MOS) on growth performance and response to *Mycoplasma hyopneumoniae* (MH) vaccine. A total of 960 17 to 21-d-old piglets were used in a complete randomized block design with 192 (8 blocks of 4 pens, 6 pigs/pen) and 768 (12 blocks of 4 pens, 16 pigs/pen) in Ontario and Quebec, respectively. After weaning, pigs were immediately given the experimental diets for 21 d following three-phase feeding programs. At the Ontario location, a MH vaccine was administered at weaning. Throughout Phase 1-3 the basal medicated diet was supplemented with 40ppm mannobiose, 60ppm yeast beta glucan, or 2000ppm MOS. The trial duration was 40 and 42 days for Ontario and Quebec locations, respectively. On d 21 and 35, blood samples were taken from the Ontario pigs for determination of serum MH antibody titres. Main and interactive effects of Diet, Location and Block were analyzed by ANOVA with Block nested within Location and weaning BW as a covariate. Dietary mannobiose significantly improved cumulative feed efficiency by 2.5% by Week 3 ($P<0.033$), 1.6% by Week 5 ($P<0.044$), and 1.6% by end of the experiment ($P<0.033$). None of the additives improved growth ($P>0.05$). Beta-glucan increased MH vaccine antibody titres in pigs in comparison to those fed MOS. It was concluded that mannobiose was a cost-effective feed additive in medicated starter pig diets and that its effect persisted post-withdrawal. The immunostimulatory effect of yeast beta glucan did not impact animal performance.

Key Words: Early-Weaned Pigs, Mannobiose, Growth Performance

83 Evaluation of plant materials for alternative adhesion of *E. coli* K88 (ETEC) in weaning pigs. R. Maiorano*[1,2], A. W. Jongbloed[1], C. M. F. Wagenaars[1], P. G. Van Wikselaar[1], and P. M. Becker[1], [1]*Animal Sciences Group*, *Lelystad, The Netherlands*, [2]*University of Milan*, *Milan, Italy*.

Specific carbohydrates in some plant materials can function as alternative adhesion matrices for e.g. *E. coli* K88 (ETEC). *In vitro* studies in our lab revealed the efficacy of several plant materials with respect to their binding capacity of various pathogenic GI bacteria. We validated the *in vitro* studies by evaluating the effect of 4 additives, yeast product (Tr II), SW7 (Tr III), SW11 (Tr IV) and sesame seed expeller (Tr V) compared to a negative control (Tr I), on *E. coli* K88 faecal shedding of post-weaning piglets challenged with *E. coli* K88. Pigs (n=72) weaned at 28 to 35 d of age with an initial BW of 7.0 ± 0.18 kg were individually allocated in 72 pens. On d 7 after the weaning, the piglets were orally infected twice with a suspension of 5×10^9 cfu/ml *E. coli* 0149K91$^+$K88ac. Individual BW was noted on the weaning day (d 1), d 6, 13, and on d 22. Feed intake (FI) and faecal consistency scores (FCS) were registered daily. Faecal samples were collected from all the pigs for 8 consecutive days after the challenge to quantify ETEC. There was a depression in FI on d 9 and 10 with all treatments. This drop was largest with treatment I and smallest with treatments II, IV and V. At d 3 post-inoculation, groups II and V showed a significantly lower concentration of faecal *E. coli* K88 compared to group I and IV ($P< 0.03$). From d 4 to d 6 after the inoculation, treatments II and V significantly reduced the *E. coli* faecal count compared to groups I, III and IV ($P<0.05$). From d 6 to 12, group II revealed a significantly better FCS than groups I and IV. These results show clear evidence of the efficacy of the yeast product, sesame seed expeller and to a lesser extent SW 7 to decrease *E. coli* K88 faecal shedding. *In vitro* predictions about the efficacy of different plant materials in inhibiting *E. coli* K88 proliferation were confirmed by the *in vivo* trial.

Key Words: Plant Materials, *E. coli* K88, Piglet

84 Effect of fermentable carbohydrates on the intestinal microbial ecosystem in growing pigs fed low-P diets. B. U. Metzler*[1], W. Vahjen[2], T. Baumgärtel[3], M. Rodehutscord[3], and R. Mosenthin[1], [1]*Institute of Animal Nutrition, University of Hohenheim*, *Stuttgart, Germany*, [2]*Institute of Animal Nutrition, Free University of Berlin*, *Berlin, Germany*, [3]*Institute of Agricultural and Nutritional*

Sciences, Martin-Luther-University Halle-Wittenberg, *Halle (Saale), Germany*.

To determine the effects of differently fermentable carbohydrates on species composition and diversity of intestinal bacteria in pigs, 8 barrows (mean BW 35.9±0.9 kg), fitted with a simple-T-cannula at the distal ileum, were used in a double incomplete 4x3 Latin square design with 4 diets and 3 periods. Dietary treatments consisted of a low-P corn-soybean meal-based control diet or 75% of the control diet and 25% of cellulose, starch and pectin, respectively. After 15d adaptation to the experimental diets, rectal samples of feces were taken during 5d for bacterial DNA determination. Afterwards, ileal digesta were collected for bacterial DNA determination over two periods of 12h each. Quantitative realtime PCR and denaturing gradient gel electrophoresis (DGGE) was applied to specify total bacterial populations both in ileal digesta and feces as well as bacterial diversity and populations of specific bacterial groups in the ileum. Total ileal and fecal bacterial populations were not affected by dietary treatment but there were specific changes in the composition of the ileal microflora. Starch stimulated the population of lactobacilli ($P<0.05$), while cellulose stimulated the growth of bifidobacteria ($P<0.05$) compared to the control. Pectin tended to promote the growth of Bacteroides-like bacteria ($P<0.1$). The bacterial diversity at the distal ileum was affected by the carbohydrates as indicated by the different DGGE band numbers ($P<0.05$). Cellulose and starch inclusion caused a higher bacterial diversity, while pectin reduced it ($P<0.05$) compared to the control. These data suggest that the ileal microbiota is sensible to changes in the carbohydrate composition of the diet which is reflected in changes in the microbial community and diversity at the distal ileum.

Key Words: Fermentable Carbohydrates, Bacteria, Pigs

85 Effect of lactoferrin on the growth performance, intestinal morphology, immune function and serum iron level of weaned piglets. Y. Z. Wang*, T. Z. Shan, J. X. Liu, and Z. R. Xu, *Zhejiang University*, *Hangzhou, Zhejiang, China*.

A total of 90 weanling female pigs (Duroc×Landrace×Yorkshire) were used in a 30-d growth experiment to investigate the effect of lactoferrin on growth performance, intestinal microflora and intestinal morphology, immune functions and serum iron levels. The pigs were allocated on the basis of BW and litter to 3 dietary treatments in a randomized complete block design. The dietary treatments were: control group (basal diet), antibiotics group (basal diet + 20 mg/kg flavomycin +110 mg/kg aureomycin) and lactoferrin group (basal diet + 1.0 g/kg lactoferrin). There were 3 replicate pens per treatment and pigs were grouped with 10 pigs per pen. Six pigs, randomly selected from each treatment (2 pigs/pen) were slaughtered for serum and spleen samples on d 30. The results showed that supplementation with lactoferrin significantly increased the ADG by 34.04% ($P<0.01$) and decreased feed efficiency (F/G) by 12.83% ($P < 0.05$), increased the villus height ($P<0.01$) and lowered crypt depth ($P<0.05$) at the small intestinal mucosa as compared with the control. Supplementation with lactoferrin improved the PHA stimulated peripheral lymphocyte proliferation by 47.19% ($P<0.01$), increased both ConA and PHA-induced spleen lymphocyte proliferation by 116.90% ($P<0.01$) and 89.08% ($P<0.01$), enhanced the serum IgG by 10.99% ($P<0.05$), IgA by 20.00% ($P<0.05$) and IgM by 12.64% ($P<0.05$), IL-2 by 46.64% ($P<0.01$) and serum iron values by 25.79% ($P<0.05$) respectively. Compared with the antibiotic group, supplemental LF also improved PHA stimulated peripheral lymphocyte proliferation by 19.30% ($P<0.05$), increased both ConA and PHA-induced spleen lymphocyte proliferation by 68.23% ($P<0.051$) and 61.10% ($P<0.05$), enhanced the serum IgM by 11.36% ($P<0.05$), IL-2 by 36.26% ($P<0.05$). These results support the possible use lactoferrin as an immunostimulant to improve immune functions and strengthen host defenses would be a good method for defending weanling piglets from infections and weanling stress.

Key Words: Lactoferrin, Weanling Piglet, Growth Performance

86 Effects of adding saturated fat to diets with sorghum-based distillers dried grains with solubles on growth performance and carcass characteristics in finishing pigs. C. Feoli*[1], S. Issa[1], J. D. Hancock[1], T. L. Gugle[1], S. D. Carter[2], and N. A. Cole[3], [1]*Kansas State University*, *Manhattan*, [2]*Oklahoma State University*, *Stillwater*, [3]*USDA/ARS*, *Bushland, TX*.

A total of 112 barrows (avg BW of 72 kg) was used in a 65-d growth assay to determine the effects of adding a source of saturated fat (beef tallow) into diets with sorghum-based distillers dried grains with solubles (DDGS). The pigs were sorted by ancestry and blocked by BW with seven pigs/pen and four pens/treatment. Treatments were a corn-soybean meal-based control and diets having 40% DDGS (US Energy Partners, Russell, KS) with none, 2.5, and 5% added tallow. Feed and water were consumed on an ad libitum basis until the pigs were slaughtered (avg BW of 130 kg) to allow collection of carcass data and jowl samples. Fatty acid composition of the jowl samples was used to calculate iodine value (IV) as an indicator of carcass firmness. The corn-soy control supported greater ADG ($P < 0.03$) and ADFI ($P < 0.001$) with no difference in G:F ($P > 0.32$) compared to the DDGS treatments. Increasing fat additions from none to 5% in diets with DDGS did not affect ADG ($P > 0.69$) but improved G:F (linear effect, $P < 0.02$) by 10%. Hot carcass weight (linear increase, $P < 0.05$), dressing percentage (linear increase, $P < 0.06$), and last rib backfat thickness (linear decrease, $P < 0.04$) responded positively as fat addition to the diets was increased from none to 5%. However, changes in IV suggested deposition of softer fat in pigs fed DDGS ($P < 0.001$) even when saturated fat was added to the diet. For the control, DDGS + no tallow, DDGS + 2.5% tallow, and DDGS + 5% tallow, ADG was 961, 885, 877, and 894 g/d, ADFI was 3.3, 3.2, 2.9, and 2.9 kg/d, G:F was 291, 277, 302, and 308 g/kg, hot carcass weight was 93, 90, 91, and 92 kg, dressing percentage was 71, 69, 69, and 71%, last rib backfat thickness was 19, 20, 18, and 18 mm, and IV was 68, 72, 73, and 74, respectively. Adding beef tallow to diets with DDGS improved efficiency of growth and several carcass measurements but resulted in less saturated carcass fat.

Key Words: Distillers Dried Grains, Iodine Value, Pig

87 Effect of feeding fermented soybean meal on plasma concentration of cortisol in LPS-challenged nursery pigs. D. A. Monson*[1], J. A. Carroll[2], R. D. Mateo[1], and S. W. Kim[1], [1]*Texas Tech University*, *Lubbock*, [2]*USDA-ARS-Livestock Lissues Research Unit*, *Lubbock, TX, USA*.

The objective of the present study was to determine if feeding nursery pigs diets containing either plasma protein (PP) or fermented soybean meal (FSBM) would alter the overall stress response to a lipopolysaccharide (LPS) challenge as indicated by plasma concentrations of

cortisol. Pigs (n=24) were weaned at d 21 of age and allotted to 3 dietary treatment groups: (1) CON (diet containing no PP or FSBM), (2) FS (diet with 10% FSBM), and (3) PP (diet with 7% PP). All the diets contained 33% corn, 3% fish meal, 25% dried whey, 0.5% salt, and 4% vitamin-mineral premix. Inclusion of PP and FSBM was done by replacing 11% of soybean meal. Crystalline amino acids were added to match amino acid contents among the diets. Vegetable oils and corn starch was added to match the ME contents among the treatment diets. Pigs were housed individually and fed the experimental diets for 15 d. Each treatment consisted of 8 replicates. Weight gain and feed intake of individual pigs were measured during the 15 d period. On d 14, all the pigs were non-surgically fitted with indwelling jugular vein catheters. On d 15, all pigs were administered a dose of LPS (25 μg/kg BW) via the jugular vein catheter. The ADG was 130.3, 139.0, and 158.5 g for CON, FSBM, and PP, respectively but did not differ (P>0.05) among the treatments. The ADFI of PP (235.9 g) was greater (P<0.05) than CON (182.9 g) and FSBM (198.0 g). Blood samples (3 mL) were collected over a 6-h period at 30-min intervals (from 1-h pre- to 5-h post-LPS challenge) to determine plasma concentrations of cortisol. Plasma concentrations of cortisol in the FS pigs tended to be lower (P<0.10) than those of CON pigs at 30 (58 and 77 ng/mL for FS and CON, respectively), 210 (139 and 180), 270 (100 and 155), and 300 (89 and 132) min after LPS challenge. Collectively, these data indicate that pigs fed a diet containing fermented soybean meal tended to handle the immune stress better than the other groups.

88 The effect of different levels of dietary mannan-oligosaccharide on specific cellular and humoral immune response in weaned piglets. I. Nochta*[1], T. Tuboly[2], V. Halas[3], and L. Babinszky[3], [1]*AGROKOMPLEX C.S.Z.R.T.*, *Zichyújfalu, Hungary*, [2]*Szent István University*, *Budapest, Hungary*, [3]*University of Kaposvár*, *Kaposvár, Hungary*.

Recently mannan-oligosaccharide (MOS) has been considered as a potential growth promoter due to its mode of action beneficially modifying the intestinal microflora and the immune status. Our trial objective was to study how different levels of dietary MOS effect the specific humoral and cellular immune response of weaned pigs. A total of 58 individually kept castrated piglets weaned at 28 d of age were used in two trial series. At 35 d of age 48 piglets were randomly allocated among dietary treatments [commercial piglet diet with 0; 1; 2 and 4g/kg AgriMos (yeast cell wall derivate MOS) or 0.2 g/kg Maxus-G (containing avilamycin; AB)] and immunized with an inactivated Aujeszky′s virus vaccine at day 0 and 14 of the trial. The remaining pigs were not immunized (NI) and given no supplement. All piglets were blood sampled weekly for 5 wk. Systemic humoral and cellular immune response was evaluated by a virus neutralization test and a lymphocyte stimulation test (LST) with Aujeszky mitogen, respectively. Statistical analysis was performed with ANOVA (SAS, 2004). Replication had no effect and according to the 2nd week results, the specific humoral response of pigs fed 1 g/kg MOS was better (3.37 vs. 1.92) than that in the other groups (P<0.0001). The effect of MOS on cellular immune response is shown in Table 1. To conclude, MOS has a dose response effect, and AgriMos at 1 g/kg was beneficial on the specific immune response of weaned pigs after 2 weeks. An earlier, stronger immune response directly after weaning is important in commercial conditions.

Table 1. The effect of MOS supplementation on LST with Aujeszky mitogen (log_2) in weaned piglets

	AgriMos (g/kg)

89 Dietary supplementation with the Lactobacillus pentosus and/or inulin influences pH and volatile fatty acid characteristics in the colon. Z. McHugh, T. Sweeney, J. J. Callan, M. Ryan, and J. V. O'Doherty*, *University College Dublin*, *Ireland*.

Our objective was to investigate the effects of probiotic inclusion (Lactobacillus pentosus) and/or inulin on nutrient digestibility, nitrogen excretion, volatile fatty acids, gut microflora and in vitro ammonia emissions from finishing pigs. Sixteen boars (65 kg) were assigned to one of four dietary treatments as follows: (T1) wheat based diet; (T2) wheat based diet + 12.5 g/kg inulin; (T3) wheat based diet + 2.5 $times; 1010 CFU Lactobacillus (L) pentosus and (T4) wheat based diet + 12.5 g/kg inulin + 2.5 × 1010 CFU L. pentosus. Feed intake, nitrogen intake, coefficient of total tract apparent digestibility of nitrogen, dry matter, organic matter, ash, neutral detergent fibre (NDF), gross energy and nitrogen balance parameters were similar between treatment groups. Similarly there were no differences in manure volume, faeces:urine ratio and NH3-N per gram of N intake between treatments. Pigs offered diets containing L. Pentosus had a higher proportion of acetic acid in the caecum (P<0.05), a lower proportion of propionic acid in the colon (P<0.001), a higher proportion of isobutyric acid (P<0.001), a higher proportion of isovaleric acid (P<0.01) and a higher colon pH (P<0.01) than pigs offered diets without L. Pentosus. Pigs offered diets containing inulin had a higher proportion of butyric acid in the colon (P<0.05) than pigs offered diets containing no inulin. In conclusion, the inclusion of 2.5 x 1010 CFU L. Pentosus in the pig diet increased the proportion of branched chain fatty acids in the colon and increased colon pH suggesting that it could have a negative impact on environmental odour emissions, while the inclusion of inulin increased the proportion of butyric acid in the colon which has a beneficial health potential.

Key Words: Lactobacillus Pentosus, Inulin, Pigs

90 Response of nursery pigs to a synbiotic based on starch (prebiotic) and an anti-*Escherichia coli* K88 colicinogenic probiotic. S. K. Bhandari*, A. Setia, D. O. Krause, and C. M. Nyachoti, *University of Manitoba*, *Winnipeg, MB, Canada*.

Probiotics are live or dead microbial cultures that provide a benefit to the gut, whereas prebiotics are carbohydrates that selectively enhance proliferation of beneficial microbial populations. Synbiotics are combinations of probiotics and prebiotics that act synergistically. The objective of the present study was to design an *E. coli*-based colicinogenic probiotic that selectively inhibits pathogenic *E. coli* K88

in the presence of starch (prebiotic), and to evaluate its efficacy in an *in vitro* competition and in an *in vivo* piglet growth assay. From 463 environmental strains of *E. coli*, two strains (UM-2 and UM-7) with enhanced colicinogenic properties and rapid growth on starch were selected. Results of *in vitro* competition assays revealed that UM-2 and UM-7 suppressed *E. coli* K88 growth in the presence of starch. In the *in vivo* assay, 40 piglets with an initial BW of 4.82 ± 0.6 kg were assigned to 4 wheat-soybean meal-based diets consisting of a control with an antibiotic (C) and three diets with no antibiotics but containing UM-2 and UM-7 as the probiotics (PRO), 14% potato starch (PS), or a combination of 14% potato starch and probiotics (PRO-PS). PRO and PRO-PS diets were prepared each morning by mixing 50 ml of 9 x 10^{10} cfu/ml overnight probiotic cultures with fresh feed. Pigs were adapted to experimental diets from d 1 to 7. On d 8, pigs were orally inoculated with a 6 ml dose of 2 x 10^9 cfu/ml *E. coli* K88. ADFI, ADG, gain:feed ratio and fecal consistency scores (FCS) were monitored. ADFI and ADG before and after *E. coli* K88 infection were higher for the PRO-PS treatment compared with the other dietary treatments ($P < 0.05$). Gain:feed ratio was higher ($P < 0.05$) for the PRO-PS diet than C diet before infection and was similar to the C treatment after infection. PRO-PS and C fed piglets had a lower FCS ($P < 0.05$) than the PS and PRO fed piglets. In conclusion, colicinogenic probiotics and potato starch acted synergistically to reduce the negative effects of *E. coli* K88 infection in piglets.

Key Words: Pigs, Probiotics, *E. coli* K88

91 Dosage and efficacy of a novel *Saccharomyces cerevisiae* strain to enhance piglets productivity. M. Lucero P*[4,1], G. E. Lanz A[4,1], A. A. Martinez A[2], and J. A. Cuaron I[3], [1]*PAIEPEME A.C.*, *Querétaro, México*, [2]*CNID-Microbiología*, *México*, [3]*CNID-Fisiología Animal, INIFAP*, *Queretaro, México*, [4]*FESC UNAM*, *Ajuchitlan, Queretaro, Mexico*.

An advantage of using yeast as a probiotic is that as an eucariotic is compatible with antibiotherapies, Use of live yeast in piglets feed is an effective ADG enhancer (40 a 60 g) as long as *Saccharomyces cerevisiae* (SC) is from known effective strains, viable in the intestine and at doses greater than 8×10^9 cfu/g of product, or, a least, 1×10^7 cfu/g of feed, but some authors will defend effectiveness based on the immune–stimulant potential of the cell wall. This novel strain of yeast (Biocel) is of interest because the cell size (20×10^9 cfu/g) is about 50% of a normal SC, thus cell wall concentration is potentially doubled. An experiment using 600 piglets (a total of 60 experimental units) was conducted, from 10.19 ± 2.96 kg of initial weight during 5 weeks to measure growth performance effects of 5 yeast inclusion levels: 0, 0.25, 0.5, 1.0 and 2 kg/MT. The experiment was a Randomized Complete Block (2 nurseries) design. No differences ($P\geq0.33$) were detected in feed intake (0.75±0.142), morbidity or mortality (12.45±3.45) but, noted after 28 days, Biocel quadratically increased ($P\leq0.01$) ADG (380, 400 440, 470 and 460, SEM = 15.6 g) and feed efficiency (500, 530, 610 600 and 600, SEM = 15.86 g/kg). The inflection point of the curve showed that most effective levels of Biocel are between 1.25 y 1.50 kg/MT of feed (2.5 to 3×10^7 cfu/g).

Key Words: Yeast, Piglets, Saccharomyces Cerevisiae

92 Strategies for enhancing microbiological gut's barrier: BMD y BioPlus 2B. D. Munoz V*[1], G. E. Lanz A[1], M. Lucero P[1], A. Soria F[1], J. A. Renteria F[3], J. A. Cuaron I[3], S. Correa N[4], and S. Martinez[2], [1]*Paiepeme, A.C.*, *Queretaro, Mexico*, [2]*Alpharma*, *Mexico*, [3]*Fisiología Animal, INIFAP*, *Queretaro, Mexico*, [4]*Synbios*, *Mexico*.

The aim of this experiment was evaluating 2 strategies for clostridium control: a non absorbable antibiotic, bacitracine (BMD 0.3 kg/Mt), and a bacterial probiotic, BioPlus 2B (BP2B 0.5 kg/Mt), in finishing pigs. A total of 1125 pigs (half gilts and barrows) were used. Pigs were allotted in 56 pens, considering each pen as an experimental unit. Pigs were offered a single diet, containing therapeutical levels of antibiotic (AB) for respiratory diseases prevention (Clortetracicline 2 kg/Mt)). Treatments (TRT) were: 1) NEGCON, 2) BMD (first 21d), 3) BP2B (first 21d), 4) BMD + BP2B (first 21d). From day 22 to 41 AB was withdrawed from all diets and at day 42, experimental units were divided to form three new treatment: 5) AB + BMD, 6) AB + BP2B, and 7) AB + BMD + BP2B (each treatment with 8 experimental units) until day 84. Pigs were weighed every 21 days, ADFI, ADG, and Gain:Feed were estimated weekly. Feces samples were collected every feeding phase change for total anaerobians, coliforms, and salmonella counts. Mortality and its causes were registered the day they happened. After 84 d on trial there was a difference ($P\leq0.05$) on ADFI, BMD or BP2B pigs were better than CON; for ADG there was an interaction ($P\leq0.03$) between BMD and BP2P compared to CON pigs; there were no differences ($P\geq0.05$) between treatments for Gain:Feed. When AB was added to the diets, growth performance was improved (ADFI, 2.8 vs. 2.1 kg/day; ADG, 0.874 vs. 0.778 kg/day; Gain:Feed, 0.439 vs. 0.406 kg/day; $P\leq0.02$). There were no differences ($P\geq0.05$) in total coliforms, anaerobians or salmonella counts in feces. A few clostridium deaths were presented but were not associated to TRT. Combining the use of BMD and BP2B may help prevent clostridium infection and improve growth performance, thus the use of a therapeutical AB may enhance the effects of obtained by the other 2 products.

Nonruminant Nutrition: Poultry Nutrition - Protein and Amino Acids

93 Ileal amino acid digestibility of protein feed ingredients at 5 and 21 days of age by broiler chickens. J. M. Rynsburger*[1], D Hoehler[2], and H. L. Classen[1], [1]*University of Saskatchewan*, *Saskatoon, SK, Canada*, [2]*Degussa Corporation*, *Kennesaw, GA*.

The amino acid (AA) digestibility of feed ingredients by broiler chickens has most often been determined using older birds. However, these values are unlikely to predict AA digestibility in chicks during the initial period post-hatch because of their immature digestive tracts and lower nutrient utilization. Therefore, the objective of this research was to compare the ileal AA digestibility of selected protein sources using 5 and 21 d old broilers. Twenty two Ross x Ross 308 broilers were randomly assigned to eight battery cages per treatment. After sampling on d 5, remaining birds for 21 d sampling were distributed into 6 replicates of 7 birds. A 2 x 6 factorial arrangement was used to examine the effect of age on the ileal AA digestibility of six protein feed ingredients. Ingredients examined included canola meal, a canola protein concentrate, fishmeal, meat meal, peas and soybean meal. Diets were formulated to derive crude protein (approximately 18%) and

AAs solely from the test ingredient. AA digestibility was higher for 21 d old broilers than their 5 d old counterparts for most ingredients. Exceptions were all the AA digestibilities for soybean meal and the digestibility of CYS, MET + CYS, THR, ARG, VAL, HIS, GLY, SER, ALA and ASP for fish meal, which did not change significantly with age. The age-associated improvement in digestibility was highly variable and dependent on feed ingredient and amino acid with the percentage improvement ranging from -1.6 to 169%. In conclusion, ileal AA digestibility generally improves with age between 5 and 21 d of age but the response to age differs among ingredients and AAs. Therefore, accurate formulation of starter diets requires the use of AA digestibility values obtained in age-appropriate birds to ensure that diets meet AA requirements of broiler chicks for growth and other performance criteria.

Key Words: Chick, Ileal Amino Acid Digestibility, Protein

94 Effects of a reduction of dietary crude protein on performance and economics in commercial Ross 708 broilers. E. A. Guaiume*[1], J. D. Firman[1], D. Hoehler[2], P. B. Tillman[3], D. Burnham[4], J. Parcell[1], L. B. Linares[1], and A. Kamyab[1], [1]*University of Missouri*, *Columbia*, [2]*Degussa Corporation*, *Kennesaw, GA*, [3]*Ajinomoto Heartland LLC*, *Chicago, IL*, [4]*Aviagen Inc.*, *Huntsville, AL*.

A study was conducted to determine the effects of reduced dietary crude protein (CP) on biological and financial performance of Ross 708 broilers fed from hatch to week 8. 1440 straight-run broiler chicks were randomly assigned to 4 treatments with 12 replicate pens containing 30 birds each. Diets were formulated to be isocaloric and to have the minimum digestible level for lysine (Lys), and the same minimum ideal amino acid ratios to lysine for total sulfur amino acids (TSAA) and threonine (Thr) across the four phases [starter (0-2wks), grower (2-4wks), finisher (4-6½wks), and withdrawal (6½-8wks)]. An industry standard diet served as the control (CT). The remainder of the treatments (CT-0.7%, CT-1.4%, and CT-2.1%) had CP reduced in 0.7% increments. Birds were weighed at 2, 4, 6½, and 8 weeks of age for feed to gain calculation. At week 8, 4 birds per pen (48/trt) were sacrificed and had fat pad and carcass weighed, and carcass and meat yield determined. Feed cost savings (FCS) per metric ton (MT) of carcass, FCS/MT breast meat, income over feed cost/MT carcass, and income over feed cost/MT breast meat, were calculated. Treatments had no effect (P>.05) on performance throughout the 8-week period. There was a linear increase (P<.05) in fat pad as CP decreased. Treatments had no effect on carcass yield (P>.05); however, there was a linear decrease (P<.05) in breast meat yield as CP decreased. For carcass, relative to CT, FCS was $5.59/MT when CT-2.1% was fed; and for breast meat, FCS was $5.78 for CT-0.7%; $11.57 for CT-1.4%. However, when CT-2.1% was fed, there was an increase in feed costs ($14.07) per MT of breast meat when compared to CT. Overall, these results suggested a decrease of CP by 2.1%, as compared with industry standards, did not affect performance and carcass yield, but it decreased breast meat yield when CT-2.1% was fed.

Key Words: Low Crude Protein, Ross 708, Economics

95 Effects of dietary protein concentration and age on gut morphology, crude mucin, and sialic acid contents of ileal digesta of turkey poults. S. A. Adedokun*, D. M. Karcher, and T. J. Applegate, *Purdue University*, *West Lafayette, IN*.

The determination of the effects of age and dietary crude protein (DCP) concentration on factors contributing to the amount of amino acids of endogenous origin is important. The effects of DCP on crude mucin (CM), sialic acid (SA), and rate of gut turnover in turkey poults were measured at d 5 and d 21. Poults were fed a nitrogen-free diet (NFD), a diet containing 10% casein (completely digestible protein, CDP), and a corn-soybean meal (C-SBM) based diet. Each diet was fed to four replicate pens containing 60 and 12 birds which were sampled on d 5 and d 21, respectively. Crude mucin and SA (d 5 and d 21: n=4) contents as well as goblet cell number (GCN), villi height (VH), crypt depth (CD), and the ratio of GCN:VH (d 5 and d 21, n = 16 and 12, respectively) were determined. The amount of CM and SA (g/100 g of dry digesta) on d 5 was higher ($P < 0.05$) than on d 21 (NFD) but there was no difference in both CM and SA when CDP diet was fed. The C-SBM diet resulted in a higher ($P < 0.05$) CM concentration on d 5 than d 21 but the SA content was not different between the two ages. For all the dietary treatments, values for GCN, VH, and CD were higher ($P < 0.05$) on d 21 than on d 5. However, the GCN:VH for birds fed the NFD was 18% or 27% lower that birds fed the CDP or C-SBM diets, respectively. Therefore, previous results showing higher endogenous amino acid losses on d 5 relative to d 21 (NFD) could be attributed to higher CM and SA production.

Key Words: Goblet Cell, Mucin, Poults

96 Protein and amino acid retention in growing White Pekin ducks receiving graded levels of dietary crude protein. N. L. Horn* and O. Adeola, *Purdue University*, *West Lafayette, IN*.

Protein and AA accretion in growing male White Pekin ducks receiving 19, 21, 23, or 25 % dietary CP were investigated. On d 0, 16 ducklings were killed as an initial slaughter group. Two groups of 96 ducklings were assigned to the 4 dietary treatments, with 6 cages per treatment and 4 birds per cage, in randomized complete block design. One group was sacrificed on d 7 and the other group on d 14. There were linear increases ($P < 0$ .05) in gain and G:F for 7-d and 14-d old ducklings. Ash and fat accretion were not significantly affected by graded levels of dietary crude protein in 7-d old ducklings, for 14-d there was a linear decrease ($P < 0$ .05) in fat accretion as dietary CP increased, but no significant differences for ash accretion. Body protein accretion increased linearly from 2.83 g/d to 3.51 g/d for 7-d old birds, and from 2.35 g/d to 3.59 g/d for 14-d old birds ($P < 0.0001$). Body lysine accretion increased from 180 mg/d to 224 mg/d for 7-d old birds, and from 150 mg/d to 220 mg/d for 14-d old birds ($P < 0.0001$). Body threonine accretion increased from 104 mg/d to 129 mg/d for 7-d old birds, and from 85 mg/d to 130 mg/d for 14-d old birds ($P < 0.0001$). There was a linear relationship between crude protein intake and accretion rate of body protein in 7-d and 14-d old ducks. Lysine and threonine accretion also showed a linear relationship with body protein accretion in 7-d or 14-d old ducks. The results from this experiment showed that 30% or 28% of dietary protein was deposited in the body of 7-d or 14-d old ducks, respectively. Additionally, approximately 62 mg and 34 mg of lysine and threonine, respectively were accreted for every g of protein accretion.

Key Words: Dietary Crude Protein, Ducks, Protein Accretion

97 Effect of strain and immune status on dietary lysine requirements in broilers as determined by indicator amino acid oxidation. R. D. Kirschenman* and D. R. Korver, *University of Alberta*, *Edmonton AB, Canada*.

The effect of recovery from an acute-phase inflammatory response on lysine requirements was determined in random-bred (since 1957;R) and modern (Ross 308;M) broilers. At 10 d of age, 8 birds (4 R and 4 M) were placed in individual chambers and adapted to one of 7 diets containing 6.07, 7.18, 8.38, 9.38, 10.49, 12.14 or 13.24g/kg of dietary Lys (55% to 120% of NRC level for birds of this age). At 13 or 14 d of age, two birds per strain were either injected with lipopolysaccharide (LPS; I) or not injected (C) 12 hours prior to each 4-h oxidation. This time frame was based on prior data assessing changes in febrile response during recovery from LPS. There were 4 replicates per strain-LPS group at each level of Lys. Individual bird weights were taken before injection and before and after each oxidation. The M strain had higher BW than the R strain at all points ($P \leq 0.0001$). Injection caused the MI birds to have a lower final BW than the MC birds (P=0.0056) while the BW of R birds was not affected . BW of all birds increased during the oxidations. Mean Lys requirements for the MI and MC birds were 11.95 ± 1.09 g/kg diet and 10.14 ± 1.14 g/kg diet, respectively (P=0.7307). The mean Lys requirements for RI and RC birds were 9.98 ± 0.26 g/kg diet and 8.32 ± 0.11 g/kg diet, respectively (P=0.0231). The M birds had a higher requirement than the R birds ($P \leq 0.0001$). The results of this study demonstrate that M and R birds had different responses to an inflammatory challenge. LPS injection has been observed to decrease Lys requirement of birds during an immune challenge, however we observed an increase during the recovery phase in R birds. It is possible that the higher requirement is required to simultaneously support the diminishing inflammatory response as well as a recovery in growth rate. The lack of an LPS effect on Lys requirement in the M strain may indicate more rapid redistribution of nutrients back to growth or a different time course of recovery from the acute phase than the R strain. As this is a novel area of study, to date the mechanisms behind these changes are unknown.

Key Words: Immunity, Requirements, Lysine

98 Dietary protein quality and feed restriction influence abundance of PepT1 mRNA in the small intestine of two lines of broilers. E. Gilbert*[1], H. Li[1], D. Emmerson[2], K. Webb, Jr.[1], and E. Wong[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*Aviagen®*, *Huntsville, AL*.

The objective of this study was to evaluate the effect of dietary protein quality on chicken intestinal peptide transporter 1 (cPepT1) mRNA abundance in two lines of broilers (A and B). Intestinal samples were collected from chicks at day of hatch (doh), and d 1, 3, 7 and 14 posthatch. At doh, chicks from both lines were randomly assigned to corn-based diets containing 20% CP with either soybean meal (SBM), a higher quality protein, or corn gluten meal (CGM), a lower quality protein, as the supplemental protein source. Birds were given ad libitum access to feed and water. Groups of chicks from both lines were also assigned to the SBM diet at a quantity restricted to that consumed by the Line A chicks fed CGM (diet consumed the least). PepT1 mRNA abundance was assayed by real time PCR using the absolute quantification method. Feed intake and BW were greater ($P < 0.0001$) for Line A compared with Line B. Chicks fed SBM had the greatest, while chicks fed CGM had the lowest BW and feed intakes ($P < 0.0001$). Chicks fed restricted amounts of the SBM diet had intermediate BW ($P < 0.0001$). With feed and protein intakes equal, greater BW in chicks fed restricted amounts of SBM compared with chicks fed CGM is reflective of SBM being a higher quality source of protein. Abundance of PepT1 mRNA was greater in Line B than Line A ($P = 0.03$). PepT1 mRNA was highest on d3, d14, and d7 and d14, in chicks fed diets containing SBM, CGM, and restricted SBM, respectively ($P = 0.005$). When feed intake was equal (CGM vs restricted SBM), a greater abundance of PepT1 mRNA was associated with the higher quality SBM ($P < 0.04$). When feed intake was restricted (SBM vs restricted SBM), a greater abundance of PepT1 mRNA was associated with the restricted intake ($P < 0.04$). These data suggest that both dietary protein quality and feed restriction influence expression of PepT1 mRNA in the small intestine of broiler chicks.

Key Words: Broiler, PepT1, Protein

99 Cysteine toxicity in chicks. R. N. Dilger* and D. H. Baker, *University of Illinois*, *Urbana*.

Previous work in our laboratory showed that 2.5% or more excess dietary L-cysteine (Cys), but not L-cystine, was lethal when fed to young chicks. Mortality resulting from ingestion of excess Cys was unique due to its acute nature; chicks began to perish after just 72 h of feeding. Our overall objective was to further characterize the unique phenomenon of Cys toxicity in chicks. Because Cys is a strong reducing agent, we attempted to counteract its effect using a strong oxidant (i.e., H_2O_2) in drinking water. Over a 9-d growth assay, chicks were provided corn-soybean meal diets containing 0 or 2.5% excess Cys, with or without 0.05% H_2O_2 in the water (i.e., the highest tolerable concentration as determined previously). Provision of H_2O_2 caused no untoward effects, but excess Cys reduced weight gain 24% and caused 44% mortality. The combination of excess Cys and H_2O_2-supplemented water still reduced weight gain 20%, but remarkably, no chick mortality was observed. Next, we evaluated the well-known principle that increased dietary CP concentration may minimize the noxious effects of consuming a single excess amino acid. Excess dietary Cys at 2.5% depressed ($P < 0.05$) weight gain in chicks fed corn-soybean meal diets containing 18% or 24% CP, but had no effect on chicks fed 30% CP diets. Cys-induced mortality, approximately 50%, was not affected by dietary CP concentration. Finally, we hypothesized that chick eating behavior (i.e., constant nibbling, many small meals) may impact the pernicious effect of excess Cys. Thus, food-deprived chicks were oral-gavaged with distilled water or a water solution providing 600 mg Cys (4.0 g/kg BW) in a bolus dose. On average, control chicks gained 21 g BW and consumed 56 g of diet during the 24-h post-intubation period, and no mortality occurred. In stark contrast, chicks gavaged with 600 mg Cys lost 28 g BW and consumed only 1 g of diet, and 83% of these chicks died (10 of 12 total) during the 24-h observation period. Collectively, these data highlight the unique phenomenon of dietary Cys toxicity, a finding potentially important for humans where over-the-counter Cys supplements are freely available without regulatory control.

Key Words: Cysteine, Toxicity, Chick

100 Digestibility and availability of the creatine source guanidino acetic acid in broilers. A. Lemme*[1], J. Tossenberger[2], and J. Ringel[1], [1]*Degussa GmbH - Feed Additives*, *Hanau, Germany*, [2]*University of Kaposvár*, *Kaposvár, Hungary*.

Creatine plays a central role in the cell energy metabolism and is considered semi-essential. Exogenous supplementation might be meaningful under certain conditions. In this context guanidino acetic acid (GAA, CreAmino™), which is a natural precursor of creatine in the metabolism, is a suitable feed additive. Knowledge on the metabolism of supplemental GAA is scarce and therefore an experiment with 24 fistulated male broilers (cannula fitted in colon) was conducted in order to investigate the digestibility and availability of supplemental GAA. A basal corn-soybean meal based diet was added with either no (CON), 0.06 % (recommended, T-B), or 0.60 % (overdose, T-C) GAA. Diets were offered for free consumption to 8 birds per treatment from 34-42 days of age. Feed intake was recorded and feces and urine were quantitatively collected twice a day from day 38-42. Samples of the four days were pooled per bird. All samples (feed, feces, urine) were analyzed for GAA, creatine, and creatinine, the latter being the excretion product of creatine. Subsequently, digestibility and utilization of digested GAA were calculated. No GAA was found in the basal diet while analytical results of the experimental diets confirmed the expected values. GAA excretion in feces was small in all treatments ($p>0.05$) resulting in true fecal digestibilities of 99.4 % and 98.9 % in T-B and T-C, respectively, suggesting a complete absorption. GAA, creatine, and creatinine were found in urine from CON birds as a result of de-novo synthesis. Consequently, utilization of the digested supplemental GAA was calculated by difference. Due to the fact that creatine and creatinine are derived from GAA, not only GAA, but also enhanced creatine and creatinine excretions must be attributed to the GAA supplementation and were thus all included in the calculations. Urinary GAA, creatine, and creatinine excretion were enhanced in T-B ($p>0.05$) and were significantly higher in T-C ($p<0.05$) compared to that of CON. Consequently, utilization of digested GAA was 77.1 % in birds of T-B, but only 46.4 % in those of T-C suggesting an effective excretion mechanism in case of overdosing GAA.

Key Words: Guanidino Acetic Acid, Availability, Broiler

101 Effect of amino acid formulation and synthetic amino acid supplementation on turkey tom performance. T. Applegate*[1], W. Powers[2], and R. Angel[3], [1]*Purdue University*, *West Lafayette, IN*, [2]*Michigan State University*, *East Lansing*, [3]*University of Maryland*, *College Park*.

A two by two factorial experiment was conducted to determine whether diets formulated with either two (Lys and Met) or three (Lys, Met, and Thr) synthetic AA to 100% or 110% of NRC (1994) AA recommendations would affect performance of turkey toms. Diets were formulated with corn, soybean meal (SBM), and six percent meat and bone meal. Diets were formulated to maximize SBM inclusion when formulated with two synthetic AA thereby resulting in 2.0, 1.5, 1.4, and 1.0 %-units more CP than diets containing three synthetic AA at 4 to 8, 8 to 12, 12 to 16, and 16 to 20 wk of age, respectively. Each diet was fed to 12 replicate pens of birds with 10 birds per pen. Body weight, feed intake, and feed/gain was not affected by AA formulation or synthetic AA supplementation (average 20 wk BW = 20.7 kg). Similarly, the weight of the Pectoralis (P) major at 20 wk of age was not different between birds fed different diet regimens (left P. major = 1.88 kg; 9.13% of BW). Calculated nitrogen (N) intake were affected by diet with birds fed 100% NRC AA consumed 139 g (7.05%) less N than those fed 110% NRC AA ($P < 0.0001$). Similarly, birds fed three versus two synthetic AA consumed 146 g less feed N (7.4%) to 20 wk of age ($P < 0.0001$). These data suggest that diets containing AA formulations above NRC (1994) recommendations do not provide any additional performance or P. major yield benefits. In addition, formulation with three synthetic AA results in a considerable reduction in N consumed.

Key Words: Amino Acid, Crude Protein, Turkey Tom

102 Increased dietary balanced protein levels at varying length of application during the starter period of broilers. A. Lemme*[1], M. G. T. Janssen[2], P. J. A. Wijtten[2], J. K. W. M. Sparla[2], and M. S. Redshaw[1], [1]*Degussa GmbH - Feed Additives*, *Hanau, Germany*, [2]*Provimi B. V.*, *Rotterdam, The Netherlands*.

Amino acid supply during early stage of life is supposed to have a strong impact on the development of broilers. Question about the optimum level of dietary balanced protein and the optimum duration of supply was raised. Therefore, experimental corn-wheat-soybean meal based diets with graded levels of balanced protein (BP) corresponding to 11.0 (control), 12.6, 14.2, 15.7, and 17.3 g true fecal digestible lysine per kg feed were produced. Amino acid profiles were kept identical in all diets. While the control was fed from day 1 through day 14, diets with higher BP were fed from day 1 either for two, four, eight, or twelve days of life (4x4). A total of 1728 male Ross 308 broilers were equally assigned to the 17 treatments comprising either eight (control) or four cages with 24 birds each. After feeding the experimental pelleted diets, dietary BP was reduced to the control level (11.0 g dig. Lys/kg) in two steps (2-day transition period) in order to avoid too strong changes in amino acid supply especially in the treatments with higher BP supply. At 14 days of age weight gain and feed conversion were significantly improved by increasing BP levels (both $p<0.05$). This non-linear effect was most pronounced when feeding the diets over 12 days (gain: numerically; FCR: interaction $p<0.05$) suggesting optimum performance at 15.7 g dig. Lys. At day 14 two birds per pen were selected for dissection. Weight and length of the empty small intestine were determined. Prolonging the length of feeding the experimental diets containing 12.6 g dig. Lys/kg and more from 2 to 12 days significantly increased the weight of the duodenum and jejunum (% of body weight, $p<0.05$) whilst dietary BP itself had no effect. However, small intestine weight of the control treatment was similar compared with that of birds receiving the experimental diets for 8 and 12 days.

Key Words: Balanced Protein, Broiler, Phase Length

103 Response of vaccinated starting broilers to the inclusion of NEAA as gelatin to high and low CP feed while maintaining EAA requirements. R. Lehman* and E. T. Moran, *Auburn University*, *Auburn, AL*.

Vaccination for coccidiosis is now common as producers remove antibiotics from broiler feeds. Because of the extensive use of NEAA for mucin formation, the use of low CP may exacerbate vaccination response during the first three weeks. Inclusion of NEAA, particularly glycine and proline, as gelatin was evaluated for any recuperative advantage when vaccinated and non-vaccinated birds received high

and low CP diets. Ross X 708 chicks (1280; 64 pens) were sexed; half were vaccinated with Coccivac-D, and placed in floor pens while the other half received Salinomycin. Two low CP corn-soybean meal diets (21% CP and 21% CP containing 2% gelatin) and two high CP diets (23% CP and 23% CP containing 2% gelatin) were fed. Birds that were vaccinated had significantly lower body weight gain (P<.001) and higher feed conversion (P<.001) compared to those that were not vaccinated. However, vaccinated birds with gelatin in their diets had a greater BW gain (P<.05) and lower feed conversion (P<.01) than vaccinated birds with no gelatin in their diets. Gelatin present in diets increased BW gain (P<.05) and greatly lowered feed conversion (P<.001). The growth performance of the broilers was not affected by the amount of crude protein in the diet. The presence of gelatin in diets of vaccinated broilers appears to aid in BW gain and feed conversion during the first three weeks.

Key Words: Crude Protein, Coccidiosis, NEAA

104 Evaluation of isoleucine and valine limitation in diets for heavy high-yield broilers. A. Corzo*[1], M. T. Kidd[1], J. Collier[1], W. A. Dozier, III[2], and D. Hoehler[3], [1]*Mississippi State University*, *Mississippi State*, [2]*USDA-ARS*, *Mississippi State, MS*, [3]*Degussa Corporation*, *Kennesaw, GA*.

Two studies were conducted from 35 to 54 d of age using Ross × Ross 708 males. The first study was composed of three dietary treatments designed to evaluate the impact on performance of broilers when neglecting the Val and Ile nutrient minimums during formulation: a control diet formulated to meet or exceed all critical amino acid needs (0.80% dig Val and 0.71% dig Ile); a diet formulated to meet the minimum needs of all critical amino acids and allowing L-Thr to enter formulation (0.74% dig Val and 0.65% dig Ile); a third diet with no nutrient minimum given to dietary Val and Ile (0.67% and 0.58% dig, respectively). All treatments contained eight replicate pens (12 broilers/pen). The second study was a factorial design with three Ile (61, 64.5 and 68) and three Val (70, 74 and 78) ratios to Lys, for a total of nine treatments, each containing eight replicate pens (12 broilers/pen). Data was analyzed for two-way interactions first, and then main effects. In the first study, feed conversion was minimized (P<0.05) with the control diet when compared to the Val/Ile deficient diet, while the second diet had an intermediate value. The same statistical response was observed when expressing BWG as a function of feed cost. The Val/Ile deficient diet was economically less profitable (P=0.06) than the control diet, while the second diet had an intermediate value. The data from the second study showed that no two-way interactions were observed. A main effect for Ile was observed on BWG, where an increase (P=0.06) in the weight gain was observed as the Ile level increased in the diet. Feed conversion values showed that the Ile/Lys ratio of 61% was poorer (P<0.01) when compared to the other two treatments. No Val main effect was observed for live performance. No main effects for either Val or Ile were observed for carcass traits. It was shown how neglecting critical amino acid needs beyond Thr can be detrimental to performance and profitability. It can also be said that during latter phases critical amino acid needs can be met via feed consumption making it difficult to comprehend the limitation of critical amino acids.

105 Dietary selenium regulation of the rat liver and kidney selenoproteomes. K. M. Hargrave*, J. K. Evenson, A. M. Rothert, and R. A. Sunde, *University of Wisconsin*, *Madison*.

The rodent selenoproteome consists of 24 selenoproteins. Using microarray analysis, we have identified 8 liver and 5 kidney selenoprotein mRNAs, including glutathione peroxidase-1 (GPX1), that were significantly down-regulated in mice fed a selenium (Se)-deficient diet. Our current objective is to identify the rat liver and kidney selenoproteins expressed, and regulated by dietary Se. We conducted 2 studies; in Study 1, male rats were fed a torula yeast based diet deficient in Se, or containing 0.02, 0.05, 0.075, 0.1, 0.15, 0.2, or 0.3 µg Se/g diet for 28 d following weaning. Total liver and kidney RNA from 3 rats per diet were analyzed by quantitative real-time RT-PCR for the mRNA abundance of the selenoproteins regulated in the mouse. Study 2 was conducted with the addition of diets containing 0.5 and 1.0 µg Se/g diet. Se status of these animals was determined by plasma GPX3 and red blood cell GPX1 activities. In Study 1, rat liver GPX1, Selenoprotein (Sel) H, and SelW were highly down-regulated ($P < 0.001$) by dietary Se, similar to the mouse. In each case, mRNA abundance neared a plateau by 0.075 µg Se/g diet. Furthermore, rat SelK, SelP, and Thioredoxin Reductase-1 (TR1) were moderately and significantly ($P < 0.01$) regulated, whereas, GPX4, SelM, and TR2 were not. In the kidney, GPX1 was highly ($P < 0.05$) and SelW moderately ($P < 0.05$) down-regulated by dietary Se. Unlike in the mouse, kidney SelH, SelM, and GPX3 were not regulated, similar to GPX4. In Study 2, plasma GPX3 and red blood cell GPX1 activities in Se-deficient rats were dramatically down-regulated ($P < 0.001$) compared to Se-adequate levels. In summary, GPX1 mRNA, when assayed by RT-PCR, as well as activity are decreased dramatically in Se-deficient rats, indicating that this is a good model in which to test mRNA regulation of the complete selenoproteome. No selenoprotein tested thus far has exhibited a pattern of regulation different or more dramatic than for GPX1. In the rat model, however, there appears to be fewer selenoproteins under significant dietary Se regulation than previously observed in the mouse (6 vs 8 in the liver and 3 vs 5 in the kidney).

Key Words: Selenium, mRNA Expression, Rat

106 Copper can be absorbed as a Cu-peptide chelate through the PepT1 transporter in the jejunum of weanling pigs. B. E. Aldridge*, K. L. Saddoris, and J. S. Radcliffe, *Purdue University*, *West Lafayette, IN*.

Jejunal tissue was harvested from eighty-four pigs on d 6,8,10 or 14 post-weaning and mounted in modified Ussing chambers to investigate the route of Cu absorption from Bioplex® Cu and $CuSO_4$. Tissues were challenged in a 2 x 2 factorial arrangement with two Cu sources (Bioplex® Cu and $CuSO_4$) with and without an inhibitor (valcyclovir) of the di- and tri-peptide transporter, PepT1. Active ion transport was measured by changes in short circuit current (Isc) following the

addition of Cu to the mucosal buffer. Additionally, Cu disappearance from the mucosal buffer was determined by atomic absorption spectrophotometry following stabilization of the Isc, post-Cu challenge. A Cu source x PepT1 inhibitor interaction (P=0.05) was observed for the change in Isc following Cu addition to the mucosal buffer. The change in Isc was 78% greater when Bioplex® Cu was added compared with $CuSO_4$. However, the addition of valcyclovir, an inhibitor of PepT1 reduced the response by 40% for Bioplex® Cu, but did not affect $CuSO_4$. This indicates that some of the change in Isc after adding Bioplex® Cu was the result of peptide absorption. A Cu source x PepT1 inhibitor interaction (P=0.054) was also observed for Cu concentration remaining in the mucosal buffer. Cu concentration in the mucosal buffer was 20% higher with Bioplex® Cu, in the presence of the PepT1 inhibitor, than without the inhibitor. However, the PepT1 inhibitor had no effects on mucosal buffer Cu concentrations when $CuSO_4$ was added. This indicates that some of the Cu in Bioplex® Cu is absorbed through PepT1.

Key Words: Pig, Copper, PepT1

107 The feeding of low-P diets to weanling pigs stimulates Na^+-dependent phosphate transport by a post-translational mechanism in the jejunum. K. L. Saddoris* and J. S. Radcliffe, *Purdue University*, *West Lafayette, IN*.

Thirty-six crossbred gilts (6.6±0.16 kg BW) were utilized to determine the mechanism of action through which Na^+-dependent P transport is stimulated in weanling pigs fed a low-P diet. Pigs were weaned at 19 d of age and allowed a 10 d adaptation period to a dry diet. Pigs were blocked by BW and randomly assigned to a 0.07 or 0.40% aP diet and injected i.p. once a day for 3d with actinomycin D (0.12 mg/kg BW), cycloheximide (0.40 mg/kg BW), or saline. Pigs were then euthanized and jejunal samples were removed and mounted in modified Ussing chambers for determination of electrophysiolgical properties. Additionally, mRNA expression (quantitative RT-PCR) of NaPi-IIb was determined from jejunal mucosal scrapings. As expected P intake was lower (P≤0.0001) for pigs fed the low-P diet compared to pigs fed the high P diet (125 vs 601 mg/d). Additionally, pigs injected with actinomycin D or cycloheximide had lower P intakes (P≤0.001) and lost a greater amount of BW (P<0.01) during the trial compared to pigs injected with saline. Basal short-circuit current (Isc) and resistance did not differ (P≥0.10) between treatment groups. Na^+-dependent P uptake increased (P≤0.05; 15.48 to 23.39 $\mu A/cm^2$) as the concentration of P in the diet was decreased as measured by the change in Isc. However, no injection or diet × injection effects were observed for Na^+-dependent P uptake despite 2.3-fold decreases in P intake in pigs injected with actinomycin D or cycloheximide compared to pigs injected with saline. Expression of NaPi-IIb gene could not be detected in jejunal samples indicating an 80% decrease in P intake over 3 d failed to induce expression of NaPi-IIb transcript. Overall, consumption of a low P diet stimulates Na^+-dependent transport in the jejunum and this increase is not prevented by administration of either a transcriptional or translational inhibitor and occurs independently of an increase in NaPi-IIb cotransporter mRNA. Therefore, in the jejunum of weanling pigs, regulation of Na^+-dependent P uptake is occurring through a post-translational mechanism.

Key Words: Phosphorus, Intestine, Pigs

108 Dietary supplementation with zinc oxide decreases the expression of the stem-cell factor in the small intestine of weanling pigs. D. Y. Ou[1], D. F. Li*[1], Y. H. Cao[1], X. L. Li[1], J. D. Yin[1], S. Y. Qiao[1], and G. Y. Wu[2], [1]*China Agricultural University*, *Beijing, China*, [2]*Texas A&M University*, *College Station*.

Supplementation of diets with a high level of zinc oxide has been shown to reduce the incidence of diarrhea in weanling pigs, but the underlying mechanisms remain largely unknown. Intestinal-mucosal mast cells, whose maturation and proliferation is under the control of the stem cell factor (SCF), play an important role in the etiology of diarrhea by releasing histamine. The present study was conducted to test the novel hypothesis that dietary supplementation with zinc oxide inhibits SCF expression in the small intestine, thereby reducing the number of mast cells, histamine release, and diarrhea. In Experiment 1, Piglets (28 d) were weaned and fed diet containing 100 or 3000 mg/kg zinc (as zinc oxide) for 10 d (16 piglets/group). In Experiment 2, sixteen piglets (28 d) were assigned randomly to two groups as in Experiment 1, except that the two groups were pair-fed the same amount of feed. Supplementation with a high level of zinc oxide reduced the incidence of diarrhea in weanling piglets. Dietary Zn supplementation reduced the expression of SCF gene at both mRNA and protein levels, the number of mast cells in the mucosa and submucosa of the small intestine and histamine release. Collectively, our novel results indicate that dietary supplementation with zinc oxide inhibits SCF expression in the small intestine, leading to reductions in the number of mast cells and histamine release. These results may have important implications for the prevention of weaning-associated diarrhea in piglets.

Key Words: Zinc Oxide, Mast Cells, Histamine

109 Net portal absorption of inorganic zinc and zinc-amino acid chelates by growing pigs. R. D. Mateo*[1], M. I. Perret-Gentil[2], M. W. Hart[1], R. A. Samford[3], and S. W. Kim[1], [1]*Texas Tech University*, *Lubbock*, [2]*Texas Tech Health Sciences Center*, *Lubbock*, [3]*Albion Advanced Nutrition*, *Clearfield, UT*.

This study was conducted to determine and compare net portal absorption (NPA) of zinc from zinc sulfate, zinc-methionine chelate (Albion Advanced Nutrition), and zinc-amino acid chelate (Albion Advanced Nutrition). Three pigs (21.5±0.7 kg BW) were surgically fitted with catheters into the carotid artery, portal vein, mesenteric vein, and pyloric region of the stomach and allotted to 3 x 3 Latin square design with 3 treatments: Injection of zinc sulfate (ZS); zinc-methionine chelate (ZM); and zinc-amino acid chelate (ZAA) through the pyloric stomach catheter and 3 periods (48-h intervals). Each period was composed of 24-h feeding (0.09 kg x $BW^{0.75}$), 19.5-h fasting, and 4.5-h infusion. A corn-soybean meal based diet with 18.2% CP and 3.35 Mcal ME/kg was fed to pigs before fasting. Para-aminohippuric acid (PAH) was infused (3.2 mg/min) into the mesenteric vein for a 4.5 h period. Zinc (230 mg) from one of the three aforementioned sources was injected into the lumen of the pyloric catheter 60 min after beginning the PAH infusion period. Blood samples (3 mL) were collected simultaneously from the carotid artery and portal vein catheters at -60, -30, 0, 15, 30, 45, 60, 90, 120, 150, and 210 min relative to zinc injection to measure PAH and zinc concentration in the plasma. Zinc NPA was calculated by multiplying the portal vein plasma flow rate by the porto-arterial plasma zinc concentration. Blood flow averaged 1.38±0.23 L/min. Zinc NPA from ZS peaked (P<0.05) at 150 min (0.94 mg/min). Zinc NPA from ZM peaked (P<0.05) at 30

and 120 min (2.40 and 2.24 mg/min, respectively). Zinc NPA from ZAA peaked (P<0.05) at 30 and 150 min (1.59 and 3.12 mg/min, respectively). ZM had greater (P<0.05) zinc NPA than other NPA at 60 min (-0.53 vs. 0.43 mg/min) and ZAA had greater (P<0.05) zinc NPA than other NPA at 150 min (0.94 vs. 3.12 mg/min). This study suggests that zinc from organic sources (ZM and ZAA) is absorbed faster and more than zinc from zinc sulfate.

Key Words: Net Portal Absorption, Zinc Amino Acid Chelate, Pigs

110 The effect of varied levels of E. Coli. phytase on phosphorus balance in weanling pigs. T. C. Tsai*[1], C. R. Dove[1], M. J. Azain[1], and M. Bedford[1], [1]*University of Georgia*, *Athens*, [2]*Syngenta Animal Nutrient*, *RTP, NC*.

The objective of this study was to examine the effect of an E. Coli. phytase on phosphorous (P) balance in weaning pigs. The study was conducted in a 2 x 5 factorial arrangement of treatments. Two levels of P, low-P (LP, 0.13% avail. P, no inorganic P added) and high-P (HP, 0.35% avail. P, with 1.15% dicalcium phosphate) were supplemented with 0, 250, 500, 2500, and 12500 U/kg of E. Coli-derived phytase. All diets were formulated to contain 20% CP, 1.15% lysine and 0.75% calcium (Ca). The study involved a total of 80 pigs (IW =18 kg, 4 wk post-weaning) in 4 replicates of 14 d each (10 d adaptation, 4 d collection). Pigs were housed in metabolism cages and fed twice each day. Growth rate and G:F were lower in pigs fed the LP diet. The addition of phytase improved ADG and G:F (P<0.01), with performance of pigs fed 2500 and 12500 U/kg phytase being similar to that of pigs on the HP-control diet. The improvements in performance were greater in the pigs fed the LP diet. Fecal P (g/d) was reduced as phytase level increased in both diets (P<0.0001), but the magnitude was greater in the LP diet. In the LP diet, apparent total tract digestibility (ATTD) for P was improved by 36, 18, 49, and 76% in pigs fed 250, 500, 2500, and 12500 U/kg, respectively (P<0.0001). In the HP diet, ATTD was improved from 39 to 45% with phytase. Urinary P was less than 5% of total P excretion in pigs fed the LP diet and was not affected by phytase. Urinary P increased with phytase addition to the HP diet and accounted for 30% of the total P excretion on the HP diet with 12500 U phytase. Calcium retention (%) was improved (P < 0.001) by the addition of phytase to both LP and HP diets. Urinary Ca was reduced by phytase (P<0.001) in both diets. These results suggest that E. Coli. phytase addition to a LP diet can efficiently reduce total P excretion and improve growth performance.

Key Words: Phytase, Digestibility, Weaning Pigs

111 Effects of different available-phosphorus levels in diets on nitrogen and phosphorus digestibilities in growing pigs. X. Wu[1], Y. L. Yin[1], G. Y. Wu[1,3], T. J. Li[1], Y. G. Zhang[1], F. Y. Yan[1], R. L. Huang[1], and M. Z. Fan*[4], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Huazhong Agricultural University*, *Wuhan, Hubei, China*, [3]*Texas A&M University*, *College Station*, [4]*University of Guelph*, *Guelph, Ontario, Canada*.

This study was conducted to determine the effect of different available-phosphorus levels in diets on the digestibilities of dietary nitrogen (N) and phosphorus (P) in growing pigs, using a 4x4 Latin square design. Four cornstarch- and soybean meal-based diets were fed to 4 barrows (average initial BW of 52 kg) housed individually in stainless cages. Dicalcium phosphate was used as the major source of dietary inorganic P whose supplemental levels were 0.0, 0.12, 0.24 and 0.36% in Diets 1, 2, 3, and 4, respectively. The corresponding levels of available P in the diets were 0.13, 0.15, 0.17, and 0.19%, respectively. Each experimental period comprised 12 d, including 5-d adaptation and 3-d collection of fecal samples. The results indicated that apparent P digestibilities in Diets 1, 2, 3, and 4 were 20.97%, 25.27%, 37.91%, and 46.15%, respectively (P<0.01) and true P digestibilities were 53.00%, 53.78%, 65.19%, and 68.09%, respectively (P>0.05). Fecal P outputs decreased (P < 0.05) with decreasing dietary P intakes. However, there were no differences (P>0.05) in apparent N digestibilities or fetal N outputs among the different groups of pigs. We conclude that feeding diets containing 0.12% to 0.24% dicalcium phosphate is effective in reducing P excretion from growing pigs.

Key Words: Available Phosphorus, True Digestibility, Growing Pigs

112 Effect of mineral status and calcium (Ca) concentration on phosphorus (P) and Ca utilization in piglets. M. P. Letourneau Montminy*[1], C. Jondreville[2], D. Sauvant[3], M. Magnin[4], C. Pomar[5], and P. Lescoat[1], [1]*INRA UR83*, *Nouzilly, France*, [2]*INRA USC340*, *Vandoeuvre-les-Nancy, France*, [3]*INRA UMR791*, *Paris, France*, [4]*BASF Nutrition Animale*, *Château-Gontier, France*, [5]*Agriculture et Agroalimentaire Canada*, *Lennoxville, Canada*.

Current formulation system may inadequately account for the impact of factors that modify Ca and P utilization by the animal. These factors could be related to the animal (e.g.: mineral status) or to the diet (e.g.: Ca concentration). An experiment was conducted to study the impact of the initial mineral status of animals and of Ca and P dietary supply, with and without phytase on P and Ca utilization by piglets. They were initially weighing 10 kg and fed maize-soybean meal diets providing adequate amounts of all nutrients except P and Ca. This study was divided into two successive periods. The first 10-day period aimed at preparing piglets with two mineral status. Sixty piglets were fed diets providing either adequate (1.42 and 0.80 %, respectively) or low (0.67 and 0.43 %, respectively) amounts of Ca and tP. At the end of this period, 6 piglets from each diet were slaughtered. The 24 remaining piglets from each diet were fed one of the 4 experimental diets for a 24-day experimental period. All four experimental diets displayed similar amounts of tP (0.56%). They contained Ca concentrations and microbial phytase (Natuphos) at (1.0%, 1000 IU), (1.0%, 0 IU), (0.6%, 1000 IU) and (0.6%, 0 IU) respectively. Body weight gain and feed conversion ratio were independent of the initial mineral status (P > 0.05). Femur ash concentration and plasma P decreased while plasma Ca and alkaline phosphatase activity increased with decreased P and Ca dietary concentration (P < 0.05) during the first 10-day period, indicating that two different mineral status could be differentiated. By the end of the 24-day experimental period, femur ash concentration was independent of the initial mineral status of the pigs (P > 0.05). This observation was in accordance with an improved Ca and P digestibility (P < 0.05) in initially depleted pigs compared to pigs with a normal initial mineral status. Lowering dietary Ca increased P digestibility (P < 0.05). Mineral status and lower dietary Ca can improve utilization of P in piglets.

Key Words: Piglets, Phosphorus, Calcium

113 Exogenous glutathione reduces cadmium toxicity to giant freshwater prawns *Macrobrachium rosenbergii*. W. Y. Chu*[1], Y. L. Yin[1], K. Yao[1], T. J. Li[1], R. L. Huang[1], and G. Y. Wu[1,2], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Texas A&M University*, *College Station*.

This study was conducted to test the hypothesis that exogenous glutathione (GSH) can improve antioxidant function and the ultrastructure of hepatopancreas (HP) in cadmium (Cd)-treated freshwater prawns *Macrobrachium rosenbergii*. Data are expressed as means ± SEM. The prawns (BW 11.3 ± 0.13 g and length 104.6 ± 2.4 mm) were fed a pellet diet consisting of 40% groundnut oil cake, 15% soybean meal, 15% fish meal, 28% rice bran, and 2% vitamin-mineral premix. Eighty prawns were assigned randomly into four groups (20 prawns/group). Groups 1 and 2, which were maintained in Cd-free water, received intraperitoneal (i.p.) administration of 0 or 0.21 g GSH/kg BW once daily for 7 d. Groups 3 and 4, which were maintained in water containing 0.06 mg Cd/L, received i.p. administration of 0 or 0.21 g GSH/kg BW once daily for 7 d. On d 3 and 7, HP tissues were obtained from 10 prawns/group for determining total glutathione, the thiobarbituric acid reactive substance, and enzyme activities. Concentrations of total GSH (1.13 ± 0.31 μmol/g tissue) in HP did not alter ($P>0.05$) in prawns not receiving Cd or GSH treatment over a 7-d period. Compared with the prawns not treated with GSH, administration of GSH increased ($P<0.05$) concentrations of total GSH in HP by 2.8- and 4.6-fold on d 3 and 7, respectively. The GSH treatment reduced ($P<0.05$) Cd-induced lipid peroxidation by 61% and increased ($P<0.05$) the activities of superoxide dismutase by 27% and glutathione peroxidase by 67% on d 7. The structural integrality of most organelles (e.g., nucleus, mitochondria, and rough endoplasmic reticulum) in HP was severely damaged in Cd-treated prawns receiving no GSH administration. GSH treatment ameliorated ($P<0.05$) the Cd-induced damage in HP. These results suggest that GSH administration is beneficial for reducing Cd toxicity to HP of the freshwater prawn.

Key Words: Glutathione, Cadmium, Antioxidant Defence

114 Factors affecting phytase activity: implication for assay development. M. F. Isaksen*[1,2] and S. Dalsgaard[1,2], [1]*Danisco Innovations*, *Brabrand, Denmark*, [2]*Danisco Animal Nutrition*, *Marlborough, Wiltshire, UK*.

Phytase is an enzyme used in feed to improve phytate phosphorus digestibility and these effects *in vivo* are dose dependent. The feed industry, therefore, needs an assay which consistently quantifies phytase activity in feed. To get a better understanding of the factors influencing phytase quantification, three different sources of phytase (E.coli, Aspergillus, Peniophora) were assayed using different methods presently used by the feed industry for determining phytase in feed. The study included the AOAC method. The standard unit definition for all assay methods was the same i.e. pH 5.5 and at 37°C, and only minor differences in the assay methodologies were noticeable. Nevertheless, the differences in measured activity between the assays were significant, ranging from no difference to 50% or more for the three phytase sources. The calcium concentration used in the assay was found to have a large effect on the recovery of the three tested phytases, with the E.Coli phytase giving lower than expected recoveries and the Peniophora phytase giving higher than expected recoveries. This study demonstrates that phytases that are quantified in units with the same basic definition, can give very different recoveries in in-feed assays, depending on quite subtle changes in assay methodology. The number of units assayed is dependent on several factors, including calcium concentration in the extraction procedure, assay buffer types and extraction time. Care should therefore be taken when interpreting the results from different phytase products, when using one specific assay method. *In vitro* comparisons should always be linked to in vivo estimations of bio-efficacy.

Key Words: Enzymes, Phytase, Assay

115 Influence of dietary reductions in CP, P, and trace minerals on DM, N, P, and mineral excretion in finishing pigs. M. Lachmann*, S. Carter, J. Bundy, S. Jenkin, and Z. Marable, *Oklahoma State University*, *Stillwater*.

Seventy-six crossbred pigs (28 kg BW) were used to evaluate the effects of reducing dietary CP, P, and trace minerals (TM) on DM, N, P, and mineral excretion during a 110-d finishing period. Pigs were blocked by BW and randomly allotted to dietary treatments. Pigs were housed in an environmentally-controlled building with 4 identical rooms, each room having a shallow pit, pull plug system (19 pigs/room, 2 rooms/trt). The control diet was a fortified corn-soybean meal diet (19.3, 17.2, 15.1 and 13.6% CP; 0.50, 0.46, 0.43, and 0.40% P) with 0.1% inclusion of TM premix for Phases 1 (28-54 kg), 2 (54-82 kg), 3 (82-100 kg) and 4 (100-118 kg). Diet 2 (LPPM) was similar to the control with the exceptions that CP was reduced by 3% units, P by 0.1% units, phytase added (500 FYT/kg), and TM premix reduced by 50, 77, 83 and 100% for Phases 1 - 4, respectively. The TM premix supplied 11, 110, 26, and 110 ppm of Cu, Fe, Mn, and Zn. Diets were formulated on true dig. Lys (0.92, 0.79, 0.65, and 0.56%) and Lys, Met, Thr and Trp were added to LPPM on an ideal basis. Pig weight, feed intake, pit volume, and slurry pH were measured weekly. Feed and slurry samples were collected weekly for DM, N, P, and mineral analyses. Slurry concentrations of N (2,010 vs. 1,438 ppm) and NH_4-N (940 vs. 632 ppm) tended to decrease ($P = 0.06$) with LPPM, while P (472 vs. 259 ppm) and pH (7.07 vs. 6.59) were reduced ($P < 0.05$). Diet did not affect ($P > 0.10$) growth performance (ADG = 839 g, G:F = 0.37). Daily intakes of N (54.4 vs. 45.7 g) and P (9.8 vs. 7.5 g) decreased ($P < 0.05$) with LPPM. Daily DM (293 vs. 260 g), N (33.5 vs. 23.1 g), and P (6.2 vs. 4.1 g) excretion were reduced ($P < 0.05$) for pigs fed LPPM. Excretion of macro- and TM was reduced by more than 11 and 38%, respectively. Cumulative DM (32.2 vs. 28.5 kg), N (3.7 vs. 2.5 kg), and P (0.68 vs. 0.45 kg) excretion per pig were reduced ($P < 0.05$) by 12, 31 and 34%, respectively with LPPM. These results suggest a marked reduction in nutrient excretion for pigs fed LPPM during the finishing period.

Key Words: Pigs, Diet, Nutrient Excretion

116 Factors affecting pre-ovulatory follicular diameter and ovulation rate following GnRH administration in anestrous beef cows. J. A. Atkins*[1], T. W. Geary[2], K. J. Wells[3], M. C. Lucy[1], and M. F. Smith[1], [1]*University of Missouri*, *Columbia*, [2]*USDA ARS Fort Keogh*, *Miles City, MT*, [3]*Michigan State University*, *East Lansing*.

Induced ovulation of small dominant follicles (< 12 mm) was associated with reduced pregnancy rates and increased late embryonic/fetal loss in beef cows. Factors affecting ovulatory follicle size following follicular wave synchrony remain unclear. The objective of the present study was to determine factors affecting ovulatory follicle size among suckled, postpartum anestrous beef cows. Follicular waves of anestrous beef cows (n = 55) were synchronized with GnRH1 on d -9, and PG on d -2, with (n = 26) or without (n = 29) an exogenous progesterone insert (CIDR) from GnRH1 to PG. Ovulation was induced 48 h after PG with GnRH2 and ovulatory follicle diameter was recorded. Ovulatory response to GnRH1 (Ov1+/Ov1-) and CIDR treatment (CIDR+/CIDR-) resulted in a 2 x 2 factorial design with 9, 17, 11, and 18 cows in the Ov1+/CIDR+, Ov1-/CIDR+, Ov1+/CIDR-, and Ov1-/CIDR- groups, respectively. There was no difference (P > 0.05) in the proportion of Ov1+ (16/20; 80%) and Ov1- (23/35; 66%) cows ovulating at GnRH2, nor was there a difference (P > 0.05) in the proportion of CIDR+ (19/26; 73%) and CIDR- (20/29; 69%) cows that ovulated at GnRH2. There was no interaction (P > 0.05) of ovulation and CIDR treatment on the proportion of cows ovulating to GnRH2 (7/9, 12/17, 9/11, and 11/18 of the Ov1+/CIDR+, Ov1-/CIDR+, Ov1+/CIDR-, and Ov1-/CIDR- treated cows, respectively). Ovulatory follicle diameter at GnRH2 was larger (P < 0.05) in Ov1+ cows (12.3 mm) than Ov1- cows (11.0 mm), but not different (P > 0.05) between CIDR+ (11.8 mm) and CIDR- (11.2 mm) cows. In summary, neither ovulation to GnRH1 nor CIDR administration affected the proportion of cows ovulating to GnRH2. Additionally ovulation to GnRH1, but not CIDR treatment resulted in ovulation of a larger follicle at GnRH2 among suckled, postpartum anestrous beef cows.

Key Words: Beef Cows, Ovulatory Follicle Size, Fertility

117 Comparison of protocols to synchronize estrus and ovulation I: Estrous cycling beef heifers. N. R. Leitman*, D. C. Busch, J. F. Bader, D. J. Wilson, M. R. Ellersieck, M. F. Smith, and D. J. Patterson, *University of Missouri*, *Columbia*.

The experiment compared estrous response, and synchrony of estrus and ovulation in estrous cycling beef heifers treated with one of four estrus synchronization protocols. Estrous cycling heifers were randomly assigned to one of four treatments (n=12 per treatment) by age and weight. Blood samples were collected 10 and 1 d prior to treatment initiation to confirm estrous cyclicity status (progesterone ≥ 0.5 ng/mL). Heifers assigned to CIDR Select (T1) received a CIDR insert (1.38 g progesterone) from d 0 to 14 followed by GnRH (100 µg Cystorelin) on d 23 and PG (25 mg Lutalyse) on d 30. Heifers assigned to Select-Synch + CIDR (T2) received a CIDR insert and GnRH on d 23 and PG at CIDR removal on d 30. Heifers assigned to CIDR-PG (T3) received a CIDR insert on d 23 and PG at CIDR removal on d 30. Heifers assigned to Select-Synch (T4) received GnRH on d 23 and PG on d 30. Heifers were fitted with HeatWatch® transmitters at the time of CIDR removal (T1, T2, and T3) or at GnRH (T4) for continuous estrus detection. Ovaries were scanned by ultrasonography on d 22, 23, and 25 to determine response to GnRH, and daily from d 30 to estrus. Beginning 20 h after the onset of standing estrus, ovaries were scanned every 4 h until ovulation. There was no difference (P > 0.05) in ovulatory response to GnRH (75, 42, and 75%; T1, T2, and T4, respectively) or estrous response (92, 100, 100, and 75%; T1, T2, T3, and T4, respectively). Variance for interval to estrus after PG differed (P < 0.002) between T1 and T2, and (P < 0.05) T1 and T4. Mean ‡SE intervals to estrus were 52 ‡ 3.7, 49 ‡ 3.5, 51 ‡ 3.5, and 48 ‡ 4.1 h for T1, T2, T3, and T4, respectively. Variance for interval to ovulation after PG differed (P < 0.05) among T1 and each of the other treatments. Mean intervals to ovulation were 83 ‡ 3.9, 80 ‡ 3.9, 81 ‡ 3.7, and 77 ‡ 4.3 h for T1, T2, T3, and T4, respectively. These smaller variances, for interval to estrus and ovulation, among CIDR Select treated heifers resulted in a significant improvement in synchrony of estrus and ovulation compared with the other three treatments.

Key Words: Progestin, Estrus Synchronization, Beef Heifer

118 Comparison of protocols to synchronize estrus and ovulation II: Prepubertal beef heifers. N. R. Leitman*, D. C. Busch, J. F. Bader, D. J. Wilson, M. R. Ellersieck, M. F. Smith, and D. J. Patterson, *University of Missouri*, *Columbia*.

The experiment compared estrous response, and synchrony of estrus and ovulation in prepubertal beef heifers treated with one of two CIDR-based estrus synchronization protocols. Prepubertal beef heifers were assigned to one of two treatments by age and weight. Blood samples were collected 10 and 1 d prior to treatment initiation to confirm estrous cyclicity status (progesterone < 0.5 ng/mL). Heifers assigned to CIDR Select (n=14; T1) received a CIDR insert (1.38 g progesterone) from d 0 to 14 followed by GnRH (100 µg Cystorelin) on d 23 and PG (25 mg Lutalyse) on d 30. Heifers assigned to Select-Synch + CIDR (n=11; T2) received a CIDR insert and GnRH on d 23 and PG at CIDR removal on d 30. Heifers were fitted with HeatWatch® transmitters at the time of CIDR removal for continuous estrus detection. Ovaries were scanned by ultrasonography on d 22, 23, and 25 to determine ovulatory response to GnRH, and daily from d 30 to estrus. Beginning 20 h after the onset of estrus, ovaries were scanned every 4 h until ovulation. More (P = 0.02) T1 heifers responded to GnRH than T2 heifers (86% T1; 36% T2). There was no difference (P > 0.05) in estrous response, or in the interval from PG to estrus or ovulation. In summary, there was no difference between treatments in the variances for interval to estrus or ovulation among prepubertal heifers. Results from a concurrent experiment (See Leitman et al., 2007; Experiment I) were analyzed with these data to compare these two treatments among mixed groups of estrous cycling and prepubertal beef heifers. Response to GnRH (P < 0.01; 81% T1 and 39% T2), and the variances for interval to estrus and ovulation were smaller (P < 0.01) for T1 than T2. After results for the two treatments (prepubertal and estrous cycling) were combined, the CIDR Select protocol improved (P < 0.01) synchrony of estrus and ovulation compared with the Select Synch + CIDR protocol. These data suggest that the CIDR Select protocol may facilitate fixed-time AI more effectively in mixed groups of estrous cycling and prepubertal heifers.

Key Words: Progestin, Estrus Synchronization, Beef Heifer

119 Pregnancy rates following fixed-time AI in beef heifers after administration of CIDR-based protocols to synchronize estrus and ovulation. D. C. Busch*[1], D. J. Wilson[1], D. J. Schafer[2], N. R. Leitman[1], J. K. Hadek[2], M. R. Ellersieck[1], M. F. Smith[1], and D. J. Patterson[1], [1]*University of Missouri*, *Columbia*, [2]*MFA Inc.*, *Columbia, MO*.

Pregnancy rates after fixed-time AI (FTAI) were compared in beef heifers following administration of two CIDR-based protocols. The objective was to determine if long term progesterone treatment prior to a GnRH-prostaglandin $F_{2\alpha}$ (PG) regimen would improve estrous response and FTAI pregnancy rates compared to a CO-Synch + CIDR protocol. Heifers at three locations (n = 78, 61, 78) were assigned to one of two treatments by reproductive tract score (RTS; 1 to 5, 1 = immature, and 5 = cycling) age, and weight. Heifers assigned to treatment 1 (CIDR Select) received an EAZI-BREED™ CIDR® insert (CIDR; 1.38 g progesterone) from d 0 to 14 followed by GnRH (100 µg, i.m. Cystorelin) 9 d after CIDR removal (d 23) and PG (25 mg, i.m. Lutalyse) 7 d after GnRH treatment (d 30). Heifers assigned to treatment 2 (CO-Synch + CIDR) were injected with GnRH and equipped with a CIDR insert on d 23 and PG was injected and CIDR removed on d 30. Heifers at location 1 were fitted with HeatWatch® transmitters at PG until 24 d after FTAI to allow for continuous estrus detection. FTAI was performed at predetermined fixed-times for heifers in both treatments at 72 or 54 h after PG for the CIDR Select and CO-Synch + CIDR groups, respectively. All heifers were injected with GnRH at AI. Blood samples were collected 10 d before and immediately prior to treatment initiation (d 0) to determine pre-treatment estrous cyclicity (progesterone ≥ 0.5 ng/mL). At Location 1, estrous response during the synchronized period was higher (P = 0.06; 87 vs. 69%, respectively) and the variance for interval to estrus after PG was reduced among CIDR Select (P < 0.01) versus CO-Synch + CIDR treated heifers. FTAI pregnancy rates were higher (P = 0.02) following the CIDR Select protocol (62%) compared to the CO-Synch + CIDR protocol (47%). In summary, the CIDR Select protocol resulted in a higher and more synchronized estrous response and significantly higher FTAI pregnancy rates compared to the CO-Synch + CIDR protocol.

Key Words: Artificial Insemination, Beef Heifers, Estrus Synchronization

120 Timing of fixed-time AI in beef cows following the CO-Synch + CIDR protocol. D. C. Busch*[1], D. J. Schafer[2], N. R. Leitman[1], D. J. Wilson[1], J. K. Haden[2], M. F. Smith[1], and D. J. Patterson[1], [1]*University of Missouri*, *Columbia*, [2]*MFA Inc.*, *Columbia, MO*.

The objective was to compare pregnancy rates in postpartum beef cows to fixed-time AI (FTAI) after administration of the CO-Synch + CIDR protocol. Cows (n = 435) at two locations (n = 210, 225) were stratified by age, BCS and days postpartum (DPP) to one of two FTAI intervals. Cows assigned to CO-Synch + CIDR were injected with GnRH (100 µg, i.m. Cystorelin) and equipped with an EAZI-BREED™ CIDR® insert (CIDR, 1.38g progesterone, d 0). CIDR inserts were removed 7 d later at the time PG (25 mg i.m. Lutalyse) was administered (d 7). Continuous estrus detection was performed at Location 1 using HeatWatch®. Transmitters were fitted at the time of PG and removed at the time of AI. Artificial insemination was performed at predetermined fixed-times [54 h (TAI 54; n = 216) or 66 h (TAI 66; n = 219) after PG] and all cows were injected with GnRH (100 µg, i.m. Cystorelin) at AI. Blood samples were collected 10 d and 1 d prior to treatment initiation to determine pre-treatment estrous cyclicity [progesterone ≥ 0.5 ng/ml; (TAI 54, 170/216, 79%; TAI 66, 177/219, 81%); P=0.45]. At Location 1, more cows exhibited estrus prior to TAI 66 than TAI 54 (P = 0.02; 46/106, 43% and 28/104, 27%, respectively). Pregnancy rates were higher (P < 0.01) among cows that exhibited estrus than for those that did not (60/74, 81% and 71/135, 53%, respectively). There were no treatment by location interactions (P > 0.10) for age, DPP, or BCS, thus the results were pooled for the respective treatments. Pregnancy rates resulting from fixed-time AI did not differ between treatments [P = 0.20; (TAI 54, 126/215, 59%; TAI 66 141/219, 64%)], among sires (P = 0.13) or technicians (P = 0.15). However, when only considering cows ≥ 3 year of age, significantly more cows conceived to the FTAI when AI was performed at 66 h compared to 54 h (118/167, 71% and 96/163, 59%, respectively). There was no difference between FTAI pregnancy rates based on pre-treatment estrous cyclicity status (P = 0.12), and no difference (P = 0.53) between treatments in final pregnancy rates. In summary, cow age group should be considered when recommending timing for FTAI following the CO-Synch + CIDR protocol.

Key Words: Artificial Insemination, Estrus Synchronization

121 Comparison of the 7-11 estrous synchronization protocol between suckled Angus (AN) and Brangus (BN) cows. R. D. Esterman*, B. R. Austin, S. A. Woodall, and J. V. Yelich, *University of Florida*, *Gainesville*.

Suckled AN (n=44) and BN (n=38) cows were used to evaluate the effectiveness of GnRH to initiate ovulation when given 4 d after a 7 d melengestrol acetate (MGA) treatment and to eventually synchronize estrus. Mean BW, days postpartum, and body condition score (Scale 1-9) for AN and BN were 488 ± 10 and 514 ± 11 kg, 63.1 ± 3.7 and 57.4 ± 4.0 d , and 5.5 ± 0.8 and 5.6 ± 0.8, respectively. Start of experiment was d 0 and blood samples were collected on d -12 and -2 to determine estrous cycling status by measuring blood progesterone (P). On d 0, MGA (0.5 mg/head/d) treatment was started with prostaglandin F2α (PG1; Lutalyse®) on d 7 followed by GnRH (100 µg; Cystorelin®) on d 11. On d 18, PG (PG2) was administered and estrus was detected for 5 d with HeatWatch®, followed by AI 8 to 12 h after the onset of estrus. On d 0, 7, 11, and 18, blood samples were collected to evaluate P. Three groups of cows were used to evaluate ovarian function via ultrasonography on d 7, 11, 13, and 18, including anestrus (low P, < 1 ng/mL, d -12 and -2; ANEST; AN=6, BN=6), estrous cycling with low P on d -12 and high P (> 1 ng/mL) on d -2 (CYCH; AN=6, BN=6), and estrous cycling with high P on d -2 with PG on d 0 to mimic a low P environment during MGA (CYCL; AN=6, BN=6). Ovulation rate and size of follicle ovulating to GnRH were similar (P > 0.05) for AN (17/18=94.4%; 16.9 ± 0.8 mm) and BN (17/18=94.4%; 17.7 ± 0.8 mm), respectively. Size of follicle ovulating to GnRH tended (P = 0.09) to be greater for CYCL (18.6 ± 0.9 mm) and ANEST

(17.7 ± 0.9 mm) compared to CYCH (15.8 ± 0.9 mm). Largest follicle at PG2 (13.3 ± 0.3 mm) was similar (P > 0.05) for scan group, breed, and scan group × breed. Luteolysis tended (P = 0.09) to be greater for AN (39/41=95.1%) compared to BN (31/37=83.8%). Estrous (70.5, 65.8%), conception (67.7, 76.0%), and synchronized pregnancy rates (47.7, 50.0%) were similar (P > 0.05) for AN and BN, respectively. In conclusion, suckled AN and BN cows responded similarly to the 7-11 synchronization protocol.

Key Words: Estrous Synchronization, GnRH, PG

122 The use of estrus synchronization, resynchronization, and ultrasound to facilitate two timed artificial inseminations without heat detection in beef cattle. W. E. Beal*, M. D. Utt, and T. E. Wiseman, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

The objective was to evaluate the use of AI after synchronization and resynchronization of estrus without heat detection. Angus cows (n=37) or heifers (n=22) received GnRH (100 µg, i.m.) and an intravaginal progesterone-releasing device (CIDR). The CIDR remained in place for 7 d. Animals received 25 mg of $PGF_2\alpha$ (PG; i.m.) at CIDR removal. The control group (C; n=28) was observed for estrus and bred 12 h after estrus detection. The timed AI group (TAI; n=31) was inseminated and received GnRH 64 h after CIDR removal. Animals in both groups were fitted with a used CIDR 13 d after TAI. The used CIDR was removed after 7 d. Following removal of the used CIDR, C animals not detected in estrus after the first CIDR received an injection of PG. Animals in the C group were inseminated 12 h after estrus detection. Sixty-four hours after removal of the used CIDR, pregnancy was diagnosed by ultrasonography (Aloka 500V) in the TAI group. Non-pregnant animals in the TAI group were inseminated and received GnRH. At the time of the first or second AI, the maximum diameter and estimated blood flow serving the ovulatory follicle were determined by B-mode and color-flow Doppler ultrasonography (Aloka 3500V). Pregnancy diagnosis was performed 30 d after the last AI. Pregnancy rate following the removal of the first CIDR did not differ (P=.10) between C (14/28; 50%) and TAI (22/31; 71%). Final pregnancy rates were 19/28 (68%) and 27/31 (89%) in the C and TAI groups, respectively (P=.08). Mean diameter of the ovulatory follicle (15.6 ± .34 mm) did not differ between treatment groups. However, blood flow to the ovulatory follicle was greater (P<.02) in C than in TAI animals. This method of AI after synchronization and resynchronization of estrus without heat detection resulted in pregnancy rates similar to those achieved when AI was performed after heat detection.

123 Effect of GnRH at time of insemination on initiation of LH pulses and subsequent progesterone. S. D. Fields*, B. L. Perry, and G. A. Perry, *South Dakota State University*, *Brookings*.

Research has indicated that LH pulses play a vital role in CL formation and subsequent progesterone concentrations. Therefore, our objectives were to determine when LH pulses begin following onset of estrus, what effect an injection of GnRH would have on initiation of LH pulses, and what effect LH pulse initiation had on subsequent progesterone concentrations. Cows were synchronized with the Select Synch+CIDR protocol (d -7 100 µg GnRH and CIDR; d 0 25 mg PG and removal of CIDR; estrus detected with HeatWatch). Following detection in estrus, a jugular catheter was inserted in each cow (n = 10). Based on initiation of estrus, cows were allotted into two treatments: 1) GnRH given 12 h (12.5 ± 1.2 h) after the initiation of estrus (n = 5; 100 µg) and 2) Control (n = 5). Blood samples were collected at 15-min intervals for 6 h at 12 h (bleed 1), 26 h (bleed 2), 40 h (bleed 3), 54 h (bleed 4), and 68 h (bleed 5) after the onset of estrus. Interval from onset of estrus to bleed 1 and ovulation was similar between treatments ($P = 0.80$). GnRH cows tended ($P = 0.08$) to have a greater area under the LH curve for bleed 1 compared to Control. No differences were detected ($P > 0.47$) in bleeds 2, 3, 4, or 5. Average concentration of LH for GnRH cows in bleed 1 tended ($P = 0.07$) to be greater than control. No differences were detected ($P > 0.53$) in bleeds 2, 3, 4, or 5. No differences ($P > 0.31$) were detected in pulse frequency between treatments in bleeds 1, 3, 4, or 5, but in bleed 2, Control tended ($P = 0.095$) to have more pulses than GnRH (2.5 ± 0.5 vs 1.4 ± 0.4, respectively). GnRH treated cows tended ($P = 0.07$) to have greater subsequent progesterone concentrations; however, GnRH-treated cows that had no LH pulses during bleed 2 had lower ($P = 0.02$) progesterone concentrations than cows with pulses (Control or GnRH). In summary, injecting cows with GnRH approximately 12 h after the onset of estrus tended to reduce LH pulses 26–32 h following initiation of estrus, and elimination of LH pulses between 26–32 h resulted in decreased concentrations of progesterone during the subsequent cycle.

Key Words: LH, GnRH, Progesterone

124 Effect of pretreatment with prostaglandin $F_{2\alpha}$ 12 days before initiation of Resynch on fertility of lactating dairy cows. E. Silva*[1], R. A. Sterry[1], D. Kolb[2], M. C. Wiltbank[1], and P.M. Fricke[1], [1]*University of Wisconsin*, *Madison*, [2]*Lodi Veterinary Clinic*, *Lodi, WI.*

Our hypothesis was that pretreatment with $PGF_{2\alpha}$ (PGF) 12 d before initiation of Resynch would increase the number of cows with a CL at the first GnRH injection of Resynch thereby increasing fertility to Resynch. Lactating Holstein cows diagnosed not pregnant 31 d after their first postpartum timed AI (TAI; d 0) were randomly assigned by parity to receive each of two resynchronization treatments as follows: 1) RES (n=255), GnRH (d 32), PGF (d 39), GnRH 54 h after PGF, or 2) PGF+RES (n=272), PGF (d 34), GnRH (d 46), PGF (d 53), GnRH 54 h after PGF. All cows received TAI 16 h after the last GnRH injection, and cows failing to conceive to first Resynch TAI remained in the same treatment for a second Resynch TAI. Blood samples were collected from all cows at the first GnRH injection of Resynch to determine luteal status based on serum progesterone (P4). Fertility to first postpartum TAI 31 d after Presynch+Ovsynch was 37.0 % (n=836). Overall, PGF+RES cows had more P/AI 31 d (38.5 vs. 31.1 %; P=0.06) and 66 d (35.2 vs. 25.6 %; P=0.01) after TAI and fewer pregnancy losses from 31 to 66 d (7.6 vs. 17.1 %, P=0.04) after TAI than RES cows. Although cows with low P4 at initiation of Resynch had fewer P/AI 31 d (25.0 vs. 37.8 %, P=0.008) and 66 d (20.3 vs. 33.2 %, P=0.005) after TAI than cows with high P4, pretreatment with PGF did not affect the number of cows with high P4 at initiation of Resynch (76.1 vs. 73.1 for RES vs. PGF+RES cows, respectively) which was inconsistent with our hypothesis. In conclusion, although pretreatment with PGF resulted in more P/AI at 66 d after TAI than traditional Resynch due to both more P/AI at 31 d after TAI and reduced pregnancy

losses, this effect could not be attributed to increasing the number of cows with a CL at initiation of Resynch. Furthermore, PGF+RES cows had a 2 wk delay in the Resynch TAI compared to RES cows which would diminish the impact of improved fertility on 21-day pregnancy rate.

Key Words: Resynch, Prostaglandin F $_{2\alpha}$, Dairy Cows

125 Reducing the interval from Presynchronization to initiation of timed AI improves fertility in dairy cows. K. N. Galvao*, M. F. Sa Filho, and J. E.P. Santos, *School of Veterinary Medicine, University of California Davis*, *Tulare*.

Objectives were to determine if shortening the interval from presynchronization to the first GnRH (G1) in a Presynch/timed AI (TAI) protocol improves conception rate (CR). Holstein cows, 1214, at 37±3 d in milk (DIM) were stratified by parity, DIM, and milk yield, and randomly assigned to: PShort (n = 410), two injections of PGF2a (PG) at 40 and 54 DIM, then enrolled in a TAI 11 d later; PShortG (n = 392), same as PShort, but with an injection of GnRH 7 d before G1; Control (n = 412), two injections of PG at 37 and 51 DIM, then enrolled in a TAI 14 d later. All cows received the same TAI protocol (d 65, G1; d 72, PG; d 73, 1 mg of ECP; d 75, TAI). A subset of 1000 cows had their ovaries scanned at 65 and 72 DIM, which coincided with injections of GnRH and PG of TAI, respectively, to determine CL and ovulation to G1. Pregnancy was diagnosed on d 38 and 65 after AI. Data were analyzed with pre-planned orthogonal contrasts to determine the effect of interval (PShort + PShortG vs. Control) and GnRH treatment (PShort vs. PShortG). Results are depicted in the following sequence: PShort, PShortG, and Control. Presence of a CL at G1 was not influenced (P=0.95) by interval, but GnRH increased (P<0.01) the proportion of cows with CL (74.2, 88.2, and 80.6%). Ovulation to G1 was greater (P<0.01) for the short interval compared with Control, but GnRH did not improve (P=0.28) ovulation (61.4, 62.2, and 44.7%). The increased ovulation to G1 was primarily caused by greater (P<0.01) ovulatory response in cows with a CL at G1 (54.4, 59.7, and 37.2%), but did not differ (P=0.64) for cows without a CL at G1. Treatment affected the CR on d 38, and was greater (P=0.04) for the short interval compared with Control, but addition of GnRH did not improve (P=0.19) CR (40.5, 39.8, and 33.5%). The same effects were observed for CR on d 65 after AI (36.7, 36.2, and 30.5%). Cows ovulating to G1 had greater (P<0.05) CR regardless if they had (42.2 vs. 37.7%) or not (27.6 vs. 15.4%) a CL at G1. Shortening the interval from presynchronization to initiation of TAI from 14 to 11 d increased ovulatory response and conception rates in dairy cows.

Production, Management & the Environment - Livestock and Poultry: Dairy Production and Management I

126 Effects of dim light at night on milk yield, milk composition and endocrine profile of lactating dairy cows. M. A. Bal*[1], G. B. Penner[1], M. Oba[1], and A. D. Kennedy[2], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*University of Manitoba*, *Winnipeg, MB, Canada*.

Twenty-four multiparous lactating dairy cows (139 ± 34 DIM) were assigned to two different light intensities from 6 PM to 4 AM daily in a cross-over design with 28-d periods to evaluate the effect of night dim-light. It was hypothesized that night dim-light would increase milk production by decreasing melatonin concentration and increasing IGF-1 concentration in plasma. Light intensity during the day was approximately 200 lux and light treatments at night were 0-5 lux (CONTROL) and 40-60 lux (DIM LIGHT). Each group of animal (n=12) was placed on either the north or south side of the tie stall barn. Light intensity of the barn ranged from 40 to 60 lux at night but was reduced to < 5 lux for the CONTROL by placing black tarps near the light fixtures. Feed was offered in a TMR once daily at 9 AM. Blood samples for hormone analyses were taken every two hours at the last day of each period from 6 PM to 2 AM. There was no significant difference for milk, fat, protein, and lactose yields between CONTROL and DIM-LIGHT treatments, averaging 33.2, 1.04, 1.02, and 1.45 kg/d, respectively. Similarly, milk fat and protein concentrations were not affected by treatment. Concentration of lactose was significantly higher ($P < 0.01$) for DIM LIGHT than CONTROL (4.42% vs. 4.38%). Plasma prolactin concentration at 6 PM (during day-time) tended to be higher ($P = 0.07$) for DIM-LIGHT (15.1 ng/ml) than CONTROL (11.4 ng/ml). No change in prolactin was seen from 6 PM to 10 PM with DIM-LIGHT, but it increased 61% from 6 PM (11.4 ng/ml) to 10 PM (18.7 ng/ml) with CONTROL. Plasma IGF-1 concentration was not affected by treatment at 6 PM (123.1 ng/ml) or 10 PM (127.1 ng/ml). Day-time (6 PM) plasma melatonin concentration was relatively high (10.3 pg/ml). Treatment had no effect on the night-time plateau in melatonin found at 10 PM (21.5 pg/ml) and 12 AM (19.8 pg/ml). These data indicate that night dim-light (40-60 lux) modified the natural diurnal rhythm in plasma prolactin but not melatonin, and had a positive effect on milk lactose concentration but not yield.

Key Words: Dim Light, Milk Production, Melatonin and Prolactin

127 Effects of dairy dry lot corral management on air emissions. L. M. Nuckles* and F. M. Mitloehner, *University of California*, *Davis*.

The objective of this study was to evaluate the effects of drylot corral waste management on emissions of smog-forming compounds and greenhouse gases. The San Joaquin Valley of California is the leading dairy region of the United States but also known as the worst non-attainment area for smog. A total of 96 Holstein dry cows were housed in four, totally enclosed cattle pen enclosures (CPEs) and were fed a TMR *ad libitum*. Eight cows were housed in each of the four CPEs during each of three, 14 day replications. The experimental design was a CRD. Cows were randomly sorted into four groups and stratified by weight. Treatments were (1) control, manure accumulated for 14 days (CON), (2) acidifier surface application (sodium bisulfate, SBS), (3) frequent harrowing (HAR), and (4) scraping (SCR). Emissions of the smog-forming alcohols ethanol (EtOH) and methanol (MeOH) as well as the greenhouse gases (GHG) carbon dioxide (CO_2), nitrous oxide (N_2O), and methane (CH_4) were measured continuously from the CPEs′ air inlets and outlets. Gaseous concentrations were sampled using a photoacoustic gas-analyzer (INNOVA 1412) and emission rates (kg/cow/yr) calculated. Data were analyzed using Proc MIXED procedures in SAS. Overall, alcohol emissions for SBS were lower ($P < 0.05$) compared to all other treatments. EtOH emission rates

for SBS, CON, HAR, and SCR were 1.54, 7.8, 8.9, and 7.8 kg/cow/yr, respectively. MeOH, emission rates for SBS, CON, HAR, and SCR were 3.4, 10.3, 12.2, and 10.8 kg/cow/yr, respectively. SCR compared to SBS, CON, HAR showed reduced ($P < 0.05$) emission rates for N_2O, CO_2, and CH_4. Emission rates for CH_4 and N_2O were higher in SBS ($P < 0.05$), while CO_2 emission rates were lower compared to the other treatments ($P < 0.05$). This study suggests that surface acidifier (SBS) applied to dairy drylot corrals can reduce alcohol emissions, thus lowering resulting smog pollution. Surface acidifiers have inconclusive effects on GHG emissions. Scraping and harrowing of corral surface manure show little promise to reduce emissions of both smog forming compounds and greenhouse gases from dairies.

Key Words: Waste, Greenhouse Gases, Alcohols

128 Characterization and quantification of emissions from dairies. N. M. Marcillac*[1], F. M. Schwander[1], R. F. Follett[1], J. L. Collett[2], and N. P. Hanan[1], [1]*Colorado State University*, *Fort Collins*, [2]*USDA/ARS*, *Fort Collins, CO*.

Animal agriculture is a major source of atmospheric pollutants, but the nature and dispersion of those pollutants is not well known. This study aimed at quantifying emissions of ammonia (NH3), ammonium (NH4), nitric acid (HNO3), PM2.5, methane (CH4), carbon dioxide (CO2), and nitrous oxide (N2O) from dairy systems, and characterizing the spatial, diurnal, and seasonal variability of those emissions. Using a unique mobile sampling methodology employing helium balloons, filter packs, syringe pumps and a tethersonde climate sampling system, gases and particulates were measured at five heights (2 to 40 m high) at three locations downwind and one location upwind of a dairy. This innovative technique provided a spatially resolved characterization of the emission plume. Measurements were made at two dairies, seasonally, over two years from summer 2005 to winter 2006. Preliminary results show that the concentration of each compound varies spatially with height and has a strong seasonal variability. HNO3 had an inverse concentration to NH4 and typically was lower in downwind air, indicating consumption by conversion to ammonium nitrate. NH3 had a large differential from the upwind concentration ($P < 0.05$), especially in the summer months, and indicated a strong source from the dairy. The differential concentration of CH4 was greater than the other greenhouse gases ($P < 0.05$), while N2O and CO2 had very small contributions to total emissions. Peak concentrations were found at or near ground level ($P < 0.05$) with differentials 2 to 3 times greater than the upper heights, reflecting a strong local source. This data is helpful in characterizing the emission plume from dairies, aiding scientists and regulators in better understanding emissions from dairy operations.

Key Words: Dairy Emissions, Ammonia, Greenhouse Gases

129 Effects of waste management techniques to reduce dairy emissions from freestall housing. M. S. Calvo*, K. R. Stackhouse, and F. M. Mitloehner, *University of California*, *Davis*.

The objective of this study was to reduce smog-forming and green house gas emissions (GHG) from lactating Holstein cows using industry typical freestall waste management. The San Joaquin Valley (SJV) in Central California is the largest milk producing region in the United States. The valley suffers from substantial smog forming gases (aka Volatile Organic Compounds, VOC), and GHG emissions. Typical dairy freestall waste management in the SJV includes flushing and scraping. In the present study, four treatments were compared in groups of three cows/group. A total of nine lactating Holstein cows were randomly assigned into three groups and each group underwent all treatments using a CRD. The four treatments were 1) no waste removal (CON), 2) flushing three times daily (FL3), 3) flushing six times daily (FL6), and 4) scraping three times daily (SC3). Cows were fed a TMR *ad libitum* and housed in freestalls that were located inside an environmental chamber. VOC and GHG emission concentrations were measured using a photo acoustic gas analyzer (INNOVA 1412). Emission rates were calculated in kg/cow/year and analyzed using PROC MIXED in SAS. All emission compounds showed differences across treatments. As a general trend, CON showed highest emissions ($P < 0.05$), followed by SC3, FL3, and FL6. Flush vs. dry waste removal techniques (flushing vs. scraping) is approximately twice as effective ($P < 0.05$) in reducing VOC emissions under freestall conditions. More frequent flushing of dairy waste (FL6 vs. FL3) leads to further reduction of VOC emissions. GHG emissions were similar across treatments. The results of this study indicate that waste removal techniques used on modern dairies can decrease dairy air emissions. Consequently, VOC and GHG that promote smog and climate change can be reduced effectively through management of cow housing.

Key Words: Dairy, Waste, Emissions

130 Nitrogen losses from dairy manure estimated through nitrogen mass balance or using markers. A. N. Hristov*[1], S. Zaman[1], M. Vander Pol[1], P. Ndegwa[2], S. Silva[3], and C. Kendall[2], [1]*University of Idaho*, *Moscow*, [2]*Washington State University*, *Pullman*, [3]*U.S. Geological Survey*, *Menlo Park, CA*.

The objective of this study was to estimate N losses from dairy manure using N mass balance and other indirect approaches. The study was conducted at the University of Idaho Dairy Center, which is a free-stall facility with scraping system for manure removal. The study was conducted with one pen of 18 lactating Holstein cows. The duration of the trial was 30 d. Manure was scraped and removed from the pen once daily. Feed delivered and milk yields were recorded daily. The amount of manure removed from the pen was recorded daily and samples were collected for analyses, 24 h after excretion. Grab fecal and spot urine samples were colleted weekly from each cow. Output of urine and feces was estimated using acid-insoluble ash and creatinine as markers. Feces, urine, and manure samples were analyzed for N, ^{15}N, P, Cu, and Ca. Average daily N input with feed was 12.9±0.10 kg, or 385.8 kg for the duration of the trial. Average milk yield per cow was 37±0.2 kg/d with 3.9±0.08% crude protein content. Total N secreted with milk was 100.5 kg. Excretion of N with feces and urine was estimated at 224.3 kg. Manure N collected from the pen during the trial was 134.3 kg. Thus, 40% of the N excreted by the cows could not be accounted for in manure removed from the pen 24 h after excretion. Using N:P, N:Cu, and N:Ca ratios in fresh and 24-h manure, 60, 61, and 63% of the excreted N could not be accounted for. ^{15}N abundance of manure N increased in 24 h, from 1.344‰ to 4.887‰, presumably due to the loss of highly depleted in ^{15}N ammonia. Under the conditions in which this study was conducted (15.6±3.9°C; 2.3±1.0 m/s wind speed; and 72.6±12.5% RH), N losses from manure were high in the first 24 h after excretion. Data suggest that ratios of N to non-volatile elements and ^{15}N analyses may be useful in estimating N losses from cattle manure.

Key Words: Dairy Cow, Manure, Nitrogen Losses

131 Comparision of the Intergovernmental Panel on Climate Change (IPCC) system for estimating methane emission from dairy cows. S. K. Nes*, H. Volden, and S. J. Krizsan, *Norwegian University of Life Sciences*, *Ås, Norway*.

The objective of this study was to compare IPCC (2001) guidelines for estimating CH_4 emission by using a more advanced model, which include information on diet composition and animal production level. The IPCC has a 2-tiered system for estimating emission from enteric fermentation. Tier 1 is a simplified approach based on a fixed emission factor (EF) for each animal category. Until 2006 Norwegian calculations have been based on Tier 1. Tier 2 is a more complex approach where EF is developed based on country-specific data as nutrient requirements and feed intake. However, the IPCC has recommended using more advanced methods that goes beyond the Tier 2. About 90 % of the dairy cows in Norway are registered in the Cow Recording System (CRS), which contains detailed information regarding annual milk production and proportion of concentrate in the diet. Information from 1.16 million observations was used to calculate standard lactation curves and feed rations at different yields, feed intake, forage quality and forage:concentrate ratio. Using these data simulations average values of CH_4 production was calculated from 2 equations (Kirchgessner et al., 2005; Mills et al., 2003). Moreover, 2 multiple regression equations were developed where proportion of feed concentrate and milk yield were the only variables used to predict intake of GE and CH_4 conversion rate. to compare different methods CH_4 emission (kg/head per year) was calculated at 5000 (LP) and 9000 (HP) kg milk/year and at 2 levels of concentrate: 20% (LC) and 50% (HC). Estimated emission was constant regardless of level of yield and concentrate with Tier 1. Within LP and HP, Tier 2 and Tier 3 estimated 107 and 150, and 135 and 153 kg, respectively. There was no difference in estimating emission between LC and HC according to Tier 2. However, Tier 3 predicted higher emission at LC and HC at both yields but the difference was more pronounced at HP.

Key Words: Concentrate Level, Methane Emission, Milk Yield

132 Prediction of DHI udder health values from bulk tank information. A. J. Young*[1] and S. P. Tripp[2], [1]*Utah State University*, *Logan*, [2]*DHI-Provo Computing Service*, *Provo, UT*.

Identifying and predicting udder health problems are easily accomplished using DHIA information. However, many herds are not on DHI or experience problems between tests. The objective of this study was to determine if bulk tank somatic cell information could be used to predict potential udder problems and milk loss. DHI test information was collected from 17 dairies (13 Utah, 2 Idaho, 1 Montana and 1 Nevada) from January 2004 to December 2006. Bulk tank milk values were also collected and matched with test day information. After editing, 449 individual test days were used in the analysis. The bulk tank average SCS for the dataset was 4.19 with a range of 1.45 to 6.46. Correlation between DHI and bulk tank SCC and somatic cell score (SCS) were 0.842 and 0.898, respectively. Correlations with bulk tank SCS and the percent low (0-4), medium (5-6) and high (7-9) SCS from DHI were -0.834, 0.712 and 0.827, respectively. Linear and quadratic equations were developed using proc mixed models to predict percentage of cows in each of the SCS categories from bulk tank milk SCS. Both equations gave similar results for SCS of 3, 4 and 5 (range of differences was -0.6% to 0.37%). However, for SCS of 6, the quadratic equation predicted a higher percentage (+2.76%) of cows in the high category than the linear equation. Proc mixed results suggest that the quadratic equation was a better model than the linear. Several equations predicting milk loss percentage based on bulk tank SCS or SCC were found in the literature. Linear and quadratic equations were developed using milk loss percentage for each equation compared with bulk tank SCS. Using linear equations, the average milk loss for a bulk tank SCS of 3, 4, 5 and 6, was 0.94, 3.29, 5.65 and 8.0%, respectively. Using quadratic equations, the average milk loss based on a bulk tank SCS of 3, 4, 5 and 6, were 1.24, 2.84, 5.77 and 10.03%, respectively. We conclude that in the absence of DHI information, bulk tank SCS can closely predict values expected from DHI in terms of percent cows with high, medium or low SCS and percent milk loss.

Key Words: DHI, Bulk Tank, SCS

133 Variance components of test-day milk, milk components, and somatic cell score useful for management advice. M. Caccamo*[1], R. F. Veerkamp[2], G. de Jong[3], M. H. Pool[2], R. Petriglieri[1], G. Azzaro[1], and G. Licitra[1,4], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*Animal Breeding and Genomics Center, ASG, WageningenUR*, *Lelystad, The Netherlands*, [3]*NRS*, *Arnhem, The Netherlands*, [4]*D.A.C.P.A. University of Catania*, *Italy*.

Test-day (TD) models are used worldwide to perform national genetic evaluations for dairy cattle. TD models estimate (changes in) lactation curves, and variation around typical population or herd lactation curves, after adjustment for fixed effects and removal of environmental effects. Although potentially useful, little attention has been put on application of TD models for management purposes. The aim of this study was to estimate variance components for milk, milk components, and somatic cell score of dairy cows in Ragusa and Vicenza area, focusing on those variance components that are potentially useful for management advice to dairy farmers. Non informative records were extruded and the final dataset comprised 1,080,637 test-day records from 42,817 cows on 471 herds. Variance components were estimated using the multi-lactation, random regression, TD animal model adopted by NRS. The model comprised four fixed effects and a random herd × test date (HTD) effect. Random regressions were included for herd curve (HCUR), animal additive genetic effect, and permanent environment, using fourth-order Legendre polynomials. HCUR variances for milk and protein production were highest around the production peak (DIM 50 - 150), whereas for fat production the HCUR variance was relatively constant in lactation 1 and decreasing after a peak around 40 - 90 DIM throughout lactations 2 and 3. For SCS, the HCUR variances were relatively small compared to the other variance components. For all the traits except SCS the HTD variance was much lower than the HCUR variances and HCUR over phenotypic variances had a peak around 50-150 DIM and decreased at the end of the lactation to about 0.15 except for the first lactation where they slightly decreased to 0.35. Results for HCUR and HTD variance indicate that the development of management parameters should focus on between herd parameters during peak lactation for milk and milk components. For SCS the within herds variance components were higher than the between herds variance suggesting that focus should be on management parameters explaining variances at cow level.

Key Words: Dairy Cattle, Test-Day Production, Management Curves

134 Waste milk supply and pasteurizer performance on California dairy farms and calf ranches. M. C. Scott, R. E. James*, and M. L. McGilliard, *Virginia Polytechnic Institute and State University*, *Blacksburg, VA*.

Waste milk (WM) can be an economical and viable source of nutrition for young calves, but feeding it raw poses biosecurity concerns. Pasteurization effectively reduces health risk associated with feeding WM. This study was to track effectiveness of on-farm pasteurizers and determine amount and composition of WM generated by 9 dairy farms and used by a 30,000-head calf ranch in Tulare and Kings County, CA. Standard plate count (SPC), alkaline phosphatase, fat percentage, and protein percentage were measured prior to and immediately following pasteurization and at 20 min intervals until the last calf was fed. Farms ranging in size from 530 to 7000 milk cows were visited once in June 2005 and once in January 2006. There were 2 batch, 3 turbulent batch and 5 high temperature short time pasteurizers used on these operations. Standard plate count (SPC) of waste milk before pasteurization averaged 1.6 million cfu/ml, but ranged from 3,000 to 5.9 million cfu/ml. Fat and protein averaged 3.7% and 3.8%. However, fat varied from 1.1% to 5.3% and protein from 2.9% to 4.7%. Pasteurizer performance was evaluated based on SPC and alkaline phosphatase activity. Pasteurizers were effective, deactivating alkaline phosphatase more than 95% of the time, with post-pasteurized SPC averaging 13,000 cfu/ml. Farms using buckets to feed calves experienced higher SPC post pasteurization and during feeding than those using bottles. Five of nine dairies and the calf ranch added additional milk replacer to increase total solids of liquid feed, but only the calf ranch succeeded in increasing total solids. Most dairy farms had sufficient quantities of waste milk to meet the needs of the calf-feeding operation.

Key Words: Pasteurization, Calf, Waste Milk

135 Investigating relationship between protein-fat difference and milk yield of Iraninan Holstein dairy cows. B. Saremi*[1], J. Ghaseminejad[2], and J. Eslami[3], [1]*Education center of Jihad-e Agriculture, Animal Science Department*, *Khorasan Razavi, Mashhad, Iran*, [2]*Animal Science Department of Agricultural and Natural Resources University of Gorgan*, *Iran*, [3]*Animal Science Department of Zabol University*, *Iran*.

Aim of this study was investigating effects of protein-fat difference on milk production of Holstein dairy cows. Milk, fat, Protein and Somatic cell count (SCC) records from North, south and Razavi Khorasan states of Iran (59044 record) were adjusted using days in milk, parity, milking times, year and month of recording. Data was obtained from Jihad-e Agriculture Organization of Khorasan state of Iran, Animal Science section. Protein-fat difference was determined using fat and protein records based on grouping (cows were divided to 8 groups: protein fat differences Less than -1, -0.99 to -0.5, -0.49 to 0, 0.01 to 0.25, 0.26 to 0.50, 0.51 to 0.75, 0.76 to 1.00 and more than 1.01). Data were analyzed based on a completely randomized design. Means were compared using Duncan multiple range test (P<0.01). Results shows that protein fat difference can influence milk yield (P<0.01). Also it has a significant effect on SCC in milk (P<0.01). When milk fat is more than protein (negative groups), it shows that milk yield is lowest and gradually by decreasing fat content and constant amount of protein, milk yield increased (Negative relationship between milk yield and fat percent). When fat content is more than 0.5 percent below protein, again milk begins to reduce. At difference about 0.75, rate of milk reduction get higher. This difference between milk protein and fat is an indicator of acidosis. So 31.03 percent of records show cows that are influenced with one kind of acidosis in their rumen. It can adversely affect milk production as can be seen. SCC has a trend just like milk production, unless most SCC take place at protein fat difference about 0.51 to 0.75. According to these data it seems that efficient use of monthly records which usually exist in each herd are a suitable tool to investigate herd nutrition and may be a good indicator of distribution of acidosis in herds because of the high correlation.

Table and figure 1 Effect of protein fat difference on milk yield and somatic cell count of Holstein dairy cattle

Items	Grouping

136 Best management practices to improve milk quality and udder health in organically-managed dairy herds in Southeastern Pennsylvania. K. E. Griswold*[1], H. Karreman[2], and J. Mylin[3], [1]*The Pennsylvania State University Cooperative Extension*, *University Park*, [2]*Penn Dutch Cow Care*, *Gap, PA*, [3]*Lancaster DHIA*, *Manheim, PA*.

The effects of various management practices on milk quality and udder health in organically-managed (OM) dairy herds in Southeastern Pennsylvania were examined using a combination of survey and DHIA data. Initially, 38 OM herds using Lancaster DHIA services were recruited for the study, but only 29 herds returned completed surveys. The survey consisted of 308 questions concerning herd demographics, milk quality, health, reproduction, nutrition, and youngstock. The DHIA information included monthly 202 report data for 2006. Data were analyzed using PROC MIXED within SAS. The milking procedures model included the fixed effects of wearing gloves (WG), dry wiping (DW), pre-dipping (PRD), fore-stripping (FS), wiping dry prior to unit attachment (WD), and post-dipping (POD). The mastitis control practices model included the fixed effects of using California Mastitis Test (CMT), hand stripping infected quarters (HS), using quarter milkers (QM), culturing infected cows (CIC), culturing infected quarters (CIQ), and milking infected cows last (MICL). The dry period model included the fixed effects of abrupt dry off (ADO), seal teat ends (STE), and vaccinate during dry period (VDP). In milking procedure results, only WG and PRD significantly (P < 0.05) improved milk quality and udder health. Wearing gloves was associated with reduced average actual SCC (122,000 vs 374,000; SE = 70.8), and a lower % of cows with SC scores = 7-9 (1.2 vs 9.2; SE = 2.19). Pre-dipping was associated with reduced average actual SCC (134,000 vs 363,000; SE = 69.7), and a lower % of cows with SC scores = 7-9 (1.9 vs 8.5; SE = 2.16). Among mastitis control practices, only CIC was significantly (P < 0.05) associated with improved udder health. Herds that CIC had a greater % of cows with SC scores = 0-3, and lesser % of cows with SC scores = 5 and 6. In the dry period, there was a trend (P = 0.069) for VDP to reduce the % cows with SC scores = 7-9 (1.9 vs 8.8; SE = 2.8). These results suggest that BMP used with conventionally-managed dairy herds can effectively improve milk quality and udder health in OM dairy herds.

Key Words: Organic, Milk Quality, BMP

137 Increasing lighting program effects on production characteristics of modern broilers. K. Schwean-Lardner*[1], H. L. Classen[1], and B. I. Fancher[2], [1]*University of Saskatchewan*, *Saskatoon, Saskatchewan Canada*, [2]*Aviagen North America*, *Huntsville, AL*.

An experiment was conducted comparing growth parameters, meat yield characteristics and mobility indices of broilers (Ross × Ross 308) when raised under three lighting programs, initiated at 7 d of age (14L:10D; 23L:1D; increasing (INC) (7-14 d = 14L:10D, 15 -19d = 16L:8D, 20 - 24 d = 18L:6D, 25 - 29 d = 20L:4D, 30 - 34 d = 22L:2D, and 35 - 38 d = 23L:1D)). Three room replications were used per lighting program, and each room contained 6 pens for each sex of Ross x Ross 308 broilers (total number placed - 5022). Interactions between sex and lighting program were minor, so only overall lighting effects are reported. All numeric data is presented in order of 14L, 23L and INC, respectively unless otherwise stated. Bird weights at 31 (1.683c, 1.714b and 1.751a) and 38 (2.380b, 2.339b and 2.438a) d were highest with the use of an INC program. FCR was lowest for birds raised on 14L, and equal for INC and 23L (F:G 1.642b, 1.719a and 1.697a). Although not statistically different, mortality was highest when birds were raised on 23L (4.50%, 8.01% and 6.02%). Using an INC program resulted in an intermediate proportion of breast meat yield as a percentage of carcass weight (26.11c; 28.06a; 27.13b). In contrast, birds raised on 14L had heavier percent whole thighs (9.32a vs 8.87b for INC and 9.03b for 23L) and drums (7.01a vs 6.74b and 6.76b for 23L and INC respectively). Mobility (measured by gait scoring) was best when birds were raised under 14L, and intermediate when an INC program was used (0.75b, 1.13a and 0.90ab), indicating better welfare with regards to leg defects than birds raised under 23L. In conclusion, use of an INC program resulted in the most rapid growth and was intermediate in the level of mortality, breast muscle production, and leg weakness to 14L and 23L programs.

Key Words: Broiler, Photoperiod, Gait Score

138 Does broiler breeder flock age influence embryonic metabolism in different genetic strains? J. A. Hamidu*[1], G. M. Fasenko[1], E. E. O'Dea[1], J. J. R. Feddes[1], C. A. Ouellette[1], V. L. Christensen[2], and M. J. Wineland[2], [1]*University of Alberta*, *Edmonton, Alberta, Country*, [2]*North Carolina State University*, *Raleigh*.

The study examined the effect of genetic strain (Ross 308 (R); Cobb 500 (C)) and flock age on eggshell conductance (G), and embryonic metabolism. The G value was calculated on 30 hatching eggs from mature (M) (45 wk), old (O) (55 wk), and very-old (VO) (59 wk) flocks during 9 d from egg moisture loss and vapor pressure difference. Ten eggs per strain by flock age were also weighed and incubated for 21.5 d in individual metabolic chambers to measure embryonic O2 consumption and CO2 output. The data were then used to calculate the respiratory quotient (RQ = CO2/O2) and embryonic metabolic heat production during incubation. After hatching the chicks were euthanized, the yolk sacs removed, and the wet and dry wt obtained. Data were analyzed by SAS® GLM at P≤0.05. Genetic strain did not affect the G value but flock age had an effect; the O flock had a higher G (20.20±0.79 mg/day/mmHg) than the M flock (17.46±81), but neither of these differed from the VO flock (19.17±0.78) over the 9 d. However the R strain produced more average heat (88.48±1.78 mW) than the C (83.56±1.76 mW) over 21 d. Flock age did not affect embryonic heat production. Strain did not influence mean RQ but mean RQ was higher in M (0.82±0.009) versus the O (0.67±0.008) and VO (0.67±0.008) flocks. Chick wt did not differ between strains, but chicks from the VO flock were heavier (49.22±0.28g) than either the M (47.33±0.29g) or O (47.04±0.29) flocks. Wet carcass was significantly heavier in M (81.37±0.46) than O (79.95±0.46) flocks while dry carcass was heavier in M (16.18±0.251) than both O (15.82±0.25) and VO (15.43±0.24) flocks. Wet yolk sac was heavier in O (19.30±0.44) than VO (17.89±0.44) and M (18.20±0.42) flocks while dry yolk sac was heavier in O (10.96±0.27) than M (10.04±0.27) but not VO (10.24±0.26) flocks. The study showed that genetic selection of modern broiler strains has impacted embryonic heat production. The results also showed that as flock age increased the embryos increasingly used more fat substrates than carbohydrates.

Key Words: Genetic Strain, Flock Age, Embryonic Metabolism

139 Effects of *in ovo* injection of select salt solutions and metabolic compounds on chicken embryo livability and growth. B. M. McGruder*[1], E. D. Peebles[1], D. A. Braasch[1], M. A. Dekich[2], P. D. Gerard[1], and R. W. Keirs[1], [1]*Mississippi State University*, *Mississippi State*, [2]*AviTech, LLC*, *Salisbury, MD*.

Pilot trials were conducted to evaluate the effects of various physiological salts and metabolic compounds administered *in ovo* on the livability and growth of broiler embryos. Solutions of 200 µL were injected into the amnion of embryos at d16 of incubation using an AviTech Intellijject™ single egg injector. Based on their potential to augment nutrient metabolism and subsequent growth, the efficacies of potassium chloride (KCl) (110, 118, 125, 130 mM), sodium acetate (0.5, 1.0, 1.5, 2.0 mM), and monosodium phosphate (4.0, 4.5, 5.0, 5.5 mM) were evaluated in trial 1. Also, based on their potential to affect diverse metabolic pathways and stimulate growth, the efficacies of tripotassium citrate (1x, 2x, 4x, 8x), a carbohydrate/electrolyte nutrient solution (CEN) (1x, 2x, 4x, 8x), and caffeine (1x, 3x, 6x, 9x), in relative concentrations, were examined in trial 2. Physiological saline and non-injected treatments were used as standard controls in both trials. In both trials, the following were examined on d18 of incubation: embryo mortality; relative embryo weight and moisture content; relative dry embryo weight; and relative yolk sac weight and yolk moisture content. None of the injected solutions had a significant effect on embryo mortality. However, KCl at all molarities and physiological saline increased relative yolk sac weight in comparison to non-injected controls. All relative concentrations of the metabolic compounds decreased relative embryo BW, and the CEN injection at all 4 relative concentrations increased embryo moisture and decreased embryo dry matter content. In conclusion, injection of physiological saline and KCl into the amnion at d16 may provide a yolk sparing effect and may subsequently have a positive effect on post hatch chick growth. Furthermore, all the salt solutions tested have the potential for use in commercial egg injection, and might also be combined with the metabolic solutions examined to promote hatchability and post-hatch growth.

Key Words: Embryogenesis, *In Ovo* Injection, Physiological Compounds

140 Partial coefficients of nutrient partitioning of broiler breeders using different feeding strategies during the production phase. L. F. Romero*[1], M. J. Zuidhof[2], A. Naeima[1], F. E. Robinson[1], and R. A. Renema[1], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Alberta Agriculture and Food*, *Edmonton, AB, Canada*.

This study was conducted to identify a model to estimate partial coefficients of nutrient partitioning of broiler breeders using a set of biologically meaningful explanatory variables of ME intake and compare the coefficients among different feed allocation strategies. A total of 288 pullets (Ross 708) were reared in floor pens, individually caged at 16 wk and assigned to one of four feed allocation groups. Three groups had feed allocated on a group basis with divergent target BW reached at 20 wk: Standard (STD), HIGH (STD × 1.1), and LOW (STD × 0.9). The fourth group had feed allocated on an individual bird basis (IND) and followed the STD BW target. Models explained average daily ME intake using weekly data from 20 to 52 wk and regressions used generalized least squares. Maintenance estimates were based on Metabolic BW (MBW=$BW^{0.67}$). Model fit was assessed with the Bayesian Information Criterion (BIC). A total of 9394 valid observation sets were used. Besides MBW, Average Daily Gain (ADG) and Egg Mass (EM) (BIC=94187.9), improvements of fit allowed the inclusion of MBW × temperature (T), MBW × T^2, percentage of yolk, wk from first egg, wk before first egg, corrections due to negative ADGs, and hours of photoperiod (BIC=83958.3). The residuals showed a peak at the beginning of egg production in all groups. ME requirements increased by 3.26 kcal/wk (SE=0.22) before, and decreased by 4.16 kcal/wk (SE=0.04) after the first egg. From a model including MBW, ADG and EM, partial coefficients of the pooled data were 117.36 kcal ME/kg MBW (SE=0.73), 3.33 kcal ME/g ADG (SE=0.04) and 2.16 kcal ME/g EM (SE=0.03). Compared to STD, LOW hens showed higher MBW and lower ADG and EM coefficients, and HIGH hens showed higher ADG and EM coefficients (P<0.001). IND hens showed lower MBW and higher ADG and EM coefficients than STD hens (P<0.001) although there were no differences in the residuals between these two groups (P=0.127).

Key Words: Broiler Breeders, ME Partitioning, Residual Feed Intake

141 Broiler breeder strain and egg size affect egg characteristics, hatchability, and broiler performance in old flocks. A. M. Franco*, G. M. Fasenko, and E. E. O'Dea, *University of Alberta*, *Edmonton, Alberta, Canada*.

Broiler breeder flock age is an important factor in determining egg and chick quality. This trial analyzed the effects of strain and egg size on egg characteristics, hatchability, and broiler performance using eggs from 59 wk old flocks. Eggs were collected from two strains (Ross308 (R), Cobb500 (C); n=1380/strain) and three egg sizes (small (S), medium (M), large (L); n=920/size). Specific gravity, albumen, shell and yolk weights were measured in 30 eggs/strain/size, the remaining eggs were incubated. Saleable chicks were weighed, placed in floor pens (n= 2 pens of 119 chicks/strain/size) and grown out for 42 days. Daily mortality, 3 and 6 wk feed consumption and BW were recorded. Data were analyzed using SAS proc Mixed (P≤0.05). C eggs were heavier (71.3±0.09g) than R (68.3±0.09g), had higher specific gravity (1.075±0.0005) than R (1.071±0.0005), and higher % dry shell (C=8.6±0.07%; R=8.3±0.07%). S eggs had higher % dry shell (8.6±0.08%) than L (8.3±0.08%). Strain and size affected % egg weight loss at transfer: R was higher (13.4±0.08%) than C (11.8±0.08%) and S (13.3±0.1%) higher than M (12.4±0.1%) and L (12.2±0.1%). Infertility was greater in R (20.7±0.86%) than in C (5.5±0.86%). Early embryo mortality was greater for R (6.4±0.64%) than for C (4±0.64%), but late embryo mortality was the opposite (C=4.5±0.56%; R=2.9±0.56%). S eggs had lower late embryo mortality (2.4±0.69%) than M (3.5±0.69%) and L (5.2±0.69%) and higher hatchability of fertile eggs (S=87.3±1.22%; M=86.3±1.22%; L=84±1.22%). S eggs hatched sooner (496.7±1.19h) than M (501.4±1.19h) or L eggs (503.1±1.19h). C eggs hatched heavier chicks (48.9g±0.07g) than R (44.3±0.07g), and L eggs hatched heavier chicks (51.6g±0.08g) than M (48±0.08g) and S (44.6g±0.08g). The results indicate that strain and egg size affected egg quality and hatchability in old flocks; future research should evaluate specific incubation conditions based on strain and size to improve hatchability.

Key Words: Broiler Breeder Strain, Egg Size, hatchability

142 Effect of early and late incubation temperature profiles and hatching basket ventilation on broiler embryonic development. K. E. Brannan*, N. Leksrisompong, P. W. Plumstead, J. H. Small, E. O. Oviedo-Rondon, and J. T. Brake, *North Carolina State University*, *Raleigh*.

An experiment was conducted to examine the effects of early and late incubation temperature profiles and hatching basket ventilation during the last 4 d of incubation on embryonic development. Eggs from a 52-wk-old Ross 344 × 708 broiler breeder flock were divided equally between two incubators to create an Early Hot (EH) treatment with an average air temperature of 38.1°C and an Early Cool (EC) treatment with an average air temperature of 36.9°C during E0 to E3 of incubation. From E4 to E18, both machines were adjusted to maintain an egg shell temperature of 37.5°C. On E15, 40 eggs from each early temperature treatment were sampled. Embryo weight and length were significantly larger in the EH treatment while yolk and albumen weights were significantly smaller. At transfer on E18, eggs were randomized by tray within each early temperature treatment and placed into plastic hatching baskets with 170 eggs in each basket. The plastic hatching baskets were divided into two ventilation treatments of top taped (TT) and control (CN) and then equally divided between two hatchers representing two late temperature treatments. One machine was designated as Late Hot (LH) and maintained at an air temperature of 38.2°C, while the other machine was designated as Late Cool (LC) and maintained at an air temperature of 36.1°C. At hatching, chick BW and relative weights of the yolk, heart, proventriculus, and gizzard were determined. The EH treatment chicks were longer and exhibited larger gizzard and proventriculus weights despite having a smaller BW and yolk sac. The LH treatment produced a smaller BW but no other differences. Basket ventilation also did not product any differences. Although there were no two-way early by late incubation temperature interactions the EC treatment consistently produced smaller proventriculus weights across the three-way interactions.

Key Words: Ventilation, Incubation Temperature Profile, Egg Temperature

143 Effect of early and late incubation temperature profiles on broiler long bone development. J. H. Small*, K. E. Brannan, N. Leksrisompong, P. W. Plumstead, J. Brake, and E. O. Oviedo-Rondón, *North Carolina State University*, *Raleigh*.

Incubator conditions during the plateau stage of incubation can affect avian long bone development. This experiment was conducted to evaluate the effects of early and late incubation temperature profiles on broiler long bone development at hatching. A 2 × 2 factorial design of treatments was applied during early, E0-E3, and late, E18-E21, incubation. Eggs from 52-wk-old Ross 344 x 708 breeders were divided equally among two incubators to create Early Hot (EH) and Early Cool (EC) air temperatures of 36.9 and 38.1°C, respectively. Both machines were adjusted to maintain eggshell temperatures of 37.5°C from E4 to E18. At transfer on E18, eggs were randomized by tray within each early temperature treatment and placed into plastic hatching baskets in both machines. One machine was then designated as Late Hot (LH) with an air temperature of 38.2°C, and the other was designated as Late Cool (LC) to maintain an air temperature of 36.1°C. At hatching, 15 chicks from each treatment were randomly selected. BW and yolk sac weights were recorded, and legs were removed. Weight and length of tibia, femur and shanks were determined. Relative percentages of bones and fluctuating asymmetry for each limb section were calculated. Hatchlings from the EC treatments had the heaviest BW ($P < 0.001$) and reduced yolk absorption ($P < 0.001$), but yolk-free BW was not affected by the treatments. The EC profiles increased ($P \leq 0.05$) shank weights. The highest relative asymmetry of femur ($P < 0.01$) and tibia length ($P < 0.05$) was observed with the ECLH profile. In conclusion, the EC incubation profiles may affect long bone development and increase relative asymmetry of legs in day-old chickens especially when they are placed in hatchers with hot temperature profiles. These results may have implications on broiler leg health during grow-out.

Key Words: Incubation Temperature Profile, Bone Development, Broiler Leg Health

144 Feeding broiler breeder hens twice a day after photostimulation improves reproductive performance. J. M. Spradley*, M. E. Freeman, J. L. Wilson, and A. J. Davis, *University of Georgia*, *Athens*.

After photostimulation, the reproductive performance of broiler breeder hens is sensitive to extended periods of fasting. In a past experiment, extending a skip-a-day feeding program past photostimulation until five percent egg production decreased total egg production by more than 19 eggs per broiler breeder hen through 65 weeks of age, as compared to commencing a once a day feeding program after photostimulation. In the current research the effects on reproductive performance of shortening the fasting period even further by implementing a twice a day versus a once a day feeding program after photostimulation was investigated. Pullets were reared using a skip a day feeding program from 2-21 weeks of age. All pullets were weighed at 20 weeks of age and then distributed into 30 laying pens (35 hens and 4 roosters per pen) such that each pen had a similar body weight distribution. At 21 weeks of age 15 of the laying pens were placed on a once a day feeding schedule while the other 15 pens were placed on a twice a day feeding schedule. The total amount of feed provided per day to all the laying pens was the same; however, the birds fed once a day received all of their feed at 6:30AM, while the birds fed twice a day received 60% of their total feed allotment at 6:30 AM and the other 40% at 3:00PM. Even though both treatment groups began egg production at the end of week 23, the birds receiving feed twice a day have laid significantly more eggs through 45 weeks than those fed once a day. Since 26 weeks of age, eggs produced by birds fed twice a day have been significantly and consistently heavier by about 1g than the eggs produced by the birds fed once a day. Feeding hens twice a day has also improved their body weight uniformity compared to the hens fed once a day. These results further demonstrate that to achieve optimum reproductive performance in broiler breeder hens it is necessary to limit fasting durations after they have been photostimulated for reproduction.

Key Words: Broiler Breeder Hen, Twice a Day Feeding, Egg Production

145 Relationships between broiler breeder body weight, breast meat development, and reproductive tract development. N. Leksrisompong*, E. O. Oviedo-Rondon, and J. T. Brake, *North Carolina State University*, *Raleigh*.

A study was conducted to investigate the relationships between broiler breeder female BW, breast meat development, and reproductive tract development as influenced by two feed allocation programs during the rearing period followed by two feed increase rates from photostimulation to peak egg production. Females were reared on litter with either of two feeding programs (Low or High) from hatching to 23 wk of age and then moved to individual cages and subjected to either Slow or Fast feed increments from photostimulation to peak egg production in a 2 × 2 factorial design. BW was determined on individual hens at 24 wk, fifth egg, and 44 wk of age. Breast muscle weight was estimated by real time ultrasound at 24 wk and fifth egg while all birds were killed and deboned to determine actual breast meat at 44 wk of age. Weights of the ovary and oviduct segments were also taken at 44 wk. Hens were inseminated artificially at 39 wk and eggs collected for 14 d. Pullets from the High feeding program weighed more at 24 wk but only the High-Fast combination hens were heavier than the other hens at 44 wk. Larger hens possessed greater breast meat at 24 wk and 44 wk. BW at fifth egg was positively correlated with uterus and magnum, but not ovary and other oviduct segment weights at 44 wk. Hens from the Low and Slow feeding programs had the heaviest magnums while hens from the High and Slow programs had the smallest magnums. In a similar manner, breast meat weight at 44 wk was correlated only with magnum weight. These data suggest that the oviduct segments and ovary were not developing in a synchronous manner relative to BW and breast meat development. Feeding programs consistently caused variations in magnum weight but not in any other part of the oviduct. The High feeding program during rearing produced hens that exhibited poorer fertility probably due to their greater biological age at the time of insemination.

Key Words: Broiler Breeders, Oviduct, Ovary

146 Effect of female broiler breeder BW profile and rate of lay on broiler chick traits, growth performance and meat quality. A. Naeima*[1], L. F. Romero[1], M. J. Zuidhof[2], R. A. Renema[1], and F. E. Robinson[1], [1]*University of Alberta*, *Edmonton, AB., Canada*, [2]*Alberta Agriculture and Food*, *Edmonton, AB., Canada*.

The impact of divergent female BW profiles from 16 wk of age on broiler offspring chick quality, yield, and meat quality was assessed

in Ross 708 broiler breeders. At hatch, 216 pullets were assigned to a BW profile group and reared in floor pens on a common BW target. Pullets were individually caged at 16 wk. Feed allocation was altered for each group to achieve the following BW profile targets by 20 wk of age: Standard (Std), High (Std × 1.1), and Low (Std × 0.9). In the first study (32 wk of age), eggs from 1 wk were incubated and the 988 resultant broilers assessed for chick quality traits and grown to either a 39 or 49 d processing age. Eggs from this period (30-31 wk of age) from Low hens were smaller and had a lower proportion of yolk than eggs from Std or High hens (P<0.0001). Chick length and weight were also lower in Low chicks (P<0.0001), but differences disappeared by 11 d of age. Maternal BW profile did not affect broiler feed efficiency or meat quality traits (pH, color, drip loss, cook loss and tenderness). At 45 wk of age, broiler growth efficiency and yield was assessed in a comparison of the offspring of the 11 best (high: HE) and 11 worst egg producers (low eggs: LE) from each BW profile. The progeny were brooded on litter-floored cages, separated by dam and sex (2 × 3 × 2 factorial design). At this maternal age, eggs from Std hens had the lowest transfer and hatch weights (P<0.0001), although differences did not persist. The best egg layers (HE) produced 40.2 g chicks compared to 44.3 g chicks in the LE treatment, reflecting their smaller egg size. The HE chicks also had a reduced length at hatch (P<0.0028). Their BW remained 5% lower, but with similar % breast yield. Breast muscle from HE broilers was brighter (L*) than breast from the LE broilers (P<0.0002). While this suggests potential differences in muscle quality, drip loss, cooking loss and tenderness were similar.

Key Words: Broiler Breeder, Growth Rate, Meat Quality

147 The relationship between female feather cover, mating frequency and male–to–female aggression in Broiler Breeders. D. E. Holm*[1], R. A. Renema[1], F. E. Robinson[1], and M. J. Zuidhof[2], [1]*University of Alberta*, *Edmonton, Alberta, Canada*, [2]*Alberta Agriculture and Food*, *Edmonton, Alberta, Canada*.

A 3 × 4 factorial design study was performed to examine the relationship of feather cover in female broiler breeders with male BW distribution, aggression, and sexual behavior. Ross 308 broiler breeders (264) were housed in 8 rooms (17.13m^2 with 60% slats) of 30 hens and 3 roosters. Hen feather score (FS) was based on a 5–point scale with 6 focal hens per room consisting of 2 hens/FS1 (poor), FS3 (moderate) and FS5 (excellent). Male tmt (2 pens/tmt) were based on BW distribution: High Uniform (HU) (BW range<500g), Uniform (U) (BW range= 600g), Skew High (SH) (2 males 700g>1 male), and Skew Low (SL) (2 males 700g<1 male). Rooms were videotaped using ceiling–mounted cameras for 3–hr/d for 3 consecutive days from 6 to 9 pm. Focal scan sampling of all 72 hr of tape documented incidence of specific aggressive and mating behaviors and instantaneous location scans done every 5 min. Birds were dissected to characterize reproductive morphology. Proc MIXED was used to assess differences in mating and aggressive behaviors, and reproductive morphology. Hens with poor feather cover (FS1) had a lower BW (3.65kg) than hens with moderate (3.97kg) (FS3) or excellent (4.16kg) (FS5) feather cover. The better-feathered FS3 and FS5 hens spent more time on the slatted area compared to the FS1 hens. This could indicate a relationship between feather score and mating frequency. The HU and SH (mean of 5.81 events) male BW treatments demonstrated more male to female aggressive pecks and grabs compared to males of the U and SL (mean of 0.78 events) treatments. The U and SL treatments may have more behavioral stability because one male of higher BW being able to maintain a dominant role. No relationship between feather cover and reproductive morphology was found. Feather cover may be used as general but not definitive indicator of mating frequency while male BW distribution can be used as an indicator of potential male to female aggressive behaviors.

Key Words: Broiler Breeders, Feather Cover, Aggression

148 Novel isolation procedures for developing probiotic cultures against *Campylobacter* for poultry. V. F. Aguiar*[1], I. Reyes-Herrera[1], F. Solis de los Santos[1], M. L. Dirain[1], J. Metcalf[1], P. J. Blore[1], A. M. Donoghue[2], and D. J. Donoghue[1], [1]*University of Arkansas*, *Fayetteville*, [2]*PPPSRU, ARS, USDA*, *Fayetteville, AR*.

Campylobacter is a pathogenic bacterium that is a leading cause of food borne illness associated with the consumption of poultry products. *Campylobacter* is commonly present in the intestinal tract of poultry and one strategy to reduce enteric colonization is the use of probiotic cultures. These cultures consist of beneficial bacteria which may displace enteric pathogens. Although probiotic cultures have been successfully used to reduce enteric *Salmonella* colonization, their use has met with limited success against *Campylobacter*. In an effort to improve the efficacy of probiotic cultures, new isolates have been collected and identified by our laboratory. Cecal contents from approximately 300 healthy chickens were collected and diluted in Butterfield′s Phosphate Diluent and inoculated onto both Blood Agar Plates and Lactobacilli MRS broth and incubated at 37°C over night. Isolates were identified using Gram stain and the Biolog© system. Only isolates meeting the GRAS (Generally Recognized as Safe) status according to the Food and Drug Administration were considered for probiotic development. The 45 isolates meeting this criterion were co-incubated with *Campylobacter*, *in vitro*, to determine their ability to reduce *Campylobacter* growth. Of these 45 isolates, 11 isolates inhibited *Campylobacter* growth. We are currently in the process of evaluating the ability of these isolates to reduce gastrointestinal *Campylobacter* colonization in chickens.

149 Effects of chemical treatment of canola meal on nutrients ruminal degradation in Zel sheep using in situ methods. A Teimouri Yansari*[1] and H. MohammadZAdeh[1], [1]*University of Agriculture and Bioresource*, *Sari, Mazandaran, Iran*, [2]*University of Agriculture and Bioresource*, *Sari, Mazandaran, Iran*.

The experiment was conducted to determination the effect of chemical treatment on in situ degradation of dry matter, crude protein and neutral detergent fiber (NDF) of canola meal (CM). Canola meal was treated by spraying with acetic acid, formic acid, hydrochloric acid, sulfuric acid and formaldehyde at 0.0, 1.0, 2.5 and 5.0% (vol/wt). Ruminal degradability of CM was measured by the nylon bag technique using two fistulated Zel ewes (approximately 1 yr old, BW= 30±2 kg) fed alfalfa hay and barely grain in a ratio of about 75:25 (DM basis). Incubation time consisted of 1, 3, 6, 12, 24 36 and 48 h. This experiment was a completely randomized design with 5×3 factorial arrangement of treatment. Ruminal degradability of DM, CP and NDF were significantly influenced by chemical treatment, level, and the interaction of chemical treatment and level. The acids and formaldehyde significantly reduced the soluble, potential degradable fraction, and rate of degradation of DM and protein. Only acids significantly increased the soluble, potential degradable fraction, and rate of degradation of NDF. However, formaldehyde was not influenced by rumen degradability of NDF. In addition, as the concentration of acids increased, their influences were similarly increased. The results of this experiment showed that chemical treatment can improve the utilization of CM in ruminants by reducing and increasing of ruminal degradation of protein and NDF, respectively.

Key Words: Canola Meal, Ruminal Degradability, Nylon bag Technique

150 Effects of chemical treatments of rice straw on rumen fermentation, fibrolytic enzyme activities and populations of liquid- and solid-associated ruminal microbes in vitro. X. L. Chen, J. K. Wang, Y. M. Wu, and J. X. Liu*, *College of Animal Sciences, Ministry of Education Key Laboratory of Molecular Animal Nutrition, Zhejiang University*, *Hangzhou, China*.

The study was to investigate the effects of treatment of rice straw (RS) with NaOH (SH) and NH_4HCO_3 (AB) on fermentation, fibrolytic enzyme activities and populations of liquid- and solid-associated ruminal microbes in vitro. Fibrolytic specific activities were estimated by the amount of reducing sugars released from the solid-bound microbes. Total DNA was extracted from the liquid- and solid-associated ruminal microbes, respectively, and populations of rumen fungi, *Ruminococcus flavefaciens* (Rf) and *Fibrobacter succinogenes* (Fs) were determined by real-time quantitative PCR. Microbial protein mass increased with incubation time, and was higher for the treated straws than for the untreated ($P<0.05$). Both treated and untreated straws maintained a typical roughage type of fermentation with a high proportion of acetate. The SH treatment increased carboxymethyl cellulase and avicelase activities at all incubation times. Both SH and AB treatments significantly increased xylanase activity. Rumen fungi were significantly increased with incubation time in both liquid and solid phases for SH-RS, but not affected by AB treatment. Both solid- and liquid-associated Rf were higher in treated straws than in the untreated, with higher solid-associated Rf in SH-RS than in AB-RS at early incubation. Solid-associated Fs was lower and liquid-associated Fs was higher in SH-RS than in other two straws. Liquid-associated Fs was lower at early incubation in AB-RS. It is inferred that chemical treatments enhance the nutritive value of RS through improving rumen fermentation and fibrolytic enzyme activities, and has great influences on rumen microbial distribution and populations, but their fluctuating pattern with incubation time is slightly different between two treated straws.

Key Words: Rice Straw, Fermentation, Ruminal Microbes

151 Effects of feeding thermochemically-treated wheat straw and corn stover on lamb performance and digestibility. N. A. Pyatt[1], P. H. Doane[1], M. J. Cecava*[1], J. L. Dunn[1], J. R. Sewell[2], and L. L. Berger[2], [1]*ADM Animal Nutrition Research*, *Decatur, IN*, [2]*University of Illinois*, *Urbana*.

Fifty-two individually-fed lambs (39.37 ± 0.62 kg) were utilized in a 28-day 2 × 3 (+1) factorial design study to assess if thermochemically-treated wheat straw and corn stover can replace corn in ruminant diets. Wheat straw or corn stover were treated with 5% CaO and water in a double-shaft enclosed mixer (Readco® Continuous Processor) and subsequently pelleted with DDGS (75% residue:25% DDGS; DM basis) to form corn replacement pellets (CRP). The Control diet consisted of 45% cracked corn, 24% DDGS, 12% soyhulls, 10% grass hay, 6% supplement, and 3% cane molasses. The CRP was fed at 0%, 20%, 40%, or 60% of diet DM and replaced corn and DDGS. Final weight tended greatest for lambs fed Control, 40% CRP-straw, or 20% CRP-stover diets, and least for animals fed either 60% CRP treatment. Final BW decreased linearly with CRP inclusion but more so for stover than straw. Feeding 20% CRP-stover and 40% CRP-straw lambs maintained gain at about 90% of Control. Intake increased with increasing amounts of CRP-straw, but decreased with CRP-stover. Cumulative feed efficiency of 20% CRP-stover and 40% CRP-straw lambs was maintained at 81.5% and 88.9% of Control lambs. Gain and efficiency decreased linearly with CRP inclusion, but at a greater rate for CRP-stover. Fecal DM output increased and DM digestibility decreased linearly with CRP treatment, but at a greater rate and extent for CRP-stover. In general, CRP lambs had 9.7% greater DMI, 52.3% greater manure output, and 26.4% lesser DM digestibility. However, lambs fed 20 or 40% CRP-straw or 20% CRP-stover had similar ($P>0.31$) DM and OM digestibility versus Control. Lambs fed CRP tended to have greater intakes of protein, NDF, and ADF but similar digestibility of these nutrients versus Control. Phosphorus digestibility tended lower for CRP diets. Feeding treated straw or stover at ≤ 30% of diet DM to replace corn may be feasible in ruminant diets.

Key Words: Ruminants, Corn Replacement, Treated Crop Residues

152 Effects of feeding thermochemically-treated crop residues on lamb intake and performance. N. A. Pyatt[1], P. H. Doane[1], M. J. Cecava*[1], J. L. Dunn[1], J. R. Sewell[2], and L. L. Berger[2], [1]*ADM Animal Nutrition Research*, *Decatur, IN*, [2]*University of Illinois*, *Urbana*.

Two 30-day lamb growth experiments were conducted to assess thermochemically-treated crop residues in lamb diets. In both studies,

residues were mixed with 5% CaO and water in a double-shaft enclosed mixer (Readco® Continuous Processor) and subsequently pelleted with DDGS (75% residue:25% DDGS; DM basis) to form a corn replacement pellet (CRP). The Control diet contained (DM basis) 45% cracked corn, 24% DDGS, 12% soyhulls, 10% cottonseed hulls, 6% supplement, and 3% cane molasses. In Exp 1, 7 treatments were fed to lambs (n = 55; 25.6 ± 1.3 kg) in a 3 × 2 (+1) factorial. The CRP containing treated switchgrass, wheat straw or wheat chaff was fed 30% or 60% of diet DM and replaced corn and DDGS. In Exp 2, lambs (n = 56; 32.0 ± 1.4 kg) were fed Control diets in which CRP was fed at 30% of diet DM to replace corn and DDGS. Residues evaluated were wheat straw, wheat chaff, corn fiber, switchgrass, and 3:1 blends of corn fiber:wheat straw or corn fiber:wheat chaff. In Exp 1, feeding CRP increased feed intake with 30% CRP causing greater final weight and cumulative ADG (quadratic; P<0.05). Cumulative feed efficiency was 8.5% better (quadratic; P<0.05) for 30% CRP but 21.9% worse for 60% CRP versus Control. Relative efficacy of treated residues as potential corn replacements were wheat chaff > wheat straw > switchgrass. In Exp 2, interim and final weights were not different, but tended less for lambs fed CRP. Cumulative ADG for CRP diets was 15.9% less than Control but feeding CRP containing corn fiber and corn fiber:wheat chaff maintained growth at 90% of Control. Cumulative DMI was not different but cumulative feed efficiency was 20.3% worse for lambs fed CRP diets. Feed efficiency was similar for Control and CRP containing corn fiber:chaff or corn fiber. Thermochemically-treated corn fiber and crop residues fed at ≤ 30% of diet DM may be feasible alternatives to corn in ruminant diets.

Key Words: Ruminants, Corn Replacement, Treated Crop Residues

153 Digestibility of corn replacement pellets in growing lamb diets. J. R. Sewell*[1], L. L. Berger[1], M. J. Cecava[2], P. H. Doane[2], J. L. Dunn[2], and N. A. Pyatt[2], [1]*University of Illinois*, *Urbana*, [2]*ADM Animal Nutrition Research*, *Decatur, IN*.

The objective of this study was to evaluate nutrient digestibility of native (NAT) and thermochemically-treated crop residues (wheat straw, WS; corn stover, CS) relative to corn in ruminant diets. Treated residues were processed with 5% CaO and water in a double-shaft enclosed mixer (Readco® Continuous Processor) and subsequently pelleted with DDGS (75% residue: 25% DDGS; DM basis) to form corn replacement pellets (CRP). The Control diet consisted of 54% cracked corn, 22% DDGS, 22% corn silage, 2% CaCO3, and 0.04% urea on a DMB. Native and treated residues and DDGS were fed at 0, 30, or 60% of diet DM with the amount of DDGS in the diet equalized within feeding level for treated or NAT residue. All diets contained 0.4% urea and non-CRP diets contained 2% CaCO3 (DMB). Lambs (6 per treatment; 31.45 kg) housed in metabolism crates were fed diets at 1.8% of BW and used to determine total tract nutrient digestion. In Exp 1, diets were (DMB): 1) 54% corn, 2) 30% WS CRP, 3) 60% WS CRP, 4) 30% ground NAT WS: DDGS, and 5) 60% ground NAT WS. In Exp 2, CS replaced WS in CRP and NAT CS replaced NAT WS in diets. Data were analyzed using the MIXED procedure of SAS. In Exp 1, DM digestibility for diets 1-5 were: 87.7%, 81.3%, 69.6%, 74.1%, and 60.9%, respectively. Treating crop residue and feeding as part of a CRP increased digestion of DM, NDF, and ADF compared with feeding NAT residue (P<0.05). Feeding WS CRP versus a blend of NAT WS and DDGS at 30% and 60% of diet DM increased NDF digestibility by 48.3% and 103%, and ADF digestibility by 86.0% and 55.7%, respectively. In Exp 2, DM digestibility of diets 1-5 were: 92.2%, 83.3%, 70.7%, 76.4%, and 66.9%, respectively. Feeding treated CS as part of a CRP increased DM, NDF, and ADF digestibility versus feeding NAT CS (P<0.05). Feeding CS CRP versus a blend of NAT CS and DDGS at 30% and 60% of diet DM increased NDF digestibility by 46.5% and 44.2%, and ADF digestibility by 92.2% and 35.2%. Thermochemically treating crop residues improved nutrient digestibility by growing lambs.

Key Words: Corn Replacement, Digestibility, Lambs

154 Effects of diet adaptation on performance and health of steers grown on a high-concentrate, program-fed diet. B. P. Holland*, C. R. Krehbiel, D. L. Step, L. O. Burciaga-Robles, and J. J. Cranston, *Oklahoma State University*, *Stillwater*.

Five hundred thirty-six steers (initial BW = 284 kg) originating from auction markets were used to evaluate four methods of adaptation to a high-concentrate diet for a 60 d growing period. Steers were blocked by arrival date and BW and allocated by adaptation treatment into 24 pens. Treatment 1 included three diets with an increasing percentage of concentrate from 65% to 80% fed ad libitum during the first 21 d prior to feeding an 88% concentrate diet (TRAD). Steers in Treatment 2 were fed ad libitum the same 65% concentrate diet as in TRAD for the first 28 d, followed by adaptation to and feeding of the 88% concentrate diet (REC). Steers in Treatment 3 were fed similarly to TRAD; however, maximum feed intake was limited to 2.1, 2.3, and 2.5 times the arrival maintenance energy requirement for wk 1, 2, and 3, respectively (LMI). Steers in Treatment 4 were initially fed a restricted level of the 88% concentrate diet with daily increases in intake of 0.23 kg/d (PF). Steers in all treatments were fed the final diet at a level that targeted ADG at 1.13 kg/d. Fecal samples were obtained on d 11, 22, 43, and 60 from 6 steers/pen for pH measurement. BW, ADG, and ratio of daily ME intake:ADG (MEG) did not differ among treatments for the first 22 d (P=0.58; 0.41; 0.57, respectively). However, on d 43, REC steers had greater (P<0.01) BW and ADG than TRAD, LMI, and PF steers. Day 60 BW tended (P=0.056) to be greater for REC (352 kg) and TRAD (350 kg) steers than LMI (347) and PF (345 kg) steers. REC steers had the greatest (P<0.01) daily ME intake and lowest (P=0.03) MEG over the growing period. Fecal pH was not affected by treatment, but decreased (P<0.01) from d 11 (6.73) and 22 (6.72) to d 43 (6.59) and 60 (6.61). Bovine respiratory disease morbidity was greater (P=0.02) for TRAD (45.9%) and PF (43.6%) than REC (34.0%) and LMI (29.6%). Feeding a 65% concentrate receiving diet for 28 d after arrival improved growth efficiency and decreased morbidity of high-risk steers.

Key Words: Adaptation, Limited Maximum Intake, Program Feeding

155 Effects of roughage level and Fibrozyme™ supplementation on site and extent of digestion by finishing beef steers. J. J. Cranston and C. R. Krehbiel*, *Oklahoma State University*, *Stillwater*.

Eight ruminally and duodenally cannulated crossbred beef steers (initial BW = 620.4 ± 57.2 kg) were randomly allotted to 1 of 4 treatments in a replicated 4 x 4 Latin square design with a 2 × 2 factorial arrangement of treatments. Dietary treatments were dry-rolled corn-based, and included (DM basis): 1) no enzyme and 9% alfalfa hay; 2) no enzyme and 4.5% alfalfa hay; 3) Fibrozyme (10 g•steer^{-1}•d^{-1}; Alltech Inc., Nicholasville, KY) and 9% alfalfa hay; or 4) Fibrozyme (10 g•steer^{-1}•d^{-1}) and 4.5% alfalfa hay. Roughage level had an effect (P = 0.04)

on DMI. Averaged across enzyme supplementation levels, steers fed diets containing 9.0% alfalfa hay consumed more DM than steers fed diets containing 4.5% alfalfa hay. With the effect on DMI, roughage level also influenced intake of OM, ADF, NDF, starch, and nitrogen ($P \leq 0.10$). Duodenal flow of any measured nutrients was not affected ($P \geq 0.12$) by treatment. With the increased intake, roughage level also affected ($P \leq 0.06$) fecal excretion of OM, ADF, and NDF. However, fecal excretion of starch and nitrogen were not affected ($P \geq 0.15$) by roughage level. Ruminal digestibility, postruminal digestibility, and total tract digestibility of OM, N, ADF, NDF, and starch were not affected ($P \geq 0.11$) by treatment. Similarly, ruminal microbial efficiency was not affected ($P \geq 0.44$) by treatment. Increasing roughage level decreased ($P = 0.01$) particulate passage rate and increased ($P = 0.02$) the outflow of ruminal liquid. Increasing roughage level in the diet also increased ($P = 0.04$) the amount of time steers spent ruminating. The greater dietary roughage level decreased ($P = 0.02$) ruminal ammonia concentrations. An enzyme supplementation × roughage level interaction was detected ($P = 0.02$) for ruminal pH. Neither total ruminal VFA concentrations, nor molar proportions of acetate and propionate were affected by treatment ($P \geq 0.12$). While small changes in roughage level may influence intake and passage kinetics, it appears that nutrient digestibility remains fairly constant in dry-rolled corn-based finishing diets.

Key Words: Beef Cattle, Roughage Level, Fibrolytic Enzyme

156 The effect of delaying initial implant on finishing performance and carcass characteristics. W. A. Griffin*, D. C. Adams, and R. N. Funston, *University of Nebraska West Central Research and Extension Center*, *North Platte*.

Two separate two yr experiments were conducted to determine the effect of delaying initial feedlot implant on performance and carcass characteristics. Steers were preconditioned prior to feedlot entry. At receiving, steers were assigned to one of two treatments: 1) implant at feedlot entry (Norm) or 2) implant 30 d after feedlot entry (Delay). In exp. 1, steers (n = 200) were not implanted until feedlot entry; however, in exp. 2 steers (n = 209) were implanted at branding with Synovex C (Fort Dodge Animal Health, Overland Park, KS). Initial feedlot implant was Synovex S (Fort Dodge Animal Health, Overland Park, KS). At reimplant steers were given Synovex-Choice (Fort Dodge Animal Health, Overland Park, KS). Steers were reimplanted an average of 83 and 115 d after initial implant for Delay and Norm, respectively in exp. 1, and an average of 89 and 119 d after initial implant for Delay and Norm, respectively in exp. 2. In exp.1, initial BW, reimplant BW, and final live BW were not different (P = 0.16); however, BW at initial implant for Delay was 10 kg heavier for Norm (P < 0.01). In exp. 1 overall ADG was not different (P = 0.68); however, Norm had higher ADG for the first 30 d of the finishing period (P = 0.02). In exp. 2, BW measures were not different for Norm and Delay (P = 0.89). In both experiments, HCW, 12th rib fat thickness, LM area, and yield grade were not different (P = 0.28). In exp. 1, there was a significant yr*treatment effect for marbling score (P = 0.05) and percent of steers grading choice or higher (P = 0.05) with Delay grading 22.0% units more choice than Norm in yr 1 and Norm grading 14.5% units more choice than Delay in yr 2; however, in exp. 2, marbling score and percent choice were not different (P = 0.28). In these studies, delaying initial feedlot implant had no affect on animal performance. However, because of the yr*treatment interaction in exp. 1, delaying implant may affect quality grade.

Key Words: Feedlot, Implant, Performance

157 Effect of Dakota Bran inclusion on DMI, gain, efficiency, and carcass characteristics of finishing steers. D. M. Larson*[1], M. L. Bauer[1], G. P. Lardy[1], K. K. Karges[2], and M. L. Gibson[2], [1]*North Dakota State University*, *Fargo*, [2]*Dakota Gold Research Association*, *Sioux Falls, SD*.

A study was conducted to evaluate the effect of Dakota Bran (DB) inclusion on DMI, ADG, G:F, and carcass characteristics of finishing steers. Fifty-eight beef steers (454 ± 10 kg initial BW) were assigned randomly within weight strata to one of five dietary treatments. The diet DM consisted of 84% dry-rolled corn, 8% mixed hay, 5% liquid supplement, and 3% dry supplement providing 27.5 mg/kg monensin. Treatments consisted of DB replacing 0 (n = 8), 40 (n = 10), 50 (n = 8), 60 (n = 9), or 70% (n = 9) of dry-rolled corn DM. Steers were fed individually once daily using a Calan Broadbent feeding system. Body weight was measured every 28 d, individual feed offered recorded daily, and individual feed refusal recorded weekly. Steers were implanted with Synovex Choice on d 0 and were fed for 57, 77, or 105 d. Data were analyzed with the MIXED model of SAS with 0 vs. 40% DB, and linear and quadratic within DB level contrasts ($P \leq 0.05$). There were no differences ($P \geq 0.17$) between 0 and 40% DB treatments. Final BW (600 ± 7 kg; $P = 0.34$) and ADG (1.81 kg/d; $P = 0.40$) were not affected by DB level. The DMI increased ($P = 0.05$; quadratic) to 60% DB (11.25 ± 0.40 kg) and decreased at 70% (10.07 ± 0.40 kg) while G:F decreased ($P = 0.02$) linearly with increasing DB (192 to 170 ± 8 g/kg). Calculated apparent NEg decreased ($P = 0.02$) linearly with increasing dietary DB. Level of DB did not affect ($P \geq 0.18$) 12th rib fat (1.03 ± 0.17 cm), LM area (87.3 ± 2.9 cm2), KPH (2.11 ± 0.14%), or yield grade (2.71 ± 0.23) but marbling responded quadratically ($P = 0.05$) and was lowest at 50% and greatest at 70% (420 vs. 493 ± 25; 400 = small^0). It appears that replacing more than 60% of corn with DB negatively influences DMI while G:F is negatively impacted by increasing DB inclusion above 40%. However, further study with an increased number of observations is needed to fully quantify the effect of high levels of DB inclusion on finishing steer performance.

Key Words: Steers, Dakota Bran, Finishing

158 Effect of corn endosperm type and processing method on site and extent of nutrient digestion and ruminal metabolism in Holstein steers fed a high-grain diet. C. A. McPeake* and S. R. Rust, *Michigan State University*, *East Lansing*.

This experiment was conducted to evaluate the interaction between corn grain endosperm type and processing method on site of nutrient digestion and ruminal metabolism in steers consuming a high-grain diet. Ten ruminally, duodenally, and ileally cannulated Holstein steers (initial BW = 200 ± 21 kg) were used in a replicated 4 × 4 Latin square design experiment with a 2 × 2 factorial arrangement of treatments. Treatments were grain endosperm type (floury and flinty) and processing method (high moisture and dry-rolled). Interaction of treatments had no effect on any measure of digestibility or ruminal metabolism. Starch intake tended to be greater for diets containing dry-rolled corn, resulting in lower apparent ruminal degradability (P = 0.02) and greater starch passage (P = 0.01) to the duodenum. When expressed as a percentage of duodenal flow, 21% less starch was digested in the small intestine of steers consuming diets containing dry-rolled corn. Likewise, an 8% decline in apparent total-tract starch digestibility was witnessed when feeding dry-rolled corn. Ruminal passage rate of liquid was significantly higher (P = 0.03) for floury

endosperm treatments, while diets containing dry-rolled corn tended to have higher ruminal passage rates of starch. Total molar proportion of volatile fatty acid tended to be greater for diets including grain comprised of floury endosperm. While ruminal pH was unaffected by treatments, diets consisting of flinty endosperm resulted in greater ruminal ammonia levels ($P < 0.05$). Dry-rolled corn treatments tended to result in higher molar concentrations of lactate. Relative to nitrogen digestibility, diets containing high moisture corn resulted in greater amounts of microbial nitrogen flow to the duodenum, greater apparent post-ruminal nitrogen digestibility, and greater microbial efficiency ($P < 0.05$). Preservation method of corn grain appears to have a more profound impact on site and extent of nutrient digestibility than corn grain endosperm type.

Key Words: Corn Hybrid, Digestibility, Processing

159 The effects of feeding ground flaxseed on morbidity, mortality, and performance in receiving heifers and subsequent feedlot performance. M. J. Quinn*, E. S. Moore, B. E. Depenbusch, M. L. May, J. J. Higgins, and J. S. Drouillard, *Kansas State University*, *Manhattan*.

Two trials were conducted at the Kansas State University Beef Cattle Research Center to determine the effects of feeding ground flaxseed during the receiving period on growth, health, and subsequent feedlot performance of finishing heifers. Crossbred heifers (trial 1 n=363, initial BW 214±1 kg; trial 2 n=377, initial BW 222±1 kg) were purchased from salebarns in Edmonton, KY during January and March of 2006. Heifers were fed receiving rations based on steam-flaked corn with 0 (Control), 2, 4, or 6% ground flaxseed (DM basis) for 56 d. Following the receiving period, cattle were fed steam-flaked corn based diets until slaughter for 150 d and 147 d, respectively. Heifers were implanted 91 and 109 d prior to slaughter, respectively. In trial 1, DMI during the receiving period tended to increase linearly with increasing flaxseed in the diet ($P<0.10$). ADG was 1.46, 1.56, 1.58, and 1.61 kg/d for heifers fed 0, 2, 4, and 6% flax, respectively (linear, $P<0.03$). Final BW after the finishing period was significantly increased with increasing inclusion of flax in the receiving diets (linear $P<0.05$). In trial 2, growth performance, morbidity, or mortality during the receiving period were not different between treatments ($P>0.05$). During the finishing period DMI were 8.4, 8.4, 8.0, and 8.1 kg/d for 0, 2, 4, and 6% flax, respectively (linear, $P<0.05$). In trial 2, LM areas were greatest for cattle fed 2% flax at receiving (quadratic, $P<0.05$). In general, feeding flaxseed during the receiving period may improve growth performance and carcass weights through finishing. However, there is some variation that exists, and cattle fed flax may not always respond similarly.

Key Words: Flax, Receiving, Heifers

160 Effect of feeding das-59122-7 corn grain and non-transgenic corn grain to finishing feedlot steers. T. J. Huls*[1], G. E. Erickson[1], T. J. Klopfenstein[1], M. K. Luebbe[1], K. J. Vander Pol[1], D. W. Rice[2], B. L. Smith[2], M. A. Hinds[2], F. N. Owens[2], and M. K. Liebergesell[2], [1]*University of Nebraska*, *Lincoln*, [2]*Pioneer Hi-Bred Internation, Inc.*, *Johnston, IA*.

An experiment was designed to evaluate the performance of steers fed grain produced from a non-segregating transgenic maize line containing event DAS-59122-7 (59122). 59122 expresses the Cry34Ab1 and Cry35Ab1 proteins from *Bacillus thuringiensis* strain PS149B1. These proteins control corn rootworms. 59122 also contains the phosphinothricin acetyltransferase (*pat*) gene from *Streptomyces viridochromogenes* for herbicide tolerance. Sixty steers (initial BW = 396 ± 15 kg), individually fed using Calan gates, consumed finishing diets containing either transgenic corn (59122), or a non-transgenic, near isoline hybrid (Control), or a conventional non-transgenic corn hybrid (Pioneer hybrid 35P12) for 109 d to determine nutritional equivalency. Dry rolled corn comprised 82% of diet DM along with 8.5% alfalfa hay, 5% molasses, and 4.5% supplement containing monensin and tylosin. Steer performance and carcass traits were statistically compared between steers consuming diets produced with 59122 corn and steers consuming diets produced with Control corns. False discovery rate was used to control for multiplicity. Steers fed diets produced with the conventional corn were used as an additional comparator creating tolerance intervals to evaluate the biological significance of any statistical differences. Dry matter intake, ADG, and G:F for steers fed diets containing the 59122 corn were not significantly different from steers fed Control corn, and fell within the tolerance intervals. Similarly, carcass characteristics were not different between Control and 59122. Feeding 59122 did not impact steer performance or carcass quality.

Table 1. Performance and carcass characteristics of steers fed different corn hybrids.

Item	CONTROL	59122	SEM	P-value
Final BW, kg [1]	553	562	7	0.357
DMI, kg/d	9.51	10.11	0.25	0.083
ADG, kg	1.45	1.53	0.06	0.377
G:F	0.153	0.151	0.006	0.799
Marbling score [2]	463	475	19	0.651
Fat depth, cm	1.04	0.95	0.06	0.294

[1] Final BW calculated from HCW/0.63. [2] 400 = Slight°, 450 = Slight^{50}, 500 = Small°

Ruminant Nutrition: Ruminal Fermentation - Dairy

161 Effects of *Saccharomyces cerevisiae* on ruminal pH and microbial fermentation in lactating dairy cows. M. Thrune[1], A. Bach[2], M. Ruiz-Moreno[1], M. D. Stern*[1], and J. G. Linn[1], [1]*University of Minnesota*, *St. Paul*, [2]*IRTA-Unitat de Remugants*, *Spain*.

An experiment was conducted with eight ruminal fistulated cows using a cross over design with 2 periods to determine the effects of yeast supplementation on rumen fermentation. Holstein dairy cows in late lactation were either supplemented with 0.5g/head/day of *Saccharomyces cerevisiae*, an active dry yeast (CNCM-1077, Levucell SC20 (r)SC, Lallemand Animal Nutrition) or not supplemented (control). A basal diet consisting of 60% forage and 40% concentrate (DM basis), was fed once daily to both groups of cows throughout the entire experiment. Ruminal pH was measured continuously every 22 min using a pH probe that was placed in the ventral rumen sac for 6 d. Volatile fatty acid and ammonia N concentrations in the rumen were

measured on day 5 or 6 of the 12-d period for each cow and DMI was monitored throughout the experiment. Data were analyzed using a mixed-effects model with repeated measures. There was no difference in DMI between treatments. Mean ruminal pH was greater ($P < 0.05$) when yeast was supplemented (6.53±0.07) compared with the control (6.32±0.07). Average maximum and minimum ruminal pH were also greater ($P < 0.05$) when yeast was supplemented (7.01±0.09 and 5.97±0.08, respectively) compared with the control (6.80±0.09 and 5.69±0.09; respectively). Time spent under the subacute acidosis threshold, pH less than 5.6, was lower ($P < 0.05$) with yeast supplementation compared with the control cows. No difference was observed for ruminal ammonia N concentrations (mean = 14.0 mg/dL) between treatments. Total VFA concentration (m*M*) in the rumen was lower ($P < 0.05$) in the yeast supplemented cows (107.8) compared with the control cows (122.8), which can be related to the greater pH observed with yeast supplementation. Supplementing dairy cows with active dry yeast in the current experiment increased the mean, minimum and maximum ruminal pH; decreased time spent in subactute acidosis; and decreased total VFA concentration in the rumen compared with control cows.

Key Words: Rumen, *Saccharomyces cerevisiae*, Fermentation

162 Impacts of a *Yucca schidigera* extract on rumen fermentation and *in vitro* gas production and NDF digestion. M. D. Singer*[1], P. H. Robinson[1], A. Z. M Salem[2], and E. J. DePeters[1], [1]*University of California*, *Davis*, [2]*University of Alexandria*, *Alexandria, Egypt*.

Yucca schidigera(YS) is native to the arid Sonoran deserts of the Southwest USA and Mexico, and its extracts have been used to modify rumen microbial fermentation. Our objective was to determine effects of feeding increasing doses of YS extract (9.5% Sarsaponin) to dairy cows on rumen fermentation, as well as 24 h *in vitro* gas production and 27 h *in vitro* NDF digestion, of 11 feedstuffs. The principle was to assess the ability of YS to modify rumen fermentation and the subsequent impact of the adapted rumen fluid on feedstuff fermentation *in vitro*. Ruminally cannulated lactating Holstein cows (4; 810 average kg BW) were used in a 4*4 Latin Square design experiment with 14 d periods. Cows were housed in pens equipped with Calan gates with *ad libitum* access to water. The TMR was fed twice daily and contained 36% alfalfa hay (ALF), 9.6% whole cottonseed (WCS), 2% soybean meal (SBM), 12% almond hulls (AH), 1.8% mineral mix, .9% Energy II, .4% salt, and 64% of a corn grain based concentrate (as fed basis). The study occurred in June/August 2006, when daytime high temperatures averaged 35C. YS was added to the TMR to provide approximately 0, 5, 10, 15 g of sarsaponin/cow/day. Rumen fluid from each cow in each period was utilized in an *in vitro* gas run to measure gas production and digestion of NDF for corn silage, ALF(high and low NDF level), beet pulp, corn grain, distillers grains, SBM, AH, barley grain, wheat silage and WCS. Rumen pH, concentrations of total VFA (and their molar proportions), and ammonia N, were not impacted (P>0.05) by level of sarsaponin. In spite of the lack of differences in parameters of rumen fermentation due to increased levels of sarsaponin, gas produced at both 4 and 24 h of *in vitro* fermentation increased linearly (6.3 and 5.6% mean increase with 15 g/d of sarsaponin for 4 and 24 h; both P<0.01), and there were no treatment by feed interactions (i.e., both P>0.05). *In vitro* digestion of NDF was not impacted (P>0.05) by sarsaponin level. Sarsaponin addition at high levels, compared to previous studies, had a modest positive impact on gas production of 11 common feedstuffs.

163 Yeast culture supplementation prevented milk fat depression from a fermentable carbohydrate challenge. R. A. Longuski*, Y. Ying, and M. S. Allen, *Michigan State University*, *East Lansing*.

Effects of yeast culture (YC) on responses to a fermentable carbohydrate challenge were evaluated using eight ruminally cannulated mid-lactation multiparous Holstein cows in a crossover design experiment with 28 d periods. Treatments, top dressed at 56 g per head/d, were Diamond V XP™ Yeast Culture and control (mix of dry ground corn and soybean meal). A common base diet was fed to all animals from d 1 through 26 of each period followed by a two-day dietary challenge in which finely ground high moisture shelled corn (HMC) replaced dry ground shelled corn (DC) in the base diet on an equal DM basis. Milk fat concentration decreased from 3.31% to 3.03% for cows fed the control treatment when challenged with HMC compared to DC but remained unchanged (mean = 3.33%) during the dietary challenge for the YC treatment (interaction P = 0.10). This, combined with numerical differences in milk yield among treatments, resulted in significant interactions (P < 0.03) of main effects of YC supplementation and diet fermentability for yields of 3.5% FCM, milk fat, and SNF. Fat corrected milk yield was decreased by the HMC challenge from 38.5 to 37.0 kg/d for the control treatment but was increased from 38.0 to 40.0 kg/d for the YC treatment. Yields of milk fat and SNF followed the same trend. No treatment interactions were observed for any measure of ruminal pH, total or individual VFA concentrations in ruminal fluid, acetate to propionate ratio, or individual fatty acid isomers in milk fat (P > 0.15). Although DMI was not affected by YC, meal frequency (# of meals/d) tended to be reduced by the YC treatment (P = 0.08). The YC treatment decreased ruminating time (P = 0.05) and number of chews per day (P = 0.04) by decreasing the number of ruminating bouts from 15.7 per day for control to 12.8 per day for YC (P < 0.001). The mechanism by which YC increased milk fat concentration and yield when cows were challenged with a highly fermentable diet requires further investigation.

Key Words: Lactating Cow, Rumination

164 The effect of yeast culture and enzymatically hydrolyzed yeast supplementation on performance of dairy cattle. J. E. Nocek*[1], J. Oppy[2], and M. G. Holt[2], [1]*Spruce Haven Farm and Research Ctr*, *Auburn, NY*, [2]*Varied Industries Corporation*, *Mason City, IA*.

One hundred and fifty multiparous cows were balanced to one of three treatment groups (2 pens/trt) according to previous lactation 305d ME to evaluate yeast culture (YC) and enzymatically hydrolyzed yeast (EHY) supplementation on production performance in dairy cattle. Cows entered the groups at calving and remained through 14 weeks postpartum. Groups were randomly assigned throughout the barn. Pens were identical in layout and each pen contained an exit alley so that it would not interfere with an adjacent pen when animals were moved for milking. The three treatments were: Control: no YC or EHY, YC: same as control with YC (Amax, 28g/d), and YC-EHY: same as control plus YC and EHY manufactured as a combined supplement (Celmanax, 28g/d). Mean group dry matter intake was similar across treatments. Milk yield variables were affected by treatment (P<.01). Cows supplemented with YC and YC-EHY produced more (P<.01) milk than control cows (41.9, 42.1 and 40.5kg, respectively). There was no difference between YC and YC-EHY. These same significant production differences were revealed for 3.5 FCM and ECM. Milk fat,

SNF or lactose percentages were not affected (P>.05) by treatment. However protein percentage was higher (P<.01) for cows supplemented with YC-EHY than YC and control (2.98, 2.93 and 2.91%) with control and YC supplemented cows not being different than either. Differences in fat, protein and SNF yields were primarily reflective of milk yield (P<.05). There was no effect of treatment on MUN, with all treatments ranging from 11.1-11.4. Somatic cell count was higher (P<.01) for cows supplemented with control and YC compared to YC-EHY. These results demonstrate that cows supplemented with YC produced more milk than non supplemented cows and supplementing YC with EHY as a combined manufactured supplement increased milk protein percentage.

Key Words: Dairy Cattle, Yeast Culture, Hydrolyzed Yeast

165 Effect of pasteurized waste milk, medicated milk replacer, mannan oligiosaccharide and enzymatically hydrolyzed yeast on neonatal calf performance. J. E. Nocek*[1], J. Oppy[2], and M. G. Holt[2], [1]*Spruce Haven Farm and Research Ctr*, *Auburn, NY*, [2]*Varied Industries Corporation*, *Mason City, IA*.

This study was conducted to determine the effect of: 1) pasteurized waste milk (PWM) with no antibiotic vs. medicated milk replacer (MR) 2) mannan oligosaccharide (MOS) and enzymatically hydrolyzed yeast (EHY) sources and 3) two levels of liquid EHY on grain intake, growth and fecal scores of neo-natal calves. One hundred and twenty-five female Holstein calves were randomly assigned to the following treatments at birth: Control: PWM, MR: MR with antibiotics (North American Nutrition Companies, Lewisburg, OH), LEHY4 and 8: Liquid Celmanax at 4 or 8ml/d (Varied Industries Corporation, Mason City, IA) and DMOS: Dry MOS (Bio-MOS, Milk-Pak at 14 g/d, Altech, Inc, Nicholasville, KY). Calves were removed from their dams and fed pooled colostrum within 2h of birth. Calves remained on respective treatments 42d and abruptly weaned. All calves received the same calf starter from day one. Calves were housed in individual calf hutches. Body weights and wither heights were recorded at trial initiation, day 21 and 42. Calf starter offering and refusals were recorded daily. Fecal consistency scores (FCS) were recorded for each calf daily. Calves receiving DMOS consumed more grain during the first 5wk on treatment than those receiving MR, with others not being different. There were no differences (P>.10) among treatments for total starter intake during wk 6, There were no differences (P>.10) among treatments in growth performance parameters measured. During wk 1, treatment had no effect on FCS. However, during wk 2, calves receiving MR had a higher (P<.01) FCS than other treatments. During wk 5, those receiving MR had higher (P<.01) FCS than those receiving LEHY4, however, neither were different from the other treatments. The overall 6 wk mean showed calves receiving MR to have a higher (P<.01) FCS than other treatments. This study showed in environments of low disease challenge, the use of enteric antibiotics or the addition of MOS and EHY products may not be warranted.

Key Words: Neonatal Calves, Pasturized Milk, Hydrolyzed Yeast

166 Effects of feeding rumen-protected choline (RPC) on lactation and metabolism. F. S. Lima*[1], M. F. Sa Filho[1], L. F. Greco[1], F. Susca[1], V. J. A. Magalhaes[1], J. Garrett[2], and J. E. P. Santos[1], [1]*Veterinary Medicine Teaching and Research Center, University of California Davis*, *Tulare*, [2]*Balchem Corporation, Animal Nutrition & Health*, *New Hampton, NY*.

Objectives were to determine the effects of feeding RPC on lactation and metabolism in dairy cows. In Experiment 1 (E1), 369 cows were fed 15 g/d of RPC (Reashure, Balchem) from 25 d prepartum to 80 d in milk (DIM). In E2, 578 primigravid cows were fed 15 g/d of RPC in the 21 d prepartum. Blood was sampled from 80 cows in E1 and 47 cows in E2, and analyzed for concentrations of nonesterified fatty acids (NEFA) and glucose at 1, 14 and 21 DIM. Blood from all cows was analyzed for concentrations of 3-OH-butyrate (BHBA) at 1 and 14 DIM. Subclinical ketosis was considered when BHBA was greater than 1.0 mMol/L. Hepatic tissue from 46 cows in E1 sampled at 8 DIM was analyzed for concentrations glycogen and triglycerides. Body condition was scored at enrollment, 1, 30, 60, and 90 DIM in E1, and at enrollment and calving in E2. Monthly yields of milk and milk components in E1 and weekly yields of milk in E2 were measured for 90 DIM. Prepartum DM intake was similar (P>0.15) between treatments and averaged 12.5 and 10.5 kg/d for E1 and E2, respectively, but intake tended (P = 0.10) to be greater for cows fed RPC (23.9 vs 22.6 kg/d) in E1. In E1, yields (kg/d) of 3.5% FCM (44.6 vs 42.8), ECM (40.1 vs 38.5), and milk fat (1.61 vs 1.52) were greater (P<0.05), and of milk (43.1 vs 42.1) and true protein (1.21 vs 1.17) tended (P=0.08) to be greater for RPC than control. Energy output in milk was greater (P=0.03) for RPC than control (30.0 vs 28.8 Mcal/d), although milk NEL content was similar and averaged 0.70 Mcal/kg. In E2, milk yield tended (P=0.07) to be greater for RPC than control (28.7 vs 27.9 kg/d). Body condition was improved (P =0.01) postpartum for RPC in E1. Concentration of glucose tended to be greater (P=0.10) in E1 and of NEFA was smaller (P=0.05) at calving in E2 for RPC compared with control. Prevalence of subclinical ketosis tended (P=0.07) to be smaller at calving in all cows (28.5 vs 37.2%) and was smaller (P=0.05) in multiparous cows (22.1 vs 40.0%) fed RPC in E1, but did not differ between treatments in E2. Feeding RPC improved lactation and metabolism of dairy cows, but benefits were enhanced when it was fed prior to and after calving.

Key Words: Choline, Dairy Cow, Subclinical Ketosis

167 Effect of feeding Fermenten® on the productivity of cows fed different concentrations of sucrose. G. B. Penner* and M. Oba, *University of Alberta*, *Edmonton, Alberta, Canada*.

A study was conducted to determine the effect of feeding Fermenten® on the productivity of lactating Holstein cows fed diets differing in sucrose concentration. We hypothesized that Fermenten® would increase productivity with this response being more prominent when fed in a high sucrose diet. Eight multiparous ruminally cannualted cows (163 ± 55 DIM) were used in a replicated 4 × 4 Latin square design with 21-d periods. Treatments were arranged in a 2 × 2 factorial arrangement with the main effects of Fermenten® inclusion (FERM vs. control) and dietary sucrose concentration (6.5 vs. 2.0%). Diets were formulated to contain 18.7% CP, 23.2 % forage NDF and were offered ad libitum. Cracked corn replaced sucrose for the low sugar diets, and urea and soybean meal replaced Fermenten® in the control diets. Treatments did not affect DMI and averaged 22.8 kg/d. Significant interactions were detected for milk yield, milk component yields and BCS ($P \leq 0.05$). For cows fed low sucrose diets, FERM treatment increased milk yield (26.4 vs. 24.1 kg/d), milk fat yield (0.92 vs. 0.82 kg/d), and milk CP yield (0.91 vs. 0.83 kg/d), but decreased BCS gain (0.08 vs. 0.25/21d) compared to control whereas, cows fed

a high sucrose diet without FERM increased milk yield (26.4 vs. 24.3 kg/d), similar milk fat yield (0.91 vs. 0.85 kg/d), and milk CP yield (0.86 vs. 0.90 kg/d), but decreased BCS gain (0.06 vs. 0.19 /21d) compared to FERM. There was a tendency for an interaction (P = 0.07) for plasma glucose concentration; for cows fed low sucrose diets, FERM increased plasma glucose concentration compared to the control (65.23 vs. 64.58 mg/dl) but cows fed the high sucrose diet without FERM had higher plasma glucose concentration compared to cows fed FERM (67.14 vs. 64.96 mg/dl). In this study, effects of FERM supplementation had variable effects on nutrient partitioning in lactating dairy cows depending on the dietary sucrose concentration. Contrary to the hypothesis, high sucrose diets may not optimize the utilization of Fermenten®.

Key Words: Fermenten, Sucrose, Milk Production

168 Effect of monensin feeding and withdrawal on ruminal populations of individual bacterial species in cows fed high-starch diets. P. J. Weimer*[1,2], D. M. Stevenson[1], D. R. Mertens[1], and E. E. Thomas[3], [1]*United States Department of Agriculture*, *Madison, WI*, [2]*University of Wisconsin*, *Madison*, [3]*Elanco Animal Health, Inc.*, *Greenfield, IN*.

Monensin is known to improve ruminant animal production, purportedly by inhibition of H_2-producing Gram-positive bacteria, yet there is no *in vivo* evidence for shifts in populations of specific microbial taxa. We used real-time PCR with relative quantification to assess the fraction of 16S rRNA gene copy number (F) attributable to *Prevotella* and to each of 13 classical, well-studied ruminal bacterial species in rumen contents from 2 lactating dairy cows fed a TMR containing primarily alfalfa silage, corn silage, and ground high-moisture corn. Diets averaged 30% NDF, 41.1 % NFC (26.8% starch) and 17.4% CP (DM basis). PCR was conducted on DNA from rumen samples collected 6 h after feeding on 2 successive days prior to monensin feeding, after 28 d of monensin feeding (at 0.014 g/kg of diet DM), and at six weekly intervals after monensin withdrawal. Mean values of F attributable to genus *Prevotella* increased ($P < 0.05$) from 41.8% without monensin to 49.2% with monensin, and declined to 42.5% after monensin removal. Less than 10% of the *Prevotella* were present as classical ruminal species *P. rumincola*, *P. brevis*, or *P. bryantii*. Mean values of F attributable to 4 cellulolytic species and 4 starch- or dextrin-fermenting species were not altered ($P > 0.10$) upon monensin feeding or withdrawal. Mean values of F attributable to two biohydrogenating species (*Megasphaera elsdenii* and *Butyrivibrio fibrisolvens*) were low (< 0.4%) and declined several-fold in response to monensin, in accord with observed decreases in milk fat. No changes were observed in mean values of F for a third biohydrogenating species, *Eubacterium ruminantium*. The 13 species together contributed <10% of the bacterial 16S gene copy number. The data suggest that monensin in high starch diets does not suppress populations of classical ruminal Gram-positive bacteria, though it may affect bacteria involved in biohydrogenation of lipids that regulate bovine mammary lipogenesis.

Key Words: Monensin, PCR, Rumen Bacteria

169 Effects of nitroethane and monensin on ruminal CH_4 production and nitro-degrading bacterial populations in vitro. H. Gutierrez-Bañuelos*[1], R. C. Anderson[2], G. E. Carstens[1], L .O. Tedeschi[1], E. Cabrera-Diaz[1], T. R. Callaway[2], and D. J. Nisbet[2], [1]*Texas A&M University*, *College Station,*, [2]*USDA/ARS, Food & Feed Safety Research Unit*, *College Station, TX.*

The objectives of this study were to examine the effects of nitroethane (NE) and monensin (M) on methane production, NE-degradation and NE-degrading bacterial populations using a consecutive batch culture technique. Treatments included rumen fluid, basal medium and 0.2 g of ground alfalfa, supplemented with water (Control; C), 4.5 µmol NE (1NE), 9 µmol NE (2NE), 5 µmol M (M), and 9 µmol NE plus 5 µmol M (2NEM) in triplicate. Treatment cultures were incubated at 39°C under H_2:CO_2 (1:1) and tranferred at 24 h intervals in 16 incubation series. Methane production was determined after series 1, 2, 3, 6, 10, 13 and 16, NE degradation after series 1, 2, 3, 6 and 10, and most probable number of NE-degrading bacterial populations after series 6. Daily CH_4 production was affected ($P<0.01$) by treatment, series, and treatment by series interaction, with accumulations averaging 13.65, 2.93, 1.16, 0.80 and 0.79 after the first and 7.47, 2.93, 0.92, 0.87, and 0.79 ± 0.4 µmol/ml after the 16th incubation series for C, M, 1NE, 2NE and 2NEM, respectively. Nitroethane containing treatments (1NE, 2NE, 2NEM) maintained methane production at low levels for all incubation series. Monensin treatment had a quadratic pattern in which methane levels initially declined but increased ($P < 0.01$) after series 13. Effects of treatment, series, and treatment by series interaction were observed ($P < 0.01$) on NE degradation. Residual NE concentrations were lower for 1NE than 2NE or 2NEM treatments during the first and tenth series (0.35, 0.73, and 1.06 for the first and 0.27, 1.02, and 0.95 ± 0.4 µmol/ml for the tenth, respectively. Most probable numbers of NE-reducing bacteria were increased ($P<0.01$) in 1NE and 2NE (6.9 and 5.9 $\log_{10}$ cells/ml, respectively) compared to those in C, M and 2NEM treatments (<2.5 $\log_{10} \pm 0.8$ cells/ml). These results confirm the CH_4-inhibiting activity of NE and suggest that ruminal adaptation of bacteria to NE is likely due to an enrichment of NE-reducing bacteria. The results further demonstrate that ruminal bacteria adaptation may be overcome with 2NE, and that M treatment negatively affected NE-reducing bacteria populations.

Key Words: Methane, Monensin, Nitroethane

170 Effect of monensin concentration in starter feed on feed intake and growth of young dairy calves. E. E. Thomas*, *Elanco Animal Health*, *Greenfield, IN*.

Monensin is an ionophore cleared by FDA for increasing daily gain and prevention and control of coccidiosis in growing cattle including those maintained in a dry lot. The objective of the 3 trials was to determine the effect of monensin concentration in starter feed (33, 50, 66 ppm) on feed intake and daily weight gain in newborn Holstein dairy calves. Milk replacer was fed at a rate of 0.86 kg/hd/d in trial 1 and 0.45 kg/hd/d in trials 2 and 3. Calves were weaned at 5 or 6 wks of age and were individually housed for 12 wks (trial 1, 72 heifers) or 8 wks in trials 2 (100 bulls) and trial 3 (48 bulls). In trial 1, calves were then grouped and fed a common grower feed (38 ppm monensin) for 8 wks. During that time, 4 pens per original treatment group were maintained. Trials were statistically analyzed separately. Starter feed intake and daily gain (kg/d) during the individual housing period for 33, 50, and 66 ppm treatments, respectively, by trial were: (trial 1, 1.32, 1.18, 1.32; 0.67^{ab}, 0.63^{b},0.71^{a}) (trial 2, 1.32^{a}, 1.22^{b}, 1.22^{b}; 0.56, 0.52, 0.54) (trial 3, 0.82, 0.77, 0.77; 0.59, 0.57, 0.56). In trial 1, feed intake and daily gain (kg/d) following grouping for the original 33, 50, and 66 ppm treatment groups, respectively, were: 3.90, 3.86, 3.95;

1.03, 1.05, and 0.97. The FDA cleared dose range for controlling coccidiosis is .06 to 0.45 mg/kg body weight in calves. At the end of 8 wks in trial 3 the monensin intake (mg/kg body weight) was 0.19, 0.26 and 0.36 for the 33, 50, and 66 ppm treatments, respectively. In conclusion, during the individual housing period there were no differences in feed intake between 33, 50 and 66 ppm treatment groups with the exception of trial 2 in which 33 ppm calves ate more (P<.05) than 50 or 66 ppm calves. There were also no differences in growth rate between 33, 50 and 66 ppm treatment groups with the exception of trial 2 in which calves fed 66 ppm grew faster (P<.05) than calves fed 50 ppm but similar to the 33 ppm calves. After grouping in trial 1, there were no differences in feed intake or daily weight gain.

Key Words: Rumensin, Monensin, Growth

171 Deactivation of aflatoxin B1 in animal feed by using a selected bentonite. G. Schatzmayr*[1], S. Fruhauf[2], and E. Vekiru[2], [1]*BIOMIN Research Center*, *Tulln, Austria*, [2]*Christian Doppler Laboratory for Mycotoxin Research*, *Tulln, Austria*.

Aflatoxin B1 (AFB1) is a mycotoxin produced by *Aspergillus* fungi on a great variety of agricultural commodities. AFB1 impairs health of different animal species. In dairy cows this hepatotoxic and carcinogenic toxin can be metabolized to aflatoxin M1 and secreted into milk. It is known that hydrated sodium calcium aluminosilicates (HSCAS) in animal feed can reduce the adsorption of AFB1 in the gastrointestinal tract. The aim of this study was to select an enterosorbant out of more than 60 bentonites with a high selectivity for AFB1. As reference material in this screening study a commercially available HSCAS and charcoal were used. The evaluated chemisorption index (Cα) showed that bentonites can bind AFB1 very strongly, a fact that indicates an adsorption process due to chemisorption. From the tested bentonites only a few reached or exceeded the Cα value and the maximal adsorption capacity (Qmax) of the reference binders. Tests in real gastric juice and in vitamin solutions were used to determine selectivity of the binding agents. Charcoal proved to be a very unselective binder that definitely binds vitamins to a greater extent than bentonites. AFB1 adsorption of the reference materials was clearly decreased in real gastric juice. Only a few of the investigated binders performed better than the reference materials. This showed us that not only AFB1 binding capacity can be used as selection criterion for clay minerals as feed addtives but also parameters like binding behavior in complex environments (gastrointestinal juice) and binding of essential nutrients have to be considered. Mineralogical studies did not lead to any parameter which could be used to correlate AFB1 adsorption. One of the most promising materials was part of a feeding trial with dairy cows aiming to determine carry over of aflatoxin into milk (3 groups: control diet + AFB1; control diet + AFB1+ material at two concentration levels). The addition of the bentonite to the diet significantly reduced the milk aflatoxin M1 content at both concentrations (20g per cow and day and 50g, respectively). Feed intake and milk production were not negatively influenced by the bentonite.

Key Words: Aflatoxin, Mycotoxin, Deactivation

172 Adding liquid feed while reducing non-fiber carbohydrates (NFC) enhances feed intake and milk fat production. J. L. Firkins*, C. Reveneau, L. E. Gilligan, and A. Sprunger, *The Ohio State University*, *Columbus*.

Liquid feeds (LF) reduce forage particle sorting, improve palatability, and increase energy density of TMR. However, excess sugars could promote rumen acidosis or could reduce milk fat production, particularly if combined with Rumensin (R). Our objectives were to add LF at two concentrations while reducing NFC concentration to optimize the use of LF in dairy rations. Diets had 30% corn silage, 15 % chopped alfalfa hay, and 8% whole cottonseeds (21% forage NDF). A control was balanced for 40% NFC. Two diets with 3.25% LF (DM basis) had 40 or 37 % NFC. Two more 37% NFC diets had 6.5% LF, but the second also had R at 11.5 g/909kg of DM in the TMR. Diets contained similar CP to formulations (17.3%). Compared with formulations, forage NDF was 1% unit lower; and NFC, 1% higher. Treatments lasted 12 wk after an initial 2-wk covariate period. Treatment n = 8 multiparous and 4 primiparous Holsteins. Although repeated measures were used in a mixed model (random effect of cow), no treatment x time interactions were detected. Means were separated by protected LSD. Milk protein % was higher (P<0.01) for control (2.93%) than the LF diets (averaged 2.84%), but protein yield, milk production, and milk fat were not affected (averaged 1.15 kg/d, 40.4 kg/d, and 3.33%). Production of milk fat, 3.5% FCM, and energy-corrected milk (ECM) were higher (P<0.09) for cows fed 3.25% LF in 37% NFC diets than the control or 3.25% LF diet with 40% NFC. ECM was 26.2, 25.7, 27.4, 26.5, and 26.2 kg/d, respectively, for control, 3.25 % LF in 40% NFC and 37% NFC diets, and 6.5% LF in 37% NFC diets without or with R. The DMI were 23.9, 23.9, 25.2, 25.9, and 24.5 kg/d, respectively. DMI was greater (P<0.10) when 3.25 and 6.5% LF was added to the 37% NFC diets than the control. The ECM/DMI was not different (averaged 1.10). Because total tract OM digestibility was not affected, LF appear to be best used when replacing starch and with decreased NFC to maintain comparable rumen carbohydrate digestibility. LF did not depress milk fat, even at high levels or when R was included.

Key Words: Liquid Feed, Milk Fat, Dairy Cattle

173 The role of the NSF/National Science Digital Library in the dissemination of science, technology, engineering and mathematics information and in support of innovations in teaching and learning. L. Salisbury*[1,2], [1]*University of Arkansas Libraries*, *Fayetteville*, [2]*National Science Digital Library*.

The National Science Digital Library (NSDL) was created by the National Science Foundation to provide organized access to high quality resources and tools that support innovations in teaching and learning at all levels of science, technology, engineering, and mathematics (STEM) education. NSDL was established by the National Science Foundation (NSF) in 2000 as an online library where users can find exemplary resources to assist them in STEM instruction, education and research. The digital library provides an organized point of access to high quality STEM content that is aggregated from a variety of other digital libraries, NSF-funded projects, and NSDL-reviewed web sites. In this context, NSDL serves both as a focal point for access to and the dissemination of research results. This presentation will highlight key resources in the NSDL that will be useful in poultry and animal science research, instruction and education. It will also showcase the huge set of quality resources for teaching and instruction in general biology. The services and tools that enhance the use of the NSDL content in a variety of contexts will also be explored. This presentation will also introduce the audience to ways of participating in the National Science Digital Library, including methods for contributing resources and collections.

Key Words: National Science Digital Library, Science Information, Technology Information

174 The importance of images to the pork industry. D. J. Meisinger*, *US Pork Center of Excellence*, *Ames, IA*.

The mission of the US Pork Center of Excellence is to add value to the pork industry by facilitating research and learning for U.S. pork producers through national collaboration. The USPCE is bringing states together in a collaborative mode to accomplish many things in research, teaching and extension. The newest tools include the Pork Information Gateway or PIG which is a virtual library of resources and information on all aspects of swine and pork. PIG has peer-reviewed fact sheets, numerous other information pieces, about 2000 frequently asked questions, an events calendar, a glossary and a small image library. The latter contains only about 80 high resolution images that are all acceptable for any audience. The facilities pictures, for instance, show white buildings, blue skies, blue lagoons, etc. Because the images are all high resolution, they lend themselves to print quality for publications while also working well on presentations. Another tool available only to educators is the PIG Media Asset Portal or PIGMAP. This tool has over 4500 images but is held closely. Many of the images of unhealthy pigs or environmental situations would not be acceptable used outside of our industry. That is the reason for restricting the site only to registered users. The images are classified according to one of sixteen different categories. The intent is to not only expand the image inventory but also to add other materials such as PowerPoint presentations, movie clips, audio clips, and activities. Educators have found the image library, even in its rudimentary state, an excellent tool for developing classroom lectures or presentations for producer meetings, developing a newsletter, graphically demonstrating to make a point, etc. Equipping educators has an expanded effect due to the fact that the educator has a reach throughout the industry having exposure to many pork producers. The USPCE has the philosophy in all its areas of work that the more venues in which materials are presented, the better the opportunity to reach a maximum number of producers. To meet this end, there is an effort to transfer as many of the innocuous photos as possible into the Animal Science Image Gallery.

Key Words: Swine Images, Pork Information Gateway, PIGMAP

175 Image coupling – simplifying and linking information for enhanced learning. S. Gerard[1], A. C. Oki[2], and P. L. Senger*[2], [1]*Oei Graphics*, *Bellevue, WA*, [2]*Current Conceptions, Inc.*, *Pullman, WA*.

Teaching concepts in reproductive science usually follows a sequence in which anatomy is presented first, followed by hormonal responses by the target tissue. Although this sequence is well accepted, it does not easily allow anatomy and hormone responses to be coupled into concise, visually powerful images. Images in reproductive science generally follow two primary forms: photographs of anatomical specimens and two–dimensional graphics that are intended to convey time-related mechanisms and events. Complex two–dimensional graphics typically are presented ″all–at–once″ with no defined starting or ending point. Such images are often visually overwhelming when presented on a screen because there is too much information presented in a short period of time. We have developed a series of PowerPoint images (n = 1,100) that present complex anatomical and graphic information in a step–wise, animated fashion. This approach allows each graphic to be presented with a defined beginning and a defined conclusion and the instructor can ″build″ complex images in a logical, step–wise sequence, thus simplifying them. Further, the instructor can ″back–up″ to reemphasize or clarify points. We have also utilized Flash animation to further enhance the explanation. For example, ovarian structures can be visually added to the graphic so that the viewer observes an image that contains anatomical structures, hormone profiles and responses to hormones in one well–sequenced, step–animated series of images. Application of this technology can facilitate learning in a wide variety of disciplines. Image ″building″ and coupling was used for two semesters in a reproductive science course involving over 140 students. While not quantified, the following changes in student behavior were observed: 1) fewer students took notes and concentrated on the content of the lecture; and 2) questions transitioned from simple clarification of minor points to clarification of entire concepts.

176 Digital Image Gallery to assist learning animal science: Photos and illustrations solicited. J. W. Riesen*[1], H. D. Hafs[2], G. K. McCone[3], P. A. Schoknecht[4], and M. R. Stokes[5], [1]*University of Connecticut*, *Storrs*, [2]*Rutgers University*, *New Brunswick, NJ*, [3]*National Agricultural Library*, *Beltsville, MD*, [4]*Wagner College*, *Staten Island, NY*, [5]*University of Maine*, *Orono*.

To assist teaching baccalaureate level Animal Sciences, we are accumulating digitized images and animations at http://

anscigallery.nal.usda.gov. Sections for Beef Cattle, Companion Animals, Dairy Cattle, Ethology, Horses, Nutrition, Other Species, Pork Industry, Poultry, Reproduction, and Sheep and Goats are already installed. The potential exists to add additional sections. Instructors, researchers and graduate students everywhere are encouraged to contribute their images. Submitted images with descriptions and metadata are peer reviewed to insure accuracy and optimize their use in learning. Submitters are giving their permission to use the images for teaching purposes, but have the option of requiring a credit line when they are used. Submitters also have the option to put images in the public domain. ASAS manages the peer review process. The National Agricultural Library (NAL) manages the Image Gallery website where the images are available in perpetuity and without cost. The gallery uses the NAL thesaurus, includes a glossary, and is searchable either by keyword or by advanced search methods. Images can be downloaded in one of several resolutions. This co-operative effort makes free high quality, peer reviewed images easily available to instructors without the danger of copyright infringement. As of 2/2007 over 300 images are available on the website with more in the process of submission and review.

ACKNOWLEDGEMENTS. Supported by USDA HEC Grant #2003-04009, and the NE Section of ADSA/ASAS.

Key Words: Image Gallery, Teaching, Learning

177 ASAS operational structure for the animal science image gallery. M. C. Wulster-Radcliffe*, *American Society of Animal Science*, *Savoy, IL*.

The goal of the Animal Science Image Gallery is to continue to develop a digital image database housed on servers at the National Agricultural Library (NAL), to assist animal science instructors and their students. Animations, videos, data sets, and other teaching tools are solicited, particularly when single images are inadequate for difficult concepts. The NAL indexing system ensures that adequate metadata are included for each image. NAL will make the images available in perpetuity without charge to those who submit or use the images. While NAL will maintain the Image Gallery in perpetuity, they are not prepared to assess new images arising out of new discoveries or technical advances. American Society of Animal Science (ASAS) members possess the expertise to select new images for the Gallery, and they have peer review experience. Therefore, ASAS will assume logistical management of the Image Gallery in October 1, 2007. ASAS will establish an Image Gallery Editorial Board within ASAS. The Editorial Board will be constituted and operated similarly to that for the Journal of Animal Science. The Editorial Board for the Image Gallery will fall under the venue of the ASAS Publications Committee. Initially, the Board will consist of the current Image Gallery editors, as some have volunteered to serve beyond September 30, 2007. Each Section Editor will be encouraged to form a Steering Committee to a) set policy and b) solicit images. To ensure quality, each image and its metadata will continue to be peer-reviewed, much as papers are peer-reviewed for a scientific journal. The Gallery web site http://anscigallery.nal.usda.gov/ currently has instructions for submission and review of images. The major changes over the next several months will lead to more formal incorporation of ASAS review policies. With volunteer section editors and reviewers, the Image Gallery adopted the journal paper review model. The current volunteer editors and reviewers have validated this model. As NAL will provide the computer resources for the Gallery, the main responsibility for ASAS would be recruiting and organizing editors.

Key Words: Image Gallery, Teaching

178 The OSU Breeds of Livestock Library. D. S. Buchanan*, *Oklahoma State University*, *Stillwater*.

At about the time that the internet started to become part of the life of animal scientists, we had the idea that people might enjoy a resource on breeds of livestock. The first thought was to make a library on CD but, at the time, making a master CD was prohibitively expensive (an indication of just how much times have changed). So we turned to the internet as a location for this library. We contacted all of the breed associations that we knew anything about and asked for a description of the breed and some photographs. Response was slow but we started presenting the breeds for which we had information. Some most popular breeds did not send us information and we started getting emails from people who wondered why we did not have some of these breeds. In order to illustrate that we did know that these breeds existed, we constructed a site for each of them and just placed a statement in each site requesting information. Several breed associations contacted us with a query as to why we had not contacted them. We were able to tell each one that we had sent a letter but that they had never responded. Many responses followed quickly. The library grew rapidly and now contains more than 1000 breeds of cattle, swine, horse, sheep, goats, chickens, turkeys, ducks and geese. The library is one of the most heavily used sites at our university. Several of the pages receive in excess of 10000 hits per month. Many of the most popular pages are horse breeds (e.g. Arabian, Quarter Horse, Palomino). The pages include a link for comments. There are typically six to ten comments per day. Some of the comments are requests to use the images in other venues. We allow use of the images for educational, not-for-profit purposes. We receive a few comments every week that are asking us to update a page. In addition, a substantial portion of the comments are just random comments such as ″I like horses″ or ″Eating animals is cruel″. The most interesting comments are from teachers and students. We have realized that these pages are used in schools across the United States and in other countries. Such schools are, in many cases, in urban areas and these pages are providing an opportunity for students to learn about Animal Agriculture.

179 Images for animal breeding, archives, extension, and poultry. D. S. Buchanan*[1], G. E. Dahl[2], J. B. Hess[3], and G. K. McCone[4], [1]*Oklahoma State University*, *Stillwater*, [2]*University of Florida*, *Gainesville*, [3]*Auburn University*, *Auburn, AL*, [4]*National Agricultural Library*, *Beltsville, MD*.

Presently, how vision contributes to cognition is a major field for research in psychology and neuroscience. Nevertheless, good teachers have understood that visuals facilitate learning, and the advantages of images for learning in less structured environments such as outreach likely exceed those used in classrooms. While the on-line Dairy courses offered for credit by the University of Illinois use some real-time audio-visual interactions between instructors and students, images are critical because the majority of the learning is visual without active

interactions. Increasingly, those who specialize in archival information enhance their holdings with images. For example, the liberal use of images in the holdings within the Animal Welfare Information Center (AWIC, http://awic.nal.usda.gov/) at the National Agricultural Library (NAL) significantly enhances information transfer. As another kind of example, NAL now facilitates use of many of their holdings such as those in AWIC through the National Digital Library for Agriculture which provides easy access to up-to-date authoritative agricultural information, data, and services for consumers, policymakers, researchers and other agricultural specialists, farmers and other agribusinesses, libraries, educational institutions, and the general public. Images have proven to be especially useful to preserve historical information, such as the Poultry historical images now being assembled. The "Breeds of Livestock" and "Breeds of Poultry" web sites (http://ansi.okstate.edu/breeds/) also are examples of how images efficiently enhance cognition.

180 The effect of microbial inoculants on the fermentation and aerobic stability of orchard grass silage. C. M. Klingerman*, R. J. Schmidt, W. Hu, E. E. McDonell, and L. Kung, Jr., *University of Delaware*, *Newark*.

Microbial inoculants were tested for their effects on the fermentation and aerobic stability of silage. Wilted orchard grass (about 38% DM) was chopped and treated with A) nothing, B) a "grow up" culture (*Lactobacillus lactis* and *L. plantarum* AberF-1 with the ability to ferment fructose), C) a low dose of a dry formulation of B, D) a high dose of a dry formulation of B, E) Sil-All 4 × 4 inoculant (*L. plantarum*, *Pediococcus acidilactici*, *Enteroccus faecium* and *Bacillus pumilis* and amylase enzymes), F) Pioneer 1127 inoculant (*L. plantarum* and *E. faecium*), G) Biomax Multipurpose inoculant (*L. plantarum* and *P. pentosaceus* and H) *L. buchneri* and *P. pentosaceus*. The sources of products were: B, C and D (ABS Global, DeForest, WI), E (Alltech, Nicholasville, KY), F (Pioneer, Johnston, IW), G (Chr. Hansens Biosystems, Milwaukee, WI) and H (Lallemand, Milwaukee, WI). Silages were packed in vacuum/heat-sealed pouches. Data were analyzed separately for each time point using the PROC GLM procedure of SAS for a completely randomized design. After 90 d of ensiling, the concentrations of lactic (ave. 6.04%) and acetic (ave. 0.43%) acids were higher and lower, respectively, in silages B through G when compared to that of A (4.71% and 1.93%) ($P < 0.05$). Silages B through D had less NH3-N (ave. 0.07%) than A and H (0.14%) ($P < 0.05$). Silage H had the least lactic acetic (1.53%) but most acetic acid (6.58%) compared to all other silages ($P < 0.05$). Silages B through G had more yeasts (> 5.5 log cfu/g) than did A (2.76 log cfu/g) and H (0.85 log cfu/g). Aerobic stability was worse for silages B through G (ave. 42 h) but better for H (400 h) compared to A (178 h) ($P < 0.05$). Dry matter recovery was lowest for H ($P < 0.05$) and similar among other silages. Homolactic acid-based silage inoculants can improve silage fermentation but can make aerobic stability worse. An inoculant containing *L. buchneri* had the best aerobic stability but lowest DM recovery of all treatments. A "grow up" inoculant with the ability to ferment fructose improved the early rate of fermentation but final silage quality was generally similar to that from other treatments after storage.

Key Words: Silage, Forage

181 Effects of feeding alfalfa silage at two levels with and without Rumensin to high producing Holstein cows on animal performance. C. M. Martinez*, Y. H. Chung, T. W. Cassidy, V. Ishler, K. S. Heyler, and G. A Varga, *The Pennsylvania State University*, *University Park*.

Eight multiparous high producing Holstein cows (BW=699 kg ±13; DIM=158 d ±4.5) were used in a replicated 4x4 Latin Square design with a 2x2 factorial treatment arrangement to evaluate the effects of feeding two levels of forage inclusion with and without Rumensin on dry matter intake, milk production, milk composition and blood metabolites. The diet was formulated to contain 50 or 60% forage (DM basis) in which alfalfa haylage comprised 55% and corn silage comprised 45% of the total forage in the diet. Rumensin was top dressed at a rate of 300 mg/cow/d. The length of each period was 4 wks and samples were collected during the last wk. Dry matter intake was higher ($P < 0.01$) for cows consuming the 50% forage diet than for cows consuming the 60% forage diet (29.6 vs. 27.3 kg/d, respectively). Milk yield and fat corrected milk (46.4 and 46.6 kg/day, respectively) were not affected by forage level or Rumensin in the diet. Milk fat % increased with forage level (3.39 and 3.51% for 50 and 60% forage, respectively, $P < 0.05$). However, a significant forage level by Rumensin interaction was observed showing that Rumensin decreased milk fat % for the 60% forage diet with no effect on milk fat % for the 50% forage diet. Cows consuming the 50% forage diets had higher ($P < 0.05$) milk protein % (3.12) than cows consuming the 60% forage diets (3.07). Milk protein % was lower for Rumensin-fed cows (3.07) compared to no Rumensin (3.12). Neither fat nor protein yields were affected by forage level or Rumensin. Cows consuming the 60% forage diets had a higher ($P < 0.05$) feed efficiency (1.71) when compared to the 50% forage diets (1.56). Blood glucose was higher for cows receiving 50% forage than cows receiving 60% forage (69 vs. 65 mg/dL, respectively). Results from this study suggest that higher forage levels can be achieved in dairy cow rations without affecting milk production while improving feed efficiency compared to lower forage inclusion. When feeding alfalfa silage based rations supplemented with Rumensin, milk components may be altered dependent upon forage level in the diet.

Key Words: Rumensin, Alfalfa, Forage level

182 Trans-7-octadecenoic acid decreased milk fat and altered CLA composition in milk of lactating mice. A. K. G. Kadegowda*[1], B. B. Teter[1], J. Sampugna[1], P. Delmonte[2], L. S. Piperova[1], and R. A. Erdman[1], [1]*University of Maryland*, *College Park*, [2]*Food and Drug Administration*, *College Park, MD*.

Principal component analysis of data from studies with MFD in cows has indicated that trans-7-18:1 (t-7) could be associated with regulation of milk fat synthesis. We used a lactating mouse model to compare the effects of t-7-, t-9-, t-11-18:1, t10c12 CLA (Sigma Chemicals, Co.,

St.Louis, MO), and PHVO (partially hydrogenated vegetable oil) on milk fat content and fatty acid composition. Thirty lactating C57Bl6J mice were fed a Control diet until day 6 postpartum, and were randomly assigned (n=5) to 6 treatments until day 10 postpartum. The trans-18:1 isomers or PHVO were added as 5% and t10c12 CLA was added as 1% of the calories, replacing equal parts of the oleic acid in the Control diet. Milk samples were collected on days 6 and 10 postpartum. Milk fat did not differ among groups at day 6. On day 10, milk fat percentage was 36.4, 28.1, 20.4, 26.7, 36.6 and 32.1 in mice fed Control, PHVO, t10c12 CLA, t-7-, t-9-, and t-11-18:1, respectively. Milk fat percentage was decreased by t10c12 CLA (44%; $P < 0.001$), t-7-18:1 (27%; $P < 0.001$) and PHVO (23%; $P < 0.001$). Compared to the Control (0.25g/100g), CLA were increased in milk of mice fed t10c12 CLA (1.87g/100g; $P < 0.001$) and in those fed t-11-18:1 (1.12g/100g; $P < 0.001$) due to the endogenous synthesis of c9t11. However, the greatest increase in CLA was found in mice fed t-7-18:1 (2.24g/100g; $P < 0.001$), where t7c9 was the predominant isomer representing 87 % of total CLA. PHVO treatment also increased milk CLA content (0.76g/100g; $P < 0.001$) by providing t-11-, and t-7-18:1 precursors for endogenous synthesis of CLA. The t7c9 CLA (10% of total CLA) observed in milk of mice fed diet supplemented with PHVO, confirmed the presence of t-7-18:1 in the oil. The data showed unequivocally that t-7-18:1 was converted to t7c9 CLA in mice. These results suggested that the t-7-18:1 and/or its Δ9 desaturation product may be involved in regulation of milk fat synthesis.

Key Words: Trans fatty acids, CLA, Milk fat

183 An evaluation of two methods to cover bunker silos to maintain the nutritive value of silage. E. E. McDonell*, C. M. Klingerman, R. J. Schmidt, W. Hu, and L. Kung, Jr., *University of Delaware*, *Newark*.

The objective of this experiment was to test the effect of different methods for covering corn silage in bunker silos. Three bunker silos (44 × 7 m) were filled with chopped whole-plant corn (30% DM). Immediately after filling, one half of each silo was covered with one of two methods. The first method (**A**) was comprised of a 6 mil black/white polyethylene (Up North Plastics Bunker Covers, Cottage Grove, MN), weighted down with split-tires. The second method (**B**) was comprised of a single layer of triple co-extruded film (1.77 mil) with low permeability to O_2 (Silostop, Mongralese, Italy), a protective tarpaulin, and weighted down with reusable bags filled with pea-gravel (99 × 15 cm). Method B also included a layer of the extruded film, which was placed along the length of the sidewall prior to filling. Corn silage was sampled at 5, 7 and 10 months of ensiling. Silage was sampled at three depths extending in 15.24 cm increments downward, and three widths extending in 20.32 cm increments outward from the wall. Repeated- measures mixed model was used to test the main effects of covering system, time, width, and height, along with all interaction effects. The interaction of width × treatment is shown below. Corn silage covered with method B had higher DM, NDF, pH, and butyric acid for each width away from the silo wall ($P < 0.05$) than corn silage covered with method A. This corn silage also had numerically less lactic acid compared to corn silage covered with method A. Corn silage covered by method B maintained a higher quality than corn silage covered by method A.

Table 1.

Item	Width1* A**	Width1 B***	Width2 A	Width2 B	Width3 A	Width3 B

184 Effect of level of fermentable NDF on feed intake and production of lactating ewes. M. A. Schotthofer*, M. L. Thonney, and D. E. Hogue, *Cornell University*, *Ithaca, NY*.

The objective of this experiment was to quantify the effect of level of fermentable NDF (FNDF) on DMI and production of highly productive, lactating ewes. Within one wk of parturition, 21 ewes and their triplets or twins (2.7 lambs per ewe) were penned individually in expanded metal floor pens and fed one of three diets for 6 wk. The diets were formulated to contain 15, 25, or 35% FNDF with associated decreases in nonstructural carbohydrates based upon estimated ingredient digestibility values at 1X maintenance. The 15% FNDF diet (19% NDF) contained 48.2% corn gluten feed (CGF), 44.9% corn, 2.9% calcium carbonate, 2% mineral-vitamin premix, and 2% corn oil. Soy hulls replaced 3 percentage units (PU) of the CGF and 17 PU of the corn for the 25% FNDF diet (30% NDF), and 6 PU of the CGF and 33 PU of the corn for the 35% FNDF diet (41% NDF). Chromic oxide was used as a marker to determine digestibility. Milk production was measured during wk 3 by lamb removal, oxytocin administration, and milking followed 3 h later by a second milking. Almost all ewes had sore teats by wk 4, often followed by mastitis, which was treated with penicillin and udder balm. For ewes fed the 15% FNDF diet, DMI was similar to 2007 NRC values, but DMI was substantially higher for ewes fed the 25 and 35% FNDF diets (Table 1). In line with digestibility depression from increased intake, actual FNDF values were substantially lower than the 1X maintenance values upon which the diets were formulated, but ewe and lamb gains, and milk production increased substantially as dietary FNDF increased (Table 1). These data indicate that diets for lactating ewes with 2 or 3 lambs should contain a minimum of 25 to 35% 1X FNDF in the dry matter and that diet formulation can have a marked effect on DMI.

Table 1. Effect of fermentable NDF level on lactating ewes

	FNDF, % of DM				*P*-value	
Item	15	25	35	SEM	15 vs others	25 vs 35
Number of ewes	7	7	7			
Initial ewe weight, kg	58	63	62	2.6	0.16	0.76
Final ewe weight, kg	57	67	66	3.6	0.04	0.91

Key Words: Fermentable NDF, Lactating ewes, Fiber

185 The effect of *Lactobacillus buchneri* 40788 with or without *Pediococcus pentosaceus* on the fermentation and aerobic stability of corn silage made at different locations. R. J. Schmidt*, W. Hu, C. M. Klingerman, E. E. McDonell, and L. Kung Jr., *University of Delaware*, *Newark*.

Whole-plant corn (32 – 38 %DM) was chopped and treated with nothing (C), *Lactobacillus buchneri* 40788 (400,000 cfu/g) (Lallemand Animal Nutrition, Milwaukee, WI) (LB) or *Lactobacillus buchneri* 40788 (400,000 cfu/g) and *Pediococcus pentosaceus* (100,000 cfu/g) (LBC) from five locations and packed into 20-L buckets to determine their effects on silage fermentation and aerobic stability after 120 d of storage. The experiment was a randomized complete block design with main effects of inoculation (I), location (L) and I × L interaction. Data were analyzed by the GLM procedure of SAS. Dry matter recovery was different among L but unaffected by I ($P < 0.05$). Numbers of lactic acid bacteria and yeasts were greater and lower respectively, in LB and LBC than C ($P < 0.05$) and different among locations ($P < 0.05$). Numbers of *L. buchneri* (determined by real-time qPCR) were higher ($P < 0.05$) in four of five locations for LB and LBC *vs.* C (I × L interaction, $P < 0.05$) with values for the main effect of I ($P < 0.05$) being an average 6.7 log cfu/g of LB and LBC *vs.* 4.87 log cfu/g for C. Inoculation with LB or LBC raised ($P < 0.05$) silage pH and concentrations of acetic acid, 1,2 propanediol and decreased ($P < 0.05$) concentrations ethanol and water soluble carbohydrates but there was an I × L interaction ($P < 0.05$) for all of these components. Similarly, inoculation with LB (136 h) and LBC (136 h) improved ($P < 0.05$) aerobic stability compared to C (44 h) but there was an I × L interaction ($P < 0.05$). In general, locations with the largest increases in acetic acid due to LB and LBC had the greatest improvements in aerobic stability. The addition of *L. buchneri* 40788 alone or with *P. pentosaceus* resulted in similar effects on silage fermentation and aerobic stability but the effects were not consistent among locations suggesting that unknown factors in the field may alter the effectiveness of microbial inoculation

Key Words: Corn silage, *L. buchneri*, Real-time qPCR

186 Effect of weight gain and diet on insulin sensitivity in Thoroughbred geldings. R. W. Quinn*[1], A. O. Burk[1], T. G. Hartsock[1], K. H. Treiber[2], and R. C. Boston[3], [1]*University of Maryland*, *College Park*, [2]*Virginia Polytechnic and State University*, *Blacksburg*, [3]*University of Pennsylvania*, *Kennett Square*.

Altered glucose and insulin dynamics, including a reduction in insulin sensitivity (SI) have been observed in equine obesity and may contribute to the onset laminitis in susceptible individuals. The body condition score (BCS, scale 1-9) at which such changes occur is unknown. Fifteen mature Thoroughbred geldings (BW 516±13 kg, BCS 4.3±0.1) were fed hay and concentrate twice daily at 20 mcal/d above maintenance until ≥90.8 kg BW was gained (≤9 mo). During weight gain, horses were fed either a high starch (HS, NSC 57%, FAT 4%, n = 9) or a high fat/fiber diet (HF, NSC 20%, FAT 17%, n = 6). A frequently-sampled i.v. glucose tolerance test was carried out prior to treatment initiation (BASAL) and at the start (INITIAL) and end (FINAL) of weight gain. Thirty-six venous blood samples were collected from -30 to 240 min, with 300 mg/kg BW glucose injected at 0 min and 20 mIU/kg BW insulin at 20 min. The minimal model of glucose dynamics was used to estimate SI, glucose-stimulated glucose disposal (SG), the first-phase insulin response (AIRg) and the disposition index (DI). No treatment differences were found at BASAL, INITIAL or FINAL for SI, SG or DI. The AIRg was higher in HS vs. HF at FINAL (P = 0.02). The SG was higher (P = 0.002) at INITIAL vs. BASAL and FINAL for HF. It is likely that weight gain over the middle of the BCS range (BCS 4-7) has little impact on glucose and insulin dynamics. However, the higher AIRG in HS at FINAL suggests that the changes which have previously been observed in horses on high starch diets may be beginning. The higher SG in HF during INITIAL may reflect dietary adaptation to fatty acid utilization. Loss of this effect by FINAL may indicate a weight-gain associated loss of this adaptation. Because no negative changes to SI were observed in this study, the lower limit of fatness associated with metabolic problems remains unknown but most likely lies above the BCS range examined in this study.

Key Words: Equine, Insulin, Minimal model

187 Digestibility of limit fed high and low concentrate diets with corn silage as the sole forage for dairy heifers with *Saccharomyces cerevisiae*. G. J. Lascano* and A. J. Heinrichs, *The Pennsylvania State University*, *University Park*.

Restricted feeding and high concentrate (HC) diets are potential methods for growing dairy heifers. Ruminal manipulation with additives such as *Saccharomyces cerevisiae* yeast culture (YC) could alter digestibility when added to these diets. A study was designed to study effects of YC on dry matter digestibility (DMD) and N digestibility (ND). An additional objective was to evaluate effects of YC on DMD and ND added to limit-fed HC diets. A split plot design with heifer age as the whole plot and treatment as sub-plot was administered in a 4 period (21 d) 4 x 4 latin square. Eight Holstein heifers (288 ± 4 and 410 ± 2 d of age and 234 ± 15 and 409 ± 20 kg BW) were allocated to 4 treatments consisting of HC TMR (40% CS, 60% grain; 12.6% CP, 25% NDF), and a low concentrate (LC) TMR (80% CS, 20% grain; 12.3% CP, 35% NDF) without YC addition and the same treatments with YC top dressed (1 g/kg intake as fed basis). Diets were fed once/d to provide 0.22 Mcal ME intake/kg $EBW^{0.75}$. Periods consisted of 17 d adaptation and 4 d total fecal and urine collection. Urine was collected using non-invasive urinary devices attached to heifers (pH adjusted to minimize NH3 volatilization); feces were collected hourly and stored in airtight containers. DMD was different between HC and LC (75.67 vs.72.96 ± 0.7%; $P < 0.01$), and

YC addition increased DMD in both diets (74.97 vs. 73.65 ± 0.7%; $P < 0.05$). No differences were found among the 2 ages ($P > 0.3$). N intake (128.13 ± 1.85 g/d) and apparent ND were similar in all treatments. HC diets decreased fecal output on DM (1.49 vs. 1.77 ± 0.06; $P < 0.01$) and wet (10.48 vs. 7.28 ± 0.36 kg; $P < 0.01$) bases, and YC had a significant effect in both parameters ($P < 0.05$). Urine volume excretion was not different; therefore total manure output was lower for HC diets. We conclude that YC increased DMD in HC and LC diets; HC diets were more digestible and generated less fecal output, with YC enhancing this effect.

Key Words: Yeast culture, Forage:concentrate, *In vivo* digestibility

ADSA-SAD Undergraduate Competition - Dairy Production

188 The potential for use of sexed semen technology in the dairy industry. S. N. Van Exel*, *California Polytechnic State University*, *San Luis Obispo*.

Recent developments in flow cytometry have made sexed dairy cattle semen a potential tool for dairy producers. This technology makes possible a 90% probability of conceiving a heifer calf using sexed semen. What are the economics of this technology? Will sexed semen technology be accepted as an alternative to conventional artificial insemination in the dairy industry? Beneficial and potentially negative aspects of this technology will be discussed. What producers may likely benefit from the use of sexed semen in their reproductive programs? A profile of the potentially successful candidate for adoption of sexed semen will be discussed.

Key Words: Sexed Semen, Artificial Insemination, Reproduction

189 Management considerations for automated milking systems. S. J. Miller*, *The Pennsylvania State University*, *University Park*.

As labor costs increase and technology advances, more producers will find automated milking systems (AMS) to be a viable option. However, there are management considerations when switching from a conventional milking system to an AMS. Van de Vorst and de Koning (2002) showed that the introduction of robotic milking systems caused an increased milk SCC. Gygax et al. (2006) indicated that cows milked using AMS exhibited elevated cortisol secretion which may be linked to these higher SCC levels. Canadian producers reported between a 0% and 3.2% cull rate due to the switch to robotics. Culled cows had very close teat placement, rear teats that touched, or raised rear udders that made teats hard to detect in a horizontal plane. Genetic selection should be placed on these traits to avoid future culls. The biggest challenge will be to decrease the percentage of involuntary milkings. Involuntary milkings occur when cows do not enter the milking station in a specified period of time and producers must bring the cows to the system. Rodenburg and Wheeler (2002) found that it takes 3 to 4 weeks to reach an 80% voluntary milking rate. After the transition to an AMS, the study showed that an average of 12.6% of milkings were involuntary. Almost half of the involuntary milkings were due to lazy milkings, where cows with no signs of physical distress did not go to the milking station. Lazy milking fetch rates can be reduced by feeding small amounts of concentrate in the AMS to entice cows to be milked. The same study showed that by switching the concentrate from low energy (1.56 Mcal/kg) to high energy (1.96 Mcal/kg), voluntary visits per day increased from 3.40 to 4.04 and voluntary milkings per day increased from 1.72 to 2.06. Milk from AMS will have to comply with the Pasteurized Milk Ordinance in the U.S. The PMO has been revised to specifically address issues related to AMS. As labor becomes more of a challenge and producers become more aware of the management adaptations necessary to make a smooth transition, AMS will become more commonplace in the dairy industry as long as they are approved to meet legal milk standards according to the PMO.

Key Words: Automatic Milking System, Robotic Milking

190 The sale and consumption of raw milk. T. Webb* and D. Winston, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Niche marketing of dairy products including organic and raw milk sales are growing. Historically, raw milk has been consumed by producers themselves. Recently, the sale of raw milk has received great attention. Some consumers prefer raw milk over pasteurized milk because they believe it is more natural, is healthier and tastes better. Producers prefer it because of its convenience. Others claim that it is part of their culture to consume raw milk and milk products. The level of cheese illegally produced from raw milk in California is equivalent to four percent of all cheese produced in the state each year, much of it attributed to the culture in the area. Raw milk contains many pathogens, such as *Salmonella, Campylobacter jejuni, Escherichia coli* and *Listeria monocytogenes* that can cause severe health issues when consumed by humans. Nearly 76 million people are affected by food borne illness and 5000 people die each year, costing society nearly $20 billion. On average 250 of these deaths are from raw milk consumption, which tarnishes the image of the dairy industry. Twenty-eight states have banned the sale of raw milk to prevent such illness. Some consumers are circumventing these regulations through cow share and lease programs. Educational programs should be developed to educate dairy producers, consumers and decision makers about the health risks associated with the consumption of raw dairy products. Pasteurization has been shown to reduce microbial content in milk. The level of inactivation depends upon the temperature and time at which the milk is pasteurized.

Key Words: Raw Milk, Pasteurization

191 Breeding strategies for today's commercial dairy producers. M. M. Welper*, *Iowa State University*, *Ames*.

Implementation of crossbreeding programs is becoming increasingly popular as many commercial dairy producers try to take advantage of heterosis, or hybrid vigor. Heterosis describes the desirable outlying traits of a crossbred individual that are obtained by combining the diverse traits of its purebred parents. In today's dairy industry, many outstanding sires are readily available through AI to almost every producer across the globe, but these sires come from relatively few genetically distinct lines. Producers often utilize only bulls ranking in

the top percentiles over several generations to focus on the desirable traits that they are selecting for in their herd. Unfortunately, most of the top ranking bulls available in AI are even more or very closely related to each other since the top ranking bulls of one generation sire most of the next generation of bulls sampled in AI programs. Consequently, herds utilizing only top-ranking AI sires become increasingly inbred with each passing generation. Many producers are beginning to realize the drawbacks caused by inbreeding depression. This occurs when the genetics in a line of cattle becomes so focused that not only the desirable traits become more emergent but so do the non-desirable recessive traits. This often is expressed as negative consequences on performance parameters such as health, fertility, and longevity. Implementing crossbreeding into a dairy herd, ensures the prevention of inbreeding depression, and also incorporates into the herd traits from outside the current breed. Producers need to develop a crossbreeding strategy which maximizes heterosis, is easy to implement, and allows for long-term success.

Key Words: Heterosis, Crossbreeding

192 Waste milk vs. milk replacer. J. Downing* and C. C. Williams, *Louisiana State University*, *Baton Rouge*.

Two methods of raising dairy calves include feeding waste milk and feeding milk replacer. Waste milk is non-saleable milk such as excess colostrum, transition milk, mastitic milk, or antibiotic treated milk. Milk replacer is a powder which is mixed with water and resembles milk. Some of the common ingredients of milk replacer include whey, whey protein concentrate, animal and vegetable fats, vitamins, minerals and amino acids. Both practices have recommendations and guidelines to follow once a method of feeding has been selected. Disadvantages of feeding waste milk include microbial infections, antibiotic residues and resistance, higher calf mortality and increased veterinary costs. The most common microorganisms found in waste milk are *Streptococcus*, *Enterobacter*, *E coli, Listeria*, *Salmonella*, Bovine Viral Diarrhea, and Bovine Leukosis Virus. Organisms responsible for mastitis and Johne's disease can also be found in waste milk. If waste milk is going to be fed, pasteurization is a good idea. Pasteurization of waste milk can reduce the microbial load, decrease mortality and vet costs, and increase body weight gain of calves, but it does not remove antibiotic residues from the milk. There are guidelines for feeding waste milk which can help prevent disease causing microorganisms from being spread to calves. If milk replacer is fed, its nutritional quality should be evaluated before using. Milk replacers should contain a minimum of 20% protein and 15% fat. Vegetable oils should not be used in the milk replacer because they are poorly utilized by calves. Advantages of feeding milk replacer include disease prevention, convenience, increased performance, and economics. Beneficial additives can also be incorporated into the milk replacer which aid in growth and preventing calf-scours. Many farmers consider waste milk to be cheaper than milk replacer, but this is not the case when looking at opportunity cost. Waste milk can be a good source of nutrition for calves but negative factors such as antibiotic residues and infectious pathogens may impact your calves' health and decrease performance. Management practices are key factors in deciding which method is best in raising dairy calves.

Key Words: Calves, Waste Milk, Milk Replacer

Dairy Foods: The Dairy Management Inc. National Dairy Foods Research Center Program: Responding to Industry Needs for New Technologies, Products and Markets

193 The Dairy Management Inc.™ National Dairy Foods Research Center Program: responding to industry needs for new and improved technologies, products and ingredients. J. K. Kondo*, *Dairy Management, Inc.*, *Omaha, NE*.

Successful dairy and dairy-based product innovations rely on research. While customer and market insights fuel the product concepting process, the latest science and technologies can transform those concepts from ideas into successful products and ingredients. Through its Product Innovation Program, Dairy Management Inc.™ (DMI) provides industry with leading-edge dairy product and ingredient research and technical resources. The National Dairy Foods Research Center Program, a unified coordinated national research program conducted through six research centers, three applications labs and other universities, helps industry innovate to address unmet consumer demand for dairy and dairy-based products by providing the science for innovation as well as the knowledge to address product challenges. Presentations by center directors and scientists, representing each research center, will review current research under way in their facilities. The research covers technologies and processing methods for extended shelf-life products, high-value whey ingredients and co-product utilization, cheese with improved functionality and performance, and ingredients with enhanced functionality and performance.

Key Words: National Dairy Foods Research Centers, Dairy Centers, Dairy Research

194 Manufacture and application of casein concentrates. L. E. Metzger*, *South Dakota State University*, *Brookings*.

Milk protein concentrate (MPC) is extensively used as an ingredient in process cheese product formulations. In MPC approximately 20% of the total protein is whey protein and 80% is casein. In process cheese product applications casein provides a desirable firm un-melted texture and stringy, elastic melted texture, whereas whey protein forms a thermo-irreversible gel and produces a process cheese product that has restricted melt characteristics. Consequently the casein portion of milk protein is more valuable for use in process cheese product applications as compared to whey protein. The objective of this research was to develop a microfiltration process utilizing spiral wound membranes that is capable of producing a casein enriched protein concentrate (CEPC). Subsequently the performance of CEPC in process cheese product formulations was compared to conventional MCP. Three replicates of skim milk were processed into MPC using ultra/diafiltration and CEPC using micro/diafiltration. The mean total protein, casein, whey protein, ash, and lactose of the MPC and CEPC respectively were 74.3, 60.4, 13.1, 7.60, 11.9% and 73.2, 65.6, 6.6, 7.8, 6.1%. The MPC and CEPC were then utilized in process cheese product formulations. The process cheese product formulations were standardized to contain 15 and 25% MPC or CEPC (corrected to 75% protein). Each formulation was processed at 80 and 95°C. The process cheese products produced using CEPC had a significantly ($P<.05$) higher apparent

viscosity after manufacture and TPA-hardness as compared to those produced with from MPC. These results indicate that CEPC will have added value as compared to conventional MPC when used as an ingredient in process cheese product applications.

Key Words: Casein Concentrate, Microfiltration, Process Cheese Product

195 Creating new dairy ingredients uses – getting beyond the dairy case. P. S. Tong*, *California Polytechnic State University*, *San Luis Obispo*.

A large portion of dairy ingredients have been historically utilized in the manufacture of dairy foods. In such applications the dairy ingredients were utilized because they provided the desired sensory profile, nutrient composition and/or functional ingredient performance in a convenient and/or economical fashion. These dairy ingredient attributes continue to be important for their use in many food systems. However, as the food industry grows increasingly sophisticated in response to consumer expectations and the competitive market environment, getting beyond the dairy case will be a growing market opportunity and it will require recognition that more specific or customized ingredient solutions and associated service/support may be needed. One successful approach has been to maximize the functionality per unit of the dairy ingredient to provide the necessary economic advantage to the end-user. This has been an effective way to compete against other potentially lower cost, highly functional food ingredients. Dairy center research and applications programs have helped to characterize and optimize dairy ingredient functionality that has been one key foundation of the strong demand for dairy ingredients around the world today. However, increasing scientific evidence on the beneficial health effects of dairy protein consumption and other dairy components are creating new avenues to get us beyond the dairy case. Looking at how the other popular food ingredients are positioned and utilized in the food industry may shed some valuable insight on how dairy ingredients can get beyond the dairy case and how the national dairy centers and applications programs can help play a vital role.

Key Words: Dairy Ingredients, Dairy Protein, Food Applications

196 Defining the flavor of dairy products. M. A. Drake*, *North Carolina State University*, *Raleigh*.

Flavor plays a crucial role in customer and consumer purchase decisions. Trends come and go in the food industry but a desirable and consistent flavor is always required for market success. Defined sensory languages to describe flavor are fundamental tools which can serve as platforms to document flavor and to understand flavor chemistry and consumer perception. Sensory languages to document flavor characteristics were applied to cheese, dried dairy ingredients, butter, and fluid dairy products. Collected flavor information was used to document flavor variability and stability, to identify chemical sources of flavors and understand flavor carry-through in ingredient applications, and to construct consumer preference maps. Specific examples with cheese, dried dairy ingredients, butter, and fluid dairy products will be addressed.

Key Words: Flavor, Dairy Foods, Sensory Analysis

197 Improving the quality of low fat cheese. D. J. McMahon*, *Western Dairy Center, Nutrition & Food Sciences Department, Utah State University*, *Logan, UT*.

With the renewed interest in low fat foods, a DMI-funded collaborative project was undertaken to systematically study the differences between full fat and low fat cheddar cheese, with the aim of providing a basis for improving the flavor and texture of low fat cheeses. A method that included pre-acidification of milk to pH 6.25 and washing curd with cold water was developed to make a low fat cheese with 52 to 54% moisture and pH 5.15 to 5.25. A 50%-reduced fat cheese and a full fat Cheddar cheese were made without preacidification but with curd washing. A full fat Cheddar cheese without curd washing was also made. These cheeses were aged at 8 C and tested at 2 wk, 3 and 6 mo of aging. This presentation will present findings from analysis of these cheeses comprising sensory flavor, flavor chemistry, rheology, sensory texture, melting, bacterial microflora, and cheese biochemistry.

Key Words: Low Fat Cheese, Flavor, Texture

198 Process techniques to enhance the utilization of whey ingredients. J. A. Lucey*[1], S. Damodaran[1], and K. Smith[2], [1]*University of Wisconsin*, *Madison*, [2]*Wisconsin Center for Dairy Research*, *Madison*.

Various types of whey ingredients, including sweet whey, whey protein concentrates (WPC) and whey protein isolates (WPI), are popular food ingredients due to their excellent functional and nutritional properties. Some of the key developments over the past 20 years have included increasing purification of the protein fraction and the isolation of individual fractions. Membrane filtration techniques, such as microfiltration (MF), ultrafiltration and diafiltration, are now used for the production of WPI and polymeric spiral-wound MF membranes are also becoming popular. Currently, research is being conducted to enhance the functionality of whey powders so that they can be successfully used in applications such as nutritional bars, crispy snacks, and beverages. New processing approaches to enhance the functionality of whey ingredients include methods to reduce the residual lipids in WPC, exploring process conditions to alter the interactions between whey proteins and polysaccharides, crosslinking of whey proteins, incorporation of other proteins fractions with WPC, and the use of MF to fractionate caseins from whey prior to cheesemaking. These novel processing techniques could improve the clarity, flavor stability, heat stability, emulsification and foaming properties of whey ingredients. The goal of these research topics is to extend the functional range for existing whey ingredients into more challenging environments, e.g. clear, low pH beverages that have a high protein content and are also heat stable. Another key goal is to reduce the variability in functional performance (e.g. flavor, clarity, color) that can be observed in whey ingredients.

Key Words: Whey Ingredients, Functionality, Membrane Filtration

199 Breaking the 21 to 28 day shelf-life barrier on refrigerated HTST pasteurized milk. D. M. Barbano* and K. J. Boor, *Cornell University, Northeast Dairy Foods Research Center, Department of Food Science*, *Ithaca, NY*.

While ultra-high temperature (UHT) non-refrigerated shelf-stable milk has a long shelf-life, the U.S. consumer has not accepted the

sensory quality of this product. The refrigerated shelf-life of HTST pasteurized fluid milk has increased over the last 20 years as improved post-pasteurization milk handling and packaging systems have decreased post-pasteurization contamination. Improvements in raw milk quality have also contributed to increased shelf-life and flavor quality. Enclosed fillers with filtered air environments have allowed the best fluid milk processors to achieve 21 to 28 days of shelf-life. The organisms that typically spoil HTST milk after 17 d are pychrotolerant *Bacillus* spp. and closely related genera. These spores are present at low levels in high quality raw milk supplies, they survive HTST processing, and then grow rapidly after 17 d of refrigerated storage. In the last two years, fluid milk processors have increased HTST temperatures to improve the safety of fluid milk but this has stimulated outgrowth of spore formers and in some cases decreased shelf-life of HTST fluid milk. Alternative approaches, using removal of bacteria and spores are being explored in combination with HTST at minimum temperature and time, are being developed that will allow processors to break the 28 d shelf-life barrier.

Key Words: Fluid Milk, Shelf-Life, HTST

ADSA Southern Branch Symposium: Keeping Dairy Going and Growing

200 Structural shifts in the dairy industry. G. A. Benson*, *North Carolina State University*, *Raleigh*.

Dairy farm and cow numbers are declining, milk per cow is trending up, and milk production is increasing in the West and is flat or decreasing elsewhere. Understanding the factors causing these shifts can lead to more informed business decisions by farmers and allied industries, and is useful to policy makers. Causes include changes in product demand, technology, input availability and cost, and profitability. Government policies affect the general business climate, transportation costs, trade, and agricultural programs. There is little published work that quantifies the relative importance of each one for the dairy industry. Increased specialization has occurred to take advantage of economies of scale and size and capital has been substituted for labor. Technology has created increases in farm level productivity, both per cow and per acre. Trade and dairy policies create US prices that are above world prices and shield US producers from international competition. Productivity gains have outstripped the growth in sales, creating pressure on farm prices and reductions in cow numbers. The combined effect is the observed reductions in the size of the national dairy herd and farm numbers. Consumers are the primary beneficiaries, in the form of lower prices for dairy products. Regional changes are driven by differences in financial performance. Differences in input availability and cost affect production costs. Regional price differences are the result of local supply and demand conditions, transportation costs and, to some extent, federal and state milk pricing rules. Structural change also has occurred at the dairy cooperative, processor and retailer level. In general, the main changes have been a reduction in the number of business entities, increasing size, and greater concentration. Dairy farmers can only react to structural change as they make business plans but policy makers, new technology developers (including research and extension) can influence the direction and speed of change. Specific activities include changing the relative prices of milk in the various regions and initiatives that target specific regional rather than national issues.

Key Words: Structural change, Dairy

201 Problems associated with a dairy expansion effort. J. F. Keown*, *University of Nebraska*, *Lincoln*.

Over the years, many states have initiated projects to expand their dairy operations as a way to increase economic activity, increase employment, utilize the by-products generated by the expanding ethanol industry and revitalize rural portions of their states. To be successful, these activities take a concerted effort from all groups within the state, the Governor's Office, State Legislature, Department of Agriculture, as well as aligned dairy industries. In Nebraska, an effort to get local dairies to expand was not really successful until an effort was made to attract dairies from other parts of the country. The advertisements and promotional brochures produced discussing the Nebraska Advantage showed local producers the benefits that their own state offered the industry. Having other producers visit and discuss the opportunities that were available within the state helped local producers take a second look at the resources available to them for local and regional expansion. There are many obstacles to overcome when attempting to attract producers from other states such as climate, infrastructure, Department of Environmental Regulations for obtaining permits for easements and manure disposal, feed resources and costs, availability of multiple milk markets and local acceptance of large animal operations are all major concerns that must be considered. All of these obstacles have been encountered when working on the Nebraska effort and are common to all areas that are attempting to attract animal operations to their state. Many of these concerns cannot be addressed on a statewide basis but must be addressed individually, as each project is unique. The ability to address these issues and have all elements working in unison will result in successful or unsuccessful expansion efforts.

Key Words: Economic, Ethanol, Expansion

202 Adopting a management focus. R. A. Milligan*[1,2], [1]*Dairy Strategies, LLC.*, *St. Paul, MN*, [2]*Cornell University*, *Ithaca, NY*.

Every business needs a workforce with at least one person filling three roles as workers, managers, leader/chief executive. Over the last several decades an increasing number of dairy farms have develop expertise in the manager role. The challenge to keep the dairy industry going and growing is for each business to develop the expertise to successfully execute the chief executive role. The chief executive (CE) role is very different from the worker and manager roles. The CE is focused on strategy and people. The CE must have a greater external focus to understand what is happening in the global business environment including the quality movement, the markets for the business product, labor markets, and public policies impacting their industry. This information must then be utilized to develop and implement strategies to enable the business to thrive in our ever changing business environment. The chief executive must then assemble, inspire and develop a winning workforce team including:

1. Articulating the dairy businesses inspirational mission/vision/compelling vision.

2. Establishing a culture of quality, high expectations and continuous improvement.

3. Developing the organizational structure of the business.

4. Building the workforce team and developing and coaching leadership team members.

5. Seeking professional development opportunities to enable him or her to excel in this newer and less familiar role.

A great chief executive provides visionary leadership enabling the business (dairy business) to achieve extraordinary excellence over a long period of time. The owner can become a great chief executive for their business by making that role the number one priority. Unfortunately, few of us have the discipline to effectively operate as a CE, especially in a part-time role, without some structures to help. We need help maintaining focus on the important but not urgent tasks. Suggested vehicles to implement this priority include establishing a specific time for CE functions, structured meetings, engagement in activates to network with other CEs, professional improvement plans, and techniques for getting our good ideas on paper.

Key Words: Strategy, Leadership, Future

ADSA-SAD Undergraduate Competition - Dairy Foods

203 Dairy products shown to help reduce blood pressure. L. Gaver* and D. Winston, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Hypertension is a common disorder in which blood pressure remains abnormally high at a reading of 140 over 90 mm Hg or greater. It can be fatal if not detected and treated. Hypertension affects more than one in three American adults; 28% of adults age 18 and older have pre-hypertension. Statistics on hypertension caused the National Heart and Lung Association to begin the DASH Study, a multi-center, randomized clinical study that emphasized fruits, vegetables and fat-free or low-fat dairy products as the ideal diet for reducing blood pressure. The Dietary Approaches to Stop Hypertension Study was conducted in three phases: screening, run-in and intervention. DASH investigators concluded that a balanced diet rich in dairy products is a nutritional approach that can prevent and treat hypertension. They estimate that the DASH diet could reduce coronary heart disease by 15% and occurrence of stroke by 27%. Calcium and potassium are inversely linked to hypertension. Seventy to seventy-five percent of dietary calcium is from dairy products. The DASH diet reinforces the newly updated 2005 National Dietary Recommendations and is the basis for USDA's MyPyramid. The American Heart Association, as well as national guidelines for treatment of hypertension, support the conclusion that increasing dairy products in one's diet will help reduce blood pressure.

Key Words: DASH diet, Hypertension

204 Influence of low-fat dairy products on colorectal cancers. G. S. Christ*, *The Pennsylvania State University*, *University Park*.

Each year over 50,000 people die in the U.S. from colorectal cancer, the second leading cause of cancer deaths. The American Cancer Society estimates that in 2007 there will be 112,340 newly diagnosed cases of colon cancer and 41,420 cases of rectal cancer. Most people receive their dietary calcium from milk and milk products. It is thought that calcium binds secondary bile acids and free fatty acids in the colon, which may reduce colonic cellular proliferation. Alvarez-Leon et al. (2006) cited an inverse relationship between the intake of dairy products and colorectal cancer. Slattery et al. (2004) showed that increasing daily calcium intake up to 1200 mg from low-fat dairy products reduced the proliferation of colonic epithelial cells and returned them to normal differentiation. Holt et al. (2001) placed 40 people, all with initial signs of colorectal cancer, on one of two high calcium diets. Both diets were shown to reduce colonic epithelial cell proliferation. Kampman et al. (2000) concluded consumption of low-fat dairy products was associated with a significant decreased risk of colon cancer in men and women. These findings support an inverse relationship between high calcium consumption and colorectal cancer incidence. As a result of these studies and others highlighting the important role of dairy products in human nutrition and health, the USDA/HHS Dietary Guidelines for Americans 2005 increased the recommended servings of milk/dairy products from 2 to 3 servings per day.

Key Words: Calcium, Low-Fat, Colorectal Cancer

205 Role of dairy products in combating childhood obesity. J. A. Tekippe*, *Iowa State University*, *Ames*.

Childhood obesity continues as a growing health problem in the United States. Currently, 25% of children ages 8 to 19 in the US are overweight and 11% are obese. Several factors, including limited amounts of exercise or activity and the size of fast food portions, have been identified as contributing to this heath concern. Obese youth are at greater risk of developing type 2 diabetes, asthma, and hypertension prior to reaching adulthood. The diets of many American children contain an excess of calories but too little calcium. Over two thirds of American children are not receiving their calcium requirements. Minimum daily calcium requirement of children ranges from 800 mg during their early years to 1,300 mg during the teen years when most growth and bone building is taking place. Several controlled trials have been conducted to explore the relationship between weight loss and dairy products. Most concluded that overweight children consuming a reduced caloric diet that included recommended servings of dairy lost more weight then those who consumed little or no dairy products. The specific mechanism appears to support a role for calcium in weight loss. Specifically, consumption of a low calcium diet results in an increased production of calcitriol and promotes the entry of calcium into fat cells. The calcium in turn inhibits fat breakdown and promotes fat storage. Reducing the incidence of childhood obesity will require a two-pronged approach involving educational programs targeted at helping youth make healthy eating decisions, and motivating them to be more active or exercise regularly. Healthy eating decisions need to address portion sizes and their choice of foods, specifically those that are lower in calories and higher in needed nutrients such as calcium.

Key Words: Obesity, Weight Loss, Calcium

206 The significance of phospholipids and their emerging importance in dairy foods. R. L. Clarke*, *California Polytechnic State University*, *San Luis Obispo*.

Phospholipids are an important biological molecule in milk and milk components. Although minor in quantity comparatively (0.2-1 percent), phospholipids are important in milk fat and widely distributed as components of body cells. They are composed of fatty acids, phosphorous, and contain groups such as lecithin, cephalin, and sphingomyelin. Phospholipids exist in complexes with proteins in milk. Cream, separated from milk, contains about 65% of the lipid bound phosphorous and because of the high degree of absorption of the phospholipids by the fat molecules there is additionally provided stability. Phospholipids are distributed throughout cell membranes, and are emerging as an area of active research in Dairy products. Because the molecule is made up of two distinct regions, one hydrophobic and the other hydrophilic, they react in water to spontaneously form a bilayer. As well as being biologically significant, this property holds great many areas of nutrition and medicine. Since milk is a good source of these phospholipids it is understandable that there is current research to be able to obtain and preserve them in dairy foods such as milk powder and other products.

Key Words: Phospholipids, Milk Powder

Bio Ethics - Livestock and Poultry: The Ethics of Food

207 The ethics of food. J. M. Regenstein*, *Cornell University*, *Ithaca, NY*.

Believe Nothing That You Think! We all like to think of ourselves as ethical, and think carefully about our ethical standards, yet we often do not agree with each other on what is right and wrong. Why? Because our ideas are formed not just through our scientific/rational training but also from inputs that are beyond our scientific/rationale education. Our ethical beliefs reflect who we are. But, as a society, the only way to approach ethics with a hope to reach agreement/compromise is to address ethical issues using rational arguments and reasoning. Therefore, ethical judgments must be offered in the "Marketplace of Ideas" and be able to withstand critical evaluation by those who may disagree. Formally, this is required within the field of philosophy: "Philosophy, like morality itself, is the first and last an exercise in reason, the ideas that should come out on top are the ones that have the best reasons on their sides." (Rachels, The Elements of Moral Philosophy, 1999. p. xii). So the challenge in participating in the debate is to use rational arguments when discussing controversial ethical principles? (And admit when one's arguments are emotional?) But what are rational arguments? This can be difficult to determine although irrational ones are probably easier to identify. An important irrational one centers around the following point: If something specific is wrong (rationally unacceptable? unethical?) with a particular system, i.e., such as a number of the concerns consumers have with the food system, especially animal agriculture; what does that mean? That we should analyze the specific problem, look for rationale solutions, and work hard to apply those solutions to correct that problem and then continue to evaluate how effective the solution is and continue to seek better solutions. What the problem does not rationally imply is that the system identified should not exist (e.g., eliminate animal agriculture) and/or that because of these problems, another system should replace it (e.g., veganism). The replacement needs to justify itself on its own rationale evaluation and merit. In the meantime, we need to work hard to find solutions to these critical problems.

Key Words: Animal Agriculture, Ethics, Food

208 The ethics of semantics: do we clarify or obfuscate reality to influence perceptions of food animal production? C. C. Croney*[1] and R. D. Reynnells[2], [1]*Oregon State University*, *Corvallis*, [2]*US Department of Agriculture, Cooperative State Research*, *Washington, DC*.

According to linguists, the discourse of animal production uses metaphors, pronouns, and definitions that consistently represent animals as objects, machines, and resources, instead of as distinct, unique individuals. Thus, it is argued, genuine concern for animal welfare is either obscured by financial concerns or circumvented entirely, which permits animals to be kept and treated in ways people would otherwise find objectionable. Substituting euphemisms like "crops," "units," and "harvest" for "herds," "animals," and "slaughter," which are more likely to evoke images of grape plucking than of killing animals for food, might indeed seem disingenuous, especially given the common industry refrain that the public needs to be better educated about food production. However, the implication that the animal industries deliberately employ such techniques is debatable. What is clear is that the semantic obfuscations rampant in the language of modern farm animal production reflect underlying ambivalence about full and frank public education about many standard industry practices. First, consumers are unlikely to want full disclosure of all aspects of animal production. Second, there is real risk that certain realities of animal production would be aversive to consumers, who might consequently refuse (as is their right) to purchase particular products, thus causing significant industry losses. Yet, the animal industries' reluctance to "come clean" in public education efforts raises another problem---that adopting innocuous terminology and withholding information deemed likely to be unpalatable to the public is morally questionable in itself. Moreover, this provides an avenue for opponents of animal agriculture to exploit. In truth, animal extremists are now in a position to reveal facts about livestock production that might not only disturb consumers, but also cause speculation about the industries' failure to be forthcoming. As a matter of professional ethics and viability, animal industry members should reconsider the discourse of farm animal production to ensure that what is conveyed is accurate and intended.

Key Words: Ethics, Semantics, Animal Production

209 What would the world be like without animals for food, fiber, and labor? Are we morally obligated to do without them? S. L. Davis*, *Oregon State University*, *Corvallis*.

Numerous animal rights theorists have concluded that nonhuman animals have moral standing and non-interference rights. Therefore, they say that humans are morally obligated to stop using animals for food, fiber, labor and research. I disagree with that conclusion for at

least two reasons. First because it has been demonstrated that food production models are possible using large herbivores that might actually cause less harm to animals than a vegan food production model. This is because intensive crop production used to produce food for a vegan diet kills (harms) far more animals of the field than extensive agriculture (pasture production). So, a combined food production system that includes crops, and pasture harvested by large herbivores to be used for human food may kill fewer animals than would a vegan/crop model. Second, I say no for pragmatic reasons. It is improbable that all peoples of the world could ever be convinced that they must give up animals. In fact it may be unethical to try to do that because in poor countries these animals are essential to the survival of the human populations. But what about the richer nations? Maybe they will/should be convinced to do without animals because of the moral strength of the animal rights theories. However, I believe that there are far too many obstacles for that to happen. What then are we morally obligated to do about animals? I suggest that animals do have moral standing and that we are morally obligated to recognize their unique species-specific natures, and treat them accordingly. That would mean treating animals according to their physical and behavioral needs or telos. That, I believe is the most likely outcome of the conversation about animal rights.

Key Words: Animal Rights, Welfare, Moral Obligations

210 Ethics and the role of academics, scientists and veterinarians in the formation of public attitudes and societal decisions. W. R. Stricklin*, *University of Maryland*, *College Park*.

Ethics has to do with "doing the right thing," but reaching a societal-wide consensus on the right thing to do is often difficult. For example in the USA, there is a wide range of opinions regarding the right thing to do about the use and treatment of food animals. On the one-hand, some persons within both academia and the public at large contend that it is wrong for humans to use other sentient beings as simply a means to an end, i.e., food. Further, they contend that eating animal-based food products should be phased out. On the other hand, some persons - including a significant number of animal scientists - contend that providing food for humans is a greater good that justifies the treatment of food animals across basically all current agricultural housing systems and production practices. And there is a middle position that includes the majority of persons who wish to continue to consume animal food products but also want assurance that the welfare of the animals is appropriately considered. In the USA, the viewpoint of the educated expert or authoritarian figurehead is still generally respected by the public. However, to maintain this credibility, the public must continue to feel that the information they are presented is unbiased. In some instances, animal scientists are becoming viewed as being too closely tied to industry viewpoints and not giving a balanced view of some issues, including animal welfare. Ultimately, both veterinarians and animal scientists have roles to play in helping the public at large gain a greater understanding of the importance of doing the right thing in terms of how animals are to be treated in our society. Thus, it is important that these professionals acknowledge the importance of ethics in their research, teaching, and other professional activities.

211 Production, processing and marketing: an integrated industry's view of ethical issues. C. Klippen*, *Klippen & Associates, LLC*, *Audubon, PA*.

Decision making is a part of everyday living. In satisfying our basic needs, decisions are made about what to eat, what to wear, how to get where we are going, when to sleep. There is another type of decision that we also make that could be described as ethical. There's a purity about a decision labeled "ethical". What's the basis for that claim of its being "ethical". Whose values judgment underscore that ethical decision? In making a decision we try to balance an outcome that we perceive as morally right with what is practical and logical from our set of values. We may view the importance of the outcome as justifying the means in making that decision. Is that "ethical"? We may not know or understand all the facts, yet is it better to decide rather than be indecisive? So, we decide, basing our decision on competing moral perspectives. Evaluating complex and sometimes ambiguous scenarios adds to the dilemma in making a decision. When operating in a framework of proven principles that are reliable, our skills for decision-making are more self-assuring. We center on our beliefs about what we perceive to be right or wrong. Is this ethical? As it relates to producing animals for food, processing and marketing meat, milk or eggs, what proven principles aid the decision as to how that animal is raised, processed, or how the animal product is marketed? Is it efficiency in production, processing coupled with profitability in marketing that dictates the "ethical decision"? Or is it a practical decision that is expedient based on the current needs of society? Is there a reasoning approach from history that can help shape our ethical decisions?

Breeding and Genetics - Livestock and Poultry: Beef Cattle

212 Identification and characterization of microRNA from the bovine adipose tissue and mammary gland. Z. Gu*, S. Eleswarapu, and H. Jiang, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

MicroRNA (miRNA or miR) are a new class of small RNA molecules (~22 nucleotides) that are processed from precursor sequences that form hairpin secondary structures. miRNA inhibit translation or induce degradation of protein-coding mRNA by base-pairing. Increasing evidence suggests that these small RNA molecules play an important role in many processes of animal development and physiology. We have conducted a study to identify miRNA in cattle. By cloning and sequencing small RNA from the bovine adipose tissue and mammary gland and by predicting and folding the precursors of these small RNA sequences, we have identified 59 distinct bovine miRNA. Five of them were not homologous to any known mammalian miRNA, hence potentially novel miRNA. Twenty-five of them had 3' and (or) 5' end variants, suggesting that miRNA precursors may be alternatively processed. Ribonuclease protection assays (RPA) of 12 selected miRNA confirmed their expression in adipose tissue or the mammary gland, from which they were originally cloned. The RPA also indicated tissue-specific or tissue-enriched expression for several miRNA. For example, miR-122a was only detected in the liver, and miR-133 was detected in the heart, skeletal muscle and rumen but not in ten other

bovine tissues. These results demonstrate that miRNA are expressed and may play an important role in cattle too.

Key Words: microRNA, Cattle, Adipose

213 Feed efficiency of tropically adapted breed and breed cross steers when fed in the southern plains. S. W. Coleman*[1], W. A. Phillips[2], C. C. Chase, Jr.[1], and D. G. Riley[1], [1]*USDA ARS Subtropical Agricultural Research Station*, *Brooksville, FL*, [2]*USDA ARS Grazinglands Research Laboratory*, *El Reno, OK*.

Beef cows in the subtropical USA require that they be adapted to the stressors of the environment. However, calves produced in the region are usually grown and finished in more temperate regions. The objective of this paper is to determine the feed efficiency of steers from a 3-breed diallel mating of Angus (A), Brahman (B) and tropically adapted Romosinuano (R), a Criollo breed native to Colombia. Calves (n = 261) born over 3 yr from 2002-04 were straightbred AA, BB and RR, or crossbreds (RB, BR, RA, AR, BA, AB; letters indicate breed of sire and dam, respectively). Steer calves were weaned in September and shipped 2025 km to El Reno, OK for growing and finishing. After grazing wheat pasture until May, 2003, they were finished on a conventional feedlot diet using Calan headgates to obtain individual feed intake. Steers were serially harvested at three times each year, ranging from 93 to 168 days on feed. Feed efficiency was calculated as feed per unit gain (FdGn) and as residual feed intake (RFI). The MIXED model included effects of year, stocker treatment, and replicate. Days on feed and calf age at the beginning of the feedlot phase were fit as continuous variables. Sire within breed was the random term. Significance is denoted by + ($P < 0.10$), * ($P < 0.05$) or ** ($P < 0.01$). Direct effects for initial and final weight and daily gain were 43**, 16, and -21+; 19+,61**, and 0.31**; and -62**, -77** and -.10 kg for A, B, and R, respectively. Direct effects for daily DM intake, FdGn, and RFI were -1, 2.16*, and 0.48+; -.25, -2.73**, and -.44+; and 1.25+, 0.57, and -.05 for A, B, and R steers. Heterosis ($P < 0.01$) was noted for all breed combinations for initial and final weights, but not for rate of gain. There was negative heterosis ($P < 0.01$) for intake by A-B and for B-R crosses. There was no heterosis for feed efficiency. In conclusion, Brahman influenced steers appear to be more efficient than Angus and Romosinuano was intermediate.

Key Words: Feed efficiency, Brahman, Romosinuano

214 Genetic evaluation of growth in a multibreed beef cattle population using random regression linear spline models. J. P. Sanchez*[1,2], I. Misztal[1], I. Aguilar[1], and J. K. Bertrand[1], [1]*University of Georgia*, *Athens*, [2]*University of Leon*, *Leon, Spain*.

The objective of this study was to examine the feasibility of using random regression, spline models (RR-s) for fitting growth traits in a multibreed beef cattle population. The evaluation results from this model were compared to those obtained using a multi-trait model (MT) when both were used to fit the US Gelbvieh data set (1.8 million records and 1.1 million animals). Both models included direct and maternal additive genetic, contemporary group, age of the animal, direct and maternal heterosis, and direct and maternal additive genetic mean of the breed effects. Additionally, the RR-s model included a direct permanent environmental effect. The effect of prior information for heterosis and breed effects on the EBV of sires was also investigated. When both MT and RR-s models were fitted to the data set containing records for weaning weight (WWT) and yearling weight (YWT) within specified age ranges and medium weight was posed on prior information, the rankings of bulls direct EBV (as measured via Pearson correlations) provided by both models were comparable (≥ .99). For maternal effects, these correlations were also high, being the lower case YWT (= .92). The inclusion of prior information had negligible effect in the overall ranking for bulls with greater than 20 BWT progeny records, the correlations between EBV obtained in the situations of weak and strong prior information were ≥ .98 for direct effect and ≥ .87 for maternal effects. However, the effect of prior information for breeds or groups poorly represented in the data, i.e. Zebu, was very important. By using the random regression approach, to discard records outside the usual age ranges of measurement can be avoided and higher accuracies are achieved (2.5% WWT and 2.9% YWT). However the overall rankings after adding this extra information remains nearly unchanged, correlations between them were ≥ .96(≥ .95) for direct effects (maternal effects). RR-s model requested three times more rounds to convergence (5.0e-13) than the MT model.

Key Words: Beef Cattle, Growth, Linear Splines

215 Growth and carcass characteristics of lot-fed Wagyu beef cattle and the estimation of homozygosity from band sharing patterns of random amplified polymorphic DNA markers. A. E. O. Malau-Aduli*[1], S. Inoue[2], T. Richards[2], A. Howard[2], and A. Thompson[2], [1]*University of Tasmania*, *Hobart, Tasmania, Australia*, [2]*Tasmania Feedlot Pty Ltd*, *Perth, TAS, Australia.*

The Wagyu breed of beef cattle is renowned for its ability to deposit high levels of intramuscular fat resulting in highly marbled beef that meets consumer demands in some niche export markets. We evaluated the post-weaning growth performance and carcass characteristics at slaughter of purebred Wagyu steers raised in the feedlot after an initial backgrounding on grass and silage. Our main aim was to study the average daily gains (ADG), body condition scores (BCS) and liveweight (LWT) changes from weaning to slaughter and to estimate homozygosity and inbreeding coefficients through band sharing patterns using random amplified polymorphic DNA (RAPD) markers. LWT, ADG and BCS were monitored monthly from 2005-2006. Genomic DNA was extracted from blood samples, amplified using RAPD primers, fragments resolved by gel electrophoresis and banding patterns elucidated under UV light. A linear increase in liveweight as age increased was observed and the typical fluctuation due to seasonal variations observed under grazing conditions was unnoticeable. Average LWT ranged from an initial 110kg to 660kg, ADG ranged from 0.7–2.0kg/day and BCS reached the maximum of 5 at the end of the experiment. Average LWT at slaughter was 574kg with a hot carcass weight of 329kg and a dressing percentage of 57%. Mean eye muscle area was 94cm2, eye muscle width 8cm and eye muscle length 16cm. Marbling score was 3, subcutaneous fat depth of 17cm and total trimmed fat weight was 34kg. Average saleable meat yield based on the 4 most valuable hind muscles were: Round (11.7kg), Topside (19.3kg), Rump (13.6kg) and Silverside (15.8kg). Average band sharing frequencies ranged from 0.60 to 0.96 with estimated inbreeding coefficients ranging from 0.5% to 7%, respectively. It was concluded that the inbreeding level was low, negligible and not in any way detrimental to meat yield and carcass quality destined for the Japanese market. Finally, RAPD markers were not versatile enough to

clearly differentiate between the fastest and slowest growing animals within the Wagyu breed.

Key Words: RAPD Markers, Wagyu, Carcass Traits

216 Examination of residual feed intake with post-weaning growth and carcass traits in central test bulls. G. S. Hecht* and L. A. Kriese-Anderson, *Auburn University*, *Auburn, AL*.

Since 1978, individual feed intake has been measured on bulls (n = 2,180) consigned to the Auburn University Bull Test along with weights, heights, scrotal circumference and ultrasound carcass traits. Test length since 1977 was reduced from 140 d to 112 d to 84 d. Eight breeds were used in MTDFREML analyses to estimate heritabilities of and genetic correlations between residual feed intake (RFI) and average daily gain (ADG), scrotal circumference (SC), 12th rib fat thickness (FT), *longissimus dorsi* area (REA) and percent intramuscular fat (IMF). Breeds included were Angus (n = 857), Brangus (n = 41), Charolais (n = 380), Gelbvieh (n = 103), Hereford (n = 192), Limousin (n = 106), Santa Gertrudis (n = 106) and Simmental (n = 395). Traits were analyzed using three trait analyses and a sire-maternal grandsire model with either age or weight as covariates. Fixed effects included length of test, breed and year. Covariance estimates were averaged across analyses. Estimates of genetic correlations between RFI and ADG, SC, FT, REA, IMF and FE were 0.00, -0.03, -0.03, -0.44, 0.62, and 0.51, respectively with age as covariate. Estimates of genetic correlations between RFI and ADG, SC, FT, REA, IMF and FE were 0.12, 0.19, -0.02, -0.70, 0.64, and 0.44, respectively with weight as covariate. Heritability and genetic correlation estimates of all traits were on the lower end of reported literature estimates. These results may be due to consignment of elite bulls to a central test station and suggest that selection of animals with a lower residual feed intake should not increase individual size and should improve feed efficiency.

Table 1. Means and Heritability Estimates of Traits Across Breeds

Covariate	RFI	ADG	SC	FT	REA	IMF	FE
Age	0.08	0.17	0.14	0.17	0.07	0.16	0.12
Weight	0.09	0.16	0.17	0.15	0.12	0.12	0.12
Means	1.04 kg/d	1.73 kg/d	36.32 cm	0.80 cm	100 sq cm	3.20 %	3.42 kg/d

217 Genotype by environment interactions estimated by using reaction norms in Brazilian Nellore cattle. E. A. Maricle*[1], J. C. Souza[2,3], L. O. Campos de Silva[3], A. Gondo[3], R. L. Weaber[1], and W. R. Lamberson[1], [1]*University of Missouri*, *Columbia*, [2]*Parana Federal Univeristy*, *Palotina, PR, Brazil*, [3]*Embrapa*, *Campo Grande, MS, Brazil*.

The influence of genotype by environment interactions (GxE) on animal performance complicates selection decisions. Reaction norms are a statistical technique used to characterize GxE. The objective of this study was to evaluate GxE by comparing reaction norms among Brazilian Nellore bulls. Dependent variables were birth, 205 d weaning, 365 d yearling, and 540 d weights. Weights were adjusted for known fixed effects based on Beef Improvement Federation Guidelines. Environments were defined as progeny groups with a common herd, birth year and season (wet or dry). For data to be included, the following criteria had to be met: all four weights had to be recorded on each progeny, a minimum of four progeny were present in each environment, progeny were present in five different environments, and each environment contained three bulls (n = 4,280 progeny, n = 57 bulls, and n = 161 environments). Reaction norms for each bull were calculated by regressing progeny means within an environment, weighted by number of progeny, on environment means (SAS PROC GLM). To create pseudoreplication, bulls with progeny in ten or more environments had separate regressions determined for each set of five environments. Regression coefficients were fitted to an ANOVA model including bull and environment. Regression coefficients differed among bulls for all traits ($P < 0.0001$). Proportion of variation accounted for by bull and environment, respectively, were for birth weight 0.05 and 0.58; for weaning weight 0.08 and 0.43; for yearling weight 0.08 and 0.49; and for 540 d weight 0.07 and 0.44. These results suggest that bulls differ in the consistency of their progeny's performance across environments. Estimates of genetic merit of regressions from reaction norms may be a useful selection tool for ranking bulls to be used across diverse environments.

Key Words: Beef Cattle, Genotype x Environment Interaction, Reaction Norm

218 Genetic parameter estimates for two measures of disposition. F. E. Creason* and R. L. Weaber, *University of Missouri*, *Columbia*.

Two measures of disposition were collected on Angus and Red Angus cross steers (n=315) with known pedigree from four sources during the initial weighing of steers on a feedlot trial. Steers were weighed and disposition scores recorded through two facilities on the same farm. Disposition was measured as pen score (PS; 1=gentle, 5=aggressive) and exit velocity (EV; m/sec). Exit velocity was measured using infrared electronic triggers to start and stop an electronic recording device to time a steer as it traveled a fixed distance upon exiting a squeeze chute. Exit velocities were recorded when animals were weighed on two consecutive days. The weights and EV were averaged to produce AVGWT and AVGEV. Pen scores were recorded during the feeding trial. At the start of the trial steers in each facility weighed 342.6 ± 25.3 kg and 305.4 ± 32.0 kg, EV averaged 2.50 ± 0.68 m/sec and 2.68 ± 0.99, while PS averaged 1.95 ± 0.70 and 1.86 ± 0.81 respectively. Previous work has shown that EV and PS are positively correlated. EV and PS are negatively correlated with weight gain during the 55d post-weaning growing period and with feedlot placement weights. Sire was included in these models as a random effect and found to be a significant source of variation suggesting a heritable component of disposition. The data described above was included in a sire genetic model to estimate (co)variance components and heritabilities for EV and PS. A two-trait model was fit that included contemporary group (source, collection location, GrowSAFE group) as a fixed effect. Linear and quadratic covariates for each trait included age (d) and AVGWT. A six generation sequential pedigree of 661 animals including 315 progeny and 26 sires was generated. Genetic parameters and expected progeny differences (EPD) were calculated using MTDFREML software. Estimates of heritability (standard error) for EV and PS were 0.35 (0.078) and 0.15 (0.058) with a genetic correlation of 0.28 (0.825). Average, min. and max. EPD for EV and PS were -0.02, -0.33, 0.27 and 0.01, -0.10, 0.10, respectively.

Key Words: Temperament, Heritability, Genetic Parameters

219 Segregation of polymorphisms at Calpain and Calpastatin in beef cattle grown in the tropics. J. H. Bosques-Méndez*[1], M. Pagan[1], and E. Casas[2], [1]*University of Puerto Rico*, *Mayagüez, Puerto Rico*, [2]*Roman L. Hruska USDA MARC*, *Clay Center, Nebraska*.

The distribution of single nucleotide polymorphisms (SNP) in two regions of Calpain (CAPN1-316 and CAPN1-530) and a SNP in Calpastatin (CAST) was determined in beef cattle grown in the tropics (n = 372). Genotypic and allelic frequencies were determined for each SNP in Senepol (n=60), Charolais (n=62), Angus (n=39), Charbray (n=43), Brahman (n=19), Zebu (n=17) and crossbred bulls (n=132). For CAPN1-316, genotypic frequencies were 0.05/AA, 0.63/AG and 0.32/GG with allele frequencies of 0.21/A and 0.79/G. The AA genotype was absent in Charbray, Charolais, Angus, Zebu and Brahman breeds. In Charolais and Senepol GG was greater than AG and the inverse was observed for Zebu, Brahman and Crossbred bulls. In Angus bulls, the AG and GG genotypes were evenly distributed. The A allele was more frequent in Charolais, Angus, Zebu and Brahman, whereas the G allele predominated in Charbray and crossbred animals. Genotypic frequencies for the SNP in CAPN1-530 region were 0.17/CC, 0.40/CT and 0.43/TT. Allelic frequencies were 0.39/C and 0.61/T. Animals of CT genotype were more frequent in Charolais, Senepol, Angus and crossbred, whereas TT was more common in Charbray, Zebu and Brahman bulls. Greater allelic frequencies for C were observed in Senepol and Brahman. The inverse was observed in the other breeds. For CAST, genotypic frequencies were 0.03/CC (n=10), 0.26/CT (n=79), and 0.71/TT (n=79), respectively. Global allele frequencies were 0.46/A and 0.54/C. The allelic frequency of C was greater in Charolais and Angus bulls. Animals having CC genotype were absent in Charolais, Angus and Brahman animals genotyped. The TT animals were more frequent in Charbray, Charolais, Senepol, Angus Brahman, Zebu and crossbred animals. The segregation of the polymorphisms in CAPN1 and CAST could be implicated in differences observed in economically important traits in beef cattle grown in tropical environments.

Key Words: CAPN1, CAST, SNP

220 Genetic analysis of rebreeding to produce a calf at three years of age in beef cows. J. M. Rumph*[1], D. D. Kress[1], K. C. Davis[1], D. C. Anderson[1,2], R. M. Enns[3], C. M. McAllister[1], and D. L. Boss[2], [1]*Montana State University*, *Bozeman*, [2]*Montana State University*, *Havre*, [3]*Colorado State University*, *Fort Collins*.

Rebreeding a first calf heifer to produce her second calf at 3 yr of age can be challenging for beef producers. Heifers generally require more recovery time following their first calf which may delay the onset of estrus to a point beyond the normal breeding season. In an effort to improve heifer rebreeding, data on beef cows at 2, 3, and 4 yr of age were analyzed to determine if rebreeding of first calf heifers is under any degree of genetic control. Records on 417 females born from 1976 – 1994 were analyzed to determine genetic parameters and the percentage of females in each breed group that produced a calf as a 3-yr-old after having their first calf as a 2-yr-old. Animals included in the analysis consisted of Hereford and Tarentaise purebred cows as well as F1, F2, and 3/4 blood females created from these two breeds. Young cows in this herd were not culled unless they were open for two consecutive years. To be included in the data set, cows were required to produce a calf as 4-yr-olds to avoid bias due to culling for reasons other than ability to breed back at 2 years of age. Overall, 72% of females were successful in breeding back to produce a calf at 3 yr of age. Individual groups were 73%, 79%, 64%, and 62% successful for purebreds, F1, F2, and 3/4 blood cows, respectively. To estimate the genetic parameters associated with this trait, data was analyzed using MTDFREML with breed type, heterosis percentage, and year of birth as fixed effects. Based on the observed trait, heritability was estimated to be 0.08. Converting the observed trait to the underlying scale produced a heritability for rebreeding of 0.14. Although this is a lowly heritable trait, there does appear to be a genetic component and selection against females who fail to rebreed should result in a positive genetic response.

Key Words: Genetic Parameters, Reproduction, Beef Cattle

221 Evaluation of the relationship between scrotal circumference and ultrasound intramuscular fat measurements in Angus cattle. A. M. Arnett*, J. M. Bormann, M. E. Dikeman, and D. W. Moser, *Kansas State University*, *Manhattan*.

Recently, cattle breeders have questioned whether scrotal circumference has an impact on ultrasound predictions of intramuscular fat (IMF). The objective of this study was to investigate the relationship between ultrasound intramuscular fat (IMF), carcass marbling score (MS), and yearling scrotal circumference (SC) in Angus cattle. The American Angus Association provided pedigrees and expected progeny differences (EPD) for 290 Angus sires. All sires in the dataset had an accuracy of at least 0.50 for IMF EPD and MS EPD. Accuracies ranged from 0.50 to 0.97 (mean 0.75) for IMF EPD, 0.50 to 0.89 (mean 0.62) for MS EPD, and 0.05 to 0.96 (mean 0.73) for SC EPD. Individual performance records from 332,162 progeny of these sires and their contemporaries were also provided. These data were age-adjusted to 365 d for growth and ultrasound traits, and to 480 d for carcass traits. Correlations of SC EPD with IMF EPD and MS EPD were not significant ($P > 0.10$). Correlations existed ($P < 0.05$) between SC EPD and birth weight EPD (0.12), weaning weight EPD (0.13), yearling weight EPD (0.14), yearling height EPD (0.25), mature height EPD (0.17) and ultrasound scan weight EPD (0.22). IMF EPD was regressed on Marbling score EPD alone and with SC EPD. Intramuscular fat EPD was highly significant ($P < 0.01$) in predicting MS EPD. Scrotal circumference EPD was also a significant ($P < 0.05$) predictor of MS EPD, but only explained an additional 1% of the variation. Linear and quadratic regressions of IMF on SC were estimated from the performance data. Regression coefficients for SC were small but significant (-0.086, linear and 0.001, quadratic; $P < 0.05$). Correlations of high-accuracy sire EPD indicate that selection for SC should not significantly influence carcass traits.

Key Words: Beef Cattle, Intramuscular Fat, Scrotal Circumference

222 Phenotypic relationships among measures of feed utilization, ADG, and ultrasonic measures. K. A. Gray*, G. B. Huntington, M. H. Poore, C. S. Whisnant, and J. P. Cassady, *North Carolina State University*, *Raleigh*.

The objective of this research is to estimate phenotypic relationships among measures of feed utilization and economically important traits in beef cattle. Data were available from 124 registered Angus bulls (262 ± 3.4 Kg BW, 266 ± 1.76 d of age) from the NC State University Historic Angus Herd which is maintained at the Upper Piedmont Research Station in Reidsville, NC. Bulls were blocked based on BW

and sire into groups of 12, adapted to a corn silage-based diet (140g CP, 1.73 Mcal NEm and 1.22 Mcal Neg per kg DM), and trained to use calen gates. Feed offered was recorded on a daily basis and used to calculate average daily feed intake. Bulls were weighed every 14 d and growth (ADG) was determined by linear regression of weight against time. Mean ADG and DMI were 1.52 ± .23 DM/day and 7.25 ± 1.12 kg. Three measures of feed utilization were calculated and compared. Feed to gain ratio (FGR) was calculated by taking the average DMI of each bull divided by ADG. Residual feed intake (RFI) was calculated using two different methods. Method 1 was based on the NRC equations (NRFI) and for method 2 phenotypic regression using ADG and DMI adjusted to a common 42 day mid weight (RRFI) was used. Partial correlations with sire nested within year, year, and pen as fixed effects were calculated. Correlations between NRFI with RRFI, FGR and ADG were 0.965, 0.794 and -0.217, respectfully. Correlations between RRFI with FGR and ADG were 0.819 and -0.005. There were no relationships found to be significant between feed utilization calculations and ultrasonic measurements of intramuscular fat, rib eye area, rump fat and rib fat. As expected NRFI and RRFI were highly correlated indicating that they are the same trait. Both NRFI and RRFI were highly correlated with FGR. It was concluded that FGR is a good predictor of RFI. Alternative methods of calculating RFI were found to be nearly identical and independent of ultrasonic measures of body composition.

223 Dry matter feed intakes for first lactation Holstein, Jersey and their reciprocal crosses in the Virginia Polytechnic Institute and State University crossbreeding project. K. M. Olson*, B. G. Cassell, and M. D. Hanigan, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

The crossbreeding project at Virginia Polytechnic Institute and State University began in the fall of 2002. Holstein and Jersey foundation females were mated to four Holstein bulls and four Jersey bulls to create JJ, HH, JH and HJ breed groups (sire breed listed first). Collection of individual feed intakes on first lactation project cows began in September 2005 and continues through 2007. Individual feed intakes are measured in two week trials during every six week period (two weeks on, four weeks off) on first lactation cows less than 305 days in milk. All cows were fed the herd total mixed ration before and during the trial. Forages, grains and concentrates were submitted for nutrient analyses at least once during each trial period. An 'as-fed' intake and dry matter intake were calculated daily for the project cows during the feed intake cycle and averaged across week of production. A mixed model using repeated records was used to analyze dry matter intakes. Effects included trial, breed group [(HH (n=25), HJ (n=17), JH (n=15), JJ (n=11)], age at calving, week in milk and breed by week in milk interaction. Significant effects ($P<0.05$) for dry matter intake included breed group and week in milk however, the interaction between week in milk and breed and differences between trials were not significant. LSM for dry matter intakes across all weeks were 22.2 ± 0.3, 21.2 ± 0.3, 20.8 ± 0.4, and 17.5 ± 0.4 kg for HH, HJ, JH and JJ respectively. In general, dry matter intake reached a plateau at 13 weeks. All breed groups were significantly different from one another except the HJ and JH. Visual inspection of breed group means by week in milk suggests a positive heterosis for dry matter intake (untested).

Key Words: Crossbreeding, Dry Matter Intake, Feed Intake

224 Comparison of Holstein–Friesian, Norwegian Red and Holstein–Friesian×Norwegian Red cows on Irish dairy farms: Milk production and udder health. N. Begley*[1,2], M. Rath[2], and F. Buckley[1], [1]*Teagasc*, *Moorepark, Fermoy, Co. Cork, Ireland*, [2]*School of Life Sciences*, *UCD, Belfield, Dublin, Ireland*.

The objective of this study was to compare the milk production performance and udder health of Holstein–Friesian (HF), Norwegian Red (NRF) and Holstein–Friesian×Norwegian Red (F1) cows in first lactation. This study forms part of a 3–year on–farm crossbreeding study comprising 46 dairy herds. Milk production data was available for 1327 first lactation cows: 710 HF, 325 NRF and 292 F1. Predicted 305 d yields were obtained from the Irish Cattle Breeding Federation. These were derived using the SLAC method which adjusts for calving month, age at calving, parity and season of calving. Production data were analyzed in SAS using proc GLM and udder health data were analyzed using proc LOGISTIC. Herd, breed and calving date (udder health only) were included in the model. The 305 d milk yields of the HF and F1 were similar at 5,353 kg and 5345 kg, respectively. The NRF produced slightly less milk at 5149 kg ($P<0.001$). Fat content was highest for the HF at 4.00%, intermediate for the F1 at 3.96%, and lowest for the NRF at 3.94% ($P<0.05$). Protein content was similar for all breeds; 3.46%, 3.45% and 3.45% for the HF, NRF and F1, respectively. The NRF and F1 showed superior udder health during lactation. Compared to the HF (2.04), the F1 and NRF cows had lower somatic cell score at 1.97 ($P<0.01$) and 1.92 ($P<0.001$), respectively. The proportion of NRF cows (5.8%) with somatic cell counts averaging greater than 400,000 during lactation was lower than the HF (9.9%; $P<0.05$). That of the F1 (6.7%) tended to be lower ($P=0.097$) than the HF. The incidence of mastitis was available for 42 of the 46 herds. Fourteen percent of the HF cows had mastitis at least once during lactation, compared to 9.5% for both the F1 ($P=0.063$) and the NRF ($P<0.05$). In conclusion, based on data from year one, the F1 cows produced similar levels of milk production to the HF. Both the NRF and F1 exhibited superior udder health compared to the HF.

Key Words: Norwegian Red, Udder Health, Milk Production

225 Heritability of electronically recorded daily body weight across lactation using random regression models. J. K. Toshniwal*[1], C. D. Dechow[1], J. A. D. R. N. Appuhamy[2], and B. G. Cassell[2], [1]*The Pennsylvania State University*, *State College*, [2]*Virginia Polytechnic Institute and State University*, *Blacksburg*.

The objectives of this study were to estimate heritability for daily body weight (BW) and genetic correlations among BW at different days in milk (DIM). The Afiweigh cow body weighing system records BW of every cow exiting the milking parlor. The Afiweigh system was installed at the The Pennsylvania State University dairy herd in August of 2001 and in July of 2004 at the Virginia Polytechnic Institute and State University dairy herd. BW recorded after 365 DIM were

eliminated. Outliers were detected by generating a predicted BW curve for each cow and daily records more than four standard deviations from the curve were eliminated. The data included 202,143 observations from 575 The Pennsylvania State University and 120 Virginia Polytechnic Institute and State University Holstein cows, respectively. The random regression model in ASREML included fixed effects for age within parity, week of lactation and herd-date. Random effects included animal, permanent environment and error. The order of the polynomial was 4 for animal and 6 for permanent environment. Residual structures were grouped into the following months of lactation: 1, 2-3, 4-5, 6-8, and 9-12. Heritability estimates ranged from 0.48-0.56 and were highest between 200-230 days of lactation and lowest at 305 DIM. The genetic variance for BW declined for the first 30 DIM and climbed until the end of lactation. Genetic correlations between BW at different DIM ranged from 0.73 (DIM 0 and 100) to 1.0. The correlations among BW between early and later parts of lactation (0.83 between 0 and 305 DIM) were higher than correlations between early and mid lactation. Electronically recorded daily BW are heritable and they could be used for genetic evaluation of BW and BW change across the lactation.

Key Words: Body Weight, Heritability, Random Regression

226 Evaluation of factors affecting changes in the ranking of sires over time. A. D. Coburn*[1,2], K. A. Weigel[1], S. A. Schnell[2], and G. Abdel-Azim[2], [1]*Univeristy of Wisconsin*, *Madison*, [2]*Genex Cooperative, Inc.*, *Shawano, WI*.

Selection of sires for A.I. contract matings occurs primarily from the pool of active sires with initial progeny test results. Because high selection intensity is applied to small number of low reliability (REL) bulls, accuracy of sire evaluation significantly affects genetic progress in later generations. Our objective was to quantify mean change in rank of contract mating sires and their contemporary sires and to estimate how much of the change in rank can be attributed to redefinition of a trait or modification of the selection index. February 1999 active Holstein sires were used to determine contract mating sires and contemporary sires. Twenty-nine bulls were identified as influential mating sires with > 5 sons sampled in 2000 or later. Percentile rank of these sires was calculated annually through February 2006 for combined fat + protein (CFP), productive (PL), somatic cell score (SCS), udder composite (UDC) and Lifetime Net Merit (LNM). Mean change in rank of all active sires from 1999 to 2006 was zero for all traits. Mean absolute change in rank was 13-14% for CFP, SCS, and UDC and 20-22% for PL and LNM. The mean change in rank for contract mating sires was negative for all traits, as was mean absolute change of rank. Among subgroups based on REL of yield, bulls with high REL (>89%) tended to increase in rank for LNM, whereas bulls with intermediate (80-89%) or low (<80%) REL had negative mean change in rank with a negative skew. Multi-trait indices (MTI) were calculated weighting the aforementioned traits to mimic changes to the LNM formula in years 2000, 2003 and 2006. Mean absolute change in rank when using MTI for a given year was ≤ 8% for both sire groups. Although some change in rank can be attributed to changes in trait definition or revision of economic weights in the selection index, inaccuracy of sire evaluations for individual traits appears to contribute more significantly to the instability in rankings of A.I. contract mating sires.

Key Words: Dairy Cattle Breeding, AI Contract Mating Sires, Change in Rank

227 SNP identification in genes involved in the SREBP1 pathway in dairy cattle. J. F. Medrano* and G. Rincon, *University of California*, *Davis*.

The objective of this analysis is to identify natural sequence variations in candidate genes that determine the quantities, compositions and structures of the lipids of milk in dairy cows. We developed a strategy to detect SNPs in 6 genes in the SREBP1 pathway, which closely regulates the Stearoyl-CoA-Desaturase (SCD). The analysis consisted in re-sequencing 1000bp of the 5′UTR, coding regions and 500bp of the 3′UTR in Sterol regulatory element-binding protein-1 (SREBP1), SREBP cleavage-activating protein (SCAP), Insulin induced protein 1 (INSIG1), Insulin induced protein 2 (INSIG2, Membrane-bound transcription factor protease, site 1 (MBTPS1) and Membrane-bound transcription factor protease, site 2 (MBTPS2) genes. Vista alignments were used to identify highly conserved regions for re-sequencing. The target gene regions were resequenced in 24 animals from three dairy breeds: Holstein, Jersey and Brown Swiss. All the sampled animals were unrelated with no common ancestors in a three generation pedigree. Haploview software was used to identify linkage disequilibrium regions within the breeds and to determine tag SNPs. A total of 49 SNPs were detected and 32 were identified as tag SNPs. The number of SNPs per gene was: 7 in SREBP1, 11 in SCAP, 17 in INSIG1, 11 in INSIG2, 2 in MBTPS1 and 1 in MBTPS2. Eleven SNPs were located in exons, 7 were synonymous and 4 were non-synonymous. SIFT and Polyphen analysis were performed in the non-synonymous SNPs and two of the SNPs were classified as 'not tolerated', the first one is an amino acid change Pro/Ser in SCAP and the second one is an amino acid change Leu/Pro in the SREBP1 protein. From this analysis we have detected haplotype blocks that identify the diversity between breeds and we were able to select SNP markers that will be the basis for genotyping cows to define possible associations with milk fatty acid composition.

Key Words: SNP, Candidate Genes, Fatty Acids

228 First steps to model milk urea in a management perspective. C. Bastin*[1], A. Gillon[1], and N. Gengler[1,2], [1]*Gembloux Agricultural University*, *Gembloux, Belgium*, [2]*National Fund for Scientific Research*, *Brussels, Belgium*.

Several studies have shown that milk urea concentration is an interesting tool for herd management because of its strong links with nutritional imbalance in dietary protein. It could also be a predictor for functional traits like fertility or longevity. The objectives of this study were to estimate variance components and heritabilities for milk urea concentration during the three first lactations using a multi-lactation single-trait random regression test day model. Potentialities of predicting milk urea concentration were also studied in order to bring nutritional management tools to breeders by comparing predicted and observed productions. Available data were 3,593,575 milk urea test day concentrations from the Walloon Region of Belgium collected from 2001 to 2006. Seven herd-based random sub data sets were created and (co)variances estimation was done by REML. In order to increase usefulness of the model to predict urea for each potential test-day the classical herd - test date fixed effect was replaced by the sum of a fixed herd – year effect, a fixed herd – season effect and a random herd – test date effect as recently proposed for yield traits. Mean heritabilities estimates for milk urea were 0.21, 0.24 and 0.25 for first, second and third parity, respectively. Variances components indicated also that high variance (approximately 50% of total variance)

was associated with the random herd test-day effect. Correlations across lactations for this effect showed very high values close to 1. These results could indicate the influence of local events (e.g., diet related) covering all lactations. Results have also large implications on the predictability of successive urea records. Additional research is required to check if adapted (co)variance structures linking successive test-day records could improve predictability of urea.

Key Words: Milk Urea, Modeling, Genetic Parameters

229 Milk production, body condition score at breeding and reproductive efficiency of first lactation Holstein–Friesian, Jersey and Holstein–Friesian×Jersey cows under Irish grass–based production circumstances. R. Prendiville*[1,2], F. Buckley[1], N. Byrne[1], and M. Rath[2], [1]*Teagasc*, *Fermoy, Co. Cork., Ireland*, [2]*University College Dublin*, *Belfield, Dublin, Ireland*.

The objective of this study was to compare production, body condition score at breeding and reproductive performance of first lactation Holstein–Friesian (HF), Jersey (JE) and Jersey×Holstein–Friesian (JEX) cows across two seasonal grass–based milk production systems (low concentrate 750 kg or high concentrate 1,250 kg). The study included a total of 87 cows: 30 HF, 28 JE and 29 JEX. The mean calving date was February 19. Large differences in milk yield, fat content and protein content were observed (P<0.001). Milk yield ranged from 3836 kg for the JE to 4700 kg for the HF. The JEX produced 4294 kg. The JE had the highest milk fat content at 5.24%, compared to 3.95% for the HF and 4.67% for the JEX. Milk protein content was 3.42% for the HF, 3.71% for the JEX and 3.97% for the JE. Solids corrected milk yield (SCM) was similar for all breeds; 4387 kg, 4338 kg and 4509 kg for the HF, JE and JEX, respectively. BCS at breeding was 2.97, 3.04 and 3.13 for the HF, JE and JEX; significantly higher for the JEX compared to the HF and JE (P<0.05). Breeding started in late April and lasted 13 weeks. Mean submission rate in the first 3 weeks was 85%. Although not significantly different (due to data size), pregnancy rates observed did suggest differences in reproductive efficiency between the groups. The HF had the lowest reproductive performance (pregnancy rate to first service (PREG1) = 43%, incalf after 6 weeks breeding (PR42) = 57%, calving to conception interval (CCI) = 98 days, and number of services (NSERV) = 2.01). Comparable values for the JE and JEX were PREG1 = 64% and 65%, PR42 = 75 and 76%, CCI = 79 and 93 days, and NSERV = 1.57 and 1.55, respectively. In conclusion, first lactation results suggest that JE and JEX cows have a propensity to produce similar levels of SCM but have superior reproductive efficiency compared to the HF under Irish production circumstances.

Key Words: Milk Production, Reproductive Performance, Crossbreeding

230 Effect of service sire and cow sire on gestation length. H. D. Norman*, J. R. Wright, P. M. VanRaden, and J. B. Cole, *Agricultural Research Service, USDA*, *Beltsville, MD*.

Variance components for effect of service sire and cow sire on gestation length (GL) indicate that bull differences exist and provide an opportunity to change GL. Bull predicted transmitting abilities (PTA) for GL as either a service sire or cow sire were derived using data from >8 million calvings from 1999 through 2005. Model effects were calving year, calving herd-year, calving month, age-parity, calf birth code (gender and multiple-birth status), lactation length, milk yield, service sire, sire, and cow. All effects were fixed except service sire, sire, and cow. For bulls with ≥100 daughter records for GL, PTA were examined for all bulls (323 service sires and 397 sires with both heifer and cow records) and those in active artificial-insemination (AI) service (137 service sires and 67 sires). Standard deviations of service-sire PTA for all bulls were 1.43 d for heifer (parity 1) GL and 1.32 d for cow (parities 2 to 5) GL; corresponding standard deviations for sire PTA were 0.75 and 0.78 d. Among active-AI bulls, O-Bee Manfred Justice had the lowest PTA for daughter GL (–2.0 d) and an extremely low PTA for service-sire GL (–4.0 d); Silky Gibson had the highest PTA for daughter and service-sire GL (+2.3 d and +4.1 d, respectively). Correlation between heifer and cow service-sire PTA was 0.96 for all bulls and 0.97 for active-AI bulls; corresponding correlation for sire PTA was 0.83 for both all bulls and active-AI bulls. Correlation of sire with service-sire PTA for heifers was 0.63 for all bulls (192) and 0.49 for active-AI bulls (58); corresponding correlations for cows were 0.69 (2,441 bulls) and 0.70 (151 bulls). For bulls with ≥500 daughter records for GL, correlation of sire with service-sire PTA for cows was 0.74 for all bulls (588) and 0.69 for active-AI bulls (38). Although genetic information for GL would be useful for predicting expected calving date, substantially more research is needed to determine the potential consequences of selection for either shorter or longer GL.

Key Words: Gestation Length, Genetic Evaluation

231 Inbreeding and relationship related to genetic estimates of calf survival in one Holstein sire family. R. D. Shanks*, *University of Illinois*, *Urbana*.

Calf survival was genetically estimated by PJ Berger of Iowa State University for 271 descendants of Carlin-M Ivanhoe Bell (Bell). This included 226 sons and 45 grandsons. The purpose of this study was to evaluate the contributions of relationship to Bell, inbreeding of descendants, and inbreeding of their daughters on these estimates of survival. The model explained almost 36% of the variability in calf survival. Relationship to Bell was the most significant factor in the model ($p < 0.0001$). Genetic estimates of calf survival for sons averaged 0.0108 (standard error of 0.0004) and genetic estimates of calf survival of grandsons averaged 0.0018 (standard error of 0.0010). Genetic estimate of calf survival for Bell himself was 0.019. As expected, the genetic estimates of calf survival for descendants regressed back toward the mean of the population. Calf survival of sons was closer to estimate for Bell than that of the grandsons. Close relatives had greater resemblance for survival. The second significant factor ($p < 0.01$) was regression of genetic estimate of calf survival on inbreeding of descendants. Genetic estimate of calf survival increased 0.065 (standard error of 0.024) per one percent increase of inbreeding of descendants. Inbreeding of active AI descendants of Bell was not detrimental to the survival of their offspring. Although in this sample, the regression of genetic estimate of calf survival on daughter inbreeding was not significant ($p > 0.28$), the sign was negative, consistent with recommendation to minimize change in inbreeding in the female population. Genetic concept of resemblance between relatives is supported in this study. Consequences of inbreeding are shown to not always be detrimental. Inbreeding can be a useful genetic tool to improve calf survival.

Key Words: Genetic Estimates of Calf Survival, Inbreeding, Dairy Cattle

232 Real-time PCR quantification of reproductive hormone receptor gene expression in superovulated MOET donor cows. S. Wise*[1], M. A. Okomo-Adhiambo[1], D. Joos[1], W. Rauw[1], A. Rink[2], and L. Gomez-Raya[1], [1]*University of Nevada*, *Reno*, [2]*Animal Disease and Food Safety Laboratory*, *Reno, NV*.

Multiple ovulation and embryo transfer (MOET) facilitates production of offspring from cattle of high genetic merit world-wide. Twelve multiparous non-lactating donor cows were synchronized to estrous by intravaginal insertion of 1.38g progesterone (Eazi-Breed™ CIDR®), in addition to intramuscular injection of 1ml combination of progesterone (150mg/ml) and 17-β-estradiol (10mg/ml). Evening of day 5, 5ml FSH (Folltropin® 20mg/ml) was given intramuscular, then every 12 hrs (AM and PM) over the next 4 days. Morning and evening of day 8, corresponding to day 4 of FSH treatment, 10ml prostaglandin (Lutalyse® 5mg/ml) was given intramuscular. Morning of day 9, the last FSH shots were given and CIDR® devices removed. Cows were monitored for heat and bred thrice by AI, and embryos collected 7 days after breeding. Superovulation and embryo flushing protocol was performed twice for all cows, yielding average 0-30 embryos. Blood and serum samples for nucleic acid and hormone biochemical analysis, respectively, were taken throughout the experimental period. Quantitative real-time PCR (QRT-PCR) was used to profile expression of 5 reproductive hormone receptor genes (ESR1, FSHR, LHR, OXTR and PGR), using total RNA isolated from blood sampled over 84 hrs of FSH treatment (0h, 12h, 24h, 36h, 48h, 60h, 72h, 84h), from two cows that yielded the highest number of embryos (30 and 24, respectively) and from the cow that yielded none. All five genes were significantly over-expressed (expression ratio ≥2.0 and t-test p-value ≤0.05) in the best performing cows (#119 and #128) compared to the least performing cow (#134), in at least five of the eight experimental time-points. In cow #119 compared to #134, ESR1 was up-regulated 2- to 4-fold (0-48h) and by 10-fold at 84h, while FSHR, LHR, OXTR and PGR were significantly up-regulated at all time-points. Similar results were observed in cow #128 compared to #134, suggesting that expression of hormone receptor genes is vital to a donor cow's physiological response to reproductive hormone treatments administered for superovulation.

Key Words: MOET, Reproductive Hormone Receptor Genes, Quantitative real-time PCR

233 Poisson versus logit models for genetic analysis of mastitis in Norwegian cattle. A. I. Vázquez*[1], K. A. Weigel[1], D. Gianola[1], D. M. Bates[1], and B. Heringstad[2], [1]*University of Wisconsin*, *Madison*, [2]*Norwegian University of Life Science*, *Ås, Norway*.

Clinical mastitis incidence is typically coded as presence/absence during some period of exposure, and records are analyzed with linear or logit models. Since "presence" includes cows with multiple episodes, there is a loss of information when a count is treated as a binary response. Poisson (P) and logit (L) mixed models were fitted to clinical mastitis records on 36,178 first-lactation daughters of 245 Norwegian Red sires distributed over 5,286 herds. An R implementation (lme4 package) was modified to allow for correlations between random effects, such that pedigree information could be included. Since 26% of the cows had lactations shorter than 300 d, the log of days in milk (DIM) was included via the function log(λ*DIM)=fixed+herd+sire effects, were λ is the per-day Poisson parameter peculiar to a record. Predictive ability of models was assessed via a two-fold cross-validation using mean squared error (MSE) as end-point. On average, there were 0.295 cases of mastitis per cow; 77% of the cows did not have the disease, and only about 1% of the cows had 3 or more episodes during lactation. Between-sire variance estimates were 0.065 in P and 0.093 in L. The ratio between herd and sire variances was 4.6 and 3.7 for P and L models, respectively. The correlation between predicted random effects from the two models was 0.95 and 0.94 for sires and herds, respectively. Predictive MSE for all data was smaller for the Poisson model: 0.346 vs. 0.351. Within healthy animals, MSE was 0.053 (L) and 0.085 (P). For animals with 1 case, MSE values were 0.583 (L) and 0.499 (P). For animals with 2 cases, and 3 or more cases, the P model also had a better predictive performance. The cross-validation suggested a better overall performance of the Poisson model over the logit model, primarily due to improved predictive ability within diseased animals. The P model may be even better in situations in which the disease is more prevalent.

234 Effect of gut-loading time on nutrient content of adult feeder crickets. C. L. Dikeman*, S. D. Plesuk, D. L. Klimek, and L. G. Simmons, *Omaha's Henry Doorly Zoo*, *Omaha, NE*.

Insectivorous amphibians and reptiles in captivity are typically limited to diets consisting primarily of feeder crickets. Without supplementation, farmed feeder crickets lack proper nutrient profiles to sustain the health of preying animals. While gut-loading of crickets is common practice among herpetologists, management of gut-loading crickets is poorly defined. The objective of this experiment was to determine optimal gut-loading time to best improve the nutrient profiles of feeder crickets for amphibians and reptiles in captive environments. Farmed crickets (*Acheta domesticus*) were purchased from a vendor (The Bug Company, Ham Lake, MN) and fed a commercial high-calcium cricket diet (PMI, St. Louis, MO) for 24, 48, 72, or 168 h, in a replicated block design. Dry matter (DM) concentrations of crickets gut-loaded for 24, 48, or 72 h (31.7, 31.5, and 31.8%, respectively) were higher (P<0.05) compared with 168 h (30.1%). No differences were detected for organic matter (OM), crude protein (CP), acid-hydrolyzed fat (AHF), or crude fiber (CF) concentrations among gut-loading treatments. Calcium concentrations were higher (P<0.05) after crickets were gut-loaded for 24 h (1.39%) compared with 48, 72, or 168 h (0.42, 0.37, and 0.66%, respectively). Magnesium concentrations were higher (P<0.05) after gut-loading crickets for 24 or 168 h (0.20 and 0.18%, respectively), compared with 48 or 72 h (0.10 and 0.09%, respectively). Concentration of manganese in crickets was higher (P<0.05) after 24 h (59.5 ppm) compared with crickets gut-loaded for either 48 or 72 h (28.5 and 27.0 ppm, respectively). No differences were detected in concentrations of sulfur, phosphorus, potassium, sodium, iron, copper, or zinc. Overall, gut-loading crickets for 24 h appeared more effective in increasing mineral concentrations compared with other time treatments. Further research is needed to completely elucidate the most effective strategies to increase nutritive value of feeder crickets for captive amphibians and reptiles.

Key Words: Reptile, Amphibian, Minerals

235 Effect of supplement type on mineral content of feeder crickets and growth of leaf-tailed geckos. C. L. Dikeman*[1], S. Plesuk[1], A. Koraleski[1], A. DeVries[1], K. Bilof[2], D. Klimek[1], J. Krebs[1], and L. G. Simmons[1], [1]*Omaha's Henry Doorly Zoo*, *Omaha, NE*, [2]*University of Illinois*, *Urbana*.

Current methods of supplementation for feeder crickets to insectivorous reptiles in captivity include gut-loading and/or dusting with powders. Two experiments were conducted to address effects of supplement type on mineral content of feeder crickets and growth of captive geckos. In a replicated complete block design, farmed crickets were purchased (The Bug Company, Ham Lake, MN) and assigned to 1 of 4 dietary treatments including: fasted for 24 h (F), gut-loaded with Mazuri® high-calcium cricket diet (PMI, St. Louis, MO) for 24h (GL), gut-loaded plus dusted with Herptivite™ (RepCal Research Labs, Los Gatos, CA) (GLH) or gut-loaded plus dusted with MinerAll™ (Sticky Tongue Farms, Romoland, CA) (GLM). In Experiment 2, 6 newly hatched geckos (*Uroplatus sikorae*) were randomly assigned to GL, GLH, or GLM treatments. Geckos were fed ad lib, weights and lengths were measured weekly for 4 months. Concentrations of sulfur and iron were higher (P<0.05) in GLH crickets (0.72 %, 1,168 ppm, respectively) compared with other treatments. Calcium concentration was higher (P<0.05) in GLM crickets (6.37%) compared with other treatments (2.3, 2.4, and 2.9% for GLH, GL, and F, respectively). GL crickets had higher (P<0.05) concentrations of phosphorus (1.28%) compared with F (0.98%). Potassium was higher (P<0.05) in GLH (1.78%), GL (1.75%) and GLM (1.44%) compared with F (1.18%). Sodium concentrations were higher (P<0.05) in GLH and GL treatments. Manganese concentrations were higher (P<0.05) in both GLH (148.5 ppm) and GLM (128.5 ppm) compared with GL (49 ppm). No other differences were detected. Average weight of geckos fed GLH (2.5 g) was lower (P<0.05) than average weights of geckos fed GL or GLM (2.8 g). Mean percent gain ranged from 33 to 38.5% for GLH, and GL, respectively. All treatments supported weight gain; however, enough data are not available to conclusively demonstrate benefits of these treatments in this species.

Key Words: Gecko, Cricket, Mineral

236 Serum nutrient concentration comparisons between free-ranging and captive giraffe (*Giraffa camelopardalis*). D. A. Schmidt*[1,2], M. R. Ellersieck[3], and M. E. Griffin[4], [1]*Lincoln Park Zoo*, *Chicago, IL*, [2]*Zoological Society of San Diego*, *San Diego, CA*, [3]*University of Missouri*, *Columbia*, [4]*Purina Mills, LLC*, *Saint Louis, MO*.

Serum concentrations of amino acids, fatty acids, lipoproteins, vitamins A and E, and minerals in captive giraffe were compared to values obtained from free-ranging giraffe in an effort to identify potential nutrient problems in the captive population. Captive giraffe have a specific set of maladies, including peracute mortality, energy malnutrition, pancreatic disease, urolithiasis, hoof disease, and severe intestinal parasitism, which may be related to basic nutritional inadequacies. Dietary requirements for giraffe are not known; invasive studies used with domestic animals can not be performed on zoo animals. Though domestic animal standards are often used to evaluate nutritional health of exotic animals, they may not be the most appropriate standard to use. Twenty serum samples from captive giraffe at 10 zoological institutions in the United States were compared to previously collected samples from 24 free-ranging giraffe in South Africa. Thirteen of the captive animal samples were collected from animals trained for blood collection. Seven were banked samples obtained from previous serum collections while animals were under anesthesia. Dietary information was also collected on each captive giraffe. Most captive giraffe diets consisted of alfalfa-based pellets and alfalfa hay. Differences between captive and free-ranging giraffe, males and females, and adults and sub-adults were analyzed using a $2 \times 2 \times 2$ factorial and Fisher's LSD for mean separation. Of the 84 parameters measured, 54 (60%) were different ($P \leq 0.05$) between captive and free-ranging giraffe. Nine (11%) items were different ($P \leq 0.05$) between adult and sub-adult animals. Only one parameter, sodium concentration, was found to be different ($P \leq 0.05$) between genders. Diets for captive giraffe need further investigation to address the differences seen in this study and the potentially related health problems.

Key Words: Giraffe, Nutrition

237 Nutrient digestibility and fecal characteristics of exotic felids fed a beef-based raw diet. B. M. Vester*[1], S. L. Burke[2], C. L. Dikeman[2], L. G. Simmons[2], and K. S. Swanson[1], [1]*University of Illinois*, *Urbana*, [2]*Henry Doorly Zoo*, *Omaha, NE*.

Nutrient digestibility has been well studied and characterized in many of our domestic species; however, little has been done to evaluate digestibility in exotic felids. Large exotic felid species in captivity are often fed diets extrapolated from the requirements of the domestic cat. Furthermore, little research has been published determining the nutrient content of diets fed to these animals. The objective of this experiment was to evaluate differences in nutrient digestibility and fecal characteristics in five species of large exotic captive felid species at the Henry Doorly Zoo. The five species evaluated included Bobcats (n=2), Jaguars (n=4), Cheetahs (n=5), Indochinese Tigers (n=4), and Siberian Tigers (n=5). All animals were individually housed and adapted to beef-based raw diet (Nebraska Brand® Special Beef Feline) for 16 d. Total fecal collections were conducted on d 17 through 20. Fecal samples were weighed and scored upon collection. Scores were determined on a 5 point scale (1= hard, dry pellets; 2, dry, well formed stools; 3, soft, moist, formed stool; 4, soft, unformed stool; 5, watery, liquid that can be poured). Diet and fecal samples were evaluated for dry matter, organic matter, protein, fat, and energy to determine digestibility. A fresh fecal sample was collected to determine fecal pH. Fecal scores were greater (P<0.01) in Indochinese Tigers when compared to all other species, and Cheetahs had greater (P<0.01) fecal scores than Jaguars and Bobcats. Dry matter, organic matter, and protein digestibility were not different among species. Fat digestibility was greater (P<0.01) in Siberian Tigers, Indochinese Tigers, and Bobcats (0.96) compared to Cheetahs and Jaguars (0.94). Digestible energy tended to be lower (P<0.10) in Jaguars and Cheetahs (0.92) compared to Bobcats and Indochinese Tigers (0.93). Fecal pH was greater (P<0.01) in Bobcats (ph=8) compared to all other species evaluated (ph=6). Overall, the beef-based raw diet was highly digestible in all species. However, differences in fat and digestible energy, suggests that further work should be completed to elucidate the differences between these species.

Key Words: Digestibility, Exotic Felid

238 Influence of dietary protein content and source on digestibility patterns and fecal osmolality in dogs differing in body size. J. Nery*[1], C. Tournier[2], V. Biourge[2], H. Dumon[1], and P. Nguyen[1], [1]*École Nationale Vétérinaire de Nantes*, *Nantes, France*, [2]*Royal Canin*, *Aimargues, France*.

Large breed dogs have frequently poorer fecal quality than smaller ones when given the same diet. Previous work indicated that this difference would be due, at least in part, to differences in fermentation and a higher osmolality in the hindgut chyme of large dogs. As we hypothesized that diet formulation could alter these differences, the aim of this study was to assess the effect of protein source and level on digestibility, fecal quality and osmolality in dogs differing in body size. 24 female dogs (2.75 to 32.10 kg BW) were used. Two diets were tested in a cross-over design. The main protein source of diet A was poultry and poultry by-products (ME=15.7 MJ/kg, CP=35.2%, fat=16.0%, TDF=7.7%, Na=3.45 and K=5.17mg/g DM) and the one of diet B was wheat gluten (ME=16.2 MJ/kg, CP=19.9%, fat=18.0%, TDF=9.0%, Na=3.85 and K=8.67mg/g DM). Fecal scores and DM, energy, fat, CP, ash, Na and K apparent digestibility coefficient (ADC) were determined. Fresh stools were analyzed for fecal osmolality. Data was statistically analyzed using ANOVA. Fecal score and moisture were higher in dogs fed on diet A and larger dogs had softer stools than smaller ones. ADC of DM, energy, fat, CP and ash was consistently higher for diet B. Differences among dogs' size were found to be higher for DM ($p \leq 0.0001$), energy ($p \leq 0.001$), CP ($p \leq 0.001$) and ash ($p \leq 0.05$) considering diet B. ADC of Na did not vary with dogs' size nor with diet while ADC of K varied both with dogs' size ($p \leq 0.05$) and diet ($p \leq 0.0001$), being higher for diet B. Osmolality was consistently higher for diet A ($p \leq 0.0001$) with differences also found between dogs' size ($p \leq 0.05$). This study showed that lower ADC of K and higher fecal osmolality would stimulate a lower water absorption in the hindgut promoting softer stools. A lower content and higher ADC of protein in the diet ameliorated fecal quality. Decreasing protein content in the diet and increasing its ADC would thus improve large dogs' feces quality.

Dairy Foods: Cheese I

239 Chemical changes that predispose smoked cheddar cheese to calcium lactate crystallization. P. Rajbhandari*, J. Patel, E. Valentine, and P. S. Kindstedt, *University of Vermont*, *Burlington*.

We have observed a high incidence of calcium lactate surface crystals on naturally smoked Cheddar cheese in the retail marketplace. The objective of this study was to identify chemical changes that may occur during natural smoking which render Cheddar cheese more susceptible to calcium lactate crystal formation. Nine random weight (ca. 300 g) retail-packaged samples of smoked Cheddar cheese were obtained from a commercial manufacturer immediately after the samples were smoked for ca. 6 h at ca. 20°C in a commercial smokehouse. Three similarly sized samples that originated from the same 22-kg block of cheese and that were not smoked were also obtained. Within 2 d after smoking (0 wk), 3 smoked and 3 non-smoked samples were sectioned into 5 sub-samples at different depths representing 0-2, 2-4, 4-6, 6-8, and 8-10 mm from the cheese surface. Six additional smoked cheese samples were similarly sectioned at 4 wk and again at 10 wk of storage at 5°C. Sample sections were analyzed for moisture, pH, L(+) and D(-) lactate, and water soluble calcium. The effects of treatment (smoked, non-smoked), depth from cheese surface and their interactions were analyzed by ANOVA according to a repeated measures design with 2 within subjects variables. Smoked samples contained significantly lower moisture and lower pH, and higher lactate-in-moisture (LIM) and water-soluble calcium-in-moisture (WSCIM) than non-smoked samples at 0 wk. Smoked samples also contained significant gradients of moisture, pH, LIM and WSCIM, with lower moisture and pH, and higher LIM and WSCIM, occurring at the cheese surface. Gradients of moisture were still present in smoked samples at 4-and10 wk of storage. In contrast, the pH, LIM and WSC equilibrated and showed no gradients at 4 wk and10 wk. The results indicate that calcium and lactate in the serum phase of the cheese were elevated as a result of smoking, especially at the cheese surface immediately after smoking treatment, which presumably predisposed the smoked cheeses to increased susceptibility to calcium lactate surface crystallization.

Key Words: Cheddar Cheese, Calcium Lactate, Crystals

240 Nucleation and growth rates of calcium lactate crystals on smoked cheddar cheese. 1. Effect of storage temperature. J. Patel*, P. Rajbhandari, E. Valentine, and P. S. Kindstedt, *University of Vermont*, *Burlington*.

Previous studies have shown that storage temperature influences the formation of calcium lactate crystals on Cheddar cheese surfaces. However, the mechanisms by which crystallization is modulated by storage temperature are not completely understood. The objectives of this study were to evaluate the effect of storage temperature on: 1) the number of discrete visible crystals formed per unit of cheese surface area; 2) growth rate and shape of discrete crystals (as measured by radius, area and circularity); 3) percentage of total cheese surface area occupied by crystals. Three vacuum packaged random weight (ca. 300 g) retail samples of naturally smoked Cheddar cheese, produced from the same vat of cheese, were obtained from a retail source. The samples were cut parallel to the longitudinal axis at a depth of 10 mm from the 2 surfaces to give six 10-mm thick slabs, 4 of which were randomly assigned to 4 different storage temperatures: 1, 5, 10°C, and weekly cycling between 1 and 10°C. Samples were stored for 30 wk. Following the onset of visible surface crystals, digital photographs of surfaces were taken bi-weekly and evaluated by image analysis for number of discrete crystal regions and total surface area occupied by crystals. Also, specific discrete crystals were chosen and evaluated bi-weekly for radius, area and circularity. The entire experiment was conducted in duplicate. The effects of storage time and temperature on crystal number and total crystal area were evaluated by ANOVA according to a repeated measures design. Crystal number and total crystal area increased significantly during storage in a temperature-dependent manner as follows: 5°C<1°/10°C<10°C<1°C. However, storage temperature did not appear to have a major effect on the growth rates and shapes of the individual crystals that were chosen for analysis. The data indicated that storage temperature primarily affected the number of nucleation sites on the cheese surface that subsequently developed into discrete visible crystals.

Key Words: Cheddar Cheese, Calcium Lactate, Crystal

241 Nucleation and growth rates of calcium lactate crystals on smoked cheddar cheese. 2. Effect of packaging tightness. E. Valentine*, P. Rajbhandari, J. Patel, and P. S. Kindstedt, *University of Vermont*, *Burlington*.

Previous studies have shown that loose packaging favors the formation of calcium lactate crystals on the surface of Cheddar cheese. However, the mechanism by which crystallization is accelerated by loose packaging is not well understood. The objectives of this study were to evaluate the effect of packaging tightness on: 1) the number of discrete visible crystals formed per unit of cheese surface area; 2) growth rate and shape of discrete crystals (as measured by radius, area and circularity); 3) percentage of total cheese surface area occupied by crystals. Three vacuum packaged random weight (ca. 300 g) retail samples of naturally smoked Cheddar cheese, produced from the same vat of cheese, were obtained from a retail source. The samples were cut parallel to the longitudinal axis at a depth of 10 mm from the surface to give six 10-mm thick slabs, 3 of which were randomly assigned to 3 different levels of packaging tightness: 10 mbar (very tight), 70 mbar (slightly loose) and 960 mbar (very loose). Samples were stored at 1°C for 30 wk. Following the onset of visible surface crystals, digital photographs of the external smoked surfaces were taken bi-weekly and evaluated by image analysis for number of discrete crystal regions and total surface area occupied by crystals. Also, specific individual crystals were chosen and evaluated bi-weekly for radius, area and circularity. The entire experiment was conducted in duplicate. The effects of storage time and packaging tightness on crystal number and total crystal area were evaluated by ANOVA according to a repeated measures design. Loose packaging caused large, significant increases in the number of discrete crystals formed per unit of surface area and the total surface area occupied by crystals. However, packaging tightness did not appear to have a major effect on the growth rates or shapes of individual crystals that were chosen for analysis. The data indicate that loose packaging primarily increased the number of nucleation sites on the cheese surface that subsequently developed into discrete visible crystals.

Key Words: Cheddar Cheese, Calcium Lactate, Crystal

242 Nucleation and growth rates of calcium lactate crystals on smoked cheddar cheese. 3. Effect of cheese surface. J. Patel*, E. Valentine, P. Rajbhandari, and P. S. Kindstedt, *University of Vermont*, *Burlington*.

Previous studies have suggested that the surface characteristics of Cheddar cheese may affect the development of calcium lactate crystals. The surface of Cheddar cheese is altered considerably during natural smoking, which may contribute to the high incidence of crystallization observed in retail samples of smoked Cheddar. The objective of this study was to compare crystal nucleation and growth rates on the external surface (exposed to smoking) and a subsurface cut 10 mm below the external surface after smoking (not exposed to smoking) during storage under 4 different temperature conditions. Three vacuum packaged random weight (ca. 300g) retail samples of naturally smoked Cheddar cheese, produced from the same vat of cheese, were obtained from a retail source. The samples were cut parallel to the longitudinal axis at a depth of 10 mm from the 2 surfaces to give six 10-mm thick slabs, 4 of which were randomly assigned to 4 different storage temperatures: 1, 5, 10°C, and weekly cycling between 1 and 10°C. Samples were stored for 30 wk. Following the onset of visible surface crystals, digital photographs of the external surfaces and subsurfaces were taken bi-weekly and evaluated by image analysis for number of discrete crystal regions and total surface area occupied by crystals. Also, specific individual crystals were chosen and evaluated bi-weekly for radius, area and circularity. The entire experiment was conducted in duplicate. The effects of cheese surface, storage temperature and storage time on crystal number and total crystal area were evaluated by ANOVA according to a repeated measures design. The number of crystals and total surface area occupied by crystals were significantly higher at the external surface compared to the subsurface. Onset of visible crystals at the subsurface was delayed by ca. 20 wk compared to the external surface. However, the growth rates and shapes of the individual crystals selected did not appear to differ greatly. The data suggest that the surface of naturally smoked cheese is altered in a manner that favors nucleation site formation, increased crystal number and early onset.

Key Words: Cheddar Cheese, Calcium Lactate, Crystal

243 Influence of native pasture feeding time on conjugated linoleic acid content in Ragusano cheese. S. La Terra*[1], V. M. Marino[1], S. Carpino[1], M. Manenti[1], and G. Licitra[1,2], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*D.A.C.P.A., Catania University*, *Catania, Italy*.

Ragusano PDO is an aged pasta filata cheese. It is a farmstead traditional cheese with unique aroma characteristics correlated to the environmental conditions and traditional cheese making technology. In 1996, Ragusano cheese has been designated PDO from the European Economic Community. It has been reported that dairy cows fed native pasture produce milk and consequently cheese with higher CLA content then dairy cows fed total mixed ration including forages with similar lipid content. The most representative CLA isomer is the cis-9, trans-11, and it generally constitutes 80%-90% of total CLA. The objective of this study was to determine the effect of Hyblean native pasture diet on conjugated linoleic acid (CLA) isomers content into Ragusano cheese at different ripening stages. The identification of CLA isomers in cheese was performed by silver ion high performance liquid chromatography. As expected, no variation in CLA content and isomers was observed in cheese samples analyzed at 90-120-210 days of ripening (913,80-925,32-901,09 ng/mg fat). Confirming previous data, the results clearly showed a direct relationship between native pasture and fat level of CLA in milk and cheeses produced from grazing animals. We also found that concentration of the total CLA and the cis-9, trans-11 increased with grazing time. We detected a double CLA level in cheeses produced with milk from cows grazing longer time (1288,33 ng/mg fat with 6 hours grazing vs 2459,39 ng/mg fat with 12 hours grazing). The quality of pasture is very important for the CLA content in fact the highest value of CLA occurs in native pasture than cultivate pasture. The high level of isomers of CLA could also be considered as an additional indicator for the authenticity of raw milk cheese from cows fed native pasture (P.D.O. marker).

244 Novel approach for producing process cheese with reduced fat and reduced sodium content. L. E. Metzger and R. Kapoor*, *Midwest Dairy Foods Research Center*, *St. Paul, MN*.

The objective of the present study was to develop a novel commercially feasible approach for producing a process cheese with reduced fat and

reduced sodium content. The first objective of the present study was to develop a reduced fat reduced sodium Cheddar cheese (RFC) with modified manufacturing protocol to render a cheese that (after 1 wk of ripening) has a similar texture to full fat regular sodium Cheddar cheese. The second objective of the present study was to formulate a low-sodium-reduced-fat process cheese (LSRF) utilizing RFC and other ingredients so as to achieve a process cheese with a reduced fat and a reduced sodium content that has similar sensory and textural properties to commercial process cheeses. Results from the present project have indicated a successful production of LSRF. The final chemical properties of LSRF including its moisture, fat, sodium, and potassium were 50%, 10%, 280 mg/100g, and 1277 mg/100g respectively. Utilization of RFC as the cheese base facilitated in preventing LSRF from having a rubbery and crumbly texture typically associated with reduced fat process cheeses. One of the highlights of LSRF is the elimination of the bitter-metallic off-flavor that is typically found in reduced sodium products where potassium chloride is used as a salt substitute. Another highlight of LSRF is the enhanced cheese flavor notes that help in overcoming the typical bland flavor associated with low sodium and/or low fat cheeses. Along with RFC, that formed the major ingredient for LSRF, other ingredients such as tri-potassium citrate, maltodextrin, guar gum, and water provided LSRF with desirable texture. The ingredients that aided in enhancing the sensory properties of LSRF included a variety of cheese flavors, savory flavor-enhancer, potassium chloride based salt substitute, sugar, and lactic acid. The present approach was successful in producing a sliceable process cheese with a low sodium content (140 mg/serving) and up to 67 % reduced fat content without significantly affecting its sensory and textural properties.

245 Influence of starter bacteria and salt to moisture ratio on calcium lactate crystal formation. S. Agarwal*, J. R. Powers, S. Chen, B. G. Swanson, and S. Clark, *Washington State University*, *Pullman*.

Occurrence of L(+)-lactate crystals in hard cheeses continues to be an expense to the cheese industry. Salt tolerance of starter bacteria and salt to moisture ratio (S/M) in cheese dictates final pH of cheese, which can influence CLC formation. The research investigates the effects of (S/M) and starter bacteria on cheese pH and occurrence of CLC. A commercial starter was selected based on its sensitivity to S/M below and above 4.0 S/M. Cheddar cheese was made using either whole milk (3.25% protein, 3.85% fat, 4.74% lactose) or whole milk supplemented with ultrafiltered milk and cream (4.5% protein, 5.3% fat, 4.78% lactose). Calculated amounts of salt were added at milling (pH 5.40 ± 0.02) to obtain cheeses with low (3.5) and high (4.5) S/M. The cheeses were either vacuum packaged or gas flushed with CO2 and aged at 7.2oC for 3 months. Total and soluble calcium, lactic acid and pH were measured and CLC were observed in all cheeses for 3 months. Low and high salt concentrated milk cheeses (LSCMC and HSCMC), had 36% higher total calcium (1219 mg/100g and 1257 mg/100g cheese, respectively), than low and high salt whole milk cheeses (LSWMC and HSWMC; 908 mg/100g and 917 mg/100g of cheese, respectively). Soluble calcium was 29% higher in LSWMC and LSCMC (438 mg/100g and 454 mg/100g cheese, respectively) compared to HSWMC and HSCMC (339 mg/100g and 354 mg/100g cheese, respectively). Concentration of lactic acid in high salt cheeses ranged from 0.70 to 0.74%, while that in low salt cheeses ranged from 1.86 to 1.97% at the end of 3 months. CLC were observed in all low salt cheeses but highest intensity of CLC were observed in cheeses made with milk with high protein concentration and gas flushed packaging. These results confirm that occurrence of CLC formation is dependent on cheese milk concentration and cheese pH, which can be influenced not only by S/M but also by cheese microflora.

Key Words: Calcium Lactate Crystals, Starter Bacteria, Cheddar Cheese

246 Utilization of plant proteinase from Jack fruit *(Artocarpus integrifolis)* to accelerate the ripening of RAS cheese slurry as a functional food. E. E. El Tanboly* and M. A. El Hofi, *National Research Center*, *Dokki, Cairo, Egypt*.

The aim of the present work was to search for a novel plant proteinase enzyme from Jack fruit *(Artocarpus integrifolis)* as a source of protolytic enzymes to accelerate the ripening of Ras cheese slurry as a functional food. Plant proteinase would be natural products, which can be easily extracted at relatively low cost and no legal barriers. This enzyme was subjected to a purification scheme composed of ammonium sulfate fractionation followed by gel filtration on G-100 Sephadex column and purified proteinase properties was studied such as optimum incubation temperature and optimum incubation time, energy of activation, optimum pH, Thermal and pH stability, Michaelis-constant of (Km) values and Effect of metal ions and chemical reagents on enzyme. Crud extracted proeinase was used to accelerate ripening of Ras cheese slurry with concentration of 1 and 2 ml/100 g curd. Slurries were incubated at 37°C for 7 days. The results indicated that the ripening indices of slurries (SN/TN, tyrosin and tryptiphane) gradually increased as rate of enzyme increased and as ripening period progressed. Also, flavour of all slurries gradually improved during incubation period. At the end of incubation period slurry with 2 ml/100g curd had a high flavour scoring.

Egg and Meat Science and Muscle Biology - Livestock and Poultry: Meat Marination

247 Impact of functional ingredients on food safety. S. R. McKee*[1], C. Z. Alvarado[2], and J. W. Bowers[1], [1]*Auburn University*, *Auburn*, [2]*Texas Tech University*, *Lubbock*.

The most commonly used poultry marinades include salt and sodium tripolyphosphates which have been shown to increase meat yield, as well as improve color, water holding capacity, and texture. Recently, several poultry further processing facilities have begun using more acidic (pH ~ 4) type marinades such as sodium lactate (SL), sodium citrate (SC), and sodium diacetate (SD) (alone or in combination) to combat the growth of Listeria monocytogenes in further processed loaves. Since these acidic marinades currently used in turkey further processing have a low pH (~ 4) compared to the previously used salt and sodium tripolyphosphates (~ pH 9), these marinades may alter meat quality attributes. Current research suggest that sodium diacetate can inhibit the growth of LM during refrigerated storage, but the inclusion of this ingredient may alter the product's cohesiveness and

moisture retention. Meat quality traits and microbial analyses from inclusion of LM inhibitors alone and in combination in the formulation of turkey deli loaves and beef franks will be presented.

Key Words: Functional Ingredients in Further Processing, Listera Growth Inhibitors, Food Safety

248 Impact of marination and deboning time on poultry meat tenderness. C. M. Owens*, *University of Arkansas*, *Fayetteville*.

Marination is an increasing popular trend in the meat industry for meat quality enhancement. Sodium chloride or salt, an important component of the meat marinade solution, helps solubilize proteins to increase water-holding capacity, improves tenderness, and enhances flavor. However, there are concerns of increased sodium intake in consumer diets. Studies were conducted to determine the effectiveness of marination and level of salt concentration to improve tenderness and enhance juiciness and flavor of broiler breast fillets. In these studies, fillets were deboned at various times postmortem ranging from 0.25h to 24h postmortem and marinated with varying levels of salt (0 to 1.25%) salt (NaCl) and 0.45% phosphate in a 15% marinade solution. Cooked fillets were subjected to instrumental analyses including the MORS test for assessing tenderness as well as sensory analysis using hedonic and Just About Right scales to assess tenderness, juiciness, saltiness and flavor. All marinated treatments were significantly more tender than non-marinated controls. Using instrumental tenderness analysis, salt concentrations above 1.0% were more tender than other treatments; however, all marinated treatments were significantly more tender than non-marinated controls. Using the hedonic scale, there was no significant difference in marinated products (0.5% to 1.25% salt) for overall impression, flavor, and texture. However, fillets with the higher concentrations of salt (1% and 1.25%) resulted in high percentages of consumers who considered the product too salty. For juiciness and tenderness, a large percentage (>70%) of the consumers considered 0.5%, 0.75%, and 1% treatments to be just about right. The results indicate that marination of pre-rigor deboned meat is effective in producing product similar to marinated post-rigor deboned meat. While meat marinated with higher concentrations of salt may give more desirable levels of tenderness, there is a greater chance of a negative impact on flavor and saltiness in the end product. Furthermore, it is possible to marinate with lower concentrations of salt while still improving meat characteristics and keeping ingredient costs low.

Key Words: Marination, Salt, Tenderness

249 Characterizing the safety and quality of fresh beef cuts subjected to deep muscle marination. M. M. Brashears*, J. C. Brooks, and M. F. Miller, *Texas Tech University*, *Lubbock*.

In May 2005, USDA-FSIS published notice that establishments who produce non-intact beef products must reassess their HACCP plans because outbreaks indicate that *Escherichia coli* O157:H7 is a hazard reasonably likely to occur in these products. USDA-FSIS suggested that processors might also consider applying an allowed antimicrobial agent to the surface of the product prior to processing or tenderization. Research has shown that lactic acid bacteria (LAB) and acidified sodium chlorite (ASC) are effective at reducing pathogens in ground beef. Lactic acid spray (LAS) has also been shown to reduce pathogens when applied to beef trim. Information on the use of these interventions and their effect on the palatability of whole muscle beef products intended for enhancement is limited. Therefore, the objectives of this research were to validate the effectiveness of LAB, ASC, and LAS in reducing *Escherichia coli* O157:H7 and *Salmonella* spp in multi-needle injected and marinated beef strip loins, and to determine their effect on meat palatability. Boneless beef strip loins were transported to Texas Tech University and inoculated with a cocktail mixture of streptomycin-resistant *Escherichia coli* O157:H7. Loins were inoculated at a 10^4 level (high) to determine actual log reductions and a 10^1 level (low) to mimic potential industry levels. One-half of the low and high level inoculated samples were treated with lactic acid bacteria (1×10^9 cfu/g meat), acidified sodium chlorite (1000 ppm) or lactic acid (3%). Control and inoculated loins were vacuum packaged and stored at 2 to 4 °C in the dark for 14 and 21 d. Following the aging period, the remaining low and high level inoculated subprimals were treated with LAB, ASC or LAS. All subprimals were then injected with a brine solution formulated to provide 0.3% sodium chloride, 0.35% phosphate and 0.05% rosemary extract in the final product at a 10% injection level. Additional loins were transported to a separate facility and subjected to the same treatments, storage and enhancement prior to trained sensory panel assessment of flavor, flavor intensity, juiciness and tenderness.

Key Words: Marinate, Beef, Safety

Food Safety - Livestock and Poultry: Cattle and Swine

250 Beef traceability using a dual system based on electronic identification and molecular markers from farm to retailer. J. J. Ghirardi, G. Caja*, M. Hernández-Jover, N. Jiménez, and A. Sánchez, *Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

A total of 3,657 crossbreed calves on 14 farms in Barcelona and Lleida (Spain) were used to evaluate the efficiency of a dual traceability system based on electronic identification (e-ID), by radiofrequency boluses containing low-frequency (LF; 134.2 kHz) half-duplex 32 mm transponders (Rumitag, Barcelona, Spain), and genetic fingerprinting (DNA) by analyzing specific sets of bovine microsatellites (n = 12) from frozen biopsies. The e-ID of calves was done during the milk-feeding period using either B1 (75 g; 21 × 68 mm; n = 3,057) or B2 (73 g; 18 × 77 mm; n = 600) boluses. High-frequency (HF; 13.56 MHz) read-write inlay transponder (45 × 76 mm; Tiris, Almelo, Holland) were used for transferring e-ID to the carcasses. All animals had official ear tags (OE) made of polyurethane (2 flaps; 10.1 g; Azasa-Allflex, Madrid, Spain). Ear biopsies were taken using biopsying ear tags: E1 (n = 2,562; Biopsytec, Rheinbach, Germany) and E2 (n = 1,095; TypiFix, IDnostic, Switzerland). Calves were intensively fed and slaughtered before 1 yr of age. Blank read-write HF labels were attached to the calf shank before hide removal. Bolus LF code was transferred to the carcass by automatic reading of LF boluses and recording of HF shank labels. Carcass samples (n = 900) were taken using biopsy tubes (n = 357; Biopsytec) or plastic sticks (n = 543; Identigen, Dublin, Irland). Additionally, E2 sticks were used to sample 30 meat cuts randomly taken in nine butcheries. On-farm traceability

for B1 (99.8%) and B2 (100%) was greater than for all ear tags (OE, 96.4%; E1, 8.4%; and, E2, 99.1%). On-line readings failed in 37% of cases at the start of the experiment, suggesting the need for modifications of the equipment to adapt to the abattoir conditions. Automatic reading and label recording in the rest of the animals (n = 2,058) was 98.6% successful. When tracing back carcasses to calves in 176 random samples, five pairs (2.8%) did not match, showing 97.2% calf traceability. Retailer matching was 100%. In conclusion, the e-ID and DNA tracing system showed > 97% traceability efficiency. Improvement in label design and reading equipment is needed in practice.

Key Words: Traceability, Transponder, Microsatellites

251 Siderophore receptor/porin protein (SRP®) vaccine used as pre-harvest control of *E. coli* O157:H7 in feedlot cattle. A. B. Thornton*[1], D. U. Thomson[1], K. F. Lechtenberg[2], G. H. Loneragan[3], and T. G. Nagaraja[1], [1]*Kansas State University*, *Manhattan*, [2]*Midwest Veterinary Services*, *Oakland, Nebraska*, [3]*West Texas A&M University*, *Canyon*.

Yearling steers and heifers (n = 1,252) were used to examine effects of Siderophore receptor/porin protein (SRP) *E. coli* O157:H7 vaccine on fecal prevalence of *E. coli* O157:H7 and feedlot performance. Cattle were randomly assigned to one of two treatments: 1) SRP *E. coli* O157:H7 vaccination or 2) placebo control. Randomization was conducted by alternately assigning five cattle to a treatment until cattle within purchase group were assigned (two treatments; 10 replications; 20 pens). Cattle were fed a typical High Plains diet (74.5% DM; 58 % corn, 30 % corn gluten feed, 6.5% alfalfa hay, and supplement). Cattle were vaccinated with the assigned treatment on d-0 and d-21. Rectal fecal samples were collected on d-0. Pen floor samples were collected on d-21, d-35, and d-70. Simulated slaughter was performed on d-85 to evaluate prevalence of *E. coli* O157:H7 in rectal fecal samples, rectoanal mucosal swab samples, and hide swab samples. All samples were transported to the laboratory for *E. coli* O157:H7 isolation. Cattle were individually weighed on d-0, d-21, and d-85. Pen feed delivery was recorded daily and orts were removed and weighed. No vaccine by day interaction was observed. Cattle vaccinated with SRP had a reduced (P = .04) fecal shedding of *E. coli* O157 by 54% relative to those receiving placebo. Cattle vaccinated with SRP had a lower prevalence of *E. coli* O157:H7 in their feces (P = .01) and on their hides (P = .06) than those vaccinated with placebo at simulated slaughter. Vaccinating cattle with SRP *E. coli* O157:H7 had no effect (P > .05) on ADG or DMI. The *E. coli* O157:H7 SRP vaccine reduced prevalence of *E. coli* O157:H7 in feedlot cattle and could be used as a possible strategy to reduce the risk of foodborne illness associated with beef.

Key Words: Vaccine, *E. coli* O157:H7, Feedlot Cattle

252 Effects of distiller's grain on fecal prevalence and in vitro growth of *E. coli* O157. M. E. Jacob*, J. T. Fox, J. S. Drouillard, and T. G. Nagaraja, *Kansas State University*, *Manhattan*.

The objective was to determine effects of feeding distiller's grains (DG) on prevalence of *E. coli* O157 in feedlot cattle. Cattle (n = 379) were allocated to one of three treatments: steam-flaked corn (SFC) with 5% corn silage and 25% dried DG (DDG), SFC with 15% corn silage and 25% DDG, or SFC with 15% corn silage and no DDG. Cattle were fed in pens containing 14 to 16 animals, with 8 pens (replications) per treatment. From each pen, 10 pen-floor fecal samples were collected weekly for 12 wk and were cultured for *E. coli* O157. Cattle fed DDG with 5 or 15% corn silage had a higher (P < 0.05) prevalence of *E. coli* O157 than those fed no DDG. No differences (P > 0.05) in prevalence were observed between cattle fed DDG and either 5 or 15% corn silage. A second study was conducted to assess effects of DDG on growth of *E. coli* O157 in vitro (i.e., fermentations with ruminal or fecal microbial inoculum). Rumen fluid and feces were collected from two ruminally-cannulated steers fed high-grain diets containing 0 or 25% DDG. Fermentations (in duplicates) with 0, 0.5, 1, or 2 g of DDG (substrate) were repeated on 2 d. Each fermentation was inoculated with naladixic acid resistant (*Nal*^{R}) *E. coli* O157 and samples were removed at 0, 6, 12, and 24 h to determine concentrations of *Nal*^{R} *E. coli* O157. At 24 h, fecal fermentations with 2 g DDG had higher (P < 0.05) concentrations of *Nal*^{R} *E. coli* O157 than 0 , 0.5, or 1 g DDG. In fermentations with ruminal inoculum, the 24 h incubations with 0.5 g DDG had a higher (P < 0.05) concentration of *Nal*^{R} *E. coli* O157 than 0 , 1, or 2 g DDG. Fermentations with 0 g DDG had higher (P < 0.05) *Nal*^{R} *E. coli* O157 concentrations than 1 or 2 g DDG. The source of ruminal or fecal microbial inoculum (DDG or no DDG) had no effect on concentrations of *E. coli* O157. The results suggested inclusion of DDG in high-grain diets to have the potential to increase fecal shedding of *E. coli* O157.

Key Words: *E. coli* O157, Distiller's Grains, Cattle

253 Growth response of *Salmonella enterica* Typhimurium in co-culture with ruminal bacterium *Streptococcus bovis* is affected by time of inoculation and carbohydrate substrate. P. Herrera* and S. Ricke, *Center for Food Safety and Microbiology, IFSE, University of Arkansas*, *Fayetteville, AR*.

The purpose of this study was to characterize growth of *Salmonella enterica* Typhimurium (ST) in the presence of the ruminal bacteria *Streptococcus bovis* (SB) under different incubation conditions. The growth of SB and ST plateaued after 9 h when incubated independently at 37°C. When SB and ST were co-cultured, 15.8 ± .02% growth inhibition was observed for ST. When inoculation of ST in the co-culture was delayed, ST growth was inhibited by 41.5 ± .02% for ST inoculation at 6 h and by 27.8 ± .06 % for ST inoculation at 12 h. A decrease in the pH of SB culture media from 7.1 to 6.2 was observed at 6 h of growth. To determine the effects of alternate carbon substrates, sugars were added to the media (1 mL of 180 mg/mL w/v solution to 9 mL media). Glucose produced a marked decrease in pH of SB culture media (7.0 vs 4.9 over 6 h) whereas fructooligosaccharide (FOS) did not (6.8 vs 6.0 after 6 h) when compared to SB cultures in an unmodified media. Addition of glucose to the culture media resulted in a 2.5 fold increase in SB when compared with SB cultures grown in an unmodified media or media amended with FOS. Supplementing the media with either sugar enhanced growth of ST. Cultures of ST supplemented with glucose reached the upper limit of detection of our assay within 4 h. When both bacteria were inoculated simultaneously in media containing either sugar, no ST growth inhibition was observed. No growth inhibition of ST in glucose-supplemented media was seen when a 6 h elapsed between the initial SB inoculation and subsequent inoculation with ST. However in similar trials with FOS amended media, a 68.1 ± 0.01% inhibition in ST growth occurred. These findings

suggest that carbon substrate and time of inoculation influence ST growth in the presence of actively growing SB.

Key Words: *Salmonella*, *Streptococcus bovis*, Bacterial Growth

254 Effects of acid marinades on *Listeria monocytogenes*, shelf life, meat quality, and consumer acceptability of beef frankfurters. J. W. J. Bowers* and S. R. McKee, *Auburn University*, *Auburn, AL*.

Listeria monocytogenes (LM) is estimated to cause over 2,500 cases of illness and 500 deaths in the U.S. annually. To control LM, acid marinades are being used in formulation of ready-to-eat meat products as *Listeria* inhibitors. Sodium diacetate, sodium/potassium lactate and sodium citrate are approved inhibitors that can be used alone or in combination to prevent growth of LM, but their effects on product quality need to be determined. The objective was to determine effects of marinade ingredients including: No inhibitors (NI), sodium lactate at 2% (SL); potassium lactate at 2% (PL); sodium citrate at 0.75% (SC); sodium lactate at 2% with sodium diacetate at 0.25% (SLSD) on growth of LM in beef frankfurters stored at 4°C and 15°C. Beef frankfurters (60 per treatment) were inoculated (10^6 cfu/mL) with a streptomycin-resistant (1,500 µg/mL) strain of LM and were sampled once per week for LM growth. Additional beef frankfurters prepared with inhibitors (60 per treatment) were used for shelf life determination (up to 12 wk; stored at 4°C and 15°C) and for meat quality measurements. Shelf life was evaluated each week using a consumer sensory panel combined with microbial analyses. Objective meat quality parameters measured included pH, total moisture, and springiness. At 15°C, all treatments except SLSD reached spoilage. All treatments stored at 4°C resisted spoilage until wk 3; however, the SLSD destroyed product quality. Microbial analyses of inoculated beef frankfurters suggested that all products containing inhibitors delayed growth of LM when compared with the control (NI) until wk 3. Inoculated treatments stored at 15°C were uncountable at wk 3 due to overgrowth of molds. Overall, LM growth was delayed with inclusion of inhibitors but this benefit was not observed with higher storage temperatures (15°C). Additionally, sodium diacetate at 0.25% may decrease protein functionality and consumer acceptability of beef frankfurters, but it restricts growth of spoilage bacteria.

Key Words: *Listeria monocytogenes*, Acid Marinades, Beef Frankfurters

255 Implementation of a dual electronic identification and molecular markers system for tracing pigs. M. Hernández-Jover[1], G. Caja*[1], J. J. Ghirardi[1], J. Reixach[2], and A. Sánchez[1], [1]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*, [2]*Selección Batallé*, *Riudarenes, Girona, Spain*.

A total of 2,108 Duroc male piglets were used to validate a dual traceability system based on the use of electronic identification (e-ID) and on the use of DNA fingerprinting by analysis of a specific set of porcine microsatellites (n = 12). Piglets were identified (9 ± 3 d of age) using 32 mm half-duplex injectable transponders (Rumitag, Barcelona, Spain) injected intraperitoneally (IP). A single-shot injector with interchangeable needles (23 × 4.6 mm) was used. Needles were immersed in iodine solution before each injection, and injection area was disinfected by spraying an antibiotic. Piglets were also ear tagged and biopsied at the moment of IP injection, using two types of biopsying ear tags (E1 [n = 979; Biopsytec, Rheinbach, Germany] and E2 [n = 1,129; TypiFix, IDnostic, Switzerland]). Grow-fattening up to 120 kg BW (7 mo of age) was conducted under intensive conditions. Harvesting was done in a high throughput abattoir (500 pigs/h) and pig e-ID was automatically transferred to carcasses, using a high frequency inlay label (45 × 76 mm; Tiris, Almelo, Holland). Samples were taken from carcasses using biopsy tubes (Biopsytec) and stored frozen until DNA analysis. On-farm losses of IP transponders were 0.6%. Most of them (58.3%) occurred during wk 1 after injection. Ear tag losses were 0.7 and 0.4% for E1 and E2, respectively. On-farm traceability results were 99.3, 99.6, and 99.4% for E1, E2, and IP, respectively. Ear tag losses during harvesting (E1 [35.3%] and E2 [37.6%]) indicated their use for traceability is unsuitable. No losses of IP were reported during harvesting. Automatic transfer of e-ID to carcasses was 95.1% successful. Final pig traceability from birth to slaughter was 94.5% for IP transponders. A total of 100 pairs of samples (5%) were analyzed for DNA auditing. Results did not match in four pairs of samples, showing 96% traceability. In conclusion, the use of intraperitoneally injected transponders improved pig traceability. Nevertheless, automatic transfer of e-ID to carcasses needs to be improved in order to provide a more reliable technique for the swine industry.

Key Words: Traceability, Transponder, Fingerprinting

256 Split marketing: A risk factor for *Salmonella* in market pigs. M. H. Rostagno*[1], H. S. Hurd[2], and J. D. McKean[2], [1]*USDA, ARS, Livestock Behavior Research Unit*, *West Lafayette, IN*, [2]*Iowa State University*, *Ames*.

This study was designed to determine if split marketing affects *Salmonella* prevalence in market pigs. This was achieved by comparing *Salmonella* prevalence in the first group of pigs selected for slaughter (first pull) versus the last group of pigs selected for slaughter (close out) from typical commercial finishing barns containing approximately 1,000 animals. Nine paired observations were included in the study. Each paired sampling consisted in matched groups of pigs from the same barn as the first pull and the close out, with a 4-wk interval between groups. From each group, individual fecal (n = 45) and meat samples (n = 50) were collected, on-farm and at slaughter, respectively. In the laboratory, fecal samples were selectively enriched, and analyzed for the presence of *Salmonella* by a direct (antigen-capture) ELISA. Meat samples were kept frozen until processed, and then thawed, when the resulting liquid (meat juice) was collected and analyzed for the presence of antibodies against *Salmonella* by an indirect ELISA. All lots of finishing pigs studied were positive for *Salmonella*, based on sampling from both, first pull and close out. In seven of the nine lots studied (77.8%), an increase ($P < 0.05$) in *Salmonella* prevalence was observed based on both bacteriological and serological analysis. Overall, there was 9.3% increase ($P < 0.05$) in bacteriological prevalence and 25.1% increase ($P < 0.05$) in serological prevalence from first pull to close out market groups. The results showed that a significant increase of *Salmonella* prevalence to occur between the first and the last group of pigs from a finishing barn shipped to slaughter. Thus, split marketing affects prevalence of *Salmonella* in market pigs with close out market groups constituting a higher risk for *Salmonella* contamination of pork products.

Key Words: Swine, *Salmonella*, Food safety

257 Are there high and low *Salmonella* prevalence farms? M. H. Rostagno*[1], H. S. Hurd[2], and J. D. McKean[2], [1]*USDA, ARS, Livestock Behavior Research Unit*, *West Lafayette, IN*, [2]*Iowa State University*, *Ames*.

The objective of this study was to evaluate the stability of *Salmonella* prevalence in cohorts of finishing pig lots. Six finishing production sites were visited six times each. At each visit, 30 individual fecal samples were randomly collected directly from the rectum. At slaughter, 50 individual meat samples were randomly collected per lot. Fecal samples were selectively enriched, and analyzed for the presence of *Salmonella*. Meat samples were frozen, thawed, and the resulting liquid (meat juice) was analyzed for the presence of antibodies against *Salmonella*. All finishing production sites were positive for *Salmonella* in at least two fecal and four meat samplings. The overall *Salmonella* bacteriological prevalence was 12.9% (95% C.I. 8.0 to 17.8%), whereas the serological prevalence was 35.4% (95% C.I. 24.5 to 46.4%; $P < 0.05$). A wide variation in *Salmonella* prevalence (bacteriological and serological) of different finishing pig lots within individual production sites was found. The wide variation found did not allow the categorization of the sites (statistically) as high or low prevalence systems. Possible reasons for the variation found within production sites include: 1) occurrence of intermittent shedding and clusters, and 2) evolution and resolution of *Salmonella* infection epidemics. The results showed both, bacteriological and serological estimates of *Salmonella* prevalence in swine production systems to be inconsistent among cohorts over time. The results suggested that reporting high or low prevalence of *Salmonella* in swine farms is a matter of timing.

Key Words: Swine, *Salmonella*, Food safety

Forages and Pastures - Livestock and Poultry: Tropical Forages: Management and Environmental Issues Affecting Use Efficiency

258 Programming grazing, irrigation and fertilization cycles based on physiological and environmental data for tropical grasses. J. Rodriguez-Absi*[1] and E. Gutierrez-Ornelas[2], [1]*Raesa Mexico*, *Queretaro, Queretaro, Mexico*, [2]*Universidad Autonova de Nuevo Leon*, *Marin, Nuevo Leon, Mexico*.

An integrated system for intensive grazing management was developed using "Agroclimatic clocks" which are calculated from environmental data (mean, minimum and maximum monthly temperatures, and photoperiod) and physiological characteristics (upper and lower developmental temperature threshold for C-4 grasses). The system makes use of three types of "Clocks": a) Plant Development Clock (PDC) calculated from growing degree days b) Plant Growth Clock (PGC) calculated from optimum day and night temperatures for corn plant growth and c) Reference Evapotranspiration Clock (RETC). Actual field growing studies show that a specific corn variety required, depending on the planting date, from 55 to 120 calendar days to reach the kernel milk stage (silage making stage); however, when using the PDC the angular thermal time required for the plant to reach the same stage was 74°C regardless of planting date (angular thermal time is directly proportional to degree days). However PGC, is closely related with the quality of the daily heat received by the plant, (i.e. number of optimal growth days which occur during the plant cycle), that explains why yields are 1.3 to 1.4 times higher for the fall/winter than for the spring/summer growing seasons. Planting date for maximum yield can be established using PDC and PGC. Irrigation program requires also the RETC, FAO crop growth coefficients and soil textural analysis. Fertilization program requires soil fertility analysis and nutrient removal per unit yield. A year round rotational grazing system for perennial grasses can be set by gathering information of at least one growing and resting cycle, including data on stocking rate, forage yield and grass recovery period (50% forage removal). The system allows that grazing begins when the amount of nutrients in forage is maximum. An example of 11 grazing-fertigation cycles marked in the PDC clock for Bermuda grass in Culiacan is presented. Specific "Agroclimatic clocks" can be used for designing an efficient management plan for increase forage yield and quality improvements in harvesting or grazing systems.

259 Agroforestry livestock feeding systems in tropical America. T. Clavero*[1] and J. Iglesias[2], [1]*Facultad de Agronomia, Universidad del Zulia*, *Maracaibo, Zulia, Venezuela*, [2]*Estacion Experimental Indio Hatuey*, *Matanzas, Cuba*.

Livestock production has been questioned for a long time because its association with deforestation, subsequent environmental degradation and a decline in productivity. Distinct patterns of deforestation are found within and between countries but most of these forests are converted to unsustainable pastures. Recently, agroforestry systems for sustainable animal production have been developed. Trees and shrubs have long been considered as important sources of nutrition for grazing animals for both the quantity and quality of pastures. Among the diverse types of agroforestry systems under study, protein banks and multiple association of tree/grass systems have contributed much to the development of sustainable dairy and meat production and could be considered as systems that can be extended to farmers. There is a diverse literature on the effects of fodder trees on the productivity of cattle, sheep and goats. The main results obtained are: average daily LW gain of 20-26% higher with browsing fodder trees than animals on only grass systems in young bulls for fattering, daily milk production of 7-10 kg/cow without supplementation with 60-65% more milk/cow, milk productivity (l/ha/year) for the associated tree/grass system 75% more than the traditional grass system, daily live weight gains between 400-525 g in growing replacement heifers which allows a live weight for reproduction of 290-300 kg, growing goats with daily live weight gain of 56% more than grass systems and daily LW gain between 85-100 g in sheep with minimal use of external inputs to the systems. The renovation and introduction of appropriate pastures, adapted to local edaphoclimatic conditions, together with the strategic incorporation of tree plants and shrubs in the grazing areas, seems to be a technological alternative that would contribute to improved livestock production diminish the impact of the ecosystems where they are developed. This could constitute an economically viable solution that does not produce environmental damages and is socially accepted and whose short term benefits would be observed in a sustained increment of the animal production.

Key Words: Agroforestry, Animal Production

260 Use of limpograss (*Hemarthria altissima*) in cow-calf grazing systems in southern Florida. J. D. Arthington*, *University of Florida-IFAS, Range Cattle Research and Education Center*, *Ona*.

Over 70% of Florida's 1 million beef cows reside in the state's peninsular region. Forages capable of providing adequate DM yield in the winter are a limitation to beef production systems in this region. Limpograss (*Hemarthria altissima*) possesses superior winter yield compared to other warm season perennial grasses. First extensively evaluated in 1974, 'Floralta' limpograss is the most widely utilized of the available limpograss varieties in southern Florida. This tropical grass originates from the Limpopo River in the Republic of South Africa. Floralta is a stoloniferous perennial tropical grass that was specifically selected for persistence under grazing conditions. In southern Florida, Floralta limpograss can be expected to produce as much as 40% of its annual growth in the winter months compared to only 10% for bahiagrass (Paspalum notatum), the predominate pasture forage specie in Florida. Another distinct characteristic of Floralta is the ability to maintain appreciable digestibility at later stages of maturity, suggesting potential as a stockpiled forage crop. In one 3-yr study, fall-calving cows assigned to a bahiagrass/limpograss rotational grazing system produced calves of equal weaning weight compared to cows grazing winter bahiagrass. In that study, 0.30 ha of stockpiled limpograss was equivalent to approximately 635 kg of supplemental winter. No differences in cow pregnancy rate were observed among grazing systems. Another distinct characteristic of limpograss is its relatively low crude protein content. Research investigating the performance of growing cattle grazing limpograss suggests that growth is not enhanced by protein supplementation until after the first frost of the season. After this time, protein-supplemented heifers realize a significant improvement in BW gain compared to heifers receiving no supplemental protein. Current research in southern Florida suggests that grazing strategies incorporating stockpiled limpograss could be an effective alternative to winter hay feeding. In addition, growing cattle grazing limpograss pastures may benefit from the provision of supplemental protein, especially after a killing frost.

Key Words: Limpograss, Grazing, Cow

261 Managing tropical forages: production, environmental benefits and risks. B. C. Pengelly* and J. G. McIvor, *Agricultural Landscapes, CSIRO Sustainable Ecosystems*, *St Lucia, Qld, Australia*.

Tropical forages have been used in farming systems of the developed and developing world for several decades. Grasses such as *Panicum* spp. and *Pennisetum* spp. have been cultivated for over a century but in the past 50 years there has been a greater focus on legumes such as *Stylosanthes* and *Vigna* spp. In all, over 150 tropical grass and legume species have been identified as being of value in the wide range of tropical and subtropical farming systems. The aims of much of the tropical forage research and cultivar development has been to increase animal production by identifying higher yielding species with better forage quality. The benefits of these species have been improved nutrition of animals and subsequently greater production of meat, milk and wool as well as better reproduction. The production downsides of this pasture use have been high costs, low reliability and poor persistence in some situations. The last 20 years has seen more attention given to environmental aspects of the use of these species. Environmental benefits from such use include nitrogen fixation and raised availability of nitrogen to other species, improved soil carbon levels, greater water use, and biodiversity benefits when compared to cropping systems. However the use of tropical forages has also been associated with a range of environmental disadvantages such as loss of native biodiversity, weed potential, enhanced nitrogen causing changes in species composition, and soil acidification. Overall, there have been large production benefits and some environmental gains from the development and adoption of tropical forages but these have come at a cost. The continuing challenge is in balancing the benefits and costs of their use through the better selection of appropriate species and application of appropriate management. Science has a role in both aspects.

Horse Species: Recent Advances in Understanding Metabolic Disorders in Horses

262 The impact of variability in pasture forages on horse metabolism. B. McIntosh*[1,2], D. Kronfeld[1], R. Geor[1], W. Staniar[1], P. Harris[3], and D. Ward[4], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*Blue Seal Feeds Inc.*, *Londonderry, NH*, [3]*WALTHAM Centre for Pet Nutrition*, *Melton Mowbray, United Kingdom*, [4]*Rutgers University*, *Bridgeton, NJ*.

Nonstructural carbohydrates (NSC), which includes sugars, starches and fructans in pasture forages undergo circadian and seasonal variation which have direct effects on metabolism in grazing horses. Increased intake of NSC is implicated in the development of digestive and metabolic disorders, such as laminitis. A series of 36 h studies in Virginia examined circadian and seasonal variability in forage NSC content and circulating plasma glucose and insulin in grazing horses (n=10) compared to control horses fed timothy/alfalfa hay (n=4). The unequal group size was accounted for in the statistical analyses which included two-way repeated measures ANOVA with post tests, linear regression, and correlations. We found that circadian and seasonal patterns in forage NSC content in a 5-ha mixed grass/legume pasture were associated with environmental conditions, and NSC was in turn associated with plasma insulin and glucose in the grazing horses. Forage NSC content was highest in April (20.3±0.4 %DM) ($P < 0.001$) and was attributed mostly to sugars (18.9±0.4 %DM), including glucose, sucrose and fructose. Circadian patterns in forage NSC were evident in April, May, and August, with the most distinct pattern found in April with peaks in the afternoon (22.2±0.3 %DM) and nadirs in the morning (17.1±0.3 %DM). Plasma insulin was higher in grazing horses than control horses in April (54.6±9.9μIU/mL) and May (20.8±3.4μIU/mL) ($P < 0.05$). In grazing horses, plasma insulin was significantly correlated with forage NSC and sugar in April, May, and January. In grazing horses, plasma glucose was higher in April than all months except for May, and plasma glucose was higher in grazing horses compared to controls in April. These studies identified a potential link between forage NSC content and alterations in glucose and insulin characteristics that may increase risk of laminitis via exacerbation of insulin resistance. Management strategies to decrease intakes of pasture NSC by horses at risk of developing metabolic disorders are needed.

Key Words: Horse, Forage, Metabolism

263 Advances in diagnosis and management of equine polysaccharide storage myopathy (PSSM). M. E. McCue*, S. J. Valberg, and J. R. Mickelson, *University of Minnesota*, *St. Paul*.

PSSM is a debilitating muscle disease in diverse breeds of horses. Clinical signs range from exertional rhabdomyolysis in Quarter Horses, muscle atrophy and progressive weakness in Draft breeds to muscle soreness and gait abnormalities in Warmbloods. PSSM affects 10% of Quarter Horses and 36% of Belgian Draft horses and an unknown number of Warmbloods in both Europe and North America. The gold standard for diagnosis of PSSM is the presence of periodic acid Schiffã™ (PAS) positive inclusions in type 2A and type 2B muscle fibers which are resistant to amylase digestion. In addition, PSSM is characterized by 1.5-4 X normal glycogen concentrations in skeletal muscle. No defect in glycogenolysis or glycolysis have been identified in PSSM horses. Rather glycogen accumulation appears to be related to enhanced glycogen synthesis. In Quarter Horses enhanced insulin sensitivity is also reported. Through a limited breeding trial and a genetic association analysis of an extensive number of clinical cases, we recently identified an autosomal dominant genetic mutation that is highly associated with PSSM in both Quarter Horses and Belgian Draft horses. This mutation accounts for 80 and 89% of PSSM cases in each breed respectively. We anticipate a genetic test will be available for PSSM within the next year.

Dietary management of PSSM involves decreasing dietary starch and provision of a fat supplement as an alternative energy substrate. This stabilizes blood glucose, increases serum free fatty acids and lowers insulin concentrations. Fat supplementation should be used judiciously in overweight horses. Muscle stiffness and exertional rhabdomyolysis can be eliminated in most horses if this diet is combined with daily exercise. Quarter Horses have a low skeletal muscle oxidative capacity and low intramuscular lipid stores. Gradual training is essential to improve muscle function likely through increased glycogen metabolism, increased oxidative capacity to utilize fat and improved substrate flux.

Key Words: Genetic, Glycogen, Muscle

264 Management of obesity and insulin resistance in horses. R. J. Geor*, R. A. Carter, and K. H. Treiber, *Virginia Polytechnic Institute and State University*, *Middleburg, VA*.

Although epidemiological data are scant, it has been suggested that the prevalence of obesity in horse (and pony) populations is on the rise. There is no universal definition of obesity in equids but according to the body condition scoring system (BCS) developed by Henneke, horses or ponies with a BCS of 8 (fat) or 9 (extremely fat) can be defined as obese, while animals with a BCS of 7 might be considered overweight. Insulin resistance (IR) is associated with obesity in horses and this disturbance to metabolic regulation may underlie susceptibility to laminitis, particularly the pasture-associated form of this disease. In support of this hypothesis, Treiber et al. (2006) recently described a ″pre-laminitic metabolic syndrome″ (PLMS) in otherwise healthy ponies with high (>70%) sensitivity and specificity for identification of animals at increased risk for pasture-associated laminitis. The central features of the PLMS were hyperinsulinemia, IR and generalized and/or regional (e.g. a cresty neck) adiposity. A similar clustering of clinical conditions, referred to as the equine metabolic syndrome (EMS), likely occurs in mature horses. In susceptible horses and ponies, consumption of forage or feed rich in nonstructural carbohydrates (NSC; sugars, fructans, and/or starch) may exacerbate IR and risk of laminitis. The mechanisms linking IR and laminitis are unknown, but might involve impaired glucose delivery to hoof keratinocytes or vascular endothelial dysfunction associated with oxidative stress and/or inflammation. Specific quantitative characterization of IR can be used to identify horses and ponies in need of special measures to avoid laminitis, particularly interventions that target decreased body fat mass and improved insulin sensitivity, including a reduction in dietary energy (calories) and NSC, restricted access to pasture during high-risk periods, and increased physical activity. The administration of levothyroxine sodium may be justified for animals that do not respond to diet and exercise programs alone.

Key Words: Horse, Obesity, Insulin resistance

Lactation Biology: Metabolism and Gene Expression in Support of Lactation

265 Characterization of the utilization of trans octadecenoic acids in lactating dairy cows. C. Tyburczy*[1], A. L. Lock[1], D. A. Dwyer[1], F. Destaillants[2], Z. Mouloungui[3], L. Candy[3], and D. E. Bauman[1], [1]*Cornell University*, *Ithaca, NY*, [2]*Nestle Research Center*, *Lausanne, Switzerland*, [3]*Laboratoire de Chimie Agro-Industrielle*, *Toulouse, France*.

The biological activity of individual octadecenoic acids may be dependent on the location and orientation of the double bond. Therefore, our objective was to examine the affect of elaidic acid (trans-9 18:1; EA) and vaccenic acid (trans-11 18:1; VA) in relation to oleic acid (cis-9 18:1; OA) during lactation. Three mid-lactation Holstein cows were used in a 3x3 Latin square design, and treatments (>82% purity) involved abomasal infusion of 1) EA (41.7 g/d), 2) VA (41.4 g/d) and 3) OA (45.5 g/d). Treatment periods were 4 d, separated by a 7 d wash-out interval. Milk yield (24.2 ± 2.2 kg/d; mean ± SD) and yield of milk components were not affected by treatment. Incorporation of infused isomers into milk fat triglycerides (TG) plateaued by d 3 and transfer efficiency averaged 59.1 ± 0.1%, 54.2 ± 0.1% and 54.6 ± 0.3% for EA, VA and OA, respectively. For the VA treatment, milk fat content of cis-9, trans-11 conjugated linoleic acid (CLA) more than doubled and the ratio of VA to CLA did not change, consistent with mammary conversion of VA to CLA by delta-9 desaturase. Total lipid concentration of plasma lipid classes averaged 209.9 ± 10.5 mg/dl, 161.4 ± 15.4 mg/dl, 14.5 ± 2.0 mg/dl and 2.4 ± 0.5 mg/dl for phospholipids (PL), cholesterol esters (CE), TG and free fatty acids (FFA), respectively. Similar values for the proportion of fatty acids provided by each plasma lipid class were 60.3 ± 2.2%, 32.1 ± 1.8%, 6.4 ± 0.8% and 1.2 ± 0.3%. Infusion of EA, VA and OA increased their specific content in plasma PL, TG and FFA, but for VA the relative increase was much greater for plasma TG and FFA. Overall, data demonstrate that biological differences exist among individual octadecenoic acids in lactating dairy cows.

Key Words: Milk Fat, Trans Fatty Acids, Lactation

266 Expression of lipogenic genes in adipose tissue increases during milk fat depression induced by treatment with trans-10, cis-12 conjugated linoleic acid (CLA). K. J. Harvatine*, D. A. Dwyer, and D. E. Bauman, *Cornell University*, *Ithaca, NY*.

Trans-10, cis-12 CLA decreases milk fat synthesis through transcriptional down-regulation of genes involved in mammary fatty acid synthesis, transport and esterification. Intake is not decreased during CLA-induced milk fat depression, resulting in a calculated increase in energy balance. To investigate energy partitioning during milk fat depression, adipose tissue biopsies were taken from four cows arranged in a switchback design. Treatments were control and 4 day abomasal infusion of trans-10, cis-12 CLA (7.5 g/d). CLA decreased milk fat yield by 38% and milk fat content by 34%, but yields of milk and other milk components were unchanged. Adipose tissue was biopsied from adjacent to the tail head, and expression of lipogenic enzymes and transcription factors regulating lipogenesis was determined by Real-Time PCR. Expression of lipoprotein lipase, fatty acid synthase and stearoyl-CoA desaturase was increased more than one fold over control ($P < 0.002$). The lipogenic regulatory proteins sterol-response element binding protein 1 (SREBP1) and throid hormone responsive spot 14 were increased, and leptin and PPARgamma tended to increase. Thus, a CLA dose resulting in near maximal inhibition of mammary lipogenesis resulted in increased expression of lipogenic-related genes in adipose tissue. Overall, results are consistent with energy spared from the reduction in milk fat synthesis being partitioned towards adipose tissue fat stores during short-term milk fat depression.

Key Words: Milk Fat Depression, Fat Synthesis, Adipose Tissue

267 The relationship between trans-10 18:1 and milk fat yield in cows fed high oleic acid or high linoleic acid plant oil supplements. T. Hinrichsen[1], A. L. Lock*[2], and D. E. Bauman[2], [1]*Royal Veterinary & Agricultural University*, *Denmark*, [2]*Cornell University*, *Ithaca, NY*.

Trans-10 18:1 (t10) has been proposed to affect milk fat synthesis because its milk fat content is associated with diet-induced milk fat depression (MFD). We summarized data from 35 publications (109 treatments) and found an inverse curvilinear relationship between milk fat content of t10 and milk fat percent ($R2 = 0.54$). However, t10 may be a marker for the altered rumen biohydrogenation (BH) that occurs with MFD rather than having a direct inhibitory effect per se. In vitro studies have shown that the BH of oleic acid results in formation of a range of trans-18:1 fatty acids (TFA), whereas BH of linoleic acid produces both conjugated 18:2 and TFA. Therefore, we used plant oils enriched in either oleic or linoleic acid to examine potential effects of TFA on MFD. Cows ($n = 30$) were fed a basal TMR diet for 3 wk (Period 1). In Periods 2 and 3 (14 and 11 d, respectively) cows were divided into 3 groups: control group (C) that continued on basal diet, high-oleic (82%) sunflower oil supplemented group (O) and high-linoleic (75%) safflower oil supplemented group (L). Oils were added at 2.5 and 3.5 % of DM in Periods 2 and 3, respectively. There were no treatment differences for yield of milk, milk protein or milk lactose ($P > 0.05$). Milk fat yield was reduced by 14% ($P < 0.05$) and 34% ($P < 0.001$) in Periods 2 and 3, respectively, for treatment L compared to C; treatment O did not differ from C ($P > 0.05$). Milk fat t10 (g/100 g FA) increased 4-fold ($P < 0.01$) and 2-fold ($P = 0.17$) for L and O, respectively, in Period 2. Similar increases for Period 3 were 11-fold ($P < 0.001$) and 4-fold ($P < 0.01$) for L and O. A 4-fold increase in t10 correlated with MFD when cows received the linoleic acid supplement, but no MFD occurred with a similar increase and milk concentration of t10 induced by oleic acid supplement. Thus, the present study offers no support for t10 as a cause of MFD and highlights the limitation in concluding cause-effect relationships based on correlations between specific milk fatty acids and MFD.

Key Words: Milk Fat, Trans Fatty Acids, Lactation

268 In vivo treatment with xanthosine expands the mammary stem cell population. A. V. Capuco*[1], C. M. Evock-Clover[1], D. L. Wood[1], and A. Minuti[2], [1]*Bovine Functional Genomics Laboratory, USDA-ARS*, *Beltsville, MD*, [2]*Institute of Zootechnics, Catholic University*, *Piacenza, Italy*.

Mammary stem cells provide for growth and maintenance of the mammary gland and are therefore likely targets for means to improve the productivity and efficiency of dairy animals. Xanthosine treatment has been shown to promote expansion of hepatic stem cells in vitro. The objective of this study was to determine if in vivo treatment with xanthosine can increase the mammary stem cell population. Xanthosine was infused into the right mammary glands of four Holstein calves (3 mo old) for 5 consecutive days. The right rear quarter received a supplemental injection of xanthosine directly into the mammary parenchyma. Immediately after each xanthosine treatment, calves were injected intravenously with 5-bromo-2-deoxyuridine (BrdU). Forty days after the final treatment, mammary tissue was obtained at slaughter. BrdU-label retaining epithelial cells (LREC) were detected immunohistochemically and quantified. We and others have employed the retention of BrdU as a method for labeling putative bovine mammary stem cells. Infusion of xanthosine into the bovine mammary gland significantly increased the number of LREC in treated quarters compared to contralateral control quarters ($P = 0.06$). LREC averaged 0.4% of epithelial cells in control and 0.84% in xanthosine-treated quarters. Data indicate that in vivo treatment with xanthosine can be used to increase the number of mammary stem cells. This is the first demonstration of an in vivo treatment to increase the endogenous population of adult mammary stem cells in any species. Utility of this treatment for biomedical research and for dairy management is of considerable interest.

Key Words: Progenitor Cells, Lactation, Proliferation

269 Prepubertal nutrition effects on bovine mammary parenchyma and fat pad gene expression profiles. P. Piantoni*[1], D. Graugnard[1], K. M. Daniels[2], R. E. Everts[1], S. L. Rodriguez-Zas[1], H. A. Lewin[1], R. M. Akers[2], and J. J. Loor[1], [1]*University of Illinois*, *Urbana*, [2]*Virginia Polytechnic Institute and State University*, *Blacksburg*.

Nutrition prior to puberty appears to differentially affect bovine mammary parenchyma and fat pad development. Objectives were to evaluate gene expression profiles in parenchyma and fat pad due to enhanced nutrient intake to achieve widely-different rates of gain during the isometric growth phase in the first 63 d of life in Holstein heifers. Tissues from calves fed ($n = 6$/milk replacer diet) a control (20:20, protein:fat, fed at 450 g/d), high protein low fat (28:20, HPLF, fed at 970 g/d), HP high fat (28:28, HPHF, fed at 970 g/d), or 1.5X HPHF (HPHF+, fed at 1460 g/d) diet were used for RNA extraction. Calf starter (20% CP) was available ad libitum. A 13,257 bovine

oligonucleotide (70-mers) array and qPCR were used for gene expression profiling. Annotation was based on similarity searches using BLASTN against human, mouse and bovine RefSeq, human, mouse, and bovine UniGene, and bovine TIGR. Cy3- and Cy5-labelled cDNA from mammary parenchyma or fat pad and a reference standard were used for hybridizations (80 arrays). ANOVA (FDR-adjusted $P \leq 0.10$) identified 5,585, 203, and 20 differentially expressed genes due to tissue type, diet, and diet x tissue interaction, respectively. Among upregulated genes in HFHP+ vs. control or HFHP, regardless of tissue, Ingenuity Pathway Analysis identified cell assembly/organization, cell growth/proliferation, and cell death as modified families of related genes. However, analysis of downregulated genes between HFHP+ and HFHP showed major impacts in gene expression regulation, small molecule biochemistry, and immune response. Further, histidine metabolism, fatty acid metabolism, Val/Leu/Ile degradation, Arg/Pro metabolism, and IL2 signaling were the most significant canonical pathways among downregulated genes. We conclude that the mammary parenchyma and fat pad transcriptomes are impacted by nutrition during the first 2 mo of life. Genomic adaptations could at least in part explain tissue growth responses to enhanced nutrient intake.

Key Words: Calf, Genomics, Mammary Gland

270 Mammary gland expression of cell cyle, apoptosis, and immune response genes accompany progression through a prolonged lactation cycle. D. L. Hadsell*, D. Torres, and M. S. Bray, *Baylor College of Medicine*, *Houston TX*.

In the mouse mammary gland, the prolonged lactation cycle is a biphasic developmental process that is characterized by a wave of proliferation during the early postpartum period followed by decreased proliferation in mid-lactation and elevated apoptosis during prolonged lactation. The goal of this study was to identify the genes regulating secretory cell function and turnover during this cycle. Mammary samples (N=5 mice/time) were collected from mice on days 2, 8, 14, 21, 28, and 35 post-partum. Total RNA from these samples was analyzed using the Sentrix Mouse Ref 6 BeadChip (Ilumina, Inc.). Of the 46,119 genes and ESTs on the array, expression was detected for 17,028. One-way ANOVA identified 1,645 genes that changed ($P<0.05$) with time, and 1,056 genes that changed by at least 2-fold. Expressed genes were clustered into 10 distinct temporal patterns using k-means clustering. The 10 patterns were labeled based on the direction (Down, Flat, or Up) of each sequential change in expression for each of the pairwise comparisons between the 6 adjacent time points. Patterns 1 (DUUFF), 5 (UUFFU), 7 (UUUDU) and 9 (FUUFF) were enriched ($P<0.05$) in genes integral to immune response, defense response, cell motility, and cell death. These genes were low during early lactation and maximally expressed during prolonged lactation. Patterns 2 (DDUFU), 6 (DFUUU), 8 (DFUFU) and 10 (DDUUU) were at their highest expression on day 2 and decreased with time postpartum. These genes regulated primary metabolism, DNA metabolism, cellular protein metabolism, cell cycle, and mitosis. Patterns 3 (FDDFU) and 4 (UFDFU) were associated with metabolism and transport. These genes increased between days 2 and 8, and then decreased through the remainder of the study. These results demonstrate that previously observed changes in mammary cell turnover during the prolonged lactation cycle are supported by concomitant changes in the expression of cell cycle and cell death genes. The results also support the conclusion that the immune system is important to regulating the decline in milk synthesis during prolonged lactation.

Key Words: Mammary, Microarray, Lactation

271 SOCS3 and STAT3 are up-regulated and STAT5 down-regulated during induced involution of the bovine mammary gland. K Singh*, M Prewitz, J Dobson, and K Stelwagen, *AgResearch Ltd, Ruakura Research Centre*, *Hamilton, New Zealand*.

In dairy animals, gradual involution associated with a decline in milk yield occurs following peak lactation. In cows, abrupt termination of milking induces involution of the mammary gland which is characterized by alveolar engorgement, followed by decreased communication between mammary epithelial cells (MEC) and extracellular matrix, as well as cell-cell communication and subsequently increased apoptosis of the secretory MEC. The aim of this study was to investigate the role of STAT5, STAT3 and SOCS3 in the bovine mammary gland during this process, ultimately to understand mechanisms to improve milk production during late lactation. Alveolar tissue was obtained from non-pregnant cows in mid-lactation slaughtered at 0, 6, 12, 18, 24, 36, 72 and 192h (n=6/group) after the last milking. Western blot analysis showed STAT5a and phosphorylated STAT5 levels were decreased 2-fold by 24h post milking ($P<0.01$) and remained down-regulated to 192h by 4.4-fold and 7.7-fold ($P<0.01$), respectively, relative to 6h post milking. STAT3 expression was also down-regulated (2.4-fold, $P<0.05$), but only at 192h relative to 6h after the last milking. However, relative to 12h post milking, the level of STAT3 decreased from 36h onwards ($P<0.05$). In contrast, phosphorylated STAT3 was barely detectable at the early time points and was dramatically up-regulated by 36 and 72h post milking by 39- and 44-fold ($P<0.001$), respectively, and at 192h post milking by 22-fold ($P<0.05$), all relative to 6h. Real-time RT-qPCR analysis showed that SOCS3 mRNA levels were up-regulated by 72h post milking (2.3-fold, $P<0.05$). These results suggest that the up-regulation of SOCS3 and phosphorylated STAT3 and down-regulation of STAT5 play a key role during bovine mammary gland involution.

Key Words: SOCS3, STAT3 and 5, Bovine Mammary Involution

272 MammOmics™: transcript profiling of the mammary gland during the lactation cycle in Holstein cows. M. Bionaz*, S. L. Rodriguez-Zas, R. E. Everts, H. A. Lewin, and J. J. Loor, *University of Illinois*, *Urbana*.

Achieving greater understanding of the genomic adaptations in the mammary gland of high-producing dairy cows during lactation represents a formidable challenge. Our objective was to explore the mammary transcriptome using biopsies from 8 Holstein cows harvested at -30, -15, 1, 15, 30, 60, 120, 240, and 300 d relative to parturition. Milk composition and milk fatty acid profiles also were determined throughout lactation. A 13,257 unique oligonucleotide (70-mers) array was used for transcript profiling. Annotation was based on similarity searches using BLASTN against human, mouse and bovine RefSeq, human, mouse, and bovine UniGene, and bovine TIGR. Cy3- and Cy5-labelled cDNA from mammary tissue and a reference standard were used for hybridizations. ANOVA (false discovery rate-adjusted $P \leq 0.05$) identified 7,055 differentially expressed genes due to physiological state. A total of 701 of these genes had a ≥2-fold change in expression in at least one other time point examined relative to day -30. We verified key microarray results for 38 genes by qPCR. Expression patterns of the 701 genes relative to d -30 were grouped into 2 clusters of upregulated (283) and 4 clusters of downregulated genes (418). Ingenuity Pathway Analysis mapped 3,355 of 7,055 differentially expressed genes. Relative to d -30, network analysis of genes with ≥2-fold expression indicated that some of the most predominant

molecular functions were on d -15 immune response (6 genes), on d 1 (25) through d 60 (48) lipid metabolism and molecular transport, on d 120 (53) cell-to-cell signaling and tissue development, and on d 240 (10) and 300 (7) connective tissue development and function. Twenty-nine of 52 downregulated genes by ≥2-fold on d 60 were associated with cell-to-cell signaling. Similarly, 30 of 49 downregulated genes on d 240 and 300 were associated primarily with molecular transport. Transcriptome analysis highlighted the importance of genes associated with immune function, lipid metabolism, transport, and tissue remodeling during the lactation cycle in the bovine mammary gland.

Key Words: Gene Networks, Microarray, Genomics

273 Photoperiod alters metabolic gene expression in bovine liver potentially through suppressors of cytokine signaling. E. E. Connor*[1], E. D. Thomas[2], and G. E. Dahl[3], [1]*Bovine Functional Genomics Laboratory, USDA-ARS*, *Beltsville, MD*, [2]*Department of Animal and Avian Sciences, University of Maryland*, *College Park*, [3]*Department of Animal Sciences, University of Florida*, *Gainesville*.

Previous research has demonstrated effects of day length (photoperiod) on multiple physiological processes in cattle including reproduction, lactation, immune function, growth and carcass composition. Many of these effects are mediated by changes in prolactin (PRL) and PRL signaling. Recent research has shown a role of PRL-responsive suppressors of cytokine signaling (SOCS) in fatty liver and metabolic syndrome in rodents. Thus, to determine whether photoperiod manipulation could influence hepatic lipid metabolism in ruminants, we investigated the effects of short-day (8 h light:16 h dark; SD) and long-day (16 h light:8 h dark; LD) photoperiod exposure on hepatic *SOCS* and metabolic gene expression in Holstein steer calves (98 ± 4 d old). Liver biopsies were collected after 3 and 6 wks of exposure to SD (n = 6) or LD (n = 6) and evaluated for mRNA expression of *SOCS-1*, *SOCS-3*, enzymes of glucose and fatty acid metabolism (*phosphoenolpyruvate carboxykinase 1* [*PCK1*] and *2* [*PCK2*], *acetyl-coA carboxylase* α [*ACACA*], *fatty acid synthase* [*FASN*] and *very long chain acetyl-coA dehydrogenase* [*ACADVL*]), and a key transcription factor in lipid biosynthesis (*SREBP1-c*) by absolute quantitative real-time RT-PCR. Relative to LD, expression of *ACACA*, *ACADVL*, *SREBP-1c* and *PCK1* was decreased (P < 0.05) in steers exposed to SD for 6 wks. In addition, *SOCS-1* tended to be lower (P = 0.11) in SD steers after 6 wks. There was a tendency for an increase in *FASN* expression in SD steers at 3 wks (P = 0.06), but a suggested decline by 6 wks (P = 0.23). Expression of *PCK2* and *SOCS-3* was unaffected by photoperiod treatment. Based on our findings and those in rodents, we propose a mechanism whereby SD photoperiod lowers circulating PRL and *SOCS-1* expression, suppressing *SREBP-1c* and hepatic lipogenesis via reductions in *ACACA* and *FASN*. Suppressed hepatic lipogenesis may reduce the incidence or severity of fatty liver during metabolic imbalance. In conclusion, SD photoperiod treatment prior to calving may aid in the prevention of fatty liver and metabolic syndrome in dairy cows during the periparturient period.

Key Words: Photoperiod, Gene Expression, Fatty Liver

274 Effects of intramammary infusions of serotonin (5-HT) and methysergide (METH), a 5-HT antagonist, on milk production and composition in lactating dairy cows. L. L. Hernandez*[1], J. B. Wheelock[1], G. Shwartz[1], L. H. Baumgard[1], A. M. Parkhurst[2], and R. J. Collier[1], [1]*University of Arizona*, *Tucson*, [2]*University of Nebraska*, *Lincoln*.

The neurotransmitter 5-HT, synthesized from tryptophan, is a proposed feedback inhibitor of milk synthesis. We evaluated effects of intramammary infusions of 5-HT or METH on milk yield (MY) and composition in 6 multiparous lactating dairy cows. Cows were assigned to a repeated measures design of contralateral intramammary infusions with METH (20 mg/quarter/d) or 5-HT (50 mg/quarter/d). Udder halves were first treated with METH or saline (SAL) for 3d followed by a 7d washout period before administrating 5-HT or SAL. MY was recorded twice daily for each udder half and milk composition of each half was determined once daily. Daily blood samples were harvested for plasma to determine glucose and NEFA concentrations. Sweating rate (SR), respiration rate (RR), and left and right udder temperatures were obtained twice daily after milking. Infusions of METH and SAL increased MY 10.9% from beginning of infusion to end of infusion period (P<0.002). Infusions of 5-HT and SAL decreased MY by 11.1% compared to pre-5-HT infusion period and MY decreased further by 8.9% post-5-HT infusion (P<0.05). Infusions of SAL, METH, and 5-HT increased SCC (P<0.05). Infusing 5-HT tended to reduce mean lactose concentration (4.3%/vol) relative to SAL infusion (4.6%/vol; P=0.06). Milk protein was decreased by METH and SAL 2.0% compared to the post-infusion period (P=0.0001) and was increased 5.8% by5-HT and SAL compared to the pre-infusion period (P=0.02). SR increased 17% during intramammary infusion of 5-HT and decreased 33% post-infusion (P<0.0001). SR increased 11% by METH infusion and decreased 11% post-infusion (P<0.0001). No effect of 5-HT or METH infusions was detected on plasma NEFA or glucose concentrations, RR, or milk fat content. We conclude this data supports the concept of 5-HT as a feedback inhibitor of lactation.

Key Words: 5-HT, Milk Production, Feedback Inhibition of Lactation

275 Chitotriosidase activity in blood and colostrum at peripartum period in goats. N. Castro[1], J. Capote[2], A. Morales[1], C. Rodriguez[1], and A. Arguello*[1], [1]*Las Palmas de Gran Canaria University, Animal Science Unit*, *Arucas, Las Palmas, Spain*, [2]*Canary Agronomic Science Institute*, *La Laguna, Tenerife, Spain*.

Chitotriosidase (ChT) is a functional chitinase, with high homology to chitinases belonging to family 18 of glycosylhydrolases and present in different species. Predominantly it is a secretory protein but it is in part processed and stored in lysosomes. ChT mRNA is expressed only at a late stage of differentiation of monocytes to activated macrophages in culture indicating that the enzyme has a strongly regulated expression. Since ChT is able to cleave chitin present in the cell wall of fungi and nematodes, it is possible that this enzyme continues to play a role in defense mechanisms against parasites and fungi. There have been many studies of human ChT, but few of other mammalian endocrine chitinases. The aim of this study was to measure ChT activity in goat serum and colostrum around partum period. Blood from 30 Majorera breed goats was taken at -4, -3, -2, -1, 1, 2, 3, and 4 postpartum days, and colostrum was sampled at 1, 2, 3, 4, and 5 postpartum days. ChT activity was assayed in serum and colostrum using a fluorescence method. Blood serum ChT activity was 3887, 4023, 3682, 3333, 2658, 2955, 2575 and 3520 nMol/ml/h at -4, -3, -2, -1, 1, 2, 3, and 4 postpartum days respectively. No statistical effects of time were shown, but the lowest ChT activity level was measured around partum day.

Colostrum ChT activity was 3912, 2124, 737, 403 and 465 nMol/ml/h at 1, 2, 3, 4, and 5 postpartum days, respectively. Statistical differences ($P<0.05$) were shown between postpartum days.

Key Words: Chitotriosidase, Goat, Colostrum

276 Pre-pubertal nutrition affects mammary development and first lactation performance depending on growth potential in dairy sheep. A. Zidi[1], G. Caja*[1], M. Ayadi[2], V. Castillo[1], C. Flores[1], and X. Such[1], [1]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*, [2]*Institut Superieur de Biologie Appliquée de Medenine*, *Tunisia*.

A total of 57 ewe lambs of Manchega (MN, n = 35) and Lacaune (LC, n = 22) dairy sheep, born during winter and weaned at wk 5 of age, were used to evaluate the effects of pre-pubertal level of nutrition on long-term lactational performance. Nutritional treatments consisted of ad libitum (concentrate and alfalfa hay) or restricted (concentrate and straw) feeding to achieve the maximum ADG (MN, 254 g/d, n = 18; LC, 293 g/d, n = 12) or 65% ADG (MN, 164 g/d, n = 17; LC, 189 g/d, n = 10), respectively, from wk 5 to 22. After wk 22, ad libitum ewe-lambs joined the adult ewe flock for grazing (MN, 183 g/d; LC, 201 g/d; $P < 0.05$). Compensatory growth was applied to restricted ewe-lambs from wk 22 to 27 (MN, 223 g/d; LC, 279 g/d; $P < 0.05$) to reach puberty and pregnancy during first fall. All ewe-lambs were exposed to rams and mated under control conditions after the second estrus cycle. Computerized axial tomography (CAT) was done at wk 16 and 36. Puberty was reached earlier in ad libitum than in restricted fed ewe lambs (MN, -35 d; LC, -21 d; $P < 0.05$). CAT images at wk 16 showed greater fat pad ($P < 0.05$) due to ad libitum feeding in both breeds (MN, +54%; LC, +32%). Parenchyma percentage was lower in the ad libitum fed MN ($P < 0.05$), but no differences were detected between the other groups. Conception rate (50.9%), prolificacy (1.24 lambs/ewe) and lamb body weight at birth were not affected by the dietary treatments. Milk yield varied according to treatment and breed, the breed × treatment interaction being highly significant ($P < 0.001$). Restricted ewe lambs yielded more milk than ad libitum at first lactation (114 DIM) in MN (61.2 vs. 40.0 L; $P < 0.05$), whereas it was the opposite in LC (122.9 vs 143.5 L; $P < 0.05$). No significant differences in milk components were detected between feeding treatments, but milk of restricted MN had greater fat and protein contents.

277 The relationship between negative energy balance and mastitis in dairy cattle during early lactation. K. M. Moyes*[1], T. Larsen[2], N. C. Friggens[2], J. K. Drackley[1], and K. L. Ingvartsen[2], [1]*University of Illinois*, *Urbana*, [2]*University of Aarhus*, *Tjele, Denmark*.

Our objective was to determine whether dairy cows experiencing more severe postpartal negative energy balance (NEB) are at a greater risk for developing mastitis during early lactation. Data from a total of 138 lactations from 117 cows were used in a case-control epidemiologic study. Cows were of 3 breeds (Danish Red, Danish Holstein and Jersey) ranging from parity 1 to 4. Blood samples were collected weekly from 56 d before expected calving date through 90 DIM. Blood was analyzed for insulin, aspartate aminotransferase (ASAT), NEFA, glucose and BHBA. Daily milk yield was measured and composite SCC were analyzed. Cows were classified as 1) healthy (H) if SCC < 100,000 cells/mL and they were not treated for mastitis; 2) sub-clinical mastitis (SM) if SCC > 800,000 cells/mL but were not treated for mastitis; or 3) clinical mastitis (CM) if SCC > 800,000 cells/mL and were treated for clinical mastitis. Cows that developed mastitis during the first 7 DIM were excluded from the dataset. The time of mastitis (TOM) was recorded as the DIM in which the first rise in SCC was observed and was recorded as TOM = 0. The time prior to and after TOM was distinguished as ± n wks relative to TOM = 0. Healthy cows were paired with either a SM or CM cow and the TOM for each H cow was equal to the TOM for their paired mastitic cow. Data from wk -2 relative to TOM were analyzed using the MIXED procedure of SAS. Cows that developed SM did not differ statistically from H cows. The CM cows had higher NEFA ($P<0.05$) and ASAT ($P<0.05$) than H cows. All other variables were similar among treatment groups. Cows in more severe NEB tended to have higher NEFA than cows experiencing 'normal' postpartal NEB. In addition, higher ASAT indicates that the CM cows may have experienced more liver tissue damage prior to the development of mastitis when compared with H cows. Our results indicate that cows experiencing more severe postpartal NEB may be at a greater risk for developing mastitis.

Key Words: Negative Energy Balance, Mastitis, Dairy Cattle

278 The use of the Rumensin Premix in dairy cows: factors influencing its effects on milk production and milk composition. J. Dubuc*[1], D. DuTremblay[1], M. Brodeur[1], R. Bagg[2], P. Dick[2], J. Baril[2], and L. DesCoteaux[1], [1]*Universite de Montreal*, *Saint-Hyacinthe, Quebec, Canada*, [2]*Elanco Animal Health*, *Guelph, Ontario, Canada*.

The goal of this field trial was to evaluate the effects of 16 ppm of monensin sodium (Rumensin Premix, Elanco Animal Health, Canada) on production (PROD) and milk fat percentage (MFP) of commercial dairy herds. Another goal of this study was to identify possible interactions between monensin and nutritional factors on PROD and MFP. A randomized clinical trial was conducted on 49 Holstein herds in Quebec (Canada) between Nov. 2005 and May 2006. The herd was considered as the unit of interest. Herds were balanced in two groups for milk production, housing system, feeding system and size of farm. Monensin treatment was allocated in a crossover designed trial for each group. Monensin premix was added to the lactating dairy cow rations for a consecutive 3-month period for every herd. PROD and MFP were from weekly averages of daily bulk tank data. PROD and MFP were considered as outcome variables in linear mixed models. PROD and MFP were treated as repeated measures in herds. All models included treatment, group, season, parity and days in milk as fixed effects. Majority of herds were fed total mixed rations (TMR; n=30; 61%) and were housed in tie-stalls (n=42; 86%). Overall monensin effect on PROD was not significant (P=0.54). However, herds having high non-fiber carbohydrate level (NFC; >41.0%) in their diet had a higher milk production (+0.84kg/d; P=0.03). Monensin had a decreasing effect (-0.12%) on MFP (P<0.01). Statistical interactions

with monensin on MFP were observed for some nutritional factors. The decreased MFP effects were larger for herds: having a diet high in NFC (>39.0%; P=0.01); having low particle size in TMR when adding the results of the two top sieves of The Pennsylvania State University Particle Separator (<45.0%; P=0.03); not feeding dry hay as first meal in the morning (P=0.05); and not feeding protected fat in the diet (P=0.07). The results of this trial confirm that monensin lowers MFP at a dose of 16 ppm in lactating dairy cows. Interactions between monensin and nutritional factors having effects on PROD and MFP were mostly related to carbohydrate levels in the ration.

Key Words: Monensin, Dairy Cow, Milk Composition

279 The expression of genes regulating lipolysis in the adipose tissue of pregnant and lactating dairy cattle. J. M. Sumner* and J. P. McNamara, *Washington State University*, *Pullman*.

There is great variation among dairy cattle in body condition loss during early lactation, which affects all aspects of production, health and longevity. The objectives were to determine the change in expression of the beta 1, beta 2, and beta 3 adrenergic receptors, hormone sensitive lipase and its cofactor perilipin in the adipose tissue of Holstein dairy cattle during transition. We also wanted to know if the expression was related to animal level variables for milk production and body fat. Therefore, twenty Holstein dairy cattle were grouped by lactation number (1, 2, and 3 or more) in a randomized design and subcutaneous adipose tissue was sampled to measure lipolytic rates and gene expression. Duplicate samples were extracted for RNA and tissue was also incubated to measure basal and stimulated lipolysis. Basal lipolysis increased following parturition, stimulated lipolysis peaked at 90 days postpartum. The beta-1 receptor relative expression increased relative to prepartum by 170%, 72% and 112% at 30, 90, and 270 DIM . The beta-2 receptor relative expression increased by 75%, 121% and 100% at 30, 90, and 270 DIM compared to 30 days prepartum. The beta-3 receptor increased 111%, 125% and 69% at 30, 90, and 270 DIM. Hormone sensitive lipase increased (P = 0.09) at all postpartum sample points and was highest in primiparous animals (P = 0.002). The mean fold increase was 180%, 359% and 47% at 30, 90, and 270 days of lactation compared to prepartum. The relative abundance of the perilipin gene was the highest and the relative expression increased (P = 0.04) 227%, 1847% and 126% at 30, 90, and 270 DIM. This is the first time perilipin has been measured in the adipose tissue of dairy cattle. Expression of hormone sensitive lipase was negatively related to changes in BCS. This work demonstrates that increases in the expression of beta-adrenergic receptors, hormone sensitive lipase and perilipin is part of the regulation of lipolysis in dairy cattle during lactation.

Key Words: Gene Expression, Adipose, Lipolysis

280 Feeding a whey protein gel to prevent rumen hydrogenation of unsaturated fatty acids and increase the n3 and n6 fatty acid content of goat milk. J. A. Weinstein*, E. J. DePeters, M. Rosenberg, S. J. Taylor, and A. Aljadeff, *University of California*, *Davis*.

Developing new approaches for reducing the risk of coronary disease from eating dairy products is a common objective in research, specifically, finding methods to increase the polyunsaturated fatty acid (PUFA) concentration of milk lipids. Previously, feeding whey protein gels containing PUFA reduced rumen biohydrogenation and increased the levels of target milk fatty acids. Our objective was to test the efficacy of whey protein isolate (WPI) gels produced in a steam tunnel, as a method to alter the fatty acid (FA) composition of the triacylglycerol (TG) fraction of milk lipids in goats. Three primiparous Lamancha goats in midlactation were fed three diets in a 3x3 Latin square design. Each animal was fed an isoenergetic grain mix with WPI added as a supplemental lipid containing either: (1) 100% soybean (S) oil, (2) 100% linseed (L) oil, or (3) a 50/50 blend (S/L) of both soybean and linseed oils. S served as a source of n6 FA and L was a source of n3 FA. Periods were 22 days with the first 10 days used as an adjustment phase followed by a 12-day experimental period. During the adjustment phase all goats received yellow grease (YG) as their dietary lipid to provide a baseline for milk FA composition. During the experimental phase each goat received its assigned WPI. Significant changes in FA concentration were determined at $P<0.05$. Milk FA concentrations of C18:2 and C18:3 were 1.92 and .51 g/100g TG when goats were fed YG. Relative to YG, WPI S increased both C18:2 and C18:3 in milk fat to 9.37 and 1.51g/100g TG respectively. The S/L gel also increased C18:2 and C18:3, 6.45 and 3.86g/100g TG respectively. WPI L produced milk fat containing 3.99 and 5.97 g/100g TG of C18:2 and C18:3. WPI gels reduced rumen biohydrogenation of PUFA and increased the n6 and n3 content of milk fat in lactating does. WPI gels are a practical and efficient method to deliver PUFA postruminally.

Key Words: Goat, Polyunsaturated Fatty Acids, Whey Protein Gel

281 Effect of time of AI and supplemental estradiol on pregnancy rates of lactating dairy cows. J. Hillegass*, J. E. P. Santos, F. S. Lima, M. F. Sheley, and M. F. S. Filho, *University of California*, *Tulare*.

Objectives were to compare pregnancy rates and losses for lactating dairy cows time-inseminated either at 48 or 72 h after $PGF_{2\alpha}$ and supplemented or not with estradiol prior to AI. Holstein cows, 971, were randomly assigned to one of four treatments arranged as a 2 x 2 factorial. All cows were pre-synchronized with injections of $PGF_{2\alpha}$ at 37 and 51 DIM. At 64 DIM, they received an injection of GnRH, followed 7 d later by $PGF_{2\alpha}$. Cows were then assigned to one of four treatments; cows in the CoSynch at 48 h (CoS48) received a final injection of GnRH at the moment of timed AI 48 h after $PGF_{2\alpha}$, whereas cows in the CoSynch at 72 h (CoS72) received GnRH and were timed AI 72 h after $PGF_{2\alpha}$. Half of the cows in each CoSynch received an injection of 1 mg of estradiol cypionate (ECP) 24 h after $PGF_{2\alpha}$. Therefore, the 4 treatments were: CoS48-ECP (n = 240), CoS72-ECP (n = 246), CoS4+ECP (n = 245) and CoS72+ECP (n = 240). Blood samples were collected and progesterone measured in plasma of all cows at 7 d prior to and at the first GnRH of the CoSynch, and cows were classified as anovular when progesterone < 1.0 ng/mL in both samples. Pregnancy was diagnosed by palpation per rectum at 40 and 68 d after AI. A subset of 123 cows had their ovaries examined by ultrasonography to determine diameter of ovulatory follicle and ovulation rate. These same cows had blood sampled to evaluate plasma estradiol and progesterone concentrations after ECP and induction of ovulation with GnRH. Prevalence of anovular cows at 64 DIM was 27.6%, but it was similar across all treatments (P = 0.19). Pregnancy rates at 40 and 68 d after AI or pregnancy loss were not affected by timing of AI (P = 0.27) or supplementation with estradiol (P = 0.13). Delaying timed AI to 72 h and supplementation with ECP increased

the proportion of cows displaying estrus at AI ($P < 0.0001$), and cows in estrus had increased pregnancy rates ($P < 0.0001$). These results indicate that delaying the day of AI from 48 to 72 h and supplemental ECP, in spite of increasing display of estrus at timed AI, did not improve reproductive performance of lactating dairy cows at first AI.

Key Words: Dairy Cow, Reproduction, Estradiol

282 Interactions of unsaturated fat or coconut oil with Rumensin on milk fat production might be mediated through inhibition of specific protozoal genera. C. Reveneau*, S. K. R. Karnati, C. V. D. M. Ribeiro, E. R. Oelker, B. Mathew, D. R. Bae, C. M. Drow, and J. L. Firkins, *The Ohio State University*, *Columbus*.

Feeding animal-vegetable (AV) fat or medium chain FA to dairy cows can decrease rumen protozoal count. In contrast, AV fat with Rumensin (R) can promote milk fat depression (MFD), whereas diets supplemented with coconut oil (CO; rich in medium chain FA) + R were not expected to cause MFD. In a 6x6 Latin square design (2x3 factorial), 6 rumen-cannulated cows were fed with +/-R (260 mg/d) and either: control (no fat), 5% AV, or 5% CO. Diets were balanced to have 21.5% forage NDF, 16.8% CP and 42% NFC. The mixed model included fixed (diet) and random (period, cow) effects. Contrasts were the main effects of: 1) Rumensin (+R), 2) fat supplementation (control vs. AV+CO, and 3) fat source (AV vs. CO); and 4 and 5) the interactions of R with contrasts 3 and 4. Significance was $P<0.05$ for main effects and $P<0.10$ for interactions. The log10 of concentrations of total protozoa (cells/ml) were not different from control (5.97) vs. AV (5.95) but decreased by 93% with CO (4.79). *Isotricha* and *Entodinium* decreased by 99 and 97% by CO, whereas *Epidinium* was unchanged. In contrast, *Epidinium* were 67% lower for the main effect of +R and decreased 92% when AV was supplemented with R. Total VFA concentration (130 mM) was not affected by diet, but the A:P ratio decreased for CO (1.85) vs. control (2.95) or AV (2.58). The low A:P ratio was associated with a decreased total tract digestibility of NDF for CO (35.5%) vs. control (53.3%) and AV (46.5), with no difference in OM digestibility (averaging 67.9%). DMI was 5 kg/d lower with CO (15.3 kg/d) and not different for control and AV. Milk production was lower with +R (31.6 kg/d) and CO (30.3 kg/d) than AV (33.0 kg/d). MFD occurred with AV+R and CO: 1.08, 1.01, 0.71, 1.05, 0.87, and 0.74 kg/d for control, AV, CO, control+R, AV+R, and CO+R, respectively. Further analyses should elucidate the role of protozoal concentration and genera on bacterial biohydrogenation in the rumen.

Key Words: Protozoal Inhibition, Supplemental Fat, Milk Fat Depression

283 Effect of mannan-oligosaccharides on the mucosal immune system of dairy calves. V. C. Quezada*, B. B. Babatunde, and T. L. Frankel, *La Trobe University*, *Bundoora, Victoria, Australia*.

Eighteen Friesian bull calves were used to evaluate the effects of mannan-oligosaccharides (MOS) on immunity, in particular its effects on the jejunal and ileal Peyer's patches (PP) of the mucosal immune system. Pairs of age matched calves were obtained from two dairy farms over a 6 month period and were fed colostrum during the first 24 hours and commercial milk replacer (CMR) thereafter. At 2-3 days of age they were divided into groups and fed CMR only (CON) or CMR supplemented with 4 g of MOS/day. Blood samples were collected at 2-3 and 21 days of age. At 21 days of age 5-bromo-2′deoxyuridine was administered intravenously to detect cell proliferation and calves were killed 1 hour later. Samples from the jejunal and ileal PP were removed for histological examination. Paraffin embedded sections were stained to measure morphology, cell proliferation and distribution of T and B cells in the villi, follicles, domes and interfollicular areas of the PP. Data was analysed with a t-test assuming equal variances. The decrease in serum IgG from days 2-3 to 21 was significantly less in MOS (-2.7 ± 0.8 mg/ml) than CON calves (-6.9 ± 1.4 mg/ml) ($P<0.05$, $n = 8$). Height of ileal villi was greater in MOS (379.4 ± 25.1 μm) compared with that of CON calves (313.6 ± 23.8 μm) ($P<0.05$, $n = 7$). Cell proliferation in jejunal PP follicles was lower in MOS (29.4 ± 2.7 cells/mm) than CON calves (38.9 ± 3.1 cells/mm) ($P<0.05$, $n = 7$) but numbers of T cells in jejunal PP domes was greater (28.3 ± 2.5/mm vs 21.6 ± 2.6/mm, $n = 7$). In the ileum the only significant ($P<0.05$) difference in PP between MOS and CON calves was B cell numbers in the interfollicular area (24.0 ± 5.7/mm vs 44.6 ± 8.1/mm, $n = 6$). Supplementing CMR of calves from 2-21 days of age with MOS had a beneficial effect on IgG levels. The effect of MOS on the mucosal immune system appeared, through reduced cell proliferation, to reduce its rate of development but the increased T cell numbers suggest an improvement in the defense functions of the PP.

Key Words: Calves, Mannan-Oligosaccharides, Peyer's Patches

284 Effect of anion supplementation to low potassium prepartum diets on macromineral status and performance of periparturient dairy cows. J. M. Ramos-Nieves*[1], B. J. Thering[1], P. W. Jardon[2], and T. R. Overton[1], [1]*Cornell University*, *Ithaca, NY*, [2]*West Central®*, *Ralston, IA*.

Holstein cows (n=43) entering second or greater lactation were used to determine whether further supplementation of anions to low potassium (K) prepartum diets would improve periparturient macromineral status and performance. Beginning 21 d before expected parturition, cows were fed either a control diet (1.29% K, +10 mEq/100 g; n=21) or an anionic diet (1.29% K, -15 mEq/100 g; n=22) with anions provided through a combination of sulfate from calcium sulfate (0.40% S total ration) and chloride (1.17% Cl total ration) from SoyChlor$^{\$|reg;}$ 16-7 (West Central, Ralston, IA) in a completely randomized design. All cows were fed the same postpartum diet from parturition through 63 d postpartum. Feeding anions decreased overall urine pH (8.17 vs. 6.70, $P < 0.001$) during the prepartum period. Concentrations of plasma Ca tended to be increased in the two samples collected during the first 24 h postcalving (7.12 vs 7.99 mg/dL; $P < 0.07$) for cows fed the anionic diet prepartum. Overall concentrations of plasma P tended to be increased by feeding the anionic diet prepartum (5.05 vs. 5.36 mg/dL; $P < 0.09$); this effect was more pronounced during the immediate peripartal period (treatment by day, $P < 0.05$). Anionic supplementation did not affect incidence of clinical (< 5 mg/dL) and subclinical (5 - 8 mg/dL) hypocalcemia and clinical hypophosphatemia (<2 mg/dL), but subclinical hypophosphatemia (2 - 4 mg/dL) tended ($P < 0.09$) to be decreased at 16 h postcalving and was decreased ($P < 0.02$) at d 2 postpartum for cows fed the anionic diet prepartum. Anionic supplementation decreased prepartum DMI (15.6 vs. 14.4 kg/d; $P < 0.01$), but did not affect postpartum DMI (22.4 vs. 23.0 kg/d; $P = 0.36$), milk yield (46.5 vs. 46.1 kg/d; $P = 0.88$), or content and yield of milk fat and true protein. Overall, anion supplementation to low K diets improved Ca status on the day after calving and P status

during the early postpartum period, but did not affect periparturient performance.

Key Words: Cation-Anion Difference, Mineral, Dairy Cow

285 Effects of an injectable chelated mineral supplement on dairy calf performance. J. R. Crenwelge*[1], T. D. Nennich[2], B. D. Lambert[1,2], N. M. Cherry[2], and E. R. Jordan[3], [1]*Tarleton State University*, *Stephenville, TX*, [2]*Texas A&M University*, *Stephenville*, [3]*Texas A&M University*, *Dallas*.

In recent years, the use of trace mineral supplements to maximize growth or production of calves has gained the interest of researchers. Past research has found that trace mineral supplements may assist in enhancing immunity of the young, growing animals; but the role of these supplements on animal performance has varied. The overall objective of these studies was to determine the affect of supplementing a chelated injectable mineral product (MIN), containing 16 mg Cu/ml, 10 mg Mn/ml, 5 mg Se/ml, and 48 mg Zn/ml, on average daily gain (ADG), as well as blood and liver mineral concentration, of pre-weaned dairy calves. To meet the objectives, two separate studies were conducted. The first study (Study 1), a completely randomized design, included 123 Holstein heifers housed at a commercial dairy heifer operation. Treatment calves (n = 60) received an injection (1 ml) of MIN at one day of age. All calves were weighed at 3±2 and 42±3 days of age to determine ADG. Study 2 included ten Holstein bull calves, with treatment calves (n = 5) receiving an injection of MIN at 4 days of age. Blood samples and liver biopsies were collected 1 d previous to injection and 39 d after receiving the injection. In Study 1, calves were fed milk-replacer and calf starter; while in Study 2, calves were fed waste milk and calf starter. Average daily gains of calves receiving the mineral injection did not vary significantly ($P > 0.05$) from the control calves. The ADG for Control and MIN groups were 0.29 and 0.30 kg/d, and weaning weights were 49.0 and 50.1 kg, respectively. In Study 2, ADG for Control and MIN calves were not significantly different ($P > 0.05$) and averaged 0.49 and 0.50 kg/d, respectively. No significant treatment differences were observed in blood and liver mineral concentrations in Study 2. In summary, an injection of this chelated mineral product at birth did not significantly affect the ADG or blood and liver mineral concentrations of the dairy calves in these studies.

Key Words: Dairy, Calves, Chelated Minerals

286 Calcium and phosphorus balance and bone mobilization through lactation with varying dietary calcium concentrations. M. S. Taylor*[1], K. F. Knowlton[1], M. L. McGilliard[1], W. S. Swecker, Jr.[1], J. D. Ferguson[2], and Z. Wu[2], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*University of Pennsylvania*, *Kennett Square*.

The timing and extent of calcium (Ca) and phosphorus (P) mobilization from bone was evaluated through 20 wk of lactation to determine extent and timing of net resorption of bone mineral. Eighteen Holstein cows were blocked by parity, previous lactation milk yield, and calving date and randomly assigned to treatment. At calving cows began treatment diets of high Ca (1.1%, High), medium Ca (0.75%, Med), or low Ca (0.45%, low) concentration. Dietary P was 0.36% in all diets. Total collection of milk, urine, and feces was conducted 2 wk prior to calving and in wk 2, 5, 8, 11, and 20 of lactation. Blood samples were collected at -14 and -10 d prior to calving and 0, 1, 3, 5, 10, 14, 21, 28, 35, 56, 70, 84, 98, and 140 d relative to calving. Blood samples were analyzed for Ca, P, Mg, and parathyroid hormone concentration. Serum concentrations of osteocalcin (OC), a marker of bone formation, and deoxypyridinoline, a marker of bone resorption, were measured to determine bone mobilization. Rib bone biopsies were conducted within 10 d of calving and during wk 11 and 20. This was a complete randomized block design with significance declared at $P < 0.05$. Calcium retention increased until wk 11 and then decreased. At wk 20 Ca balance was 66.7, 40.8, and 25.5 g/d for the High, Med, and Low diets, respectively. Phosphorus balance increased until wk 20 and then decreased. Feces Ca and P excretion were higher in multiparous than in primiparous cows (153.3 vs.128.9 g Ca/d; 58.0 vs.44.8 P g/d). Serum P was lower in multiparous than in primiparous cows (4.9 and 5.4 mg/dl). Serum Ca and P were not affected by treatment. Primiparous cows had higher serum OC concentrations than multiparous cows (68.3 vs.43.2 ng/ml). Week affected urine Ca and P excretion, feces Ca and P excretion, serum P, Mg, and OC concentration. Primiparous cows appear to be building more bone regardless of dietary treatment. This information may help refine dietary mineral recommendations and ultimately reduce their excretion.

Key Words: Calcium, Bone, Cows

287 Ovulation and CL development in mature cows given pLH or GnRH. T. O. Ree*[1,2], M. G. Colazo[3], D. J. Ambrose[3,2], A. G. A. Lamont[2,3], J. P. Kastelic[4], M. K. Dyck[2], R. J. Mapletoft[5], and B. N. Ametaj[2], [1]*Lakeland College*, *Vermilion, AB, Canada*, [2]*University of Alberta*, *Edmonton, AB, Canada*, [3]*Alberta Agriculture and Food*, *Edmonton, AB, Canada*, [4]*Agriculture and Agri-food Canada*, *Lethbridge, AB, Canada*, [5]*University of Saskatchewan*, *Saskatoon, SK, Canada*.

The effects of porcine LH (pLH) versus GnRH on ovulatory response (OR) during diestrus and proestrus, and on corpus luteum (CL) development were examined. In Expt 1, nonlactating cows (24 dairy, 51 beef) were given a progesterone (P4; 1.9 g) insert (CIDR) for 10 d and 500 µg cloprostenol (Estrumate; PG) at CIDR removal. Estrus detection (estrus=D0) was done 3x/d for 5 d. On D5 follicles (>8mm) were ablated. On D12, cows received, in a complete random design, 25, 12.5 or 8 mg pLH (Lutropin-V), or 100 µg GnRH (Fertiline; n=18 or 19/group), at which time plasma P4 was 5.6±0.2 ng/mL (mean±SEM; no effect of group). Ovulation was determined by ultrasonography at 27, 48 and 72 h. The OR to 25 mg pLH (84%) or GnRH (72%) was higher ($P<0.05$) than to 8 mg pLH (32%); OR to 12.5 mg pLH tended to be lower ($P<0.07$; 58%) than to 25 mg pLH. In Expt 2, 68 cows were given PG 2x, 10 d apart. Estrus was detected as in Expt 1, and on D7, cows were given PG; 36 h later (P4=0.3±0.05 ng/mL; no effect of group), they were given pLH or GnRH as in Expt 1 (17 cows/group). Ovulation was determined at 27, 36, 48, and 72 h. In a subset of 17 cows, blood (for P4) and CL data were collected every 48 h for 14 d. Data were analyzed using Proc FREQ (chi-square) or MIXED (repeated measures) in SAS. All cows ovulated; interval from treatment to ovulation did not differ among groups, but was most variable ($P<0.01$) in cows given 8 mg pLH (28.1±0.7, 29.1±1.0, 33.5±2.8, and 29.1±1.0 h for 25, 12.5, or 8 mg pLH and GnRH, respectively). Although CL area (mm^2) was larger ($P<0.02$) in cows given 25 mg pLH (301.5±22.6) or GnRH (305.2±22.6) than those given 8 mg pLH (222.1±22.7), it did not differ from 12.5 mg pLH (260.8±20.3). Mean

plasma P4 was higher (P<0.04) in cows given 25 mg pLH (3.5±0.3) or GnRH (3.8±0.3) than those given 8 mg pLH (2.4±0.3); P4 was lower with 12.5 mg pLH (2.6±0.3) than with GnRH (P<0.02), and tended (P<0.07) to be lower than with 25 mg pLH. In summary, cows given 25 mg pLH or 100 µg GnRH had greater OR, CL area, and plasma P4 than those treated with 8 mg pLH; 12.5 mg pLH gave intermediate responses. A dose of 8 mg pLH was not consistently effective for synchronizing ovulation in mature cows.

Key Words: Porcine LH, GnRH, Ovulatory Response, CL Development

288 Early postpartum biochemical and management characteristics related to dairy cow removal. C. S. McConnel*, S. M. Hiibel, J. A. Kidd, A. E. Hill, and F. B. Garry, *Colorado State University*, *Fort Collins*.

A large proportion of dairy cow death is concentrated within the early postpartum period. Detection of discriminating characteristics within this period may be useful for defining cows at risk for premature removal from a herd. This nested case-control study explored the value of analyzing standard biochemistry and management characteristics of early postpartum cows in determining features related to removal (death and culling). Serum was collected from cows at 3 to 5 days postpartum on two intensive, Colorado dairies. Biochemistry panels for 47 cows that were removed from the dairies within 30 days of parturition (cases) were compared with herd cohorts surviving through 100 days in milk (controls), matched by calving date and lactation. Wilcoxon signed-rank test analysis demonstrated that levels of calcium, total protein, albumin, total bilirubin (TB), creatine kinase (CK), aspartate aminotransferase (AST), potassium, and anion gaps differed significantly between cases and controls (P<0.05). Associations between dairy cow removal and biochemical (19) and animal management characteristics (4) were evaluated univariately via a Chi-square test. Ten variables with P<0.15 were selected for ordinal logistic regression analysis. Stepwise backward and forward selection resulted in four significant variables (P<0.1): TB, CK, AST, and drench administration. The odds of removal were 3.3, 2.8, and 5.7 times higher among cows with elevated levels of TB, CK, and AST. The odds of removal were 5.7 times higher among cows that were assessed to need systemic treatment in the form of a drench. Appropriate fresh cow management may be guided through adjunctive biochemical analysis, highlighting areas that require modification in an effort to improve postpartum health, such as transition cow and calving management, post-partum cow-side evaluation, and therapy protocols. Similarly, fresh cow assessment that recognizes discriminating systemic characteristics (as evidenced by the application of a drench in this study) may provide insight into useful modifications for individual sick cow management.

Key Words: Dairy, Removal, Biochemistry

289 Effect of dietary energy and metabolizable protein in lactating dairy cows. A. G. Rius*, M.L. McGilliard, and M.D. Hanigan, *Virginia Polytechnic Institute and State University*, *Blacksburg, VA, USA*.

The objective of the study was to test NRC (2001) model predictions of energy and protein requirements for the dairy cow. We hypothesized that energy and protein have additive effects on production as opposed to the independent limiting effects assumed by the NRC. A complete randomized design in a 2x2 factorial arrangement was used with high and low energy (1.55 [HE] or 1.44 [le] Mcal NEL/kg DM) and RUP (6.5 [HP] or 4.5% [lp] RUP). Multiparous Holstein (n=32) and Jersey by Holstein cross-bred (n=8) cows were randomly assigned to one of the four dietary treatments (HEHP, HElp, leHP, and lelp). A common diet (HEHP) was fed from d 1 through 21 followed by the respective treatment diets from d 22 to 40. Diets were formulated for CP contents of 17.0 or 14.4%, and a constant RDP content of 10.4% using the NRC model. Feed intake, milk yield and body weight were measured daily. Milk composition and BCS was measured on weeks 3 and 7. The Proc Mixed procedure of SAS was used to test the main effects and their interactions. Milk yields were not significantly affected by treatment however, there was a tendency (P<0.09) and the LSM were 35.0, 33.5, 31.3 and, 26.8 kg/d for HEHP, HElp, leHP, and lelp respectively (SEM=2.4). Although milk yields were significantly different (P< 0.05) for the average of HElp and leHP vs lelp (5.6;SEM=2.8), there was no difference (P< 0.41) between HEHP vs the average of HElp and leHP (2.5; SEM=3). Milk protein yields were significantly affected by treatment (P< 0.05) with LSM of 1.09, 1.01, 0.92 and, 0.88 kg/d; (SEM=0.06). The DMI was significantly affected by treatment (P< 0.05) with LSM of 25.2, 25.0, 25.6, and 23.1 kg/d (SEM=0.69) for HEHP, HElp, leHP, and lelp treatments, respectively. Non-fat milk solids yields tended to be lower (P< 0.08) when dietary energy was limiting with LSM of 3.11, 2.97, 2.68, and 2.42 kg/d (SEM=0.04). The results indicate that lower RUP diets can be fed with high energy diets without compromising milk production whereas the combination of low energy and low RUP significantly depressed milk and milk protein yields.

Nonruminant Nutrition: Poultry Nutrition - Gut Health and Early Nutrition

290 Maternal dietary conjugated linoleic acid causes embryonic mortality in the absence of vitelline membrane disruption. V. A. Leone*[1], R. Aydin[2], D. Stransky[1], and M. E. Cook[1], [1]*University of Wisconsin*, *Madison*, [2]*Kahramanmaras Sutcu Imam University*, *Kahramanmaras, Turkey*.

We have previously shown that conjugated linoleic acid (CLA) fed to the laying hen in a low-fat diet reduced hatchability when eggs were stored at 4°Celsius (C) for 24 hours. Mineral analysis of yolk and albumin of eggs from CLA-fed hens stored at 4°C for 10 weeks showed a significant change in mineral composition of Ca2+, Mg2+, Fe3+, Na+, Cl- and Zn2+ compared to eggs from control-fed hens. This suggests cooling CLA-containing eggs causes disruption of the vitelline membrane, altering mineral balance, and reducing hatchability. An experiment was performed to determine if maternal CLA-feeding reduced hatchability in the absence of vitelline membrane disruption. Hens (24) were assigned to diets containing 1% Corn Oil (CO) or 1% CLA-80 (40% c9, t11 and 40% t10, c12 isomers), and were artificially inseminated once weekly beginning one week prior to the onset of experimental feeding. Eggs were collected daily and placed directly in the incubator. Production, fertility, and hatchability were recorded.

Eggs were candled daily, and eggs that candled clear or early dead were further assessed. Day of embryonic mortality was recorded (expressed as embryonic days of survival). Production and fertility were not altered by CLA. Hatchability fell to 0% after 15 days of CLA-feeding, while control stayed at 80%. Over a 3-week assessment period of embryonic survival, average days of embryonic survival from the CLA group diminished to 16.68 days, while the CO group stayed at 20.78 (21 days of survival results in a hatched chick) during the second week of feeding. During the third week, average days of embryonic survival from the CLA treatment was reduced to 6.33 days, while CO was at 19.77 days. This suggests that without the disruption of the vitelline membrane, embryonic days of survival and hatchability were still significantly reduced by maternal feeding of 1% CLA in comparison to control-fed hens. Further studies are needed to assess the causes of embryonic mortality seen in the presence of CLA, without the artifact of vitelline membrane disruption.

Key Words: Conjugated Linoleic Acid, Embryonic Mortality, Vitelline Membrane

291 Gluconeogenesis and carbon utilization in day 20 chicken embryos supplemented *in–ovo* with glucose and amino acids. N. E. Sunny*, J. Adamany, S. L. Owens, and B. J. Bequette, *University of Maryland*, *College Park*.

Late–term chicken embryos undergo a dramatic metabolic transition from maintaining high rates of gluconeogenesis *in–ovo* from amino acids and triglyceride–glycerol to maintaining high rates of lipogenesis ex–ovo from dietary carbohydrates and amino acids. The aim of this study was to quantify gluconeogenesis and glucose carbon utilization in small and large egg embryos (d 20) supplemented *in–ovo* with nutrients. Groups of small (n = 5 to 8; 54 to 58 g) and large (n = 5 to 8; 66 to 70 g) eggs were randomly dosed into the amniotic fluid on d 9 embryonic with either sterile water (200 µL, C), glucose (100 mg in 200 µL, G), an amino acid mixture (100 mg in 200 µL, AA) or a mixture of glucose and amino acids (50 mg of each in 200 µL, G+AA). Beginning on d 17 embryonic, each egg was given a daily dose of [U-^{13}C]glucose (15 mg/d in 75 µL water) into the amniotic fluid followed by tissue and blood collection on d 20. Blood was analyzed by mass spectrometry for ^{13}C–mass isotopomer distribution in glucose, alanine, aspartate and glutamate. Embryonic weights on d 20 were lower ($P \leq 0.001$) for the small vs. large eggs, and *in–ovo* nutrient treatment did not affect weights in either group (small: C 31.8, G 31.6, AA 31.3, G+AA 32.7 g; large: C 36.8, G 36.8, AA 37.1, G+AA 38.1 g). Despite differences in embryo weights, absolute rates of gluconeogenesis (0.72 ± 0.184 g/d) and glucose carbon recycling (59 ± 0.051 %) were similar between small and large eggs, and in–ovo nutrient supplementation did not affect these glucose fluxes. However, the contribution of glucose carbon to alanine flux was greater ($P = 0.002$) for the C (36 ± 0.042 %) and G (40 ± 0.045 %) treatment groups compared to the AA (25 ± 0.040 %) and G+AA (20 ± 0.034 %) treatment groups. In summary, *in–ovo* supplementation of AA or a mixture of G plus AA reduced glycolysis and the entry of glucose carbon into Krebs cycle metabolic pathways, irrespective of embryonic size.

Key Words: Gluconeogenesis, Embryo, Metabolism

292 Changes in the late term turkey embryo metabolism due to *in ovo* feeding. J. E. de Oliveira*[1], P. R. Ferket[1], C. M. Ashwell[1], Z. Uni[3], and C. Heggen-Peay[2], [1]*North Carolina State University*, *Raleigh, NC*, [2]*PAH-Embrex*, *Durham, NC*, [3]*Hebrew University of Jerusalem*, *Rehovot, Israel*.

Microarray technology has been shown to be an effective method to evaluate changes in gene expression of carbohydrate and lipid metabolism during embryonic development of turkeys. This research revealed that the embryo switches from lipid metabolism to carbohydrate (CHO) metabolism fueled by gluconeogenesis around day 22 of incubation (E), and that the liver is very active producing and utilizing glycogen almost simultaneously from E24 until hatch. These results were then used to formulate an in ovo feeding (IOF) solution hypothesized to promote CHO metabolism of late-term turkey embryos. Viable Nicholas turkey eggs of similar weights (85.2 g ± 10) were in ovo fed a 0.4 ml nutritive solution at E24. Liver samples were collected from 16 eggs each from IOF and control treatment-groups at E25, E26 and E28 (hatch), and RNA was isolated for microarray evaluation. The arrays were spotted with 300 genes selected to represent several aspects of general metabolism. At each day of incubation, the expression of several genes were significantly ($p<0.01$) different among the treatment groups. The IOF treatment clearly altered the expression of genes related to energy metabolism and growth, which may help to explain positive effects of *in ovo* feeding on hatchability, development, and growth of poults.

293 *In ovo*-fed lactose augments small intestinal surface and body weight of 3 day-old turkey poults. D. V. Bohórquez*, A. A. Santos Jr., and P. R. Ferket, *North Carolina State University*, *Raleigh*.

Avian neonatal development relies on nutrient digestion and absorption, which is integral to gut function and morphological development. Lactose, an indigestible disaccharide in poultry, and *Spirulina pacifica* may stimulate compensatory morphological development of the gut epithelium in poults. *Spirulina pacifica* is an alga that provides protein (65%), carbohydrates (20%), fat (7%) and minerals (5%). Three hundred Nicholas turkey eggs were weighed and equally distributed among 3 treatments: 1) Non-injected CONTROL, 2) Lactose-hydrate (LAC) (9% of solution) and 3) Spirulina pacifica + Maltodextrin (Sp+M) (1.4% and 10% of the solution respectively). Using Inovoject® V2303 (Embrex, Inc.), 1.5ml LAC and Sp+M solutions were injected into the amnion of turkey embryos at 22d of incubation (22E). Upon hatching, poults were fed a corn/SBM-based diet that met or exceeded the NRC recommendations up to 3d of age. Body weight (BW) was determined at 1 and 3d of age. At 1d, ileum histomorphometry (10 villi/bird) was assessed (10 poults/treatment). Villus measurements were: height (VH), apical width (VAW), basal width (VBW), crypt depth (CD), muscularis depth (MD) and mucosal height (MH). Villus height-crypt depth ratio (V:C) and apparent villus surface area (VS) were also calculated. BW was improved at 1d by both treatments (Sp+M and LAC) as compared to control (66.0, 65.5 vs 64.3g, $P<0.1$, respectively), yet only LAC maintained significantly higher BW at 3d (90.8 vs 85.7g, $P<0.05$). In ovo Sp+M feeding did not significantly affect histomorphometrical measurements. In contrast, in ovo LAC significantly increased VH (142.0 vs 119.8µm, $P<0.01$), MH (183.3 vs 162.4µm, $P<0.01$), V:C (3.45 vs 2.87µm:µm, $P<0.01$) and enlarged VS by 18% (4846 vs 3963µm^2, $P<0.01$) compared to the control at 1d. *In ovo*-fed lactose enhanced intestinal development by decreasing cell

turnover (higher V:C) and expanding intestinal surface area, which may boost nutrient absorption and bird performance.

Key Words: Turkeys, *In ovo*-fed Lactose, Intestinal Development

294 Development of an automated delivery system for *in ovo* feeding of turkey embryos. C. L. Heggen-Peay*[1], M. Garrell[1], V. W. Doelling[1], and P. R. Ferket[2], [1]*PAH-Embrex*, *Durham, NC*, [2]*North Carolina State University*, *Raleigh, NC*.

The turkey industry experiences up to 5% poult mortality losses due to starve out. Many of these poults have insufficient energy reserves left after hatch to sustain them through the first few days until they initiate feed intake and develop adequate digestive capability. *In ovo* feeding administers a nutritional formulation to embryos prior to hatch to provide substrates and co-factors that stimulate carbohydrate metabolism and intestinal development. To deliver *in ovo* feeding to turkey embryos on a large scale, an automated delivery system was developed. Injection studies were conducted to optimize the system for amnion targeting in embryonated turkey eggs at 22, 23, and 24 days of incubation (E). In each study, approximately 100 viable eggs/treatment were injected with Coomassie blue dye using an automated *in ovo* delivery system, embryos were immediately euthanized, and eggs were necropsied to evaluate site of injection. Eggs from both the Nicholas and Hybrid breeds were assessed. With Nicholas eggs, very good amnion targeting was achieved at both E24 (96.0% using a 20 gauge 1.125″ needle) and at E23 (90.5% using a 20 gauge 1.25″ needle). Successful amnion targeting in Nicholas eggs was not achieved at E22. In Hybrid eggs, excellent amnion targeting was achieved at E23 (97.8% using a 20 gauge 1.25″ needle) and E24 (96.1% using a 20 gauge 1.25″ needle). These results support optimization of an automated *in ovo* delivery system for amnion targeting in turkey eggs.

Key Words: Turkey, Amnion, *In ovo*

295 Evaluation of microbiota populations and intestinal development of different genetic lines of chickens. B. S. Lumpkins*, A. B. Batal, and M. D. Lee, *University of Georgia*, *Athens*.

The gastrointestinal tract (GIT) provides an environment for a large and diverse population of intestinal microbiota, which is unique among animal species. In the poultry industry, producers use different genetic lines of chickens with varying rates of development based on their production goal, but little is known about how the microbiota community relates to the genetic lines of chickens based on the varying rates of development. Therefore, a 35 d experiment was conducted to observe and evaluate the changes in the microbiota populations and GIT development of Cobb 500, Ross 708, and Athens Canadian Random bred (ACR) chicks. All birds were fed a standard non-medicated corn-soybean meal diet ad libitum from 0 to 35 d of age. Intestinal measurements and bacterial analysis of the jejunum and ileum were conducted at 4, 7, 14, 21 and 35 d of age. The bacterial DNA was isolated from the digesta, and denaturing gradient gel electrophoresis (DGGE) and terminal restriction fragment length polymorphism were used to examine PCR amplified fragments of 16s ribosomal DNA. Cobb chicks performed the best from 0 to 14 d of age; however, the overall performance was similar for Cobb and Ross chicks. The ACR chicks had the worst performance at all periods measured. The overall relative weight of the jejunum and ileum was not different between the 3 genetic lines, but the ACR chicks had longer relative jejunum and ileum lengths compared to the Cobb and Ross chicks from 0 to 35 d. Furthermore, the Cobb chicks had the longest villi height, while the ACR chicks had the shortest villi height in the jejunum and ileum at all measuring periods. Based on DGGE, the Cobb and Ross chicks had similar microbiota communities at similar ages. Regardless of the genetic line of chicks the microbiota populations changed with age. The performance, GIT measurements, and microbiota population of the Cobb and Ross chicks were similar, while the ACR GIT measurements and microbiota community differed. The results indicate that the different genetic lines have varying rates of intestinal development, which impact performance and the microbiota community.

Key Words: Microbiota, Gastrointestinal Tract, Genetic Lines

296 Effects of diet type, enzyme addition and *Clostridium perfringens* challenge on growth performance and gut health of broiler chickens. W. Jia*[1], B. A. Slominski[1], H. L. Bruce[2], G. Blank[1], and O. Jones[3], [1]*University of Manitoba*, *Winnipeg, Canada*, [2]*Maple Leaf Food Agresearch*, *Burford, Canada*, [3]*Canadian Bio-Systems Inc.*, *Calgary, Canada*.

The effects of diet type (corn- vs wheat-based), enzyme addition (none or multi-carbohydrase preparation at 0.2 g/kg diet) and oral challenge with *Clostridium perfringens* (none or 10^9 CFU/bird on day 13) on growth performance, digesta pH and viscosity, *C. perfringens* intestinal population and gut lesion score (from 0 to 4 where 0 = no gross lesions, 4 = severe extensive necrosis) were studied in a 40-day experiment with broiler chickens. A total of 1216 male Ross-308 chickens was assigned to 8 dietary treatments in a randomized complete block design providing 8 replicate pens per treatment. Diets were formulated to meet protein requirement of NRC but were suboptimal in energy level. When compared with corn, birds fed wheat-based diets had inferior weight gain (55.0 vs 58.4 g/bird/day) and feed efficiency (1.71 vs 1.62 g feed/g gain). Pathogen challenge significantly ($P<0.05$) impaired growth performance and increased *C. perfringens* population in the gut and intestinal lesion score. Increased digesta *C. perfringens* counts (2.4 vs 1.5 CFU/g) and intestinal lesion score (0.9 vs 0.4; $P<0.01$) were observed for challenged birds fed wheat-based diets. No difference in digesta pH was found among the treatments. Enzyme addition resulted in increased weight gain (59 vs 56 g/bird/day; $P<0.01$) in challenged birds fed corn-based diets; whereas in those fed wheat-based diets, enzyme supplementation improved feed efficiency during the grower-finisher phase (1.9 vs 2.0; $P<0.01$). A significant reduction in digesta viscosity (from 4.1 to 2.7 mPa.s; $P<0.01$) was observed in birds fed enzyme-supplemented wheat-based diets. In conclusion, enzyme addition had beneficial effect on growth performance and minimized the negative effect of *C. perfringens* challenge.

Key Words: Broiler Chicken, Enzyme, *Clostridium perfringens*

297 The effect of dietary sinapic acid on the gastrointestinal tract microbial fermentation, nutrient utilization and egg quality of laying hens. M. Johnson*, A. A. Olkowski, and H. L. Classen, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

Plant based simple phenolics, such as sinapic acid, are natural antimicrobial and antioxidant compounds. As such, they have potential to modulate gastrointestinal tract (gut) microorganisms to influence

performance and also influence the quality of food products when fed to food animals. An example of a simple phenolic that might be found in poultry diets is sinapic acid, which is the predominant simple phenolic acid found in canola meal. Sinapic acid has previously been shown to improve nutrient retention and affect gut microbiota in broiler chickens, and also to have bactericidal activity against *Salmonella enterica* subsp. *enterica in vitro*. Therefore it was of interest to investigate the impact of dietary sinapic acid in laying hens. Two experiments were conducted to investigate the impact of dietary sinapic acid on fermentation patterns of laying hen gut microbiota as judged by volatile fatty acid (VFA) level, energy and protein retention, and the deposition of sinapic acid in eggs. In trial one, hens were randomly assigned to groups of ten that were fed diets containing 0, 0.025, 0.050 or 0.075% sinapic acid for a total of 4 weeks. Dietary sinapic acid in trial one did not affect jejunal, ileal or cecal VFA level, energy and protein retention or any production trait. Sinapic acid was not found in eggs. To determine if a higher level of sinapic was required to cause an effect, the second trial used twenty hens to compare the effect of 0 and 0.5% dietary sinapic acid. Sinapic acid inclusion again failed to affect gut VFA levels. However, sinapic acid increased both the retention of energy (AME) and protein in comparison to the un-supplemented diet. Feeding sinapic acid also resulted in low levels being found in the yolk and albumen of eggs. The results indicate that dietary sinapic acid can affect laying hens and the nature of eggs, but more research is required to understand the influence of dietary inclusion level.

Key Words: Hen, Sinapic Acid, Aanola Meal

298 The use of natural antibiotic alternative and growth promoter feed additives and subsequent effects on broiler performance and carcass quality. N. P. Buchanan*[1], J. M. Hott[1], S. E. Cutlip[1], A. L. Rack[1], A. Asamer[2], and J. S. Moritz[1], [1]*West Virginia University*, *Morgantown*, [2]*Delacon International*, *Steyregg, Austria*.

The use of subtherapeutic levels of antibiotics in poultry feed improves performance and morbidity in broilers. However, consumer pressure has resulted in the development of natural feed additives that may also improve broiler performance and morbidity. Past research has shown that phytogenic feed additives containing essential oils, herbs, spices, and organic acids may enhance the production of gastric secretions, stimulate blood circulation, and accelerate cell osmosis of pathogenic bacteria. The objective of the current study was 1) to assess the use of Biostrong 505+ as a natural alternative to subtherapeutic antibiotics in broiler diets, 2) to assess the use of Biostrong 510 as a natural growth promoter and 3) to determine the effect of Biostrong 505+ and 510 on performance and carcass quality of broilers. One thousand three hundred forty four Cobb 500 broiler chicks were obtained from a commercial hatchery at 1 day of age. Three-phase feeding (starter, grower, finisher) was utilized for the 0-18, 19-30, and 31-40 day periods. Starter diets were fed as crumbles. Grower and finisher diets were fed as pellets. Broilers were reared on built-up litter. Experimental diets consisted of two diet formulations (Cobb maximum yield or least cost) arranged in a factorial design with two inclusions of either Biostrong 505+ (0 or 0.025%) or 510 (0 or 0.015%). The maximum yield diet improved live weight gain, feed conversion, carcass weight, and breast yield for broilers in the 505+ group (P≤0.05). The maximum yield diet improved carcass weight and breast yield for broilers in the 510 group (P≤0.05). Inclusion of either Biostrong 505+ or 510 improved feed conversion (P=0.0109, P=0.0438). In addition, the inclusion of Biostrong 505+ improved breast yield (P=0.0577). Biostrong 505+ or 510 may be viable natural alternatives to use of subtherapeutic antibiotics and growth promoters, respectively.

Key Words: Antibiotics, Phytogenic Feed Additive, Broilers

299 Evaluation of different additives in chicks challenged with necrotic enteritis. J. L. Shelton[1], A. R. Garcia[1], S. W. Davis[2], and D. W. Giesting*[1], [1]*Cargill Animal Nutrition*, *Elk River, MN*, [2]*Colorado Quality Research*, *Wellington, CO*.

Two experiments (EXP) were conducted at Colorado Quality Research to determine the effect of additives on growth in chicks challenged with Necrotic Enteritis (NE). Both EXP were conducted using floor pens and chicks were housed from hatching to 42 d. Initial and final body weight (BW) were 42 and 2,625 g for EXP 1 or 40 and 2,619 g for EXP 2. Feed intake and BW were measured weekly and chicks had ad libitum access to feed and water. Chicks were inoculated through the feed with coccidia (*E. acervulina*, *E. maxima*, and *E. tenella*) on d 9 and then with*Clostridium perfringens* on d 14 to d 16. Lesion scores (LS) were measured on d 16. Treatments included an unchallenged negative control (NC, no additives), a challenged NC, and a challenged positive control (virginiamycin, Vm). The additives tested in these EXP were *Bacillus* (B), a plant extract (PE), mannan oligosaccharide (M), a prebiotic added at a high (PREH) or a low (PREL) level. In EXP 1, d 21 BW was higher ($p < 0.05$) for chicks fed Vm or B+PREH and LS was lower ($p<0.05$) for chicks that were unchallenged or fed Vm, B+PREH, PE+M relative to the NC. Overall, chicks fed Vm, B+PREH, PE+M, or B+PE+M had lower ($p<0.05$) mortality relative to the NC. In EXP 2, different additive feeding programs were tested. They were: 1) feeding one level of additives for 42 d or 2) feeding one level of additives through the challenge period (d 21) and then a lower level for the remainder of the EXP. Chicks that were unchallenged or fed any of the test diets had reduced ($p < 0.05$) LS relative to those fed the NC. However, addition of Vm had no effect on growth. Overall, birds fed the 4-way combination of B+PE+PREL+M fed using feeding program 2 had increased ($p< 0.05$) gain:feed relative to the NC. Results from these trials indicate that combining additives with different modes of action could improve performance in chicks challenged with NE. Reducing the levels of additives after the starter period could be beneficial to chick performance and reduce additive costs.

Key Words: Chick, Necrotic Enteritis, Additives

300 Dietary *Bacillus subtilis* C-3102 spores influence intestinal (excreta) populations of Lactobacilli, *Clostridium perfringens*, Enterobacteriaceae (coliforms), and Salmonella, and live performance of broiler chickens. M. Kato[1], N. Otomo[1], K. Nishimura[2], Y. Tadano[3], T. Marubashi[3], H. Miyazaki[3], K. Maruta[3], and D. M. Hooge*[4], [1]*Calpis USA, Inc.*, *Schaumberg, IL*, [2]*Quality Tech. Int'l, Inc.*, *Elgin, IL*, [3]*Calpis Co. Ltd*, *Tokyo, Japan*, [4]*Hooge Consulting Service, Inc.*, *Eagle Mountain, UT*.

Intestinal Lactobacilli (Lac) counts and Lactobacilli/total anaerobes (Lac/TA%; 50% or more being optimal) are important in relationship to broiler performance and pathogen loads. CALSPORIN® (Calpis Co. Ltd, Tokyo, Japan) contains *Bacillus subtilis* C-3102 (Bs) aerobic spores which vegetate in digesta and consume oxygen causing proliferation of native colonizing, facultatively anaerobic Lactobacilli

to help improve bird performance and reduce pathogen loads. In Exp. 1 in southern Japan, Bs was added to all broiler feeds (0 or $3x10^5$ CFU/g), and excreta collected at 2 ages. At 14 d, in the Bs flock Lac increased ($P<0.05$) and Salmonella were not detected vs 4.97 Log10 CFU/g excreta in the negative control flock. At 49 d, *Clostridium perfringens* (3.22 vs 2.66 Log10 CFU/g excreta; $P<0.05$) and Salmonella (4.07 vs 3.31 Log10 CFU/g excreta, $P<0.01$; 20/20 vs 10/20, $P<0.05$) were reduced in the Bs flock. Two trials were conducted at a US broiler company to compare Bs fed flocks vs previous antibiotic growth promoter (AGP; for necrotic enteritis prevention) fed flocks. Excreta was collected at 35 d. In Exp. 2, Lac ($P<0.001$) and Lac/TA% (22.9% vs 52.2%; $P<0.05$) were higher and Enterobacteriaceae (coliforms) lower ($P<0.01$) in Bs birds. Livability was higher and farm condemnations lower in 7 Bs flocks vs 4 previous AGP flocks ($P<0.01$), and caloric conversion was lower in 7 Bs flocks vs 902 simultaneous flocks ($P=0.014$). In Exp. 3a, Lac ($P<0.001$) and Lac/TA% (21.2 vs 58.5%; $P<0.01$) were higher in Bs birds. In Exp. 3b (same control as Exp. 3a), Lac ($P<0.001$) and Lac/TA% (21.2% vs 54.8 and 59.5%; $P<0.001$) were higher and *Clostridium perfringens* lower ($P<0.05$) in Bs birds. The Bs C-3102 flocks had higher intestinal (excreta) Lac or Lac/TA%, lower pathogen counts, and/or improved performance, compared to simultaneous (or previous) negative control or AGP flocks.

Key Words: Bacillus Subtilis C-3102, Lactobacilli, Pathogens

301 Effect of synbiotic feed additive in comparison to antibiotic growth promoter on performance and health status of broilers. M. Mohnl*[1], Y. Acosta Aragón[1], A. Acosta Ojeda[2], B. Rodríguez Sánchez[2], and S. Pasteiner[1], [1]*BIOMIN GmbH*, *Herzogenburg, Austria*, [2]*Instituto de Ciencia Animal*, *San José de las Lajas La Habana, Cuba*.

The present trial was conducted to evaluate the efficacy of a synbiotic product in comparison to a commonly used AGP (antibiotic growth promoter) on broiler performance during a 42 day study. 525 one-day-old male chicks (Cuban hybrid EB 34) were randomly distributed to 3 experimental groups with 7 replicates per group and 25 animals per replicate. Experimental groups included a non-treated control group, a group which received a synbiotic product (Biomin® PoultryStar) via the drinking water on the first three days and for three consecutive days at each feed change and an AGP group which received Avilamycin (40 ppm) via the feed. The animals were fed a standard corn-soy ration in a three diet feeding program (starter (1- 14), grower (15- 28), finisher (29- 42)). Feed and water were provided at libitum. The birds were kept under observation for 42 days and performance parameters like body weight and feed intake were measured weekly. Furthermore daily weight gain and feed conversion ratio (FCR) were calculated. Clinical inspections and necropsies were conducted and mortality was registered daily. After 42 days body weight and FCR of birds which received the synbiotic product or the AGP were significantly higher ($P<0.05$) and feed intake was lower when compared to control group. Synbiotic group and AGP group increased body weight by 2.04% and 1.99% respectively in comparison to control. Mortality could be reduced in treatment groups in comparison to control (control group: 2.8%, synbiotic group: 0.9%, AGP group: 0.9%). In the present study the synbiotic product had a comparable potential to improve broiler performance as Avilamycin and might therefore be a promising alternative to the use of AGPs in broiler production.

Key Words: Synbiotic, Antibiotic Growth Promoter, Broiler Performance

Nonruminant Nutrition: Poultry Nutrition - Breeder and Laying Hen Nutrition and Broiler Environment

302 The effect of feed restriction programs and growth curves on reproductive performance, stress and metabolism in broiler breeder hens. M. de Beer*[1], J. P. McMurtry[2], D. M. Brocht[2], and C. N. Coon[3], [1]*Aviagen*, *Huntsville, AL*, [2]*USDA-ARS*, *Beltsville, MD*, [3]*University of Arkansas*, *Fayetteville*.

An experiment was conducted to compare everyday (ED) and skip-a-day (SK) feeding programs and early slow growth (SLOW) and broilerized (BROIL) treatments. Feed restriction programs were implemented from 4 weeks to 5 % production. The SLOW group was fed to reach 75 % of standard BW by 12 weeks, and then to reach standard BW by 21 weeks. The BROIL group was fed *ad libitum* till 7 weeks and then severely restricted to reach standard BW by 21 weeks. Parameters measured included BW, uniformity, age at sexual maturity (SM), total and settable egg production, body composition, liver size and composition, *in vitro* lipogenesis (IVL), metabolic hormone levels and heterophil to lymphocyte ratio (H/L). The trial period lasted 45 weeks. Birds fed ED grew more efficiently than SK or SLOW. The BROIL treatment had significantly worse feed utilization than all other groups. Frame size was consistently greater in BROIL pullets and consistently smaller in SLOW pullets. Birds fed ED reached SM before SK, who in turn reached SM before SLOW or BROIL birds. Egg production was significantly higher in ED than SK, which in turn was higher than either SLOW or BROIL. Liver weight and IVL was elevated in SK and SLOW pullets above ED pullets during rearing. Liver weight and IVL were lower in BROIL pullets than other groups during rearing, but after photostimulation dramatic increases in liver weight and IVL resulted in this trend being inverted by 27 weeks. As an indicator of stress, H/L ratios were elevated above ED pullets in SK, SLOW and BROIL pullets at various times during rearing. Corticosterone and T3 levels were elevated in SK and SLOW birds during rearing. IGF-1 was higher in ED than SK birds during rearing. Feeding regimens and growth curves have a major influence on efficiency, metabolism and reproductive performance in broiler breeders.

Key Words: Broiler Breeder, Growth Curve, Metabolism

303 Effects of feeding programs during rearing on carcass fatty acid profiles and serum α_1 acid glycoprotein levels in broiler breeder hens. M. de Beer*[1] and C. N. Coon[2], [1]*Aviagen Inc*, *Huntsville, AL*, [2]*University of Arkansas*, *Fayetteville*.

Skip-a-day feeding programs are widely employed during rearing to improve pullet uniformity. An experiment was conducted to determine the effect of everyday and skip-a-day feeding programs on fatty acid (FA) composition and serum α_1 acid glycoprotein (AGP) levels of broiler breeder hens. A total of 420 day old broiler females were randomly assigned to 12 pens at 35 chicks per pen. Chicks were full fed to 10 days, and then fed restricted amounts of feed everyday until 28 days. At 28 days, 6 randomly selected pens were changed to skip-a-day (SK) feeding while the other 6 were fed everyday (ED). The diet and total feed allocation was identical for both ED and SK pullets throughout the trial. At 20 weeks of age 8 pullets from each group were killed. All birds were fed ED after 25 weeks of age. At 40 weeks, a further 8 birds from each group were killed. Abdominal fat samples were obtained from each of the killed birds and analyzed for FA composition. Further, blood samples were obtained from 16 birds from each group at 40 weeks of age. Plasma samples were analyzed for AGP levels using a commercially available radial immuno-diffusion tray. Data was analyzed by ANOVA procedures using JMP 6.0 and means were separated using student's T-test. At 20 weeks SK birds had higher levels of C16:1 and C20:0 than ED birds. ED birds had higher levels of C18:2, C18:3, C20:2, C20:3 and C20:4. Mono-unsaturated FA levels were higher in SK birds while poly-unsaturated FA levels were higher in ED birds. By 40 weeks, C16:0 and C16:1 were marginally higher in SK birds while only C20:2 was still higher in ED birds. Serum AGP level did not differ between ED and SK hens at 40 weeks. However, serum AGP did correlate with both total egg production ($P<0.01$) and last 7 days egg production ($P<0.01$). In summary, SK feeding programs tend to increase the level of saturation of abdominal fat in broiler breeder hens. Serum AGP levels, while not affected by ED or SK feeding programs, do correlate strongly with egg production.

Key Words: Feeding Programs, Fatty Acids, Acute Phase Protein

304 Broiler and breeder feeding programs have different effects on the inflammatory response. A. Mireles Jr.* and S. Kim, *Foster Farms*, *Modesto, CA*.

The objective of this study was to compare the performance and acute phase response to E. coli lipopolysaccharide (LPS) of chicks fed a breeder or a broiler feeding program. The experimental design was a 2 feeding programs (Breeders vs. Broilers) X 2 Stress Levels (Control vs. LPS) with 25 chicks/treatment. Breeder diets were lower in protein and energy than broiler feeds. Birds were fed test feeds for 35 d. On 35 d, 50 chicks (25 Breeder + 25 Broiler) were injected 1 mg LPS/Kg body weight subcutaneously. Birds were euthanized 150 m post-injection. LPS stress increased spleen weight and body temperature, and it decreased serum Ca and N. Birds fed broiler were heavier ($P < 0.05$) than birds fed breeder feed (1.9 vs. 0.7 Kg). 150 m post-stress, relative body losses were larger ($P < 0.05$) for birds on breeder vs. broiler feed (6.63 vs. 4.87%). Liver weight of stressed Breeders was larger ($P < 0.05$) than that of Broilers (0.23 vs. -0.01%) and spleen weight was lower (0.11 vs 0.13%, $P < 0.05$). The febrile response was lower ($P < 0.05$) for Broilers vs. Breeders (0.2 vs. 0.9 C), and Breeders had higher ($P < 0.05$) levels of serum A-1 alpha glycoprotein than Broilers (365 vs. 306). Birds on broiler feed had higher ($P < 0.05$) serum Ca (92 vs 87) & total N (4764 vs 3856 PPM) than birds receiving breeder feeds. Compared to breeder feeds, broiler feeds down-regulate an inflammatory response.

Key Words: Acute Phase Response, Broilers, Breeders

305 Effect of the level of methionine, linoleic acid, and added fat in the diet on productive performance and egg quality of brown laying hens in late phase of production. H. M. Safaa[1,2], M. P. Serrano[1], D. G. Valencia[1], X. Arbe[3], R. Lázaro[1], and G. G. Mateos*[1], [1]*Universidad Politécnica de Madrid*, *Spain*, [2]*Cairo University*, *Egypt*, [3]*Cantos Blancos S.L.*, *Guadalajara, Spain*.

A total of 960 Lohmann Brown laying hens were used to study the effect of methionine (0.31 vs. 0.36%), linoleic acid (1.12 vs. 1.60%), and added fat (1.1 vs. 3.0%) level in the diet on productive performance and egg quality from 56 to 75 weeks of age. There were eight treatments arranged factorially (2 x 2 x 2) and six replicates of 20 hens per treatment. No interactions among main effects were detected and therefore, only main effects are presented. Few effects were observed among dietary treatments for body weight, daily feed intake, feed conversion ratio, egg production rate, egg weight, egg mass, and mortality rate. For the entire experiment, methionine level did not affect laying hen performance ($P > 0.10$). However, from 60 to 67 wk of age an increase in methionine from 0.31% to 0.36% increased the proportion of large eggs (> 63 g) from 79.8% to 85.9% ($P < 0.05$). Increasing the linoleic acid content of the diet from 1.12% to 1.60% did not modify any productive trait at any age ($P > 0.10$). Increasing the level of added fat from 1.1% to 3.0% increased the percentage of extra-large (> 73 g) eggs from 20.4 to 22.8% but the difference was not significant ($P > 0.10$). However, from 64 to 67 wk of age, an increase in fat content tended to increase the percentage of extra-large eggs ($P < 0.10$). Percentage of broken eggs, shell-less, and dirty eggs were not affected by treatment ($P > 0.10$). The Roche Color Fan score of eggs was higher in hens fed 3.0% added fat than in hens fed 1.1% added fat (12.5 vs. 11.8; $P < 0.05$). We conclude that laying hens, late in the production cycle, do not need more than 1.12% linoleic acid in the diet and that an increase in methionine and fat content may result in a slight increase in the commercial value of the eggs.

Key Words: Laying Hen, Linoleic Acid, Egg Quality

306 Performance and egg quality of laying hens fed diets containing different levels of total and digestible amino acids. D. E. Faria*, H. R. B. Souza, A. L. Santos, and P. W. Rizzoli, *University of Sao Paulo (FZEA/USP)*, *Pirassununga, SP, Brazil*.

This experiment was carried out to evaluate the performance and egg quality of laying hens fed diets containing different levels of total and digestible amino acids. A hundred ninety two Hy-Line Brown hens, 54 wk of age, were randomly distributed in a 2 x 4 factorial scheme: feed formulation criterion (total and digestible amino acids) and amino acid levels in the diet (100%, 95%, 90%, and 85% of the methionine, lysine and tryptophan requirements), totalizing eight treatments and five replicates of four birds each. Performance (feed intake, energy intake, egg production, egg weight, egg mass, and feed conversion) and egg quality (albumen percent, yolk percent, Haugh unit, shell percent, shell thickness, and specific gravity) characteristics were

evaluated. Egg production was influenced by the amino acid levels in the diet, showing significant positive linear response. There were interactions for egg mass and feed conversion where the best results were observed when digestible amino acids with 100% of the requirements were used. There were no effects of the treatments on feed intake, energy intake, egg weight, and on internal and external egg quality characteristics. It was concluded that the performance of laying hens can be improved when the diets are formulated based on digestible amino acids concept.

307 An examination of broiler energy need for ambient temperature dependent homeostasis, protein and fat accretion and effective caloric value. A. Beker* and R. G. Teeter, *Oklahoma State University*, *Stillwater*.

An experiment was conducted in calorimeter chambers to investigate energy and oxygen need for body weight homeostasis, efficiency of metabolizable energy (ME) use for maintenance, exponent needed to convert live body weight to metabolic weight for fed and fasted broilers, zone of thermoneutrality, efficiency of energy use for protein (K_p) and fat (K_f) accretion, as well as the effective caloric value (ECV) of ambient temperature. The study utilized 8 weight groups of Cobb x Cobb broilers housed under 3-5 ambient temperatures (AT) per weight grouping, consuming feed at 4 levels (0, 5, 10% of body weight (W), and adlib). Data indicated that energy (Kcal/$W^{0.75}$/d) and oxygen (l/$W^{0.75}$/d) need for homeostasis declined curve linearly per unit metabolic weight as weight increased from 0.09 to 1.95 $kg^{0.75}$. Results, however; were impacted by AT. Relative to birds consuming feed ad libitum, maintenance needs averaged 33% of consumption. The exponent, to linearize live body weight with heat production (HP) of birds fed to W homeostasis, was determined to be 0.758 with birds strictly housed at TN. Further, the exponent to linearize HP of fasted birds was 0.679. The zone of thermoneutrality, at body weight homeostasis, was inversely related to metabolic weight, expressed as: TN=32.64425-(5.91277*MWT) (R^2=0.99) and curvilinearly related to W as: TNMBR=32.6466-(94.4603*W)-(0.7660*W^2) ;(R^2=0.99). Proportional differences in protein and fat accretion were utilized, along with efficiency of retained energy, to estimate K_p and K_f as simultaneous equations. Efficiency of accretion for energy use above maintenance was estimated as 78.7% for lipid and 67.6% for protein. Values for K_p and K_f using regression analysis were found unreasonable, presumably due to co-linearity between intake and accretion variables. The ECV of AT, quantified as a multiple of bird maintenance energy need was found to fall between 1 to 3 % of maintenance energy per Kg body weight.

Key Words: Broiler, ECV, Homeostasis

308 Antibiotic + electrolyte intervention minimizes damage in broiler performance during abrupt severe heat stress. A. Mireles Jr.* and S. Kim, *Foster Farms*, *Modesto, CA*.

Gut bacteria likely have a role during heat stress through an inflammatory reaction. The objective of this study was to examine the effect of antibiotics and electrolytes (OTC) in the water of heat stressed battery chicks at 3 ages. The experimental design was a 3 age (36, 25, and 15 d) X 2 water (Control, + OTC) X 2 heat stress (Control, Heat Stressed) factorial, with 5 replicate cages each. An attempt was made to maintain similar stock densities. All birds were raised in cages for the first 14 days. OTC water was introduced at the time of stress. Control room temperature was 25.6 - 26.7°C. Heat stressed room was increased 2.2°C/hour to 37.8°C and cycled back for 2 days. Weight gain was affected by age, heat stress, water, and interactions ($P < 0.05$). 15 and 25 d chicks were not affected by heat or water. 36 d heat stressed chicks on control water lost 227 g in 2 days ($P < 0.05$) compared to heat stressed on OTC or non-stressed chicks. During heat stress, total serum N and serum Ca increased (0.46 vs. 0.48%; 101 vs 107 PPM, $P < 0.05$). OTC decreased ($P < 0.05$) total N in all 36 d birds (0.47 and 0.52% vs. 0.45 and 0.50%) and increased ($P < 0.05$) serum Ca (95 and 108 vs. 102 and 110 ppm). Serum pH was inversely related to serum Ca (R^2=0.24, $P < 0.05$). Water treatment can minimize damage in 36 d old broilers caused by abrupt heat stress.

Key Words: Heat Stress, Antibiotics, Gut Microflora

309 Dietary salt combinations for broiler chickens under subtropical summer conditions: Live performance, carcass, and blood responses. T. Mushtaq*[1], H. Nawaz[1], M. A. Mirza[1], M. Athar[2], M. M. H. Mushtaq[1], G. Ahmad[3,1], and U. Noreen[1], [1]*University of Agriculture*, *Faisalabad, Pakistan*, [2]*Hi-Tech Feeds*, *Lahore, Pakistan*, [3]*Shamim Feed Industries*, *Bahawalpur, Pakistan*.

The study was planned to investigate the best combination of Sodium (Na), potassium (K) and chloride (Cl) keeping the dietary electrolyte balance (DEB) at 250 mEq/kg. The desired dietary Na, K and Cl levels were adjusted by incorporating sodium bicarbonate ($NaHCO_3$), sodium chloride (NaCl), calcium chloride ($CaCl_2$), potassium chloride (KCl), ammonium chloride (NH_4Cl) and potassium sulphate (K_2SO_4). A total of 270 Male Starbro from grantparent flock was obtained and kept on 27 floor pens on new softwood shave litter up to 42 d of age in a completely randomised design. Nine (9) treatments varying in their Na, K and Cl contents were formulated using stochastic formulation method at 95% level of confidence and were offered to 3 replicates having 10 birds each. The minimum and maximum temperatures recorded were 31.1 and 38.4°C respectively with RH 56%. Diet containing Na=0.30%, K=0.80% and Cl=0.30% (with $NaHCO_3$ 0.42%, NH_4Cl 0.20%, $CaCl_2$ 0.19%, K_2SO_4 0.04%) significantly improved body weight gain at 28 d. No significant effect of treatments was found on water consumption and mortality. A significant correlation (r=0.34) was observed between water intake and dietary Na. Water intake significantly improved FCR (r=-0.30) and weight gain (r=0.56) and lowered rectal temperature (r=-0.35). However, mEq ratio of K: Na of 2.4 and K: Cl of 2.0-2.5 significantly lowered mortality and serum bicarbonate contents. The diets with low Na (0.20%) and high K (1.08 or 1.19%) and Cl (0.40 or 0.50%) held mortality to 0% during the final week of age, compared to other diets. In conclusion, in heat stress the diet with 0.30% Na, 0.80% K and 0.30% Cl containing 0.19% $CaCl_2$, 0.04% K_2SO_4,0.42% $NaHCO_3$, and 0.20% NH_4Cl gave highest BWG 0-28 d (1,033 g) whereas the lowest FCR value of 1.71 was obtained.

Key Words: Dietary Electrolyte Balance, Broiler, Heat Stress

310 Response of growing broilers to digestible lysine and metabolizable energy levels in heat stress. G. Ahmad[1,2], T.

Mushtaq*[1], M. A. Mirza[1], and T. Ahmad[3], [1]*University of Agriculture*, *Faisalabad, Pakistan*, [2]*Shamim Feed Industries*, *Bahawalpur, Pakistan*, [3]*University of Arid Agriculture*, *Rawalpindi, Pakistan*.

The study was conducted to evaluate the response of heat stressed broilers to dietary digestible lysine (digestible Lys) and metabolizable energy (ME) during 14 to 35 d of age. Two levels of digestible Lys (0.8 and 1.0% with ideal protein concept) were used with 4 levels of ME (2.600, 2.700, 2.800 and 2.900 Mcal/kg) in 2 × 4 factorial arrangement. The average minimum and maximum temperature during the experiment was 27.7 and 41.3°C, respectively. Body weight gain (BWG) during the experiment was significantly (P≤0.005) affect by the digestible Lys × ME. The lowest BWG was observed when 0.8% digestible Lys was used with 2.900 Mcal of ME/kg. The feed intake was lower (P≤0.046) in high ME diets i.e., 2.800 and 2.900 Mcal/kg. The total digestible Lys intake during the experiment was significantly high (P≤0.001) for the birds fed on 1.0% digestible Lys as compared to that of 0.80% (14.48 vs. 11.89 g) with its significantly lower (P≤0.001) efficiency for weight gain (49.5 vs. 42.3). No significant effect of digestible Lys, ME or their interaction was observed on feed:gain, mortality, ME intake or ME efficiency for BWG.

Key Words: Metabolizable Energy, Digestible Lysine, Heat Stress

311 The effects of dietary supplementation of L-Carnitine on egg production traits of white leghorns. W. Zhai*[1], S. L. Neuman[2], M. A. Latour[1], and P. Y. Hester[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*Guidant Corporation*, *St. Paul, MN*.

An earlier study in our lab has shown that yolk sac weights of progeny hatched from eggs of hens consuming 125 ppm L-carnitine were smaller than controls suggesting that carnitine improved the utilization of yolk fat by developing embryos. In addition, samples of yolks had 16.3 vs. 12.7 nanomoles of carnitine per gram of yolk in hens consuming carnitine as compared to controls, respectively (SEM=0.3, P=0.001). The effects of carnitine consumption on egg production traits are unknown; therefore, the current study determined if supplemental L-carnitine in White Leghorn diets affected egg production and egg traits. Diets were formulated to contain 0 or 125 ppm carnitine (analyzed values were 1 and 143 ppm, respectively). Diets were fed to birds beginning at hatch until 37 wk of age. Birds were transferred from pullet rearing cages to laying cages at 17 wk of age. Four hens were housed in each laying cage providing 549 sq cm/bird. Numbers of egg laid per cage were recorded daily and hen-day egg production was calculated monthly. Egg and shell traits were determined every 4 wk when the hens were 23, 27, 31, and 35 wk of age. Data were analyzed using ANOVA with repeated measurements using the mixed model procedure of SAS. Hens consuming carnitine as compared to controls had similar egg production (84 and 86%, SEM=1, P=0.30), egg weight (53.6 and 53.6 g, SEM=0.3, P=0.88), yolk weight (13.7 and 13.7 g, SEM=0.1, P=0.89), relative yolk weight (yolk weight/egg weight, 25.5% and 25.4%, SEM=0.1, P=0.54), shell weight (4.85 and 4.85 g, SEM = 0.04, P=0.96), relative shell weight (shell weight/egg weight, 9.07 and 9.06%, SEM=0.05, P=0.83), and shell thickness (0.358 and 0.358 mm, SEM=0.002, P=0.87), respectively. It is concluded that consumption of L-carnitine from hatch to 37 wk of age had no effect on egg production and egg traits.

Key Words: Carnitine, Egg Production, Yolk Weight

312 Effects of corn particle size in a corn-soybean meal diet on chick growth performance and nutrient digestibility. C. M. Jacobs*, P. L. Utterback, and C. M. Parsons, *University of Illinois*, *Urbana*.

Two experiments were conducted to evaluate the effects of corn particle size in a 23% CP corn-soybean meal diet when fed to young chicks. The first experiment was performed using New Hampshire x Columbian female chicks and the second experiment used Ross x Ross commercial male chicks. In both experiments, day old chicks were randomly assigned to one of four dietary treatments consisting of corns that were ground in a hammer mill using the following screen sizes: 1/16-in. (1.59mm) ground corn, 3/16-in. (4.76mm) ground corn, 5/16-in. (7.94mm) ground corn, or 6/16-in. (9.52mm) ground corn. Chicks were fed the experimental diets from 0-21 days post hatch. Growth performance, gizzard weight, and gizzard pH were measured in both experiments, and ME_n and apparent amino acid digestibility were determined at 7 and 21 days of age in the first experiment. When compared to the 1/16-in, ground corn, feeding the larger particle sizes had no significant (P>0.05) effect on growth performance in either experiment. Feeding larger particle sizes caused an increase in relative gizzard weight (% of body weight) in both experiments, with the greatest increase occurring with the 6/16-in. ground corn. Gizzard pH in both experiments was unaffected by corn particle size. Corn particle size also had no significant (P>0.05) effect on ME_n and amino acid digestibility values. There was, however, an age effect on amino acid digestibility and ME_n. Digestibility coefficients for most amino acids were higher (P>0.05) at 21 days than at 7 days for all dietary treatments. The ME_n values also increased (P<0.05) from 7 to 21 days for the 3/16-in. and 5/16-in. corn treatments. The results of this study indicate that feeding larger particle size corn increases relative gizzard weight and has no significant effect on growth performance, ME_n, and amino acid digestibility.

Key Words: Corn Particle Size, Growth Performance, Nutrient Digestibility

313 Changes in zebra finch (*Taeniopygia guttata*) eggshell morphology after oral estrogen exposure as chicks. S. L. Westmoreland*[1], H. Pourarsalan[1], D. H. Hawkins[3], J. R. Rochester[2], and J. R. Millam[2], [1]*The University of Texas at Arlington, Department of Biology and The Center for Electron Microscopy*, *Arlington*, [2]*The University of California, Department of Animal Science*, *Davis*, [3]*The University of Texas at Arlington, Department of Mathematics*, *Arlington*.

Environmental estrogens have been implicated in changes in the reproductive performance, song systems, oviduct histology, egg production, and shell breakage in Zebra Finch birds (*Taeniopygia guttata*); we investigated the relationship of estradiol benzoate (EB) to eggshell thickness and morphology. Zebra Finch birds from a breeding colony at The University of California at Davis were fed a mixed seed diet and water *ad libitum* and kept on a 16L: 8D photoschedule. Female chicks were treated for 7 days, from post-hatch days 5-11, with either orally administered estradiol benzoate in canola oil or canola oil alone (control) at 1 microliter/g body weight. (EB was 100 nmol/g body weight); males were treated only with canola oil. At approximately 110 days of age, 5 males and 5 females at a time were moved to a communal cage and provided with nest boxes and nest material to stimulate pair-formation and breeding. They were then removed to individual breeding cages, where eggs were collected. The 25 eggs for this study included 15 eggs from control females and 10 eggs from EB-treated females; all eggs were the second egg laid in the clutch. On the day of collection eggs were split open at the equator, emptied, rinsed with deionized water, and air dried. Three samples were taken from each egg at the equator region and were placed on aluminum stubs. The samples were oriented for a radial (cross section) view of the shell. Stubs were coated with gold and palladium and viewed using scanning electron microscopy. Digital micrographs were made for all shell samples at 500X. Micrographs of shell cross sections were analyzed for shell thickness using Image Pro Plus computer software. These data were statistically analyzed using SAS. The experimental shells were found to be significantly thinner than the control shells ($p = 0.02$, experimental mean = 70.45 µm, control mean = 76.90 µm, SE = 2.58). Future studies will include analysis of shell structure to determine the relationship of shell features to shell thickness and to determine the underlying physiology of shell formation and how it is impacted by estrogen exposure.

Key Words: Avian Eggshell, Estrogen, Endocrine Disruptor

314 Comparison of oral vs. injected dosing of the soy phytoestrogen genistein on the reproductive development of female broiler chicks. L. M. Stevenson*, C. R. James, S. S. Oates, J. B. Hess, and W. D. Berry, *Auburn University*, *Auburn, AL*.

Developmentally inappropriate exposures to estrogenic compounds are known to alter morphology and function of the reproductive tract in various species. Chickens are continually exposed to the relatively potent estrogenic soy isoflavones through the diet. Previous experiments in this laboratory have demonstrated that the primary soy isoflavone genistein induces proliferation of the chick oviduct. However, information is lacking as to specific reproductive tract developmental effects of genistein exposure in chicks. Experiments were done to compare the effects of oral exposure and injected exposure to genistein. The oral and injected effects of genistein were also compared to a classical estrogen, diethylstilbestrol (DES). To avoid the effects of dietary soy isoflavones, the experimental diets were formulated with dried egg white as a protein source. Day old female chicks were assigned to treatments: egg white based diet with daily oral gavage or subcutaneous injection of sesame oil vehicle (CV); 1mg diethylstilbestrol (DES); 10mg genistein (G10) or 40mg genistein (G40). There was also a treatment fed a standard starter diet with daily oral gavage or subcutaneous injection of sesame oil vehicle (SV). At 15 days of age, the injected treatments increased the absolute oviduct weight and oviduct weight as a percentage of final body weight as compared to the oral treatments ($P<0.05$). The DES treatments, both oral and injected, increased the absolute oviduct weight and oviduct weight as a percentage of final body weight as compared to all other treatments ($P<0.05$). The injected treatments of G40 and DES showed adult hen behaviors, marked development the right oviduct, and increased the absolute oviduct weight and oviduct weight as a percentage of final body weight as compared to the CV and SV treatments ($P<0.05$). The injected DES treatment showed partially developed right oviducts. The injected G40 treatment showed membranous cystic right oviducts. It was concluded that injected doses of genistein elicit a stronger estrogenic response in the developing female chick as compared to oral doses.

Key Words: Genistein, Oviduct, Phytoestrogen

315 Analysis of plasma serotonin levels and hemodynamic responses following chronic serotonin infusion in broilers challenged with bacterial lipopolysaccharide and microparticles. M. E. Chapman*[1], R. L. Taylor[2], and R. F. Wideman[1], [1]*University of Arkansas*, *Fayetteville*, [2]*University of New Hampshire*, *Durham*.

There has been much interest in the role of serotonin (5-hydoxytrytamine, 5-HT) in the pathogenesis of pulmonary hypertension due to episodes of pulmonary arterial hypertension (PAH) in humans linked to serotoninergic appetite suppressant drugs. In this study, we investigated the role of serotonin in the development of pulmonary hypertension induced by intravenously injecting bacterial lipopolysaccharide (LPS, endotoxin) and cellulose microparticles. In experiment 1 we employed a 5-HT ELISA kit for the in-vitro quantitative determination of 5-HT in plasma during the development of pulmonary hypertension induced by injecting 1 mg LPS and 0.35 mL cellulose microparticles suspended at 0.02 g/mL in saline i.v. in broilers (n = 240). In experiment 2 broilers were either chronically infused with 5-HT (10 mg/mL) via surgically implanted osmotic pumps designed to deliver 5 µL/hr for 14 d or received sham surgery as a control (n = 40). After a period of 10 d, the pulmonary arterial pressure (PAP) was recorded during challenge with injected LPS or microparticles. Microparticles elicited plasma levels of 5-HT more than two-fold higher than those elicited by LPS from 15-45 min post injection($P \leq 0.05$). This indicates that 5-HT is an important mediator in the pulmonary hypertensive response of broilers to microparticles, but 5-HT may not play a prominent role in the pulmonary hypertensive response to LPS. Furthermore, chronic 5-HT infusion via osmotic pumps caused an increase in the duration of the pulmonary hypertensive response of broilers to microparticles indicating that the infused 5-HT was sequestered by circulating thrombocytes and then released upon

microparticle mediated thrombocyte activation. Serotonin appears to play a less prominent role in the pulmonary hypertensive response of broilers to LPS indicating that other mediators within the innate response to inflammatory stimuli may also be involved. These results are consistent with our hypothesis that PAH ensues when vasoconstictors such as 5-HT overwhelm the dilatory affects of vasodilators such as nitric oxide (NO), thereby effectively reducing the pulmonary vascular capacity of PAH-susceptible broilers.

Key Words: Hypertension, Broiler, Serotonin

316 Chicken visfatin: The leaner side of an adipokine. S. M. Krzysik-Walker*, O. M. Ocón-Grove, S. R. Maddineni, G. L. Hendricks III, and R. Ramachandran, *The Pennsylvania State University*, *University Park*.

The adipokine visfatin (VFN), also known as pre-B-cell colony-enhancing factor 1, has been shown in mammals to be preferentially secreted by visceral fat, and elicits insulin-mimetic effects on glucose metabolism. Increased visceral fat and hyperglycemia have been correlated with higher plasma VFN levels in mammals. However, the expression of VFN in chickens, a naturally occurring hyperglycemic model, has not yet been described. The objective of the present study was to determine the level of VFN gene expression in the primary metabolic tissues, adipose, liver, and skeletal muscle, as well as to determine how this expression is altered with age in male broilers. We hypothesized that VFN gene expression in broiler chickens would be greatest in the abdominal fat pad and would change with age and/or fat accretion. Using RT-PCR and western blotting, we detected VFN mRNA and protein, respectively, in adipose, liver and skeletal muscle of male broilers. Further analysis with real-time quantitative PCR revealed that skeletal muscle had significantly greater amounts of VFN mRNA ($P<0.05$; n=5) compared with adipose and liver. To determine the influence of body composition and adiposity on VFN mRNA expression, adipose, liver and skeletal muscle were collected from 4 week and 8 week old male broilers. Quantification of VFN mRNA revealed significantly greater expression in skeletal muscle, regardless of age, with the greatest level being found in 8 week old broilers ($P<0.05$; n=5). No significant difference, however, was found in blood glucose levels at either age. Collectively, these findings indicate that skeletal muscle is one of the primary sources of VFN in chickens, in contrast to mammals where VFN is primarily expressed in visceral adipose tissue. Our data indicates that skeletal muscle VFN gene expression may be influenced by body composition and fat accretion. We propose that VFN is involved in regulating energy metabolism in broiler chickens.

Key Words: Visfatin, PBEF1, Adipokine

317 Transpulmonary pressure gradient verifies pulmonary hypertension is initiated by increased arterial resistance in broilers. A. G. Lorenzoni*, R. F. Wideman, and N. B. Anthony, *University of Arkansas*, *Fayetteville*.

Previous hemodynamic evaluations demonstrated that pulmonary arterial pressure (PAP) is higher in broilers that are susceptible to pulmonary hypertension syndrome (PHS, ascites) than in broilers that are resistant to PHS. We compared key pulmonary hemodynamic parameters in broilers from PHS-susceptible and PHS-resistant lines (selected under hypobaric hypoxia), and in broilers from a relaxed (control) line. Data were compared using one-way ANOVA by group/anatomical segment to compare data between and within lines, respectively. In experiment 1 the PAP was measured in male broilers in which a flow probe positioned on one pulmonary artery permitted the determination of cardiac output (CO) and pulmonary vascular resistance (PVR). The PAP and relative PVR were higher in the susceptible (34.3 ± 2.3 mm Hg and 0.11 ± 0.01 resistance units, ru) than in relaxed (22.4 ± 1.4 mm Hg and 0.08 ± 0.01 ru) and resistant broilers (24.4 ± 1.1 mm Hg and 0.08 ± 0.01 ru), whereas CO did not differ between lines. In experiment 2 male and female broilers from the three lines were catheterized to measure pressures in the wing vein, right atrium, right ventricle, pulmonary artery and pulmonary veins (WP, wedge pressure). The transpulmonary pressure gradient (TPG) was calculated as (PAP-WP), with PAP quantifying precapillary pressure and WP approximating post-capillary pulmonary venous pressure. When compared with resistant and relaxed broilers, PAP values in susceptible broilers were >10 mm Hg higher, TPG values were >8 mm Hg higher, and WP values were <2 mm Hg higher, regardless of sex. The combined hemodynamic criteria (elevated PAP and PVR combined with a proportionally elevated TPG) demonstrate that susceptibility to PHS can be attributed primarily to pulmonary arterial hypertension associated with increased pre-capillary (arteriole) resistance rather than to pulmonary venous hypertension caused by elevated post-capillary (venous and left atrial) resistance.

Key Words: Broiler, Pulmonary Arterial Hypertension, Transpulmonary Pressure Gradient

318 Cloning and characterization of chicken nucleobindin-2 (NUCB2) cDNA: The precursor for a putative anorexigenic peptide, nesfatin-1. P. K. Selvan*, G. L. Hendricks III, S. R. Maddineni, S. M. Krzysik-Walker, O. M. Ocón-Grove, and R. Ramachandran, *The Pennsylvania State University*, *University Park*.

Nucleobindin-2 (NUCB2) is a secreted protein that regulates intracellular Ca2+ and promotes bone maturation in mammals. Recently, NUCB2 has been characterized as a precursor molecule for three peptides (nesfatin 1-3), of which nesfatin-1 has been shown to suppress feed intake in rats through a leptin-independent melanocortin signaling pathway in the hypothalamus. However, a chicken homologue of NUCB2 has not been previously described. The objectives of the present study are to clone NUCB2 cDNA, characterize the deduced protein sequence for identifying nesfatin 1-3, and quantify NUCB2 gene expression in the diencephalon and adipose tissue in male broiler and leghorn chickens. Using RT-PCR, we found that NUCB2 mRNA is expressed in broiler diencephalon, myocardium, pituitary gland, skeletal muscle, liver, spleen, kidney, testes, and adipose tissue. For further characterization, we cloned and sequenced the full-length NUCB2 cDNA from broiler adipose tissue and found its deduced amino acid sequence to be 76.7% similar to human NUCB2 protein. The chicken NUCB2 protein sequence contained three cleavage sites, similar to human NUCB2 protein that may yield nesfatin 1-3. The putative chicken nesfatin-1 and nesfatin-2 amino acid sequences are 78% and 85% similar to that of rat, respectively. Using real-time quantitative PCR, significantly greater NUCB2 mRNA quantities were found in the abdominal fat of 8 week-old male broilers compared with male leghorns ($P<0.05$; n=4). No significant difference, however, was found in NUCB2 mRNA quantity in the diencephalon of broiler versus leghorn chickens. Based on these findings, we conclude that the

NUCB2 is expressed in multiple chicken tissues, which may possibly yield nesfatin as in mammals, and that NUCB2 gene expression is influenced by fat accretion in the adipose tissue. However, a physiological role of NUCB2 or nesfatin on feed intake in broilers remains to be studied.

Key Words: Nucleobindin, Nesfatin, Broiler

319 Gene expression in the lateral septal organ, mediobasal hypothalamus and septal-pituitary-gonadal axis following activation of the photoneuroendocrine system. H. Li*[1], J. A. Proudman[2], S. Jin[1], and W. J. Kuenzel[1], [1]*University of Arkansas*, *Fayetteville*, [2]*USDA/ARS/BGL*, *Beltsville, MD*.

Long day stimulation releases gonadotropin-releasing hormone (GnRH-1), gonadotropins, and induces testes growth in some wild and domestic avian species. Encephalic photoreceptors (EPRs) have been posited to detect photoperiodic changes. Two distinct groups of cerebrospinal fluid contacting neurons (CSFcn) residing in the mediobasal hypothalamus (MBH) and lateral septal organ (LSO) have been proposed to serve as EPRs with the former site thought to be the most likely candidate due to the presence of clock genes shown in quail. The current study examined possible roles for both the MBH and LSO in the avian photoneuroendocrine system. The hypothesis tested was that brain areas first showing expression for genes associated with photoreceptors should be the most likely region/s for housing EPRs. Gene expression profiles analyzed included vasoactive intestinal polypeptide (VIP), phosphodiesterase (PDE), type II deiodinase (D2), GnRH-1 and gonadotropins. Sulfamethazine (SMZ) mixed in the feed at 0.2% plus a long-day photoperiod was utilized to stimulate rapid gonadal development. Real time qRT-PCR (SYBR Green or TaqMan) was used to quantitate mRNA transcripts. SMZ augmented and temporally advanced the stimulatory effects of long day on gene expression of VIP, PDE, and GnRH-1. The first elevated expression of genes occurred in the LSO including VIP at 4h and PDE at 6h, followed by GnRH-1 in the bed nucleus of the pallial commissure (NCPa) at 4-8h after SMZ administration. Treatment of SMZ had no effect on VIP gene expression in the MBH within the first 8h. The long day treatment stimulated VIP gene expression at 12h in the LSO and MBH, GnRH-1 in the NCPa and D2 in the MBH. Taken together, the current study suggests that the LSO contains neurons displaying the earliest gene expression characteristic of EPRs and is followed by a neuroendocrine cascade responsible for rapid gonadal development.

320 Study of the effects of blindness on sexual maturation in Smoky Joe roosters. J. Perttula* and G. Bedecarrats, *University of Guelph*, *Guelph, ON, Canada*.

In domestic chickens, sexual maturation is generally induced by increasing the photoperiod. Stimulation of hypothalamic photoreceptors triggers the secretion of gonadotropin releasing hormone which in turn induces the synthesis and release of gonadotropins by the pituitary gland. Increasing levels of gonadotropins then stimulate the development and maturation of the gonads. In addition to this stimulatory axis, it has recently been proposed that an inhibitory pathway involving melatonin produced by the retina and pineal gland may exist. Using a genetically blind line of chickens, we previously showed that the lack of retinal stimulation advances egg-laying in hens. To determine if blindness also influences sexual maturation in males, 54 Smoky Joe roosters (24 blinds and 30 sighted) were raised under an 8 h photoperiod until 17 weeks of age, then stimulated with a 14 h photoperiod. At 14, 17, 18, 19, 21, and 23 weeks of age, 4 blind and 5 sighted birds were sacrificed, body weight as well as comb length were measured, and blood and various tissue were collected. Relative testicular weight was then calculated and total testosterone concentrations were measured in plasma by ELISA. With the exception of week 21, no difference in body weight was observed between blind and sighted roosters or between collection dates. In blind birds, comb length significantly increased between 14 and 17 weeks of age ($p<0.001$) while growth was more gradual in sighted ones. Similarly, testes were significantly larger in blind than sighted roosters at 17 weeks of age (sighted: 2.92 +/- 0.58% of body weight ; blind: 6.43 +/- 1.43%; $p<0.05$). However, following photostimulation, no significant difference could be observed. Interestingly, no significant difference in testosterone plasma concentration was observed between blind and sighted roosters or between collection dates. However, this could be explained by the small number of individuals used and the large standard deviations obtained. In conclusion, our study shows that blindness advances sexual development in roosters before photostimulation. In addition, these results suggest that signals originating from the retina may inhibit the reproductive axis in normally sighted birds.

321 Dopamine-melatonin neurons in the turkey hypothalamus controlling seasonal reproduction. S. Kang*, A. Thayananuphat, T. Bakken, and M. El Halawani, *University of Minnesota, St Paul*.

The neural and neurochemical substrate mediating the reproductive photoperiodic time measurement (PTM) in birds has not been definitively established. Our previous studies have shown that a 30 min light pulse induced c-fos mRNA expression in dopamine (DA) neurons within the premammillary nucleus (PMM) of the turkey caudal hypothalamus, as well as in GnRH-I neurons of the anterior hypothalamic/pre-optic area, where GnRH-I mRNA was also found. Double-label immunocytochemistry (ICC) showed these PMM neurons to be immunoreactive (ir) to both tyrosine hydroxylase (TH; the rate limiting enzyme in DA biosynthesis) and melatonin (MEL). Moreover, the intensity of MEL staining appeared greater in brain sections obtained during night than day. We have shown that mRNA expression of TH and tryptophan hydroxylase 1 (TPH1; the first enzyme in MEL biosynthesis), cycle rhythmically and with opposite phases in the PMM neurons of birds kept under a diurnal illumination cycle (12-h light: 12-h dark; LD). These neurons can generate 24 hr TH and TPH1 mRNA expression rhythms in constant light (LL) and constant dark (DD). In addition, the expression patterns and amplitudes of TH and TPH1 mRNAs were different between long and short photoperiods. It is suggested that endogenous oscillators within PMM neurons appear to be important in regulating the DA and MEL rhythms which are required to drive the circadian system controlling reproductive seasonality in turkeys.

322 Lipoic acid-induced changes in food intake in chickens. D. M. Denbow* and P. B. Siegel, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

The enzyme AMP-activated protein kinase (AMPK) is believed to serve as an ″fuel gauge″ monitoring the energy level in the body. It may function both within and outside the central nervous system. Using a line of chickens selected for either low- or high-eight week body weight, we investigated whether altering the activity of this enzyme affected food intake, and whether genetic selection for high or low body weight altered the effect of lipoic acid. Lipoic acid is known to inhibit AMPK. Therefore, lipoic acid was injected either intraperitoneally (IP) or intracerebroventricularly (ICV) to determine its effect on food intake in both lines of birds. Food intake was monitored for 3 or 24 hours postinjection following ICV or IP injections, respectively. The ICV injection of 0, 12, 24 or 48 μg lipoic acid dose-dependently increased ($P<0.05$) food intake in 7 week-old high weight male birds while having no effect in 15 week-old low weight male birds. The IP injection of 0, 50, or 100 mg/kg BW of lipoic acid decreased ($P<0.05$) food intake in 11-15 week-old males of both lines. Therefore, altering AMPK activity can affect food intake in chickens.

323 Clock gene expression in the premammillary nucleus (PMM) and the pineal gland of turkey hens. B. Leclerc*[1], S. Kang[1], A. Thayananuphat[1], C. Howell[1], S. Kosonsiriluk[2], Y. Chaiseha[2], and M. E. El Halawani[1], [1]*University of Minnesota*, *St. Paul*, [2]*Suranaree University of Technology*, *Thailand*.

Recent findings from our laboratory have implicated the PMM as a site of putative photoreceptive neurons. These neurons are shown to express both dopamine (DA) and melatonin (MEL), with DAergic activity up regulated during the light phase and MELergic activity during the dark phase of the light-dark illumination cycle. Theses neurons reach threshold activation (as indicated by c-fos mRNA expression) when a light period is provided during the photosensitive phase (14hr after light on). And, this is coincided with the activation of gonadotropic releasing hormone-I (GnRH-I) and the upregulation of GnRH-I mRNA expression. It is hypothesized that PMM DA-MEL neurons may be a component of a biological clock involved in reproductive photoperiodic time measurement (PTM), controlling seasonal reproduction in turkeys. In this study we cloned turkey's clock genes including Clock, Per2, Per3, Bmal1, Cry1 and Cry2 and examined their expression in the PMM which was compared to that expressed by the pineal gland. Turkey hens maintained on short photoperiod (6L:18D) were subjected to a 30 min light pulse at circadian times (CT) 8, 14 and 20. Tissues were collected 30 min, 1 hour and 3 hours following the onset of the light pulse. In the pineal gland, Per2 mRNA expression level was highest followed by mRNA expression of Cry1, Cry2, Per3, Clock and Bmal1. However, Per2 gene was not significantly modulated by light (one-way ANOVA; $P>0.05$) across all CTs. The expression of Per2, Cry1 and Cry2 genes was also examined in the PMM of turkeys following the 30 min light exposure. The expression of Cry1 and Per3 transcripts was enhanced 2-3 fold by the 1 hour light pulse at CT14 and CT20 and both were statistically significant by the ANOVA ($P<0.05$) and confirmed by the Tukey-Kramer test. It is not clear at this time whether clock genes are involved in mediating photic information to the reproductive neuroendocrine system of turkeys.

324 The expression patterns of HIF 1α, HYOU1, HO1, and cTnT during embryonic development in the chicken heart. S. Druyan*[1], A. Cahaner[2], and C. M. Ashwell[1], [1]*North Carolina State University*, *Raleigh*, [2]*Hebrew University*, *Rehovot, Israel*.

Oxygen is one of the critical determinants of appropriate embryonic and fetal development including cardiogenesis. When tissues demand for oxygen exceeds oxygen supply, hypoxic conditions develop. In the developing embryo, hypoxia is associated with increased fetal mortality, cerebrovascular anomalies, cardiovascular dysfunction and altered angiogenesis. In this study 4 genes: hypoxia inducing factor subunit a - 1 (HIF 1α), hypoxia up regulated protein 1 (HYOU1) also known as ORP150, heme oxygenase 1 (HO1) and cardiac troponin T (cTnT) , were examined in the embryonic heart of the chicken to determine the expression patterns throughout development. The effect of embryonic age on gene expression was determined by real-time quantitative PCR normalizing to the level of GAPDH. On embryonic day 7 (E7) all three hypoxic induced genes were expressed at their highest levels evaluated, likely due to the fact that the yolk sac is the principal gas exchange organ and the origin of the primitive red blood cells. All three hypoxic induced genes expression significantly decreased from d E7 to E19 (internal pipping) followed by a significant increase in expression between internal pipping and external pipping (E20). During this period a gradual hypoxia and hypercapnia develop due to the decline in the allantois gas exchange the embryo metabolic requirement depends on the lungs, as the new breathing organ, thus limiting the O2 supply. As expected cTnT expression increased with embryonic development in correlation with the cardiovascular system development. It appears that tissue hypoxia is a necessary component of normal embryonic development.

Production, Management & the Environment - Livestock and Poultry: Broiler and Broiler Breeder Production and Management

325 Dosing with the fatty acid, sodium caprylate in the water did not reduce enteric *Campylobacter* concentrations in broilers. J. H. Metcalf*[1], K. Venkitanarayanan[2], F. S. de los Santos[1], A. M. Donoghue[3], M. L. Dirain[1], I. Reyes-Herrera[1], V. Aguiar[1], P. Blore[1], and D. J. Donoghue[1], [1]*University of Arkansas*, *Fayetteville*, [2]*University of Connecticut*, *Storrs*, [3]*PPPSRU, ARS, USDA*, *Fayetteville, AR*.

Campylobacter is a leading cause of foodborne disease and poultry is an important vector for this pathogen. Water additives are one possible method to reduce Campylobacter concentrations within preharvest poultry. Previous research in farm animals using the medium chain fatty acid, sodium caprylate, demonstrated the potential to reduce enteric pathogens. To determine the ability of sodium caprylate to

reduce Campylobacter concentrations in preharvest poultry, two separate trials were conducting dosing young chickens with this compound. Chicks were dosed for the last 72 h of a 15 d study with either 0, 0.175, 0.35, 0.7, 1.4% or 0, 0.044, 0.088, 0.175, 0.35, 0.7, 1.4% sodium caprylate in the water (Trial 1 or 2, respectively, n=10 birds/group). Chicks were challenged with Campylobacter jejuni on d 3. At d 15, chicks were sacrificed, cecal contents collected, serially diluted and plated on Campy Line Agar. Colonies were counted after 48 h of incubation at 42C. In Trial 1, only the 0.175% sodium caprylate dose caused a significant reduction in cecal Campylobacter concentrations when compared with controls. In Trial 2, there were no significant differences between any of the treatment groups. There results indicate, at least for the dosing regime used, sodium caprylate was not consistently effective in reducing enteric Campylobacter concentrations in young chickens.

326 Performance comparison between the use and non-use of an enteric health antibiotic program in commercial broiler flocks. J. Bray*[1,2], T. Cherry[1], J. Carey[2], and C. Smith[1,2], [1]*Stephen F. Austin State University*, *Nacogdoches, TX*, [2]*Texas A&M University*, *College Station*.

In the US, current trends show that enteric health antibiotics are been removed from broiler diets. The use of these antibiotics in broiler production is a contentious issue. An experiment was conducted to compare the differences in performance and yield parameters between broilers that were fed enteric health antibiotics in the diets and broilers that were not fed enteric health antibiotics in the diets. For five consecutive flocks broilers were reared under commercial settings in solid-side wall, tunnel ventilated broilers houses on built-up litter. The four-house farm was divided into two separate farms with two houses being fed the enteric antibiotic program (AGP(+)) and the other two were fed a naïve feed (AGP(-)). For each flock, 27,600 broilers were placed per house and reared for 49 days. All birds were fed commercially produced starter, grower and withdrawal rations. Individual body weights of 100 birds per house were collected at 18, 35, and 49 days of age. Feed conversion and adjusted feed conversion were calculated for each of these days. Coccidiosis lesion scores using the Johnson and Reid Method were collected at 14, 21, 28, 35, and 42 days of age. At the conclusion of each flock, a yield study was conducted on 280 birds (140 per treatment). The nature of the differences in bird performance between the treatments varied from flock to flock. Through the first two flocks, the AGP(-) birds had a high body weight with a lower feed conversion and adjusted feed conversion at 49 days of age when compared to the AGP(+) birds. Furthermore, statistically higher yield weights were detected in the AGP(-) birds through the first two flocks. By the third flock, all performance and yield parameters were equal between the two treatments. Preliminary data from the final two flocks indicates there is a slight improvement in performance and gut health among flocks receiving antibiotics.

327 Saponin rich extracts from quillaja, yucca, soybean, and guar differ in antimicrobial and hemolytic activities. S. M. Hassan*[1], J. A. Byrd[2], A. M. Berhow[3], C. A. Bailey[1], and A. L. Cartwright[1], [1]*Texas A&M University*, *College Station*, [2]*USDA, Agricultural Research Service*, *College Station, TX*, [3]*USDA, Agricultural Research Service*, *Peoria, IL*.

Saponin rich extracts prepared from guar meal, quillaja bark, yucca, and soybean were evaluated for antibacterial and hemolytic activities. Ninety six multi-well plate assays for hemolytic and antimicrobial activities were tested using 8 serial dilutions of saponin concentrations from 5 to 666 µg/mL. A hemolytic assay used a 1% suspension of chicken red blood cells with water as a positive control and phosphate buffer solution as a negative control. A minimal inhibitory concentration (MIC) assay was used to evaluate the antibacterial activity of S. aureus, Salmonella Typhimurium and E. coli with ampicillin as a positive control and bacteria without saponin as a negative control. Optical densities of ELISA plate wells were read at 650 nm to assay hemolytic and bacterial growth. Results showed that saponin from different sources have different hemolytic and antibacterial activities. Guar and quillaja saponins were hemolytic, while yucca and soybean were not hemolytic at the concentrations tested. No saponin source had antibacterial activity against Salmonella Typhimurium or E. coli at the concentrations tested in this study. Both guar and quillaja saponin extracts exhibited antibacterial activity against S. aureus.

Key Words: Antibacterial, Guar, Saponin

328 Factors influencing distribution of pellets and fines in a commercial broiler pan feeding system. C. Hancock*, S. Beyer, C. Rude, S. Daly, K. Dobbeleare, and J. Burden, *Kansas State University*, *Manhattan*.

A series of studies were conducted to determine the impact of feed fines on the distribution of particles within a commercial broiler pan feeding system. A Chore-Time Model C2 Plus feed line with Brock feed bin and a Model 75 auger line with surge bin was constructed with 93 pans spanning the 240 foot line. For the purpose of these studies, feed was added directly to the surge bin. The motor was activated, feed was moved down the line, and the samples were collected from select pans for later analysis. For the purpose of the initial studies, we collected from pans 1, 2, 3, 14, 25, 36, 47, 58, 69, 80, 91 and 93. A grower ration formulated to meet the requirements of the NRC was manufactured at the Kansas State University Feed Mill. The feed was pelleted to a pellet durability index (PDI) of 92. The feed system was tested using 3 combinations of pellets and fines. Trmt 1 contained no added fines, trmt 2 contained 10% added fines and trmt 3 contained 20% added fines. To blend pellets and fines, a 1000 lb. Davis horizontal paddle mixer was used with a 1 minute mix time. Feed was then placed in plastic tubs until fed into the surge bin to begin the auger process. Each trmt was fully distributed throughout the line until the automated stopping mechanism was activated, at which point samples were collected by removing all feed from selected pans. The entire system was then purged of feed and the process was repeated. Pellets and fines were separated using an automated Ro-Tap system. Results indicate that the initial pans accumulated feed with 90% pellets, allowing fines to traverse into later pans where pellets only reached 70%. As the fines were collected in later pans, this then allowed

remaining pellets to traverse and flow into pans further down the line. This indicates that different pans may have different ratios of fines to pellets. The data indicates distribution of feed was similar in all 3 trmts. To maximize flock uniformity, it is important that the system releases feed in a uniform manner, however our results indicate pellets and fines may separate during the feeding process.

Key Words: Pellets, Fines, Feed Manufacturing

329 Characterization of atmospheric ammonia/ammonium forms in broiler production facilities. C. S. Smith*[2,1], J. L. Bray[2,1], T. E. Cherry[2], R. E. Lacey[1], and J. B. Carey[1], [1]*Texas A&M University*, *College Station*, [2]*Stephen F. Austin State University*, *Nacogdoches, TX*.

The nature and prevalence of the forms of ammonia nitrogen (ammonia/ammonium) within the environment of a broiler production facility is largely unknown. An annular denuder system was utilized to separate ammonia compounds in air samples into three categories. The air sample first passed through a cyclone filter which trapped large airborne particles. Subsequently, the air sample was passed through an annular denuder coated with citric acid in a glycerol solution. The denuder absorbed the gaseous form of ammonia. The final stage of the system was a boric acid trap which collected the very small particulate forms of ammonium. Samples were collected over 24 h periods from commercial broiler production facilities throughout the final 2-3 weeks of production. Volumes sampled over the 24 h period averaged 6.5 cubic meters. Following collection, fractions were extracted from the system and stored under acidic conditions until analyzed for ammonia nitrogen content by selective ion analysis. Results of the survey reveal that less than 0.1% of the ammonia nitrogen detected was attached to large particles found in the cyclone filter. The amount of gaseous ammonia trapped in the annular denuder accounted for less than 1.0% of the total with over 98% of the ammonia nitrogen recovered detected in the acid trap. These data indicate that under typical broiler production conditions, most ammonia nitrogen is in the ammonium form attached to small particles. This data will clarify the potential for environmental impact of emissions from broiler production facilities.

Key Words: Ammonia/Ammonium, Broilers, Annular Denuder

330 Effect of different feeding strategies on productivity of broiler breeders. L. F. Romero*[1], M. J. Zuidhof[2], F. E. Robinson[1], A. Naeima[1], and R. A. Renema[1], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Alberta Agriculture and Food*, *Edmonton, AB, Canada*.

This study was done to evaluate the effect of four feeding strategies on productivity relative to feed in settable egg production of broiler breeders ($P_{E:F}$), defined as Cumulative Settable Eggs (CSE) produced per kg of Cumulative Feed Intake (CFI). A total of 288 Ross 708 pullets were raised in floor pens, individually caged at 16 wk of age and assigned to one of four feed allocation groups. Three groups had feed allocated on a group basis with divergent target BW reached at 20 wk: Standard (STD), HIGH (STD × 1.1), and LOW (STD × 0.9). The fourth group had feed allocated on an individual bird basis (IND) and followed the STD BW target. Productivity was assessed at the end of the experimental period (56 wk) and a production function of the form $CSE=a+b(CFI^c)$ was fit in every group to compare the dynamics of $P_{E:F}$ relative to the use of feed. The F statistic was used to evaluate the fit of separate groups versus a pooled fit. Final CSE production (to 56 wk of age) of LOW hens was lower (131.67 eggs, $P<0.01$) than IND, STD and HIGH (148.71, 144.67 and 145.65 eggs), which did not differ significantly. However, HIGH birds showed lower $P_{E:F}$ (4.17 eggs / kg, $P<0.05$) than IND, STD and LOW (4.61, 4.43 and 4.28 eggs / kg), and LOW hens showed lower $P_{E:F}$ than IND ($P=0.03$). Fitting the production function in every group separately showed better fit than when pooled ($P<0.0001$). IND hens had the lowest variability of the residuals (MSE=81.76). As every bird was fed based on individual requirements, the function of this group is a reflection of the individual potential of $P_{E:F}$. This is consistent with a higher c coefficient (=1.057) of IND, which indicates a greater productivity at higher levels of CFI. In contrast, HIGH showed $c=1.021$, a more linear trend than IND hens, but had lower $P_{E:F}$ than LOW, STD and IND along the experimental period, demonstrating that this strategy was inefficient compared with the others. The c coefficients of STD and LOW were 0.941 and 0.884, showing decreasing productivity as the CFI increased.

Key Words: Broiler Breeders, Productivity, Feeding Level

331 Effect of reducing body weight variability on the sexual maturation of broiler breeder females. R. A. Renema*[1], L. F. Romero[1], A. Naeima[1], M. J. Zuidhof[2], and F. E. Robinson[1], [1]*University of Alberta*, *Edmonton, AB., Canada*, [2]*Alberta Agriculture and Food*, *Edmonton, AB., Canada*.

Sexual maturation traits of pullets fed either on a group basis or an individual basis were assessed in Ross 708 broiler breeders. Pullets (208) were assigned to a feeding treatment at hatch and reared together in floor pens prior to placement in individual cages at 16 wk of age. In order to study the impact of initial BW, pullets were grouped in one of three BW groups (Low, Std, or High) using the mean plus or minus 0.5 SD as the threshold. Half of the birds received a common feed allocation based on group BW (Control: CON), while remaining birds received a custom feed allocation to align their individual BW profile with management guide targets (Individual; IND). The IND BW profiles were fully converged by 20 wk of age. Photostimulation was at 23 wk of age. Carcass morphology was monitored between 16 wk and sexual maturity (SM). After their first egg, 64 birds (32/tmt) were dissected for determination of fleshing, fatness, and reproductive morphology. Remaining birds were kept for an egg production study. The CV of BW at 16 wk was 12.8%. By 23 wk it was 6.2% in CON birds and 1.4% in IND birds. ($P<0.0001$). Mean age at SM differed by only 0.15 d between feeding treatments (NS). However, age at first egg was affected by initial BW group ($P=0.018$). Low-IND birds entered lay 5 d faster than Low-CON birds and had an 11% longer total gut length. The range in mean SM age was 0.8 d among IND BW groups compared to 6 d among CON groups. Frame size (as shown by shank and keel length) was only affected by initial BW group, with smaller birds growing more between 16 wk and SM. Feeding treatment did not affect fleshing or fatness at SM. Mean oviduct weight and ovarian morphology parameters were also similar. Variability in LYF number was lower in IND (16.9%) compared to CON birds (22.3%), but was slightly higher for total LYF weight (CV=23.2% vs. 20.8%). Changes in the Low BW group accounted for much of the improved uniformity due to the IND feeding treatment.

Key Words: Broiler Breeder, Sexual Maturity, Ovarian Morphology

332 The energetics of female broiler breeders are affected by genotype and environment. M. J. Zuidhof*[1], R. A. Renema[2], F. E. Robinson[2], and L. F. Romero[2], [1]*Alberta Agriculture and Food*, *Edmonton, AB, Canada*, [2]*University of Alberta*, *Edmonton, AB, Canada*.

This analysis was conducted to investigate the partitioning of ME by broiler breeder (BB) hens. A 3 × 4 × 2 factorial design trial with 3 BB strains, 4 rearing BW profiles and 2 photostimulation (PS) ages determined the impact of strain and management on female BB energetics during lay. Ross 708, Ross 508, and Hubbard Hi-Y BB were reared on BW profiles that diverged at 3 wk and converged at 32 wk of age as follows: STANDARD (mean target BW profile of 3 strains used); LOW (12 wk BW target=25% lower than STANDARD followed by rapid gain to 32 wk); MODERATE (12 wk BW target=150% of STANDARD followed by lower rate of gain to 32 wk); and HIGH (12 wk BW target=200% of STANDARD followed by minimal growth to 32 wk). Birds were photostimulated at 18 or 22 wk. A total of 288 hens were evaluated. A standard metabolic BW coefficient of 0.67 was used to estimate maintenance requirements. Residual ME Intake (RI) was calculated as the difference between the theoretical ME requirements of a bird and actual ME intake. Smaller values indicate greater efficiency. The average ME requirement for maintenance was 139 kcal/kg$^{0.67}$; for BW gain was 1.53 kcal/g; and for egg production was 1.80 kcal/g. Efficiency during lay differed due to rearing BW profile, strain, and age at PS. Rearing BW profile had the most dramatic effect on BB energetics. RI increased in all treatments until 30 wk, and then decreased, except in the HIGH treatment. Birds reared on the HIGH BW profile were most efficient, followed by MODERATE, then STANDARD, then LOW birds (RI= -22, -5, 9, and 20 kcal/d, respectively; P<0.0001). Early and overall RI was reduced in 18- vs 22-wk PS birds (RI=9 vs -8 kcal/d, respectively; P>0.0001). Overall RI of Ross 708 hens was -5 kcal/d. This was more efficient than 3 kcal/d, the average RI of Hubbard Hi-Y and Ross 508 strains (P<0.0001).

Key Words: Residual ME Intake, Nutrient Partitioning, Broiler Breeder Management

333 Spread of a marker *Salmonella* in the presence of background *Salmonella* as detected from broiler litter. R. J. Buhr*[1], L. J. Richardson[1], N. A. Cox[1], and B. D. Fairchild[2], [1]*USDA, ARS*, *Athens, GA*, [2]*University of Georgia*, *Athens*.

The impact of preexisting *Salmonella* in day old chicks on the colonization ability of subsequent marker *Salmonella* strains is not known as both may compete for the same intestinal niches. Chick-box pads were sampled to detect the presence of background *Salmonella* at placement and the flock was determined to be positive (serogroup C3). Day old chicks were placed 40/pen into 6 adjacent pens. In the two end pens (pens 1 and 6) one chick was orally inoculated with 0.1 mL of a 10^3 cfu/mL suspension of a naladixic acid resistant *Salmonella* cocktail (*S. heidelberg*, *S. montevideo*, and *S. typhimurium*). At 1 through 7 wk, the pens were sampled using both conventional drag swabs (CDS) and intermittently stepped on drag swabs (ISODS), two of each per wk. At 1 and 2 wk both the challenge and adjacent pens were positive for the marker *Salmonella* from all drag swab samples (16/16). At 2 wk the middle pens were still negative for the marker strain and 1 positive sample for the background *Salmonella* was detected with an ISODS. At 3 wk the number of marker *Salmonella*-positive samples peaked and extended into the middle pens with 4/4 ISODS and 2/4 CDS positive samples (overall 22/24). Then at 4 and 5 wk, the number of marker *Salmonella*-positive samples gradually decreased, mainly from the middle pens from 17/24 to 16/24 total samples positive. The marker *Salmonella* continued to decline at 6 and 7 wk from 12/24 and 3/24. Overall, ISODS samples had significantly more positive samples (57/84) than CDS (45/84) and all but 10/84 positive samples coming from the challenged or adjacent pens. By challenging only one chick per pen, the marker *Salmonella* spread easily from the challenged to adjacent pens and into the center pens. The *Salmonella* prevalence in the litter was the highest at 3 wk and then decreased by 7 wk. The presence of a background *Salmonella* at placement does not appear to inhibit colonization by the marker *Salmonella* or the spread into adjacent pens. However, at 6 wk *Salmonella* recovery from litter had progressively declined from the challenge pens (7/8), to the adjacent pens (4/8), to the middle pens (1/8).

Key Words: *Salmonella* Detection, Litter Sampling, Drag Swab

334 Effect of starter period duration on live oocyst vaccination efficacy and broiler performance following subsequent *Eimeria* challenge. J. T. Lee*[1], N. H. Eckert[1], S. M. Stevens[1], S. Anderson[1], P. Anderson[1], H. D. Danforth[2], A. P. McElroy[3], and D. J. Caldwell[1], [1]*Texas A&M University*, *College Station*, [2]*USDA-ARS*, *Beltsville, MD*, [3]*Virginia Polytechnic Institute and State University*, *Blacksburg*.

An experiment was conducted to investigate the effect of dietary starter period duration on broiler performance during a live oocyst vaccination program followed by field-strain Eimeria challenge. The experimental design was a 3 x 2 x 2 factorial with the variables of starter diet duration (13, 17, and 21 d), vaccination, and a mixed species *Eimeria* challenge. On d 21, broilers were challenged with a mixed species *Eimeria* inoculum containing *E. acervulina*, *E. maxima*, and *E. tenlla*. On d 27, 10 broilers from each replicate pen were necropsied for the determination of intestinal lesion development. Average body weights for vaccinated and non-vaccinated broilers were similar (P>0.05) at 13 d of age. On day 17 and 21, vaccinated broilers had lower (P<0.05) average body weights compared to non-vaccinated broilers while no effect was observed with respect to starter duration. Feed conversion ratios were similar (P>0.05) for vaccinated and non-vaccinated broilers pre-challenge. Broilers switched to the grower diet on d 13 had an increased (P<0.05) feed conversion compared to broilers switched to the grower diet on d 17 and d 21. During the challenge period, body weight gains and feed conversion ratios were similar for all non-challenged treatments. In challenged broilers, all vaccinated treatment groups gained more (P<0.05) body weight and displayed reduced (P<0.05) feed conversions ratios than non-vaccinated broilers post-challenge. Cumulative feed conversion ratios (1d to 27d) were similar for all non-challenged treatments. Lesion development was reduced (P<0.05) in the upper and lower intestinal segments in vaccinated challenged broilers compared to non-vaccinated challenged broilers. Live oocyst vaccination resulted in improved broiler performance and reduced lesion development during a field strain *Eimeria* challenge regardless of starter period duration.

Key Words: *Eimeria*, Broiler, Vaccination

335 *Campylobacter* contamination of broilers fed cottonseed or cottonseed products. J. A. Byrd*[1], R. D. Stipanovic[2], J. L. McReynolds[1], L. F. Kubena[1], and D. J. Nisbet[1], [1]*USDA/ARS/SPARC, Food and Feed Safety Research Unit*, *College Station, TX*, [2]*USDA/ARS/SPARC, Cotton Pathology Research Unit*, *College Station, TX*.

Previous research has demonstrated that broiler breeders fed cottonseed meal had significant reductions in *Campylobacter* when compared to soybean controls. In the present experiment, three studies were conducted to evaluate the effect of dietary cottonseed meal or gossypol on the incidence of *Campylobacter* and *Salmonella* colonization in broilers. In the first study, an *in vitro* fermentation using cecal contents from six-week-old broilers were combined with gossypol (4 µg/mL) and challenged with either *Campylobacter jejuni* (10^4 cfu/mL) or *Salmonella* Typhimurium (ST; 10^4 cfu/mL) and evaluated for the presence of these bacteria at 1, 3, 5, or 18 hours after challenge. *Campylobacter* was significantly reduced from the gossypol treated contents one h after exposure as compared to the controls. *Salmonella* was not significantly reduced compared to the control. In the second study, day-of-hatch broiler chicks were fed a diet containing 0, 300, or 600 mg/kg of gossypol for 10 days and challenged with ST at d 3. The incidences in cecal *Salmonella* concentrations were not significantly different in broilers fed gossypol when compared to the controls. In a third study, market-age-broilers were fed a diet containing either a corn-soybean control, 20% cottonseed meal, 5% cottonseed hulls, or 5% whole cottonseeds for 12 weeks to evaluate the effects on *Campylobacter* cecal colonization. Broilers fed each diet became *Campylobacter* positive after one week and remained positive until termination of the experiment. The results of the present study suggest that broilers fed cottonseed or cottonseed products were not protected from *Campylobacter* or *Salmonella* colonization.

Key Words: Broiler, *Campylobacter*, Cottonseed

Production, Management & the Environment - Livestock and Poultry: Dairy Production and Management II

336 Reasons for culling in Iranian Holstein cows. A. A. Naserian[1], M. Sargolzaee[1], M. Sekhavati[1], and B. Saremi*[2], [1]*Ferdowsi University Of Mashad, Agric college, Animal Science Department*, *Mashhad, Khorasan Razavi, Iran*, [2]*Education Center of Jihad-e Agriculture, Animal Science Departemnt*, *Mashhad, Khorasan Razavi, Iran*.

Culling of dairy cows is probably one of the most complex decisions in dairy operations. It involves several factors and farmers consider e.g. stage of lactation, age, health status, level of milk production and current reproductive status of cows while making decisions about which cows to keep and which ones to call. The aim of this study was to determine the profiles of culled cows in order to access the possible contribution to economic losses due to health disorders in the dairy herds of Khorasan province (Northeast of Iran). Data regarding all exits of cows from the herd were collected during a 5-year prospective survey in 15 large dairy commercial Holstein herds with over 4000 milking cows totally (From March 1999 to March 2004). All herds were recorded by an official milk-recording scheme. The management and feeding systems were almost similar in all herds. Rolling herdâ€™s averages were also similar in all herds; over 24000 lb. A polytomous stepwise logistic regression method was used because it allows the use of a non-ordinal categorical variable. The model was run (Procedure PR of BMDP). Table 1 shows the results of this study. The most frequent primary culling reasons were infertility and health disorders, 25.13, 28.57 of total cull respectively. Percentages of six groups of culling reasons for level of parity showed that the first parity level had more frequent reproductive problems and health problems too. Therefore, in this study, more than one half of the cows were declared culled for health or reproductive related problems.

Table 1. Primary culling reasons across parities (Iranian Holstein cows 1999-2004)

	Parity						Total
Problem	1	2	3	4	5	>5	%
Reproductive	6.02	4.62	3.54	3.76	3.97	3.22	25.13
Mastitis	4.08	1.84	0.97	1.18	1.50	1.50	11.06
Lameness	2.15	1.50	2.47	2.50	1.18	2.26	11.07
Milk fever	0.54	0.75	1.18	0.86	1.07	1.61	6.02
Low Milk yield	2.26	2.79	3.44	1.61	2.15	5.91	18.15
Health disorders	5.70	3.22	4.83	5.59	4.19	5.05	28.57

Key Words: Culling, Parity, Health and Production

337 Commercial application of sex-sorted semen in Holstein heifers. J. M. DeJarnette*[1], R. L. Nebel[1], B. Meek[2], J. Wells[3], and C. E. Marshall[1], [1]*Select Sires, Inc.*, *Plain City, OH*, [2]*Cache Valley Select Sires*, *Logan, UT*, [3]*All West Select Sires*, *Turlock, CA*.

Flow cytometric procedures were used to produce sex-sorted (SS; ~90% X-bearing), cryopreserved Holstein semen for commercial use at 2.1 x 10^6 sperm/dose. Data were obtained from 108 herds of Holstein heifers via electronic back-up of herd records and personal communications. Conception rates (CR) achieved at first services with conventional semen (CS) were used to assess relative field performance and were assumed to be 60% when CS data were not available. The unadjusted CR to SS across 121 herds was 44% (n=16,587). The CR achieved by SS averaged 85±2.9% of that achieved with CS at first service and 74% of herds achieved CR ≥70% of that obtained with CS at first service. Among 25 herds that used ≥100 doses of SS (n=608±122 per herd), CR to SS averaged 48±1.9% (range 33 to 72%) compared to a CS first service CR of 54±1.8% (range 38 to 70%; n=525±109 per herd). Among heifers bred to SS, the average age at AI (425±0.81 d, n=3969) and at calving (708±1.31 d, n=2280) was shorter ($P<0.01$) than for heifers bred to CS (461±1.05 d, n=2367; 745±1.19 d, n=4028, respectively) reflecting recommendations for preferential use of SS at first service. Among heifers that failed to conceive at AI, the percentage re-bred in a normal 18 to 24 d interval was greater ($P<0.05$) for SS (70%, n=5,495) than CS (64%, n=3,712), which may be a function of more accurate estrus detection among SS bred heifers or a result of increase rates of fertilization failure to SS. The percentage of abortions did not differ ($P>0.05$) among heifers that conceived to SS or CS (1.4%, n=1810 vs. 1.9%, n=4902, respectively). Among single births, the percentage of female calves was greater ($P<0.001$) for SS (90%, n=3,361) than CS (48%, n=10,999). Among twin births, a greater percentage ($P<0.01$) of female-female pairs were observed for SS (75%, n=20) than CS (22%, n=121). Legitimate comparisons of CR for SS and CS in the commercial setting are difficult due to bias in semen use, however these data imply >70% of herds achieved CR with SS that were ≥70% of first service CR obtained using CS with a resulting female gender bias of ~90%.

Key Words: Sexed Semen, Flow Cytometry, Heifer AI

338 Effect of out-wintering pad design on cow hoof health. K. O'Driscoll*[1,2], L. Boyle[1], P. French[1], and A. Hanlon[2], [1]*Moorepark Dairy Production Research Centre*, *Fermoy, Co. Cork, Ireland*, [2]*University College Dublin*, *Dublin, Ireland*.

This study aimed to evaluate four over-wintering options for spring calving dairy cows; uncovered [UP] and sheltered [SP] woodchip pads, both with a concrete feed face, a woodchip pad with a self-feed silage pit on top [SF] and indoor cubicles [IC], with regard to hoof health. Cows (n=96) were assigned to treatment using a randomized complete block design from 17 Nov (pluriparous) or 5 Dec (primiparous) until calving (mean=21 Feb 06) then turned out to pasture. Sole lesions (SL) heel erosion (HE) and dermatitis (D) on hind feet were scored according to severity at housing, calving, 8 & 14 weeks post partum (pp). Hardness (Shore D scale) of all claws was recorded at each inspection using an analogue duromoter. Data was analyzed using SAS. A mixed model was used to analyze SL and HE. Kruskall-Wallis and Wilcoxon tests were used to analyze D. Correlations between hardness and pathologies were investigated. Treatment had no effect on SL score, but scores increased over time ($P<0.001$), with an interaction between treatment and time ($P=0.1$). There were higher HE scores on SF than IC and SP ($P<0.01$). Cows on SF had highest D scores and IC lowest ($P<0.05$). Higher D scores occurred in SF than IC ($P<0.01$) and SP ($P<0.05$) at calving, and SF tended to have higher scores than IC 8 weeks post calving ($P=0.06$). Lateral claws were harder than medial claws ($P<0.001$). Hardness was highest at housing, lower at calving and 8 weeks pp ($P<0.05$), but no different 14 weeks pp. The hooves of IC and SP cows were harder than those of SF and UP cows ($P<0.05$). There was no correlation between hardness and D, and only weak correlations with SL ($P<0.001$; $r=-22.602$) and HE ($P<0.05$; $r=-0.061$). Exposure to excreta and moist conditions are risk factors for D and HE, explaining higher levels of these pathologies in SF than the other treatments as the feedface had no manure removal system. In IC the passageways as well as feedface were cleaned of manure explaining lower D scores. Provision of shelter on SP reduced exposure to environmental moisture which ensured hooves remained as hard as those in IC. However, low correlations between hardness and pathologies indicate that other factors are involved in pathology development.

Key Words: Dairy, Housing, Hoof Health

339 Correlation between tarsal lesions on dairy cows housed in free-stalls and culling rate, somatic cell count, percent mature cows, and milk production by stall base. W. K. Fulwider*, T. Grandin, D. J. Garrick, T. E. Engle, W. D. Lamm, N. L. Dalsted, and B. E. Rollin, *Colorado State University*, *Fort Collins*.

The objective of this study was to determine relationships between tarsal lesions, management, and outcomes by base: rubber-filled mattress (RFM), sand, and waterbeds (WB) from data collected on 85 dairies. Somatic cell count (SCC) was correlated with stall width (-0.26, $P = 0.02$). Percent of cows with tarsal swelling was correlated with stall length (-0.23, $P = 0.05$). Somatic cell count was correlated with stall width (-0.50, $P = 0.01$) and length (-0.46, $P = 0.01$) on RFM. Severe swellings were correlated with stall width (-0.52, $P = 0.01$) and SCC (0.60, $P = 0.001$) on RFM. Inadequate stall dimensions may increase lesions and SCC. Percent mature cows (fourth lactation or greater) was 13% (RFM), 14% (sand), and 20% (WB). Percent mature cows on sand was related to stall length (0.56, $P = 0.01$). Base types may require different stall dimensions to maximize cow well-being and productivity. Cull rates were 29% (RFM), 26% (sand), and 23% (WB). Within base type dairies were split into thirds according to the percentage of cows with tarsal swellings. Percent of cows with swellings differed for RFM ($P < 0.0001$): 4% in the best herds and 27% in the worst; corresponding best and worst for sand were 0% and 5% ($P < 0.01$); while (WB) were 1% and 9% ($P < 0.0001$). Sand and waterbeds may require less management than RFM. Rolling herd average (RHA) by bases were 8,399 L (RFM), 8,626 L (sand), and 8,172 L (WB). When base type dairies were split into thirds according to tarsal swelling, only RFM was different for RHA ($P = 0.01$). The worst dairies produced 1,816 L additional milk, with the highest culling rate (31%). Sand dairies differed in production by 227 L, the high third for lesions had the high RHA. There was no difference in RHA for (WB). Annual death rate (0.34, $P < 0.002$) and percent lame on visit day (0.45, $P < 0.0001$) were correlated with SCC; these rates were highest on RFM dairies (0.52, $P = 0.004$) and (0.52, $P = 0.003$). Inadequate stall dimensions may contribute to lameness, lesions, premature culling and increased death rate. Lameness and lesions may increase SCC.

Key Words: Somatic Cell, Lesion, Cull

340 Effect of body condition score at calving on production and reproduction performance in dairy herds of Argentina. J. Grigera*[1], F. Busso[2], F. Bargo[1], and C. Corbellini[2], [1]*Elanco Animal Health, ACBSCR*, [2]*INTA Pergamino*.

Claves is a program conducted by INTA and Elanco to monitor body condition score (BCS) and metabolic diseases of transition dairy cows in Argentina. A 4000-cows data set from 15 dairies was used to determine the relationship between BCS at calving and production and reproduction performance. Body condition score (1 to 5 scale) was measured at calving, milk production at 15, 45, and 75 DIM, and subclinical ketosis (milk BHBA concentration, Ketotest) at 30 DIM. A complete randomized blocked design was used to analyze the data using the SAS PROC MIXED model with dairy as random variable and parity and calving season as fixed variables. A significant ($P <0.05$) interaction between BCS at calving and parity was found for milk production. Primiparous cows produced more ($P < 0.05$) milk when calving at 3.75. Milk production of primiparous cows decreased ($P < 0.05$) linearly as cows calved with BCS lower than 3.75. Multiparous cows produced more ($P < 0.05$) milk when calving at 3.25. Milk production of multiparous cows was lower ($P < 0.05$) when calved with BCS lower or higher than 3.25. Cows losing 0.75 of BCS during the first 30 DIM produced more ($P < 0.05$) milk than cows losing 0.25 (28.4 vs. 27.6 kg/d). Losing more than 0.75 points of BCS did not increase ($P > 0.05$) milk production. Days to first service and days to conception were lowest ($P < 0.05$) for cows calving at 3.25 or 3.75. Subclinical ketosis positive cows (≥ 100 µm/L milk BHBA) had higher ($P < 0.05$) BCS at calving (3.52 vs. 3.40) and lower ($P < 0.10$) milk production at 15 DIM (25.5 vs. 26.7 kg/d) than negative cows. Positive cows were 0, 1.9, 1.5, 3.3, and 3.5% for cows calving at 2, 2.25, 2.75, 3.25, and 3.75, respectively. The low incidence of ketosis is probably associated to the use of monensin in the transition diets. Body condition score at calving affected production and reproductive performance of dairy herds in Argentina. Optimum BCS at calving for production and reproduction performance were 3.75 and 3.25 for primiparous and multiparous cows, respectively.

Key Words: BCS, Performance, Ketosis

341 Ration sorting in freestall dairy herds. M. I. Endres* and L. A. Espejo, *University of Minnesota*, *St. Paul*.

The objectives of this study were to evaluate ration sorting and investigate herd-level risk factors for sorting by high producing dairy cows housed in freestall barns. Fifty randomly selected dairy herds participated in the study which was conducted during the summer. Five representative samples of TMR were collected from the high group feed bunk during the one time visit to represent the initial ration as delivered to the cows, three other samples collected every 2-3 hours, and the accumulated orts cleaned out of the bunk by the feed manager. At every sampling time, measurement of the particle size of the TMR was performed in triplicate by the same person using the 3-screen and bottom pan The Pennsylvania State University Particle Separator, and a sample was taken for DM, NDF, and CP analysis. The average of mass retained at each sampling time was used to calculate the geometric mean of particle length. No herds were below the minimum recommendation of 2% particles retained on the upper screen; however, 52% of them were above the maximum recommended limit of 8%. The geometric mean particle length of the TMR delivered to the 50 high production groups was 6.4 mm ± 1.4 mm. The TMR had physical and chemical changes across the samples. After feed delivery cows sorted the TMR against long particles favoring the consumption of shorter particles. The overall geometric mean of particle size increased from 6.4 mm in the initial ration to 9.2 mm in the orts. The NDF content increased 6.75 percentage units whereas the CP content decreased 1.52 percentage units in the orts compared to the initial sample. The multivariate regression model used for the analysis of factors associated to changes in the geometric mean of the particle size of the ration indicated that frequency of feed delivery, initial geometric mean of the particle size of the ration, hay content of the ration, and time after feed delivery were associated with ration sorting. Additionally, linear feed bunk space per cow tended to be associated with ration sorting. In contrast, type of feed bunk barrier, frequency of feed push-up, percent of forage in the ration, and DM content of the initial ration were not associated with ration sorting.

Key Words: Ration Sorting, Rsk Factors

342 The effect of breed and feeding a split ration to lactating hair sheep on ewe body temperature in the tropics. R. W. Godfrey*, M. C. Vinson, and R. C. Ketring, *University of the Virgin Islands, Agricultural Experiment Station*, *St. Croix, US Virgin Islands*.

Lactating St. Croix White and Dorper × St. Croix White ewes grazing guinea grass pastures were used to evaluate the effect of breed and feeding a split ration on body temperature during the cool (March through April) and warm (July through August) seasons. In each season ewes were assigned to treatments (n = 8/treatment) based on breed, age and number of lambs. Treatments consisted of individually feeding 0.9 kg concentrate (16.4% CP, 68% TDN) in the morning (AM) or afternoon (PM), 0.45 kg in the morning and afternoon (AM-PM) or no feed (Control) for 46 d beginning on d 6 (lambing = d 0). Ewes were fitted with intravaginal temperature data loggers, set to record vaginal temperature (VT) at 5-min intervals, for 48 h in wk 2, 5 and 8 postpartum. The mean temperature, relative humidity and and temperature humidity index during the cool and warm seasons were 25.8 °C, 85.9% and 76.1 and 28.3 °C, 86.7% and 80.6, respectively. There was no effect of season ($P > 0.10$) so all data were pooled across season. During wk 2 there was no difference ($P > 0.10$) in VT around the AM or PM feeding times among treatment groups. During week 5 the AM-PM fed ewes had higher ($P < 0.01$) VT than ewes in other groups around the times of feeding. During wk 8 the AM-PM and the PM fed ewes had higher VT ($P < 0.01$) than either the AM fed or Control ewes. Data from all ewes fed in the PM (PM and AM-PM; PMALL) was pooled and compared to the Control and AM ewes. During wk 2 there was no difference ($P > 0.10$) in VT around the AM or PM feeding times among the groups. During wk 5 and 8 the PMALL ewes had higher ($P < 0.01$) VT than Control or AM ewes around the times of feeding. To determine breed differences, data were pooled across treatments and compared between breeds. Dorper × St. Croix White ewes had higher ($P < 0.05$) VT than St. Croix White ewes during wk 5 and 8 but not during wk 2 ($P > 0.10$). The results show that body temperature of ewes can be influenced by time of feeding and breed. Ewes fed in the afternoon had elevated body temperatures which could make them more susceptible to heat stress.

Key Words: Sheep, Feeding, Body Temperature

343 Effects of heat stress on production, lipid metabolism and somatotropin variables in lactating cows. M. L. Rhoads*[1], R. P. Rhoads[1], S. R. Sanders[1], S. H. Carroll[1], W. J. Weber[2], B. A. Crooker[2], R. J. Collier[1], M. J. VanBaale[1], and L. H. Baumgard[1], [1]*University of Arizona*, [2]*University of Minnesota*, *St. Paul*.

To delineate differences between heat stress and decreased feed intake on physiological and metabolic indices, we conducted a heat stress experiment where a thermal-neutral control group (n=6) was pair-fed/underfed (UF) to match nutrient intake with heat-stressed (HS) Holstein cows (n=6). Multiparous cows (140 DIM, 663 kg BW) were subjected to two experimental periods: 1) thermal neutral (TN) and ad libitum intake for 9 d and 2) HS or UF for 9 d. HS conditions were cyclic with temperatures ranging from 29.7 to 39.2°C. During each period all cows received an I.V. challenge of epinephrine (EPI, 1.4 µg/kg BW, d 6), growth hormone releasing factor (GRF 4 µg/100 kg BW, d 7), and a somatotropin (ST, 15 µg/kg BW, d 9) and had ST profile characteristics assessed (sampled every 15 min for 6 hr, d 8). Results were analyzed as repeated measures using PROC MIXED of SAS. Rectal temperatures and respiration rates increased during HS (38.7 to 40.2°C and 46 to 82 breaths/min). HS reduced DMI by 32% and by design, UF cows had similar intake reductions (34%). Milk yield was decreased by HS (45%, 14.5 kg/d) and UF (19%, 6.7 kg/d), but there were little effects on milk composition. Reduced DMI only accounted for 46% of the decreased milk production by HS. Both HS and UF markedly reduced EBAL, but only UF increased basal NEFA levels (136 vs. 298 µEq/l). Neither NEFA response to EPI nor ST response to GRF differed between treatments. Area under the curve and rate of ST disappearance in response to the ST challenge did not differ between treatments. During the 6 h bleed, there were little or no treatment differences on ST pulsatility and mean ST (4.25 ng/ml). Reduced nutrient intake accounted for about 50% of the HS-induced decrease in milk yield and this appears to have occurred independent of changes in the ST system. Differences in basal NEFA between UF and HS suggest a shift in metabolism and nutrient partitioning which may help explain reduced milk yield during heat stress.

Key Words: Heat Stress, Somatotropin, Lipid Metabolism

344 Effect of encapsulated niacin on resistance to acute thermal stress in lactating Holstein cows. R. B. Zimbelman*, J Muumba, L. H. Hernandez, J. B. Wheelock, G. Shwartz, M. D. O'Brien, L. H. Baumgard, and R. J. Collier, *University of Arizona*.

Twelve multiparous Holstein cows producing an average of 31.7 kg/d and balanced for parity and stage of lactation were randomly assigned to either 0 g encapsulated niacin/d (C) or 12 g niacin/d (NIASHURETM®) (Trt) and were exposed to two environmental temperature patterns, thermoneutral (TN) and heat stress (HS). The temperature humidity index (THI) range of TN pattern never exceeded 72 while HS consisted of circadian THI temperature range exceeding 72 for 12 hours per day. Milk yields were recorded twice a day and milk sampled once a day for composition. Cows were fed twice a day and refusal and water intake was measured once a day. Respiration rates, surface temperatures of both shaved (S) and unshaved (U) areas were taken at the rump, (ST-R-S, ST-R-U) shoulder, (ST-S-S, ST-S-U), and tailhead (ST-T-S, ST-T-U), and sweating rates (SR) of the shoulder shaved (SR-S) and unshaved (SR-U) areas 4× daily. Rectal temperatures (RT) were measured four times a day. Cows in Trt had increased DMI (40.7 vs 37.7,g/d) compared to cows in C. Surface temperatures were unaffected by Trt but were affected by shaving (32.5 shaved vs. 31.4°C unshaved). Cows given Trt had a tendency for higher average sweating rates when shaved (66.3 vs 57.8 g/M2/hr, P=0.11) and numerically for unshaved (57.4 vs 52.7 g/M2/hr) over the entire 24 hour period and these differences grew larger during periods of peak thermal stress along with the entire study (62.0° shaved vs. 55.0° unshaved). Between 11:00AM and 4:00 PM average sweating rate for Trt group was higher than C (81.1 vs. 68.2 g/M2/hr shaved; P<0.0001 and 70.6 vs. 62.3 unshaved; P<0.0001). Vaginal temperatures recorded at 15 min intervals and averaged over last 72 hours of period 2 (HS) were lower (38.4 vs. 38.0°C; P <.0001) for cows given Trt compared to cows in C. We conclude that cows given encapsulated Niacin had higher sweating rates and lower core temperatures during acute thermal stress.

Key Words: Niacin, Heat Stress, Sweating Rate

345 Effect of level of production and intensive cooling in summer on productive and reproductive performance of high yielding dairy cows. I. Flamenbaum*[1] and E. Ezra[2], [1]*Ministry of Agriculture, Extension Service*, *Beit-Dagan, Israel*, [2]*Israel Cattle Breeders Association*, *Caesarea, Israel*.

The effects of production level and heat stress relief were studied during 2005 in a large scale survey including 22 dairy herds, averaging 300 cows each and a total of 6600 cows. All the dairy herds were located in the coastal part of Israel. Cows in all the herds were held under similar housing system, milked 3 times per day and fed for ad libitum intake a TMR, distributed twice daily. Twelve of the herds were of high and 10 of low production level (previous year winter Economical Corrected Milk - ECM yields averaged 41 and 35 kg/d, respectively). Cows in half of the herds in each production level were intensively cooled (IC) during summer, using a combination of wetting and forced ventilation for 10 cooling periods and a total of 7 cumulative hours/d. Cows in the second half of the herds in each production level were moderately cooled (MC) by a combination of wetting and forced ventilation in the holding pen, only before milking. Winter (Jan-Mar), spring (Apr-Jun), summer (Jul-Sep) and autumn (Oct-Dec) ECM production averaged 41.5, 41.0, 40.7, 41.7 kg/d, respectively, for the IC herds, and 38.5, 37.7, 33.8, 35.7 kg/d, respectively, for the MC herds of the high production level. During the same seasons, in the low producing herds, ECM production averaged 36,5, 38.0, 36.8, 37.8 kg/d, respectively, for the IC herds, and 34.4, 34.6, 30.2, 33.5 kg/d, respectively for MC herds. Intensive cooling, significantly reduced summer decline in ECM production and conception rate for herds of both production levels (P<0.01). Conception rate of first and second insemination, performed in winter, spring, summer and autumn averaged 39, 31, 19, 29%, respectively, for the IC, and 39, 30, 12, 29%, respectively, for the MC high producing herds. For the same seasons, in the low producing herds, conception rates averaged 40, 38, 25, 40%, respectively in the IC and 39, 25, 3, 29%, respectively, in the MC herds. Intensive cooling almost eliminated summer decline in milk production, regardless of the level of production and reduced about half of the summer decline in conception rate. Intensive cooling had greater impact on improving conception rate in low, than in high producing herds.

Key Words: Intensive Cooling, Milk Production, Conception Rate

346 Reducing freestall availability without limiting feed access during dry period does not affect subsequent milk yield. J. M. Velasco*, K. K. Fried, T. F. Gressley, E. D. Reid, T. C. Hausman, and G. E. Dahl, *University of Illinois*, *Urbana*.

Comfortable housing during the dry period may impact the dairy cow as reflected in her health, reproductive and productive performance during lactation. Stocking density is a critical component of overall cow comfort, yet the impact of stocking density during the dry period is unknown. Further, the relative contribution of limiting feed access versus stall access to stocking density effects is unknown. To determine if reduced freestall availability during the dry period had an impact on subsequent milk yield and performance, we used 40 Holstein cows dried off approximately 58 ± 12 d before calving and assigned to 70% stall availability (70SA; n=20) or 100% stall availability (100SA; n=20) for the entire dry period. All cows were fed individually using a Calan gate system and dry matter intake (DMI) was recorded during the dry period. Prolactin (PRL) concentration was measured in samples collected every other week from dry off until calving as an indicator of relative stress. Body condition score (BCS) was measured every other week. Treatments ended at calving when all cows were managed in a commercial facility throughout lactation. Cows were milked 3 times per day; milk production was recorded until 150 d in milk. Days dry averaged 57.3 for 70SA and 59 for 100SA (P>0.4). There was no difference between treatments in DMI, PRL, BCS and milk production (P>0.5). When dry, cows on 70SA consumed 15.3kg/d DM compared with 14.9 kg/d for cows on 100SA. BCS was not different between treatments, and scores averaged 3.2 for 70SA versus 3.1 for 100SA cows. One day after treatment began and at calving, PRL concentrations averaged 14.8 and 25.8 ng/mL for 100SA and 16 and 24.4 ng/mL for 70SA, respectively. Milk production was 43.9 kg/d for 100SA and 43.5kg/d for 70SA. These results suggest that dry cows can adapt to substantial reductions in stall availability during the dry period if adequate access to feed is maintained, and not experience a reduction in subsequent milk yield.

Key Words: Freestall Availability, Dry Period, Milk Yield

347 Using ear canal temperature to predict vaginal temperature. B. H. Carter*, T. H. Friend, M. A. Tomaszewski, J. R. Fisher, and G. M. Bingham, *Texas A&M University*, *College Station*.

The objective of this study was to evaluate the efficacy of using ear canal placement of a temperature data logger as a predictor of vaginal temperature. Temperature data loggers are commonly used to sample body temperature in unrestrained animals. Temperature loggers have previously been placed in the vagina and(or) ear canal of cattle, horses and sheep. Two trials were conducted in Texas during summer (n = 7) and winter (n = 9) conditions when ambient temperature ranged from -2.0 to 9.5°C and 18.3 to 36.56°C respectively. Holstein-friesian cows were fitted with two iButton® temperature loggers programmed to sample every five min. The data loggers were placed vaginally using progesterone free CIDRs®. Data loggers were placed in the ear canal by first inserting the logger into the tip of a cotton infant sized sock which was then filled with polyester fiber batting. The data logger portion was placed in the ear canal and the batting packed firmly against the canal opening to insulate it from external thermal influence. Finally, the pinna of the ear was wrapped around the sock and taped closed using 3 inch wide Elastikon™ tape to hold the sock and batting in place. The resulting data was analyzed using the GLM procedure of the SAS® system. Ear canal temperature predicted vaginal temperature for the summer ($r^2 = 0.58$) and for the winter ($r^2 = 0.70$) trial. To adjust for variation due to moisture cooling the data loggers during udder washes or overhead sprinkling, the data were edited to drop outlying data points. Adjusting the data yielded a correlative value of $r^2 = 0.75$ for the summer trial and $r^2 = 0.73$ for the winter trial. Measuring ear canal temperature as described can be used for predicting vaginal temperature, although ear canal temperature may be susceptible to external influences, especially water.

Key Words: Cattle, Temperature, Data Logger

Ruminant Nutrition: Nitrogen Metabolism/Immunology

348 Effects of N solubility on metabolisable protein value of grass silage. P. Huhtanen*[1], M. Rinne[2], and J. Nousiainen[3], [1]*Cornell University*, *Ithaca, NY*, [2]*MTT-Agrifood Research*, *Finland*, [3]*Valio Ltd.*, *Finland*.

Proportion of soluble N in grass silage total N (SOLN) is related to protein degradability, especially determined in situ. Hence the concentration of metabolisable protein (MP) should decrease with higher SOLN. To test this hypothesis a meta-analysis based on 253 treatment means from 79 dairy cow production studies was conducted. In each study forage treatments (e.g. date of cut, fermentation quality and wilting) were investigated. Both the level and composition of concentrates were fixed within a study. Silage SOLN was divided into ammonia N and soluble non-ammonia N (SNAN). Silage MP was calculated as amino acids absorbed from the small intestine using constant values for ruminal protein degradability and intestinal digestibility of RUP. Mixed model regression analysis (SAS) with a random study effect (intercept random) was used to model milk protein yield (MPY), efficiency of N utilisation (NU) and milk urea N (MUN) concentration using estimated MP supply alone or together with SOLN fractions as independent variables. MPY was closely related to MP supply (residual mean squared error (RSME) of MPY adjusted for random study effect 15.7 g/d) suggesting that the simple MP model estimated the variation in silage MP precisely. MPY decreased with increasing soluble N concentration in silage, but the effect was almost completely related to ammonia N, and the effects of SNAN were non-significant and small. The effects of soluble N fractions on MUN and NU were consistent with milk production responses. The lack of MPY responses to silage SNAN concentration suggested that the division of silage N between soluble and insoluble N (excluding ammonia N) does not markedly influence silage MP concentration. In is concluded that analysis of silage SOLN has a limited value in practical feed evaluation and silage MP concentration can be estimated accurately using constant values for ruminal protein degradability and intestinal digestibility of RUP.

Key Words: Dairy Cow, Protein Utilization, Degradability

349 Ruminal metabolism of ^{15}N labelled ammonium-N and grass silage soluble non-ammonia-N. S. Ahvenjarvi*[1], A. Vanhatalo[1], P. Huhtanen[1], and A. N. Hristov[2], [1]*MTT Agrifood Research Finland*, *Jokioinen, Finland*, [2]*University of Idaho*, *Moscow*.

Ruminal metabolism of ^{15}N labelled ammonium-N and grass silage soluble N fractions was investigated in a change-over study using four dairy cows. Timothy grass (Phleum pratense) grown on a field plot was fertilized with ^{15}N enriched ammonium-N. Grass was preserved as silage, and then fractionated into soluble and insoluble fractions. Labelled ammonium-N (821 mg of ^{15}N in excess of background enrichment) and grass silage soluble N (840 mg ^{15}N) was administered into the rumen as a single dose. Grass silage soluble N fractions comprised 59 mg of ammonia-^{15}N and 781 mg of soluble non ammonia-^{15}N (SNAN). To follow the ruminal metabolism of ^{15}N-labelled N-fractions grab samples of ruminal digesta were collected at 0.5, 1.0, 1.5, 2, 3, 4, 6, 8, 11, 14, 17, 22, 27, 33, 39, 47, 55, 63 and 72 h after the dose. Digesta samples were treated with mercuric chloride, then fractionated into ammonia-N, SNAN, insoluble-N, and bacteria-N. Rumen liquid passage rate was determined using LiCoEDTA and particle passage rate was determined based on ADIN-^{15}N excretion in feces. A dynamic mechanistic model was developed to describe the ruminal N metabolism. The model comprised five ruminal compartments: grass silage SNAN, ammonia-N, bacteria-N associated with non-escapable particles, bacteria-N associated with escapable particles, and liquid associated bacteria-N. The model indicated that of ammonia-N administered into the rumen 32% disappeared by absorption, 19% escaped in the liquid phase, 14% in liquid associated bacteria-N, and 36% in particle associated bacteria-N. Of grass silage soluble N 17% was absorbed as ammonia-N, 11% escaped the rumen in liquid phase as ammonia-N, 19% escaped the rumen in liquid associated bacteria, 33% in solids associated bacteria, and 19% of grass silage SNAN escaped the rumen as undegradable feed N. In conclusion, a greater proportion of silage soluble N compared with ammonia-N is incorporated into microbial N, and a considerable proportion of silage SNAN escapes rumen degradation.

Key Words: Grass Silage, Rumen N Metabolism, Modelling

350 The aerobic stability of forage maize silage preserved with microbial inoculant with and without preservatives. J. K. Margerison*[1], S. A. Hall[2], and D. Wilde[3], [1]*Massey University*, *Palmerston North, New Zealand*, [2]*University of Plymouth*, *Plymouth, UK*, [3]*Alltech Ltd*, *Stamford, Lincs, UK*.

Forage maize (FM) was (harvested DM 29 ± 1.29 %) ensiled in experimental silos with: No additional additive and 100 ml of water / 100 kg FM (NA 0.5); No additional additive and 200 ml of water / 100 kg FM (NA 1); Sil-All fireguard at 0.25g/100kg FM (SAFS 0.5); Sil-All fireguard 0.5g/100kg FM (SAFS1); Maize All GS 0.5g/100kg FM (MAS 0.5); Maize All GS 1g/100kg FM (MAS 1). Replicate (3) silos were stored (constant 17 to 20 °C) for 30 d. On opening silage was analysed for: DM, pH, lactic acid, acetic acid, NDF, ADF, crude protein, ME and ash at 0, 24, 48, 96 and 168 h and aerobic stability (AS) was assessed. AS significantly increased in silage treated with SAFS FR and HR and MAS at FR. AS; HR (0.5) NA 29.4, SAFS 73.2, MAS 33.0, (sem 14), at FR (1) NA 41.1, SAFS 76.5, MAS 56.4, (sem 10.30). Time to maximum pH was significantly lower with additive applied at FR compared with HR, maximum pH (h); HR (0.5) 0 7.2, SAFS 7.4, MAS 6.3 (sem 0.34), FR (1), 0 7.3, SAFS 6.7, MAS 7.4 (sem 0.22). Lactic acid (g/kg DM) up to 168 hrs decreased significantly in all treatments, HR (0.5) NA -57.6, SAFS -53.3, MAS -50.7, (sem 2.01), FR (1) NA -53.2, SAFS -72.4, MAS -64.2, (sem 5.56). ME (g/Kg DM) was significantly higher at FR SAFS. ME level (g/kg DM); HR (0.5) NA 9.4, SAFS 9.4, MAS 9.5 (sem 0.03), FR (1) NA 9.4, SAFS 9.6, MAS 9.5 (sem 0.06).

Key Words: Silage, Forage Maize, Stability

351 Effect of corn hybrid and processing on ruminal and intestinal digestion using the mobile bag technique. F. W. Harrelson*[1], N. F. Meyer[1], G. E. Erickson[1], T. J. Klopfenstein[1], and W. A. Fithian[2], [1]*University of Nebraska*, *Lincoln*, [2]*Golden Harvest Seeds, Inc.*, *Waterloo, NE*.

Ruminal and post-ruminal DM and starch digestibility can be influenced by corn hybrid as well as processing method. An in situ trial, utilizing the mobile bag technique, was conducted to evaluate the effect of corn hybrid, processing, and interactions on ruminal and intestinal digestion. A finishing trial was conducted to evaluate feedlot performance and compare it with digestion characteristics. Two ruminally and duodenally fistulated Holstein steers (490 kg BW) were used in a 2×6 factorial design, including 2 processing methods (high-moisture, HMC, or dry-rolled corn, DRC) and 6 commercially available hybrids. Corn samples were composites from the finishing trial and were ground to simulate mastication (6.35 mm screen). Bags were ruminally incubated for 22 h; duodenal bags were then subjected to a simulated abomasal pepsin digestion prior to insertion, and collected in the feces. Significant interactions were observed between hybrid and processing method for ruminal and total-tract DM disappearance, as well as ruminal, post-ruminal, and total-tract starch digestibility (P<0.01). Within processing method, post-ruminal and total tract digestibilities of starch and DM were affected by hybrid (P<0.05). Ruminal starch digestion ranged from 37.5% - 42.0% for DRC and from 59.1% - 81.2% for HMC. Post-ruminal starch digestion ranged from 54.8% - 68.8% for DRC and from 78.9% - 92.8% for HMC. Total-tract starch digestion ranged from 71.6% - 81.6% for DRC and from 91.5% - 98.4% for HMC. Relationships were observed between G:F and post-ruminal starch digestibility (r=0.84), as well as total-tract starch digestibility (r=0.73). Correlations among hybrids within both processing methods were not significant. We conclude that processing method has a larger impact than hybrid. HMC showed an improvement of 13.6% to 23.6% in total-tract starch digestion compared to DRC. The results of this trial suggest that hybrid as well as processing have an impact on starch digestion.

Key Words: Corn Hybrid, Corn Processing, Starch

352 Ruminal L-dopa degradability and *in vitro* fermentation kinetics of *Mucuna pruriens* and soybean meal treated with or without L-dopa. S. K. Chikagwa-Malunga*, A. T. Adesogan, S. C. Kim, N. J. Szabo, R. C. Littell, and N. Krueger, *University of Florida*, *Gainesville*.

Mucuna pruriens (velvet bean) is an underexploited protein supplement because mucuna L-dopa causes adverse symptoms in non-ruminants but not ruminants. To understand ruminant tolerance of L-dopa, the kinetics of ruminal fermentation of mucuna seeds (M), M L-dopa, and soybean meal treated without (SB) or with 13.8% of DM of L-dopa (SBD) were measured. Ground (1 mm) samples of M (4.89 % L-dopa), and SB (Experiment 1) or SB and SBD (Experiment 2) were fermented in triplicate in buffered rumen fluid in culture bottles and headspace gas pressure was measured hourly for 24 h. Each experiment was repeated once. A non-linear exponential model was fitted to the data. Furthermore, SBD and M were fermented in triplicate for 0, 4, 8, 16, and 24 h and residual L-dopa concentration was measured. Fermentation of M vs. SB produced more ($P < 0.01$) total gas (255 vs. 97 ml/g DM), but required a longer ($P < 0.01$) lag phase (3.53 vs. 1.38 h). Fermentation of M vs. SB produced more ($P < 0.05$) total VFA (203 vs. 180 mmol/L) and butyrate (20.0 vs. 14.5 molar %), less acetate (34.7 vs. 42.9 molar %; $P < 0.10$, tendency), and a lower acetate:propionate ratio (1.35 vs. 1.87; $P < 0.05$). Addition of L-dopa to SB increased ($P < 0.01$) total gas production (85.3 vs. 173.9 ml/g DM), total VFA concentration (132 vs. 188 mmol/L) and molar % of butyrate (13.6 vs. 27.1) and isobutyrate (7.5 vs. 8.2; $P < 0.10$, tendency), but reduced ($P < 0.05$) the fermentation rate (0.09 vs. 0.07 ml/h). The concentration of L-dopa in fermented M and SBD decreased by 53 and 47%, respectively. In conclusion, M was more extensively fermented than SB, and degradation of L-dopa by ruminal microbes was confirmed. Adding L-dopa to SB did not impair ruminal fermentation.

Key Words: Mucuna L-dopa, Soybean Meal, Gas Production

353 Study internal molecular-structural changes of flaxseeds affected by dry roasting at various conditions in relation to rumen degradation kinetics of dairy cattle. K. Doiron* and P. Yu, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

The objective of this study was to reveal internal molecular-structural changes of flaxseed (cv. Vimy) affected by dry roasting at the temperature of 120°C for 20 (T1), 40 (T2) and 60 min (T3), respectively, in relation to rumen degradation kinetics in dairy cattle. The internal structural changes of roasted flaxseeds were determined by globar-sourced FTIR spectroscopy in the mid-IR region from 4000 to 400 cm-1 and were analysed using Cluster (CLA) and principal component analysis (PCA). The rate and extend of rumen degradation of the raw (T0) and roasted flaxseeds (T1, T2, and T3) was determined using in situ nylon bag technique. The hypothesis of this study was that the roasting changes the flaxseed inherent structures and rumen degradation kinetics. The results showed that dry roasting did not affect

Kd of DM and EE with average of 7.04 and 19.77%/h, respectively (P>0.05), but decreased (P<0.05) Kd of CP from 7.20 to 5.54%/h. Dry roasting reduced (P<0.05) ED of DM and CP from 571 to 532, and 139 to 109 g/kg DM, respectively without affecting ED of EE with average of 215 g/kg. With the FTIR spectroscopy and CLA and PCA spectral analyses, the internal molecular-structural changed were revealed. The results showed that in the fingerprint region (1800-800 cm-1), protein amides (1715-1485 cm-1) and carbohydrate region (1200-800 cm-1), the cluster of the raw (T0) and roasted flaxseed (T3) were significantly different, indicted the internal structures were different between the raw and roasted flaxseed. The roasting affected both protein region and carbohydrate region. Further study is needed to understand the relationship between internal molecular structural changes and nutrient availability in ruminants.

Key Words: Molecular Structure, Raw and Roasted Flaxseeds, Nutrient Availability

354 Microbial characteristics, microbial nitrogen flow, and urinary purine derivative excretion in steers fed at two levels of intake. G. I. Crawford*, M. K. Luebbe, J. R. Benton, T. J. Klopfenstein, and G. E. Erickson, *University of Nebraska*, *Lincoln*.

Ruminally and duodenally fistulated Holstein steers (569 ± 40 kg) were fed at two levels of intake to determine purine:N ratio of ruminal microbes, endogenous purine derivative (PD) contribution to urinary PD excretion, the effect of spot sampling time on ratios of urinary PD to creatinine (PD:C), and the relationship between urinary PD excretion and duodenal purine flow. Steers were arranged in a crossover design and were fed 40 or 85% of their previously determined individual ad-libitum DMI of a diet consisting of 70% high-moisture corn, 20% corn bran, 5% alfalfa hay, and 5% dry supplement. The diet was provided by automatic feeders in equal portions delivered every 4 h. On average, steers consumed 5.3 and 11.3 kg DM/d with the 40 and 85% intake levels, respectively. Microbial purine:N ratio (g:g) did not differ (P = 0.59) between intake levels, and ranged from 0.127 to 0.251 with an overall average of 0.205. Urinary PD:C and microbial CP (MCP) flow estimated from duodenal purine flow were both greater (P < 0.05) with the 85% intake level than the 40% intake level. Microbial efficiency, measured as either g of CP/kg OM truly digested (P = 0.08) or g of CP/kg TDN intake (P = 0.05), increased with the 85% intake level compared with the 40% intake level. Urinary PD excretion (mmol) was related (P < 0.05; r^2 = 0.603) to duodenal purine flow (mmol), and resulted in an equation of 0.412× + 57.774. This implies a 41.2% recovery of absorbed purines and an endogenous PD contribution of 501 µmol/kg BW $^{0.75}$. Diurnal variation in urinary PD:C ratio was not evident (P = 0.86) when diets were fed in six evenly spaced and equal portions/d. Results from this experiment suggest that microbial purine:N ratio is not affected by level of feed intake, and that urine spot samples may be used to estimate relative differences in MCP flow, although low recoveries of duodenal purines may occur.

Key Words: Microbial Protein, Purine Derivatives, Steers

355 The incidence of liver abscessation in pasture based bull beef systems of New Zealand. J. Gibbs*, J. Laporte-Uribe, C. Trotter, and J. Noel, *Dairy Science Group, Agriculture and Life Sciences, Lincoln University*, *Canterbury, New Zealand*.

Bull beef systems for manufacturing grade beef in New Zealand (NZ) account for almost 50% of the national beef output. Dairy calves comprise approximately 85% of bulls, with suckled beef breeds the remainder. From weaning stock are almost entirely pasture fed until target slaughter carcass weight (CW) 240-270 kg at 18-24m. This has led to intensified grazing management in the last decade. Liver abscessation in cattle is usually associated with cereal feeding systems, and was traditionally uncommon in pasture based NZ livestock, but anecdotal industry reports of slaughter bulls and clinical cases in dairy cows suggest the incidence is sharply increasing. There is no existing research on liver abscessation in NZ. This project sought to establish the mean, breed and seasonal incidences and CW effect of liver abscesses at slaughter in NZ bulls. A large commercial database of source farm, breed, CW, liver abscess scores (absent, mild, moderate or severe) from all bulls slaughtered in that operation between 2000 and 2005 was analysed. The mean incidence of abscessation over all years was 10% (range: 9-13%), and increased across the years studied. The incidence increased each month across spring and summer and declined in autumn and winter. There was great variation in incidence between farms (range: 2-45%). Dairy breeds had a twofold greater mean incidence (9.3%) compared to beef breeds (4.6%), with Friesians the highest at 11.2%. Severe grade comprised 66% of all abscess cases. In each year, the range of mean CW for each liver grade group was <20kg, and mean CW was lowest in the severe grade, greater for absent grade, and highest for mild or moderate grades. Conclusions: Liver abscess incidence at slaughter appears to be increasing in NZ beef bulls, and is at similar levels to grain fed cattle systems internationally. Dairy breeds have a higher incidence, and there is a reduction in CW only with severe grade. Concurrent research in NZ suggesting the traditional understanding of rumen function in pasture fed cattle is inadequate for contemporary high intake dairy cows on high quality pastures under intensive management may help explain these findings.

Key Words: Liver Abscess, Dairy Beef

356 Metaphylaxis therapy interacts with temperament to influence performance of growing beef steers. Z. D. Paddock*[1], J. E. Sawyer[1], G. E. Carstens[1], R. R. Gomez[1], B. M. Bourg[1], D. K. Lunt[2], S. A. Moore[3], and D. S. DeLaney[3], [1]*Texas A&M University*, *College Station*, [2]*Texas A&M University*, *McGregor*, [3]*King Ranch*, *Kingsville, TX*.

The effects of metaphylactic therapy on growth, intake, and feeding behavior traits were evaluated using 119 Santa Gertrudis steers (initial BW 265 ± 24 kg). Steers were preconditioned at the source of origin, transported 550 km, and allowed to rest overnight before processing. At processing, steers were weighed, blocked by weight, and randomly assigned within weight block to receive 1.5 mL/45.5 kg BW ceftiofur crystalline free acid (EXC) administered at the base of the ear, or to receive no antimicrobial (CON). Steers within blocks receiving both treatments resided in common pens. Mean exit velocity (EV) was measured on d 0 and 28, as rate of distance traveled exiting from a chute, and used as an objective measure of temperament. Steers were weighed on d 0, 14, and 28. Meal frequency, duration, and DMI were recorded continuously using a GrowSafe feeding system. Data were analyzed as a mixed model with block as a random effect, treatment as a fixed effect, and EV as a covariate. An unequal slopes model was fit for treatment by EV interactions, with treatment differences tested at the mean EV and at ± 1 SD. Meal frequency increased with EV for EXC steers, but was unaffected by EV in CON steers (P = 0.02). Meal

duration was similar for steers with low EV, but decreased at a greater rate for CON than EXC steers (P = 0.01); at high EV, EXC steers had greater meal duration. Intake declined with increasing EV in CON steers, but was unaffected by EV in EXC steers (P = 0.01). High EV steers treated with EXC consumed more feed than high EV steers that were untreated. Interactions between EV and metaphylaxis resulted in differences in ADG from d 0 to 14 (P < 0.01) and d 0 to 28 (P = 0.01). At low EV, ADG was similar among treatments, but at mean or high EV, steers treated with EXC had greater ADG, and treatment differences increased with EV. Only one steer was clinically morbid during this trial. Results demonstrate that metaphylaxis therapy resulted in positive effects on ADG, DMI and feeding behavior during the receiving period for steers with high EV, whereas, metaphylaxis therapy had less utility for steers with low EV.

Key Words: Metaphylaxis, Temperament, Morbidity

357 Effects of *Mannheimia haemolytica* challenge on blood flow and net splanchnic flux of amino acids in fed or fasted steers. L. O. Burciaga-Robles*[1], C. R. Krehbiel[1], D. L. Step[2], C. A. Loest[4], L. Chen[4], M. Montelongo[2], A. W. Confer[2], J. N. Gilliam[2], B. P. Holland[1], and C. L. Goad[3], [1]*Department of Animal Science*, [2]*Department of Health and Veterinary Sciences*, [3]*Department of Statistics, Oklahoma State University*, *Stillwater, OK*, [4]*Department of Animal and Range Sciences, New Mexico State University*, *Las Cruces, NM*.

This experiment evaluated blood flow and net splanchnic flux of AA during a bovine respiratory disease (BRD) challenge. Twenty two steers (BW = 320±24 kg) with chronic catheters to measure blood flow and net flux across the portal drained viscera (PDV) and liver were used. Arterial, portal, and hepatic blood samples were collected at 1.5-h intervals on d 0, 1, 2, and 3. Treatments (2×2 factorial arrangement) applied to steers were: 1) ad libitum feeding and not challenged (FED/CON); 2) ad libitum feeding and challenged (d 0) with *M. haemolytica* via a tracheal tube (FED/CH); 3) 72-h fasting and not challenged (FAST/CON); 4) 72-h fasting and challenged (FAST/CH). All data were analyzed using repeated measures and first-order autoregressive covariance structure. Diet affected (P < 0.05) portal, hepatic, and arterial blood flow, which were greater for FED compared with FAST steers (461, 708, and 170 vs 427, 522, and 97 L/h, respectively). Challenge increased haptoglobin concentration, and was greater for FAST/CH than FAST/CON steers (Diet×Challenge; P = 0.004). Concentration of total AA was greater (P = 0.01; 1,966 vs. 1,645 μM) in CON than in CH steers. In addition, there was a net removal of total AA (-117.8 mmol/h) by liver of CH and a net release for CON steers (21.5 mmol/h; P = 0.03). Although arterial concentrations of essential AA were not different (P = 0.22), CH tended (P = 0.11) to have a greater net removal (-65.2 vs. -22.3 mmol/h) of essential AA by the liver than CON steers. Nonessential AA concentration was greater (P = 0.001) for CON (1,173 μM) vs. CH (924 μM) steers. Similar to total AA, there was a net removal of nonessential AA (-52.8 mmol/h) by the liver for CH and a net release for CON steers (42.5 mmol/L; P = 0.02). These results suggest that BRD increases removal of AA by the liver of steers, potentially in support of an acute phase response.

358 Effects of endotoxin and dietary protein on N metabolism, and serum cortisol and haptoglobin in growing beef steers. J. W. Waggoner*, C. A. Loest, J. L. Turner, C. P. Mathis, K. K. Kane, D. M. Hallford, and M. K. Petersen, *New Mexico State University*, *Las Cruces*.

Bacterial lipopolysaccharide (LPS) stimulates the immune system and mimics metabolic responses of gram(-) bacterial infection in cattle. Effects of LPS and dietary protein on N metabolism and serum concentrations of cortisol and haptoglobin (HAPT) in 24 steers (250 ± 2.8 kg BW) were studied. Treatments were a 2 × 3 factorial of LPS (0 vs 1.5 μg/kg BW; **-LPS** vs **+LPS**) and diets containing (DM basis): 1) 14.5% CP, 11.6% DIP and 2.9% UIP (**CP14.5CON**); 2) 16% CP, 13.3% DIP and 2.7% UIP (**CP16DIP**); and 3) 16% CP, 11.3% DIP and 4.7% UIP (**CP16UIP**). Source of DIP was casein and sources of UIP were fish meal and corn gluten meal. Steers were adapted to diets (±1.2 Mcal/kg NE_g; DM fed = 1.8% BW) for 14 d, and were infused (i.v. 1 mL/min) with LPS (in 100 mL saline) on d 15. Blood samples were collected before LPS infusion and every 2 h for 12 h thereafter. Feces, urine, and orts were collected for 5 d starting d 16 and composited. Serum cortisol and HAPT increased (P ≤ 0.05) in response to +LPS, but were not affected by diet. Serum cortisol of +LPS steers increased at 2 h, peaked at 4 h (5.4 vs 75.6 ng/mL for -LPS vs +LPS), and remained elevated for 12 h (P ≤ 0.05); serum HAPT of +LPS steers were elevated at 4, 6, 10, and 12 h (P ≤ 0.05). Dietary DM and N intakes were lower (P ≤0.05) for +LPS vs -LPS steers, and N intakes were greater (P ≤ 0.05) for higher CP diets. There was a LPS × diet interaction (P = 0.06) for N retained (% of intake); diet did not alter N retention of -LPS steers, but +LPS steers retained more N when fed CP16DIP and CP16UIP than CP14.5CON. These results imply that growing steers exposed to endotoxin may require greater dietary protein concentrations to offset altered intake and metabolic demand.

Table 1.

	-LPS			+LPS			
Nitrogen, g/d	CP14.5-CON	CP16-DIP	CP16-UIP	CP14.5-CON	CP16-DIP	CP16 UIP	SEM
Intake[a,b]	104	118	116	98	107	110	2.7
Feces	36	39	36	33	30	36	2.6
Urine[c]	42	53	49	52	52	50	2.8

359 Effect of dietary boron on the immune function of growing steers. R. S. Fry*, K. E. Lloyd, S. K. Jacobi, and J. W. Spears, *North Carolina State University*, *Raleigh*.

An experiment was conducted to determine the effects of dietary boron (B) on the performance and immune response of growing steers. Thirty-six Angus and Angus-cross steers (average initial BW 270

kg) were blocked by weight within breed and randomly assigned to treatments. Treatments consisted of: 1) control (no supplemental B), 2) 5 mg/kg of supplemental B, 3) 50 mg/kg of supplemental B. Supplemental B was supplied from sodium borate. The control diet contained 10.2 mg/kg of B. Steers were housed in slotted floor pens with 2 animals per pen. Weights were taken at 14 d intervals. Jugular blood was obtained from steers on either d 42 or 44 for assessment of lymphocyte blastogenesis. One-half of the steers in each treatment group were sampled on each date. Supplemental B tended ($P = 0.12$) to increase the blastogenic response of B lymphocytes to pokeweed mitogen, but did not affect proliferation of T lymphocytes when stimulated with concanavalin A or phytohaemagglutinin (PHA). Humoral immunity was assessed on d 49 by injecting steers IM with a pig red blood cell (PRBC) suspension. Blood samples were collected at d 0, 7, 14, and 21 following PRBC administration for determination of antibody titers. Specific anti-PRBC IgG titers were affected by a treatment × day interaction ($P < 0.07$). Boron supplemented steers had greater ($P < 0.05$) IgG titers than controls on d 7 but not on d 14 or 21 post-injection. Cell-mediated immune response was also evaluated following an intradermal injection of PHA on d 77 of the study. Skinfold thickness following PHA injection was not affected by dietary B. Performance of steers during the 77 d study was not affected by dietary B. Results of this study indicate that supplemental B did not affect the performance of growing steers, but may affect the immune response.

Ruminant Nutrition: Opportunities to Improve Forage Utilization and Rumen Function

360 Utilizing fats and carbohydrates in forage-based diets for lactating cows. M. S. Allen*, *Michigan State University*, *East Lansing*.

Forages contain relatively high concentrations of fiber that is slowly and incompletely digested, limiting energy intake for high producing cows. Therefore, cows with high energy requirements are fed forage-based diets supplemented with feeds containing readily digested carbohydrates and (or) fats. However, specific fuels can have physiological effects that alter intake and utilization of dietary energy. The profile and pattern of absorption of fuels depend on the composition of the diet, including not only its chemical composition, but physical characteristics which influence ruminal fermentation and dynamics. Rapidly fermented carbohydrates and some fat sources can decrease feed intake, ruminal fiber digestibility, efficiency of microbial protein production, and increase flow of intermediates from fatty acid biohydrogenation from the rumen. Physiological effects of specific fuels might involve alteration of hormone or enzyme concentrations affecting gluconeogenesis, lipolysis and lipogenesis in tissues, fat and protein production by the mammary gland, gut motility, or feeding behavior. These physiological effects can influence energy intake, yield of milk and milk components, and body condition independent of the energy contributed by the fuel itself. Furthermore, physiological and production responses to specific fuels are dependent upon animal characteristics (e.g. glucose demand, lipolytic state, adiposity). Therefore, physiological effects of energy concentrates must be considered when formulating diets rather than formulating for energy density alone. The objective of this presentation to discuss physiological effects of specific fuels and how these effects can be utilized to optimize diets for cows in different stages of lactation.

Key Words: Feed Intake, Energy Partitioning, Physiological State

361 The role of ionophores in improving utilization of forage and forage-based diets. V. Fellner*, *North Carolina State University*, *Raleigh*.

Ionophores have been routinely added to non-lactating ruminant diets to improve animal performance and efficiency of feed utilization. Although several ionophores have received FDA approval, the most common and widely studied ionophore is monensin that is now also approved for use in lactating cow rations. Benefits of ionophores are attributed, almost exclusively, to changes that occur in the rumen. A shift in the ruminal acetate:propionate ratio, with a concomitant decrease in methane and ammonia, are classical responses to feeding ionophores. The magnitude of change can vary, however, and is not always predictable. Preferential binding of ionophores to specific ions, level of ionophore inclusion in the diet, and dietary composition are some of the reported factors contributing to the variability in ionophore action. Managing the diet is perhaps the most critical factor in maximizing the benefit of ionophores, irrespective of type or level of inclusion. With high forage diets a lower dose of ionophore elicits maximal ruminal response. This is in contrast to high concentrate diets that typically provide for a greater ionophore response at higher doses. Generally, the fiber digesting microbes are most sensitive to ionophores whereas starch fermenters tend to be more resistant. Yet, a decrease in nutrient digestibility, specifically fiber, is more pronounced in diets having low, rather than high forage content. Changing the forage:concentrate ratio alters several factors, including intakes, passage rates and pH, all of which impact microbial shifts. Among the predominant fibrolytic bacteria, some that may even be resistant to ionophores, there is considerable difference in kinetics of microbial growth in response to ionophores. The major starch utilizing bacteria are less sensitive to ionophores but seem to alter their metabolism with source and level of starch. The driving force in ruminant production is energy whether it's from grain or forage. Varying dietary ingredients varies the substrate for the microbes as well as ruminal kinetics, both of which interact to determine the response to ionophores.

Key Words: Ionophore, Forage, Rumen

362 Lactating dairy cow responses to yeast products. P. H. Robinson*[1] and L. J. Erasmus[2], [1]*University of California*, *Davis*, [2]*University of Pretoria*, *Pretoria, South Africa*.

Studies with lactating Holstein cows, from peer review publications, were used to determine responses to feeding Saccharomyces cerevisiae yeast products (YP) from diet composition. The 21 studies reflected 6 YP, with 3 used in 6, and 3 used in 1 study. In spite of differences (i.e. NDF/starch; P<.05) in diets, and milk yield, milk energy output and milk fat % (P<.05) among control group cows (CGC) in studies of the 3 major YP, proportional milk, milk component, milk energy and DMI responses of cows to these YP did not differ. Thus all 21 studies were pooled and simple correlations showed that higher diet NDF or

ADF levels reduced responses to any YP, while higher diet starch had little impact. Increased milk and milk energy output of CGC reduced benefits of YP, and results suggest that YP milk yield response was absolute (~0.9 kg/cow/d) and decreased proportional to CGC milk yield as that increased. Multiple correlation analysis showed that only milk and milk protein yield responses to YP could be acceptably, but modestly (r^2 = .52 and .45 respectively), predicted based on milk yield of CGC and diet NDF and starch levels (both negative). Precision of predictions appeared compromised by unequal allocation of NEl between milk and BW change among studies. A reduced study set (i.e. 10), with BW and BW change reported, allowed % response in NEl output to feeding YP to be calculated. Results suggest that % increase in NEl output to YP increased modestly in diets with higher starch levels and decreased in diets with higher NDF levels, although changes were more positive as NDF fermentability increased. While findings support 2 currently proposed modes of action of Saccharomyces cerevisiae YP that suggest that they stimulate rumen microbes to increase fermentability of fiber and/or allow rumen microbes to more effectively metabolize end-products of ruminal starch fermentation, benefits in milk, milk energy and NEl output to YP were modest (i.e., 2.7, 3.1 and 5.3% respectively). Future studies in feeding YP should consider dose response designs at YP feeding levels higher than those in past studies, as well as report BW and BW change, in order to allow YP impacts on animal energetics to be determined.

Key Words: Yeast, Lactation

363 Enzymes to improve forage utilization by ruminants: What's on the horizon. K. A. Beauchemin* and J. -S. Eun, *Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

This paper reviews the research on the development of enzyme additives for ruminants and attempts to provide a rationale for enzyme selection with emphasis on future research needs and opportunities. Ruminant feed enzyme additives are concentrated fermentation products with specific enzyme activities, primarily hemicellulases and cellulases. Enzyme additives have significant potential to improve fiber digestion in cattle, thereby enhancing feed utilization and animal performance. Enzymes help bridge the gap between actual digestibility of the feed in vivo and the potential digestibility of the feed that would occur under ideal conditions. However, in previous research, the response to enzyme additives has been variable because many of the products used were not specifically formulated for ruminants. The optimum array of enzymic activities in products designed for ruminants depends mainly on forage composition. In vitro assays that reflect conditions in the rumen and measure fiber degradability can be used to identify effective enzyme candidates and optimum dose rates. Recent studies indicate that, depending on the forage, about 50% of the improvement in in vitro fiber degradability due to added feed enzymes can be predicted from the main enzymic activities provided. Method of providing the enzyme additive to the animal must be also considered. Applying a liquid solution of enzymes to the feed allows the enzyme to bind to the target substrate, thereby increasing the resistance of the enzymes to proteolysis within the rumen and facilitating a pre-ingestive attack of the enzymes upon the plant fiber. Enzyme additives provide cattle producers the opportunity to feed higher fiber diets, thereby minimizing digestive upsets associated with feeding higher grain diets while still maintaining productive performance. The challenge is to develop a better understanding of the mode of action and the critical enzyme activities needed, such that product formulations and application methods and rates can be tailored to elicit the desired response at minimal cost.

Teaching/Undergraduate & Graduate Education: Enhancing the Undergraduate Learning Experience in Animal Agriculture, Through the Integration of Teaching and Research

364 Enhancing learning through inquiry. B. Wuetherick*, *University of Alberta*, *Edmonton, Alberta, Canada*.

Almost two decades ago Ernest Boyer called on educators to ″move beyond the tired old research versus teaching debate.″ That has resulted in several studies exploring the interrelation and integration of teaching and research in higher education in the North American, Europe and Australasia. Over a decade ago a well-known meta-analysis was conducted that explored commonly used measures of excellent teaching and research and demonstrated that there was at best only a minor positive correlation between them. The researchers concluded that it would be far more useful to investigate ways to increase the relationship than to try to insist that the status quo is acceptable. That was followed in 1998 by the well-known Boyer Commission, which criticized the current higher education system in the US and called on universities to make research-based learning the standard throughout undergraduate education. Undergraduate education is intended to furnish students with both generic and discipline specific skills, including inquiry and research skills, in preparation for a supercomplex, knowledge-based economy. Recent shifts toward a research-based curriculum have been attempting to provide this. Questions continue to be asked, however, about what it means to bring teaching and research together effectively to benefit undergraduate student learning. Recently attempts have been made to conceptualize the integration of teaching and research in order to help shape the debate about how to move forward with making research-based learning the standard. This introduction to the symposium ″Enhancing the Undergraduate Learning Experience in Animal Agriculture, Through the Integration of Teaching and Research″ will explore different conceptions of the integration of teaching and research and will set the stage for further discussion by the co-presenters.

Key Words: Inquiry-Based Learning, Undergraduate Research, Research-Based Teaching and Learning

365 Why should we integrate our teaching and research? C. Colbeck*, *The Pennsylvania State University*, *University Park*.

Actual synergies between teaching and research are masked by institutional evaluation practices that fragment academic roles and

by endless debates about how these roles conflict. To ascertain how academics integrate teaching and research and why they should, academics were observed on the job for hundreds of hours. On average, they integrate teaching and research around one-fifth of their work time. Academics do so as they: 1) teach students how to conduct disciplinary research in courses for academic credit or in out-of-class settings, 2) teach their current disciplinary research in the classroom, or prepare for class and for research presentations or publications using the same sources, 3) engage in scholarly inquiry about their own teaching and their studentsâ€™ learning, and 4) conduct public scholarship, applying disciplinary expertise in partnership with community members and students to address public issues. Such teaching-research integration benefits students, academics, institutions and the profession. Across many varied disciplines, students say they learn more when their instructors discuss research and real-world problems and provide opportunities to solve meaningful ill-defined problems. When academics focus on synergies rather than on conflicts between their roles, they report they enhance their teaching effectiveness and research productivity while using their time more efficiently. Similarly, joint production of teaching and research is efficient and cost effective for colleges and universities. Finally, an overall integrated approach to scholarly work may retard creeping deprofessionalization of academic work that is occurring as it is subdivided into separate tasks performed by different people in increasingly bureaucratic institutions. Synergies between research, teaching, and community service are better realized by complex professionals who are able to bring their research into the classroom, engage students in inquiry, explore systematically what works with their own teaching and studentsâ€™ learning, and partner with students and community members to develop new knowledge that serves the public good.

366 Integrating research and teaching in an introductory course setting: There's a heifer in your tank. F. E. Robinson*, N. J. Wolanski, B. Wuetherick, and S. Varnhagen, *University of Alberta*, *Edmonton, AB, Canada*.

Educators have presented reasons why the integration of research and teaching has not progressed as fast in freshman courses as it has in senior capstone courses. Typically, first-year courses have many students with a very heterogeneous background with limited knowledge of the discipline. The emphasis in introductory courses is mostly on content, rather than on process, as the learning begins with details and works up to the big picture. Nonetheless, entry level students can work very effectively in groups to achieve many of the objectives of senior level inquiry-based programs. In particular, group work, oral and written communication, can form a key component of corner-stone courses and also build a valuable sense of community. A program initiated at the University of Alberta has worked to engage students through inquiry of both big picture and small picture views of animal agriculture. Since 2004, ″There's a Heifer in Your Tank″ has evolved with groups of students ″answering questions you didn't know you had about animal agriculture″. Students have experienced public forum presentations with 350 to 700 people in attendance as quirky facets of animal production, welfare, and food processing are communicated with multi-media, drama and music. Short magazine style reports have been produced and released to the public and print media. Linkages with grades 4-7 students have provided a platform for student recruitment in urban and rural settings. The success of this program has been measured in terms of increased enrolment, enhanced public media interest, and very high levels of current and alumni student engagement. Graduate students serve as teaching assistants and senior undergraduates serve as ″learning coaches″ to provide support to the class. Both these groups attend most lectures and position themselves around the class in a ″Surround Learning″ model. The program has become a focal point of academic interaction of the Faculty with prospective students, the public and the Agri-Food industry.

Key Words: Undergraduate Teaching, Group Projects, Introductory Courses

367 Integrating research and teaching in a senior course setting. W. L. Hurley*, *University of Illinois*, *Urbana*.

The relationship between research and teaching at the college level provides unique opportunities for enriching the undergraduate learning environment. The desire to integrate research and inquiry into the undergraduate experience arises in part through recognition of the extensive learning that occurs when conducting research. Encouraging undergraduate students to conduct structured research projects in a laboratory or field setting provides this experience for a subset of our undergraduates. However, the goal is to integrate the inquiry process more broadly into student learning. This requires providing students the opportunity within our courses to more fully understand the inquiry process and to practice the skills that allow them to succeed. Inquiry is about asking questions, investigating potential solutions, creating new knowledge from information gathered, discussing experiences and outcomes, and reflecting on the new knowledge, which in turn generates new questions. Even at the senior level, many students have had only fragmented and discontinuous experiences practicing skills needed to successfully navigate the inquiry process. When a course focuses primarily on delivery of course content the expectation often is that students will achieve an identical knowledge outcome from that content. Students should be given the opportunity to pursue the inquiry process in an environment that allows them to achieve individual knowledge outcomes. The instructor's role becomes one of facilitator of inquiry and guiding students through the process. Effective integration of inquiry into courses can result in greater understanding of what has been learned, as well as enhancement of critical thinking and other skills employed during the inquiry process. Examples to be presented include active and collaborative learning approaches, encouraging student creation of course content, expanding the learning beyond the classroom, effective use of educational technologies, and alternative approaches to assessment of learning, each of which may help instructors facilitate integrating more inquiry based learning into their courses.

Key Words: Teaching, Undergraduate, Inquiry

368 Teaching opportunities for graduate students: Who benefits? N. J. Wolanski* and F. E. Robinson, *University of Alberta*, *Edmonton, Alberta, Canada*.

Enabling graduate students as teaching assistants can improve the educational process for undergraduate students as well as academics. Allowing graduate students to work as educators helps to further develop graduates as successful teachers. As class sizes increase,

and as undergraduate students embark on research, graduate students can be intermediates between large undergraduate classes and the professor. Graduates who are actively conducting research understand the plight of the over worked researcher/professor. Graduate students also display a strong commitment to assisting undergraduates in understanding course material. At the University of Alberta, student based learning where they cooperate to solve complex real world problems has replaced simple memorization. In order to facilitate this type of learning, graduate students and senior level undergraduates are utilized to assist junior students with solving inquiry type problems. Senior students have a broad range of experiences which allows for the integration of both scientific knowledge and life experiences to provide undergraduates with necessary insights to solve these complex issues. When undergraduates desire a greater proportion of an academics time tasks such as research and administrative responsibilities are sacrificed however, teaching assistants can field questions and answer concerns as they arise. Teaching assistants can address student concerns and make undergraduates cognizant of the many responsibilities of an academic; therefore graduate student's can bridge the gap between busy academics and concerned undergraduates. While assisting in the educational process graduate students have opportunities to teach, receive mentored training, and are eligible for graduate student teaching awards. Some of the negative consequences of a teaching appointment include increased work loads which may delay graduation or increase graduate student stress. A teaching appointment can provide necessary financial support during a graduate degree and, the sense of satisfaction from a positive teaching appointment may propel graduates to investigate careers in education.

Key Words: Graduate Teaching Assistant, Undergraduate Research, Teaching Experience

369 Researching teaching. C. K. Varnhagen*, *University of Alberta*, *Edmonton, Alberta, Canada*.

As animal scientists, we apply a range of methodologies to address research technique and solve applied problems. As teachers, however, we seldom even examine our teaching critically and objectively, much less scientifically. A key component of integrating teaching and research is researching teaching. Researching teaching involves applying the scientific method to understanding and improving teaching and learning. One viewpoint from which to consider research on teaching is as a pyramid of empirical evidence regarding teaching and learning. According to this conception, we can organize research on teaching according increasingly sophisticated scholarly and empirically based methods. At the base of the pyramid is scholarly reflection involving a critical examination of personal goals and objectives for teaching and learning and rational consideration of effectiveness of teaching methods. The next level in the pyramid of research on teaching is rational ideas and opinions. This involves reflecting on and applying the often empirically based ideas and opinions expressed by others. Moving up through the levels of the pyramid are increasingly controlled and generalizable methods for empirically investigating teaching and learning, from case studies to correlational and cohort analyses, to quasi-experimental designs to meta-analyses of a wide range of studies conducted at a wide range of institutions. Work at these levels of the pyramid o generates presentable and publishable results that stimulate scholarly discussion among researchers and educators and promote research-based teaching methods. Adopting a pyramid of evidence approach to research on teaching brings these often-disregarded endeavors into scholarly focus at the same time as documenting important improvements and innovations in teaching and learning.

Key Words: Research, Teaching, Evidence

ADSA-SAD Undergraduate Competition - Original Research

370 Probiotic ice cream manufactured with honey, a natural sweetener with several health benefits. A. Greenbaum*[1] and K. J. Aryana[2], [1]*Louisiana State University*, *Baton Rouge*, [2]*Louisiana State University Agricultural Center*, *Baton Rouge*.

Lactobacillus acidophilus offers several health advantages. Honey is a sweetener which aids in the prevention of seasonal allergies, is effective in treatment of stomach ulcers. Honey is also a good source of antioxidants which play a big role in prevention of cancer and heart disease. Darker the honey more is the level of antioxidants. Moreover, honey increases counts of probiotics namely bifidobacteria and lactobacilli in the colon. Objective was to study the effect of light, amber colored and dark honey on the physico-chemical, microbiological and sensory characteristics of probiotic ice creams. Ice cream mixes were made using light, amber colored and dark honeys separately. Mixes were pasteurized, homogenized, cooled and aged overnight. Mixes were inoculated with Lactobacillus acidophilus in the amount of 0.7% w/v mix. Mixes were flavored with vanilla and frozen using a batch freezer. Product manufacture was replicated three times. The mean L_* (lightness) value of ice creams mixes with light and dark honeys were 55 and 25 respectively. The mixes with the darker honeys had a lower pH (6.5) compared to the lighter honeys (6.7). There were no differences in the viscosities of the mixes. Neither were there any differences in lactobacilli counts of the ice creams with the use of different colored honeys. Average meltdown volume in 1 hour for the ice creams with darker honey was significantly more (76 mL) compared to the ice creams with light honeys (44 mL). As expected the lighter honey resulted in lighter colored ice creams and the dark honeys resulted in darker ice creams. Use of different colored honeys altered some characteristics of the probiotic ice creams.

Key Words: Honey, Sweetener, Ice Cream

371 Determining the efficacy of infra-red technology as part of a mastitis preventitive routine. D. M. Tearney*[1], T. R. Lane[2], D. R. Bray[1], and R. P. Natzke[1], [1]*University of Florida*, *Gainesville*, [2]*Spirit Solutions*, *Dayton, OH*.

Mastitis is the major economic loss in the dairy industry today. To ameliorate this problem, a good routine of early mastitis detection and adjustment of management is needed. Infra-red technology is a promising tool for early mastitis detection. Hand-held infra-red cameras may become a convenient tool to measure the temperature of cows instantaneously. The ultimate goal of the project is to be able to integrate routine recording of cow temperatures as a tool to monitor udder health. Therefore, the primary objective of this preliminary study was to find an area on the body that would accurately reflect the rectal temperature. The rectal temperatures of 200 cows were compared to

the IR camera measurements of: flank, rear udder, side udder, eyes, and shoulder. Prior to data collection, the IR device was calibrated by using a can filled with hot water and comparing a mercury thermometer reading with the IR camera reading. Data was recorded and analyzed using Microsoft's Excel program. All body areas had relatively low correlations with rectal temperature. The rear udder provided the highest correlation with rectal temperature. The side udder was shown as a close second. While the correlation between rectal temperature and rear udder temperature was relatively low, it is quite possible that an udder infection remains localized and thus does not always result in an elevated rectal temperature. Further investigation is needed to correlate the rear and/or side udder temperature with the somatic cell count of the milk.

372 Genetic analysis of the relationship between ketosis and milk fat in Holsteins. E. E. Yeiser*[1], C. D. Dechow[1], J. Vallimont[1], C. G. Sattler[2], and J. S. Clay[3], [1]*The Pennsylvania State University*, *University Park*, [2]*Select Sires, Inc.*, *Plain City, OH*, [3]*Dairy Records Management System*, *Raleigh, NC*.

Excessive body fat mobilization during periods of early lactation negative energy balance is associated with metabolic disorders and high milk-fat percentages. The objectives of this study are to estimate genetic parameters for ketosis and to estimate the genetic relationship of ketosis with the following milk-fat percentage (MFP) traits: fat % on test-day 1 (F1), ratio of fat % on test day 1 to fat % on test day 3 (F1/F3), fat to protein ratio on test-day 1 (F1/P1), average fat to protein ratio across lactation (F/P), and fat % for the entire lactation (F). Test date, days in milk, fat %, protein % and disease records from progeny test herds that use PCDART to record health events were provided by Dairy Records Management System (Raleigh, NC). There were 19,201 ketosis observations for cows calving between 20 to 120 months of age in lactations 1 through 5. A total of 74,479 observations were available for F1 and F1/P1; 85,304 observations were available for F and F/P; and 57,995 observations were available for F1/F3. Two-trait animal models with ketosis and one MFP trait were analyzed using ASReml. The fixed effects were contemporary group and age within parity. Contemporary groups were herd-year-season of calving for ketosis, F, and F/P, and herd-test-date for F1, F1/F3, and F1/P1. The random effects were animal and error. The heritability estimate of ketosis was 0.04. Heritability estimates for MFP traits ranged from 0.04 for F1/F3 to 0.31 for F. Significant genetic correlation estimates were 0.32 for F1/F3 and F1/P1, and -0.30 for F. Genetic correlation estimates for F/P (-0.12) and F1 (0.15) were not significant. The genetic correlations indicated that higher average fat % over the lactation is associated with less ketosis. However, a high fat/protein ratio on test day 1 and a large decrease in fat % from test-day 1 to 3 were associated with more ketosis. Producers can continue to select for higher fat % across lactation without compromising metabolic health of lactating cows. Additionally, early lactation fat % may be useful as a genetic selection tool for resistance to ketosis.

Key Words: Ketosis, Milk Fat, Heritability

373 Short-interval unilateral frequent milking during early lactation of dairy cows results in acute and persistent increases in milk yield. A. C. Kissell*, E. H. Wall, and T. B. McFadden, *Lactation and Mammary Gland Biology Group, Department of Animal Science, University of Vermont*, *Burlington, VT*.

A short-interval unilateral frequent milking model (UFM) involving twice daily milking (2X) of the left udder half and four-times daily milking (4X) of the right udder half with 1.0 ± .3 h between regular and extra milkings was imposed during early lactation to test the hypothesis that remilking after a short interval would stimulate both acute and long-term increases in milk yield from the 4X half of the udder. Eight multiparous Holstein cows were assigned to UFM for d 1 to 21 of lactation, and were milked 2X thereafter. At the first milking post-calving, cows were quartermilked to verify similar milk production between the right and left halves of the udder. In order to quantify the milk yield response to UFM, cows were quartermilked on d 3, then weekly through 5 wk and once at 8 wk of lactation. Milk samples were collected during quartermilking and fat percent, protein percent, and SCC were measured by Vermont DHIA. During UFM, the 4X udder halves produced 1.3 ± .6 kg/d more milk than the 2X halves ($P < 0.05$). The difference in milk yield during UFM reached a maximum on d 21 (2.0 ± .6 kg/d; $P < 0.001$). After cessation of UFM, milk production from the 4X halves decreased slightly, but remained 1.6 ± .3 kg/d greater than the 2X halves through 55 DIM ($P < 0.05$). Milk SCC, fat percent, and protein percent were not affected by UFM ($P > 0.20$). We conclude that, although the interval was only 1 h, UFM increased milk production of the frequently-milked udder halves through 8 wk of lactation. Our results indicate that short-interval frequent milking during early lactation could increase milk production efficiency on small dairy farms.

Key Words: Frequent Milking, Half-udder, Milking Interval

374 Planting date may affect yield and nutrient composition of whole-plant small-grain forages. L. W. Manson*[1], M. A. Bal[1], M. Oba[1], and V. S. Baron[2], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lacombe, AB, Canada*.

The objective of this study was to evaluate effect of planting date on nutrient composition of whole-plant small-grain forages harvested at the mid-dough stage. Two barley (AC Lacombe and Vivar), one oat (AC Murphy) and one triticale (Wapiti) varieties were planted at the Lacombe Research Station at 7 different dates, from May 12th to June 23rd 2005, and harvested at the same physiological stage of maturity (mid-dough stage). Dry matter (DM) yield and concentrations of crude protein (CP), neutral detergent fiber (NDF), in vitro fiber digestibility (IVFD), starch, and free glucose were determined. Earlier planting dates were associated with greater DM yield for barley, but not for triticale. The DM yield was positively related with the cumulative temperature ($r = 0.67$) and cumulative precipitation ($r = 0.44$) from heading to harvest. Concentrations of free glucose, CP and NDF at harvest were not affected by planting date for all varieties. However, CP concentration was related positively with the cumulative temperature from seeding to heading ($r = 0.33$) and negatively with that from heading to harvest ($r = -0.54$). Contrarily, free glucose concentration was associated negatively to cumulative temperature from planting to heading ($r = -0.43$), but positively from heading to harvest ($r = 0.54$). Planting date affected IVFD of oat ($P < 0.01$) and starch concentration of triticale ($P < 0.01$), but did not affect nutrient composition of barley varieties. In summary, planting date affected DM yield and nutrient composition of whole-plant small-grain forages. Altering planting date may allow for increased management options to optimize forage quality by changing growing environment characterized by cumulative

temperature and precipitation. Further studies are required to determine if planting date consistently affects forage quality and to evaluate its effects on productivity of ruminant animals.

Key Words: Planting Date, Forage Quality, Cereal Grain Forages

375 Using percent of mature body weight to manage dairy heifer growth. N. Keene* and D. Winston, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

When raising dairy replacement heifers, producers face the challenge of determining whether differences in heifer growth are caused by genetics or management. Heifer growth is generally measured using body weights at breeding and calving and growth rates are then compared with breed standards. One problem with this approach is the large genetic variance for size that may be found within a breed. To address this issue, Van Amburgh and Meyer, 2005, proposed a system to express heifer growth as a function of mature body weight. Hoffman, 2006, applied this system, which reduces the growth variance attributed to genetics, and developed a universal heifer growth chart to use as a reference for all breeds. To practically apply this system, heifer weights were collected monthly at the Virginia Polytechnic Institute and State University Dairy Center. For the first 21 days post-calving, dam's body weights were electronically measured twice daily using scales in the parlor exit lanes. Mature body weight for each dam was estimated using Hoffman's equations, which convert the average weight to a 4th lactation equivalent. Data was then compared to breed standards to analyze strengths and areas of improvement in the heifer raising program overall and to identify outlier animals. This system could be utilized by any producer with the resources to regularly weigh heifers and lactating cows and record the data. A spreadsheet to aid dairy producers with calculating and graphing growth rates by the percent of mature body weight is being developed through this research.

Key Words: Mature Bodyweight, Growth

376 Effects of Black Seed Oil (Niagra Sativa) on the life cycle and reproductive behavior of C. elegans. C. G. Gerald*, M. W. Worku, P. M. Matterson, and Z. L. Liu, *North Carolina A&T State University*, *Greensboro*.

Nematode drug resistance is impacting the health of grazing livestock globally. Natural alternatives that may affect the parasite life cycle, impact pathogenesis or boost the host's immune response are being sought. Niagra Sativa L (Black seed) has been reported to have antihelminthic properties and is considered an immunomodulator. The free-living nematode Caenorhabditis elegans (C. elegans) is a well established biological model. This model can be used to evaluate immunomodulation and therapeutic drug action. Chemotaxis is an important behavior in enabling it to locate food sources such as E.coli. This study evaluates the effects of Black Seed Oil exposure on the life cycle and chemotactic behavior of C. elegans. A ring of bacteria (food) on NGM agar medium served as attractive signals to encourage C.elegans to move. Ten nematodes were placed in the center of the agar plate in 0, 0.25, 0.50 and 0.75 microliters of black seed oil. Over the three day life cycle the reproduction (number of worms), and chemotaxis (Number migrating to the ring of bacteria through the black seed oil) was recorded. Nematodes that had reached the food were picked individually to new seeded plates and allowed to recover and reproduce. As the concentration of Black seed oil increased the number of worms on a plate increased. Following the three day life cycle the total numbers of nematodes were higher following exposure to Black seed oil. A dose dependent effect of Niagra Sativa extract was observed on the numbers of nematodes migrating to E.coli. The chemotactic behavior was inhibited at 0.25ul of Black seed oil. Maximum numbers of worms migrating were observed at 0.75 ul. The molecular basis for these effects and the biochemical pathways involved will be evaluated.

Key Words: Black Seed Oil, C. Elegans

Animal Behavior & Well-Being - Livestock and Poultry

T1 Impact of elevated embryonic corticosterone on development, stress, and fear in broilers. S. M. Brougher and S. J. Snow*, *Delaware State University*, *Dover*.

Corticosterone (B), an adrenal steroid, is known to elevate in response to stressful poultry housing conditions (e.g. temperature extremes, density, negative behavioral interactions, and feed restriction). Negative consequences associated with elevated stress in poultry include reduced growth, increased fear, developmental instability, and compromised welfare overall. One concern is the deposition of B from stressed female broiler breeders into the yolks of their developing offspring. We hypothesized that an exogenous increase in embryonic B could disrupt development of the hypothalamic-pituitary-adrenal system, potentially manifesting through long term alterations in endpoints such as growth, fear, developmental stability, and plasma B. Broiler eggs were incubated at 37°C and 65% relative humidity, and randomly assigned to four treatment groups: control (C), sham control (S), low dose (L: 10 ng/mL) and high dose (H: 20 ng/mL) of B. Exogenous B was delivered via corn oil vehicle into the air cell of fertile eggs at d4 of incubation. Hatchlings were placed in 8 pens with 4 birds/treatment/pen (n=16 birds/pen) for 5 wks. Body weight was recorded weekly, and the following measurements were taken at 5 wks of age: (1) tonic immobility to determine the fear response; (2) the degree of asymmetry in tarsometatarsal length and width to evaluate developmental stability; and (3) plasma B by ELISA to determine overall levels of stress. Data were analyzed using a one-way ANOVA. Results showed no significant differences in growth rate degree of fluctuating asymmetry or the length of tonic immobility. Although there were no significant impacts of treatment on B levels, there was a trend (P = 0.08) for control and sham control females to have lower plasma B than males. In conclusion, the results of our study indicate that elevating B exposure during embryonic development does not seem to have any lasting residual effects on growth, fear response, or plasma B, therefore is unlikely to have any long term impact on broilers during the growout phase.

Key Words: Broiler, Stress, Fear

T2 The effects of rearing broiler chickens under different light intensities on fear responses. G. Fagerberg, J. A. Mench* and G. S. Archer, *University of California*, *Davis*.

It has been suggested that welfare of commercial broilers could be improved by increasing the ambient light intensity during growout. However, there is also concern that broilers reared under high light intensities may be more fearful and difficult to catch at market age. Straight-run Cobb broiler chickens (N=240) were housed in environmental chambers providing either 5 (LOW), 50 (MED) or 200 (HIGH) lux illumination during the 16-hour photophase. There were 4 chambers of chickens/treatment. Beginning at week 4 of age, four tests were used to evaluate fearfulness: 1) induction of tonic immobility; 2) response to novel object placed in the home pen; 3) response to novel human entering the home pen; 4) response to inverted handling after catching. Data were analyzed using the GLM. There was a trend (F=3.69; p=0.068) for a difference in the novel human test, with the latency for the last, but not the first, bird in the pen to approach the novel human being greater in HIGH (120.07±41.63) than in either MED (17.40±3.40) or LOW (54.40±21.37), with the difference between HIGH and MED being statistically significant. However, there were no significant treatment differences for the three other tests, with the number of attempts to induce tonic immobility and tonic immobility duration; number of vocalizations and number, intensity and duration of wingflaps during inverted handling; and latencies to approach the novel object; being similar among the treatment groups. These results suggest that rearing broilers at higher light intensities has little effect on fearfulness or on responses to catching and handling at market age.

Key Words: Broiler, Fear, Lighting

T3 Effect of feeding space availability on aggressive behavior of Holstein heifers on high-concentrate diets. L. A. González*[1], A. Ferret[1], X. Manteca[1], J. L. Ruíz-de-la-Torre[1], S. Calsamiglia[1], M. Devant[2], and A. Bach[2], [1]*Universitat Autonòma de Barcelona*, *Bellaterra, Spain*, [2]*Unitat de Remugants-IRTA*, *Barcelona, Spain*.

Seventy two Holstein heifers (BW 138.0 ± 2.4 kg) were randomly assigned to a 3 × 3 complete block design, similar BW between treatment pens of each weight block, to study the effect of the feeding space availability on social behavior. Treatments consisted of 1 (T1), 2 (T2) or 4 (T4) concentrate feeding places/pen separated by vertical feed barriers (8 heifers/pen). The linear space available in the 2 straw feeders per pen was 0.35 m/animal in T1 and T2, and 0.25 m/animal in T4 pens with no feed barriers. Concentrate (3 Mcal of ME/kg, 16.4% CP, 20.3% NDF, DM basis) and straw were fed daily at 0830 ad libitum and in different feeders. Video recordings were analyzed by continuous sampling for the number and location of displacements over 2 d in wk 8, 16 and 28 of the fattening period. Data were analyzed as

a Poisson regression model considering the fixed effects of treatment, block and week (repeated measure), and pen as a random effect. The number of displacements (ND) per pen and day in the concentrate feeders was greatest in T1 (67.0 ± 2.6), intermediate in T2 (33.7 ± 1.8) and lowest in T4 (19.3 ± 1.4; P < 0.05). The ND in the straw containers was greater in T4 (54.8 ± 3.5) compared to T1 (36.2 ± 3.0; P < 0.05) and T2 (38.3 ± 3.2; P < 0.10). The ND in the water bowls (2 per pen) was greater in T2 (22.2 ± 1.4) compared to T1 (12.8 ± 1.1) but no different from T4 (17.2 ± 1.3; P < 0.05). These led to a treatment effect (P < 0.05) for the total ND per pen and day being greatest in T1 (122.4 ± 6.2), intermediate in T2 (100.6 ± 5.3) and lowest in T4 (81.9 ± 4.5). Although the ND from the concentrate feeders were highest with the lowest number of feeding places per pen (T1) and the ND from straw feeders were highest with the lowest linear space per animal (T4), it is possible that T2 groups re-directed part of the aggressive interactions, needed to establish or maintain the priority of access to resources, towards the water bowls.

Key Words: Heifers, Feeding Space, Aggressive Interactions

T4 Relationship between calves' social rank and performance after arrival at the feedlot with different feeding place availability. L. A. González*[1], A. Ferret[1], X. Manteca[1], J. L. Ruíz-de-la-Torre[1], S. Calsamiglia[1], M. Devant[2], and A. Bach[2], [1]*Universitat Autonòma de Barcelona*, *Bellaterra, Spain*, [2]*Unitat de Remugants-IRTA*, *Barcelona, Spain*.

Seventy two Holstein female calves (BW = 110.4 ± 2.5 kg) were randomly assigned to a 3 × 3 complete block design to study the effect of social dominance on ADG during wk 1 and 3 after arrival at the feedlot with different levels of social pressure at the concentrate feeders. Calves were blocked by BW and treatments consisted of 1 (T1), 2 (T2) or 4 (T4) feeding places/pen (8 calves/pen). Pelleted concentrate and straw were fed at 0830 ad libitum and in different feeders. Displacements between calves from the concentrate and straw feeders, and water bowls, were registered over 3 d at wk 1 and 3 after arrival at the feedlot, and DMI and ADG were determined weekly. Angular dominance value (ADV) was calculated as the arcsine square root of the average proportion of displacements won by an animal against each dyad member in the pen. Data were analyzed with a linear mixed regression model considering the fixed effects of treatment and block, and the linear and quadratic effect of ADV. Week as a repeated measure, animal within pen and pen were random effects. DMI and ADG increased linearly (P < 0.05) during wk 1 as the number of feeding places per pen increased. DMI increased quadratically at wk 3 (P = 0.02) with the lowest DMI for T1 calves. A significant ADV × week × treatment interaction was observed (P < 0.001). In T1 calves, increasing ADV resulted in a linear decrease in ADG at wk 1 (β = -0.55; P = 0.03) and a quadratic increase at wk 3 (β = 5.49; β^2= - 3.45; P < 0.01) showing a high positive slope. In T2 calves, increasing ADV resulted in a linear decrease of ADG at wk 1 (β = -0.50; P = 0.04) but a linear increase at wk 3 (β = 0.56; P = 0.02). No significant effect of social rank on ADG was observed in T4 calves. Increasing social pressure at the concentrate feeders reduced DMI and ADG because the repercussions of dominance values were greater.

Key Words: Calves, Feeding Place, Dominance

T5 Behavior and welfare of laying hens in single-tier aviaries with and without outdoor area. T. Tanaka*[1], T. Shinmura[1], T. Suzuki[1], S. Hirahara[2], Y. Eguchi[1], and K. Uetake[1], [1]*Azabu University*, *Sagamihara, Japan*, [2]*Kanagawa Prefectual Livestock Industry Technical Center*, *Ebina, Japan*.

The objective of the present study was to examine the behavioral frequency and pattern of laying hens in single-tier aviaries with and without outdoor areas, and to compare the welfare level between the two systems in association with other important measurements. In total, 144 interbred cross layers (WL × RIR) were used. At the age of 16 weeks, the hens were randomly divided into two groups consisting of four single-tier aviaries (SA) with 18 hens per pen and four free-range systems (FR) with 18 hens per pen. The free-range system was a single-tier aviary with an outdoor area (1.1 m2/hen) with planted clover. Behavioral observations were conducted before (0600-0800), during (1000-1200 and 1300-1500) and after (1700-1900) the pasturage. Eating, grazing, drinking, preening, aggressive pecking, feather pecking, litter pecking, object pecking and mate pecking were defined as pecking behavior. Feather condition, foot condition, TI test, H/L ratio were also measured. 18% of FR hens spent their time grazing. Conversely, eating (P <0.01), preening (P <0.01), litter pecking (P <0.05), object pecking (P <0.05), aggressive pecking (P <0.01) and feather pecking (P <0.01) were more frequently performed in SA than in FR. The total frequency of pecking behavior in SA was similar to that in FR (61.7±2.0% and 64.0±0.8%, respectively). While pre-laying behavior decreased from 0600-0800 to 1700-1900, pecking behavior increased. Aggressive pecking and feather pecking were observed frequently at 1000-1200 and 1300-1500 in SA, and at 1700-1900 in FR (system × observation time, both P <0.01). Feather condition on the part of vent as worse in SA than in FR (P <0.05). Claw lengths of the center front and rear were shorter in FR than in SA (P <0.001 and P =0.06, respectively). TI duration was shorter in FR than in SA (P <0.05). In conclusion, it was suggested that total frequency of pecking behavior was similar between these systems either with or without outdoor area. The risk for cannibalism is lower, and hens' fear reaction and claw length is also improved by the existence of an outdoor grazing area. It was indicated that welfare level is higher in FR compared with SA.

Key Words: Non-cage System, Welfare

T6 Relation between social order and use of resources in small and large furnished cages for laying hens. T. Shimmura*[1], T. Azuma[1], S. Hirahara[2], Y. Eguchi[1], K. Uetake[1], and T. Tanaka[1], [1]*Azabu University*, *Sagamihara, Japan*, [2]*Kanagawa Prefectual Livestock Industry Technical Center*, *Ebina, Japan*.

The objective of the present study was to determine the relation between social rank and use of resources such as the nest box and dust bath by using a popular smaller furnished cage and an approved large one. In total, 92 interbred cross layers (WL × RIR) were used. At the age of 16 weeks, the hens were randomly divided into two groups consisting of four small furnished cages (SF, 90 cm wide × 46.5 cm deep) with five birds per cage, and four large furnished cages (LF, 240 cm wide × 62.5 cm deep) with 18 birds per cage. The dominance hierarchy was determined; by which high, medium and low ranked hens in each cage were identified. The behavior, use of resources and physical condition of these hens were measured. Data were analyzed by using repeated measure ANOVA. The high ranked hens spent more

time in the dust bath than the medium and low ranked hens in LF (both $P < 0.05$), while no significant difference was found between them in SF. The high ranked hens performed dustbathing and litter scratching more frequently than the medium and low ranked hens in LF (both $P < 0.01$), while no significant difference was found between them in SF. The amount of time spent in the nest box was similar between each rank in SF and LF. However, the amount of time spent by LF low ranked hens performing pre-laying (sitting in nest) was lower compared with LF medium and high ranked hens (Social order × Cage design, $P = 0.08$). Concerning hens in the nest box, more than 90% of SF hens, LF high and medium ranked hens performed pre-laying. Conversely, LF low ranked hens spent thier time escaping (33.1%), pre-laying (27.7%), standing-resting (25.7%) and moving (13.5%) in the nest. In conclusion, under the condition that aggressive interaction occurred frequently, higher ranked hens would have priority using the dust bath. In contrast, low ranked hens would spend more time in the nest box for 'refuge' rather than for laying. It was also suggested that allowances for the size and/or arrangement methods of each resource be made in furnished cages, especially large ones.

Key Words: Furnished Cage, Social Order, Resource

T7 Effects of dust bath and nest box arrangement on behavior of high-, medium- and low-ranked hens in furnished cages. T. Shinmura*, Y. Eguchi, K. Uetake, and T. Tanaka, *Azabu University*, *Sagamihara, Japan*.

In our previous studies, it was confirmed that aggressive interaction occurred frequently in the dust baths in furnished cages. In later research, we demonstrated that dominant hens had priority in using the dust bath. Also, it was reported that this tendency was more pronounced in the larger furnished cages. Therefore, we contrived a new medium furnished cage with separated resources. The objective of the present study was to evaluate the effects of dust bath and nest box arrangement on the behavior of hens from each rank in the new furnished cages compared with small and medium furnished cages with concentrated resources. In total, 150 White Leghorn layers were used. At the age of 17 weeks, the hens were randomly divided into three groups consisting of small furnished cages (SF, 90 cm wide × 46.5 cm deep; six cages; five birds per cage) and two types of medium furnished cages (180 cm wide × 46.5 cm deep; six cages; 10 birds per cage) with separated resources on both sides (MFS) and concentrated resources on one side of the cage (MFC). The dominance hierarchy was determined, by which high, medium and low ranked hens in each cage were identified. The behavior, use of resources and physical condition of these hens were measured. Data were analyzed by using repeated measure ANOVA. Significant interaction between social order and cage design were found in reference to the amount of time spent in the dust bath and on performing dustbathing (both $P < 0.001$), and these proportions of time were higher among the SF high ranked hens, MFC high and medium ranked hens than in the low ranked hens. Conversely, the MFS low ranked hens used the dust bath more than the SF and MFC low ranked hens. In MFS, hens from each rank used the dust bath equally, though the high ranked hens used this resource less than the SF and MFC high ranked hens. In conclusion, higher ranked hens had priority over use of the dust bath in SF and MFC. In contrast, it was confirmed that each rank of hens used the resources equally in MFS. It was suggested that separation of the resources in furnished cages is an effective measure in improving hen welfare.

Key Words: Furnished Cage, Social Order

T8 Effect of stocking density on the short-term behavior of dairy cows. C. T. Hill[1,2], P. D. Krawczel*[1,2], H. M. Dann[1], C. S. Ballard[1], R. C. Hovey[2], and R. J. Grant[1], [1]*W.H. Miner Agricultural Research Institute*, *Chazy, NY*, [2]*The University of Vermont*, *Burlington*.

The objective of this study was to determine the effect of stocking density on the short-term behavior of dairy cows. Holstein cows (n = 136) were housed in a freestall barn, fed a total mixed ration daily and milked 3× daily. Cows were assigned to 4 pens with stocking densities (100, 113, 131, and 142%) imposed in a 4 × 4 Latin square for 7 d. Each cow was provided a stall and headlock at 100% stocking density while the greater stocking densities were simulated by denying access to freestalls and headlocks. The mean percentage of cows feeding, lying, and standing was determined using 10-min scan samples from digitally-recorded video data collected during the final 2 d at each stocking density. Milk composition was determined for all cows during a 24-h period at each stocking density. Although the mean percentage of cows feeding during a 24 h period (20.5%) did not differ among treatments ($P = 1.0$), increased stocking density reduced the percentage of cows feeding following their return from milking (67.2 at 100% stocking density versus 54.8 at 142%; $P = 0.009$). The percentage of cows lying decreased from 50.8 at 100% stocking density to 47.4 at 142% ($P = 0.007$). The percentage of cows standing in an alley increased from 8.8 at 113% stocking density to 12.6 at 142% ($P < 0.001$), while the percentage standing in stalls decreased from 10.8 at 100% stocking density to 9.2 at 142% ($P = 0.02$). Milk fat was reduced from 3.8% at 100% stocking density to 3.6% at 142% ($P = 0.03$). The decreased percentage of cows lying, increased percentage of cows standing, and reduced milk fat percentage suggest that increased stocking densities were detrimental. However, similar behavioral responses at 100% and 113% stocking density indicate cows can be housed at 113% before observable changes in behavior occur.

Key Words: Stocking Density, Behavior

T9 Survey of calf and heifer husbandry practices on dairies in the mid-western and eastern U.S. W. K. Fulwider*, T. Grandin, D. J. Garrick, T. E. Engle, W. D. Lamm, N. L. Dalsted, and B. E. Rollin, *Colorado State University*, *Fort Collins*.

The objective was to determine how heifers are being managed on dairies up until the time of calving. Dairies were visited during the fall and winter in WI, MN, IN, IA, and NY. Data were collected on 113 dairies regarding colostrum feeding, dehorning, tail docking, custom calf-raising, and the level of satisfaction with calf-raising by producers. Three feedings of colostrum were received by calves on 24% of dairies, 2 feedings on 62% of farms, 1 feeding on 30% of farms, and no colostrum fed on 4% of farms. Many farms (62%) administered 3.8 L at first feeding. Calves were dehorned at various ages by various methods. Between 2 and 4 wk was the most common time to dehorn, with 25% of calves processed. By 20 wk, 83% of calves were dehorned. The majority of calves were dehorned by burning (66%). The remainder was dehorned by gouging (9%), paste (10%), saw (4%), and unknown by calf owner (12%). Anesthetic use was reported by 12% of dairy owners, and analgesia use by 2%. Tail-docking was reported on 86% of dairies. None of the dairies trimmed switches. The most common reported docking period was pre-, or post-calving (27.68%). The second most commonly reported period was day 1 of life (13%). Banding was the most common method (75%) followed by pruning (25%). Three dairies pruned pre-calving, one at 2-mo, and

two at day 1. Cleanliness was the most common reason to dock (73%), parlor milking (17%), and udder health (1%). Calves were raised by the owner on 50% of dairies, while 44% custom raise calves for at least a portion of the growing period. Only one producer sold calves and purchased heifers back pre-calving. Only 29% of dairies had heifers' custom raised during a portion of the milk feeding period. Satisfaction reported by producers regarding calf-raising was highly satisfied (51%), satisfied (31%), okay (8%), less than satisfied (6%), and need to change (3%).

Key Words: Calf, Dehorn, Tail-dock

Animal Health - Livestock and Poultry: Poultry/Swine/Goat/Sheep

T10 Colicin E1 prevents *Escherichia coli* F18 caused post-weaning diarrhea in pigs. S. A. Cutler*, N. Cornick, S. M. Lonergan, and C. H. Stahl, *Iowa State University*, *Ames*.

The use of dietary prophylactic antibiotics to prevent post-weaning diarrhea (PWD) in pigs is common practice in the U.S. swine industry. Despite this preventive measure, PWD still causes substantial losses to the swine industry due to both mortality and reduced growth performance in surviving pigs. With world-wide concern over the use of antibiotics in animal agriculture, alternatives to conventional antibiotics are desperately needed. The bacteriocin, Colicin E1 (ColE1), is effective against the *E. coli* strains responsible for PWD in vitro. In this study, we examined the efficacy of dietary inclusion of ColE1 in preventing experimentally induced PWD. Weaned pigs (n=16, 18d of age), all genetically susceptible to *E. coli* F18, were allocated into 2 groups, based on body weight, and fed corn-soy diets containing either 0 or 16.5mg ColE1/kg diet. After 2d on the treatment diets, all animals were orally inoculated with 1×10^9 CFU of 2 *E. coli* F18 strains isolated from pigs with PWD. Body weight (BW) and fecal scores were recorded daily, and *E. coli*. coli from rectal swabs were enumerated daily. All animals were euthanized 4d post-inoculation and sections of the ileum were collected for histology, *E. coli* enumeration, and gene expression. The inclusion of ColE1 decreased ($P\leq0.05$) the incidence and severity of PWD as demonstrated by the reduction ($P\leq 0.05$) in incidence of diarrhea (none in ColE1 fed pigs vs. 6 out of 8 in the controls). Inclusion of ColE1 improved ($P\leq0.05$) BW gain for ColE1 fed pigs compared to the controls (940g/d vs. 380g/d, respectively), and it is interesting to note that 3 control pigs, but none of the pigs fed ColE1, lost weight during this trial. Additionally, dietary addition of ColE1 reduced the gene expression of the cytokines *IL1*β ($P\leq0.02$), *iNOS* ($P\leq0.08$), and *TNF*β, ($P\leq0.06$) in ileal tissue compared to the control animals, suggesting a decreased inflammatory response in these pigs. Dietary inclusion of ColE1 appears to be an effective alternative to conventional antibiotics in the diet of swine for the prevention of PWD.

Key Words: Pigs, Colicin, PWD

T11 Evaluation of photonic imaging in the gastrointestinal tract of swine following oral inoculation with lux-modified *Salmonella typhimurium*. K. Moulton*[1], P. Ryan[1], R. Youngblood[1], M. McGee[1], S. Laird[1], A. Harris[1], D. Moore[1], I. Kim[1], D. Lay[2], and S. Willard[1], [1]*Mississippi State University*, *Mississippi State*, [2]*USDA-ARS*, *West Lafayette, IN*.

The objective was to evaluate photonic emitting bacteria through different segments of the gastrointestinal tract of swine. Pigs (~ 80 kg) were inoculated orally with 3.1 or 4.1×10^{10} CFU of *Salmonella typhimurium* transformed with plasmid pAK1-lux (S. typh-lux) for a 6 (n=6) or 12 (n=6) h incubation in vivo. Pigs were euthanized at 6 or 12 h. Intestinal regions (duodenum, jejunum, ileum, large intestine) were divided into 5 replicates of 4 segments (5 cm) each for imaging. For each replicate, two segments of each region were intact, while 2 segments were opened to expose the digesta. Sub-samples of digesta were analyzed for CFU, and images were analyzed for relative light units/sec (RLU/sec). At 6 h, a higher ($P<0.05$) concentration of emitting bacteria and consequently higher ($P<0.05$) detection of photonic emissions was observed in small intestine than large intestine. The correlations (6 h) of photonic emissions in opened segments to bacterial concentrations were r = 0.73, 0.62, 0.56, and 0.52 ($P<0.05$) in duodenum, jejunum, ileum, and large intestine, respectively. Photonic emissions were higher ($P<0.05$) in jejunum, ileum, and large intestine than in duodenum of intact segments post 6 h incubation. At 12 h, a higher ($P<0.05$) concentration of emitting bacteria in jejunum and ileum of open segments was observed than in duodenum and large intestine of open segments. Photonic emissions were higher in ileum than duodenum, jejunum and large intestine of open segments ($P<0.05$). The correlations (12 h) of photonic emissions in opened segments to bacterial CFU's were r = 0.71 and 0.62 for jejunum and ileum, respectively ($P<0.05$). At 12 h, a higher ($P<0.05$) concentration of emitting bacteria in jejunum and ileum of intact segments was observed than in duodenum and large intestine. These data indicate CFU were higher in small intestine after 6 and 12 h incubations, and a minimum of 2.0×10^5 CFU yields detection through these tissues (~ 1.0 to 21.0 RLU/sec). This study demonstrates feasibility of using biophotonics in research models for evaluating pathogenicity of *Salmonella* in swine.

Key Words: Swine, Biophotonics, *Salmonella*

T12 Development and optimization of species-specific PCR for rapid detection of Dermatophilus congolensis. S. Valipe, M. Amalaradjou, J. Nadeau*, A. Thirunavukkarasu, and K. Venkitanarayan, *University of Connecticut*, *Storrs*.

Dermatophilosis is a contagious and zoonotic disease in farm animals caused by *Dermatophilus congolensis*. Dermatophilosis is responsible for significant economic losses due to reduced milk production in cattle, wool losses in sheep, lameness and loss of days in showing horses. Accurate and rapid diagnosis of dermatophilosis is essential for specific therapeutic and preventive measures against the disease. The currently available methods for identification of *D. congolensis* are laborious and time-consuming; thus there is a need for a rapid method for detecting the bacterium. Polymerase chain reaction (PCR) is a highly specific and sensitive method used for the rapid detection of microorganisms. In this study, we developed a species-specific PCR to detect *D. congolensis* based on a 1029-bp internal, conserved region of its alkaline ceramidase gene. Chromosomal DNA from 8 strains of *D.congolensis* and 33 strains of negative control bacteria, including other common equine pathogens, environmental bacteria and

phylogenetically related bacteria were used as templates in the PCR. Amplification was carried out in 25-µL volumes of reaction mixture containing 2.5 mM $MgCl_2$, 50 mM of each nucleotide, 0.5 µM of each primer, 0.125 U of Taq polymerase and approximately 50 ng of template DNA from each bacterium. Initially the reaction mixture was heated to 94°C for 5 min and subjected to 30 cycles of PCR. Each PCR cycle consisted of denaturation at 92°C for 30 sec, annealing at 56°C for 45 sec and extension at 72°C for 45 sec. At the end of 30 cycles, a final extension at 72°C for 10 min was provided. The presence and the size of the PCR products were determined by agar gel electrophoresis. PCR amplified a 1029-bp DNA fragment from all the 8 strains of *D. congolensis*, but not from the negative control bacteria. Results indicate that the PCR developed in this study could potentially used for the rapid diagnosis of dermatophilosis, but it needs to be validated in farm animals.

Key Words: Dermatophilosis, PCR, Detection

T13 Necrotic Enteritis control in broilers chickens fed the feed additives RepaXol, AciXol, or Virginiamycin. G. Mathis*[1] and N. Scicutella[2], [1]*Southern Poultry Research, Inc.*, *Athens, GA*, [2]*SODA Feed Ingredients*, *Monaco*.

The objective was to compare the level of Necrotic Enteritis in Clostridium perfringens challenged broilers fed the feed additives RepaXol, a blend of double coated essential oils, AciXol an encapsulated blend of organic and inorganic acids along with the essential oils (as in RepaXol) or Virginiamycin, an antibiotic. A randomized block design with 6 replications of 10 birds per cage was used. The treatments were nonmedicated, non-challenged (NMNC), nonmedicated, challenged (NMC), RepaXol 100 ppm, AciXol 500 ppm, and Virginiamycin (VIR) 20 ppm. Birds were challenged on Day 14 with E. acervulina and E. maxima and on Days 19, 20, and 21 with Clostridium perfringens. The performance parameters measured were feed conversion and weight gain. Level of Necrotic Enteritis (NE) was determined by NE mortality and NE lesion scores. There was a significant improvement in feed conversions and weight gains for RepaXol, AciXol and VIR. The percent NE mortality for NMC was 33%. There was no significant difference in percent NE mortality between RepaXol (23%), AciXol (22%) and VIR (12%). All treatments had significantly lower NE lesion scores compared to NMC. This study demonstrated the benefits of adding RepaXol 100 ppm, AciXol 500 ppm, or Virginiamycin 20 ppm into the feeds of broiler chickens exposed to Clostridium perfringens.

Key Words: RepaXol, AciXol, Virginiamycin

T14 Molecular ecology effects of essential oil blends on identified broiler cecal digestive bacteria. Y. Leontieva*[1], A. Syvyk[1], A. Nalian[1], M. Hume[2], E. Oviedo-Rondon[3], S. Clemente-Hernández[4], and A. Martynova-Van Kley[1], [1]*Stephen F. Austin State University*, *Nacogdoches, TX*, [2]*USDA, ARS, SPARC, Food and Feed Safety Research Unit*, *College Station, TX*, [3]*North Carolina State University*, *Raleigh*, [4]*Universidad Autónoma de Chihuahua*, *Chihuahua, México*.

Essential oil blends are generating increased attention as alternatives to antibiotic treatments in broiler production. The aim of this study was to identify the intestinal microbial species most affected by different blends of essential oil supplements, Crina Poultry (CP) and Crina Alternate (CA). Cecal contents from three broiler treatment groups were analyzed: 1) birds on basal diet (BD); 2) birds on basal diet supplemented with (CP); 3) birds on basal diet supplemented with (CA). Digestive bacteria banding profiles were examined by the PCR-based denaturing gradient gel electrophoresis (DGGE). In order to carry out a conclusive phylogenetic identification of the species and to overcome the limitation of the sequencing of short fragment PCR products required for DGGE analysis, we generated clone libraries from longer ~520bp 16S rDNA PCR products. To select unique clones representing predominant and minor members of the bacterial community, PCR of short fragments (~250bp) was carried out using clone DNA as a template. The short PCR products were then screened using DGGE against the original field samples and unique short fragments and their corresponding clones were identified. Subsequently, clones containing long fragment and matching to DGGE bands affected by the presence of essential oil supplements in the broiler diet were selected for sequencing. This methodology provides a simple way of screening clone libraries to obtain longer and more useful sequencing data for phylogenetic identification of members of broiler digestive microbial population.

Key Words: Essential Oil Blends, DGGE, Microbial Community

T15 Electrospray-ionization mass spectrometric analysis of lipid restructuring in the chick liver: Effect of maternal dietary conjugated linoleic acid. G. Cherian*, *Oregon State University*, *Corvallis*.

The effects of egg yolk conjugated linoleic acid (CLA) on hatched chick liver phospholipid molecular species were determined by electrospray-ionization mass spectrometry. Eggs with no, low or high levels of CLA were produced by feeding hens a corn-soybean meal basal diet containing 3% (wt/wt) corn oil (Control), 2.5% corn oil +0.5 % CLA oil (CLA1) or 2% corn oil + 1.0% CLA oil (CLA2).Yolk total CLA was 0.0, 1.0 and 2.6% for Control, CLA1 and CLA2, respectively ($P<0.05$). Chicks hatched from CLA1 and CLA2 eggs incorporated higher levels of cis9, trans11 CLA in the liver than did chicks from Control ($P<0.05$). A 21 and 38% reduction in the abundance of total phosphatidylethanolamine (PE) species was observed in the liver of CLA1 and CLA2 chicks respectively, as compared to Control chicks ($P<0.05$). The largest observed change in PE was a 32% decrease in 18:0/20:4 ($P<0.05$). Total phosphatidylcholine (PC) in the liver of CLA1 and CLA2 chicks was reduced by 16 and 28% respectively, when compared to Control chicks ($P<0.05$). The major changes in PC were a 40% reduction in the abundance of 18:0/20:4 ions in CLA1 and CLA2 ($P<0.05$). Significantly reduced 16:0/18:1 and 16:0/20:4 ions were also observed in the PC of CLA1 and CLA2 than Control ($P<0.05$). Significant increases in the abundance of 16:0 and 18:0 in the lyso PC and lyso PE were observed in CLA1 and CLA2. These results suggest that maternal or egg yolk CLA results in a remodeling of phospholipid molecular species in the chick liver. Though very little is known about the physiological or pathological role of specific molecular species during embryogenesis, it is likely that this remodeling will impact a range of cellular functions affecting embryo health and hatchability.

Key Words: Electrospray Ionization Mass Spectrometry, Conjugated Linoleic acid, Phospholipid Species

T16 Maternal dietary n-3 fatty acids alter proinflammatory eicosanoid production in broiler birds. J. Bautista-Ortega*, D. E. Goeger, and G. Cherian, *Oregon State University*, *Corvallis*.

The objective of this research was to evaluate the contribution of a maternal diet enriched with omega-3 fatty acids on eicosanoid metabolism and antioxidant enzyme activities in broiler birds. Fertile eggs with high or low n-3 fatty acids were obtained by feeding breeder hens diets containing 3.0% sunflower oil (Low n-3), 1.5% sunflower oil and 1.5% fish oil (Medium n-3), or 3.0% fish oil (High n-3). These oils were chosen due to their high content of n-6 or n-3 fatty acids. The hatched chicks were fed a commercial diet devoid of long chain n-3 fatty acids. On the day of hatching, generation of proinflammatory eicosanoid (prostaglandin E2) was highest in the heart tissue of Low n-3 chicks ($P<0.05$). Heart tissue of chicks hatched to hens fed High and Medium n-3 diets synthesized higher thromboxane B3 than those of Low n-3 chicks ($P<0.05$). At day 42 of growth, prostaglandin E2 and thromboxane B2 (proaggregatory) generation was highest in the cardiac ventricles of chicks hatched to hens fed Low n-3 diets ($P<0.05$). Weight of the ventricle as a percentage of heart weight was higher in Low n-3 birds as compared to High n-3 birds. Chicks hatched to hens fed High n-3 diets had lower catalase activity in their heart tissue than did Low n-3 chicks ($P<0.05$). Maternal diet did not alter the activities of glutathione peroxidase, total glutathione, glutathione reductase or superoxide dismutase in the heart tissue. On day 42, the total lipid content of plasma was lowest in High n-3 birds ($P<0.05$). These results indicate that maternal dietary n-3 fatty acids alter proinflammatory eicosanoid production in chicks, which could lead to fewer inflammatory-related disorders in broiler chickens.

Key Words: n-3 Fatty Acid, Eicosanoid

T17 Immunomodulatory potential of feed borne *Fusarium* mycotoxins in broiler breeders Iinfected with coccidia. G. N. Girgis*, T. K. Smith, S. Sharif, J. R. Barta, and H. J. Boermans, *University of Guelph*, *Ontario, Canada,*.

The potential for *Fusarium* mycotoxins to modulate immunity was studied in broiler breeders raised to 10 weeks of age using a coccidia infection model. Day-old breeders were randomly divided into 3 groups, 40 birds each. Diets included: (1) control (2) contaminated grains (3) contaminated grains + a polymeric glucomannan mycotoxin adsorbent (GMA, Mycosorb®, Alltech Inc., Nicholasville, KY). Contaminated diets contained up to 3.8 ppm deoxynivalenol (DON), 0.3 ppm 15-acetyl DON and 0.2 ppm zearalenone. Half of the birds in each group were orally inoculated at 8 weeks of age with a cocktail comprising *Eimeria acervulina*, *E. maxima* and *E. tenella*. Serum, whole blood and caecal tonsils were collected from all birds prior to inoculation, at the end of challenge period (7 days post inoculation, PI), and at the end of recovery period (14 days PI). Serum IgA levels in infected birds fed contaminated diet were found to be significantly reduced at the end of recovery period. Flow cytometry of isolated blood lymphocytes revealed that CD8+ cell populations in the same birds were significantly lower than controls. Using real-time PCR, interferon-γ gene expression in caecal tonsils at the end of challenge period was significantly higher in birds fed contaminated and GMA-containing diets compared to birds fed the control diet. It was concluded that *Fusarium* mycotoxin-induced immunomodulation involves intestinal immunity and interferes with recovery from *Eimeria* infection.

Key Words: *Fusarium*, immunity, coccidia

T18 Broiler performance on a Maxiban® anticoccidial program with exposure to a mixed *Eimeria* population. A. Barri[1], C. L. Novak[1], H. D. Danforth[2], S. J. Steinlage[3], and A. P. McElroy*[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*USDA/ARS*, *Beltsville, MD*, [3]*Elanco Animal Health*, *Greenfield, IN*.

This study compared inclusion of Maxiban® in the diet to *Eimeria* vaccination for broiler performance during exposure to a mixed environmental coccidia exposure. The 37-d day trial consisted of three treatment groups (n=540/trt): negative control (CON; non-medicated diet/no vaccination), Maxiban diet (MAX; 72g starter, 81g grower, 0g finisher) and a group vaccinated (VAC) with a commercial live *Eimeria* vaccine. Evaluation included body weight (BW), BW uniformity and gain (BWG), feed intake, mortality, adjusted feed conversion (FC), intestinal lesion scores, and tensile strength. Prior to this trial, birds challenged with a mixed *Eimeria* population were placed in pens to seed the litter. MAX or VAC resulted in heavier ($P<0.05$) BW as compared to CON for the starter period (d0 to18), and MAX broilers were heavier than CON or VAC on d37. On d18 and d32 MAX resulted in more uniform BW as compared to CON, while VAC birds were not different from CON or MAX. MAX resulted in increased BWG overall as compared to CON, and MAX or VAC resulted in increased BWG for d0-18 in comparison to CON. No differences in BWG were observed for the grower (d19 to 32) or finisher (d33 to 37) periods. During all periods, MAX had better FC as compared to CON. For d0 to 37, MAX (1.64) resulted in the most efficient FC as compared to VAC (1.68), as an intermediate, or CON (1.74). FC of VAC birds was better than CON for d0 to 18, while it was intermediate to MAX and CON for d33 to37. MAX had lower mortality (%) in the starter (2.0) and grower (1.2) periods as compared to CON (20.6 and 17.5). For these periods, mortality of VAC birds (4.4 and 5.3) was not different from either CON or MAX. For d0 to 37, MAX (4.0) and VAC (9.9) had lower mortality than that of CON (33.1). MAX had less severe *E. maxima* and *E. tenella* as compared to CON. Similarly, VAC broilers had less severe lesions for *E. tenella*. No differences were observed for *E. acervulina* lesions or tensile strength. These data suggest that MAX, and to a lesser extent VAC, improved performance of broilers exposed to a mixed environmental *Eimeria* population as compared to non-medicated, non-vaccinated broilers.

Key Words: *Eimeria*, Broilers, Vaccination

T19 Rapid detection of avian reoviruses in cloacal swabs using real-time RT-PCR. K. Guo*, T. Dormitorio, and J. Giambrone, *Auburn University*, *Auburn, AL*.

Avian reoviruses (ARV) can cause a variety of diseases, such as tenosynovitis, malabsorption syndrome, chronic respiratory disease, and immunosuppression in young commercial poultry. Therefore, early detection is critical for proper vaccination and prevention of ARV infections. In the current study, we applied the previously reported Sigma NS primer-probe set, which was designed by our lab, for the

detection of the ARVs in cloacal swab samples, from infected chickens with the Roche LightCycler. Preliminary studies indicated that this method identified 60% of the swab samples as positive at 3-day post-infection (PI) with an ARV strain 2408. At 7-day post-infection, 40% were detected positive with this method. The whole process of sample collection, RNA extraction, and real-time RT-PCR was completed within 4hrs, compared with virus isolation in cell culture or embryos, which takes up to 3days. This technique can be used for the rapid detection of ARVs in the diagnostic laboratory.

Key Words: Avian Reovirus, Real-time RT-PCR, Cloacal Swab Sample

T20 Development of a polymerase chain reaction assay for rapid identification of the causative agent of ulcerative enteritis. L. Bano*[1], K. S. Macklin[2], S. W. Martin[2], R. S. Miller[2], R. A. Norton[2], O. A. Oyarzabal[2], and S. F. Bilgili[2], [1]*Istituto Zooprofilattico Sperimentale delle Venezie*, *Treviso, Italy*, [2]*Auburn University*, *Auburn, AL*.

Clostridium colinum is the causative agent of ulcerative enteritis (UE), an important disease of bobwhite quail (Coluinus virginianus). UE has been reported also in chickens between 4 and 25 weeks of age, with a mortality rate of up to 50%. The aim of the present study was to develop a polymerase chain reaction (PCR) assay specific for C. colinum and to determine the detection limit of this assay in artificially inoculated fecal material. The 16S rDNA sequences of C. colinum, C. disporicum and C. piliforme were aligned and two primers were developed that would react only with C. colinum. The specificity of these primers were tested with American Type Culture Collection (ATCC) strains of C. colinum, C. perfringens, C. sporogenes, C. septicum and C. sordelii. The expected amplified product (935 bp) was observed only with DNA from C. colinum. Results from performing PCR assays on fecal samples from quails spiked with different concentrations of C. colinum showed that the detection limit of the assay was 1.6 x 104 CFU of C. colinum per g of fecal material. This PCR assay can be used in diagnostic laboratories to confirm the presence of C. colinum from pure cultures, and to screen enriched samples or fecal samples for the presence of C. colinum. This assay can also be formatted into an in situ PCR for detection of C. colinum in tissue samples or adapted to a real time PCR for a large screening of enriched or fecal samples.

Key Words: Clostridium Colinum, Bobwhite Quail, Ulcerative Enteritis

T21 Effect of oral administration of *Lactobacillus brevis* on turkey poult performance and immune development. K. Novak*, E. Davis, K. Bos, T. Rehberger, and C. Kromm, *Agtech Products, Inc.*, *Waukesha, WI*.

Immune cell populations in turkey poults were evaluated at d 9, 16, and 37 post-placement in response to dosing with a porcine-derived *Lactobacillus brevis* for the first three days of the brooder phase. Four brooder houses on a commercial turkey farm were evaluated and two treatments were administered orally through the water, such that two brooder houses received *L. brevis* in the water for the first three days after placement, and the other two houses served as controls. Six poults from each house were bled and euthanized at d 9, 16, and 37. Peripheral blood mononuclear cells and intraepithelial lymphocytes from the duodenum were evaluated by flow cytometry to determine T cell subpopulations as defined by the cell surface markers, CD4 and CD8. Poults provided with *L. brevis* had greater ($P = 0.08$) ADG from placement to d 9, but this effect diminished later in the brooder phase such that control birds had greater ($P < 0.01$) ADG from d 9 to 16. The double positive T cell population ($CD4^+CD8^+$) in the peripheral blood did not differ between control and *L. brevis* supplemented birds at d 9, but was greater ($P \leq 0.05$) at d 16 and 37 in *L. brevis* supplemented birds compared to control birds (treatment x day interaction, $P = 0.06$). The $CD4^+$ population in the peripheral blood was lower ($P = 0.08$) in *L. brevis* supplemented birds at d 9 compared to control birds, but was greater ($P \leq 0.07$) than control birds at d 16 and 37 (treatment x day interaction, $P = 0.06$). The $CD8^+$ population in the duodenum did not differ between control and *L. brevis* supplemented birds at d 9, but was lower ($P = 0.02$) at d 16 and greater ($P = 0.09$) at d 37 in the *L. brevis* supplemented birds than control birds (treatment x day interaction, $P = 0.04$). The results of this study indicate that *L. brevis* supplementation to turkey poults at an early age has the potential to improve growth response in the brooder phase and enhance immune development in the gastrointestinal tract and in the peripheral blood. However, duration and timing of administration should be further explored to maintain the performance benefits of early supplementation.

Key Words: Poultry, Probiotic, Immunity

T22 Evaluation of the efficacy of a bio-hygienic additive in ammonia level control in broiler houses. G. Tacconi[1], A. Zanierato*[2], and A. Covarelli[1], [1]*University of Perugia*, *Perugia, PG, Italy*, [2]*SOP Srl*, *Busto Arsizio, VA, Italy*.

The present field study investigates the efficacy of a new bio-hygienic bedding additive (SOP C POULTRY) in ammonia control in broiler houses. Bedding is considered one of the major sources of pollutants; in particular, ammonia often reaches high levels causing limited poultry performance and environmental pollution; the need to manage this using additives, has been considered for the last few years but has not resolved the situation conclusively. This study was carried out during 2003-2006 in an Italian commercial poultry farm. Two large broiler houses, control (C) and treated (T), were selected for their similarity in size, density, ventilation system, drinking and eating equipment. The buildings had a conventional layout and housed about 8,200-8,600 1 day old broiler chicks each cycle, to 7-8 weeks. Bedding consisted of 5-7cm deep wheat straw, regularly changed at the end of each cycle, and treated (T) covering the surface with the additive at a dosage of 2g of additive plus 25g of calcium carbonate (to enable even distribution) per m^2, the day before the chicks' housing and repeated twice a month during the 1st month; after, 1g of additive plus 25g of calcium carbonate per m^2 twice a month, until the end of each cycle. Ammonia concentrations were assessed in each house using Draeger PAC-III (PA-USA) in the 1st and 7th weeks, in six different points. The ammonia mean values of the ten cycles were, in house C and T respectively, in the 1st week 3.90 ± 3.05 ppm and 3.26 ± 3.91 ppm, and in the 7th week 19.07 ± 12.41 and 7.12 ± 4.39. The difference between the mean values was low (P=0.09) in the 1st week, but resulted in a 17.00% reduction; the reduction in the 7th week was significant (P=0.002) 62.9%. The control of ammonia levels in commercial poultry houses is essential in order to: improve the air quality in the housed environment; improve health, performance and welfare of both animals and

human attendants; reduce significantly the environmental ammonia emissions.

Key Words: Ammonia, Poultry, Bedding

T23 Characterization and expression of the ryanodine receptor 2 gene in furazolidone induced cardiomyopathic turkeys. E. Ndegwa* and M. M. Corley, *Tuskegee University*, *Tuskegee, AL*.

Intracellular calcium acts as a secondary messenger involved in signal transduction in almost all body cells and is a major player in contraction and relaxation in muscle cells. Altered calcium cycling is a major hallmark of end stage heart disease and has been linked to altered expression of the calcium cycling proteins. The cardiomyopathic turkey and human hearts have been shown to be similar in terms of the patho-physiological, gross and microscopic lesions. Therefore, investigation of genes involved in turkey cardiomyopathy can lead to further insight into cardiovascular disease in turkeys and serve as a good model for the human condition and thus benefit both the poultry industry and the human population. In this study, we attempted to identify and characterize the ryanodine receptor 2 gene from turkeys that carry a genetic trait (unknown) which renders them susceptible to cardiomyopathy. The ryanodine receptor is the main calcium channel that releases calcium from sarcoplasmic stores in the heart. The expression of this gene as it relates to heart disease in turkeys has not been investigated. Cardiomyopathy was induced in 25 three week old turkey poults by feeding furazolidone (600ppm) over a five week period. A control group (25) was fed regular turkey chick starter without the Furazolidone. Reverse transcriptase polymerase chain reaction (RT-PCR) was performed on total RNA from 0.1g of cardiomyopathic and non cardiomyopathic turkey heart tissue. Primers were designed from the chicken ryanodine 2 gene. The expected 576 bp cDNA fragment was successfully amplified. Nucleotide sequencing will provide verification of this gene. Expression studies will give further insight into the dynamics of the ryanodine 2 gene in cardiomyopathic turkeys and their suitability as a genetic model for human cardiovascular disease.

Key Words: Ryanodine 2, Cardiomyopathy, Turkeys

T24 The effect of anti-coccidiosis antibody on growth performance in broiler chicks. E. Hellestad*, J. Susko-Parrish, and M. E. Cook, *University of Wisconsin*, *Madison*.

A study was conducted to determine the ability of anti-coccidia egg antibody to prevent growth depression resulting from a coccidia challenge. Treatments consisted of control or coccidia challenged chicks factorially arranged (2x2) with adjuvant control egg yolk or anti-coccidiosis egg yolk. 10 pens of 5 chicks were assigned to each experimental treatment. The oral challenge consisted of either 0.2ml water (C) or 0.2 ml 10X commercial coccidiosis vaccine (V) containing viable oocysts of *Eimeria acervulina*, *Eimeria maxima* and *Eimeria tenella* at 0,7, and 14 days. The dietary treatments consisted of freeze dried yolk powder from adjuvant or adjuvant plus coccidia injected hens. The control yolk powder (C) came from hens injected with an emulsion containing Freund complete adjuvant on day 0 and Freund incomplete adjuvant on day 7. Anti-coccidiosis egg yolk (AB) was obtained from hens injected as described above, with the emulsion containing the commercial coccidiosis vaccine at 3mg protein/ml emulsion. Yolks from eggs collected 21-30 days after initial vaccination were freeze dried, powdered and added to a standard chick diet at 1g dried yolk/kg feed. Chicks receiving the vaccine and control diet (V/C) gained significantly less weight over 3 weeks than chicks receiving no vaccine and the control diet (C/C: 574g ±17 vs. 636g ±17, $p<0.05$). Chicks receiving the vaccine and AB diet (V/AB) gained significantly more weight over 3 weeks than the V/C chicks (621g±30 vs. 574g±17, $p<0.05$). V/AB chicks were not significantly different from C/C chicks or chicks on the antibody diet (C/AB) over 3 weeks (621g±30 vs. 636g±17 or 654g±30, $p=0.5$). There were no significant differences in feed efficiency between treatments (C/C= 0.65, V/C=0.65, C/AB=0.66, V/AB=0.65). The growth depression observed in chicks infected with coccidiosis was overcome with the addition of egg yolk containing anti-coccidiosis antibody to the diet.

Key Words: Egg Antibody, Coccidiosis, Broiler Chicks

T25 Oxidative stress and toxin-induced dilated cardiomyopathy in the turkey (*Meleagris gallopavo*). K. Gyenai*, J. Xu, T. Geng, L. Pyle, and C. Larson, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Dilated cardiomyopathy (DCM) or round heart disease is a muscle disease of the heart which is characterized by ventricular dilatation and abnormal systolic and diastolic left ventricular function. In animals, including turkeys and humans, DCM is the major cause of morbidity and mortality which results from heart failure. In the turkey, DCM can be idiopathic or induced. Here, our primary objective was to determine the effect, if any, of oxidative stress on the incidence and severity of toxin-induced DCM in the commercial turkey. Using glutathione (GSH), malondialdehyde (MDA), and plasma uric acid (PUA) as biomarkers, oxidative stress levels in DCM-affected and -unaffected poults fed varying concentrations of Vitamin E and selenium were also evaluated. Results from the MDA and GSH measurements were inconsistent. However, PUA levels increased by 5-fold between two and four weeks of age in birds fed furazolidone while the increase in non-furazolidone fed control birds was about 150 fold. The effect on the increase in antioxidant status though significant was not consistently affected by feeding either Vitamin E or selenium. Combined with the mortality data, the present work appears to suggest that DCM appears to influence the level of oxidative stress in turkeys.

Key Words: Turkeys, Oxidative Stress, Dilated Cardiomyopathy

T26 Effect of a *Bacillus*-based direct-fed microbial on turkey poult performance and changes within the gastrointestinal microflora. S. Gebert*, C. Kromm, and T. Rehberger, *Agtech Products, Inc.*, *Waukesha, WI*.

Two studies were conducted to evaluate the effect of a *Bacillus*-based direct-fed microbial (DFM) on poult performance and on the gastrointestinal microflora. In both studies, the DFM was incorporated into a standard turkey diet in a commercial facility in the Midwest to provide 4.75×10^4 CFU/g of treated feed. The first study was conducted to evaluate the duration of feeding the DFM on poult performance.

The DFM was fed from placement until the first five weeks of age at 17 sites and from placement to market at 24 sites. Performance was evaluated at market age. The adjusted feed conversion was improved (P = 0.10) in poults fed the DFM from placement to market compared to poults fed the DFM for only the first five weeks after placement. An additional study was conducted in which the poults were fed a standard commercial diet (control) or the control diet supplemented with the DFM from placement to market, and the gastrointestinal microflora was evaluated. Twelve control poults and 10 poults treated with the DFM were euthanized and gastrointestinal tracts were sampled to enumerate avian pathogenic *Escherichia coli* and *Clostridium perfringens* type A. Avian pathogenic *E. coli* encompass a division of pathogenic *E. coli* that cause colibacillosis in young turkey poults. *Clostridium perfringens* type A is an enteric bacterial pathogen and is the major contributing factor associated with necrotic enteritis in poultry. Avian pathogenic *E. coli* and *C. perfringens* type A levels did not differ between control and DFM supplemented poults at 9 weeks of age. However, at 18 weeks of age, supplementation with the DFM reduced avian pathogenic *E. coli* (1.6×10^7 vs. 2.0×10^4 CFU/g; $P < 0.01$) and *C. perfringens* type A (1.9×10^6 vs. 3.6×10^3 CFU/g; $P < 0.01$) compared to control birds. These results indicate that supplementation with a *Bacillus*-based DFM from placement to market improves feed conversion and beneficially alters the gastrointestinal microflora of turkey poults.

Key Words: Poultry, Probiotic, Gastrointestinal Microflora

T27 *Campylobacter jejuni* Colonization Alters Mucin Dynamics And Gut Architecture In Broilers. F. Solis de los Santos*[1], M. L. Dirain[1], P. J. Blore[1], I. Reyes-Herrera[1], A. M. Donoghue[2], and D. J. Donoghue[1], [1]*University of Arkansas*, *Fayetteville*, [2]*Poultry Production and Product Research Unit, Agricultural Research Unit*, *Fayetteville, AR*.

Campylobacter is a significant foodborne pathogen. To our knowledge, the impact of *Campylobacter* colonization on enteric morphology has not been evaluated. Understanding how *Campylobacter* may affect the gut might provide insights into ways to reduce its colonization. To this end, day old chicks (n=108) were randomly allocated in 6 sterile isolators. At d 14, 3 groups of birds (n=36 per group) were orally challenged with 10^6cfu/mL of *C. jejuni*, 10^4 cfu/mL *Salmonella* enteriditis (positive enteric pathogen control) or nothing (negative control), respectively. Six birds from each group were randomly selected at d 7, 14, 21, 28, 35 and 42 for *C. jejuni* enumeration and *Salmonella* detection in the ceca and determination of mucus thickness, villus and crypt depth and goblet cell number and type in the duodenum, jejunum, ileum and ceca. *Campylobacter* and *Salmonella* were detected at d 21, 28, 35 and 42 while negative control birds remained pathogen free. *C. jejuni* colonization decreased mucus thickness in the ileum and ceca on d 42 compared to Salmonella colonized birds and negative control. Ileal acidic goblet cells were reduced in *C. jejuni* and *Salmonella* birds compared to negative control on d 42. Ileal acidic goblet cells were lower in the ceca of *C. jejuni* birds compared to *Salmonella* and negative control on d 35. Ileal sulfuric goblet cells were higher in *C. jejuni* and *Salmonella* treated birds compared to negative control on d 35 and 42. Furthermore, cecal sulfuric goblet cells were higher in *C. jejuni* birds compared to *Salmonella* and negative control on d 28 and on d 42. Ileal crypt depth was lower in *Campylobacter* and *Salmonella* treated birds compared to negative control on d 42. Cecal crypt depth was lower in *C. jejuni* compared to *Salmonella* on d 35 and on d 42 compared to *Salmonella* and negative control. This study suggests that *C. jejuni* colonization alters mucin dynamics and gut architecture in broiler chickens reared in isolation units.

Key Words: *Campylobacter*, Isolator, Mucin

T28 Dietary soybean oil adjust protein and mineral metabolism and antioxidant enzyme activity in male broiler chicks during inflammatory response. T. S. Koh*, C. R. Choi, M. J. Chang, K. C. Lee, and S. Y. Kim, *Konkuk University*, *Seoul, South Korea*.

In order to study an effect of dietary soybean oil on protein metabolism during inflammatory response, two experiments were conducted in male broiler chicks. In experiment 1, Dietary soybean oil decreased urinary nitrogen (UN) in excreta, and improved BV (protein retention/AN) of protein and ash retention, but did not altered digestibility of protein. In experiment 2, compared with birds fed basal diet, in broiler chicks activated inflammatory response, soybean oil 5.0% diet increased daily gain, and feed efficiency, dietary protein utilization (NB/NI; BV:NB/absosbed N) ($p<0.05$), activity($p<0.05$) of CuZnSOD or MnSOD in erythrocyte cytosol, and activity of ceuloplasmin in liver cytosol and plasma. Also soybean oil 5.0% diet decreased fecal nitrogen (FN/NI) and urinary nitrogen (UN/NI) in excreta ($p<0.05$) but did not affect dietary calcium or phosphorus balances. Compared with control birds, in birds fed soybean oil 5.0% diet, the inflammatory response did not affect daily gain and feed efficiency, the excretion of FN/NI or UN/NI, NB/NI and BV of dietary protein, calcium or phosphorus balances, and CuZnSOD activity in liver cytosol, but reduced the feed consumption and significantly the MnSOD activity in liver cytosol, and increased significantly the CuZnSOD or MnSOD activity in erythrocyte cytosol and tended to enhance the ceruloplasmin activity in plasma but in liver cytosol. These results indicated that the improvement (extra calorific effect) of assayed ME value in soybean oil was partly due to decreased heat increment by enhanced lipid retention and biological value of dietary protein and ash retention. And the alleviatin of inflammatrory response in broiler chicks fed dietary soybean oil is interacted with decreased protein decomposition and changed activities of superoxide dismutase and ceruloplasmin

Key Words: Inflammatory Response, Biological Value of Protein, Antioxidant Enzyme Activity

T29 Prevalence of gastrointestinal parasites in sheep of the Brisas Town, Culiacán, Sinaloa. M. C. Rubio Robles*, S. M. Gaxiola, C. N. Castro, D. J. Zazueta, G. A. Felix, and E. Sanchez, *Universidad Autonama de Sinaloa*, *Culiacan, Sinaloa, Mexico*.

The objective of this work was to determine the prevalence of gastroenteric parasites in ovine of the town the Brisas, municipality of Culiacán, Sinaloa, which counts on a total of 260 animals (163 adults and 97 young); the sampling was representative in each explotaction, considering itself the young and adults without determining the race and cradle in the technique of sampling of population described by Thrusfield (1995), that is next: Where: n: sample size, t: value of the normal distribution (t of Student) for a level of confidence of 95% (t it is 1.96), L: accepted error or precision (5%), SD: "waited for

Prevalence of disease (%). On the basis of the mentioned technique the total number of samples animals was of 59; of each ovine were collected feces of the rectum of the animal directly, using plastic bags previously identified. The samples was transported under refrigeration to 4º C and it was sent to the Parasitology laboratory of the FMVZ-UAS, where process by the sedimentation technique; being the 100% from the positive samples to gastroenteric parasites with a prevalence of 94.9% (56 ovines) to some of the following parasites: 78.8% (46) positives to Eimeria spp., 35.6% (21) to Moniezia spp., 11.9% (7) Strongyloides spp. 8.5 % (5)Haemonchus spp., 6.8 % (4) to Buxtonella spp and 3.4% (2) to Trichuris spp. it is concluded that exists high prevalence of gastroenteric parasites in ovines in the town of Brisas, municipality of Culiacán, in the state of Sinaloa. Reason why is advisable to make studies in which determines the parasitic quantity as well as its effects in the ovine production.

Key Words: Parasites, Ovines, Prevalence

T30 Presence of *Mycoplasma sp.* in lambs with lung lesions. J. A. Daniel*[1], J. E. Held[2], and L. Holler[2], [1]*Berry College*, *Mount Berry, GA*, [2]*South Dakota State University*, *Brookings*.

Previous research in cattle and sheep has indicated that lung lesions result in decreased animal growth, and lung lesions in sheep are often associated with *Mannheimia haemolytica* and *Pasteurella multocida* infection in the lungs. The purpose of this research was to identify other bacterial agents associated with lung lesions. White-faced, Polypay-sired, February born wether lambs from the South Dakota State University (SDSU) Sheep Unit were utilized for this study (n = 76). After weaning, lambs were fed a high concentrate finishing diet *ad libitum* in the same barn with natural ventilation. Lambs were transported to a commercial packing plant in two groups for harvest. The first group was harvested when a minimum of 30 lambs were estimated to have a hot carcass weight over 27.2 kg, and the second group was harvested when 66% of the remaining lambs were estimated to have a hot carcass weight over 27.2 kg. Lungs were collected at slaughter, and transported on ice to the SDSU Animal Disease Research and Diagnostic Laboratory. Lungs were classified as having normal (<5 % consolidation of any lobe; n = 13), moderate lesions (5-50% consolidation of any lobe; n = 8) or severe lesions (>50% consolidation of any lobe; n = 61). A portion of the right cranial lobe of each lung was collected. Samples of lungs were cultured aerobically and for *Mycoplasma sp.* As observed previously, culture analysis confirmed the presence of *M. haemolytica* and *P. multocida*. Additionally, *Mycoplasma sp.* were detected. Data were tested for effect of lung lesion prevalence or severity on the detection of *Mycoplasma sp.* by Chi square analysis. *Mycoplasma sp.* was cultured from a greater percentage of lungs with lesions than normal lungs (51% vs. 15% respectively, $P = 0.04$). However, the severity of the lung lesions did not affect the percentage of lungs which had positive cultures for *Mycoplasma sp.* (38% vs. 53% for moderate vs. severe lung lesions, $P = 0.42$). These results indicate *Mycoplasma sp.* may play a role in the formation of lung lesions.

Key Words: Lambs, Lung lesion, *Mycoplasma sp.*

T31 Effects of herbal and chemical deworming agents on internal parasite control comparing fecal egg counts, hematocrits and FAMACHA(R) on sheep and goats. H. Swartz*[1], A. Stewart[1], F. Wulff[1], D. Sommerer[1], and M. Ellersieck[1,2], [1]*Lincoln University*, *Jefferson City, MO*, [2]*University of Missouri*, *Columbia*.

An herbal dewormer was compared with the commercial Ivomec dewormer in two groups of sheep and a group of Boer/cross goats plus a control group in 2006. Katahdin hair sheep, Dorset wool sheep and Boer/cross goats (n=36) were fed herbs consisting of 40.5% wormwood (Artemisia sp.), fennel (Foeniculum vulgare), gentian (Gentian sp.), psyllium (Plantaga sp.) and quassia (Quassia sp). All treatment groups were dewormed with Cydectin at the beginning of the project. Herbs were fed to the three breeds once a week in a corn based ration from June through October. Ivomec was drenched every 30 days from July through October to both the Katahdin and Dorset sheep at the rate of 3 ml to 11.8 kg body weight and Boer/cross goats at the rate of 4.5 to 11.8 kg body weight. The control group received no treatment. Fecal eggs counts (FEC) were collected at the beginning of the project in all three treatment groups, hematocrits and FAMACHA® were scored at the same time throughout the project. Results of breed differences in FEC, hematocrits and FAMACHA® statistically reported ($P<.0001$), lowest count in the Katahdin and highest in the Dorset, over time ($P<.0001$) and interactions of breed x time x treatment ($P<.0001$). The FEC peaked in July, hematocrits and FAMACHA® readings lowered showing the Hoemonchus contortus barberpole blood sucking stomach worm a hot weather worm. Seasonal differences were also observed in the hematocrits and FAMACHA® results in breed, time and treatment in the trial. The results of this study suggest that herbs are effective in controlling internal parasites in Katahdin sheep and Boer goats throughout the hot summer months.

Key Words: Herbs, FAMACHA®, Deworming

T32 Indirect contact: A possible dissemination route of Caprine arthritis encephalitis among goat kids. A. Asmare*[1,2], K. E. Washburn[3], J. T. Saliki[4], A. L. Goetsch[1], L. J. Dawson[5], R. C. Merkel[1], and T. Sahlu[1], [1]*E (Kika) de la Garza American Institute for Goat Research, Langston University*, *Langston, OK*, [2]*Alemaya University*, *Dire Dawa, Ethiopia*, [3]*Texas A&M University*, *College Station*, [4]*Oklahoma Animal Disease and Diagnostic Laboratory*, *Stillwater, OK*, [5]*Oklahoma State University*, *Stillwater*.

Twenty Alpine goat kids were randomly assigned to four groups of five animals. Kids were removed from their dams at birth and penned individually. Kids in all groups were fed colostrum during the first 48 h after birth. Group 1 was fed Caprine arthritis encephalitis virus (CAEV) free colostrum, Group 2 received CAEV positive colostrum, Group 3 consumed CAEV positive colostrum subjected to conventional heat treatment, and Group 4 was given CAEV positive colostrum treated with methylene blue and fluorescent light. Thereafter, all kids were fed pasteurized goat milk until weaning. No CAEV specific antibodies were detected in serum of any kids collected prior to colostrum consumption. Despite efforts to aviod vertical transmission of the virus among kids , three goat kids of Group 1 showed seroconversion at the age of 48 h and the remaining two kids displayed seroconversion at 2 months of age. All animals in Groups 2, 3, and 4 had seroconvertion at the age of 48 h. Presence of CAEV was confirmed in 17 kids (85%) by polymerase chain reaction at the age of 1.5 months. The early appearance of CAEV specific antibodies was

probably caused by consumption of antibody containing colostrum and maintenance of maternal antibodies. Results of this study suggest that factors other than direct contact of kids with their dams i.e. ingestion of infected colostrum and milk could be means of CAEV transmission. Therefore, the risk of indirect contact in the dissemination of CAEV should be taken into account in control and eradication programs.

Key Words: Caprine Arthritis Encepahlitis Virus, Goats, Colostrum

T33 Identification of Cydectin targets in *C. elegans*. M. Worku*, O. Alexander, and P. Matterson, *North Carolina Agricultural and Technical State University*, *Greensboro*.

Model systems such as the free living nematode *Caenorhabditis elegans* (*C. elegans*) are being used to identify drug targets. With the availability of the genome sequence it can be used to study the function and expression of drug target genes on a global scale. Macrocyclic lactones are chemical compounds that represent the main treatment for parasitic diseases of animals. The objective of this study was to evaluate the effect of cydectin on global gene expression in *C. elegans* to identify drug targets that may contribute to the development of anit-helminthic resistance. Nematodes were grown and exposed to 7 ml of a sub-lethal dose of Cydectin (Quest®Gel), (0.016 mg/ml in sterile water) and washed in PBS. Controls were exposed to PBS. RNA was isolated using RNeasy (Qiagen) kits. RNA integrity and size distribution was checked on a bioanalyzer. Total *C. elegans* array chips (Washington State University) were used for expression profiling. A dye swap system was used (N= 6 slides). Data acquired using Jaguar analysis software was analyzed using Magic tool. Differential gene expression was observed. Twenty up or down regulated genes/array slide (200 total) were selected. Four fold differences were used to select genes common to five slides used. Exposure to Cydectin resulted in increased transcription, (3.06 ug in controls, 4.89 ug treated). In addition to genes with unknown function we have identified two genes that may be the site of action of cydectin, PtP3 and unc-11. Unc-11 is a highly conserved gene that functions to regulate the neuronal network that controls the pharynx. PtP3 is a phosphatase which may be important in post transcriptional modification. Further studies are needed to define the pathways of action. Characterization of these genes may contribute to the understanding of the molecular basis for drug resistance and genetic diversity of nematodes.

Key Words: *C. elegans*, Nematode, Drug Target

T34 Composition of amino acids in typical Chinese herbs is not unique among feeds of plant origin. X. Wu*[1], X. F. Kong[1], Y. L. Yin[1], F. G. Yin[1], P. Zhang[1], H. J. Liu[1], F. F. Xing[1], Q. H. He[1], T. J. Li[1], R. L. Huang[1], and G. Y. Wu[1,2], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences*, *Changsha, Hunan, China*, [2]*Texas A&M University*, *College Station*.

As an initial step to define the mechanisms responsible for the beneficial effects of typical Chinese herbs on health and growth performance of swine and poultry, we determined concentrations of CP and amino acids in *Astragalus membranaceus, Acanthopanax senticosus, Salvia miltiorrhiza bunge, Crataegus pinnatifida Bge, and Salvia miltiorrhiza Bge*. Ten representative samples for each herb were hydrolyzed in 6 N HCl under nitrogen at 110°C for 24 h and the resultant amino acids were determined using an automatic amino acid analyzer. Results are expressed on the DM basis. Concentrations of CP in these five Chinese herbals were 14.1%, 13.9%, 3.06%, 2.06%, and 6.28%, respectively. Concentrations of total amino acids in *Astragalus membranaceus, Acanthopanax senticosus, Salvia miltiorrhiza bunge, Crataegus pinnatifida Bge, and Salvia miltiorrhiza Bge* were 10.6%, 2.84%, 3.43%, 3.99%, and 7.02%, respectively. Concentrations of Arg, Lys, Glu+Gln, branched-chain amino acids, and Asp+Asn in *Astragalus membranaceus* were 0.64%, 1.08%, 1.37%, 1.49%, and 1.64%, respectively. Concentrations of Arg, Lys, Glu+Gln, branched-chain amino acids, and Asp+Asn in *Salvia miltiorrhiza Bge* were 0.77%, 0.36%, 1.05%, 1.10%, and 0.64%, respectively. The composition of amino acids in the Chinese herbs is largely similar to that in feeds of plant origin. These results indicate that typical Chinese herbs are not unique in the composition of protein-precursor amino acids among plants. Other components in the herbs are likely major active components that beneficially regulate intestinal barrier integrity, nutrient metabolism, immune function, health, and growth in animals. (Supported by NSFC and CAS)

Key Words: Chinese Herbs, Amino Acids, Nutritive Value

Beef Species

T35 Effects of season and bull breed of semen on pregnancy rate in beef cattle. K. Kreausukon[1], S. Teepatimakorn[2], P. Vinitchaikul*[1], P. Yamsakul[1], and W. Suriyasathaporn[1], [1]*Chiang Mai University*, *Muang, Chiang Mai, Thailand*, [2]*Chiangmai Artificial Insemination Research and Biotechnology Center*, *Muang, Chiang Mai, Thailand*.

The objectives of this study were to identify the factors associated with conception risk in beef cattle. Data of artificial insemination of beef cows during September 2003 to October 2004 recorded by AI center were used. The data included bull breed of semen, date of artificial insemination, and results of pregnancy check. Season included winter (Nov-Feb), summer (Mar-May), and rainy (Jun-Oct). Bull breed of semen included Charolais (CHA) and American Brahman (AB). The generalized estimating equation (GEE) was used to analyze the effect of season and bull breed of semen on pregnancy rate. The final data included 2,823 observations. Overall pregnancy rate was 79.14%. The pregnancy rates for winter, summer, and rainy seasons were 82.5, 83.2, and 74.4%, respectively, and the rates for CHA and AB were 78.5 and 83.1%, respectively. Results from GEE showed that both factors were associated with pregnancy rate ($P<0.05$). In comparison to rainy season, beef cattle inseminated during winter and summer seasons had higher conception risks (OR = 1.63 and 1.71, respectively). Beef cattle inseminated with semen from American Brahman bull had lower pregnancy risk than the semen from Charolais bull (OR=0.74). In Thailand, the high temperature with high humidity might cause more heat stress in cattle. In conclusion, pregnancy risks in beef cattle are associated with season and bull breed of semen.

Key Words: Season, Beef, Conception

T36 TG-repeat microsatellites of growth hormone receptor and their associations with growth performances in Angus Plus calves raised on subtropical pasture. J. Yang*[1], J. Lee[1], R. Ferreira[2], M. DuPonte[1], and G. Fukumoto[1], [1]*University of Hawaii*, *Honolulu*, [2]*Olumau Angus Plus LLC*, *Lihue, HI*.

Growth hormone receptor (GHR) plays a significant role in animal growth through mediating the actions of growth hormone on the target cells. A polymorphic microsatellite (TG)n, located 90 base pairs upstream of the GHR gene, has been associated with growth performances in beef cattle. The 16-20 TG-repeat, named long allele (L), are mostly presented in Bos taurus breeds while the 11 TG short allele (S) is common in Bos indicus cattle. Angus Plus cattle are bred by maintaining a minimum o 4% Brahman in the Angus or Brangus breed. To investigate allele distributions of the microsatellite and their applications to growth trait selection, we genotyped the GHR microsatellites by PCR amplification and DNA fragment analysis, and compared growth performances between different genotypes of the GHR microsatellite. Calves were raised on 100% improved pastures of Pangola Rhodes and Guinea throughout the year in Kauai Island. Data for birth weight (BWT), 205-adjusted pre-weaning weight (PWT) and average daily gain (PWADG), hip height at birth and weaning (HHB and HHW) were obtained. Data were analyzed by MIXED procedure of SAS and all means were generated from LSMEAN. The frequency of long and short allele was 80.2% and 19.8% in the herd (N=96), respectively. Calves with LL, SS and SL genotype had BWT of 35.52±0.97, 34.21±0.91, 31.02±2.00 kg, respectively; the mean of analyzed growth traits of SL genotype is between SS and LL genotypes. No significant associations (P>0.1) of the GHR genotypes with growth traits (BWT, PWT, PWAGT, 68-d post-weaning ADG, HHB, HHW) were observed in the calves (n=42) born in 2004. Based on a limited number of the animals, the results demonstrate a moderate frequency of short GHR allele in the current Angus Plus herd. The application of this GHR microsatellite genotyping to selection of growth traits needs to be further validated with a large number of animals.

Key Words: Angus Plus Cattle, Growth Hormone Receptor, DNA Polymorphism

T37 Influence of dietary roughage source on growth performance and carcass characteristics of Korean native cattle (Hanwoo). S. O. Lee[1], K. K. Jung[1], C. B. Choi[1], and I. S. Jang*[2], [1]*Yeungnam University*, *Daegu, Korea*, [2]*Jinju National University*, *Jinju, Korea*.

Korean native beef cattle (Hanwoo) destined for production of high-quality grade beef must be castrated, and fed for a long time to achieve highly-marbled beef deserving of premium prices. The objective of this study was to determine whether dietary roughage source during the growing and fattening periods would affect growth performance and characteristics of carcass in Hanwoo cattle. Traditionally, the entire feeding period (2 yr) is divided into the growing (6 to 13 month), fattening (14 to 22 month) and finishing phases (23 to 30 month). A total of 35 Hanwoo, half-sib calves (initial BW 163±11.0 kg, housed in 7 pens of 5 calves/pen) were allotted to one of two dietary roughage sources (Control vs.Treatment). Steers in the treatment group were fed timothy hay as the only source of roughage, while control steers received a combination of timothy and alfalfa hay, and rice straw during the growing (up to 4.0kg/head/day) and fattening (down to 1.5kg/head/day) periods. Dietary source of roughage did not affect ($P > 0.05$) growing performance (ADG and BW) or feed efficiency in during the growing, fattening or the entire feeding period. Feeding timothy hay as the only roughage source resulted in 15% increased profit ($P < 0.05$) compared with the control. Back fat thickness($P = 0.28$), longissimus area (P=0.13), and yield grade (P=0.36) in carcasses from steers in the treatment group tended to be improved by 10%, 6.6% and 6.9%, respectively. However, marbling score and quality grade were similar in the two groups. The physico-chemical characteristics of carcasses including moisture, CP and drip loss were unaffected ($P > 0.05$) by dietary roughage source. In conclusion, feeding timothy hay was beneficial for the production of Hanwoo steers due to greater yield grade and improved profit, although growth performance and carcass quality were unaffected by roughage source.

Key Words: Hanwoo Beef Cattle, Dietary Roughage Source, Carcass Quality

T38 Predicting beef carcass retail products of Mediterranean buffaloes by real-time ultrasound measures. A. M. Jorge*, C. Andrighetto, C. L. Francisco, A. P. Neto, and R. C. Mourão, *Sao Paulo State University*, *Botucatu, SP, Brazil*.

Twenty eight Mediterranean buffaloes bulls were scanned with real-time ultrasound (RTU), slaughtered, and fabricated into retail cuts to determine the potential for ultrasound measures to predict carcass retail yield. Ultrasound measures of fat thickness, ribeye area and rump fat thickness were recorded three to five days prior to slaughter. Carcass measurements were taken, and one side of each carcass was fabricated into retail cuts. Stepwise regression analysis was used to compare possible models for prediction of either kilograms or percent retail product from carcass mesaurements and ultrasound measures. Results indicate that possible prediction models for percent or kilograms of retail products using RTU measures were similar in their predictive power and accuracy when compared to models derived from carcass measurements. Both fat thickness and ribeye area were over-predicted when measured ultrasonically compared to measurements taken on the carcass in the cooler. The mean absolute differences for both traits are larger than the mean differences, indicating that some images were interpreted to be larger and some smaller than actual carcass measurements. Ultrasound measurements of REA and FT had positive correlations with carcass measures of the same traits (r=.96 for REA and r=.99 for FT). Standard errors of prediction currently are being used as the standard to certify ultrasound technicians for accuracy. Regression equations using live weight (LW), rib eye area (REAU) and subcutaneous fat thickness (FTU) between 12th and 13 th ribs and also over the biceps femoris muscle (FTP8U) by ultrasound explained 95% of the variation in the hot carcass weight when measure immediately before slaughter.

Key Words: Ribeye Area, Rump Dat, Backfat Thickness

T39 Correlations among carcass traits taken by ultrasound and after slaughter in Mediterranean (Bubalus bubalis) buffaloes. A. M. Jorge*, C. Andrighetto, R. S. B. Pinheiro, C. L. Francisco, and A. P. Neto, *Sao Paulo State University*, *Botucatu, SP, Brazil*.

The objective of this work was to estimate the correlations among measurements taken in vivo with ultrasound equipment with some

carcass traits measured after slaughter. Twenty eight Mediterranean bulls, with average shrunk body weight of 330 kg and 14 months of age, were fed high concentrate diets for 120 d. Shrunk body weight, ribeye area (REAU), fat thickness (FTU) over the Longissimus dorsi muscle between 12th and 13th ribs, and rump fat (EGP8U) were measured at 28-d intervals. A Piemedical Scanner 200 VET real time ultrasound scanner, with 18 cm linear array transducer, was utilized. After slaughter, hot carcass weight (PCQ) and kidney, pelvic and inguinal fat (GRPI) were weighed and dressing percentage (DP) calculated. After 24 hours of cooling, ribeye area (REAC), fat thickness (FTC) and rump fat (EGP8C) were measured. The REAC, FTC and EGP8C were underestimated by ultrasound measurements. The Pearson correlation coefficients for ribeye area, backfat thickness and rump fat measured in the carcass with ultrasound measurements were 0.96, 0.99 and 0.91, respectively. The correlation between DP and REAU was 0.47; 0.45 between DP and REAC, 0.56 between DP and FTU and 0.58 between DP and FTC. Dressing percentage had a correlation of 0.59 with EGP8U. Spearman correlations estimated between REAU and REAC, FTU and FTC, EGP8U and EGP8C, were 0.96, 0.99 and 0.91, respectively. Ultrasound measures could be used to estimate carcass traits in buffaloes with acceptable accuracy.

Key Words: Ribeye Area, Rump Fat, Backfat Thickness

T40 Influence of shade in pen on performance of feedlot calves received during the autumn in the Northwest of Mexico. R. Barajas*[1], B. J. Cervantes[2,1], E. A. Velazquez[1], F. Juarez[1], and J. A. Romo[1], [1]*FMVZ-Universidad Autonoma de Sinaloa*, *Culiacan, Sinaloa, Mexico*, [2]*Ganadera Los Migueles SA de CV*, *Culiacan, Sinaloa, Mexico*.

Sixty Brahman cross bull calves (BW = 244 kg) were used in a 28-d feedlot experiment to determine the influence of shade on performance during the autumn in Northwest Mexico (24° 50′ N-latitude and 107° 26′ W-longitude). Calves were blocked by weight and placed in each of six dirt-surfaced shaded pens (5 hd/pen) providing 3.4 m^2 of shade/head or in six unshaded pens. Calves were fed ad libitum a 20% CP receiving diet containing (DM basis) 44% corn silage, 17% corn straw, 10% ground corn, 22% soybean meal, 3% meat and bone meal, 3% mineral premix, and 1% buffer premix twice daily. Calves were weighed on days 1, 14 and 28. Air temperature, soil temperature and relative humidity were recorded daily at 1400 h. Shade decreased (P = 0.08) air (32.3 vs. 31.4°C) and soil (P < 0.01) temperature (33.9 vs. 31.6°C). Relative humidity was not affected (P = 0.18) by shade (38.13 vs. 41.85%), and THI was similar (P = 0.60) between treatments (79.03 vs. 78.66). Over the 28-d experiment, use of shade increased (P = 0.05) ending weight (280.8 vs. 285.8 kg) 1.9% and (P = 0.06) average daily gain (1.30 vs. 1.47 kg/d) 12%. Dry matter intake measured both as daily intake or percentage of body weight was not altered (P > 0.13) by shade. Feed/gain ratio was similar (P = 0.14) in both treatments. A 30% of compensatory growth estimated as observed/expected NEm ratio was shown by calves during the complete 28 d trial, mostly due to 65% impetus displayed during the first 14 d, the remainder time (d 15 - 28) observed/expected NEm ratio was 0.98. These results suggest that shade in feedlot pen contributes to enhance performance of calves during their first two weeks in the feedlot.

Key Words: Feedlot, Bulls, Shade

T41 Effect of weaning and post-weaning management of beef steers on carcass characteristics and tenderness. A. E. Radunz*, H. N. Zerby, J. F. Grimes, G. D. Lowe, and F. L. Fluharty, *The Ohio State Univeristy*, *Columbus*.

To evaluate effect of weaning and post-weaning management on carcass characteristics and tenderness, 104 steers from a closed Angus herd, born over a four year period, were assigned to one of three weaning management systems based upon chronological birth order. The management systems were 1) early weaned (EW) at 100 days of age (DOA); 2) normal weaned (NW) at 200 DOA; 3) yearlings (YR) weaned at 200 days of age and fed a forage-based diet until 400 DOA. Steers were fed a finishing diet starting a 100, 200, and 400 DOA for EW, NW, and YR, respectively. The finishing diet contained 65% whole corn, 15% timothy hay, 12 % soybean meal, and 8% vitamin/mineral supplement and was formulated to contain 14.6% CP, 2.019 NE_m, and 1.371 NE_g. Cattle were harvested at 395, 415, and 540 ± 5.0 DOA for EW, NW and YR, respectively. Two steaks were removed from 12th rib location, aged for 72 h and 14 d, and used to determine Warner-Bratzler shear force (WBS). Data were analyzed using the MIXED model of SAS with year as a random variable and mean separation by LSD ($P = 0.05$). Yearling steers had greater ($P < 0.05$) hot carcass weights compared to EW and NW steers (344.0, 329.5 and 328.8 ± 3.6 kg, respectively). Weaning and post-weaning management had no affect on ribeye area; however, carcasses from YR had less ($P < 0.05$) 12th rib fat than from EW and NW steers (1.18, 1.63 and 1.52 ± 0.07 cm, respectively), which resulted in lower ($P < 0.05$) USDA yield grade (3.25, 3.61 and 3.60 ± 0.11, respectively). Conversely, carcasses from EW and NW steers had greater ($P < 0.05$) marbling scores than from YR (582.0, 558.7, and 494.1 ± 26.66, respectively). Steaks from YR steers' carcasses had greater ($P < 0.05$) WBS than from EW and NW at both 72 h (5.56, 3.94, and 2.73 ± 0.22 kg, respectively) and 14 d (4.12, 3.88 and 2.85 ± 0.29 kg, respectively). Weaning age and post-weaning management systems in which steers are harvested at an older age can result in heavier carcass weights, less backfat, lower quality grades and tougher steaks.

Key Words: Beef, Weaning Manangement, Meat Quality

T42 Effect of Wagyu- versus Angus-sired calves on feedlot performance, carcass characteristics, and tenderness. A. E. Radunz*, H. N. Zerby, S. C. Loerch, G. D. Lowe, and F. L. Fluharty, *The Ohio State Univeristy*, *Columbus*.

Thirty-nine Wagyu-sired (n = 21; WAG) and Angus-sired (n = 19; ANG) steers and heifers were used to compare the effects of sire breed on feedlot performance, carcass characteristics and meat tenderness. Calves were weaned at 138 ± 15.7 d of age and individually fed a finishing diet consisting of 65% whole corn, 20% protein/vitamin/mineral supplement, and 15% corn silage on a dry matter basis. Heifers and steers were harvested at 535 and 560 kg, respectively. Carcasses were ribbed between the 12th and 13th (USDA grading system) and the 5th and 6th ribs (Japanese grading system) to measure fat thickness, longissimus muscle area (LMA), and intramuscular fat (IMF). Two steaks were removed from the 12th rib location and aged for 72 h and 14 d to determine Warner-Bratzler shear force (WBS) and cooking loss. Data were analyzed using the MIXED procedure of SAS. Breed of sire by gender interactions were not significant ($P > 0.05$). Angus-sired calves had greater ($P < 0.05$) ADG and DMI and improved ($P < 0.05$) G:F than WAG. Breed of sire

did not affect hot carcass weight, 12th rib fat, USDA yield grade, or percentage boneless closely trimmed retail cuts ($P < 0.05$). Carcasses of WAG had greater ($P < 0.001$) marbling scores at the 12th rib than those of ANG (770.9 vs 597.3 ± 41.01, respectively). Carcasses of WAG also had greater ($P < 0.05$) 12th rib IMF (12.91 vs 10.54 ± 1.00 %), and 5th rib IMF (15.15 vs 11.90 ± 0.956%) than ANG. Carcasses from WAG tended ($P < 0.07$) to have greater LMA at 12th rib, while ANG carcasses had greater ($P < 0.05$) LMA at 5th rib. Sire breed did not affect ($P < 0.05$) tenderness following aging for either 72 h or 14 d. Cooking loss was greater ($P < 0.05$) for ANG than WAG steaks at 72 h and 14 d. Angus-sired calves had greater feedlot performance; however, the resulting carcasses of Wagyu-sired calves had greater marbling with no difference in percentage of retail product and tenderness at a similar harvest weight.

Key Words: Angus, Wagyu, Meat Quality

T43 Impact of using proven genetics in an AI program. D. J. Schafer*[1], J. K. Haden[1], S. R. Bartholomew[1], M. T. Griffin[1], M. E. John[1], J. L. Parcell[2], and D. J. Patterson[2], [1]*MFA Inc.*, *Columbia, MO*, [2]*University of Missouri*, *Columbia*.

This experiment evaluated the economic impact of using proven genetics in an AI program. Steers (n = 328) representing 4 sire groups from 4 locations were vaccinated, fed standardized nutrition and weaned for a minimum of 45 d before placement in the same feedlot. Steers were the result of AI and natural service (NS) matings. Sires of these steers were categorized on the basis of EPD accuracies: High Accuracy AI (HA); Low Accuracy AI (LA); Calving Ease AI (CE); or NS. HA sires were bulls with EPD accuracies ≥ 0.85 for BW, WW, and YW. Steers were assigned to pens within sire groups by weight, and received the same ration throughout the duration of the trial. Individual carcass measurements were collected for all steers at harvest, which was performed at the same commercial packing facility. Steers were determined to be finished based on ultrasound measurements and fat deposition patterns. Feeder calf value was determined using the Kansas State University price slide equation based on the 3 yr average of fed cattle and corn futures. Carcass value was determined using a 3 yr average of USDA reported values to establish fixed values for base price, premiums, and discounts to eliminate any market seasonality. Although all sire groups were harvested at the same yield grade (P = 0.18), steers sired by HA sires finished relative to all other sire groups at a younger age (P < 0.0001; HA, 408 d; LA, 430 d; CE, 443 d; NS, 416 d) with better average quality grades (P < 0.0001; HA, Choice +; LA, Choice -; CE, Choice; NS, Choice -). Steers sired by HA sires also finished with more (P < 0.0001) net return than the other sire groups (LA, $50.69; CE, $53.83, NS, $89.66). The estimated lifetime value of the HA sired replacement females compared to the NS sired replacement females ranged from $248.43 (4 yr expected productive life) to $416.40 (7 yr expected productive life). Artificial insemination to sires with high accuracy EPDs provides the opportunity to increase profitability and marketability of both terminal and replacement female calf crops. Furthermore, AI to HA sires offers the greatest probability of making improvements in the traits to which selection pressure is applied.

Key Words: AI, EPD, Economics

T44 Performance and carcass characteristics of straightbred and crossbred Bonsmara and Tabapua steers at the same carcass weight. E. L. A. Ribeiro*, I. Y. Mizubuti, L. D. F. Silva, M. A. Rocha, and S. M. Climaco, *Universidade Estadual de Londrina*, *Londrina, Brazil*.

This experiment was carried out to evaluate the performance of steers of four genetic groups: 1) Bonsmara (B), 2) ½ Bonsmara - ½ Nelore (B1), 3) ½ Bonsmara - ¼ Red Angus - ¼ Nelore (B2), and 4) Tabapua (T). Twenty animals, 22 mo of age at the initiation of the study, were maintained under the same conditions in a feedlot, in the state of Parana, Brazil. The five steers of each genetic group were collectively fed. They were slaughtered, on average, after 112 d in feedlot. Traits were evaluated on a final carcass weight (260 kg) basis. Initial weight was also used as covariate in the statistical analyses. Tabapua steers were lightest (P<0.05) at slaughter, had the lowest (P<0.05) average daily gain (ADG), but the greatest (P<0.05) dressing percentage (55.2%). Averages for live weight at slaughter and ADG were: 493, 490, 506 and 471 kg, and 1.035, 0.952, 1.122 and 0.630 kg, respectively, for B, B1, B2 and T. Tabapua steers needed 43 more days (P<0.05) to achieve the same carcass weight than Bonsmara steers. Bonsmara steers had the largest (P<0.05) ribeye area (82.9 cm^2) and percentage of muscle (68.2%) in the carcass, and the lowest percentage of fat (17.1%). Averages for subcutaneous fat thickness were 3.7, 8.8, 7.0 and 4.5 mm (P<0.05), respectively, for B, B1, B2 and T. Percentages of carcass cuts (sawcut, forequarter and sidecut) were similar (P>0.05) among the genetic groups. Meat tenderness measured by a texturometer fitted with a Warner-Bratzler shear attachment were 4.9, 5.6, 4.9 and 7.3 kgf (P<0.05), respectively, for B, B1, B2 and T. Straightbred and crossbred Bonsmara steers had similar performance, on the other hand the zebu (Tabapua) steers produced less tender meat.

T45 Efficacy of rumen temperature boluses for health monitoring. T. K. Dye*, C. J. Richards, L. O. Burciaga-Robles, C. R. Krehbiel, and D. L. Step, *Oklahoma State University*, *Stillwater*.

Remote rumen temperature monitoring is a potential method for early disease detection in beef cattle. The objective of this experiment was to determine the efficacy of disease detection using remote monitoring rumen temperature boluses (SmartStock, LLC) in steers challenged with Bovine Respiratory Disease pathogen (*Mannheimia haemolytica*) following exposure to Bovine Viral Diarrhea (BVD). Twenty-four Angus crossbred steers (initial BW=305 ± 20 kg) were allotted to 4 treatments: 1) no challenge (Control); 2) challenge with *M. haemolytica* (MH); 3) 72 h exposure to persistently infected BVD steers (BVD); and 4) 72 h BVD exposure and challenged with *M. haemolytica* (BVD+MH). Remote monitoring rumen temperature boluses programmed to transmit temperature every minute were placed in the rumen prior to the time of exposure to persistently infected BVD steers. Rectal temperatures were taken prior to MH challenge (0) and 2, 4, 6, 12, 18, 24, 36, 48, 72 and 96 h post challenge. Rumen temperatures were recorded for 14 d post MH challenge. Rumen temperatures were analyzed using repeated measures analysis using a first-order autoregressive covariance structure. Average daily rumen temperature resulted in a treatment x day interaction (P < 0.01). Steers challenged with MH had increased rumen temperatures on d 1 and 2 post MH challenge, whereas steers exposed to BVD had increased rumen temperatures on d 6 and 7. Post MH challenge, hourly rumen temperature peaked

at approximately 8 h for MH and 112 and 136 h for BVD. Maximum rumen temperature was increased ($P < 0.02$) for the MH (1.32°C), BVD (0.54°C) and BVD+MH (1.44°C) steers. On average, rumen temperature measured by the boluses at the same time points as the rectal temperatures were 0.19°C lower than rectal temperatures with a R^2 of 0.78. Rumen temperature boluses appear to have potential as a tool for detecting responses to adverse health events such as exposure to BRD and BVD.

Key Words: Rumen Bolus, Temperature Monitoring, Health Monitoring

T46 Relationships between MUFA ratio of marbling flecks and image analysis traits in *M.longissimus* muscle for Japanese Black cattle. Y. Nakahashi*[1], M. Oishi[1], Y. Hamasaki[1], S. Hidaka[1], S. Maruyama[2], and K. Kuchida[1], [1]*Obihiro University of Agricalture and Veterinary Medicine*, *Obihiro, Japan*, [2]*Gifu Prefectual Livestock Reseach Institute*, *Gifu, Japan*.

It is known that monounsaturated fatty acid (MUFA) ratios to total fatty acid are different among inter- and intra-muscular and subcutaneous fat even for the same animal. But there are few reports for the variation of the MUFA ratio by geometric change of marbling. Our objective was to investigate the variation of the MUFA ratio by the geometric and sectional change of marbling in rib eye. *M.longissimus* muscle of 8 Japanese Black steers from a common sire and a common maternal grand sire were used. Three slices (one was from rib roast and the others were from sirloin) were used for each animal. For each slice, 5 marbling flecks were randomly sampled to obtain the MUFA ratio by gas chromatography. High quality digital images of all slices were taken by a mirror type camera for carcass cross section. The area and coordinates of each marbling fleck were calculated by image analysis. The marbling flecks were categorized by area (S:<0.4 cm^2, M:0.4~2cm^2, L:>2cm^2), coordinate (dorsal, ventral), and slice section (rib roast, cranial and caudal sirloin). ANOVA was performed using SAS software. The MUFA ratio was treated as a dependent variable, and the classification of the area, coordinate and slice section were treated as fixed effects. The fixed effects were significant for the MUFA ratio ($P<0.05$). Least square means of S, M and L for the area of marbling flecks were 56.8%, 58.4% and 60.2%, respectively. Those of dorsal, ventral, rib roast, cranial and caudal sirloin were 59.1%, 57.8%, 55.4%, 59.9%, and 60.1%, respectively. Large marbling flecks revealed higher MUFA ratios ($P<0.05$). The MUFA ratio of the marbling flecks located in the rib eye of the dorsal part was higher than in the ventral part ($P<0.05$). Those from sirloin were higher than from rib roast ($P<0.01$). Interaction between slice section and coordinate was significant ($P<0.05$). MUFA ratios of marbling flecks located in the ventral part were higher than those in the rib roast of the dorsal part, but lower in sirloin.

Key Words: Japanese Black, MUFA Ratio, Image Analysis

T47 Effect of Zilpaterol or Ractopamine on productive performance of finishing bullocks. G. Aranda-Osorio*, R. Aguayo-Garcia, A. Carreño-Aviles, and J. C. Garcia-Ortiz, *Universidad Autonoma Chapingo*, *Chapingo, Mexico*.

The objective of this study was to evaluate the effect of adding β-agonists, Zilpaterol or Ractopamine, to the finishing diets of bullocks on: feed intake (DMI), average daily gain (ADG), and feed conversion (FC), under feedlot conditions. This investigation was carried out at the Experimental Farm of the Animal Husbandry Department of the University of Chapingo, Chapingo, Mexico. Thirty-six bullocks of commercial cross (Zebu x Brown Suiss) were used with initial liveweight of 427 ± 60 kg, which were housed in individual pens (2 × 2 m) and randomly allotted to the following treatments: T1, diet A without β-agonists; T2, diet A + zilpaterol; T3, diet A + ractopamine; T4, diet B without β-agonists; T5, diet B + zilpaterol; and T6, diet B + ractopamine; with 5 replicates per treatment. Diet A was elaborated using a true protein source (soybean meal) and the addition of a probiotic (Saccharomyces cerevisiae). In contrast, diet B was elaborated using poultry litter as a main source of protein and without probiotic. Both diets were formulated to meet the requirements of this type of cattle according to the NRC (1996). The experimental period lasted 92 d, and from d-60 to the end, β-agonists were added to the feed into the feedbunks and thoroughly mixed by hand for treatments 2, 3, 5 and 6. Feed was offered twice a day (0800 and 1600 h). Sixty mg of Zilpaterol hd^{-1} d^{-1} were supplemented to treatments 2 and 3; and 400 mg of Ractopamine hd^{-1} d^{-1} were supplemented to treatments 5 and 6, during the morning feeding only. Data were analyzed as completely randomized design using the GLM procedure of SAS. The comparison of Zilpaterol (T2 + T5) vs Ractopamine (T3 + T6) revealed no differences ($P>0.05$) in DMI (9.93 vs 9.59 kg hd^{-1} d^{-1}) or ADG (1.02 vs 1.08 kg hd^{-1} d^{-1}), although a difference ($P<0.05$) was found for FC (10.64 vs 9.29 kg d^{-1}). When β-agonists were added to diets A or B, animal performance tended ($P>0.05$) to improve, with no differences ($P>0.05$) between β-agonists. It is concluded that the β-agonists (Zilpaterol or Ractopamine) hardly represent an alternative to improve animal performance for beef producers using this type of diets and cattle.

Key Words: B-Agonists, Beef Cattle, Animal Performance

T48 Comparison of color value measured by colorimeter and image analysis method for beef muscle. Y. Hamasaki*[1], T. Saito[2], Y. Sato[2], S. Hidaka[1], and K. Kuchida[1], [1]*Obihiro University of A&VM*, *Obihiro, Hokkaido, Japan*, [2]*Hokkaido Animal Research Center*, *Sintoku, Hokkaido, Japan*.

Beef lean color is usually measured with a colorimeter. The marbling area percentage of Japanese Holstein steers is over 20%, so the diameter of the colorimeter (8mm) may be too large to measure the lean color accurately. The objective of this study were to compare the values from the colorimeter and from the high resolution digital image analysis as an accurate measurement of lean color of *M. longissimus thoracis* (ribeye) and to investigate whether the image analysis method is applicable to measure meat color. Digital images of the 6-7th rib cross section from 80 Holsteins were photographed for the beef carcass cross section. The ratio of marbling area to ribeye area (FATPER) was obtained by image analysis. Also, RGB components and luminance for lean, marbling and whole ribeye were calculated by the image analysis method. The L* value of lean was measured using the colorimeter (Minolta CR-13:Φ8mm) during the same time of photographing of the digital images. The L* values were measured 3 times per carcass then averaged. A multiple regression analysis was performed by REG procedure in SAS to predict the L* value by colorimeter. The L* value was used as a dependent variable, and traits obtained by the image

analysis were used as candidates of independent variables. Correlation coefficients between BCS (Beef Color Standard) numbers evaluated by graders and L*, and between BCS and luminance by the image analysis were -0.39 and -0.62, respectively. FATPER of ribeye was classified into 3 levels (S:<19%, M:19%~23% and L:>23%). Correlation coefficients of L* value and luminance of lean were 0.80 for S, 0.50 for M and 0.20 for L. The L* value of lean with a low FATPER level might reflect the accurate lean color. However, the L* value with more marbling meat might not be as accurate as the lean color value. In the multiple regression analysis predicting the L* value by colorimeter, the most affected image analysis traits for S, M and L were the luminance of lean, R component of whole ribeye, and G component of marbling, respectively. The diameter of the colorimeter probe might be oversized for measuring the lean color of beef, marbling included.

Key Words: Beef Color, Image Analysis, Colorimeter

T49 Alternative supplementation strategies for replacement beef heifers grazing dry California foothills annual range during summer. R. B. Monteiro*[1,2], G. D. Cruz[1], D. M. Myers[1], J. W. Oltjen[1], and R. D. Sainz[1], [1]*University of California*, *Davis*, [2]*University of Sao Paulo*, *Piracicaba, SP, Brazil*.

California's annual foothill rangelands are the main forage source for the state's range livestock industry and are characterized by marked seasonal variations in forage availability and quality. Due to the inadequate quality of dry forage during summer and fall, cattle require supplemental feed to balance deficiencies in protein, energy and minerals. The objectives of this study were to evaluate the effects of different types of supplementation for weaned heifer grazed in dry range and analyze the cost-benefit within the treatments. The supplements were: a commercial molasses-based tub supplement (COM; 30% CP) and a low-cost protein/energy/mineral formulation (UCD; 58% CP, 60% TDN, 3% P, 500 mg/kg Cu, 3 mg/kg Se). In 2005 and 2006, 60 weaned replacement Angus-Hereford heifers (248 ± 11.8 kg BW) were stratified by BW and allocated randomly to 6 groups of two supplement types with three replicate groups of 10 heifers for each treatment in each year. Heifers were given supplements every 3 d (UCD) or every 20 d (COM) for 70 d, and weighed every 28 d. Average daily gains were determined by regression. The data were analyzed by ANOVA with year and supplement as main effects and pasture group as the experimental unit. Supplement intakes were different ($P < 0.05$) between years, but ADG only tended to differ ($P < 0.10$). Across years, supplement intakes and costs per heifer averaged 547 and 398 g/d and \$0.331 and \$0.184 ($P < 0.05$) for the COM and UCD groups, respectively. Heifers' ADG were 78 and 246 g/d for the COM and UCD groups, respectively ($P < 0.01$). The UCD supplement produced greater gains (>3X) compared with a commercial tub supplement, at much lower cost. With appropriate feeders the UCD supplement can be fed free choice to improve calf performance and reduce costs of production.

Key Words: Beef Heifers, Annual Range, Supplementation

T50 Effects of deworming nursing calves 90 days prior to weaning on calf weaning weight. J. E. Rossi*[1], D. T. Ensley[2], and B. G. Mullinix, Jr.[1], [1]*University of Georgia*, *Tifton*, [2]*University of Georgia*, *Athens*.

Two trials were conducted to determine the effects of deworming winter born (Jan/Feb) calves 90 days (June) prior to weaning on calf weaning weight. In trial 1, nursing Angus calves (n=117, 174 ± 5.3 kg) were allotted by weight and sex in each of six fescue pastures. Treatments consisted of no deworming (CON) or deworming (DW) with Doramectin injectable (1 mL/50 kg BW). Equal numbers of steers and heifers were in each treatment within each pasture. All cows were dewormed with Doramectin pour-on (1 mL/10 kg BW) on d 0. Calves were weighed on d 0, 30, 60, and 90 of the trial. Data were analyzed using the MIXED procedure of SAS. Overall ADG was greater ($P < 0.10$) for DW (0.87 kg/d) compared with CON (0.84 kg/d) calves. Daily gain was not different ($P > 0.18$) from d 0 to 30 (1.03 and 1.00 kg/d for DW and CON; respectively), d 31 to 60 (0.95 and 0.91 kg/d for DW and CON; respectively) or d 61 to 90 (0.68 and 0.66 kg/d for DW and CON; respectively). In trial 2, nursing Angus, Angus × Charolais, and Hereford × Charolais calves (n=209, 175 ± 9.7 kg) were dewormed 90 days prior to weaning. Calves were allotted by weight, sex, and breed to each of three bermudagrass pastures. Treatments consisted of no deworming (CON) or deworming (DW). Equal numbers of steers and heifers were in each treatment within each pasture. Deworming and weighing procedures were the same as in Trial 1. Overall ADG was not different ($P = 0.59$) between treatments (0.95 and 0.93 kg/d for DW and CON; respectively). Daily gain was not different ($P > 0.32$) from d 0 to 30 (0.99 and 0.97 kg/d for DW and CON; respectively), d 31 to 60 (0.85 and 0.80 kg/d for DW and CON; respectively) or d 61 to 90 (0.99 and 1.00 kg/d for DW and CON; respectively). Calves that were dewormed returned \$5.15 per hd in Trial 1 and \$2.77 per hd in Trial 2 more than the CON calves when valued at \$1.00 per 0.45 kg of BW at weaning. Cost of the dewormer would be approximately \$1.60 per calf, excluding the cost of labor. Deworming nursing calves in early June (90 days prior to weaning) increased calf weaning weight in Trial 1 and increased the value of the calf at weaning in both trials.

Key Words: Calves, Deworming

Breeding and Genetics - Livestock and Poultry

T51 Joint analysis of egg and production traits in broilers. R. L. Sapp[1], T. Wing[2], and R. Rekaya*[3], [1]*USDA-ARS*, *Miles City, MT*, [2]*Cobb-Vantress, Inc.*, *Siloam Springs, AR*, [3]*University of Georgia*, *Athens*.

The objective of the study was to investigate the relationship between egg and production traits in chickens. The data were obtained from a closed, fully pedigreed, commercial broiler line. Records included measurements of body weight (BW), residual feed intake (RFI), percent breast meat (PBM), egg production (EP) and egg weight (EW) from 13,836 birds. A total of five analyses were conducted: 1) joint analysis of BW, RFI, PBM, EP, and EW in parent data (PA); 2) joint analysis of BW, RFI, and PBM in progeny data (PR1); 3) PR1 with EP and EW covariates (PR2); 4) PR1 with covariates of EP and EW grouped into 6 classes; and 5) joint analysis of BW, RFI, PBM, EP, and EW in both progeny and parent data (PR4). The mixed model included

fixed effects of contemporary group (flock-week of hatch-parent's flock) and sex; and random additive effects of bird, maternal effects of hen, maternal permanent environment and residual. For PA and PR4, random effect of permanent environment was also included in the analysis. The structure of the data was such that if birds had RFI, then they would not have PBM and vice versa. Heritability estimates obtained from PA for BW, PBM, RFI, EP, EW, and maternal BW were 0.16, 0.53, 0.26, 0.22, 0.47, and 0.16. For progeny data, heritability estimates of PBM and RFI were consistent across PR1 — PR4. In contrast, estimates for BW and maternal BW varied across PR1 — PR4 with PR2 and PR3 having higher estimates. Heritability estimates of the six traits using PR4 were similar to those obtained from PA. However, BW estimates obtained from PR2 and PR3 were significantly different from the estimates obtained using PA; thus indicating that methods including EP and EW as covariates overestimated BW heritability. Genetic and residual correlations ranged in magnitude and direction depending on the type of analysis. In conclusion, heritability estimates for the egg and production traits suggest that genetic improvement could be made. However, the relationship between these traits varies with the type of data and method used in the analysis. The fluctuation in these relationships could be due to the large number of missing records for PBM and RFI.

Key Words: Breast Meat, Egg Weight, Feed Conversion

T52 Cow/calf pre-weaning efficiency of Nellore, British × Nellore and Continental × Nellore crosses[1]. Liana Calegare*[1], Maurício Mello de Alencar[2], Irineu Umberto Packer[1], and Dante Pazzanese Duarte Lanna[1], [1]*ESALQ*, *Piracicaba, SP, Brazil*, [2]*Embrapa*, *Sao Carlos, SP, Brazil*.

In Brazil, purebred Nellore and its crosses represent around 75% of the total beef cattle herd. Crossbreeding programs have introduced different breed types with higher growth potential. However, knowledge of nutritional requirements and biological efficiency is vital to match maternal breed types to the environment. The objective of this study was to determine cow/calf efficiency. Data from fifty-eight cows from three breed types Nellore (NL), Angus × Nellore (AN), and Simmental × Nellore (SN) were used. Cows were randomized in blocks by calving date during two separate years (2002 and 2006). Crossbred cows were bred to Canchim (5/8 Charolais) bulls and NL cows to Nellore bulls. Cows and respective calves were individually fed from postpartum to weaning (20-190 d). The estimated ME and CP content of the diet were 2.2 Mcal and 16% CP for 2002 and 1.9 Mcal and 12% CP/kg DM for 2006. Calves received the same diet of their dams *ad libitum* beginning at 35 d of age. Milk yield was estimated by weighting calves before and after suckling. ME intakes by cow/calf pairs were different ($P<0.01$); 4212±66.9 for SN, 3895±67.3 for AN and 3433±70.7 Mcal for NL. The energy intake was parallel to milk yield and calf's growth rate. At birth the ¼S calves were heavier ($P<0.05$; 43.2±1.4) than ¼A (38.8±1.4) and Nellore (32.5±1.5 kg). This group had lower BW at weaning ($P<0.01$; 171±7.2) than ¼A (231±6.9) and ¼S calves (241±6.8 kg). NL pairs had lower ($P<0.05$) cow/calf efficiency (grams of calf BW gain/Mcal of MEI by cow/calf pair); 40.9±1.6 vs. 47.4±1.5 for SN and 49.5±1.6 g/Mcal for AN. The lower efficiency of purebred Nellore is confounded by the fact that there is no heterosis in this group. The higher MEI by crossbred pairs was more than compensated by the higher BW gain. There was high individual variability of efficiency (between and within-breed). Crossbred cows had 15% greater energy requirements than Nellore cows and may not be adapted to certain environments.

Key Words: Biological Efficiency, Breed Type, Weaning Weight

T53 Morphologic evaluation of Murrah water buffalo through regression and principal component analysis. J. R. B. Sereno*[1], M. V. Snel-Oliveira[2], S. M. Vasconcelos[2], A. A. Egito[3], M. S. M. Albuquerque[3], C. McManus[4], and J. C. Souza[5,6], [1]*Embrapa Cerrados*, *Planaltina, DF Brazil*, [2]*UPIS-Faculdades Integradas*, *Brasilia, DF Brazil*, [3]*Embrapa Recursos Geneticos e Biotecnologia*, *Brasilia, DF Brazil*, [4]*Universidade de Brasilia*, *Brasilia, DF Brazil*, [5]*Universidade Federal do Parana*, *Campus Palotina, PR Brazil*, [6]*University of Missouri-Columbia Scholarship of CNPq, Brazil*, *Columbia, Mo USA*.

This study aimed to analyze morphometric data of the Murrah water buffalo using principal component and regression analysis. Traits included ear length and width, horn length and width, back diameter, head length and width, body length, hip height, thoracic and cannon bone perimeter, height and length of croup, distances observed between pelvic bones, width of haunches, head profile and body score. Two hundred and twenty seven females were used, divided in four categories (suckling, weaned, intermediate and adults). These were measured using a tape measure and a measuring stick. The first two principal components explained 78% of all variation between traits. Correlations between traits were in general high (>0.60), except for diameter at the ribs. The first component showed that as a one trait increased in size the other traits also increased in size, as expected. The second component separated the animals into those that were long and thin from those that were short and stocky. Two different groupings were observed, those represented by suckling and weaned heifers and another by intermediate and adult cows. Within group variation for the traits was low (CV<10%). Among the traits analyzed those related to head conformation were the most heterogeneous. The regression analysis showed that these animals increase in size up to 80 months of age, when there is a tendency for a plateau. These data serve as a basis for comparison with a larger number of animals, with the objective of confirming these tendencies for the Murrah breed.

Key Words: Management, Phenotypical Evaluation, Animal Breeding

T54 Genetic parameters for weaning weight by age of dam for Brazilian Nellore. L. O. Campos da Silva*[1], J. C. Souza[2,3], A. Gondo[3], C. H. M. Malhado[4], J. A. Freitas[2], I. W. Santos[2], J. R. B. Sereno[6], R. Weaber[8], L. D. Van Vleck[7], and W. R. Lamberson[8], [1]*Embrapa-GNPGC*, *Brazil*, [2]*Scholarship of CNPq*, *Brazil*, [3]*Parana Federal Univeristy*, *Palotina, PR Brazil*, [4]*Bahia State University*, *Brazil*, [5]*Mato Grosso do Sul Federal University*, *Brazil*, [6]*Embrapa-CPAC*, *Brazil*, [7]*University of Nebraska*, *Lincoln*, [8]*Univeristy of Missouri*, *Columbia*.

The objective was to estimate genetic parameters by age of dam subclass for weaning weight of Nellore cattle raised on pasture in two regions of São Paulo State, Brazil, between 1975 at 2001. The data were from ABCZ / EMBRAPA and included 51,664 weights at 205

d (W205) from progeny of 24,996 cows. Records were grouped on the basis of age and number of calves of dams. Seven groups were established: G1 included all dams; G2 had dams with a minimum of 2 calvings, age of first calving greater than 60 mo, and calving between 280 and 1095 d; G3 had dams with one parturition (first) between 22 and 84 mo; G4 to G7 included dams calving between 35 and 60; 61 and 84; 85 and 120; 121 and 240 mo of age, respectively and all had at least two parturitions with no restriction for calving interval. Estimates of variances and covariates were obtained from single trait analyses using the MTDFREML set of programs. Fixed effects were contemporary group [season (dry or wet), year, sex and farm combination] with age of dam as linear and quadratic covariates. Random effects were direct and maternal genetic effects with covariance, and the uncorrelated maternal permanent environmental effect. Estimates of direct heritabilities ranged from 0.14 ± .02 to 0.19 ± 0.02 for all groups except G5 which had an estimate of 0.26 ± 0.06. Maternal heritabilities ranged from 0.02 ± 0.09 to 0.11 ± 0.11. Estimates of the direct-maternal genetic correlation were negative and increased from -0.14 ±.66 for G4 to -0.87± 0.20 for G6, although the estimate was near zero with a large standard error for G7. These results suggest that heritabilities remain relatively constant across age of dam groups for Nellore, but that the direct-maternal genetic correlation may become more negative for older dams.

Key Words: Age of Dam, Heritability, Weaning Weight

T55 Dairy cattle mortality trends in southeastern states. G. W. Rogers*[1], J. B. Cooper[1], and J. S. Clay[2], [1]*University of Tennessee*, *Knoxville*, [2]*Dairy Records Management Systems*, *Raleigh, NC*.

Lactation records from dairy herds in 9 Southeastern states processed through the Dairy Records Management Systems were utilized to determine rates of dairy cow mortality between 1982 and 2005. Over 1.1 million cows in 2038 herds born on or after January 1, 1980 were used for calculating the frequency for died code (termination code of 6) by calving year, lactation number and breed (Holstein or Jersey). Herds were required to have 10 or more years of continuously collected Dairy Herd Improvement data and 5 or more first calvings per year. These edits resulted in 1768 Holstein herds and 270 Jersey herds averaging over 1500 calvings. The percentage of cows that died during first lactation increased from the early 1980s to early 2000s; Jersey death losses in first lactaton increased from 1.4% to 2.6% and Holstein death losses in first lactation increased from 1.7% to 4%. Actual mortality rates in this age group may be higher as cows that calve and die before their first test date often are not included in records. Frequencies for mortality in lactation 2 and lactations 3 or greater are conditional on survival during the previous lactation. The percentage of cows that died during second lactation also increased from the early 1980s to early 2000s; Jersey death losses in second lactation increased from 2.2% to 4% and Holstein death losses in second lactation increased from 2.3% to 5.7%. The percentage of cows that died in third and later lactations increased from the mid 1980s to early 2000s; Jersey death losses in this group increased from 4.4% to 9% and Holstein death losses increased from 3.8% to 10.1%. Average death losses in the 24-year period for Jersey herds was less than that for the Holstein herds: 4.4% versus 4.8% for all lactations, 1.9% versus 2.9% for first lactations, 3.0% versus 3.8% for second lactations and 7.0% versus 7.2% for lactations 3 or greater. Cow mortality has increased approximately 2.5 fold over the past 2 decades in Southeastern dairy herds.

Key Words: Dairy Cow Mortality, Death Losses, Southeastern US

T56 Weaning weight and wool traits in a grade-up program of Rambouillet sheep with Australian Merino genetics. W. M. Rauw*[1], H. A. Glimp[1], T. Wuliji[1], M. Teglas[1], W. Jesko[2], and L. Gomez-Raya[1], [1]*University of Nevada*, *Reno*, [2]*Rafter 7 Ranch*, *Yerington, NV*.

The aim of the present study was to evaluate the influence of inclusion of Merino genetics on weaning weight (WW), greasy fleece weight (FW), staple length (SL) and fiber diameter (FD) and to calculate heritabilities, and phenotypic (rp) and genetic correlations (rg) for the wool traits. Records were available on 4408 to 9597 animals between 1992 and 2005. The Rafter 7 flock was initiated in Nevada in 1990 with the purchase of 500 purebred Rambouillet (R) ewes. A grade-up program (1/2, 3/4, 7/8, purebred) was initiated using Australian Merino semen (M) with the aim of developing a purebred Merino flock. The Rafter 7 line (approximately 5/8 M and 3/8 R), was created in 1999 and has been a closed line since. The percentage of M in the flock increased during this time interval. Least squares means of WW were estimated from a model that included the effects of sex, breed, year of birth, birth-rearing type, age of the dam and age at weaning. Least squares means of wool traits were analyzed with the same model but including age at shearing instead. Phenotypic correlations were estimated after adjustments were made for the traits included in the model. Heritabilities and genetic correlations were estimated with a multi-trait animal model. Heritabilities were 0.20 for SL (± 0.018), 0.39 for FD (± 0.013), and 0.27 for FW (± 0.019). Animals with higher SL had higher FD (rp = 0.22, $P<0.0001$; rg = 0.26 ± 0.053) and higher FW (rp = 0.31, $P<0.0001$; rg = 0.52 ± 0.055). Animals with higher FD had higher FW (rp = 0.32, $P<0.0001$; rg = 0.38 ± 0.042). Results indicate that in general, within year of birth, the inclusion of Merino genetics resulted in decreased WW ($P<0.05$), increased FW ($P<0.05$), and decreased FD ($P<0.05$). Clear effects on SL were not apparent. This indicates that the grade-up program had a somewhat negative effect on WW, but resulted in improved wool quantity and quality.

Key Words: Merino Sheep, Weaning Weight, Wool Traits

T57 An evaluation of SNP associations with calpastatin enzyme activity and shear force measures in Brahman steers. D. E. Franke*[1], M. G. Thomas[2], A. J. Garrett[2], and T. D. Bidner[1], [1]*Louisiana State University Agricultural Center*, *Baton Rouge*, [2]*New Mexico State University*, *Las Cruces*.

Objectives were to associate SNPs in the GeneSTAR tenderness panel of genetic markers (www.bovigen.com) with calpastatin (CAST) enzyme level and Warner-Bratzler shear force of steaks aged for 7 (SF7) and 14 (SF14) d from purebred Brahman steers (n=382). Steers were fed postweaning and harvested when they reached 10 to 15 mm fat thickness and acceptable market weight. Samples of DNA were collected from each steer prior to slaughter. Genotypic frequencies at a CAST locus in the 3′ untranslated region were 0.107 for C/C, 0.469 for C/T, and 0.424 for T/T nucleotides, respectively. Allelic frequencies were 0.342 for C and 0.658 for T nucleotides. Genotypic frequencies

at the calpain (CALP316) locus were 0.063 for C/G and 0.937 for G/G nucleotides, resulting in allelic frequencies of 0.031 and 0.969 for C and G, respectively. Similarly, genotypic frequencies at the CALP4751 locus were 0.099 and 0.901 for C/T and T/T nucleotides, respectively. Allelic frequencies were 0.050 and 0.950, respectively, for C and T nucleotides. No C/C nucleotide pairings at the CALP316 locus or C/C nucleotide pairings at the CALP4751 locus were observed. Genetic markers at the CAST locus significantly influenced variation in calpastatin enzyme activity but not in SF7 or SF14. Regression of calpastatin enzyme activity on number of favorable marker alleles at the CAST locus was -0.343 ± 0.071 ($P \leq 0.01$). Genetic markers at the CALP316 or the CALP4751 locus did not influence variation in shear force. However, regression on combinations of CALP316 and CALP4751 favorable markers predicted variation in SF7 (-.226 ± 0.110) and SF14 (-0.240 ± 0.091), respectively. Eight haplotypes were identified among the three loci with C-G-T and T-G-T having the highest frequencies at 0.314 and 0.606, respectively. Haplotype T-G-C had a frequency of 0.032 and all other haplotypes had frequencies less than 0.02. Results suggest that combinations of SNP genetic markers in the GeneSTAR tenderness panel will significantly reduce SF7 and SF14 in Brahman steers. Most importantly, a SNP within CAST influenced the activity of this protein.

Key Words: Brahman, Genetic Markers, Shear Force

T58 Gene polymorphisms associated with mastitis and reproduction traits in Holstein cows. G. M. Pighetti*, C. J. Kojima, and A. M. Saxton, *University of Tennessee*, *Knoxville*.

Genetically identifying cattle less susceptible to mastitis and more fertile will be a key factor in producing healthier cattle populations. Because mastitis and fertility are influenced by a variety of factors, several markers most likely will be needed to identify an animals genetic potential. As a step towards this goal, we evaluated the association of a series of single nucleotide polymorphisms (SNP) in two immune related genes (CXCR1 and NRAMP1) on BTA2 with mastitis and reproductive traits in 96 Holstein cows. Of the >40 SNP identified, 5 were chosen that best represented the genetic variation in that region of BTA2. Of the SNP evaluated, 3 were associated ($P<0.10$) with disease and/or reproductive traits, 4-226 and 5-577 in CXCR1 and K1-245 in NRAMP1. The 4-226 SNP tended to be associated ($P<0.10$) with clinical mastitis, subclinical mastitis, and days open. In our sample population, cows with an AA or AG genotype were twice as likely to develop subclinical and clinical mastitis as cows with the GG genotype. Interestingly, the AA genotype tended to have fewer days open then the other two genotypes. A second SNP in CXCR1, 5-577, introduces an early stop codon in the receptor which has a strong potential to influence immune function. This SNP tended to be associated with subclinical mastitis. The NRAMP SNP was significantly associated ($P<0.05$) with clinical mastitis: heterozygous cows experienced twice as many infections as cows homozygous for the C allele. No significant associations with were observed with somatic cell score, however this may be related to low SCS observed in the herd (<3.0). Nor were any significant associations observed with days to first service. Based upon these findings and our prior research indicating a significant association between mastitis and immune function with another SNP in the CXCR1 gene, we believe this region of BTA2 is a relevant mastitis resistance locus and potentially reproductive trait locus. To further define a desirable genetic background, the next step is to evaluate these 3-5 SNP in a larger, well-defined Holstein population.

Key Words: Marker, Mastitis, Reproduction

T59 The genomic architecture of a major QTL region on chicken chromosome 4: CpG islands, gene density and repetitive elements. G. A. Ankra-Badu and S. E. Aggrey*, *University of Georgia*, *Athens*.

This study was conducted to characterize the genomic landscape of a major QTL region and to identify novel candidate genes by CpG island detection and comparative mapping. One hundred and nine genes and 179 CpG islands were detected at this locus and thirty four percent of these genes contained CpG islands. The region spanning 68-70 Mb had the highest CpG island density and the second highest number of genes. Analysis of the distribution of repetitive elements showed that LINE, low complexity and simple repeats constituted the majority of repetitive DNA in the QTL region. Generally regions with a high GC content and gene and CpG island density had a relatively low percentage of repeats. Seventy three genes from a match with twenty species which are involved in protein synthesis, transcriptional regulation and other functions were identified by comparative mapping. Six probable novel genes were identified on GGA4 by blasting a selection of these genes against the chicken genome. Three of these genes are housekeeping genes which are either involved in protein transport or signal transduction. A putative ortholog of rhotekin, which is a housekeeping gene with nucleotide binding and apoptosis functions, was detected in the region orthologous to the Fugu (puffer fish).

Key Words: QTL Region, CpG Islands, Repetitive Elements

T60 Modeling social competition assuming a single dominant animal per pen. J. M. Achi*, I. Misztal, and R. Rekaya, *University of Georgia*, *Athens*.

The model of social competition by Muir and Schinckel (MS) assumes continuous expression of social dominance. The purpose of this study was to examine a model where such an expression is binary. The simulated data set included 18,000 animals across three generations. A pen effect was included with six animals per class. Two additive values were assigned per animal, direct and social dominance; both effects were assumed correlated. Liability of social dominance was calculated as a sum of the social dominance effect plus a residual term. For each pen, the animal with the highest liability was declared dominant. The simulated growth phenotype was calculated as a sum of effects of pen, generation, direct, dominance advantage, and the residual. The effect of dominance advantage was only present in records of dominant animals. It was fixed to a constant value in model 1 (M1) or equal to the effect of social dominance in model 2 (M2). A bivariate linear-threshold was used for analysis where the second trait was the dominance status assumed known. Initial analyses assumed M1. When the second trait was ignored, the estimate of the dominance advantage was unbiased when the covariance was 0, was biased upwards when the covariance was positive, and downwards if negative. There was no bias when the second trait was considered in the analysis.

Variance components were estimated for a scenario with a positive correlation. There was an upward bias for the direct variance and downward for the competitive variance and the covariance. The biases were traced in part to the fixed threshold used for all records. A variable threshold is required so that exactly one animal per pen is selected as dominant. Variance components were estimated and animal effects predicted with the MS model. The correlations between the competitive effects from the two models were close to 0. When M2 was used, the same correlation was -0.1. It seems that modeling social dominance with different models may result in drastically different rankings.

Key Words: Social Dominance, Competitive Effects, Simulation

T61 Obtaining multiple QTL solutions without inverting the IBD matrix. M. Jafarikia*, J. A. B. Robinson, and L. R. Schaeffer, *University of Guelph*, *Guelph, Ontario, Canada*.

The inverse of an Identity By Descent (IBD) probability matrix is required for most Quantitative Trait Loci (QTL) studies. Although different methods are available for the calculation of an IBD matrix, direct inversion of that matrix can be computationally very demanding for large data sets. In order to obtain the QTL solutions without inversion, an average gametic relationship IBD matrix was used so polygenic and QTL incidence matrices were equal. A subset of the mixed model equations consisting of fixed and polygenic effects was created and after obtaining the solutions for this subset, the following formula was used to obtain the QTL solutions: $\hat{\mathbf{u}}_n=(\sigma_{un}^2\mathbf{G}_n\mathbf{A}^{-1}\hat{\mathbf{a}})/\sigma_a^2$ where $\hat{\mathbf{u}}_n$ is the vector of solutions for qtl n and σ_{un}^2 is the variance of QTL n and $\mathbf{G}_n$ is the IBD matrix of haplotype n, $\mathbf{A}^{-1}$ is the inverse of additive relationship matrix, $\hat{\mathbf{a}}$ is the vector of polygenic solutions and σ_a^2 is the additive genetic variance. Using an iteration procedure, the predicted QTLs effects were subtracted from observations and the fixed/polygenic subset of equations were re-solved with the adjusted observations. Then the QTL effects were solved as above and the cycle repeated until convergence was reached. The proposed methodology was applied to a simulated chromosome with 20 markers and four QTLs located in the middle of four haplotypes. The number of markers on each haplotype was four, ten, two and four respectively. A half-sib population with five grand sires, 50 sons per grandsire and 50 daughters per son was simulated. The model included fixed contemporary groups, random polygenic, QTL and residual terms with variances of 22.08% for polygenic, 1.92%, 1.92%, 4.48%, 9.6% for the four QTLs and 60% for the residual. The example converged after 39 iterations and there were no significant differences between the solutions of the full equations and proposed shortcut method. Both the Pearson and Spearman rank correlations were 1.00.

Key Words: IBD, QTL, Inverse

T62 A Microsatellite Repeat Search (MRS) tool for eukaryotic genomes. L. Klein*[1,2], S. Puri[1,2], G. Blachut[3], and E. Smith[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg*, [2]*Blacksburg High School*, *Blacksburg, VA*, [3]*Hinsdale South High School*, *Hinsdale, IL*.

There continues to be significant interest in microsatellites because of their implication in neurological diseases and their utility as DNA markers for common disorders. Their distribution in the genomes of model, human and agriculturally important species therefore remains of interest to scientists. Previous studies, supported by annotation results of the recently released chicken genomic DNA sequence, suggest that microchromsomes have a higher gene density and by inference lower repetitive sequences than macrochromosomes. Here, we developed a bioinformatics tool, Microsatellite Repeat Searcher (MRS), that was used to evaluate the relative distribution of microsatellites on micro- and macrochrosmosomes in the chicken, Gallus gallus. A total of 9,138 repetitive elements were identified within a total of 1,133,629,576 bp of sequence scanned. Though inconsistent, an inverse correlation was observed between chromosomal length and microsatellite frequency. The tool described here should be useful for searching whole genomes of other vertebrates for repetitive elements. Our data appears to support the hypothesis that the gene-rich microchromosomes also have a lower percentage of repetitive elements.

Key Words: Microsatellites, Bioinformatics Tool, Chicken

T63 Analysis of protein in pig blood serum at growing stages. H. Y. Chung*, S. H. Yoon, B. H. Choi, K. T. Lee, and G. W. Jang, *National Livestock Research Institute*, *Suwon, KY, Korea*.

The purpose of this study was to detect differentially expressed proteins in pig blood serum at growing stages, which were constructed with birth, 6, 12, 18, 24 and 30 weeks of age. A total of 16 spots from 2D gels were observed for differential expression at each growing stage. Mass spectrometric (MS/MS) analysis of the spots identified Ig kappa light chain, Ig lambda chain C, haptoglobin alpha 1S, gamma fibrinogen, Ig gamma 1 chain, Retinol-Binding Protein, albumin, apolipoprotein A-IV, antithrombin protein, alpha-1-antitrypsin and fibrinogen A-alpha-chain. Most of the proteins were gradually expressed from birth to 30 weeks, but a few proteins were not expressed at birth. SNPs from the identified loci were genotyped across 300 pigs from a commercial population. Three loci for the Ig lambda chain C and haptoglobin alpha 1S gene were significantly associated with birth and weaning weights ($P<0.01$). Therefore, genes identified in this study may account for some of the genetic variation and differential protein expression in animal growth.

Key Words: Growing Stages, 2D Analysis, Polymorphism

T64 Construction of SNP maps in the region of the swine SLA class I for miniature pig. H. Y. Chung*, S. H. Yoon, B. H. Choi, K. T. Lee, and G. W. Jang, *National Livestock Research Institute*, *Suwon, KY, Korea*.

In order to construct SNP maps focusing on the swine leukocyte antigen region, the SLA class I region was screened by PCR using miniature pig BAC clones. The swine leukocyte antigen (SLA) class I region containing MHC class Ia, Ib, related genes, and pseudogenes, was analyzed to provide genetic information for transplantation research in pig. A total of 990 primers were designed and covered 1,500,000 bp locating on pig chromosome 7q11-16. Miniature pigs were used to infer haplotypes and SNP maps, with a total of 4,000 SNPs discovered. The sequence information from miniature pigs was compared with 5 pig breeds (Landrace, Hampshire, Yorkshire, Duroc,

and Berkshire). The SNPs discovered in this study may provide useful genetic information for organ transplantation research.

Key Words: SNP, Swine Leukocyte Antigen (SLA), Haplotype

T65 Impact of inbreeding on IBD probabilities and estimates of QTL variance. G. Freyer[2] and N. Vukasinovic*[1], [1]*Monsanto Animal Genomics and Breeding*, *Saint Louis, MO*, [2]*Research Institute for the Biology of Farm Animals (FBN)*, *Dummerstorf, Germany*.

QTL mapping in complex pedigrees using a variance component approach has become popular as increasing numbers of animals are routinely genotyped in dairy populations. In this approach, the QTL effect is modeled as a function of the probabilities that two alleles in the same or in different animals at a particular position in the genome are identical by descent (IBD probabilities). Proper calculation of IBD probabilities and therefore, modeling and estimation of QTL variances depend on many factors such as the number of markers, their information content, and the level of relatedness of the animals in the pedigree. In this simulation study, we investigated how the level of inbreeding, coupled with varying marker information content, influenced IBD probabilities and the estimates of QTL variances. Four multi-generational pedigrees with 850 individuals each were simulated. The final offspring of 9 sires originated from two founder (great-grand) sires. Four family structures (FS) with different levels of inbreeding were considered: FS0 was non-inbred; FS1 contained an inbred sire originating from an aunt-nephew mating; FS2 contained a 25% inbred sire, originating from a half-sib mating. FS4 in addition contained a grand sire originating from a father- daughter- mating, where one of the two resulting sires was mated to his dam to further increase the level of inbreeding. All animals were assumed genotyped for 11 unevenly spaced markers within a 55cM long putative QTL region, containing a QTL within the 7th marker bracket. The number of marker alleles was 2, 4, or 6. Complete marker information and 20% randomly missing marker genotypes were considered. IBD probabilities for each cM in the segment were calculated using the nearest informative marker bracket. Means and variances of IBD probabilities increased with both increasing level of inbreeding and increased marker information. Estimates of the QTL variances at the true QTL position obtained from data sets with 2 marker alleles and without missing genotypes were closest to the simulated values, regardless of the inbreeding level.

Key Words: Inbreeding, Pedigree, QTL

T66 Relationship of herd-heritability with sire misidentification and entry into a proven sire lineup. C. D. Dechow[1], H. D. Norman*[2], and N. R. Zwald[3], [1]*The Pennsylvania State University*, *University Park*, [2]*Animal Improvement Programs Laboratory*, *Beltsville, MD*, [3]*Alta Genetics, Inc.*, *Watertown, WI*.

The objectives of this study were to estimate the relationship of individual herd heritability with sire misidentification rate and the likelihood of a sire entering an active sire lineup after progeny testing. Milk, fat and protein yield and somatic cell score (SCS) were provided by the Animal Improvement Programs Laboratory at USDA. Paternity verification results from DNA marker analysis were provided by Alta Genetics, Inc. for 145 herds. The number of cows tested per herd ranged from 5 to 274. Herd heritability was calculated with daughter-dam regression and daughter-sire predicted transmitting ability (PTA) regression using 6,848,885 records from 17,608 herds. Herd heritabilities were estimated with regression models in AS-Reml that included fixed breed, age within parity, herd-year-season of calving, dam records nested within state, and sire PTA within state; random regression coefficients were dam records and sire PTA within herd. Average daughter-dam herd heritability estimates ranged from 0.26 (SCS) to 0.41 (fat yield), whereas daughter-sire herd heritability ranged from 0.11 for SCS to 0.20 for fat yield. Correlations between herd heritability and sire misidentification rate ranged from -0.23 to -0.43. The correlation between a principal component for all measures of herd heritability and sire misidentification rate was -0.45. Sires that were proven in low heritability herds were less likely to enter a proven sire lineup than sires proven in average to high heritability herds. Individual herd heritabilities can be generated with simple regression techniques for several thousand herds simultaneously. The herd heritability estimates could be used to identify herds that might provide inaccurate data for progeny testing, and could be used to identify sires with potentially underestimated genetic evaluations.

Key Words: Herd Heritability, Sire Misidentification, Daughter-Dam Regression

T67 Heritability estimates for producer recorded clinical mastitis events. C. D. Dechow[1], J. Vallimont*[1], C. G. Sattler[2], and J. S. Clay[3], [1]*The Pennsylvania State University*, *University Park*, [2]*Select Sires, Inc.*, *Plain City, OH*, [3]*Dairy Records Management System*, *Raleigh, NC*.

The objective of this study was to estimate heritability for producer-recorded clinical mastitis events. Cow health events were provided by Dairy Records Management Systems (Raleigh, NC) for progeny test herds that use PCDART. First through fifth lactation data from cows calving between 20 and 120 months of age and that calved in a herd-year with at least 1% of cows with a clinical mastitis event were retained. The edited dataset contained 105,527 records. Mastitis (1 = at least one mastitis event during lactation, 0 = no mastitis events) was analyzed with two single trait animal models in AS-Reml with fixed effects for age within parity and herd-year-season of calving; random effects were animal, permanent environment and error. Mastitis was treated as a linear response variable in the first analysis and as a binary response variable in the second analysis. The incidence of clinical mastitis was 14%. When data was restricted to herds with a minimum of 5% clinical mastitis, the average lactation incidence rate was 19%. Heritability estimates were 0.02 when mastitis was treated as a linear response variable and 0.15 when treated as a binary response variable. Repeatability estimates were 0.07 and 0.16 for the linear and binary response variables, respectively. The correlation between PTA from the linear and binary models was 0.98. Significant genetic variation exists for clinical mastitis and health events recorded by producers could be used to generate genetic evaluations for cow health. While heritability estimates varied between linear and binary models, sires ranked similarly for daughter mastitis susceptibility with both methods.

Key Words: Mastitis, Heritability, Repeatability

T68 Different UBX domain D Gene from subtraction cDNA isolated from Korean native chicken. S. S. Sun*, K. Kuk, and K. H. Myung, *Chonnam National University*, *Gwangju, Korea*.

The objectives of this study are to identify specific functional genes which related with growth and structure of pectoral muscle in Korean native chicken. Pectoral muscle was isolated from the Korean native chickens (KNC, red brown, 12 months old, 2.41kg±0.24) and Cornish chickens (16 month old, 2.76±3.04kg). The subtraction cDNA library was prepared in PCR4 Blunt-TOPO vector and the insert was sequenced. The DNA sequence homology was compared with other breeds and species in GenBank. A clone NDS-10 was unique for the DNA sequence homology with UBX family. NDS-10 has 612 nucleotides. This partial sequence has high homology (98%) with chicken UBX domain D. The expression of DNS-10 could change three-dimensional structure of skeletal muscle and could modify texture of breast muscle. Several regions were mutated from T in chicken to C or G in NDS-10. It may have severe structural modification due to not making H-bond between T and A. They are going to make G-C linkage for their three-dimensional structure. The late regions were point deleted and then can not be translated or expressed to different protein. Chicken UBX domain containing 4 (UBXD4) and mRNA for hypothetical protein from clone 10c14 ND were compared. They are 98% (571/579nt) homology of nucleotide sequence. Chicken UBX domain has chicken (93%), cattle (68%), dog (67%), and mouse (64%), human (63%) nucleotide sequence homology. We conclude that the clone NDS-10 could be a new candidate gene for UBX family gene.

Key Words: UBX Domain D, cDNA, Korean Native Chicken

T69 Efficiency of Brown Swiss, Holstein and their crosses estimated with data envelopment analysis. C. D. Dechow[1], M. I. Phelps*[1], S. Roth[1], G. W. Rogers[2], and J. B. Cooper[2], [1]*The Pennsylvania State University*, *University Park*, [2]*The University of Tennessee*, *Knoxville*.

The objective of this study was to compare the efficiency of Brown Swiss (BS), Holstein (HO) and crosses among BS and HO using data envelopment analysis (DEA). A multi-dimensional efficiency frontier that is derived from of the most efficient production units (cows) is generated by DEA. Cows that do not reside along the frontier must reduce inputs relative to their level of output to become efficient. The output variables were first lactation total milk, fat and protein yield obtained from six herds. Input variables were days in milk, age at calving, days open and estimated body weight. BS and HO were assumed to have equivalent body weights and heterosis for body weight was assumed to be 3%. The analysis was performed with the DEA Excel Solver for each herd individually. A solution was successfully attained for three herds totaling 334 cows of the following breed combinations: 184 HO, 89 BS, 27 first generation crosses (F1) and 34 backcrosses (F2). Resulting efficiency values were analyzed with the GLM procedure of SAS. Breed combination and herd-year-season of calving were independent factors and least squares means for efficiency were estimated for breed combination. Least squares means for efficiency were 0.79, 0.86, 0.91 and 0.83 for BS, HO, F1 and F2, respectively. The heterosis estimate for efficiency in the first generation of crossbreeding was 10.3%, and F1 were significantly more efficient than BS or HO. Relative to F1, BS were required to reduce all inputs and increase milk production to become more efficient. HO were generally required to reduce days open and increase fat and protein yield when compared to F1. To raise efficiency of F1 further, milk production needed to increase when compared to HO and protein yield needed to increase relative to BS. An efficiency value that does not require assumptions about the economic value of inputs or outputs can be obtained with DEA in order to compare cows of different breeds. However, more advanced software was required to handle large datasets. There was evidence that crossbreeding with BS increased the efficiency of production when compared to pure HO.

Key Words: Data Envelopment Analysis, Crossbreeding, Efficiency

T70 Estimation of genetic and phenotypic parameters for days open and test day milk yields in Japanese Holsteins. Y. Masuda*, H. Abe, and M. Suzuki, *Obihiro University of Agriculture & Veterinary Medicine*, *Obihiro, Japan*.

The objective of this study was to estimate genetic and phenotypic parameters for days open and test day milk yield in the first two lactations of Holstein cattle in Japan. Monthly test day yields and insemination data were provided by the Hokkaido Dairy Milk Recording and Testing Association. Cows with first test day yields recorded after 35 days in milk and with days open less than 22 d or greater than 300 d within lactation were excluded. The first five test day records for each cow were extracted and treated as a separate trait. All data were split along lactation numbers into two data sets; days open and test day records from 158,994 and 73,290 cows calving between 1990 and 2002 for first and second parities, respectively. (Co)variance components within lactation were estimated using a bivariate animal model and the AI-REML procedure. The model included herd-year of calving, age at calving and month-year of calving as fixed effects, and random animal and residual effects. Heritability estimates for days open were 3.0% and 2.6% for first and second parities, respectively. Genetic correlations between days open and 1st to 5th test day milk yields were 0.42, 0.48, 0.52, 0.54 and 0.48 (0.27, 0.36, 0.34, 0.38 and 0.30) for the first (second) lactation, respectively. These results indicate that genetically high milk production during early lactation may lead to increase days open especially in first parity. Phenotypic correlations between days open and test day yield ranged from 0.04 to 0.07 and 0.03 to 0.05 for first and second parities, respectively. In another analysis, averages and standard deviations for days open decreased as the production level of the herd increased. Although there is an undesirable genetic relationship between days open and milk yields in early lactation, phenotypic correlation is close to zero due to an effort to improve reproductive efficiency in the individual herd.

Key Words: Days Open, Test Day Milk Yield, Genetic and Phenotypic Correlations

T71 Residual feed intake and temperament breed differences among Florida heifers. D. G. Riley*[1], G. R. Hansen[2], S. W. Coleman[1], and C. C. Chase[1], [1]*USDA, ARS*, *Brooksville, FL*, [2]*University of Florida*, *Marianna*.

The objective of this work was to evaluate residual feed intake, average daily gain, chute temperament score, and exit velocity of Brahman (B), Angus (A), and Romosinuano (R) (n = 40, 19, and 26, respectively)

and F_1 (n = 7, 8, and 12 for BA, RA, and RB, respectively) heifers. One month after weaning in September 2006, heifers were transported 485 km to the Florida panhandle. Heifers were placed in feeding pens and acclimated to a corn-based diet for 3 wk. Subsequently, they completed a 70-d intake test. Body weight, chute temperament score (from 1 to 5; higher scores indicated more nervous behavior), and exit velocity (m/s) were recorded weekly. Body weight and feed consumption records were used to generate residual feed intake values (RFI). Average daily gain and feed conversion ratio (FCR) were calculated. Pen (n = 6), breed (n = 6; 3 purebred and 3 crossbred groups), and age of dam were fixed effects. Age in days at test start was included as a covariate. Body weight was a covariate in analyses of chute score and exit velocity. Records were placed in 3 RFI groups: high, medium (mean ± 0.5 SD), and low values, and this term was modeled as a fixed effect in additional analyses. Sire was a random effect. Brahman heifers had more favorable ($P < 0.05$) RFI (–1.08 ± 0.25 kg) than other groups which ranged from 0.06 ± 0.17 (R) to 0.46 ± 0.2 kg (A). Brahman ADG (0.84 ± 0.06 kg) was less than ($P < 0.05$) that of Angus heifers (1.06 ± 0.05 kg). Means for ADG of crossbred heifers were 0.86 ± 0.08 (RB), 1.08 ± 0.1 kg (BA), and 1.1 ± 0.09 kg (RA). No breed effect was detected for FCR ($P = 0.31$). Brahman and Brahman-cross heifers had the largest exit velocity means (range from 2.89 ± 0.15 for RB to 3.43 ± 0.19 m/s for BA); these were larger ($P < 0.05$) than Angus (2.22 ± 0.12 m/s) and Romosinuano (2.12 ± 0.1 m/s). Chute temperament score means for Angus (2.38 ± 0.1) and RA (1.9 ± 0.26) were lower ($P < 0.05$) than those of all other breed groups. Groups for RFI did not explain variation in analyses of temperament traits ($P > 0.29$).

Key Words: Brahman, Residual Feed Intake, Temperament

T72 Organ weights and ulcer severity of 1980 vs. 2005 pigs when fed 1980 or 2005 feeding programs. J. S. Fix, E. van Heugten, D. J. Hanson, J. P. Cassady, and M. T. See*, *North Carolina State University*, *Raleigh*.

The objective of this study was to assess changes over 25 years in pig organ weights and ulcer severity. Pigs (n=162) representative of current commercial industry were compared to pigs representative of commercial industry 25 years ago. The 1980 genetic line was produced from dams selected to minimize genetic improvement and frozen semen from boars available in 1980. Pigs within sex, farrowing group, and genetic line (GL) were randomly assigned to a feeding program (FP) and placed 3 per pen (n=54) at an initial wt of 7±0.4 kg. The 2005 FP included 7 pelleted diets (lysine from 1.51 to 0.73% and ME from 3428 to 3651 Kcal/kg) and current diet formulation. The 1980 FP consisted of 4 meal diets (lysine from 1.05 to 0.62% and ME from 3262 to 3317 Kcal/kg) based on formulations from 1978 PIH. Pigs were slaughtered and viscera were collected on a weekly basis when average pen wt exceeded 116 kg. Heart, lungs, liver, kidneys, pancreas and all non organ matter were separated and weighed. Stomach, small intestine and large intestine were separated, cleaned and weighed. Weights were adjusted to constant BW of 116 kg. Stomachs were scored for ulcer and keratinization severity on a scale of 1-7 (1=normal to 7= severe ulceration). The 2005 GL pigs had heavier small intestines (1599 vs. 1375 g; $P < 0.01$), large intestines (1548 vs. 1405 g; $P < 0.05$), hearts (392 vs. 374 g; $P < 0.05$) and livers (1614 vs. 1550 g; $P = 0.05$) than pigs from 1980 GL. Pigs fed 1980 FP had heavier large intestines (1582 vs. 1371 g; $P < 0.01$) and lungs (673 vs. 611 g; $P < 0.05$) than pigs fed 2005 FP. A GL x FP interaction ($P < 0.01$) was observed for kidney weight where 1980 GL pigs fed 1980 vs. 2005 FP had heavier kidneys while 2005 GL pigs fed 1980 vs. 2005 FP had lighter kidneys. Pigs fed 1980 FP had heavier stomachs (624 vs. 518 g; $P < 0.01$) and less ulcer severity (2.26 vs. 3.53; $P < 0.01$) than pigs fed 2005 FP. Changes in genetics led to heavier organ weights but did not affect stomach ulcer severity. Changes in feeding program resulted in lower organ weights and an increase in stomach ulcer severity.

Key Words: Pigs, Genetics, Stomach Ulcers

T73 Genetic and environmental factors that affect gestation length. H. D. Norman, J. R. Wright, M. T. Kuhn, S. M. Hubbard*, and J. B. Cole, *Agricultural Research Service, USDA*, *Beltsville, MD*.

Genetic and environmental factors that might affect gestation length (GL) were investigated so that more accurate predictions of calving dates could be provided to dairy producers. Data from >8 million calvings from 1999 through 2005 for 5 dairy breeds were assembled from lactation, reproduction, and dystocia records from across the United States. Effects examined were calving year, calving herd-year, calving month, age-parity, calf birth code (gender and multiple-birth status), lactation length, milk yield, service sire, sire, and cow. All effects were fixed except for service sire, sire, and cow. Mean GL for cows (parities 2 through 5) was 279.5 d for Holsteins, 280.1 d for Jerseys, 281.9 d for Ayrshires, 285.8 d for Guernseys, and 287.6 d for Brown Swiss. Mean GL for heifers (parity 1) was 277.9 d for Holsteins, 278.6 d for Jerseys, 281.8 d for Ayrshires, 285.0 d for Guernseys, and 287.0 d for Brown Swiss. Estimated standard deviation of GL was greatly affected by data restrictions but appeared to be near 6 d for all breeds. For Holstein cows, calving year differences in GL were small, but effect of calving month was large; mean GL was 278.2 d for July compared with 280.4 d for November. Mean GL for Holstein cows with twins was 274.9 d compared with 279.4 and 280.5 d for those with single-birth females and males, respectively. Holstein cows with lactations of ≤250 d had a mean GL of 280.1 d compared with 278.8 d for cows that were milked for >500 d. Holstein cows with standardized yield of ≤6,000 kg had a mean GL of 279.0 d compared with 279.8 d for cows with yield of >16,000 kg. Heritability estimates for GL derived from parities 2 to 5 were 24% for service sire and 8% for sire. Better prediction of time of parturition can help herd managers to fulfill the nutritional needs of pregnant cows and to administer better preventive health care so that metabolic diseases are minimized during high risk phases of cows' lives.

Key Words: Gestation Length, Calving Date

T74 Construction of a cDNA library of the guinea fowl adipose tissue and evaluation for expressed sequence tags. S. N. Nahashon*, G. Kelley, J. Johnson, J. Tyus II, and A. Amenyenu, *Institute of Agricultural and Environmental Research, Tennessee State University*, *Nashville*.

Fat accretion in poultry directly influences the efficiency of feed utilization and consumer acceptability of poultry and poultry products. Excessive fat deposition, which is undesirable to poultry processors and consumers alike, also reduces meat quality. Losses estimated at about US$250-300 million are incurred by consumers and processors annually in pollution control, fat extraction and in discarding excess

carcass fat. Understanding the mechanisms that lead to excessive fat deposition in birds will be an avenue to improving poultry carcass quality while minimizing production cost. The aim of the proposed project was to generate a cDNA library for the guinea fowl adipose tissue. The guinea fowl is genetically diverse from other avian species such as chickens and turkeys and its carcass and abdominal fat content is significantly lower than that of these other avian species. Therefore, genome sequence information realized from the cDNA library would provide a tool for comparative mapping of the avian species and an understanding of the factors associated with fat accretion in poultry. A partial sequence cDNA library of the guinea fowl adipose tissue was constructed using the Stratagene® cDNA library construction kit. DNA sequences were cloned into the pBluescript cloning vector and screened by the polymerase chain reaction. Two hundred clones were cycle-sequenced using the Dye Terminator® cycle sequencing kit and the ABI 3100 Genetic Analyzer. Similarity of DNA sequences was evaluated using the National Center for Biotechnology Information (NCBI) databases using the BLAST (http://www.ncbi.nlm.nih.gov/BLAST/). About 90% of the DNA sequences retrieved were unique to the guinea fowl and they range in size from 386 to 1,059 bases. About 15% of these sequences had less than 20% match with mammalian sequences, whereas 85% exhibited homology ranging from 55-96% with avian species and 44-75% with mouse and human DNA sequences. These sequences provide an invaluable tool for comparative mapping of the avian genome and an understanding of the mechanisms underlying excessive fat accretion in poultry.

Key Words: cDNA Library, Guinea Fowl Adipose Tissue, Poultry

T75 Optimising turkey parent stock selection for an integrated processing company and a non-integrated poult supply company. B. J. Wood* and N. Buddiger, *Hybrid Turkeys*, *Kitchener, Ontario, Canada.*

Mass selection on body weight is an effective method that can improve the commercial performance of progeny from selected parent stock (PS). Selection on body weight is a common procedure within the North American industry with the industry averaging 50% selection from the total number of PS tom poults placed. Increased selection pressure increases costs in two ways, first, increased numbers of PS are required, and second, facilities in to house additional PS. The aims were to economically model PS selection to determine the optimum selection intensity to maximise profit when either an independent poult supplier or integrated turkey processing company. Poult production costs increased slowly above non-selection to $0.01 per poult at 50% selection and then increased more rapidly to $0.04 and $0.12 at 20% and 10%, respectively, thereafter, at higher intensities the price increased exponentially. For a non-integrated company, returns are generated purely on the sale of poults with benefits accrued from increased market share or higher poult price and so must be determined on an individual company basis. For integrated companies return on investment comes in the form of improved live performance and processing. Body weight was assumed to have a heritability of 0.4 and genetic (r_g) and phenotypic (r_p) correlation between male and female bodyweight was assumed to be r_g = 0.85 and r_p = 0.70, respectively. Correlations between bodyweight and feed intake, BMY and mortality were assumed to be to be r_g = -0.15, -0.16, 0.2 and $_p$ = -0.15, -0.12 and 0.15, respectively. The optimal intensity was between 15% and 25% depending on breast meat and feed price which corresponded to the level where there was substantial increase in poult cost. Optimal selection age was always the same as slaughter age and hen selection was shown not to be profitable at any selection pressure level. It could be concluded that current PS tom selection intensities could be increased with substantial increases in profit compared with current industry levels.

Key Words: Economic Model, Parent Stock Selection, Genetics

T76 Defining the haplotype blocks in outbred livestock populations. M. Jafarikia*, J. A. B. Robinson, and D. Ashlock, *University of Guelph*, *Guelph, Ontario, Canada*.

Recent studies propose a block-like structure for genome haplotypes. There are two major methods for defining the haplotype blocks based on finding a region with limited diversity, and detecting regions with high levels of historical recombination. In order to develop a methodology to define the haplotype blocks in outbred livestock populations, maximum likelihood was used in a simulation study to detect the hotspot regions, using the information from the genotypes of grand sires and their sons in the following formula:

$$X^2 = -2\ln(\Pi[(p^{r_i}q^{(n_i-r_i)})/(p_i^{r_i}q_i^{(n_i-r_i)})]\Pi q^{n_i})$$

where X^2 was the LR value for every informative interval and p as a population measurement, was the probability of having recombination in an informative interval computed from the total number of recombinations divided by the total number of informative intervals in the population: $p=\Sigma r_i/\Sigma n_i$ where the number of grand sires (families) was from i=1 to GS. r_i and n_i denoted the number of recombinations in the progeny of every grand sire, and the total number of informative intervals in the progeny of every grandsire respectively. p_i was a family measurement which is the number of recombination in the progeny of a grandsire divided by the total informative intervals of that grand sire, $p_i=r_i/n_i$. q and q_i were the possibility of having no recombination in an informative interval in the population and family respectively. n_i-r_i was the number of progeny which did not show any recombination in meiosis. In order to test the method, a simulated ten cM chromosome having 30 SNPs in a population with five grand sires and 80 sires per grandsire and two blocks of haplotypes was developed. The possibility of recombination was 95% in hotspot region and 5% in coldspots region. The proposed method was able to successfully detect the hotspot regions ($P<0.001$).

Key Words: Haplotype Blocks, Recombination Hotspot, Maximum Likelihood

T77 Nutritive value of corn protein co-products from the ethanol industry. M. R. C. de Godoy*, L. L. Bauer, C. M. Parsons, and G. C. Fahey, Jr, *University of Illinois*, *Urbana*.

The objectives of this study were to determine the chemical composition and nutritive value of corn protein concentrates, (CPC_1, CPC_2), novel co-products from the ethanol industry, compared with conventional plant protein ingredients (soybean meal [SBM], distillers dried grains with solubles [DDGS], corn gluten meal [CGM], and corn germ meal [CGeM]). Protein efficiency ratio (PER), standardized amino acid digestibility, and true metabolizable energy (TME_n) data were obtained with chicks. Corn protein concentrates were produced from a pilot modified wet milling plant, with CPC_1 having a higher degree of purification than CPC_2. Crude protein values for CPC_1 and CPC_2 were 57.3 and 49.7%, respectively. Total dietary fiber concentration was 29% for CPC_1 and 23.5% for CPC_2. Acid hydrolyzed fat and gross energy concentrations were similar for these ingredients. No statistical differences in feed intake, weight gain, or protein intake were noted among CPC_1, CPC_2, and CGM. However, CPC_1 resulted in a higher gain/feed and PER ratio than CPC_2 and CGM. Overall, SBM was superior for all growth outcomes analyzed in this assay. For standardized amino acid digestibilities, CGM had the highest numerical values for total amino acids (TAA), total essential amino acids (TEAA), and total nonessential amino acids (TNEAA), but they were not statistically different from CPC_1 and SBM values. Corn germ meal resulted in the lowest values for the same criteria and were not significantly different from DDGS and CPC_2. Corn protein concentrates were not different from each other in TNEAA digestibility. Highest values for TME_n were obtained with CGM, followed by CPC_1, DDGS, CPC_2, SBM, and CGeM. Distillers dried grains with solubles and CPC_2 had similar values and were not different than CPC_1 and SBM. In conclusion, CPC_1 was of higher quality than CPC_2 and CGM in the PER assay. As regards amino acid digestibility, CPC_1, CGM, and SBM were of comparable quality, and CPC_2 was similar to DDGS and CGeM.

Key Words: Corn Protein, Nutritive Value, Ethanol

T78 Chemical composition of fiber rich corn co-products from the ethanol industry. M. A. Guevara*[1], L. L. Bauer[1], C. A. Abbas[2], K. E. Beery[2], M. A. Franklin[2], M. J. Cecava[2], and G. C. Fahey, Jr.[1], [1]*University of Illinois*, *Urbana*, [2]*Archer Daniels Midland Company*, *Decatur, IL*.

Understanding the impact of different processing methods and steps on preparation of fiber-rich corn co-products is a pre-condition to the interpretation and potential use of these products as fiber sources in dog foods. To determine the chemical composition of selected fiber-rich corn co-products from the ethanol industry, samples of native corn fiber (NCF), hydrolyzed corn fiber (HCF), and hydrolyzed extracted corn fiber (HECF) were analyzed for concentrations of total dietary fiber (TDF), acid hydrolyzed fat (FAT), crude protein (CP) , and hydrolyzed monosaccharides corrected for free sugars (HMC). Compositional data are presented in the following table. Values in parentheses represent the range in values among the co-products. Data indicate that compositional differences exist dependent upon processing methodology utilized. The desired outcome is to produce a consistent high fiber corn co-product with little variation in chemical composition and with a predictable physiological effect when incorporated into canine diets.

Table 1.

Co-Product	%TDF	%CP	%FAT	HMC, mg/g
NCF	67.3 (52.6-73.5)	12.3 (10.4-14.5)	6.8 (4.9-8.3)	683 (600-754)
HCF	57.3 (46.4-71.5)	14.4 (11.1-15.9)	7.2 (5.5-8.6)	473 (450-524)
HECF	70.8 (61.7-79.3)	12.5 (11.9-13.5)	2.4 (1.6-3.8)	575 (520-693)

Key Words: Corn Fiber, Composition, Ethanol

T79 Using ultrasound as an alternative method for determining body fat content in beagles. R. M. Yamka*, K. G. Friesen, C. A. Stiers, and B. A. Stone, *Hill's Pet Nutrition, Inc.*, *Topeka, KS*.

The objective of this study was to determine if % body fat content in beagles can be determined using ultrasound. Three hundred beagles (average age = 7.3 ± 2.7 years and average weight = 14.8 ± 3.1 kg) were identified for this study. All dogs underwent dual-energy x-ray absorptiometry (DXA; DXA-QDR-4500, Hologic, Inc., Waltham, MA) scans to determine body fat, muscle and bone content (average % fat = 35.6 ± 6.1). Prior to the DXA scans, each dog was weighed and back fat depth was measured three times via ultrasound at the spine between wings of the ileum (average back fat = 1.2 ± 0.4 cm). In addition, girth (average = 53.2 ± 5.6 cm) and femur length (average = 16.5 ± 1.6 cm) measurements were also taken. Through stepwise regression it was determined which measurements were important for predicting % body fat. Body weight was excluded from all models. The three models identified for predicting body fat, included: Equation 1) 24.99 + (9.12*back fat); R2 = 0.38; Equation 2) 24.13 + (0.72* girth) - (1.64*femur length); R2 = 0.39; Equation 3) 31.06 + (0.38*girth) - (1.43*femur length) + (6.73*back fat); R2 = 0.51. The results of this study indicate that ultrasound can be used to accurately predict body fat content in beagles.

Key Words: Dogs, Ultrasound, Body Fat

T80 Effects of feeding increasing levels of base excess on stool quality and output in dogs. R. M. Yamka*, K. G. Friesen, L. J. Kats, and T. G. Forster, *Hill's Pet Nutrition, Inc.*, *Topeka, KS*.

The objective of these studies was to determine the effects of feeding varying levels of base excess on stool quality and number of defecations (output). Seven foods varying in base excess (-107 to +62 meq) were fed to groups of 10 beagles (average age = 9.6 ± 2.0 years; average weight = 10.0 ± 1.2 kg) for a period of 7 days in order to determine the effect of base excess on stool quality and output. Base excess (in meq) was calculated as (Na + K + Ca + Mg) - (Cl + S + P). All foods were fed at maintenance level. Stool quality and output was determined daily. Stool quality was rated on a five point scale (5 = dry formed stool and 1 = unformed wet stool). The data from these stool studies

indicate that base excess is directly related to dog stool quality (R2 = 0.81) and to stool output or number of defecations (R^2= 0.69). Dogs fed foods with decreasing base excess (more positive) had higher stool scores and a reduction in total stool output. When formulating foods for dogs, base excess can be used to manipulate the type of feces desired. Foods with decreased base excess (positive) would be beneficial for increasing stool quality and foods with increased base excess (negative) could prevent constipation.

Key Words: Dogs, Stool, Base Excess

T81 Estimating intestinal protein digestion in the canine animal using a ruminant *in vitro* model. M. Thrune[1], M. D. Stern*[1], M. Ruiz-Moreno[1], and G. C. Fahey, Jr[2], [1]*University of Minnesota*, *St. Paul*, [2]*University of Illinois*, *Urbana-Champaign*.

An experiment was conducted to test the viability of using a modified three-step procedure for estimating intestinal crude protein in ruminants on intestinal digestion in the canine for a variety of dry kibble diets containing various protein sources. The original three-step *in vitro* procedure was developed to determine small intestinal crude protein digestion in ruminants. A modification of this published protocol was used in the present experiment, comparing measured values to *in vivo* values determined in experiments using dogs as the experimental animal. Nineteen different plant and animal by-product protein sources were used in this experiment: high protein corn (HP), high protein, low phytate corn (HPLP), high amylase corn (HA), conventional corn (CONV), amylomaize starch corn (AM), control (CON), 1% chicory (CH), 1% mannanoliogosaccharide (MOS), 1% chicory + 1% mannanoligosaccharide (CM), soy hull 1.86 (SH 1.86), soy hull 2.65 (SH 2.65), soy hull 3.17 (SH 3.17), soy hull 5.18 (SH 5.18), soy hull 7.21 (SH 7.21), beet pulp (BP), control (CONB), soybean meal (SBM), poultry meal (PM) and Profine-E (SPC2). Samples were exposed to a shaking water bath and a pepsin (1 hr, 38.6°C, pH=1.9)-pancreatin (24 h, 38.6°C, pH=7.8) enzymatic solution to mimic digestion in the small intestine. Simple regression analysis of *in vitro* protein digestibility versus *in vivo* protein digestibility was performed. *In vitro* intestinal protein digestion values were numerically similar ($P < 0.05$) to those measured *in vivo*, however there was not a high correlation between values ($r^2 = 0.41$). Results from this experiment do not substantiate the use of the *in vitro* intestinal ruminant protein digestion model to assess *in vivo* dietary crude protein digestibility in dogs.

Key Words: Canine, Intestinal Digestion, *In Vitro*

T82 The ameliorating effect of ascorbic acid on subacute sperm toxicity in male New Zealand White Rabbits treated with endosulfan. A. Ata, F. S. Hatipoglu, O. Y. Gulay*, and M. S. Gulay, *Mehmet Akif Ersoy University*, *Burdur, Turkey*.

Protective role of oral ascorbic acid (AA) was evaluated against changes in sperm parameters in New Zealand White (NZW) rabbits treated with endolsulfan. Rabbits (6 to 8 months old) were divided into four groups of six animals each. Rabbits in TRT-I served as control and received corn oil by oral gavage for 6 weeks. Rabbits in TRT-II received endolsulfan (1 mg/kg bw/day) in corn oil. TRT-III group received oral corn oil daily and ascorbic acid (AA; 20 mg/kg bw) every other day for 6 weeks. TRT-IV group received the same amounts of endosulfan and AA. Endosulfan alone significantly reduced the sperm count and motility and increased the presence of sperm with morphological problems ($P<0.01$). AA treatment showed significant amelioration on sperm count and motility decreased the presence of sperm with morphological problems when coupled with endosulfan ($P<0.01$). Ameliorations were up to control levels in all cases except for sperm motility. Data suggested that AA has beneficial influences in neutralizing the negative effects of endosulfan in the spermatologic parameters of NZW males.

Key Words: Ascorbic Acid, Endosulfan, Subacute Sperm Toxicity

T83 Subacute oral endosulfan toxicity in male New Zealand white rabbits. F. S. Hatipoglu*[1], M. S. Gulay[1], O. Y. Gulay[1], A. Balic[2], and S. Volkan[3], [1]*Mehmet Akif Ersoy University*, *Burdur, Turkey*, [2]*Sakarya State Hospital*, *Adapazari, Turkey*, [3]*Dunya Tip Center*, *Burdur, Turkey*.

The present study was conducted on 6 to 8 month old New Zealand white rabbits (9 rabbits per treatment group). Daily gavages of 3, 1.5, 0.75 or 0 mg endosulfan/kg resulted in the death of 5, 3, 0, and 0 animals, respectively, in each group of 9. All rabbits were monitored for any observable toxic symptoms throughout the experimental period (30 d) and they were also weighed weekly to monitor body weight gain. Nervine symptoms like tremor, head down condition and torticolis were noticed only for few minutes before death. All deaths occurred within the first 3 weeks. Some alteration had been recorded in hematological parameters within the groups (hemoglobin, packed cell volume, and total erythrocyte count) due to endosulfan exposure. Serum alkaline phosphatase (ALP) and aspartate aminotransferase (AST), but not Alanine aminotransferase (ALT), levels were significantly elevated in the 3 mg/kg dose group. Gross postmortem and histopathological changes in various organs (lung, liver, kidney, and testes) of rabbits treated with endosulfan were typical to dose dependent organochlorine insecticide toxicity signs. Thus, although some animals appear to adjust to relatively high daily doses of endosulfan, biochemical and histological evidence indicates varied liver and kidney damage according to dosage administered in these animals. Current subacute study suggested in a "no-observed-effect-level" of 0.75 mg endosulfan/kg in New Zealand white rabbits.

Key Words: New Zealand White Rabbits, Subacute Oral Endosulfan Toxicity, Blood Parameters

T84 Effects of feedborne Fusarium mycotoxins with and without a polymeric glucomannan mycotoxin adsorbent on body weight, feed intake, serum chemistry, and nutrient digestibility of mature beagles. M. C. K. Leung, T. K. Smith*, N. A. Karrow, and H. J. Boermans, *University of Guelph*, *Guelph, ON, Canada*.

There have been several mycotoxin outbreaks involving commercial cereal-based dog food in the recent years. While acute aflatoxicosis in dogs is frequently reported and studied, little canine research has been devoted to Fusarium mycotoxins which are commonly found in temperate regions, including Canada and United States. An experiment was, therefore, conducted (1) to investigate the effects of feeding

cereal-based diets naturally contaminated with a combination of Fusarium mycotoxins to dogs and (2) to test the efficacy of a polymeric glucomannan mycotoxin adsorbent (GMA) in prevention of Fusarium mycotoxicosis. Twelve mature beagle females averaging 10.1 ± 1.1 kg of body weight and 2.8 ± 1.6 years of age were assigned to one of three diets for 14 days in a 3 × 3 Latin square design. The diets included (1) control, (2) contaminated grains, and (3) contaminated grains + 0.2% GMA (Mycosorb, Alltech Inc., Nicholasville, KY). The two contaminated diets averaged 3.3 mg deoxynivalenol, 0.3 mg 15-acetyl deoxynivalenol, 0.4 mg zearalenone, and 9.2 mg fusaric acid per kg feed. Feed intake and body weight of dogs fed the contaminated diet were significantly reduced compared to controls. Reductions in serum concentrations of total protein, globulin, fibrinogen, alkaline phosphatase, and amylase were also detected ($P < 0.05$). The feeding of GMA did not ameliorate the effects of the Fusarium mycotoxins. Dogs fed the contaminated diet + GMA had higher digestibility of carbohydrate, protein and lipid as compared to controls, possibly due to physiological adaptation to reduced feed intake. It was concluded that the feeding of grains naturally contaminated with Fusarium mycotoxins can adversely affect feeding behavior and metabolism of dogs. The protective efficacy of GMA, however, was not seen at the current level of dietary inclusion.

Key Words: Dog, Fusarium Mycotoxin, Glucomannan Mycotoxin Adsorbent

T85 Prevalence of gastrointestinal parasites in dogs housed at the Animal Protection Association of Culiacan, Sinoloa. M. C. Rubio Robles*, S. M. Gaxiola, N. Castro, I. Padilla, J. Raygoza, E. D. Vega, F. Valdez, and B. A. Zazueta, *Universidad Autonama de Sinaloa*, *Culiacan, Sinaloa, Mexico*.

The objective of this work was to determine the prevalence of gastroenteric parasites in dogs housed at the animal protection association of Culiacán, Sinaloa. A representative sample with both sexes and cradle described by the technique of Thrusfield (1995) was used: n=[t*SD/L]2. Where n = sample size, t = value of the normal distribution (Student t) for a 95% confidence level (t = 1.96), L = accepted error or precision (5%), and SD = weighted disease prevalence (%). On the basis of the technique described, the total number of sample animals determined for random sampling was 25. For each dog feces were collected rectally by digital stimulus into previously identified plastic bags. The samples were transported under refrigeration at 4°C to the Parasitology Laboratory of the FMVZ-UAS, and processed by the flotation technique with sugar solution. The results indicate that of the data from the 25 dogs analyzed 12(48%) were positive for gastrointestinal parasites, with the following distribution: Isospora canis 4 (16%), Giardia spp., 3 (12%), Ancylostoma caninum 3 (12%), Dipylidiun spp. 2 (8%). This is a considerable number and proportion of animals testing positive continues to be an issue of importance in the local community because frequently these dogs are adopted and taken to different points throughout the city with new pet owners that are not informed about parasitisms afflicting these animals. Further, these adopted dogs can serve as vectors for the transmission of parasites to the broader community if left untreated.

Key Words: Parasites, dog, Prevalence

Contemporary & Emerging Issues - Livestock and Poultry

T86 Survey of *Clostridium septicum* isolated from market-age turkeys with cellulitis. T. Neumann*, D. Karanakarun, and T. Rehberger, *Agtech Products, Inc.*, *Waukesha, WI*.

Subcutaneous clostridial infections have become increasingly problematic for poultry producers in the United States. One of the most commonly implicated organisms is the anaerobic, spore-forming bacteria *Clostridium septicum*. Although poorly understood, *C. septicum* is regarded as the causative agent of atraumatic myonecrosis. Cellulitis is a disease of turkeys that is similar in its presentation to gangrenous dermatitis in broilers. Symptoms include severe necrosis of the subcutaneous tissues of the abdomen and inner thighs accompanied by edema and gas production. The disease occurs most often with no identifiable loss in the skin's integrity. This survey was conducted to gain a better understanding of the prevalence and diversity of *C. septicum* on endemic disease farms. A total of 189 tissue samples from turkeys suspected to have died from cellulitis were received from 62 endemic cellulitis farms. Turkeys sampled came from producers located in five states; Missouri (MO), Wisconsin(WI), Virginia(VA), North Carolina(NC) and Minnesota(MN). Isolates of *C. septicum* were cultured anaerobically on TSC agar and identified by PCR. DNA fingerprints of the isolates were generated by RAPD PCR. A family tree was constructed from the fingerprints to examine relationships among the strains. *C. septicum* was identified on 69.35% of the farms sampled. The prevalence in MO, VA and NC was 80% (24/30), 80% (8/10) and 100% (6/6) respectively. Only three WI farms out of thirteen sampled tested positive for *C. septicum*. Two out of three MN farms tested were positive. It is probable that the prevalence is actually higher than what is reported here due to low sample size from a number of farms. Interestingly, the WI farms sampled had a substantially lower prevalence of *C. septicum* than the other four states (23.1% vs. 81.6%). Field observations indicated a less severe manifestation of the disease at these WI farms, and most farms sampled (76.9%) were positive for *Clostridium perfringens* in examined tissues. Also interesting was the identification of two unique subtypes of C. septicum, one found in VA and NC and the other predominant in the Mid-West.

Key Words: Clostridium, Cellulitis, Turkeys

T87 Assessment of clostridial challenges present in asymptomatic birds raised in a commercial broiler facility. S. Dunham*[1], J. A. Smith[2], and T. Rehberger[1], [1]*Agtech Products, Inc.*, *Waukesha, WI*, [2]*Fieldale Farms Corporation*, *Baldwin, GA*.

Gangrenous dermatitis (GD) is a reemerging acute bacterial disease of poultry that causes necrosis of the skin, abdominal subcutaneous tissue, and underlying musculature that progresses rapidly. With mortality reaching as high as 1% each day for up to two weeks, GD is a significant concern for poultry producers throughout the U.S. *Clostridium* species, specifically *C. perfringens* and *C. septicum*, are the most common causative agents isolated from skin lesions

associated with GD. The objective of this study was to assess the clostridial challenges present in asymptomatic broilers raised under different feeding regimes: a conventional program, including non-endemic and endemic GD sites, and an antibiotic free (ABF) program. Three birds from seven different flocks from each of the three groups were sampled at approximately five weeks of age to obtain gastrointestinal tract (GIT), liver, and spleen samples from 63 total birds. The samples were plated on selective media and multiplex PCR was performed to verify toxigenicity. Of the total birds sampled in each group, 33.3% from the conventional GD broilers, 19.0% from the conventional non-endemic broilers, and 38.1% from the ABF broilers were positive for toxigenic *C. perfringens* but not for *C. septicum*. All livers and spleens were negative for known toxigenic *Clostridium*. RAPD PCR was performed on the *C. perfringens* isolates and used to construct a dendrogram to determine genetic diversity. Isolates from different birds within a site, as well as isolates from different sites in the same program showed genetic relatedness, however, no clear correlation could be made to identify pathogenic lineages. The most notable finding in this study was that an unidentifiable anaerobic gram positive rod-shaped organism, possibly a unique toxigenic *Clostridium* species was found in 28.6% of endemic GD birds, 23.8% of nonendemic birds, and 14.3% of ABF birds. Future research will focus on obtaining samples of live birds with symptoms of GD from endemic sites to determine if this unknown organism is involved in GD disease.

Key Words: Poultry, *Clostridium*, Broilers

T88 Prevalence of unusual viral RNA, enteropathogens, Cryptosporidia in poultry litter, pig wastes and waterways of Ireland and their impact on environmental health. J. R. Rao*[1,2], D. W. A Nelson[2], L. Xiao[3], M. Matsuda[4], T. Sekizuka[4], C. J. Lowery[6], J. S. G. Dooley[6], B. C. Millar[5], P. J. Rooney[5], and J. E. Moore[5], [1]*Environmental and Public Health Microbiology Unit, Agri-Food & Biosciences Institute*, *Belfast, Northern Ireland, UK*, [2]*The Queen's University of Belfast*, *Belfast, Northern Ireland, UK*, [3]*Division of Parasitic Diseases, Centers for Disease Control and Prevention*, *Atlanta, Georgia*, [4]*Laboratory of Molecular Biology, School of Environmental Health Sciences, Asabi University*, *Fuchinobe, Sagamihara, Japan*, [5]*Northern Ireland Public Health Laboratory, Department of Bacteriology, Belfast City Hospital*, *Belfast, Northern Ireland, UK*, [6]*School of Health and Life Sciences, University of Ulster*, *Coleraine, County Londonderry, Northern Ireland*.

Contaminated straw and water used in the poultry houses were among the most likely sources suggested for the entry of viruses including highly pathogenic H5N1 (AIV) in France or Germany. We found (see review Rao et al 2007 CIMB, 9: 103-122) that mushrooms and substrate composts (raw ingredients straw and poultry litter) carried unusual compendium of dsRNAs associated with mushroom virus (X). In Ireland, a viable option for disposal of raw or composted animal agriculture farm waste is land spreading as a cheap nutrient supplement but many are unaware of the silent dangers of pathogen spreading from this practice. Our results indicated that a number of novel eubacteria together with faecal parasites (e.g. Cryptosporidium spp) and some complex viral RNA components were prevalent in mostly wet straw / compost wastes arising from poultry litter and slurry or slurry solids from pig farms, particularly of those located in the vicinity of the mouth of rivers. Our model study was carried out in Lough Neagh, County Antrim, Northern Ireland as it enters into the province's largest watercourse, a niche for flocks of mute swans (Cygus olor) from north-western continental Europe which are partially migratory or nomadic. The migratory bird populations inhabit surface waters, including rivers, ponds and lakes. Following varying degrees of water treatment, the water is utilized for t animal production, particularly poultry and/or pig farms; the Lough itself is frequently used for recreational purposes, including wind-surfing and water/jet-skiing. We also report our findings on the potential risk of avian carriage of viral elements, bacteria or parasitic faecal pathogens and emerging zoonoses that could be potentially transmitted via poultry dwellings in contact with the water and the impending risk to plant, animal and human health.

Key Words: Unusual Viral RNA, Enteropathogens, Avian Influenza

T89 The impact of fat reduction on flavor and flavor chemistry of Mozzarella cheeses. A. J. Krause*, R. E. Miracle, J. P. Evans, and M. A. Drake, *North Carolina State University*, *Raleigh*.

Mozzarella cheese is available on the market in whole milk, part-skim milk, and fat-free varieties. Fat-free Mozzarella lacks the milkfat flavor and richness of its whole and part- skim milk counterparts. It has been theorized that lactones may be responsible for the delicate sweet aromatic flavor in full fat Mozzarella cheeses and their addition to lower fat cheeses could produce more desirable flavors. In this study, the sensory profiles and volatile compounds in all three types of Mozzarella cheese were characterized. Whole milk, part-skim, and fat-free Mozzarella cheeses were obtained from a commercial supplier on multiple occasions. Cheeses were evaluated by a trained descriptive panel and by instrumental volatile analysis. For instrumental analysis, volatiles were extracted by solid phase micro-extraction (SPME) and solvent extraction followed by solvent assisted flavor evaporation (SAFE). SPME samples were injected on a gas chromatograph with mass spectrometry detection (GC-MS). Duplicate samples extracted with diethyl ether and concentrated were evaluated by subsequent GC–olfactometry and GC–MS with aroma extract dilution analysis (AEDA). Compounds were identified by retention index, aroma of reference compounds and mass spectra. The mozzarellas were differentiated by both sensory and instrumental volatile analyses ($p<0.05$). Descriptive panelists differentiated the full fat, part-skim and fat-free cheeses by the attributes cooked, milkfat, and sour taste. Fat free cheeses lacked milkfat flavor and exhibited lower cooked flavor and sour taste when compared to the other cheeses. Volatile flavor compounds that differed significantly ($p<0.05$) among the cheeses included: esters, sulfur compounds, and lactones which corresponded to the main flavor variables from the trained panel. Direct injection of solvent extracts showed higher levels of delta lactones in whole milk cheese versus part-skim or fat-free product. These results suggest that lactones contribute to the characteristic sweet aromatic flavor of whole milk Mozzarella cheese.

Key Words: Mozzarella, Flavor Chemistry, Flavor

T90 Fate of lysostaphin in milk through the cheesemaking process. D. L. Van Hekken*[1], R. J. Wall[2], G. A. Somkuti[1], and P. M. Tomasula[1], [1]*USDA-ARS*, *Wyndmoor, PA*, [2]*USDA-ARS*, *Beltsville, MD*.

Transgenic cows secreting over 3 µg lysostaphin/mL milk are usually resistant to mastitis caused by *Staphylococcus aureus*, but it is unclear if active lysostaphin will persist through dairy processing steps or impact the production of fermented dairy foods. The objective of this study was to determine the fate of lysostaphin as milk is pasteurized and then processed into cheese. Raw milk from transgenic cows was heat treated at 63°C for 30 min, 73°C for 15 sec (HTST), and 135°C for 2 s. Only the HTST milk was processed into a semi-hard cheese. Aliquots were taken at each processing step and assayed to determine the quantity (ELISA) and activity (ability to inhibit S. aureus growth) of lysostaphin. Results indicated that the majority of the lysostaphin was present in the skim milk portion and was not affected by pasteurization. Although the quantity and activity of the lysostaphin decreased during cheesemaking, active lysostaphin was present in the whey and cheese, even after 90 d of 4°C aging. Because lysostaphin is not a natural milk constituent, further research is required to evaluate its potential as a bioprotective agent against staphylococci and its impact on food quality.

Key Words: Cheese, Milk, Transgenic Cows

T91 Effects of High Pressure Processing on the reduction of *Listeria monocytogenes* in the manufacture of soft cheeses. C. P. Rodriguez*[1], E. Patazca[1], and J. E. Schlesser[2], [1]*National Center for Food Safety and Technology-Illinois Institute of Technology*, *Summit-Argo, IL*, [2]*National Center for Food Safety and Technology-FDA*, *Summit-Argo, IL*.

During the ripening or storage of soft cheeses food borne pathogens may survive and grow due to the high moisture content and increase in pH during aging. High pressure processing (HPP) has been proposed as an alternative to heat treatment for the reduction of pathogens in the manufacture of soft cheese. Possible advantages of HPP of cheese would include reduction of pathogens levels without affecting cheese aging. The effectiveness of HPP to reduce *L. monocytogenes* on Camembert cheese was evaluated. Camembert cheese was inoculated with a cocktail of 5 *L. monocytogenes* strains (903, 1364, 1446, Scott A and OSY 8578). Samples were tested at various levels of high pressure, processing time and final temperature. Cheese samples (~35g) were immersed in the *L. monocytogenes* cocktail, drained, and packed in high barrier nylon/EVOH/PE vacuum pouches with a double seal. Samples were triple bagged. Quality assessment was determined by analyzing untreated uninoculated whole cheeses for texture, color and regrowth of mold mycelium. Cheese samples treated at 400 to 500 MPa, 25°C for 2 to 5 min resulted in less than $1\log_{10}$ reduction in levels of *L. monocytogenes*. HPP at 600 MPa, 25°C and 45°C for 2 to 5 min and HPP at 700 MPa, 35°C for 5 min resulted in a 4 to $5\log_{10}$ reduction in levels of *L. monocytogenes*. A 5 or more $\log_{10}$ reduction was observed at 700 MPa HPP levels for 5 min at 25°C and 45°C. Whole camembert cheeses were pressure treated at 600 MPa for 2 min at 25, 35 and 45°C to conduct preliminary quality assessment of Camembert cheese after HPP. The HPP Camembert cheese seemed more dense and firmer in texture. Mold mycelium destruction resulted in loss of white color of the surface of the cheese. No change in flavor was noted. Experiments were conducted on Camembert cheese to determine optimal conditions for the reduction of *L. monocytogenes* after HPP. A $5\log_{10}$ reduction level of Lm was observed on cheese samples pressure treated at 600 to 700 MPa for 2 to 5 min.

Key Words: Listeria Monocytogenes, Soft Cheese, High Pressure Processing

T92 Sensory and instrumental classification among Ragusano P.D.O cheeses of different quality. S. Carpino*[1], I. Caminiti[1], T. Rapisarda[1], and G. Licitra[1,2], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*D.A.C.P.A. Catania University*, *Catania, Italy*.

Sensory and instrumental profiles of ripened Ragusano cheeses (three to seven months), representing 100 batches produced during the 2006 season, from different farms throughout the P.D.O. production area in Sicily were measured. The current study was undertaken to determine if sensory and instrumental analysis discriminate different qualities, gold quality ($Q \geq 90$) and good quality ($Q < 90$) of the tested cheeses. The cheeses were tested using a MS-based Electronic Nose (EN) and a trained sensory panel. EN data were collected from a head space extraction of volatile organic components from each cheese. An EN was used to detect volatiles in the mass-to-charge (m/z) range of 10 to 160 amu. Statistical analyses on normalized data sets found a group of mid-range masses that efficiently separated cheeses by PCA. Twelve trained panelists tested all the products and QDA was used to describe the cheeses. A quality score (Q) was developed by comparing mean ratings on 14 descriptive attributes with means and standard deviations of 'gold' standard cheeses on the same attributes. Gold quality cheeses ($Q \geq 90$) had significantly lower salt content than good quality ones ($Q < 90$). Gold quality cheeses also had smaller surface holes, weaker in bitterness and bad taste and were more yellow and softer than their good-quality counterparts. Principal components analysis on the EN data separated all cheeses by quality score with an high gold cheeses axis on PC1 (57%) and a separation between good quality cheeses on PC2 (26%). Principal components analysis on the sensory data separated cheeses by quality score with a gold quality cheeses axis on PC1 (23%) and a separation between good quality cheeses on PC2 (16%) confirming the EN results for bitterness, taste, and aroma. Both EN and traditional sensory analysis found similar differences among cheeses. While EN technology is simpler and faster to use, especially if there are a lot of samples, the human perception is probably still superior in detecting subtle differences.

Key Words: Ragusano, Electronic Nose, Sensory analysis

T93 Changes in acidification during cheesemaking in relation to the aroma development of a farmstead cheddar cheese: A preliminary study. M. Almena*[1], P. Kindstedt[1], S. Carpino[2], T. Rapisarda[2], and G. Licitra[2,3], [1]*University of Vermont*, *Burlington*, [2]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [3]*D.A.C.P.A. Catania University*, *Catania, Italy*.

Among the reasons why farmstead cheeses are greatly appreciated by consumers are: their complex sensory quality, the close link to the environment where the cheese itself is produced, and the cheesemaker ability. Farmstead cheesemakers have to cope with greater changes in milk composition than commodity producers, and often their practices

are only based on experience rather than control processing techniques. However, the importance of controlling pH during cheesemaking is well known, as well as the major effect of pH on textural quality. This study explores how changes in the acidification pattern during cheesemaking affect the aroma development of a farmstead cheddar cheese. Five cheese fabrications were manufactured following 2 different acidification patterns. Two fabrications were made following an acidification pattern with pH values of 6.25 at draining and 5.25 at milling, and three with pH values of 6.40 at draining and 5.30 at milling. After pressing, all cheeses were analyzed for pH, salt and moisture; and after 1-year of ripening, aroma compounds were evaluated using both gas chromatography olfactometry analysis (GCO) and gas chromatography mass spectrometry. Young cheeses had similar physicochemical characteristics, with average values of 5.10 for pH; 35% moisture and 1.65% salt contents. Interestingly, the volatile compounds extracted from all the ripened cheeses were fairly similar, with the significant exception of acetic acid. Acetic acid (sour aroma) was only found on the 3 cheeses using the acidification model with higher pH values, indicating that post-acidification during manufacture occurred. Some of the common volatile compounds in all the samples and the sensory descriptors associated with were: dimethyl sulfide (sulfur/cabbage) – diacetyl (buttery) – thiophene (garlic) – ethyl butyrate (apple) – butanoic acid (cheese/butyric) – methional (potato) and 1-octen-3-one (mushrooms).

Key Words: Acidification Profile, Aroma, Farmstead Cheddar

T94 Texture profile analysis and melting in relation to proteolysis as influenced by aging temperature and cultures in Cheddar cheese. T. C. Rasmussen*[1], D. J. McMahon[1], J. R. Broadbent[1], and C. J. Oberg[2], [1]*Western Dairy Center*, *Logan, UT*, [2]*Weber State University*, *Ogden, UT*.

Changes in cheese physical properties during aging are related to proteolysis by coagulant type, culture enzymes and non-starter lactic acid bacteria. Storage temperature also affects aging rate. Cultures are important for flavor development, but less is understood about their role in melting and textural properties. Our objective was to make Cheddar cheese using different cultures, to age it at 5 and 15 C, and measure physical and proteolytic properties over 12 mo. Cheese was manufactured using Lactococcus lactis starter culture either alone or combined with one or both of lac- Lc. Lactis or Lactobacillus helveticus adjunct cultures. Three replicates of cheese were made using 682 kg milk. Cheese composition was 35.5 ± 1.0% moisture, 52.5 ± 2.5% FDB, 1.65 ± 0.05% salt, and pH 5.2 ± 0.1. All cheeses were initially stored at 5 C, then half moved to 15 C after 21 d. Texture profile analysis was performed using 25% and 60% compression and melting measured using a Meltmeter at 60 C. The data were analyzed based on culture and temperature over 12 mo storage time. The overall hardness decreased, while the cohesiveness decreased for all treatments. Extent of melting was correlated with hardness ($R = 0.62$, $P < 0.0001$), cohesiveness ($R = 0.40$, $P < 0.0001$), and inversely with adhesiveness ($R = 0.24$, $P < 0.0001$). Correlations with adhesiveness and cohesiveness were not linear. Proteins were extracted from cheese at 1 wk, 1, 2, 4, 6, 9 and 12 mo of aging using 0.5 M sodium citrate solution containing 1% NaCl. Purified extracts were then applied to an HPLC C8 reverse phase column and large hydrophobic peptides and protein peaks monitored at 214 nm. Melting was inversely correlated with the amount of intact α_{s1}-casein remaining in the cheese ($R = -0.54$, $P < 0.0001$) and directly correlated with a peak assigned to α_{s1}-casein (f 24 – 199) peptide ($R = 0.56$, $P < 0.0001$).

Key Words: Cheese Ripening, Melting, Proteolysis

T95 Strategies for the manufacture of low fat Cheddar cheese. S. P. Adams*[1], D. J. McMahon[1], J. R. Broadbent[1], S. L. Larsen[1], and M. Drake[2], [1]*Western Dairy Center*, *Logan, UT*, [2]*SouthEast Dairy Foods Research Center*, *Raleigh, NC*.

Common problems with low fat cheeses include lack flavor and hard and rubbery texture. This has limited market growth for low fat cheeses. Our objective was to make interventions that would improve low fat Cheddar cheese quality, by increasing moisture content and altering physicochemical properties. These interventions included, changes to the make-procedure in cooking temperature, increasing pasteurization temperature from 72 C to 85 C to denature whey proteins, homogenizing half the milk at 5.5 MPa to incorporate fat globules into the protein matrix, and pre-acidifying milk to pH 6.3 to reduce calcium content. These modifications were initially studied individually using milled and washed curd techniques. Cheese was made from 160 kg milk standardized to 0.5% fat and a 9-kg block of cheese produced. Cheeses with 52 to 54% moisture and pH 5.15 to 5.25 were preferred, and the inclusion of a cold water curd wash step helped achieve this goal. Higher pasteurization temperature and pre-acidification had beneficial effects but homogenization did not improve cheese appearance or texture. A 2x2 factorial experiment was then undertaken to compare pasteurization temperature and preacidification. Cheeses were stored at 6 C for 1 mo and analyzed by texture profile analysis. Descriptive sensory analysis of flavor was performed after 2 mo using a trained panel. Higher pasteurization temperature significantly increased moisture by 4% and subsequently decreased instrumental hardness ($p = 0.024$) and cohesiveness ($p = 0.001$). Preacidication increased instrumental cohesiveness ($p = 0.002$). No change in meltability was observed between the cheeses. Compared to full fat cheese made with the same cultures, the low fat cheeses had more intense cooked flavor, whey flavor, diacetyl flavor and sulfur flavors. They had less milkfat (lactone) flavor. The cheeses made from milk heated to 85 C had a slight rosy flavor.

Key Words: Low Fat Cheese, Preacidification, Flavor

T96 Prato and Roquefort cheeses from dairy ewes fed with protected fat. R. M. S. Emediato*, E. R. Siqueira, M. M. Stradiotto, M. I. F. B. Gomes, S. A. Maestá, A. Piccinin, E. O. Queiroz, and C. Móri, *São Paulo State University*, *Botucatu, São Paulo, Brazil*.

This trial aimed to evaluate the effect of the milk from Bergamasca ewes fed with inclusion of 3.5% of protected fat in the concentrate on cheese yield, cheese composition, its caloric value and acceptation index of Prato (typical Brazilian cheese) and Roquefort (typical French cheese) cheeses. Seventy seven ewes allocated in 2 groups according to parturition and age: Control (C) and protected fat (PF). Diets were isoenergetic and isonitrogenous, containing 16% CP and 70% TDN on a dry-matter basis. For both treatments it was used the mixed milk production system (lambs housing at night and with its mothers after milking at morning) with one daily milking. Lambs were weaned with

45 days of age. Milked milk was identified and frozen at -15°C for a period of 3-6 months and then used for cheese manufacture. For Prato cheese, each replication has represented milk from each fortnight of the experimental period (60 days) and for Roquefort cheese, each replication has represented milk from the whole experimental period. After cheeses ripening, it was calculated cheese yield and samples were collected for cheese composition and caloric value. Acceptation index was performed with at least 50 people for each cheese. Statistical analysis was performed by means of SAEG 9.0 software. For Prato cheese, treatment C have presented higher protein content and caloric value (26.64 vs 24.60% and 364.52 vs 359.52 Kcal/100g, respectively) and lower fat content (17.82 vs 19.46%) than PF. For Roquefort cheese, treatment PF have presented higher humidity and fat content (49.58 vs 46.83 and 13.40 vs 11.80, respectively) which resulted in higher cheese yield (6.51 vs 7.34 liters of milk/kg of cheese) than C. Both cheeses from both treatments have presented acceptation index higher than 70%, which represented a good acceptation. The fat content in the Roquefort cheese was lower than the usual, which can be explained by lower milk fat content during suckling period than the weaned period (2.25 vs 7.75%, respectively). Mixed Protected fat increases cheese composition and yield without modify its acceptation, which is interesting for cheeses producers and industry.

Key Words: Acceptation Index, Prato, Roquefort

T97 Optical measurement of kinetic changes in curd moisture content and whey fat concentration during syneresis in cheese manufacturing. M. Castillo*[1], C. C. Fagan[2,1], F. A. Payne[1], C. P. O'Donnell[2], and D. J. O'Callaghan[3], [1]*University of Kentucky*, *Lexington*, [2]*University College Dublin*, *Ireland*, [3]*Moorepark, Teagasc*, *Cook, Ireland*.

Syneresis is crucial in cheese making and exerts a tremendous impact on the final quality attributes of cheese. Currently, no technologies are available to control curd moisture content on-line and, as a result, syneresis is empirically controlled. The regulation of curd moisture actually requires control of milk coagulation, cutting time and syneresis. A novel light scatter sensor technology, which is able to monitor milk coagulation and curd syneresis using just one sensor, was used to study the kinetics of changes in curd moisture and whey fat contents induced by curd shrinkage in a stirred, pilot-scale cheese vat. A three-factor, randomized, central composite design (20 runs and three replicates) were used to evaluate the effect of temperature, $CaCl_2$ and cutting time on the kinetics of syneresis. We hypothesized that the varying response of the sensor during syneresis may be a result of curd shrinkage or compositional changes in whey fat content. It has been widely documented that curd shrinkage, whey separation, and fat globules dilution follow a first order kinetic reaction. Thus, the changes in curd moisture and whey fat contents and in the sensor response (R) during syneresis were fitted to first order kinetic equations. The R^2 values between the experimental and fitted data for curd moisture content, whey fat concentration, and R ranged between 0.95-0.97, 0.98-1.00, and 0.87-0.96, respectively. The magnitude of the kinetic rate constants obtained agreed with the existing literature and the rate constants responded consistently to temperature. These results suggest that changes in the variables studied during syneresis followed first order kinetics. Indeed, the optically derived kinetic rate constants were significantly and positively correlated with the kinetic rate constants for changes in curd moisture and whey fat contents. These results clearly show not only the potential of the proposed technology for a comprehensive control of curd moisture content in cheese making but also reveals its potential as a powerful research tool to study coagulation and syneresis.

Key Words: Syneresis, Kinetics, Light Backscatter

T98 Effect of high fat supplements for grazing dairy cows on textural properties of Cheddar cheese. R. Nyoka*, A. R. Hippen, A. N. Hassan, and K. F. Kalscheur, *South Dakota State University*, *Brookings*.

Previous studies showed that grazing on pasture and feeding diets supplemented with fish meal increased the level of conjugated linoleic acid (CLA) and its related isomers in cow's milk. The objective of this study was to determine the effects of such diets on the textural characteristics of Cheddar cheese. The diets of 27 multiparous Holstein (18) and Brown Swiss (9) cows grazing alfalfa/grass pasture were supplemented with partial Total Mixed Rations (pTMR) containing 1) dried distillers grains with solubles (DDG), 2) soybean meal (SB), or 3) fishmeal (FM). Milk was collected from morning milking and stored at 4°C for cheese making the following day. Cheddar cheese was manufactured from pasteurized milk (heated at 63°C for 30 min, and then cooled to 31°C) standardized to casein: fat ratio of 0.78. Moisture, fat, free oil and pH were tested in the fresh Cheddar cheese. No significant differences in moisture, pH and fat on dry matter basis were observed among treatments. Free oil was higher ($P<0.05$) in the DDG (17.78%) and FM (17.59%) cheeses than in the control Soybean cheese (15.78%). Cheese texture, free oil, and pH were monitored during ripening. Texture attributes (hardness, springiness, cohesiveness, gumminess and chewiness) decreased ($P<0.05$) during the first mo of ripening. Whereas, hardness, gumminess and cohesiveness continued to decrease between mo 1 and 3, an increase in chewiness and springiness was observed in all cheeses during this period. There were no significant differences among treatments in all cheese texture attributes. In conclusion, this study shows that diets that increase the level of CLA in milk did not affect cheese texture.

Key Words: High Fat Diets, Cheddar Cheese, Texture

T99 Evaluation of chemical composition of traditional Chinese goat's milk cake. H. Zhang*[2], S. Gokavi[1], C. Maduko[3], Y. Park[3], and M. R. Guo[1], [1]*University of Vermont*, *Burlington*, [2]*Inner Mongolia University*, *Huhott, China*, [3]*Fort Valley State University*, *Fort Valley, GA*.

Goat's milk cake is a fresh cheese-like product, which has been traditionally produced and consumed for centuries in the Southwestern province Yunnan of China. It is made by acidifying the milk using natural acidulant extracted from the leaves and vines of *Marsdenia tenacissima*. Thirteen milk cake samples collected from different households were analyzed for gross composition, mineral content protein and fatty acid profiles. The pH value ranged from 4.08+0.02 to 6.51+0.01, total solids 42.41+0.14 to 52.53+0.10%, fat 19.75+0.32 to 28.40+0.31%, protein 17.93+0.07 to 21.56+0.77%, ash 1.66+0.00 to 2.07+0.04% and lactose 0.91+0.36 to 1.52+0.33%. The average contents of calcium, phosphorous, potassium, magnesium, sodium, zinc and sulphur are 0.58, 0.50, 0.12, 0.03, 0.03, 0.002 and 0.16 g

/100 g, respectively. The major proteins identified by sodium dodecyl sulphate polyacrylamide gel electrophoresis were caseins (35.35+5.44 – 60.37+5.61%), β-lactoglobulin (7.41+1.18 – 10.50+2.13%) and α-lactalbumin (3.65+1.48 – 6.87+1.00%) and their amounts were comparable to those of cow's milk (casein 57.00+6.36%, β -lactoglobulin 10.80+0.42% and α-lactalbumin 6.41+0.44%). Gas chromatography analysis showed that the major fatty acids present in goat's milk cake were butyric acid (C4:0), caproic (C6:0), capric (C10:0), lauric (C12:0) and myristic acid (C14:0). The only unsaturated fatty acid present in significant amount was oleic acid (C18:1) (5.47+0.24 – 12.97+3.32%). Variations in chemical composition of these goat's milk products might due to lack of manufacturing standard, which may require further studies.

T100 Development of cholesterol-reduced Camembert cheese made by crossliked β-CD cyclodextrin. K. H. Seon, E. K. Hong, and H. S. Kwak*, *Sejong University*, *Seoul, Korea*.

The present study was carried out to examine the physicochemical and sensory properties in cholesterol-reduced Camembert cheese made by crosslinked β-cyclodextrin (β-CD). The composition of Camembert cheese treated by crosslinked β-CD was similar to the control and the cholesterol removal reached 90.6%. No significant difference was found in total amount of short-chain free fatty acids between experimental cheese and control at every storage period. The release of butyric and capric acid mostly contributed to the increase of total amount of short-chain free fatty acids in both groups. The cheese made by β-CD-treated cream produced similar amount of individual free amino acids to control in 4 wk ripening period. All rheological properties increased continuously during 4 wk ripening and those were higher in cholesterol-reduced Camembert cheese than those in control. Moldy characteristic in appearance, flavor and taste were increased dramatically through ripening period in both experimental and control cheeses. Based on these results, no profound difference was found in most physicochemical and sensory properties between cholesterol-reduced Camembert cheese and control. Therefore, this study may suggest the possibility to develop the cholesterol-reduced Camembert cheese using crosslinked β-CD.

Key Words: Camembert Cheese, Crosslinked β-CD, Cholesterol Removal

T101 The effect of salt on chemical and sensory attributes in cholesterol-reduced Cheddar cheese made by crosslinked β-cyclodextrin. K. H. Seon, E. K. Hong, and H. S. Kwak*, *Sejong University*, *Seoul, Korea*.

This study was designed to examine the effect of salt on the quality of cholesterol-reduced Cheddar cheese, which was resulted in changes in fatty acids, bitter amino acids and sensory evaluation. The sample cheeses were made by cream separation followed by 10% of crosslinked β-cyclodextrin(β-CD) treatment, and various concentrations of salt added were 1.0, 1.5, 2.0, 2.5 and 3.0%. The samples were tested periodically during 9 week ripening time. In previous study in our lab the ripening time was accelerated extensively in β-CD treated Cheddar cheese making. The cholesterol removal from the cheese was 91.7%. The production of short-chain free fatty acids(SCFFA) increased during ripening. When the contents of salt were added more into the cheese, the amounts of SCFFA significantly decreased during ripening. Higher salt-added cheese produced lower levels of bitter amino acid during ripening. In sensory analysis, the score of bitterness also showed lower levels from higher salt-treated sample. Hardness scores in texture increased during ripening in all samples, however, the levels were lower at higher contents of salt. On the basis of the results, this study suggested that higher levels of salt-treated Cheddar cheese made from crosslinked β-CD improved bitterness and sensory aspects.

Key Words: Cheddar Cheese, Salt, Crosslinked β-Cyclodextrin

T102 The effect of high pressure and low temperature on chemical properties and nutrients in milk. H. Y. Kim, S. A. Maeng, S. H. Kim, and H. S. Kwak*, *Sejong University*, *Seoul, Korea*.

This study was carried out to investigate the effect of pasteurization treated by high pressure and low temperature on chemical properties and nutrients in milk. The factors used were pressure(200MPa), temperature (-4, 4, 12 and 20°C) and time (10, 20 and 30 min). Thiobarbituric acid value(TBA) showed higher at longer time(30 min) and higher temperature(20°C). In the production of short-chain free fatty acid, samples were not different from treated time and low temperatures, however, significantly($P<0.05$) different from high temperatures(12 and 20°C). The productions of free amino acids in the samples were higher than that of control, and they were increased in proportion to treated time and temperature. In the analysis of water-soluble vitamin, L-ascorbic acid, niacin and riboflavin decreased significantly in proportion to treated time and temperature, however, pyridoxine and thiamine did not decrease significantly($P<0.05$). Based on the results of this study, short time and low temperature are effective on properties and nutrient in pasteurized milk treated by high pressure and low temperature.

Key Words: High Pressure, Milk, Vitamin

T103 Microencapsulation of Korean mistletoe extract with polyacylglycerol monostearate. N. C. Kim[1], J. B. Kim[2], J. Ahn[1], and H. S. Kwak*[1], [1]*Sejong University*, *Seoul, Korea*, [2]*Handong Global University*, *Pohang, Korea*.

The present study was carried out to find the optimum conditions for Korean mistletoe extract microencapsulation and its stability in simulated fluids in vitro. As a coating material, polyacylglycerol monostearate (PGMS) was used. Three different conditions were investigated such as the ratio of coating to core materials, amount of distilled water addition and spray pressure. The highest efficiency of microencapsulation was found in the ratio of 15:1 (w/w) as coating to core material. In addition, 40 mL of distilled water addition at 2000 psi spray pressure increased the microencapsulation efficiency up to 78.3%. The shape of microcapsule was spherical and irregular, and the average size was about 30.0Î¼m. In vitro study, only 14.8% of Korean mistletoe extract was released in stimulated-gastric fluid (pH 2) for 60

min incubation. Comparatively, the release of Korean mistletoe extract increased dramatically from 15.8% (0 min) to 83.2% (pH 8) for 60 min incubation in simulated intestinal fluid. Therefore, this study indicated that PGMS cane be used as an effective coating material to microencapsulate Korean mistletoe extract

Key Words: Microencapsulation, Polyacylglycerol Monostearate, Korean Mistletoe Extract

T104 Microencapsulated Korean mistletoe extract for milk fortification. N. C. Kim[1], J. B. Kim[2], J. Ahn[1], and H. S. Kwak*[1], [1]*Sejong University*, *Seoul, Korea*, [2]*Handong Global University*, *Pohang, Korea*.

This study was designed to develop a microencapsulated Korean mistletoe extract that could be used to fortify milk and to determine the sensory properties of milk fortified with microencapsulated Korean mistletoe. Coating material was polyacylglycerol monostearate. The highest efficiency of microencapsulation was 78.3% with 15:1:40 ratio (w/w/v) as coating to core materials to distilled water at 2,000 psi. When microencapsules were added and stored at 5°C for 12 days, 8.3 mg of Korean mistletoe extract was released in 100 mL milk. The TBA value was increased during storage and was significantly lower in capsulated group compared with that in uncapsulated group. In addition, the color values (L, a and b) viscosity were significantly different between capsulated and uncapsulated Korean mistletoe extract added groups when 1 or 2% Korean mistletoe extract added. With 1% microencapsulation addition, most sensory aspects were slightly different between capsulated and control, however, a significant difference was found between capsulated and uncapsulated groups in all storage periods. The present study indicated that the addition of microencapsulated Korean mistletoe extract with PGMS is effective for fortifying milk.

Key Words: Korean Mistletoe, Milk, Microencapsulation

T105 Occurrence of aflatoxin M1 in Manchego cheese. G. Battacone*[1], M. I. Berruga[2], M. Palomba[1], M. P. Molina[3], M. Roman[4], and A. Molina[2], [1]*Università degli Studi di Sassari*, *Sassari, Italy*, [2]*Universidad de Castilla-La Mancha*, *Albacete, Spain*, [3]*Universidad Politécnica de Valencia*, *Valencia, Spain*, [4]*Qualiam*, *Madrid, Spain*.

Manchego is a cured, hard, enzymatically coagulated cheese, made in the four provinces of the Castilla-La Mancha Region (South East Spain) with milk of the Manchega breed ewes. It is the most popular Spanish sheep cheese, produced according to the EU regulation for Guarantee of Origin (POD, 1984), with a total yield of about 8000 Tn per year (44 % of POD Spanish cheeses in 2006). Currently eighty cheese factories are registered in the Council of POD Manchego. A different processing technology is adopted whether the milk has been previously pasteurized or not. In order to guarantee high standard of safety for this internationally recognized product, according to the international regulations about consumer health risks, it is important to investigate the possible occurrence of Aflatoxin M1 contamination. The aim of this work was to determine the level of Aflatoxin M1 contamination in Manchego cheese in a representative sample of cheese factories of the region of Castilla-La Mancha. Two months aged samples of cheese (ready to be sold at the market) from fifty five cheese factories were randomly collected in spring 2006. Chemical composition (fat, protein, salt and moisture) was determined by a FoodScan™ Lab Dairy Analyser (Foss). The immunoaffinity technique was used to extract the Aflatoxin M1 from the cheese samples, and its concentration was determined by HPLC method. The results showed a mean composition of Fat/DM = 51.06±2.2 %; Protein/DM = 39.89±2.6 %. No statistical differences were found among provinces or method of elaboration. All analyzed cheese samples showed Aflatoxin M1 concentrations lower than the detection limit (2.2 ng/kg), suggesting a high safety standard of this dairy product.

Key Words: Aflatoxin M1, Ewe's milk, Cheese

T106 Prediction of fatty acid contents by mid-infrared spectrometry. P. Dardenne[1], F. Dehareng[1], H. Soyeurt*[2,3], and N. Gengler[2,4], [1]*Agricultural Walloon Research Centre, Quality Department*, *Gembloux, Belgium*, [2]*Gembloux Agricultural University, Animal Science Unit*, *Gembloux, Belgium*, [3]*FRIA*, *Brussels, Belgium*, [4]*FNRS*, *Brussels, Belgium*.

The interest for the dairy products with higher nutritional quality increases. The aim of this research was to elaborate different calibration equations to predict by Mid-Infrared Spectrometry the fatty acid contents in bovine milk. 1,609 milk samples were collected between March 2005 and May 2006 for 475 cows from 6 dairy breeds (Dual Purpose Belgian Blue, Holstein, Jersey, Montbeliarde, Normande and Red and White) in 8 herds. 78 samples were chosen using Principal Components approach based on spectral variability. All samples were scanned by MilkoScan FT6000. The reference fatty acid concentrations were measured by gas chromatography with a capillary column of 100 m length. The calibration with Partial Least Squares (PLS) on 78 samples showed a ratio of standard error of cross-validation to standard deviation (RPD) ranged between 1.5 and 6.76. The FA present in high concentration in milk were better predicted as in previous studies. In conclusion, the development of this fast method to predict the FA contents and directly integrating in the milk recording structure gives new perspectives for the dairy industry to detect easily and finally improve nutritional quality of their dairy products.

Key Words: Fatty Acid, Mid-Infrared, Milk

T107 Isolation and characterization of growth factor in goat milk. F. Y. Wu*, M. W. Chien, P. H. Tsao, Y. J. Tsai, Y. C. Lee, and T. Y. Kuo, *National Ilan University*, *I-Lan, Taiwan, ROC*.

Human milk contains various growth factors important for neonatal gastrointestinal tract development. The major growth factor activity in human milk has been identified as epidermal growth factor (EGF). Goat milk also contains growth factor activity. However, the type of growth factor has not been characterized. Further gained knowledge of the growth factor will be useful for developing goat milk-based nutraceutical products. Milk from pregnant does was centrifuged at 3,000 × g for 20 min at 2°C to remove fat and pellet. Casein was precipitated at pH 4.2. The activity, measured by ^{3}H-thymide incorporation in MME cell line, remained in the whey. Growth factor activity was harvested by ammonium sulfate precipitation at 70%

saturation. After dialysis, the sample was ultrafiltrated and separated into different molecular weight fractions with 50, 30 and 3 kDa cutoff membranes. More than 90% activity was present in the >50 kDa fraction, in contrast to the 6 kDa molecular weight of EGF. Subsequently, activity was found within the eluent of 15 to 19ml when gel filtration chromatography was performed by Superdex 200 HR 10/30. Isoelectric focusing using Rotofor cell showed that the activity was in around pH 6.3 fraction, which also differs from the pI 4.6 of EGF. ECL-western blots using different antibodies against various growth factors were performed on all fractions. Since serum albumin, with 67 kDa molecular weight, is also present in the milk extract, blotting results should be carefully interpreted to avoid false positives because some antibodies were generated against antigens conjugated to BSA. Our results showed that the major growth factor in goat milk is different from that of human milk.

Key Words: Growth Factor, Goat Milk, Isolation

T108 Production of conjugated linoleic acid by a mixed commercial culture of L acidophilus, L bulgaricus and S. thermophillus in whole milk. P. Ramírez-Baca*[1,2], E. Escárcega-Padilla[1], S. Torres-Ceniceros[1], J. Meza-Velásquez[1], S. Esparza-González[1], J. Vázquez-Arroyo[1], R. Rodríguez-Martínez[2], and G. V. Nevárez-Moorillon[3], [1]*Universidad Juárez Edo. de Durango*, *Gómez Palacio, Durango, México*, [2]*Universidad Autónoma Agraria Antonio Narro, Unidad Laguna*, *Torreón, Coahuila, México*, [3]*Universidad Autónoma de Chihuahua*, *Chihuahua, Cihuahua, México*.

CLA is a mixture of positional and geometrical linoleic acid isomers with nutritional and health beneficial properties such as being an antiatheroesclerotic, anticarcinogen and antidiabetic agent and an immune system modulator naturally found in food products with fats from animal origin. Since fermented milks have an important role because of its nutritional properties and benefits to digestive tract, the objective of this study was to evaluate CLA production of L acidophilus associated or not with commercial mixed cultures, during milk fermentation. Whole milk was inoculated with L acidophilus alone or L acidophilus associated with S thermophilus and L bulgaricus and incubated at 35°C at four different incubation times. CLA production was measured and data were analyzed by the proc GLM of SAS, considering time and interaction of microorganisms as factors for analysis. Although there was no significative difference (P>0.05) in CLA production, neither by microorganism or time, there is a necessity to continue elucidating the biological mechanisms involved in CLA synthesis with different microorganisms and higher fermentation times.

Key Words: Conjugated Linoleic Acid, L. Acidophilus, Fermented Milk

T109 Poly(L-lactic acid) production from whey permeate. Y. Gao*, F. Zhao, A. Richardson, J. Mendes, D. Savin, and M. Guo, *University of Vermont*, *Burlington*.

The extensive use of commodity plastic products results in serious environmental pollution. Poly(lactic acid) is a biodegradable and biocompatible polymer of lactic acid. In the present study, whey permeate was used as the substrate for poly(lactic acid) production. A mixed culture system including *L. casei* and *L. lactis* was selected based on the ratio of L- to D-lactic acid produced, yield, and productivity from nine homofermentative lactic acid bacterial cultures. After optimization of fermentation conditions, the content of lactic acid is 192 g/L of original broth, the productivity, lactose utilization and purification of L-lactic acid is 4.46 g/Lh, 96.01% and 95%, respectively. The lactic acid recovery process consists of removal of cells and proteins by centrifugation and low molecular weight membrane (<10000 NMWC) separation of the fermentation broth. Decolorization of the product is achieved using 1% activated charcoal stirring overnight. L-lactic acid purification is achieved by extraction of the broth at pH 7 using diethyl ether to remove organic components followed by extraction at pH 2 with the same solvent followed by vacuum evaporation to recover lactic acid. The poly(L-lactic acid) was prepared by using the purified lactic acid with a condensation polymerization process initiated by sulfuric acid. The characterization of poly(L-lactic acid) will be discussed.

Key Words: Poly(lactic acid), Fermentation, Cheese Whey Permeate

T110 Digestion of CLA-enriched milk fatty acids studied in a dynamic *in vitro* gastrointestinal model. R. Gervais*[1], I. Fliss[1], E. E. Kheadr[1], E. R. Farnworth[2], M. R. Van Calsteren[2], C. Champagne[2], and P. Y. Chouinard[1], [1]*Nutraceuticals and Functional Foods Institute (INAF), Université Laval*, *Québec, QC, Canada*, [2]*Agriculture and Agri-food Canada*, *St-Hyacinthe, QC, Canada*.

The objective of the present study was to evaluate the digestibility of fatty acids (FA) from CLA-enriched milk using a dynamic, multicompartmental *in vitro* model (TIM-1; TNO, Zeist, The Netherlands) simulating the human stomach and small bowel. More precisely, the model consisted of 4 compartments simulating the stomach, duodenum, jejunum and ileum. Temperature was maintained at 37° and the pH was monitored and controlled in each compartment. In order to produce CLA-enriched milk, 28 Holstein dairy cows were fed a total mixed ration supplemented with 4% safflower oil. Milk was sampled from each cow and analyzed for milk FA composition. CLA-enriched milk was collected from the cow with the highest CLA content (47 mg/g of fatty acids). Milk was standardized at 3.25% fat, pasteurized, distributed in 300-ml aliquots, and then stored at 4°C until used. Briefly, 300 ml milk was subjected to *in vitro* digestion study using TIM-1 model. Gastric (0.25ml/min), biliary (0.25ml/min) and pancreatic (0.25ml/min) secretions were delivered to the appropriate sections in TIM-1 model through computer-controlled pumps. Ileal delivery of chyme was collected during 360 min of digestion and subjected to FA analysis. Lipid extraction was performed using the Bligh and Dyer method and FA were methylated and analyzed using GLC. Results revealed that the digestibility of total milk FA was 70.2% (SD±3.0). CLA appeared to be highly digestible compared with other long-chain FA of CLA-enriched milk. The TIM-1 model could provide important data regarding the digestibility of FA according to their chain length, degree of saturation, lipid form, or their triglyceride positional distribution.

Table 1. Digestibility coefficients of individual FA of CLA-enriched milk in TIM-1 model (n=2).

FA	%	FA	%	FA	%
10:0	94.2±3.0	18:0	65.4±9.5	*c*11 18:1	65.9±1.5

T111 Sensory profiles and volatile components of milk protein concentrates and isolates. R. E. Miracle*, J. Childs, and M. A. Drake, *North Carolina State University*, *Raleigh*.

Milk protein concentrates and isolates (MPC, MPI) have been recently utilized in food processing as protein fortifiers. MPC and MPI, unlike whey protein concentrates and isolates (WPC, WPI) contain both casein and whey proteins. MPC have a wide protein content range, 35 to 85 % (w/w), with no standard identity. Characterizing flavor variability of this emerging dried ingredient across the world market is crucial. Identification of distinguishing sensory properties and key volatile flavor compounds is the important first step in learning how the inclusion of milk proteins may affect product flavor. The objective of the current study was to characterize the flavor properties of domestic and international MPC and MPI using sensory and instrumental analyses. Milk proteins (MPC and MPI) were received from commercial facilities in North America and Europe. Products were stored in the dark at 21C, 40% RH and sampled for sensory and instrumental analysis. Milk proteins were rehydrated at 10% solids (w/w) for all analyses. A trained descriptive sensory analysis panel conducted flavor profiling of the rehydrated milk proteins. Instrumental volatiles were extracted by solid phase micro-extraction (SPME) followed by gas chromatography-mass spectrometry. Compounds were identified by comparison of retention indices and GC-MS data against reference standards. Selected compounds were quantified by the construction of standard curves in water. The milk proteins were differentiated by both sensory and instrumental volatile analyses ($p<0.05$). Higher protein products (70-90 % protein) were characterized by tortilla, animal and mushroom flavors while lower protein products (9.6 – 56 % protein) were characterized by sweet aromatic, cereal, and cooked/milky flavors. Principal component analysis of volatile compounds likewise grouped the milk proteins by protein content. As protein content increased, volatile sulfur compounds and aldehyde levels decreased. Flavor properties of MPC and MPI are impacted by protein content and these results will be useful in optimization of processing methods and formulation design.

Key Words: Milk Proteins, Flavor, Milk Protein Concentrates

T112 Characterization of cucumber off-flavor in whey protein concentrate and isolate. J. M. Wright*, R. E. Miracle, and M. A. Drake, *North Carolina State University*, *Raleigh*.

Whey proteins are value-added proteins with multiple ingredient applications. A bland flavor is expected in both whey protein isolate (WPI) and concentrate (WPC). Off-flavors can carry through into ingredient applications and limit the use of these proteins in food products. A cucumber off-flavor was documented in WPI and WPC80. The objectives of this study were to characterize the volatile compounds responsible for this flavor and to document the impact of storage time on the development of this flavor. Additionally, proteins that initially exhibited the off-flavor were agglomerated with lecithin, so both agglomerated and non-agglomerated products were evaluated. Agglomerated and non-agglomerated WPI and WPC80 were collected from suppliers previously noted to develop this off-flavor, stored at 21C, and evaluated every 2 mo through 18 mo storage. At each timepoint, descriptive sensory analysis was conducted on the rehydrated whey proteins to document flavor profiles. Volatile compounds were extracted using solid phase micro extraction (SPME) followed by gas chromatography-mass spectrometry (GC-MS) and gas chromatography-olfactometry (GC-O) to identify and characterize aroma active compounds. Cucumber flavor developed with storage time (average time = 9 mo storage) and products agglomerated with lecithin developed this flavor more quickly than non-agglomerated products. Proteins exhibiting cucumber flavor had more aroma-active volatile compounds characterized as green/vegetative and higher levels of specific aldehydes (ex. hexenal, heptanal, 2,4-nonadienal, 2,4-nonadienal, 2-nonenal) than whey proteins without cucumber flavor. These results suggest that this off-flavor is caused by lipid oxidation and its formation is accelerated by the application of lecithin in the agglomeration process.

Key Words: Whey Proteins, Flavor, Flavor Chemistry

T113 Impact of storage temperature on flavor stability of low heat skim milk powder. R. E. Miracle*, A. E. Croissant, M. A. Lloyd, and M. A. Drake, *North Carolina State University*, *Raleigh*.

Fresh low heat skim milk powder (SMP) should ideally exhibit a mild and bland flavor reminiscent of fluid skim milk. A shelf life of anywhere between 6-36 months for non-instantized unfortified SMP stored at optimal storage conditions has been proposed by various sources. Optimal storage conditions (< 21C and < 50 % relative humidity (RH)) are often not feasible in primary U.S. export countries. The objective of the current study was to evaluate the impact of temperature on storage stability of low heat SMP using instrumental and sensory analyses. Low heat SMP commercially packaged in 3-ply 22 kg bags were received from six commercial facilities on the west coast of the United States within 3 weeks of production on three occasions. SMP were stored in the dark at 21C, 40% RH or 35C, 60% RH and sampled every 3 mo for sensory and instrumental analysis through 36 months. SMP were rehydrated at 10 % solids (w/w) for analysis. A trained descriptive sensory analysis panel conducted flavor profiling of the SMP. Instrumental volatiles were extracted by solid phase microextraction (SPME) followed by gas chromatography-mass spectrometry. Compounds were identified by comparison of retention indices and GC-MS data against reference standards. Selected compounds were quantified by standard addition. Instrumental and sensory profiles were impacted by both storage temperature and storage

time ($p<0.05$). For SMP stored at 21C, cardboard flavor and astringency increased and the concentration of many aldehydes increased while the abundance of maltol decreased with storage time ($p<0.05$). In contrast, similar flavors were detected in SMP stored at 35C along with other flavors: tortilla, burnt feathers, and brothy. Higher concentrations of aldehydes and sulfur compounds were also identified in samples stored at 35C when compared to SMP stored at 21C ($p<0.05$). Sensory and instrumental changes occurred more rapidly in SMP stored at 35C than products stored at 21C ($p<0.05$). Comparison of SMP storage stability at these two temperatures is useful for design of storage regimes and marketing programs.

Key Words: Skim Milk Powder, Flavor, Storage Stability

T114 Fatty acid profile and sn-2 fatty acid distribution of infant milk fat fortified with EPA and DHA. C. O. Maduko[1], Y. W. Park*[2,1], and C. C. Akoh[1], [1]*University of Georgia*, *Athens*, [2]*Fort Valley State University*, *Fort Valley, GA*.

Long chain polyunsaturated fatty acids, arachidonic acids (AA) and docosahexaenoic acid (DHA) contained in human milk have been identified with the proper development and function of the brain. The preferred sn-2 positions for palmitic acid in the triacylglyceride skeleton of human milk fat guarantees maximum fat and calcium absorption. Unlike human milk, vegetable oils as well as cow and goat milks do not contain eicosapentaenoic acid (EPA) and DHA. Vegetable oils contain low amount of AA, and they do not have an appreciable quantity of palmitic acid at the sn-2 position of their triacylglycerides. The objective of this study was to produce modified fat containing similar fatty acid profile and triacylglyceride composition to human milk fat for infant feeding. A blend of 2.1:1.1:0.8:0.4 ratio of coconut oil, safflower oil, soybean oil and menhaden fish oil was enzymatically interesterified with palmitic acid at a 1:1 substrate ratio, using commercial sn-1,3-specific lipase lipozyme RM IM, obtained from Rhyzomucor miehei as a biocatalyst. The mixture was separated by Thin Layer Chromatography (TLC) and the triacyglycerol (TAG) band was assayed for fatty acid content by a gas chromatography. Sn-2 positional determination of the TAG band was done by pancreatic lipase hydrolysis and separation by TLC. Fatty acid profile of the 2-monoacylglyceride band produced was analyzed by GC. The fatty acid profile of the modified fat appeared similar to that of human milk with appreciative quantities of EPA and DHA content. The sn-2 profile of the modified fat had a high percentage incorporation of C16:0, followed by C18:1, which is very similar to the sn-2 profile of human milk. It was concluded that infant milk containing EPA and DHA can be successfully produced by interesterification of palmitic acid using vegetable oil blends fortified with fish oil.

Key Words: Fatty Acid Profile, sn-2 Position, Infant Milk Fat

T115 Impact of agglomeration on the storage stability of whole milk powder. B. J. Wright* and M. A. Drake, *North Carolina State University*, *Raleigh*.

Whole milk powder (WMP) is a common ingredient used in many food products. Agglomeration is commonly applied to WMP to enhance solubility and dispersability. Research has not examined agglomeration effects on flavor and storage stability of WMP. The objective of this study was to determine the effects of agglomeration on the flavor and storage stability of WMP. Unagglomerated WMP (362 kg) was collected from two suppliers and batch-agglomerated with and without lecithin by a commercial agglomerator. The control (non-agglomerated) and agglomerated products were stored at 21C and evaluated every two months through 12 months storage. At each time point, descriptive sensory analysis was conducted on the rehydrated WMP to document flavor profiles. Volatile compounds were extracted using solid phase micro extraction (SPME) followed by gas chromatography-mass spectrometry (GC-MS) and gas chromatography-olfactometry (GC-O) to identify and characterize aroma-active compounds. Physical tests including color, solubility index, peroxide value, and dispersibility were also measured. Initial time zero tests indicated that agglomeration with or without lecithin did not impact flavor, volatile compound profile, or peroxide value of WMP ($p>0.05$). Agglomeration increased dispersability ($p<0.05$). Grassy and painty flavors developed in WMP with increasing storage time concurrently with changes in volatile compound profiles (e.g. increases in aldehydes and alcohols). Sensory and instrumental volatile compound changes occurred more rapidly in agglomerated products compared to non-agglomerated WMP, and these changes occurred more rapidly in WMP agglomerated with lecithin compared to products agglomerated without lecithin ($p<0.05$). These results suggest that agglomeration diminishes shelf stability of WMP and that lecithin further decreases shelf stability by enhancing lipid oxidation.

Key Words: Whole Milk Powder, Agglomeration, Shelf Life

T116 Cloning, expression and antibody production of caprine platelet-activating factor acetylhydrolase. P. H. Tsao*[1,2], T. Y. Kuo[1], J. T. Hsu[2], L. P. Chow[2], and F. Y. Wu[1], [1]*National Ilan University*, *Ilan, Taiwan*, [2]*National Taiwan University*, *Taipei, Taiwan*.

The presence of platelet-activating factor acetylhydrolase (PAH-AH) activity in goat milk (our unpublished data) could be responsible for the anti-inflammatory effect of goat milk as described in the text of ancient Chinese medicine. DNA sequences or amino acid analysis of caprine PAF-AH will be helpful for further study; however, these sequences have not been resolved. Degenerative primers were designed based on the consensus sequence of human, cow, and mouse PAF-AH, for the RT-PCR amplification of PAF-AH mRNA isolated from the buffy coat of goat blood. A full-length PAF-AH DNA, 1.3 kb in size, was generated. Subsequently, translation analysis predicted a 53 kDa protein. The DNA sequence shows 82% and 94% identity to human and cow PAF-AH sequences respectively, while amino acid sequence shows 78% and 92% identity to that of human and cow respectively. Caprine PAF-AH has a distinct N-terminal sequence of 17 amino acids when comparing it to other species. Using *pET24a* vector, a 20 kDa recombinant protein was generated. LC-MS/MS analysis showed a 26.1% coverage with the predicted 20 kDa sequence, indicating the protein was as expected. The recombinant protein was used to immunize rabbit, and using western blot, the anti-serum generated was able to detect both the 20 kDa recombinant protein and a 67 kDa band from the crude extract of goat colostrums, further confirming that the gene cloned was for PAF-AH.

Key Words: Platelet Activating Factor Acetylhydrolase, Caprine, Gene Cloning

T117 Wet distillers grains plus solubles do not alter the relationship between fat content and marbling score in calf-fed steers. A. S. de Mello Junior*, C. R. Calkins, J. M. Hodgen, B. E. Jenschke, and G. E. Erickson, *University of Nebraska*, *Lincoln*.

Some research has suggested feeding dried distillers grain plus solubles can have a negative effect on marbling score in beef. One hypothesis is that feeding this byproduct of ethanol production alters the relationship between lipid content and marbling score by reducing the ability to visualize fat present in the ribeye. The objective of this study was to determine the effects of finishing diets with different levels of wet distillers grains plus solubles (DG) on the relationship between fat and marbling in beef cattle. Ninety-four, calf-fed, crossbred steers were randomly distributed to three treatments (0%, 15% and 30% DG – DM basis) for 133 d. Forty-eight h postmortem, marbling score, marbling texture and marbling distribution were assessed by a USDA grader. For the treatments (0%, 15% and 30%) 37.5%, 62.5% and 46.9% of the carcasses of each respective treatment were considered USDA Choice, with mean marbling scores ($P = 0.456$) of $Slight^{93}$, $Small^{03}$ and $Small^{04}$, respectively. For all treatments, there were linear relationships ($P < 0.008$) between marbling score and fat percentage in the ribeye. Slopes were statistically similar at $P = 0.721$. Treatment did not significantly influence marbling texture, marbling distribution or fat content of the ribeye. These results indicate that finishing diets containing up to 30% wet distillers grains plus solubles can be used without affecting the relationship between fat and marbling in beef.

Key Words: Distillers Grains, Fat, Marbling

T118 Effects of distillers grains finishing diets on fatty acid profiles in beef cattle. A. S. de Mello Junior*, B. E. Jenschke, J. M. Hodgen, G. E. Erickson, T. P. Carr, and C. R. Calkins, *University of Nebraska*, *Lincoln*.

Ninety-four, calf-fed crossbred steers were randomly allocated to three different treatments (0%, 15% or 30% wet distillers grains plus solubles - WDGS – DM basis) and fed for 133 d to test the influence of different levels of WDGS on fatty acid profile in the ribeye. After grading, one ribeye slice (*M. Longissimus thoracis*) about 7 mm thick was excised from each carcass, trimmed and analyzed for fatty acid profile and lipid content. Treatment did not influence the content of total lipid (5.44, 5.91, and 5.94%; $P > 0.187$), unsaturated ($P = 0.762$) and saturated fatty acids ($P = 0.788$). As amount of WDGS in the diet increased (0, 15 and 30%), there were higher concentrations (g per 100 g) of C 18:2 fatty acids (3.27^{b}, 4.22^{a}, and 4.50^{a}, respectively; $P < 0.001$), C 18:2 trans fatty acids (0.003^{b}, 0.011^{b}, 0.034^{a}, respectively; $P < 0.011$), total amount of trans fatty acids in the lean (2.87^{c}, 3.61^{b}, 4.86^{a}, respectively; $P < .001$), conjugated linoleic acid 9*c*, 11*t* (CLA: 0.21^{b}, 0.22^{ab} and 0.27^{a}; $P < 0.041$) and an elevated omega 6:omega 3 ratio (26.72^{c}, 33.64^{b}, and 41.75^{a}; $P < 0.001$) in the lean. Conversely, increasing WDGS in the diet reduced concentrations (g/100 g) of *cis*-vaccenic acid [C 18:1, n7] (3.20^{a}, 2.77^{b} and 2.41^{c}; $P < 0.014$), which has been related to development of off-flavors in beef. The elevated content of polyunsaturated fatty acids could lead to greater oxidation, which could negatively affect color and rancidity. Results from this study demonstrate that inclusion of WDGS in finishing diets can alter the fatty acids profile, which may have negative implications to product quality.

Key Words: Beef, Fatty Acids, Distillers Grains

T119 Influence of complexed trace mineral supplementation on carcass grade and meat quality of broilers processed at 42 and 56 d of age. B. Saenmahayak*, S. F. Bilgili, and J. B. Hess, *Auburn University*, *Auburn, AL*.

A total of 1920 male Ross × Ross 708 broilers were utilized to evaluate the influence of complexed zinc (C-Zn) and manganese (C-Mn) on skin quality and meat quality of broiler chickens at 42 and 56 d of age. Four dietary treatments (60 birds per pen; 8 pens per treatment), consisting of (1) Inorganic Control (80 ppm Zn and 80 ppm Mn), (2) 40 ppm C-Zn [complexed Zn replaced 40 ppm Zn from $ZnSO_4$], (3) 40 ppm C-Zn [complexed Zn provided additional 40 ppm Zn on top of control] and (4) 40 ppm C-Zn + 40 ppm C-Mn [40 ppm complexed Zn and 40 ppm complexed Mn added on top of control] were provided on a four stage feeding program. At 41 d of age, 2 birds per pen were randomly selected to measure skin puncture strength (displacement, load at break point and energy at break point). At 42 and 56 d of age, 10 birds were randomly selected from each pen, processed and chilled in static slush ice. Whole carcass, abdominal fat yields (42 and 56 d), carcass defects (42 d), parts yield (56 d) and deboned breast (fillet and tender) yields (56 d) were also determined. At each age, drip loss (24 and 48 h), cook loss, water holding capacity (WHC) and meat color (L*, a* and b*) were determined on breast fillets. Few differences in live performance were detected throughout the study. Skin puncture strength did not vary ($P>0.05$) between the dietary treatments. Birds on Treatment 3 (40 ppm C-Zn) exhibited significantly lower ($P<0.05$) incidence of sores, scabs and scratches as compared to other treatments. Overall carcass grade, whole carcass and parts yields were not significantly different among the treatments. Breast fillet drip losses and WHC did not show any differences due to treatments at either age. However, at 42 d of age, cook loss was significantly reduced with Treatment 4 as compared to Treatment 1 (22.3% vs. 29.7%). Color measurements at 42 d of age showed highest L* value and lowest a* values with Treatment 1. Response of broiler chickens to complexed trace mineral supplementation was variable and age dependent.

Key Words: Complexed Zinc, Manganese, Skin Quality

T120 Analysis of veal shoulder muscles for chemical attributes. G. A. Sullivan*[1], C. R. Calkins[1], D. D. Johnson[2], and B. G. Sapp[2], [1]*University of Nebraska*, *Lincoln*, [2]*University of Florida*, *Gainesville*.

Veal muscles from the loin, rack and round are being fully utilized using conventional culinary application and therefore sell for a premium; conversely, few applications are commonly applied to shoulder muscles thus causing a lower-value primal. The objective of this study was to characterize the shoulder muscles, using their chemical properties, for the potential to upgrade their value. Twenty

paired veal shoulders from two processors were dissected to isolate nine muscles for the determination of expressible moisture on day 3 and objective color (L*, a*, b*), composition (fat, moisture, ash) and pH on day 13. All traits showed a significant muscle effect ($P < 0.008$). The *M. Supraspinatus* was the lightest colored muscle with an L* of 51.37 ($P = 0.023$). The *M. Serratus ventralis* had the highest fat content at 5.04% ($P = 0.043$) followed by the *M. Complexus* at 4.41% ($P = 0.003$) with the remaining muscles ranging from 2.28-3.26%. The *M. Teres major* was numerically highest in expressible moisture at 39.53% and was significantly different than all but two muscles ($P < .044$). The *M. Infraspinatus* had the highest pH at 5.99 ($P = 0.002$) and the *M. Triceps brachii* and *M. Pectoralis profundus* had a significantly lower pH than the remaining muscles at 5.69 and 5.67, respectively ($P < 0.039$). The *M. Infraspinatus* and *M. Rhomboideus* were statistically superior ($P < 0.050$) in chemical traits compared to muscles with the least desirable values. Conversely, the *M. Pectoralis profundus* was statistically similar to the least desirable value ($P > 0.050$) for expressible moisture, pH and b*. From a chemical profile perspective, all of the muscles possessed some favorable characteristics and in the proper application could be utilized for a value-added muscle.

Key Words: Properties, Quality, Veal

T121 Influence of gender and slaughter weight on growth, carcass characteristics, and meat quality of Duroc and Landrace crossbred pigs. L. L. Lo*[1], C. C. Tsai[1], Y. C. Yang[1], R. S. Lin[2], T. H. Huang[3], and J. Chen[1], [1]*Chinese Culture University*, *Taipei, Taiwan, ROC*, [2]*National ILan University*, *ILan, Taiwan, ROC*, [3]*Taiwan Farm Industry Co., Ltd.*, *Pingtung, Taiwan, ROC*.

One hundred and twenty Duroc and Landrace crossbred pigs were divided into two genders (barrows and gilts) and 5 slaughter weight (85, 95, 105, 115, and 125 kg) to detect the effects of gender and slaughter weight (SW) on growth, carcass and meat quality traits. Pigs were raised under commercial farm condition, and were transported to a commercial slaughter plant when reached the slaughter weight to collect the carcass performance data. Sections of Longissimus muscle (LM) from 9th to last rib were removed and transported to Chinese Culture University for meat quality evaluations. Barrows were grow faster and had shorter days to reach 110 kg of body weight than those of gilts (P<0.05). Gender had no significant effect concerning backfat thickness and saleable lean percentage. LM areas (LMA) of gilts, however, were larger (P<0.05) than that found in barrows (54.33 vs. 51.22 cm^2 , respectively). While no significant differences were detect for subject scores of firmness score, LM from barrows showed higher color (P<0.10) and marbling scores (P<0.05) than in gilts. Significant differences were found for most of the carcass traits between 85 and the other groups of pigs. For most of the carcass traits, slaughter weight larger than 95 and lower than 125 kg were acceptable and showed no differences across groups. Gender showed no difference on most meat quality traits. However, intramuscular fat content was higher in the barrows than in gilts (P<0.01). LM from lighter pigs tended to had more water and less intramuscular fat content (P<0.05). Meat pH, Hunter L value, and water holding capacity were found to not be different across groups. For eating quality, LM from barrows had higher scores on flavour and overall acceptability (P<0.05). No differences were found for sensory evaluation across groups except for lighter pigs had less off-flavor score. Results from this study indicated that LM from barrow had better meat quality and increased SW to 125 kg might have some benefits on marbling and intramuscular fat content.

Key Words: Slaughter Weight, Gender, Meat Quality

T122 Effect of seaweeds on the physical quality and the sensorial characteristics of eggs enriched with omega-3 fatty acids and stored for long time under different conditions. V. H. Ríos[1], S. Carrillo*[1], M. M. Casas[2], M. E. Carranco[1], E. Avila[3], and F. Pérez-Gil[1], [1]*Instituto Nacional de Ciencias Mérdicas y Nutrición Salvador Zubirán*, *México D.F.*, [2]*Centro Interdisciplinario de Ciencias Marinas*, *La Paz, Baja California Sur, Mexico*, [3]*Facultad de Medicina Veterinaria y Zootecnia, UNAM*, *México D.F.*

The aim of this study was to determine if the inclusion of seaweeds in laying hen diets contribute for maintaining the physical quality and the sensorial characteristics of egg enriched with omega-3 fatty acids stored for long time under different conditions. During 8 weeks 144 Leghorn laying hens were distributed in four treatments: T1 (control diet), T2 (2% fish oil+10% M.pyrifera), T3 (2% fish oil+10% Sargassum spp.) and T4 (2% fish oil+10% Enteromorpha spp.). At the end of the trial 122 eggs were taken, which 61 eggs were storage at 20°C and other 61 at 4°C. The egg physical quality was evaluated at 0, 15, 30 and 45 days of storagement; while that the sensorial characteristics of egg (flavor and yolk color) were evaluated by an acceptation test at 0, 15 and 30 days. The results showed a low egg weight loss when the eggs were stored at 4°C (P<0.05), mainly with M.pyrifera and Enteromorpha spp. Time and temperature of storagement did not have any effect on the weight of egg shell. Egg shell thickness did not seem to be affected by time, temperature and seaweeds (P>0.05). Haugh Units were drastically reduced through days (from 0 days until 45 days) when the eggs were stored at 20°C (87 vs 40 UH, respectively). However, when the eggs were stored at 4°C a less reduction was observed (87 vs 63 UH, respectively), mainly with Sargassum spp. and Enteromorpha spp. seaweeds. Egg yolk colour was not affected by time and temperature. The egg flavor was affected on 30 day in all eggs stored at 20°C and 4°C. Treatment with Enteromorpha spp showed a less acceptation for yolk colour at 0 and 15 days because the egg yolk colour was low (8 Roche color Fan). It is concluded that there is a low egg weight loss when Sargassum spp and Enteromorpha spp are included in laying hens diets, similarly, they preserver the Haugh Unit for a long time when eggs are enriched with omega 3 fatty acids.

Key Words: Seaweeds, Egg Physical Quality, Storage

T123 A direct method for fatty acid methyl ester (FAME) synthesis. J. V. O'Fallon, J. R. Busboom, M. L. Nelson*, and C. T. Gaskins, *Washington State University*, *Pullman*.

The objective of this paper was to develop a method to directly synthesize fatty acid methyl esters (FAME) from muscle tissue, oils, and feedstuffs in aqueous solution without prior organic solvent extraction. Wet tissues, or other samples, were permeabilized and hydrolyzed for 1.5 hr at 55°C in 1N KOH in methanol containing C13:0 as internal standard. The KOH was neutralized and the free fatty acids methylated by H_2SO_4 catalysis for 1.5 hr at 55°C.

Hexane was added to the reaction tube, which was vortex-mixed and centrifuged. The hexane is pipetted into a GC vial for subsequent gas chromatography. All reactions were conducted in a single screw cap Pyrex tube. Freeze-dried beef longissimus muscle fatty acids were methylated using sodium methoxide, boron trifluoride and direct FAME synthesis. ANOVA of beef longissimus muscle FAME was calculated using a model with methylation method as the treatments and animal as a blocking factor in a randomized complete block design. When the F-ratio for the methylation methods was significant, Student ′s t-test was used to make pairwise comparisons among the means. Direct FAME synthesis recovered more ($P \leq 0.01$) fatty acids (FA) than did sodium methoxide and much more than did boron trifluoride. Apparently there were fatty acid structures in beef longissimus muscle that were easily methylated by direct FAME synthesis but not by boron trifluoride. When expressed as % FA, sodium methoxide and direct FAME synthesis were quite similar in their results, but boron trifluoride was different ($P \leq 0.01$), and in this latter case (BF_3) the % FA values were higher when the concentration of fatty acid was lower. Direct FAME synthesis consistently methylated more fatty acid, averaging 1.3 times that of sodium methoxide and 2.2 times that of boron trifluoride. The method met a number of criteria for fatty acid analysis including not isomerizing CLA or introducing fatty acid artifacts. Its unique performance, including easy sample preparation, was achieved because water is included in the FAME reaction mixtures rather than eliminated.

Key Words: Fatty Acid Analysis, FAME Synthesis, Longissimus Muscle

T124 Intramuscular tenderness, sensory, and color attributes of two muscles from the *M. Quadriceps femoris* when fabricated using a modified hot boning technique. B. E. Jenschke*, B. J. Swedberg, and C. R. Calkins, *University of Nebraska*, *Lincoln*.

The *M. Quadriceps femoris* from USDA Choice and Select carcasses were fabricated traditionally (**COLD**) or innovatively (**HOT**) in which the seams it shares with the top round and bottom round were separated pre-rigor to test this effect on intramuscular variation in tenderness and color. At harvest, alternating carcass sides were assigned either the HOT or COLD treatment. At 48 h post-harvest, subprimals were removed, vacuum-packaged and aged for an additional 5 d. Following aging, the *M. Rectus femoris* (**REC**) and *M. Vastus lateralis* (**VAL**) were cut into 2.54 cm thick steaks, and allowed to bloom 1 h. For both muscles, L^* values significantly ($P < 0.050$) decreased when moving from the proximal to distal position within the muscle. Similarly, a^* and b^* values decreased in the VAL when moving from the proximal to the distal aspect. Following color measurement, steaks were vacuum-packaged and frozen (-26°C) until shear and sensory data were collected. Significant position (proximal to distal) and location effects (anterior to posterior) were noted for both muscles. For the REC, Warner-Bratzler shear force (**WBSF**) values were not greater than 4.35 kg and all regions were rated slightly tender or better. For USDA Choice REC steaks, the HOT treatment was significantly more tender when compared to COLD treatment. However, treatment did not affect the VAL. For both muscles, a trained sensory panel found a decrease in tenderness moving from the proximal to distal aspect which agrees with WBSF values for both muscles. Additionally, juiciness decreased when moving from the proximal to distal aspect of the VAL that received the HOT treatment. Results from this study indicate that the modified hot boning technique had minimal effects on the tenderness, sensory, and color attributes of the REC and VAL thus making it a feasible fabrication strategy for the industry. Since minimal differences in WBSF and taste panels values between the ball tip portion and the rest of the knuckle were detected, there is little need for value differences between these two portions.

Key Words: Hot Boning, Knuckle, Tenderness

T125 Effect of juvenile clenbuterol exposure on growth in mice. A. C. Dilger*, R. N. Dilger, L. W. Kutzler, and J. Killefer, *University of Illinois*, *Urbana*.

Clenbuterol (clen), a β-2 adrenergic agonist, increases muscle and decreases adipose tissue growth, though it is unclear if clen administration to dams confers similar benefits to offspring. Therefore, our objective was to determine the effect of clen administration to gestating and lactating mice on subsequent growth of their offspring. Clen was administered free choice as 20 ppm of clen HCl mixed in tap water. This study was designed as a 3×2×2 factorial arrangement with main effects of juvenile clenbuterol treatment, adult clen treatment and gender. Juvenile clen treatments consisted of clen administered to dams during the 3 weeks of gestation (GC), clen administered to dams during the 3 weeks of lactation (LC) and no clenbuterol administered to dams (NC). All pups were weaned at 3 weeks of age. At 5 weeks of age, offspring were assigned to adult clen treatment groups - clen or control (no clen) for 2 weeks - and were sacrificed at 7 weeks of age. GC increased 3- and 5-week-old pup weight while LC reduced 3- and 5-week-old pup weight when compared to NC. At 7 weeks of age, pup weight between GC and NC were not different, though both were greater than LC. For all juvenile clen treatments, adult clen treatment increased weight gain from 5 to 7 weeks. However, weight gain was not different between GC and NC pups treated with clen, though both were greater than LC pups treated with clen. Weights of the tibialis anterior (TA) muscle and the combined weight of the soleus and gastrocnemius (SG) muscles were determined. Weight of the TA was increased by adult clen treatment for all juvenile clen treatments. GC TA muscles weighed more than NC which weighed more than LC. Weight of the SG muscles were also increased by adult clen treatment, however, juvenile clen treatment had no effect. These data suggest that LC treatment may reduce growth performance while GC treatment may have beneficial effects. Furthermore, exposure of dams to clen during gestation and lactation does not seem to alter the adult response to clen in their offspring.

Key Words: Clenbuterol, Mouse, Growth

T126 Hematocrit and carcass parameters in broiler chickens submitted to acute heat stress in climatic chamber. E. F. Delgado*[1], C. C. Santos[1], A. C. M. S. Pedreira[2], I. J. Silva[1], and J. F. M. Menten[1], [1]*Escola Superior de Agricultura*, *Piracicaba, São Paulo, Brasil*, [2]*Agência Paulista de Tecnologia do Agronegócio*, *Piracicaba, São Paulo, Brasil*.

Acute heat stress (AHS) occurs in several physiological conditions and may depreciate broiler meat production and quality. The present experiment aimed to simulate in climatic chamber conditions of AHS (35°C; 85% RH) to evaluate the following parameters: hematocrit

(Ht); weight loss (WL, g); carcass weight and yield (CW and CY,%); breast weight and yield (BW, g and BY, %); wing weight (WW), leg weight (LW); visceral weight (VW); and breast free water (BFW, %) of broiler chickens. Animals were slaughtered with 40, 42 or 44 days of age, in three different slaughter times (ST) with average weight of 2.85 Kg (1st ST), 3.00 Kg (2nd ST) and, 3.28 Kg (3rd ST), respectively. In each ST, ten animals were weighed, placed into transport crates (10 by crate) and submitted to AHS conditions for 120 min. Simultaneously, other 10 animals (NS) were evaluated in crates kept in room temperature (22°C). Blood was collected in different times of crate confinement (t0, t30, t60 e t120 min) followed by slaughter. The Ht values showed a decline ($P<0.01$) during crate confinement from 30.0 ±0.4 (t0) to 27.8±0.4 (t120), but there was no effect of AHS. Higher WL ($P<0.01$) and CY ($P=0.078$) were observed for heat stressed broilers (112.0 vs 56.2 and 71 vs 70, respectively). In the 1st ST, there were also higher BW and BY ($P<0.01$) for AHS broilers compared to NS (705 vs 617 and 34 vs 31, respectively). The AHS animals had similar BFW among ST. Within ST, BFW was higher ($P<0.01$) in AHS compared to NS only in the 2nd ST (3.4 vs 2.5, respectively). The BFW in the 1st ST for NS broilers was higher compared to the others ST, and not different from AHS. The Ht reduction would be a preventive measure to avoid hipovolemia that may occur due to WL represented mainly by transpiration. The drainage of water from body tissues during AHS may be concentrated in determined non-carcass tissues and/or groups of skeletal muscle, with a preservation of water in the breast. The AHS can have a detrimental effect in the muscle water distribution.

Key Words: Weight Loss, Carcass Yield, Muscle Water Distribution

T127 Effect of DEX Treatment on Ca^{2+} Content in the satellite cell from broiler muscle. S. G. Wu, Y. Miao, H. J. Zhang, and G. H. Qi*, *Feed Research Institute, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

The effect of glucocorticoid (GC) on Ca^{2+} content of satellite cells (SCs) from broiler muscle was determined to confirm if GC can activise Ca^{2+} signal transmit system in the muscle cells. The SCs were picked up from leg and breast muscle of day-old Abor Acres broilers respectively, and cultured in DMEM culture medium which contained 20% FBS. After 2 day culture, the SCs was marked with Fluo-3/AM. Using laser scanning confocal microscope (LEICA TCS SP2 SE) and highly sensitive Ca^{2+} fluorescent dye, Fluo-3/AM, kinetic changes of Ca^{2+} in single intact living SCs were measured before and after Dexamethasone (DEX) directly treatment. The results showed that intracellular Ca^{2+} content decreased as DEX concentration reduced. The maximum relative values of intracellular Ca^{2+} content of SCs from breast muscle and leg muscle were 144, 80, 63 and 66, 60, 48 for treatment 10^{-4},10^{-5} and 10^{-6} mol/L DEX, respectively. Time for intracellular Ca^{2+}content to reach the maximum relative value increased as DEX concentration reduced; The values for treatment 10^{-4}, 10^{-5}, and 10^{-6} mol/L DEX, SCs from breast muscle and leg muscle were 59s, 130s, 158s and 80s, 98s, and 216s, respectively. More time was needed for intracellular Ca^{2+} content to decrease to the initial level from maximum one; The figures for treatment 10^{-4}, 10^{-5}, and 10^{-6} mol/L DEX, SCs from breast muscle and leg muscle were 542s, 389s, 606s, and 260s, 675s, and 533s, respectively. Compared to the SCs from leg muscle, the SCs from breast muscle were more sensitive to DEX treatment. Treating SCs with DEX at 10^{-4}-10^{-6}mol/L can enhance intracellular Ca^{2+} content. These results indicate that extra cellular DEX can enhance intracellular Ca^{2+} content through active Ca^{2+} signal transmit system in the muscle cells from broilers.

Key Words: Intracellular Ca^{2+}, Dexamethasone, Satellite Cell

T128 Effect of low refrigeration temperature storage on physicochemical properties of packaged shell eggs during retail display. D. K. Shin*[1], C. Narciso-Gaytan[1], M. A. Sartor[1], J. Regenstein[2], and M. X. Sánchez-Plata[1], [1]*Texas A&M University*, *College Station*, [2]*Cornell University*, *Ithaca, NY*.

Approximately 89.9 billion eggs were distributed in the United States, and 86% of the total is table egg. However, most egg quality deterioration reported by egg processing industry is closely related to ″running whites″ and n″flaccid yolks″ during transport and/or retail display. Such deteriorated physicochemical properties of shell eggs may be associated with inadequate handling and/or storage condition. To establish a threshold temperature limit during transport and/or retail display, standard quality parameters and other physicochemical functionalities of shell eggs were evaluated under six different refrigeration temperatures (-1.1, 0.6, 2.2, 3.9, 5.6 and 7.2°C). Three eggs from each temperature were used at days 0, 2, 7, 14, 21 and 28 of storage. As standard quality parameters, Haugh units (HU), yolk index (YI), pHs of albumin (pHA) and yolk (pHY) and vitelline membrane strength were performed. Foaming (CD) and coagulation properties of eggs were also estimated. As expected, HUs was decreased but pHA was increased as storage day increased ($P<0.05$). Additionally, HUs of eggs stored at -1.1, 0.6 and 2.2°C were significantly differed when compared to the eggs under 3.9, 5.6 and 7.2°C of storage temperature and 28 days of storage ($P<0.05$). In conclusion, although storage temperatures below 1°C positively affected some of the quality and functional characteristics of shell eggs, storage temperature around 2°C would match economically.

Key Words: Refrigeration Temperature, Storage, Quality

T129 Isolation and characterization of μ-calpain, m-calpain, and calpastatin from postmortem bovine muscle. I Initial steps. J. P. Camou*, S. W. Mares, J. A. Marchello, R. Vazquez, M. D. Taylor, V. F. Thompson, and D. E Goll, *University of Arizona*, *Tucson*.

The calpains have been suggested to be an important contributor to proteolytic postmortem tenderization. Studies have shown that μ-calpain activity decreases rapidly during postmortem storage, and is nearly zero after 3 d postmortem. Activity of calpastatin, the specific inhibitor of the calpains, also decreases rapidly during postmortem storage, but not as rapidly as activity of μ-calpain does. Activity of m-calpain decreases only slightly during postmortem storage, but it is unclear whether Ca2+ concentrations in postmortem muscle get high enough to activate m-calpain. Hence, μ-calpain has been proposed as the principal contributor to postmortem proteolysis. However, because μ-calpain loses its activity rapidly postmortem, it is not clear how it could be a major contributor to postmortem proteolysis. Therefore, we have initiated attempts to purify μ-calpain, m-calpain, and calpastatin from 10-13-d postmortem bovine muscle. Several properties of postmortem calpains and calpastatin make their purification difficult. 1. Calpastatin is degraded into small fragments, some but not all of

which may have inhibitory activity, so purification of calpastatin from postmortem muscle will require purification of a number of fragments. 2. μ-Calpain is proteolytically inactive, so its purification from postmortem muscle will require detection by antibodies. 3. Because postmortem μ-calpain is autolyzed, it is too hydrophobic to be eluted from phenyl Sepharose columns, and these columns, which are powerful tools in purification of the calpains, cannot be used. We have developed a procedure using a hexyl-TSK hydrophobic interaction column as a first step in purification of the calpains and calpastatin from postmortem muscle. All calpastatin fragments pass straight through this column, and both autolyzed and unautolyzed calpains bind and are eluted quantitatively with 0.1 mM EDTA, 0.1% Brij35. After anion-exchange chromatography, it is possible to isolate two active calpastatin fractions, two μ-calpain fractions, one active and the other inactive, and one m-calpain fraction. Supported by the NIH,NRI,MDA.

Key Words: Calpain, Calpastatin, Postmortem

T130 Sarcomere length dynamics of postmortem ovine *Psoas major* and *Longissimus dorsi* muscles. I. Zapata*[1], T. D. Leeds[2], M. R. Mousel[2], and M. Wick[1], [1]*The Ohio State University*, *Columbus*, [2]*USDA-ARS U.S. Sheep Experiment Station*, *Dubois, ID*.

Understanding the biological mechanisms of postmortem events in muscle is of enormous importance for the meat industry because of their relationship with quality. Because sarcomere length has been previously related to tenderness issues in lambs we decided to study two contrasting types of muscle with known differences in tenderness characteristics. The objective of this study was to compare the sarcomere length (SL) dynamics of postmortem ovine *Psoas major* (PM) and *Longissimus dorsi* (LD) muscles at two time points and to relate LD tenderness to SL. Samples from the PM and LD muscles were removed from 57 animals at 50 min and at 36 h postmortem at the abattoir in the Ohio State University meat science laboratory. Muscle tissue free of evident fat or connective tissue was dissected from each sample and fixed in a glutaraldehyde/cacodylic acid buffer (pH 7.1). Samples were homogenized in cacodylic acid buffer (pH 7.1), mounted on glass slides, observed by phase contrast microscopy and images were captured with a CCD camera. SL were measured using image analysis software. LD chops were assayed at 7 d postmortem for tenderness using Warner-Bratzler sheer (WBS) force. Statistical analysis of the SL was performed using the MIXED procedure and a correlation test with SAS. SL was significantly different from each other within each muscle group and over time ($P < 0.001$). SL least square means estimate for the PM were 2.275 ± 0.023 μm at 50 min and 2.888 ± 0.032 μm at 36 h. SL least square means estimate for LD were 1.835 ± 0.023 μm at 50 min and 1.736 ± 0.016 μm at 36 h. Estimate differences were 0.613 ± 0.040 μm ($P < 0.001$) for PM and -0.098 ± 0.028 μm ($P < 0.001$) for LD. A Pearson′s correlation test showed no relation between LD SL and WBS force at either time point. These results demonstrate inherent differences in the postmortem SL dynamics between the two muscles. That is, the PM exhibited a positive slope in SL during postmortem aging while the LD SL exhibited a negative slope over the same time frame. Currently, the biological mechanism underlying this phenomenon has yet to be elucidated and is actively being pursued in our laboratory.

Key Words: Microscopy, Tenderness, Sarcomere Length

T131 Effect of pig age at slaughter on postmortem muscle protein degradation and fresh pork quality. C. E. Wagner*[1], E. Huff-Lonergan[1], A. A. Sosnicki[2,1], S. B. Jungst[2], and S. M. Lonergan[1], [1]*Iowa State University*, *Ames*, [2]*PIC North America*, *Hendersonville, TN*.

The objective of this study was to investigate if genetic selection of sires for improved growth rate is associated with changes in fresh pork quality. A pig population derived from the cross between a commercial line of Duroc sires and white line dams was subdivided according to the sires' estimated breeding value (EBV) for age at 125 kg. Differences in age at 125 kg were achieved by slaughtering pigs sired by High EBV growth boars (n=48), Low EBV growth boars (n=48) or a control group (n=32). Loin pH and temperature decline were monitored on each carcass. Fresh pork quality characteristics and water holding capacity were monitored at 2 d postmortem. Sensory traits (juiciness, tenderness, chewiness, flavor, and off-flavor) and star probe texture were measured 10 d postmortem. Proteolysis was estimated by desmin degradation and μ-calpain autolysis at 2 d postmortem. Pork quality data were analyzed in a one-way analysis of variance by age at 125 kg. Progeny were divided into groups based on standard deviation from the mean age at 125 kg (165 d) into groups A (142-157 d, mean=149.88 d), B (158-174 d, mean=166.61 d), and C (175-202 d, mean=182.61 d). Loins from pigs in group A had a significantly higher pH at 24 hr and 10 d than groups B and C. Loins from pigs in group A had higher subjective marbling scores and higher lipid content than loins from pigs in groups B and C. Loins from pigs in group C had a higher moisture content than loins from pigs in groups A and B. All groups differed in cook loss, with group A having the most and group C the least amount of cook loss. All groups differed when evaluated for sensory juiciness with loins from group A scoring the lowest and loins from group C the highest. Loins from pigs in group A had lower scores for sensory tenderness than loins from pigs in group C. Loins from pigs in group A had more intact desmin than pigs in groups B and C, as well as a greater amount of autolyzed μ-calpain than pigs in group C. Variation in pork quality could not be attributed to lower pH but could be due to proteolysis differences associated with growth.

Key Words: Growth, Pork Quality, Proteolysis

T132 Effects of concentrate on forage digestion *in vitro*, pH and volatile fatty acids. K. Reed*, D. J. R. Cherney, and J. H. Cherney, *Cornell University*, *Ithaca, NY*.

It is common practice in the dairy industry to use a mixed concentrate and forage diet. The ways in which feeds interact in the rumen at early time points to affect digestion are not characterized. Further understanding of concentrate-forage relationships could aid in the development of a more efficient diet. The objective of this study was to determine the early effects (0-6h) of concentrate type on rumen pH and forage digestion *in vitro*. An initial trial was conducted to compare the effect of buffer strength (full vs. half) on pH change during *in vitro* digestion of orchard grass (*Dactylis glomerata* L.) with or without sucrose. It was determined that using a full strength buffer allowed for sufficient changes in pH for the purposes of this study with the observed pH for the full strength buffer dropping from 6.6 to 5.4. Two forages, orchardgrass and corn (*Zea mays* L.) stover were combined with 5 concentrate treatments (no concentrate, corn meal, corn gluten meal, barley (*Hordeum vulgare* L.) and wheat (*Triticum aestivum* L.) in a 50:50 ration using 0.5 g samples. The samples were incubated *in vitro* in a 1:4 buffer to rumen fluid mixture for 420 min. The pH was measured at 30, 90, 150, 210, 270 and 420 min. Samples were collected at the end of the trial for lactic, propionic, and acetic acid analysis. Samples containing orchardgrass alone had a significantly lower pH ($P<0.05$) than those samples containing concentrate beginning at T=150 min and continuing to 420 min. The corn stover samples were significantly lower in pH ($P<0.01$) at T=270 min which correlates with a high mean lactic acid concentration(535 ppm) compared to the mean lactic acid concentration of the other four corn stover treatments(177 ppm). These preliminary results suggest that a diet containing a mixture of corn and forage minimizes the initial decline in rumen pH in comparison with forage alone, mixed barley and forage, or mixed wheat and forage. Further study to determine differences in the extent of forage digestion in forage-concentrate diets will supply additional information about the effects of mixed rations on rumen digestion.

T133 Fermentation profile and dry matter recovery of *Panicum maximum* cv. Mombaça silages treated with microbial inoculant at different regrowth ages. E. M. Santos, O. G. Pereira*, and C. L. L. F. Ferreira, *Universidade Federal de Viçosa*, *Viçosa, Minas Gerais, Brasil*.

Dry matter recovery and fermentation profile of *Panicum maximum* cv. Mombaça silages treated with microbial inoculant were evaluated at different regrowth ages. A 4×2 factorial arrangement (four regrowth ages × with or without inoculant) was used in a complete randomized design, with three replicates per treatment. The grass was harvested at 35, 45, 55 and 65 days of regrowth and ensiled in 20-l buckets, with or without the inoculant Sil-All C4 (Alltech, Brazil). Ammonium nitrogen/total nitrogen ratio ($N\text{-}NH_3$), pH and volatile fatty acids profile (lactic, acetic and butyric acids) were determined in the silage aqueous extract. Silage dry matter recovery was also calculated. The pH decreased by 0.0037 and 0.0041 units per regrowth day in silages without and with inoculant, respectively. Independently of the age, the lowest pH and $N\text{-}NH_3$ values ($P<0.05$) were recorded for the silages that were inoculated. Lactic acid increased linearly ($P<0.05$) with regrowth age, whereas acetic and butyric acids decreased. Lower values of acetic and butyric acids ($P<0.05$) were recorded for inoculated silages at all the ages. Levels of lactic acid increased ($P>0.05$) with inoculant addition except for the age of 65 days, at which there was no difference ($P>0.05$). Dry matter recovery increased linearly ($P>0.05$) with regrowth age, with greatest values ($P<0.05$) recorded for inoculated silages. The microbial inoculant improved the fermentation profile in silages of *Panicum maximum* cv. Mombaça plants harvested up to 55 days of regrowth.

Key Words: Acetic Acid, Butiric Acid, Lactic Acid

T134 Microbial populations and fermentation profile of signalgrass (*Brachiaria decumbens* Stapf) silages harvested at different regrowth ages. E. M. Santos, O. G. Pereira*, C. L. L. F. Ferreira, and R. Garcia, *Universidade Federal de Viçosa*, *Viçosa, Minas Gerais, Brasil*.

Microbial populations, pH, ammonium nitrogen/total nitrogen ratio ($N\text{-}NH_3$) and volatile fatty acid concentration were evaluated in signalgrass silages produced from plants harvested at different regrowth ages (30, 40, 50, 60 and 70 days), being ensiled into 2-Kg laboratory silos. A 5×6 factorial arrangement (5 regrowth ages × 6 fermentation periods) was used in a complete randomized design, with three replicates. The fermentation periods were 1, 3, 7,14, 28 and 56 days. Lactic acid bacteria (LAB) populations ranging from 3.93 to 5.51 log colony-forming units (CFU)/g of fresh forage were detected. Maximum populations of these microorganisms were found in the silages on the seventh fermentation day (8.69 log CFU/g silage). Enterobacterium populations persisted up to the twenty-eighth fermentation day, with maximum values being found at the first day (7.89 log CFU/g silage). $N\text{-}NH_3$ content decreased linearly ($P<0.05$) with the regrowth age, whereas it increased linearly ($P<0.05$) with the fermentation period. The pH decreased exponentially ($P<0.05$) as fermentation period increased, reducing from 4.95 to 4.29, from the first to the last age, at the end fermentation period. The contents of lactic acid increased, whereas the butyric acid decreased linearly ($P<0.05$) with the regrowth age. However, the content of both acids increased linearly ($P<0.05$) as the fermentation period increased, with ratios of 0.031, 0.012 and 0.003 units per day of fermentation, for lactic, acetic and butyric acids respectively. Signalgrass plants harvested from the 50^{th} day had adequate LAB populations which guarantees good fermentation, resulting in a good quality silage, considering pH, NH_3 and organic acid values.

T135 Silage inoculant effects on *in vitro* rumen fermentation. R. E. Muck[1], F. E. Contreras*[2], and D. R. Mertens[1], [1]*USDA-ARS, Dairy Forage Research Center*, *Madison, WI*, [2]*University of Wisconsin-Madison*, *Madison*.

Four inoculants, B (*Lactobacillus plantarum* and *Enterococcus faecium*), C (*Lactobacillus plantarum*), D (*Lactobacillus pentosus*), E (*Lactococcus lactis*), were compared with an uninoculated treatment (A) on alfalfa (38% DM, AS), corn (36% DM, CS), and brown midrib corn (33% DM, BMR) silages. All inoculants were applied at 105 CFU/g forage. Four 1-L jars were ensiled of each treatment. Silages were analyzed for fermentation characteristics. Additionally, 100 g from each silo were wet ground (2 to 5 mm) and frozen (-20°4C) until used for *in vitro* incubations. Two *in vitro* rumen fermentations were conducted per each treatment and crop. For each run, 1.0 g wet-ground silage from each silo was placed in a 160 mL serum bottle. Buffer (17 mL) and inoculum (12 mL) were added to each bottle. The bottles were sealed with butyl rubber stoppers and crimps and incubated at 39°C. Gas pressure was measured at 3, 6, 9, 24, and 48 h. At 9 and 48 h each treatment was analyzed for microbial biomass yield (MBY) and volatile fatty acids (VFA). Silage pH and lactic acid concentration were not affected by treatment across three trials. Silage pH was higher on AS (4.60) than CS (3.84) and BMR (3.89). Lactic acid concentration was similar between AS (74 g/kg DM) and BMR (73), but greater than CS (45). At 9 h incubation, gas and VFA production were different among crops ($P < 0.05$) but not among treatments ($P > 0.05$). However, MBY differed across treatment and crop. MBY in CS was similar to AS and greater than BMR (39.5, 39.3 and 32.7 mg/100 mg truly digested (TD) respectively). Among inoculants, C, D, and E (37.9, 39.0, and 38.0 mg/100 mg TD respectively) were similar and greater than A and B (35.4 and 35.5 mg/100 mg TD respectively). Similar trends in MBY were observed at 48 hr incubation. We conclude that the biggest impact of silage microbial inoculants on *in vitro* rumen fermentation was increasing microbial biomass yield, but this effect was not equal across all microbial inoculants.

Key Words: Silage Inoculants, Gas and Microbial Yield

T136 Enzyme and bacterial inoculant effects on hybrid corn (Zea mays) silage composition. O. Ruiz-Barrera*[1], Y. Castillo[1], C. Rodriguez[1], O. La O[2], R. Beltran[1], and C. Arzola[1], [1]*Facultad de Zootecnia*, *Chihuahua, Chih., Mexico*, [2]*Instituto de Ciencia Animal*, *La Habana, Cuba*.

Treating silages with fibrolytic enzymes and bacterial inoculants has been shown to improve digestibility, fermentation and aerobic stability of a variety of forages. The objective of this experiment was to evaluate the effects of three additives on chemical composition and fermentation characteristics of silage from seven different corn (Zea mays) hybrids: DK641™, Eagle 238W™, Golden Harvest EX313™, Golden Harvest H9403,™, Pioneer 32R25™, Pioneer 31G98™, and Producers 725™. Corn plants were planted in 14 experimental plots (1 ha each, replicated once) in Bachiniva, Chihuahua, Mexico and harvested at stage of maturity of 1/3 of milkline. Whole corn plants were cut and subsamples were chopped and ensiled in mini silos (1.3±0.1 kg and 4 minisilos per treatment) for 42 d. Treatments were control: CT 20 ml distilled water); SA (0.0065 g Sil All™ 4×4 L. plantarum, P. acidilactii, E. faecium, and B. salivarus); BS (0.182 g Bio-sile™ L. plantarum and P. pentosaceus) and FB 0.31 g Fibrozyme™(xylanases and T. viride). Silage corn samples were analyzed for dry matter (DM), crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF), cellulose (CE), hemicellulose (HE), in vitro dry matter digestibility (IVDMD), in vitro organic matter digestibility (IVOMD), pH and lactic acid (LA). Inoculation with SA and BS increased content of NDF of silage of corn hybrids 31G98 and DK641 ($P<0.05$). Addition of SA increased CP of corn silages from H9403, 238W and EX313 ($P<0.05$). However, FB decreased NDF concentration of 31G98, H9403 and 238W, lowered pH of DK641 and EX313 and increased concentration of LA content of EX313 and increased concentration of LA content of EX313 ($P<0.05$). No effect on DM and OM digestibility was observed for FB, but when BS and SA were added a significant difference ($P<0.05$) was observed for the hybrids DK641, 32R25 and Producers 725. These show that when applied at ensiling certain inoculants and fibrolytic enzymes can improve various chemical characteristics of corn silage hybrids, however, effects vary depending of the particular corn hybrid.

Key Words: Silage, Fermentation, Additives

T137 Use of solid state fermentation to increase nutritious value of apple byproducts. C. Rodríguez-Muela*[1], A. Becerra[2], O. Ruiz[1], A. Ramírez[1], A. Flores[1], and A. Elías[3], [1]*Universidad Autónoma de Chihuahua*, *Chihuahua, México*, [2]*Universidad Autónoma de Nayarit*, *Tepic, México*, [3]*Instituto de Ciencia Animal*, *La Habana, Cuba*.

To improve nutritious value of apple byproducts (AP) by solid state fermentation (SSF), two experiments were carried out. In experiment I, a complete random 2 × 3 factorial design with two urea levels (UR; 1.5 and 2.0%) and three ground corn levels (GC; 0, 10 and 20%) added to AP was used. In experiment II, a complete random 4 × 3 factorial design was used in an AP mix, with four times (0, 24, 48 and 72 h) of repose before fermentation (RT), with 0, 10 and 20% of GC. In experiment I, an interaction ($P<0.05$) on crude protein (CP) and on true protein (TP) between UR and GC was detected, where protein contents diminished as higher levels of GC were added to the mix. A greater ($P<0.05$) optic density (OD) of yeasts with 1.5% (10.6 UFC*1000) Vs 2% (7.3 UFC*1000) of UR was observed. Organic matter digestibility (OMD) increased as UR was increased ($P<0.01$; 62.2% and 73.4% for 1.5 and 2%, respectively) in the mixture. The urea level did not affect ($P>0.05$) NDF, but ADF values increased ($P<0.05$) from 36.5 to 42.9% with 1.5 and 2% of urea, respectively. The OD decreased ($P<0.01$) as the level of GC increased (12.9, 7.5 and 6.5 UFC*1000 for 0, 10 and 20% of GC, respectively). The OMD was improved ($P < 0.01$) with the addition of GC (58.7, 65 and 68.3% for 0, 10 and 20% of GC). The NDF decreased ($P<0.01$) with the level of GC added to the mixture (64.5, 55.5 and 47.4% for 0, 10 and 20% of GC, respectively). Also, ADF decreased ($P<0.01$) when GC was increased (53.2, 35.2 and 30.7% for the 0, 10 and 20% levels of GC). In experiment II, NDF was lower ($P<0.01$) for the 72 h (46.2%) than 24, 48 and 96 h of RT (53.8, 51.5 and 53.1%, respectively). As GC was added to the mixture NDF decreased (59.0, 52.3 and 42.0% for 0, 10 and 20% of GC; $P<0.01$). In conclusion, urea added to apple byproducts increased crude protein and true protein values during the solid state fermentation, if ground corn is not added to apple byproducts; however, as ground corn was increased, true protein content was reduced and the organic matter digestibility was improved.

Key Words: Apple Byproducts, True Protein, Fermentation

T138 Protein production by solid state fermentation of apple waste and pomace. H. E. Rodríguez-Ramírez*, C. Hernández-Gómez, C. Rodríguez-Muela, O. Ruíz-Barrera, and F. Salvador-Torres, *Universidad Autónoma de Chihuahua*, *Chihuahua, Chihuahua, México*.

In order to evaluate protein production by solid state fermentation (SSF) of apple waste (AW), apple pomace (AP) and their combinations, four treatments (t): t1 (100% AP, n=6); t2 (33.4% AW and 66.4% AP, n=6); t3 (66.6% AW and 33.4% AP, n=6) and t4 (100% AW, n=5) were evaluated. The mixtures were added with urea (1.5%), minerals (0.5%) and ammonium sulfate (0.4%). They were fermented at 32°C during 6 days (d0, d1, d2, d3, d4 and d5) in an incubator, and were mixed thoroughly every 4 h. On d5 temperature was incremented to 60 ammonium sulfate (0.4%). They were fermented at 32°C to dry the mixtures. This was considered the final product (d6). The variables measured were temperature (T, d0 to d3), pH (d1 to d5), yeast count (YC, d0 to d5), true protein on dry matter basis (TPDM, on d0 and d6) and dry matter (DM, on d0 and d5). Data were analyzed by ANOVA, using treatment, day and their interaction as main effects, on GLM procedure of MINITAB 13. T showed increment (P<0.01) on t1 (from 12.2 to 35.2°C) and t2 (from 16.0 to 36.7°C) during d0 and d1, these were higher than t3 and t4 increment (from 15.2 to 29.5°C and from 16.0 to 26.4°C, respectively). After this moment all treatments showed T close to 29.5°C. pH showed an increment (P<0.01) from d1 to d3 on t1 (d1=3.3, d3=5.2), t2 (d1=3.2, d3=6.5) and t3 (d1=3.6, d3=5.5); t4 showed a different behavior (d1=4.0, d3=3.3, d5=5.0) where the pH first decreased from d1 to d3 and after it was increased from d3 to d5. YC showed an increment (P<0.01) on all treatments. t1 had the highest increment (d0=11.0*10^6 Ucf/ml to d5=293.0*10^6 Ucf/ml), and the lowest increment was for t4 (d0=2.7*10^6 Ucf/ml to d5=83.2*10^6 Ucf/ml). TPDM had a sustained increment (P<0.01) from 4.0% (d0) to 19.6% (d6). TPDM means by treatment at d6 were 15.5, 19.3, 23.2 and 20.5% for t1, t2, t3 and t4 (P>0.05) respectively; DM showed differences (P<0.01) at d5 (t1=69.3%, t2=82.5%, t3=71.4% and t4=44.3%). We concluded that AW is more efficient for TPDM production; AW had the lower YC with high final protein content. Microbial population was responsible of the different T and pH differences between byproducts.

Key Words: Apple, Fermentation, Protein

T139 Temperature, dry matter, pH, yeast count and protein behavior on the solid state fermentation of apple pomace. C. Hernández-Gómez*, H. E. Rodríguez-Ramírez, C. Rodríguez-Muela, A. Flores-Mariñelarena, and C. Arzola-Alvarez, *Universidad Autónoma de Chihuahua*, *Chihuahua, México*.

In order to evaluate the behavior of temperature (T), dry matter (DM), pH, yeast count (YC), crude protein (CP) and true protein (TP) during the first 7 days by solid state fermentation (SSF) of apple pomace (AP); there were prepared 3 mixtures with 2,780, 3,480 and 3,500 kg of AP (M1, M2 and M3, on October 6, October 18 and October 25 of 2006 respectively). There were added 1.5% of urea, 0.5% of a mineral supplement and 0.4% of ammonium sulfate, wet basis. The temperature and samples to determine DM (at 100º C), pH, CC (cell count on Neubauer chamber), CP and TP were taken daily during 7 days (d0, d1, d2, d3, d4, d5, and d6); data were analyzed by ANOVA on MINITAB 13. The main factors were mixture and day. There were not differences (P>0.05) between mixtures or days for T: M1 (28.34), M2 (25.19), M3 (30.10) and DM: M1 (22.34), M2 (23.06), M3 (26.70). M1 had a pH average of 5.48 and was lower (P<0.01) than M2 and M3 (6.80 and 8.41 respectively). pH was incremented daily (P<0.01) from 4.45 (d0) to 10.16 (d6). YC showed difference (P<0.05) between mixture and day. The lower YC was for M1 (10.07*10^6 Ucf/ml), M2 (30.55*10^6 Ucf/ml) and M3 (46.73*10^6 Ucf/ml). YC on d0 was 20.23*10^6 Ucf/ml and on d6 was 51.29*10^6 Ucf/ml. CP was lower for M1 (P<0.05) than M2 and M3 with values of 24.53%, 32.87% and 32.14% respectively. TP did not show difference (P>0.10) between mixtures. There was an increment (P<0.10) of TP from d0 (13.43%) to d6 (19.12%). We conclude that solid state fermentation increment the protein content of AP. pH is changed from acid to basic trough the time and yeast quantity is incremented, but this can be distinct between mixtures. The behavior of temperature and dry matter is similar between mixtures trough time.

Key Words: Apple Pomace, Fermentation, True Protein

T140 Effect of fibrolytic enzymes and an inoculant on in vitro digestibility and gas production of low-dry matter alfalfa silage. L. K. Kozelov[1], F. Iliev[1], A. N. Hristov*[2], S. Zaman[2], and T. A. McAllister[3], [1]*Institute of Animal Sciences*, *Kostinbrod, Bulgaria*, [2]*University of Idaho*, *Moscow*, [3]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

The objective of this study was to investigate the effect of polysaccharide-degrading enzymes (a cellulase and a xylanase) alone or in a combination with a bacterial inoculant on fermentation parameters and *in vitro* degradability and gas production of low-DM alfalfa silage. First cut alfalfa (*Medicago sativa* L.), harvested at about 5% bloom stage (260 g/kg DM) was ensiled in laboratory-scale silos. Treatments were: control (water); formic acid (FA), 4 L/t fresh silage; a cellulase enzyme preparation (Cell) applied at 5 kg/t silage; a xylanase (Xyl) applied at 5 kg/t silage; a mix of Cell and Xyl, 2.5 kg/t silage of each enzyme; a lactic acid bacteria-based inoculant (Inoc) applied at a rate providing 1.0×10^5 cfu per gram of silage; and a mix of Cell (5 kg/t silage) and Inoc (1.0×10^5 cfu per gram of silage) (Inoc/Cell). Triplicate silos were open on d 3, 7, 15, and 60. The FA silage maintained the lowest pH through d 60 (5.21; $P < 0.05$). The inoculant- and Inoc/Cell-treated silages had lower ($P < 0.05$) pH than the control silage on d 7 and 60. Ammonia N and total free amino acids concentrations (23 and 158 g/kg silage N) were the lowest ($P < 0.05$) for the FA silage. *In vitro* degradability of silage DM was not affected ($P = 0.998$) by treatment. Compared with the control (51.3 ml/100 mg silage DM), most treatments increased ($P < 0.001$) the 24-h cumulative gas production; Inoc/Cell (65.1), Cell (64.0), Inoc (63.4), Xyl (61.7), and FA (61.6 ml/100 mg). Overall, enzyme- and lactic acid bacteria-based preparations had minor effects on silage fermentation in this experiment. The increased cumulative gas production indicates some preservation of fermentable organic matter with most treatments. This effect, however, is unlikely to trigger corresponding response in ruminal digestibility *in vivo*.

Key Words: Alfalfa Silage, Exogenous Enzyme, Microbial Inoculant

T141 The use of bacterial silage inoculants to ensile crushed corn grains and its effects on ensilability and aerobic stability. G. Böck[1], K. Schöndorfer[2], Y. Acosta Aragón*[1], A. Klimitsch[1], and G. Schatzmayr[1], [1]*BIOMIN Research Center*, *Tulln, Austria*, [2]*University of Applied Sciences*, *Krems, Austria*.

The primary purpose of ensiling is the conservation of forage and crops for feed. To improve feed quality of silages especially to inhibit growth of *Clostridia*, yeasts and moulds and their production of toxins chemical and biological silage additives are used. In contrast to chemicals the usage of lactic acid bacteria (LAB) poses a natural, non-corrosive and cheaper alternative to chemicals. The objective of this experiment was to study novel mixtures of homofermentative and heterofermentative LAB under laboratory conditions. The ensiling trial was performed with crushed corn grains using product 1 and 2 at a dosage of 1×10^6 CFU/g of raw material. A control was compared to product 1 (*Lactobacillus kefiri* and *Lactobacillus brevis*), product 2 (*Enterococcus faecium*, *Lactobacillus plantarum*, *Lactobacillus kefiri* and *Lactobacillus brevis*), Chemical A (2.5 l/ton) and a product consisting of *Lactobacillus rhamnosus*, *Lactobacillus plantarum* and *Lactobacillus buchneri* (product 3). Three silos per treatment were opened after 2, 7, 47 and 90 days of ensiling. The following parameters were analysed: pH, sugars and organic acids (HPLC), aerobic instability and dry matter (DM) loss. As expected product 1 showed the highest DM loss after 90 days (1.42 %) followed by product 3 (1.32 %) and the control (1.14 %). Product 2 showed smaller DM losses than the control. Chemical A showed the lowest DM loss with 0.81 %. The differences in pH decrease were very small among all groups. Lactic acid fermentation was fastest in the group with product 2 and slowest in the group with product 3. Acetic acid is most abundant in the group with product 1, followed by the group with product 2. However, acetic acid content is very low in all groups ranging between 3.16 and 14.82 g/kg DM. Aerobic stability was excellent after both 47 and 91 days for all trial groups except the control, which showed instability after 5.8 and 8.5 days, respectively.

Key Words: Silage Inoculant, Corn, Aerobic Stability

T142 Liquid urea by product as an additive to improve intake and digestibility of grass hay. J. L. Rodríguez-Rivera*, E. Valencia, and A. A. Rodríguez, *University of Puerto Rico, Mayaguez Campus*, *Mayaguez, Puerto Rico*.

This experiment evaluated the effect of applying liquid urea (LU; 16% N) on the nutritive value of old world bluestem hay (GH; Dichanthium annulatum). Four male rams (31 kg) were fed during four consecutive periods with chopped GH mixed with one of four rates of LU [0 (T1), 0.2 (T2), 0.4 (T3) and 0.6% (T4), (DM basis; wt/v)]. Experimental diets were offered at 3% of expected dry mater intake based on animal body weight. In each period, the LU was diluted with 600 ml of distilled water and sprayed to the GH 24-h before feeding. For each experimental period, there was a 5 d diet adaptation and 5 d of data collection. GH on offer, orts, and feces were measured daily for each ram. GH offered, refused and 10% aliquots of feces collected in bags were used to determine GH intake (GHI) and GH digestibility (GHD). Data were analyzed using the GLM procedure of SAS in a randomized complete design and means separated with Bonferroni t-test. Crude protein concentration increased with increasing rates of LU (2.26, 2.92, 5.49 and, 6.35% for T1, T2, T3 and T4, respectively. GHI with T3 (1160 g/d) was higher (P<0.05) than for T4 (1046 g/d), T1 (1026 g/d) and T2 (987 g/d). However, GHD was similar (P=0.05) for all LU rates. In summary, LU is a potential feed additive to improve the nutritive value of old world bluestem hay. Results indicate that LU-carbohydrate source combination studies are needed.

Key Words: Liquid Urea, Rams, Grass Hay Intake

T143 Effects of irrigation system and level of water on corn silage hybrid NDF digestibility in northern Italy. E. Raffrenato[1], A. Formigoni[2], I. Fusaro*[3], A. Palmonari[2], N. Brogna[2], M. E. Van Amburgh[1], and C. J. Sniffen[4], [1]*Cornell University*, *Ithaca, NY*, [2]*DIMORFIPA, Università di Bologna*, *Ozzano dell'Emilia, BO, Italy*, [3]*Dipartimento di Scienze degli Alimenti, Università di Teramo*, *Teramo, Italy*, [4]*Fencrest, LLC.*, *Holderness, NH*.

Increasing temperature and light with excess water has been shown to increase lignification and reduce digestibility. The objectives of this study were to assess the effects of two irrigation systems, flood (F) or sprinkler (S), and two application levels on in vitro NDF digestibility (IVNDFd) of three hybrid corn silages. Three hybrids selected to have different digestibility were provided by the Long Island Cauliflower Association (NY) and were grown in summer 2006 under similar conditions in the Po Valley, Italy. Irrigation was applied at two levels of water, low (FL and SL) and high (FH and SH), as a randomized block with a split-plot treatment and three replicates. Nitrogen was applied as urea at 350 kg per ha. The forages were harvested at 30-32% DM and ensiled in mini silos. Silages were analyzed for chemical composition and IVNDFd. There were no effects of hybrid, so hybrids were pooled by irrigation method and level. Starch and NDF content were not different by irrigation method, however, F irrigation resulted in lower CP, greater ADL, and reduced IVNDFd and rate of NDF digestion ($P < 0.05$, Table 1). These results demonstrate that excess water decreased forage nutritional values, inconsistent with the differences expected by hybrid. Thus, irrigation strategies may aid in optimizing forage quality.

T144 Utilization of silage of *Albizia lebbeck* as supplement of sheep. F. Fernández, T. Clavero*, R. Razz, and O. Araujo-Febres, *Facultad de Agronomia, Universidad del Zulia*, *Maracaibo, Zulia, Venezuela*.

Diets with silage of *Albizia lebbeck* were fed to sheep with the objetive to study daily intake and nitrogen metabolism. Sixteen confined west african sheep were offered with different levels of supplementation of silage in a region characteristics as dry tropical forest at north west of Venezuela. The rations used were 100% *Brachiaria humidicola* hay (HBH); 75%HBH + 25% silage *A. lebbeck*; 50% HBH + 50% silage *A. lebbeck* and 25% HBH + 75% silage *A. lebbeck*. Individual animals were housed in a designed crate having provision for collection of faeces and urine separately. Animals were fed during the pre-experimental period for 21 days, followed by experimental metabolic trial of 7 days. The experimental design was a randomized blocks with four replications. Silage supplementation increased total dry matter intake from 478.3 g/animal/d in the control to 712.8 g/animal/d in 50%HBH + 50% silage ($P \leq 0.01$). There were not significant ($P \geq 0.05$) differences between silages treatments. *Albizia lebbeck* silage supplementation had a highly significant ($P \leq 0.01$) effect on nitrogen utilization by sheep. All diets resulted in a positive N balance. Nitrogen intake and nitrogen retained as percent of intake rose with increasing levels of silage until 50%. However, there were not significant diferences ($P \leq 0.05$) among silages diets. Nitrogen intake and nitrogen retention were the highest (7.7 g/animal/d and 59.9%) in the 50% HBH + 50% silage diet and the lowest (3.1 g/animal/d and 12.99%) in the HBH diet. It can be concluded that supplementation with *Albizia lebbeck* silage had potential as protein source for sheep fed with a poor quality basal diet.

Key Words: *Albizia lebbeck*, Silage, Intake

T145 *In sacco* rumen disappearance of condensed tannins, fiber, and nitrogen from herbaceous native Texas legumes in goats. D. L. Pawelek*[1,2], J. P. Muir[1], B. D. Lambert[1,2], and R. D. Wittie[2], [1]*Texas Agricultural Experiment Station*, *Stephenville*, [2]*Tarleton State University*, *Stephenville, TX*.

Condensed tannins (CT) can play a role in rumen protein and fiber degradability, especially in legumes high in CT. In order to better understand their potential role in ruminant nutrition, three legume species native to Texas, *Acacia angustissima* var. *hirta* (prairie acacia) (288 g/kg neutral detergent fiber (NDFom), 41 g/kg N), *Desmodium paniculatum* (panicled tick-clover) (480 g/kg NDFom, 25 g/kg N), and *Lespedeza procumbens* (trailing bush-clover) (401 g/kg NDFom, 22 g/kg N) were studied to determine *in sacco* rumen disappearance rates of key nutritional components compared to that of *Medicago sativa* (alfalfa) (227 g/kg NDFom, 35 g/kg N). Herbage was incubated in rumen-cannulated goats fed a basal diet of *Sorghum bicolor* ×x *S. sudanense* (sorghum-Sudan) hay, with disappearance measured at 0, 4, 8, 16, 28, 48 and 96 h. Among the native legumes, the highest CT concentrations were measured in prairie acacia (263 g CT/kg DM foliage) and the lowest (120 g CT/kg DM) in trailing bushclover. The lowest concentrations of acid detergent fiber (ADFom), NDFom, and sulfuric acid lignin (lignin (sa)) were measured in prairie acacia, the first two fractions being comparable to alfalfa. Proportion remaining was calculated for CT, ADFom, lignin(sa), NDFom, and N for 0, 24 and 48 h of rumen incubation. Disappearance parameters were measured for ADFom, lignin(sa), NDFom and N for the three native legumes and compared to alfalfa. Alfalfa had the highest disappearance of all degradable fractions except lignin(sa). Potential disappearance (PD) fraction for ADFom, lignin(sa) and N were lower for the native legumes vs. alfalfa. No differences in N proportion remaining at 24 and 48 h occurred in the native legumes despite differences in protein-bound CT proportion remaining at those same times. Of the native legumes studied, prairie acacia shows the greatest potential for contributing rumen-escape protein, suggesting it may be a candidate for further development as a pasture and rangeland renovation legume.

Key Words: Proanthocyanidins, Escape Protein, Protein-Bound Condensed Tannins

T146 Season and drying method effects on condensed tannin levels in perennial herbaceous legumes. R. M. Wolfe*[1], T. H. Terrill[2], and J. P. Muir[1], [1]*Texas Agricultural Experiment Station*, *Stephenville*, [2]*Agricultural Experiment Station, Fort Valley State University*, *Fort Valley, GA*.

Several factors affect condensed tannin (CT) levels in plants and the precision and accuracy of the butanol-HCl colorimetric assay for CT in extractable and bound forms. Six native, perennial, herbaceous legumes from Texas were harvested at three different stages of growth over a growing season; young vegetation, initial flowering, and late in the season before leaf drop. Legumes examined were Eastern prairie acacia (*Acacia angustissima*), Illinois bundleflower (*Desmanthus illinoensis*), Panicled tick-clover (*Desmodium paniculatum*), Creeping bush-clover (*Lespedeza procumbens*), Tall bush-clover (*Lespedeza steuvei*) and Tropical neptunia (*Neptunia pubescens*). The samples were subjected to oven-drying and freeze-drying and then analyzed for extractable (ECT), protein-bound (PBCT), and fiber-bound (FBCT) condensed tannin concentration using a butanol-HCl procedure with purified quebracho CT as the standard. There was a wide range of CT concentration in the legumes, but little change in ECT and total (TCT) tannin concentrations over the growing season. Oven-drying decreased ($P < 0.05$) ECT and increased ($P < 0.05$) PBCT and FBCT concentrations in the legumes compared with freeze-drying, but both methods ranked the forages similarly throughout the growing season relative to TCT. Use of quebracho tannin as a standard increased CT values for the forages compared with purified legume CT standards, but all standards ranked the forages similarly relative to tannin concentration. Quantitative CT values are affected by many factors and have limited value except to allow a relative ranking of forages. Biological activity and potential nutritional/medicinal benefits of CT in native legumes needs further evaluation.

Key Words: Legumes, Tannins, Drying

T147 Effects of individual terpenes and terpene mixtures on intake by lambs. R. E. Estell*[1], E. L. Fredrickson[1], D. M. Anderson[1], and M. D. Remmenga[2], [1]*USDA/ARS Jornada Experimental Range*, *Las Cruces, NM*, [2]*New Mexico State University*, *Las Cruces*.

Rangeland degradation due to shrub encroachment is a major concern to livestock producers and land managers in the western United States and in arid and semiarid regions worldwide. Most invasive shrubs contain secondary compounds that reduce their consumption by herbivores, but knowledge concerning the effects of specific

compounds is limited. Four experiments were conducted to determine the effects of individual terpenes (*cis*-β-ocimene and *cis*-sabinene hydrate; Exp. 1 and 2) or mixtures of monoterpenes (borneol, camphene, camphor, 1,8-cineole, limonene, myrcene, and α-pinene; Exp. 3) or sesquiterpenes (β-caryophyllene, caryophyllene oxide, α-copaene, and α-humulene; Exp. 4) on intake by lambs. After a 10-day adaptation period with untreated alfalfa pellets, lambs (n = 45) were individually fed treated alfalfa pellets for 20 min each morning for 5 days. Five treatments (0X, .5X, 1X, 2X, and 10X; multiples of the concentrations of the same terpenes in *Flourensia cernua*) were applied to alfalfa pellets (637 g, DM basis) in an ethanol carrier. Except during the 20-min test, lambs were maintained outdoors and fed untreated alfalfa pellets (total mean intake = 4.7% of BW, DM basis). Day × treatment interactions were detected ($P < 0.04$) in Exp. 1 and 4 because of greater intake for 0X than other treatments on day 1 (Exp. 1) and lower intake for the 10X treatment on day 1 and 2 in Exp. 4. A trend for decreased intake (g/kg BW) as concentration of the sesquiterpene mixture increased was observed ($P = 0.093$ for the linear contrast; Exp. 3). Although there was a tendency for the sesquiterpene mixture to decrease intake, *cis*-β-ocimene, *cis*-sabinene hydrate, and the monoterpene mixture did not appear to affect intake by lambs.

Key Words: Intake, Shrubs, Terpenes

T148 Evaluation of hay treated with acid based preservatives at two cuttings and three moisture levels on their effect on feeding value. D. Sapienza[1], F. R. Valdez*[2], D. Westerhaus[2], and W. Rounds[2], [1]*Sapienza Analytica LLC*, *Slater, IA*, [2]*Kemin Industries, Inc.*, *Des Moines, IA*.

The production of hay with high feeding value is dependent upon drying conditions. This evaluation was designed to quantify the upper limit in moisture content in hay and to evaluate the effectiveness of hay additives. Four hay additives were used, three in accordance with label and one, FRESH CUT® Plus brand hay preservative (FC+), outside label directions to evaluate the range of its effectiveness. Six bales were made of each treatment in two cuttings (May and October 2005). After twenty-one days, temperature measurements were taken at four locations in each bale. The data were then converted into heat units and the effects of the treatments were evaluated. There was a significant reduction ($P<0.05$) of heat units produced in the bales made at less than 20% moisture; those bales treated with FC+ showed a significant 13-unit reduction ($P<0.05$) in heat units when compared to bales made with no additive. FC+ also showed a significant reduction in heat units produced ($P<0.05$) when compared to treatment with two other commercial products. All bales exhibited some heating and the internal temperature of all bales trended with the highs and lows of the environment. Over all moisture levels tested (26%, 20 to 25% and <20%), the FC+ treated bales demonstrated the ability to maintain a visual color score corresponding to normal good green bale color (score 3.2 to 2.2). It appears from the data that FC+ was able to reduce the negative effects of the normal temperature cycle of wet and dry bales observed throughout this experiment. It was also apparent that the TDN values for all of the 15 and 22% moisture bales treated with FC+ were greater than the positive control. FC+ improved TDN mainly by increasing crude protein digestibility (r = -0.918) and lowering % acid insoluble digestible crude protein (r = -0.926). No treatment was effective at 27% moisture.

Key Words: Hay Preservatives, Heat Units, Crude Protein Digestibility

T149 Loss of dry matter of pure and inoculated sugarcane (*Saccharum spp*) silage. G. S. Dias Júnior, D. C. L. Miranda, M. N. Pereira*, G. Santos, F. Lopes, and R. Spuri, *Universidade Federal de Lavras*, *Brazil*.

Sugarcane is a viable forage for feeding bovine, since it has a high potential for producing dry matter, of high energy content, per hectare. The ensiling of sugarcane may be an alternative to the traditional feeding management of daily harvesting fresh forage. The ensiling of the forage may facilitate the management of the herd, allows use of the forage during the rainy season, and maximizes the efficiency of cultural practices, among other advantages. However, consequences of the alcoholic fermentation of the sugarcane are the high sucrose loss and the low aerobic stability of the unloaded silage. We evaluated the loss in nutrient mass, along 767 days of ensilaging, of nine 1.9 kg pure sugarcane samples. The NDF content increased from 47.0% of DM to 68.7%. Silage loss, proportional to the original, was: 32.8% for toluene DM, 44.1% for 100°C DM, 18.3% for NDF and 67.0% for the non-NDF DM. We also evaluated the loss of nutrient mass and heating following unloading of sixty 7.9 kg sugarcane samples ensiled for 40 days. The three treatments were: Control, *L. plantarum* (1 × 106 cfu/g of FW) or *L. buchneri* (6.6 × 105 cfu/g of FW). The ensiling increased the sugarcane NDF content from 47.5% of DM to 70.5%. On average, the losses in nutrient mass were: 23.9% for toluene DM, 34.0% for 100°C DM, 1.9% for NDF and 62.9% for the non-NDF DM. While *L. plantarum* reduced, *L. buchneri* increased the loss of 100°C DM loss ($P<0.05$), in spite of the small biological magnitude of the effect (±1.6 percentage units). There was no treatment effect on silage heating following unloading. The ensiling of the sugarcane induced a significant increase in NDF content of the fresh forage and a high nutrient loss.

T150 Determinants of degradability among sugarcane (*Saccharum spp*) clones in the bovine rumen. C. B. Teixeira, M. N. Pereira*, M. A. P. Ramalho, M. H. Ramos, J. F. Santos, and M. L. Chaves, *Universidade Federal de Lavras*, *Brazil*.

The objective of this study was to evaluate the variability of nutritive value among sugarcane clones, to estimate the correlation between plant digestibility and productivity, and to define which agronomical and chemical traits would be the most important determinants of nutritive value. Twenty sugarcane industrial clones were evaluated in a completely randomized block design with four replicates. Clones cultivated in Campos, RJ state, originated from the Plant Breeding Program for Sugar and Alcohol Production of the Federal Rural University of Rio de Janeiro. Plants were harvested when the Brix was superior to 18%, at an starting age of 370 days after the second ratoon cut. Nine agronomical traits, ten chemical traits and the ruminal NDF and DM *in situ* degradability were evaluated. Productivity was 21.2 ± 5.7 t of DM per hectare, ruminal DM degradability was 57.1 ± 2.6% of DM, and ruminal NDF degradability was 19.8 ± 2.42% of NDF (mean ± SD). None of the variables evaluated had a significant correlation to NDF degradability ($P>0.10$). The ADF as a % of DM (%ADF), stalk length (SL) and the percentage of stalk in whole plant DM (SP) were the only variables included in the multivariate regression model

correlating ruminal DM degradability to chemical and agronomical traits. Models were: 95.13 - 1.238 (%ADF) (r^2=0.70); 100.80 - 0.452 (SL) - 1.140 (%ADF) (R^2=0.75); 83.48 - 0.052 (SL) + 0.179 (SP) - 1.009 (%ADF) (R^2=0.81). There was no evidence for decreased productivity as a consequence of a possible selection of clones to achieve high digestibility, since the phenotypic as well as the genetic correlation between these traits were close to zero. The estimated h^2 for the ruminal DM degradability trait was 87,9%, for %ADF it was 19.5%, for SL it was 41.4% and for SP it was 63.1%. Improving digestibility by indirect selection did not seem justifiable, since traits indirectly correlated to the digestibility had smaller estimated h^2 values than the value obtained for the ruminal DM degradability trait.

Key Words: Digestibility, Heritability, Plant Breeding

T151 Change in dry matter content of sugarcane silage treated with chemical and microbiological additives. D. C. L. Miranda, G. S. Dias Júnior, M. N. Pereira*, R. Spuri, F. Lopes, and G. Santos, *Universidade Federal de Lavras*, *Brazil*.

The ensilaging of sugarcane may be an alternative to the traditional feeding management of daily harvesting fresh forage. However, consequences of the alcoholic fermentation of sugarcane are the high sucrose loss and the low aerobic stability of the unloaded silage. We evaluated the use of chemical and microbiological additives in sugarcane silage. Around 9 kg forage samples were ensiled in 20 l buckets. A 4x3 factorial arrangement of treatments was adopted. Chemical additives: Control, potassium sorbate (0.05% of fresh weight, FW), urea (1% of FW) and calcium hydroxide (1% of FW). Microbiological additives: Control, *L. plantarum* and *L. buchneri* (both at 1 × 106 cfu/g of FW). Each one of the twelve possible combinations of treatments was replicated six times in each day of silage opening: 7, 14, 28 and 77 days of ensilaging. There was no treatment effect on the 126-hour heating of the unloaded silage (P>0.13). The inclusion of calcium hydroxide reduced the NDF content from 79.9% of DM to 69.2% (P<0.01). Both urea and calcium hydroxide increased silage pH, being the increase more accentuated on day 77 (P<0.01 for the interaction between chemical additive and day of opening), and was associated to the occurrence of 39% of silages with clostridial fermentation in the urea treatment and 56% with calcium hydroxide, both only during day 77 of silo opening (P<0.01, Chi-Square). The association of sorbate with microbiological additives increased the DM content at 7 and 77 days of ensilaging, while the association between urea and inoculum had a positive action only on day 77 (P=0.04 for the interaction among chemical additive, microbiological additive and day of opening). The association between potassium sorbate and microbial inoculum improved the action of homo as well as heterofermentative microorganisms. However, the effect of microbial inoculants on DM content was small. The use of calcium hydroxide in sugarcane ensiled for less than 28-day periods, may be a way to reduce the fiber content of the feed.

Key Words: Calcium Hydroxide, Potasium Sorbate, Inoculum

T152 The effect of feeding sugar cane (*saccharum officinarum*) or corn silage to Holstein heifers on development and reproductive performance. J. A. Reyes-Gutierrez[1,2], J. M Palma-García[2], J. M. Tapia-Gonzalez*[1], I. E. Morales-Zambrano[1,2], and G. Rocha-Chavez[1], [1]*CUSUR Univ de Guadalajara*, *Cd Guzman Jalisco Mexico*, [2]*Univ de Colima*, *Mexico*.

The objective of this study was to asses developing and reproductive performance of Holstein-Freisan heifers from weaning up to 470 days of age comparing sugar cane (*saccharum officinarum*) silage (SCS treatment 1) and corn silage (CS treatment 2). Twenty eight weaned heifers averaging 80 ± 16 days of age and initial weight of 79.5 ± 12.9 kg were used in a randomized block arrangement with weight as the blocking factor. Heifers were offered the respective silage *ad libitum* and a supplement was used to reach requirements. Body weight, BW (Kg) was measured every 30 days as well as height at cross HC (cm), body condition score BCS (1-5 scale), daily gain DG (kg), feed efficiency FE (Kg), forage intake FI (Kg), supplement intake SI (kg), and feed costs per pound of gain FCPG (US Dollars). Furthermore, age in days was registered at the time of puberty and first mating as well as BW, BCS and HC. Analysis of variance was used to compare treatments and significance was set to P<0.05. Growth performance of heifers at the end of the trial is described in table 1. Heifers reached puberty at 346.8 and 335.2 days old, weighing 250.6 and 279.1 kg for treatment 1 and 2 respectively (significantly different at P<.05). The body condition score and height at cross for SCS and CS groups were 2.6 and 3.2 and 116.8 and 118.9 cm respectively. At first mating, heifers were 441.1 and 430.1 days old, weighing 331.9 and 332.6 kgs, with a BCS of 2.8 and 3.5 and HC of 123.8 cm and 125.6 cm respectively for treatment 1 and 2. Reproductive performance at first mating was as the following: 1.1 and 1.3 matings per pregnancy and 92.8% and 78.5% fertility rate for SCS and CS respectively. It was concluded that, under conditions of this study, the SCS-based system allows for a satisfactory daily gain and reproductive performance at a low cost compared with corn silage.

Table 1. Development performance of heifers feed on corn or sugar cane silage

	BCS	Daily Gain (Kg)	Feed effiency (Kg)	Forage intake (Kg)	Supplement intake (Kg)	Feed costs per pound of gain (USD)
Sugar cane silage	2.7 a	.666	7.1 a	3.1	1.6	0.58
Corn silage	3.11 b	.743	9.2 b	5.3	1.6	0.63

Different letter in the same column differ significantly (P<0.05)

T153 Evaluation of the nutritive value of traditional forages collected during the growing season for improving livestock production in Mali. B. Dembele*[1], S. Fernandez-Rivera[2], B. Simpson[3], and M. Yokoyama[3], [1]*Institut Polytechnique Rural de Formation et de Recherche Appliquee*, *Katibougou, Mali*, [2]*International Livestock Research Institute*, *Addis Ababa, Ethiopia*, [3]*Michigan State University*, *East Lansing*.

Mali is a landlocked, semi-arid country in West Africa and one of the ten poorest countries in the world. Poor animal nutrition is the

limiting constraint to increased livestock productivity and the major contributory aspects of the problem are feed availability and quality. Livestock are fed natural grasses, fodder and farm residues during the dry season, which are poor in quality. The inability of the market place to meet the demand for feed places increasing pressure on existing natural resources. Changes in the nutritive value of forages over the growing season are unknown. In this study, traditional forages were randomly collected monthly from the beginning of the rainy season to the dry season (July, 2004-February, 2005) and analyzed for their nutritive value(DM, CP, Ether Extract, Ash, NDF, ADF, ADL, Gross Energy, In Vitro Dry Matter Digestibility) and mineral content (Ca, P, K, Fe, Mg, Cu, Zn, Na, Mn). The dominant forages during the growing season were Angropogon pseudapricum, Loudecia togoenesis and Pennisetum pedicellatum. Many forages disappeared late in the growing season. Mean CP of the forages decreased from 12.6% to 1.9% (range:12.6-1.3%) during the growing season. Mean ADF increased from 33% to 48% (range:33-50%). Mean ADL increased from 4.6 to 5.3% (range 4.6-6.1%). Mean NDF increased from 50% to 73% (range: 50-76%). Mean OM% increased from 89.9% to 95.5% (range 89.9-95.5%). Mean Ash decreased from 10.1 to 4.5% (range 10.1-4.5%). Mean Ether Extract % decreased from 1.28% to 0.76% (range: 1.28-0.68%). Mean In Vitro Dry Matter Digestibility decreased from 73% to 65% (range:73-60%). Mean Ca, P, K, Mg, Na, Cu, and Zn content all decreased, while Mn increased. The data indicates that traditional forages decline in nutritive value during the growing season in Mali. (Supported by USDA, ISE Competitive Grant No. 2005-51160-02276).

Goat Species II

T154 *In vitro* volatile fatty acid profile of shrub and cacti species selected by grazing goats. M. Guerrero-Cervantes[1,2], R. G. Ramírez-Lozano[2], R. Montoya-Escalante[1], A. S. Juárez-Reyes[1], and M. A. Cerrillo-Soto*[1], [1]*Universidad Juárez del Estado de Durango, Durango, Dgo., Mexico*, [2]*Universidad Autónoma de Nuevo León, Monterrey, N.L., Mexico*.

Samples from species commonly selected by range goats in the semiarid region of North Mexico were collected to study their *in vitro* volatile fatty acid production. Samples from *Quercus grisea*, *Acacia shaffneri*, *Proposis leavigata*, *Opuntia leucotricha*, *O. leptocaulis* and *O. imbricata*, were collected . Five hundred mg DM were incubated in triplicate in calibrated 100 ml glass syringes using rumen fluid from two sheep fed alfalfa hay: concentrate (75:25) as inoculum. Incubations were terminated after 24 h. The syringe contents were then centrifuged and 5 ml of the supernatant were mixed with 1 ml of 25% metaphosphoric acid. Volatile fatty acid determination was performed using gas chromatography. Data were analyzed by ANOVA according to a completely randomized design. Total VFA concentrations were highest for *Opuntia leucotricha* whereas lowest values were recorded in *Acacia shaffneri* ($P < 0.05$). A similar trend was observed for acetate concentrations among species. *Opuntia leucotricha* produced 24.2% more acetate than *Acacia shaffneri*. Intermediate values were obtained in *O. leptocaulis* and *O. imbricata* ($P < 0.05$). Propionate concentrations were different among species ($P < 0.05$). *O. imbricata* recorded the highest values, *Proposis leavigata* was intermediate and *Acacia shaffneri* the lowest. Regarding butyrate values, a similar pattern as propionate was observed. *O. imbricata* produced 42.5% more butyrate than *Acacia shaffneri* ($P < 0.05$). *Opuntia leucotricha* resulted in higher valerate values, *O. imbricata* and *Q. grisea* ranked intermediate and *A. shaffneri* the lowest ($P < 0.05$). A higher A:P ratio was observed in *O. leucotricha* and lowest in *P. leavigata*. Results indicated that cacti species, specially *O. leucotricha* represents a good energy source and an important emergency feed in harsh semi-arid areas.

Table 1. *In vitro* VFA profile (mM L^{-1}) of shrub, tree and cacti species

	Total	C:2	C:3	C:4	C5	A:P
Q. grisea	14.17^{c}	8.91^{cd}	1.44^{cd}	1.17^{c}	0.96^{b}	6.10^{c}
A. shaffneri	10.88^{c}	6.05^{d}	1.10^{d}	0.94^{c}	0.86^{d}	5.53^{c}
P. leavigata	16.14^{bc}	9.49^{cd}	3.13^{b}	1.03^{c}	0.92^{c}	3.00^{d}
O. leucotricha	30.25^{a}	24.95^{a}	1.99^{cd}	1.82^{b}	1.03^{a}	12.6^{a}
O. leptocaulis	23.00^{ab}	17.90^{b}	2.12^{c}	1.72^{b}	0.87^{d}	8.45^{b}

T155 Methane emission by goats consuming a condensed tannin-containing lespedeza, alfalfa and sorghum-sudangrass. G. Animut*[1], R. Puchala[1], A. L. Goetsch[1], A. K. Patra[1], T. Sahlu[1], V. H. Varel[2], and J. Wells[2], [1]*E (Kika) de la Garza American Institute for Goat Research, Langston, OK*, [2]*US Meat Animal Research Center, Clay Center, NE*.

Twenty four Boer × Spanish (1/2 Boer; initial BW of 38.3 ± 0.69) wethers six per treatment were used to assess effects of a condensed tannin (CT)-containing forage (sericea lespedeza, *Lespedeza cuneata*; S) with or without polyethylene glycol (PEG), a legume (alfalfa, *Medicago sativa*; A), and grass (sorghum-sudangrass, *Sorghum bicolor*; G) on ruminal methane emission. Treatments were S, S plus 25 g/d of PEG mixed with 50 g/d of ground corn (P), A, and G. Forages harvested daily were fed at 1.3 times the maintenance energy requirement. The experiment lasted 15 d, 7 d for adaptation and 8 d for measurement.
